The venomous serpents belong to the *Proteroglypha* and *Solenoglypha*, the first including the *Elapidæ* (coral-snakes, etc.), *Najidæ* (cobras, etc.), and the second the *Viperidæ* (vipers) and *Crotalidæ* (rattlesnakes, etc.).

The order is represented by over 1,500 living species. The

representatives of the order as a whole live in hot regions, and are averse to cold. They are absent altogether in the extreme northern and southern countries, and sparingly developed and hibernating during cold weather in the temperate regions, but almost equally abundant in the tropical regions of the several quarters of the globe. In the northern part of the U. S. only three species of the poisonous snakes (the scale-headed and plate-headed rattlesnakes and the copperhead) occur, and the greatest number in any one region within the U. S. are found in Arizona and New Mexico. See Poison of Serpents and the names of different genera and species. Revised by F. A. Lucas.

Serpent-stars: See Ophiuroidea.

Serpent-worshipers: See Ophites.

Serpukhof': town; in the government of Moscow, Russia; on the Nara; 57 miles by rail S. of Moscow (see map of Russia, ref. 7–E). It has a fine cathedral of the fourteenth century, and manufactures of linen fabrics of different descriptions, mostly coarse; also leather, paper, earthenware, and furniture. Pop. (1888) 22,718.

Ser'pula [Mod. Lat., from Lat. *ser'pula*, little snake, deriv. of *ser'pere*, creep]: a genus of annelids which build calcareous tubes in which they live. The head is surrounded with feathery tentacles, one of which is modified into a stopper to close the aperture of the tube when the animal is retracted.

Serra, Junipero: missionary; b. in the island of Majorca, Nov. 24, 1713. He entered the Franciscan order, was sent to Mexico in 1749, and labored for years among the Indians of the northwestern districts. When the Jesuits were expelled, in 1767, their missions were placed in charge of the Franciscans. Father Junipero was made president of those of California, then confined to the peninsula of Lower California. One of his first measures was to extend his field to Upper California (now California). The San Diego mission was founded July 16, 1769, Monterey soon after, and others later. These were the first civilized communities within the bounds of the present State. Many of the buildings remain. D. at the San Carlos mission, Aug. 28, 1784. See Bancroft, *History of the Pacific States: California*, and *The Century Magazine* (May, 1883). H. H. S.

Serra do Mar: a division of the Brazilian Coast Range bordering the coast or running near it from Southern Paraná to Espirito Santo. The Parahyba valley separates it from the Serra da Mantiqueira. The bizarre forms of many of its peaks make this region extremely picturesque. It culminates in the Organ Mountains (*q. v.*). H. H. S.

Serran'idæ [Mod. Lat., named from *Serra'nus*, the typical genus, from Lat. *ser'ra*, saw]: a family of fishes of the sub-order *Acanthopteri*, including the sea-bass, groupers, jewfish, etc. The body is oblong and compressed; the scales ctenoid and generally moderate; the head compressed, and more or less pointed; the supramaxillary bones not retractile behind under the supraorbital bones; the spinous portion of the dorsal fin about as long as the soft or longer; anal like the soft portion of the dorsal, and with three spines. The variation in size among the species of the family is great, some being only a few inches long, while others exceed 7 or 8 feet. Among the gigantic forms are the jewfish (*Promicrops guasa*) of the Southern States and Cuba, which attains a weight of 500 or 600 lb., and the *Stereolepis gigas* of California, which appears to attain an equally large size. Almost all the species are esteemed as food.

Serrano y Dominguez, sãr-raa'nō-ee-dō-meen'gāth, Francisco, Duke de la Torre: soldier and statesman; b. at San Fernando, near Cadiz, Spain. Sept. 18, 1810; entered the army and rose rapidly in rank; joined Narvaez in effecting the overthrow of the regent Espartero in 1843; became lieutenant-general and senator in 1845, and obtained such influence over the young queen after her marriage (1846) as to give rise to much scandal. After taking part in several political intrigues and holding some important offices, he became captain-general of Cuba 1860–62, and won a dukedom as a reward for his successful efforts to reannex San Domingo to Spain. In 1866 he became president of the senate in Spain and suffered a short imprisonment in the same year. His continued opposition to the Government caused his exile to the Canary Islands July, 1868, when he took part with Prim and Topete in effecting the revolution which drove Isabella from the throne. He then became the ostensible head of the Government as president of the council of ministers and commander-in-chief of the army; was elected regent June 16, 1869; negotiated the acceptance of the Spanish crown by Prince Amadeus of Italy, by whom he was made premier Jan., 1871; resigned that post in July of the same year; took the field as commander-in-chief against the Carlists Apr., 1872; concluded with them the convention of Amorevieta in May; returned to office as premier for a few months; fled to France soon after the proclamation of the republic (Apr., 1873), but shortly returned; was made chief of the executive after the *coup d'état* of Gen. Pavia Jan., 1874, and remained at the head of the Government till the end of the year, when he resigned his authority into the hands of Alfonso XII. D. in Madrid, Nov. 26, 1885. F. M. Colby.

Serto'rius, Quintus: Roman general. He was a native of Nursia in the country of the Sabines; distinguished himself in the battle of Aquæ Sextiæ (102 B. C.) under Marius. He fought with Cinna at the Colline gate in 87 B. C. against Pompeius Strabo, but he did not participate in the bloody massacre which Marius instituted at the capture of Rome; on the contrary, he put to death a gang of about 4,000 slaves whom Marius had let loose on the city, and who had perpetrated the most horrible cruelties. In 82 B. C. he was sent to Spain as proprætor, but in the same year Sulla returned to Rome from Asia, and the power of the democratic party came to a sudden end. Although he had in the beginning only a small army, Sertorius maintained his position in Spain against the leading generals of Rome. He gained the favor of the natives, especially the Lusitanians, who became his faithful allies, and gradually drew about him the remnant of the Marian party. In 74 B. C. he formed an alliance with Mithridates. Metellus Pius, whom Sulla first sent against him, was repeatedly defeated, and even Pompey, who came to Spain in 76 B. C., achieved nothing, and was driven back across the Ebro. But intrigues and jealousies arose in Sertorius's camp, and in 72 B. C. he was invited to a banquet by Perpenna and treacherously assassinated at the festival. His biography by Plutarch is very interesting, though more full in its description of his personal character than in its narrative of his exploits. Revised by G. L. Hendrickson.

Sertula'riæ: a group of Hydroida (*q. v.*) of uncertain position. They form colonies sometimes 10 inches in height. The individual polyps are situated in horny cases (thecæ). No medusa (jellyfish) stage occurs in the life-history.

Serum [from Lat. *se'rum*, whey; cf. Gr. *ὀρός*, whey, and Sanskr. *sāra-*, curds]: the watery portion of certain animal fluids. Serum of milk is whey containing no albuminous matter, whereas serum of blood, the fluid part left after the separation of the coagulum from blood, is a strong solution of albumen in a liquid containing certain salts, neutral and alkaline. The total amount of saline matter in the serum of a healthy man is somewhat over 10 per cent., and there are present carbonates and phosphates of sodium, potassium, calcium, and magnesium, with considerable chloride of sodium, some chloride of potassium, and sulphate of sodium and potassium. The amount of albumen is in the neighborhood of 7 per cent. Both the saline and the albuminous matter prevent the solution of the blood-globules, which are very soluble in water itself, and are attacked at once on addition even of a very little water to blood. The physiological and pathological properties of blood serum have recently occupied much attention, and there bids fair to be great advancement in the treatment of disease, based upon these studies. The serum of an animal is known to possess properties which render it more or less destructive to invading micro-organisms. According as this is ill or well developed will be the likelihood or unlikelihood of a severe attack. Revised by W. Pepper.

Serum Therapeutics: that department of medical practice which secures Immunity (*q. v.*) by the introduction of certain substances in the blood which act in an antagonistic manner to the bacteria of the disease in question, or to the toxic substances developed from these or by them. According as the protective substances are present in large or small quantity, permanently or temporarily, so will be the permanence and completeness of the immunity. The same sort of immunity may be developed by artificial inoculation with the specific micro-organisms themselves. The latter may be made less powerful by certain methods of cultivation, as was done by Pasteur in the case of the anthrax bacillus, or they may be injected in small amounts, and thus immunity developed without risk of a serious attack. Immunity may, however, be obtained by injection of the products of the bacteria, obtained either from cultures of

the micro-organisms or from the blood of a person or animal previously rendered immune by a natural or experimental attack of the disease. The same substances in larger doses act also in a curative way.

Recently this treatment has been particularly lauded in diphtheria. The exact method by which the antitoxic substances in this disease are prepared is as follows: Horses or goats, preferably the former, are inoculated with cultures of the specific micro-organisms, rendered less virulent by addition of trichloride of iodine or other substances, or with small doses of the toxine of these organisms. There is thus established a specific intoxication of slight intensity, with development of antitoxic substances and leaving a certain degree of immunity, so that the animal may be injected with greater quantities the second time, etc. After repeated injections of this kind the animal becomes practically immune from any dose of the poison. The blood-serum obtained from such an animal will be active for the production of artificial immunity in another animal, or in larger dose it will prove curative of the developed disease. Whatever the outcome of this method of treatment may prove to be in man, it is sufficiently established that immunity may be conferred upon animals in this way for infection with the organisms of diphtheria, malignant œdema, anthrax, cholera, typhoid fever, pneumonia, and other diseases. WILLIAM PEPPER.

Serval: the *Felis serval*, an animal of the *Felidæ* or cat family, having a slender body, small head, long legs, long and shaggy hair, body spotted with dark brown, the general color being yellow, and the lower parts white. It is about 3 feet long, exclusive of the tail, which is tipped and ringed with black. It is found in the southern part of Africa.

Servant: See MASTER AND SERVANT.

Serva'tus Lupus: polemical writer; b. about 805; was educated in the monastery of Ferrières, in the diocese of Sens, France, and studied afterward in Fulda under Rabanus Maurus. For some time he lived at the court of Louis the Pious, and in 842 he was made abbot of Ferrières by Charles the Bald. D. after 862. He played quite a prominent part in the ecclesiastical history of his time. In the controversy between Gottschalck and Hincmar he sided with the former, and defended him both by his words in the synods and by his pen: *De tribus quæstionibus* and *Collectaneum*. His works, which also comprise a number of very interesting letters (best ed. by G. Desdevises du Dezert, Paris, 1888), are found in Migne, *Patrol. Lat.*, xix. See Nicolas, *Études sur les lettres de Servat-Loup* (Paris, 1861); F. Sprotte, *Servatus Lupus* (Ratisbon, 1880). Revised by S. M. JACKSON.

Serve'tus, MICHAEL [the popular Latinized name of MIGUEL SERVETO]: theologian; b. at Villanueva, near Saragossa, Spain, in 1509, or more probably at Tudela, in Navarre, 1511, his own testimony, though contradictory, inclining to the latter place and date; son of a notary, who sent him at the age of nineteen or seventeen to study law at the University of Toulouse, France; gave his attention principally to theology, in which he became proficient; visited Italy, and was present at the coronation of Charles V. at Bologna 1530; traveled in Germany and Switzerland; became acquainted with many of the Reformers, and partially adopted their doctrines; resided some months at Basel, where he discussed theology with the celebrated Hans Hnssgen (Œcolampadius), and broached for the first time his criticism of the current doctrine of the Trinity; proceeded to Strassburg; acquainted himself with the teachings of the Protestant divines Bucer and Capito; went thence to Hagenau, Alsace, where he published his *De Trinitatis Erroribus* (1531) and *Dialogorum de Trinitate Libri duo: de Justitia Regni Christi Capitula quatuor* (1532), works which embroiled him both with Roman Catholics and Protestants; took up his residence at Lyons under the name of Michel de Villeneuve about 1533; studied medicine, and supported himself by working as an editor of scientific works; settled at Paris 1536; studied medicine under Günther, Dubois, and Fernel; took the degree of M. D. with high honors 1536, in which year he first met with Calvin; became an eloquent and popular lecturer at the university on medical science and mathematics; published a treatise, *Syruporum Universa Ratio* (1537), attacking opinions of Galen and of the Paris faculty of medicine; had about this time several conferences on theology with Calvin, who proposed, as he himself says, to set him right on theological matters; proceeded to Charlieu, near Lyons, 1538; lived some time at Avignon; published at Lyons editions of Ptolemy's *Geographia* (1541) and of the Bible (1542) with Latin notes, which were condemned as heretical by the Roman Catholic Church; took up his residence in 1543 at Vienne, Dauphiné, living as confidential physician in the palace of the archbishop, Pierre Paulmier, a former pupil; carried on with Calvin, then at Geneva, an active theological correspondence, which resulted (1546) in a bitter quarrel; published anonymously his chief work, *Christianismi Restitutio* (Vienne, 1553), the authorship of which was recognized by Calvin, to whom he had sent much of it in MS., and made known by him to the Roman Catholic Archbishop of Lyons, Cardinal Tournon. Arrested and imprisoned by the Inquisition at Vienne, at the instance of that prelate, Servetus would probably have been acquitted for lack of evidence had not Calvin supplied portions of his correspondence as proofs against him. Servetus escaped from prison, crossed the frontier into Piedmont, and remained in concealment several months. Meanwhile his trial went on; he was condemned for heresy, and burned in effigy at Vienne June 17, 1553. He then resolved to go to Naples, but by a strange fatality went first in disguise to Geneva, where, his presence having become known to Calvin, he was arrested, brought to trial (Aug. 14) before the municipal court on charges of heresy, sedition, insult to the Fathers of the Church, and calumny against Calvin and other Protestant divines; was forced to discuss doctrinal points with Calvin, who appeared as prosecutor and drew up the final articles of accusation, thirty-eight in number; was condemned to the stake, and, notwithstanding the desire of Calvin for his decapitation as a milder form of death, was burned alive on a hill near Geneva Oct. 27, 1553. The Roman Catholic Inquisition had previously (June 17) sentenced him to the same punishment. The Reformers generally, including Melanchthon, approved his execution. Calvin might easily have been mindless of his accidental presence in Geneva, but he had threatened him with death if he came within his reach and he kept the promise he had made. *Lives* of Servetus have been published by Mosheim (1750), Trechsel (1839), W. H. Drummond (London, 1848), and Brunnemann (1865). Cf. Schaff's *Church History*, vol. vii. The most careful study of his career and the best authority on his life is H. Tollin's *Characterbild Michael Servets*, and many articles that Tollin published in various journals. The theological position of Servetus was extremely individual. He was no Arian, and while denying the tri-personality of the Godhead and the eternity of the Son, he was passionately devoted to the person of Christ and equally to the Bible as the sole standard of authority. His was a boundless intellectual curiosity, a wide and various culture, an absolute sincerity, but withal a love of controversy, not peculiar to him in his generation, which brought him into frequent danger and finally to a cruel death.

Revised by J. W. CHADWICK.

Ser'via [from Russ. *Serbiya*, deriv. of *Serbŭ*, a Servian, from Serv. *Srb*, a Servian (Turk. *Syrp*)]: a kingdom of Southern Europe in the Balkan peninsula; between 42° 20′ and 45° N. lat., and 19° 10′ and 22° 45′ E. lon. It is bounded N. by the Austro-Hungarian empire, from which it is separated by the Save and Danube rivers, E. by Roumania, from which it is separated by the Danube, and Bulgaria, S. by Bulgaria and Albania, W. by Albania and Bosnia. Area, 19,050 sq. miles.

Topography, Products, Commerce, etc.—Servia is divided by the river Morava into two unequal sections. The western section is broken by the Dinaric Alps, the eastern by the Balkans. At Orsova, on the Danube, the Balkans are separated from the Carpathians by a narrow cleft, called the Iron Gates, through which the Danube rushes. From its southern frontier, dominated by the Kopaonik Mountains nearly 7,000 feet high, Servia slopes to the north in a roughly inclined plane, and on the northwest spreads out in level tracts. The soil in the valleys and lower regions is fertile, producing rice, maize, wheat, flax, hemp, and tobacco. Along the Danube are numerous vineyards and orchards, especially of plum-trees, whence the *slivovitza*, a popular sort of brandy, is obtained. More than half the territory is covered with forests, wherein oaks and walnuts abound. Iron, copper, lead, and coal are found in certain localities, but absence of roads and lack of enterprise prevent their being worked. From the same cause the forests are untouched, except that they are given over to raising immense herds of swine. These hogs are exported, and constitute the chief industry and the principal source of revenue. There are practically no manufactures except in a primitive way, as each household supplies its own necessi-

ties. Commerce is confined to the exportation of raw materials and the importation of the most essential manufactured goods. The system of agriculture is simple and rude: little attention is paid to education, and the condition of the country and people presents a striking contrast to the progress made by Roumania and Bulgaria since 1870.

The unit of value is the dinar or franc. For the fiscal year 1901 the budget estimates were: receipts, 74,018,070 dinars; expenditures, 73,992,543. The public debt is 424,725,713 dinars. In 1899 the imports amounted to 46,428,600 dinars, seven-twelfths of which were from Austria-Hungary; exports, 65,744,388, about five-sixths of which were to Austria-Hungary. There are 354 miles of railway. Length of telegraph lines, 2,526 miles; offices, 142.

Servia is an hereditary monarchy. The national assembly or Skuptchina consists of 262 members and meets annually. Pop. (1895) 2,312,484. Except 159,510 Roumanians and 46,212 gypsies (1895), there are few not of the Servian race. With rare exceptions the inhabitants belong to the national Church, the Eastern Orthodox or Greek. Pop. of chief towns (1895): Belgrade, the capital, 59,494; Nisch, 21,524; Kragujevatch, 13,870; Lescovatch, 13,165: Pojarevatch, 11,699. In 1899 there were 24,456 marriages, 96,246 births, and 59,548 deaths. By statute of 1889 military service is obligatory on every able-bodied male Servian from the age of twenty-one to fifty-one: 2 years in active service, 8 in the reserve, 10 in the first division, and 10 in the second division of the national militia. Servia claims ability to put into the field 5,700 officers, 353,366 men, with 45,100 horses and 402 cannon.

History.—The Servians are a branch of the Slavic family. During the seventh century they were induced by the Byzantine emperor Heraclius I. to abandon their homes in the Carpathians and colonize the then depopulated territory between the Danube and Adriatic. Bound to the Byzantine empire by friendship and allegiance, they formed an efficient defense against the barbarians of the north. Christianized in the ninth century, Servia became independent in the eleventh, and its sovereign, the Grand Shupane, was recognized as a king by Pope Gregory VII. Stephen Dushan, the tenth sovereign, conquered nearly all the Balkan peninsula, threatened Constantinople, and in 1346 took the title of czar. In 1389, at the terrible battle of Kossova where the Servian king Lazarus and Sultan Murad I. were slain, Servia lost its independence, and disappears from history till the early part of the nineteenth century. Then the peasant Kara George, aided by Russia, expelled the Ottomans, and ruled from 1804 to 1813. Again the Ottomans overran the country when the swineherd Milosch Obrenoviteh, who had assassinated Kara George, headed a desperate resistance during fifteen years. Supported by Russian diplomacy he forced the Porte in 1830 to recognize him as hereditary prince of Servia. In 1869 a constitution was framed, according to which the Government appointed one-third of the Skuptschina, while the electorate of the other two-thirds was greatly restricted. In 1876 Servia declared war against the Ottomans, and was saved from destruction only by the interference of Russia. The Congress of Berlin (1878) recognized the independence of the principality, and increased its territory on the south at the expense of the Ottoman empire. Servia declared itself a kingdom Mar. 6, 1882. In Nov., 1885, King Milan made an unjustifiable attack on Bulgaria, but was ignominiously defeated and his kingdom maintained intact only through the intervention of Austria-Hungary. In 1889 a more liberal constitution was granted, all taxpaying citizens becoming electors, by whose votes the entire Skuptschina was elected. The Servians are a brave and generous people, and the unfortunate history of Servia since 1868 is largely due to the influence of their incapable and pusillanimous ruler, Milan I. (*q. v.*), who on Mar. 6, 1889, abdicated in favor of his son, Alexander I. The latter in May, 1894, by a *coup d'état*, abolished the new constitution and restored that of 1869.

Servian Language: See Slavic Languages.

Servian Literature: in its broadest sense, the literary monuments of the Servian or Servian-Croat language, spoken by most of the inhabitants of Servia, Bosnia, Herzegovina, Montenegro, Dalmatia, and Croatia (including Slavonia), about 6,000,000 in all. This belongs to the southern division of the Slav languages, and, though somewhat influenced by Turkish, is most closely related to Bulgarian, Slovenian, and Russian. In a narrower sense the term Servian is restricted to Servia alone. The Servian and Croat languages and literatures, although essentially of the same origin, and differing in little except that the former employs the Cyrillic (Russian) alphabet and the latter the Latin, had for centuries an independent development, owing to political, religions, and territorial influences. While Croat literature developed under the Roman Catholic Church and Western European influences, Servian literature, as the intellectual medium of a people belonging to the Greek-Oriental Church, grew under the influence of that Church and the Byzantine empire. Consequently the Servians received with the Old Slovenian liturgy also the Old Slovenian or Old Bulgarian language. This, by an admixture of dialectic peculiarities, was gradually moulded into the so-called Servian Church Slavonic, in which, until the destruction of the Old Servian realm (battle at Kossova in 1389), a rather extensive Church literature was produced.

Early Servian Literature.—Among the first writers was Stephen, first King of Servia (crowned in 1217), who wrote a biography of his father, Stephen Nemanjas (ed. by Šafařik, *Život sv. Simeuna*, Prague, 1868 and 1870). His brother Sava, who founded the Servian monastery Chilander on Mt. Athos, and was in fact the apostle of the Servian people, wrote a legend, a ritual, and a liturgy from Old Bulgarian sources. Domentian wrote lives of St. Sava and St. Simeon (ed. by Daničić, Belgrade, 1865). The *Rodoslov*, by Archbishop Danilo (1291–1338), is a genealogical account of Servian kings and archbishops (ed. by Daničić, Agram, 1866). These works were of a panegyric ecclesiastical nature, hardly popular enough to encourage secular literature.

The most important productions for the study of the old language and history of Servia are the documents and records of the old kings, and especially the *Zakonik* (a collection of laws), by King Stephen Dushan (d. in 1356). The Turkish yoke after Kossova almost completely checked literary life in Servia for nearly 400 years; but the Gospels were printed in Belgrade in 1552, and Georg Branković, during his captivity in Eger, wrote a chronicle of Servia from the origin of the Servian people to about 1700.

Literary Activity during the Turkish Supremacy.—While Servian literature was thus suppressed by the Turkish conquest, a similar and cognate literature sprang up and attained full development in the Illyrian towns or the Dalmatian cities and islands from the end of the fifteenth to that of the seventeenth century, gradually declining thereafter. Its language was Croat (West Servian-Croat) in the old historic sense, although in the south (at Ragusa) the South Servian or Herzegovinian dialect predominates. This literature frequently loses the national Slavic color owing to the imitation of the various Italian literary movements. A considerable portion of it is actual translation from the Italian, but most of it is lyric poetry, love songs in the style of the Italian sonnet poetry, idyllic tales, and epics; even the drama is represented in both tragedy and comedy. The oldest writer of this literature is Marko Marulić, at Spalato (1450–1524); his poetry is biblical, its form yet rather imperfect. The island of Lesina produced two masterly poets—Hannibal Lučić (1480–1525), author of lyric songs and the drama *Robinja*, and Peter Hektorović (1486–1572), who wrote the descriptive poem *Ribanja* (a fisherman's tale). Then Ragusa took the leadership, owing to such lyric poets as Menčetić (1457–1501) and Držić (d. about 1510), both masters of love poetry. Greatest of all was Ivan Gundulić (d. 1658), the author of the epic *Osman*, celebrating the Polish victory over the Turks at Chocim. In 1667 Ragusa was destroyed by an earthquake, which ended its material and intellectual development. Jacob Palmotič (d. 1680) portrays its destruction and rebuilding in his epic *Dubrovnik ponovljen* (Ragusa Renewed). The works of Dalmatian poets have been edited by the South Slavonic Academy at Agram (1869, *seq.*).

The revival of Servian literature was due to the political struggles carried on by Austria against the Turks for the liberation of the Servian people, at the end of the seventeenth and the beginning of the eighteenth centuries. A considerable part of Servia was thus restored to Western European life and civilization, but at the same time a reaction against the latter took place; Russian teachers were called to the schools, and the Church-Slavonic language in its Russian form introduced into the service of the Church.

The Archimandrite Iovan Rajić's *History of the Slavic Peoples, especially the Bulgarians, Croats, and Servians* (Neusatz, 1768; n. e., 4 vols., Budapest, 1823), was an incentive to nationality. Dositheus Obradović and Vuk Karadžić, and later the eminent Daničić, reorganized and reformed the popular Servian language proper, and with the liberation of the Servian nation from the Turkish yoke its literature took a high stand among those of Europe. The monk Obradović (1739–1811), who was the teacher of the children of Kara George and died a senator, exerted a paramount influence in the revival of national life and literature in Servia. Vuk Karadžić (1787–1864) collected the Servian songs which attracted much attention in Germany and England as pearls of popular poetry. The first modern poet was Lucian Mušicki (1777–1837), but his pseudo-classicism did not exercise a beneficial influence upon the developing literary taste of his people. More popular and natural is the poetry of Sima Milutinović, who wrote poems on the Servian war of independence (Leipzig, 1826) and the history of Servia in 1813–14 (Leipzig, 1837). The greatest poetical treasure of the nation, however, is their ballads. (See *Serv. Ballads*, by Child, vol. i., p. 468.) With the increasing enlightenment of the nation many prose works also were printed, and journals sprang up over the country, the most important among them being the *Srpski Letopis* (Servian Annual Record), published since 1825. During the second half of the nineteenth century Servian poetry became more and more original, national, and independent, reflecting the peculiar life of the aspiring state.

Peter Petrović Njegos (Vladika of Montenegro) wrote the celebrated epic *Gorski vijenac* (Vienna, 1847), describing the heroic liberation of Montenegro from the Turkish yoke (at the end of the eighteenth century). The other names best known are those of the lyric poets Branko Radičević, Iovan Iovanović, and Djuro Iakshić, and the novelist Milićević with his *Zimne veeri*, tales of Servian life. The *Glasnik*, edited by the Society of Savants since 1847, contains valuable articles on history, geography, literature, and philology.

The new Croat literature, permeated by the Panslavic desire to become intellectually united with the Servian sister literature, has been so modified that the only differenec between them is one of external form. The publicist Ljudevit Gaj (1809–72), at Agram, the center of the South Slavic movement, was especially active in this respect since 1834. The Croat-Servian dialect and the Latin eharaeters were to be employed by the authors of this school, but to avoid jealousies and for ethnological and political reasons, this literature was to be called Illyrian. Since 1848, however, the names Croat and Servian-Croat have prevailed. The most eminent poets of this literature are Peter Preradović (1818–72); Stanko Vraz, by birth a Slovene (1810–51), excellent in lyric poetry; Mažuranić, the author of the famous patriotic song, the epic of hate, *Smrt Smail-aga Cengijiča* (Death of Ismail Agha); and Bogović, author of dramas, songs, and historical novels. The epic popular songs of the Croats have been collected and edited by Bogošić (*Narodne pjesme iz starijih zapisa*, Belgrade, 1878), and partly by Miklosich (*Beiträge zur Kenntniss der slaw. Volkspoesie, I. Die Volksepik der Croaten*, Vienna, 1870).

Bibliography.—*Narodne Srbske pjesme*, a work on Servian popular poetry, by Karadžić (Germ. trans. by Talvj, Leipzig, 1853); Kapper, *Gesänge der Serben* (Leipzig, 1852); Ignaz Iagić, *History of Servo-Croat Literature* (1867); A. Dozon, *L'Épopée Serbe* (Paris, 1888); A. N. Pypin and V. D. Spasovič, *Istorija slavjanskich literatur* (Germ. trans. by T. Peeh, vol. i., Leipzig, 1880). Hermann Schoenfeld.

Service: See the Appendix.

Service-berry: See June-berry.

Service-tree: a rosaceous tree, *Pyrus domestica*, of Europe, Asia, and Africa, much resembling the Medlar and Sorb-tree (*qq. v.*). Its fruit, when overripened and bletted, is soft and pleasant to eat. It is considerably cultivated. The wood is very hard and valuable, and is used as a substitute for box. In parts of North America the name is applied to the shad-tree, and in others to the mountain-ash.

Servites: a community of Augustinian friars, called Servants of the Virgin Mary; founded at Florence in 1233. Bonfiglio Monaldi was their first general and one of their founders. They were confirmed in 1255 by the pope, and in 1493 a part received a reformed rule. There is also a congregation of Servite Tertiaries, and there are a few houses of Servite nuns. The Servites are mostly found in Europe, but have a monastery at Chicago, Ill. J. J. K.

Servitudes [from Lat. *servitu'do*, deriv. of *ser'vus*, slave]: The term servitude, as employed in the Roman law, covers not only the Easement (*q. v.*) of the English law, but also life-estates in land and life-interests in personal property. It is a right to use the property of another, whether real or personal. The term does not include purely contractual rights of use, such as are established by lease or loan, but is restricted to such property rights as are enforceable against all the world by actions *in rem*.

Servitudes on land, if established in favor of an adjacent and "dominant" estate, are termed real or *prædial* servitudes. These are again divided into *rustic* and *urban* servitudes. The former include rights of way, rights of drawing water from or conveying water across neighboring land, etc. Examples of the latter class are rights of light and prospect, right of discharging rain-water on neighboring land, right to have a wall or beams supported by the neighbor's wall. The modern European law of real servitudes is substantially Roman.

Servitudes upon land, if created in favor of a particular person without regard to his ownership of adjacent land, and property rights less than ownership in movables, are *personal* servitudes. They are always limited to a single life, while the real servitudes are in principle perpetual. The most important of the personal servitudes is *usufruct* This may be established not only in land (life-estate of the English law), but in any property which is capable of being used without material impairment of its substanee (so-called "non-consumptibles," e. g. a eollection of books or jewels, a service of plate). The right may be exercised directly. or it may be sold or leased. The usufructuary is bound not to deteriorate the property, and he must give security for its restoration. In the case of consumptibles (including money) a so-called *quasi-usufruct* is reeognized. Here the usufruetuary is really owner, and gives security for the restoration, not of the things or money which he has received, but of their equivalent or value.

Limited rights of using land may be conferred by law upon a neighbor or upon the public generally. In such cases continental jurists speak of *legal* servitudes.

Authorities.—Elvers (Marburg, 1856); Gavini de Campile (Paris, 1870); special works upon usufruct: Genty (Paris, 1859); Hanausek (Erlangen, 1879). Munroe Smith.

Ser'vius: a Roman grammarian of the latter half of the fourth century A. D. He is frequently mentioned in the *Saturnalia* of Macrobius, but is chiefly noted for his complete commentary upon Vergil, whieh is based upon the labors of many earlier scholars, and embodies much useful information on the text and in general on Roman religion, history, and antiquities. This commentary exists in a longer and shorter form, and the relation between the two has caused much discussion. The best edition is by Thilo [and Hagen] (Leipzig, 1881–87). See also E. Thomas's *Essai sur Servius* (Paris, 1880), and Nettleship *Lectures* (Oxford, 1885; p. 322 ff.). M. Warren.

Ser'vius Tul'lius: the sixth King of Rome (legendary dates 578–534 B. C.). The accounnt of his life is full of fables and wonderful traditions—his being the son of a female slave by the god Vulean; his edueation in the royal household under the special care of Queen Tanaquil; his marriage with the king's daughter, and his aceession to the throne by the stratagem of his mother-in-law; his death in Vicus Sceleratus, by being thrown down by the younger Tarquin from the stone steps of the senate-house, then overtaken and stabbed by Tarquin's servants on his way home, and finally driven over by the chariot of his unnatural daughter, Tullia, the wife of Tarquin. But amid the many mythical elements whieh eling to his name there appear to be some remnants of tradition that have a genuine historieal value. To him is attributed a eonstitution which made landed property the basis of the military system, and thus admitted the plebeians to a place in the army and a share in the government. He formed an alliance with the Latins, and completed the city by ineorporating with it the Quirinal, Viminal, and Esquiline hills, and surrounding the whole with a wall 5 miles in circumference, which was the legal boundary of the city up to the time of Sulla. Revised by G. L. Hendrickson.

Ses'ame, or **Benne-plant**, as it is called in the southern parts of the U. S. [*sesame* = Gr. *σησάμη, σήσαμον* (whence Lat. *se'same, se'samon*): cf. Arab. *simsim* and Hind. *samsam*, sesame]: an herbaceous plant, *Sesamum indicum*, belonging to the small family *Pedaliaceæ*, sometimes annexed to *Bignoniaceæ*, valued for the oil expressed from its seeds.

There are several varieties, which have been regarded as species. They are annual Oriental plants, naturalized in most warm climates. Sesame was probably introduced into the U. S. by slaves from Africa. Its rich oily seeds are prized by the Negroes, who also make a thick gelatinous drink of the leaves, which is very bland and useful in diarrhœas. The seeds can be made to yield half their weight in oil, which is in some respects better than olive-oil. The oil is called oil of benne and gingelly-oil.

Revised by CHARLES E. BESSEY.

Sesame-grass: a large grass, *Tripsacum dactyloides*, of the U. S. growing in moist soil near the Atlantic coast from Connecticut southward, with broad leaves and a solid stem, like that of Indian corn or sugar-cane, which it somewhat resembles. It is very coarse, and in the North is not valued, but in parts of the South and in the West Indies and Mexico is used as fodder.

Ses'amoid Bones [*sesamoid* is Gr. σησάμη, sesame + suffix *-oid*, like; so called from their supposed resemblance to a sesame-seed]: bones developed in the tendons of muscles. The most familiar example is the patella or knee-pan. They do not belong to the vertebral appendages proper, but to the sclero-skeleton.

Sesos'tris [Gr. Σέσωστρις, or Σεσόωσις; cf. Egypt. *Sesetsu* = Ramses II.]: the name applied by Greek writers to Ramses II. of the nineteenth Egyptian dynasty, about whom they grouped the record of the deeds of other famous Pharaohs as well as those which belonged to himself, thus forming a single exaggerated personality. Views have differed as to the persons thus combined, Bunsen holding to a commingling of two kings of the ancient empire, while Lepsius held that Ramses II. formed the central figure. Manetho applies the name Sesostris to Usertasen II. of the twelfth dynasty, while Herodotus and Diodorus evidently have Ramses in mind. According to the Greek story, Sesostris was reared with children born on the same day, apparently 1,700 in number, and in his youth led victorious expeditions into Ethiopia and Libya. After his father's death he equipped an army of 600,000 infantry, 24,000 cavalry, and 27,000 chariots, giving the command to his fellow students, marched against Ethiopia and took heavy tribute. He then fitted out a navy of 400 vessels and sailed to the end of the Arabian peninsula. Thence he proceeded through Arabia and along the coast, crossing the Indus and conquering India. Returning by land he subdued the Scythians. According to one account he left a portion of his army in this region, and they became the ancestors of the Colchi. Then, after conquering Thrace, he returned to Egypt with great spoil and many captives, having been absent exactly nine years. The remainder of his reign occupied fifty-nine years. He divided Egypt into thirty-six nomes or districts; built roads, canals, cities, and temples, using his captives as laborers; by grace of Thoth was learned in the law, and was reckoned among the great Egyptian lawgivers; introduced the worship of Serapis; and divided the Egyptians by a system of caste, forbidding also that a son abandon the calling of his father. In his old age he became blind and took his own life. The Greek story is in accordance with the actual facts only in a few particulars. For the Egyptian account, see RAMSES. See Herodotus (ii., §§ 102–110) and Diodorus (i., §§ 53–58), and the authorities quoted by Wiedemann, *Aegyptische Geschichte*, p. 429. CHARLES R. GILLETT.

Sessa Aurun'ca (anc. *Suessa*): town; in the province of Caserta, Southern Italy; on the crater of an extinct volcano about 6 miles from the Tyrrhene Sea (see map of Italy, ref. 6–F). Suessa was a conspicuous city of the Auronians or Aurunci ans as early as 418 B. C., and, judging from the position of important architectural remains, antiquarians and geologists are of opinion that the town was, in part at least, buried by a volcanic eruption. The present town is poorly built, but it has a cathedral, a theological seminary, and a technical college. Pop. 6,000.

Sester'tius [Lat., liter., two and a half; *se'mis*, half + *ter'tius*, third, i. e. the third (*as*) being only a half]: in ancient Rome, a silver or bronze coin worth one-fourth part of a denarius. Originally, it was worth two and a half asses, but in later times four asses made one sestertius, and the coin, originally of silver, was struck in fine bronze. The sestertium was a money of account equal to 1,000 sestertii, but it was never coined. The value of the sestertius, roughly stated, was from one and a half to five cents of U. S. money, for the value declined greatly after the fall of the republic.

Sesto, CESARE, da; painter; b. at Sesto, Milan, in the sixteenth century. He was a pupil or imitator of Leonardo da Vinci. He afterward went to Rome and became acquainted with Raphael, whose style he adopted. Baldassare Peruzzi engaged him to assist in executing the frescoes in the citadel at Ostia. His masterpiece is the picture in the Church of San Rocco of Milan, in several compartments. At Saronno he painted four narrow pilasters with figures of St. Martin, St. George, St. Sebastian, and St. Roch (San Rocco), which he inscribed *Cæsar Magnus fecit*; this has led some critics to believe that he belonged to the de Magni family, or that these frescoes were by another painter, but the similarity of workmanship does not allow of the latter hypothesis. The date of his death is supposed to be 1524.—His brother STEFANO was a sculptor whose bas-reliefs in the Certosa of Pavia are remarkable. W. J. STILLMAN.

Sestri Ponen'te: town; in the province of Genoa, Italy; beautifully situated on the seashore about 5 miles W. of Genoa (see map of Italy, ref. 4–B). It has a delightful climate, and is a favorite summer resort. The inhabitants of Sestri Ponente are extensively engaged in ship-building, and are otherwise very industrious. Pop. of commune, 10,686.

Sestus, or **Sestos**: See ABYDUS.

Sete Quedas: See PARANÁ (river).

Seth, ANDREW, M. A., LL. D.: educator and philosopher; b. in Edinburgh, Scotland, Dec. 20, 1856; educated in Edinburgh, Berlin, and other universities; became assistant in logic in Edinburgh in 1880; professor in University College, Cardiff, 1883: lecturer in the University of Edinburgh 1883; professor at St. Andrews 1887; and Professor of Logic and Metaphysics in Edinburgh University 1891. His principal works are: *The Development from Kant to Hegel, with Chapters on the Philosophy of Religion* (1882); *Essays in Philosophical Criticism* (1883; edited in conjunction with W. R. B. Haldane); *Scottish Philosophy: a Comparison of the Scottish and German Answers to Hume* (first series of Balfour Lectures, 1885; 2d ed. 1890); *Hegelianism and Personality* (second series of Balfour Lectures, 1887; 2d ed. 1893). J. MARK BALDWIN.

Se'ti [*Seti meri-n-Ptah*, belonging to Set, beloved of Ptah: Gr. Σέθως]: name of two Egyptian kings, the first and fourth rulers of the nineteenth dynasty.

SETI I., son of Ramses I. and father of Ramses II. (see RAMSES), ruled for about twenty-seven years. The period just preceding had been one of weakness, in which the limits of the kingdom were narrowed from those established by Thothmes III. (See THOTHMES.) This resulted from the internal dissensions caused by the effort of KHUNATEN (*q. v.*) to establish the solar monotheism of Aten and to abolish the worship of Amon. Monumental proof of the return of the nation to the old religion under Seti is seen in the inscriptions and representations on the walls of the hypostyle hall at Karnak, which Seti founded. Besides this great building, he was architecturally active elsewhere in Thebes and also in many parts of Egypt. He was a patron of art, and left many monuments bearing his name, some of them undoubtedly usurped. From some of his monuments even his own name has been erased, indicating the later revulsion of the Egyptians against the cult of the foreign deity Set, in whose honor Seti was named.

Manetho marked a dynastic division between Ramses I. and Seti I., and, for reasons unknown, began a new dynasty with the reign of the latter. On obvious grounds, however, the dynasty is reckoned by some from the ascent of Ramses I. to the throne. In his first year Seti I. was compelled to proceed to Asia against the beduin (*Shasu*) and the peoples of Palestine and Syria. Among the conquered peoples the Hittites (*Kheta*) are enumerated, but the strength which they exhibited under Ramses II., the succeeding king, renders this record somewhat doubtful. Later Seti I. engaged in war with the Libyans and overcame them. Gradually they enlisted as mercenaries under Seti and his successors, till some 400 years later they had grown to such power that the Libyan Shishak usurped the throne and founded a new dynasty. Seti's inscriptions claim for him a dominion extending from Mesopotamia to Punt, Nubia, and Libya, and they show that under him the mines of Sinai and Nubia were worked. The record of his exploits is sculptured on the north wall of the hypostyle hall at Karnak. (Lepsius, *Denkmäler*, iii., 126a–130b; Brugsch, *Geschichte Aegyptens*, pp. 457 ff., Broderick's English edition, pp. 242 ff.; Wiedemann, *Aegyptische Geschichte*, pp. 416 ff.; Lushington,

Transactions of the Society of Biblical Archæology, vi., pp. 509–534.) Seti's tomb at Biban el-Moluk contains a copy of the myth of the destruction of mankind by Ra. See Brugsch, *Die neue Weltordnung* (1881), and Naville, *Records of the Past* (first series, vol. vi., pp. 103 ff.).

Seti II. was the fourth king of the same dynasty. Little is known concerning him, except that he was the grandson of Ramses II. His name is found on various small objects and upon monuments of his predecessors, which he usurped. His tomb at Biban el-Moluk is ornamented with well executed inscriptions and reliefs. The famous *Tale of the Two Brothers* (in the d'Orbiney papyrus in the British Museum), resembling somewhat the story of Joseph and Potiphar's wife was prepared for his edification. Charles R. Gillett.

Set-off: in law, a cross-demand existing in favor of a defendant which in certain actions and under certain conditions may be interposed as a defense, either partly or wholly defeating recovery by the plaintiff or even resulting in a recovery against him. A set-off is distinguished from a defense in the common sense of the latter word by the fact that if an ordinary defense, as of payment, former judgment, *non-assumpsit*, etc., be not pleaded upon the trial of the action against which it is a defense, the right to set it up is lost, whereas as a set-off, except as otherwise provided by statute in a few States of the U. S., if not pleaded as a defense may be sued upon in a separate action. Set-off should be discriminated from Recoupment (*q. v.*), although it is often difficult to say in which form the opposing demand should be set up as a defense. The word *counterclaim* has a broader meaning, ordinarily including both set-off and recoupment.

This species of defense (analogous to the *compensation* of the civil and Scots law and the *reconvention* of the law of the State of Louisiana) was unknown to the common law, and was first authorized by the English statutes 2 Geo. II., ch. 22, § 13, and 8 Geo. II., ch. 24, § 4, which have been substantially re-enacted in the several States of the U. S. The original statute only permitted a set-off in the case of mutual "debts" of a definite character. The use of the technical word "debts" restricted the set-off to actions brought for the recovery of a fixed certain sum of money due upon a contract, and the demand in favor of the defendant had to be of the same nature. There could be no set-off of unliquidated damages resulting from the breach of contracts, but only of those claims the amount of which had been ascertained and settled by the promise itself, whether that promise were express or implied. The debts had to be also mutual and due to the parties in the same right.

The provisions of the original statute, however, have now been generally more or less modified by later statutes enlarging the scope of the defense. In Great Britain a defendant in an action may now set off or set up by way of counterclaim against the claims of the plaintiff any right or claim, whether such set-off or counterclaim is sound in damages or not. The provisions of the statutes in the different States of the U. S. vary, but in the majority of them the restriction of the defense to liquidated claims is retained and also the restriction as to mutuality. Where the cross-demand accrued in favor of the actual parties, the plaintiff and the defendant, if the defendant's claim is the greater of the two he may not only defeat the plaintiff's recovery, but recover a judgment for the excess. Where the cross-demands originally accrued in favor of persons who are not both the parties to the action (as, for example, where the plaintiff is an assignee of the demand in suit and the defendant's claim is against the assignor) and set-off is allowed, it can only avail as a partial or total defense. No judgment for any excess can be recovered by the defendant, since the plaintiff is not his debtor. Courts of equity, acting upon the analogies of the statute, have created an equitable set-off broader and more comprehensive than that administered by the courts of law. See Parsons on *Contracts*; Waterman's *Law of Set-off, Recoupment, and Counterclaim*; and Barbour's *Law of Set-off*. F. Sturges Allen.

Seton [= Fr., liter., augmentative of Lat. *sæ'ta*, bristle, coarse hair, (in Late Lat.) silk]: in surgery, a twist of silk or a piece of leather, India-rubber, or other material passed through a fold of skin and beneath the subcutaneous tissue for the purpose of exciting suppuration. Its action may be derivative, or it may tend to promote a salutary adhesive inflammation. The use of setons is less common than formerly, but they nevertheless often serve a very useful purpose.

Seton, Elizabeth Ann (*Bayley*): philanthropist: b. in New York, Aug. 28, 1774; married William Seton about 1794, and on his death at Pisa, 1804, returned to New York; joined the Roman Catholic Church Mar. 14, 1805; conducted a school at Baltimore 1805–08. She and her sisters-in-law, Harriet and Cecilia Seton, took the veil as Sisters of Charity Jan. 1, 1809, at Emmittsburg, Md., being the first members of that order in the U. S. A conventual establishment was opened at Emmittsburg July 30, 1812, with Mother Seton as superior-general. The new order took charge of orphan asylums in Philadelphia 1814, and in New York 1817, in which year it was incorporated by the Legislature of Maryland. At the death of the founder, at Emmittsburg Jan. 4, 1821, there were fifty members. There are in the U. S. about 110 houses and 1,450 Sisters of Charity.

Revised by J. J. Keane.

Settembri'ni, Luigi: author; b. in Naples in 1812; was appointed professor in the Lyceum of Catanzaro in 1835, but, becoming compromised in political affairs, was arrested in 1839 and imprisoned at Naples. Being set at liberty in 1842, he gave private lessons in literature until 1848, publishing in the meantime his bold *Protesta dei Popoli delle Due Sicilie*. In 1848 he held an important post in the ministry of public instruction; on May 16, 1849, the reaction having triumphed, he was arrested and thrown into the prison of San Stefano, where he occupied himself in translating the works of Lucian into Italian. On his release he devoted himself wholly to literature, and published *Lezioni di Letteratura Italiana* (3 vols., Naples, 1867–72). In 1873 he was appointed senator of the kingdom of Italy. D. in Naples, Nov. 4, 1876. See his *Ricordanze della mia vita* (2 vols., Naples, 1876–80).

Setter: a hunting-dog of a breed apparently intermediate between the pointer and the spaniel. This dog was formerly trained to sit or drop when marking down game, but at present it stands at its work like a pointer. There are several distinct strains, as the Irish and the English setters, and of late there are several new stocks which are highly prized. Notable among these are the Gordon, the Macdona, and the Laverack setters. The colors vary, but a liver color is a favorite one. See Dogs.

Settignano, set-tēēn-yaa'nō, Desiderio, da: sculptor; b. at Settignano, a suburb of Florence, in 1428. He is reported to have studied with Donatello. Very little is known of his life, which was probably spent in and near Florence. According to Vasari, he died very young, but recent writers have disputed this. His most important work, which, moreover, is not disputed, is the wall-tomb in Santa Croce in Florence, erected in memory of the scholar Carlo Marsuppini of Arezzo, one of the finest of the many splendid monuments of the Renaissance. The portrait-bust of Marietta degli Strozzi, placed in the Berlin Museum about 1880; the bust of Beatrice d'Este, in the Louvre: an exquisite bas-relief in the Via Cavour in Florence; a tabernacle, or rather ambry (Italian, *ciborio*), in the Church of San Lorenzo, are generally recognized as his work. Probably he was one of the most busily employed of those able designers in mingled architecture and sculpture in which the Florentine Renaissance was so rich. D. Jan. 16, 1464. Russell Sturgis.

Settlement of Decedents' Estates: See the Appendix.

Set-Ty'phon: an Egyptian deity. Set (Gr. Σήθ) was classed as parallel with the monster Typhon (Gr. Τυφῶν, or Τυφάων), son of Tartarus and Ge, or of Hera, who desired to gain mastery over the gods, but was slain by Zeus and buried in Tartarus. Set was believed to be the son of Seb and Nut, brother of Osiris, Isis, and Nephthys, the last being also his wife. As a solar deity he stood for the evil power of the sun's heat, and in general represented the principle of evil and harm, just as Osiris was the type of all that was good and beneficent. The worship of Set was very ancient, dating from the fifth dynasty at least, and his principal sanctuary was at Ombos in Upper Egypt, where he was regarded as the lord of the South. There he was sometimes confounded with the crocodile-headed god Sebak. It is probable that at the time of the eighteenth to the nineteenth dynasties Set was still worshiped, since several kings and other persons bore names compounded with his, such as *Seti*, "belonging to Set." As Osiris, the god of the dead, was revered out of hope, Set held his worshipers through fear of the evil which he had power to inflict on gods and men. For his connection with the Osiris myth, see Osiris.

In general Set was regarded as a foreign deity like Baal, and was in fact the principal god of the Hyksos, under the name

of Sutech. It was the demand of the Hyksos king Apepi addressed to the Egyptians, that they should adopt Set as their chief god, which led to the religious war that ended in the expulsion of the Hyksos by Aāhmes, the first king of the eighteenth dynasty. In the Hyksos city Tanis Set was regarded as a solar deity, the enemy of the serpent Apep, whereas the general Egyptian view identified the two. Set was not only a foreign god, but came to be regarded as the god of the foreigners, and after the evils of foreign oppression had been experienced, the honor paid to him gradually ceased, till during the twenty-second and following dynasties the general detestation in which he was held is evidenced by the fact that his name was erased from the monuments and his images destroyed. He is also found as the god of the Hittites, and consequently he was regarded as the enemy of Rā, the sun-god. Set was represented in the hieroglyphies as an ass-headed figure, or as an ass seated on his haunches with a forked tail in a vertical position. The ass, crocodile, and hippopotamus were sacred to Set, and red-haired men were under his special protection. See Meyer, *Set-Typhon* (Leipzig, 1875). CHARLES R. GILLETT.

Setu'bal (sometimes called ST. UBES): town; in the province of Estremadura, Portugal; on the Bay of Setubal; 20 miles S. of Lisbon (see map of Spain, ref. 17–A). It has an excellent harbor, lined with broad quays and defended by five forts. It is an old town, the *Cetobriga* of the Romans, and is surrounded by walls, but it is well built and clean. It is the chief seat of the Portuguese salt-trade, and has also an extensive trade in wine and oranges. Considerable pilchard-fisheries are carried on. Pop. 15,600.
Revised by M. W. HARRINGTON.

Seul: same as SEOUL (*q. v.*).

Seurt, or **Saird**: town; on the upper Tigris; in the vilayet of Bitlis, Kurdistan (see map of Turkey, ref. 5–I). It is probably the ancient *Tigranocerta*, built by Tigranes the Great (80 B. C.). It carries on trade in wheat, barley, mohair, and gallnuts. Pop. 12,000, Kurds, Armenians, Syrians, and Chaldeans. E. A. G.

Seuse: See SUSO.

Sevasto'pol, or **Sebas'topol**: seaport and fortress; near the southwest extremity of the Crimean peninsula in the Black Sea (see map of Russia, ref. 11–C). The roadstead and the harbor, and the extensive establishments connected with them, form the most important features of the place. It was a Tartar village (*Akhtiar*) until 1780, when the Russian Government commenced the work of establishing here its naval arsenal. The great harbor fortifications which existed at the period of the siege were planned in 1834, and also at the same time land-defenses. The latter had not been constructed when (Sept., 1854) the allied armies of Great Britain and France established themselves before the place and the memorable siege commenced. Every effort was then made to increase the strength of existing intrenchments, and the process continued *pari passu* with the siege. The bastions (of earth) mentioned in accounts of the siege had been previously thrown up. The connecting lines had not the strength of ordinary field-fortifications, the scarcity of earth preventing the excavation of ditches, except about the bastions and other points of support (e. g. the Malakoff, originally a stone tower; the Redan, an earthwork, etc.). To compensate for want of ditches, every practicable expedient was adopted to render access difficult.

Though compressed into comparatively small linear space, the real magnitude of these defenses was enormous, 5,000 or 6,000 men being at some periods daily engaged on them, and the labor being uninterrupted during the eleven months of the siege. The garrison during this period (always in free communication with the external forces by which it was replenished) was usually about 30,000 men; the number of guns mounted at the final assault is said to have been 800, several times that number having been rendered unserviceable in the course of the siege (Oct., 1854–Sept., 1855). The Russian loss in the defense was 84,000 men. (*Todleben.*) The forces actually engaged were, during the latter months, about as follows: French, 120,000; British, 27,000; say, 147,000 men. The Sardinians (5,000) and Turks are not included, as they were not directly engaged. The former and a portion of the Turkish force helped to hold the base (Balaklava) and communications of the besiegers. The French loss was 44,500 (*Niel*); hence the total loss of allies must have been about 60,000. The total loss of besieged and besiegers must have been nearly 150,000.

The fortifications and naval establishments were, after the capture, destroyed by the allies, and by the Treaty of Paris, which terminated the war, Russia was debarred from building arsenals and maintaining a naval force in the Black Sea beyond a very limited magnitude; but this restriction was removed by the abrogation of the neutrality of the Black Sea by the Conference of London (1871). The town has been rebuilt, and since 1885 the fortifications have been actively replaced and the docks reconstructed. Sevastopol has become a pleasant watering-place, and is Russia's greatest southern naval headquarters. It has ceased to be a commercial port since the opening of the new harbor at Kaffa (1895). Pop. (1897) 54,442. See CRIMEAN WAR.
Revised by M. W. HARRINGTON.

Seven Pines, Battle of: See FAIR OAKS.

Seven Sages (or **Wise Men**) **of Greece**: according to most authorities, Bias, Chilon, Cleobulus, Periander, Pittacus, Solon, and Thales, but the names are variously given. Many aphorisms in prose and verse, chiefly practical observations for the regulation of life, the work of these and other wise men of the antephilosophic period of Greece, have been collected in Orelli's *Opuscula Græcorum Veterum Sententiosa et Moralia* (vol. i., p. 138, *seq.*). J. R. S. S.

Seven Sleepers: according to an early tradition, seven Christian brothers of Ephesus who, during the persecution of Decius (251), took refuge in a cave, the entrance of which was walled up immediately after by the heathen. There they slept miraculously until 447. Then they awoke, told their story to many persons—among others to the Emperor Theodosius II.—and died after having thus confirmed the faith of the Christians. The Roman Catholic Church commemorates them on July 10. This legend can be traced at least as far back as the beginning of the sixth century. It is also told by Mohammed in the Koran. Kindred tales are found in various forms in the folk-lore of the East. E. A. G.

Seventeen-year Locust: See CICADA.

Seventh-day Adventists: See ADVENTISTS.

Seventh-day Baptists: a denomination of Christians formerly called *Sabbatarians*. They hold to the immersion of adult believers, and also to the observance of the seventh day of the week as the Sabbath, arguing that since the institution of the Sabbath at the close of creation and its formal annunciation as a part of the Sinaitic code there has always been an unbroken chain of men who have kept the seventh day of the week as a Sabbath, according to its original institution and enjoyment, and considering the introduction of the observance of Sunday, in the middle of the second century, as the first step to apostasy. Traces of the peculiar practice of observing the seventh day of the week as the Sabbath among some of the early Reformers are not few. The Sabbatarians began to attract attention in England about the time of the Commonwealth. In 1650 they assumed a denominational form in that country. The first Sabbatarian church in America was organized at Newport, R. I., in 1665, under the care of Stephen Mumford. In 1671 they left the Baptist denomination. In 1818 they assumed their present name. In the U. S. they have three colleges, one at Alfred Centre, N. Y., one at Milton, Wis., and one at Salem, W. Va., a number of academies and periodicals, a tract and publication society, and a missionary organization. The number of organizations in 1900 was 114, the number of members 9,161. In England they are at present few in number.—SEVENTH-DAY BAPTISTS (GERMAN), a small sect which in 1728 seceded from the Dunkers of Pennsylvania, and established at first a solitary, and then a conventual, life at Ephrata, Lancaster co., Pa. They hold a part of their property in common, adopt the Capuchin habit and a system of monastic names, and recommend, but do not absolutely require, celibacy. At present their leading establishment is at Snowhill, Franklin co., Pa. In 1890 there were six organizations and 194 members. Their founder was Conrad Beissel. See *A General History of the Sabbatarian Churches*, by Mrs. Tamar Davis (1851). See BAPTISTS. Revised by W. H. WHITSITT.

Seven Up: a game at cards known also as *all-fours* and *old sledge*. It is designed for two players and is played with a full pack, the cards ranking as in whist. Six cards are dealt each player, three at a time, and the next is turned face up. If the non-dealer is dissatisfied with this for trump he "begs," and the dealer must either immediately add one point to his opponent's score or lay the turned card aside and deal three more to each player, turning the next card for trump; but if this be of the same suit as before he must

lay it aside and deal three more to each, and so on until a new trump is turned. The eldest hand leads first, and thereafter the winner of the trick. A player must follow suit if he can, except that he may play a trump instead. One point is scored for (1) playing the highest trump (*high*), (2) playing the lowest trump (*low*), (3) turning up a knave or taking the knave of trumps (*jack*), and (4) taking the most valuable cards (*game*), counting here each ten as 10, ace 4, king 3, queen 2, and knave 1. The first to score seven points wins; in the last hand the points are scored in the order given above (not in the order in which they are made), except that the point for turning a knave is scored when it is turned. This game is much played, and is of especial interest as being a game from which many others have been derived by greater or less modifications and additions: examples are California jack, pedro, cinch or double pedro, draw pedro, and pitch.

Seven Wonders of the World: variously given, but generally as follows: The Colossus of Rhodes (see CHARES), Diana's temple at Ephesus (see DIANA, TEMPLE OF), the Mausoleum at Halicarnassus (see MAUSOLEUM), the PYRAMIDS (*q. v.*), the Pharos at Alexandria (see LIGHTHOUSE), the HANGING GARDEN OF BABYLON (*q. v.*), and the colossal gold and ivory statue of Zeus, by Phidias, at Olympia.

Seven Years' War: the contest between Prussia and several of the other powers of Europe extending from 1756 to 1763. Prussia, which had previously seized the Austrian province of Silesia, held it despite the efforts of Maria Theresa to regain it. The latter was determined to crush, or at least humiliate, the house of Brandenburg; and since the Peace of Aix-la-Chapelle (1748) the Austrian generals had been busy in reorganizing and increasing their armies, while the empress and her agents had been forming alliances against Prussia. The Czarina of Russia, Elizabeth, was a willing ally; she knew that Frederick II. used to make her immoralities the favorite subject of his sarcasms. But with respect to France, the hereditary enemy of Austria and just then at war with England, the former ally of Maria Theresa, the difficulties seemed almost insurmountable. Nevertheless, when George II. concluded an alliance with Prussia Jan. 16, 1756, in order to secure his Hanoverian possessions against a French invasion, and when Maria Theresa stooped to write a letter to Madame de Pompadour, Prince Kaunitz succeeded in forming an alliance between France and Austria (May 1, 1756). Sweden, whose possessions in Northern Germany were confined to Stralsund and the island of Rügen, was easily persuaded by France to make a descent on Pomerania. In Saxony the elector was so exasperated at Prussia that he even came forward with a proposal of alluring the Prussian king into Bohemia by a feigned neutrality, and then throwing an army into his rear to cut off his lines of retreat and communication. Frederick II. knew of all these plans, and when he saw that war was unavoidable he fell at once, without any declaration of war, upon Saxony with 60,000 men (Aug., 1756), took Dresden Sept. 9, shut up the Saxon army of 18,000 men in its camp between Pirna and Königstein, defeated the Austrian army under Braun, who from Bohemia hastened to the support of Saxony, compelled the Saxon army to surrender Oct. 15, and placed the whole country under Prussian control. But notwithstanding this brilliant beginning the situation in the spring of 1757 was almost overwhelming. At the north 22,000 Swedes gathered in Stralsund ready to cross the Peene; in the east 100,000 Russians under Apraxin pushed onward to Memel; in the southeast two Austrian armies approached through Bohemia—the one, of 76,000 men, under Charles of Lorraine, destined for Silesia, the other, of 46,000 men, under Daun, destined for Saxony; in the southwest two French armies marched toward Prussia—the one, of 100,000 men, under d'Estrées, through Hanover, the other, of 36,000 men, under Soubise, through Hesse-Cassel; in the south an army from the contingents of the South German states was destined to manœuver in connection with the Western Austrian and Eastern French armies. In the center of this circle stood Frederick II. with an army of about 200,000 men. Great Britain, his only ally, promised and paid him for several years a handsome subsidy, but her representative, the Duke of Cumberland, commanded an army of only 40,000 British-Hanoverian troops in Hanover. In Apr., 1757, Frederick broke into Bohemia; attacked the Austrian army under Charles of Lorraine before Prague May 6; split it in two, of which the one part retired into Prague, and the other retreated to the southwest to join Daun; invested and besieged Prague; marched with one division of his army against Daun, who came to re-enforce the city; met him at Kolin June 18; was completely defeated, and retreated with his whole force into Saxony, slowly followed by Daun, while Charles of Lorraine marched onward to Silesia. In Hanover the Duke of Cumberland was totally defeated by d'Estrées at Hastenbeck July 26, and compelled to conclude the capitulation of Kloster-Zeven Sept. 8, by which his army was dissolved. D'Estrées's successor, the Duke of Richelieu, was too much occupied with plundering Hanover to do anything serious, but in the meantime Soubise, with the second French army, had conquered Hesse and penetrated into Saxony. Frederick II. met him at Rossbach Nov. 5, and literally scattered his army to the winds. With incredible rapidity he then turned to Silesia, which had fallen into the hands of the Austrians; routed Charles of Lorraine at Leuthen Dec. 5, and reconquered the whole province with the exception of Schweidnitz. In the north the Swedes were driven back into Stralsund, and the Russians, although victorious at Grossjägerndorf Aug. 30, and still occupying Memel, suspended all hostilities on account of the illness of the czarina, which changed the whole policy of the country. Thus, when winter set in and stopped all military operations, the actual loss which Frederick II. had sustained was not great, and the prestige he had gained was enormous. The capitulation of Kloster-Zeven was not ratified by the British Parliament. On the contrary, a new British-Hanoverian army was organized and placed under the command of Duke Ferdinand of Brunswick, and during the subsequent campaigns he succeeded by his vigilance, energy, and shrewd tactics, and by several brilliant victories—at Crefeld June 23, 1758, over Clermont, and at Minden Aug. 1, 1759—in keeping the French on the other side of the Rhine. In the sea-war between Great Britain and France, Spain joined the latter in 1761, but Great Britain was so successful in North America, the West Indies, the African coast, and India, and showed herself so superior to France in all their great naval encounters—at Quiberon, 1759, and Belleisle, 1761—that she then laid the foundation of her great maritime empire. In 1758 Frederick II. defeated the Russians at Zorndorf Aug. 25, but he was himself defeated at Hochkireh Oct. 14, by the Austrians under Daun. He nevertheless kept both Silesia and Saxony, but in 1759 was so completely routed at Kunersdorf, Aug. 12, by the Russians and Austrians, that the morning after the battle he could hardly gather 5,000 men. Dresden and a large part of Saxony fell into the hands of the allies, and although he reconquered it in 1760 by the brilliant victories at Liegnitz Aug. 15, and at Torgau Nov. 3, his ruin seemed, nevertheless, unavoidable. On Oct. 25, 1760, George II. died, and the British subsidies stopped. The Russians under Todleben took Berlin and plundered it for three days. In large districts, especially of the eastern part of his kingdom, the houses were burned, the animals driven away, the men killed, and the women and children left to starve. Frederick's army, mostly foreigners and young recruits, numbered only 50,000, and with this force he had to face three hostile armies at once, each superior in numbers to his own. But the czarina died Jan. 5, 1762, and her successor, Peter III., was an enthusiastic admirer of Frederick II. Peace was concluded with Russia May 5, and with Sweden May 22, and although the projected Russo-Prussian alliance was frustrated by the assassination of Peter III., Catherine II., his successor, declared herself neutral; Austria felt too weak to carry on the war alone. Almost without any preliminary negotiations peace was concluded between Prussia and Austria at Hubertsburg Feb. 15, 1763, by which "all should remain as it had been before the war." The effort to wrench Silesia from Prussia had failed, and the heroic and triumphant resistance of the king gave him the permanent appellation of Frederick the Great. See Frederick II., *Histoire de la Guerre de Sept Ans* (6 vols., 1794–1801); Carlyle, *Frederick the Great*; Ranke, *Ursprung des siebenjährigen Krieges* (1871). Revised by C. K. ADAMS.

Severi'nus, SAINT: the apostle of Noricum; b. in Italy in the beginning of the fifth century; made a journey to the East, where he adopted a life of the severest asceticism, and devoted himself, after his return to the West, to missionary work. He first visited Pannonia, but afterward settled in Noricum, a Roman province comprising the present Austria, Styria, Carinthia, Carniola, and Tyrol. He died, after an eventful life, at Faviana, a city situated on the Danube, near the present Vienna, Jan. 8, 482. His *Life*, by his pupil Eugippius, is in Migne, *Pat. Lat.*, lxii., 550, *seq.*

Severn: a river of England which rises in Montgomeryshire at an elevation of 1,500 feet above the level of the sea, flows east, south, and then southwest, and falls into the Bristol Channel after a course of about 210 miles, though the distance from source to mouth is only 80 miles in a straight line. It is navigable for 150 miles, and the tide, which in its estuary assumes the character of the bore, locally called *hygre*, is perceptible 120 miles from its mouth. Its chief affluents are the Terne and the upper and lower Avon on the E. and the Teme and the Wye on the W. A canal 18½ miles long, and navigable for vessels of 400 tons, extends from Gloucester to the upper portion of the estuary. Other canals establish communication between the Severn and the Thames, Trent, and Mersey.

Seve'rus, Alexander: See Alexander Severus.

Severus, Septimius: Roman emperor (193–211 A. D.); b. near Leptis in Africa in 146; married the famous Julia Domna, daughter of Bassianus, priest of the Sun at Emesa. While commander-in-chief of the Roman armies in Illyria and Pannonia he was proclaimed emperor by his troops. He deposed the Emperor Julianus and crushed the rival claimants Pescennius Niger and Clodius Albinus; captured Byzantium (197) after a memorable siege which lasted three years; invaded Parthia and captured Ctesiphon; from 203 to 207 remained peacefully at Rome, where he remodeled the constitution of the Pretorian Guards: was then called to Britain to repress rebellion and marched the entire length of the island, subduing the Caledonians; died at Eboracum (York) in 211, his death being hastened by the unnatural conduct of his son Caracalla. E. A. Grosvenor.

Severus, Sulpicius: See Sulpicius Severus.

Severus, Wall of: a wall of stone partly built or repaired by the Emperor Severus in 208 A. D. to protect Roman Britain from the Caledonians. It was originally erected by Hadrian. It extended from the Solway to the Tyne, immediately N. of the wall of Hadrian, and consequently far S. of that of Antoninus. Considerable portions of the wall still remain. See Hadrian's Wall.

Sevier, sev-eer', John: pioneer and soldier; b. on Shenandoah river, Virginia, in 1745, of French parents; originally named Xavier; explored the Holston river in East Tennessee (then North Carolina), built Fort Watauga, and fought successfully against the Indians. During the Revolutionary war he distinguished himself by his bravery. He was foremost in almost all the battles and skirmishes, as well as treaties and negotiations, with the Indians during many years, and was regarded by the settlers as their friend and protector; was chosen in 1785, without opposition, Governor of the anomalous State of Franklin, comprising Western North Carolina and Eastern Tennessee. He received from President Washington the commission of brigadier-general of the territory S. of Ohio river. In 1796 the State of Tennessee was erected and admitted into the Union, and Sevier was chosen Governor, served for two consecutive terms, and was re-elected in 1803; was elected a Representative in the U. S. Congress in 1811, and re-elected in 1813. D. near Fort Decatur, Ga., Sept. 24, 1815, while on a mission to the Creek Indians. F. M. Colby.

Sevier Lake: a body of salt water in Western Utah; in lat. 39° N., lon. 130° 10′ W.; altitude, 4,000 feet. Its sole tributary is the Sevier river, which enters at the north end. Its valley is a southward arm of the Sevier desert, limited at the W. by the House Range of mountains and at the E. by the Beaver Creek Range. The lake, having no outlet, is of variable size, its extent depending on the relation between inflow and evaporation. In 1872 its length was 28 miles, its width 10 miles, its area 188 sq. miles, and its depth 15 feet; but its natural size was somewhat greater, for at that time a portion of the water of the Sevier river was used for purposes of irrigation. The whole of the river is now utilized in that way through the entire spring and summer, so that little water reaches the lake except in winter. As a result its bottom generally becomes dry each year, and the water acquires in winter a depth of but a few inches. The salts which made the natural water a strong brine have been precipitated and form a crust over the lake-bottom. This crust is estimated to contain 1,500,000,000 tons, of which about three-fourths is sodium chloride and the remainder sodium sulphate and magnesium sulphate. The only inhabitants of the lake are a species of brine-shrimp (*Artemia*) and the larvæ of certain insects. Such fishes as reach it from the river are poisoned by the brine. Old water-lines about the margin of the valley show that the lake was once of greater extent. At the time of its extreme depth, 590 feet, it coalesced with Great Salt and other lakes, the whole forming a vast inland sea. See Bonneville, Lake.

G. K. Gilbert.

Sévigné, sā'vēn'yā', Marie de Rabutin Chantal, Marquise de: writer; b. in Paris, France, Feb. 6, 1626; was left an orphan very early, but received an excellent education from her uncle, Abbé de Coulanges, and married in 1644 the Marquis Henri de Sévigné (d. 1651), to whom she bore a son and a daughter. She was rich, spirited, beautiful, one of the most prominent members of the literary circle of the Hôtel Rambouillet, and on intimate terms with all the principal actors in the civil war of the Fronde. In 1669 her daughter, to whom she was passionately attached, was married to the Marquis de Grignan, governor of Provence; the consequent separation occasioned a correspondence which, although not intended for publication, appeared after the death of the authoress, and has made her name celebrated, the letters being at once of great historical interest and of the highest literary merit. D. at Grignan, Apr. 18, 1696. The chief edition of her *Letters* is that of Regnier (14 vols., 1862-67; new ed. begun 1887). See also Walckenaer, *Mémoires touchant la Vie et les Écrits de Madame de Sévigné* (1842); Capmas, *Lettres inédites de Madame de Sévigné* (1876); Combes, *Madame de Sévigné historienne* (1885); the biographies by Bossier (1887) and Vallery-Radot (1888); and Saporta, *La famille de Madame de Sévigné en province* (1889).

F. M. Colby.

Seville, sev'il (Span. *Sevilla*, anc. *Hispalis*): capital of the province of Seville, Spain; on the left bank of the Guadalquivir, 70 miles from its mouth (see map of Spain, ref. 19–C). Under the Romans, Goths, and Moors it was the capital of wealthy and powerful empires. The earlier kings of modern Spain also resided here; and though Charles V. removed the royal residence to Valladolid, Seville rose to a still higher degree of splendor and prosperity when America was discovered, as it became the mart of the new colonies. During the French invasion (1810–13), and by the subsequent loss of the Spanish colonies, it suffered very much, but it recovered rapidly, and is an enterprising modern town. Its old Moorish walls, 5 miles in circuit, pierced by fifteen gates, and surmounted by sixty-six towers, have disappeared, except the single gate called Triana. Across the city runs the Alameda, a broad, open street lined with palaces, planted with magnificent elms, and adorned with numerous fountains, which, like the city in general, are provided with water by several great aqueducts, of which that built by Julius Cæsar and rebuilt by the Moors in 1172 is a magnificent structure resting on 410 high arches. The rest of the city, with the exception of the numerous public squares and promenades, consists mostly of narrow streets lined with high, somber-looking, but substantial houses of Moorish construction. Among its edifices the cathedral is the most remarkable. It is one of the greatest Gothic structures in the world, 431 feet long, 315 feet wide, and 145 feet high under the transept dome, and it is most magnificently adorned with paintings by Murillo, the Herreras, and other masters of the school of Seville, besides being almost overloaded with sculptures. Unique of its kind is the Giralda, a belfry 350 feet high; and most interesting on account both of their architecture and ornamentation are the Alcazar or royal palace and the university, founded in 1579. Besides the university, to which several scientific establishments are attached, Seville has many good educational institutions, and several valuable libraries and art collections. Among its manufactures are an immense cigar-factory, a cannon-foundry, several manufactories of muskets and other firearms, powder, saltpeter, soap, leather, cotton thread, etc. Its chief exports are oranges, olive-oil, wine, wool, cork, copper, lead, and quicksilver. As Seville was held by the Moors for five centuries and entirely rebuilt by them from the materials of former Roman edifices, it became a purely Moorish city, and to a certain extent it still preserves that character, though the narrow, tortuous streets are gradually giving way to broad and straight boulevards. Pop. (1887) 143,182. The province of Seville occupies the lower valley of the Guadalquivir, bounded W. by Huelva and S. by Cadiz; area, 5,295 sq. miles; pop. (1887) 544,815.

Revised by M. W. Harrington.

Sèvres, sev'r: town; in the department of Seine-et-Oise, France; on the Seine; 10½ miles S. W. of Paris by rail (see map of France, ref. 3–F). It is celebrated for its manufactures of

porcelain, which are generally acknowledged to be the most elegant ever produced, in both design and painting. The porcelain museum contains a large collection of china and earthenware from all parts of the globe. Pop. (1896) 7,317.

Sèvres, Deux, dö- : department of Western France, deriving its name from two rivers—the Sèvre-Niortaise, which flows into the Bay of Biscay, and the Sèvre-Nantaise, which joins the Loire. Area, 2,317 sq. miles. The northern part is hilly, even mountainous; the southern level. The soil is everywhere fertile; it produces more wheat than is necessary for home consumption, and affords excellent pastures. Cattle, horses, mules, and asses are extensively reared. Iron, marble, and granite are found, and considerable manufactures are carried on. Pop. (1896) 346,694. Capital, Niort.

Sewall, syu'el, JONATHAN, LL. D.: b. in Boston, Mass., Aug. 24, 1728; graduated at Harvard 1748; taught school at Salem till 1756; began the practice of law at Charlestown in 1758; became attorney-general of Massachusetts 1767; gained a suit by which a slave recovered his freedom at common law 1769; resided at Cambridge until 1774, when his Tory sentiments caused his house to be wrecked by a mob; went to England in 1775; was included among the sufferers by the penal act of Apr. 30, 1779, against the loyalists; settled at St. John, New Brunswick, 1788, and was judge of the court of vice-admiralty until his death Sept. 26, 1796. He was long reputed the author of the letters signed Massachusettensis published in defense of British policy, and replied to by John Adams over the signature of Novanglus, but it is now known that they were written by Daniel Leonard, of Taunton.—His son, JONATHAN SEWELL, LL. D. (1766–1839), who adopted the English form of the name, was chief justice of Lower Canada 1808–38.

Sewall, MAY (*Wright*): educator; b. at Milwaukee, Wis., May 27, 1844; educated at the Northwestern University; taught public schools in Michigan, and was soon made principal of the High School in Plainwell, in that State; later became, successively, the principal of the High School in Franklin, Ind., and teacher of English and German in the High School in Indianapolis; married in 1880 Theodore L. Sewall, principal of a private school for boys in that city. In 1882 Mr. and Mrs. Sewall opened a girls' classical school. Mrs. Sewall's energies were enlisted in reforms soon after reaching womanhood. She was first actively connected with the National Woman Suffrage Association, in which she held for many years the office of chairman of the executive committee. She was one of the promoters of the International Council of Women which convened in Washington in 1888, and conceived the idea of perpetuating its influence through permanent International and National Councils of Women. In the organization of both these bodies she subsequently aided, and has served as president of the National Council and vice-president at large of the International Council. She was also one of the committee that formulated the plan for the general federation of women's clubs. In Indianapolis she was one of the founders of the Woman's Club; of the Art Association; of the Equal Suffrage Society; of the Ramabai Circle; of the Indiana Branch of the Association of Collegiate Alumnæ; of the university extension work in Indianapolis, under the auspices of this latter society; of the Local Council; of the Woman's Exchange; and of the Contemporary Club. She also originated the plan of the Indianapolis Propylæum, an incorporated joint-stock company of women, which has erected a handsome building for social and educational purposes. Mrs. Sewall was appointed member at large of the board of World's Fair managers for Indiana, was chairman of the committee on women's work, and a member of the committee on education in that body. She was also made the chairman of the committee on the World's Congress of Representative Women, in the World's Congress Auxiliary of the Columbian Exposition of 1893. She has lectured frequently on social, educational, literary, and reform topics, is a contributor to periodicals, and has edited *The Historical Résumé of the World's Congress of Representative Women* (2 vols.).

SUSAN B. ANTHONY.

Sewall, SAMUEL: jurist; b. at Bishopstoke, England, Mar. 28, 1652. His parents emigrated to New England and settled at Newbury, Mass., 1667, and he entered Harvard, graduating 1671; studied theology; preached for a short time; acquired a fortune by his marriage (Feb. 28, 1676) with Hannah, daughter of John Hull, master of the mint at Boston; was assistant governor 1684–86 and 1689; visited England 1688–89; was annually chosen a member of the executive council from 1692 to 1725; was judge from 1692 to 1718, when he was made chief justice, being at the same time judge of probate for Suffolk County; presided at the trial of some of the victims of the witchcraft delusion of 1692, but was soon convinced of his error, for which he publicly asked pardon of God and man in a paper read to the congregation of the Old South church, Boston, on Fast Day, Jan. 14, 1697, by his pastor, Rev. Samuel Willard; was noted for his charity and philanthropy, having been perhaps the first American writer against slavery, on which theme he published a tract, *The Selling of Joseph* (1700); was secretary and treasurer of the society for the maintenance of Indian missions, and was author of *An Answer to Queries respecting America* (1690); *Accomplishment of Prophecies* (1713); *A Memorial relating to the Kennebec Indians* (1721); and *A Description of the New Heaven* (1727). He resigned his judicial offices 1728. D. in Boston, Jan. 1, 1730. His *Diary* and other papers have been published by the Massachusetts Historical Society.—His son, JOSEPH, b. in Boston, Aug. 26, 1688, graduated at Harvard 1707; studied theology: was ordained colleague pastor of the Old South church Sept. 16, 1713; declined the presidency of Harvard College 1724; received the degree of D. D. from the University of Glasgow 1731; gave to that institution a fund for the education of indigent students; was a friend of learning and a man of great benevolence and worth. D. in Boston, June 27, 1769. Author of *Four Sermons* (1741) and of twenty-three other sermons separately printed.

Sewall, STEPHEN: scholar; b. at York, Me., Apr. 4, 1734; graduated at Harvard 1761; taught the grammar school at Cambridge; became instructor in Hebrew in Harvard 1762, and was Hancock Professor of Hebrew 1765–85; published a *Hebrew Grammar* (1763); wrote seven of the Greek and Latin poems in *Pietas et Gratulatio* (1761) and other works, and left several MSS., now in the library of Harvard, including a *Chaldee and English Dictionary*. D. in Boston, Mass., July 23, 1804.

Seward, syu'ard: city; capital of Seward co., Neb.; on the Big Blue river, and the Fre., Elk. and Mo. Val. and the Burlington Route railways; 25 miles W. by N. of Lincoln, the State capital (for location, see map of Nebraska, ref. 10–G). It is in an agricultural region, and contains 2 national banks with combined capital of $100,000, a State bank with capital of $60,000, a savings and investment company with capital of $50,000, and a monthly and 4 weekly newspapers. Pop. (1880) 2,032; (1890) 2,108; (1900) 1,970.

EDITOR OF "BLUE VALLEY BLADE."

Seward, ANNA: poet; b. at Eyam, Derbyshire, England, in 1747; obtained some celebrity as a poet, chiefly by her elegies upon her friend Maj. André (1781), and upon Capt. Cook; resided most of her life at Lichfield, where her father was a canon residentiary; published a *Life* of her friend Dr. Erasmus Darwin (1804), in which she laid claim to the authorship of the first fifty lines of *The Botanic Garden*; also *Louisa*, a poetical novel (1782), and *Sonnets* (1789). D. at Lichfield, Mar. 23, 1809, bequeathing her MSS. to Sir Walter Scott, who published her *Poetical Works and Correspondence* (3 vols., 1810), with a prefatory memoir, but the collection met with little favor, though by her contemporaries she was called the Swan of Lichfield. Constable published six volumes of her correspondence (1811–13).

Revised by H. A. BEERS.

Seward, THEODORE FRELINGHUYSEN: author, composer, and teacher; b. at Florida, Orange co., N. Y., Jan. 25, 1835; studied music with Dr. Lowell Mason and others; taught vocal music and edited and compiled many sacred and secular music-books; edited several music periodicals; managed the concerts of the Jubilee Singers in Europe; introduced the tonic sol-fa system of instruction into the U. S. in 1880; in 1891 founded the Brotherhood of Christian Unity; author of *Hadesian Theology, or the Gospel according to Satan*; *The School of Life, or Divine Providence in the Light of Modern Science* (1894); *A Plea for the Christian Year*, and other books.

D. E. HERVEY.

Seward, WILLIAM HENRY, LL. D.: statesman; b. at Florida, Orange co., N. Y., May 16, 1801; educated at Farmers' Hall, Goshen, and at Union College, where he took the degree of A. B. in 1820; studied law in New York and Goshen, and was admitted to the bar at Utica in 1822; settled in Auburn in 1823, where he soon took a prominent place among the leaders of the profession. In 1824 his political proclivities be-

came conspicuous, and from that time he was prominently connected with all the political movements of importance in the State and nation. He earnestly advocated the election of John Quincy Adams; was one of the State committee to welcome Lafayette in 1827; was elected in 1830 as an anti-Masonic candidate for the State Senate, where he labored for the improvement of schools, construction of railroads and canals, and for the collection of those documents which form the monumental *Colonial History of New York*. During the next four years he delivered frequent addresses, denouncing the course of President Jackson, and supporting the newly formed Whig party with such fervor and success that in 1834 he was nominated for Governor. In this he was unsuccessful, but on the triumph of the Whigs in 1837 he was again nominated, and was elected by a small majority. Though his administration was one of peculiar difficulties, owing to bitter factions within the party, he recommended and succeeded in carrying so many wise measures that his position in the party was much strengthened. He was re-elected in 1840. During his administration Roman Catholics were first admitted to the public schools, many of the disabilities of foreigners were removed, the natural history and geological survey of the State were begun, and the State Museum of Natural History at Albany was established. From 1843 to 1849 his activities were confined to professional practice and to occasional addresses on scholastic and political subjects. In 1849 he was chosen as a Whig to the U. S. Senate, where at once he took a position of prominence not only as one of the leaders of his party, but also as an influential adviser of President Taylor. It was in Mar., 1849, in a speech on the admission of California, that he spoke of the exclusion of slavery from all new States as demanded by "the higher law," a phrase which was so severely criticised as treasonable by Southern members that it became famous as a watchword of abolition. On the accession of Fillmore after the death of President Taylor, Seward declined to follow his party in the support of what was deemed Fillmore's pro-slavery policy. His speeches in the Senate and before public audiences during this period gave him great prominence by reason of their comprehensiveness and independence. In 1852 he favored the nomination of Gen. Scott, but opposed the statement of the party platform concerning slavery. Re-elected to the Senate in 1855, he took prominent part in the political agitations extending to the outbreak of the war. In 1858, in the course of a speech at Rochester, he coined the second of the famous phrases that are inseparably connected with his name when he declared that the slavery question indicated "an irrepressible conflict" which could only terminate by making the country either entirely a free nation or entirely a slave-holding nation. Both in 1856 and in 1860 he was the most conspicuous candidate of the Republican party for the nomination for the presidency. In 1860 the New York delegation, headed by William M. Evarts, went to the Chicago convention with much confidence that their candidate would be chosen. On the first ballot Seward received 173½ votes and Lincoln 102. The vote of Pennsylvania went over to Lincoln and other States followed. Seward, though defeated in the convention, supported Lincoln earnestly by speaking in the West as well as in the East. When Lincoln assumed office the arduous and delicate post of Secretary of State was given Mr. Seward. Though he habitually underestimated the strength and the earnestness of the South, his management of the delicate foreign relations of the Government were characterized by tact and skill. When the Confederates Mason and Slidell were taken from the British vessel the Trent, Great Britain made a peremptory demand for their restoration, and for a time war seemed almost inevitable. The answer, first drawn by Mr. Seward and then slightly modified by President Lincoln, was a masterpiece of tact and diplomatic skill. The position taken was that the exemption from search claimed by Great Britain was what the U. S. had fought for during the war of 1812 against Great Britain, and that as Great Britain had come to the position of the U. S. the Government very cheerfully released the prisoners. In all the negotiations with foreign powers to induce them to preserve a position of strict neutrality the duties of the Secretary were performed with great skill. On the evening of Apr. 14, 1865, when President Lincoln was assassinated, one of the conspirators forced his way into Mr. Seward's bedroom, where he was lying ill, and struck him several times in the face and neck with a dagger. The wounds, though severe, did not prove mortal. Recovery, however, was very slow. Seward was retained in his position by President Johnson, whom the Secretary supported in his policy of reconstruction. After a memorable service of eight years he retired in Mar., 1869. Though much enfeebled in body he undertook with his family a voyage around the world in 1870, and published in 1871 an account of his observations. He died at Auburn, Oct. 10, 1872. His works, in 5 vols., include the most important of his speeches.

C. K. Adams.

Sewell, Elizabeth Missing: author; b. in the Isle of Wight in 1815; became well known as the author of novels of the so-called High Church school of fiction, among which were *Amy Herbert* (1844); *Gertrude* (1845); *Laneton Parsonage* (1846); *Margaret Percival* (1847), which were republished in the U. S. She also wrote works of travels, many volumes of a devotional character, poems, and histories of Greece, Rome, and Egypt for young people. D. in London, June 10, 1884. Revised by H. A. Beers.

Sewel'lel [from native (Amer. Ind.) name]: a rodent, *Haplodon rufus*, representing a special family, *Haplodontidæ*. It is noted for its rootless molars; is reddish brown, with very small eyes and a short tail; is about the size of a musk-rat, and has very strong jaws and a plump, heavy body. It is found on the Pacific coast in California, Oregon, and Washington, is gregarious, and lives in burrows. Its skin is employed by the Indians as an article of dress.

Sewen: See Bull-trout.

Sewerage [deriv. of *sewer* < M. Eng. *assewer*, from O. Fr. *esseuwer*, to drain < Lat. *ex*, out + deriv. of *aqua*, water]: a system of sewers or underground channels for carrying off the sewage or liquid refuse and the storm-water of a locality. The construction of such a system for a town is also called sewerage.

In all densely populated areas a proper regard for the health of the community requires the removal of solid and liquid refuse from the neighborhood of dwellings. Where dwellings are far apart, as in country districts, the liquid wastes from the house may be safely disposed of on the soil by very simple means; but when dwellings are crowded together, as in towns, there is no longer sufficient available open ground in the vicinity for such disposal, and sewers become a necessity. In towns where there are no sewers the sewage is run into cesspools, where it decomposes, contaminating the earth, air, and water in the vicinity, and becomes the disseminator of disease. To provide for the prompt and rapid removal of this sewage is the object of sewerage. The requisites for a sewer are that it be so constructed as to carry the sewage to its outfall with the least possible delay; that it be smooth on its interior surface, so as not to retard the flow of sewage and afford no lodging-place for the solid particles; that it be water-tight throughout its entire length.

The foremost nations of antiquity understood the necessity for sewerage, and their great cities had carefully designed and well-constructed sewers. In the ruins of Babylon and Nineveh and of the ancient cities of Egypt are found the remains of systems of sewerage. Exploration has brought to light the extensive sewers of ancient Jerusalem, and the visitor in Rome to-day sees in the Cloaca Maxima a sewer which still fulfills the purpose for which it was constructed twenty-five centuries ago.

During the dark ages sanitary works were neglected, but fatal epidemics and plagues brought thinking men at last to realize in some degree the necessity for attending to matters relating to the public health. Sanitary works were again undertaken, and with advancing civilization sanitary science has received more and more attention.

Sewers designed to carry both the liquid wastes and the storm water from any locality are called combined sewers. Those designed to carry only the sewage proper are called separate sewers.

The Separate System of Sewerage.—In this the first thing to be determined is the size of the sewers. The proper size of any sewer depends upon the number of people contributing sewage to it; the amount of sewage per day for each person; the maximum rate of discharge; and the form, grade, and interior surface of the sewer. In estimating the number of people provided for on any line of sewers, provision must be made for the extension and growth of towns and a liberal allowance made for an increase in the volume of sewage.

Amount of Sewage.—The amount of sewage per capita depends very largely upon the water-supply. It is also dependent upon the habits of the people, the amount of manufacturing in which large quantities of water are used, and

the use of water-motors for elevators, etc. The volume of sewage to be provided for per day may be taken as equal to the volume of water supplied. This varies greatly in different towns, and in different years in the same town. U. S. statistics show that the use of water varies in the different cities from 25 to 175 gal. per day per capita, and that the amount used is rapidly increasing. In many cases the increase has been 100 per cent. in twenty years. It would not be safe, in any case, to assume the consumption of water to be less than 100 gal. per day per capita, and where water is much used for manufacturing purposes and for motors a still larger amount must be provided for.

Varying Rate of Discharge.—The consumption of water, and hence the discharge of sewage, is not constant. It varies with the different hours of the day, the days of the week, and the months of the year. The time of maximum discharge varies in different places with the habits of the people and the climate. The daily maximum of water consumption is from five to seven o'clock A. M., and the amount of maximum flow per hour is from 20 to 100 per cent. in excess of the mean hourly consumption. The maximum daily consumption for the week is on Monday. Taking the whole year into consideration there are two maxima of daily consumption. One of these is during the coldest weather in winter, and the other in the hot, dry weather in summer. The maximum daily consumption varies from 20 to 50 per cent. in excess of the mean daily consumption.

The flow of sewage not being uniform, the sewers must be made large enough to provide for the maximum flow. On the other hand, any unnecessary size is a serious detriment to the efficient working of the sewer. Any increase in size of the sewer, the amount of sewage remaining the same, decreases the depth and velocity of flow of the sewage, and hence its transporting power and effectiveness.

The following table shows the comparative depth and velocity of flow in circular sewers of different sizes, laid on the same grade and carrying the same amount of sewage:

SEWER.	Depth of flow, inches.	Velocity in feet per minute.	Discharge in cubic feet per minute.
6-inch sewer	3·00	147	14·40
8-inch "	1·92	129	14·40
10-inch "	1·36	112	14·40
12-inch "	1·03	100	14·40
15-inch "	0·75	83	14·40

The following table shows the comparative velocity and discharge of a circular sewer at different depths of flow. The depth is given in fractions of the diameter, and the velocity and discharge are given in fractions of the velocity and discharge when the depth is the diameter of the sewer.

Depth of flow.	Velocity.	Discharge.	Depth of flow.	Velocity.	Discharge.
0·067	0·414	0·0277	0·600	1·0534	0·6302
0·100	0·498	0·0498	0·700	1·0932	0·7642
0·1465	0·602	0·0883	0·750	1·0984	0·8238
0·200	0·6942	0·1388	0·800	1·1028	0·8822
0·250	0·7698	0·1914	0·8535	1·1010	0·9397
0·300	0·8210	0·2463	0·900	1·0918	0·9826
0·400	0·9264	0·3702	0·933	1·0794	1·0071
0·500	1·0000	0·5000	1·000	1·0000	1·0000

Grade.—A certain velocity of flow is required in a sewer to prevent deposit. The minimum velocity to prevent deposit varies with the size of the sewer, and is from 2 to 3 feet per second. The following table gives the minimum allowable inclination for self-cleansing sewers, running half full:

6-inch pipe ..... 1 in 142 = 0·704 per 100
9-inch " ..... 1 in 203 = 0·494 per 100
12-inch " ..... 1 in 385 = 0·260 per 100
24-inch " ..... 1 in 775 = 0·129 per 100

While in extreme cases sewers may be laid with a lower grade than that indicated above, it is always at the risk of unsatisfactory working and ultimate stoppage.

In localities where the surface of the ground is nearly level and sufficient grade can not be obtained to dispose of the sewage by gravity, the sewage may be carried to its outfall by pumping, or by one of the pneumatic processes. The three most important of the pneumatic processes are the Liernur, Berlier, and Shone.

In the Liernur and Berlier systems the sewage is carried through air-tight iron pipes by atmospheric pressure, the air being exhausted from the pipes by large air-pumps.

In the Shone system the sewage is raised from a lower to a higher level by being admitted to a receiving-chamber or pneumatic ejector, and then forced by compressed air out of the ejector and to the desired elevation, when it again runs on through the sewer-pipes by gravity.

The ordinary hydraulic formulas for the flow of water in pipes will apply to sewers. The amount of sewage which any pipe will carry depends upon its velocity. The following formulas are among the best in use:

Weisbach's formula is $v = \frac{\sqrt{2gh}}{\sqrt{1 + e + c\frac{l}{d}}}$,

in which v = velocity of flow in feet per second.
h = head of water in feet.
l = length of pipe in feet.
d = diameter of pipe in feet.
e = coefficient of resistance for entrance of water into the pipe.
c = coefficient of friction in the pipe.

Baldwin Latham, in his *Sanitary Engineering*, gives tables of values for the coefficients, and extensive tables of velocities for different-sized pipes at different inclinations, according to Weisbach's formula.

Kutter's formula is

$$v = \left\{ \frac{41{\cdot}66 + \frac{1{\cdot}8113}{n} + \frac{{\cdot}002807}{S}}{1 + \left(41{\cdot}66 + \frac{{\cdot}002807}{S}\right)\frac{n}{\sqrt{R}}} \right\} \sqrt{RS} = C\sqrt{RS}$$

in which v = mean velocity in feet per second.
C = coefficient of mean velocity.
S = sine of slope.
R = hydraulic mean radius.
n = coefficient of resistance to flow, determined by experiment.

Flynn's hydraulic tables are based on this formula.

The most rapid method of determining the necessary size of sewers under given conditions is from diagrams or graphical tables. Pierson's graphical calculations, published in Staley and Pierson's *Separate System of Sewerage*, give results for pipe-sewers by both Weisbach's and Kutter's formulas.

Material for Pipes.—The best material thus far produced for sewers up to 2 feet in diameter is salt-glazed, vitrified, earthenware pipes. Sewers more than 2 feet in diameter may be constructed of brick, stone, or concrete. Sewer-pipe is sometimes made of hydraulic cement. Pipe of excellent quality can be made of this material, but it is difficult to secure uniformity of quality. Vitrified earthenware pipe has a smooth surface, is impervious to moisture, is not affected by sewage, and does not deteriorate with time. It is made of all sizes up to 2 feet, and special forms are manufactured for certain purposes. It is usually made of cylindrical form, and in lengths of 2 or 3 feet. In the usual form each length has a bell, or socket, at one end to hold the spigot end of the adjoining piece in laying. This is called the bell and spigot joint. Another method of making the joints is to make the pipes plain cylinders, and provide separate collars to slip over the joints where the pipes meet. A hand-hole is a length of pipe with a detachable section, which can be removed at any time after the pipe is laid without disturbing the line of pipe. Junctions are formed by Y or T branches. The T-branch is a socket on the side of a pipe to receive a branch at right angles. The Y-branch is a socket made to receive a branch at an acute angle. Curved pipes are prepared for turning bends. Junctions of laterals with mains, and of house-sewers with street lines, should be made with Y-branches. Fig. 1 shows in plan and elevation a junction. The Y should be elevated so that the curved piece, joining the Y with the lateral, will bring the top of the branch sewer as high or higher than the top of the main sewer.

Sewers more than 2 feet in diameter are usually built of hard-burned brick, laid in hydraulic cement. All junctions for lateral branches and house-connections should be put in when the sewer is built, as much better workmanship can then be secured in making the connections, and with less danger to the sewer.

Location.—Sewers may be located either in the streets or, where alleys are regularly laid out through the center of the blocks, in the alleys. When only one line is laid in a street it should be on the center line. In some cases, where the streets are wide or the center line is occupied by street-railway tracks, it may be advisable to put a line of sewers on each side of the street.

Depth.—The sewers should be far enough below the bottom of the cellars, to afford sufficient fall for the house-drains starting from beneath the cellar floor. The minimum depth will usually be from 6 to 8 feet.

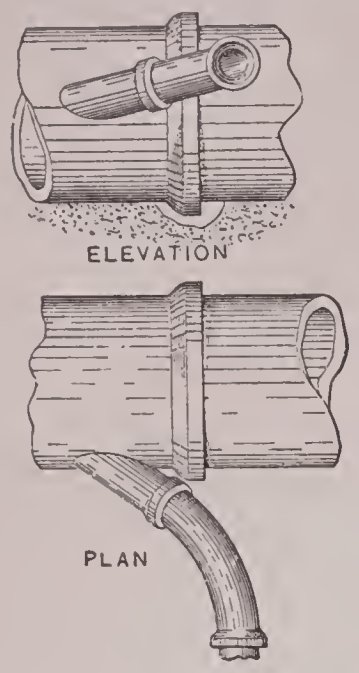

Fig. 1.

Laying.—In laying the sewers care should be taken to keep the flow-line on a continuous grade, and to make the joints water-tight. The joints should first be caulked with a gasket of oakum, or some similar material, to prevent the entrance of cement to the inside of the pipe, and the joint filled with pure cement, mixed with sufficient water to make it of the proper consistency for working. Y-branches should be placed along the line of sewers in front of each lot, so that house-drains may be connected at any time without cutting or disturbing the main line of sewers. The opening of the Y-branches should be closed with an earthenware cover.

Manholes are masonry shafts extending from the sewers to the surface of the ground, and large enough to admit a workman to inspect or clean the sewers. They are usually formed of an 8-inch brick wall. The form is the frustum of a cone with the large end down. The top should be about 2 feet in interior diameter, and the bottom about 4 feet. The form at the bottom is sometimes elliptical. The top is finished by a cast-iron cap, level with the surface of the street. The cover is perforated to aid in ventilation. Sometimes a dust-pan is placed under the cover to catch the dirt which falls through the openings in the cover.

The bottom should be of concrete, and built so as to be water-tight. It should be formed to the contour of the invert of the sewer, so that the flow of the sewage will not be checked in the manhole. Steps should be built into the wall to facilitate getting in and out. Fig. 2 is a vertical section of a manhole at right angles to the axis of the sewer. Manholes should be placed at the junctions of the laterals with the mains, and at changes of direction in the line of sewers.

Lampholes, or observation openings, are formed by a T-branch extending from the sewer to the surface of the ground. The top of the vertical pipe is covered with a cast-iron cap having a movable cover level with the pavement. Sometimes the vertical pipe is not carried to the surface, but is capped below the pavement and its position carefully recorded.

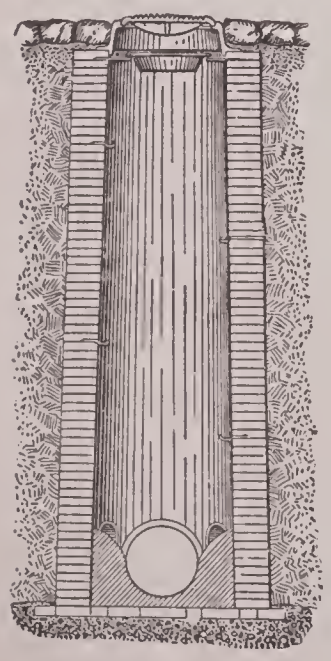

Fig. 2.

The Combined System of Sewerage.—Where the ground-water needs to be removed as well as the sewage, as is usually the case, special provision must be made for this purpose. A good sewer is not a good drain. A sewer should be water-tight, while a water-tight conduit would be of no use as a drain. The drainage should be provided for by a separate system of drain-pipes so laid as to admit the water and carry it away. They may be laid beside the sewer-pipe or under it or over it, as the circumstances may require. Where the sewers are deep enough they may be laid above the sewer and discharged into the manholes. The advantage of this method is that each section between the manholes is independent of the rest of the system, and any stoppage in one section will not affect any of the other sections.

Size of Combined Sewers.—In determining the size necessary in any case, the disposal of the storm-water is the only question to be considered. The ordinary flow of sewage is so small compared with the volume of storm-water delivered to the sewers during and immediately after a storm that the sewage may be left out of consideration. In estimating the necessary size the following conditions must be taken into consideration: The area to be drained; the rate of rainfall; the percentage of the rainfall reaching the sewer; the grade of the surface of the ground; the grade of the sewer; and the amount of ground-water.

Sewers are rarely built large enough to provide for all of the water which falls in extraordinary storms lasting only a short time. Besides this, not all of the rainfall reaches the sewers. The percentage of that which does pass into the sewers depends upon the relative proportion of roofed and paved area to the whole area to be drained, and the nature of the soil of the unpaved part. The grade of the natural surface of the ground affects the rapidity with which the storm-water reaches the sewer. It is customary to assume a certain depth, varying from half an inch to 2 inches per hour, as reaching the sewer, although the rainfall may occasionally be several times that amount.

Different formulas have been proposed for determining the size of sewers. The following are some of these. Julius W. Adams's formulas:

$$D = \sqrt[6]{\frac{QL}{1542H}}$$

in which D = diameter of sewer in feet.
Q = cubic feet per second to be provided for.
L = length of sewer.
H = rise for length L.

$$\log. D = \frac{2 \log. A + \log. N - 3{\cdot}79}{6}$$

in which D = diameter, in feet, of sewer.
A = acres to be drained.
N = length in feet in which the sewer falls 1 foot.

These formulas are on the basis of 1 inch of rain per hour, half of which reaches the sewer within the hour.

Thomas Hawksley's formula, used in the main drainage of London:

$$\log. \text{diameter of main (in inches)} = \frac{3 \log. A + N + 6{\cdot}8}{10}$$

in which A = acres drained.
N = length in feet in which the sewer falls 1 foot.

This is on the basis of 1 inch of rain per hour.

The principal difference in the various formulas is in the assumption of the amount of water which the sewer is to provide for. They are never built large enough to carry all of the water of the heaviest rainfall. Having decided the amount of water which the sewer is to carry, the size may be calculated by the formulas previously given for the flow of sewage in pipes.

Form of Sewers.—If a sewer has an approximately constant flow and is to run half full or more, the best form is circular. In combined sewers, however, the ordinary flow of sewage usually fills but a small part of the cross-section of the sewer, and in that case the egg-shaped section with the small end down is best. This concentrates the flow in the bottom of the sewer, so that the depth and velocity of flow may be kept as great as possible when the quantity of sewage is at its minimum, and by expanding in the upper part provides for the greatly increased amount delivered to the sewers by storms.

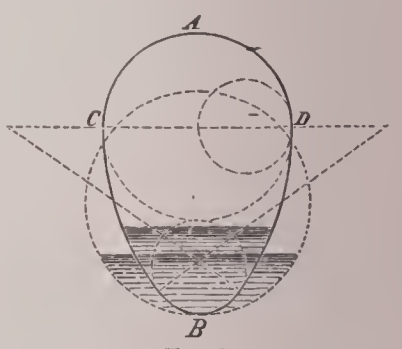

Fig. 3.

Fig. 3 shows one of the many forms of egg-shaped sewers. The vertical diameter A B is one and a half times the greatest diameter C D. C A D is a semicircle described on C D. The lower arc is described with a radius equal to one-fourth C D, and the sides are described with a radius equal to the vertical diameter. The shaded portion at the bottom of the figure shows the relative depth, and hence velocity, of the same amount of sewage in a circular and in an egg-shaped sewer of the same capacity.

Manholes.—The manholes for the combined system differ from those in the separate system, as shown in Fig. 2, only in resting on the sewer itself instead of a concrete founda-

tion. The construction of the manhole begins at the springing line of the upper arch of the sewer.

Catch-basins.—The storm-water in passing over the surface of the streets and along the gutters carries with it dirt, pieces of stone and brick, leaves, sticks, and other refuse. In order to keep this *débris* out of the sewers the storm-water is first received into a catch-basin, where the solid matter is held and the water passed on into the sewer. The opening into the sewer should be several feet from the bottom, and should be so arranged as to guard against admitting any of the solids from the catch-basin.

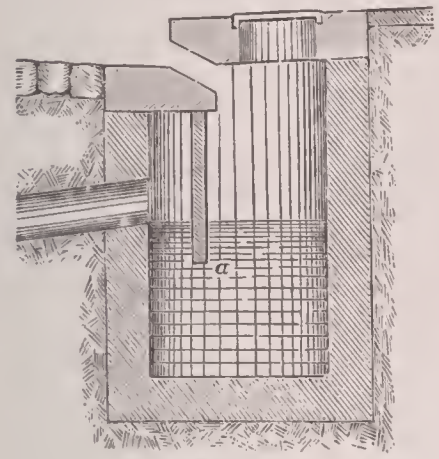

FIG. 4.

Fig. 4 is a vertical cross-section of a catch-basin placed under the outside edge of the sidewalk. The storm-water passes directly into it from the gutter, but must pass under the partition *a* to reach the outlet to the sewer, shown on the left. So long as the water in the catch-basin is above the bottom of the partition *a*, the gas from the sewer can not escape. Sometimes the outlet to the sewer is trapped.

Catch-basins should be cleaned frequently, as the organic matter carried into them by storms will decompose and become offensive. They should be placed at the lowest points, and from 200 to 300 feet apart on both sides of the street.

Sometimes when combined sewers are built provision is made for purifying the ordinary flow of sewage, but not the much larger volume of storm-water. In that case a storm-overflow is arranged, as shown in Fig. 5. It depends for its action upon the fact that an increase in the depth of flow in a sewer will increase the velocity. A is a combined sewer. With the ordinary flow of sewage, and at the beginning of a storm, when the stream will be loaded with filth from the streets, the stream will be shallow and sluggish, and will drop through the opening O into the sewer B, and be carried to the disposal-works. As the flow deepens with the storm-water the velocity increases until it is sufficient to leap the opening O and pass out through the storm-water overflow A′.

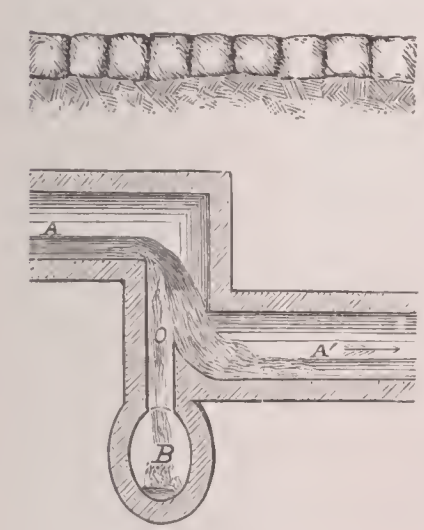

FIG. 5.

Flushing and Ventilation.—In order to keep sewers in the best possible condition and reduce the evolution of sewer-gas to a minimum, provision should be made for flushing and ventilation. In the separate system, with its comparatively small pipes, this is not difficult. With an even flow of sewage on low grades there is always a tendency to form deposits on the bottom of the sewer on account of the fungus growth on the pipes under the sewage. It needs a rush of water to detach the fungus and carry along the sediment. By discharging into the sewer the down-spouts from the gutters of a few houses near the head of each lateral sewer, flushing can be accomplished whenever there is sufficient rain. Sewers may also be flushed by making a connection between the upper ends of the laterals and the pipes supplying water to the town, and admitting the water to the sewers by turning a valve, or by taking the water from a hydrant and conducting it to the sewer through a hose. Where there are no water-works, flush-tanks mounted on wheels have been used. In some cases underground tanks are used to collect the house-sewage, and when full they discharge automatically.

The best method is to place at each dead end an automatic flush-tank supplied with water from the water-works. This can be set so as to discharge as often as may be thought desirable. A good form of flush-tank is shown in Fig. 6. It is built of brick laid in hydraulic cement, and plastered with cement outside and in, so as to be water-tight. The top is finished with a cast-iron cap provided with a movable perforated cover. Water is supplied to the tank from

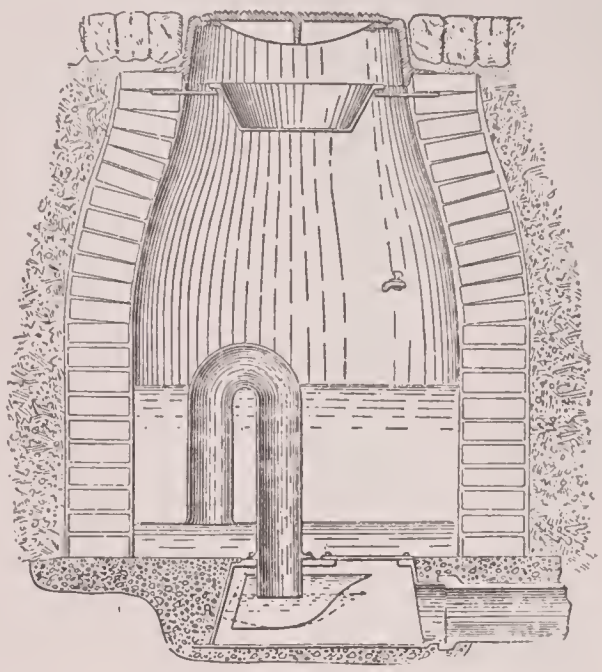

FIG. 6.

the pipes of the water-works, and the faucet so adjusted as to fill the tank as often as is desired. The tank is supplied with an automatic emptying device, which discharges the water into the sewer whenever the tank is full. There are several devices for this purpose. Under ordinary circumstances the tank should hold about 200 gal., and should be set so as to discharge once in twenty-four hours.

Ventilation of Sewers.—Separate sewers are best ventilated by continuing the house-drains, untrapped, above the roofs of the houses, either inside or outside of the house. If the holes in the manhole and flush-tank covers are kept open, and the sewers are properly flushed, the air in the sewers will be changed so frequently that comparatively little trouble will be experienced from sewer-gas from separate sewers.

In combined sewers the case is very different. The difficulties in the way of flushing and ventilating large sewers are almost insurmountable. The interior surface of brick sewers is rough, and becomes smeared with organic matter from the sewage which is constantly undergoing decomposition. During storms, detritus and the litter from the streets is swept into the sewers, and when the flow slackens to the usual dry-weather volume the *débris* from the streets is stranded and forms obstructions to the shallow, sluggish stream, formed by the sewage proper in the large sewer. Pools of sewage are formed along the line, and the decomposition of the organic matter in these pools produces sewer-gas in enormous quantities, and affords a breeding-ground for bacteria. To flush such a sewer thoroughly is usually impracticable, as it requires too much water. Sometimes an attempt is made in this direction by damming up the sewage for a time and then releasing it, producing a current strong enough to carry forward the sediment. This improves the lower lines of sewers, but is not applicable to the upper ends. Where this method is applied there is always danger of a deposit on the line above the temporary dam.

Since the evolution of sewer-gas can not be avoided, the question of ventilation becomes the more important. Several plans have been proposed for the ventilation of large sewers, but none have been as successful as could be desired. High chimneys have been used, and in some cases a draught has been secured by means of a fan or a fire. Owing to the many openings into the sewer, one chimney will affect only a limited section of the sewer. Another plan is to purify the air from the sewer by passing it through charcoal filters.

Fig. 7 is a manhole fitted with a charcoal filter for purifying the air from the sewer. It consists of a sheet-iron cylinder, open at both ends, containing a series of pans with perforated bottoms, placed one above another and filled with charcoal. The cover of the manhole is water-tight, to exclude moisture from the filter, and a separate chamber with a perforated cover is built beside the manhole to pro-

vide an escape for the air. The charcoal is about 3 inches deep in the pans. It is renewed about once a month by being reburned in retorts from which air is excluded.

Plans.—The design for a system of sewers for any town depends upon local circumstances. No one system, however well adapted for a given locality, will be universally applicable. The separate system is to be preferred where the storm-water can otherwise be provided for, or where the sewage must be pumped, or where sewage disposal-works are necessary, and its cost is a small fraction of that of combined sewers for the same locality. In some cases in addition to the small sewers, special conduits for storm-water are needed for a limited area. These need not be placed deep in the ground, and they can be discharged into the nearest natural watercourse, even within the town, where sewage could not be discharged.

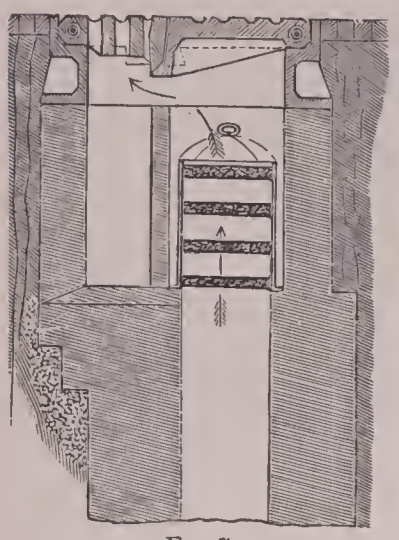

Fig. 7.

Disposal of Sewage.—After the sewage has been collected and carried away from a locality the problem of its disposal remains to be solved. It may be discharged without purification into a stream or large body of water; it may be partly purified by subsidence, or filtration, or chemical process, or by a combination of these, and then discharged; or it may be purified by application to the soil in several ways. When sewage is emptied into a large stream or body of water its disappearance is due to several causes. It is diluted by the large volume of water into which it is discharged; part of the impurities are deposited by subsidence; part of the organic matter becomes food for aquatic plants and animals; and part of it is destroyed by oxidation and nitrification. So long as the amount of sewage is very small in comparison with the volume of water into which it is discharged, this method may not be objectionable, unless the stream receiving the sewage is to be used for water-supply. The pollution of streams and lakes by sewage is a growing evil. In many countries in Europe it has been forbidden by law, and in the U. S. such laws are imperatively required in order to preserve sufficient unpolluted water-supply for the large towns.

When sewage is purified by subsidence it is collected in tanks and allowed to stand until the particles in suspension are deposited on the bottom of the tank, when the partly clarified liquid is drawn off. Sieves and filters are also employed for purifying sewage. Chemical processes of many kinds have been used. In these processes certain chemicals are mixed with the sewage, and it is purified by the precipitation of the suspended impurities, and some of those held in solution. All of these methods remove the suspended impurities and the organic matter from the sewage to a greater or less extent, but the effluent is still unfit to be turned into the natural watercourses.

A still more efficient method of purification is by applying the sewage to the soil. This may be done by broad irrigation, intermittent filtration on limited areas, or by sub-surface irrigation. Where broad irrigation is employed the ground is first underdrained and the sewage is applied to the surface by leading it in furrows. The method of application depends upon the crop under cultivation. Sometimes it is spread over nearly all of the surface for a time, and sometimes it is only run in the furrows, placed from 2 to 4 feet apart. The sewage is absorbed by the soil, and wherever the sludge accumulates it is spaded under. The city of Berlin (*q. v.*) has an excellent system of sewage farms.

Where the method of intermittent filtration is employed, filter-beds of soil are prepared with the sole object of filtering the sewage, and no attempt is made to raise any crop. The sewage is applied to the filter-beds in succession, time being given between the applications for the aëration of the soil. In sub-surface irrigation the sewage is delivered to the soil through drain-tile laid from 6 to 10 inches below the surface of the ground. The sewage passes out of the tile at the joints, and is absorbed by the soil. This method is especially applicable on private grounds, where no sewers are available. The action of the soil in purifying sewage is somewhat complicated. It filters out the suspended particles, and the organic matter in the sewage is destroyed by oxidation and by the bacteria in the soil. The effluent water is collected by drain-tile and delivered to the natural watercourses.

Cady Staley.

Sewing-machines [*sewing* is pres. partic. of *sew* < M. Eng. *sewen*, sew < O. Eng. *sēowan* : O. H. Germ. *siuwan* : Icel. *sȳja* : Goth. *siujan* < Teuton. *siu-* : Lith. *siuti* : Lat. *su'ere* : Gr. κασ-σύειν]: machines for stitching fabrics, operated by the foot, hand, or other motive power.

In 1790 Thomas Saint, an Englishman, secured a patent for a machine intended for "quilting, stitching, and sewing, making shoes and other articles." This machine, although made chiefly of wood, had many features similar to those common in modern sewing-machines, such as the overhanging arm, a vertical reciprocating needle-bar, having secured in its lower end by means of a set-screw a straight needle with a terminal notch instead of an eye. There was also, at a short distance from the needle, a straight awl to make the holes through which the thread was to be pushed by the notch-ended needle. On the top of the needle-bar was a large spool, from which the thread was drawn as required to form the stitch. This machine also had what is now called a feed, for moving the material after each stitch the proper distance for the next, and thread-tighteners (tensions) above and below it. The stitch used by Saint was known as the tambour stitch (now called the chain stitch)—the continuous thread was pushed by the notch-ended needle through a hole made by the awl, and the needle was then withdrawn, leaving a loop of thread below the material, which was then moved by the feed the proper distance for the next stitch, a second loop being formed passing through the first, which was then drawn tight.

At intervals in the first half of the nineteenth century machines for embroidering and ornamental stitching were invented. These could have been made to fasten two or more pieces together, but they were not intended for that work, and therefore can not with propriety be called sewing-machines. Several machines were also patented for making a running stitch, by means of fluted rollers which folded the cloth in short vertical convolutions and forced it on to a horizontal needle. Such machines used needles full of thread, and the needle was threaded in the ordinary way. In 1818 the Rev. John Adams Dodge, of Monkton, Vt., invented and (with the assistance of John Knowles, a mechanic) constructed a sewing-machine which made a back stitch in a satisfactory manner, but it was never patented or manufactured for sale.

The first sewing-machine that was manufactured for sale was patented in France in 1830, and in a modified form in the U. S. in 1850. Its inventor, Barthélemy Thimonier, constructed of wood eighty machines which made a chain stitch of such strength that they were used in the year 1830 for manufacturing army clothing. These machines were destroyed by a mob which alleged that they were depriving tailors of their bread. A few years later Thimonier had other machines constructed of metal, which were driven by a treadle and cord. These were also destroyed. Thimonier's machine anticipated many of the more important features of the machines of to-day. It had the overhanging arm, flat cloth-plate, vertical post, vertical reciprocating-needle, continuous thread, and a presser-foot.

The Hunt Machine.—About 1832–34 Walter Hunt, a New York mechanician, invented, manufactured, and sold a few sewing-machines which were successfully operated. His machine had a curved needle with an eye near its point, attached to the end of a vibrating arm. It used two continuous threads, the lower being wound on a bobbin carried in a shuttle, and made a lock stitch—i. e. one in which the thread from the needle and that from the shuttle are interlocked at or near the middle of the thickness of the materials being sewn. Hunt neglected to apply for a patent for his invention for about twenty years, and during that time the manufacture and sale of the machine was not prosecuted; his tardy application for a protecting patent was denied on the ground that he had forfeited his rights by neglect and the sale and public use of the machine at the

time of its invention. In 1842 J. J. Greenough patented a machine for sewing leather and other heavy material. This machine had a needle pointed at each end, and an eye at its middle; this needle was passed to and fro through holes previously punctured in the material by an awl, and was automatically manœuvered by pincers on each side of the goods. This machine would make either a back stitch or a "shoemaker's stitch," at the pleasure of the operator. The needle used single lengths of thread, and required frequent stoppages of the machine for rethreading. Greenough's machine did not come into extended use.

In 1843 a sewing-machine somewhat similar to Greenough's was invented by George H. Corliss (later an improver of the steam-engine), but it used two needles with eyes near their points, which were thrust horizontally through holes previously made by awls in the material to be sewed, which was secured between clamps, and automatically moved at right angles to the path of the needles. The feed was automatic, and all the movements were derived from suitably shaped cams on a revolving shaft.

The Howe Machine.—In 1846 a patent was issued to Elias Howe, Jr., for a sewing-machine on which he had been experimenting for three years. It had a curved needle (with an eye near its point) attached to the end of a vibrating arm; this needle carried the upper thread, the lower thread being wound upon a bobbin in a shuttle which was made to pass between the needle and its thread at each vibration of the arm. The cloth was suspended on pins projecting from the edge of a thin steel bar called a baster-plate, provided with perforations in which worked the teeth of a small pinion by which the baster-plate was given an intermittent movement or "feed" after each stitch. When the machine was manufactured it was found to be unsalable. The chief difficulties experienced in operating it were these: The baster-plate was not satisfactory as a "feed," the vertical suspension of the cloth was awkward and unmanageable, and the tension could not be regulated to prevent the skipping of stitches, the making of large loops in some places, and the drawing of the thread too tight in others.

Between 1848 and 1851 several inventors attempted to devise sewing-machines of more practical value. Messrs. Lerow and Blodgett made a machine which was used to a limited extent in the manufacture of clothing. This had a circular hoop studded with pins for a baster-plate; its shuttle was curved and had a continuous revolution in a circular groove; its feed was adjustable, and its tension automatic. Messrs. Morey and Johnson and John Bachelder constructed single-thread machines for making the loop or chain stitch, and these were the first in the U. S. which made that stitch.

The A. B. Wilson Machine.—In 1849 Allan B. Wilson (of the original firm of Wheeler & Wilson) made and in 1850 patented a sewing-machine having a vibrating shuttle, and the original form of what he afterward patented as his four-motion feed. This machine had a considerable sale, but was not satisfactory to its inventor, who set himself to work to produce something more practical. His efforts resulted in the invention of the revolving hook (patented Aug. 12, 1851), which carried within its concavity a double-convex circular bobbin, and a ring which held it in place. This hook caught the loop from the descending curved needle, whose eye was near its point, and passed it around the bobbin, thus dispensing with the shuttle. Wilson afterward perfected the four-motion feed and other details.

The Singer Machine.—In Sept., 1850, Isaac M. Singer, a mechanic of New York, who had become interested in sewing-machine experiments and was familiar with the Lerow and Blodgett machine, made a contract to invent an improved sewing-machine and have it built for $40. He accomplished this within twelve days, and the machine was found to be practical and efficient. This machine was the first which had the rigid overhanging arm to guide the vertical needle, in combination with a shuttle and what was called a wheel-feed. A patent for this machine was issued Aug. 12, 1851. At about this time William O. Grover (afterward of the firm of Grover & Baker), of Boston, was attempting the solution of the sewing-machine problem in a different manner.

FIG. 1.—Singer shuttle.

The Grover & Baker Machine.—On Feb. 11, 1851, Messrs. Grover & Baker patented a sewing-machine making what has been called the double-loop (or Grover & Baker) stitch, which was made by a combination and joint action of a circular reciprocating under needle, with a curved upper needle having an eye near its point, thus dispensing with both shuttle and bobbin, and enabling both the upper and under threads to be taken from commercial spools. These machines were very popular and for several years took the lead of all others, but they are no longer manufactured. Although up to this time Elias Howe, Jr., had never made a practical sewing-machine, his patents were so skillfully drawn that Grover & Baker, Singer, and Wheeler & Wilson were obliged to pay him royalty which amounted to $25 per machine, but in 1853 an agreement was entered into between the above-named manufacturers and Howe by which the royalty was considerably reduced to them, but under it manufacturers outside "the combination" (as the quadruple syndicate was called) were still obliged to pay a heavy royalty. Howe's patent was extended in 1860 for the term of seven years, at the expiration of which he again applied for a further extension; but, as he acknowledged that he had received between $1,000,000 and $2,000,000 for the use of his invention, it was thought that he had been sufficiently remunerated and his application was rejected.

Previous to the final expiration of Howe's patent (1867) but few machines for making the lock stitch had been invented and manufactured except by "the combination."

The Willcox & Gibbs Machine.—In June, 1857, James E. A. Gibbs, of Millpoint, Va., took out his first patent for a machine having a rotating hook for using a single thread to make the twisted loop stitch, a variety of the chain or tambour stitch which possesses much merit. This, with some improvements of its details by James Willcox, of Philadelphia, became the Willcox & Gibbs sewing-machine, the most popular of the single-thread machines. Several years later this machine was improved by Charles H. Willcox, who invented an automatic tension which readily adapts itself to the requirements of varying thicknesses of cloth, seams, folds, etc., and draws the stitch equally tight under all conditions.

At the expiration of Howe's patent in 1867 a large number of new machines were brought out, but few or none of them are in use.

Button-hole Machines, Leather-sewing Machines, etc.—There have been two machines and two attachments invented for finishing button-holes by the button-hole stitch—viz., the Union button-hole machine, made by the Singer Manufacturing Company, and the House or Wheeler & Wilson button-hole machine; the American button-hole and the Wheeler & Wilson button-hole attachments. A multitude of other accessories and attachments to sewing-machines, such as hemmers, braiders, corders, tuckers, fellers, pleaters, binders, quilters, rufflers, and gatherers, have been invented for the purpose of executing special kinds of work with facility, and the total number of patents issued for sewing-machines and their adjuncts is upward of 3,000.

Among the more important inventions for sewing by machinery must be mentioned machines for sewing leather goods with waxed thread. Of these, the Keats No. 1 and the Keats lock-stitch machines, the McKay shoe sewing-machine, and the Goodyear & McKay sewing-machine are the most prominent. Each of these machines has been largely used in the manufacture of boots and shoes, harness, and other articles made of leather. Machines have also been invented for sewing books; of these, the Smyth and the Boynton are the best known.

Classification of Machines.—Sewing-machines are best classified by the kind of stitch produced, and although upward of seventy kinds of stitches and machinery for making them have been invented, yet there are at the present time but three types of stitches used in machine-sewing—viz., the lock stitch, the chain stitch, and the button-hole stitch.

Lock-stitch machines may properly be divided into two types—those making the lock stitch by means of a shuttle which is thrust through the loop of the upper thread, and those in which that loop is carried by a revolving hook over a stationary bobbin. More than half of the machines manufactured are of the first-named type, of which the Singer and Domestic machines are the chief examples, the Wheeler & Wilson machine being the original and still by far the most prominent of the rotating-hook type of lock-stitch machines. These machines are all made on the "interchangeable principle," each part being exactly like its corresponding part in every machine; and to such perfection is this system

carried that the machines are assembled by selecting their component parts at random from the hundred or more receptacles containing them. This interchangeable method of construction is adopted by all sewing-machine manufacturers, and by its use the business can be thoroughly systematized and the manufacture be carried on at a minimum cost.

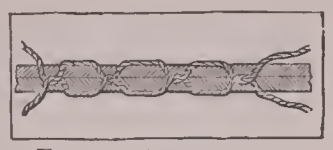

Fig. 2.—The lock stitch.

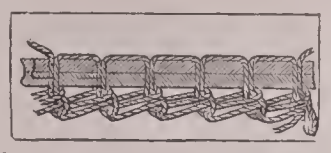

Fig. 3.—Grover & Baker stitch.

Fig. 4.—Twisted loop stitch.

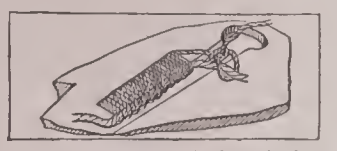

Fig. 5.—Button-hole stitch.

The revolving hook used in the Wheeler & Wilson sewing-machine has been much modified and improved; that at present used in their No. 9 machine is represented in Fig. 7. A greater possible rate of speed is claimed for these machines than for those which employ a shuttle; a further advantage is found in their running with less noise.

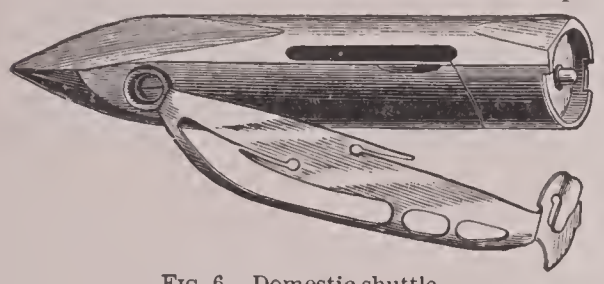

Fig. 6.—Domestic shuttle.

A variety of rotating-hook lock-stitch machine, and one which embodies an entirely new departure in sewing-machines, is the invention of Mrs. Harriet Ruth Tracy. It has a rotating bobbin-holder provided with three hooks, which in turn operate to carry the loop from the upper thread over the bobbin-holder, and a bobbin or cop containing 1,000 yards of thread. The special features of this machine are: (1) its large thread-carrying capacity in the bobbin-holder; (2) the fact that it has no take-up above the bed, the three rotating hooks disposing of all the slack (a feature which permits a large amount of thread to be carried); and (3) the rotating positive motion of the entire mechanism, which allows of very rapid running. In five seconds, by a slight change of adjustment, this machine can be made to take a chain stitch with a single thread or a chain stitch having a second or locking thread run through it on the under side of the cloth, which prevents raveling and at the same time

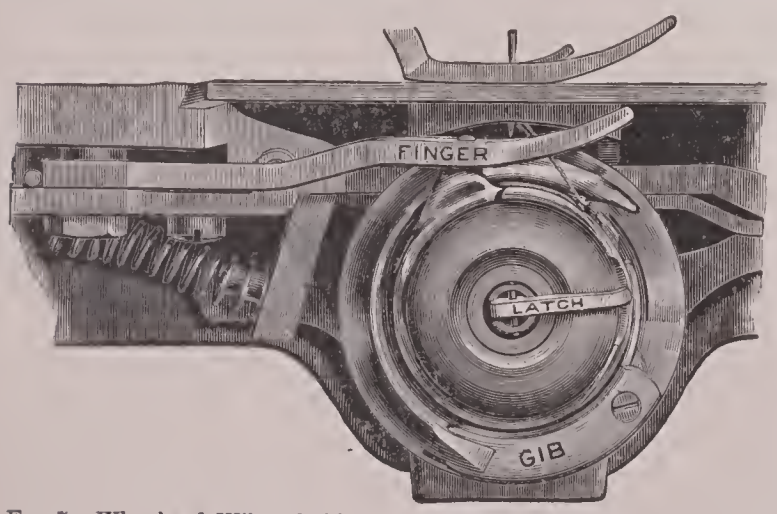

Fig. 7.—Wheeler & Wilson bobbin and bobbin case in the rotary hook.

leaves the stitch elastic. The machine is characterized by simplicity and great ingenuity.

The twisted loop or chain stitch is made only by the Willcox & Gibbs machine. A short straight needle is carried by a vertical reciprocating bar, actuated by a vibrating lever, put in motion by a link connecting it to an eccentric on the main shaft of the machine. At the front end of the main shaft is a peculiarly shaped hook, which in its rotation catches the upper thread as the needle, having an eye near its point, descends through the cloth, and forms a loop through which the needle passes on taking the next stitch; the hook then engages the upper thread again, and at the same time the first loop is thrown off the hook and the first-named stitch drawn tight by the operation of forming the

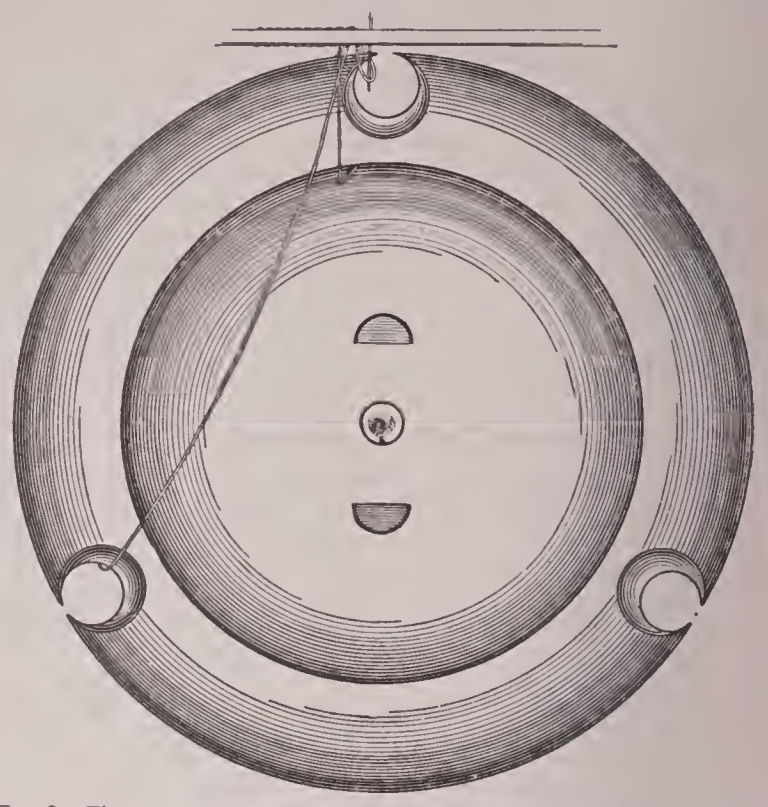

Fig. 8.—The Tracy circular three-pointed rotary-shuttle with bobbin placed inside its case ready for use.

second loop. This machine is practically silent in its operation, even when running as rapidly as to make 3,000 stitches per minute.

The button-hole sewing-machines do their work in a thoroughly efficient manner, the button-hole finished by it being much more durable than those made by hand-work. Button-hole attachments are intended to be used in connection with an ordinary lock-stitch sewing-machine; they not only make a perfect button-hole, but will also make the button-hole stitch on the edges of garments, shoes, etc., which the button-hole machine can not do.

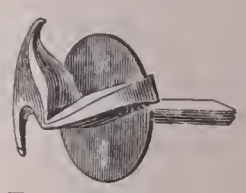

Fig. 9.—Willcox & Gibbs hook.

Besides those already enumerated, there is a large variety of sewing-machines manufactured for doing special work. Among them are the cylinder sewing-machine, having a cylindrical work-holder, for sewing seams on sleeves, trousers, water-hose, boot-legs, leather buckets, and other articles of tubular form; and the carpet sewing-machine, for making up carpets.

The operations required for the manufacture of a sewing-machine are very numerous, embracing designing, drawing, pattern-making, casting, pickling, tumbling, tool-making, forging, annealing, stamping, swaging, filing, polishing, screw-making, turning, drilling, plating, japanning, ornamenting, assembling, testing, and packing. For the manufacture of sewing-machine needles, see NEEDLES AND NEEDLE-MAKING.

There are but two sewing-machine factories in which all parts of the machine, including cases and needles, are manufactured. The manufacture of sewing-machine needles and cases has reached large proportions as independent industries. The census returns of 1890 showed that 59 establishments manufacturing sewing-machines and attachments reported. These had a combined capital of $16,043,136, employed 9,121 persons, paid $5,170,555 for wages and $3,502,173 for materials, and had products valued at $12,823,147. There were also reported 7 establishments manufacturing sewing-machine cases, which had a combined capital of $1,430,403, employed 1,842 persons, paid $886,725 for wages and $990,439 for materials, and had products valued at $2,249,551.

W. F. DURFEE.

Sexage'sima [= Late Lat. (sc. *di'es*, day), liter., fem. of *sexage'simus*, sixtieth, deriv. of *sexagin'ta*, sixty]: in the calendar the eighth Sunday, nearly sixty days, before Easter. See SEPTUAGESIMA.

Sextant [from Lat. *sex'tans*, *sextan'tis*, the sixth part of an as, also a sixth of certain other measures of land, length,

volume, etc.]: a portable astronomical instrument, invented by Newton, and reinvented by Thomas Godfrey, of Philadelphia, in 1730, and John Hadley, of England, in 1731 (see HADLEY, JOHN), using for the measurement of an angle a graduated arc of the sixth part of a circle, and employing in its construction the following theorem of optics: If a pencil be reflected by each of two plane surfaces, the deviation of the axis of the pencil is double the inclination of the reflecting planes, supposing its course to be in one plane perpendicular to the intersection of the surfaces. To show the application of this theorem to the sextant in Fig. 1, let I be the index-glass, H the horizon-glass, S the star, S I H E the pencil of light from the star S as it suffers the two reflections at the respective glasses. The star will be seen by the eye projected in the horizontal line E S'. Since S I r = r I H by the law of reflection of light,

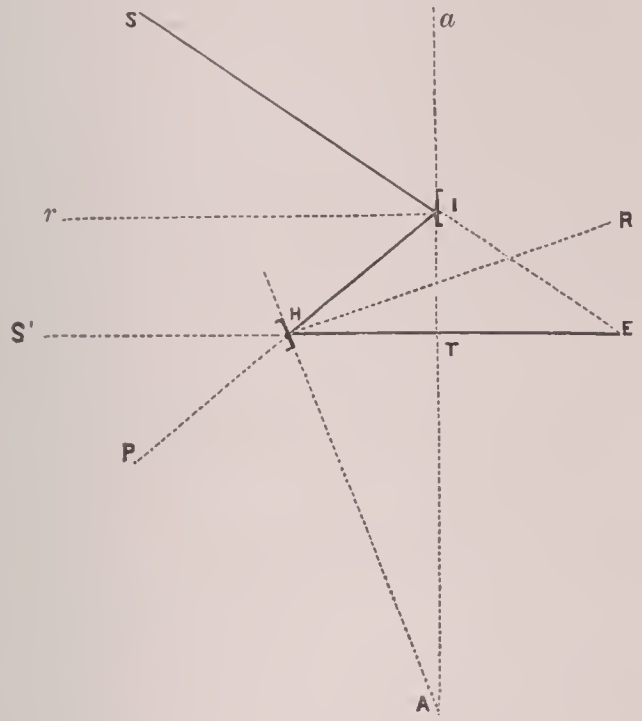

FIG. 1.

$$\therefore \text{SI}a = \text{HI}A;$$
$$\therefore \text{EI}A = \text{HI}A.$$

In a similar manner EHA = PHA,

$$\text{HEI} + \text{AIE} = \text{AHE} + \text{IAH},$$
$$\text{HEI} + \text{HIA} = \text{PHA} + \text{IAH},$$
$$= \text{HIA} + 2\text{IAH};$$
$$\therefore \text{HEI} = 2\text{IAH}.$$

But HEI is the deviation of the pencil produced by the double reflection, and we see this angle is twice the angle of the inclination of the mirrors. So long as the line of sight E S' is directed to any fixed point the angular distance to any other point may be determined by the revolution of the mirror at I; the angle through which this mirror is moved may be indicated by the revolution of the line a A, which carries at some part of it an index sweeping over a graduated arc, which is graduated to twice as many degrees as it measures in its own circumference.

The following description of the instrument is taken from Chauvenet's *Astronomy*, vol. ii., art. 81: Fig. 2 represents the most common form of the sextant constructed upon these principles. The frame is of brass, constructed so as to combine strength with lightness; the graduated arc, inlaid in the brass, is usually of silver, sometimes of gold or platinum. The divisions of the arc are usually 10′ each, which are subdivided by the vernier to 10″. The handle, H, by which it is held in the hand, is of wood. The mirrors, M and m, are of plate-glass, silvered. The upper half of the glass m is left without silvering, in order that the direct rays from a distant object may not be intercepted. To give greater distinctness to the images, a small telescope, E, is placed in the line of sight m E. It is supported in a ring, K K, which can be moved by means of a screw in a direction at right angles to the plane of the sextant, whereby the axis of the telescope can be directed either toward the silvered or the transparent part of the mirror. This motion changes the plane of reflection, which, however, remains always parallel to the plane of the sextant, the use of the motion being merely to regulate the relative brightness of the direct and reflected images. The vernier is read with the aid of a glass, R, attached to an arm which turns upon a pivot, S, and is carried upon the index-bar. The index-glass, M, or central mirror, is secured in a brass frame, which

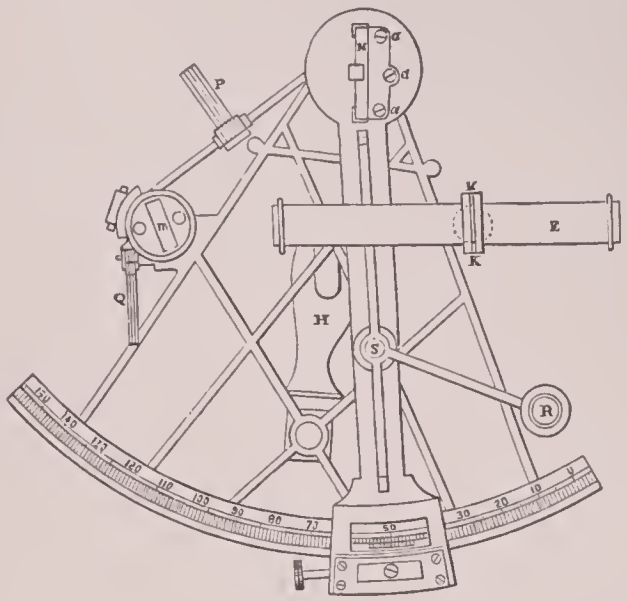

FIG. 2.

is firmly attached to the head of the index-bar by screws, a a a. This glass is generally set perpendicular to the plane of the sextant by the maker, and there are no adjusting screws connected with it. The fixed mirror m is usually called the horizon-glass, being that through which the horizon is observed in taking altitudes. It is usually provided with screws, by which its position with respect to the plane of the sextant may be rectified. At P and Q are colored glasses of different shades, which may be used separately or in combination, to defend the eye from the intense light of the sun.

For astronomical purposes the sextant is sometimes modified by making the arc a complete circle. The instrument is then known as a reflecting circle. This form has the advantage of securing higher precision in the observations.

For a discussion of the sextant generally, see William Chauvenet, *Manual of Practical and Spherical Astronomy* (Philadelphia, 1874); Dr. C. M. Bauernfeind, *Elemente der Vermessungskunde* (Munich, 1872); Merrifield and Evers, *Navigation and Nautical Astronomy* (London, 1868); E. Loomis, *Practical Astronomy* (New York, 1855). For special problems and capacity of the sextant for scientific purposes, see *Monthly Notices R. A. S.*, vol. xiii., p. 61; 1873, November; *Washington Astron. Obs.*, 1867, App. ii.; 1869, App. i.; *Pogg. Ann.*, vol. lxxix., p. 136; *Astron. Nach.*, vol. vii., p. 262; vol. xxiii., p. 321. Revised by S. NEWCOMB.

Sextus Empir'icus: Greek philosopher of the end of the second century; a physician of the "empirical" school, whence his surname. He revived the skepticism of Pyrrho and laid down the *Outlines of Pyrrhonism* in his Πυρρώνειοι ὑποτυπώσεις (three books), and in a work on skepticism (ten books), commonly cited under the title *Adversus Mathematicos*—a formal assault on all branches of learning, and valuable for the information it contains about the things assailed. His works were edited by Bekker (Berlin, 1842); German translation by Pappenheim (Leipzig, 1877). B. L. G.

Sexual Selection: a factor in organic evolution, in which there is a struggle of the individuals of one sex for the possession of the other. In the struggle for existence the less fitted perishes; in sexual selection the unfortunate one is left without offspring. Usually the struggle is between the males, and may take the form of actual battle, but not infrequently it is one in which the æsthetic senses seem to be important. See EVOLUTION. J. S. K.

Seychelles, *sā'shel'*: a group of over thirty small islands in the Indian Ocean, between lat. 3° 30′ and 5° 45′ S., and between lon. 55° 20′ and 56° 20′ E., belonging to Great Britain and a dependency of Mauritius. Area, 100 sq. miles. They are rocky and high, but very fertile and covered with a luxuriant vegetation, especially of palms. Cotton is cultivated with some success. The largest is Mahé, 16 miles long and 4 miles broad. The Seychelles were discovered by the Portuguese early in the sixteenth century; they were first settled by the French in 1756, and became a British possession in 1794. Pop. (1891) 16,440.

Revised by M. W. HARRINGTON.

Seyffarth, zīf'fȧȧrt, Gustav, Ph. D., D. D., LL. D.: scientist and archæologist; b. at Uebigau, Prussian Saxony, July 13, 1796; educated at Leipzig University, where he was Professor of Oriental Archæology from 1825 to 1855; professor in the Concordia Lutheran Theological Seminary at St. Louis, Mo., 1855–71, and afterward took up his residence in New York. He was the author of numerous works in German and Latin upon theology, Oriental philology, mythology, history, and chronology, chiefly notable for their extreme advocacy of the literal school of biblical interpretation and their entire rejection of the system and results of the Egyptian researches of Champollion and Bunsen. He resided in New York from 1871 till his death Nov. 17, 1885. See his autobiography, *Literary Life* (New York, 1886).

Revised by S. M. Jackson.

Seymour, see'mōr: town; New Haven co., Conn.; near the junction of the Naugatuck, Bladen, and Little rivers, and on the N. Y., N. H. and Hart. Railroad; 10 miles N. W. of New Haven (for location, see map of Connecticut, ref. 11–F). It contains 5 churches, new high-school (building cost $40,000), several other schools, public library, a weekly newspaper, and manufactories of paper, rubber, woolen goods, pins, nails, and mechanics' tools. The manufacture of woolen cloth was begun here over a century ago. In 1803 Gen. David Humphreys, who imported the first merino sheep into the U. S., bought the clothing-works here and built a large mill. The place was incorporated as the borough of Humphreysville in 1836, and as a town under its present name in 1850. Pop. (1880) 2,318; (1890) 3,300; (1900) 3,541.

W. C. Sharpe, editor of "Record."

Seymour: city (laid out in 1852); Jackson co., Ind.; on the Balt. and Ohio S. W., the Evansv. and Terre H., and the Pitts., Cin., Chi. and St. L. railways; 18 miles S. of Columbus, 51 miles N. of Louisville, Ky. (for location, see map of Indiana, ref. 9–E). It is noted for its manufactories, which include rolling and planing mills, foundry, woolen-mill, and spoke, carriage, furniture, harness, and cradle factories. It contains the machine-shops of the Ohio and Mississippi Division of the Balt. and Ohio S. W. Railway, 10 churches, 5 public-school buildings, including the Shields high school, 2 national banks with combined capital of $200,000, and 2 daily and 3 weekly papers. Pop. (1880) 4,250; (1890) 5,337; (1900) 6,445.

Editor of "Democrat."

Seymour, Edward, Duke of Somerset: See Somerset, Duke of.

Seymour, Frederick Beauchamp Paget, first Baron Alcester: naval officer; b. in London, Apr. 12, 1821; entered the navy in 1834, and passing through the different grades became admiral in 1882. In 1880 he was appointed commander-in-chief in the Mediterranean, and assumed supreme control of the allied fleet on the coast of Albania. In the military operations in Egypt in 1882 he bombarded the forts of Alexandria July 11–13, for which service he received the thanks of Parliament and was raised to the peerage. D. in London, Mar. 30, 1895.

Seymour, George Franklin, D. D., LL. D.: bishop; b. in New York, Jan. 5, 1829; graduated at Columbia College in 1850 and at the General Theological Seminary in 1854; had charge of a mission station at Dobbs Ferry for six years; became first head of St. Stephen's College, Annandale, 1860, and in 1861 rector of St. Mary's church, Manhattanville, N. Y.; in 1863 went to St. John's church, Brooklyn, N. Y., and was in 1865 elected Professor of Ecclesiastical History in the General Theological Seminary; in 1874 was chosen bishop of the diocese of Illinois, but the General Convention refused to confirm him; in 1875 was elected dean of the General Theological Seminary. In 1877 he was chosen Bishop of Springfield, Ill., and was consecrated June 11, 1878. Bishop Seymour has published numerous pamphlets and works, all of a theological nature, and chiefly written in defense of church doctrine.

Revised by W. S. Perry.

Seymour, Horatio, LL. D.: Governor of New York; nephew of Senator Horatio Seymour; b. at Pompey, Onondaga co., N. Y., May 31, 1810; removed in childhood to Utica; studied at Oxford and Geneva Academies, N. Y., and at Partridge's Military Institute, Middletown, Conn.; was admitted to the bar at Utica 1832, but soon withdrew from practice to devote himself to the management of the large estate he inherited by the death of his father; was a member of the staff of Gov. Marcy 1833–39; was elected to the State Assembly as a Democrat 1841, and three times re-elected, serving as Speaker in 1845; was chosen mayor of Utica 1842; was an unsuccessful candidate for Governor 1850; was Governor 1853–55; vetoed a prohibitory liquor-law Mar., 1854; was defeated in the election of that year by the Prohibitionist candidate, Myron H. Clark; was again elected Governor as a War Democrat 1862; aided in suppressing the riots in New York, and rendered efficient co-operation to the national Government in the war for the Union; was defeated for re-election in 1864, in which year he presided over the national Democratic convention at Chicago, as he did again at New York 1868, when he was nominated for the presidency much against his will, and received 80 electoral votes. D. at Utica, Feb. 12, 1886.

Seymour, Lady Jane: third queen of Henry VIII., sister of Protector Somerset, and daughter of Sir John Seymour; b. in England about 1510; became maid of honor to Queen Anne Boleyn; married Henry May 20, 1536, the day after the execution of Anne, and died shortly after giving birth to a son (Edward VI.) Oct. 24, 1537. She was chiefly notable for her sympathy with the Protestant Reformation.

Seymour, Thomas Day: scholar; b. at Hudson, O., Apr. 1, 1848; graduated at Western Reserve College 1870; studied in Berlin and Leipzig 1870–72; Professor of Greek in Western Reserve College 1872–80; appointed Professor of Greek in Yale College 1880; chairman of the managing committee of the American School of Classical Studies at Athens since 1887. He has published as author and editor *Selected Odes of Pindar* (1882); *Homeric Language and Verse* (1885); *Homer's Iliad* (i.–iii., 1887, iv.–vi., 1891); *School Iliad* (1889).

C. H. Thurber.

Seymour, Thomas Hart: Governor of Connecticut; b. at Hartford, Conn., in 1808; educated at Partridge's Military Academy at Middletown; became a lawyer at Hartford, and editor of *The Jeffersonian* (1837), a Democratic newspaper; was some time judge of probate; sat in Congress 1843–45; entered the Mexican war as major of the Ninth Regiment; became lieutenant-colonel Aug. 12, 1847; commanded the regiment after the death of Col. Ransom at Molino del Rey; was breveted colonel for services at Chapultepec Sept. 13, 1847; was Governor of Connecticut 1850–53, and minister to Russia 1853–57. D. at Hartford, Sept. 3, 1868.

Seymour, Truman: soldier; b. at Burlington, Vt., Sept. 25, 1824; graduated at West Point 1846; entered the First Artillery; was breveted lieutenant and captain for gallantry in the Mexican war; was assistant professor at West Point 1850–53; served under Maj. Anderson at Fort Sumter Apr., 1861; became chief of artillery of McCall's division in the Army of the Potomac Mar., 1862; was commissioned brigadier-general of volunteers Apr. 28, 1862; was distinguished in the Virginia and Maryland campaigns, commanding a brigade at Mechanicsville, Gaines's Mill and Glendale, and a division at Malvern Hill, Manassas, South Mountain, and Antietam; was severely wounded at Fort Wagner July 18, 1863; commanded an expedition to Florida Feb., 1864; was taken prisoner at the Wilderness; commanded a division in the Shenandoah valley Oct., 1864, and in the operations around Petersburg up to the close of the war. Breveted from major to major-general in both the volunteer and regular army. Mustered out of volunteer service Aug., 1865, he returned to his regiment; received the degree of A. M. from Williams College; major Fifth Artillery 1866; retired 1876. D. at Florence, Italy, Oct. 30, 1891.

Revised by James Mercur.

Sfax (probably the *Taphoura* of Ptolemy): fortified city on the Gulf of Gabes, or Lesser Syrtis, Tunis; lat. 34° 44′ N., lon. 10° 45′ E.; is divided into two cities, the upper and lower, the latter also called Rabat. The harbor is safe, but shallow, and large ships must anchor 2 miles out. The commerce is very large, and is chiefly with France, Italy, Great Britain, and Greece. Sfax is celebrated for its camels, sponges, and gardens. It is intensely Mohammedan, and is much admired in Arabic literature. Pop. 30,000, of whom about 5,000 are Europeans.

M. W. H.

Sforza, sfort'sȧȧ: the name of an Italian family which ruled Milan as a dukedom in the fifteenth and sixteenth centuries and exercised considerable influence on the politics of Italy by their ambition, which was generally accompanied with violence and faithlessness, and by their talent, which was not always accompanied with education, though several members showed interest for and gave much protection to science, poetry, and art. The founder of the family was (1) Giacomuzzo Attendolo, a peasant-boy from Coti-

gnola in the Romagna, b. June 10, 1369. He distinguished himself by his bodily strength, and received the surname *Sforza*, the forcer; became chief of a band of condottieri, and entered the service of Queen Joanna II. of Naples, who made him grand constable; served afterward Pope Martin V., who made him a count, and died Jan. 4, 1424.—(2) His son, Francesco, b. July 25, 1401, was chief of a large troop of mercenaries, and served the highest bidder. He invented a new tactical trick which made his troop very effective in battle; entered the service of Visconti, Duke of Milan, and was very successful in his undertakings; received Visconti's daughter, Bianca, in marriage, and Cremona as her dowry; and took Ancona from the pope. In 1447 Visconti died without any male heirs, and Milan instituted a republican government; but in 1450 Francesco seized the ducal crown, defeated his adversaries both in Milan and among the other states in Northern Italy, reigned well, and died in Milan, Mar. 8, 1466, much beloved by his subjects.—(3) His son, Galeazzo Maria, b. Jan. 24, 1444, was vicious and cruel, and was assassinated Dec. 26, 1476.—(4) He was followed by his son, Giovanni Galeazzo, b. in 1468, during whose minority the government was carried on by his mother, Bona of Savoy.—(5) In 1480, Lodovico the Moor, b. in 1451, a brother of Galeazzo Maria, banished Bona and assumed the regency, and in 1494 he poisoned his nephew and ascended the ducal throne himself. As Giovanni Galeazzo had married a Neapolitan princess, Naples remonstrated against the usurpation, and in order to avert the impending danger Lodovico induced Charles VIII. of France to assert his claim on Naples. The success of the French, however, alarmed him more than the threats of Naples, and he formed a league between all the North Italian states against France. To punish him, Louis XII. invaded his country, which he claimed as a grandson of Valentina Visconti, captured him in 1500, and confined him in a castle of Loches in the present department of Indre-et-Loire, where he died in 1510. He was possessed of great talents and considerable literary and scientific accomplishments, and the magnificent encouragement he gave to literature and art made him very popular; but he was a weak character, of a low moral standard, and all his astuteness and cunning were of very little avail to him on account of the violence of the time.—(6) His son, Massimiliano, b. in 1491, was made duke in 1512, but expelled by the French in 1513; reinstated in the same year by Charles V. after the battle of Novara, but was again driven out by Francis I. after the battle of Marignano, 1515, and finally sold his claims to the dukedom to France for a pension.—(7) His brother, Francesco II., b. in 1492, was made Duke of Milan by Charles V. in 1522 after the battle of Pavia, but rendered himself unpopular by oppressive taxes, and at his death (Oct. 24, 1535), the country was incorporated with Austria. The Counts of Santa Fiora and the Dukes of Sforza-Cesarini are descended from collateral branches of the family. Revised by F. M. Colby.

Sgambati, Giovanni: See the Appendix.

Shabbatai Tsevi, shăă-băă-tī'tse-vee': the most noted of the many impostors and self-deluded aspirants to be the Messiah of the Jews; b. in Smyrna, 1626, of Spanish descent; followed the mystic Cabbala, and became an ascetic. The air was full of Messianic ideas, the year 1666 being looked forward to by both Christians and Jews. Having divulged his intentions in 1648 he was banished; went to Salonica, Morea, Athens, Cairo, and Jerusalem, and achieved success, which was largely due to the circumstances in which his brethren lived and to the active assistance of his second wife Sarah; of Raphael Chelebi, a rich Jew of Cairo; and of Nathan of Gaza, who pretended to be Shabbatai's Elijah. In 1665 the company traveled in great pomp to Aleppo and Smyrna; in December Shabbatai was officially proclaimed Messiah. Mystic rites of all sorts led to immoral actions; but his fame spread abroad. Jews all over Europe believed in him, even deified him. They hoped for a speedy restoration to Palestine. In the early part of 1666 Shabbatai went to Constantinople, where he was imprisoned. Sept. 14 he saved his life by becoming a Mohammedan under the name of Mehmed Effendi. He played the double game of being a Mohammedan to his captors and a Jew to his followers. The Turks soon tired of this. He was banished to Dulcigno in Albania, where he died 1676. Even after his death the movement continued; there are still secret believers in his Messiahship, as the Dönmēs or Mamin in Salonica (*Ausland*, 1888, 10, 11). The most complete account will be found in Graetz, *Gesch. d. Juden* (x., chap. vii.). For the older literature, see Graetz (*ibid.*, notes 3–7); Fürst, *Bibl. Judaica* (1863, iii., pp. 184, *seq.*). See also Jost, *Gesch. d. Judenth.* (iii., p. 153); Neubauer, *Wahnwitz der Sabbatianer*, in Graetz's *Monatsschrift* (1887, p. 204); Emanuel Frances's *Life* of Shabbatai, in the *Sammelband*, published by the Mekitze Nirdamim (i., p. 133); *Wiener Zeit. f. Kunde d. Morgenl.* (ii., p. 261).

Richard Gottheil.

Shad [O. Eng. *sceadda*: Germ. dial. *schade*; cf. Welsh *ysgadenyn*: Ir. and Gael. *sgadan*, herring]: any one of several species of the family *Clupeidæ*, agreeing in the possession of a rather high and compressed body, with trenchant and serrated belly, the preoperculum and suborbital higher than long, a deep re-entering notch in the upper jaw, and the roof of the mouth and tongue at least toothless; these are by some naturalists combined in a peculiar genus, *Alosa*, but by others they are regarded as constituents of the enlarged genus *Clupea*, including the salt-water herrings, etc. The species are all inhabitants of the northern hemisphere, and anadromous, like the salmon, living for the greater portion of the year in the sea, but in the spring ascending the rivers in large schools for the purpose of spawning. The time of ascent is determined by the temperature, and the point is only limited by insurmountable obstacles in the form of dams or falls which can not be overleaped, although the larger portion spawn at intervals far below this final point. The eggs are moderate in size, the ovaries of a single female having generally, it is said, about 25,000 eggs, although sometimes as many as 100,000 to 150,000. They are discharged near the surface, and slowly sink to the bottom. The time between impregnation and hatching depends on the temperature, and varies from about three to six days; thus when the temperature is about 75° to 80° F. they hatch in about seventy hours or little more, while at a temperature of 62° to 67° they are delayed to about six days. The best-known species are four—viz., *Alosa vulgaris* and *Alosa finta* of Western Europe, *Alosa sapidissima*, ranging from the Miramichi to the Alabama, and the *Alosa reevesii* of China, which especially ascends the Yang-tse-Kiang. The European species are held in much less esteem than the American and Asiatic. The last are esteemed among the best of fishes in their respective countries, and their ovaries are also regarded as special objects of luxury. The capture of these fishes gives rise to a large industry, and in the early spring months the fishermen are to a large extent engaged in their capture by means of fixed nets as well as seines, and to a small extent by dipnets. Shad eat little or nothing when in fresh water, but sometimes rise to the fly. In the salt water and estuaries they feed chiefly on small crustaceans, such as species of *Mysis*, etc. See Fisheries, Fish-culture, and Pisciculture. Revised by F. A. Lucas.

Shad-bush or **Shad-tree**: See June-berry.

Shaddock (also called *pompelmoose*, *pomelo*, and *grapefruit*): the large fruit of the *Citrus decumana*, a small tree of the orange family (*Rutaceæ*). It has a watery pulp, cooling, acid, aromatic, and somewhat bitter. It is used for preserves. It was named from one Shaddock, who is said to have carried it from India to Jamaica. Risso describes six varieties. The tree differs from the oranges in having a pubescent young growth, the leaves very large and often emarginate and pubescent beneath, petioles much winged. It is a native of Polynesia, but is widely spread in the tropics.

Revised by L. H. Bailey.

Shadow-bird: a wading bird (*Scopus umbretta*) related to the storks and herons, found in Madagascar and Africa. It is named from its color, a deep brown with bronze reflections. The tail is barred with black, the bill is deep and compressed and hooked at the tip, and the head bears a long crest. The bird is rather sluggish. Although only 20 inches in length it builds a hollow nest of twigs about 6 feet in diameter, on a tree or ledge of rocks. F. A. L.

Shadwell, Thomas: dramatist; b. at Stanton Hall, Norfolk, England, about 1640; educated at Caius College, Cambridge; acquired considerable reputation by his comedy, *The Sullen Lovers*, produced in 1668; devoted himself thenceforth to literature, chiefly dramatic; was author, among many other plays, of *The Virtuoso* (1676), *Lancashire Witches* (1682), *The Squire of Alsatia* (1688), and *Volunteers, or The Stock-jobbers* (1693); became poet-laureate and royal historiographer 1688, succeeding Dryden in both posts, and was unjustly impaled by that poet as the hero of *Mac Flecknoe* in the character of "monarch of dullness." D. Dec. 6, 1692. His collected *Works* appeared in 4 vols., 1720.

Shafter, William Rufus: soldier; b. at Galesburg, Mich., Oct. 16, 1835; was for many years a farmer. In the civil war (1861–65) he rose to the rank of colonel and brevet brigadier-general; lieutenant-colonel in the regular army 1866; colonel 1879; brigadier-general 1897; major-general of volunteers May 4, 1898. He commanded the U. S. army at the siege of Santiago de Cuba, which he occupied July 17, 1898, the Spanish army having surrendered.

Shaftesbury, Anthony Ashley Cooper, First Earl of: party leader; b. at Wimborne St. Giles, Dorsetshire, England, July 22, 1621; entered Exeter College, Oxford, 1637; was elected for Tewkesbury to the Short Parliament in 1640; at first supported the king, but after ten months' service in the royalist army went over to the popular party in 1644, and took an active part in the war. He was a member of the "Barebones" Parliament in 1653, and of Cromwell's council of state in the same year, but later separated from the cause of the Protector and co-operated in the restoration of Charles II. As a reward for his services he was made a privy councilor in 1660 and Chancellor of the Exchequer in 1661, having previously been raised to the peerage with the title of Baron Ashley. He was one of the grantees of the province of Carolina 1663 and 1665; secured the services of John Locke as private secretary 1666, and prepared with Locke the famous aristocratic constitution for the government of the Carolinas. A member of the "Cabal" 1670, he allowed himself to be deceived as to the true nature of the disgraceful Treaty of Dover. In 1672 he was made Earl of Shaftesbury and Lord Chancellor, but in 1673 went over to the opposition and lost his office. Protesting against the prorogation of the Parliament, he was imprisoned in the Tower 1677–78, but on his release continued as the bitter foe of the court party, and, professing to believe the perjured testimony of Titus Oates, took the lead in the persecutions of the Catholics. He procured the passage of the Habeas Corpus Act 1679; presented the Duke of York before the court of king's bench as a "Popish recusant" in 1680; brought armed followers to the Oxford Parliament in 1681; was thrown into prison by order of the council on a charge of high treason July 2, but released Dec. 1, 1681, the grand jury having refused to find a true bill; went to Amsterdam Nov., 1682, and died there Jan. 22, 1683. He was the Achitophel of Dryden's satire, is brilliantly sketched by Macaulay in his *History*, and gave name to Ashley and Cooper rivers in South Carolina. See his *Life*, by W. D. Christie (1871); also Fox-Bourne's *Memoir of John Locke* (1876); and a biography by H. D. Traill in the English Worthies Series (1886).

Revised by F. M. Colby.

Shaftesbury, Anthony Ashley Cooper, Third Earl of: grandson of the first earl; b. in London, Feb. 26, 1671; was educated under the supervision of Locke; entered Parliament 1693; resided in Holland 1698–99; succeeded to the peerage 1699; supported the administration of William III., and retired from public life on the king's death; was noted as a philanthropist and stigmatized as a free-thinker; published a *Letter on Enthusiasm* (1708) in defense of the rights of the "French Prophets," *The Moralist, a Philosophical Rhapsody* (1709), *Sensus Communis* (1710), *A Soliloquy, or Advice to an Author* (1710); spent much of his time on the Continent, and was preparing a work upon the arts of design when he died at Naples, Feb. 15, 1713. His principal work, *Characteristics of Men, Matters, Opinions, and Times*, was posthumously published (3 vols., 1713–23; often reprinted), and enjoyed great popularity. See Fowler, *Shaftesbury and Hutcheson* (London, 1882).

Shaftesbury, Anthony Ashley Cooper, Seventh Earl of: b. in London, Apr. 28, 1801; took a first class in classics at Oxford, 1822; was made D. C. L. 1841; entered Parliament 1826, representing the borough of Woodstock from 1826 to 1830, Dorchester 1830 and 1831, the county of Dorset, in which the estates of the family are situated, from 1833 to 1846, and the city of Bath from 1847 to 1851; supported the administrations of Liverpool and Canning; was made a commissioner of the India board of control by the Duke of Wellington 1828; was a lord of the admiralty under Sir Robert Peel 1834–35; succeeded his father in the peerage 1851. He was chairman of the Lunacy Commission from 1828 till his death, and did much to secure the passage of bills which have been called the Magna Charta of the liberties of the insane. He labored zealously to improve the condition of the working classes; carried through the Ten Hours' Bill, and followed it up by obtaining the assent of Parliament to other measures regulating defective workshops and factories, night work, and the treatment of children by their employers in trades and manufactures, etc. His course in public life was always very independent. He was the leading philanthropist in English-speaking lands, and stood in public estimation as the embodiment of every virtue. His endorsement of any scheme was sufficient to give it success. He was therefore continually called upon to preside at meetings of all sorts. He was president of the British and Foreign Bible Society, the Pastoral Aid Society, the Evangelical Alliance, and other organizations for the propagation of evangelical doctrines, and was long regarded as the head of the so-called Exeter Hall school of Low Churchmen. He was an active promoter of the abolition of slavery throughout the world. D. at Folkestone, Oct. 1, 1885. See his *Life*, by Edwin Hodder (3 vols., London, 1886; n. e., 1 vol., 1887).

Revised by S. M. Jackson.

Shagreen' [from Fr. *chagrin*, from Turk. *sāghrī*, back of a horse (from the skin of which shagreen was first made), shagreen]: a variety of tawed leather made in Persia and other parts of the East, and long celebrated for its hardness and strength. The name shagreen is also given fish-skins, principally those of sharks and rays, covered with calcified papillæ. Shagreen prepared from the tuberculous skin of the ray (*Trygon sephen*) is called *galuchat* by the French. Shagreen is dyed in various colors, and is used as a covering for small articles, as boxes and handles of swords.

Shah [from Pers. *shāh*, king; cf. *chess*, *pasha*, and *satrap*; Pers. *khṣatra*, province: Sanskr. *kshatra-*, rule, power]: the title of the ruler of Persia and of certain other Asiatic princes. The sons and other male relatives of the Persian shah also assume this title, the full title of the monarch being *shah-in-shah*, king of kings.

Shāh Abbās: See Abbās I.

Shahap'tian Indians: a family of North American Indians, comprising the following named tribes: Chopunnish, Sahaptin, Nez Percé or Nĭmapu (the last being their own name), Klikatat, Paloos, Tenaino, Tushepaw, Tyigh, Umatilla, Walla Walla, Yakima.

Habitat.—The tribes occupied a large section of country along the Columbia river and its tributaries, their western boundary being the Cascade Mountains. The Chopunnish were found in 1804 occupying a large area in Western Idaho, Northeastern Oregon, and Southeastern Washington, on the lower Snake river and its tributaries. The Klikatat occupied the head waters of Cowlitz, White Salmon, and Klikatat rivers, Washington. The Paloos in 1805 were on Clearwater river, Idaho, above the Forks, and on the small streams tributary to it, W. of the Rocky Mountains. The Tushepaw appear to have been an eastern branch of the Nez Percé. According to Lewis and Clark's report the Walla Walla lived on both sides of Columbia river, from the mouth of Lewis (or Snake) river to the Musselshell Rapid, wintering on Tapteel (or Yakima) river. It is probable that under the general name Lewis and Clark included one or more other divisions, the Umatilla, for instance, who originally lived on Umatilla river, Oregon. The Tenaino, who are nearly related to the Warm Spring Indians, formerly lived at Celilo, Oregon, on Columbia river. The Tyigh originally occupied Tyigh creek and valley, the former being a tributary of the Des Chutes river, Oregon, about 30 miles S. of the Dalles. The Yakima (called Shanwappam by Lewis and Clark) were found in 1805 on the head waters of Cataract (or Klikatat) and Tapteel (or Yakima) rivers, Washington.

General Characteristics.—Comparatively little is known of the mutual relations of the several members of this family. The linguistic family as a whole is a rather well-defined one, though in some of its sounds and in its harsh character the language considerably resembles the Chinookan and Salishan. In habits of life the Shahaptian tribes differed considerably from the Chinook of the Columbia, to whom they were much superior, and more nearly resembled the inland Salishan tribes. Living as they did on the large watercourses, salmon constituted their most important food, but the possession of horses (for all the tribes were "horse Indians") undoubtedly wrought considerable change in their habits, and caused them to become, to some extent, hunters. At the time of Lewis and Clark's visit (1804–05) none of these tribes had any idea of agriculture, and some of the bands met by the explorers on Snake river periodically suffered from hunger. The Chopunnish were then living, like the Chinook, in communal houses, and the same custom probably prevailed also in the other divisions of the family.

One village on the Clearwater was 150 feet long, and accommodated about 50 families and 100 fighting men. Each village was under the nominal control of a chief, but nothing is known of the nature of the federation of the separate villages, if any such existed. Of late years, at least, the Nez Percé (Pierced Noses) have not worn ornaments inserted in the nose, but it is probable that at one time the custom was a general one.

History.—When Lewis and Clark passed down the Columbia, in 1804–05, the lowermost Shahaptian tribe, the Eneeshur, was at the Falls, while the first Chinookan tribe, the Echeloot, was found at the Dalles, the two tribes being but 6 miles apart. They were then at war, and there is evidence to show that during the next few years the Shahaptian tribes encroached upon the Chinookan territory, and even wrested from the Chinook the Dalles, probably the best fishing-station on the Columbia. The Klikatat, who, according to Gibbs, had crossed the Cascade Mountains from the Klikatat river, Washington, crossed the Columbia between 1820 and 1830 and overran the Willamette valley, making their way as far S. as the Umpqua valley, Oregon. Subsequently they were compelled to retire to their own country. In 1866 they were found in the wooded and prairie country between Vancouver and the Dalles, at the base of Mt. Hood, Washington. In 1849 the Paloos dwelt N. of the Cayuse. Lord (1866) mentions the Pelouze (Paloos), who were then in British Columbia, at the mouth of Pelouse river. The Shahaptian Indians are now located on various reservations in Idaho, Washington, and Oregon.

Population (1886).—Nez Percé, 1,515; Klikatat, 115; Paloos, number unknown (181 in 1851); Tenaino, 69; Tyigh, 430; Umatilla, 179; Walla Walla, 405; Yakima (numbered 400 in 1805), 943.*

Authorities.—Bancroft, *Native Races of the Pacific States*, iii., 565, 620 (1882); Cox, *History of the Nez Percés*, in *Nation*, xxxiii., 95 (1881); Gallatin, in Schooleraft's *Indian Tribes*, iii., 402 (1853); Hale, in *United States Expl. Exp.*, vi., 198, 212, 542 (1846); Gen. O. O. Shahjahanpur′: large city of Rohilkand, Northwest Provinces, British India; in lat. 27° 52′ N., lon. 79° 28′ E.; on the Garrah, a tributary of the Ganges (see map of N. India, ref. 5–F). The city was founded in 1647 during the reign of Shah Jahan, whose name it bears, and contains some fine mosques and the ruins of a castle. It has some export trade in cereals and sugar. Pop. (1891) 78,522. It is the chief place of a district of the same name. Area, 1,746 sq. miles. Pop. 860,000. Shahjahanpur is the name of several other towns in Northern India.

Revised by M. W. Harrington.

Shairp, John Campbell: author and critic; b. at Houstoun House, Linlithgowshire, Scotland, July 30, 1819; educated at Edinburgh Academy, Glasgow University, and Baliol College, Oxford; was for some years assistant master of Rugby School; became Professor of Humanity at the United College, St. Andrews, 1861, and principal of that institution 1868, and was elected Professor of Poetry in the University of Oxford in 1877. He was the author of *Kilmahoe, a Highland Pastoral* (1864); *Studies in Poetry and Philosophy* (1868); *Lectures on Culture and Religion* (1870); *Poetic Interpretation of Nature* (1877); *Aspects of Poetry* (1881); *Life of Robert Burns* in the English Men of Letters Series; and numerous contributions to magazine literature. D. at Ormsary, Argyleshire, Sept. 18, 1885. *Glen Desseray and Other Poems* was published posthumously in 1888, edited by F. T. Palgrave. See *Portraits of Friends* (New York, 1889) for a memoir of Shairp, by William Young Sellars.

Revised by H. A. Beers.

Shakers [so called from certain rhythmical movements of the members in dancing, which forms part of their worship]; more accurately, The Millennial Church, or United Society of Believers: a religious body which originated in England about the middle of the eighteenth century, having as its first leaders James Wardlaw, a tailor, and his wife Jane, members of the Society of Friends. Jane Wardlaw, who claimed to have received from on high a call to announce the second coming of Christ in the form of a woman, gained as one of her followers Ann Lee, daughter of a blacksmith, who was born in Manchester, Feb. 29, 1736, married Abraham Stanley, a blacksmith, and united with the society of James and Jane Wardlaw in Sept., 1758. She was imprisoned in the summer of 1770, during the persecution that arose against the Shakers, and while a captive received a revelation from the Lord which showed her that by celibacy only could mankind be restored to a proper relation with God, and became the acknowledged head of the society.

On May 19, 1774, in obedience to a revelation, she embarked for North America with seven adherents, including her husband, who afterward left her, and John Haeknell, who had some property. She landed in New York Aug. 6; settled in Watervliet, 7 miles N. W. of Albany, 1776. On the famous "Dark Day" (May 19, 1780) Elder James Whittaker preached the first public testimony of Mother Ann's gospel in America. Between that time and her death at Watervliet, in Sept., 1784, it is thought that over 2,000 people received her testimony. James Whittaker succeeded as leader of the people till his death at Enfield, Conn., July, 1787.

After him Elder Joseph Meacham led the people, and, assisted by able helpers, established communal order and regulation in all their families, guiding them till his death at New Lebanon, July, 1796. He had been a Baptist elder, and was son of a Baptist elder of the same name; was born in Enfield, Conn., in 1740. He is called the Father of Church Order.

After him Lucy Wright, who was Father Joseph's chief helper on the sisters' side, guided the people twenty-five years, till her death, at the age of sixty-one, at Watervliet, Feb., 1821. She was born in Pittsfield, Mass. During her ministration five societies were established in Ohio and Kentucky, and believers increased in number threefold. Ebenezer Bishop, Rufus Bishop, Ruth Landon, and Ascenath Clark were the leading ministry from 1821 to 1852. From 1820 to 1826 three new societies were established, and the population of the seventeen societies then existing was about 5,000 souls.

In 1837 remarkable spiritual manifestations began at Watervliet, and in less than a year spread through all the families. First the youthful and unbaptized class, taken away in visions and trances, described scenes and dwellers in the spirit spheres, being, as they believed, inspired to deliver messages, both vocally and in writing, from Mother Ann and her colaborers when in the body, and their successors, from Jesus, from apostles, patriarchs, and prophets, and other excarnated witnesses, to the effect that they had come to help the leaders, to purge out disorder, and to restore church rules and discipline to the rectitude of their beginning. They brought a flood of light and of spiritual gifts, humiliating and mortifying to a carnal nature, to the vanity of youth, and pride staining to all flesh, but edifying and strengthening to the little child in Christ. They said it was to prepare us for the gospel to go forth to mankind. At the end of fifteen years one spoke in the name of Mother Ann, that evil was that day so bound and put down that it had no power to rise in the church, which then stood in purer rectitude than ever it had before. Mother Ann's special ministration lasted, it is claimed, about three years. But there were many subsequent spiritual manifestations, and many were converted by them. Crowds of spirits from Hades were taught the gospel of the judgment, and the absolute necessity of confessing and forsaking their sins to find acceptance with God.

Shakers believe that Christ has made his long and anxiously awaited second appearing in Ann Lee and her followers; that God is one in essence, but dual in his complete and perfect manifestation, the redeemed and perfected man and woman; that they are in the work of the harvest, the resurrection, the judgment day, ending the world in themselves by obedience to the everlasting gospel, and ushering in the dawn of the millennial age. They own no wives, nor husbands, nor private personal property, nor have carnal relations; they hold their possessions as a united and consecrated interest, each toiling for the good of the whole, in love serving one another, in honor preferring one another as brothers and sisters of one family. The government is wholly parental. The leading authority is vested in four persons, two of each sex, called ministry. The head of a family is an eldership, consisting when complete of four,

* Of late years the term Yakima includes a considerable proportion of the tribes speaking the Shahaptian language, and probably originally having little or no connection with the Yakima proper.

two of each sex. Elders are assisted by deacons, two of each sex when the order is full, or more if necessary, who manage temporal affairs. The total number of Shakers in the U. S. is about 1,000, forming 15 societies or settlements, of which 2 are in the State of New York, 3 in Massachusetts, 1 in Connecticut, 2 in New Hampshire, 2 in Maine, 3 in Ohio, and 2 in Kentucky. New Lebanon, in Columbia co., and Watervliet, in Albany co., N. Y., are the most important.

The Shakers publish a monthly, called *The Manifesto*, at East Canterbury, N. H. It was started in 1871. See also *The Concise History of Shakers* (East Canterbury, 1894); *Pearly Gate* (Chicago, 1894); and *The Millennial Church* (Albany, N. Y., 1848). ALONZO G. HOLLISTER, Elder.

Shakespeare, WILLIAM: dramatic poet; b. at Stratford-on-Avon, Warwickshire, England, in Apr., 1564—on the 23d of that month, O. S. (N. S., May 3), it is supposed. His father, John Shakespeare, was of the yeoman class; his mother, Mary Arden, was of a family of the minor gentry. John Shakespeare seems to have been a man of character and ability. He became a landholder, and rose rapidly through all the grades of office in Stratford until he became chief alderman and *ex-officio* justice of the peace. Misfortune, however, befell him, and he was reduced to comparative poverty, and was even subject to arrest for debt. Of Shakspeare's boyhood nothing is known; but he was doubtless educated at the grammar school in Stratford, where he got the "small Latin and less Greek" with which Ben Jonson credits him. Passages in his works showing more than ordinary familiarity with law-terms have been regarded as indicating that he was for a time in an attorney's office. This is more probable than the tradition that he was apprenticed to a butcher. The first fact that is really known about him, after his baptism, is that in his eighteenth year he had become entangled with a woman of twenty-five, Anne Hathaway, the daughter of Richard Hathaway, who lived at Shottery, near Stratford. He married this woman by special license, dated Nov. 28, 1582, and their first child, Susanna, was baptized May 26, 1583. Twin children, a boy and girl, named Hamnet and Judith, were baptized Feb. 2, 1585. Shakespeare soon (perhaps in 1585) left Stratford to seek his fortune in London. Tradition says that he had killed some of the deer of Sir Thomas Lucy, of Charlecote, near Stratford, and that the knight's vindictiveness was one of the causes of his leaving his native village. The story, not improbable in itself, finds a certain confirmation in the fact that Sir Thomas is apparently caricatured as Justice Shallow in *The Merry Wives of Windsor*.

Absolutely nothing is known of Shakespeare's first years in London. Tradition says that he began by holding horses at the door of the theater. It is certain that he soon got some humble position inside the theater (another tradition says as a mere "prompter's attendant"), and after a time became an actor, though he seems never to have risen higher than a position of what is known as "general utility." He was one of the original performers in Ben Jonson's *Every Man in his Humour*; he appeared in the same author's *Sejanus*; and there is a tradition that he played the Ghost in *Hamlet*, and that his brother Edward saw him play the part of an old man, which was probably that of Adam in *As You Like It*. A few years later he began his career as a dramatist by rewriting old plays in conjunction with others, his seniors in years and as playwrights. It was the custom of the various companies of players to have several playwrights in their pay, who, working together, produced new plays and patched up old ones. Marlowe, Greene, and Peele were perhaps among Shakespeare's collaborators. His superiority to all his contemporaries soon asserted itself, and he began to write alone or with little assistance. His first wholly original play was probably *Love's Labour 's Lost*; for in *Titus Andronicus*, a revolting tragedy characteristic of a kind of drama then in vogue, there are but slight traces even of his 'prentice hand. He probably also in his earliest dramatic days had some small share in the revision of Part I. of *Henry VI.*, which was almost certainly an old play by another author or authors.

Shakespeare's success provoked the jealousy and excited the enmity of at least one of those whom he eclipsed—Robert Greene, a gifted but dissolute man, who died in wretchedness, and who, in a pamphlet written during his last illness, sneered at Shakespeare as "an upstart crow, beautified with our feathers; . . . and that being an absolute *Johannes factotum*, is in his own conceit the only Shake-scene in a country." "Beautified with our feathers" may mean that he got credit by acting what others wrote; but some take it to be a charge of plagiarism in the revision of plays written by others. A few months later, Henry Chettle, who was one of the knot of writers to which both Greene and Shakespeare belonged, came to the defense of the latter in a pamphlet in which he says that Shakespeare's demeanor was "no less civil than he was excellent in the quality he professes": adding that "divers of worship [people of rank and reputation] have reported his uprightness of dealing, which argues his honesty, and his facetious [felicitous] grace in writing which approves his art." Among the friends that Shakespeare won was the Earl of Southampton, a nobleman of taste and culture, who took great interest in literature and the drama. To him the poet dedicated his first published poem, *Venus and Adonis*, which was his first purely literary effort: he calls it "the first heir of his invention." There is a tradition that Southampton gave Shakespeare £1,000, quite equal to £6,000 at present. This may be an exaggeration, though such munificence was not unknown in those days among English noblemen. When Shakespeare published *Lucrece*, his second poem, he dedicated this also to Southampton, saying, "The love I dedicate to your lordship is without end. . . . What I have is yours; what I have to do is yours; being in part all I have devoted yours." This is apparently the acknowledgment of a great service; and it was possibly through the nobleman's generosity that the poet-dramatist became a very considerable sharer in the Blackfriars theater, at which the company with which he was connected was in the habit of performing. Having attained this advantageous position, Shakespeare soon reached the utmost height of success, as to both reputation and profit, possible to one of his profession. The notion long prevalent that he was neglected during his life, and that his plays rose into popularity only a long time after his death, is entirely unfounded. Contemporary evidence shows that he was the most admired of all the dramatists of his day, and that when the productions of the best of his contemporaries—Ben Jonson included—failed to pay the expenses of their representation, his plays filled the house to overflowing. He entered upon a career of dramatic production which is without a parallel in the history of literature, and which soon placed him in independent circumstances. He had money to spend and money to lend; and he used it to place his father in comfort and to acquire landed property and other wealth in his native town. The Heralds' College made his father a gentleman by coat-armor, and this may have been done at the instance of the successful playwright, who thereby became a "gentleman" by descent both on his father's and his mother's side. He invested a part of his money in the tithes of Stratford, and he bought New Place, the best house in the town, and gradually added other lands to the estate. To this house he retired on his withdrawal from the theater about 1611, and there he died Apr. 23, 1616, and was buried on the 25th in the Stratford church. His daughter Judith was married to Thomas Quiney, a vintner, about two months before her father's death. Her sister Susanna became the wife of Dr. John Hall, a Stratford physician, in 1607.

Of Shakespeare's life in London very little is known, almost nothing except the successive production of his plays. Fuller says that he and Ben Jonson used to have many "wit-combats," in which he compares Jonson to a heavy Spanish galleon and Shakespeare to a light English man-of-war. Jonson was his junior, but was one of those who knew him intimately; and jealous, hot-tempered Ben loved him well and honored his memory after his death. He supports Fuller's comparison by saying, with a classical allusion, that Shakespeare was distinguished by great copiousness and facility of thought and language—so great as to be almost oppressive to his hearers. There was a sort of club of which Raleigh, Jonson, Beaumont, Selden, and Donne were members, and which met at the Mermaid Tavern; and the wit-combats probably took place at these meetings. Tradition says that Jonson owed to Shakespeare's influence the performance of his first comedy, *Every Man in his Humour*, which had been offered and rejected. This story agrees with Shakespeare's reported kindliness of nature, and with the gruff and cynical scholar-dramatist's love for him.

Shakespeare's *Sonnets*, 154 in number, were published in 1609, and were dedicated to a "Mr. W. H." as their "only begetter," but by the publisher, not by the poet, who seems to have had no agency in the publication of any of his works except *Venus and Adonis* and *Lucrece*. If, as the great majority of editors, critics, and commentators believe (among them Wordsworth, Coleridge, Sir Henry Taylor, Swinburne,

Rossetti, Victor Hugo, Malone, Farmer, Steevens, Drake, Hallam, Knight, Collier, Furnivall, Trench, and Dowden), the *Sonnets* are autobiographical, most, if not all, of the first 126 were addressed to one person—a man, not a woman—and the rest (except the last two) to the "dark lady" with whom this man and Shakespeare were both entangled. Among those who believe that the poems are mere "exercises of fancy," with no foundation in the personal experience of the author, are the poets Browning and R. H. Stoddard, with Staunton, Halliwell-Phillipps, Grant White, and Hudson—the two last, however, believing that some of the sonnets are personal. The autobiographical theory has received strong confirmation from the researches of Thomas Tyler (*Shakespeare's Sonnets*, 1890), who has proved quite conclusively that "Mr. W. H." was William Herbert, afterward Earl of Pembroke; and that the "dark lady" was probably Mary Fitton, maid of honor to Elizabeth, and a mistress of Herbert's, by whom she had a child. There are minor difficulties in this theory yet to be cleared up; but at present (1895) it seems more plausible than any other.

Was Shakespeare happy in his married life? After the birth of his children he lived for more than twenty years in London, visiting Stratford, tradition says, only once a year. While in London, if the *Sonnets* are autobiographical, he was captivated by the "dark lady." His will has no mention of his wife except in an interlined bequest of the "second-best bed," apparently inserted during his last sickness. But as soon as he was prosperous in London he bought a house in Stratford, and gradually made it the elegant home which must have been his ideal from the first. Did he look forward to sharing that home with a wife whom he did not love? How he repented of his relations with the "dark lady" the 129th sonnet clearly shows. As to the will, his wife was amply provided for by her rights of dower, which are seldom referred to in wills of the time; and the bequest of the bed was doubtless a token of affection, not the insult it would else have been. On the whole, it may be assumed that the marriage had its foundation in mutual love, and that, after any transient estrangement which may have occurred, it ended as happily as it had begun.

Shakespeare's dramas are unlike those of his predecessors, his contemporaries, and his successors, but their unlikeness is not in form or in purpose. He assumed the forms of comedy and tragedy, and of history or historical play, which had been established before he began to write, and he conformed in every external respect to the fashion of his time and the needs of the theater. His difference from other dramatists consists in his thought and his language, and in his power of dramatic characterization; in all of which he is unapproached by any writer who ever lived. No other writer ever united imagination, fancy, humor, knowledge of human nature, worldly wisdom, psychological insight, and creative power, as all these were united in him. The fertility of his mind appears to have been inexhaustible, the profundity of his thought illimitable. He throws away upon a minor personage and an unimportant situation poetical thoughts and philosophical reflections which other writers, if they could have originated them, would have carefully reserved for elaboration upon great occasions. His dramatic isolation from his creations appears to have been perfect; once evoked from his mind, they exist independently and altogether outside of it, and act and speak altogether according to the laws of their own being, not of his. He does not hesitate to show us that even both good and bad may, and often do, act from mixed motives, good and evil. It is in this inflexible justice, characteristic of only the very highest quality of intellectual and moral nature, that one of the chief evidences of his superiority is found.

Such of his plays as were published during his lifetime seem to have been given to the press entirely without his agency. They were written not to be read, but to be performed; and it was to the interest of all concerned in the theater that they should not get into print. But the publishers eagerly sought copies of them for publication, and obtained them surreptitiously; sometimes, it would seem, by corrupting persons connected with the theater, and sometimes, as the text which they printed shows, by sending shorthand-writers to the performance. Twenty of Shakespeare's plays were thus published during his lifetime. They are known as "the quartos" from the form in which they are printed. Most of them are full of errors, and, with one or two exceptions, they are all more or less imperfect; but they are nevertheless of great value in the formation of the text, and they have been freely used for that purpose. For the text of the remaining seventeen of the plays we are entirely dependent upon the folio edition of the whole thirty-six (not including *Pericles*), published by Isaac Jaggard and Edward Blount in 1623, under the authority—and, in some sort, the editorial supervision—of two of Shakespeare's fellow actors, John Heminge and Henry Condell. This edition, known as the "first folio," although greatly superior, as to the text of almost all the plays, to the quarto copies of the twenty plays before mentioned, is yet marred by so many and so great errors, and sometimes even by such important omissions, that it has required the labors of editors and commentators during 150 years to produce the text as now generally accepted.

The order in which the poems and plays were written is much disputed, and it is not likely that it can ever be fully settled; but in recent years certain facts have been pretty well established. If Shakespeare wrote *Titus Andronicus*, it was probably his first play, and produced before 1590; or whatever he did in revising that play and *1 Henry VI.* for the stage was probably done between 1588 and 1591. *Love's Labour 's Lost*, it is generally agreed, was his first original play (1590), followed by the *Comedy of Errors*, the *Two Gentlemen of Verona*, and *A Midsummer Night's Dream* between 1591 and 1594; to which period must also be assigned *2* and *3 Henry VI.* and *Richard III.* The first draft of *Romeo and Juliet* may have been as early as 1591 (revised 1596 or 1597). Then followed *Richard II.* (1594), *King John* (1594 or 1595), *The Merchant of Venice* (1596 or 1597), *1* and *2 Henry IV.* (1597–98), and *Henry V.* (1599). *As You Like It*, *Much Ado*, and *Twelfth Night* must have been written in 1599–1600, and *Julius Cæsar* by 1601. The *Merry Wives of Windsor* is to be grouped with the other Falstaff plays; and *The Taming of the Shrew* (not wholly Shakespeare's), the exact date of which is not easily fixed, must be put between 1594 and 1598. The first form of *Hamlet* is dated by some critics before 1600, but it may have been as late as 1602. The dates of the rest of the plays are probably as follows: *All 's Well*, 1602 (perhaps the revision of a draft ten years earlier); *Measure for Measure*, 1603; *Troilus and Cressida*, 1603 (? very difficult to date); *Othello*, 1604; *Lear*, 1605; *Macbeth*, 1606; *Antony and Cleopatra*, 1607; *Coriolanus*, 1608; *Cymbeline*, 1609; *The Tempest*, 1610; *Winter's Tale*, 1610–11. *Timon of Athens*, (1607–8 ?), *Pericles* (1608 ?), and *Henry VIII.* (1612–13 ?) are Shakespeare's only in part, and their history is perplexing. *Venus and Adonis* was probably written in 1592 or earlier, *Lucrece* in 1593 or 1594, and the *Sonnets* between 1595 and 1599, though some may have been several years later.

There are few traces, even in tradition, of any intercourse between Shakespeare and the eminent men of his time except Ben Jonson, Drayton, and the Earls of Pembroke and Southampton. Shakespeare and Bacon lived at the same time in the same city, then not a large one, passed each other in the street, and yet probably never interchanged one word. The reason was that one was a player and a poet, the other a statesman and a philosopher, and that each was absorbed in his own affairs. The notion that Shakspeare's plays were written by or in conjunction with Bacon—which has found a few ingenious advocates—is unworthy a moment's consideration by any reasonable creature.

There is a stone over Shakespeare's grave on which there is this inscription:

> Good frend for Iesus sake forbeare
> To digg the dust encloased heare:
> Blest be ye man yt spares thes stones,
> And curst be he yt moves my bones.

These lines, which may embody a wish expressed by Shakespeare, but which are hardly of his writing, have prevented the removal of the remains of the greatest Englishman to Westminster Abbey. Against the wall of Stratford church there is a monument to Shakespeare, with a laudatory inscription in Latin; but of far greater interest is the bust of the poet which forms part of the monument. It is coarse and rude in execution, but there is no reason for doubting that it gives at least a general idea of his personal appearance. According to this, he was at fifty-three a portly but not at all corpulent man, with a high forehead, a head somewhat bald, a small aquiline nose, and a well-formed mouth and chin. Aubrey, the antiquarian, who lived two generations after him, had heard that he was "a handsome, well-shapt man." An engraved portrait upon the title-page of the first collected edition of his works, which Ben Jonson,

in some verses almost as hard and expressionless as the engraving itself, assures us was a good likeness, has a general conformity in the features and the form of the head to the bust. The latter was originally colored after life, and had hazel eyes and auburn hair and beard. These traits were afterward obliterated by a coat of white paint. The bust and the engraved portrait in the folio are the only portraits of Shakespeare which are of undoubtable authentieity; but one known as the Chandos portrait has tradition of very respeetable antiquity in its favor. There is a very slight and vague tradition that Shakespeare "died a papist," but this is very improbable. His works favor no religious form, seet, or dogma. There was also a tradition in Stratford fifty years after his death that he, Drayton, and Ben Jonson had "a merie meeting, and it seems drank too hard, for Shakespeare died of a feavour there contraeted." This tradition has probably as little foundation as the other.

Although Shakespeare was aeknowledged as the greatest dramatist of his time, his reputation rather diminished than inereased during the century after his death. He had no followers or imitators; he established no school. Dramatie taste and dramatie writing steadily deelined after the Elizabethan age (about 1575 to 1625), and by the beginning of the eighteenth century Shakespeare was lightly thought of by the literary eritics, and mueh neglected by the aetors. There had been among the reading publie, however, a steady although not a large demand for his plays. The folio of 1623 was sueceeded by another folio in 1632, and a third edition was ealled for and published in 1664. In the last *Pericles* and six spurious plays whieh had been published in quarto in Shakespeare's lifetime, with his full name or his initials upon the title-page, were ineluded. A fourth edition, also in folio, appeared in 1685. Upon these four folios, and upon the existing old quarto edition of twenty of the plays, the readers of Shakespeare depended until Rowe's edition appeared in 1709 (see bibliography below). From the time of the appearance of this edition the fame of Shakespeare steadily grew until about the beginning of the nineteenth century he was acknowledged to be the first of poets and of dramatists, the most ereative mind, the greatest master of imagination and of language, that the world has known. The number of Shakespeare's commentators has much exceeded that of his editors. His text was left in sueh a condition by the printers of the old quartos and folios that, although it may be read even in those impressions with pleasure and with a full comprehension of its general meaning, there is to its perfeetion need of more critieal labor than is required by most old manuscripts; and of sueh there is none to eonsult, for of Shakespeare's writing not a line has come down to us—not even a word, except his own signature. It is safe to say that more critieal ability and learning has been displayed upon this subjeet than upon any other in the whole range of literature, the poems of Homer perhaps exeepted. The works written upon Shakespeare form a library in themselves, and a eomplete bibliography (unfortunately there is none sueh in existenee) would fill a good-sized volume.

Shakespeare, like so many other men of great eminenee, left little traee of his personality behind him. His only son, Hamnet, died at the age of twelve years. His two married daughters left ehildren, but the family, even on the female side, became extinct in the third generation. New Plaee, his residence upon his retirement from the theater, after passing through several hands was in 1759 razed to the ground by its last owner, the Rev. Franeis Gastrell, who was exasperated by a quarrel with the town authorities and by the perseeution of prying visitors to the home of the great poet. John Shakespeare's house, whieh stands in Henley Street, and in whieh it is probable that William was born, was a comfortable dwelling for that age. After falling into decay, it was bought by an assoeiation and restored for preservation as a memorial of the poet. More reeently, the grounds of New Plaee and the eottage at Shottery in which Ann Hathaway is supposed to have lived before her marriage have been bought for the same purpose.

Richard Grant White. Revised by W. J. Rolfe.

Bibliography.

Editions.—Among eomplete editions (besides the early folios mentioned above) that are of any eritieal value, the following may be named: Nicholas Rowe's (6 vols., 1709); A. Pope's (6 vols., 1723–25); Louis Theobald's (7 vols., 1733; 2d ed. 1740); Sir Thomas Hanmer's (9 vols., 1744); Bishop Warburton's (8 vols., 1747); Edward Capell's (10 vols., 1760–68); Dr. Samuel Johnson's (8 vols., 1765); Isaae Reed's (10 vols., 1785); Edmond Malone's (10 vols., 1790); George Steevens's, with Boydell's illustrations (9 vols., 1802; in parts, 1791–1802); Reed's (first ed. with his name, 21 vols., 1803; 2d ed. 1813); Alexander Chalmers's (10 vols., 1805); the *Variorum of 1821*, edited by James Boswell from a eorrected copy left by Malone (21 vols.); S. W. Singer's (10 vols., 1826); Charles Knight's Pietorial ed. (8 vols., 1838–43); J. P. Collier's (8 vols., 1842–44; 2d ed. 6 vols., 1858); G. C. Verplanck's (3 vols., 1844–47); H. N. Hudson's (11 vols., 1851–56); J. O. Halliwell's, afterward Halliwell-Phillipps's (16 vols. folio, 1853–65; only 150 copies printed); Singer's 2d ed. (10 vols., 1856); R. Grant White's (12 vols., 1857–66); Alexander Dyce's (6 vols., 1857; 2d ed. 9 vols., 1864–67; 3d ed. 9 vols., 1875); Howard Staunton's (3 vols., 1858–60); the Cambridge ed., by W. G. Clark and W. Aldis Wright (9 vols., 1863–66; 2d ed., by W. A. Wright, 1891–93); Charles and Mary Cowden-Clarke's ed. (3 vols., 1863–66); W. J. Rolfe's (40 vols., 1870–83; Friendly ed. 20 vols., 1884); Horace Howard Furness's *New Variorum* (10 vols. issued, 1871–95); Clarke and Wright's Globe ed. (the standard for line numbers, 1874); H. N. Hudson's Harvard ed. (20 vols., 1880–81); R. G. White's Riverside ed. (6 vols., 1883); the Henry Irving ed., by Sir Henry Irving and F. A. Marshall (8 vols., 1888–90); the Bankside ed., by Appleton Morgan (20 vols., ineluding the twenty plays of whieh early quartos exist, 1888–92); the Temple ed., by Israel Gollancz (1894—not eompleted in May, 1895). The Leopold ed. (1 vol., 1877), with the German Delius's text, is valuable for the elaborate biographieal and eritical introduction by F. J. Furnivall.

Editions of single plays and series of plays (mostly for edueational use) are too numerous to be eatalogued here. The Clarendon Press and Rugby series, and Charles Wordsworth's *Shakespeare's Historical Plays* (3 vols., 1883), are noteworthy among those whieh have some critical value.

The *Poems and Sonnets* are ineluded in most of the recent standard editions. The first eomplete edition of both was issued in 1709 (an ineomplete edition appeared in 1640). The *Sonnets* were first colleeted in 1609. The best modern edition is Edward Dowden's larger ed. (1881). Another important one is Thomas Tyler's (1890).

The first eomplete Ameriean edition of the works (with life, glossary, and notes by Dr. Johnson) was published in 8 vols. in 1795–96. at Philadelphia. The first Boston edition (ineluding only the plays) was in 8 vols., 1802–04. Three editions of this appeared, eaeh reset, stereotyping being then unknown. An edition in 17 vols. was published at Philadelphia in 1809, and one in 7 vols. (edited by O. W. B. Peabody, though his name does not appear in it) in Boston in 1836 (reprints of Reed's text had been issued in 1813 and 1814). An edition of the plays in 10 vols. (Reed's text) appeared in New York in 1821, and again in 1824. The first Ameriean edition of the *Spurious and Doubtful Plays* was published at New York in 1848.

Life, Birthplace, etc.—S. Neil, *Shakespeare, a Critical Biography* (1861); Halliwell-Phillipps, *Outlines of Life of Shakespeare* (7th ed. 1887); F. G. Fleay, *Life and Works of Shakespeare* (1886); D. W. Wilder, *Life of Shakespeare* (1893); T. S. Baynes, *Shakespeare Studies* (1894); C. M. Ingleby, *Shakespeare, the Man and the Book*, parts i. and ii. (1877–81); C. Knight, *Biography of Shakspere* (in Pietorial ed., but also published separately); G. R. French, *Shakespeareana Genealogica* (1869; on the Shakespeare and Arden families, persons, and plaees in Warwiekshire mentioned by Shakespeare, and eharacters in the historical plays); J. R. Wise, *Shakespeare, his Birthplace and its Neighborhood* (1861); Sidney Lee, *Stratford-on-Avon* (n. e. 1890); J. L. Williams, *Homes and Haunts of Shakespeare* (superbly illustrated, 1891–93); W. Winter's *Shakespeare's England* (illustrated ed. 1893); and *Old Shrines and Ivy* (1894). J. Walter's *Shakespeare's True Life* (1890) is copiously illustrated, but not always trustworthy.

Dictionaries and other Reference-books.—A. Sehmidt, *Shakespeare Lexicon* (2d ed. 1886); Dyce's *Glossary* (vol. ix. of ed. of Shakespeare published separately); R. Nares, *Glossary* (rev. ed. 1859); Charles and Mary Cowden-Clarke, *Shakespeare Key* (1879); J. Bartlett's *Concordance to Shakespeare* (1895; supersedes all earlier works of its elass); Mrs. H. H. Furness, *Concordance to the Poems of Shakespeare* (1874: gives every instance of every word); E. Abbott's *Shakespearian Grammar* (1873); W. S. Walker's *Shakespeare's Versification* (1854) and *Critical Examination of Text of Shakespeare* (1860); A. J. Ellis's *Early English Pronunciation* (part iii. published separately); E.

Dowden's *Shakspere Primer* (1877; small, but invaluable), or his *Introduction to Shakespeare* (1894); *The Shakespeare Library* (for the sources of the plays; rev. ed. 6 vols., 1875); W. W. Skeat, *Shakespeare's Plutarch* (for sources of Roman plays, 1875); L. Booth's facsimile reprint of *Folio of 1623* (1864), or H. Staunton's photo-lithographic reproduction of the same (1866), and the Griggs facsimiles of the early quartos, valuable for the original texts (for twenty of the plays, see also Bankside ed. of Shakespeare); F. Douce, *Illustrations of Shakspeare* (n. e. 1839); G. L. Craik, *The English of Shakespeare* (Am. ed. by Rolfe, 1867); H. P. Stokes, *Chronological Order of Shakespeare's Plays* (1878); T. F. T. Dyer, *Folk-lore of Shakespeare* (Am. ed. 1884); H. N. Ellacombe, *Plant-lore of Shakespeare* (1878); J. E. Harting, *Ornithology of Shakespeare* (1871); Lord Campbell, *Shakespeare's Legal Acquirements* (1859); F. F. Heard, *Shakespeare as a Lawyer* (1883); J. C. Bucknill, *Medical Knowledge of Shakespeare* (1860) and *Mad Folk of Shakespeare* (2d ed. 1867); C. Wordsworth, *Shakspeare's Knowledge of the Bible* (3d ed. 1880); W. A. Wright, *Bible Word-book* (2d ed. 1884; contains many illustrations from Shakespeare); J. P. Norris, *Portraits of Shakespeare* (1885; exhaustive); A. Roffe, *Handbook of Shakespeare Music* (1875; fuller treatment in *List of Songs, etc., by Shakspere, set to Music*, published by New Shakspere Society, 1884). The *Papers of the Shakespeare Society* (1844–49) and the *Transactions* and other publications of the New Shakspere Society (from 1874 onward) contain much valuable textual, critical, and illustrative matter.

Critical Commentaries.—S. T. Coleridge's *Notes on Shakspeare* (in eds. of his works); Mrs. Charlotte Lennox, *Shakespear Illustrated* (the first critical work on Shakespeare by an American; 3 vols., 1753–54); A. W. Schlegel, *Lectures on Dramatic Art* (1815); Mrs. A. Jameson's *Characteristics of Women* (1832; Am. ed. 1866); N. Drake, *Shakspeare and his Times* (1817); Joseph Hunter, *New Illustrations of Shakespeare* (1845); H. Giles, *Human Life in Shakespeare* (1868); G. Fletcher, *Studies of Shakespeare* (1847); W. Hazlitt, *Characters of Shakespear's Plays* (1817; n. e. by Bohn, with the *Lectures on Age of Elizabeth*, 1870); E. Dowden, *Shakspere: his Mind and Art* (Am. ed. 1881); H. N. Hudson, *Life, Art, and Characters of Shakespeare* (1872); R. G. White, *Shakespeare's Scholar* (1854) and *Studies in Shakespeare* (1886); J. Weiss, *Wit, Humor, and Shakespeare* (1876); D. J. Snider, *System of Shakespeare's Dramas* (1877); Lady Martin, *Some of Shakespeare's Female Characters* (1884); Mrs. F. A. Kemble, *Notes on Shakespeare's Plays* (1882); R. G. Moulton, *Shakespeare as a Dramatic Artist* (3d ed. 1893); B. E. Warner, *English History in the Plays of Shakespeare* (1894); B. Wendell, *William Shakspere* (1895); A. C. Swinburne, *Study of Shakespeare* (1880); T. P. Courtenay, *Commentaries on the Historical Plays of Shakespeare* (1840); J. W. Hales, *Essays and Notes on Shakespeare* (1892); B. Ten Brink, *Five Lectures on Shakespeare* (1895); G. G. Gervinus, *Shakespeare Commentaries*, translated by F. E. Bunnett (n. e. 1875); H. Ulrici, *Shakespeare's Dramatic Art*, translated by L. D. Schmitz (1876); H. Corson, *Introduction to Study of Shakespeare* (1889).

Miscellanea.—R. Farmer, *Essay on the Learning of Shakspeare* (2d ed. 1767; several times reprinted); L. M. Griffiths, *Evenings with Shakspere* (1889; very useful in Shakespeare reading-clubs); Charles and Mary Lamb, *Tales from Shakspeare* (many eds.; one with notes by W. J. Rolfe, 2 vols., 1890); Mary Cowden-Clarke, *Girlhood of Shakespeare's Heroines* (best ed. 5 vols., 1891); C. M. Ingleby *et al.*, *Shakespeare's Centurie of Praise* (references to Shakespeare between 1591 and 1693; 2d ed. 1879, published by New Shakspere Society); M. R. Silsby, *Tributes to Shakespeare* (1892); W. Andrews, *Bygone Warwickshire* (1893); W. Black, *Judith Shakespeare* (1884; a novel, but a careful study of the scene and the times).

For the "Collier controversy" concerning the emendations which J. P. Collier asserted that he had found in a copy of the second (1632) folio, see A. Dyce's *Strictures on Collier's New Edition of Shakespeare* (1858); N. E. S. A. Hamilton's *Inquiry into the Genuineness of the MS. Corrections in Collier's Shakespeare* (1860); S. W. Singer's *The Text of Shakespeare Vindicated*, etc. (1853); and C. M. Ingleby's *Complete View of the Shakespearian Controversy* (1861).

For the Baconian theory of the authorship of the plays and poems, see W. H. Wyman's *Bibliography of the Bacon-Shakespeare Controversy* (1884), and supplements to the same in the magazine *Shakespeariana*. The most important work on the Baconian side is N. P. Holmes's *Authorship of Shakespeare* (3d ed. 2 vols., 1886; sufficiently answered by J. Spedding's letter to the author, printed in the appendix, pp. 612–618); and on the other side Mrs. C. C. Stopes's *The Bacon-Shakspere Question Answered* (2d ed. 1889). See also Donnelly, Ignatius. W. J. Rolfe.

Shak'opee: city; capital of Scott co., Minn.; on the Minnesota river, and the Chi., Mil. and St. P. and the Chi., St. P., Minn. and Omaha railways; 28 miles W. S. W. of St. Paul (for location, see map of Minnesota, ref. 10–E). It is in an agricultural region, and contains a steam flour-mill, wagon-factory, railway repair-shops, orphan asylum, a national bank with capital of $50,000, and two weekly newspapers. Pop. (1880) 2,011; (1890) 1,757; (1900) 2,047.

Shale [from Germ. *schale*, scale, shell, husk, thin layer; cognate with O. Eng. *scealu* > Eng. *shale*, husk, pod (nearly obsolete). The same Teuton. word coming viâ O. Fr. appears in Eng. as *scale*]: a laminated argillaceous rock resulting from the induration of mud or clay stratified in water. A shale containing much organic matter, sand, or calcium carbonate is characterized as bituminous, arenaceous, or calcareous. The shales are the most abundant of all stratified rocks, and are the most highly composite. From the mixed sediments washed down from the land by streams and deposited in the ocean, the larger grains are usually sorted out and separately deposited, giving rise to sandstones; the soluble matter, chiefly calcium carbonate, is also in the main separately deposited as limestone; and the residuum is deposited as mud, and eventually converted into shale. As these various rocks, being lifted into the land, are degraded by rains and streams, the sandstones and limestones, being relatively hard and resistant, come to constitute mountains and hills, while the shales are eroded into valleys. Economically the shales are of growing importance, being wrought for the manufacture of bricks, especially paving-bricks, and for mixture with other substances in the manufacture of hydraulic cement. G. K. G.

Shaler, Nathaniel Southgate, S. D.: geologist; b. near Newport, Ky., Feb. 22, 1841; graduated at Lawrence Scientific School of Harvard University 1862; during the civil war served for two years in the Union army with Kentucky volunteers as an artillery and staff officer; returned to the Lawrence School as assistant and afterward instructor in zoölogy and geology; professor in Harvard University since 1868, at first of Palæontology, afterward of Geology; dean of the Lawrence School since 1891; director of the Geological Survey of Kentucky 1873–80; geologist of the U. S. Geological Survey in charge of the Atlantic coast division since 1884; commissioner of the Commonwealth of Massachusetts for various periods on agriculture, topographic surveys, the gipsy-moth, and highways; president of the Geological Society of America 1895. Prof. Shaler is a prolific author and has entered many fields, but his favorite themes are those branches of geology and physical geography which bear most directly on the activities of man. Among his writings are the Kentucky Geological Reports and Memoirs (7 vols., 1876–82): *On the Nature of Intellectual Property and its Importance to the State* (1878); *Aspects of the Earth* (1889); *The Story of our Continent* (1892); *Nature and Man in North America* (1892); *The Interpretation of Nature* (1893); *Sea and Land* (1894); *The United States of America* (2 vols., 1894); and reports to the U. S. Geological Survey on *Marine Marshes*, *Freshwater Swamps*, *Soils*, *Harbors*, and the geology of Cape Ann, Martha's Vineyard, Nantucket, and Mt. Desert. G. K. G.

Shallot [from O. Fr. *eschalote*, an altered form of *escalone*, whence Eng. *scallion*]: an onion-like plant (*Allium ascalonicum*), native of the Old World, growing in cloves somewhat like the garlic. The cloves are set in the ground early, and become large enough for market two months before seedling onions are ripe. They much resemble onions in taste, and in the U. S. they are sold as such by market-gardeners. Both tops and bulbs are eaten.

Sha'manism [from Pers. and Hind. *shaman*, idolater]: the religion of a large number of primitive North Asiatic tribes, blended in Central Asia with Lamaism (*q. v.*). It has no idols, save perhaps some fetishes and charms and rude ancestral images. The Shaman is a combination of priest and wizard, who performs incantations and sacrifices, mainly for the two objects of procuring oracles and purifying houses of the defilement of the dead body. Although the

Supreme Being is good, yet so great are the power and desire of the king of the lower world to injure man that the principal worship conducted by the Shamans is intended to placate him. Hence the declaration that Shamanism is devil-worship. See Tylor's *Primitive Culture* (2 vols., 1871).

Sham'mai (shortened from Heb. *Shemáya*): one of the leaders of the Sanhedrin during the reign of Herod. He is always mentioned together with Hillel, from whom he is said to have differed greatly by his harshness of manner and his rigorous interpretation of the Law. The followers of these two teachers, who still existed in Jerome's days, preserved the traditions of their masters, though the freer interpretations of the Bēth Hillel prevailed over the more rigorous of the Bēth Shammai. Shammai is supposed to be identical with the Σαμέας (Josephus, *Ant.*, xiv., 9, 4) who alone dared to oppose Herod when he appeared before the Sanhedrin in 47 B. C., and who was spared by Herod on the taking of Jerusalem (*ib.*, xv., 1, 1). RICHARD GOTTHEIL.

Shamo, Desert of: See GOBI.

Shamokin: borough; Northumberland co., Pa.; on the Lehigh Valley, Northern Central, and Reading railroads; 19 miles S. E. of Sunbury, the county-seat (for location, see map of Pennsylvania, ref. 4–G). It is in the center of the anthracite coal region; contains iron-works, machine-shops, flour and planing mills, and other manufactories; 19 churches, 8 public-school buildings, public-school property valued at $200,000, a parochial school, gravity water-works, 2 electric-railway plants, 2 electric-light plants, a national bank (capital, $100,000), a State bank (capital, $50,000), and a guarantee trust and safe deposit company (capital, $250,000). It has 3 daily and 4 weekly newspapers, an assessed valuation (1895) of $1,004,020, and a local debt (1895) of $70,600. Pop. (1880) 8,184; (1890) 14,403; (1900) 18,202.

WM. F. HARPEL, SUPERINTENDENT OF SCHOOLS.

Shamrock: the national badge of Ireland, as the thistle is that of Scotland. It is a plant with trifoliate leaves, which was used by St. Patrick to illustrate the doctrine of the Trinity. The plant now generally called by the name is a hop clover (*Trifolium minus*). The wood-sorrel (*Oxalis acetosella*), the common white clover, and the black medick or nonesuch (*Medicago lupulina*) have each been identified with the original shamrock.

Shanghai, or **Shanghae**, shaang'hī': a hien or district city of the province of Kiangsu, China, and the most important emporium of foreign trade in the empire; on the west or left bank of the Hwang-pu, near its junction with the Wu-sung river, and 12 miles above its embouchure into the estuary of the Yangtse-kiang; lat. 31° 14′ 42″ N., lon. 121° 28′ 55″ E. (see map of China, ref. 6–L). In shape it is an irregular oval, surrounded by a wall 3½ miles in circuit and pierced with seven gates. Its principal native suburb lies between the east gate and the river, and opposite this is the anchorage for junks. Except in the foreign settlement, which lies outside the north gate and stretches N. and N. E. for 2 miles along the bank of the river, the streets, both within and without the walls, are narrow and dirty. The foreign settlement consists of three so-called "concessions," known as the French, the British, and the American concessions respectively. The first mentioned is a narrow strip bounded on the N. by a canal called the Yang-King-pang; thence for three-fifths of a mile to the Wu-sung river (or Soo-chow creek, as it is called by foreigners) stretches the British settlement (the first to be laid out). Beyond this lies Hon-Kew, called the "American" settlement by foreigners, because here the first U. S. consul took up his abode. In 1863 it was incorporated with the British for municipal purposes. The French settlement has its own municipal government. There is no restriction, however, as to the nationality of residents or land-renters in any of these concessions. So efficient has been the municipal management of both that Shanghai has earned the distinction of being the "Model Settlement" of the East. The streets are well made and well kept, and are lined with imposing buildings. Those parallel with the Yang-tse road, which runs along the river bank, and is known as *The Bund*, are named after Chinese provinces, while the cross streets are named after cities. Excellent roads constructed during the military occupation of Shanghai, when threatened by the Taipings, radiate from the settlement to the W. and S., and are much used for driving, while a complicated systems of creeks and canals, connecting with the Grand Canal, makes communication with the interior both easy and inexpensive.

The western half of the Settlement is occupied almost entirely by Chinese, for whose benefit a Mixed Court has been provided. In all civil, criminal, and political matters the subjects and citizens of the different treaty powers are, as elsewhere in China, subject to the jurisdiction of their own consuls, except in the cases of Great Britain and Germany, which have provided special courts.

Shanghai was first opened to foreign residence and trade in 1843, in accordance with the treaty concluded at Nanking in the preceding year, though its importance as a commercial center had long been recognized. In 1893, according to the reports of the imperial maritime customs, the gross value of the trade of the port amounted to 177,017,836 haikwan or custom-house taels (= $185,868,727 U. S. gold). In 1899 the imports were valued at 153,808,291 haikwan taels ($110,741,970), and the exports at 90,937,476 haikwan taels ($65,474,983); total trade 244,745,967 taels ($176,216,943). The chief foreign imports are opium, cotton and woolen goods, metals, coal, window-glass, indigo, machinery, matches, needles, sandal-wood, kerosene oil, paper, sugar, soap, planks, seaweed, silk, skins, stores, and ebony and other woods. The countries from which most of the commodities were received are:

Great Britain	26,896,967	taels.
Hongkong	20,524,125	"
India	16,729,415	"
Japan	6,296,517	"
United States	5,193,584	"
Continental Europe, excluding Russia	4,984,866	"

The articles of native produce exported to foreign countries include beans and bean-cake, chinaware, cloth, raw cotton, ground nuts, Chinese drills, hemp, medicines, oils, paper, rice, raw silk, rugs, straw-braid, sugar, tea, tobacco, wax, and wheat. The shipping statistics show that in 1893 2,822 steamers, aggregating 3,147,734 tons, and 343 sailing vessels (117 151 tons) entered port; and that 2,821 steamers (3,154,379 tons) and 331 sailing vessels (110,606 tons) cleared. The population of Shanghai is estimated at 400,000, of whom about 2,000 are foreigners. R. L.

Shan-hai-kwan [literally, mountain-sea-barrier]: a strongly fortified town of China, pleasantly situated on the shore of the Gulf of Peh-chih-li, at the eastern end of the Great Wall. It consists of three towns separated by strong walls and surrounded by one outer wall. The large inner city is the business center; the inclosure on the E. is occupied by official and soldiers, and that on the W. by tradespeople and soldiers. The place is said to be impregnable. It is a station on the Tientsin-Mukden Railway, complete for a few miles beyond Shan-hai-kwan.

Shannon: the largest river of Ireland. It rises in the county of Cavan at 256 feet above sea-level, flows first S. to Limerick, then W., and enters the Atlantic through an estuary 10 miles wide at its mouth. In its course, which is 254 miles in length, it forms several lakes, viz.: Loughs Allen, Boderg, Bofin, Forbes, Ree, and Derg. Vessels of 1,000 tons burden can ascend to Limerick, and small steamers to Athlone. The river is canalized between Limerick and Killaloe, and some distance below Athlone. The Inny, Brosna, Mulkear, Maigue, and Deel fall into the Shannon on the left, and the Suck and the Fergus on the right.

Shanny: a marine spiny-rayed fish of the genus *Pholis*, or a related genus, of the family *Pholididæ*. The common shanny (*Pholis pholis*), found in shoals on the coasts of England and France, is usually about 5 inches long, and is remarkable for the habit of creeping, by means of its ventral fins, out of the water into the crevices of the rocks, and there remaining until the return of the tide. It has been known to live thirty hours out of salt water, but soon dies in fresh water. The American radiated shanny (*Eumesogrammus subbifurcatus*) is found, though rarely, on the coasts of Massachusetts and New York.

Shans: Burmese name for the most numerous of the races of Indo-China, extending from Assam to Kwangtung, and from Yunnan to the Gulf of Siam, though not occupying all this territory. They form the chief race of the Siamese, and are represented among the Miautze communities farther N. in Chinese territory. They probably migrated from the mountains of Sze-chuen, and appeared on the upper waters of the Irawadi about 2,000 years ago. Their languages are very similar, and they are remarkably homogeneous in appearance, manners, and customs, though much divided geographically and politically.

Shansi, shaan'see': an inland province of China; bounded N. by the outermost part of the Great Wall, E. by Chih-li, S. by Honan and the Hwang-ho or Yellow river, and W. by the Yellow river. Area, 56,268 sq. miles. The surface is mountainous, and may be divided into seven great basins. It has no large rivers except the Hwang-ho. The mineral resources of the province are great; coal is found everywhere; iron of superior quality abounds and is worked; copper has been found in over 100 localities; tin is found at Mt. Ki and in several other places; silver, near Tai-yuen and elsewhere; sulphur is plentiful, and hot springs are numerous. Quantities of salt are produced from the salt-marshes in the southern part of the province. The cities and villages are numerous and the people everywhere civil. The men of Shansi are the bankers and pawnbrokers of the country. Besides the usual cereals, cotton is grown in the south. Pop. about 13,000,000. Capital, Tai-yuen-foo.

Shan States: semi-independent states occupied by peoples of Shan race, in the northern part of the Indo-Chinese Peninsula, S. of China, between Burma and Tonquin, and N. of Siam. From the seventh or eighth century they have warred with each other and with neighboring states with varying fortune. In the thirteenth century they formed a federation of nine states under the name of Muan Man, and reached their highest development. Later the northern states were permanently subjected by China, and the southern by Siam. The most of the remainder were under nominal Burmese protection at the time of its conquest, and passed with Burma under British. Those adjoining Tonquin are under nominal French protection, and a disputed central area, by agreement between France and Great Britain, is to be guaranteed independence as a "buffer" state between China, Siam, Burma, and Tonquin. See Hallett, *A Thousand Miles in the Shan States* (1890). M. W. H.

Shantung, shaan'toong' [literally, east of the mountain —that is, of Mt. *Tai*]: a maritime province of China, which, in the form of a mountainous promontory, juts out eastward into the Yellow Sea. It is bounded on the N. by the province of Chih-li and the Gulf of Peh-chih-li, E. by the Yellow Sea, S. by Kiangsu, and W. by Honan and Chih-li. Area, 65,104 sq. miles. Pop. about 36,000,000. The surface is diversified, but consists in the main of a very fertile plain along the western, southwestern, and northern borders of the great central mass of mountains, which, with its numerous spurs and secondary ridges and their ramifications, occupies the rest of the province eastward. The general trend of the mountains is from N. E. to S. W., but several important ridges run E. and W. The highest peak is Tai-shan, which is over 4,100 feet. Next in point of grandeur and height come the Lao-Shan, occupying a small peninsula on the south coast, lat. 36° 5′ to 36° 30′ N. and lon. 120° 10′ to 120° 45′ E., with peaks ranging from 2,500 to 3,500 feet; the Saw-teeth Mountains S. of Chefoo, 2,900 feet; and the Ai-shan Mountains S. W. of Chefoo, 2,065 feet. S. of Wei-hai-wei the highest elevation is 1,600 feet, while still farther to the E., near the city of Yung-ching, the highest is 1,860 feet. Mt. Tai, which, according to Chinese reckoning, is 15 miles high, is one of the five sacred mountains of China, and is much resorted to by pilgrims, for whose benefit paths have been made and steps cut in the rock clear up to the summit. The plain on the W. is traversed by the Grand Canal (to which many small but historic streams contribute their waters), and on the N. by the Yellow river, formerly called the Ta-tsin. There are no other rivers of importance, and yet Shantung is well watered.

The coast is deeply indented with good harbors. The best on the north coast are CHEFOO and WEI-HAI-WEI (*qq. v.*). On the southern side of the promontory there are Shih-tao, in lat. 36° 53′ N. and lon. 122° 23′ E., and Kin-Kia-Kow, near the important city of Kiao-Chow, in lat. 36° 16′ N. and lon. 120° 10′ E. The waters which surround Shantung are rich in fishes of all kinds and fishing is extensively carried on along the coast. The province is very fertile and produces wheat, barley, maize, millet, pulse, tobacco, hemp, and indigo; and medicines of many kinds are extensively produced. Very little rice is grown. Coal and iron abound, and are worked in several places, but extensively at Po-shan-hien, which is the "Black Country" of Shantung. Galena and copper have been found, and gold is obtained in considerable quantities from the sands of the rivers. Precious stones are found principally in the Lao-shan range; sulphur is obtained in several places, and there are many hot sulphur-springs which are resorted to for fever and skin diseases. The best known are those of Ai-shan, 40 miles S. W. of Chefoo; Wŭn-shih-t'ang, 25 miles S. of Tŭng-chow-foo: and Lung-chuen-t'ang, a few miles S. of Wei-hai-wei. Other natural products are asbestos, saltpeter, and insect wax. Cotton cloth of various kinds is woven; silk is produced, the best being in the plain lying W. of the mountain area, and silk-weaving is extensively carried on. The finest brocaded silk is made near Tsinan-foo, the capital, and the province is famous for its pongees. Straw-plaiting is also important.

On account of the destruction of a Catholic mission and the murder of two German missionaries in Shantung, a German squadron seized Kiao-Chow in Dec., 1897, and the next month Germany secured from the Chinese emperor a lease of that city and the surrounding district for 99 years. R. L.

Shark [of uncertain origin; usually regarded as derived through O. Fr. from Lat. *carcharus*, a shark, from Gr. καρχαρίας, deriv. of κάρχαρος, having jagged teeth; but the word does not occur in O. Fr. or M. Eng.]: any fish-like vertebrate of a group (*Squali*) of plagiostomous selachians distinguished from the *Raiæ* (rays and skates) by the gill-openings being at the sides of the body. The body also is elongated and more or less cylindrical, and passes gradually into the tail. The jaws are homologous with the lower jaw and with the palatal arch of higher vertebrates. The teeth are generally movably articulated with the jaws, and occur in several rows which are successively shed and renewed from behind forward. The outermost row generally is the only one functional, the rest being bent backward and downward. There are usually five gill-openings, though sometimes, as in the *Hexanchidæ*, six or seven. The integument never has scales, but is often developed into calcified papillæ, which, when small and closely set, constitute shagreen. The eggs of the oviparous species have a leathery investment as in rays, and in some of the viviparous species, as in certain species of *Galeus* and *Carcharinus*, the embryo is attached to the uterus by a placenta.

Sharks are found in all seas, but are most abundant in those of warm regions, while some enter fresh water, and one species is confined to Lake Nicaragua. They are mostly carnivorous and predatory, but some, as the basking shark and the whale-shark, have very small or weak teeth, and feed on small marine animals or are even herbivorous. Of the species that attack man the most formidable is the great white shark or man-eater, an isurid (*Carcharodon carcharias*), sometimes about 40 feet long. The fossil teeth of the larger extinct *Carcharodon megalodon* are found in great numbers in Tertiary beds of the South Atlantic coast of the U. S., where they are quarried and exported for conversion into artificial manure. Other formidable species are galeids or typical sharks, belonging to *Carcharinus*, the largest genus and one abundantly represented in all warm seas, and *Galeocerdo*. The great blue shark (*Carcharinus glaucus*) reaches the coast of both Europe and the U. S., and the tiger-shark (*Galeocerdo maculatus*), common in the Indo-Pacific, also reaches the Atlantic coast of the U. S. The sharp-nosed shark (*Scoliodon terræ-novæ*) is another galeid, common on the southern Atlantic coast of the U. S. The voracious gray shark or sand-shark (*Carcharias littoralis*), common on the Northern Atlantic coast of the U. S., is a wide-ranging species, about 6 feet long. The Greenland shark, nurse-shark, or sleeper is a scymnid (*Somniosus microcephalus*), about 15 feet long, noted among whalers for its voracity. The basking shark (*Cetorhinus maximus*), about 40 feet long, inhabits the open sea, and is named from its habit of floating on the surface in calm weather. Its liver yields from a ton to a ton and a half of oil. The whale-shark (*Rhinodon typicus*) exceeds a length of 50 feet. The HETERODONTIDÆ (*q. v.*), which are noted as being an archaic type, have broad flattened molar teeth arranged in oblique series, all functional at once and adapted for crushing molluscs and crustaceans. The tiger-shark, a ginglymostomid (*Stegostoma tigrinum*) of the Indian Ocean, attains a length of 15 feet, of which the blade-like tail makes one-half. The spinous shark (*Echinorhinus spinosus*) has its body studded with bony tubercles, each of which bears a thorn-like elevation. The existing cow-sharks, or *Hexanchidæ*, are represented by teeth in the Jurassic. *Chlamydoselachus anguineus* of Japan has an eel-like body 6 feet long. Each of its teeth consists of a slender median cusp separated from the two lateral ones by a small projection. The *Pristiophoridæ*, represented in Australian and Japanese seas, have the snout produced into a saw as in the sawfishes. The smaller littoral forms are known as dogfishes

and hounds. One of the commonest of these in the North Atlantic is *Squalus acanthias*, with a stout spine in each dorsal. Its liver is valued for its oil. The small-spotted dogfish (*Scylliorhinus canicula*) and the large-spotted (*S. catulus*) are found on the British coast.

The so-called false sharks are species of another group, HOLOCEPHALI (*q. v.*). Dr. Gill, in a revision of his *Arrangement of the Families of Fishes*, allocates the families to four orders: *Opistharthri*, including *Chlamydoselachidæ* and *Hexanchidæ* (*Notidanidæ*); *Prosarthri*, the *Heterodontidæ* (*Cestraciontidæ*); *Tectospondyli*, the *Echinorhinidæ*, *Oxynotidæ*, *Squalidæ*, and *Dalatiidæ* (*Scymnidæ*); and *Asterospondyli*, the remaining families.

See Müller and Henle, *Systematische Beschreibung der Plagiostomen* (Berlin, 1841); Hasse, *Natür System der Elasmobranchier* (Jena, 1879, and suppl., 1885); and Balfour, *A Monograph on the Development of Elasmobranch Fishes* (London, 1878). Also ANGEL-FISH, DOGFISHES, FOX SHARK, TOPE, and HAMMERHEAD. Revised by F. A. LUCAS.

Sharon: borough; Mercer co., Pa.; on the Shenango river, and the Erie, the Lake Shore and Mich. S., and the Penn. railways; 14 miles W. of Mercer, 41 miles S. S. W. of Meadville (for location, see map of Pennsylvania, ref. 3–A). It contains 2 national banks with combined capital of $250,000, a private bank, 4 public schools, public-school library (founded in 1877), Hall Institute (Baptist, chartered in 1888), and a daily and 4 weekly newspapers. It is principally engaged in mining coal and manufacturing iron and steel, having large rolling-mills, blast-furnaces, foundries and machine-shops, and nail-factories. Pop. (1880) 5,684; (1890) 7,459; (1900) 8,916. EDITOR OF "TELEGRAPH."

Sharon Springs: village; Schoharie co., N. Y.; on the Del. and Hudson Railroad; 20 miles E. N. E. of Cooperstown, 59 miles W. by N. of Albany (for location, see map of New York, ref. 5–I). It is a popular summer resort in a narrow valley, 1,100 feet above sea-level, surrounded by high hills, and has four noted mineral springs—chalybeate, magnesia, white sulphur, and blue sulphur—which, with a spring of pure water, flow into a small stream below a wooded bluff W. of the village, after a descent of 65 feet over a ledge of perpendicular rocks. Pop., permanent (1880), 627; (1890) 622; (1900) 567.

Sharp, GRANVILLE: abolitionist; b. at Durham, England, Nov. 10, 1734; studied law, and for several years was a clerk in the ordnance office; was the chief patron of the slave Somerset in suing for his freedom, which resulted in the famous decision against the legality of slavery in England (1772); resigned his post in the ordnance office on account of opposition to the American war Apr., 1777; devoted himself thenceforth to philanthropic objects, especially the overthrow of slavery and the slave-trade; was the first chairman of the Association for the Abolition of Negro Slavery in 1787; was the principal promoter of the colony of Sierra Leone; opposed the impressment of seamen; advocated parliamentary reform, and favored the claims of Ireland. D. in London, July 6, 1813. He was the author of sixty-one publications, chiefly pamphlets, in advocacy of the causes to which he devoted his life, philologieal tracts in favor of Trinitarianism, and millenarian interpretations of biblical prophecies. See his *Memoirs*, by Prince Hoare (1820) and by Charles Stuart (1836).

Sharp, JAMES, D. D.: archbishop; b. in the castle of Banff, Scotland, May 4, 1618; educated at the University of Aberdeen, where he figured among the students who declared against the Solemn League and Covenant 1638; became Professor of Philosophy at St. Leonard's College, St. Andrews 1643; minister of Crail, in Fifeshire, 1648; was the representative of the Presbyterians sent to Cromwell 1656, to Monk and to Charles II. 1660; was appointed king's chaplain for Scotland and Professor of Divinity in St. Mary's College, St. Andrews; consecrated Archbishop of St. Andrews and Primate of Scotland upon an Episcopalian foundation Dec., 1661; was regarded as a tool of Charles in the persecution of the Covenanters, and consequently assassinated by "a band of nine enthusiasts" on Magus Muir, St. Andrews, May 3, 1679. Revised by S. M. JACKSON.

Sharp, JOHN, D. D.: archbishop; b. at Bradford, Yorkshire, England, Feb. 16, 1644; educated at Christ's College, Cambridge, on leaving which he became chaplain to Sir Heneage Finch, then attorney-general, through whom he obtained the archdeaconry of Berkshire 1672; a prebend at Norwich 1675; the rectorship of St. Bartholomew, London, 1676; of St. Giles-in-the-Fields 1677; and the deanery of Norwich 1681. He became chaplain to Charles II. and James II., was deprived of his preferments by James for preaching against his policy 1686. He became Dean of Canterbury 1689, and Archbishop of York 1691. D. Feb. 2, 1714. Seven volumes of his *Sermons* were published in 1709.

Sharp, WILLIAM: See the Appendix.

Sharpe, SAMUEL: Egyptologist; b. in London, Mar. 8, 1799. Though a London banker, he was best known on account of his accomplishments in the study of the Oriental languages, Hebrew, Coptic, and the Egyptian hieroglyphics. He was also a careful writer on historical subjects connected with his linguistic studies. Of his numerous works, the following are the most notable: *The Holy Bible Translated, being a Revision of the Authorized English Version* (1880); *The New Testament, Translated from Griesbach's Text* (1840; 5th ed. 1862); *History of the Hebrew Nation and its Literature* (1869; 4th ed. 1882); *Texts from the Holy Bible Explained by the Help of the Ancient Monuments* (1866; 2d ed. 1869); *Hebrew Scriptures Translated* (3 vols., 1865); *The Chronology of the Bible* (1868); *Short Hebrew Grammar* (1877); *Inquiry into the Age of the Moabite Stone* (1879); *The Epistle of Barnabas* (1880); *History of Egypt from the Earliest Times till the Conquest by the Arabs in A. D. 640* (1846; 6th ed. 2 vols., 1876, combining three publications in their second revision, viz.: *Early History of Egypt*, 1838; *Egypt under the Ptolemies*, 1838; and *Egypt under the Romans*, 1842); *Alexandrian Chronology* (1857); *Egyptian Mythology and Egyptian Christianity* (1863); *Egyptian Inscriptions from the British Museum* (several series, 1837–56); *Vocabulary of Egyptian Hieroglyphics* (1837); *The Triple Mummy-case of Aroeri-ao* (1858); *Egyptian Hieroglyphics: being an attempt to Explain their Nature, Origin and Meaning* (1861); *Egyptian Antiquities in the British Museum Described* (1862); *The Decree of Canopus* (1869); *The Rosetta Stone* (1871); and *Hebrew Inscriptions from the Valleys between Egypt and Mt. Sinai* (2 parts, 1875–76). D. in London, July 28, 1881. C. R. GILLETT.

Sharpless, ISAAC: See the Appendix.

Sharpsburg: borough; Allegheny co., Pa.; on the Allegheny river, and the Penn. and the Pitts. and West. railways; 5 miles N. E. of Pittsburg (see map of Pennsylvania, ref. 5–B). It is in a coal-mining region, and contains rolling-mills, blast furnaces, foundries, a State bank, and two weekly newspapers. Pop. (1890) 4,898; (1900) 6,842.

Sharpsburg: a village in Washington co., Maryland; lying between the Antietam and Potomac rivers (see map of Maryland, ref. 2–D). It was the scene of the battle of Antietam, Sept. 17, 1862. Pop. (1890) 1,163; (1900) 1,030.

Sharpsville: borough (organized in 1874); Mercer co., Pa.; on the Shenango river, and the Erie, the Penn., and the Sharpsville railways; 3 miles N. E. of Sharon (see map of Pennsylvania, ref. 3–A). It is in a coal-mining region, is engaged in the manufacture of pig iron, and has 7 churches, 2 public-school buildings, a private bank, and a weekly newspaper. Pop. (1880) 1,824; (1890) 2,330; (1900) 2,970. EDITOR OF "ADVERTISER."

Shah-shih, or **Sha-szĕ**: a river-port in the province of Hupeh, China; opened to foreign trade Sept. 26, 1896. It is situated on the left bank of the Yang-tse, nearly midway between the entrance to the Tung-ting Lake and the treaty-port of ICHANG (*q. v.*).

Shasta, Mount: See ROCKY MOUNTAINS.

Shas'tra [from Sanskr. *çāstra-*, order, command, saered book, deriv. of *çās-*, order, instruct, govern]: an authoritative book of the Hindus upon religion and civil and religious law. The principal works of this class are collectively called *Dharma-s'âstra*, or "Law Shastra."

Shattuck, AARON DRAPER: See the Appendix.

Shaw, ALBERT, Ph. D.: journalist and author; b. at New London, O., July 23, 1857; graduated in 1879 at Iowa College, Grinnell, Ia.; became a journalist in Iowa; also studied at Johns Hopkins University; in 1883 became connected with the Minneapolis *Daily Tribune* as an editorial writer, but completed his work at Johns Hopkins, and received from that institution in 1884 the degree of Ph. D.; returned to Minneapolis and became chief of the editorial staff of the *Tribune*, which position he held until 1891, with the exception of a year and a half (1888–89) in Europe, which was devoted largely to the study of municipal government. He declined professorships in several colleges, and in 1890 became the founder and editor of the American edition of

The Review of Reviews, the first number of which appeared in 1891. He has lectured at Johns Hopkins University and Wisconsin State University. Among his works are *Co-operation in a Western City* (Baltimore, 1886) and *Icaria: a Study of Communistic History* (New York, 1884). He edited *National Revenues* (Chicago, 1888), and has contributed to the *Chautauquan Magazine* and other periodicals, but is perhaps most widely known by his articles in *The Century Magazine* on the government of European cities. An outcome of these is *Municipal Government in Great Britain* (New York, 1895). C. H. THURBER.

Shaw, ANNIE CORNELIA: See the Appendix.

Shaw, CHARLES LEWIS: See the Appendix.

Shaw, EDWARD RICHARD: See the Appendix.

Shaw, GEORGE: naturalist; b. in Bierton, Buckinghamshire, England, Dec. 10, 1751; graduated at Oxford 1769; took orders in the Church of England 1774; studied medicine at Edinburgh and Oxford, taking the degree of M. D. 1787, after which he settled in London as a scientific lecturer; became librarian and assistant keeper of natural history at the British Museum 1791, and principal keeper 1807. D. in London, July 22, 1813. He was the author of *The Naturalist's Library* (24 vols., 1790–1813); *Zoölogy of New Holland* (1794); *General Zoölogy, or Systematic Natural History* (11 vols., 1800–19); *Zoölogical Lectures at the Royal Institution* (2 vols., 1809).

Shaw, GEORGE BERNARD: See the Appendix.

Shaw, HENRY WHEELER: humorist; b. in Lanesborough, Mass., Apr. 21, 1818; entered Hamilton College about 1832, but did not remain long; resided for twenty-five years in various parts of the Western States, where he was successively farmer and auctioneer; settled at Poughkeepsie, N. Y., in the latter capacity about 1858; began to write humorous sketches signed *Josh Billings* 1863; became popular as a writer and as a lecturer; published several volumes of humorous sketches, and edited an annual *Allminax*. His *Complete Works* were published in 1877. D. in Monterey, Cal., Oct. 14, 1885.

Shaw, LEMUEL, LL. D.: jurist; b. at Barnstable, Mass., Jan. 9, 1781; graduated at Harvard 1800; became assistant editor of the Boston *Gazette*; studied law, and was admitted to the bar in New Hampshire Sept., 1804: sat in the Legislature 1811–16 and in 1819, and in the State Constitutional Convention 1820; was State Senator 1821–22 and 1828–29; and chief justice of the Massachusetts Supreme Court from Aug. 31, 1830 (previous to which he had held no judicial office), to Aug., 1860. His reported decisions form a large part of more than fifty volumes, and his judicial reputation in Massachusetts was second only to that of Theophilus Parsons. The city charter of Boston was drafted by him in 1822. He was a member of the American Academy, of the Massachusetts Historical Society, and for twenty-seven years one of the corporation of Harvard College. He published a few orations, addresses, and judicial charges, the most important being his charge to the jury in the celebrated trial before him of Prof. John White Webster, who was convicted of the murder of Dr. George Parkman (1850). D. in Boston, Mar. 30, 1861. Revised by F. STURGES ALLEN.

Shaw, THOMAS: professor of agriculture; b. at Niagara-on-the-Lake, Ontario, Canada, Jan. 3, 1843; educated in public schools; made farming his profession; also taught school for more than ten years; edited *The Canadian Live Stock and Farm Journal* 1883–88; Professor of Agriculture at Ontario Agricultural College 1888–93; became Professor of Animal Husbandry at Minnesota agricultural experiment station Oct., 1893. He has published *The First Principles of Agriculture* (1890) and *Weeds and how to Eradicate them* (1893).

Shawa'no: city; capital of Shawano co., Wis.; on the Wolf river, at the head of navigation, and the Chi. and N. W. Railway; 38 miles W. N. W. of Green Bay City, 58 miles N. of Oshkosh (for location, see map of Wisconsin, ref. 4–E). It is in an agricultural and lumbering region, and has a State bank, capital $30,000, and three weekly newspapers. Pop. (1880) 890; (1890) 1,505; (1900) 1,863.

Shawano Indians: See ALGONQUIAN INDIANS.

Shawl [: Fr. *châle*; Germ. *schahl*: Arab. and Hind. *shāl*, from Pers. *shāl*, shawl, mantle]: a kind of loose garment worn on the shoulders or around the waist, manufactured by the different nations of different materials, as the Kashmir shawl of goat's hair, the Chinese of silk, the barège of wool, etc., and in different patterns, as the palm pattern of India, the plaid pattern of Scotland, etc. The most celebrated kind is the Kashmir shawl, famous over the whole world as early as the sixteenth century. Its manufacture was then under the supervision of the Government, and each shawl which issued from the looms received a separate description in the royal registers. The manufacture is still flourishing in Kashmir, though it is imitated extensively in France, Germany, and Great Britain. In Europe shawls are mostly made of wool, of cotton, or of mixed cotton and silk.

Shaw-Lefevre, -*le*-fev'r, GEORGE JOHN, M. P.: statesman; b. in 1832; son of Sir John George Shaw-Lefevre, of Mapperly Hall, Nottingham, England; educated at Eton and Cambridge; called to the bar 1856; entered Parliament as a Liberal and retained his seat to 1885; returned as a Gladstonian Liberal in 1886; civil lord of the admiralty May–July, 1866; secretary to the Board of Trade 1868–71; secretary to the admiralty 1871–Feb., 1874, and again Apr.–Nov., 1880; first commissioner of works 1880; succeeded Mr. Fawcett as Postmaster-General Nov., 1884: first commissioner of works again in 1892. He is the author of several statistical works, mainly on the English and Irish land questions.

Shawnee': village; Perry co., O.; on the Balt. and Ohio and the Col., Sandusky and Hocking railways; 43 miles S. by E. of Newark (for location, see map of Ohio, ref. 6–G). It is in an agricultural and coal-mining region, has several iron-foundries, sawmills and planing-mills, a private bank and two weekly papers. Pop. (1890) 3,266; (1900) 2,966.

Shawnee or **Shawano Indians**: See ALGONQUIAN INDIANS.

Shaw'neetown: city; capital of Gallatin co., Ill.; on the Ohio river, and the Balt. and O. S. W. and the Louisv. and Nashv. railways; 182 miles S. E. of Springfield (for location, see map of Illinois, ref. 11–F). It is in a coal-mining and lead region, is a shipping-point for coal and farm products, has pork-packing and manufacturing interests, and contains a national bank with capital of $50,000, a private bank, and two weekly newspapers. Pop. (1880) 1,851; (1900) 1,698. EDITOR OF "NEWS."

Shays, DANIEL: insurgent; b. at Hopkinton, Mass., in 1747; attained the rank of captain during the war of independence, after which he resided at Pelham (now Prescott); took part in an insurrectionary movement in Western Massachusetts directed against the State government 1786, and, though not at first a leader, became ultimately so prominent that the movement is generally known as "Shays's rebellion," the pretexts of which were the high salary paid the Governor, the aristocratic character of the Senate, the extortions of lawyers, and the pressure of taxation—grievances which were to be met by the removal of the general court from Boston and the issue of paper-money. In Dec., 1786, he led a considerable force of insurgents to Springfield to capture the arsenal (Jan., 1787), but was repulsed by the militia under Gen. William Shepard (Feb. 4, 1787). His forces were surprised and completely dispersed by Gen. Lincoln, and Shays fled to New Hampshire; was pardoned in June, 1788, by the Massachusetts Legislature, and removed to Sparta, Livingston co., N. Y., where he received a pension for his Revolutionary services, and survived until Sept. 29, 1825. See Minot's *History of the Insurrection* (Boston, 1810) and Holland's *History of Western Massachusetts* (Springfield, 1855).

Shea, JOHN DAWSON GILMARY, LL. D.: historian; b. in New York, July 22, 1824; educated at the grammar school of Columbia College; studied law, and was admitted to the bar, but devoted himself to literature, and rendered great service in illustrating the obscure early annals of French colonization and Jesuit missions. He published *The Discovery and Exploration of the Mississippi Valley* (New York, 1853); *History of the Catholic Missions among the Indian Tribes of the United States* (1854); *The Catholic Authors of America* (1858); *Early Voyages up and down the Mississippi* (Albany, 1862); *Novum Belgium, an Account of New Netherlands in 1643–44* (New York, 1862); *The Operations of the French Fleet under Count de Grasse* (1864); translated, with extensive notes, Charlevoix's *History and General Description of New France* (6 vols. 8vo, 1866–72); edited from the MSS. the Cramoisy series of *Memoirs and Relations concerning the French Colonies in North America*, embracing documents on the early history of Canada and Louisiana (24 vols., 1857–68); Alsop's *Maryland* (1869); published *Library of American Linguistics*,

fifteen volumes of grammars and dictionaries of Indian languages (1860–74); edited *The Historical Magazine* (1859–65); and published *The Catholic Church in Colonial Days* (1883); *The Hierarchy of the Catholic Church in the United States* (1886); *Life and Times of Archbishop Carroll* (1888); and three of five projected volumes on *The History of the Catholic Church in the United States*. D. at Elizabeth, N. J., Feb. 22, 1892.

Sheaffe, Sir Roger Hale: soldier; b. in Boston, Mass., July 15, 1763; obtained a commission in the British army, 1778, through Earl Percy, whose headquarters had been at his mother's house in Boston three years before; served in Holland 1799, and in the expedition to the Baltic 1801; served in Canada 1802–11, and again 1812–13; had risen to the rank of major-general in 1811; took command of the British forces at the battle of Queenstown, after the death of Gen. Brock, and succeeded in inflicting a serious defeat upon the American invaders, for which service he was made a baronet Jan. 16, 1813; defended York (now Toronto) against the attack of Apr., 1813; became full general in 1828, and colonel of the Thirty-sixth Regiment in 1829. D. in Edinburgh, July 17, 1851.

Shearman, Thomas Gaskell: lawyer and writer on economic subjects; b. in Birmingham, England, Nov. 25, 1834. His parents removed to New York when he was nine years of age; he was educated privately; was admitted to the bar in 1859; practiced law for many years in New York and Brooklyn; was counsel for Henry Ward Beecher in his trials; Republican in politics from 1856–80; after 1880 devoted most of his time, outside of business, to propagation of free-trade ideas, declining office. D. Sept. 29, 1900. He was joint author of *Law of Practice and Pleadings* (1861–65); *Law of Negligence* (four editions, 1870–88); and author of *Talks on Free Trade* (1881); *Does Protection Protect?* (1883); *Pauper Labor of Europe* (1885); *Distribution of Wealth* (1887); *The Single Tax* (1887); *Henry George's Mistake* (1889); *Who Own the United States?* (1889); *Crooked Taxation* (1890); *Natural Taxation* (1891).

Shearwater: any one of several birds of the genus *Puffinus*, and the family *Procellariidæ*. The greater shearwater (*Puffinus major*) is from 18 to 20 inches in length, and the Manx shearwater (*P. anglorum*) about 15. They are often seen hundreds of miles from land. The majority are brown or cinerous above and white below; but the sooty shearwater (*P. fuliginosus*) is an almost uniform sooty brown; the tail is rather long and rounded; the feet large; the tarsus shorter than the middle digit; the nasal tubes are short, flat, and obliquely truncated, instead of being pronounced, as in the true petrels. See Procellariidæ.

Revised by F. A. Lucas.

Sheathbill: any bird of the family *Chionididæ*. Only two species are known, and both are inhabitants of the southern hemisphere—one, *Chionis alba*, being native to the Falkland islands, etc., and the other, *Chionis* or *Chionarchus minor*, peculiar to Kerguelen's island. Much difference of opinion has prevailed among naturalists respecting the relations of these birds to others in the class, some having regarded them as waders (*Grallæ*), others as swimmers (*Longipennes*), and others still as gallinaceous forms. They are now generally placed with the waders, near the peculiar plover-like *Glareola*, but they also have undoubted affinities with the gulls. In their economy and habits they strongly resemble pigeons and fowl; according to Kidder, who studied the species of Kerguelen's island in life, the "observer is first struck by the strong resemblance which *Chionis* bears to the pigeons in general appearance, gait, and mode of flight. The general shape of the body is of an ordinary columbine character, the head being notably small, as usual in that group, the neck short and full, and the body plump; the tail, moreover, having but twelve rectrices." "The feet, in almost every particular, are thoroughly gallinaceous, even to the character of the marginal fringe of the toes." In color, however, they recall rather the characteristics of the gulls than of either gallinaceous or columbine forms. "On the other hand, the bird's omnivorous diet, habits under confinement, easy domestication, dislike of water, entire inability to swim, and many other points in its habits are strongly gallinaceous characteristics, by so much removing it from the vicinity of either grallatorial or natatorial birds." Nevertheless, the indications furnished by the skeleton outweigh all such superficial correspondences, and conclusively prove that the birds in question are derivatives from gull-like (and therefore primarily natatorial) types, but modified for terrestrial life. They are omnivorous in diet, feeding upon vegetable substances (seaweeds, etc.), molluscs, and eggs. *Chionis alba* has a total length of 17 inches or more, and *C. minor* about 14 or 15 inches. They are called white paddy by whalers.

Revised by F. A. Lucas.

Sheathing: a covering for a ship's bottom, made of sheet copper, and first introduced about 1800. It not only serves to protect wooden ships from boring-shrimps, teredos, and other small destructive animals, but to a great extent it prevents the fouling of the bottom by seaweeds and barnacles.

Sheba, or **Saba** [from Heb. *Sh'bhā'*, or *Shebhā'*; cf. *shebhā'*, seven]: the name of three persons in the Old Testament: (1) A great-grandson of Ham (Gen. x. 7), who appears to have settled somewhere on or near the shores of the Persian Gulf. (2) The tenth of the thirteen sons of Joktan (Gen. x. 28), who settled in Southern Arabia, and gave his name to the kingdom of the Sabæans, whose queen visited Solomon in Jerusalem (1 Kings x. 1–13). (3) A grandson of Abraham and Keturah (Gen. xxv. 1–3), whose descendants were nomads, in close connection with the descendants of the Hamitic Sheba mentioned above. The same name in a slightly different form occurs in the Old Testament as that (4) of the Benjamite who revolted against David, was defeated by Joab, and beheaded by the people of Abel-Beth-maachah, where he had taken refuge; (5) of a Gadite (1 Chron. v. 13); and (6) of a town in Simeon.

Revised by S. M. Jackson.

Sheboy'gan: city (settled in 1836, chartered as a village in 1846, incorporated as a city in 1853); capital of Sheboygan co., Wis.; on Lake Michigan, at the mouth of the Sheboygan river, and on the Chi. and N. W. Railway; 52 miles N. of Milwaukee, and 137 miles N. of Chicago (for location, see map of Wisconsin, ref. 6–F). It has an excellent harbor and a large lake commerce, particularly in lumber, coal, and tan bark. A line of steamers connects the city with Milwaukee, Chicago, and other points on the lake, and the railway and its branches make the city the trade-center of a large and rich agricultural region. There are two public parks, one of which, Fountain, contains an artesian well whose waters are strongly impregnated with mineral salts and form an important article of commerce. The city is lighted by gas and electricity, derives its supply of water from the lake, is well sewered, and has an efficient street-railway service. Among the public institutions are 18 churches, high, grammar, intermediate, and primary schools, kindergartens, Roman Catholic and Lutheran parochial schools, Day School for the Deaf, hospital, insane asylum, and Home for the Friendless. In connection with the public schools is a library of 3,000 volumes. There are 2 State banks with combined capital of $300,000, and 3 daily and 7 weekly newspapers. The assessed valuations in 1892 aggregated $5,415,980. Sheboygan is particularly noted for its manufacture of chairs and other furniture. There are 5 chair-factories, which employ about 2,000 persons and turn out 7,000 chairs per day. About 40,000 feet of lumber are used daily in the manufacture of furniture. The various manufacturing industries employ about 5,500 persons, who receive in wages about $225,000 per month. Other important establishments are 2 manufactories of enameled ware, 2 boot and shoe factories, 3 foundries and machine-shops, 2 tanneries, 2 carriage-factories, 2 breweries, and manufactories of toys, office and hotel furniture and fixtures, veneer, folding-beds, venetian-blinds, wire-mattresses, and excelsior bottle-wrappers. There are also dry docks, brick-yards, lime-kilns, a ship-yard, and 5 large cheese-warehouses. Pop. (1880) 7,314; (1890) 16,359; (1900) 22,962. J. E. Riordan.

Shechem: See Nablus.

Shechi'nah [from Late Heb. *shekhīnāh*, dwelling, presence, deriv. of *shākhan*, dwell]: a name which first appears in the Jerusalem Targum to designate the Divine Presence wherever it exists in a special manner, but more particularly as manifested in the holy of holies within the ancient sanctuary of Israel.

Shedd, William Greenough Thayer, D. D., LL. D.: theologian; son of a clergyman; b. at Acton, Mass., June 21, 1820; graduated at University of Vermont in 1839, and at Andover Theological Seminary in 1843; was pastor of the Congregational church in Brandon, Vt., 1844–45; Professor of English Literature in the University of Vermont 1845–52; Professor of Sacred Rhetoric and Pastoral Theology in Auburn Theological Seminary 1852–53; Professor of Ecclesiastical History and lecturer on pastoral theology in Ando-

ver Theological Seminary 1853–62; pastor of the Brick church (Presbyterian), New York, 1862–63, and Professor of Biblical Literature in Union Theological Seminary, New York, 1863–74, when he was transferred to the chair of Systematic Theology in the same institution, which office he held until 1890. D. in New York, Nov. 17, 1894. Besides editing the *Works* of Coleridge (7 vols., 1853) and the *Confessions* of Augustine (1860), he published *Outlines of a System of Rhetoric*, from the German of Theremin (1850); *Lectures upon the Philosophy of History* (1856); *Discourses and Essays* (1856); Guericke's *Church History* (2 vols., 1857, 1870); *A History of Christian Doctrine* (2 vols., 1863); *Homiletics and Pastoral Theology* (1867); *Sermons to the Natural Man* (1871); *Theological Essays* (1877); *Literary Essays* (1878); *Commentary on St. Paul's Epistle to the Romans* (1879); *Sermons to the Spiritual Man* (1884); *Endless Punishment* (1886); a treatise on *Dogmatic Theology* (3 vols., 1889–94); and *The Proposed Revision of the Westminster Standards* (1890). Revised by G. P. Fisher.

Shediac': town of Westmoreland County, New Brunswick; on the Point du Chêne branch of the Intercolonial Railway; 106 miles from St. John, and on the border of an estuary of Northumberland Strait (for location, see map of Quebec, etc., ref. 5–I). It is celebrated for its oysters. Pop. 6,250. M. W. H.

Shee, Sir Martin Archer, D. C. L.; painter and author; b. in Dublin, Ireland, Dec. 23, 1770; studied painting at the school of the Royal Dublin Society; was introduced in 1788 by Edmund Burke to Sir Joshua Reynolds, under whose patronage he entered as a pupil in the Royal Academy; became an exhibitor in the following year; was elected an associate of the academy 1798 and a member 1800, and was chosen successor to Lawrence as president of that institution in 1830, on which occasion he was knighted. He was especially successful in portrait-painting, and in a long career preserved the lineaments of many illustrious men. He retained the presidency of the academy through life; was an effective orator on public occasions; published *Rhymes on Art, Alasco, a Tragedy*, and a novel. D. at Brighton, Aug. 19, 1850. See the *Life* by his son (2 vols., London, 1860).

Sheeahs: same as Shiites (*q. v.*).

Sheep [M. Eng. *scheep* < O. Eng. *scēp, scēap*: O. H. Germ. *scāf* < Mod. Germ. *schaf* < Teuton. *skēpo-*; cf. Sanskr. *chāga-*, goat (?)]: animals constituting the genus *Ovis*, although some writers claim that they form a group of genera. They are hollow-horned ruminants, and belong to the artiodactyl, or pair-toed, section of the ungulate, or hoofed, mammals. In nearly all the wild breeds horns are present in both sexes, but in many of the domestic breeds they are entirely absent. The tail is usually short, though in some of the domestic breeds it is unusually developed. Sheep are further distinguished by a covering of wool, which varies in length, color, and strength and fineness of fiber, with variations under different climatic and other conditions.

Geographically, the wild breeds are or were distributed over some of the islands of the Mediterranean, in Europe, the greater portion of the temperate highlands of Asia, nearly the whole of the Rocky Mountain ranges of a certain altitude in North America, and throughout some of the upland regions of the Andes in South America. More than twenty different species have been described. Of these, *O. montana* is the bighorn or Rocky Mountain sheep.

The origin of many of the breeds of sheep under domestication can not be traced with certainty. Some suppose that the originals from which these sprang are descendants of the musimon of Corsica or the argali of Asia. They are to be found wherever there is a settled agriculture, but are best adapted to the temperate zones. In North America they are reared only for their meat and wool, but in some countries they are also kept for their milk.

North American Breeds.—The recognized breeds in North America are all of European origin. They are enumerated in the classification given below:

Fine-wooled breeds: Merino, and sub-varieties of the Merino, of which there are several.

Medium-wooled breeds: Southdown, Dorset Horn, Suffolk, Shropshire, Hampshire Down, Oxford Down, Cheviot.

Coarse-wooled breeds: Leicester, Lincoln, Cotswold, Black-faced Highland.

The above classification is based on variations in the character of the wool, which, in going down the list, gradually increases in coarseness; but there is a slight difference of opinion as to the order in which some of the breeds should stand, as in a few instances the character of the wool found on different parts of the body varies in some of the breeds, and in other instances it also differs materially in certain families and sub-families of the same breed.

Care of Sheep.—Adaptation should be carefully considered. The various wild species never frequent swamps, exposed plains, or dense forests from choice. In the management of sheep under domestication these preferences should always receive recognition. The smaller the breed the higher and more rugged may the pastures be, and the larger the breed the richer and more level should they be. The pastures in summer, and also the fodder in winter, should be characterized by variety and fineness of herbage, and where practicable the sheep should be frequently changed from one pasture to another. Sheep kept for breeding uses should be given the largest liberty practicable both winter and summer, but where they are being fattened they will bear close confinement for a time under suitable conditions. Except at the lambing season, they only require to be protected from storms, as they are not easily injured by low temperatures. In circumscribed pastures, and with the larger breeds, the flocks should be small, summer and winter, but with the smaller breeds, and ample foraging-grounds, they may run up even into the thousands. Where sheds are necessary in winter, it is imperative that they should be built on ground dry naturally, or made so, and the aim should be to admit plenty of morning and forenoon sunlight. They should be entirely free from draughts, and should be divided by feeding-racks, or otherwise into small compartments. Each compartment requires a door leading into an inclosed yard. These doors should be low and wide to prevent crowding, and should be kept open day and night except in time of storms. It is also important that the yards be kept dry by littering or otherwise.

In winter it is not necessary to cut the fodder or to grind the grain for sheep. After going into winter quarters, breeding ewes require only a moderately generous diet until the lambing season. A variety of fodders, a small quantity of roots or corn ensilage, and sometimes a little grain, preferably oats, will be found very suitable. But as soon as the lambs are a few days old their dams require most liberal feeding, until they are put upon pastures succulent and abundant. The food factors which are best adapted to produce an abundant flow of milk should predominate, such as early-cut and well-cured grasses, roots or corn ensilage, and oats and bran. Emaciation in the dams may be prevented by adding such foods as corn or peas, and oilcake. The lambs also should be given early and continued access to free supplies of grain, fed at first in the ground form, and in a place inaccessible to the dams. Docking should receive attention within a few days of birth, and castration in a few weeks. When pastures are fresh and abundant, sheep or lambs do not usually require any grain until the latter are weaned. This period arrives when they are from four to five months old. As soon as weaned the lambs should get a grain supplement to build up the frame or to fatten it, according to the object sought. Sheep and lambs thrive much better when plentifully supplied with salt and pure water, at all seasons.

For autumn fattening the Dwarf Essex rape is very suitable where it can be profitably grown. Sheep and lambs will fatten quickly when pastured upon it, and without any supplement of grain. Young clover, mixed grasses, and rye are also suitable, but grain is required in addition. In winter fattening the ration may be the same in kind as that already mentioned as being suitable for breeding ewes after the lambing season, but with the difference that more, relatively, of the concentrated foods, such as corn, peas, or oilcake, should be given. Lambs of the mutton breeds, which average about 100 lb. live weight, will usually gain from 6 to 10 lb. per month in winter, while being fattened on a daily ration of 1½ to 2 lb. hay, 4 lb. corn ensilage or 5½ lb. roots, and 1¼ to 1¾ lb. grain.

In breeding sheep for the block females of mixed blood, though variously bred, will be found suitable. To cross upon these, rams should be chosen successively from the same pure breed, rather than from breeds alien in blood. In choosing them adaptation in size, form, feeding, and mutton qualities, and the needs of the market should be considered. It is pretty generally conceded that stimulating food fed to rams and ewes at the mating season tends to increase the number of the lambs, and also to shorten the duration of the lambing period. Early maturity is much

sought for in all the mutton breeds. Medium-sized lambs of quick development, compact build, and good quality stand high in favor in the markets, and they can be raised at a minimum of cost. It is generally considered more profitable to dispose of them before they pass the age of one year. THOMAS SHAW.

Sheepshead: a well-known fish (*Archosargus probatocephalus*) of the family *Sparidæ*, found along the Atlantic coast of the U. S. south of Cape Cod, but most abundant in the warmer waters. The name is given in allusion to a fancied resemblance of the head to that of a sheep, produced by the form and color as well as the cutting teeth of the jaws. The body is deep and robust with the back arched; the dorsal fin has twelve spines and eleven rays, and is preceded by a recumbent spine; the anal fin has three spines and ten rays; the color is gray, with about seven blackish bands; the front teeth are broad and incisor-like, the lateral teeth molars, and in several rows. The sheepshead sometimes exceeds 2 feet in length, although averaging less. It is one of the most esteemed fishes found in American waters, and on account of the delicacy of its flesh has been likened to the English turbot. It is also highly regarded as a game-fish. It feeds chiefly on molluscs and crustaceans, and its molar teeth and stout jaws are eminently adapted for breaking shells. The fresh-water drum (*Haplodinotus grunniens*) is among the fishes loosely called sheepshead in the U. S.

Sheep-tick: a wingless parasitic insect (*Melophagus ovinus*) of the order *Diptera* and family *Hippoboscidæ*, often extremely annoying to sheep. There are various arsenical washes which will destroy them; a solution of carbolic acid is also recommended for the purpose.

Sheeraz: See SHIRAZ.

Sheerness': a strongly fortified seaport in Kent, England; on the right bank of the Medway, at its junction with the Thames; 52 miles by rail E. of London (see map of England, ref. 12–L). The harbor is safe and commodious, and, being almost at the mouth of the Thames estuary, is often crowded with vessels. The Government dockyard, with wet and dry docks, storehouses, etc., covers 60 acres. The principal trade is due to the oyster-fisheries. Sheerness is also a favorite summer resort. Pop. (1891) 13,841.

Sheffield: town; in the West Riding of Yorkshire, England; at the junction of the Sheaf and the Don; 41 miles E. of Manchester and 165 miles N. N. W. of London (see map of England, ref. 7–H). It is situated at the foot and on the slopes of a range of hills, and is generally well built, a street-improvement scheme having been carried out after 1875. Noticeable among its public buildings are the parish church of St. Peter, erected in the reign of Henry I.; St. Mary's Roman Catholic church (1850); the Cutlers' Hall, the Albert Hall, the new market-hall (1851), and the new town-hall, crowned with a statue of Vulcan. Among educational institutions are the Firth College (1879), with thirteen professors or lecturers, the Technical School, the Wesley College, and the Free Grammar School. The St. George's Museum, founded by Ruskin in 1890, contains a collection of engravings, minerals, etc., and the Mappin Art Gallery has a fine collection of pictures. There are several public parks and extensive botanical gardens. The cutlery business of Sheffield dates from very early times. The Sheffield whittle of Chaucer was the common knife used by those whose social rank did not permit them to carry a sword. The Cutlers' Company was founded in 1624, but Sheffield was of little importance up to the middle of the eighteenth century. Sheffield Castle, rebuilt in 1270, was the place of imprisonment of Mary Queen of Scots (1572–86). It was taken by the parliamentary army in 1644, and shortly afterward was demolished. Sheffield is the center in England of the manufacture of knives, files, saws, carriage-springs, boilers, stoves, grates, buttons, and all kinds of agricultural, mechanical, medical, and optical instruments. Silver-plating and britannia metal were both invented here, and have given rise to a comprehensive manufacturing industry. Since 1871 rails, railway-springs, tires, steel blocks for naval and military artillery, and armor-plates have been largely manufactured. Sheffield returns five members to Parliament. Pop. (1891) 324,243; (1901) 380,717. R. A. ROBERTS.

Sheffield: city (founded in 1884); Colbert co., Ala.; on the Tennessee river, and the Birm., Shef. and Tenn. Riv., the Louisv. and Nashv., and the Memphis and Charleston railways; 2 miles W. of Tuscumbia, the county-seat (for location, see map of Alabama, ref. 1–B). It is in an agricultural region, and contains 8 church organizations, several public schools, 5 blast-furnaces, and 2 weekly papers. Pop. (1890) 2,731; (1900) 3,333. EDITOR OF "REAPER."

Sheffield, JOHN, Duke of Buckinghamshire and Normanby: statesman and poet; b. in England in 1649; succeeded his father as Earl of Mulgrave 1658; served in the Dutch wars of 1666 and 1672; became privy councilor and lord chamberlain in 1685; favored the revolution of 1688; was made Duke of Normanby in 1694, lord privy seal and Duke of Buckinghamshire in 1703, and built in St. James's Park the residence now known as Buckingham Palace and belonging to the crown. He was said to have been an early lover of Queen Anne; was author of some poems which enjoyed fame during his own generation, and was a friend of Dryden, to whose memory he erected a monument in Westminster Abbey. D. Feb. 24, 1721. Besides minor poems he wrote a metrical *Essay on Satire* and an *Essay on Poetry*. His poetical works were first printed in 1723.

Shehâb-Eddin: See CHEHAB-EDDIN.

Shehr, or **Sahar**: town; in South Arabia, on the Gulf of Aden; manufactures coarse cotton cloth, and carries on a brisk general trade, though it has no harbor, but only an open roadstead. Pop. probably 5,000. Four miles E. are remains of another town of the same name, once important, but now a decayed fishing-village. E. A. G.

Sheik [from Arab. *sheikh*, *shaykh*, elder, venerable old man, chief, deriv. of *shākha*, grow old, be old]: a title, among Arabs applied to the head of a tribe. Among Mussulmans in general it is prefixed to the name of a religious dignitary, or one versed in theology, or a reputed saint.

Sheikh-ul-Islam: See MUFTI.

Sheil, RICHARD LALOR: patriot and orator; b. at Drumdowney, Tipperary, Ireland, Aug. 17, 1791; was educated at the Jesuit College, Stonyhurst, England, and graduated at Trinity College, Dublin, 1811; studied law at Lincoln's Inn; was called to the bar at Dublin 1814; wrote several successful dramas; contributed *Sketches of the Irish Bar* to Campbell's *New Monthly Magazine*, republished in the U. S. by R. S. Mackenzie (New York, 2 vols., 1854); became an effective popular orator in the agitation for Roman Catholic emancipation; was chosen by the Catholic Association, in conjunction with O'Connell, to represent that body at the bar of the House of Lords 1825; was active in promoting the election of O'Connell to Parliament in 1828; was himself chosen member for Milburne Port shortly after the passage of the Relief Act 1829; was returned for the county of Louth 1831, and later for Tipperary and Dungarvan; became noted as a brilliant and effective parliamentary orator, and aided O'Connell for several years in his campaign for the repeal of the Union, until 1838, when he accepted the sinecure post of commissioner of Greenwich Hospital. He subsequently became vice-president of the Board of Trade, member of the privy council 1839, and judge-advocate-general 1841; was master of the mint 1846–50, and was appointed minister to Tuscany 1850. D. in Florence, May 23, 1851. His *Memoirs* were written by W. Torrens McCullagh (2 vols., 1855); a collection of his *Speeches* was published in London, 1845, and his *Speeches, Legal and Political*, in 1855. —His younger brother, Sir JUSTIN SHEIL, became major-general and minister to Persia, and aided his wife in the preparation of a valuable work, *Glimpses of Life and Manners in Persia* (1856). Revised by H. A. BEERS.

Shekel [from Heb. *shegel*, shekel (liter., a weight), deriv. of *shāqal*, weigh; cf. Gr. *σίγλος*, shekel]: a standard weight among the ancient Israelites, and also a coin of gold, silver, or copper, originally of a shekel's weight. The shekel of the sanctuary (Ex. xxx. 13; Num. iii. 47) was made of silver and was equal to 20 gerahs (Ezek. xlv. 12), or about 54 cents. There were other kinds of shekels. The gold shekel was worth about $5.69; the copper shekel, a little more than 3 cents. Revised by S. M. JACKSON.

Shel'burne: a seaport; capital of Shelburne County, Nova Scotia; 141 miles S. W. of Halifax (see map of Quebec, etc., ref. 3–B). It has a very fine harbor. Shelburne Lights, on Cape Roseway, are in lat. 43° 38·5′ N., lon. 65° 15·5′ W. There is excellent water-power, afforded by the river Roseway. Fishing, commerce, and ship-building are extensively pursued, and the port is one of the best in the province. The place has lost greatly in importance. During the war for American independence it was the center of loyalist influence, and then had about 12,000 inhabitants. Pop. 2,500. Revised by M. W. HARRINGTON.

Shelburne, William Petty Fitz-Maurice, Earl of, afterward Marquis of Lansdowne: b. in Dublin, Ireland, May 20, 1737; was educated at Christ Church, Oxford; entered the army in 1757, and served with honor; was elected to Parliament for Chipping Wycombe early in 1761, but before taking his seat succeeded to the earldom, by the death of his father May 10, 1761; became president of the Board of Trade and privy councilor in the Grenville ministry Apr., 1763; opposed the policy which led to the enactment of the Stamp Act and other measures oppressive to America; became a personal friend of Benjamin Franklin; was dismissed from office Sept. 8, 1763; separated from Bute and Fox, attaching himself to Pitt; declined entering the Rockingham ministry 1765; became Secretary of State for the Southern Department in Pitt's administration July, 1766; resigned his post Oct., 1768; visited Italy and France; became Secretary of State in the Foreign Department in the Rockingham cabinet Mar., 1782, and Premier on the death of Rockingham July, 1782; negotiated the preliminaries of peace with the U. S.; resigned Feb. 21, 1783, giving place to the coalition of Fox and North; was created Marquis of Lansdowne 1784, and passed the remainder of his life in political retirement. D. in London, May 2, 1805. His valuable collection of historical MSS. was sold to the Government, and is in the British Museum. See his *Life*, by his grandson, Lord Edmond Fitz-Maurice (London, 1875–76).

Shelburne Falls: village in Shelburne and Buckland townships, Franklin co., Mass.; on the Deerfield river, and the N. Y., N. H., and Hart. Railroad; 13 miles W. of Greenfield, the county-seat, 119 miles W. by N. of Boston (for location, see map of Massachusetts, ref. 2–E). The river here has a picturesque fall of 47 feet, affording excellent power for manufacturing, which is utilized by a silk-mill, a peg-shop, and cutlery and hardware factories. There are 6 churches, the Arms Academy, 2 village schools, a national bank with capital of $100,000, a savings-bank, and a weekly paper. The town was founded in 1755, and incorporated in 1768. Pop. of Shelburne township (1880) 1,621; (1890) 1,553; (1900) 1,508. Editor of "Deerfield Valley Echo."

Shelby, Isaac: first Governor of Kentucky; b. near Hagerstown, Md., Dec. 11, 1750; son of Gen. Evan Shelby; received a common-school education; became a surveyor in Western Virginia; served as lieutenant in a company under his father's command at the battle of Point Pleasant 1774; became captain 1776; was commissary of the frontier 1777; major and member of Virginia House of Delegates 1779; colonel 1780; rendered distinguished service at King's Mountain Oct. 7, 1780; served under Marion 1781, and under Greene with 500 mounted volunteers 1781–82, in which years he sat in the North Carolina Legislature, from which he received a vote of thanks and a sword; settled in Lincoln co., Ky. (then Virginia), 1788; was a member of the constitutional convention 1791; Governor of Kentucky 1792–96 and 1812–16; joined Gen. Harrison in Canada with 4,000 Kentuckians raised by proclamation; took part in the victory of the Thames, for which Congress voted him a gold medal; declined the post of Secretary of War 1817, and was commissioner with Gen. Jackson in negotiating a treaty with the Chickasaw Indians 1818. D. at Traveler's Rest, Lincoln co., Ky., July 18, 1826. His services are commemorated in the names of counties in nine of the Western and Southern States and in the name of a college at Shelbyville, Ky.—His son, James, b. 1784, served as major in the war of 1812, became general of militia, and died in Sept., 1848.

Shelbyville: city; capital of Shelby co., Ill.; on the Kaskaskia river, and the Chi. and E. Ill. and the Cleve., Cin., Chi. and St. L. railways; 23 miles W. by S. of Mattoon, 32 miles S. by E. of Decatur (for location, see map of Illinois, ref. 7–E). It is in an agricultural, lumbering, and coal-mining region, and contains a foundry, several large flour-mills, woolen-mill, agricultural-implement works, and other manufactories, a national bank with capital of $75,000, and a daily, a monthly, and five weekly papers. Pop. (1880) 2,939; (1890) 3,162; (1900) 3,546. Editor of "Union."

Shelbyville: city; capital of Shelby co., Ind.; on the Big Blue river, and the Cleve., Cin., Chi. and St. L., and the Pitts., Cin., Chi. and St. L. railways; 24 miles N. N. E. of Columbus, 27 miles S. E. of Indianapolis (for location, see map of Indiana, ref. 7–F). It is in a rich farming region, and has saw, planing, and flour-mills, furniture, carriage, ice, and barrel factories, etc., and a large general trade. There are 12 churches, 5 public-school buildings, 9 building and loan associations, 2 national banks with combined capital of $200,000, a private bank, and a monthly, 2 daily, and 2 weekly papers. Pop. (1880) 3,745; (1890) 5,451; (1900) 7,169. Editor of "Democrat."

Shelbyville: town; capital of Shelby co., Ky.; on the Louisv. and Nashv. and the Southern railways; 20 miles W. of Frankfort, 30 miles E. of Louisville (for location, see map of Kentucky, ref. 3–G). It is in an agricultural, stock-raising, and tobacco-growing region, and contains 3 State banks with combined capital of $100,000, 2 weekly newspapers, Science Hall School (Methodist Episcopal South, opened in 1825), Stuart Female College (opened in 1839), and Shelbyville Male Academy (1881). Pop. (1880) 2,393; (1890) 2,679; (1900) 3,016.

Shelbyville: town; capital of Bedford co., Tenn.; on the Duck river, and the Nashv., Chat. and St. L. Railway; 40 miles E. S. E. of Columbia, 63 miles S. by E. of Nashville (for location, see map of Tennessee, ref. 7–F). It is an important grain and mule market; contains Shelbyville Female College (non-sectarian, opened in 1853), a national bank with capital of $100,000, a State bank with capital of $28,000, and a monthly and three weekly newspapers; and has 5 churches, extensive lead-pencil factory, large lumber-yards, iron-foundries and machine-shops, cotton and woolen mills, and flour, saw, and planing mills. It is a shipping point for telegraph and telephone poles, and pencil-cedar. The town and its vicinity were the scene of important military operations in the civil war (June, 1863). Pop. (1880) 1,869; (1890) 1,823; (1900) 2,236.
Editor of "Bedford County Times."

Sheldon: town; O'Brien co., Ia.; on the Chi., Mil. and St. P., the Chi., St. P., Minn. and Omaha, and the Ill. Cent. railways; 36 miles W. of Spencer, 58 miles N. N. E. of Sioux City (for location, see map of Iowa, ref. 2–D). It is in an agricultural, dairying, and stock-raising region, has important manufactories, 3 State banks (combined capital $150,000), a national bank (capital $50,000), and 2 weekly papers. Pop. (1880) 730; (1890) 1,478; (1900) 2,282.

Sheldon, Edward Austin, A. M., Ph. D.: educator; b. at Perry Center, N. Y., Oct. 4, 1823; educated at Hamilton College, Clinton, N. Y.; superintendent of schools at Syracuse, N. Y., 1851–53, and at Oswego, N. Y., 1853–69; principal of Oswego State Normal and Training-school from 1862 till his death, at Oswego, Sept. 16, 1897. Author of *Manual of Elementary Instruction* (1862); *Lessons on Objects* (1875); and a number of school text-books. C. H. T.

Sheldon, Edward Stevens, Ph. D.: philologist; b. at Waterville, Me., Nov. 21, 1851; studied one year in Colby University; graduated at Harvard 1872; studied in Berlin, Leipzig, and Paris 1874–77; instructor in modern languages at Harvard 1877–84: Assistant Professor of Romance Philology at Harvard 1884–94; appointed full professor 1894; secretary of the American Dialect Society since its organization, 1889. His work lies chiefly in the field of phonetics and historical phonology, particularly as relates to the French element in English. He has also done much to stimulate the investigation of the living English of America. Author of *A Short German Grammar* (1879); *Some Specimens of a Canadian French Dialect Spoken in Maine*, in *Transac. Mod. Lang. Assoc.* (1887); etymologies in *Webster's International Dictionary* (1890); *Origin of the English Names of the Letters* in *Harvard Studies* and *Notes* (i. and ii., 1892; 1893); also various articles in the *Modern Language Notes*, the *Transactions of the Modern Language Association of America* and *The Dialect Notes*. B. I. W.

Sheldon, Gilbert, D. D.: archbishop; b. at Staunton, Oxfordshire, England, July 19, 1598; graduated at Oxford 1617; became fellow of All Souls' College 1622; obtained the vicarage of Hackney 1633, and the rectories of Ickford and Newington; was appointed warden of All Souls' and chaplain to Charles I., May, 1635; was ejected from the wardenship and imprisoned for loyalty to the royal cause 1647–48; lived in seclusion until the Restoration; became Bishop of London 1660, Archbishop of Canterbury 1663, and chancellor of Oxford University 1667, and built for that institution, at a cost of £16,000, the famous Sheldonian theater, opened 1669. D. at Lambeth Palace, Nov. 9, 1677.

Sheldon, Henry Clay, D. D.: minister and educator; b. at Martinsburg, N. Y., Mar. 12, 1845; educated at Lowville Academy, Yale College (A. B. 1867), Boston University (S. T. B. 1871), and Leipzig University (one year); joined Maine Conference of the Methodist Episcopal Church 1873; was agent of Maine Wesleyan Seminary 1874–76; assistant

professor (1876–82) and Professor (since 1882) of Historical Theology in Boston University. He has published *History of Christian Doctrine* (2 vols., New York, 1886) and *History of the Christian Church* (5 vols., 1894). A. O.

Sheldrake, or **Shieldrake** [*sheldrake* is from Eng. *sheld*, variegated, spotted + *drake*; cf. O. N. *skjoldungr* (< *skjöldr*, a patch); *shieldrake* is identified with the secondary meaning of *skjöldr*, shield, given in allusion to the markings on the breast]: a river-duck of either of the genera *Tadorna* and *Casarca*. The common sheldrake (*Tadorna tadorna* or *cornuta*) is about the size of a goose, and has a red bill with a basal protuberance, head and neck green, with a white collar below, and a brown belt extending across the upper portion of the back. The shoulders and a median abdominal stripe are black, the speculum is green, and the rest of the plumage is white. It is found on sandy seacoasts in the Old World, making nests lined with down

The common sheldrake of Europe.

in abandoned rabbit-burrows. The ruddy sheldrake or Brahminy duck (*Casarca rutila*) is found mostly in Southeastern Europe and in Asia. *Casarca tadornoides* and *C. variegata* inhabit Australia and New Zealand respectively, and are plain-colored. The so-called sheldrakes of North America are mergansers.

Shellac, or **Shell-lac**: See Lac.

Sheller, Aleksandr Mikhaïlovich: author; b. in St. Petersburg, Russia, July 30, 1838; educated at the university in that city; interested himself in questions of popular education, and founded a school for the poor which, at first very successful, incurred the suspicions of the Government and came to an end in 1863. In the same year he published his earliest verses, and in 1864 *Gnilyïa Bolota* (Dank Marshes), a novel that had numerous successors, among the best of which are *Khleba i Zrelistch* (Bread and Amusements); *Des rubïat-Stchepki letïat* (When Wood is cut Splinters fly); and *Chuzhie Grekhi* (The Sins of Others). In 1877 he became editor of the *Zhivopisnoe Obozrenie*; he has also written on questions of religion and sociology, and is especially known for a *History of Communism*.

Shelley, Harry Rowe: See the Appendix.

Shelley, Mary Wollstonecraft (*Godwin*): author; daughter of William Godwin and Mary Wollstonecraft; b. in London, England, Aug. 30, 1797; educated in accordance with the peculiar social theories of her parents; married the poet Shelley Dec. 30, 1816, after having lived with him two years previously to the death of his first wife. She was the author of *Frankenstein, or the Modern Prometheus* (1818), a singular novel, displaying great power, of *Valperga* (1823), *Lodore* (1835), and other less successful romances; contributed to *The Cabinet Cyclopædia* a series of biographies of eminent literary and scientific men of France, Italy, and Spain, and edited the works of her husband, with biographical prefaces and notes (1839–40). D. in London, Feb. 21, 1851. See the *Life* by Mrs. Julian Marshall (2 vols., 1889).

Revised by H. A. Beers.

Shelley, Percy Bysshe: poet; b. at Field Place, near Horsham, Sussex, England, Aug. 4, 1792. His grandfather, Bysshe Shelley (b. at Newark, N. J., 1731), acquired a large fortune, was made a baronet in 1806, and died Jan. 6, 1815. His father, Timothy, b. Sept., 1753, married, in 1791, Elizabeth, daughter of Charles Pilfold, of Effingham, Surrey. The domestic surroundings of the poet were unfortunate, neither of his parents having given him suitable training or inspired him with affection—a circumstance to which much of the waywardness of his career may be attributed. He received his early education at a school taught by the parish clergyman at Warnham; entered at the age of ten Sion House School, Brentford, where he was noted rather as an insatiable reader than as a successful student; entered Eton College in 1805; was addicted to experiments in chemistry; read much upon ghosts and the "occult sciences"; was careless of his tasks, but translated half of Pliny's *Natural History* for his own satisfaction; wrote an incredible amount of fragmentary verses, mostly "poor stuff," as he afterward perceived; composed, with his cousin Medwin, one or more plays and novels, and with another cousin, Harriet Grove (of whom he was deeply enamored), a romance entitled *Zastrozzi*, which was printed in 1810, and, strange to relate, brought him £40; printed also a volume of poems, "by Victor and Cazire," which he quickly withdrew from circulation, and of which no copy is known to be extant, and another romance, *St. Irvyne*, all within the same year (1810) in which he entered University College, Oxford; published under the pseudonym of *Margaret Nicholson* a volume of burlesque poems; was expelled from his college Mar. 25, 1811, for having printed a pamphlet entitled *The Necessity of Atheism*; went to London with his friend Hogg, who was also expelled in connection with the same affair; was left without support by his offended father, but received occasional supplies from the savings of his sisters, then at school; eloped to Scotland with one of their schoolfellows, Harriet Westbrook, the beautiful daughter of a retired innkeeper, and married her in Edinburgh, Sept., 1811; effected a settlement with his father, by which he received a small annuity; traveled with his wife to York and Keswick, where he met Southey and perhaps De Quincey; proceeded to Dublin, Feb. 12, 1812, where he printed three revolutionary pamphlets, addressed one or more political meetings, and fancied that he had been requested by the police to leave the city; went to the Isle of Man, to North and South Wales, Devonshire, and Carnarvonshire, making but brief residences at any point; after flying visits to Dublin and Killarney, finally settled in London, May, 1812; printed early in 1813 *Queen Mab*, his first poem of real literary merit, a production strongly tinctured with anti-religious fanaticism. His first child, Ianthe, was born in June, 1813. Shelley was remarried in London, Mar. 24, 1814, but soon found his married life uncongenial; separated from his wife, settling upon her nearly all his disposable income, and about this time conceived a passion for Mary Godwin (daughter of William Godwin and Mary Wollstonecraft), which was fully returned. As neither of them had any respect for the marriage bond, they saw no difficulty in consulting their own inclinations, and proceeded to Switzerland, traveling as man and wife; returned to England at the close of 1814. In consequence of the death of his grandfather he obtained an annuity of £1,000 and his father's succession to the baronetcy (Jan., 1815); studied surgery during the winter of 1815–16, and daily walked a London hospital; wrote in 1815 his second poem of permanent interest, *Alastor, or the Spirit of Solitude*, published, with other poems, in 1816; proceeded to the Lake of Geneva in the spring of 1816; resided there some months in daily intercourse with Byron; returned to London in the autumn; legalized his connection with Mary Godwin by marriage Dec. 30, 1816, Harriet having shortly before (Nov. 10) drowned herself in the Serpentine; conducted an unsuccessful chancery suit against Mr. Westbrook (Harriet's father) for the custody of his two children, decision being given against him by Lord Eldon on the ground of atheism Aug. 23, 1817; settled at Great Marlow, Buckinghamshire, where he played the part of a country gentleman; made about this time the acquaintance of Keats and the brothers James and Horace Smith, and became very intimate with Leigh Hunt; published in 1818 *The Revolt of Islam* (originally called *Laon and Cythna*), a grandly conceived, sublime, and highly original poem, but with many inequalities and blemishes; suffered much from pulmonary disease, which led him in Mar., 1818, to leave England for the last time; traveled with his early friend Hogg to Italy, residing successively at Milan, Pisa, Leghorn, and the Bagni di Lucca; visited Byron at Venice, remaining there some weeks; completed *Rosalind and Helen* (published 1819), a poem of little value; translated, or rather abridged, the *Symposium* of

Plato; wrote at Byron's villa, near Este, *Julian and Maddalo*, one of his poetical masterpieces, not published during his life; proceeded to Rome in November, and to Naples, Dec., 1818; spent the winter at the latter and the spring of 1819 at the former city; proceeded to Florence, Oct., 1819; made in each of the Italian capitals an assiduous study of their works of art; wrote, chiefly at Florence, during this year, his two greatest works, the tragedy *Prometheus Unbound* and the tragedy *The Cenci*, both of which, as well as *Œdipus, the Tyrant*, a burlesque drama, were published in London in 1820; removed to Pisa, Jan., 1820; wrote in this year his *Witch of Atlas*, not published till 1824; in 1821 *Adonais*, a beautiful monody on the death of Keats, *Epipsychidion*, and *Hellas*, a noble drama inspired by the insurrection in Greece; made a long visit to Byron at Ravenna Aug., 1821; was joined by the latter at Pisa during the ensuing winter (1821–22); began his poem *The Triumph of Life*, which was never finished; took a summer residence Apr., 1822, in the Villa Magni, at Lerici, a village on the Genoese coast; went frequently upon boating excursions with his friends, Capt. Trelawney and Lieut. Williams, and was drowned, along with the latter, in the Bay of Spezia, July 8, 1822, owing to their boat having capsized in a squall, while returning from a visit to Leigh Hunt at Leghorn. The bodies were cast upon the shore ten days later, and, in the presence of Byron and Leigh Hunt, were burned, in accordance with the quarantine laws of Tuscany. The ashes were buried by Trelawney in the Protestant burial-ground at Rome, near the tomb of Keats. Shelley's posthumous poems were edited by his widow in 1824, and *The Mask of Anarchy* by Leigh Hunt in 1832. Mrs. Shelley published a collection of his works in prose and verse in 1839 and 1840, and again in 1845. His daughter-in-law, Lady Shelley, collected the *Shelley Memorials* in 1859. Of recent editions the best have been those edited by William M. Rossetti in 2 vols., in 1870, and by H. Buxton Forman, in 8 vols., 1876–80. The earliest *Life* was that of Medwin, in 1847. Trelawney's *Records of Shelley and Byron* appeared in 1858, and Hogg's fragmentary *Life of Shelley* in the same year. J. A. Symonds published a *Life* in 1878, and Prof. E. Dowden another in 1886. D. F. McCarthy issued *Shelley's Early Life* in 1872. Dr. Richard Garnett's *Relics of Shelley* dates from 1862. Revised by EDMUND GOSSE.

Shell-heaps: artificial deposits constituting a leading feature of the aboriginal remains of North America, and occurring more or less plentifully in all habitable countries.

Nature and Extent.—These heaps are the kitchen middens of mollusc-eating peoples, and their contents vary with the nature of the food-supply. Oysters, clams, mussels, and numerous varieties of univalves yield a very large percentage of compact and durable refuse. In some cases the shape and height of the heaps were modified for domiciliary and defensive purposes, and when the sites became places of sepulture the shells were utilized in building mounds; but they are studied here only as accumulations of refuse inclosing in their mass reliable records of the food-supply, the customs, arts, industries, and movements of the people. Some of these heaps cover areas 10, 20, or even 40 acres in extent. On the shores of some of the Atlantic bays and rivers the deposits are practically continuous for many miles, and reach back from the water for distances varying from a few rods to half a mile or more according to the nature of the ground. It is estimated that in the State of Maryland alone the oyster-banks cover an area of upward of 100,000 acres. The deposits are heaviest where favorable dwelling-sites occurred near prolific shallows, and it is not exceptional to find them from 10 to 25 feet deep. A depth of 40 feet is occasionally reported, and certain deposits in Brazil are said to be 100 feet deep. The shells on decomposing yield a dark rich marl, and where decay is well advanced the fields covered are exceedingly fertile. In many places the shells are calcined in kilns and employed as a fertilizer. At Pope's Creek, Md., a single midden has yielded upward of 200,000 cubic feet of oyster-shells for this purpose.

History and Age.—In the main the shell-banks of the Atlantic coast are so nearly homogeneous that they must be regarded as representing a simple and rather brief period of occupation, but examples in Florida, especially the fresh-water deposits, show successive depositions as well as more advanced decomposition in the lower beds, indicating distinct periods of occupation and considerable lapse of time. Dr. Dall found very decided indications of the greater antiquity of the lower beds of the Alaskan middens. In some cases mounds composed of marine forms are found far back from the present salt-water shore-lines, and long periods are assumed to have passed since their accumulation, but the rates of silting and of land-oscillation are not so well determined as to make such data of great value as time-measures. In some localities the forms of life utilized by the ancient inhabitants have changed in character, or have greatly decreased in abundance or size, or have entirely disappeared. These changing conditions are an index of age, but not a definite or valuable one. In the main the species of animals whose remains occur in these artificial deposits are identical with or vary but little from the living or historic species of the regions in which they occur.

Art and Peoples.—The American natives who resorted to the shores of the sea in search of food were not a peculiar people, and did not belong to a particular period of time or stage of culture. Some of the more advanced native peoples occupied the interior of the country and took no part in the marine fisheries, but nearly all grades of culture are represented in the art of these deposits. In some regions the tribes resorted to the fisheries at stated seasons only, and in such cases the relics left do not fully represent the art of the people. The utensils and implements were to a large extent prepared for temporary and local use, and are exceptionally rude; but in passing along the coast from Maine to Mexico the artificial contents of the shell-banks of each section represent somewhat fully the art-remains of the adjacent regions. For example, rude cord-marked pottery is found in the northern middens, stamped wares in southern, painted wares in those of the Gulf States, and highly elaborated and artistic wares in the deposits of the western and southern Gulf shores. The art and people represented by the relics these heaps contain are those of which knowledge has been obtained through other sources.

AUTHORITIES.—Atlantic coast: Wyman, *Fresh-water Shell-mounds of Florida*, in *Memoirs of the Peabody Academy of Sciences*, vol. i., No. 4 (1875); Brinton, *Artificial Shell-deposits of the United States*, in *Smithsonian Institution Report* (1866); Rau, *Artificial Shell-deposits of New Jersey*, in *Sm. Inst. Rept.* (1864). Pacific coast: Schumacher, *Kjokenmoddings of Oregon*, in *Bulletin Geol. Survey of Territories*, vol. iii., No. 1; Dall, *Tribes of the Extreme Northwest*, in *Contributions to North American Ethnology*, vol. i. Interior: White, *Congrès International d'Anthropologie* (Boulogne, 1871). W. H. HOLMES.

Shells, in artillery: See PROJECTILES.

Shells, in natural history: See MOLLUSCA.

Shelly's Case: a celebrated case at law, decided in 1591, and reported in the first part of Lord Coke's *Reports*. It constitutes one of the landmarks of the English law of property, and established a technical rule of real property law, known as the Rule in Shelly's Case, which may be stated as follows: When a person takes an estate for life, under a deed or will, and in the same instrument there is a limitation by way of remainder to his heirs or to the heirs of his body as a class of persons, the limitation to the heirs merely operates to enlarge the estate of the person to whom the life-estate is given; if the remainder be to the heirs of his body, he takes an estate in fee tail; if to his heirs generally, an estate in fee simple. The rule had no application, however, to the limitation of a remainder to any particular person, who might, nevertheless, be the heir of the life-tenant. Thus a limitation of a life-estate to A, with remainder to his eldest son and the heirs of the latter, was not within the rule. The rule itself has been abrogated by statute in New York and many other States, and in such jurisdictions a limitation of the kind affected by it would now take effect according to the terms of the conveyance. See ESTATE, FEE, PROPERTY, REMAINDER, and consult text-books on real property, especially Leake and Williams, and the *Commentaries* of Blackstone and Kent. GEORGE W. KIRCHWEY.

Shelter Island: island and town; Suffolk co., N. Y.; between the Peconic and Gardiner's Bays, near the eastern extremity of Long Island (for location, see map of New York, ref. 8–G). It is reached by ferry from Greenport on the Long Island Railroad; is about 14 miles long and 4 miles wide; contains several pretty bays and small fresh-water lakes; is a popular summer resort and a Methodist camp-meeting place; and has two large hotels and choice facilities for boating and fishing. The island belonged originally to the Manhasset Indians; was acquired by Lord Stirling; and for many years was under the jurisdiction of Connecticut. Pop. (1880) 732; (1890) 921; (1900) 1,066.

Shema'kha (anc. *Kamachia*): town of Russia; in Transcaucasia; on the Pirsaghut, at an elevation of 2,230 feet. It is fortified, and has large and well-stocked bazaars and manufactures of silk and cotton stuffs. Much wine and fruit are produced in the vicinity. Pop. (1892) 22,139.

Shemitic Languages: same as Semitic Languages (*q. v.*).

Shenando'ah: town (founded in 1870); Page co., Ia.; on the Nishnebotne river, and the Burlington Route, the Humeston and Shen., and the Omaha and St. L. railways; 19 miles N. E. of Hamburg, 40 miles S. E. of Council Bluffs (for location, see map of Iowa, ref. 7–D). It is the center of a rich agricultural region, and contains 12 churches, the Western Normal College (opened in 1881), 3 public-school buildings, 2 national banks with combined capital of $115,000, a private bank, and a semi-weekly and 3 weekly newspapers. The vicinity includes among its industries some of the largest wholesale nurseries in the West. Pop. (1880) 1,387; (1890) 2,440; (1900) 3,573. Editor of "Sentinel."

Shenandoah: borough; Schuylkill co., Pa.; on the Lehigh Val., the Penn., and the Phil. and Read. railways; 13 miles N. by E. of Pottsville, the county-seat, and 105 miles N. W. of Philadelphia (for location, see map of Pennsylvania, ref. 5–H). It is in the heart of the richest coal district in the anthracite region, the development of which has given it rapid growth. Six of the largest collieries in the coal region are within the borough limits, and eight others, equally productive, are within the radius of a mile. The borough has gas and electric-light plants, an electric railway connecting adjoining towns and villages, 2 national banks with combined capital of $200,000, 3 building and loan associations, each local and serial, and a daily and 2 weekly newspapers. There are 18 churches, 7 public-school buildings (valued at $60,000), a public library connected with the schools, 2 parochial schools, a brewery, 2 hat and cap factories, and other industries. Shenandoah was laid out in 1862, and incorporated as a borough in 1866. Pop. (1880) 10,147; (1890) 15,944; (1900) 20,321.

M. E. Doyle, editor of "Sunday Morning News."

Shenandoah River: a stream which rises in Augusta co., Va., and flows N. E. 170 miles to the Potomac at Harper's Ferry, W. Va. The north fork joins the main stream at Front Royal. The Shenandoah affords great water-power. During the civil war its valley was the scene of many military operations, and was laid waste by Gen. Sheridan in 1864.

Shen'di: town of Nubia, on the Nile, in lat. 16° 38′ N.; was a place of some commercial importance before the Mahdist revolt. Almost the entire population of the town and district perished of famine in 1889. C. C. A.

Shenshin, Afanasiĭ Afanasievich: poet, who has written under the name of Fet (that of his mother by a first marriage); b. in the government of Orel, Russia, Nov. 23, 1820; studied in the University of Moscow, and from 1844 to 1856 served in the army, after which he settled in the country. His first volume of verses was published in Moscow in 1840. As a writer Fet belongs to the school of pure art. His short poems, though at times lacking in warmth, are characterized by perfect form and delicate grace. He has also made excellent translations of the whole of Horace and Juvenal, Goethe's *Faust*, Shakspeare's *Julius Cæsar* and *Antony and Cleopatra*, etc. A. C. Coolidge.

Shensi, shen'sec' [literally, western defiles]: a province of China, bounded N. by Mongolia, E. by the Hwang-ho (which separates it from Shansi) and Honan, S. by Hupeh and Szechuen, and W. by Kansuh. Area, 67,400 sq. miles. S. of the Tsing-ling range it is mountainous and well wooded; N. of it the Loess (*q. v.*) formation prevails, and everything is yellow. The houses are made of yellow earth, vegetation is covered with yellow dust, and even the atmosphere is seldom free from a yellow haze. The chief rivers are the Wei (a long, shallow affluent of the Hwang-ho), which flows E. along the northern base of the Fu-niu and Tsing-ling ranges (some of whose peaks reach an elevation of 11,000 feet), and the Hankiang (*q. v.*). Iron and coal abound, but are not much worked, except near the upper waters of the Han. Being a loess region, Northern Shensi is unfit for rice cultivation. Wheat, barley, pulse, millet, maize, ground-nuts, poppy, hemp, tobacco, and cotton are extensively grown. Wheat is the staple. Capital, Si-ngan-foo. Pop. about 8,500,000. R. L.

Shenstone, William: poet; b. at the Leasowes, near Halesowen, Shropshire, England, in Nov., 1714; studied at Pembroke College, Oxford, and passed his life in retirement on his hereditary estate, writing elegies, ballads, odes, and pastorals which had considerable popularity. The Spenserian poem entitled *The Schoolmistress* (1742), the *Pastoral Ballad* (1743), and the well-known stanzas *Written in an Inn at Henley*, are the only ones remembered. D. at the Leasowes, Feb. 11, 1763. His *Works* and *Letters* were collected in 3 vols., 1764–69. An edition of his *Poems*, by Gilfillan, with a memoir, appeared at Edinburgh in 1854, and his *Essays on Men and Manners* were republished at London in 1868. Shenstone was also one of the best amateur landscape-gardeners of his time. Revised by H. A. Beers.

She'ol: the transliterated Hebrew word, meaning a hollow place, a cave, used in the Revised Version of the Bible to denote the place of departed spirits. It therefore corresponds with Hades in classical Greek literature. In the Authorized Version it is translated by pit, grave, hell. S. M. J.

Shepard, Charles Upham, M. D., LL. D.: geologist; b. at Little Compton, R. I., June 29, 1804; graduated at Amherst College 1824; studied botany and mineralogy at Cambridge under Nuttall; taught those branches at Boston; was for two years assistant in the laboratory of Prof. Silliman at New Haven, and for one year lecturer at the Brewster Scientific Institute at New Haven; employed on a Government commission to investigate the methods of sugar-culture and manufacture in the Southern States 1832–33; lecturer on Natural History at Yale College 1830–47; associate of Dr. James G. Percival in the geological survey of Connecticut 1835; Professor of Chemistry and Natural History at Amherst 1845–52, and in the Medical College at Charleston, S. C., 1854–61; afterward became again Professor of Natural History at Amherst; was author of a *Treatise on Mineralogy* (1832; 3d ed. enlarged, 1855), and of a *Report on the Geology of Connecticut* (1837). D. May 1, 1886. —His son, Charles Upham Shepard, Jr., M. D., born at New Haven, Oct. 4, 1842, graduated at Yale College 1863, and in medicine at Göttingen, Germany, 1867; became Professor of Chemistry at the Medical College of Charleston, S. C., in 1867. He wrote many papers on mineralogy, and has been active in the development of the phosphate industries of South Carolina and Florida. Revised by G. K. Gilbert.

Shepard, Elliott Fitch, LL. D.: lawyer; b. at Jamestown, Chautauqua co., N. Y., July 25, 1833; was educated at the University of the City of New York; was admitted to the bar in 1858. During the civil war he raised the 51st New York Volunteer Regiment, which was called in his honor the Shepard Rifles. He was one of the founders of the New York State Bar Association, and founded the American Sabbath Union. He was owner and editor of the New York *Mail and Express*. D. in New York, Mar. 24, 1893.

Shepard, Irwin: See the Appendix.

Shepard, Thomas: clergyman; b. at Towcester, Northamptonshire, England, Nov. 5, 1605; graduated at Cambridge, 1627; became a preacher at Earle's-Colne, Essex; was silenced for nonconformity in 1630. He emigrated to Massachusetts, arriving at Boston, Oct. 3, 1635; succeeded Thomas Hooker as pastor of the church at Cambridge, Feb., 1636; was influential in founding Harvard College; published *New England's Lamentation for Old England's Errors* (London, 1645); *The Sound Believer* (1645); *The Clear Sunshine of the Gospel breaking forth upon the Indians in New England* (London, 1648; reprinted New York, 1865); *Theses Sabbaticæ* (1649); and other theological works. After Hooker's death he was esteemed the most learned and skillful exponent of Puritan theology in New England. D. at Cambridge, Aug. 25, 1649. He left numerous works in MS., some of which were published in England, especially *Subjection to Christ* (1652), to which was prefixed a *Life* of Shepard by Samuel Mather and William Greenhill; *The Parable of the Ten Virgins Opened and Applied* (London, folio, 1660; new eds. 1839, Aberdeen, 1838 and 1853); and various collections of *Sermons*. He left an *Autobiography*, first printed at Cambridge (1832) for the Shepard Congregational Society. A collected edition of his *Works* appeared at Boston (3 vols., 1853), with a memoir by Rev. Horatio Alger, of Cambridge. A memoir by Cotton Mather may be found in the *Magnalia Christi Americana* (best ed. Boston, 1855, 2 vols.). Revised by S. M. Jackson.

Shepardson College: See Denison University.

Shepherd-dog: any one of the breeds of domestic dogs which are trained to assist in attending the flocks of sheep. Of all strains of shepherd-dogs the Scotch collie is the most celebrated. It is one of the most sagacious and docile of dogs. A good Scotch collie should have a long, narrow

head; small, semi-erect ears, set high on the head; long, straight fore legs, placed well under the body; long and thick, but not woolly, hair. The color is extremely varied, but is more usually black and tan, or black, tan, and white, or yellow and white. F. A. Lucas.

Shepherd Kings: certain rulers of Egypt, known also as Hyksos (*q. v.*).

Shepherdstown: town; Jefferson co., W. Va.; on the Potomac river, the Chesapeake and Ohio Canal, and the Norfolk and Western Railroad; 8 miles W. of Harper's Ferry, 60 miles W. of Washington, D. C. (for location, see map of West Virginia, ref. 5–N). It contains Shepherd College (one of the State normal schools), large cement-mills and flour-mills, machine-shops, a savings-bank, and a weekly newspaper. Pop. (1880) 1,533; (1890) 1,515; (1900) 1,184.
H. L. Snyder, publisher of "Register."

Shepley, Ether, LL. D.: jurist; b. at Groton, Mass., Nov. 2, 1789; graduated at Dartmouth College 1811, in the same class with Amos Kendall, Joel Parker, and Daniel Poor; became a lawyer at Saco, and subsequently at Portland; sat in the Massachusetts Legislature 1819, and in the Maine constitutional convention 1820; was U. S. district attorney for Maine 1821–33; U. S. Senator 1833–36; became a justice of the Supreme Court of the State Sept. 23, 1836; was chief justice 1848–55. He was a man of great constructive ability, and was appointed sole commissioner to prepare the Revised Statutes of Maine (1856–57). D. Jan. 15, 1877. —John Shepley, his brother (b. 1787; d. 1857), reported and published *Maine Reports*, the decisions of the Supreme Court of Maine 1836–49. Revised by F. Sturges Allen.

Shepley, George Foster: soldier and lawyer; b. at Saco, Me., Jan. 1, 1819; graduated at Dartmouth College in 1837, and at Dana Law School, Cambridge, 1829; admitted to the bar of the supreme judicial court, Bangor, Me., 1840; in 1844 removed to Portland; was appointed U. S. attorney for Maine district in 1848, and reappointed in 1853 and 1857, subsequently devoting himself exclusively to a very extensive and general practice of his profession, in the course of which he was called upon to argue several cases of great importance in the U. S. Supreme Court, until Sept. 21, 1861, when he was commissioned colonel of the Twelfth Maine Volunteers; commanded a brigade in Gen. Butler's expedition against New Orleans, and on the occupation of that city was appointed military commandant and acting mayor, charged with the administration of civil affairs in the city, and was also assigned to the command of the defenses of New Orleans. On July 17, 1862, he was commissioned brigadier-general of volunteers by President Lincoln, who appointed him military governor of Louisiana June 3, 1862. In 1864 he commanded the military district of Virginia and North Carolina; served with the Army of the James 1864–65; entered Richmond with the Twenty-fifth Army-corps Apr. 3, 1865, and was appointed military governor of that city. Resuming his profession at the close of the war, he declined the appointment of judge of the Supreme Court of Maine, but in 1869 accepted that of U. S. circuit judge for the first judicial circuit. His decisions are reported in Shepley's *Circuit Court Reports*. D. at Portland, July 20, 1878. Revised by James Mercur.

Sherbrooke: *chef-lieu* of Sherbrooké County, Quebec, Canada, and by courtesy called The Capital of the Eastern Townships (see map of Quebec, ref. 6–C). It is a flourishing town situated on both sides of the river Magog at its confluence with the St. Francis, one of the large tributaries of the St. Lawrence. It is a station on the Grand Trunk Railway which has its terminus in Portland, Me., being 94 miles from Montreal. The Canadian Pacific Railway also passes through it on the line between Montreal and New Brunswick. The Quebec Central Railway has its head office here, and with the Boston and Maine Railroad connects Quebec with the railway systems of the U. S. Sherbrooke has a splendid water-power, and on both sides of the Magog are several large and important factories, the largest being the Paton woolen and worsted mills. The town possesses several fine buildings, including the post-office, the Eastern Townships Bank, and several churches. The Magog and the St. Francis are spanned by bridges. There are three weekly newspapers, one of which is printed in the French language. Pop. (1881) 7,227; (1891) 10,110, mostly French-Canadians. J. M. Harper.

Sherbrooke: a seaport of Guysborough County, Nova Scotia; at the head of navigation of the beautiful St. Mary's river, 12 miles from its mouth (see map of Quebec, etc., ref. 2–C). Ship-building, the lumber-trade, gold-mining, and quartz-milling are carried on. Pop. 1,600, mostly Scotch.

Sherbrooke, Viscount: See Lowe, Robert.

Shere Ali, sheer-aa'lĕĕ: Ameer of Afghanistan; b. in 1825; succeeded his father in 1863, and seemed at first to be open to British influence, introducing numerous reforms after British models, but was subsequently compelled by a revolt of the conservative party, headed by his own son, Yakoob Khan, to change his policy completely and submit to the Russian influence. As he declined to receive a British embassy, though a Russian embassy lived in Cabul in great state, the British invaded the country in the last months of 1878. Shere Ali fled across the frontier, and died suddenly at Mezaricheff, a place under Russian authority, Feb. 21, 1879.

Sheribon: See Cheribon.

Sheridan, Frances (*Chamberlaine*): novelist and dramatist; b. in Ireland in 1724; wrote at the age of fifteen a romance, *Eugenia and Adelaide*, which was dramatized by her daughter long afterward, and successfully acted at Dublin; made the acquaintance of Sheridan, the theatrical manager, during the controversies in which he was involved, by the publication of a pamphlet in his favor; married him about 1748; wrote two popular novels, *Sidney Biddulph* (3 vols., 1761) and *Nourmahal* (1788), and two comedies, *The Discovery* (1763) and *The Dupe* (1764), and left an unpublished play, *The Trip to Bath*. D. at Blois, France, Sept., 1766. Revised by Brander Matthews.

Sheridan, Philip Henry, LL. D: soldier; b. at Albany, N. Y., Mar. 6, 1831; graduated from the U. S. Military Academy, and assigned to the First Infantry as brevet second lieutenant July 1, 1853. After a brief term in barracks he was ordered to Texas; transferred to the Pacific coast in 1855, serving in Washington and Oregon Territories until the fall of 1861, at which date he was captain in the Thirteenth Infantry. In December he was assigned to the army of Southwest Missouri as chief quartermaster. After the battle of Pea Ridge (Mar., 1862) he was relieved, and in the Corinth campaign accompanied Gen. Halleck as quartermaster until May 25. On this date he was appointed colonel of the Second Michigan Cavalry; three days later was off on a raid to Booneville, and May 30 in pursuit of the Confederates retreating from Corinth. On July 1, in command of a cavalry brigade, he defeated a superior cavalry force at Booneville, and was commissioned brigadier-general of volunteers from that date. Transferred to the Army of the Ohio, he commanded a division at the battle of Perryville (Oct. 8), where "he held the key of our position, and used the point to its utmost advantage." At the battle of Murfreesboro (Dec. 31) Sheridan's division held the left of the right wing. An attack on his front had been met and the enemy driven back, when by the giving way of the two divisions on his right his flank became exposed to the advancing foe. Hastily forming a new line under cover of a charge, he made a brave resistance for an hour, when he was again compelled to take up a new line, this time connecting with Negley of the center. The two divisions repulsed three desperate assaults by four divisions of the enemy, when, Sheridan's ammunition giving out, he ordered a bayonet charge and withdrew his lines from the field; but by his obstinate resistance priceless time had been gained for Rosecrans to make his new dispositions. Sheridan's commission as major-general of volunteers followed, dating from this battle. With the exception of skirmishes with Forest and Van Dorn, little of interest occurred until late in June, 1863, when Rosecrans advanced against Bragg, who fell back into Georgia. The battle of Chickamauga took place Sept. 19–20, where Sheridan fought with great gallantry, rescuing his division from a perilous position. Grant superseded Rosecrans in October, and on Nov. 24–25 was fought the battle of Chattanooga, where, on the 25th, Sheridan, by his fearless assault at the head of his division upon the center of the enemy's line on Missionary Ridge, gained additional renown. The march to Knoxville, where Burnside was besieged, next followed. Upon Grant's promotion to be lieutenant-general (Mar., 1864) he applied for the transfer of Sheridan to the East, and appointed him chief of cavalry of the Army of the Potomac. In the campaign of 1864 the cavalry covered the front and flanks of the infantry through the battles of the Wilderness until May 8, when the greater part of it was withdrawn, and next morning Sheridan started on a raid against the enemy's lines of communication with

Richmond. On the 25th he rejoined the army, having destroyed the dépôts, trains, and track at Beaver Dam and Ashland stations, liberated 400 Union men, and defeated the enemy's cavalry at Yellow Tavern, where their cavalry leader, J. E. B. Stuart, was mortally wounded. The outer line of works around Richmond was taken, but the second line was too strong to be carried. Resuming the advance, the battle of Hawes's Shop was fought May 28; Cold Harbor was occupied on the 31st, and held until the arrival of the infantry. On June 7 Sheridan, with two divisions, started around the left of Lee's army and destroyed the Virginia Central Railroad in the rear. The Richmond and Fredericksburg railroad was struck at Chesterfield, and the Virginia Central was again cut at Trevilian's, where he routed Wade Hampton (June 11); next day he tore up the railway nearly to Louisa Court-house, when, on the advance toward Gordonsville, an indecisive engagement took place; not hearing from Hunter, who was to meet him here, he withdrew, rejoining the army June 19. On Aug. 7 the Middle Department and departments of West Virginia, Washington, and Susquehanna were constituted "the Middle military division," and Sheridan assigned to command of the same. Numerous severe cavalry skirmishes occurred during August and early in September, but no general engagement, although the two armies lay in such position—the Confederates under Gen. Early on the west bank of Opequan Creek, covering Winchester, and Sheridan in front of Berryville—that either could bring on a battle at will. The imperative necessity of having the unobstructed use of the Baltimore and Ohio Railroad and the Chesapeake and Ohio Canal led Grant to take the initiative, although Sheridan's defeat would have exposed Maryland and Pennsylvania to invasion; but before giving orders to attack he visited Sheridan (Sept. 16), the latter expressing such confidence of success that Grant gave him but two words of instruction: "Go in!" Three days later, at the crossing of the Opequan, he attacked Early, whom he routed after a vigorous battle, and captured 3,000 prisoners and 5 guns. Early rallied his army at the strong position of Fisher's Hill, where, on the 22d, he was again defeated, with heavy loss, and pursued to the mountains. Sheridan devastated the valley on his return, rendering it untenable for an enemy's army. He was then (Sept. 20) appointed a brigadier-general in the regular army. On Oct. 19 Early, after surprising the Union army in the morning, was disastrously defeated, owing to the arrival of Sheridan from Winchester. (See CEDAR CREEK.) The thanks of Congress were bestowed upon Sheridan and his army, and Nov. 8 he was appointed major-general in the regular army. On Feb. 27, 1865, starting out with 10,000 cavalry, he destroyed the Virginia Central Railroad, the James River Canal, and immense quantities of supplies, and defeated Early again at Waynesboro, rejoining Grant before Petersburg Mar. 27. Sheridan had now a force of about 9,000, and in subsequent operations was under the immediate orders of Gen. Grant. He commanded at the battle of FIVE FORKS (*q. v.*) with his customary vigor. The loss of this battle compelled Lee to evacuate Petersburg. Sheridan pursued the flying army to Sailor's Creek, where he captured 16 guns and 400 wagons. When the Sixth Corps came up a combined attack resulted in the capture of upward of 6,000 prisoners. On Apr. 8 four supply-trains were captured at Appomattox Station, and at Appomattox Court-house the advance of Lee's army was resisted until dark. On the morning of the 9th the enemy endeavored to break through his dismounted command, but abandoned the attempt when Sheridan, moving aside, disclosed the infantry behind. Mounting his men, Sheridan was about to charge when the white flag betokening surrender was displayed in his front. In June, 1865, he was placed in command of the military division of the Southwest, of that of the Gulf in July, of the department of the Gulf, Aug., 1866, and of the fifth military district (Louisiana and Texas) Mar., 1867. In Sept., 1867, he was transferred to the department of the Missouri, continuing in command until Mar. 4, 1869, when he was promoted to be lieutenant-general, and assigned to command of the division of the Missouri, headquarters at Chicago, assuming command Mar. 16. In 1870 he visited Europe and witnessed the Franco-German war. During the political disturbances in Louisiana in 1875, Gen. Sheridan was sent to New Orleans, returning to Chicago on quiet being restored. He assumed command of the army Nov. 1, 1883; was appointed general June 1, 1888. D. at Nonquitt, Mass., Aug. 5, 1888. See his *Personal Memoirs of P. H. Sheridan* (1888); and Davies, *General Sheridan* (Great Commanders Series, 1895). JAMES MERCUR.

Sheridan, RICHARD BRINSLEY BUTLER: dramatist; son of Thomas Sheridan, actor and author, and Frances Chamberlaine, author; b. in Dublin, Ireland, Sept., 1751; educated in Dublin and at Harrow School; published a rhymed translation of Aristænetus, Aug., 1771; married Miss Linley, a beautiful oratorio singer, of Bath, in 1773; brought out his first comedy, *The Rivals*, at Covent Garden, Jan., 1775; followed it in November with an opera, *The Duenna*, for which his father-in-law composed the music, and which was acted seventy-five nights the first season; became part-purchaser of Garrick's half of Drury Lane theater in June, 1776; produced *A Trip to Scarborough* Feb., 1777, altered from Vanbrugh's *Relapse*; and in May followed it with *The School for Scandal*, the most successful comedy of manners in the English language; became owner of one-half of Drury Lane 1778; wrote *Monody on Death of Garrick* 1779; brought out the farce of *The Critic, or a Tragedy Rehearsed*, Oct., 1779. Elected a member of The Club, he became a friend of the leading wits and statesmen of the time; was elected to Parliament from Stafford 1780; was Secretary of the Treasury 1782; cultivated oratory with great success; crowned his fame as a public speaker by two great speeches against Warren Hastings, one in bringing charges in Parliament, Feb., 1787, and one on the trial at Westminster Hall, in June of same year; held his own in debate even against Pitt; revised Thomson's adaptation from Kotzebue, *The Stranger*; rebuilt Drury Lane 1794; produced in 1799 his patriotic play, *Pizarro*, also an adaptation from Kotzebue; became treasurer of the navy and a privy councilor in 1806; was ruined by the burning of Drury Lane 1809; made his last speech in Parliament 1812. Having fallen into habits of dissipation and carelessness in money matters, his last years were harassed by the importunities of creditors, pursuing him even to his deathbed. D. July 7, 1816, and was buried in Westminster Abbey. His *Life* was written by Thomas Moore (1825), who also edited his plays, admitting one piece, *The Camp*, which he did not write. His *Speeches* have been collected in five volumes (1816). The *Rivals* and *The School for Scandal* were published in 1884, with biography, introductions, and notes, by the present writer. BRANDER MATTHEWS.

Sheridan, THOMAS: actor and author; b. in 1721 at Quilca, near Dublin, Ireland (the residence of Dean Swift); educated at Trinity College, Dublin; became an actor 1743; played tragedy at Covent Garden theater 1744 and at Drury Lane 1745; was by some considered a rival of Garrick; was manager of the Dublin theater 1746–55; was ruined by a wanton riot; withdrew temporarily from the stage; became a successful teacher of elocution at London, Oxford, and Cambridge, and in Scotland and Ireland; returned to the stage 1760; was pensioned by George III.; was acting manager of Drury Lane 1776–79, after his son obtained control of that theater; published several works on elocution; edited the works of Swift (1784); wrote his *Life*, and was author of a *General Dictionary of the English Language* (1780) of considerable phonetic value.. D. at Margate, England, Aug. 14, 1788. Revised by BRANDER MATTHEWS.

Sherif, she-reef' [Arab. *sherif*, noble]: a title; applied by Mussulmans to descendants of Fatima, the daughter of the prophet Mohammed. The Sherif of Mecca is the guardian of the KAABA (*q. v.*), and chief dignitary of the city. E. A. G.

Sheriff [M. Eng. *shereve* < O. Eng. *scīr-gerēfa*; *scīr*, shire + *gerēfa*, reeve, officer]: a county officer with administrative and generally also judicial functions.

In England, Ireland, and Wales the sheriff is the chief officer of the crown, in every county or shire, who does all the sovereign's business in the county, the custody of the county being committed to him alone by letters patent of the crown. The office of sheriff is one of the most ancient and honorable known to the English law. The custody of the county is said to have formerly been committed to the earl or (Lat.) *comes*, and anciently the sheriff, whose Latin title is *vicecomes*, was his deputy. The earls in time became unable to transact the business of the county, and the burden was laid on the sheriff, who is now entirely independent of the earl.

Sheriffs were formerly chosen by the inhabitants of the several counties, but now by statute they are annually appointed by the crown (on nomination by the judges and the great officers of the crown) on Nov. 12, and the person appointed must have sufficient land within his county or bailiwick to answer the crown or the people. The discharge of the office is compulsory, and within one month after a

person's appointment is gazetted he must nominate a fit person for his under-sheriff. Until 1888 the citizens of London had the right to elect the sheriffs for Middlesex and London, but now the crown appoints the sheriffs for the county of Middlesex and the (newly created) county of London, and the city elects sheriffs for the city of London only.

The sheriff was formerly a judicial officer before whom might be held the trial of disputed facts in certain cases; but now he is relieved of this burden, except that he is charged with the assessment of damages (by the aid of a jury) and of compensation in certain cases, and that he is bound to hold a county court whenever the holding of such court is required for the purpose of election or any other specific purpose only. He is charged also with certain other duties, as a returning officer, etc., in regard to parliamentary elections.

As the keeper of the king's peace he is the first man in the county, and superior in rank to any nobleman therein during his term of office. He may apprehend and commit any one who breaks the peace, or attempts to break the peace; and may bind any one in a recognizance to keep the peace. He is bound to pursue all traitors, murderers, and other law-breakers, and commit them to jail. He is also to defend his county against any of the king's enemies, and for this purpose, as well as for the purpose of keeping the peace, or of apprehending offenders, he may command all the people of the county to attend him. See Posse Comitatus.

The sheriff, as an officer of court, is also bound to execute processes issuing from the high court of justice, and to attend on the judges when they come into the county at the assizes. In civil causes he may serve all processes by which actions are begun, unless he is a party (when service is to be made by the coroner); he must, upon a proper order, arrest and take security from the defendant (where the defendant is liable to arrest); he executes mesne process by levying attachments, etc.; and in any action or cause he must, when the case comes to trial, summon and return the jury; and when the case is determined he must see the judgment or sentence of the court carried into execution. In these matters he is liable, like other ministerial officers, to an action for the negligent or improper discharge of his duties. To protect himself against liability for mistake he may, in cases of doubt, require from the proper party a bond of indemnity.

In executing criminal process the sheriff may break open the outer door of any dwelling-house or other building, but in executing civil process he can not force an entrance into a dwelling-house, although when once admitted he may break an interior door; and he may break the outer doors of buildings which are not dwellings. It is also the sheriff's business as the bailiff to preserve the rights of the crown within his county, or, as it is often called in his writs, his bailiwick. He must seize escheated lands, levy fines and forfeitures, and seize waifs, wrecks, estrays, etc.

Although the sheriff's authority extends in general over the whole county, there are many liberties exempt from his jurisdiction, in which, by ancient crown grants, the execution of legal process, etc., is bestowed upon other persons. These liberties, though still recognized, are now partly subjected to the surveillance and control of the sheriff.

The sheriff, for the better execution of the duties imposed upon him, has under him many inferior officers—an under-sheriff, a deputy, and bailiffs; and these under-officers may not buy, sell, nor farm their offices on forfeiture of £500; and the sheriff himself is forbidden to "let to farm" his county or any part of it. The under-sheriff, deputies, and bailiffs of the sheriff are in all respects his agents, and may perform in his name only acts which are purely administrative in their nature, and not any which are judicial. Their acts are his acts; he is responsible for all their defaults done under color of office, even when willful and intentional trespasses or violations of law. To protect himself he can take from them bonds with sureties for their good behavior.

In Scotland the sheriff is the chief local judge of the county. His jurisdiction in civil matters extends to all personal actions on contract, bond, or obligation, to the greatest extent; to actions for rent; to possessory actions; and generally to all civil matters not especially committed to other courts; his criminal jurisdiction in general extends to the trial of all crimes which do not involve as a punishment death or banishment from Scotland; and he may fine, imprison, banish from the county, and generally even inflict corporal punishment without a jury.

In the several States of the U. S. the sheriff is the chief administrative officer of each county, and his general duties and powers are essentially the same as in England in matters pertaining to the execution and enforcement of the law, whether civil or criminal. He is *ex officio* the administrative organ of all the superior courts sitting within his county, charged with the duty of carrying into effect their judgments and orders. He is wholly a State official, and has never been incorporated into the executive branch of the U. S. Government. He is generally elected by popular vote for a fixed term (usually three years); but in a few States the ancient practice of appointment by the Governor is still retained. Of his common-law judicial functions the only one retained is the assessment of damages, by the aid of a jury, in certain classes of cases in which defendants have made default.

For a full treatment of the subject, see the statutes of the jurisdiction in question and Stephen's *Commentaries on the Laws of England*; Churchill and Bruce's *Law of the Office and Duties of Sheriffs* (London, 1879); Erskine's *Principles of the Law of Scotland*; Tytler's *History of Scotland*; Bell's *Dictionary of the Law of Scotland*; Binmore's *Instructions for Sheriffs, Coroners, and Constables* (Chicago, 1894); and Crocker's *Duties of Sheriffs, Coroners, and Constables* (3d ed. New York, 1890). F. Sturges Allen.

Sherlock, Thomas, D. D.: bishop and author; son of Dean William Sherlock; b. in London, England, in 1678; educated at Eton; graduated at Cambridge 1697; was master of the Temple forty-nine years (1704–53); was made a prebendary of London 1713, vice-chancellor of Cambridge 1714, dean of Chichester Nov., 1715, prebendary of Norwich 1719, Bishop of Bangor Feb. 4, 1728, of Salisbury 1734, and of London 1748, having declined in 1747 the Archbishopric of Canterbury. He took an active part in the Bangorian controversy in opposition to Dr. Hoadly (1716), wrote several controversial works on Christian evidences, of which the most celebrated were *The Use and Intent of Prophecy* (1725) and *Tryal of the Witnesses of the Resurrection of Jesus* (1729), and published four volumes of his *Discourses at the Temple Church* (1754–58), which gained him a high reputation as a pulpit orator. D. in London, July 18, 1761. His *Works* were edited by T. S. Hughes, D. D. (London, 5 vols., 1830). Revised by S. M. Jackson.

Sherlock, William, D. D.: clergyman and author; b. in Southwark, London, England, 1641; educated at Eton; graduated at Cambridge 1660; took orders in the Church of England; became rector of St. George's, Botolph Lane, London, 1669, prebendary of St. Paul's 1681, master of the Temple 1684, and dean of St. Paul's 1691, in which year he at first refused to take the oaths of allegiance to William and Mary, but subsequently took them; published a pamphlet in justification of his course, *The Case of Allegiance Due to Sovereign Powers Stated* (London, 1691), which caused a great sensation and elicited many replies. D. at Hampstead, June 19, 1707. Author of over sixty publications, chiefly theological and controversial, of which the *Vindication of the Doctrine of the Trinity* (1690), directed against Dr. South, and the *Practical Discourse concerning Death* (1689; n. ed. 1883) made a great impression at the time, but are now little read. Other works are *The Judgment* (1692) and on *The Divine Providence* (1694; edited by T. O. Summers, Nashville, Tenn., 1853; 3d ed. 1875).

Sherman: city; capital of Grayson co., Tex.; on the Hous. and Tex. Cent., the Mo., Kan. and Tex., the St. L. S. W., and the Tex. and Pac. railways; 13 miles S. of the Red river, and 67 miles N. of Dallas (for location, see map of Texas, ref. 2–I). It is in a wheat, corn, cotton, and fruit region, and within 50 miles of the great Ardmore coal-fields, and has large manufacturing and shipping interests. It contains one of the largest cottonseed-oil mills in the South, a cotton-gin (cost about $250,000, and said to be the largest in the world), several flour, saw, and planing mills, foundries and machine-shops, marble-works, cigar, furniture, carriage, broom, and mattress factories, and brick-yards. There are 7 churches, Austin College for boys (Presbyterian), St. Joseph's Academy (Roman Catholic), Sherman Institute, the North Texas Female College, a commercial college, improved water-works, electric street lights and railway, a national bank with capital of $600,000, a State bank with capital of $300,000, and 2 daily and 3 weekly newspapers. The city has an altitude of about 1,000 feet above sea-level. Pop. (1880) 6,093; (1890) 7,335; (1900) 10,243.

Sherman, Frank Dempster: poet; b. at Peekskill, N. Y., May 6, 1860. He was educated at Columbia College and

Harvard University; became a fellow of Columbia in 1887, and afterward instructor in the Columbia School of Architecture. He has published *Madrigals and Catches* (1887); *Lyrics for a Lute* (1890); and, with John K. Bangs, *New Waggings of Old Tales* (1888). H. A. B.

Sherman, John: clergyman; grandson of Roger Sherman; b. at New Haven, Conn., in 1772; graduated at Yale College 1792; was pastor of the First Congregational church at Mansfield, Conn., from Nov., 1797, to Oct., 1805, when he left that post on account of having adopted Unitarian principles; was for a short time pastor of a Unitarian church at Trenton Falls, N. Y., where he established and conducted an academy. D. at that place Aug. 2, 1828. He was the author of *One God in One Person Only* (1805), the first elaborate defense of Unitarianism that appeared in New England; and *Philosophy of Language Illustrated* (1826).
Revised by G. P. Fisher.

Sherman, John: statesman; b. at Lancaster, O., May 10, 1823; brother of Gen. W. T. Sherman; was admitted to the bar 1844; was a delegate to the Whig conventions of 1844 and 1848; sat in Congress 1855–61; was Republican candidate for the Speakership 1859, but was defeated after a prolonged contest; became chairman of the House committee of ways and means; was re-elected to Congress 1860, but before taking his seat was chosen U. S. Senator; re-elected 1866 and 1872; was long the chairman of the Senate committees on finance and on agriculture; took a prominent part in debates upon finance and the conduct of the war, was one of the authors of the reconstruction measures adopted 1866–67, and was appointed Secretary of Treasury Mar. 7, 1877. He was again U. S. Senator from Ohio 1881–97; president *pro tem.* of the U. S. Senate from Dec., 1885, till Feb., 1887. In 1888 he was a prominent candidate for the presidential nomination, which was finally awarded to Harrison. From Mar., 1897, till Apr., 1898, he was Secretary of State under President McKinley. Author of *Recollections of Forty Years* (2 vols., Chicago, 1895). D. Oct. 22, 1900.

Sherman, Roger, M. A.: signer of the Declaration of Independence; b. at Newton, Mass., Apr. 19, 1721; was in childhood apprenticed to a shoemaker, and followed that occupation until 1743, when he settled at New Milford, Conn., and joined an elder brother in keeping a small store; studied privately law, politics, and mathematics; was chosen county surveyor 1745; made for several years the astronomical calculations for an almanac issued in New York; studied law; was admitted to the bar 1754; sat for several years in the colonial assembly; removed to New Haven in 1761; was assistant governor nineteen years (1766–85), judge of common pleas and of the superior court twenty-three years; treasurer of Yale College 1766–76; sat in Congress from 1774 until his death; was one of the five members of the committee to draft the Declaration of Independence 1776; served on many important committees on the board of war and ordnance and on the treasury board; assisted in codifying the laws of Connecticut 1783; was one of the framers of the original Articles of Confederation 1777, and an active member of the Federal constitutional convention 1787; U. S. Senator 1791–93; and mayor of New Haven from 1784 till his death in that city July 23, 1793.

Sherman, Thomas West: soldier; b. at Newport, R. I., Mar. 26, 1813; graduated at the U. S. Military Academy July, 1836, when he was assigned to the artillery as second lieutenant and sent to Florida, where he served against the Indians until 1842; was subsequently employed in recruiting and in garrison until 1846; was promoted captain in May, 1846. In the war with Mexico he commanded his battery at Buena Vista, and was breveted major; again in garrison and on frontier duty 1848–61, in April of which latter year he attained a majority in his corps, and was assigned to guard the Philadelphia and Baltimore Railroad and to restore communications with Washington. On May 14 he was promoted to be lieutenant-colonel, and three days later appointed brigadier-general of volunteers. In the Port Royal expedition (Oct., 1861) he commanded the land-forces, which he had organized, continuing in command in South Carolina until the end of Mar., 1862, when he was assigned to the Army of the Tennessee as division commander, participating in the Corinth campaign (April to June). Transferred to the department of the Gulf, he commanded a division in the vicinity of New Orleans until May, 1863, when he joined the expedition to Port Hudson, and in the investment of the place commanded the second division Nineteenth Corps, forming the left wing of the besieging army. In the assault of May 27 he lost a leg while leading the assaulting column. Colonel of artillery June 1, 1863. Returning to duty in Feb., 1864, he held various commands in Louisiana until 1866, when he was mustered out of the volunteer service. He was breveted brigadier-general and major-general for gallantry, and Dec. 31, 1870, was retired from active service with the full rank of major-general. D. at Newport, R. I., Mar. 16, 1879. Revised by James Mercur.

Sherman, William Tecumseh, LL. D.: soldier; b. at Lancaster, O., Feb. 8, 1820; son of Judge Charles R. Sherman. From 1829, when his father died, he was reared in the family of the Hon. Thomas Ewing; in July, 1836, he was appointed a cadet at the U. S. Military Academy, and in July, 1840, he graduated and was appointed a second lieutenant in the Third Artillery; first lieutenant Nov., 1841. He served in Florida until 1842; was in garrison at Fort Moultrie, S. C.; in 1846 he was ordered to California, serving as acting assistant adjutant-general of the department of California until Feb., 1849, when he was transferred to San Francisco on similar duty on the staff of Gen. Persifor F. Smith, commanding the division of the Pacific. Ordered to New York in Jan., 1850, as bearer of dispatches, he was married on May 1 to Ellen, daughter of Thomas Ewing, then Secretary of the Interior. In September of that year he was transferred to the commissary department, with the rank of captain, and stationed at St. Louis and New Orleans until Mar., 1853, when, after a six months' leave of absence, he resigned from the army Sept. 6, 1853, to engage in the banking business in San Francisco; removed to New York in 1857, in which year the affairs of his firm were closed. In 1858 he removed to Leavenworth, Kan., where he practiced law until July, 1859, when he was elected superintendent of the proposed military academy in Louisiana. The institution was opened Jan. 1, 1860, as the Louisiana State Seminary of Learning and Military Academy, and Sherman remained at its head until Jan. 18, 1861, when he addressed a letter to the Governor asking to be relieved "the moment the State determined to secede." His request was soon after granted, and in the latter part of February he left for St. Louis, where for a short period he held the presidency of a street-railway. On May 14, 1861, he was appointed colonel of the Thirteenth Regular Infantry, and soon after his arrival in Washington was placed in command of a brigade in Tyler's division, which he led at the battle of Bull Run July 21. On Aug. 3 his commission of brigadier-general of volunteers was issued, to date from May 17, and Aug. 24 he was ordered to duty in the department of the Cumberland under Gen. Anderson, succeeding to the command of that department Oct. 8, 1861, but was relieved in November and sent to Missouri. After a brief service on inspection duty he was (Dec. 23) placed in command of the camp of instruction and post of Benton Barracks, whence in Feb., 1862, he was transferred to Paducah, Ky., to aid in the operations then in progress on the Tennessee river. Here he organized the division which he subsequently commanded at the battle of Shiloh (Apr. 6–7), where his conduct did much to check disorder and overcome the shock of the unexpected onset. Gen. Halleck reported that Sherman's firmness on the 6th saved the day. Grant officially announced that he was indebted to Gen. Sherman for the success of the battle. The advance upon and siege of Corinth next followed, resulting in the evacuation of that place May 29. In the meanwhile (May 1) he had been promoted to be major-general of volunteers. In July, having been assigned to command the district of Memphis, he occupied that place on the 21st, where he remained until called upon in December by Gen. Grant to take command of the expedition for the capture of Vicksburg. As this movement was intended to be a surprise, the preparations were hastily executed. Embarking his troops Dec. 21, a landing was effected on the 26th at Johnston's Landing, some 12 miles up the Yazoo. On the 29th the attempt to carry the position by assault was bravely made, but without success, and, owing to the surrender of Holly Springs, which overthrew Gen. Grant's plan of co-operation, re-enforcements were arriving to the enemy. Sherman returned to Milliken's Bend, where Gen. McClernand took command Jan. 4, 1863. Sherman was assigned to the Fifteenth Corps, which took a leading part in the assault and capture of Arkansas Post (Fort Hindman) on the 11th.

In the Vicksburg campaign which succeeded, Sherman bore a prominent part with his command—in the expedition up Steele's Bayou to the Yazoo (March); the feint upon Haines's

Bluff (Apr. 29–May 1); movement to Grand Gulf (May 1–6); capture of Jackson (May 14); the occupation of Walnut Hills; and subsequent assaults upon the land-defenses of Vicksburg (May 19 and 22), in each attempt the colors of the corps being planted on the enemy's works; and in the siege which resulted in the surrender of the city July 4, 1863. Sherman with a detached command was at once ordered to pursue Johnston, who with a relieving force had been lying E. of the Big Black, but retreated hastily on the news of the surrender, being eventually driven behind the intrenchments of Jackson. On the night of the 16th Johnston succeeded in escaping. After destroying the railways in all directions Sherman fell back to the W. of the Big Black, along which he lay when summoned (Sept. 22) to the relief of Rosecrans's beleaguered army at Chattanooga. Meanwhile he had been appointed brigadier-general in the regular army, to date from July 4. On Sept. 27 the last of his command were embarked at Vicksburg, reaching Memphis Oct. 4, whence he marched eastward, repairing the railway as he proceeded, until the 27th, when orders reached him at Tuscumbia from Gen. Grant, who had superseded Rosecrans, to abandon all work and hasten on to Chattanooga. On Nov. 15 Sherman arrived at that place, and, after viewing the situation, hastened back to his command, which by forced marches was in position on the 23d, and at 3 P. M. the next day had carried the north end of Missionary Ridge, which position he strongly fortified during the night. At sunrise on the 25th, by orders, Sherman attacked Bragg's right so furiously as to weaken the Confederate center, on which Gen. Thomas was thrown at 3 P. M., and by midnight Bragg's army was in full retreat. Sherman and Hooker pursued at daylight (26th) the routed army, the former turning back on the 29th to take command of the force for the relief of Burnside, besieged at Knoxville and reported to be unable to hold out later than Dec. 3. He moved rapidly, making the last 84 miles in three days, and Longstreet was compelled to raise the siege and retreat to Virginia, whereupon Sherman returned to Chattanooga and ordered his command into winter quarters. Since Oct. 27 Sherman had commanded the department of the Tennessee, though retaining command of troops in the field.

The following year (1864), on Feb. 2, Sherman moved out from Vicksburg with four divisions, and, making his way to Meridian, the great railway center of the Southwest and chief source of supplies for the Confederate army in that region, destroyed the railways in every direction, bridges, locomotives, etc.; but, owing to the failure of the cavalry division of Smith to perform its part, the expedition was obliged to return (Feb. 26). Gen. Grant having been promoted to be lieutenant-general, he named Sherman as his successor in command of the military division of the Mississippi, composed of the departments of the Ohio, the Cumberland, the Tennessee, and the Arkansas. Assuming this command about the middle of Mar., 1864, Sherman at once entered upon the task of organizing his army and enlarging his communications preparatory to the spring campaign, which was to be directed against Atlanta, Ga., and to begin simultaneously with the opening of the Richmond campaign by Grant. Accordingly, on May 6, Sherman set forth with his army from the winter quarters about Chattanooga. To oppose him was the army of Johnston, lying about Dalton and numbering not far from 45,000. Sherman's force numbered 98,797 men of all arms, with 254 guns. Johnston was compelled, by Sherman's flank movement, to abandon Dalton May 13, and fall back upon Resaca, which in turn he evacuated after a severe battle (May 15), and retreated to Allatoona Pass. Without attempting to force this strong position in front, Sherman, on the 23d, by a circuit to the right, marched on Dallas. Johnston took up a strong position about New Hope Church, where severe fighting occurred May 25–28. On June 1 Allatoona was occupied by Sherman and made a secondary base of supplies; on the 4th Johnston retreated to the strong positions of Kenesaw, Pine, and Lost Mountains. From June 10 to July 2 almost constant fighting occurred, when, after two unsuccessful assaults on Kenesaw (June 27), Sherman began (July 2) another flank movement by the right. That night Kenesaw was abandoned by Johnston, and by July 10 the latter had fallen back across the Chattahoochee and taken up a line covering Atlanta. Here he was superseded in command (July 17) by Hood. On this day Sherman completed his crossing of the Chattahoochee, and on the 19th and 20th the battle of Peach-tree Creek was fought, resulting in the withdrawal of the enemy to the intrenchments of Atlanta. On the 22d Hood, by a night march, had gained the left of Sherman's line, which he attacked furiously, a fierce battle ensuing, the enemy finally retiring to their defenses. A movement to flank Hood out of Atlanta by cutting the railways in his rear was in progress when (July 28) Hood made a vigorous attack, but was repulsed with great loss. On Aug. 12 Sherman was made a major-general in the regular army. Sending Kilpatrick out to destroy the railways in the rear, he swung around to the S. W., and by Aug. 28 his entire army, excepting the Twentieth Corps, was behind Atlanta, busily engaged in destroying the only railways by which that city was supplied. During the night of Sept. 1 Hood evacuated Atlanta, after destroying everything that could be used, and on the 2d Slocum with the Twentieth Corps entered the city. Sherman's losses from Chattanooga amounted to 31,687; the Confederate loss was near 35,000. Hood had been re-enforced from time to time, and had yet an effective force of 40,000. Sherman received in June Blair's Seventeenth Corps, numbering 13,000. Hood then drew off to about Lovejoy's, uniting with Hardee, while Sherman gave his army a much-needed rest. On Sept. 28 Hood resumed operations by crossing the Chattahoochee and operating against Sherman's communications, appearing before Allatoona Oct. 5, held by a garrison of 1,944 men. The repeated assaults of the Confederates were of no avail, and were finally abandoned, but not until 707 of the little band had fallen, while the loss of the enemy was not less. Hood then moved N. W., Sherman following as far as Galesville, Ala., when, becoming convinced that Hood's only design was to draw him out of Georgia, he abandoned further pursuit, and detaching the Fourth and Twenty-third Corps to re-enforce Thomas at Nashville, and leaving the latter to defend Tennessee against Hood, he ran back all the surplus property and supplies to Chattanooga, broke up the railway, destroyed Atlanta, and, cutting the telegraph behind him Nov. 12, started on the 15th upon his famous "march to the sea." The history of this march is well known. On Dec. 10 Sherman was before Savannah; Fort McAllister was carried on the 13th; and on the night of the 20th Savannah was evacuated while Sherman was on his way to Hilton Head to arrange for making this very step impossible. Returning to Savannah, he entered the city on the 23d. His loss from Atlanta was 809, including 103 killed, 428 wounded, and 278 missing. By resolution of Jan. 10, 1865, the thanks of the people and of the Congress of the U. S. were tendered to Gen. Sherman and his command. After resting at Savannah and refitting his army he moved northward Feb. 1. Columbia was occupied on the 17th; Cheraw, Mar. 3; Fayetteville, Mar. 11; the battle of Averysboro was fought Mar. 16; that of Bentonville, Mar. 19–20; Goldsboro was occupied Mar. 22; Raleigh, Apr. 13; and Apr. 18, at Durham Station, Sherman accepted the surrender of Johnston's army on a basis of agreement which was rejected by the Government, but on the 26th received the surrender on the terms accorded to Lee by Grant. Resuming his march, Washington was reached May 24, 1865, where, after the grand review, his army was dissolved. On June 27, 1865, he was appointed to command the military division of the Mississippi; was promoted to be lieutenant-general July 25, 1866, and Aug. 11 assigned to command the military division of the Missouri. On the accession of Gen. Grant to the presidency he became general (Mar. 4, 1869). In 1871–72 he made an extended tour in Europe and the East. In Oct., 1874, the headquarters of the army were removed from Washington to St. Louis, but in Apr., 1876, were re-established at Washington. He published in 1875 *Memoirs of General W. T. Sherman, by himself* (revised edition, 1886). Retired Feb. 8, 1884. D. in New York, Feb. 14, 1891. Revised by JAMES MERCUR.

Sherry Wine: SEE WINE AND WINE-MAKING.

Sherwood, MARY E. (*Wilson*): See the Appendix.

Sherwood, MARY MARTHA (*Butt*): author; b. in Stanford, Worcestershire, England, May 6, 1775; married Capt. Sherwood of the army 1803, with whom she lived in India 1804–18, settling on her return in Wickwar, Gloucestershire, where they lived many years. Her husband died in 1849; she died in Twickenham, Sept. 22, 1851. She was the author of 90 vols., chiefly with a moral object, and many for juvenile readers. The best-known are *Little Henry and his Bearer*, *Henry Milner*, *Ermina*, *Roxobel*, and *The Lady of the Manor*. A *Memoir*, with an autobiography, was published by her daughter, Mrs. Sophia Kelly (London, 1854), and an edition of her works appeared in New York about 1852.

Sherwood, WILLIAM H.: See the Appendix.

Sherwood Forest: a hilly region in the west of Nottinghamshire, England, between Nottingham and Worksop, about 25 miles in length by 8 in breadth. It was once a royal hunting-forest, and known to legend as the scene of Robin Hood's exploits. It is divided into farms, and it includes the town of Mansfield, several villages, and many parks and gentlemen's country-seats. The soil is gravelly and usually unproductive.

Shetland (or **Zetland**) **Islands**: a group of about 100 islands, of which 23 are inhabited, in the Atlantic Ocean between lat. 59° 50′ and 60° 52′ N., and belonging to Scotland. Area, 551 sq. miles. Pop. (1901) 27,755. The largest island is Mainland, with the town of Lerwick; among the others are Yell, Unst, Barra, and Foula. They are all treeless, high, and rocky, presenting steep, abrupt, and bold coasts, with fine natural harbors, and a rugged, wild surface in the interior. In the valleys some oats, barley, and potatoes are cultivated. The climate is mild and damp. Many cattle and sheep are reared, but the principal occupation of the inhabitants is fishing, especially for cod and herrings, giving employment to 7,500 men and 300 boats. Eggs form an important article of export. See Hibbert, *A Description of the Shelland Islands* (new ed. 1892).

Shevchen'ko, Taras Grigorovich: the greatest of Little Russian writers; b. Feb. 25, 1814. He was the son of the serf of a German landed proprietor in the government of Kiev, and from his childhood was exposed to brutal treatment, but picked up the rudiments of an education, early showing a talent for song and also for painting, which caused him to be apprenticed to a house-decorator in order to learn that business. In 1832, with his master, he moved to St. Petersburg, where he attracted the interest of the poet Zhukovskiĭ and others, who bought his freedom. At first all went well with him, but in 1847, owing to some of his writings and to his participation with Kostomarov (*q. v.*) in a society of which the Government disapproved, he was banished as a common soldier to the Asiatic frontier of the empire. In this vicinity he passed the next ten years, part of the time in prison and forbidden to write or paint. After the accession of Alexander II., the intercession of powerful friends procured his pardon, but although he began to compose again his health was broken and he died in St. Petersburg, Feb. 26, 1861. Shevchenko's *Kobzar*, a volume of lyrics in the Little Russian dialect, appeared in 1840 (new ed. 1860), and achieved great popularity. The deep poetic sympathy for the life of the people in these pieces made their author the idol of his countrymen, while the hopeless sadness and pessimism of his tone were the natural result of his own experiences. In 1841 he brought out *Haidamaki*, a Cossack epic, also the only Russian one with claims to greatness, and this was followed by *Hamalia*, *Maiak*, and other pieces. See article in the *Revue des Deux Mondes* (1874), and *The Peasant Poets of Russia*, by W. K. Morfill, in *The Westminster Review* (July, 1880). A. C. Coolidge.

Shib'boleth [from Heb. *shibbōleth*, ear of corn, stream, deriv of **shābhal*, increase, flow]: a test or password by which one's rank in society is indicated. It is recorded in Judges xii. that after Jephthah's victory over the Ephraimites the men of Gilead detected their fugitive enemies by requiring them to pronounce the word *shibboleth*, which the Ephraimites called *sibboleth*, and thus betrayed their origin; whereupon they were put to death.

Shield [O. Eng. *scield*: O. H. Germ. *scill* (> Mod. Germ. *schild*): Icel. *skjöldr*: Goth. *skildus*]: a buckler, a broad defensive weapon carried upon the arm to protect the body from blows and missiles. Most savage nations employ shields of some form, and all the nations of antiquity used them, as in mediæval Europe, down to the general introduction of gunpowder in warfare. The shield is of great importance in heraldry. For practical use, shields were of leather, wood, basketwork, etc. See Heraldry.

Shieldrake: See Sheldrake.

Shields: the name of two towns of England, about 8 miles from Newcastle, opposite to each other on the Tyne, near its entrance into the North Sea—North Shields on the northern bank, in the county of Northumberland; South Shields on the southern, in the county of Durham (see map of England, ref. 4–I). North Shields has two docks—the Northumberland, of 55 acres, opened 1857, and the Albert Edward, of 24 acres, opened 1884. There are large exports of coal and coke and imports of timber, grain and esparto-grass. North Shields forms part of the borough of Tynemouth (*q. v.*). The total tonnage entered and cleared at both ports, exclusive of that coastwise, was, in 1893, 3,540,869. South Shields is an old town, but is well built in its modern part. It has a town-hall, public library and museum, marine school, etc., and a park of 45 acres. The south pier, a breakwater nearly a mile in length, was begun in 1854, and is not yet completed (1895). The Tyne docks of the North Eastern Railway, covering 50 acres, are chiefly used for shipping coal and coke. The harbor is lined with ship and boat yards, and alkali, glass, and iron works. On an eminence overlooking the harbor are the remains of a Roman station where coins, portions of an altar, etc., have been dug up. South Shields sends one member to Parliament. Pop. (1891) 78,431.

Shields, Charles Woodruff, D. D., LL. D.: educator; b. at New Albany, Ind., Apr. 4, 1825; graduated at Princeton College (1844) and Theological Seminary (1847); pastor of Presbyterian churches at Hempstead, Long Island, 1849–50, Philadelphia, 1850–65; since 1865 Professor of the Harmony of Science and Revealed Religion in Princeton College; ordained priest in the Protestant Episcopal Church May 28, 1899. He has published *The Presbyterian Book of Common Prayer according to the Revision of the Westminster Divines* (New York, 1864; 4th ed. 1886); *Liturgia Expurgata* (Philadelphia, 1864; 3d ed. New York, 1884); *Philosophia Ultima, or Science of the Sciences* (vol. i., New York, 1877; 3d ed. 1889; vol. ii. 1889); *Order of the Sciences* (1884); *Religion and Science in their Relations to Philosophy*; *Essays on Church Unity* (1891); *The Historic Episcopate* (1894); and *The Question of Unity* (1894).

Shi-Hwang-Ti: See Chi-Hwang-Ti.

Shi'ïtes [Arab. *shiah*, sect]: the most numerous of Mussulman heretical sects. Their main characteristics are rejection of the Sunna (see Sunnites) and extravagant devotion to Ali, the son-in-law of the prophet Mohammed and the fourth caliph. The most advanced maintain that the revelation of the Koran was intended by God for Ali, but given to Mohammed through an error of the archangel Gabriel. The majority, however, are content with denouncing the first three caliphs, Abubekir, Omar, and Othman, as usurpers, and asserting that Ali was the rightful successor of Mohammed. The memory of the tragic death of Ali by murder, and of his two sons, Hassan and Housseïn, by poison and murder, inflames the Shiïtes to this day beyond conception and is annually commemorated with bloody rites. The bitterness of hatred between the Sunnites and Shiïtes has never been equaled even in the most envenomed wars of Christendom. To kill one Shiïte is declared by the Sunnites more acceptable in the sight of God than the slaughter of seventy Christians. In the treaties imposed by the Ottomans on Persia the first clause has commonly stipulated that the Persians, who are Shiïtes, should not hereafter curse the memories of the first three caliphs. The Shiïtes are found mainly in Persia, India, and among the Tartars. They number probably not more than 18,000,000, and are divided into many minor and hostile sects. E. A. Grosvenor.

Shikarpur': town; in the Presidency of Bombay, British India; in a low, level, regularly inundated, but fertile and not unhealthful plain; in lat. 27° 57′ N., lon. 68° 45′ E.; 15 miles W. of the Indus, with which it communicates by a canal (see map of N. India, ref. 5–A). It is an entrepôt for transit trade between the Bolan Pass and Karachi. Pop. (1891) 42,004.

Shiko'ku: the third in importance of the islands forming the empire of Japan: between lon. 132° and 135° E. and lat. 32½° and 34½° N.; area, 6,855 sq. miles. The mean temperature is about 59° F. The island comprises the provinces of Tosa, Awa, Sanuki, and Iyo. The surface is hilly, and there is no mountain over 4,600 feet high. The chief towns are Kochi, Matsuyama, Takamatsu, and Tokushima. Pop. (1891) 2,827,397. J. M. D.

Shil'laber, Benjamin Penhallow: humorist; b. in Portsmouth, N. H., July 12, 1814; entered a printing-office at Dover 1830; was a compositor at Demerara, Guiana, 1835–37, and in the office of *The Boston Post* 1840–47; was editorially connected with the latter paper 1847–50, acquiring celebrity by his "sayings of Mrs. Partington"; was printer and editor of *The Pathfinder* 1850–52; proprietor and editor with Charles G. Halpine ("Miles O'Reilly") of *The Carpet-bag* 1850–52; returned to the *Post* 1853–56, and was one of the editors of *The Saturday Evening Gazette* 1856–66: retired to his home at Chelsea, Mass., and devoted himself to

literature. He published several very successful volumes, among which were *Rhymes with Reason and Without* (1853); *Poems* (1854); *Life and Sayings of Mrs. Partington* (1854); *Knitting-work* (1859); *Partingtonian Patchwork* (1873); *Ike and his Friends* (1879); and *Wide Swath*, a volume of collected verse (1882). D. at Chelsea, Nov. 25, 1890. H. A. B.

Shilling [O. Eng. *scilling*: O. H. Germ. *scilling*: Icel. *skillingr*: Goth. *skilliggs*, possibly deriv. of *skellau*, ring]: a British coin containing 87·27272 grains of silver, ·925 fine, and equal to $\frac{1}{20}$th of a pound sterling, or to 24·3 cents U. S. Prior to Henry VII. the shilling was a money of account equal to a certain number of silver pennies, fixed at twelve by the Conqueror. When the decimal system was introduced in the U. S. the shilling had a value ranging from $\frac{1}{8}$th of a dollar in New York to $\frac{3}{14}$ths in Georgia.

Shi'loh [from Heb. *Shīlōh*, liter., tranquillity, rest]: an ancient town of Palestine; the present *Seilun*; 20 miles N. of Jerusalem. It was the seat of the ark of the covenant from the last days of Joshua to the time of Eli, but sank into total insignificance when the ark was carried away by the Philistines. Some insignificant ruins of a Roman town are found on the spot, but none of Jewish origin. A large fountain is in the neighborhood.

Shiloh: a locality in Hardin co., Tenn.; about 2 miles W. of Pittsburg Landing: on Tennessee river, taking its name from a rude log chapel there known as Shiloh Church. During the civil war and after the fall of Forts Henry and Donelson Gen. Grant moved by transports up the Tennessee, and by the middle of Mar., 1862, his army lay stretched out from Shiloh Church to Pittsburg Landing, the latter a mere steamboat landing, as its name implies. The division of Lewis Wallace was stationed at Crump's Landing, some 8 miles lower down and nearly opposite Savannah, at which last-named place Gen. Grant established his headquarters and dépôt of supplies. Gen. Buell, then on his way from Nashville, was to join with Grant at this point, when a general advance was to be made. Meanwhile Gen. Beauregard had assembled at Corinth, an important railway center 92 miles E. of Memphis, all the available forces from the Mississippi valley, where he was joined on Mar. 22 by the command of Gen. A. S. Johnston from Kentucky and Middle Tennessee, who assumed control of the combined forces of between 40,000 and 50,000 men; the order giving the detailed organization of the army was dated Mar. 29. Aware of Buell's approach, it was decided on the 2d to attack Grant before Buell could join him. The attack was arranged for the morning of the 5th, and on the 3d the Confederate army moved out from Corinth. A heavy rain and other causes delayed the attack until the 6th, when at an early hour the blow was struck, taking the Union army by surprise, and their front line was driven out of its camps, excepting two of Sherman's brigades, whose position outreached the first line of battle. These brigades resisted stubbornly, and by the personal efforts of Sherman a gallant stand was made, but their flank becoming exposed they were compelled to give ground and take position on McClernand's right, which was held until afternoon, when both divisions were forced back. Grant had arrived on the field at 8 A. M., and ordered Lewis Wallace to hasten up with his division, while he set to work to reform his troops and repair his lines. The divisions of Hurlbut and W. H. L. Wallace next received the enemy's attention, assault after assault being delivered along the whole line, but these were each time repulsed, until at about 4·30 P. M. Hurlbut's exhausted division fell back, thus compelling Wallace to retire half an hour later. At this moment that heroic leader, whose gallant defense had been the admiration of all, received a mortal wound. The road taken by Lewis Wallace's advance not leading him to the point where Grant wished him to go, he was compelled to countermarch, and did not reach the field till nightfall. The Union army was then crowded back nearly to the river, with all their encampments, some sixty guns, and 3,000 prisoners in possession of the enemy. During the brief interval, while the enemy halted in attack after the withdrawal of W. H. L. Wallace, the remaining Union artillery was hastily assembled by Gen. Webster, chief of Gen. Grant's staff, advantageously posted on a commanding ridge covering Pittsburg Landing, so that at 6 P. M. a renewal of the attack was successfully resisted, and, two gunboats adding their fire, the enemy withdrew. Buell's advance had reached Savannah on the evening of the 5th, but it was after 6 P. M. of the 6th when Ammen's brigade crossed—just at the close of the day's battle. By next morning all of Nelson's, Crittenden's, and McCook's divisions had crossed, and, with Lewis Wallace's, some 25,000 fresh troops were now available. The Confederate leader, Gen. Johnston, had fallen at 2·30 P. M. on Sunday, the command devolving upon Beauregard, by whom the plan of operations was prepared and carried out. At daylight on Monday Grant attacked along the whole line, but was gallantly resisted, a stubborn battle continuing until 4 P. M., when the Union lines of the day before and thirty guns were regained, and the Confederate army was in full retreat for Corinth; but pursuit was not pressed. Beauregard reported a loss of 1,728 killed, 8,012 wounded, and 959 missing. Grant's loss was 1,735 killed, 7,882 wounded, and upward of 3,000 in prisoners. The armies were about equal in strength on the first day, but on the second the Confederates were largely outnumbered. Revised by JAMES MERCUR.

Shimo'da: a port of Japan; situated at the extremity of the Idzu Peninsula, and interesting as being the earliest port opened for U. S. shipping (see map of Japan, ref. 7–D). It was first visited by Commodore Perry and the U. S. squadron in 1854, and became in 1857 the residence of Townsend Harris, the first U. S. representative in Japan, and it continued to be his residence until the substitution of Kanagawa (now Yokohama) in 1859. A frightful earthquake in 1857, accompanied by a tidal wave, devastated the town and injured the harbor, leaving a slippery rock-bottom. From Shimoda is shipped most of the stone used in Yokohama and the capital; the quarries are at Kisami in the neighborhood. Pop. (1890) 7,000. J. M. DIXON.

Shimonosek'i: town of Japan; at the southwestern extremity of the main island; in lat. 33° 56′ N. It was formerly the entrepôt for European goods coming from Nagasaki and destined for the interior of Japan; is now a port of entry (see map of Japan, ref. 7–A). It commands the Strait of Shimonoseki, which forms the western entrance from the open ocean to the Inland Sea. Pop. (1890) 12,000. During the summer of 1863 three vessels, U. S., Dutch, and French, were fired upon from batteries on the north shore of the Shimonoseki Strait, and the next year this insult was avenged by a combined fleet of these powers, acting along with Great Britain, which bombarded and destroyed the town. In a subsequent convention the sum of $3,000,000 was demanded by these four powers in compensation for "damages resulting to the interests of treaty powers" and for expenses of the expedition. The final installments of this indemnity were paid by the Japanese Government in 1874. The U. S. Government afterward refunded its share. Revised by J. M. DIXON.

Shiner: any one of several small North American freshwater cyprinoid fishes, with a compressed body and shining, silvery color. *Notemigonus chrysoleucus*, a form allied to the breams (*Abramis*) of Europe, but smaller, is one of the most abundant species in the streams of the Eastern and Middle States. The name is also loosely applied to various other silvery fishes, as the dollar-fish.

Shing-king: the most southerly province of Manchuria, sometimes called *Liao-tung* (which properly denotes only the part E. of the Liao river), and sometimes *Kwan-tung*, i. e. the region "east of the *kwan* or barrier," at the end of the Great Wall. It forms an irregular triangle, with the apex pointing southward into the Gulf of Peh-chili, and consists of a fertile alluvial plain in the S. W. and an elevated mountainous country in the N. and E. The chief ports are NIU-CHWANG (*q. v.*), Taku-shan, on the Ta-yang river, 12 miles from the Yellow Sea, and Pi-tse-wo, with a shallow but well-protected harbor, lat. 39° 18′ N., lon. 122° 18′ E. Capital, Mukden.

Shinn, GEORGE WOLFE: See the Appendix.

Shinn, WILLIAM POWELL: civil engineer; b. at Burlington, N. J., May 4, 1834. At the age of sixteen he was a rodman on an engineer corps of the Ohio and Pennsylvania Railroad (now Pittsburg, Fort Wayne and Chicago Railway), and a year later became assistant engineer. For twenty years following he was engaged as engineer, manager, and agent for important railways, involving trusts of great responsibility. He had charge, during 1873–79, of the buildings and operating of the Edgar Thomson steel-works at Braddock, Pa. From 1881 to 1886 he was vice-president of the New York Steam Heating Company, and from 1886 to 1891 he was vice-president and general manager of the New York and New England Railway Company. He published many papers on railway transportation, accounts, and economics.

which are regarded as of great value. He was elected president of the American Institute of Mining Engineers in 1880, and president of the American Society of Civil Engineers in 1890. D. at Homewood, Pa., May 5, 1892.

Shinshiú, or **True Doctrine** (known also as *Ikko-* or *Monto-shiu*): a powerful sect of Japanese Buddhists, having their headquarters at Kioto, in the great *Nishi* (West) *Hongwanji* temple. Its founder was a man of good family, Shinran Shonin (1173–1262 A. D.), who studied as a lad at Hiyeizan. (See Kioto.) The Shinshiu sect finds salvation in the "extinction of passion," a doctrine at once the cause and effect of salvation, which salvation is called Nirvâna. The doctrine of "help from another" is also taught, and Amita, or "the boundless" Buddha, is relied upon for the completion of merits and a rebirth into paradise. In this sect there is less difference than in any other between laymen and priests, the latter being allowed to marry and to eat flesh and fish.

J. M. Dixon.

Shinto (liter., Way of the Gods): the ancient cult of the Japanese, which has scarcely a title to be classed among religions, having no moral system and no eschatology. It has passed through three phases: the early stage, when it was part and parcel of the national life, and was as much political as religious; the second stage, when it had to struggle with the powerful and profound system of Buddhism, which almost swallowed it entire; and the modern stage, when a brilliant band of literary men sought to rescue it from the obscure condition into which it had fallen. These strove to identify it with a reformed patriotism and a restored imperialism, and their views finally triumphed in the restoration of 1868. The first period may be considered to have lasted until about A. D. 550, and its history is told in the *Kojiki* and the *Nihongi*, written a century and a half later —books which may be called the Japanese scriptures, in so far as they are concerned with the creation of the race and its early history from a religious standpoint.

Probably about the year 400 A. D. the ancestral worship out of which Shinto developed was so far organized that the home was no longer deemed sufficient, and a separate temple was erected. Over it was placed as custodian, or chief priestess, a daughter of the Mikado. When Buddhism arrived from the West in the sixth century it seems to have adopted wholesale the Shinto pantheon, and all that remained distinctive of the old ritual was the *gohei*. From this era is to be dated the term *Shinto*, way of the gods, in contrast with *Butsudo*, or way of Buddha, both Chinese terms. The *gohei* (liter., august cloth or present) was originally a piece of hempen cloth hung on the sacred *sakaki* (*Cleyera Japonica*) in honor of the gods. The material was changed successively to cotton, silk, and finally to paper. In modern temples all that is visible to the eye of the worshiper is a mirror and a bundle of these zigzag paper-cuttings attached to a rod. The paper is usually white, but on occasion a succession of *gohei* may be seen—yellow, red, black, white, blue—in honor of the gods of wood, fire, earth, water, and metal respectively. The wand plays a considerable part in the divination with which Shinto became associated during the thousand and odd years of its eclipse. The god was supposed to come in answer to the worshiper's call and to possess the wand, and through it the *gohei*, the whole rite resembling closely the Shamanism of Northern Asia. The priests of Shinto seem to have made clever use of the phenomena of water boiling on mountain heights at a low temperature, and of the heat-absorbing qualities of salt, in their ordeals of water and fire. See *Esoteric Shinto*, by Percival Lowell, in vols. xxi.–xxii. of the *Transactions of the Asiatic Society of Japan*.

The Tokugawa shogunate strongly favored Buddhism, with its gorgeous ritual and magnificent temples; but a reaction toward the simplicity of early Japanese life and customs set in among native scholars, Mabuchi (1697–1769), Motoori (1730–1801), Hirata (1776–1843) being the most prominent. This movement is known as the revival of pure Shinto, and was directly hostile to the dual rule under the shogunate. Satsuma, always less Buddhistic than the rest of Japan, led the restoration movement in 1868, and the result was altogether favorable to Shinto, which became the only state religion. Buddhist temples were stripped, "purified," and handed over to Shinto keeping. The revived religion, however, proved entirely too feeble to supplant Buddhism and quickly lost ground. "Pure Shinto," indeed, was largely the fad of scholars, for Buddhism had appropriated and assimilated almost everything that was dear to the people in their old religion.

The Shinto temple proper (*yashiro* or *jinja*) differs from the Buddhist *tera* (monastery or temple) in being thatched, destitute of furniture, smaller, and usually double. The inner shrine (*honsha*) at the back contains, carefully inclosed in a succession of boxes, the sword (if a male deity), or mirror (if a female), which is jealously guarded as the sacred treasure of the place. With this mirror the mirror exposed to view in the outer shrine or oratory (*haiden*) has nothing whatever to do, being a loan from Buddhism. Worshipers ascend the steps in front, strike the temple-gong with a rope provided for the purpose, smite or rub their hands together, and then depart after throwing some coins on the floor. At the entrance to the temple is a torii, or sacred arch. Shinto morality is practically a Rousseau-like following of natural impulses, and proclaims neither heaven nor hell; its priesthood is not a caste, nor wholly devoted to a religious life; it is largely a form of hero-worship, and intensely national, and its chief deity is Amaterasu, goddess of the sun, from whom the Mikado traces his descent.

Other deities are Susano, a kind of Mars, presiding over the moon; and his daughter Uga-no-mitama, popularly worshiped as Inari, the goddess of rice. Most of the deities appear to be deified human beings. See article on Ise; for Japanese mythology, the *Introduction to the Kojiki*, *Transactions of the Asiatic Society of Japan* (vol. x., supp.), and various articles in these *Transactions* by Ernest Satow.

J. M. Dixon.

Ship-building: naval architecture, or the art of designing and constructing vessels for navigation, and more particularly the larger vessels, or those which carry masts, whether intended for war or for commercial purposes. It is impossible to state with any degree of accuraey the time or the portion of the globe in which ship-building originated. Among razor-knives found in Denmark, belonging to the "bronze age" in Europe, are several with representations thereon of galleys which compare favorably with those of ancient Rome. The Phœnicians were the greatest commercial people of ancient history, and, instructed by the Egyptians, seem to have been the first to make material progress in the construction of vessels. Among the paintings in the tomb of Rameses the Great is a representation of a naval combat between the Egyptians and a people, supposed to be Phœnicians, whose ships are propelled by sails. A biblical reference to the power of Tyre, capital of Phœnicia, describes its vessels and their construction; the planking being made of the fir-trees of Senir (Hermon), the masts of cedars of Lebanon, the oars of the oaks of Bashan, the rowing-benches of ivory, and the sails of fine linen of Egypt. Reference is also made to mariners, pilots, calkers, and men of war, showing the progress made in the arts of ship-building and navigation. A peculiar feature in the construction of the ships of the Egyptians was the planking, which was about 3 feet square, and was laid overlapping, like shingles upon a roof, being fastened to the ribs or frames by wooden tree-nails. According to Herodotus the Nile vessels were fitted with rudders at the stern, thus antedating the application of that invention to seagoing vessels by several centuries. The vessels of the Phœnicians served as models to the Greeks, whose ships, at the height of their civilization, show a marked resemblance to those of the dwellers in Tyre.

Ship-building in Europe.—The nations of the north of Europe developed a class of vessels which, from specimens found buried in mounds in Scandinavia and Denmark, show a remarkable knowledge of the forms of least resistance, together with the strength of materials and their proper distribution, and suggest that the influence of the Phœnician ship-builders had in some way penetrated to the north of Europe.

Cæsar, in his history of the campaign against the Veneti in the year 54 B. C., states that their ships were built entirely of oak, and designed to endure the force and violence of the tempests; the rowers' benches were fastened by iron spikes; instead of cables, they secured their anchors with chains of iron. A Roman ship of the time of Trajan, sunk in Lake Ricciola, was raised after more than 1,300 years: the planking was of pine and cypress, covered on the outer side with sheets of lead fastened with copper nails.

The Greeks and Romans had a peculiar method of girding their vessels with long hempen cables, which, passing through holes at the stern-post, continued all around the vessel fore and aft immediately under the wales; also the hulls were undergirded transversely in the same manner.

The ropes were tightened by levers, and by shrinking when wet drew the members of the vessel closely together, after the fashion of hoops upon a barrel. The hulls were thus strengthened to resist the violence of heavy seas and for ramming.

The sailing vessels of the early Roman empire, such as those engaged in the corn-trade with Egypt, were the direct precursors of the large sailing vessels which superseded the galleys propelled by oars.

In the fifteenth century the Spaniards and French made great progress in the art of ship-building, the French being the first to apply the principles of mathematics to the design and construction of vessels. The English availed themselves of the researches of the French, and adopting the forms of the French vessels captured by them soon acquired renown as builders of fast and powerful vessels.

Ship-building in America.—The great forests of North America enabled the English colonists to take the lead in the production of vessels at small cost. For many years the models and methods of the English and French were followed, but the impetus given by the fitting out of privateers during the latter part of the seventeenth century and the beginning of the eighteenth did much to create a new era in American ship-building. As has been well stated, "there was assembled in New York between the year 1685 and the year 1700 such a swarm of fighting sailor-men, and such strong stimulus was given to the marine industries of ship-building, rope-making, and the putting up of sea-stores, that only a few cities in Europe could compare in completeness of equipment with New York."

In 1850 the ship-builders of the U. S. cut loose from the trammels of precedence and brought out the clipper ships which, owing to their remarkable performances, soon influenced the naval architecture of foreign nations. One of this class, the Red Jacket, of New York, made the trip from Sandy Hook to Melbourne, 12,720 miles, in 69 days and 11 hours; another, the Sovereign of the Seas, of Boston, sailed 5,391 miles in 22 days. The Great Republic was the largest of this class of vessels; she was 325 feet long, 53 feet wide, and 37 feet deep, with a capacity of 4,000 tons. She had four masts, the main-yard being 120 feet long; a suit of her sails contained 15,653 sq. yards of canvas, or sufficient to cover about 3¼ acres of land. So fleet were these vessels that for long distances, especially where the trade-winds could be utilized, they were scarcely inferior to vessels propelled by steam, and so were enabled to carry a large amount of the world's trade long after steam-vessels were successfully introduced.

A great change took place in the art of ship-building when the steam-engine was applied to ships. "The old proportions and forms so well suited for the speed of sailing ships and the forces impressed upon them were ill adapted for propulsion by the paddle-wheel, and still more so for propulsion by the screw." The form now adopted for propulsion by the screw has been arrived at by successive steps, as experience and investigation have pointed the way.

The investigations with regard to the strength of materials, the forms of least resistance, and the character of the stresses and strains brought upon ships from the action of wind and waves have brought ship-building almost to an exact science.

Materials.—Vessels are built of wood, of iron, of steel, and of a combination of wood and iron or steel. The era of wooden vessels in the U. S. reached its perfection in the building of the war-vessel Trenton, which was wrecked at Samoa during the great storm of 1889. Great Britain early saw the advantages of constructing its vessels, both merchant and naval, of iron, and has led the way in the development of iron and steel construction.

From the difficulty of obtaining the necessary strength without excessive weight wooden ships have been confined to moderate dimensions. Their advantages are the ease with which they can be constructed and consequent low cost, and the fact that below the water they can be covered with copper, which by exfoliation clears the bottoms of barnacles and marine growths, thus enabling them to remain afloat a long time without docking. On the other hand, owing to the nature of the material of which they are constructed, frequent and extensive repairs are necessary.

The introduction of iron and steel as a material for ship-building made possible ships of almost any size, the only limit being the cost of production and maintenance, and the size of existing docks. The difficulties experienced are deterioration from the action of salt water upon the metal, and the fact that barnacles and marine growths seem to claim the bottoms of iron and steel vessels as their own peculiar field for operation, especially in tropical waters, thereby retarding the speed to a marked degree, and making necessary the frequent docking of vessels to clean and paint the bottoms. To obviate this trouble many medium-sized vessels are built of iron or steel throughout, except the outer skin and deck plank, which are of wood. The bottom planking, being of wood, is readily coppered, while the framework and topsides, being of metal, confine the repairs chiefly to the renewal of the planking. This style of construction is called "composite."

Ship-designing.—It is not proposed to enter into a discussion of the theoretical principles involved in the science of ship-design, but simply to state certain conditions that confront the naval architect in the preparation of a design for an ordinary seagoing merchant vessel, and to illustrate the principal steps in the preparation of the design. The naval architect must provide a hull with continuous fair lines, alike pleasing to the eye and giving economy in propulsion—that is, no abrupt forms should be found tending to create eddies and so increase the resistance in propelling the vessel through the water. The vessel must have a certain capacity for carrying cargo, accommodation for a specified number of passengers and crew, and power sufficient to drive her at a given speed, with due regard to the economical consumption of fuel used in generating the power. A sufficient amount of coal must be carried to allow the machinery to be driven at full power during the entire trip. Appliances must also be provided that will enable the vessel to be under control at any and all times. It is the function of the naval architect to combine these features so that the vessel may be easy in her movements at sea, float at a predetermined draught-line, possess under all circumstances the property of returning to an upright position when inclined by the action of wind and waves, and to provide a structure that in all conditions of service shall have ample strength to resist any stresses brought to bear upon it. To effect this the naval architect must possess a knowledge of complex physical laws and a well-trained judgment in applying reliable experimental data. The minimum cargo capacity, passenger accommodations, speed, and the maximum draught are readily determined from the requirements of the company for which the steamship is to be built. The first step is to assume by comparison a total displacement of vessel that will fulfill the given conditions. The factors upon which the exact displacement or weight of the vessel depends are the power necessary to attain the given speed, with the weight involved, the amount of fuel necessary, and the weight of the hull structure. The most reliable method of determining the indicated horse-power required is to construct curves of the powers and speeds, ascertained by trial, of vessels similar in form but of different displacements. Similar vessels are those having the same ratio of length to breadth and to draught and the same degree of fineness. Mr. Froude found by repeated experiments that the resistances of such vessels, at speeds proportional to the square roots of their displacements, vary as the displacements. The speeds and powers taken from the platted curves are then raised by Froude's law of comparisons to the assumed displacement and a new curve drawn through the points thus established. From this curve the power required for the given speed may be obtained and the weight of the machinery ascertained by direct calculation. The amount of coal necessary is also computed direct from the power, experience having shown that an average of 2½ lb. of coal per hour is required for each indicated horse-power of the machinery. By comparison with the known weight of the hull of a similar vessel the architect is enabled to establish a ratio of weight of hull to volume of displacement that will allow him to fix upon a close approximation to the weight of the completed hull. Having then the weights of hull, machinery, coal, cargo, passengers, outfit, etc., the total weight or displacement of the vessel must equal the sum of these weights, so that the architect can at once begin the plans showing the underwater form of the vessel and make the necessary computation of cost. The behavior of the vessel at sea and the line at which the vessel will float depend upon certain geometrical properties of the form of the vessel. A ship floating at rest displaces a volume of water which is in weight equal to the weight of the ship. The weight of the vessel may be supposed to be acting downward through a point which is the center of gravity of the entire ship, including cargo, machinery, coal, etc. There is an equal force derived from

the buoyancy of the water acting in an opposite direction through a point which is the center of gravity of the volume of displacement, called the center of buoyancy. When the vessel is at rest in an upright position the two points lie in the same vertical plane. The position of the center of buoyancy is calculated about two axes—one taken at the load-line and the other at the mid-length of the vessel. In order that the vessel may float at a given draught at the bow and stern, the center of gravity of the vessel in a fore-and-aft direction must lie in the same vertical line with the center of buoyancy of the immersed body. When these points are thus located the vessel is said to be in trim and proves the correctness of the designer's calculations, for in order to ascertain with accuracy the position of the center of gravity of the vessel the weight of each particle that goes to make up the entire vessel must not only be calculated, but also its moment about some point in the length taken as an axis. In a similar manner, the vertical center of gravity must be determined in order to ascertain its distance, called the metacentric height, below the metacenter of the vessel. The metacenter is a point above the vertical center of buoyancy at a distance equal to the moment of inertia of the load-water plane divided by the volume of water displaced. The metacentric height is a measure of the initial stability of the vessel, but not of the range of stability. (See HYDROSTATICS, *Stability of Floating Bodies.*) For good easy behavior the metacentric height should not exceed 3 feet, and for safety not be less than 18 inches, provided that the vessel has a reasonable amount of free-board or height out of water. There are many other calculations that can be made in regard to the stability of the vessel in various conditions of load or when some of the compartments are filled with water.

The plans necessary to give a clear idea of the design are given below, but these must be supplemented by detail plans of the principal parts of the vessel: 1. Plan of lines, or half-breadth and body plan. 2. Midship section. 3. Profile inboard. 4. Deck plans. 5. Cross-sections. 6. Sail plan.

The plan of lines shows the form of the vessel, and is in reality the "traces" of planes taken at right angles to each other throughout the ship. From these the shape of the vessel is laid down full size upon the mould-loft floor. The midship section is taken at the mid-length of the vessel and shows the character of the framing, the disposition and thickness of the plating of sides and bottom, decks, bulkheads, stringers, etc., in fact, all the parts upon which the strength of the vessel depends. If the vessel is not built according to the rules of one of the insurance companies, plans and calculations showing the strength of the structure must accompany the application, and this involves considerable mathematical investigation, for the ship must be taken as a girder, and the maximum stresses the material is subject to calculated for the top and bottom flanges of the girder. The inboard profile gives the location of the principal weights in a fore-and-aft direction, the spacing of the frames, the location of bulkheads, the distances between the decks, the position of cargo hatches, and the portions devoted to cargo, coal, passengers, crew, etc. The deck plans and cross-sections show the general arrangement of the deck framing and plating, and the arrangement of the cabins and passenger accommodations. The sail plan gives the general outside appearance of the vessel, with the amount of sail carried, the height of masts, etc. The many questions of handling cargo quickly and effectively, of steering-gear for controlling the vessel, providing sufficient sail-power to prevent the vessel falling off in the trough of the sea when the machinery is disabled, the working and stowing of lifeboats, give the designer occasion for the careful application of scientific and experimental data. The work involved in the preparation of the design for a war-vessel is of a much more complex nature. The features of speed, armament, protection, accommodation, and endurance are so thoroughly interwoven and depend so much one upon the other that the emphasizing of any one feature must be at the expense of some of the others. Thus the most thorough and scientific investigation must be made of the vessel in all its features to enable the maximum of efficiency to be attained in the ship as a whole.

Laying Down.—The form of the vessel or the lines having been determined in the draughting-room, the frames or ribs are next drawn full size upon the floor of a building known as the mould-loft, in order that moulds or scrive-boards may be made, to which each frame is shaped or bent. To facilitate the work in the loft, the ship is divided into two parts called the fore and after bodies, being divided by an imaginary line amidships, or a point near which the curvature of the lines is reversed. On the bodies are laid off the edges of the plating, the line of the stringers and keelsons, the undersides of the decks, the outline of the floors, etc. For the wooden vessels the moulds represent the shape and taper of the frame timbers. Pieces of timber are then selected and worked exactly to the moulds, their edges beveled to conform to the curvature of the vessel taken from the mould-loft floor, and the joints or butts carefully doweled together. For metal vessels the moulds are made to show the shape of the outer edge of the frame and the line of the floors; the object in thus moulding, shaping, and bending the frames is to have them their true shape, so that when put together they shall form the outlines of a vessel agreeing with the plan of the naval architect, and giving, when the planking or plating is fastened to them, the complete outline of the hull. While this part of the work is going on, the shipwrights are preparing the foundation and laying the keel-blocks upon which the vessel is to be built.

Ordering Material.—For convenience in ordering the material of an iron or steel vessel an exact model of it is made in wood on a scale $\frac{1}{24}$th or $\frac{1}{48}$th of full size; on this model are marked off the stations or the frames, the deck-lines, the edges of the plating and stringers, and the plates laid off in their proper lengths so as to have a proper shift of the butts or joints. The dimensions of the frames and plates are then measured from the model, and after verification as to width in the loft are sent to the mills. An allowance is made for machining the plates, or such of them as form the outer strakes, for the inner strakes are often placed on the ship without planing the edges, the ends only being machined in order to have close joints for calking metal to metal.

Keel-blocks.—As the entire weight of the vessel must come upon the keel-blocks, it is essential that they shall have a very firm foundation, such as piling or concrete; they generally slope lengthwise toward the water, and are placed about 4 feet apart from center to center. Each block is built up of several pieces of timber, the bottom pieces often of sufficient length to serve as a foundation upon which to build up the supports of the launching ways; the upper pieces are in some yards so put together as to permit of being removed from under the keel without splitting, while in others the removal of the blocks is effected by splitting out the cap pieces. The blocks are generally given an inclination to the foot of from five-eighths of an inch in heavy vessels to three-quarters of an inch in light ones, to facilitate launching.

Keel.—The first operation, be the ship of wood or metal, is to place the keel upon the blocks; if the vessel is of metal the keel may be constructed after one of several methods. The bar-keel consists of a plain bar in suitable lengths with scarfed butts, the plating of the garboard strakes being flanged or turned down against the bars, and riveted through and through. Another variety is the side bar-keel, which is built up of three parts, the middle piece extending above the keel proper to a depth equal at least to the floors, and the garboard strakes being riveted through in a manner similar to that employed with the ordinary bar-keel; this is one of the strongest of keels, and also one of the most costly. Another variety, and one that, in these days of cellular or double-bottom construction, finds general acceptance, is the flat keel; this consists merely of flat plates bent to shape. If the keel laid is a bar-keel of either type, the garboard strakes are at once put in place to afford a landing for the frames. The stem and stern post are set up, and, if the vessel is of wood, the deadwood and other pieces in the center line are bolted in place.

Stem and Stern Post.—The stem of a metal vessel is usually a simple forging rabbeted to receive the ends of the plating—that is, a recess is cut in it on each side so that the plates may end in it and form a fair and flush surface. The stern-post, if of a single-screw vessel, is quite an elaborate forging, although of late years castings of steel have been substituted for forgings with great success. The post is made up of two parts in one, first the post proper on which the plating ends, and through which the screw-shaft passes, forming incidentally a part of the stern bearing, and second the rudder-post or the support of the rudder; the two connected form a continuous frame about the propeller. In twin-screw vessels the stern frame is scarcely less elaborate, for provision is usually made for heeling thereon the shaft brackets or struts which support the screws. The frame must also receive the ends of the hull-plates and support the rudder.

Raising Frames.—In wooden ships the frames are raised upon, and securely fastened to the keel, and are set at right angles to the keel, except that at the ends they are placed normal to the outside planking. These end timbers are called "cants," and are adjusted at their heels to mortises made in the deadwood. In iron vessels of the plainer class the frames and floors are often riveted up entire upon the ground, and then raised to their place upon the keel or garboard plates, but first the frames and floors must be bent to shape, and this is done as follows: The frames are usually of shape iron rolled in one length, either of angle bar, angle bulb, channel, or Z bars. The long bars are placed in a furnace especially designed for this purpose, and heated until they can be readily bent to the shape of the mould, which has been marked off upon the bending slabs; the slabs are of cast iron, from 3 to 4 inches thick, perforated with square holes closely set, and arranged so as to form a smooth floor of sufficient size to accommodate the largest frames, and give room to the workmen. In the square holes iron stops are placed agreeing in contour with the shape of the mould; the bars after being heated are forced back against the stops and at the same time beveled to conform to the bevels taken from the mould-loft floor. After cooling, holes are punched for the rivets used in connecting the frames with the floors, skin-plating, beams, etc.

The upper ends of the frames are held by crosspieces of plank, called spalls. Each frame is adjusted so as to be exactly perpendicular to the keel, and is held in place at the top by strips of timber called rib-bands, which have been prepared from measurements taken from the loft, and the proper positions of the frames marked thereon. The rib-bands and frames are shored up to keep them in position until the inner strakes of plating are on.

Main Keelson.—The main keelson is then placed upon the floors directly over the keel; if of wood, it is fastened through floors and keel, but if of metal it is riveted to the floors, they in turn being riveted to the outside plating. This keelson serves to keep the floors from tripping and enters into the stress-resisting element of the vessel.

Double-bottom Framing.—A much better disposition of the material, on the same weight, is known as the cellular construction or double-bottom system; on this system are constructed nearly all of the large and magnificent vessels engaged in the transatlantic trade, and nearly all war-vessels. The frames in the double bottom, or the space between the inner and outer skins, are made up of short frames and bracket-plates somewhat like the lattice-work of bridge girders, between the keelsons or longitudinals, so that the erection of the longitudinal and transverse framing must be carried on together; outside of and above the double bottom the raising of the frames is substantially the same as described above.

Putting on Planking or Plating.—Before the planking is placed on the vessel the sheer lines at side and the normal lines or spilings of the bottoms are marked on the outside surface of the frames; the spilings are found by fastening a broad, flexible, and straight-edged batten to the frames in such a manner as to cross the midship frame at right angles; the batten itself will then assume a line at all points normal or square to the frames of the ship. These lines are laid off at intervals of from six to eight seams or widths of planking. The planks are worked either in parallel strakes or in combination of two strakes with the alternate edges straight. This is sometimes called the "anchor-stock method," the object being to have the narrowest portion of one strake always opposite the widest portion of the other. The butts of the plank are shifted so as to have at least three strakes between butts in the same frame space. The strakes next the keel, called the garboard strakes, and those at the heads of the frames are made thicker than the balance of the plank, in order to have the greater amount of material at the parts of the vessel where the greatest strains are experienced. Before the planks are placed in position the frames are often bound together inside and strapped diagonally by iron bands 2½ to 3 inches wide; thus the frames are bound longitudinally by the planking and ceiling and diagonally by the bands. In metal vessels the plates forming the outside skin are worked in lengths from 12 to 20 feet, and in widths varying from 24 to 60 inches. Templates are constructed from the loft, giving the exact size of the plates with the position of the rivet-holes marked thereon; the plates are then planed to the required sizes and the rivet-holes punched and countersunk, and are then ready to be put in place. The inside strakes are placed in position first and bolted up. Templates of the rivet-holes in the edges are taken off for the outer strakes in order that the holes in the inside and outside strakes may exactly coincide for riveting. The necessary holes for the stringers and keelsons are also punched at the same time. As the finished surface of the vessel beneath the water must be smooth and free from all protuberances, the rivets that pass through the plates are beaten down to a conical head to fit countersinks in the outer surfaces of the plate.

Deck Beams.—The beams not only serve to carry the deck and its load, but are also struts and ties which prevent in a certain measure the ship's sides from collapsing; it is very necessary therefore that they shall have good connection with the frame and the outer skin. In wooden vessels the beams are made in one length, if possible, but are sometimes built up, that is, composed of several pieces of timber securely scarfed and bolted together. The beams rest at their outer ends upon clamps, which are thick pieces of plank running fore and aft on the inner side of the frames, and are securely fastened by means of vertical knees to the framing and planking. They are also braced in a longitudinal direction by smaller knees placed horizontally. The whole structure—beams, knees, clamps, frames, and planking—is thoroughly bolted and doweled together.

In order to give the beams strength to resist deck loads, and at the same time throw the water to the sides, where the waterways are located, they are slightly arched; the arch is called spring or round.

The beams of metal vessels are usually formed of iron or steel rolled to shapes known as T or angle bulb. They vary in weight and in depth from 4 to 15 inches. The lengths are taken from the plans and ordered in one piece for each beam, with the proper round or spring. The beam so ordered is slightly longer than the distance from side to side of the ship, to allow for turning down the lower half at the ends to form knees through which they are fastened to the frames. The method of forming the knee is to split the beam for a slight distance at each end, midway of its depth, and turn down the lower half upon a former; a piece of metal is then welded in to connect the upper and lower parts. After the beams are in position the spalls can be removed from the frames, leaving the space between decks free for the workmen. In framing the decks the beams are arranged to allow of the boilers and machinery being lowered to their beds without disarrangement of the deck-plating; provision is also made for the cargo-hatches, mast-partners, and other openings.

Inner Skin or Ceiling.—In wooden vessels the ceiling and the thick strakes and keelsons form a complete lining to the vessel, worked on the inner side of the frames. In metal vessels the inner skin is more often called the inner bottom, and is worked only when the vessel is constructed on the cellular system. It is usually placed from 3 to 3½ feet from the outer skin, to allow ready access for thorough inspection, cleaning, and painting. It is worked on the upper side of the bracket frames very much in the same manner as the outside plating is put on. For structural purposes the inner bottom enters largely as a factor of strength. Many freight-vessels, oil-steamers, and colliers are provided with inner bottoms, the space between the inner and outer bottoms being used as tanks for water ballast.

Bulkheads.—At certain positions throughout the ship are located water-tight partitions or bulkheads; those in the middle portion of the vessel are necessarily determined by the arrangement of the boilers and machinery, but every effort is, or should be, made to allow at least any two of the compartments bounded by the bulkheads to be filled with water without endangering the stability of the vessel. The foremost bulkhead of all is called the collision bulkhead, and is located half the maximum breadth of the vessel from the bow. This bulkhead is especially stiffened and braced to withstand the pressure of the water against it in case of injury to the ship forward of it. In metal vessels bulkheads have two functions to perform: one to serve as a structural tie uniting the sides of the vessel, the other, by far the more important, to confine the inflow of water in case of damage to the compartment injured. The pressure per square inch due to a head of water of 25 feet is about 11 lb. Very efficient stiffening must be provided to enable the plating to withstand such pressure. The best method of construction is to have the plating worked horizontally, with heavy vertical stiffeners bracketed at the heads and heels. The stiffeners may be of rolled shapes or built up of plates and angles, as the depth and width of the bulkhead may

require. In addition to the vertical stiffening, horizontal webs are sometimes worked on the opposite side of the bulkhead, with their ends securely bracketed to the ship's side.

Decks.—The upper deck, to which is carried the full scantling of the vessel, plays a very important part in the structural strength. The arrangement of the material subject to longitudinal stress may be compared to a beam of which the upper deck is the top and the keel the bottom flange, the outside plating forming the web of the beam; therefore in vessels of large size this deck is plated completely over in order to secure for the top flange of the girder the proper sectional area. On the ends of the beams are worked stringers of heavier plating than the balance of the deck-plating, making good connection with the sheer strake by means of heavy angle bars; the space between the stringers is filled in with plating as required. In wooden vessels the strength at the deck is made up through the waterways, thick strakes, and clamps, which are strong pieces of timber or plank running longitudinally.

The remaining decks of an iron vessel are worked in a manner similar to the upper deck. Where the frames pierce the plating staple-angles are sometimes worked about the frames to make them water-tight. Deck beams should be supported by stanchions; so far as possible these should be in the midship line, but for convenience of staterooms and deck arrangements they are sometimes worked two to a beam, and placed beside the joiner-work bulkheads.

Fastenings.—The fastenings of a wooden vessel are composed of copper and iron bolts, iron spikes, and treenails of wood. The plank is fastened generally by spikes or treenails, except at the butts, which are bolted. For additional security the frames, outside and inside planking, are often fastened together by through-bolts, driven from the outside and riveted on washers against the inside of ceiling. The deck plank is usually fastened by spikes. The fastenings of a metal vessel consist almost entirely of rivets, which are hammered into place while hot.

Calking.—When the planking is fastened the seams or slight spaces between the edges of the plank are filled with oakum, and this is driven in with great care until it is as hard as the plank. To hold the oakum the planks are laid with a slight bevel outward, about $\frac{1}{16}$th of an inch for each inch of thickness of plank; otherwise the oakum would be easily forced through the seam. An improved method is to cut a recess in the edges of the plank about midway of the depth, so that the oakum will spread into the recess and render it impossible to be driven through. After the calking the seams are paid with hot pitch or marine glue. In metal vessels all water-tight work must be calked metal to metal, that is, a slight layer of metal must be driven over against the adjacent metal until the joint is absolutely tight. This work was formerly done entirely by hand; now a calking-tool operated by compressed air or electricity is used, the blows being given with great rapidity.

Launching.—The vessel has been built resting upon the keel-blocks and shores; while here the shafting and propellers have been put in place, the rudder hung, the bottom painted, and all work below the water-line on the outside surface finished. Now the vessel is to be transferred from the fixed keel-blocks to a movable platform which shall allow the vessel to move easily and without damage into the water. This is done by building on each side of the vessel, about one-fourth of the breadth of beam from the keel, a platform or foundation to which the weight of the vessel shall be transferred. In laying the keel-blocks the bottom pieces were made of sufficient length to allow of their forming the foundation for this platform. On these are built up the groundways, which are shored to prevent spreading and are capped with strong pieces of timber, $3\frac{1}{2}$ to 4 feet wide, with smooth upper surfaces; on these are laid the bilgeways, which are also large smooth pieces of timber, free to slide with the vessel; on the bilgeways are constructed the cradles, which are fitted to the ship's bottom; between the cradles and the bilgeways are fitted rows of long wedges of such thickness that when driven up the vessel will be lifted from the keel-blocks, and the weight brought to bear on the groundways. The upper surface of the groundways and the bottom surface of the bilgeways are coated with tallow, and the bilgeways secured to the groundways by pieces of plank at the bow so that they can not move until they are sawn asunder. Then the wedges are set up until the keel-blocks can be removed and all clear for launching; when all is clear, the planks at the bow are sawn off, and the vessel, resting only on the greased surfaces, begins slowly to slide down the inclined plane; she soon gains headway, and in a few seconds is in the water. After launching, the fitting of the joiner work and cabins, the putting together of the machinery, stepping and securing the masts and rigging of the ship, are proceeded with until the vessel is complete in all respects.

PHILIP HICHBORN.

Ship-canals: canals intended for the passage of ships proper; hence, therefore, canals to connect sea with sea, and thus by a short cut to obviate a long ocean navigation. Such canals are usually laid across an isthmus or peninsula. The Suez Canal is an apt instance; so also are the projected canals across the Central American isthmus and the isthmus of Florida. The CALEDONIAN CANAL (*q. v.*) of Scotland is an instance of a class of minor ship-canals. In another sense ship-canals are those proposed to connect routes of natural navigation (rivers or lakes), by allowing a passage of the vessels, whatever they may be, used in such navigation. To this class belong many of the works described in the cyclopædia under separate heads—e. g. the ILLINOIS AND MICHIGAN CANAL (*q. v.*); see also the article CANALS.

The importance of a navigable connection between the Atlantic and Pacific Oceans through the isthmus which connects North and South America calls for a condensed view of the chief plans proposed at different dates, and of the natural obstacles baffling them all up to the present. From the era of the Spanish conquest of America the search for the secret of the supposed natural strait was carried on along the whole coast-line of the two continents; and when this ceased, the possibility of the construction of an artificial route began to be discussed. Governments, companies, and individuals have devoted much time and money to the search for a practical route for a ship-canal. Tehuantepec, Honduras, Nicaragua, Chiriqui, the Isthmus of Panama (or Darien), and the Atrato river, have all figured in connection with this question, and a full statement of the various surveys and projects made prior to 1866 will be found in the report of the superintendent of the U. S. Naval Observatory (Admiral C. H. Davis), made in compliance with a resolution of the U. S. Senate (*Ex. Doc.* $62^{3}_{1}{}^{2}$). See also *Engineering* (London), in a series of articles entitled *The Nicaragua Canal* (Feb. 24, 1893, *et seq.*).

The results of the surveys since 1875 of the American isthmus for ship-canals and their substitute, the ship-railway, will be found under *Nicaragua Canal* and *Panama Canal*, below, and in the article SHIP-RAILWAYS. Since 1879 important results at both Nicaragua and Panama have proceeded from efforts to construct the canals. The remaining projects have ended either in surveys and estimates, or in lapsed concessions from the governments on whose territory the canals were to have been constructed.

Panama Canal.—Across the Isthmus of Panama occurs, next to Nicaragua, the greatest depression yet found on the isthmus, the summit-level of the railway being 287 feet above sea-level. The route from Porto Bello or Chagres to Old or New Panama has been the established line of communication since 1653, nearly coeval with the first settlement in America. A survey was made in 1843 by the French engineer, M. Garella (*ingénieur-en-chef des mines*), of which the report was printed in the *Journal of the Franklin Institute*, and in the French *Journal des Ponts et Chaussées* (1844). George M. Totten, chief engineer of the Panama Railroad, subsequently made an estimate for a canal with locks, to cost from $60,000,000 to $115,000,000, according to the summit-level adopted. The survey was renewed by the U. S. Government, by Commander E. P. Lull, U. S. navy, resulting in the location of a practicable line for an interoceanic ship-canal, 26 feet deep, from the Bay of Aspinwall on the Caribbean Sea to Panama on the Pacific.

In 1879 Count Ferdinand de Lesseps made an appeal to the several nations to send delegates to a proposed congress to meet in Paris, to decide upon the route and the plan for an interoceanic canal between the Atlantic and Pacific Oceans through the American isthmus. On May 15 of that year the congress met in Paris. Twenty-four countries were represented. Count de Lesseps was elected president. The congress decided that a canal with a constant level was desirable, and that this canal should be by way of Limon Bay to Panama.

Immediately after the adjournment of the congress the Universal Interoceanic Canal Company was organized under

the French law for building the canal under a concession previously granted to Lieut. Lucien N. B. Wyse by the Government of Colombia, and sold by him to Count de Lesseps.

The total length of the canal as projected is 46 miles; the heaviest cutting, that in the Culebra, is 330 feet. The route in general follows that of the Panama Railroad. The dimensions of the canal are as follows: The breadth at the bottom is 22 to 24 meters (72 to 78 feet); the breadth at the surface of the water, 28 to 50 meters (92 to 164 feet); depth, 8½ to 9 meters (28 to 29½ feet). The curves on the canal are to have a minimum radius of 2,000 meters (6,560 feet). The greatest obstacle to be overcome on the Atlantic side, both in construction, maintenance, and operation, is the Chagres river. It was the original intention to dam back this river and carry its floods to the sea by an artificial channel along the slopes of the mountains, but the great cost and doubtful practicability of the plan led to its abandonment.

The canal, if built according to the original design, would require a tide-lock at Panama, where the ordinary range of tides is 18 feet. During storm-tides the range is much greater. The materials in general to be excavated are, on the marshes and valley of the Chagres river, a very fine alluvium in which is but little mineral silt; elsewhere, solid rock, clay mixed with conglomerate, with tufa (or compressed volcanic ashes) in the Cerro Culebra. From Culebra to Panama the route is through pyroxenic rock, sandstone tufa, and conglomerate. The total amount of materials to be excavated in the canal proper, according to the originally steep sections, is 143,000,000 yards, and, with the lateral cuts for the Chagres river, not including those required for the Chagres dam at Gamboa, is 13,000,000 cubic yards, or a total of 156,000,000 cubic yards.

The original estimate made by the Panama Canal congress was 600,000,000 francs = $120,000,000. At the close of the year 1888 the amount expended, not all on the actual work, however, was 1,000,000,000 francs, equal to $200,000,000. It was necessary to raise much more money, as there was at that time not more than one-third of the whole work completed. It was found impracticable to raise this money except by a lottery loan, but this scheme failed, and work ceased on the isthmus in 1889. A commission sent out by the French Government reported that it would cost $342,000,000 to complete the canal. The canal was thrown into the hands of a receiver, M. Monchicourt being appointed by the Government as liquidator. In 1890 he estimated that it would require to complete the canal at sea level three milliards of francs, or about $600,000,000.

Nicaragua Canal.—The Nicaragua route follows the most deeply marked depression of the American isthmus, and has the natural advantage of the great lake of the same name as a canal-feeder. It would perhaps be more directly in the world's highway than the Panama route. A route for a ship-canal was in 1850 surveyed by Orville Childs, C. E., whose report will be found in the *Journal of the Franklin Institute*, June, 1870. A Government survey was also made by Commander Edward P. Lull, U. S. navy.

In 1879 a commission was appointed by President Grant for examining the reports of the various isthmian surveys. After an examination of all the routes they reported and estimated the cost of construction, including the harbor improvements, as at least $100,000,000. Other estimates were those of Maj. Walter McFarland, U. S. A., $140,000,000, and of A. G. Menocal, C. E., U. S. N., $40,910,839. A congressional committee which investigated the subject and the estimate of Mr. Menocal placed the total cost at $92,881,124.

Concessions have been given to various companies by the Nicaraguan Government. The first given to a U. S. company was that called "the Vanderbilt concession of 1849." This was abrogated in 1856 on account of the non-fulfillment by the company of the conditions of the concession, but in 1857, by another administration, the concession was renewed, to be abrogated only upon the decision of arbitrators who have as yet not been appointed. The concession of 1849 and the complications that existed, particularly on account of the claim by Great Britain to the territory at the northern terminus of the canal, led to a treaty (still in force) between the governments of the U. S. and Great Britain, called the Clayton-Bulwer Treaty of Apr. 19, 1850, which in Article I. states: "The governments of the U. S. and Great Britain hereby declare that neither the one nor the other will obtain or maintain for itself any exclusive control over the said canal." On Jan. 10, 1888, a bill was introduced in the U. S. Congress to incorporate the Maritime Canal Company of Nicaragua under a concession granted by that Government. This bill became a law on Feb. 20, 1889. In the meantime the Nicaragua Canal Construction Company was incorporated under the laws of the State of Colorado. This latter company contracted with the canal company to complete the surveys and construct the canal. In June, 1889, the preliminary work on the construction was begun. Before Oct., 1890, over $2,000,000 had been expended, as certified by the Nicaragua Government commissioners, the concession requiring this expenditure within three years after the inception of the work.

The route which was finally located and on which work has been begun is from Greytown, on the Atlantic, to Brito, on the Pacific, 169½ miles apart. In detail, the line of the canal extends from Greytown in a southeasterly direction 9¼ miles through the low grounds of the heavily wooded plains and swamps. The cross-section of the canal here is to be 120 feet wide at bottom, 288 feet at surface, and 28 feet deep. Lock No. 1 will have a lift of 31 feet; dimensions of lock, 650 feet by 80 feet. Lock No. 2, 1¼ miles from No. 1; lift, 30 feet. Lock No. 3, about 2 miles from No. 2; lift, 45 feet. About 3 miles from No. 3 is the "Eastern divide" cut, 2·9 miles long; summit depth of cut, 298 feet; average depth entire length of cut, 141 feet; material mostly rock; dimensions of the cut, 80 feet at bottom, 80 feet at surface, with ⅕ to 1 slopes above water; depth of water, 30 feet. The route from the divide cut is through the basin of the San Francisco river. It is a tributary of the San Juan and flows across the axis of the canal. It and all other openings are dammed up to make an impounded reservoir, or lake, extending from the divide cut 12½ miles to the main San Juan at Ochoa, where the river is to be dammed by an immense work of loose rock, to be hauled from the divide cut. This dam is to be 70 feet high, 1,900 feet long, and it will raise the water above it to a level of 106 feet above the sea, and this will raise the level of Lake Nicaragua from 105 feet, its present level, to 110 feet above the sea.

The San Carlos river now discharges into the San Juan above the dam site, and the lower reach of this river must be dammed also. From 6 to 8 miles of embankments are required, some of them 60 feet high, to impound and hold the waters.

Several waste weirs, or sluices, to relieve the basin of excessive flood waters, are provided for in the plans. These dams and embankments will make slack-water navigation from lock No. 3 to the lake.

Considerable dredging is required in the river channel, especially near the lake, for about 20 miles. It is then necessary to dredge 20 miles out into the lake, as the shore has a very flat slope. On the opposite side of the lake submarine rock dredging is required for 9 miles. The depth from shore to shore of the lake is to be 30 feet. From the Ochoa dam to the west shore of the lake the distance is 121·04 miles, the lake being 56½ miles wide. From the lake to the Pacific the distance is 17·04 miles.

There are three locks, Nos. 4, 5, and 6, located near each other. Their lifts are each 42½ feet, No. 6 having a variable lift on account of the fluctuations of the tides of the Pacific.

The harbor of Greytown before 1855 was a good and capacious port. Drifting sands have closed up its connection with the sea and only a shallow lagoon exists, with its entrance practically closed to navigation. The work of restoration has been attempted by building a jetty out from the shore about 1,000 feet and dredging a channel under its protection, which is about 12 feet in depth. The work thus far executed is some dredging on the axis of the canal by the great Panama dredges, which were purchased and taken to Nicaragua, and the construction of several miles of the ordinary railway, to be used as an auxiliary to the canal work; also some clearing in advance of the work and a telegraph line for some distance. At Brito, on the Pacific, is an open roadstead which must be inclosed by heavy stone dikes, or breakwaters. The cost of the entire work, estimated in May, 1889, by the commission of civil engineers employed for the purpose by the construction company, is $87,799,570. On account of financial difficulties the work was suspended in 1893. See SHIP-CANALS in the Appendix.

Florida Ship-canal.—The U. S. Congress has made a number of appropriations for surveys for a Florida ship-canal. Four routes have been surveyed under the direction of the Secretary of War; these surveys were made in 1824, 1855, 1856, and 1878–79. A survey was made by the city of Mobile in 1872, but with the exception of discussions on the subject nothing has been done for some time to pro-

mote the undertaking. For a full history and complete statement of facts see the *Florida, Atlantic, and Gulf Ship-canal Company*, published in New York (1881); also report of Gen. Quincy A. Gillmore, in the annual report of the chief of engineers U. S. army (1880).

Cape Cod Ship-canal.—To shorten the distance and avoid the dangers of navigating around Cape Cod a proposition for a ship-canal between Barnstable Bay on the north and Buzzard's Bay on the south has been brought forward. Probably the best route follows a natural depression between Sandwich on the north coast and Monument, at Buzzard's Bay, on the south, a distance of about 8 miles. At an earlier geological period this depression was a sea-channel separating Cape Cod from the mainland, and it is so low even now that within the nineteenth century the storm-tides have met each other.

Many examinations, surveys, and reports were made from 1776 to 1878, when Clemens Herschel, C. E., made an exhaustive report on the subject, and estimated the cost of a canal and jetties with a depth of 18 feet at mean low water, and a width of 111 feet, at $2,000,000 in cash.

Although the State Legislature has granted many charters to different companies, yet very little actual work has been done on the construction of the canal. There are (1895) several bills for charters before the present session of the Legislature.

Suez Canal.—According to Diodorus Siculus (B. C. 60) there was a canal from the Gulf of Pelusium (not far from the present terminus of the canal) to the Red Sea. It was begun by Necos, continued by Darius, and finished by Ptolemy II. The canal was said to be wide enough for two galleys to pass abreast.

For the modern canal nothing was done except to make careful surveys until 1849, when the project of a ship-canal was finally taken up, to be carried through by Count Ferdinand de Lesseps. After the route had been carefully surveyed and favorably reported on, the Viceroy of Egypt granted the first concession to M. de Lesseps in Nov., 1854. At Constantinople, where de Lesseps had an interview with the prime minister, the project was favorably received; but through the interest of the representative of Great Britain, Lord Stratford de Redcliffe, the sanction was not given. In order to place the subject prominently before commercial nations de Lesseps wrote to the principal foreign ministers, asking that they would name engineers of high rank, and would secure their uniting in a commission to examine the routes for a ship-canal. The commission met and appointed a sub-commission to prosecute the study of the proposed route on the ground, which they did, and presented to Said Pasha a preliminary report dated Alexandria, Jan. 2, 1856. The commission rejected the plan for an indirect canal from Alexandria as "inadmissible from a technical and an economical point of view," and reported in favor of a direct route, making an estimate of 200,000,000 francs as the cost of the work. A second concession was given on Jan. 15, 1856, the terms of which were designed to satisfy the opposition which had already begun in Great Britain, and to guarantee fair returns to the stockholders who might invest. The viceroy made an official declaration for himself and his successors, subject to the ratification of the sultan, that the canal and all its ports should be open at all times as a neutral highway to every merchant ship passing from one sea to another, without any exclusive distinction or preference to persons or nationalities. The statutes which were to govern the company fixed its capital stock at 200,000,000 francs.

The Egyptian Government engaged to furnish a contingent of the fellaheen, and the work was at once begun. The location of the northern terminus of the canal was changed from Pelusium to Port Said. The first work on the canal was at this terminus, and was begun on Aug. 25, 1859, by de Lesseps in the presence of about 150 persons. For a description and illustration of the artificial harbor at Port Said, see HARBORS.

From Port Said the distance across the isthmus in a direct line is about 70 miles. The length of the canal is 100 miles, of which over 60 per cent. is through shallow lakes. The material excavated was usually sand, but in places it was necessary to blast through strata, 2 or 3 feet in thickness, of solid rock. The total excavation was 80,000,000 cubic yards.

On account of the complications with Great Britain and its opposition to the construction of a canal, obstructions were placed in the way of the work from time to time which greatly delayed its completion and increased its cost. The most important result was the withdrawing of the fellaheen from the work by peremptory orders from the British Government to the viceroy. Although the work was delayed by this, it served to bring into use a much more extensive plant of machinery, specially constructed to perform work hitherto done by men. The appliances thus used were various and very efficient. With them the contractors excavated 50,000,000 cubic meters, with the assistance of less than 4,000 men and in the space of less than five years. The work was all performed in daylight.

The canal was formally opened by vessels from nearly all the maritime nations of Europe on Nov. 17, 1869. The canal at that time was in a very imperfect state, not being fully completed in width and depth, but the company has since finished the work and maintained the depth needed. The canal has a sufficient depth and width to permit the safe passage of ships drawing 25 feet of water. The following table shows the increase in the number of ships, tonnage, and receipts:

YEAR.	Number of vessels.	Net tonnage.	Receipts from tolls and passengers.
1870	486	435,911	* $869,152
1875	1,494	1,887,578	5,286,158
1880	2,026	3,057,421	7,501,627
1885	3,624	6,335,753	12,423,354
1890	3,389	6,890,094	12,882,502
1891	4,207	8,698,777	16,789,113
1892	3,559	.....	14,890,475
1893	3,341	7,710,000	14,133,722
1894	3,352	8,039,106	14,770,081

* Computed at 5 francs to the dollar.

In the concession it was laid down that the maximum charge was to be 10 francs per ton "of capacity." The business of the canal became so great that it was necessary to widen and deepen it. This work is now nearing completion. The new dimensions are 31·2 feet depth; bottom width, 108·2 feet; surface width, 420 feet; area of prism, 8,240 sq. feet. There are sidings—called *gures*—excavated for the passage of vessels at several points; the radius of the curves is 2,000 feet. The cost of the canal as originally completed was $95,000,000.

The Corinth Canal.—This canal extends from the Bay of Corinth to the Gulf of Athens. It was across this isthmus that the Athenians, 300 years before Christ, hauled their triremes, which are thought to have been of about 150 tons burden. The canal saves 185 miles (342 km.) from Adriatic ports and 95 miles (178 km.) from Mediterranean ports. The average tolls are 18 cents per ton and 20 cents per passenger. The length of the canal is 3·9 miles (6,290 meters), part of which is excavated in alluvial soil and part in calcareous and granitic soft rock. There is no lock or tunnel, it being a sea-level canal. There are generally quiet harbors at each end, but jetties have been constructed for further protection. The width of the canal is 22 meters (72 feet) at bottom, and 24·20 meters to 28 meters (79½ to 92 feet) at the low-water level. The depth of the canal below low-water level is 8 meters (26¼ feet). The heaviest cutting is about 79 meters (259 feet); the average cutting is 45 meters (147½ feet). The amount of material excavated was 11,500,000 cubic meters (14,453,400 cubic yards). The total cost was nearly $5,000,000. The work was begun in 1884, but suspended at various times by financial embarrassments. It was completed so as to permit its inauguration by the King of Greece on Aug. 6, 1893, but it was not opened to navigation until Nov. 9, 1893. Owing to the slips of the canal sides, developed in the original excavation, it was found necessary to construct retaining walls for rather more than half of its length. The total amount of masonry in these walls and used in protecting the slopes of the cuttings was 165,000 cubic meters (216,000 cubic yards).

Cronstadt and St. Petersburg Canal.—This is a work of great strategical and commercial importance to Russia. The plans were matured in 1874, and work was begun in 1877. The canal and sailing course in the Bay of Cronstadt are about 16 miles long together, the canal proper being 6 and the bay channel 10 miles, and extend from Cronstadt, on the Gulf of Finland, to St. Petersburg. The available depth prior to its construction was 9 feet in the river. The canal, opened in 1890, is navigable for vessels drawing 20½ feet; its greatest width is 350 feet and its least width 220 feet; the total cost was $9,000,000. For a descriptive and historical sketch, see London *Times*, Oct. 17, 1884.

The Brussels Canal in Belgium is (1895) approaching realization. This has been contemplated and urged for over 400 years. The distance by water from Brussels to Antwerp is about 32 miles, of which 17½ are on the Willebrach Canal, now 10½ feet deep, 4½ miles on the canalized river Rupel, and 8 miles on the Scheldt. Vessels of 300 to 400 tons can now sail to Brussels, but the narrowness of the canal and locks excludes larger vessels. It is intended to deepen the canal to 21½ feet. The cost is estimated at $5,000,000.

Manchester Ship-canal.—The city of Manchester, England, is situated on the Irwell, about 50 miles from the Liverpool bar. The canal avoids cost and delay in transshipment at Liverpool. In 1882 a plan was proposed by E. Leader Williams as engineer, and James Abernethy as consulting engineer. The terminus in the estuary of the Mersey was to be a point opposite Garston. The canal in the estuary was to consist of low training-walls. Several modifications were made in the route and plans of the canal during the various discussions that took place in Parliament. The final total estimate on the plan before that body in the spring of 1884 was £6,904,186 12*s.* 2*d.* The plan was opposed in Parliament by the Mersey docks and harbor board on the ground that it would reduce the depth on the Liverpool bar at the mouth of the estuary, and as this view was sustained by James B. Eads, the engineers of the ship-canal changed the route so as to reach the estuary at Eastham, about 6 miles from Liverpool, on the south bank of the estuary. The necessary parliamentary approval was then obtained.

The locks for admitting vessels at Eastham (three in number) are respectively 600 feet long by 80 feet wide, 350 feet long by 50 feet wide, and 150 feet long by 30 feet wide. The four other sets of locks between there and Manchester are of similar dimensions. The total length of the canal is 35½ miles. The total rise from the ordinary water-level of the canal at Eastham to the docks at Manchester is 60 ft. 6 in. Dividing this between the four sets of locks gives an average rise of about 15 ft. 1½ in. All the lock-gates are worked by hydraulic power. Sluices are provided on Stoney's patent. The railways and highways crossing the route of the canal have been raised by expensive constructions, so as to give a clear height of 75 feet for the vessels traversing the canal. An ordinary canal was carried across by a swinging aqueduct composed of a long iron caisson resting on a pivot pier.

The canal is excavated throughout its whole length to a minimum width of 120 feet at the bottom, and it averages 172 feet wide at water-level. The upper portion, from Barton to Manchester, is 170 feet wide at the bottom and 230 feet at water-level. At the various locks the canal is widened considerably, and vessels can be turned there if necessary. The width adopted permits large steamers to pass each other at any part of the canal. The minimum depth of the canal is 26 feet. The sills for all the locks are placed 28 feet below water-level to allow future deepening of the canal by dredging. Extensive docks have been constructed at Manchester, and at Warrington there is one of 23 acres. The time required for navigating the whole length of the canal is from five to eight hours.

The masonry, both brick and stone, used in the locks, basins, piers, and retaining walls is of the best quality, both in materials and workmanship. The total amount in cubic yards of brickwork is 175,000, and 220,000 cubic yards of masonry. The lower portion of the dock and lock walls is made of concrete, the culverts being lined with masonry of brickwork. At the water-level granite or limestone fender courses, slightly projecting from the face of the wall, are inserted to protect the concrete facing. The deepest cutting is near Runcorn, where, for a short distance, it is 60 feet. The cutting with the largest prism is at Latchford, where, for a distance of 1½ miles, the depth averages 55 feet. The slopes of the excavations varied with the nature of the soil from 1 to 1 to 2 to 1. In the lock excavations the sides are nearly vertical. The total amount of excavation in the canal and docks was about 46,000,000 cubic yards. 10,000,000 cubic yards of which was in sandstone rock. All this waste material from the canal was used in filling up the bends of the river Mersey which are cut off by the canal, and in raising the low lands so as to make them available for shipping, building, and other purposes. The canal was opened for operation throughout on Jan. 1, 1894. The total cost was about $77,000,000. The excess over the estimated cost ($46,000,000) was largely due to extraordinary cost of right of way. The engineer of the work was Sir E. Leader Williams.

The Baltic and North Sea Canal (now known as the *Kaiser Wilhelm Canal*), between the Baltic Sea and the North Sea, in Germany, opened June 20, 1895, was constructed mainly for military and naval purposes, although largely used for general mercantile traffic. The work was begun June 6, 1887. The canal is 61·31 miles long, the terminal in the Baltic Sea being at Holtenau, at the harbor of Kiel. The route lies mostly through marshes, shallow lakes, and the valleys of two small rivers, the summit of the watershed being about 79 feet above sea-level. The normal water-level is that of the Baltic Sea, but there are protective locks at each end. The canal has a depth of 29·52 feet below mean water. The width at bottom is 72 ft. 2 in. and the minimum width on the surface is 190 ft. 3 in. Six passing-places of ample length and width are provided. The total amount of earth removed was about 107,000,000 cubic yards, and the total cost of the canal was about $39,000,000. E. L. Corthell.

Ship-fever: See Typhus Fever.

Shipley, Orby: clergyman and author; b. at Southampton, England, July 1, 1832; educated at Cambridge; was for twenty-three years a clergyman of the Church of England; was received into the Roman Catholic Church Oct. 26, 1878; edited many ascetic and devotional works; translated from Catholic authorities three volumes of religious poetry (*Lyra Eucharistica*, *Messianica*, and *Mystica*) and a number of volumes of essays by different authors (*The Church and the World*, *Tracts for the Day*, *Ecclesiastical Reform*, *Studies in Modern Problems*, *Carmina Mariana*).

Shipman, Nathaniel: See the Appendix.

Ship-money: a tax formerly laid in England on the cities, ports, towns, and boroughs of the kingdom in order to provide and furnish ships for a navy. It was first imposed about 1007 to resist the invasion of the Danes. Ship-money was among the wrongs complained of in England in 1641, and was one of the causes which led to the death of Charles I. on Jan. 30, 1649. He was very much in need of money, and Parliament, which alone could vote him a subsidy, he would not convoke, or perhaps he dared not. He then undertook to levy a tax on his own authority, the so-called ship-money. Such a tax had been levied previously without any special vote of Parliament, but only in the sea-towns and coast-districts, and only in time of war; it was simply another form of the old duty resting on this part of the country of furnishing ships for the navy. In 1636 the king arbitrarily extended this tax to the inland counties and to times of peace. John Hampden (*q. v.*) was taxed twenty shillings, but refused to pay, and asked for a decision by the courts. The courts decided against Hampden, holding that the ship-money was not a tax, but in 1640 and 1641 the Long Parliament declared this exaction illegal, and the bill stating this principle received the assent of the king in Aug., 1641.

Shipp, Albert Micajah: educator; b. in Stokes co., N. C., Jan. 15, 1819; graduated at the University of North Carolina 1840; became a Methodist preacher 1841, president of Greensboro Female College 1848, Professor of History and English Literature in the University of North Carolina 1849, president of Wofford College, South Carolina, 1859, and Professor of Exegetical Theology in Vanderbilt University, Nashville, Tenn., 1875. He was author of *History of Methodism in South Carolina* (1887). D. June 27, 1887.

Shippard, Sir Sydney G. A.: See the Appendix.

Shippen, Edward, LL. D.: jurist; b. in Philadelphia, Pa., Feb. 16, 1729; studied law in Philadelphia and at the Temple, London, where he was admitted a barrister 1750; became prothonotary of the Supreme Court of Pennsylvania and judge of admiralty 1753; held various judicial positions, and was chief justice of Pennsylvania 1799–1806. D. in Philadelphia, Apr. 16, 1806.—His daughter Margaret was second wife of Benedict Arnold. F. S. A.

Shippensburg: borough (laid out by Edward Shippen in 1734, incorporated in 1819); Cumberland co., Pa.; on the national pike road, and the Cumberland Valley, the Phila. and Read., and the W. Md. railways; 11½ miles N. N. E. of Chambersburg, 41 miles W. of Harrisburg (for location, see map of Pennsylvania, ref. 6–F). It is in an agricultural region; has large deposits of iron ore in its vicinity; and contains water-works, gas and electric-light plants, macadamized streets, paved sidewalks, the Cumberland Valley State Normal School, a national bank with capital of $75,000, 2 weekly newspapers, and manufactories of clothing, furniture, hosiery, engines, flour, carriages, and fly-nets. Shippensburg was the seat of the first courts of the county,

the headquarters of Gen. Braddock's army, and the site of several colonial forts built to protect the settlers from Indians. Pop. (1880) 2,213; (1890) 2,188; (1900) 3,228.

JOHN C. WAGNER, EDITOR OF "NEWS."

Shippigan': post-village in Gloucester co., New Brunswick; on the Gulf of St. Lawrence, near the northeast angle of the province: 254 miles N. of St. John (see map of Quebec, etc., ref. 3–I). It has a magnificent harbor, which serves as a port of refuge, and important herring, cod, and mackerel fisheries. It occupies an important point in the scheme to shorten the transatlantic passage. It is the proposed terminus of the Continental Railway, and from this port ferry-steamers are to cross to St. George's Bay, Newfoundland. Just beyond Shippigan is the wide flat island of Miscon, said to be the best district for plover in the Dominion. Pop. 2,500, nearly all French-Canadians. M. W. H.

Shipping-articles: See SEAMAN.

Shipping, Law of: the body of rules governing the ownership and employment of vessels, as well as the relations and conduct of persons engaged in their navigation. It is a branch of MERCANTILE LAW (*q. v.*).

What is a Ship?—The term has a very broad signification in this branch of the law, unless narrowed by a statute. Whether a particular water-craft is subject to the rules of shipping depends not on its size, form, capacity, or means of propulsion, but upon the use for which it was designed and to which it is put. Hence a floating elevator, a steam-dredge, and a floating bath-house have been treated as ships, because intended and employed for navigation and transportation. A bath-house built on several boats, with a view to its transportation whenever and wherever desired, is to be deemed the permanent cargo of the boats. *Public Bath No. 13*, 61 *Federal Reporter*, 692.

Ownership of Vessels.—This may be acquired by capture (see *The General Usages of War* under INTERNATIONAL LAW), by operation of law, as in the case of the bankruptcy or the death of the former owner, or by contract between the former and the present owners. A contract to purchase a vessel from a ship-builder and to pay the price in installments as the work progresses does not pass the title to the purchaser until the vessel is in a deliverable state and the purchaser is notified thereof, unless the parties stipulate that it shall pass sooner. Such has been the rule always in the U. S. (*Clarkson* vs. *Stevens*, 106 U. S. 505), and was finally established in Great Britain by the House of Lords in *Seath* vs. *Moore*, 11 Appeal Cases 350 (A. D. 1886).

The present sale of a chattel passes title to the purchaser at common law, although the contract is oral, and the chattel is not delivered nor the price paid, except in cases within the statute of frauds. (See FRAUDS, STATUTE OF.) This rule is believed to apply to ships in the U. S. British courts, however, declare that "a ship is not like an ordinary chattel; it does not pass by delivering, nor does the possession of it prove the title to it," and that as well by the law merchant as by the Merchant Shipping Act (17 and 18 Vict., c. 104, §§ 55–65) a bill of sale is necessary to the transfer of title from the seller to the purchaser of a ship.

Because of the costliness of ships and of the risks and repairs incident to them, it has been customary from an early period for several persons to unite in their ownership. Generally the title of such persons is that of part-owners and not of partners—a form of title much older than that of partnership (see PART-OWNERSHIP), although by agreement they may constitute themselves partners. If part-owners of a vessel can not agree as to its employment, English mercantile law permits the majority in value to "employ it upon any probable design," upon their giving a stipulation to the dissenting owners, in a sum equal to the shares of the latter, either to restore the ship or to pay the value of such shares. Such dissenting owners then bear no part of the expense and reap none of the profits of the adventure. This rule is based on the idea that ships "are built to plow the sea, and not to lie by the walls"—that their employment is a matter of public concern. If the part-owners are equally divided, the court will decide between them. In the U. S. it has gone to the extent of ending such conflicts by forcing a sale of the vessel, but in Great Britain it never exercised such power until authorized by statute. (24 Vict. c. 10, § 8).

Liability of Owners.—English maritime law determined the liability of ship-owners for the conduct of persons in charge of the vessel on their behalf by the common-law rules of agency. (See AGENT.) In case of loss occasioned by their agents, their responsibility was coextensive with the loss. Such was not the rule of the general maritime law of Europe. By that rule innocent owners were chargeable for the acts of the master and crew to the extent of their interest in the ship only, and if the ship was lost their liability was at an end. The reason given by Grotius for this rule is that men would be deterred from owning and operating ships if they were subject to the fear of an indefinite liability for the acts of the master. This fear induced Parliament to limit the liability of ship-owners (see preamble to 7 Geo. II., c. 15), although British legislation has not adopted fully the doctrine which prevails on the Continent; it leaves innocent owners responsible, in many cases, to the value of ship and freight immediately before the injury, although the ship be destroyed or injured by the same act, or afterward on the same voyage. (See 17 and 18 Vict., c. 104, § 503, and 25 and 26 Vict., c. 63. §§ 54–56.) The U. S. Government has abolished the English rule which it inherited, and has adopted the continental rule, graduating the liability by the value of the ship after the injury as she comes back into port, and the freight actually earned; and enables the owners to avoid all responsibility for acts done without their privity or knowledge, by giving up the ship and freight, if still in existence, in whatever condition the ship may be; and without such surrender subjects them only to a responsibility equivalent to the value of the ship and freight as rescued from the disaster. U. S. Rev. Statutes, §§ 4282, 4283; *The Scotland*, 105 U. S. 24.

Master's Duties and Powers.—The master is responsible for the proper navigation of the ship, and is entitled to the obedience of all the officers and crew. He is bound to exercise due care and skill in keeping the vessel in a seaworthy condition, and in properly guarding all interests committed to him by the owners of the ship or of the cargo. Accordingly, he has authority to make contracts relative to the usual employment of the ship and to its repairs and necessaries. He may even sell it when the prosecution of the voyage becomes impossible and immediate necessity to sell exists. His power to pledge the ship and crew is described in the articles on BOTTOMRY and RESPONDENTIA (*qq. v.*). When the vessel is in her home port, or subject to the supervision of the SHIP'S HUSBAND (*q. v.*), the master's implied authority is greatly limited.

Nationality and Registration.—The registration of British ships begins with the Navigation Act of 1660 (12 Car. II., c. 18, § 10), whose professed object was "the increase of shipping and encouragement of the navigation of this nation, wherein, under the good providence and protection of God, the wealth, safety, and strength of this kingdom is so much concerned"; but whose real objects, according to Blackstone, were dealing a blow to the sugar islands and "clipping the wings of those our opulent and enterprising neighbors." (1 *Commentaries* 418.) Under this act ships might be registered as a rule by English owners, whether built in England or elsewhere; but a statute of the next year required them to be of English building. (13 and 14 Car. II., c. 11, § 6.) This remained the policy of Great Britain until 1850. The subject is now governed by 17 and 18 Vict., c. 104, which provides that any ship may be registered which is owned by natural-born subjects, or by persons legally naturalized or denizated, or by corporations established under the laws of, and having the principal place of business within, the British dominions. Unless registered, a ship is not to be recognized as a British ship, so as to be entitled to any of the advantages or to the protection enjoyed by such a ship, or to use the national flag or to assume the national character.

The registry laws of the U. S. are based upon an early act of Congress (ch. i. of 1792) which copied very closely the English statute then in force. (26 Geo. III., c. 60.) Only vessels built within the U. S. and belonging wholly to citizens thereof, and vessels which may be captured in war by citizens of the U. S. and lawfully condemned as prize, or which may be adjudged to be forfeited for a breach of the laws of the U. S., being wholly owned by citizens, or vessels wrecked in the U. S. and purchased and repaired by a citizen, in case the repairs cost three-fourths of the value of the vessel when repaired, can be registered (U. S. Rev. Stat., §§ 4132 and 4136), with the exception of a limited class provided for by ch. 63 of the laws of 1892 and other special statutes. The place of registration is the vessel's home port. In order to register a vessel, the owner must take and subscribe the oath required by statute, must give a bond that the certificate of registry shall be used solely for this vessel, must produce a certificate of construction from the carpen-

ter who built it, and must have it surveyed. If the ship or any interest therein is sold, or if it is altered in form or burden, a new registry is required. If the vessel is not to be engaged in foreign commerce, but in the coasting trade or in fishing, instead of being registered it must be enrolled, if of 20 tons and upward, or if of less than 20 tons it must be licensed. (U. S. Rev. Stat., §§ 4311–4390.) Under this legislation U. S. ships have a virtual monopoly of the coasting trade.

Inspection of Steam-vessels.—The owners of registered or enrolled steam-vessels navigating the public waters of the U. S. are required to have them inspected from time to time, and to obtain a certificate that they are suitable for the service in which they are employed. U. S. Rev. Stat., §§ 4399–4462.

Many of the rules relating to this branch of the law are set forth in other articles and need not be repeated here. See Admiralty, Average, Bill of Lading, Carriers, Common; Charter-party, Demurrage, Freight, Jettison, Lien (*Maritime Liens*); Marine Insurance, Pilot, Road, Law of the; Salvage, Seamen, and Stoppage in Transitu.

The literature on this subject is very extensive. Among the most important treatises are Abbott, *Law of Merchant Ships*; Dixon, *Law of Shipping*; Maude and Pollock, *Law of Merchant Shipping*; Parsons, *Law of Shipping*; Reeves, *History of the Law of Shipping and Navigation*; Wynkoop, *Vessels and Voyages*.

Francis M. Burdick.

Shipping-master: See Seaman.

Ship-railways: railways for the transportation of ships overland between separated bodies of navigable water. The connection between the water and land-transportation is effected by lowering the ends of the railway-tracks into the water to such a depth that the ship floats on and off a carriage or cradle. This is done by means of hydraulic lifting-docks, inclined planes, or any of the other methods in common use for raising ships out of the water for repairs.

Method of Operating a Ship-railway.—The cradle, having on its deck a line of supports along the center to receive and sustain the keel, with other supports for the bilges arranged on each side, is lowered on the rails into the water. The vessel is then brought into position and the cradle is raised to a bearing along the keel, and the bilge-supports are adjusted to place, after which the cradle and vessel are lifted out of the water to the level of the tracks on shore. The motive power is then applied, and the ship is taken across the railway line to the other harbor and lowered into the water by the means employed in raising it.

Early Methods of Overland Transportation.—Transportation by means of portage is the most ancient form of artificial navigation. The first ship-road recorded is one that was used through centuries, the Diolcus of Corinth, which existed at the time of Aristophanes, 400 B. C., and which is said to have been in operation 300 years. It connected Schænus to Port Lechæum, and its remains can still be seen there. It is thus described in the *Lexicon* of Cornelius Schrevelius: "A track on the Corinthian isthmus where ships were hauled out of the Ionian into the Ægean Sea." The ships carried are said to have been about 150 feet long and 18 feet wide, with a draught of 8½ feet. It is very probable that before the Diolcus was built the practice of transporting ships overland was long in use, for the ability to handle such ships as those mentioned must have had a long and slow development, with the limited knowledge and power at the service of the engineers of those days. It is said that this method of ship transport was employed by the Greek admiral Nicetas Ooryfas in the year 831 to attack the Arabian corsairs who were then devastating the coasts of the Peloponnesus.

In 1438 the Venetians transported under the direction of Nicolo Sorbolo, a civil engineer of Venice, a fleet of thirty-three vessels overland from the river Adige to Lake Garda, a distance of 90 miles, the motive power on the plains being oxen and on the mountains windlasses worked by men. The largest ships of the fleet averaged 148 feet in length, 40 feet beam, with a displacement of 300 tons, and were armed with the ponderous stone-throwing artillery of the period, and laden with large stores of cross-bows, arrows, lances, and all the usual munitions of war in vogue.

The object of the expedition was to relieve the city of Brescia, at the time besieged by the Milanese. This was accomplished in a measure, but the Milanese captured and burned the fleet. Early in the spring of 1440 a larger and more powerful fleet was in like manner transported to Lake Garda, and accomplished the relief of Brescia. Thirteen years later, at the siege of Constantinople in 1453, the mouth of the Golden Horn being closed to their ships by heavy chains, the Turks moved a large fleet from the Bosphorus into the Golden Horn behind the chains in a single night, over rudely constructed timberways 5 miles long, thereby almost doubling the length of line which the besieged had to defend, and largely contributing to the city's fall and the consequent end of the Greek empire. In 1718 Swedenborg conveyed a shallop, two galleys, and four large boats 5 leagues over mountains and valleys from Stromstad, Sweden.

Application of Railways to Navigation.—The first application of railways to navigation occurred in providing substitutes for locks on canals and in one notable instance for the canal itself. The Bude Canal in Cornwall, England, between Bude and Launceston, has been in use since 1826. At Hobbacote Downs the canal-boats, which are furnished with small iron wheels, ascend to the uplands by an inclined plane 900 feet long provided with two lines of rails terminating at each end in the canals. There are seven of these inclined planes on the Bude Canal.

The Morris and Essex Canal in New Jersey is operated with inclined planes connecting different levels.

Before the Pennsylvania Railroad was built a portage railway 30 miles long was in operation across the Alleghanies between Johnstown and Hollidaysburg, upon which canal-boats were carried in sections from one canal to another.

In 1860 Sir James Brunlees and E. C. Webb proposed to the Emperor Napoleon III. a ship-railway across the Isthmus of Suez in lieu of the ship-canal. Marshal Vaillant, Minister of War, referred the matter to M. de Lesseps, who rejected the idea. It was proposed to make the railway level throughout, have ten rails in its track, and to use there for the first time the hydraulic lift invented by Edwin Clark, and since so successful at the Victoria Docks and elsewhere. The speed was to be 20 miles per hour; that on the ship-canal, for steam-vessels, is 5 miles per hour, a difference in favor of the ship-railway which, as soon as its practicability is demonstrated elsewhere by everyday use, may cause it to supersede its one-time successful rival. Messrs. Brunlees and Webb also in 1872 prepared plans for a ship-railway which the republic of Honduras proposed to build across its territory from Puerto Caballos to the Bay of Fonseca. It was to carry vessels of 1,200 tons, and doubtless would have been successful had the republic found the money to carry out the work. Another plan of great interest for a ship-railway was that of Sir John Fowler for passing the cataracts of the Nile.

The Chignecto Railway.—In 1875 H. G. C. Ketchum, C. E., of Fredericton, New Brunswick, proposed a ship-railway as a substitute for the Baie Verte Canal across the Isthmus of Chignecto, to connect the navigation of the Gulf of St. Lawrence and that of the Bay of Fundy. From the report in 1783 of Col. Robert Morse, chief of the Royal Engineers, recommending the construction of the Baie Verte Canal as an important necessity of commerce, the question of where and how it should be built was never allowed to drop. In 1822 the first actual survey for a canal was made by the government of New Brunswick, and from that time until Mr. Ketchum's survey in 1881 of the ship-railway line there was no possible canal route that had not been gone over and reported on, so great was the interest of Government and individuals in the question. The ability and perseverance of Mr. Ketchum, and the superiority of a ship-railway for the purpose intended, finally carried the day. The proposal to form a company to build a ship-railway was accepted by the Dominion Government, and an annual subsidy of $170,602 was granted for twenty years. The company was not to call on the Government for any portion of the subsidy except what might be necessary to make up the net earnings of 7 per cent. on the authorized capital of $5,500,000, and it agreed to pay over to the Government half of the surplus profit beyond the 7 per cent. until the whole of the subsidy which might have been paid to the company should be repaid.

In 1888, under Sir John Fowler, Sir Benjamin Baker, and H. G. C. Ketchum as engineers, the construction of the Chignecto ship-railway was begun. It is 17 miles long, and on a straight line from end to end, running through a country moderately rolling, with only one watercourse to cross, and generally favorable to the rectilinear location and $\frac{2}{10}$ per cent. maximum grade adopted.

Fig. 1 shows a vessel as it will look on the lifting-dock

ready for transportation. The vessel, resting on blocks along its keel and bilges, is supported on platform-cars 38 feet wide, carried on 240 wheels, arranged in four lines to run on two tracks of standard gauge, 18 feet apart between

Fig. 1.

centers. The gridiron on which the ship and cradle move up and down in the lifting-dock is like the deck of a bridge with floor-beams arranged in pairs, slightly separated to admit the hydraulic presses between them, and are connected in the usual way by track-stringers under the rails. The hydraulic presses are 25 inches in diameter and twenty in number, and are designed to lift a vessel carrying 1,000 tons of cargo, together with the cradle and gridiron, a total weight in all of 2,500 tons. They are placed 21 feet apart longitudinally and 64 feet transversely, and have a maximum stroke of 40 feet. The cross-heads on the inner cylinders or rams are attached to the floor-beams with eye-bars.

When a vessel is to be lifted the gridiron, with a cradle on its tracks, is lowered, and the vessel is hauled into position with hydraulic capstans. Water is then forced into the presses until the keel-blocks are brought to a bearing; next the bilge-blocks are drawn into place and the pumps are again started, raising the gridiron in less than ten minutes to a position where its tracks are slightly above those of the railway. A connected system of heavy iron chocks, supported by the masonry, is then moved under the ends of the girders by hydraulic power, the gridiron is lowered to a bearing on them, and its tracks are connected with those of the railway. Two locomotives will haul the ship across the isthmus in less than two hours, and the lifting-dock at the other end by a reverse operation quickly replaces it in the water.

The track is composed of rails weighing 110 lb. per yard, laid on very heavy ties, some of which extend under all four rails. It is stone-ballasted, on the most solid cuttings and embankments, and is characterized by smoothness and rigidity.

A novel feature is the way in which the difficulties arising from the immense tides of the Bay of Fundy are overcome. A basin 500 feet long and 300 feet wide is constructed at the south end. The entrance-gates and sea-walls are of heavy masonry, the top being at the common level of the top of the lifting-dock and railway. The top of the gate proper is 17 feet lower, or 13 feet below high water spring tide, and retains a minimum depth of 32 feet in the basin. The lifting-dock at the inner end of the basin is 270 feet long. Vessels will be able to enter or leave during the high stages of the tide, while the excellent anchorage off shore, and the large storage capacity of the basin, insure a continuity of traffic uninterrupted by the fluctuations of the bay. This pioneer ship-railway is (1895) more than three-fourths finished. Awaiting the completion of this great work are many others that are projected, and whose construction will doubtless quickly follow.

The Hurontario Railway.—This is to connect Georgian Bay with Lake Ontario at Toronto. It is to be 66 miles long, probably in one straight line; the maximum grades going south (the direction of heaviest traffic), 8 feet per mile; going north, 22 feet per mile; its track will consist of six rails, and the estimated cost is $15,500,000. The available water-power along its line is over 100,000 horse-power, from which electricity for doing all the work of operating the railway will be generated. The saving in distance over the route around by way of Detroit is about 300 miles, while the country through which it is to run favors facility and permanence of construction.

Columbia River Railway.—A boat-railway along the Dalles of the Columbia river, U. S., between Three Mile Rapids and Celila, is under way, Congress in Aug., 1894, having appropriated $100,000 for the preliminary work. The novel feature of this work is the proposed use of one-degree curves on the railway. The track would be similar to the Chignecto ship-railway, and the general features are also alike with some variation in details to suit the flat-boat traffic for which it is designed.

The Tehuantepec Railway.—This was first proposed by Capt. James B. Eads in 1879, and with characteristic energy, in a few years, in the face of almost universal opposition, he pushed through all the stages of preliminary surveys, detailed plans, congressional inquiries, procurement of concessions from Mexico, and some actual construction at a cost of more than half a million dollars. A table of the distances the railway would save is unnecessary, for it is plain that lengths and breadths of continents are involved. With the opening of the Suez canal, one of the two great barriers to interoceanic navigation was removed. The completion of the Tehuantepec ship-railway would remove the other.

Tehuantepec was selected as the proper location because of its greater proximity to the U. S., its superior advantages

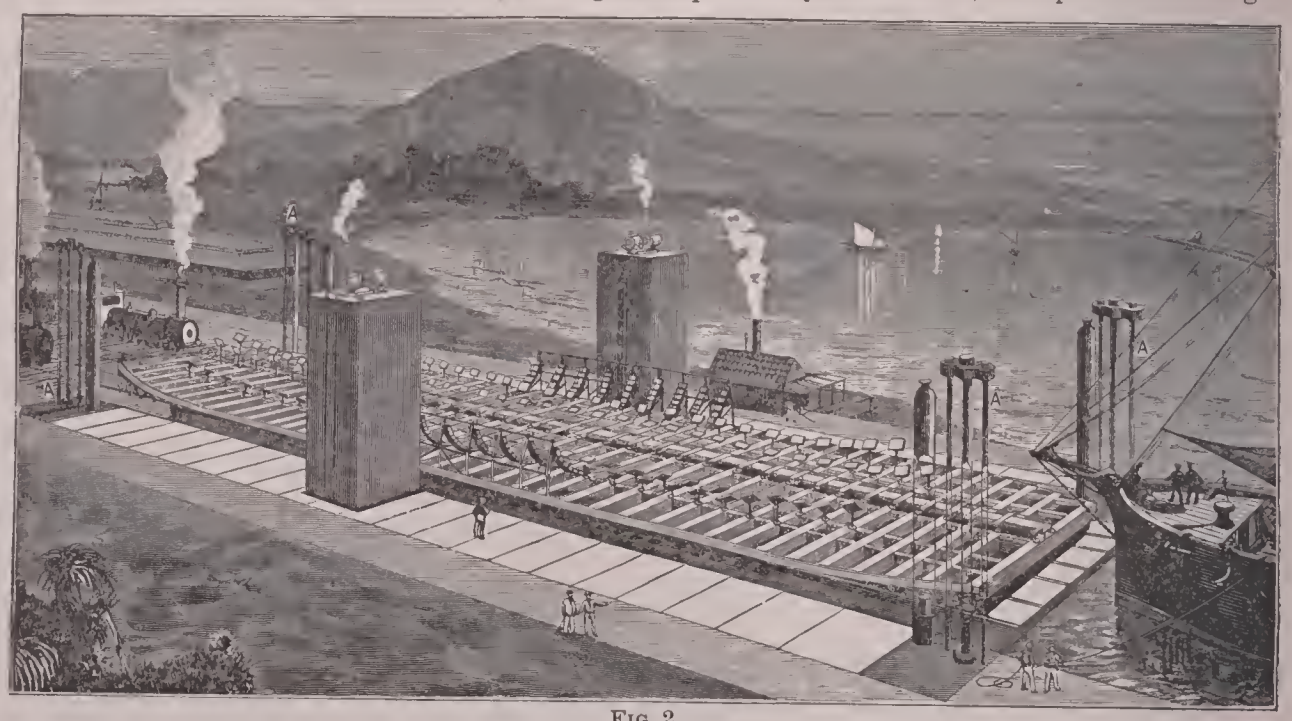

Fig. 2.

in distance and time to the main lines of commerce, its more healthful climate, the easy grades that are practicable

for the railway, and the excellence of the harbors (when improved) on each side. The summit between the two oceans is 736 feet above low tide; the heaviest grade on the line is $52\frac{8}{10}$ feet per mile, between the summit and the Pacific plains; on the remainder of the railway the grades where they occur are from 20 to 40 feet per mile. The total weight of ships carried will not exceed 7,000 tons; there will be six rails of very large section, laid in the most substantial manner, forming the railway, which is to be 134 miles long; all of which, with the lifting-docks, harbors, machinery, stations, shops, and all equipments, will cost less than $50,000,000.

Fig. 2 shows the proposed lifting-dock and cradle ready to receive a vessel as soon as submerged. The lifting-dock is to be a steel pontoon 450 feet in length, 75 feet in breadth, and 15 feet in depth. The pontoon is sunk very quickly by admitting water through sluice-gates in its sides, and can be raised again by powerful pumps in about fifteen minutes. The cradle is to be fitted with hydraulic appliances to properly distribute the weight of the vessel over the keel and bilge supports.

It is quite plain that a loaded ship's cradle presents exceptional difficulties as regards curves on the ship-railway.

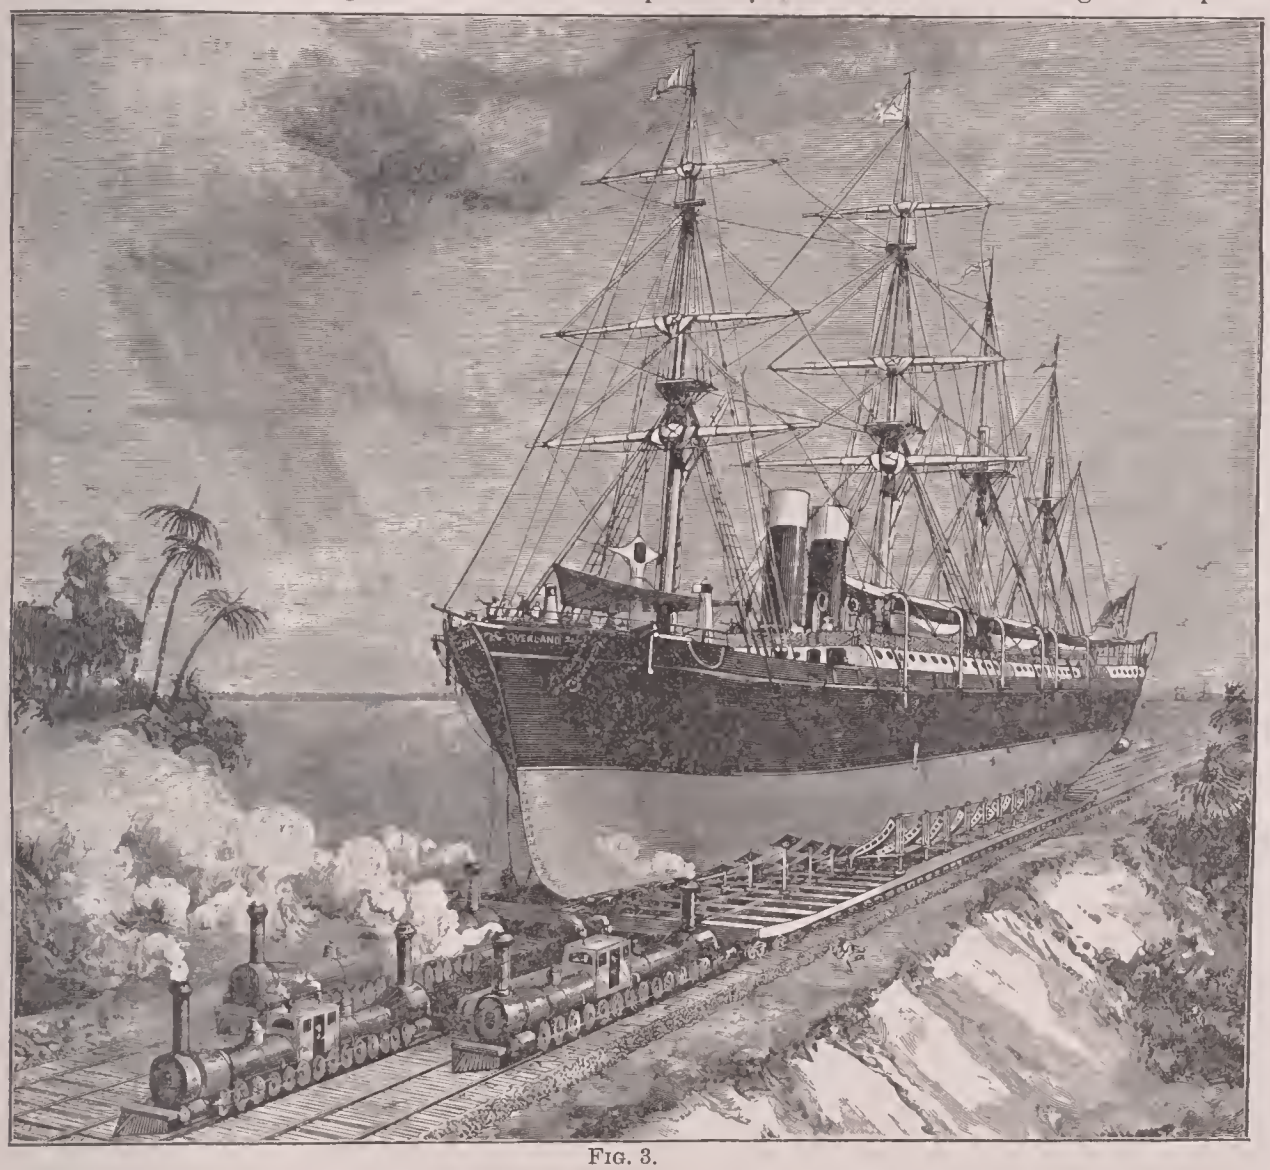

FIG. 3.

This difficulty is met at Tehuantepec by locating the railway on practically straight lines (no curves of less than 15 miles radius being permitted) connected with each other by turn-tables at their intersections.

Fig. 3 shows a steamer crossing the isthmus and hauled by the special locomotives designed for that purpose. As the electrical transmission of power is being rapidly developed into practical form, it is not unlikely that electrical motors on the axles of the cradle may be substituted for locomotives. The speed on the railway will be about 10 miles an hour, and the time elapsing between the taking of the vessel from one ocean and placing it in the other will not exceed eighteen hours.

E. L. CORTHELL.

Ship's Husband: the person to whom the owners of a ship delegate "the management of their common concern." Early treatises on the law of shipping show that the ancient practice was to confer this office on a part-owner, but at present a stranger is frequently employed in this capacity. If a part-owner holds the position he is known generally as managing owner. (See U. S. Rev. Stat., § 4145; 39 and 40 Vict., c. 80, § 36.) The ship's husband sees to the outfit for the voyage; procures provisions and sea-stores; provides proper master and seamen; looks after her legal registration and documents, as well as her due clearance from the custom-house; engages and settles for freight, adjusts averages, salvage, etc., enters into charter-parties, and keeps true and proper accounts of all contracts, payments, and receipts in the course of his employment. The master is sometimes called the ship's husband, but all that is meant in such cases is that when the ship is beyond the jurisdiction of owners and of husband, the master possesses many of the latter's powers. As the ship's husband is the agent of the owners in their capacity of joint adventurers in her employment, and not in their capacity of part-owners of the vessel, the scope of his authority is limited accordingly. He can do what is necessary to enable the ship to prosecute her voyage and earn freight, but he has no implied authority to bind the owners by a contract for altering the size of the ship, or for her insurance. Mercantile usage, however, seems to be extending the scope of this peculiar agent's authority. See Maclachlan's *Law of Merchant Shipping*, pp. 186–192 (ed. 1892); Abbott's *Law of Shipping*, pp. 99–111 (ed. 1892). He is paid by commissions generally, and is not entitled to additional compensation for any of the duties incident to his position. If he makes a secret profit out of his agency, it belongs to his principal. *Williamson* vs. *Hine* (1891), 1 Chancery Division 390.

F. M. BURDICK.

Ship's Magnetism: the disturbing effect produced on a compass by the magnetism of the iron in a ship. For the general principles of which ship's magnetism is a special case see the articles MAGNETISM, MAGNETISM OF IRON, and MAGNETISM, TERRESTRIAL.

So long as ships were chiefly built of wood it sufficed to avoid the use of iron about the compass within a radius of a few yards, and, in case metal had to be employed, to substitute copper. With the increased use of iron in the shape of beams, girders, posts, stanchions, guns, large anchors, engines, funnels, wire rigging, and its special use in ships of war, and when the ship itself could be regarded as a large magnet under the earth's inductive force, the subject of the deviation of the compass assumed a vast practical and theoretical importance.

The disturbance of the compass is principally due to subpermanent magnetism of the ship's iron, and is always produced by the transient induced magnetism of masses of soft iron. In wood-built ships there is little permanent magnetism, the generally small observed deviation being due to temporarily induced magnetism. In iron-built ships the generally large deviation is dependent on permanent magnetism, and remains indicative of the direction in which the ship was built, its magnetism, as a whole, having then become fixed by the process of hammering and riveting.

The inductive effect of the earth's magnetism is greatest in the line of the magnetic dip. By means of a small com-

pass C. A. Schott was enabled to trace out with chalk on the iron gun-turret (sides 11 inches thick) of an ironclad vessel its magnetic equator, and found its plane inclined to the horizon at an angle of nearly 90° dip; after revolving the turret 180°, the line of no polarity again was traced out, when the plane, passing through the intermediate horizontal position, gradually approached its former place after a lapse of about twelve hours; it probably takes weeks before the fixed position is reached, depending on the action of the iron. Inside such turrets the magnetic intensity is very much weakened, but 12 per cent. was found to be left in the above case. The reader is referred to Sir George B. Airy's *Treatise on Magnetism* (London, 1870) and to the *Admiralty's Manual for the Deviations of the Compass*, by Capt. F. J. Evans, R. N., and Archibald Smith (London). This manual is the standard work on the subject of the deviation of the compass.

The earth's magnetic force has been represented by three component forces, to the ship's head, to the starboard side, and to the keel respectively; similarly, the components of the combined total magnetic force of earth and ship are in these directions: their respective differences or components of disturbance can be expressed by linear equations possessing each a constant and three coefficients, which are to be determined by experiment for each ship and position of compass, and must be numerically worked out by application of the method of least squares.

The general character of the deviation in wood-built sailing ships, with compass as usual on the quarter-deck and over the middle fore-and-aft line of the ship, is found as follows: No deviation when heading (magnetically) N. or S.; greatest deviation when heading (magnetically) E. or W.; deviation easterly when head in eastern semicircle, and westerly when head in western semicircle. In steam-vessels, with the compass aft, these directions of no and maximum deviation will often be found displaced by several degrees, yet preserving their general symmetrical character. In the southern (magnetic) hemisphere the deviations are reversed, though for steam-vessels they may be only partially changed. In iron-built ships an individual character has to be recognized. The points of no deviation are shifted from the N. and S. points, and lie nearly in the direction (by compass) of the ship's head and keel while building; they may not be opposite to each other, nor be removed exactly at right angles from the point of maximum deviation. In general, the deviation is easterly when the part of the ship which was S. in building is E. of the compass; westerly when W. The deviation described above is technically known as the semicircular deviation, and may be expressed by $B \sin \zeta' + C \cos \zeta'$. In the general deviation formula $\delta = A + B \sin \zeta' + C \cos \zeta' + D \sin 2\zeta' + E \cos 2\zeta'$, the angle ζ being the azimuth or the compass-bearing of the ship's head reckoned from the disturbed magnetic meridian positive to the eastward; it is a constant, generally small, + if easterly deviation is in excess. $+ B$ is approximately the deviation at E., and $+ C$ at N.; in the last terms of the harmonic function involving $2\zeta'$, and which are technically known as the quadrantal deviation, $+ D$ is the mean deviation approximately at N. E. and S. W.: the coefficient E is generally small or zero; the deviation δ is reckoned + when the N. end of the needle is drawn to the E.; and the above empirical expression applies, provided the deviation on any course does not much exceed 20°, or about two points, in which latter case the formula becomes more complicated. The correct magnetic course will be $\zeta = \zeta' + \delta$. The semicircular deviation rarely exceeds 10° in wood-built vessels, but in iron-built ones may reach double and treble this amount. The quadrantal deviation seldom exceeds 1° or 2° in wood-built ships, but in iron-built ones may reach three or four times this amount. The semicircular deviation is principally due to the effect of permanent or sub-permanent magnetism. The quadrantal deviation, which undergoes no change with a change in the ship's place, is mainly due to the effect of induced magnetism.

The heeling error in wood-built ships is not appreciable, but in iron-built ones it may be serious; generally, the error vanishes with the ship's head at or near E. or W., and attains a maximum value with headings at or near N. or S. The sign of the error changes with a change from the northern (magnetic) to the southern hemisphere. In the northern (magnetic) hemisphere, with the compass above the upper deck, the majority of iron ships have the N. end of their compass-needle drawn to windward, and in the southern hemisphere to the leeward. The heeling error is due to the joint disturbing effect of the vertical components of permanent and of induced magnetism.

The values of the coefficients A, B, C, D, E, are found directly from observations, the deviation of the compass being observed with the ship heading in a number of equidistant points around the horizon, usually either 32, 16, or 8. If the deviation is observed on four cardinal compass-points, D remains indeterminate; if on four quadrantal compass-points, E remains indeterminate. These observations are made by swinging the ship (or allowing it to swing by the tide), and noting for the several headings the bearing of a distant object, or by reciprocal bearings if the locality be confined, or when at sea by azimuths of the sun, the local time and latitude being known. The deviations being determined for a number of points, they may be plotted on what is known as Napier's diagram, and graphically interpolated by drawing a curve with a free hand through the several fixed positions. The deviations for any compass course will then become known. They may also be tabulated. If we deduce numerically the coefficients A, B, C, D, E, we can compute directly the values of δ for plotting or tabulation. In either case we know the correct magnetic course corresponding to the disturbed or compass course, as well as the reverse of the compass course belonging to any correct magnetic course.

It has been remarked that inside iron turrets the magnetic intensity is greatly diminished; the same is the case with nearly all iron ships, the directive force of the needle being diminished. The relative horizontal force is found by means of the number of oscillations in a given time of a small needle, and the proportion of the disturbed to the undisturbed horizontal force, usually called λ, is determined from oscillations in four equidistant azimuths. It is usually less than 1, and is closely connected with the coefficient D, as may be surmised from the fact that λ is due to the effect of the horizontal induction of soft iron. D and λ are nearly constant. A knowledge of the value of λ is of importance; by its assistance the values of B and C may be found without swinging the ship from observations of δ and λ on one course; similarly, observing on two courses, we may determine B, C, D and λ. The value of λ is further needed in the computation of the heeling error, which is expressed—$\left(D + \frac{\mu}{\lambda} - 1\right) \tan \theta \,.\, i \,.\, \cos \zeta'$ for a heel of the vessel of $+ i$ degrees to the starboard. Here μ is the ratio of the disturbed vertical force at the compass to the earth's vertical force; it is found by means of oscillations of the dipping-needle in the plane of the magnetic prime vertical; μ changes with a change in the geographical position; θ is the magnetic dip. It is therefore not actually necessary to heel the ship in order to determine the heeling deviation. It should be added to the general deviation table.

The mechanical correction of the deviation of the compass is properly resorted to in case no suitable position for the standard compass can be found where the deviations are comparatively small; in ships built head S. (northern hemisphere), and intended for navigation in northern magnetic dips, the compass should be placed as far forward as practicable. It may also be elevated 3 or 4 yards above deck. The semicircular deviation may be corrected mechanically, either by means of two magnets or by one magnet; the quadrantal deviation may be corrected by a mass of soft iron placed near the level of the compass; the same may be effected by the mutual action of two compasses placed side by side; the heeling deviation may be corrected by the application of a vertical magnet. In mechanically corrected compasses there is always some danger that, with change of geographical position, loss of magnetism of magnets, and change in the sub-permanent magnetism of the hull, deviation may reappear, though the disturbing force may have been completely neutralized in one place and at one time. It is therefore never to be trusted, and, as a rule, deviation tables should be formed whether mechanical corrections have been applied or not.

An excellent collection of important memoirs, entitled *A Series of Papers from the Transactions of Foreign Societies by Poisson, G. B. Airy, A. Smith, F. J. Evans, W. W. Rundell*, with other papers and documents, has been published by the British Admiralty. Revised by Frank H. Bigelow.

Ship's Papers: See the Appendix.

Ships of War: vessels built and armed for offensive or defensive purposes. Modern war-ships include the fol-

lowing types: armored vessels for the line of battle and for coast service, armored cruisers, rams, protected cruisers, unarmored cruisers and auxiliaries, gun-vessels, gunboats, torpedo-vessels, torpedo-catchers, torpedo-boats, and various vessels for harbor service. It is the endeavor to give in this article a brief historical sketch of modern naval construction in Great Britain, France, and the U. S., which, until the later activity of the Italian authorities, have alone originated types of war-vessels; this to be followed by descriptions of the more important typical war-ships of the various classes, which may serve to render more intelligible the tabular statement of the ironclad navies of the world.

Incentives to the Application of Armor.—Since about the middle of the nineteenth century a revolution has been brought about in naval construction, and new systems have been adopted through the influence of the following agents: (1) The application of steam, strictly the screw-propeller; (2) shell-firing and the increased power of artillery; (3) the use of armor; (4) the submarine torpedo. Up to the time that the advantages of the screw were established to the satisfaction of admiralty boards, steam-vessels were regarded valuable merely as auxiliaries, owing to the vulnerability of paddles and machinery, the limited scope of the battery, the enormous coal-consumption of their engines, and the difficulty in making paddle-wheel steamers good sailing vessels. The U. S. steamer Princeton (1842–43) was the first screw war-steamer. She was designed by Ericsson, and her construction and success were mainly due to the efforts of Capt. Robert F. Stockton, U. S. navy. Great naval powers are reluctant to begin changes that involve costly reconstruction; this, with the conservatism regarding any new system, was the reason of the otherwise inconceivable reluctance of the British to take up the project of a screw-navy. When the French built the line-of-battle screw-ship Napoleon (1850), the British took alarm and began reconstruction with vigor; and the renovation of their navy by the application of the screw was well advanced in 1859, when the French launched the ironclad wooden frigate La Gloire. Then began the decline of unarmored battle-ships.

The principal incentive to the application of armor was the destruction anticipated from shell-fire. It was not until 1854 that naval batteries consisted entirely of shell-guns, the magazines being filled with loaded shells entirely fused. Admiral Dahlgren carried the application of this missile to great perfection in the U. S. frigates of 1854. The Merrimac, one of these, visited Europe in 1856, startling naval administrations by the enormous shell-power of her battery. The swift destruction of the Turkish fleet at Sinope by the shells of the Russian ships during the war in the Crimea (1853) had much to do with hurrying forward the application of armor; the destruction of the Congress and the Cumberland during the civil war in the U. S., and the Monitor and the Merrimac engagement, gave it fresh stimulus.

Early Forms of Armored Ships.—The first definite proposal for building an ironclad was made in 1841 by Robert L. Stevens, of Hoboken, N. J.; armor, it is stated, was suggested by his father, John Stevens, in 1812. An act approved Apr. 12, 1842, authorized the Secretary of the Navy to enter into a contract with Stevens for the construction of a "war-steamer for harbor defense, shot and shell proof, to be built principally of iron." The contract was made Feb. 10, 1843, and altered Nov. 14, 1844, increasing the dimensions so as to make them as follows: Length, 415 feet; beam, 48 feet; depth, 33 ft. 6 in.; protection, 6¾ inches of iron; horse-power intended, 8,624. Work was begun in 1854; and when the vessel was about half completed, the Government refused further appropriations.

It was the initiative taken by the Emperor Napoleon III. which brought about a complete revolution in modern naval construction of war, as the first ironclads used in battle were the French batteries Dévastation, Lave, and Tonnante, begun for service in the Crimea in Sept., 1854, two months after the keel of the Stevens battery was laid at Hoboken. They were all of the same dimensions—namely: Length, 171 ft. 9 in.; beam, 43 ft. 1 in.; draught, 8 ft. 8 in.; hulls, of wood; armor, 4·33 inches thick; armament, 16 guns of French "50," corresponding to 68-pounder, carried 2 ft. 11 in. above water-line. They were about 1,600 tons displacement, with speed about 4 knots an hour. They formed part of the fleet, carrying 1,500 guns, which destroyed Fort Kinburn, an inferior barbette work. The ironclads engaged at about 1,000 yards, at which range they were proof against 32-pound shot with 10-pound charges. The British adopted the design and built five, but they were never in action.

In view of these successful results, the French determined to build ships which should combine with their protective armor satisfactory seagoing qualities, and in Mar., 1858, the first ironclad frigate, La Gloire, was begun at Toulon. The construction of two other wooden armored frigates—the Invincible and the Normandie, of the same type as the Gloire—and the Couronne, an iron vessel, was ordered. The latter ship differed from the others not only in the materials employed, but in the strength of the deck, which afforded protection against the projectiles then in use. The Couronne was especially constructed with a view of establishing comparison between wooden vessels and those of iron. The four frigates were completely armored above the water-line with 5-inch plates resting on a 26-inch wood backing. The armament consisted of thirty-six 5-ton guns mounted on a single battery, extending the whole length of the ship, 6 ft. 3 in. above the water-line.

Great Britain at last decided to follow in building armored ships. The Warrior was ordered in June, 1859, a few months before the completion of the Gloire. The Warrior and her counterpart, the Black Prince, were one-half greater displacement than the Gloire, and 132 feet greater length; they were built entirely of iron and armored with 4½-inch iron plates over a length of 218 feet out of a total length of 380 feet. Their speed was 14 knots, compared with 12·8 for the Gloire. The wise choice of the material of construction leaves them serviceable vessels to-day, while the French ships were some years since stricken from the list. The Defense and the Resistance, of 6,150 tons displacement, with similar disposition of armor, were begun at the same time. In 1861, following upon the four ships just mentioned, Great Britain undertook the construction of not less than eleven ironclads, representing four different types—the Achilles, 9,820 tons displacement, armored along the whole length with 4½-inch plates, then the Minotaur, the Northumberland, and the Agincourt, of 10,700 tons displacement, similar to the Achilles, except that the armor was 5½ inches thick amidships, tapering to 3 inches at the extremities. The vessels of the fourth type, the Hector and the Valiant, have proved more serviceable than the others, being smaller, more manageable, and much more economical; they were armored throughout the whole length with 4½-inch plates, the protection being only above the water-line at the bow and stern. The Magenta and the Solferino, laid down two years after the Gloire, formed part of the first group of French ironclads. The second group consisted of ten vessels of the Provence or Flandre class. The displacement was slightly augmented, but the protection was increased to 6 inches of armor.

Up to 1855 the vessels built for the U. S. navy were the best possible specimens of their class; among the early steamers, the Powhatan and the Susquehanna, at the time they were launched, in 1850, were the most efficient naval vessels afloat. The screw frigates, built in 1855, were regarded all the world over as the model men-of-war of the period. Of these, the largest was the Niagara. The other five—the Roanoke, the Colorado, the Merrimac, the Minnesota, and the Wabash—were vessels of about 5,000 tons, and carried a powerful battery of shell-guns. The twelve screw-vessels were of two classes, built in 1858, the first, of about 3,000 tons, including the corvettes Lancaster, Hartford, Richmond, Brooklyn, and Pensacola; the second class, small sloops. These were all admirable vessels, but they were no advance upon the type of the Wabash class. At the beginning of the civil war, of the ninety ships on the naval register fifty were sailing vessels, and only twenty-four of the forty others were serviceable steamers. The construction of iron or armored vessels had not been begun, and sail-power had been only partly replaced by steam-power. At the outbreak of the war a special naval board was appointed to determine upon types of ironclads to be built for immediate service. The three ships ordered on the recommendation of the board were the broadside vessels Galena and New Ironsides, and the Monitor. The first vessel was armored with bars, of 2½ inches total thickness, put on in a very complicated manner, which proved so deficient that the vessel failed in the first test under fire, in the James river, in an action from which the Monitor came out unharmed. The New Ironsides was a casemated ironclad wooden frigate with unarmored ends, except that the water-line belt was complete all around. Her armor consisted of 4½-inch solid plates backed by 21 inches of oak, the whole inclined throughout the casemate at an angle of 30° from the vertical. Her battery consisted of fourteen 11-inch

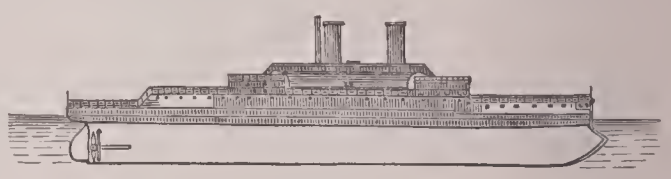
smooth-bores and two 8-inch Parrott rifles. Though her speed was only about 6 knots at the best, this vessel performed most valuable and effective service throughout the war, both before fortifications and on the blockade. In a period of about six months she was struck some 193 times, but never forced to go into a home port or to depend upon outside assistance for repairs. The MONITOR (*q. v.*) was built of iron under the superintendence of, and from an original design by, Ericsson. The opportune appearance of the Monitor in Hampton Roads in Mar., 1862, and her successful combat with the Merrimac, gave a fictitious value to this vessel as an example of naval architecture. Nevertheless, these vessels performed invaluable services and furnished the type of modern coast-service ironclads and a system of armament which has been followed in the most powerful ironclads of recent construction. At the termination of the war it was determined to build four seagoing double-turreted monitors without overhanging armor-shelf at either the end or the sides. These were the Miantonomoh, the Monadnock, the Terror, and the Amphitrite. Their hulls were of wood, and were armored with laminated plates an inch thick, with a total thickness of 6 inches at the sides and 12 inches on the turrets. The Miantonomoh made a voyage to England, where she attracted much attention, and was no doubt the progenitor of the Devastation; the Monadnock was sent around Cape Horn to San Francisco. In 1874 these vessels were broken up and rebuilt into the double-turreted monitors of the same names.

Improvements in the Construction of Ironclads.—During the period of the civil war in the U. S. construction of ironclads proceeded rapidly in Europe, but until a later period it was more influenced by the developments in artillery than by the results of the war. The introduction, in 1864, of the 7¾ and 15½ ton guns into the French armaments made the Flandre class ineffective before they were completed. In 1865 the Océan was begun, and later the Marengo, the Suffren, and the Friedland, after the same type, only the latter being completely of iron. They were protected at the water-line by 8-inch armor. The armament consisted of four 23-ton guns mounted in a central battery protected by 6½-inch armor, and four 15½-ton guns in barbette turrets at each of the four corners, projecting beyond the sides of the ship, and armored with 6½-inch plates. The Friedland differs from the other ships in having only two barbettes, each armed with a 23-ton gun. In 1868–69 a fourth group of ships was begun, the Richelieu, the Colbert, and the Trident, plated with 9-inch armor and very similar to the preceding group, the excess of 1,200 tons displacement being devoted mainly to armor and armament. The hulls of these ships were constructed of wood, except the extremities forward and abaft of the central battery, which were of iron. Such was the construction of the French ironclad navy up to the time of the Franco-German war.

E. J. Reed, appointed in 1862 to the office of chief constructor of the British navy, undertook the building of the Bellerophon, in which the cellular system of construction was first fully introduced, realizing a considerable saving in weight with great increase in the strength of the structure, and obtaining a system of water-tight subdivision which is the only protection against rams and torpedoes. Designs for the best mode of defense combined with the most powerful means of attack sprang up with the rivalry between guns and armor. For masted ships Capt. Coles advocated the turret system and Mr. Reed the broadside system, each striving to give the utmost protection armor could afford to the battery and other vital parts, while enabling the largest guns to be worked safely under these defenses. The broadside system armored the battery and the water-line, while the sides and the upper portions of the ships remained much as in the older frigates. The turret aimed at lower sides, as offering less target to the enemy, while affording an all-round protected fire. In 1862 the Enterprise, the Favorite, and the Research were adapted to Mr. Reed's principle—the belt and the battery—upon which, also, with the addition of indented ports at the corners of the battery, to give wider range of fire, were built the Pallas, the Penelope, the Bellerophon, and the Hercules. In the Sultan an upper-deck battery with four guns was added. On the Sultan pattern the Audacious and several other vessels were built. As the guns increased in size the batteries decreased and the guns became fewer, but the belt remained.

The Monarch, ordered in 1865, was designed as a seagoing rigged turret-ship having 7-inch armor, a free-board of 14 feet, and an armament of four 25-ton guns in two turrets plated with 8-inch and 10-inch armor. Then came the Captain, a ship designed by Capt. Coles and Messrs. Laird in rivalry of the Monarch. She was intended to combine a low free-board with the qualities of a seagoing frigate, and the result of her first cruise seemed to indicate the value of the combination; but an investigation of the calamity of her capsizing in the Bay of Biscay, on the night of Sept. 6, 1870, with 500 men, only eighteen of whom were saved, showed that, in comparison with the other qualities, the small stability due to lack of free-board was a fatal error in her design. This disaster led to more complete and exact investigations of the stability of ships than had ever before been customary. A seagoing mastless turret-ship, or improved and enlarged monitor, was then devised, and three such ships were built—the Devastation, the Thunderer, and the Fury.

The Devastation is a mastless, twin-screw, sea-going turret-ship, 285 feet long, 62 ft. 3 in. beam; mean draught, 26 ft. 8 in.; displacement, 9,300 tons. Her sides, which rise 4 ft. 6 in. above the water-line right aft, are protected along the whole length by armor 12 inches thick; right forward this belt drops to 6 inches above the water-line, and is covered by an armored deck, 3 inches thick, arranged so as to give great support to the bow in ramming. Armor of the same thickness covers the deck aft. On the middle of the upper deck there is a raised breastwork about 150 feet in length, protected by 10-inch and 12-inch armor, covered by a deck 2 inches thick and 11 feet above the water, forming a glacis for two turrets, each containing a pair of 35-ton guns, protected by armor 12 and 14 inches



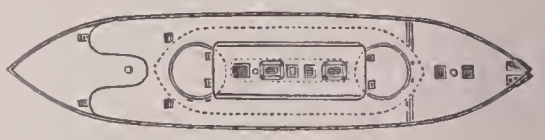


FIG. 1.—Devastation.

thick. All the necessary hatches, openings, smoke-pipes, etc., are led up by iron trunks to a light flying-deck which extends between the two turrets, slightly overlapping each. The sides of the vessel above the armor-belt are continued, forming an unarmored superstructure extending 9 ft. 3 in. above the water-line forward, and to the height of the breastwork throughout its length and slightly abaft it, the open deck aft having 4½ feet free-board. The trial at load-draught showed a speed of 13·84 knots, the engines developing 6,650 indicated horse-power. She carries 1,350 tons of coal, which enables her to steam 4,700 knots at 10 knots an hour.

In 1894 the Devastation was refitted throughout, supplied with new machinery and armament, and extensive internal rearrangement. The tables at the end of this article give the present outfit.

In the construction of the third ship, the Dreadnought—first named Fury—a new design was followed, making the breastwork of the same width as the ship itself—in other words, raising the armored side of the ship to a level with the upper deck of the breastwork. The Dreadnought was 35 feet longer and of over 1,500 tons greater displacement than the Devastation, and the armored belt was carried for the whole length of the ship at the same height above the water-line, increased to 14 inches thickness amidships. In 1885 this vessel, whose design was then sixteen years old, was commissioned as the flagship of the British Channel squadron.

In 1872–73 the Italian first-class battle-ships Duilio and Dandolo were begun. They were the first vessels of the central-citadel type with revolving turrets *en échelon*. For their general design the naval authorities accepted the view of the British committee on designs, trusting for both buoyancy and stability to their unarmored raft. The principal dimensions are as follows: Length between perpendiculars, 340 ft. 11 in.; beam, 64 ft. 9 in.; mean draught, 26 ft. 7 in.; displacement at deep load-line, 11,200 tons.

There is a central citadel or compartment, 107 feet in length and 58 feet in breadth, which descends to 5 ft. 11 in. below the water-line, protecting the machinery and boilers, the magazines and shell-room, and a portion of the

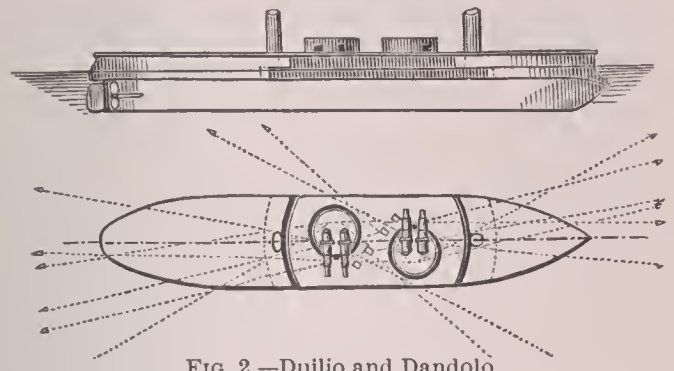

Fig. 2.—Duilio and Dandolo.

machinery for working the turrets and guns. Forward and aft of this citadel, the decks, which are 4 ft. 9 in. under water, are defended by horizontal armor. Over this citadel is built a second central armored compartment, inclosing the bases of the turrets and the remaining portion of the mechanism employed in loading and working the guns. Lastly, above this second compartment rise the two turrets, placed at diagonally opposite corners of the citadel, the effect of which arrangement is to render possible the discharge of three guns simultaneously in a direction parallel with the keel. Each turret is armed with two 100-ton Armstrong muzzle-loading guns. The armor of the central portion of the vessel is 21·67 inches thick, and that of the turrets is 17·72 inches. The decks are protected by horizontal armor of steel and iron, the latter being under the former. The Duilio has twin screws, driven by a pair of Penn's trunk-engines. On the trial, in 1880, with all weights on board, at a mean draught of 26 ft. 9 in., the vessel showed on the measured mile, with 7,710 indicated horse-power, a speed of 15 knots per hour.

The Inflexible.—Upon the construction of these ships Mr. Barnaby, director of naval construction in Great Britain, brought forward the design of the Inflexible, of similar type, until 1886 the largest vessel in the British navy. The Inflexible, begun in 1874 and launched in 1876, is a

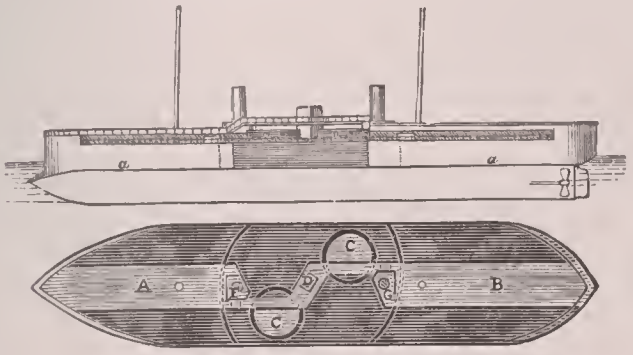

Fig. 3.—Inflexible.

twin-screw double-turret ship with a central armored citadel. Her length is 320 feet, and she has the extraordinary breadth of 75 feet. The displacement at the mean load-draught of 25 ft. 3 in. is 11,880 tons. The general design is similar to that of the Duilio. The protected portion of the ship is confined to the citadel or battery, within whose walls are inclosed the engines and the boilers, the turrets, the hydraulic loading-gear, the magazines, and, in fact, all the vital parts of the vessel. It measures 110 feet in length, 75 feet in breadth, and is armored to the depth of 6 ft. 5 in. below the water-line and 9 ft. 7 in. above it. The sides of the citadel consist of two thicknesses of 12-inch armor, each backed by iron girders and teak backing. Inside of this are two thicknesses of skin-plating, to which the horizontal girders are secured, the whole of the armor-backing and plating being supported by and bolted to transverse frames 2 feet apart, composed of plates and angle-irons. It will thus be seen that the total thickness of armor at the water-line is not less than 24 inches. The armor-belt, however, is not of uniform strength throughout, but varies in accordance with the importance of the protection required and the exposure to attack. Consequently, while the armor at the water-level is 24 inches, in two thicknesses of 12 inches each, above the water-line it is 20 inches, in two thicknesses of 12 inches and 8 inches, and below the water-line it is reduced to 16 inches, in two thicknesses of 12 inches and 4 inches. Outside the citadel a 3-inch armor-deck, 6 ft. 6 in. below the water-line at the sides, extends to the extremities of the vessel, depressed at the fore end to meet the spur of the ram. Over this shot-proof deck, at a level a little above the water-line, comes the middle deck; and the entire space between the two decks is divided into compartments arranged partly to carry coal and partly stores packed in water-tight tanks, forming further subdivisions of the space. At the sides of the ship the compartments, about 4 feet wide, are filled with cork, inside which, again, are compartments, 2 feet wide, filled with layers of canvas and oakum. The cork and canvas compartments are carried above the main deck, 4 feet and 2 feet respectively, and 30 feet forward of the citadel and 37 feet aft of it. Thus if a shot hit the unarmored ends of the vessel at right angles to the water-line, it would travel through, first, 4 feet of cork, then 2 feet of canvas and oakum, then such coal and stores as were uneonsumed, and would finally pass through oakum and cork to the sea on the opposite side from which it entered. The cork is, of course, intended as a life-belt to the ship, to give her additional buoyancy and stability when the unprotected ends are riddled and filled with water. The turrets are set *en échelon*, or diagonally in opposite corners of the citadel, so that all the guns can be fired together, either forward or aft, without either turret obstructing the fire of the other. They are protected by armor-plates 16 inches thiek. The internal diameter of the turrets is 28 feet; in each are two 80-ton muzzle-loading rifled guns mounted on Armstrong's hydraulic system. The guns themselves are 26 ft. 9 in. in length; the bore is 24 feet long and 16 inches in diameter. The weight of each projectile is 1,700 lb., and the powder-charge weighs 450 lb. The guns are loaded by depressing the muzzles bencath the level of the armor-deck covering the citadel, where a hydraulic hoist lifts the charge to the muzzle, whence it is put home by a hydraulic rammer. The Inflexible is propelled by twin screws—an arrangement adopted in all ironclads and most recent unarmored vessels. Each screw is driven by an independent three-cylinder inverted compound engine. On trial, when in commission and complete in every respeet, the engines developed an indicated power of 8,010, giving a speed of 13·81 knots per hour. The ship carries 1,200 tons of coal, enabling her to steam 4,900 knots at 10 knots per hour. Two years after the construction of this vessel was begun, Mr. Reed stated in Parliament and in the public prints that his investigations showed that in action the cork and stores might be shot away and the unprotected ends riddled and waterlogged, and that in sueh an event, though the citadel were still intact, the ship would capsize. The reply was that the supposed case was too remote a possibility to be considered, and that without any unprotected ends the ship would still float, and under the most unfavorable circumstances would have a margin of stability. A technical committee, appointed to investigate the matter, after most elaborate calculations of great value to naval architecture, completely sustained the views of the admiralty.

The Italia and the Lepanto.—In these great vessels of the Italian navy, launched in 1880 and 1883, of 15,900 tons displacement, side-armor is not used as a means of preserving stability when the ship is pierced at the water-line. Their buoyancy is preserved in such an emergency by the cellular subdivisions of the space just above an arched armored deck extending the whole length of the ship beneath the water-line. Armor is used only at the openings to the engine and boiler rooms, and to protect the heavy guns mounted *en barbette* and the communications leading to them from the magazines. The Lepanto was tried at sea in 1888 at a displacement of 14,800 tons, and made a maximum speed of 18·38 knots over a course of 80 miles, with the engines developing 16,150 I. H.-P. The trial is notable from the facts that the power and speed surpassed those of any ironclad afloat, and also because a large number of locomotive-boilers were used with complete success in connection with boilers of the usual type.

In 1883–84 Italy began the construction of the Andrea Doria, Ruggiero di Lauria, and the Francesco Morosini, first-class battle-ships of some 11,000 tons displacement; these ships were completed in 1892, and are similar in design to the Duilio. They were followed in 1885–86 by the Re Umberto and Sicilia, sister ships, similar to the Lepanto, and the Sardegna, a still more formidable ship of the same class, was begun in 1887.

The "Admiral Class" of British Vessels.—Following the Inflexible, the British built the Ajax and the Agamemnon, reduced copies of the first vessel, and then the Colossus and the Edinburgh of the same type, with 18 inches side-armor and armed with 43-ton breech-loading guns. A great gain was made in the speed of the latter two vessels over their predecessors, partly by a better form and partly by improved propelling machinery, by which much greater power has been obtained from the same weight of material. The "Admiral" class, of which the Collingwood was the first, begun in 1880, followed by the Rodney, the Howe, the Anson, the Camperdown, and the Benbow, in 1883–84, while following the same system of construction, have their battery mounted *en barbette*. This modifies the distribution of the armor by dispensing with the upper part of the citadel—necessary with turrets to protect their training, loading-gear, etc.—and allows the maximum thickness of the armor to be concentrated on the water-line where required to protect the machinery and the boilers. A part of the weight thus saved, and that due to the less weight of barbettes over turrets, is devoted to ordnance; for the Howe, the Camperdown, and the Anson carry four 66-ton guns each, the Rodney four 68-ton guns, and the Benbow has two 111-ton guns. In addition to the heavy guns they all carry six 6-inch guns in a machine-gun proof battery on the upper deck, between the barbettes.

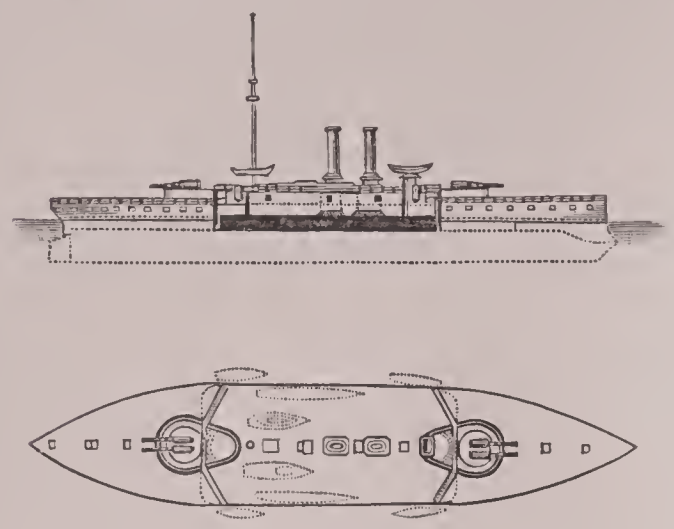

FIG. 4.—Collingwood.

British Turreted Ships.—The steady progress of France and Italy in the building of armored vessels of the first class had in 1884–85 aroused the attention of the British to the probability that if their rate of construction were to continue the French fleet would soon be superior to theirs, and eminent authorities contended that upon certain methods of comparison the French fleet was then the more powerful. The relative merits of the central-citadel type of British battle-ship and the completely armor-belted battle-ships of the type of the Amiral Duperré received careful attention, and though most serious allegations were made by Sir E. J. Reed, popularly considered an authority, against the safety of the citadel-ships when their ends were riddled by shot, the balance of favor seems to remain with the British type. As the result of this discussion Great Britain laid down in 1885 two turreted battle-ships, the Victoria (afterward sunk by collision with the Camperdown) and Sans Pareil, of 10,470 tons displacement each, the armament consisting of two 110-ton 16¼-inch guns in a single turret forward, protected by 18-inch compound armor, and twelve 6-inch guns in broadside on the upper deck, protected by a 3-inch steel side and steel traverses. The citadel is 170 feet long and the armor 18 inches thick at the sides. Also were then begun the Nile and Trafalgar, two double-turreted battle-ships of type similar to the Inflexible, of 11,940 tons displacement. Their armor-belt is of unusual length and 20 inches thick. The two turrets, each mounting two 66-ton guns, are situated, like the Dreadnought's, on the middle line, but, unlike this ship, the Nile and Trafalgar have a broadside battery of eight 5-inch guns between the turrets. These vessels attained on trial in 1890 a speed of 17 knots.

These vessels were regarded when designed as the maximum displacement and power to be hereafter required, and indeed it was predicted by some authorities who favored the building of protected cruisers that these vessels might be the last ironclad battleships. They were hardly launched when the British authorities formulated in 1889 the most extensive programme ever adopted by them. Under the title of the Navy Defense Act $105,000.000 was appropriated for building and completing by Apr., 1894, 70 vessels to carry 566 guns, having an aggregate of 336,000 tons displacement and of 594.000 horse-power. These vessels comprise 10 armored battle-ships, 8 of the first and 2 of the second class; 40 protected cruisers, 9 of the first and 31 of the second class; and 18 torpedo-vessels. The distinguishing features of the programme were the rapidity with which the vessels were to be built, the great increase of engine-power and speed, and the increase in size and power of the armored vessels. Nine out of ten of these are barbette-vessels, in contrast to the recent turret-ships, and are of greater free-board and superior sea-keeping qualities to the earlier vessels. The Royal Sovereign, the first of these battle-ships, was completed in Apr., 1892. The rapidity of construction surpasses all previous records in the building of great war-ships, as the Royal Sovereign was laid down in Sept., 1889. This vessel is the largest battle-ship hitherto constructed for the British navy, and has six counterparts, named the Renown, Repulse, Ramillies, Resolution, Revenge, and Royal Oak. The eighth vessel of this class is a turret-ship, the Hood. The armament of the Royal Sovereign comprises four 13½-inch 67-ton guns, mounted in barbette in pairs, and firing a projectile weighing 1,250 lb. with a powder-charge of 630 lb.; ten 6-inch 100-pounder quick-firing guns, double-banked, the four on the main deck being mounted in casemates protected by 6-inch armor, while the six on the upper deck are mounted in sponsons; sixteen 6-pounder and twelve 3-pounder quick-firers, 8 small machine-guns, and two 9-pounder field-guns. The auxiliary armament is distributed all over the ship and extends from bow to stern. The ship is also fitted with seven torpedo-tubes, of which two are submerged. The following table gives the principal dimensions of the Royal Sovereign and her predecessor in design, the Trafalgar, and includes the results of actual trials for speed and power as obtained in smooth-water trials:

DIMENSIONS, ETC.	Royal Sovereign.	Trafalgar.
Length	380 ft.	345 ft.
Breadth	75 ft.	73 ft.
Draught, mean	27 ft. 6 in.	27 ft. 6 in.
Displacement, tons	14,150	12,500
Free-board { forward	19 ft. 6 in.	11 ft. 3 in.
Free-board { aft	18 ft.	11 ft. 3 in.
I. H.-P. { natural draught	9,700	8,440
I. H.-P. { forced draught	13,300	12,900
Speed { natural, knots	16·77	16·22
Speed { forced, knots	18·0	17·28
Coal carried at the designed load-draught, tons	900	900
Coal endurance at 10 knots	5,000	5,000
Total weight of armament, tons	1,410	1,035
Weight of auxiliary armament, tons	500	135
Height of heavy guns above water-line	23 ft.	15 ft.
Length of belt	250 ft.	230 ft.
Greatest thickness { side armor	18 in.	20 in.
Greatest thickness { protective deck	3 in.	3 in.
Total weight of armor and backing, including protective deck, tons	4,550	4,400

Growth of the French Navy.—The modern navy of France dates from the close of the Franco-German war, when a programme was elaborated, according to which the armored fleet was to consist of 16 first-class ironclads, 12 second class, and 20 coast-service vessels of two classes. It was then definitely decided to use only iron or steel in future construction, a conclusion which was arrived at very tardily considering the progress upon the opposite side of the Channel.

The Redoutable, 8,800 tons, the first vessel built in accordance with the new programme, was begun in 1872 upon designs of M. de Bussy, and was then classed as a first-class ironclad. The Dévastation and Foudroyant (since named Courbet), ships of nearly 10,000 tons displacement, were begun in 1876 upon the same general plans as the Redoutable, masted, high free-board, central battery.

The Amiral Duperré, begun in 1876, has proved the type upon which the later French ships have been designed without substantial variation, excepting only that the later vessels have been fitted with military masts instead of the full ship-rig of spars and sails. The designers, believing that mastless low free-board turret-ships would not make good seagoing battle-ships, and in order to reduce the armored area and increase its thickness, discarded the central battery of the preceding first rates, which was also no longer suitable to the heavy guns required, and mounted on the Amiral Duperré four 13½-inch 48-ton guns, each in an armored bar-

British Battle-ship Royal Sovereign.

THE UNITED STATES BATTLE-SHIP "OREGON.

bette on the upper deck, 27½ feet above the water. There are fourteen 5½-inch guns in an unprotected gun deck-battery. The armor consists of a complete water-line belt 8 feet deep and 21·6 inches maximum thickness. The bar-

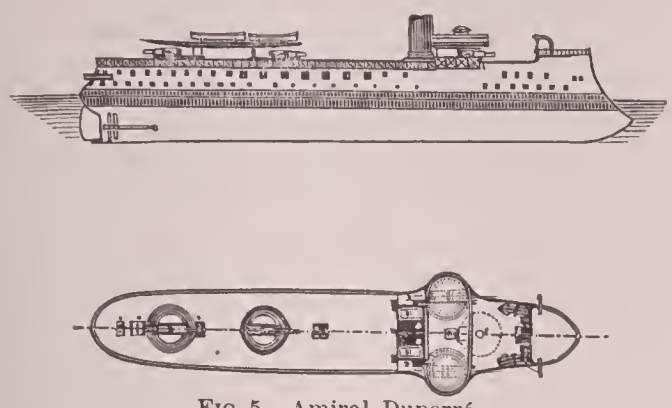

Fig. 5.—Amiral Duperré.

bettes have 15½-inch armor-plates and armored ammunition-tubes leading to the armor-deck, 2¼ inches thick at the level of the top of the belt. The Amiral Duperré has in a marked degree the distinguishing peculiarity of all the French vessels, a great "tumble home" or decrease in breadth from the water-line up. This serves the double purpose of decreasing the weight of upper works and giving better command to the battery. The Formidable and Amiral Baudin, sister ships, begun in 1878 and 1879 respectively, were practically upon the same design as the Amiral Duperré, the modifications consisting in mounting three 15-inch 75-ton guns in barbettes on the middle line of the upper deck and having two military masts, and consequently no sail-power. These two vessels were ten years in building, and were completed and successfully tried in 1889, the Formidable making under forced draught a speed of 16·2 knots with 9,700 I. H.-P. In 1880 four first-class battle-ships of 10,500 tons, from the same design by M. Huin, the Marceau, Hoche, Neptune, and Magenta, were begun. Each was to carry four 13½-inch guns in barbettes placed one forward and one aft on the middle line and one on each side in sponsons, obtaining a fore-and-aft fire. Subsequent changes were made by which the Hoche carries the forward and after guns in turrets with a comparatively low free-board at the extremities, similar to the British sixteen 5½-inch, as in the earlier designs, the armor being confined to the complete water-line belt and the barbettes.

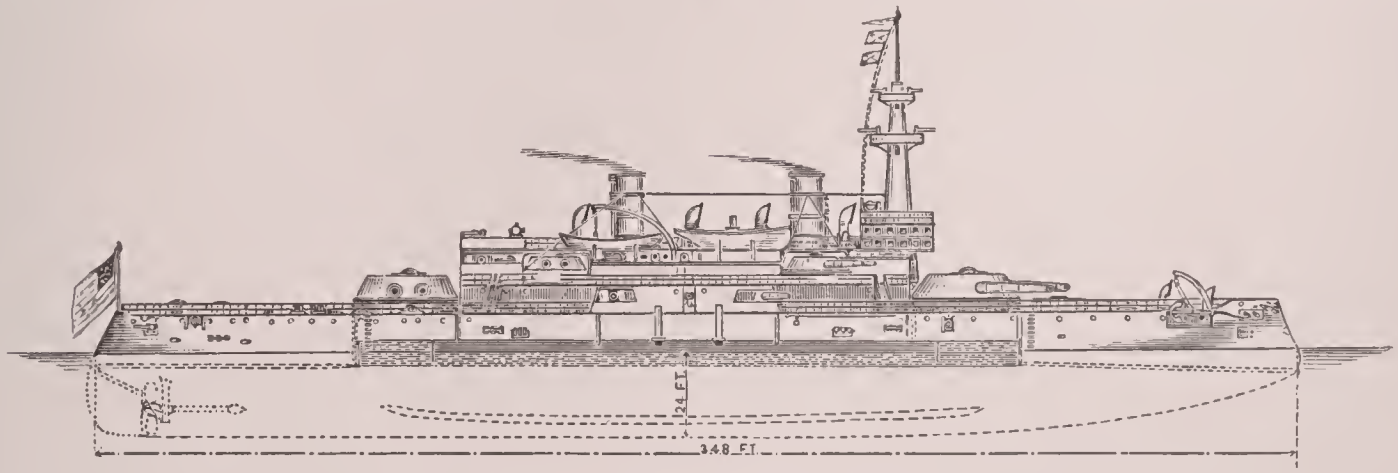
After these vessels some years elapsed before new designs for first-class battle-ships for the French navy were decided upon, and of these the Brennus, begun in 1889, was the first to show the marked influence of the great development during that time of quick-firing guns and high-explosive shells. The Brennus is nearly 11,000 tons displacement. The armor consists of a complete water-line belt 15¾ inches thick, covered by an armor-deck of 4 inches of steel. Above this the side is protected by a belt of thin armor, 4¾ inches thickness, 5 feet in height forward and 4 feet aft. Two 13½-inch guns are mounted in a pear-shaped turret forward with 17¾-inch armor, and one in a similar turret aft, each protected by 15¾-inch armor. The secondary armament consists of ten 4½-inch quick-firing guns, six mounted in a central fort of 4-inch armor which rises from the armor-belt to the upper deck, and four mounted in independent revolving turrets of 4-inch armor located upon the top of the central fort. The speed is 17½ knots.

In 1891 the Jauréguiberry, Carnot, and Charles Martel, of 12,000 tons displacement, were begun. The heavy guns are mounted in turrets, one 12-inch gun forward and one aft, and one 10¾-inch gun on each side in turrets at a lower level. On the central superstructure above all these turrets are eight 5½-inch guns, mounted in turrets of 4-inch armor, those of the Jauréguiberry in pairs and the others singly. The armor-belt at the water-line is 18 inches thick amidships and 11 inches at the ends, surmounted by an armor-deck 2¾ inches thick, and a cofferdam extending around the whole side, covered with 4-inch armor.

It will be seen that in these later ships the barbette has been abandoned for the turret, individual protected stations are provided for the smaller guns, and the side in the vicinity of the water-line is protected for the whole length by thin armor and minute water-tight subdivision.

The Masséna and a sister-ship of very similar design to the preceding vessels were begun in 1892. These are to have triple screws and a speed of 18 knots.

Of armored vessels for coast-defense of more modern type than the Tonnerre class the French have four ships from the same design, the Indomptable, Terrible, Caiman, and Requin, begun in 1877 and completed in 1886–87. Four ships of about the same class were begun in 1891, namely,



U. S. COAST-LINE BATTLE SHIP, MASSACHUSETTS.

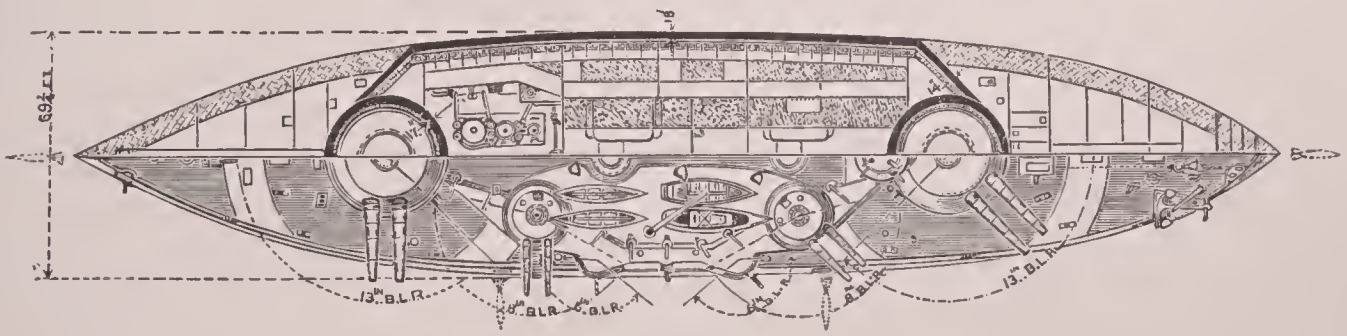


Fig. 6.

Admiral class. This, with the great height of the central superstructure carrying the boats, gives the vessel the appearance of a floating castle. The Hoche and Marceau were completed in 1891 and the remaining two in 1892. These vessels retain the unprotected gun deck-battery of small guns, the Tréhouart, Bouvines, Valmy, and Jemmapes. The first two of these vessels will be seagoing second-class ironclads.

First-class Battle-ships of the U. S. Navy.—These are represented by the Massachusetts, Oregon, and Indiana, begun in 1891 and designated for coast-line defense. The prin-

cipal dimensions are: Length, 348 feet; beam, 69¼ feet; mean draught, 24 feet; free-board, 11½ feet; displacement, 10,300 tons. There is a belt of 18-inch armor extending over slightly more than half the length, rising 3 feet above the water-line, and extending 4½ feet below it. The under-water protective decks at the ends of the belt are 3 inches thick, and the armor-deck over the belt 2¾ inches thick. Above the 18-inch belt and for the same length the side is covered with 5-inch armor to the upper deck.

The armament consists of four 13-inch guns mounted, two in a turret, one forward on the central line of the ship and one aft, each turret protected by 17-inch armor. At a higher level than these turrets are four others of 8½-inch armor, each containing two 8-inch guns. The battery is thus so arranged that four 8-inch guns fire straight ahead and four right astern, in addition to the 13-inch guns. There are also four 6-inch guns protected by 5-inch armor, two on each broadside on the main deck at the same level as the 13-inch guns. There are twenty-eight rapid-firing and machine guns and six torpedo-tubes. The battery of these vessels far exceeds that of any vessel in the world of their size, and equals that of any ship. The engines are of 9,000 I. H.-P., and a maximum speed of 16¼ knots is expected, with a sustained sea-speed of 15 knots. The normal coal-supply is 1,400 tons, and the bunker capacity 1,800 tons.

The seagoing battle-ship Iowa was authorized in 1892 and begun in 1893. This vessel will exceed her predecessors in size by about 1,000 tons and in speed by a knot, but will be of about the same general design, although greatly improved by considerable increase of free-board forward and better security against interference of the lines of fire of the guns of the battery.

In 1895 Congress authorized two additional battle-ships and six composite gunboats of 1,000 tons displacement.

The Texas and Maine, begun in 1889, should be, according to the latest classification adopted in the British navy, rated as third-class battle-ships. The Maine has been officially called an armored cruiser in the U. S.

CRUISERS.

There no longer exists in the classification of war-vessels a definite size or class which may actually be distinguished as armored or unarmored, as was the case so recently as 1880. Then began the extensive introduction of armored decks in all classes of cruisers, and since then the rapid improvement in rapid-firing and machine guns, and also the improvement in machinery with greater possibilities of speed, have tended to a rapid increase in the size of cruisers, and an increased amount of armored protection by the use of thin armor-plating on the sides in addition to protective decks, armored protection for individual guns, and coffer-dams of water-excluding material. The use of sails in the larger cruisers has practically disappeared, and the greater dependence upon fuel has also tended to increase the size of these ships in order to increase the supply of coal carried, and thus increase the endurance at sea under steam.

The following tabulated particulars relate to eight of the most important cruisers in the world:

water amidships; it is 6 inches thick on the slopes, 3 inches at the flats, reduced to 2½ inches at the ends of the vessel. In addition to this there is a belt of 5-inch armor in wake of the machinery spaces between the protective and main decks. Behind this belt is a cofferdam or cellular space 3 ft. 6 in. deep, extending all around the ship, filled with cellulose, a very light and water-excluding material. The armament consists of six 8-inch guns, two mounted in a barbette forward plated with 10-inch armor, two similarly mounted aft, and one on each broadside amidships on the spar-deck. Twelve 4-inch rapid-firing guns are mounted in sponsons of 4-inch armor on the main deck, and eight 6-pounder guns in 2-inch armored sponsons on the same deck. The 8-inch guns are 25 feet and the 4-inch guns 16½ feet above the designed load-line. There are six torpedo-tubes for ejecting Whitehead torpedoes above the water-line, one forward and one aft and two on each broadside. There are twin-screws, and each screw has two sets of three cylinder triple-expansion engines, making four sets of engines, each in a separate water-tight compartment. It is estimated that the vessel can maintain at sea a speed of 18·5 knots.

The first-class cruiser Brooklyn, authorized in 1892 and begun in 1893, is similar in design to the New York, but of greater size and armament.

The Columbia was built for the express purpose of preying upon commerce, and when begun in 1890 it was stated by the Secretary of the Navy that "no merchant vessel that she meets, armored or unarmored, can escape from her." She and her sister ship, the Minneapolis, are of 7,375 tons displacement, 412 feet long, 58 ft. 2½ in. beam, and 22 ft. 6½ in. draught. The Columbia is expected to maintain at sea a speed of 21 knots an hour. There are three screw propellers, one placed amidships as in ordinary single-screw ships, and one on each side, slightly forward of the middle screw. Each screw has a separate triple-expansion engine in an independent water-tight compartment. All the motive machinery and boilers are below the armored deck, which is 4 ft. 6 in. below the water-line at the sides and 1 foot above amidships; the slopes are 4 inches thick, and the flat 2½ inches. There is a cellular structure 5 feet wide extending the whole length of the ship at the outer edge of the protective deck. The coal carried at the designed draught is 750 tons, and the total capacity of the bunkers is 2,000 tons. The battery of this vessel is a light one, being only intended to cope with small cruisers and armed merchantmen; it consists of two 40-caliber 6-inch guns mounted in the open on the spar deck forward, one 8-inch gun aft, eight 4-inch rapid-firing guns in 4-inch steel sponsons on the main deck, and eighteen machine-guns of various sizes.

Growth of the U. S. Navy.—The navy of the U. S. began modern construction in 1883 by the building of the cruisers Chicago, Boston, and Atlanta, and the dispatch-boat Dolphin. During the period of the building and completion of these ships it became necessary also to establish in the U. S. the manufacture of the class of steel of which such vessels were built, and the construction of modern ordnance and ammunition. At this time twenty-five years had elapsed since the construction of powerful modern iron-

Cruisers of the U. S. Navy.—The armored cruiser New York, begun in 1890 and completed in 1893, is of the same type as the Blake and Blenheim of the British navy, but slightly inferior in size and battery-power. She has an armored protective deck the whole length of the ship, extending 4 ft. 9 in. below the water at the side to a foot above the

clads was begun abroad, and during the greater part of that period, since the close of the civil war, none of the new types of war-vessels had been built in the U. S., and the republic was absolutely without rank as a naval power. In effective force the navy was in 1886 rated as nineteenth among the nations. Thus the U. S. followed Japan, Turkey,

Greece, Brazil, Chili, and Portugal. In 1895, counting as effective the vessels built and building, the U. S. takes rank as a naval power, fifth among the nations, in the following order: Great Britain, France, Russia, Italy, U. S. This classification is probably an unduly favorable comparison which does not actually represent the rank for active service, on account of the large proportion of vessels uncompleted.

Propelling Machinery of War-ships.—The gradual increase in the working-pressure of steam with the single engine, the consequent introduction of the compound engine, which has come into universal use since 1870—lately developed into the triple-expansion engine—and the continual rise in the steam-pressure since, have produced two very important effects: (1) A reduction in the expenditure of coal, making longer voyages possible, or increasing the endurance under steam and decreasing the necessity of sail-power, which is destructive to speed and hampers and obstructs the battery; (2) a reduction in the weight and space occupied by the machinery, both of which are most important elements in the efficiency of a man-of-war. The type of engine most in use at present for ironclads is the three-cylinder vertical inverted-cylinder engine, and the triple-expansion principle is almost universal. The piston speeds employed vary from 600 to 900 feet per minute, and are continually increasing with improvement in materials for machinery and the increased use of steel; the faster the engines run the smaller and lighter the parts. The Scotch type of boiler is generally employed, carrying 100 to 180 lb. per square inch of steam-pressure and burning 16 to 20 lb. of soft coal per square foot of grate per hour with natural draught. Such engines usually develop on trial from 8 to 10 indicated horse-power per square foot of grate surface of the boilers, and the usual weight of the latest types of machinery, engines, and boilers, including water, is from 350 to 380 lb. per indicated horse-power under natural draught. The French have adopted in several new vessels a type of multitubular boiler which effects a great reduction in weight of boilers and contained water. This type of boiler meets with increasing favor, and is being fitted in the latest and most powerful cruisers building.

The use of forced draught, by making the boiler compartments air-tight and forcing large volumes of air into them, has recently been revived, and is now an element in the design of all modern war-vessels, enabling them, by a largely increased consumption of fuel, to develop about from 30 to 50 per cent. more than the ordinary maximum power of the machinery for a few hours in cases of emergency when the greatest available speed is required. This method of forcing the fires was used so long ago as 1850 in U. S. river-vessels, but was first used by the French in war-vessels. It was the subject of considerable experiment in the British navy in 1883, on the Conqueror, the Satellite, and other vessels, in which the indicated horse-power per square foot of grate was increased from 8 or 10, under natural draught, to 16 with an air-pressure in the fire-rooms equivalent to a column of 1½ inches of water. These experiments have led to the introduction of the system in all new war-vessels, but, owing to the rapid deterioration of boilers subject to great forcing, its use has been carefully restricted.

In unarmored vessels horizontal engines are used only where necessary to get the machinery below the water-line and beneath the protective deck. Short-stroke vertical inverted engines are more generally employed on account of their greater simplicity and endurance, and because of their less weight and bulk for corresponding power. War-ships of over 1,500 tons displacement are now almost invariably provided with twin-screws and have two complete sets of propelling machinery, in separate, water-tight compartments, by which arrangement the danger of total disablement is reduced to a minimum. Twin-screws offer the additional advantage that they admit of adequate protection to the rudder and the stearing-gear, which is impossible in an unarmored single-screw ship and difficult to accomplish in an armored vessel. They also furnish a valuable auxiliary steering-power, and are equally efficient as propellers in comparison with the single screw. The system of trials of steamships initiated in the U. S. by Chief Engineer B. F. Isherwood, U. S. navy, but never developed, although for years in vogue in Europe, has done much toward economy in the expenditure of the power of marine engines and the determination of the power necessary for certain speeds of ships. In 1874 the system of obtaining the resistance of ships by towing models, established by William Froude in Great Britain, was confirmed by towing a full-sized ship, the Greyhound, and is now regarded as a means of immense advantage in design of ships. It forms the complement of the progressive speed-trials of the ship over a measured distance in smooth water, at which all data can be obtained under uniform conditions, and in a systematic manner.

Materials of Construction.—Since 1875 rapid progress has been made in the use of mild steel or ingot iron. This metal is chiefly produced by the open-hearth process, cast into large ingots, and then rolled into plates or shapes. It has not the distinctive property of tempering peculiar to steel, and contains from ·12 to ·20 of 1 per cent. of carbon. It is very ductile and malleable, and can be produced in large quantities of uniform quality; it has 25 to 30 per cent. greater tenacity than the best iron ship-plates, and is only 2 to 2¼ per cent. heavier for equal volumes. The cruisers begun in 1883 for the U. S. navy were the first in the U. S. built throughout of mild steel. The elaborate tests made by the Government have shown an average ultimate tensile strength of about 63,000 lb. per square inch, and an elongation under tension of 25¾ per cent. in a length of 8 inches. The use of this material, while adding considerably to the strength of a vessel, from its great ductility and uniform strength in all directions, enables a reduction in the weight of the structure of from 10 to 14 per cent. over that of iron. This fact led to its use even when the steel cost much more than iron. The cost of manufacture is so much less that it has practically replaced iron as a structural material.

The remarkable developments in ocean steamships and in ironclad and unarmored war-ships could never have been attained if wood had continued to be the material of construction. In wooden ships the limits of size and of proportion were practically fixed by the capabilities of the material of which they were built, but in iron ships the designer is left free to adopt such dimensions as will conduce to efficiency, safety, and economy. The greater strength of iron and steel, and increasing skill in the fashioning and disposition of the material in the structure of vessels have led to a continuous increase in the size of ships, which, combined with the corresponding decrease in the proportion of weight of hull to weight carried or to the load-displacement, has largely increased the efficiencies of ships—that is, it has increased their speed, both from absolute size and greater available weight for machinery, and their war-power by increased proportion of weight of armor and batteries. The decreased weight of hull, with, also, a gain in structural strength, has had equally remarkable effects in small as in large vessels, for through no other means could a torpedo-boat 63 feet long, weighing but 12·5 tons, capable of a speed of 18 knots an hour, stand the strains of the machinery and be sufficiently strong to be lifted from the water to rest on crutches on board an ironclad.

ARMORED VESSELS.*

* In this table names of ships building or being rebuilt in 1898 are named in Italics; b. p. = between perpendiculars; B.-L., breech-loading; R.-F., rapid-fire; S.-B., smooth-bore; M.-L., muzzle-loading; *, length on water-line; †, with forced draught; ‡, estimated.

NOTE.—The U. S. has, in addition, one second-rate, eight third-rate, and one fourth-rate wooden vessels, and seven torpedo-boats.

FRANCIS T. BOWLES.

Ship-worm: any bivalve of the family TEREDINIDÆ (*q. v.*).

Shipwreck (in law): See WRECK.

Shiras, GEORGE, Jr., LL. D.: justice U. S. Supreme Court; b. at Pittsburg, Pa., Jan. 26, 1832; educated at Ohio University, at Yale College, where he graduated 1853, and at Yale Law School; admitted to the bar at Pittsburg and practiced in that city; appointed associate justice of the Supreme Court of the U. S. July 19, 1892. The degree of LL. D. was conferred upon him by Yale University in 1883. C. H. T.

Shiraz, shee'răăz, or **Sheeraz**: town; capital of the province of Fars, in Persia; in lat. 29° 36′ N. and lon. 52° 44′ E. (see map of Persia and Arabia, ref. 4–H); situated at an elevation of 4,500 feet above the sea, in a valley made familiar by Moore's *Lalla Rookh*, and still celebrated for the abundance and excellence of its fruits of every description. Founded in 697, it was during more than five centuries a favorite residence of the Persian princes, and a seat of science and art. Sa'di and Hafiz were born, lived, and died here. Shiraz contains the tomb of Hafiz, and that of Sa'di is a few miles to the N. E. The city suffered fearfully from earthquake in 1812 and again in 1824. Rebuilt, it was almost destroyed by another earthquake 1853. It was again rebuilt, but on a less extended scale. Its manufactures and trade have greatly declined, but its wine, rose-water, carpets, and inlaid work are still famous in the East. Pop. about 25,000. E. A. GROSVENOR.

Shire: See COUNTY.

Shiré, shee'rā: river of Southeastern Africa, issuing from the Lake of Nyassa, in lat. 14° 28′ S. It flows with many rapids and cataracts from the elevated plateau of the interior into the flat coastland, where it forms a broad, calm stream, navigable for the largest vessels, and joins the Zambesi about 90 miles above its mouth.

Shirlaw, WALTER: genre-painter; b. at Paisley, Scotland, Aug. 6, 1838. His parents removed to the U. S. in 1840, and in time he became a bank-note engraver; in 1870 he went to Munich, where he was a pupil of Raab, Wagner, Ramberg, and Lindenschmidt; became a National Academician 1888. His *Sheep-shearing—Bavarian Highlands* (1876), exhibited in 1877 at the National Academy, New York, attracted much attention. As an illustrator his designs for Goldsmith's *Hermit* are notable. Studio in New York. W. A. C.

Shirley, JAMES: dramatist; b. in London, Sept. 13, 1596; educated at Merchant Taylors' School, St. John's College, Oxford, and Catharine Hall, Cambridge; took orders in the Church of England, and obtained a curacy in Hertfordshire, but soon vacated it by becoming a Roman Catholic; taught for some time a grammar school at St. Albans, but, being unsuccessful, became a dramatic writer in London; had produced thirty-nine plays before the Great Rebellion; founded a classical academy at Whitefriars, and wrote several grammatical treatises. D. in London from exposure consequent upon the great fire of 1666, and was buried Oct. 29. His *Dramatic Works and Poems* (6 vols., 1833) were first edited by Gifford and Dyce. He is regarded as the last of the Elizabethan dramatists. *The Traitor* (1631) is, by common consent, his best tragedy, and *The Lady of Pleasure* (1635) his best comedy. Revised by H. A. BEERS.

Shirley, WILLIAM: colonial governor of Massachusetts; b. at Preston, Sussex, England, in 1693; became a lawyer; settled in Boston, Mass., 1734; was commissioner for fixing the boundary-line between Massachusetts and Rhode Island; was royal governor of Massachusetts 1741–45; planned the successful expedition against Cape Breton 1745; was in England 1745–53; returned to Massachusetts as governor in the latter year; treated with the Eastern Indians 1754; explored Kennebec river, erecting there several forts; was commander-in-chief of the forces in British North America at the outbreak of the French war 1755; planned the expedition of Gen. Prideaux against Niagara, and proceeded himself as far as Oswego; was appointed lieutenant-general 1759; became afterward governor of the Bahama islands, but returned to Massachusetts, where he built a fine residence at Roxbury. D. at Roxbury, Mar. 24, 1771. Author of *Electra*, a tragedy; *The Birth of Hercules*, a masque; *A Letter to the Duke of Newcastle, with a Journal of the Siege of Louisburg* (1745); and *The Conduct of Gen. William Shirley briefly Stated* (1758).—His son WILLIAM, an officer in the army, was killed at Braddock's defeat 1755.—Another son, Sir THOMAS, b. in Boston, became a major-general in the British army, was created a baronet 1786, and was governor of the Leeward islands. D. Mar., 1800.

Shir'wa: lake; a little S. E. of Lake Nyassa. Southeast Africa; formerly supposed to have as its outlet the Lujenda river, but discovered (1887) to be nothing more than a huge evaporating-pan with an area of about 350 sq. miles, into which a number of small rivers discharge. Its waters are brackish, are gradually drying up, and there is evidence that formerly the lake stood at a much higher level and discharged into the Lujenda river. C. C. A.

Shi'shak: the Hebrew name of the Egyptian king *Shashanq*, first ruler of the twenty-second (Bubastite) dynasty (966–800 B. C.). He was probably of Libyan lineage, and at the close of the twenty-first (priestly) dynasty grasped the royal power which he had actually wielded previously. This was largely due to the increased influence of the Libyan mercenaries from whom the Egyptian army had been recruited since the time of Seti I. and Ramses II. The dominion of Egypt was much extended by Shishak, who waged war in Palestine against Rehoboam, King of Judah. His inscriptions on the south wall of the Temple of Amon at Karnak contain the names of 128 cities or regions in Palestine and Syria which fell into his hands. The list is really larger, but a considerable number of names are no longer legible. Jerusalem was among the captured places,

and from it he removed much booty (1 Kings xiv. 25, 26). Jeroboam, who had fled from Solomon, sought protection in Egypt under Shishak (1 Kings xi. 40), and later, upon the disruption of the Hebrew nation, became king of the ten tribes, presumably with the support and aid of Shishak. The name also belonged to the fifth, seventh, and ninth kings of the twenty-second dynasty, but particulars concerning them are meager, beyond the statement that the last two reigned fifty-two and thirty-seven years respectively. Their period is one of the darkest and least known in Egyptian history. CHARLES R. GILLETT.

Shit'tim: (1) wood of the shittah-tree, repeatedly mentioned in Exodus as the timber principally employed in building the tabernacle. It has been identified with the *Acacia seyal*, which abounds in the Sinaitic peninsula. The wood is light, but close-grained and enduring, and of a fine orange brown. The leaves are small, and in spring the tree is covered with tufts of yellow blossoms. It yields the gum arabic of commerce. (2) A fertile plain, so called from its acacia-groves, just opposite Jericho, in which the Israelites were encamped before crossing the Jordan. There the Israelites fell easy victims to the seductions of the Moabite women, who prostituted themselves in honor of their god Baal-peor, and there the punishment followed on them and on the Midianites (Num. xxv., xxxi. 1–12). Thence went the spies to Jericho (Josh. ii. 1). Revised by S. M. JACKSON.

Sho'a: the most southern part of the Abyssinia highland, East Africa; formerly an independent state, but since 1888 a part of Abyssinia, the rule of its king, Menelek, having been extended over the whole of Abyssinia, except the northern district, appropriated by Italy. The whole territory of the king became (1889) a protectorate of Italy. The capital and chief residence of the king is Antotto, and there are several other large towns, of which the most important are Ankobar and Roggie, situated about 8,000 feet above sea-level. The soil is very fertile, and most of the inhabitants are Coptic Christians. Pop. less than 2,000,000. Area about 15,000 sq. miles. C. C. ADAMS.

Shoals, Isles of: See ISLES OF SHOALS.

Shock [from M. Dutch *schock*, a bounce, jolt: O. H. Germ. *scoc*, a swing; cf. O. Eng. *scacan*, shake, and Fr. *choc*, collision (from M. Dutch)]: sudden vital depression, the peculiar effect upon the animal system produced by violent injuries. Surgical shock must be distinguished from mental shock, caused by grief, terror, or other mental emotions. Following serious accidents, the crushing of a limb by a railway injury or its removal by a cannon-ball, extensive superficial burns, extensive surgical operations, as amputations or ovariotomy, and as the result of blows over important organs, concussion of the brain, a kick or sudden blow in the region of the stomach over the solar plexus—a powerful impression is made on the nerve-centers proportionate to the extent of the superficial or peripheral nerve-irritation. The condition is induced by paralysis of the vaso-motor centers, but is not limited in its manifestations to the nervous system, all the tissues of the body being affected in sympathy with the injured part. The symptoms of shock are extreme pallor and coolness of the face and surface of the body, a small, feeble, slow pulse, infrequent and often irregular respiration, pinched features, cold sweat, and the appearance of impending dissolution. If the bodily temperature falls more than 2° F., death is apt to follow. In special cases, delirium, hiccough, or convulsions are present. The circulation and respiration may be so depressed that death is immediate, or speedily ensues unless reaction is artificially hastened. Sensation of pain is annulled: in the gravest injury, as the laceration and removal of a limb by a cannon-ball, there may be no pain and no loss of blood during the period of shock. The period of shock, if survived, is followed by reaction, a resumption of ganglionic or central nerve-power, and revival of the dependent functions. Extreme loss of blood renders the patient more susceptible to shock, producing sudden anæmia, inanition, and disturbed action of nerve-centers. Concussion of the brain is often accompanied by shock, but is in itself an entirely distinct condition. Exposure to cold increases shock, and is particularly to be avoided in operations. No satisfactory lesion or organic change has been found to explain shock, the only marked *post-mortem* lesion being distension of the right side of the heart and great venous trunks with blood, sometimes fluid and always coagulating with difficulty. The treatment of shock is to be directed to the immediate development of reaction. The sinking pulse must be rallied by ammonia and alcohol, by stimulating enemata, by heat to the extremities and surface. Hypodermic injections of digitalis, atropia, strychnia, ether, or brandy are often useful. Quinine is sometimes given before an operation as a prophylactic. In mild cases of shock external warmth, a little diffusible stimulant and rest are all that is required. Reaction is sometimes excessive, the patient passing into a condition of traumatic delirium, or may be imperfect, when he falls into the state of prostration with excitement. What is called secondary or insidious shock is due to the formation of heart-clot, and often proves fatal.

Revised by JOHN ASHHURST, Jr.

Shoddy [originally, the wool that was *shed* or wasted in carding and spinning]: in a strict sense, a fiber made by tearing in pieces in a suitable mill rags of worsted or combed-wool goods. The corresponding fiber of carded-wool rags is called mungo; but more frequently both kinds are classed together as shoddy or "devil's dust." Some classes of useful goods can not be profitably made without shoddy; and if used in reasonable proportion its presence can not be detected, and the wear of the goods is not much diminished. None but the very best sorts of woolen goods are perfectly free from shoddy.

Shoe [O. Eng. *scōh*: O. H. Germ. *scuoh* (> Mod. Germ. *schuh*): Icel. *skōr*: Goth. *skōhs*]: in general, any covering for the foot (with the exception of hosiery) of which warmth and protection are the special purposes. If the foot-covering consists mainly of a sole, it is called a sandal; if it also has a part coming up to the ankle, it is called a shoe; while one that covers a portion of the leg is called a boot. (See BOOTS.) A loose light shoe into which the foot may be easily slipped is appropriately called a "slipper." The earliest form of the shoe was the simple sandal, which was secured to the foot by thongs, and often by a button coming between the first and second toes. Almost every material has been used for the construction of shoes, the skins of animals, tanned or untanned, more frequently than any other. In some parts of Europe wooden shoes, or *sabots*, are very common among the poorer classes. In Japan the sandals worn by the common people are made of straw; in South America they are made of plaited thongs of hemp. There have been great changes in the forms of shoes as worn in different countries and at different periods among civilized nations. The early Greeks usually went barefoot, or confined themselves to simple sandals, which in time came to be highly ornamented. The early shoes of the Romans were buskins, not very dissimilar to the moccasins of the American Indians; thick soles, sometimes of metal, were a later invention. In time they grew into shoes, or even boots, sometimes covering the entire leg. In Europe, during the Middle Ages, shoes often were made in fantastic shapes. At one time they had pointed toes about two feet long, which were often brought up and tied to the knee; and not unfrequently a man of fashion would wear them of different colors, as a red one on one foot and a yellow one on the other. For many years there has been very little change in the general form of the covering for the foot as worn by either sex; the main variations being in the height of the heel and the shape of the toe, whether pointed, round, or square.

Manufacture.—A boot or shoe consists essentially of two parts, the sole, almost universally made of thick leather, and the upper, usually of a softer leather, but not unfrequently of cloth of some kind, for women often of silk or satin. These parts are attached to each other in various ways, usually by sewing. A few years ago a boot or shoe was made throughout by a single person; at present the production of a shoe is the work of several persons, each performing only a single part of the operation, a considerable portion being done by ingenious machinery. Indeed in no single trade is there a more perfect division of labor or a greater adaptation of machinery. Boots and shoes put together by pegging were in extensive use a few years ago. Now only some of the cheapest grades are pegged, much of the work being done by the pegging-machine invented by A. C. Gallahne in 1851. Pegging, however, as a method of fastening the soles to the uppers, has been almost entirely superseded by a process known as the "standard screw," in which the outer soles are fastened to the inner soles and the uppers by a machine that uses a threaded brass wire, which is supplied from a reel. In the performance of its work the machine thrusts a portion of the wire into the substance of which the shoe is composed, gives it a half turn, and automatically detaches it. An-

other important invention is that of a machine for sewing soles, which was improved by Gordon McKay. One of these machines in the hands of a good operator will easily sew on the soles of 800 pairs of women's shoes in ten hours. Originally, shoes made by the McKay process were not so well finished as to the inner part of the sole where the stitches came through, but this defect was overcome by the use of a smooth inner sole, cemented to the sole in such a way as entirely to cover the stitches. A later and more important invention is that of the Goodyear welt machine, as it is called, which has enabled manufacturers of shoes to produce footwear so closely resembling hand-work in appearance and durability as to render it extremely difficult to distinguish one from the other. Indeed in the best grades what difference exists may be fairly said to be in favor of the machine-sewed goods. A great part of the boots and shoes used in the U. S., especially the finer kinds, are made in large establishments in New York, Philadelphia, Baltimore, and other large cities, but more in several towns in Massachusetts, Maine, and New Hampshire; Lynn, Mass., is the greatest seat of this manufacture, and among the other large centers are Haverhill, Brockton, Milford, Marblehead, Worcester, Braintree, and Danvers, in Massachusetts; Portland, Augusta, and Lewiston, in Maine; Dover and Farmington, in New Hampshire. Until about 1890 the U. S. did but little export business in boots and shoes.

Revised by VAUGHAN SNIDER.

Shoebill: a large wading bird (*Balæniceps rex*) inhabiting the region of the White Nile, Africa. It is named from its large, peculiarly shaped beak, and is also termed whale-headed stork, although its affinities are rather with the herons. It stands nearly 5 feet high, is gray, and has a little recurved crest. F. A. L.

Shoebill.

Shoe'buryness: a promontory in the county of Essex, England; on the northern shore of the estuary of the Thames, directly opposite Sheerness (see map of England, ref. 12–L). Shoeburyness was selected by the Government as the locality of experimental firing at armored targets and for trial of new guns. It is the seat of a school of gunnery, with artillery, barracks, batteries, targets, etc.

Shoeing of Horses: See FARRIERY.

Shōgun (Jap., liter., general, the Chinese *Tsiang-Kiun*): a Japanese military title, said to have been first employed by the Emperor Suijin in the first century B. C., when he divided the empire into four military divisions. The name began to have a political significance with YORITOMO (*q. v.*), who was appointed in 1192 *Sei-i-tai-Shogum*, or generalissimo, against the barbarians. Henceforward the shogunate more and more represented the real governing force in the empire, until in the seventeenth century the Tokugawas (see IYEYASU) became a real reigning dynasty. The empire was centralized afresh from Yedo, so that in 1868 when the emperor resumed power he merely fell heir to the bureaucratic system developed by these rulers. J. M. DIXON.

Sholapur': district and city in the southern part of the Bombay Presidency, British India; on the border of Haidarabad. The district lies between the parallels 17° 13′ and 18° 35′ N.; has an area of 4,521 sq. miles; is bleak and treeless, and generally flat or slightly undulating, and is subject to great irregularity in the amount of rainfall, making agriculture dependent on irrigation. Its silks, finer cotton cloths, and blankets have a good name, and the chief exports besides cloths are oil, oil-seeds, ghee, and turmeric. The population numbers about 600,000, mostly Hindus. The city of Sholapur, chief town and administrative headquarters of the district, is in lat. 17° 40′ N., lon. 75° 57′ E., near the Sina river (see map of S. India, ref. 4–D). It is a station on the Great Indian Peninsular Railway. It is one of the principal cotton-markets of the Dekkan. Pop. (1901) 74,521. MARK W. HARRINGTON.

Sho'mer, Shammer, or **Jebel Shomer**: a territory, part of the great central plateau of Arabia; bounded N. by the Syrian desert, from which it is separated by mountains 9,000 feet high, N. E. by Irak Arabi, S. by the sultanate of the Wahabees, and W. by Turkish Arabia. The Arabs here have always remained in a savage condition, little influenced by the rise of the Mussulman empire. About the end of the eighteenth century they came under the power of the Wahabees, but since the overthrow of the latter have been independent. The country is divided into five provinces, said to contain eighty-six towns and villages, the chief of which is Hayel. Between it and Medina considerable trade is carried on. Corn and fruit are raised by artificial irrigation. Dates, cotton, horses, and asses are exported. Pop. of territory estimated at 450,000. E. A. G.

Shooting Stars: See METEORS.

Shore: See COAST.

Shore, JANE: mistress of Edward IV.; b. in London, England, about 1445; married a rich London goldsmith named Matthew or William Shore; became mistress of King Edward IV. about 1470, and of Lord Hastings after the death of the former, 1483. She was accused of witchcraft as an accomplice of Hastings, who was beheaded for that pretended crime, though the real reason for the proceedings against them was their known partiality to the cause of the young princes. According to More's account, Jane Shore was charged by King Richard III. with having withered his arm by her arts of sorcery; was committed to the Tower and her property confiscated; was never brought to trial, but was compelled by the Bishop of London to do public penance for impiety and adultery. The king's solicitor, Thomas Lynon, desired to marry her after the death of Hastings, but Richard tried to dissuade him, and whether the marriage took place is not known. She survived until after the accession of Henry VIII., and popular legend represented her as having died of hunger in a ditch—a version which long retained currency through the famous drama of Rowe bearing her name; but the legend was probably derived from the name of a London locality still called Shoreditch. Sir Thomas More bears emphatic testimony to her beauty, kindliness, and wit.

Shore, Sir JOHN: See TEIGNMOUTH, BARON.

Short, CHARLES, LL. D.: educator; b. at Haverhill, Mass., May 28, 1821; received his early education at Bradford Academy and Phillips Andover Academy; graduated at Harvard 1846; classical instructor in Roxbury and Philadelphia 1847–63; president of Kenyon College, O., and Professor of Intellectual and Moral Philosophy 1863–67. On the death of Dr. Anthon, Professor of Greek in Columbia College, New York, Dr. Henry Drisler was transferred to the Greek chair, and Dr. Short succeeded Dr. Drisler as Professor of Latin in 1868. He edited, with additions, *Advanced Latin Exercises* in Schmitz and Zumpt's Latin Series (1860); revised Mitchell's *New Ancient Geography*; wrote an elaborate essay on the *Order of Words in Greek*, prefixed to Dr. Drisler's edition of Yonge's *English-Greek Lexicon* (1870); and, with Charlton T. Lewis, revised (1879) Andrews's *Freund's Latin Dictionary*. He contributed many articles, mostly critical, to reviews and other periodicals, chiefly to the *Bibliotheca Sacra*. He was from the outset a member of the American committee co-operating with the British committee in the revision of the English Bible. D. in New York, Dec. 24, 1886.

Revised by BENJ. IDE WHEELER.

Short, WILLIAM: diplomatist; b. at Spring Garden, Va., Sept. 30, 1759; studied at William and Mary College; was at an early age a member of the executive council of Virginia; accompanied Thomas Jefferson on his embassy to France as secretary of legation 1784; was appointed *chargé d'affaires* to France by Washington 1789 (being the first commission signed by him as President), and was subsequently minister to the Netherlands and to Spain, where in 1795 he concluded the negotiations which resulted in the treaty of friendship, commerce, and boundaries. D. in Philadelphia, Pa., Dec. 5, 1849.

Shorthand: See PHONOGRAPHY and STENOGRAPHY.

Shorthorns: a breed of beef-cattle which originated in the valley of the river Tees, between the counties of Durham and York, in England. They are often called Durham, shorthorned Durham, and Teeswater cattle. Since very early times the cattle of the northeastern coast of England have differed in type from those of other parts of Great Britain, and there are many reasons for believing that this is due to an admixture of the blood of the cattle of the adjacent countries of continental Europe, brought over at the time

of the Danish invasions. At all events, in their large size, heavy heads, short horns, and angular forms the aboriginal cattle of this part of England closely resemble the Danish, Dutch, and Flemish races of cattle. Durham, Yorkshire, and Northumberland have long been famous for the amount and superior quality of the beef produced there, and early in the eighteenth century numerous breeders became famous for the size, quality, and great fattening propensities of their cattle.

However, it is to a few men who were in active life in the closing years of the eighteenth century and the early part of the nineteenth that most of the fame of the breed as we now know it is due. The more famous of these men were Charles and Robert Colling, Thomas Bates, and Richard and John Booth. The Collings were the earliest improvers of the shorthorns. Charles in particular practiced extensively and with great skill the closest inbreeding in the foundation of all or nearly all his various families. The bull Comet brought at public sale in 1810, when six years old, 1,000 guineas.

The Durham Ox and The White Heifer that Traveled, animals bred by Charles and Robert Colling respectively, were fattened to a great weight, and were taken from town to town to be exhibited. Their fame had a great effect in making the breed widely known throughout Great Britain. The Durham Ox, supposed to have been the largest animal of the cattle kind ever bred up to that time, is estimated to have weighed 3,400 lb.

The most famous family of the shorthorns is that known as the Duchess, or Bates Duchess. They are descended from a cow, Duchess, that Charles Colling bought from the Stanwick estate of the Duke of Northumberland, and the bulls Hubback and Favorite. They were closely inbred by Colling, and afterward by Thomas Bates, who for nearly forty years (1810–49) bred this family with scarce an admixture of outside blood. After Bates's death some of the best representatives were taken to the U. S., where they were still kept pure in the herds of Samuel Thorne, of Thornedale, Dutchess co., N. Y., J. O. Sheldon, of Geneva, N. Y., and Wolcott and Campbell, of New York Mills. Their fame grew both in the U. S. and in England, and culminated in Sept., 1873, when the eighth Duchess of Geneva brought at public sale $40,600.

Shorthorns are large, symmetrical, squarely built animals, maturing early, and producing large amounts of best-quality beef. In color they are red, white, or any admixture of these two colors. Roan is a very common color. White or a large proportion of white is not liked in the U. S. Their legs are short, the bone fine, the hair soft and thick, and the horns short, incurved, and of a waxy texture.

In numbers they far exceed all other breeds of pure-bred cattle in the U. S. *The American Shorthorn Herd-book* (39 vols.) records the pedigrees of nearly 120,000 bulls, and a much larger number of cows and heifers. H. H. Wing.

Shorthouse, John Henry: novelist; b. in Birmingham, England, in 1834; was educated at Grove High School, Tottenham, and engaged in manufacturing at Birmingham. He is best known from his novel *John Inglesant* (1881), a tale with a strong Anglo-Catholic or Tractarian flavor. Others of his books are *The Little Schoolmaster Mark* (1883–84); *Sir Percival* (1886); *A Teacher of the Violin* (1888); and *Blanche, Lady Falaise* (1891). H. A. B.

Shosho'nean Indians: a linguistic stock of North American Indians. The term Shoshoni, of which the stock name is an adaptation, is not a Shoshoni word, although recognized by the tribe as applying to themselves. *Shoshon* signifies female dog in the Teton dialect; *shishoka*, robin, and *shoshona*, long-eared (alluding to the mule), in Yankton. It is not improbable that *shoshoni* originated in one of these roots, and was of opprobrious significance. The habitat of this great stock extended from the head-waters of the Missouri in Central Montana to Southern Texas, and from Western Kansas to Western Central Oregon, and the coast of Southwestern California. See the map accompanying the article Indians of North America.

According to some authorities the Shoshonean stock, as here recognized, is but part of a linguistic group embracing the Shoshonean, Piman, and Aztecan or Nahuatl tribes; but the relationship of these peoples is not proved. The principal Shoshonean tribes are Bannock, Comanche, Gosiute, Paiute (including the Chemehuevi), Paviotso, Shoshoni (including the Tukuarika), Tobikhar, Tusayan, Ute. The estimated population is 20,000.

Owing to the extent of country occupied, and its varied climatic and topographic features, the Shoshonean tribes differ widely. The habits of the Shoshoni, Bannock, Ute, and Comanche divisions in the north were essentially those of hunting Indians. The Comanche and Eastern Shoshoni alone can be said to have been "buffalo Indians," although the buffalo was hunted more or less by all the northern Shoshonean tribes. In general character these were fierce and warlike. To the W. of the Rocky Mountains the tribes (Paiute, Paviotso, Gosiute, and western Shoshoni) were of a different character. Rabbits and small game generally, fish, roots, and seeds formed the chief support of these tribes, among which were included the lowest representatives of the stock. It was principally to these that the name Diggers was opprobriously applied, although they were by no means so low as many writers have asserted. They made and used bows and arrows, were potters, lived under a complex social system, and even practiced a rude agriculture.

Bannock.—The native tribal designation of the Bannock is Panaqti, from which their common name is derived. This tribe was divided into two geographically distinct portions—one claiming the territory between lat. 42° and 45° and from lon. 113° to the main chain of the Rocky Mountains; the other division, or northern Bannock, formerly occupying Southwestern Montana, where they had been forced by the Blackfeet. It is probable that at no very distant time the scattered bands of both divisions were united in one locality—Southeastern Idaho and extreme Western Wyoming, where they were pressed upon by the Shoshoni, and to some extent incorporated with them. The Bannock were a tribe of widely roving habits, which favored their dispersal and separation. In language they differ markedly from the Ute, Comanche, Paviotso, and others. About 1829 the southern Bannock—always the more populous division—numbered about 8,400 in 1,200 lodges. Many of them affiliated with the Shoshoni of Western Wyoming, and as early as 1859 had extensively intermarried with them. In 1869 500 or 600 of this division were placed on the newly established Wind river reservation, Central Wyoming (where they are now officially classed as Shoshoni). In 1874 all the scattered Bannock and Shoshoni of Southeastern Idaho were assigned to Fort Hall reservation, Idaho. The northern or Salmon river Bannock, after having been decimated by the smallpox and ravages of the Blackfeet, numbered in 1869 about 350 in fifty lodges. There were 455 Bannock on Fort Hall reservation in 1891, and 75 on Lemhi reservation, Idaho, in 1890.

Comanche.—The popular name of this tribal division originated with the Spanish Mexicans. Their own tribal designation is *Nüma*, i. e. people, Indians. This was formerly one of the most powerful divisions of the Shoshonean family. Evidence, mostly traditional, tends to show that their priscan habitat was in the Snake river region of the northwest, more recently occupied by the Shoshoni. In the sixteenth and seventeenth centuries they were found under the name Chuman and Jumano in Western Texas, in the east of New Mexico, and in northern Chihuahua; in 1724 they were on upper Kansas river, and later appear to have entered to the S. of the Red river, Texas. The later Comanche territory may be given as the extensive plains from the Rocky Mountains eastward into Indian Territory and Texas, to about lat. 97°, although they raided the country from Kansas southward as far as Durango, Mexico, a distance of 800 miles. Always a wandering tribe, the early possession of the horse by the Comanche intensified their nomadic propensities and gave full scope to their martial character. The theft of horses and the capture of women and children for adoption or ransom were the chief motives for their raids, particularly into Mexico, until 1783, when their power in that direction was broken. They suffered severe loss in numbers at the hands of the Texans in the Texo-Mexican war. They depended largely upon the buffalo for subsistence, and lived in skin tents or tipis during their periodical settlements. They have a tribal chief, and are divided into fourteen bands, each headed by a recognized chief. In 1780 the warriors were estimated to number 5,000, equivalent to a population of about 25,000. The reservation in Oklahoma occupied by the Comanche was set aside for them in 1867, when their population was about 2,500. In 1891 they numbered 1,624.

Gosiute.—This name, with the variants Goshoot, Goshaute, etc., is contracted from Goship (the name of a former chief) and Ute. The group was a confederacy of five tribes—the Pagayuats, Pierruiats, Torountogats, Tuwurints, and

Unkagarits—inhabiting the northwestern part of Utah, west of Utah and Great Salt lakes, and a strip in Eastern Nevada. They were one of the few Shoshonean divisions engaging in agriculture, and were scattered over the country as the springs and watercourses afforded arable land. According to some authorities the Gosiute are a mixture of Shoshoni and Ute. There seems to be no aboriginal name of the confederacy—a fact indicating very recent organization as such. Pop. (1890) 256.

Paiute.—The generally accepted idea is that the term originated from *pah*, water, and Ute, hence "water Ute"; more likely it is derived from *pai*, true, and Ute, thus signifying "true Ute." The name has been applied at various times to most of the Shoshonean tribes of Eastern Utah, Northern Arizona, Southern Idaho, Eastern Oregon, Nevada, and Eastern and Southern California, whereas it properly belongs exclusively to the Corn creek tribe of Southwestern Utah. Paiute, however, is a convenient divisional name for the tribes occupying the southwestern part of Utah, Central Nevada, and Northern Arizona, and including the Chemehuevi of Colorado river. Under it are also included the tribes of Southeastern California from the neighborhood of Owens valley along the eastern slopes of the sierras, and to the S. of Tulare Lake and E. of the Coast Range. The principal Paiute tribes are: Chemehuevi or Tantawats, formerly about the great bend of Colorado river and now attached to the Colorado river agency—population about 200; Kwaiantikwokets, formerly E. of Colorado river, in Arizona, where they affiliated largely with the Navajo, and numbered 62 in 1874; Shivwits and Uinkarets in Northern Arizona—population 182 and 40, respectively, in 1874. There are 19 insignificant tribes or bands in California, among them the Mono (a term collectively applied), Keats, and Moquats; 17 in Nevada, and 8 in Utah (including the Kaivavwits and Unkakaniguts). The Paiute population approximates 2,500, there being in Utah 500, Northern Arizona 500, Southern Nevada 1,000, and Southeastern California 500.

Panamint.—This division is linguistically related more closely to the Shoshoni than to any other of the tribes of the stock, and it is not improbable that they became detached from that body through the intrusion of the Gosiute, and gradually drifted to their later habitat in and around Panamint and Death valleys, between lat. 36° and 37°, Eastern California. A few individuals live in the mining town of Darwin, while about 150 are scattered in the desert country to the E. of Panamint valley.

Paviotso (strong, able).—These Indians form a confederacy of twenty-eight insignificant tribes, chiefly in Western Nevada, but extending into Oregon as far north as Lakes Harney and Malheur, and westward to about Warner Lake near the southern boundary, and Camp Bidwell in Northeastern California. The shores of Honey Lake in Eastern California were also occupied by them. In the east they extended to the Shoshoni territory in lon. 117° 30′. Their lowermost settlements were in Owens valley, Eastern California. Like many other tribes of this region, the Paviotso were early confounded with the Paiute, whom they closely resemble. Their extension north into the Pyramid Lake region of Western Nevada and into Oregon has been comparatively recent, having after a long conflict displaced the Saitüka. They probably number about 4,000.

Shoshoni.—This is the most northerly division, and formerly occupied Wyoming, the entire central and southern parts of Idaho, except the area occupied by the Bannock, a small part of Eastern Oregon, Eastern and Central Nevada, and a small strip of Utah W. of Great Salt Lake. The Snake river country in Idaho is perhaps to be considered their chief seat, whence they are also called Snake Indians. In 1803 Lewis and Clark found the northern bands of the Shoshoni on the head-waters of the Missouri in Montana, but they had earlier ranged farther east on the plains, whence they had been driven into the Rocky Mountains by the hostile Atsina and Blackfeet, who early obtained firearms.

The more northerly and eastern Shoshoni were horse and buffalo Indians, and in character and warlike prowess compared favorably with most western tribes. Those of Snake river and to the south in Nevada represented a lower type, since most of this country was barren and comparatively devoid of large game. They depended for food to a large extent upon fish, supplemented by rabbits, roots, nuts, and seeds. The Shoshoni, more commonly than any others of the Shoshonean tribes, were called Diggers and Shoshokos (walkers.) None of them were agriculturists. In general, the style of their habitations corresponded to the two types of Shoshoni. In the north and east they lived in pole and skin lodges, but in the sage country to the west brush shelters were used, some of them in the Snake river region being mere roofless semicircles that afforded little protection against the wind and snow. There were many dialects corresponding to the degree of isolation of the several tribes, but mutually intelligible. The most important of the original divisions or bands of the Shoshoni are the Tukuarika or Sheep-eaters, Tussawehe, and Wihinasht. They have materially decreased in numbers; those surviving are in Nevada; on Fort Hall and Lemhi reservations, Idaho (pop. 948 and 357 respectively); western Shoshoni reservation, Nevada (pop. 367), and the Shoshoni reservation, Wyoming (pop. 883). Their entire number approximates 5,000.

Tobikhar.—This term, meaning settlers, belongs strictly to a group of small tribes formerly about San Gabriel mission and Los Angeles, Southern California, but has been adopted as a group name to include the Shoshonean tribes who spoke related dialects, and lived about the missions of San Luis Rey, San Juan Capistrano, San Fernando, Los Angeles, San Bernardino, and San Gabriel. These formed the southwestern or coast division of the stock, and their remnants compose the bulk of the so-called Mission Indians, which embrace also a few representatives of the Yuman stock. The status of the Indians of this group and their relation to the State government have never been fully defined. They appear not to have been agriculturists prior to the mission period; hence upon the disestablishment of the missions some of the Indians returned to their primitive mode of life, while others practiced the rude arts of agriculture learned under mission sway. Notwithstanding their docile and submissive character the Tobikhar, like most of the Shoshonean tribes, were doubtless once of a more aggressive and warlike disposition, and were able to force their way to the coast through the Chumashan and Mariposan tribes on the north, and those of Yuman stock on the south. The population is about 2,200.

Tusayan (probably from the Navajo *Zilh-Täsäun*, signifying country of the isolated buttes).—The so-called province of Tusayan comprises seven pueblos on the summits of four mesas in Northeastern Arizona, about 50 miles E. of the Rio Colorado Chiquito, and about the same distance S. of the Rio San Juan. The pueblos constitute three groups: Walpi, Sichumovi, and Hano or Tewa in one; Mashongnovi, Shumopovi, and Shupaulovi the second, 7 miles westward; Oraibi the third, 8 miles still farther west. Six of these villages are inhabited by the Hopi (signifying "people," but improperly called by the opprobrious Zuñi term Moki), the seventh pueblo, Hano, being occupied by a division of the Tewa tribe, of Tanoan stock, who left their kindred on the Rio Grande about 1680, and settled at Tusayan, where they maintain their distinctness. The Hopi afford the only instance of tribes of the predatory Shoshonean stock who have adopted a strictly pueblo life. Tusayan was known to the earliest Spanish explorers of the Southwest. Marcos of Niza in 1539 spoke of it under the name Totontcac. It was first visited by whites in 1540, when Tobar and Padilla, and afterward Cardenas, of Coronado's army reached the so-called province from Zuñi. Expeditions to Tusayan were also made by Espejo in 1583 and Oñate in 1598. Missions were established at the now ruined pueblos of Awatobi and at Mashongnovi and Shumopovi at an early date, but were abandoned upon the murder of the missionaries and destruction of the churches during the Pueblo revolt of 1680. Tusayan tradition seems to indicate that the present Hopi villages are a confederacy of phratries, or perhaps independent groups, who, after various wanderings, settled in one place. The union is not a close one, and tradition points to feuds and even to bitter wars between the towns, during one of which Awatobi (once the principal pueblo) was totally destroyed. Like the other Pueblo tribes, the Hopi have been agriculturists since first known to history. They early acquired possession of sheep, and are expert weavers, potters, and basket-makers. The estimates of population given by the early explorers are greatly exaggerated. They number about 1,750.

Ute.—This division formerly occupied the central and western portions of Colorado and Southeastern Utah, including the eastern part of Salt Lake valley and Utah valley. They extended also into New Mexico, occupying much of the drainage area of the Rio San Juan. None of the Ute were agriculturists, but they appear to have been always a warlike people, and their early possession of horses intensified their aggressive character. The various divisions or

geographic bodies were probably originally united into a loose confederacy, and, while dialectic differences exist in the language, intercourse was carried on with little difficulty. The Ute divisions in the northeastern part of the range have intermarried more or less extensively with the Bannock, Shoshoni, and Paiute, and in the south with the Jicarilla Apache. The first Ute treaty was proclaimed Sept. 9, 1850. In 1864 a treaty was made with the Tabaguache band and a reservation set apart for it and the Muache band in Southwestern Colorado. In 1868 a third treaty provided for all the different bands, while the final treaty, by which the Ute are confined within the present reservation limits, was made in 1873. The restless character and unfriendly spirit of these Indians have rendered even an approximately correct census impossible. The official figures of the reserves for 1891 are: Southern Ute agency, Colorado, 998; Ouray reserve, Utah, 1,028; Uintah reserve, Utah, 840—total, 2,866. There are probably twice as many more not confined to reservations. See INDIANS OF NORTH AMERICA.

Shoshone (shō-shō-nee') **Falls**: a cataract in Idaho; formed by Snake river plunging over a cliff of trachyte 190 feet high. Half a mile above the falls the river is 1,200 feet broad, and flows in a cañon 800 feet deep. At the falls the stream narrows to 1,000 feet, and descends into a gorge 1,000 feet deep. The falls are due to the fact that the river in deepening its channel in horizontal sheets of basalt has reached a ridge of more resistant rock beneath. I. C. R.

Shot: projectiles for firearms. For those used in cannon, see PROJECTILES. The smaller kinds, ranging in size from buck-shot to dust-shot, are composed of an alloy of lead with about 1 per cent. of arsenic, the addition of which gives greater softness and ductility. They are made in shot-towers by pouring the molten metal through colanders perforated with holes from $\frac{1}{30}$th to $\frac{1}{360}$th inch in diameter, and letting the particles fall from 100 to 150 feet into water. Another method lessens the height through which the particles must fall in order to assume the spherical shape and harden, by using a tube through which a strong upward current of air is forced. The shot are afterward assorted, rolled down an inclined plane so arranged that the misshapen shot fall out, and finally polished by being placed in a rotating cylinder with some powdered graphite.

Shoup, FRANCIS ASBURY: See the Appendix.

Shoveler, or **Spoonbill Duck**: a river duck of the genus *Spatula*, so named from the widening of the bill toward the tip. The common shoveler (*S. clypeata*) of the northern hemisphere has the head and neck green, breast white, belly chestnut, wing-coverts blue, speculum green (bordered by black and white), rump and tail-coverts black. The female is brownish, with blue wing-coverts. *S. platalea* (South America), *S. capensis* (South Africa), *S. rhynchotis* (Australia), and *S. variegata* (New Zealand) are the other species.

Shrapnel: See PROJECTILES.

Shreve, HENRY MILLER: inventor; b. in Burlington co., N. J., Oct. 21, 1785; was reared in Western Pennsylvania, and became interested in the navigation of the Western rivers. In 1810 he took a cargo of lead from Galena river to New Orleans, and opened a business which had been previously monopolized by the British. In 1814 he took command of a steamboat, and a few days before the battle of New Orleans carried supplies to Fort St. Philip, passing the British batteries, his vessel being protected from their fire by cotton-bales. In May, 1815, he ascended the Mississippi to Louisville in the Enterprise, the first steam-vessel that had ever performed that voyage, and subsequently built the Washington, of 400 tons burden, with improvements upon Robert Fulton's steamboat, especially in the saving of fuel. On Mar. 3, 1817, the Washington made her first trip. The return trip from New Orleans was made in twenty-five days. The enterprise of Capt. Shreve soon excited the hostility of Fulton and his associates, who had obtained the exclusive rights to "navigate all vessels propelled by fire and steam" in the rivers of the Territory of Orleans. His boats were seized in New Orleans, and he was arrested. A protracted lawsuit followed, which was finally decided in his favor. He finished the George Washington in 1824 upon a new model, which continued in use for over fifty years, having side-wheels each worked by a separate engine. In 1829 he completed his snag-boat, the Heliopolis, for removing snags and sawyers from rivers, and with it removed the great Red river raft, a collection of timber and driftwood 15 miles in length. In 1829 Capt. Shreve invented a steam marine battering-ram for harbor defense. He was made superintendent of Western river improvements in 1826, and continued in that position until 1841. D. in St. Louis, Mar. 6, 1854.

Shreve, SAMUEL HENRY, A. M., LL. B.: civil engineer; b. in Trenton, N. J., Aug. 2, 1829; graduated at Princeton 1848, at Harvard Law School 1850; studied civil engineering; was chief engineer of several railroads; published in 1873 a treatise on the *Strength of Bridges and Roofs*, and became in 1875 engineer of the New York Rapid Transit Commission. He was consulting engineer of the Metropolitan Elevated Railroad and engineer-in-chief of the Brooklyn Elevated Railroad. D. in New York, Nov. 27, 1884.

Shreveport: city (incorporated in 1839); capital of Caddo parish, La.; on the Red river, and the Houston and Shreve., the Queen and Crese. Route, the St. Louis S. W., and the Tex. and Pac. railways; 41 miles S. of Louisville, Ky., and 326 miles N. W. of New Orleans (for location, see map of Louisiana, ref. 6–B). It is the second city in population in the State, is in a cotton-growing region, has an extensive river trade, and handles large quantities of cotton, hides, wool, and wax. The city is provided with improved waterworks, gas and electric-light plants, sewers, and street-railways, and contains a U. S. Government building, parish court-house, a public hospital, the headquarters of the State board of health, several cotton-compresses, cottonseed-oil mill, ice-factories, and machine-shops. There are 10 public-school buildings, public-school property valued at $20,000. 2 national banks with combined capital of $300,000, an incorporated bank with capital of $150,000, a private bank, and 3 daily and 3 weekly newspapers. In 1892 the city had a total assessed valuation of $3,250,000, and in Feb., 1894, the total debt was $156,500. Pop. (1880) 8,009; (1890) 11,979; (1900) 16,013.

Shrew, or **Shrew-mouse**: a small, insectivorous, mouse-like mammal of the family SORICIDÆ (*q. v.*). Shrews are found in nearly all parts of the northern hemisphere; they are

Shrew.

nocturnal, frequently aquatic, produce their young blind and naked, do not hibernate, and have an elongated and pointed muzzle, small eyes, plantigrade, five-toed feet, and glands which secrete a musky fluid.

Shrewsbury (anc. *Penywerne*): capital of Shropshire, England; on the Severn, which is crossed here by three bridges; 42 miles W. by N. of Birmingham and 163 N. W. of London (see map of England, ref. 9–G). It is an old and picturesque town, though the streets are steep and narrow. The Norman castle still remains, and of the same date is the Church of the Holy Cross. St. Mary's church, a cruciform building with a tower and spire, was founded in the tenth century. Among other buildings are the market-house (1595), the shire-hall, rebuilt in 1883, and the new market-hall (1868). Shrewsbury School, founded in 1551, is one of the seven great public schools of England, and has a rich endowment. Near here on July 21, 1403, Henry IV.

defeated Hotspur, and in 1644 the town was besieged by the parliamentary army. Shrewsbury sends one member to Parliament. Pop. (1891) 26,967.

Shrike [O. Eng. *scrīc*, thrush, (perhaps also) shrike : Icel. *shrīkja*, shrike, liter., shrieker; cf. Eng. *shriek*]: any one of the *Laniidæ*, a family of passerine birds. The best known North American species is the butcher-bird (*Lanius borealis*). They are noted for their habit of impaling insects and small birds upon the points of thorns. See Wood-swallows.

Shrimp [cf. *shrimp*, another form of *scrimp*]: a name properly restricted to crustaceans of the genus *Crangon*, but

The shrimp.

more usually applied to any of the smaller long-tailed crustaceans. The common shrimp of Great Britain, *C. vulgaris*, is esteemed a delicacy as food.

Shropshire, or **Salop**: a west midland county of England; on both sides of the Severn, and bounded W. by Wales. Area, 1,319 sq. miles. The northern part is level, with the exception of the Wrekin (1,320 feet), and is chiefly under tillage; the southern is hilly, reaching 1,800 feet in the Clee Hills, and mainly devoted to cattle-breeding. The county has a fine breed of sheep. There is a considerable production of coal and some of iron, limestone, and freestone. Pop. (1891) 236,827; (1901) 239,297.

Shrove-Tuesday [from *shrive*, to confess sin]: the day preceding Ash-Wednesday, so called from the old custom of confessing and receiving shrift on that day as a preparation for the forty days' fast. It is in general a day of pleasure in most Roman Catholic countries. It is the Carnival of the Italians, the Mardi Gras of the French, and the Pancake-Tuesday of former days in England.

Shu'brick, William Branford: rear-admiral U. S. navy; b. on Bull's island, South Carolina, Oct. 31, 1790; entered Harvard in 1805, but was appointed midshipman June, 1806. He became lieutenant Jan., 1813; commanded a gunboat in Hampton roads in 1813, and assisted in the defense of Norfolk and the navy-yard at Gosport; in 1813 was transferred to the Constitution, and made two cruises, aiding in the capture of three ships of war, including the Cyane and the Levant; was awarded a sword by his native State and a medal by Congress; was promoted to the rank of commander 1820, and served at the navy-yards at Charlestown, Mass., and New York until Apr., 1826, when he was appointed to the command of the Lexington; in 1831 was commissioned captain; commanded the West India squadron 1838–40; was in command of the navy-yard at Norfolk, Va., Oct., 1840–Oct., 1843; chief of the bureau of provisions and clothing for the navy 1845–46; was appointed to command the Pacific squadron July, 1846, and during the war with Mexico captured several ports; was appointed to the lighthouse board Sept., 1852; placed in command of the eastern coast squadron for the protection of American fishermen July, 1853, and in September returned to Washington and resumed his duties as chairman of the lighthouse board; appointed president of board to prepare regulations for the navy Aug., 1857; commanded the Brazil squadron and Paraguay expedition 1858–59, returning to resume duty as chairman of the lighthouse board; was retired in 1861, but continued a member of the advisory board until 1870; was commissioned rear-admiral in 1862. D. in Washington, D. C., May 27, 1874.

Shu'feldt, Robert W.: rear-admiral U. S. navy; b. in Red Hook, N. Y., Feb. 21, 1822; entered the navy as a midshipman May 11, 1839; commanded several vessels on the coast during the civil war, and was actively engaged against the defenses of Charleston; commanded the flag-ship of the East Indian squadron during 1865 and 1866, and that of the Mediterranean from 1871 to 1873; in 1875 appointed chief of the bureau of equipment and recruiting. He was consul-general to Cuba during the first year of the civil war, and acted with admirable judgment and discretion. Retired Feb. 21, 1884. D. in Washington, D. C., Nov. 7, 1895.

Shullsburg: city; Lafayette co., Wis.; on the Chi., Mil. and St. P. Railway; 24 miles E. by N. of Dubuque, 60 miles S. W. of Madison (for location, see map of Wisconsin, ref. 7–C). It is in an agricultural and lead-mining region, and contains 4 churches, 3 hotels, a national bank with capital of $50,000, a State bank with capital of $50,000, and two weekly newspapers. Pop. (1880) 1,168; (1890) 1,393; (1900) 1,250. Editor of "Pick and Gad."

Shu'magin Islands: small archipelago of Alaska, in lat. 55° N., lon. 160° W., just E. of the peninsula of Alaska, from which they are separated by Unga Straits, consisting of Unga, Nagai, Popoff, Korovin, Big Koniushi, Little Koniushi, Simeonoff, and many smaller islands and islets. Unga is about 10 miles long by 7 broad, and contains the only settlement of any size on the islands, viz., the little town of Unga near the southeast angle. Nagai is about 30 miles long by 4 broad, and of very irregular shape. The islands are generally mountainous, are without tree-growth, have abundant rainfall, and several excellent harbors. Good lignite has been found on Unga. Salmon abound in the streams in early summer, and good cod-banks are near by. These islands were discovered by Lieut. Waxel in 1741, and were given the name of one of his sailors buried there. Area about 600 sq. miles. Mark W. Harrington.

Shumla: town; in Bulgaria, half way between Rustchuk and Varna; in a fertile plain, inclosed on three sides by inaccessible spurs of the Balkans and strongly fortified (see map of Turkey, ref. 3–D). It is also an important commercial center and manufactures leather, copper ware, and cloth. Pop. (1893) 23,517. E. A. G.

Shur [Heb., wall]: the name applied by the Hebrews to the desert which bordered Egypt on the E. of the southern half of the Isthmus of Suez (Ex. xv. 22). Some have derived the name from the wall, 1,500 stadia long, which is alleged by Diodorus (i., 57) to have been built by Sesostris from Pelusium to Heliopolis for the defense of Egypt against the eastern Bedouin. (Trumbull, *Kadesh Barnea*, pp. 44 ff.) An *anbu ḥaq* (wall of the ruler) in this region certainly is mentioned in a papyrus of the twelfth dynasty, but it antedated Sesostris-Ramses by more than the whole Hyksos period. In most of the Old Testament passages Shur seems to have been the name of a place near Egypt (Gen. xvi. 7, xx. 1, xxv. 18; 1 Sam. xv. 7, xxvii. 8), and it has been conjectured that it corresponded with the Egyptian *Anbu* (wall, Gr. *Gerrhon*), which probably lay near the Mediterranean to the N. of the isthmus, and was a fortified place on one of the highways to the East (Strabo, *Geogr.*, xvi., 2, 33). Charles R. Gillett.

Shurtleff, Nathaniel Bradstreet, M. D.: antiquary; b. in Boston, Mass., June 29, 1810; graduated at Harvard 1831, and at the Medical School 1834; became a physician in Boston; mayor of Boston 1868–70. He was the author of *An Epitome of Phrenology* (1835); *A Perpetual Calendar for Old and New Style* (1848); *Passengers of the Mayflower in 1620* (1849); *Notice of William Shurtleff of Marshfield* (1850); *Genealogy of the Leverett Family* (1850); and *A Topographical Description of Boston* (1871), besides many minor publications and contributions to *The Genealogical Register*. He edited *Records of the Governor and Company of Massachusetts Bay 1628–86* (6 vols. 4to, 1853–54), and, with David Pulsifer, *Records of the Colony of New Plymouth* (12 vols. in 11, 4to, 1855–61). D. in Boston, Oct. 17, 1874.

Shurtleff, Roswell Morse: See the Appendix.

Shusha: town of Elisabethpol, Asiatic Caucasus, Russia; lat. 39° 46′ N., lon. 46° 25′ E.; formerly a fortress, on an isolated rocky hill, inaccessible on three sides; celebrated for its silk-culture, carpets, and horses; 70 miles S. by E. of the city of Elisabethpol (see map of Russia, ref. 12–G). The climate is rigorous. This place was formerly capital of the khanate of Karabagh, annexed by Russia in 1822. Pop. (1897) 25,656. M. W. H.

Shuvaloff: another form of the name Schuvalov (*q. v.*).

Sial'agogues [Gr. σίαλον, saliva + ἀγωγός, leading, deriv. of ἄγειν, lead]: drugs that cause an increased secretion of saliva. Mercury has this property more than any other substance, but as the increased salivary flow is simply one among many effects of a poisonous dose of the drug, the term sialagogue is not a proper definitive appellation.

Sialkot', or **Sealkote**: ancient city of the Punjaub, British India; 65 miles N. of Amritsar, lat. 32° 31′ N., lon. 74° 36′ E.; not far E. of the Chinab, a station on the braneh railway from Ramnagar to Janin; capital and commercial eenter of the district of Sialkot (see map of N. India, ref. 3–D). It is a well-built and healthful city, with wide paved principal streets and sewers. In the center are the ruins of a very old fort used during the revolt of 1857–58. It is a saered plaee for the Sikhs, and contains the mausoleum of Baba Nanak, their first apostle or *guru*. The old highways converge from Lahore, Amritsar, Gurdaspur, and Gudpranvalla at the bridge near this place over the Aïk, tributary to the Chinab, but are usually lost in the sand before reaching that stream. It is a center for great bankers and merchants, who are usually Jains. Cottons and paper are manufaetured, but the industry is deeaying. The foundation of the city is attributed to heroes of the *Mahâ-bhârata*. Pop. (1891) 55,087, two-thirds Mohammedans. M. W. H.

Siam, sĕe-aam′, or sī-ăăm′ [from Malay *Sāyām*, the brown race; Siamese *Muang Thai*, liter., kingdom of the free]: kingdom of Central Indo-China. consisting of a eentral kingdom in the Menam valley and several tributary states around it and on the Malay Peninsula (see map of East Indies, ref. 3–B). On the E. it was long limited by the Annam watershed, but in 1893 France took possession of the whole territory E. of the Mekong. On the S. E. it is bounded by Cambodia. On the N. and W. the boundaries are ill defined and subjeet to negotiations with the British and French, but Siam claims the territory N. to beyond the parallel of 20° N. and westward to the Salwen river in latitudes 18° to 20° N. Farther S. the boundary is more to the eastward and is irregular. On the Malay Peninsula the Siamese influenee is exerted on the east coast from the head of the Gulf of Siam to Pahong, lat. 4° 50′ N., and over the whole peninsula from the Isthmus of Kra to the British provinee of Wellesley in lat. 5° 35′ N. The total area is about 200,000 sq. miles.

Configuration.—Siam is bounded N. and W. by mountain-ranges having a general N. and S. direction, and consists of three distinct areas. Thc first is the Menam basin, praetieally a plain rising to the northward, at first slowly, then rapidly, and occupied by the kingdom proper and some of the tributary states to the N. It is about 400 miles long by 150 broad, and ascends only 300 feet in the first 200 miles, but 700 to 1,000 feet in the next 150. The northern end, in which lie the sourees of the Menam, is mountainous. The second is the Mekong or Lao plateau, to the E. of the preceding, about 300 miles N. and S. by 250 E. and W., separated from the preceding by hills and low mountains, and drained by the left-hand affluents of the Mekong, S. of its great bend to the eastward. It is somewhat more elevated than the Menam basin adjacent. The last is the Malay Peninsula, consisting of a central ridge of mountains flanked by extensive plains. The kingdom is well watered. The Menam has so level a course that it divides several times into two or more streams which unite farther down after inelosing islands of large size. This delta-like characteristic extends to about 250 miles from the mouth. The stream is well suited to navigation by native craft and by rafts. The climate is tropical, but moderate and generally healthful. There are three seasons in the year, each of four months' duration. The hot season begins in January and the temperature rises until the rains begin in early May. The mean temperature in April in Lower Siam is about 83°. The rains come with the S. W. monsoons, but are less heavy than on the Burmese coast. The rainfall is heaviest on the west coast of the Malay Peninsula (100 inches) and deereases northeasterly to 40 inches. The cool season begins in September and brings pleasant temperatures, clear skies, and serene weather. The thermometer at Bangkok may deseend in this season to 55°, or even lower. This is the season for public festivals, to which the Siamese are much devoted.

Mineral Products.—Siam is rich in minerals, especially in the peninsula and along the western mountains. Gold, tin, iron, copper, argentiferous galena, and antimony have been found, but only the first two are mined. Preeious stones are found in considerable quantities in the southeast. The production of rubies is important; that of sapphire, onyx, topaz, and jade less so. Rich mines of sapphire were opened near Chantabun in 1874, but were soon abandoned because of the insalubrity of the climate. Coal has been found in the peninsula; petroleum springs oecur in the Shan states to the N., and roek-salt in several plaees. Considerable marine salt is produced along the eoast of the gulf.

Vegetation and Agricultural Products.—The forests of Siam have been much eneroached on where they lie along rafting streams, but elsewhere they eontinue in unexcelled luxuriance, and contain many valuable woods, as teak and ebony. At the higher elevations in the north the forests become like those of the temperate zone, resembling those of Central Japan and eontaining oaks and pines. The soil is alluvial and very fertile, and eopious erops are produeed with little labor. The chief agrieultural product and the staple article of diet is riee, of which the Siamese have about forty varieties. In 1893 it is estimated that the rice product was about 600,000 tons. Other crops are pepper, sesame, hemp, ramie, opium, tobacco, cotton, coffee, and maize, most of them only in quantities sufficient for loeal consumption.

Fauna.—The fauna is very rich and varied. This is the traditional land of the elephant, though the natives are not so skillful in rearing and breaking them in as are the natives of Hindustan. The tributary state of Chiengmai is estimated to have 8,000 domesticated elephants, that of Lakhon 10,000, and they are not less numerous elsewhere. The priee of an elephant is from $750 to $1,000. So-ealled white elephants are eonsidered sacred and are tenderly eared for. These are albinos, and the test is not so much the color of the skin as of the eyes and the hair on the temples. Albino monkeys are also sacred. The simians are very numerous, and their most important representatives are the gibbons, anthropoid apes, of whieh there are several speeies. Bats are abundant, and in mountain eaves form large collections of guano. Edible birds'-nests are colleeted in such quantities that the tax on them produees $135,000 annually. Among the numerous and varied domestic animals, besides the elephant, may be mentioned the ox, several kinds of horse, a peculiar raee of hog, the sheep, the goat, and several kinds of domestic fowls. The horned eattle form the most important souree of wealth. About 70,000 are annually exported to Singapore, the Shan states, and Burma. Fishing is an important industry, and considerable quantities of dried fish are exported.

Inhabitants.—The population is estimated at 5,000,000, of whom about two-fifths are Siamese proper and the remainder about equally divided between other Shans, the Chinese, and the Malays. The Chinese are generally from Kwangtung, and there are many Sino-Siamese half-breeds. They are for the most part in the kingdom proper, where they have largely appropriated trade and commerce to themselves, and form the chief souree of free labor. They are of independent spirit, and their turbulent charaeter causes the Government mueh trouble. The other people of the same ethnic race as the Siamese are the Shans proper in the north and the Laos in the northeast and east. They occupy the tributary states, and the Siamese influenee has been extended over them by conquest. The Malays are found chiefly in the tributary states of the peninsula.

The Siamese proper are found ehiefly up the Menam valley to the vieinity of Pitsanulok (about lat. 17° N.) and around the head of the gulf. Though for many centuries warlike, they appear indolent, gentle, and patient. They are small but well formed, with an olive or yellowish complexion and jet-blaek hair, hospitable, humane, not inventive, untruthful, and eaprieious. In eustoms, manners, and eivil institutions they are curiously intermediate between India and China, and thus especially deserve the name of Indo-Chinese. The religion is Buddhist. Indeed Siam assumes in an espeeial way the character of protector of Buddhism, and this has made the relations between Siam and Ceylon especially elose.

Language and Literature.—The language is of the Shan stock, monosyllabic in character, very different from Annamese and Burmese, and written with a script borrowed from the Pali. The literature is abundant and varied, consisting of religious, legal, and scientific books and a considerable body of *belles-lettres*. The religious works are largely derived from Buddhist sources; the others are chiefly of indigenous origin. The chief science is astronomy, and they have their own system of ehronology. The romances and stories are said to be tedious and lacking in refinement. There is relatively little industry because of a system of foreed labor under which each man, except a few privileged classes, owes the Government three months' labor each year. Domestic slavery is little practieed, and is in process of abolishment. Free labor is difficult to obtain. Foreign ideas are making considerable progress. Edueation is generally in the hands of the priests and is much hampered by tradition. Three large public schools have been established in Bangkok, where

European arts, sciences, and languages are taught, and for many years it has been the custom to send a few young Siamese abroad for a technical education.

Government.—The throne is hereditary, but the king may choose his successor in his own family. The legislative power is in the hands of the king, assisted by a council of ministers. The tributary states are ruled sometimes by their own princes, sometimes by a royal commissioner, and there is a strong tendency toward increased centralization. The kingdom proper is divided into forty-one districts under royal governors. The king's annual revenue is estimated at $10,000,000, produced by a land-tax, customs, taxes on opium, spirits, tin mines, fruit-trees, edible birds'-nests, fisheries (in the order of the amount of revenue from each), and other sources. All taxes, except customs, are farmed. There is no public debt. The standing army consists of 12,000 men, well supplied with arms and artillery, is largely officered by Europeans, and is said to be in a very effective condition. All males of suitable years are subject to military duty. The Government has a small navy, and the mouth of the Menam is fortified at Paknam.

Commerce.—Bangkok, the capital, is also the commercial center and chief port. In 1899 the imports were valued at $12,306,186 and the exports at $15,181,546. About one-fourth of the imports in value was cotton goods, and of the exports five-sevenths consisted of rice. Other exports were teak, pepper, salt and dried fish, and bullocks and hides. Both imports and exports are chiefly exchanged with Hongkong and Singapore, and there is a considerable trade to the northward to the Shan states and Yunnan. In 1899 462 vessels (301 of them British) entered Bangkok, and 467 vessels (303 British) cleared from that port. A railway, 14 miles long, connecting Paknam, at the mouth of the river, with Bangkok was opened in 1893. A railway from Bangkok to Korat, 165 miles N. E., was opened Nov. 1, 1900, and many others have been projected. Bangkok has an electric tramway in operation. Telegraph lines with a total length of 1,820 miles, connect Bangkok with Chiengmai, Chantabun, and other Siamese cities; also with Saigon in Tonquin and Maulmein in Burma. There is a postal service with 168 stations outside of Bangkok (1899), and Siam belongs to the International Postal Union. In 1899 479,648 domestic and 436,243 foreign letters were handled. The unit of money is the *tical*, a silver coin worth forty-one cents in average exchange. Silver and bronze are coined in fractions of the *tical*, and paper money is current in multiples of this coin. The unit of weight is the *chang* (2⅔ lb., avoirdupois); and of length, the *niu* (1⅔ English inches) or the *wah* (48 niu = 80 inches).

History.—The Siamese apparently came from the north and first appear in history in 575 A. D., when they founded Labong, about lat. 18° N., in the Upper Menam valley. The date of introduction of Buddhism among them is put at 638 A. D. They pressed steadily southward as invaders until in the thirteenth century they had reached the gulf and peninsula, and had apparently more territory than they have now. In 1350 they made Ayuthia the capital, and it so continued until 1782, when the Government removed to Bangkok, where it remains. For many centuries they carried on wars with their neighbors, the Burmese, Peguans, Cambodians, and with the people they displaced, with varying fortune but final success. The Burmese twice took their capital (1555 and 1767), the second time only after two years' siege. In 1592 Siam entered into close diplomatic and commercial relations with Japan, and many Japanese settled in the country, where they played the part now taken there by Europeans, but native jealousy finally resulted in their expulsion with violence in 1632. Very similar is the history of their relations with France, begun in 1684. The present dynasty succeeded a Chinese one, and began with the removal of the capital to Bangkok (1782). The conquests of Shans and Laos have been chiefly under this dynasty. The last three kings have made especial effort to extend the relations of Siam with the Western world. Maka Mongkut (1852 to 1868), the immediate predecessor of the present king, was a man of great learning and enterprise, and the present king, Chulalongkorn, continues his broad-minded policy. Siam is, however, weak, and, wedged in as she is between British and French possessions, owes her continued existence to sufferance on their part. In 1893 France possessed herself of Siam's territories across the Mekong; but in Jan., 1896, the central region, watered by the Menam and several smaller rivers flowing into the Gulf of Siam, was declared neutral by France and Great Britain, and its integrity guaranteed to Siam.

Siamese Twins: See Eng and Chang.

Sibe'ria [from Russ. *Sibirĭ*, Siberia, a word perhaps of Tartar origin from *Ssibir*, the name of the seat of the Tartar rulers on the Irtish]: a territory in Northern Asia, belonging to Russia. It is bounded on the N. by the Arctic Ocean from the mouth of the Kara river on the W. to Bering Straits; on the E. by Bering Sea, the Sea of Okhotsk, the Tartar Channel, and the Sea of Japan S. to the mouth of the Tumen-kiang on the Korean frontier; on the S. by Korea, Manchuria, Mongolia, and the Russian provinces Semipalatinsk, Akmolinsk, and Turgai of the steppes; on the W. by the upper Ural river, the Ural Mountains, and the Kara river. It includes portions of the governments of Orenberg and Perm usually classed as European. Thus limited Siberia has an area of 4,925,000 sq. miles, and a population of about 7,000,000. It is about a quarter larger than all Europe, but its population is not much greater than that of Belgium.

Political Divisions.—Politically, Siberia includes Saghalien with the above, but excludes Orenburg and Perm, giving an area of 4,833,496 sq. miles, and a population, in 1897, of 5,731,732, or a little more than one to the square mile. In this territory are the governments of Tobolsk and Tomsk, formerly composing the government of Western Siberia, but now directly administered under the Russian Minister of the Interior; the governments of Yeniseisk and Irkutsk, and the province of Yakutsk, formerly composing the general government of Eastern Siberia, now called the general government of Irkutsk; the provinces of Transbaikalia, and of the Amur, the Coast Province or Primorskaia Oblast, and the circle of Saghalien, forming the general government of the Amur. For details as to these governments and provinces, see each under its own heading.

Configuration.—The Ural Mountains, which separate Siberia from European Russia, reach an elevation of only 5,522 feet at their culminating point at Mt. Konchakof in the government of Perm. They can be traversed without difficulty, and their slopes are especially gentle on the Asiatic side. These mountains aside, Siberia has a very simple structure, consisting of an elevated plateau in the southeast, set in mountains, and passing toward the W. and N. by an enormous plain. The plateau is called the plateau of Vitim, from the branch of the Lena which takes its rise there. It is the northward extension of the great plateau of Asia, which has its highest and broadest part abutting the Himalaya Mountains and extends nearly to Bering Straits. In Siberia it is narrow and relatively low, rarely surpassing 3,000 feet. In this plateau all the great rivers of Siberia take their rise. The margins consist of a series of mountain ranges with relatively gentle slope where they abut on it, and abrupt descents toward the plain or sea. On the sea of Okhotsk the mountains rise abruptly from the water, and there is an outlying range in Kamchatka. In the Amur region plains of considerable magnitude intervene between the ranges at the eastern margin of the plateau and the coast ranges, which extend from Korea to the mouth of the Amur. The termination of the plateau toward the N. E. is in a region very imperfectly explored. The area so far described includes only about one-fourth of Siberia. The remainder consists of an enormous plain extending W., N. W., and N., and sloping N. and W., with an ill-defined intermediate hilly region. This is the great plain of Asia, and is continued beyond the Urals in the plain of Russia and Germany. In Asia it consists southwestward of steppes, grassy and sandy, which rise very gradually to the low, rounded, imperceptible watershed between the Arctic and Turkestan systems of drainage. Its slope northward is rapid near the mountains, thence growing more and more gradual. The steppes pass gradually into the tundras of the north, which extend to the Arctic Ocean along the entire northern boundary. They are level or rolling plains, subarctic and arctic in character, with an alluvial soil. They are of a depressing sameness, are well-watered, and would be suitable for cultivation did the climate permit. Their

slope northward is extremely gentle, and is continued under the Arctic Ocean as far as soundings have been made. At 150 miles from the coast soundings have given depths of 13 or 14 fathoms only.

The coasts of Siberia measure 19,000 miles, of which 10,000 belong to the Arctic Ocean. The northernmost point of the mainland is Cape Cheliuskin in lat. 77° 36′ N., about 5° farther N. than Point Barrow, the northernmost point of the U. S., and 6° farther N. than North Cape of Norway. On the north coast are the great indentation called the Gulf of Obi, the two great peninsulas of Yalmal and Tamyr, and to the N. of Yakutsk the large archipelago of the New Siberian islands, the northernmost known point of which is on Bennett island in about the same latitude as Cape Cheliuskin. Nordenskiöld first traversed this coast in 1878–79, in his celebrated voyage in the Vega. The rigor of the climate of these high northern latitudes prevents profitable commerce, notwithstanding the ready access given to the interior in summer by the great Siberian rivers. The shores of Bering Sea are provided with harbors, and are accessible for a longer season each year, but the country inland is barren and relatively inaccessible. Along the Sea of Japan the coast is bold and rocky, furnishing generally little protection for commerce. The exceptions are the bays of St. Vladimir (lat. 43° 55′ N.), of St. Olga (lat. 43° 44′ N.), which afford good anchorages, and the Gulf of Peter the Great near the Korean border, where the Russian naval station and town of Vladivostok is situated. It has several smaller bays, and the town is on a peninsula between the Bay of America and the Bay of Ussuri. At the Korean border is the Bay of Possiet, with the Pallas anchorage and two interior bays. The entire Siberian coast is rising slowly, and marine shells are found far inland from the Arctic shore.

Hydrography.—Siberia is provided with a magnificent series of rivers. Belonging entirely or in part to it are 38 streams 400 miles or more long, when the minor meanders are neglected, 27 more than 600 miles long, and 8 which are 1,250 or more miles long. The four longest are the Obi (3,200 miles), the Lena (2,880 miles), the Amur (2,800 miles), and the Yenisei (2,500 miles). All rise about the plateau already described—if of sufficient length—and all, except the Amur and Anadyr, contribute to the Arctic Ocean. The long and relatively straight course of many of these streams adapts them to display the effects of the earth's rotation under which all moving bodies in the northern hemisphere tend to diverge toward the right of their course. The long Siberian rivers show a decided tendency to leave their left-hand (western) banks, leaving them low, flat, and subject to overflow, while they eat out their right (eastern) banks, making them high and steep. The Siberian towns are practically all riverine. The length and magnitude of the streams greatly favor navigation in its season, and in 1893 there were 102 steamers plying on the streams of Western Siberia, with an aggregate traffic of 322,000 tons. There were also sixty-eight steamers on the interior waters of Eastern Siberia. The case of river traffic N. and S. is evident, but their great bifurcations also adapt these rivers to an east and west traffic, and Siberia can be crossed from Ekaterinburg to Nikolaevsk, at the mouth of the Amur, almost entirely by water. The principal land stretch is at the western end from Ekaterinburg to Tiumen, and this was supplied with a railway in 1885. The principal difficulties to navigation are to be found in shiftings of the channels and in the shortness of the warm season. The rivers are closed by ice from two to eight months; the opening begins at the S. and proceeds slowly N. In front of the open water accumulate great ice-packs, and these serve as dams and cause the most serious floods. Several parts of Siberia are rich in small lakes. The plains of the west are thickly strewn with them, usually shallow, and in the midst of marshes, and their diminution in area and depth is progressing more rapidly than usual elsewhere. The plateau of Vitim is also thickly studded with small bodies of fresh water. On the other hand, large lakes are relatively rare. The largest is Lake Baikal, area 13,200 sq. miles, just W. of the plateau of Vitim, long and narrow, in a deep valley between two mountain ranges, drained by the Angara, an affluent of the Yenisei. There are two others with areas between 1,000 and 1,500 sq. miles, two of between 700 and 1,000 sq. miles, three of between 400 and 700 sq. miles, and ten of between 200 and 400 sq. miles.

Climate.—The climate of Siberia is continental, rigorous, and cold. The temperatures are especially low; they are like those around Hudson Bay, but are colder. The mean annual temperatures through Central Siberia from Tobolsk to Kamchatka are like those of the Yukon basin in Alaska and of Labrador. They vary from a mean annual temperature of 32° F., along a line which extends from Archangel on the White Sea to Lake Baikal and thence eastward, to 15° F.—or 17° below freezing—along a line which extends from Nova Zembla to Yakutsk and thence northeastward. To the S. of the first line is a narrow strip with the temperatures of New Brunswick and Manitoba. To the N. of the second line the mean temperatures are below 15°, and for a considerable part of the coast are near 0° F. The coldest place known in the world, and not at high altitudes, at which observations are taken is Verkoyansk (lat. 67° 54′, lon. 133° 52′ E., on the Yona river), where the mean annual temperature is 2° F. The mean temperature of January is 20° below zero, and the observed minimum is 80° F. below zero. This is the best-known pole of cold on the earth. All Siberia is colder than the average for the other places on the same parallels of latitude, and at this pole of cold it is about 20° colder. At the same time the change of temperature between summer and winter is greater than known elsewhere at low altitudes, and at Verkoyansk the difference between the January and July mean temperatures is 116°. For the Missouri valley it is only 55°, and for Manitoba 65° or 70°. With the other continental features Siberia is dry, having a rainfall varying from 5 to 45 inches. In general the rainfall or snow is about that of the Great Plains E. of the Rocky Mountains, but in the northeast it is still less. The principal rainfall is in summer and autumn. Blizzards are not rare, and are very destructive to stock toward the end of winter.

Mineral Productions.—The most productive metalliferous districts of Russia are along the Urals, and especially in those governments which lie partly in Asia, partly in Europe. It is not always possible therefore to separate the Asiatic from the European statistics, but the Asiatic versant of the Urals is in general much richer in mineral products than the European. Siberia is celebrated for her gold, platinum, and precious stones. The mines belong chiefly to the state, and their income to the imperial family. Gold is for the most part from places in the Urals and Altai Mountains, but has been found in several other districts. The production began in 1726, reached its maximum in 1825–50, and has since declined, except for a favorable fluctuation in 1871–76. The total production of the Russian empire (mostly from Siberia) to 1876 has been estimated at two-thirds of a billion of dollars, and the annual product remains about one-sixth of the world's total output of gold—in 1898 it was 38,792 kilogrammes. Russian platinum is from the Urals, chiefly from the Asiatic slope in Perm. Most of the platinum product of the world comes from this area. Mines of precious stones are numerous, and their product large, and the best are on the eastern slope of the Urals—diamonds, sapphires, emeralds, superb beryls from several places in Perm, aqua-marines and topazes from Ilmen in Orenburg, etc. There are equally rich mines in the Altai Mountains and in Transbaikalia. Silver, copper, iron, carbon, graphite, and rock-salt are also important products.

Flora and Fauna.—The flora is very varied, as might be expected for so large an area, but it falls naturally into five principal types, viz., that of Kamchatka and the islands, which is closely allied to that of the Aleutian islands of the U. S.; that of the Amur basin, which is a continuation of the Manchurian; that of the southwest steppes, which are an extension of those of Russian Turkestan; that of the tundras along the Arctic Ocean; and that of the forests covering Central Siberia, an extension of those of Russia. The tundras have a considerable variety of low woody plants or shrubs, especially of the genera *Rubus* and *Vaccinium*, also alders and willows. Mosses predominate, but some flowering plants extend even to Cape Cheliuskin. The northern margin of the forest area is generally formed by two species of larch which, between the Yenisei and the Kolyma, reach N. of the Arctic Circle, sometimes passing the parallel of 70° N., and on the Bay of Khatanga reaching 72° 30′ N. W. of the Yenisei the margin of forest growth descends below the Bays of Tazovsk and Obi, and E. of the Kolyma the forest-line descends rapidly southward to Kamchatka. Next to the larches come the pines, spruces, the poplar, and birches, and the last replaces the larches in the extreme east. The forest area of Siberia is enormous. That of Tomsk and Tobolsk is estimated at 250,000 sq. miles, and probably this is only a third or a quarter of the area for all Siberia, but the forests are visibly decreasing in Asiatic as in European

Russia. The Siberian forests are sometimes dense and continuous, but they are more often open, with intervening prairies. The oaks, lindens, and maples are found only on the Pacific versant, and here they are of unfamiliar species. The common fruits—the apple, pear, cherry, gooseberry—do not flourish in Siberia, but the hop is very common. The northern limit of cereals is about 60° N. lat. in the basin of the Obi, and rises to 61° or 62° in Yakutsk and the Aldan basin, but descends to 54° N. on the Sea of Okhotsk and in Kamchatka. They do not flourish on the elevated plateaus.

The fauna is not unlike the European, except in the southwest, where it is like that of Turkestan, and the southeast, where it is closely allied to the Manchurian. The northern shores have the reindeer, the northern hare, two species of fox and a wild dog, two species of lemmings, and the Siberian bear, the last becoming more and more rare. The mammoth and a rhinoceros abounded in these plains apparently at a time antedating the Glacial epoch. Farther S. animal life is abundant, and even the tiger penetrates into the Amur valley. Lake Baikal, though a body of fresh water, has its own species of seal, and the waters, both running and standing, abound in fish. Among the domesticated animals is the reindeer, which here descends to lat. 50° N. on the mountains bordering on Mongolia, where its habitat touches that of the camel. Siberia offers abundant pasturage, and is especially suited to the raising of live stock. According to recent estimates, it possessed over 2,000,000 each of horses and horned cattle, nearly 3,000,000 sheep, 500,000 swine, 200,000 goats, 146,000 domesticated reindeer, and 3,600 camels. The collection of furs (fox, ermine, marten, sable, bear, squirrel) forms an important industry.

Agriculture.—The amount of arable land is estimated at from one-third to one-fifth of the total area, more in proportion in Western than in Eastern Siberia. The maritime province, adjoining Manchuria and the Pacific, is more favorable for agriculture, so far as climate and water-supply are concerned, but it is little known. Agriculture is very primitive, but the virgin lands yield enormous crops. The chief crops are wheat (spring and winter), rye, oats, barley, the potato, and tobacco. There are few manufacturing industries. Trade is mostly with European Russia, but is very profitable, with high prices and high rates of interest.

Population.—The population is most dense over a long and slender triangle, whose base is on the Ural Mountains, and whose axis passes from Ekaterinburg to Vladivostok, through Lake Baikal. In this space the greater portion of the inhabitants are of European descent, mostly Russians, with a few Poles and still fewer Germans. N. of this area, and over three-fourths of Siberia, the population is very sparse, and consists of tribes of Finnish relationship in the west (Ostiaks, Samoyedes, etc.) and of uncertain relationships in the east (Chukchees, Koriaks, Kamchadales, etc., with a few Eskimos about Cape East). S. of the area above described are Turco-Tartars in the west (Kalmuks, etc.) and Mongols in the east (Buriats, Tunguses, etc.). The Buriats occupy much of the Amur valley, and the Tunguses extend northward into the Yenisei basin until their area adjoins that of the Samoyedes. There are also a few thousands of Jews and gypsies scattered through Siberia. The abundant archæological remains show that Siberia has been occupied from the earliest times, and the peoples along the Arctic coast appear to be the ethnic remnants of the aborigines. Peoples of Turkish or Mongolian races in wave after wave have swept over the country and left remnants of their own tribes in its southern parts. The lot of the indigenes, whether aboriginal or not, is not pleasant. Oppressed by imposts of the nature of tribute, robbed of their lands most suited for the chase, fleeced by functionaries and merchants, exposed to new and destructive maladies, and demoralized by spirituous liquors, their number is decreasing rapidly.

The religions are as diverse as the peoples. The Russians are generally Orthodox, but many dissenters have been deported. The Poles are usually Roman Catholics, the Tartars Mohammedans, the Mongols Lama-Buddhists, and the northern indigenes pagans of the Shaman type. Missionary effort is active throughout the country, and especially in the west. Many of the indigenes profess Christianity.

The conquest of Siberia was begun in 1582. The latest addition to its territory was Saghalien (*q. v.*) in 1875. From the beginning a stream of voluntary colonists has poured into Siberia from European Russia, although immigration was at times forbidden by the Government and is strictly regulated. The number of such colonists from 1860 to 1880 is officially estimated at about 100,000. In the latter part of the eighties it had increased to abont 35,000 per year, and since the Samara famine it has greatly increased, and is estimated to have been 100,000 in 1892 and 175,000 in 1897.

Increase through Deportation.—Deportation to Siberia was important in the seventeenth century, and adds annually about 20,000 to the population, of whom about one-fourth are voluntary, accompanying their families. From 1823 to 1869 there were over 600,000 persons deported to Siberia, and of them 167,000 were voluntary. About 15 per cent. of the deported were women; 12 per cent. were sentenced to hard labor, 20 per cent. to loss of civil rights, 13 without such loss, and 2½ were free to change residence in Siberia; 52 per cent. were deported by executive act, or otherwise without process of courts. When deported they are sent to prisons at Tiumen and thence distributed, some to the extreme north, some to hard labor in mines in the Amur, some to the convict island of Saghalien, but generally to some less remote or less forbidding place where the chief reminder of their condition is the strict police surveillance to which they are subjected. The political exiles are the most intelligent and worthy, but the worst treated. The criminals sometimes become vagabonds, and may continue their unlawful careers. The exiles in Siberia make 5 per cent. of the population as a whole—1 in Yakutsk, 3 in Tomsk, 4 in Transbaikalia, 5 in Tobolsk, 10 in Yeniseisk and Irkutsk, and in Saghalien about 70.

Vital Statistics, etc.—Aside from the unfavorable conditions induced by the introduction of criminals by deportation, the social state of Europeans in Siberia is not bad. The birth-rate is very high (45·5 in 1890) and the death-rate somewhat high (31), but not so high as in European Russia. Only 9 per cent. of the population as a whole live in the towns. The number of males (1897) surpassed that of the females by 7 in 100. In 1891–92 there were 1,446 primary schools with 49,118 pupils, 55 middle schools with 7,401 pupils, 17 professional schools with 974 pupils (only 75 girls in the last), and a university at Tomsk, opened in 1887.

Means of Communication, etc.—A telegraph line extends from the Urals to Nikolaevsk at the mouth of the Amur. Besides the railway to Tiumen one from Orenburg to Vladivostok (4,950 miles) was begun in 1892. In 1899 the last section from Sryetensk to Lake Baikal (685 miles) was completed and opened Dec. 28, completing the line of communication from Vladivostok to European Russia. The trains are transported across Lake Baikal on ice-breaking ferry-boats. The chief towns are Tomsk (pop. 52,430 in 1897); Irkutsk (51,484); Omsk (37,470); Tiumen (29,588); Vladivostok (28,896). See Siberia in the Appendix.

Literature.—The encyclopædic and more complete works on Siberia are naturally in Russian, and the German literature is large. The following are the works available in English and the more classical of the German books: Middendorff, *Reise in dem äussersten Norden und Osten Sibiriens* (4 vols., 1851–60); Kennan, *Tent-life in Siberia* (1870), also magazine articles by this author; Seebohm, *A Visit to the Valley of the Yenisei* (1879); Mudge, *Fur-clad Adventures through Alaska, Kamtchatka, and Eastern Siberia* (1880); Nordenskiöld, *Voyage of the Vega* (1881); Iadrintzef, *Sibirien, geographische, ethnographische, und historische Studien* (trans. from Russian, 1886); Landsdell, *Through Siberia* (2 vols., 1882); Woeikof, *Die Klimate der Erde* (2 vols., 1887); De Long, *Voyage of the Jeanette* (2 vols., 1883); Melville, *The Lena Delta* (1885); *Lenamündung* of the Russian International Polar Expedition; Price, *From the Arctic Ocean to the Yellow Sea* (1892). Mark W. Harrington.

Sibilants [from Lat. *si'bilans*, partic. of *sibila're*, to hiss]: in phonetics, a group of fricatives or spirants characterized by a hissing sound. This hissing sound is produced by a current of breath directed by the blade of the tongue against the teeth. The commonest examples are *s* as in *sun*, *sh* (š) as in *shine*, *z* as in *zinc*, *zh* (ž) as in *azure*; *s* and *sh* are voiceless, *z* and *zh* are voiced; *s* and *z* are produced by a sharper or more concentrated current of breath than *z* and *zh*, in which the tongue is drawn back and the point slightly raised. See Spirants and Consonant.

Benj. Ide Wheeler.

Sibler, Wilhelm, Ph. D.: clergyman; b. at Breslau, Prussia, Nov. 12, 1801. After a gymnasium course he served for two years and a half in the Prussian army, rising to a lieutenancy; studied in the military school at Berlin; abandoning military life, studied philosophy and philology in Breslau and Berlin: gymnasium professor at Dresden 1830–37; tutor in Livonia, Russia, 1837–41. Having studied the-

ology privately, he answered an appeal for German missionaries for the U. S. and removed to North America in 1843. He became a member of the Joint Synod of Ohio, first for a brief time as pastor at Pomeroy, O., and then at Fort Wayne, Ind. He founded a seminary at Fort Wayne, Ind. (1846), of which he became professor, and was one of the founders and leaders of the Synod of Missouri. He was the author of *Sermons on the Gospels* and *Epistles of the Church Year*, and of various controversial treatises. D. Oct. 27, 1885. His biography (*Lebenslauf*) in two volumes was published at St. Louis, Mo., 1880. H. E. Jacobs.

Sibley, Henry Hopkins: soldier; b. at Nacogdoches, La., May 25, 1816; graduated at the U. S. Military Academy July 1, 1838; appointed second lieutenant of Second Dragoons; first lieutenant 1840, captain 1847, and major First Dragoons 1861; served in Florida war 1838–39 and 1840–41; adjutant of his regiment 1841–46. In the war with Mexico he participated in the siege of Vera Cruz, battles of Cerro Gordo, Contreras, Churubusco, Molino del Rey, and final capture of the city of Mexico, gaining the brevet of major for gallantry in the affair at Medellin, near Vera Cruz, Mar. 25, 1847. Before the civil war he was actively engaged on frontier duty and on numerous expeditions, notably the Utah expedition (1857–58, 1859–60), and that against the Navajoes (1860). The breaking out of civil war in 1861 found him in New Mexico, where he resigned from the U. S. army, in which he had just been promoted to the rank of major (May 13), and entered the Confederate service, in which he was soon a brigadier-general. Having organized a brigade in Northwest Texas, he left Fort Bliss in Jan., 1862, with between 2,000 and 2,500 men, to effect the conquest of New Mexico, and Feb. 16 appeared before Fort Craig, commanded by Col. E. R. S. Canby. The action of Valverde was fought Feb. 21, closing by the withdrawal of Col. Canby's troops to the fort. Albuquerque and Santa Fé were occupied by Sibley in March, but the following month he was compelled to evacuate the territory and return to Fort Bliss. After the close of the war he was in the service of the khedive in Egypt as brigadier-general 1869–73. He was the inventor of the tent known by his name. D. at Fredericksburg, Va., Aug. 23, 1886.

Revised by James Mercur.

Sibley, Hiram: financier; b. at North Adams, Mass., Feb. 6, 1807; was a shoemaker by trade; removed early to New York State, where he became a machinist, and also engaged in manufacturing machinery. When telegraphy came into practical use he associated a few gentlemen with himself, and bought or leased several unsuccessful lines, until finally over twenty corporations were merged into the Western Union Telegraph Company. Sibley subsequently conceived the idea of a line to California, and was mainly instrumental in carrying through Congress, in the face of the most intense skepticism, a bill which secured a line to the Pacific coast. He also completed negotiations with the British and Russian Governments for a European line across Bering Strait. The Atlantic cable proved a success and, consequently, the Asiatic line a failure. He engaged in railway-building, in manufacturing lumber and salt, seed-raising, and in farming, on a large scale. He expended $200,000 in founding Sibley College of Mechanical Engineering at Cornell University, and $100,000 on a fire-proof library building for the University of Rochester. D. at Rochester, N. Y., July 12, 1888.

Sibthorp, John, M. D., F. R. S.: botanist; b. at Oxford, England, Oct. 28, 1758; graduated at Oxford University about 1778; studied medicine at Oxford, Edinburgh, and on the Continent; made botanical researches in France, Switzerland, Southern Italy, Crete, Cyprus, Asia Minor, parts of European Turkey, and Greece; Professor of Botany at Oxford; one of the founders of the Linnean Society; made a second botanical exploration of Greece and the Ionian islands 1794–95; published the *Flora Oxoniensis* (1794); died at Bath, Feb. 8, 1796. He bequeathed to the university £1,200 per annum for the publication of his great work, *Flora Græca*, which was edited by J. E. Smith and John Lindley (20 vols., royal folio, with 1,000 colored plates, 1807, *seq.*).

Revised by Charles E. Bessey.

Sibyl [from Lat. *sibyl'la* = Gr. σίβυλλα, sibyl]: the name given to certain old women inspired by the god of prophecy. Plato knew of but one sibyl, Aristotle of several, and Varro of ten. Libyssa, the first sibyl, was the daughter of Zeus and Lamia, and prophesied at Delphi. The second and famous sibyl was Herophile, a sister or daughter or wife of Apollo, who is heard of even before the Trojan war. Troyland seems to have been her real home, though, from her wanderings in the interests of her god, she was known as the Sardinian, Trojan, Samian, Delphian, Cymæan, Cumæan, Erythræan sibyl. She lived for ages, and she it was who sold the books of prophecy to Tarquinius Superbus. The twelve extant books of sibylline oracles are of late (even Christian) origin, and have nothing in common with the old sibyls.

Sicard, Montgomery: See the Appendix.

Sicil'ian Vespers: the uprising of the Sicilian people against the French usurper, Charles of Anjou, at Palermo on Easter Day, Mar. 30, 1282. In 1264 Pope Urban IV. had granted the kingdom of the Two Sicilies to the bigoted Charles of Anjou, brother of King Louis IX. of France. Charles defeated Manfred at Benevento, took possession of the kingdom, and converted the government into an oppressive despotism. This was long borne without organized resistance, but the brutality of a French soldier toward a Sicilian woman produced an outburst of popular resentment which began with the instant massacre of the French soldiery, and ended with the slaughter of most of Charles's foreign and native adherents throughout the island, and the final overthrow of his domination in Sicily. See Amari, *La Guerra dei Vespri Siciliani* (2 vols., Palermo, 1842; many times reprinted).

Sic'ilies, The Two: the name given formerly to a kingdom composed of the island of Sicily and the southern part of the mainland of Italy. In 1130 the Norman Roger (*q. v.*), King of Sicily, having obtained the Italian territories of Apulia, Capua, Naples, and the Abruzzi, was crowned at Palermo as King of Sicily and Italy, a title afterward altered. Thus was formed a dominion whose two parts were frequently divided and united and transferred from one ruler to another, but always with hardly any change of boundary. Ferdinand the Catholic (1479–1515), King of Aragon and the island of Sicily, conquered the continental Sicily and called himself the king of the Two Sicilies, which then remained united up to 1706. (See Sicily.) From 1735 up to their annexation to the kingdom of Italy in 1860 the parts were again united, except during the period 1805–15, when the continental Sicily was ruled over by Joseph Bonaparte and Murat as Kings of Naples. The continental Sicily comprised what are now the five *compartimenti* of Abruzzi e Molise, Campania, Apulia, Potenza or Basilicata, and Calabria, and is divided into sixteen provinces. See Ferdinand IV. (King of Naples), Ferdinand II., Francis I., and Francis II. (Kings of the Two Sicilies).

R. A. Roberts.

Sicily, sis'i-le (Ital. *Sicilia*; Lat. *Sicilia, Sicania, Trinacria*; Gr. Σικελία, Σικανία, Τρινακρία): the largest and most important island in the Mediterranean, lying near the center of that sea, between 36° 41′ and 38° 18′ N. lat., 12° 30′ and 15° 40′ E. lon. It is separated from Italy by the narrow Faro or Strait of Messina. Its western extremity, Cape Boeo (anc. *Lilybæum Promontorium*), is 90 miles from Cape Bon in Africa. It forms a nearly isosceles triangle, its shortest side fronting the E. Area, 9,936 sq. miles. Together with the islands Pantellaria and Ustica and the Lipari or Æolian group on the N. and the Ægates group on the W., it constitutes a *compartimento* of the kingdom of Italy.

Physical Features, etc.—The coast is about 700 miles long, but has few natural harbors. The most important are those of Messina, Catania, Agosta, and Syracuse on the E. and of Palermo on the N.; also in the small harbors of Trapani and Marsala on the W. and in the roadstead of Licata on the S. a large trade is carried on. The most northeast point is Capo del Faro; most S. E., Capo Passero; N. W., Capo San Vito. Near the northeast corner of the island begins a mountain chain corresponding to the Calabrian range on the mainland. Its general direction is S. S. W. to Taormina, then westward, running parallel to and near the north coast with a general elevation of from 2,000 to 3,000 feet. Its highest summit, the Pizzo dell' Antenna or Pizzo di Case, S. W. of Cefalu, is 6,478 feet high. There the chain divides into three ridges, or rather series of detached mountains, diminishing in height, which run S. W., S., and S. E. The general surface of the island is an uneven plateau descending toward the S. E. Its most famous and important mountain is the isolated volcanic peak of Etna (*q. v.*). There are few lakes or ponds. Lago Pergusa, near Castro Giovanni (anc. *Enna*), and the Biviere di Lentini, or Lake of Lentini, are the largest. The forests, which were formerly extensive, have been largely destroyed in modern times, not only by volcanic eruptions, as along the slopes of Etna, but by im-

provident felling and abuse of pasturage. In consequence the water-supply is uncertain and limited. The heavy winter rains are of little benefit, being neither absorbed by the soil nor collected in natural or artificial storehouses for the dry season. Still, evaporation from the surrounding seas mitigates the heat, and its condensation on the summits of the northern coast range furnishes a supply of water which, though badly economized, somewhat protects the soil from droughts. The principal rivers are the Giaretta, formed by the union of the Simeto and Gurnalunga, the Cantara, Salso, Platani, and Belici. The numerous smaller streams are often obstacles to internal communication from the violence of their currents in winter and from the difficulty of constructing secure bridges over them. The larger number are dry in summer. The temperature is generally agreeable, except during the prevalence of the parching sirocco. The climate is not unhealthful, except in the many localities rendered almost uninhabitable by malaria.

Minerals.—The minerals correspond with the geologic formations of which the island is composed—Primitive at the N. E., Secondary along the N., and mainly Tertiary through the rest of Sicily. Sulphur and rock-salt are the most important mineral products. The marbles, jaspers, and agates are fine. Lignite and alum are found, and also at the eastern coast amber, usually of a transparent yellow, but sometimes blue or green.

Agriculture and other Industries.—The soil, almost nowhere alluvial, is exceedingly fertile wherever water can be secured for irrigation. Agriculture is carried on only in the rudest and most primitive way, and until recent years insecurity of life and property have prevented investment in rural improvements. Excellent wheat is raised in large quantities, but generally exported, the necessities of the inhabitants being supplied by the importation of a cheaper and inferior article. The vineyards produce delicious wines of various kinds. Hemp, saffron, and sumach are grown. The mulberry is cultivated for the silkworm. Almonds, figs, olives, lemons, oranges, and tobacco are raised extensively. The cultivation of cotton and the sugar-cane has greatly decreased. Manufactures are unimportant and hardly more than supply the wants of the working-classes. Fishing is prosecuted with energy. The tunny is taken and cured at different points along the coast, and sardines and anchovies are shipped to foreign ports in large quantities. Means of intercommunication are very defective. There are few highways, the roads are mostly bridle-paths, and the towns of the interior are generally not accessible by small carriages. In 1894 633 miles of railway had been opened up.

Language and Literature.—The Sicilian dialect resembles that of Calabria. It generally agrees with the Tuscan in vocabulary, but with the frequent substitution of *u* for *o* final, of *ll* by *dd*, and with the omission of the *u*-sound after *q*; but it possesses many words from the Arabic and others from unknown sources. Though not a literary language, it has ancient chronicles in the popular speech and some modern poems justly admired. Education, though making progress, is still in a backward state, and Sicily is far behind continental Italy.

History.—The earliest known inhabitants were the Sicani or Siculi, who crossed from Italy. At an early period the Phœnicians planted their factories along the coast and introduced the Phœnician worship. They were shortly followed by Greeks, who so thoroughly colonized the island in the eighth and seventh centuries before Christ that all its ancient culture and civilization were of Greek origin: but the colonists, being from many different states, were disinclined to unite in any common organization. The cities they founded were governed by oligarchies or tyrants, but though often at war with each other rose to great wealth and power. The Carthaginians in great force invaded Sicily, but received a crushing defeat at Himera (480 B. C.). Then followed the most brilliant half century of the Greek domination. Troubles among the cities furnished a pretext for the disastrous Athenian expedition (415 B. C.). After 409 B. C. the Carthaginians gradually mastered most of the island, but were sturdily resisted by Dionysius, tyrant of Syracuse. At the close of the first Punic war (241 B. C.) they were forced to cede their Sicilian possessions to the Romans, Syracuse still remaining independent; but all Sicily became a Roman province—the first Rome possessed—at the close of the second Punic war, and so continued until 395, when, on division of the Roman empire, it became part of the empire of the East. Christianity was early introduced, apparently from Rome. Overcome by the Goths, Sicily was delivered by Belisarius and continued a Byzantine possession until 827, when its subjugation was commenced by the Saracens and was completed in 878. Under the Mussulman sway agriculture, manufactures, and commerce steadily increased. In 1061 the wealthy island tempted the Normans under Roger Guiscard, but it was not wholly subdued until 1090. The Normans held it until 1194, when it passed to the Hohenstaufen emperors, who were replaced in 1268 by Charles of Anjou and the French. The massacre of the SICILIAN VESPERS (*q. v.*) ended the power of the latter (1282), and the island came into the hands of Peter III. of Aragon. The Aragonese dynasty reigned till 1504, after which until 1706 Sicily was under the Spanish crown. Then for brief periods it was held by Austria, Savoy, Austria, and Spain, till in 1735 it was reunited with Naples under Don Carlos as King of the Two Sicilies, and was ruled by his house until its liberation (1860) by Garibaldi and its incorporation into the kingdom of Italy. Its condition in the Middle Ages was deplorable. Its nominal independence was limited to control of its internal affairs, while its rulers constantly neglected to defend it against the Mussulmans; but great progress has been made since 1860.

All the ancient peoples who ruled Italy—the Siculi, Phœnicians, Greeks, Carthaginians, and Romans—have left monuments of their occupation. Those by the Greeks are stupendous, and include the vastest and most splendid existing remains of Greek temples. These are specially to be seen at Selinonte, Girgenti (*Agrigentum*), Segesta, Syracuse, and Himera. Even the reconstructed Roman theaters of Syracuse, Segesta, Taormina, and Palazzolo rest on Greek foundations. In Sicily are found very beautiful ancient pottery and unsurpassed medals. Some edifices date from the Byzantines and Saracens, but the most important memorials of the latter are the useful plants, such as sugar-cane and cotton, which they introduced.

Population.—Sicily is divided into the provinces of Caltanisetta, Catania, Girgenti, Messina, Palermo, Siracusa, and Trapani. Total population 1893 (official estimate), 3,404,665. Principal cities: Palermo, 276,000; Messina, 146,400; Catania, 121,000. See SICILY in the Appendix.

LITERATURE.—See Freeman, *History of Sicily* (4 vols., Oxford, 1891); also Freeman, *Story of Sicily* (New York, 1892); Amari, *Storia dei Musulmani di Sicilia* (3 vols., Florence, 1854–72); Lloyd, *History of Sicily to the Athenian War* (London, 1872); Chiesi, *La Sicilia illustrata nella Storia, nell' Arte, nei Paesi* (1892); Di Giovanni, *Filologia e Letteratura Siciliana* (2 vols., Palermo, 1871); Lo Faso, Duca di Serradifalco, *Antichità della Sicilia* (5 vols. folio); Evans, *The Classic and Connoisseur in Italy and Sicily* (3 vols., London, 1835); also the *Tours* of Brydone, Sir R. C. Hoare, and Simond. E. A. GROSVENOR.

Sic'kingen, FRANZ, von: champion of the Reformation; b. Mar. 2, 1481, in the castle of Ebernburg, near Kreuznach, in the present Rhenish Prussia; was one of the wealthiest and most powerful knights of his time, and was treated with much regard both by Charles V. and by the French king, Francis I. He spent all his time in feuds with his neighbors, and, having come into contact with the new religious ideas through his friend Ulrich von Hutten, he formed a plan of carrying through the Reformation by force. As the despoiling of the Roman Catholic Church of all its property and the distribution of its estates among the knights formed the principal points of his plan, he expected support from the nobility, and pamphlets were written and spread among the peasantry in order to arouse them, too, against their ecclesiastical lords; but the attempt entirely failed. One after another his castles were taken, and at last he was compelled to surrender himself, together with his last castle, Landstuhl, near Kaiserslautern. D. May 8, 1523.

Sickles, DANIEL EDGAR: soldier; b. in New York, Oct. 20, 1825; was educated at the University of New York, but left without graduating; learned the printer's trade, then studied law, and was admitted to the bar in 1846. He soon became identified with politics, and in 1847 was elected to the State Legislature as a Democrat. In 1853 he was appointed corporation attorney of New York city, and the same year accompanied Mr. Buchanan to England as secretary of legation. Returning in 1855, he was elected State Senator, and the following year was chosen member of Congress from New York city, and re-elected in 1858 and in 1860. On Feb. 27, 1859, he shot and killed Philip Barton

Key in Washington for improper intimacy with his wife, and was placed on trial for murder, but acquitted. On the outbreak of civil war he raised the Excelsior Brigade, and in June, 1861, was appointed colonel of one of its regiments, the Seventieth New York. In Sept., 1861, he was nominated a brigadier-general of volunteers. The appointment was at first negatived by the Senate, but subsequently confirmed to date from original appointment. In the Virginia Peninsular campaign his brigade was attached to Hooker's division of the Third Corps, to the command of which he succeeded in Sept., 1862, and having been commissioned major-general of volunteers Nov. 29, 1862, was assigned to the command of the Third Army-corps in Feb., 1863. He was distinguished at the battle of Chancellorsville May 3–4. At Gettysburg he lost a leg early in the second day's fight. In 1865–67 he commanded the military district comprising North and South Carolina. On July 28, 1866, he was appointed colonel of the Forty-second Infantry of the regular army, and in Apr., 1869, was retired from active service with the rank of major-general. In the latter year he was appointed U. S. minister to Spain, which position he resigned in 1873. Returning to New York he became president of the State board of civil service commissioners. He received the brevets of brigadier and major-general U. S. army for gallantry. In 1866 he was appointed minister to Holland and in 1869 minister to Mexico, but declined both positions. In 1890 he was appointed sheriff of New York by Gov. Hill, and in 1892 was elected to the Fifty-third Congress.

Sicyon, sis'ĕĕ-on (Gr. Σικυών): capital of the province of Sicyonia, in the Peloponnesus, which was bounded on the N. by the Corinthian Gulf, on the W. by Achaia and Arcadia, on the S. by Cleonæ and Phliasia, on the E. by Corinthia. Its site is occupied by the village of Vasilika. Sicyon was distinguished in earliest times as the original home of painting and bronze-casting. In history Sicyon played only a secondary *rôle*. Excavations have been made by the American School of Classical Studies at Athens. J. R. S. S.

Siddons, Sarah: actress; daughter of Roger Kemble; b. at Brecon, South Wales, July 5, 1755; played as a girl in her father's company; married Mr. Siddons, an actor, at the age of eighteen; made her first appearance at Drury Lane, with Garrick, as Portia in *The Merchant of Venice*, in 1775, but made no mark; retired in disappointment, but played in the provinces with success, and reappeared in London in 1782. This time she made a deep impression as Isabella in *The Fatal Marriage*, and began her career of extraordinary success. For thirty years, until her retirement June 29, 1812, she was the queen of the English stage. Her favorite and famous characters were Lady Macbeth, Queen Constance, Queen Catharine, Jane Shore, Isabella, Ophelia, Desdemona, Portia, and Imogen—impersonations of tragic pathos and majesty. To her contemporaries she was a prodigy of genius. Yet in the opinion of judges her ordinary recitation was imperfect. Her effects were produced by presence, mien, attitude, expression of voice and countenance, and by intense concentration of feeling, which lifted and dilated her form, transporting her audience as well as herself. The public readings she gave from Shakspeare after her withdrawal from the stage did not add to her fame. Her last appearance as an actress was in 1818, when she played for Charles Kemble's benefit. Thenceforth she lived in retirement, honored as a woman of stainless reputation, and respected in all the relations of life. D. in London, June 8, 1831. Her portrait was painted by Sir Joshua Reynolds, and is one of his best; her *Life* was written by Thomas Campbell (1834) and by Mrs. Kennard (London, 1886).

Sidell, William Henry: soldier; b. in New York, Aug. 21, 1810; graduated at the U. S. Military Academy, sixth in his class, July, 1833, when assigned to the First Artillery as brevet second lieutenant; resigned the following October, and adopted the profession of civil engineering. For a time he was a city surveyor of New York, an assistant engineer on the Croton aqueduct, and division engineer of railways in Massachusetts and New York; was assistant engineer in the hydrographic survey of the delta of the Mississippi river; in 1851–52 was assistant in the exploration and survey of a railway route across the Isthmus of Tehuantepec. The work of construction was abandoned till 1858, when he became chief engineer. On the outbreak of civil war he was commissioned major of the Fifteenth U. S. Infantry, but without joining his regiment was at once assigned to duty as mustering officer in the department of the Cumberland. In July, 1862, he was detailed as acting assistant adjutant-general of that department, continuing as such until transferred to Louisville, Mar., 1863, as acting assistant provost-marshal-general of Kentucky, resuming soon after the duties of general superintendent of recruiting and chief mustering officer of the State. In 1867 he joined his regiment, the Tenth Infantry (to the lieutenant-colonelcy of which he had been promoted in 1864), with which he served in Dakota Territory until 1869, when placed in charge of the dépôt of the general recruiting service at Fort Leavenworth, Kan. He retired from active service Dec. 15, 1870. D. in New York, July 1, 1873. For meritorious and faithful services in the war he was breveted colonel and brigadier-general U. S. army.

Sid'erite [from Gr. σίδηρος, iron]: the mineralogical name for spathic iron ore. See Iron.

Sidgwick, Henry, Litt. D., LL. D., D. C. L.: philosopher and economist; b. at Skipton, Yorkshire, England, May 31, 1838; educated at Rugby School and Trinity College, Cambridge; became fellow and lecturer at Trinity College 1859, reader in moral science in 1875, and Professor of Moral Philosophy in Cambridge University in 1883. He has published *Methods of Ethics* (1874; 4th ed. 1894); *Principles of Political Economy* (1883); *Outlines of the History of Ethics* (1886); *Elements of Politics* (1891); and many articles and special publications. J. M. B.

Sidmouth, Henry Addington, Viscount: statesman; b. at Reading, England, May 30, 1757; educated at Winchester School and at Brasenose College, Oxford; studied law; was admitted to the bar 1784; entered Parliament the same year through the influence of the younger Pitt, to whom he gave an efficient support during his administration; was Speaker of the House of Commons from 1789 until 1801, when, on the resignation of Pitt as Prime Minister, he formed a new ministry, accepting the posts of Chancellor of the Exchequer and First Lord of the Treasury; directed the negotiation of the Peace of Amiens 1802; supported a war policy 1803; resigned office 1804; was raised to the peerage and made president of the council Jan. 12, 1805; was Lord Privy Seal in the Grenville and Fox ministry 1806–07; was Home Secretary 1812–22, and a member of the cabinet without a portfolio 1822–24, when he became unpopular on account of his coercive measures, after which he retired from public life. D. at Richmond Park, Feb. 15, 1844.

Sidney: village; capital of Shelby co., O.; on the Miami river, the Miami and Erie Canal, and the Cin., Ham. and Dayton, and the Cleve., Cin., Chi. and St. L. railways; 31 miles S. of Lima, 40 miles N. of Dayton (for location, see map of Ohio, ref. 4–C). It is in an agricultural region, is principally engaged in manufacturing, and contains a public high school, public library (founded in 1886), 2 private banks, and a daily and 4 weekly newspapers. Pop. (1880) 3,823; (1890) 4,850; (1900) 5,688.

Sidney, or **Sydney**, Algernon: revolutionist; b. at Penshurst, Kent, England, in 1622, a son of the second Earl of Leicester; in 1632 accompanied his father, who was appointed ambassador to Denmark, and four years later to France. In 1641 he served as captain of a troop of horse in Ireland, of which his father had been made lord-lieutenant. When the great rebellion broke out, he took the side of the Parliament, and was made a captain of horse in the regiment of the Earl of Manchester. He was severely wounded at the battle of Marston Moor July 2, 1644; and in 1645 was made colonel of a regiment in Fairfax's army and governor of Chichester. In 1646 his brother, Lord Lisle, was appointed Lord-Lieutenant of Ireland, and he was made lieutenant-general of horse and governor of Dublin; in 1647 he received the thanks of the House for his services in Ireland, and was made governor of Dover. In 1648 he was one of the judges at the trial of Charles I., but was not present when sentence was passed, and did not sign the warrant for the execution, though he afterward characterized it as "the justest and bravest action that ever was done in England or anywhere else." Being opposed to the protectorate of Cromwell, he retired from Parliament in 1653, but when the Long Parliament was restored in 1659, he resumed his seat, and was named one of the council of state, and was sent as one of the

English commissioners to negotiate a peace between Sweden and Denmark. He was absent from England at the time of the Restoration, and, not acceding to this, he lived abroad in exile for nearly eighteen years. In 1677 he received a pardon from the king, with permission to return to his native country; twice unsuccessfully stood for a seat in Parliament, and was considered as being in league with Monmouth, Essex, William Lord Russell, and other popular leaders. The discovery of the Rye House plot in 1683 gave the court an opportunity of ridding itself of so dangerous an opponent. He and Russell were arrested and committed to the Tower on a charge of high treason. The only witness as to the main facts charged was Lord Howard, who by his own confession had been a party to the plot, and was ready to swear away the lives of his associates in order to save his own. The law required two witnesses to prove the alleged crime, and under the decision of the infamous Chief Justice Jeffreys the other witness was found in a manuscript on government which had been discovered among the papers of Sidney, in which it was maintained that a people had the right to depose an unworthy sovereign. The trial was opened Nov. 7, 1683; sentence was pronounced on the 26th; and on Dec. 7 he was beheaded on Tower Hill, London, and buried the next day at Penshurst. The reversal of the act of attainder was one of the earliest acts of the first Parliament of William and Mary. His *Discourses concerning Government* was published in 1698, and a 4th ed., with some miscellaneous writings, in 1772. *Lives* of Sidney have been written by Meadley (London, 1813), Van Santvoord (New York, 1851), and A. C. Ewald (London, 1873).

Sidney, or **Sydney**. Sir PHILIP: author and statesman; b. at Penshurst, Kent, England, Nov. 9, 1554; studied at Oxford and at Cambridge; traveled extensively, visiting Belgium, Germany, Hungary, and Italy, in all of which countries he was noted for his skill in knightly exercises as well as for his fondness for literature and art. He returned to England in 1575, and, aided by the influence of his uncle, the Earl of Leicester, rose to high favor at court. In 1576 he was sent on a mission to Vienna, but after his return he lost the queen's favor, probably in consequence of his bold remonstrance against the project of her marriage to the Duke of Anjou, and retired for a time to the seat of his brother-in-law, the Earl of Pembroke, where he devoted himself mainly to literary pursuits. Here he wrote, between 1579 and 1581, his pastoral romance *Arcadia*, which was never completed, and his *Defence of Poesie*, upon which his literary fame mainly rests. In the meantime the queen's favor for him revived, and he took a prominent part in all pageants of the court. He fell deeply in love with Lady Penelope Devereux, afterward Lady Rich and Lady Mountjoy, whom he celebrated under assumed names in his *Arcadia* and in the series of love sonnets entitled *Astrophel and Stella*, published soon after his death (1591). In 1583 he was knighted, and married the daughter of Sir Francis Walsingham. In 1585 he wished to join Sir Francis Drake in his second expedition against the Spaniards in the West Indies, but the queen forbade this, fearing, as she said, "lest she should lose the jewel of her dominions." It is said, probably without good grounds, that the crown of Poland was offered to him. The war was raging between Spain and the Netherlands, and Elizabeth made some show of assisting the Dutch. In 1585 Sidney was appointed governor of Flushing, and soon after was made general of horse under his uncle, the Earl of Leicester, in which capacity he gave promise of much military ability. On Sept. 22, 1586, he encountered a body of the Spaniards under the walls of the town of Zutphen. Sidney was severely wounded, and died at Arnheim, Oct. 7, 1586. The well-known story of his refusing the cup of wine, when fainting from loss of blood, in order to give it to a wounded soldier, has been questioned, but, whether true or false, well illustrates his chivalrous and generous character. His body was conveyed to England, where it lay in state for several days, and a general mourning, the first of the kind in English history, was observed. Sir Philip Sidney is perhaps the best English model of knightly virtues, and his character has always been a favorite theme with poets. His writings had great celebrity in their day, but they are marked by the strained and artificial style of the period. His *Arcadia* was first published soon after his death (1590) as *The Countess of Pembroke's Arcadia* (reprinted, London, 1868). His *Complete Works* appeared in London in 3 vols. in 1725; his *Miscellaneous Works*, with a memoir, were published at Oxford in 1826, reprinted at Boston in 1860; his *Complete Poems*, edited by Rev. A. B. Grosart, were published at London in 1873. See the *Life*, by J. A. Symonds (London, 1886; 2d ed. 1889). See ENGLISH LITERATURE.

Sidon, or **Zidon** [from Lat. *Si'don* = Gr. Σιδών, from Heb. *Tsīdhōn*, Sidon, liter., fishing-place]: an ancient city in Phœnicia, on the Mediterranean, in lat. 33° 34′ N. (see map of Palestine, ref. 3–E). Its origin, lost in antiquity, is due, according to Josephus, to Sidon, the oldest son of Canaan, and it is referred to even in the book of Genesis. Celebrated for its manufactures and commerce, its name was applied to the whole country and nation. Homer calls the Sidonians "skillful in all things." Sidon had trade-stations in Sicily, Sardinia, Spain, and Northern Africa; its fleets visited the British islands and the Baltic; and its purple, glass, linen, gold, silver, and ivory wares were famous a thousand years. Its most brilliant period began about 1600 B. C., but it was ultimately eclipsed by Tyre. Captured by Shalmaneser, King of Assyria, about 720 B. C., it was almost utterly destroyed during its revolt against the Persian Artaxerxes (351 B. C.). Rebuilt, it never regained its former splendor. Under the Greek, Syrian, and Roman dominion, it further declined. Alternately held during the crusades by the Christians and Mussulmans, it was razed by Malek Ashraf in 1291. In the vicinity were discovered (1887) sarcophagi of unsurpassed workmanship (now the chief treasure of the Museum of Constantinople), one of which is perhaps that of Alexander the Great.

Siebold, zee'bōlt, PHILIPP FRANZ, Freiherr von: traveler, physician, zoölogist, and botanist; b. at Würzburg, Bavaria, Feb. 17, 1796; studied medicine and natural sciences; entered the service of the Dutch East India Company, and was appointed leader of a scientific mission which arrived at Nagasaki in 1823. He soon acquired an extraordinary influence over the Japanese, whose language he mastered, and in 1826, when he accompanied the Dutch embassy to Yedo, he was allowed to remain behind, the only foreigner in the hermit city. The sale of a map, however (see IXO), brought him into difficulties, and after a term of imprisonment he was finally banished from the country in 1830. On his arrival in Holland he was created a baron, and spent the next twenty-nine years of his life in writing and in arranging his scientific collections at Leyden, Munich, and Würzburg. European gardeners owe to him the introduction of Japanese lilies, peonies, camellias, chrysanthemums, and other attractive plants. At the close of his life he returned to Japan. His great work is a folio, magnificently illustrated, *Nippon, Archiv zur Beschreibung von Japan*. D. at Munich, Oct. 18, 1866. J. M. DIXON.

Siedlce, si-ed'l'tsă: town of Russia; the capital of the government of Siedlce (see map of Russia, ref. 8–A). It has a fine palace surrounded with beautiful gardens, distilleries, sugar-refineries, and manufactories of agricultural implements. Pop. (1890) 14,015, two-thirds Jews. The government of Siedlce, comprising an area of 5,535 sq. miles, with 774,139 inhabitants in 1897, is situated to the W. of the river Bug, between the governments of Lomza, Warsaw, Radom, Lublin, Volhynia, and Grodno, and occupies nearly the same territory as the old palatinate of Podlachia.

Siege [from O. Fr. *siege*, Fr. *siège*, deriv. of *segier*, besiege: Span. *sitiar*: Provenç. *setjar* < Lat. **sedica're*, deriv. of *sede're*, sit]: the investing of a fortified place by an enemy for the purpose of compelling its surrender by continued offensive operations. Modern fortresses are of two general types—single fortresses, consisting of an enceinte and its outworks (see FORTIFICATION), and intrenched camps, consisting of the former combined with detached works. (See INTRENCHED CAMPS.) The latter may be defended simply by its garrison or by a large army in addition to the garrison. The methods of attack will vary with these different circumstances, and may be classified as (1) siege of a single fortress; (2) siege of an intrenched camp defended by its garrison simply; and (3) siege of an intrenched camp occupied by an army.

I. The method perfected by Vauban in the latter half of the seventeenth century applied to the first case, and under ordinary circumstances with the proper force—five or six

times the garrison—was almost certain of success. This method has been employed without essential change for 200 years, and it is only within a very brief period that military engineers have found it necessary to introduce some modifications in order to adapt it to modern instruments of war. It consists, in brief, in taking up a strong intrenched position in front of the work, beyond the range of its artillery, and clearing a path thence to the interior. To do the latter it is necessary to subdue the fire of the work, to batter down a portion of the scarp, and to excavate a path by which troops can advance under cover. The occupation of the ground is called the investment. The intrenchments on the side of the work are called lines of countervallation. Sometimes defenses are thrown up to guard against attack from the exterior; these are called lines of circumvallation. The covered roads constructed toward the work are called approaches, zigzags, or boyaux. To prevent their being enfiladed they are run in a zigzag direction, each branch being so placed that its prolongation shall fall outside the salients of the collateral works. Whenever it is practicable several zigzags are pushed forward simultaneously from different points and converge toward the point of attack. During the earlier portions of the siege these approaches are constructed by digging a trench and throwing the earth up on the side toward the enemy, thus forming a simple trench. When within easy range of artillery, cover is more quickly obtained by placing a row of gabions and filling them with earth. This is called a flying sap. During the latter portions the excavation is pushed forward by sappers, foot by foot, under the cover of a rolling shield called a sap-roller. It is revetted with gabions and is called a full sap. As the heads of these approaches offer an easy prey to sorties, they are united from distance to distance by lines of trench running nearly parallel to the front of attack. These are called parallels. They are arranged for infantry defense something like rifle-trenches (see FORTIFICATION), but their bottoms are made wider to afford means for the free circulation of troops. Each parallel should be nearer to the preceding one than it is to the work attacked, and must be within easy supporting distance from it. The number of parallels therefore depends upon the distance of the first one from the work, and that depends upon the range of the artillery. In Vauban's time there were usually three; at Sebastopol in 1854–55 there were seven. When the approaches have advanced within easy artillery range—about the second parallel—batteries are constructed to silence the artillery of the works. When practicable, they are placed on the prolongation of the faces of the work. The artillery fire having been subdued, the approaches are pushed forward toward the crest of the glacis. In the old method, when within a short distance from it, mounds of earth, called trench-cavaliers, were thrown up to command the covertway, and served to drive out the defenders. Their construction is now considered impracticable. The occupation of the crest of the covertway is called the crowning of the glacis. Here, in the old method, breaching batteries were constructed to batter down the scarp and a gallery was excavated to lead into the ditch, the advance through the ditch and breach being continued with the full sap or by assault. In these operations the miner goes hand in hand with the sapper. He searches out and destroys the countermines, creates large craters in which the sapper can make lodgments, and is frequently employed to make the breach.

The driving of a full sap, and the establishment of these breaching batteries, in the later stages of the siege, always difficult, may be said to have become of late years impracticable, assuming always that the defense is vigorous. At Sebastopol the fortifications were not strong, their profile being that of field-works. At the siege of this place, which lasted eleven months, during which the French executed 42 miles and the British 8 miles of trenches, the approaches never reached the ditch. At the final assault the ramparts were intact, and the troops had to advance without cover, at some points more than 200 yards. The assault failed at six points out of seven, and it was the opinion of Gen. Niel, commandant of the French engineers, that the place would have been impregnable if it had been provided with good revetted scarps. This opinion, however, assumes that the scarps remained unbreached, and it is qualified by the statement that the place possessed an armament such as is only found in a great maritime arsenal, and a garrison perpetually replenished by communication kept open with the interior of Russia. Since that date further great improvements have been made in the caliber, range, and accuracy of artillery fire, as well as in small-arms. It has become possible to effect the breach by indirect fire from a distance, while the difficulties of the assault have been proportionately increased. The introduction of machine-guns and of the breech-loading musket, by means of which a thin line of troops can keep up a steady sheet of fire, has rendered impracticable the open assault of even slight intrenchments if resolutely defended. It has fair chance of success, however, when made from a point close up to the works, and against a garrison worn out with the labors and anxieties of a long siege, or when following closely after the explosion of a mine.

The prompt capture of many of the single fortresses of France during the Franco-German war of 1870–71 has but little bearing on the subject, as many of them were of an ancient pattern, none was in a complete state of preparation, the artillery was inferior to that of the enemy, and the defense was often lukewarm or unintelligent, or both. The method of the Germans was to observe the places by detachments until operations in the field afforded leisure for a serious attack against them, and then to plant powerful batteries at distances varying from 1 to 2 miles, and bombard them until they capitulated. The bombardment of Schlettstadt lasted 5 days; of Neu-Brisach and Fort Mortier, 5 days; of Thionville, which had been blockaded three months, 2 days; of Montmédy, after four weeks' investment, 2 days; of Longwy, which had been invested seven weeks, 9 days; of Mezières, after being observed by detachments three months, and regularly invested ten days, 1½ days; of Rocroi, 7 hours with field artillery; of Toul, after being observed four weeks by a brigade and closely invested by a division eleven days, 8 hours; of Soissons, 4 days; of La Fère, after ten days' investment, 30 hours; of Péronne, after six days' investment, two of them employed in bombardment with field-guns, 7 days, etc. These facts do not militate against the value of these fortifications in themselves. Even defended as they were, they caused great annoyance and delay to the invaders, and they enabled the hastily organized armies of France to make a defense of which otherwise they would not have been capable. Phalsburg required a blockade of over four months for its reduction, and Bitche held out to the end of the war. Verdun resisted a *coup de main* Aug. 24, was observed by detachments until Sept. 23, when it was closely invested, resisted a bombardment of 54 hours from captured French guns Oct. 14–16, but surrendered Nov. 8 without standing a regular siege, after preparations had been made for carrying it on with German artillery. Strassburg, with a garrison of 17,000 men, resisted for 51 days a besieging army of about 60,000. The attack was by regular approaches, the outworks being breached by distant fire and by mining, and the main rampart by the fire of batteries in the second parallel. These batteries, called demolition batteries, were about 800 yards from the place, and effected their purpose by indirect firing, the masonry not being visible. The crowning of the glacis was successfully accomplished, followed by the descent into the ditch. The ditches, being filled with water, were crossed by dams, or, where the water was deep, by floating bridges of barrels floored over with planks. Everything having been prepared for the assault, the garrison capitulated without waiting to receive it.

In a vigorous defense of a single fortress the enemy will be kept at a distance as long as possible by the occupation of favorable points on the exterior. His approaches and other works will be harassed or destroyed by a concentrated artillery fire, with occasional sorties in large bodies. Counter-approaches will be run out to obtain favorable positions for enfilading his lines, and sharpshooters will be posted in rifle-pits well to the front to pick off his gunners. Countermines will be prepared, and sprung at the proper time. Damage to the works suffered during the day will be repaired at night. *Débris* will be removed from the foot of the breach, and when the latter has become practicable it will be obstructed by crows'-feet, chevaux-de-frise, or other obstacles, and intrenchments will be thrown up to command it. If the garrison has not been overworked the assault should be repulsed.

II. The siege of an intrenched camp, defended simply by its garrison, may take the form on an enlarged scale of the operations described above, or of a blockade. In the former case one or two of the detached works are selected for attack, and proceeded against until their capture, the difficulties being greatly magnified by the position of the artillery of the place. The siege of Belfort (Nov., 1870, to

Feb., 1871) is an illustration. The works planned for the defense of this place were not all completed at the breaking out of the war, and some of the points selected for the detached works were occupied by field-fortifications of the semi-permanent type. These were selected by the Germans as the point of attack. The investment was completed Nov. 3, the garrison consisting of 16,000 and the attacking force of 30,000 men, increased about the middle of January to 80,000. A bombardment was opened Dec. 3, and continued night and day until Feb. 13, during which time more than 500,000 projectiles were thrown into the place. In five days nearly every house in the city had been struck. The defense, under Col. Denfert-Rochereau, was gallant and skillful. For many weeks he kept the enemy at a distance by first occupying exterior positions, and then freely using his projectiles at long range. This kept the line of investment so attenuated that the attacking force was inadequate. Moreover, the latter was compelled to throw up lines of circumvallation against the threatening force under Gen. Bourbaki, and to use part of its artillery in defending them. The detached field-works were finally evacuated Feb. 3–8, the approaches having reached the ditch. Thus, after 98 days' investment and 68 of bombardment, the attack found itself just where it would have been on the first day of the siege had it not been for these field-works. Further operations were to be pushed against the main works, but the garrison was ordered out of the place by the French Government, and turned it over to the Germans Feb. 17 and 18, Paris having capitulated Jan. 28. That a well-managed assault may sometimes be successful against an intrenched camp was proved by the capture of Kars by the Russians on the night of Nov. 17–18, 1877. The defenses consisted of twelve detached permanent forts and a citadel, all built since the Crimean war. Some of the forts were connected by lines of trenches thrown up during the war of 1877. They were manned by a full garrison of about 23,000 Turks armed with the best modern breech-loaders. The attacking force was about 35,000 men. The Turks are considered the equals of any troops in the world when fighting in a fixed position, as behind fortifications, yet this assault resulted in the killing or capture of the entire garrison, with the exception of thirty or forty men. The most prominent features of its management were that no intimation had been given to the enemy that it was contemplated, the points of attack were skillfully selected, the various columns attacked simultaneously, and a moonlit night was selected for it, when the light was sufficient to prevent confusion among the columns, though not sufficient to expose them at a distance to the view of the enemy.

III. When the intrenched camp is occupied by an army, the difficulties of forcing an entrance are greatly magnified; and if the army is not very much inferior to the attacking force, they will probably be insuperable. The method of blockade may then be resorted to, with a view to exhausting the supplies of the besieged of ammunition and provisions. Here the attack and defense consist at first of a struggle for the possession of the communications with the place. These being once all secured by the attack, their further operations consist mainly in harassing the garrison by a distant bombardment while vigilantly guarding against the introduction of supplies or re-enforcements. The defense consists in keeping up a fire upon the enemy, with occasional sorties in large bodies, the object of which is to make a permanent break in the cordon, with a view to its destruction or to cover the introduction of re-enforcements. The sieges of Atlanta and Richmond during the civil war in the U. S., and of Metz and Paris in the Franco-German war, are illustrations. In the cases of Atlanta and Richmond the operations were confined to the preliminary struggles for the communications. Having lost these, the defenders withdrew at their last opportunity, preferring the immediate loss of the place to the sacrifice of both place and troops a few weeks later. At Metz, although the army of Bazaine was driven into the fortress and kept there against its will, and weakened the fortress for resistance to blockade, nevertheless it offered an immense obstacle to a forced entrance. The general method of occupying the ground by the Germans was about the same both around Metz and Paris. A first line of outposts was established from half a mile to a mile from the works. These were intrenched, and were strong enough to resist small parties of the enemy, but not a heavy force. Behind these was a carefully selected position, forming the main line. Its distance from the works depended upon the nature of the ground, and varied from 1 to 3 miles, the normal distance being 2¼ miles, or a little more than the effective range of the guns of the enemy. It was fortified by rifle-trenches and gun-emplacements of the strongest profile, strengthened by abattis or other obstacles, with occasionally an inclosed work capable of offering independent resistance. Farther to the rear central points were selected and fortified, at which the reserves were posted, and upon which the troops were to rally in case of the enemy's success in breaking through the cordon. The length of the line of investment of Metz was 24 miles, and of that at Paris 45 miles. In each case the besieging force was about 200,000 men. The holding of such lines by such numbers would have been utterly impracticable previously to the modern improvements in small-arms and the introduction of the free use of continuous lines of intrenchments. As it is, when the investment is once closed the besieging army has a great advantage over the defenders, since it can accomplish its purpose without leaving its works. The *rôles* are reversed, and the besieged are compelled to throw themselves against the intrenchments, where they are sure to meet with destruction. The army in Metz was 173,000 strong and that in Paris 500,000, many of the latter, however, worthless as soldiers. The former capitulated after 70 days' blockade, and the latter after 129 days'. The operations about these cities, especially Metz, give rise to the curious but essential question, Can one army invest and besiege another of equal magnitude? The object of the sorties from Metz was to break through the cordon and get away with the active army, leaving the place to be held by its garrison. The fortifications aided such attempts; and if they had been mere field-intrenchments which were being evacuated, the beleaguered army would have had still less chance of success. The answer, then, seems to be, Let an army somewhat demoralized by defeat simply lie dormant for a while, and it may be invested by equal numbers and taken by siege. The so-called siege of Plevna, July to Dec., 1877, was one of the most prominent features of the Russo-Turkish war of 1877–78. Upon its occupation by the Turkish army, about the middle of July, Plevna was without defenses. The construction of field-fortifications was continued, almost under the fire of the enemy, during the five months which followed, until there was an intrenched camp, having 47 detached works, supplemented by numerous lines of trenches, and occupying a perimeter of about 22 miles. The Russians attacked the place on July 20 with a small force—about 7,000 men—and were repulsed with a loss of more than one-third their number. They assaulted again on July 30 with 30,000 men, and were repulsed with a loss of over 7,000. They again assaulted Sept. 11, with 90,000 men, after a four days' bombardment, and were repulsed with a loss of 18,500 men. They then concluded to resort to a blockade. The investment of the place was completed Oct. 24, after a hot contest for the last communications, the Turks committing the error of allowing themselves to be shut in, instead of abandoning the place before it was too late. The line occupied by the Russians was 46 miles long, the force employed being about 110,000 men. The Turks at this time had about 40,000. Subsequent operations were limited to strengthening the defenses on both sides, with the exception of the partial assaults of Oct. 19 and Nov. 8, the object of which was to gain certain points by which the line of investment could be shortened. By Dec. 10 the Turkish commander, Osman Pasha, having consumed all of his provisions, found himself compelled to surrender or to leave his works and throw himself against the fortifications which surrounded him, in a desperate attempt to cut his way out. He chose the latter alternative, lost in the attempt 6,000 men, killed and wounded, while inflicting a loss of but 1,800 upon the enemy, and then surrendered.

The blockade may be applied to a single fortress, but its chances of success will then be less favorable, for the reason that the number of mouths in the place being comparatively small, the stock of provisions may be such as to enable it to hold out longer than the requirements of the besieger will permit.

IV. For a long period in the early history of war, when the arms employed were slings and arrows, the high and thick walls of fortresses offered insuperable obstacles to a forced entrance. Sieges then were simple blockades. At a later date mining was resorted to; ramps of earth and wood were thrown up, beginning beyond the range of an arrow, and sloping upward to the top of the wall; or the battering-ram was employed to effect a breach. The method of carrying on the operation among the Greeks and Romans

was as follows: The place was surrounded by a strong continuous intrenched line. In front of the point of attack a covered gallery was established parallel to the work, composed of vines. A vine was a sort of hut on wheels, about 8 feet wide, 20 feet long, and 7 feet high, with a double-sloped roof strong enough to resist anything the besieged could throw upon it, and covered with raw hides or clay to protect it from fire. It was closed in front with wickerwork (from which its name) provided with loopholes. From this parallel gallery several similar galleries were run forward, the head of each being occupied by a special vine, having an overhanging roof projecting about 10 feet to the front, under cover of which workmen leveled the ground or built up the ramp. Through these galleries the material was carried forward to fill up the ditch. When the wall was reached, the battering-ram was brought up, covered by a long hut of a construction similar to that of the vines. In great sieges these attacks were supported by square wooden towers, which were either moved up to the walls on wheels or put together on the spot; in their lower stories they contained rams; in the middle, drawbridges, which could be lowered upon the walls; and in the upper stories, parapets of hides, wickerwork, or cordage to protect slingers and archers. They were sometimes as much as 150 feet high, and had from ten to twenty stories. Towers of these dimensions, however, could not be moved. The besieged endeavored to retain a commanding position. When the ramp rose, they raised the wall opposite to it; and when the towers were constructed, they increased the height of those on the ramparts. They opposed the enemy's works by mining and inundations and by fire.

The invention of gunpowder rendered the wooden approaches and the towers useless, and the vines were at once replaced by trenches. The change in the character of fortifications (see FORTIFICATION) rendered the defense a more active one. The garrison could sally and easily envelop the head of the approach. If an outwork were taken, it was difficult to hold it, for the reason that the supports were at a distance. (At the siege of Candia an outwork was taken and retaken thirty-six times.) During the youth of Vauban the approaches were generally pushed forward to the glacis when the covered way was assaulted. A covered descent was then made into the ditch, and a breach was made by the miner. This also was assaulted. After the capture of the outworks the main work was breached and assaulted, and then the interior retrenchments. These operations were bloody and precarious. Vauban rendered them sure and comparatively safe. He secured his approaches from being enveloped by the introduction of parallels, and, avoiding assaults, accomplished his purpose by well-directed manual labor, establishing the method sketched at the beginning of this paper.

The principal sieges during the civil war in the U. S. were the following: At Yorktown, Va. (Apr. and May, 1862), a parallel was constructed about a mile from the works, and heavy batteries were established, but the enemy evacuated before the latter opened fire. This siege is interesting from the fact that it was the first struggle of earthwork against earthwork in that war. At Vicksburg the investment was closed May 19, 1863, and an assault was made and repulsed in the afternoon of the same day. A vigorous assault on the 22d having failed, it was determined to make gradual approaches. There were no engineer troops in the command, and only four regular engineer officers. Every graduate of the Military Academy below the grade of general was detailed for engineer service; practical miners were selected from the different regiments for mining; and the sapping, fabrication of gabions, fascines, etc., were executed by some pioneer companies and by details from the line. The artillery was simply the field-artillery of the army and a heavy battery borrowed from the navy. There being no light mortars, wooden mortars were made by shrinking iron bands upon cylinders of tough wood and boring them out for 6 or 12 lb. shells. The broken nature of the ground gave ample protection to the attack up to within 600 yards, and often to within 400 yards of the works. By June 30 there were 220 guns in position. A line of circumvallation was thrown up to oppose the efforts of Gen. Johnston to relieve the place. On June 25 a heavy mine was sprung under one of the salients. The crater was assaulted and occupied, but the besieged, having been warned, had prepared an inner line, to which they retired. Another mine was at once begun, which was sprung July 1, blowing up an entire redan, with its defenders; but the interior line was not destroyed, and no assault was made. The besieged attempted to obstruct the advance by countermines, but obtained only slight success. Occasional sorties were also made, and at one point 90 yards of trench were run out as a counter-approach. By July the approaches had in many places reached the ditch. Orders were given to prepare the heads of approaches for the easy debouch of troops, to widen the main approaches so that men could easily move by fours, and to prepare planks and sandbags for crossing the ditches. On July 4 the place capitulated, with over 30,000 men. In the operations against Richmond in 1864 it was found necessary to occupy Petersburg. Desperate assaults were made June 15, 16, 17, and 18, but only an outer line of intrenchments could be taken. A mining-gallery was begun June 25, and a regular siege was determined upon July 9, and work begun July 11. Gradual approaches were attempted, but the difficulties of pushing them against a long line of strong works, which could not be enveloped and were defended by forces nearly equal to the attack, were found to be so great as to offer small chance of success. The mine was sprung July 30, the main gallery being 510 feet long, and its two branches 37 and 38 feet respectively, and the charge 8,000 lb. of powder. It was followed by a badly managed assault, which failed. Gradual approaches were abandoned, and steps were taken to prepare the lines of investment to be held by a small force, with a view to moving the main body upon the communications which were still held by the enemy. The latter operations gradually extended the lines until in October their length was 32 miles, comprising thirty-six forts and fifty batteries. The system consisted of inclosed fieldworks placed in commanding positions at intervals of about 600 yards, connected by strong rifle-trenches, well protected by obstacles in front. Many of the inclosed works were provided with bombproofs in addition to the magazines, etc. In some parts small redoubts were placed 300 or 400 yards in advance of the main line, to insure time for manning the latter in case of assault, the ordinary pickets not being deemed sufficient. The line extended from the Appomattox southerly and westerly, embracing two sides of Petersburg, and thence back as a line of circumvallation to the James river, thus inclosing the Army of the Potomac in a loop. The movements of the forces operating upon the communications finally rendered an assault practicable by drawing a large part of the defenders away from their works. It was given Apr. 2, 1865, and a large part of the works were captured, the defenders evacuating the city during the night which followed. The fall of Petersburg necessitated the evacuation of Richmond. In the pursuit which followed, the whole Confederate army of Northern Virginia was captured. Mention may be made of the sieges of FORT PULASKI (*q. v.*); Corinth, Miss., May, 1862; Port Hudson, La., May, 1863; Forts Gaines and Morgan, Mobile, Ala., Aug., 1864; and Fort Blakely and Spanish Fort, Mobile, Ala., Apr., 1865. See BOMBARDMENT. O. H. ERNST.

Siegfried: See NIBELUNGENLIED.

Siemens, ERNST WERNER, von: electrician; b. at Lenthe, near Hanover, Dec. 13, 1816; was educated in the gymnasium of Lubeck and in the school of artillery and engineering at Berlin; entered the Prussian army as an officer of artillery in 1838; studied chemistry and electro-magnetism; took out a patent for electro-plating and gilding in 1841, and laid in 1848 the first submarine mines exploded by electricity; left the army in 1849, and founded, in connection with Halske, a telegraph-building establishment in Berlin, which built the telegraph lines of Russia, Spain, Brazil, Northern Germany, etc. Among the many inventions and improvements which are due to him, and of which he gave an account in *Proceedings* of the Berlin Academy, *Poggendorfs Annalen*, etc., are the methods of determining the position of injuries in subterranean and submarine lines, of examining insulated wires, of charging subterranean and submarine conductors in order to lessen the disturbing influences of induced currents in the cables. D. in Berlin, Dec. 6, 1892.—His brother, Sir WILLIAM (Karl Wilhelm) SIEMENS, physicist, b. at Lenthe, Apr. 4, 1823, was educated at Göttingen; settled in 1843 in London as a civil engineer, and founded there in 1853 a branch of the Berlin house, with immense telegraph-building establishments at Woolwich and extensive steel-works at Landore in Wales. He invented the regenerative furnace (see FURNACE), in which he utilized the heat which would otherwise escape, the bathometer, an instrument for measuring ocean-depths,

a pyrometer, etc.; and published *On a Regenerative Condenser* (1850); *On the Conversion of Heat into Mechanical Effects* (1853); *On a Regenerative Steam-engine* (1856); and *On the Increase of Electrical Resistance in Conductors, with Rise of Temperature, and its Application to the Measure of Ordinary and Furnace Temperatures* (1871). He was knighted Apr., 1883, and died Nov. 20 the same year. See his *Life* by W. Pole (London, 1889).

Siemens's Armature: See ELECTRIC MOTOR.

Siemens's Regulator: See ELECTRIC LIGHTING.

Sienkiewicz, syen-kye'vich, HENRYK: Polish novelist; b. in the government of Siedlee, Polish Russia, in 1846. He was educated in Warsaw, which has long been his home, and he has traveled much. Many of his works have been translated into English (by Jeremiah Curtin) and other languages. Among them are: *With Fire and Sword* (1884); *The Deluge*; *Pan Michael*; *Without Dogma* (1890); *Children of the Soil* (1894): and *Quo Vadis* (1895), a story of Roman and Christian life at the time of Nero.

Sien'na [It. *terra di Siena*, earth of Sienna]: an ocherous earth which when ground forms an excellent pigment called raw sienna, and when burnt assumes a still richer orange-red tint. It is brought from Italy.

Sienna (Ital. *Siena*, anc. *Sena Julia*): city of Tuscany, Italy; chief town of the province of Sienna; covering a beautiful hill 1,100 feet above the sea, a spur of the Chianti chain; in lat. 43° 22′ N., lon. 11° 11′ E.; 60 miles by rail S. of Florence (see map of Italy, ref. 4–D). The walls are about 4 miles in circumference; the citadel occupies the northwest corner of the town, which is entered by nine gates; and the principal streets radiate in irregular lines from the Piazza Vittorio Emanuele, a fine large open space nearly in the heart of the city. The Duomo, or Chiesa Metropolitana, one of the finest specimens of Gothic architecture in Italy, stands on an elevation not far from the center of the town. Its length is about 300 feet, its mean width 120 feet. The western façade is magnificent in color and in the richness of its sculptures. The effect of the interior is peculiarly picturesque, partly from the horizontal layers of black and white marble of which not only the walls but even the columns are composed, and partly from the roofing, which is a vault of blue studded with stars. The pavement is of marble inlaid in various styles, the work of different artists from the fourteenth to the sixteenth century, the most distinguished of these being Beccafumi (1517). The marble pulpit is adorned with some of the finest reliefs of Nicola Pisano and his school. The bronze tabernacle, the pictures by Duccio (1300), several early works of Michelangelo, the celebrated frescoes of Pinturicchio (1502) representing scenes from the life of Pius II., the fonts, the vases for holy water, the large collection of old choir-books exquisitely adorned with miniatures, are among the countless other objects of the highest interest to the student of art. In the Church of S. Agostino and in several others, in the ex-convent of S. Domenico, and in many private palaces are choice pictures by early painters, above all by Sodoma. The Academy of Fine Arts is very rich, especially in pictures of the Siennese school. The university, founded in 1321, was formerly very celebrated. There are cloth and furniture factories, but the industries are small.

As early as the reign of Charlemagne Sienna was governed by a count. In the disputes between the papacy and the German emperors it at first took the side of the former, and like its neighbors, Florence and Pisa, developed into an independent commonwealth. In 1186 Sienna joined the other large Tuscan commonwealths in their resistance to Henry, son of Frederic Barbarossa, but after some successes was reconciled to the emperor, and thenceforward it continued, for the most part, steadfastly Ghibelline. In 1260 the Siennese inflicted a crushing defeat on the Florentines at Montaperto, but hostilities were frequently renewed afterward. An awful plague, known as the black death, broke out in 1348, and continued to appear until toward the close of the century. During the first year of this frightful malady 80,000 persons are said to have perished in the city and territory of Sienna. In 1480 the government of the commonwealth fell into the hands of Pandolfo Petrucci, who continued to direct public affairs successfully until 1512. After his death the Medici, with Spanish help, annexed Sienna to the territory of Florence. From this time its history is almost one with that of the rest of Tuscany. Pop. (1893) 29,000.

Revised by M. W. HARRINGTON.

Sierra: See MOUNTAIN.

Sierra Leone, si-ăr'raă-lēĕ-ō'nēĕ: a British colony on the northern end of the Guinea coast, Africa, from 7° to 9° N. lat., including about 150 miles of coast and extending 100 miles inland. Area about 15,000 sq. miles. The soil is fertile, especially in the low coast-land, but the climate is extremely hot and unhealthful, especially in the wet season. The rainfall at Freetown is about 110 inches, of which two-thirds fall in July, August, and September. All tropical plants and fruits grow luxuriantly, and palm oil, pepper, ginger, gum-copal, ground-nuts, etc., are exported. Sugar, coffee, indigo, and cotton have been introduced, and succeed well. The settlement was made in 1787 with a philanthropic purpose, the idea being to form a home, or at least a place of refuge, for free Negroes, and in spite of its climate, which is very unhealthful for Europeans, the colony is steadily growing. The chief products and exports are palm oil, palm-kernels, benni-seeds, ground-nuts, kola-nuts, India-rubber, coal, and hides. The capital and chief port of the coast is Freetown, which is fortified and is a naval coaling-station. Pop. (1893) 180,000, with 224 whites. Administration is actually effective over only about 75,000 of the population. See SIERRA LEONE in the Appendix.

Sierra Madre, -măă-drā', or **Sierra Madre del Pacífico**: the irregular chain of mountains which borders and frames the western side of the Mexican plateau. (See MEXICO.) It may be regarded as a continuation of the mountains on the western border of the Great Salt Lake basin, and the name Sierra Madre is applied to it also in Southern Arizona. Entering Mexico near lon. 109° W. it separates Chihuahua from Sonora, occupies the western part of Durango, and is continued through Jalisco. On the eastern or plateau side the declivity is gentle, but the Pacific side is marked by steep slopes, numerous precipices, and magnificent scenery. Few of the peaks exceed 10,000 feet. The chain is much broken, and often there are several parallel ranges. In Jalisco, especially, the mountains are cut by deep cañons where rivers break through them. The higher slopes are covered with pine-forests. The Sierra Madre del Sur, in Southern Mexico (Guerrero, Oajaca), is an E. and W. range, parallel to and near the Pacific, and rising in parts to 10,000 feet; apparently it has no structural connection with the Sierra Madre del Pacífico. The mountains forming the eastern border of the plateau are sometimes called, collectively, the Sierra Madre del Oriente or Eastern Sierra Madre.

HERBERT H. SMITH.

Sierra Morena, -mō-rā'năă: a mountain range of Spain, separating the basin of the Guadiana from that of the Guadalquivir, and extending between lon. 3° and 4° W. Its aspect is generally rugged and somber; its highest peak is Aracena, about 5,500 feet high.

Sierra Neva'da [Span., snowy mountains; *sierra*, saw, mountain range < Lat. *serra* + *neva'do*, snowy, deriv. of *nieve*, snow < Lat. *nix*, *nivis*]: a mountain range of Southern Spain, 75 miles long and 25 broad, between the Guadalquivir and the Mediterranean. Its highest peaks are Mulahacen, 11,658 feet, and Veleta, 11,387 feet, and it has received its name from its being covered on many of its peaks with perpetual snow and ice. Its southern slopes are clad with chestnut forests, olive and orange groves, and vineyards.

Sierra Nevada: a mountain range of Eastern California, separating the great valley of California from the interior basin of Nevada. The general trend is N. N. W. The range is continued at the N. by the Cascade Mountains, and at the S. turns S. W., uniting with the Coast Ranges. It is essentially a broad plateau inclined toward the W., except at the extreme N., where it divides into several ridges. The crest-line and highest peaks are along the eastern margin, and the eastern slope is steep. The long western slope is broken by deep cañons. Among its highest peaks are Dana (12,992), Lyell (13,042), Brewer (13,886), Tyndall (14,386), and Whitney (14,898), the loftiest point of the U. S. south of Alaska. The principal passes are Tehachapi (3,830), crossed by the Southern Pacific Railroad, Walker (5,320), Truckee (7,200), crossed by the Central Pacific Railroad, and Beckworth (5,190). The snowfall on the western slope is heavy, and the rivers nourished by its melting irrigate the Californian valley. The eastern slope is characterized by the arid climate of the interior basin. Among the higher peaks are a few small glaciers.

Sierra Nevada de Santa Marta: See SANTA MARTA.

Siete Corrientes: See CORRIENTES.

Sievers, EDUARD: philologist; b. at Lippoldsberg, Prussia, Nov. 25, 1850; studied at the Universities of Leipzig and Berlin; Professor of Germanic Philology at Jena 1871–83 (ordinarius since 1876), at Tübingen 1883–87, at Halle 1887–92, and since 1892 at Leipzig; distinguished by quickness of scholarly insight and soundness of judgment; author of *Tatian, lateinisch und altdeutsch, mit Glossar herausgegeben* (1872; 2d ed. 1893); *Das Hildebrandslied, die Merseburger Zaubersprüche und das fränkische Taufgelöbniss* (1872); *Die Murbacher Hymnen* (1874); *Paradigmen zur deutschen Grammatik* (1874); *Der Heliand und die angelsächsische Genesis* (1875); *Grundzüge der Lautphysiologie* (1876; 2d ed. as *Grundzüge der Phonetik* (1881; 3d ed. 1885; 4th ed. 1893); *Zur Accent- und Lautlehre der german. Sprachen* (1878); *Heliand* (1878); *Angelsächsische Grammatik* (1881; 2d ed. 1886, Eng. transl.); *Proben einer metrischen Herstellung des Eddaliedes* (1885); *Tübinger Bruchstücke der älteren Frostuthingslög* (1886); *Oxforder Benedictinerregel* (1887); *Althochdeutsche Glossen* (with E. Steinmeyer, 1879–82); *Altgermanische Metrik* (1892). He has been joint editor since 1891 of *Beiträge zur Geschichte der deutschen Sprache und Literatur*. BENJ. IDE WHEELER.

Sieyès, sĕĕ-es', EMMANUEL JOSEPH (commonly known as the ABBÉ SIEYÈS): publicist and statesman; b. at Fréjus, department of Var, France, May 3, 1748; was educated for the Church at the seminary of St. Sulpice, Paris; took orders and became vicar-general and chancellor to the Bishop of Chartres in 1784. He had attained some reputation as an acute thinker when suddenly, in Jan., 1789, he attracted the attention of the French people by his celebrated pamphlet, *Qu'est-ce que le Tiers État?* and having been elected a member of the States-General by Paris, he became for some time the actual leader of the Assembly and originated some of the first and most decisive steps toward the Revolution. He proposed that the three estates should examine their credentials in common, that the third estate should constitute itself as a national assembly, etc.; and his pamphlet, *Reconnaissance et Exposition des Droits de l'Homme et du Citoyen* (July, 1789), was the precursor and immediate occasion of the declaration of the rights of man. The new administrative division of France into departments and the abolition of the old provincial system, with its many feudal remnants and artificial barriers, were also due to him. Nevertheless, as the Revolution ceased to be a philosophy and became a passion, Abbé Sieyès lost his influence. In the Convention he sat silent, though he voted for the death of Louis XVI. without any appeal to the people, and during the Reign of Terror he entirely disappeared from public life. After the fall of Robespierre he returned, was successfully employed in several diplomatic negotiations, and became a member of the Directory May 16, 1799; and it was he, as much as if not more than Gen. Bonaparte, who prepared and carried through the *coup d'état* of the 18th Brumaire (Nov. 9, 1799), by which the Directory was overthrown and the consular government instituted, he himself being chosen one of the three consuls. Very soon, however, finding that this, the best beloved of the various constitutions which he had framed, was disregarded, and that he had in effect brought in a military despotism with Napoleon as First Consul in complete control, he retired from his consulship and took part very little in politics. Napoleon enriched him and made him a count of the empire. After the Restoration, Sieyès was banished from France as a regicide, and went to Brussels. After the Revolution of 1830 he returned to Paris, and died there June 20, 1836. Boulay published, in 1836, *Théorie constitutionelle de Sieyès*, drawn from his *Mémoires inédits*. There are also *Études Sieyès*, by Mignet (1836) and Beauverger (1851). Revised by F. M. COLBY.

Sigel, zee'gel, FRANZ: soldier; b. at Sinsheim, Baden, Nov. 18, 1824; graduated in the military school at Carlsruhe; became a lieutenant of infantry in the army of the Grand Duke of Baden; resigned in 1847 from political reasons. He took part in the revolutionary movement of 1848; led a corps of 4,000 men through the Black Forest to the attack of Freiburg, and, narrowly escaping capture, he fled to Switzerland. At the beginning of the insurrection of 1849 he was appointed Minister of War by the revolutionary authorities; took part in the unsuccessful campaign against the Prussians, and after fighting several battles, including Rastadt, he successfully conducted the demoralized remnants of his forces into Switzerland on the dissolution of the provisional government, but, being expelled by the Swiss Government, he went to England, and after remaining there two years he embarked for the U. S.; was for some years teacher of mathematics in an academy in New York, and became major of the Fifth Regiment of New York militia; settled in St. Louis, Mo., 1858, as professor in a college; was commissioned early in 1861 colonel of the Third Missouri volunteers; took part in the capture of Camp Jackson; fought the desperate battle of Carthage July 5; was second in command under Lyon at Wilson's Creek Aug. 10; conducted the retreat from Springfield to Rolla; was thereupon commissioned brigadier-general to date from May 17; commanded a division under Fremont in his campaign in Southern Missouri; took an active part in the battle of Pea Ridge Mar. 6–8, 1862; tendered his resignation in May, in consequence of unpleasant relations with Gen. Halleck, in command of the district; was summoned to Washington and made major-general, dating from Mar. 21; was placed in command of Harper's Ferry June 2; succeeded to the command of Gen. Fremont's army-corps June 26; served under Pope in his Virginia campaign, taking a prominent part in the second battle of Bull Run Aug. 29–30; was placed in command of the Eleventh Army-corps Sept. 14, 1862; became commander of the department of West Virginia Mar., 1864; was defeated by Breckenridge at Newmarket May 15; relieved from command shortly afterward by Gen. Hunter; resigned May 4, 1865, and became editor of the Baltimore *Wecker*; removed in 1867 to New York, where he was chosen register Nov., 1871. He was U. S. pension agent for New York 1885–89. Revised by JAMES MERCUR.

Sighing: an act consisting of a full, long, and slow inspiration, which is immediately followed by a more rapid expiration unusually prolonged, and characterized by the presence of a sound as air passes out of the mouth. Although usually a reflex act, presumably excited by an almost imperceptible sensation due to imperfect aëration of the blood, sighing is often voluntarily performed, although it is in some respects not a perfect counterpart of that which is produced reflexly. It ordinarily takes place about once in every six respirations, but when the attention is concentrated upon some subject of great interest, the reflex excitability is diminished for the time being, and then, when the mind becomes disengaged, the act of sighing is so prominent as to attract at once not only the notice of the individual, but of those around him. The apparent object of sighing is to aërate the blood more perfectly than ordinary respiration, and through it the lungs are more effectually filled and emptied than would be the case were the breathing uniformly regular. Sighing is also a means of expressing certain emotions, particularly those of a sorrowful and tender character. In this relation it is to a certain extent under the operation of the will, and may be assumed, like smiles and tears, for purposes of deception. Figuratively, the act of sighing is often associated in our minds with desires, and we are said to sigh for the objects of our wishes; but the connection is in reality not primary. We sigh not because we desire anything, but because during the concentration of the mind upon a subject or object of engrossing interest we are for the time incapable of appreciating the sensation which prompts us to inspire air until it becomes overwhelming, and then the long-drawn sigh takes place. Sighing is not peculiar to the human species, but is a normal phenomena of respiration in all mammals, and perhaps in other classes of animals. Revised by E. T. REICHERT.

Sight: See VISION, EYE, and HISTOLOGY (*Organs of Special Sense*).

Sigilla'ria [Mod. Lat., from Lat. *sigil'lum*, seal. Named in reference to the scars left by the leaf-stalks]: a genus of fossil trees of the Carboniferous period. Trunks have been found 5 feet in diameter and 70 feet long. The roots called *Stigmaria* belong, at least in some instances, to this genus. See PLANTS, FOSSIL (*Lycopodineæ*).

Sigillum Confessionis: See CONFESSION.

Sig'ismund: Emperor of Germany 1411–37; the last of the house of Luxemburg; b. Feb. 14, 1362; a son of the Emperor Charles IV.; received after his father's death (1378) the margraviate of Brandenburg, while his elder brother, Wenceslaus, King of Bohemia, succeeded as emperor. Having been betrothed to Maria, the eldest daughter of Louis the Great, King of Hungary and Poland, he became heir-apparent to these two crowns. But on the death of

Louis (1383) the Poles chose his younger daughter, Hedvig, queen, Charles Durazzo seized the regency in Hungary, and Maria was kept in captivity by John Horvath, ban of Croatia. Sigismund rescued and married her, and was crowned King of Hungary in 1387. He then undertook a war against the Turks, supported by the German and Freneh chivalry, but was completely routed at Nieopolis (1396) by Bajazet, fled to Greeee, and found, when in 1401 he returned to Hungary, his queen dead, his throne occupied by Ladislaus of Naples, and his brother deposed in Germany, and vindicating himself only with diffieulty in Bohemia. In 1403 he expelled Ladislaus, and again took possession of the throne of Hungary, and in 1410 was even eleeted Emperor of Germany. In 1414 an œcumenical council was convoked at Constanee in order to put an end to the schisms in the Church, and reeoncile the Hussite party. He gave his assent to the deeree of the council eondemning Huss to be burned at the stake; and the Hussite war began. D. at Znaim, Moravia, Dec. 9, 1437. He was succeeded by his son-in-law, Albert II. of Hapsburg.

Sigismund: the name of three kings of Poland of the Jagellonian dynasty: SIGISMUND I., THE GREAT, b. in 1466, a son of Casimir IV., suceeeded his brother Alexander on the Polish throne in 1507. His was probably the most sueeessful reign in the history of Poland. A treaty with the Turks gave Poland the free navigation of the Blaek Sea, the sovereignty of Moldavia, and secured her against the invasions of the Mongols. He knew how to curb the arrogant nobility; was prudent in his expenses, and a patron of literature, which flourished highly under him and his son; and he favored the Reformation, which from Germany spread rapidly among the Poles. After the death of his first wife, Barbara Zapolska, he married Bona Sforza of Milan, an intriguing, avaricious, and licentious woman, who exercised great influence over him, and alienated to some extent the love of his subjeets from him. D. Apr. 1, 1548, and was suceeeded by his son, SIGISMUND II., AUGUSTUS, b. Aug. 1, 1520, who, although educated purposely by his mother in effeminacy and dissoluteness, opposed the ambitious schemes of the queen-dowager with great decision. At the Diet of Lublin (1569) Sigismund sueeeeded in uniting Lithuania firmly to Poland, and at the Diet of Warsaw (1572) he granted religious liberty, but the intolerance of the nobles prevented anything like freedom of worship to the serfs. Volhynia, the Ukraine, and Livonia were also incorporated, and his reign was, in both external and internal respeets, a period of great prosperity. D. July 14, 1572, and with him the male line of the Jagellonian dynasty became extinet. His sister Catharine, however, who was married to John III., King of Sweden, had a son, Sigismund, who was eleeted King of Poland as SIGISMUND III. after the death of Stephen Báthori (1587), and was crowned at Cracow; but his only aim was to unite Sweden and Poland, in order to reestablish Roman Catholicism in the former and suppress the Reformation in the latter. In 1592 John III. died, and Sigismund suceeeded him as King of Sweden, but in 1604 he was formally deposed by the Swedish estates, and his unele, Charles IX., raised to the throne. Unwilling to give up his claims, he then began a long series of wars with Sweden which contributed much to the final ruin of Poland. D. at Warsaw, Apr. 30, 1632.

Sigmaringen: See HOHENZOLLERN.

Sign [viâ O. Fr. from Lat. *sig'num*, mark, sign, token; cf. SEAL]: in astronomy, a portion of the eeliptie, containing a twelfth part of the eomplete cirele, or thirty degrees. The first sign begins at the point of the equator through which the sun passes at the time of the vernal equinox in the upper hemisphere; and the signs are counted onward, proceeding from W. to E., aeeording to the annual course of the sun around the cirele. The signs and their characters are as follows:

♈, Aries, *Ram.*	Spring.	♎, Libra, *Balance.*	Autumn.
♉, Taurus, *Bull.*		♏, Scorpio, *Scorpion.*	
♊, Gemini, *Twins.*		♐, Sagittarius, *Archer.*	
♋, Cancer, *Crab.*	Summer.	♑, Capricornus, *Goat.*	Winter.
♌, Leo, *Lion.*		♒, Aquarius. *Waterman.*	
♍, Virgo, *Virgin.*		♓, Pisces, *Fishes.*	

The first eharaeter, ♈, indicates the horns of a ram; ♉, the head and horns of a bull; ♊, the aneient statues of Castor and Pollux; ♋, the claws of a erab; ♌, a corruption of the Greek letter Λ, initial of Λέων, lion; ♍, eorruption of παρ for παρθένος, virgin; ♎, seales; ♏, the tail of a scorpion, or the legs and tail; ♐, an arrow; ♑, for τρ, initials of τράγος, goat; ♒, running water; ♓, two fishes joined. See ZODIAC.

Sign: in algebra, a symbol indieating a relation subsisting between two quantities, or an operation to be performed. Of the latter, those most commonly used are +, denoting addition; −, subtraetion; ×, multiplication; ÷, division; $\sqrt{}$, square root; $\sqrt[3]{}$, cube root; and $\sqrt[n]{}$, *n*th root. The signs denoting relations are =, equal to; >, greater than; <, less than, etc.

Signaling: a means of transmitting intelligence to a distance by means of signals appealing to the sense of sight or of hearing. For army signaling, espeeially in the U. S., see SIGNAL SERVICE and HELIOTROPE, and for signaling at sea see the former artiele and FOG-SIGNALS, NAVAL SIGNALS, and ROAD, LAW OR RULE OF THE. Signaling is of great importance on railways, for whieh see RAILWAYS (*Signals and Interlocking*). Signals are also used to make annouueements of weather predietions. (See WEATHER SIGNALS.) For the signals used before the invention of the electric telegraph to transmit messages to a great distanee, see TELEGRAPH.

Signal Service: that branch of the public serviee of a country which is concerned with transmitting intelligenee by means of signals, espeeially in the army and navy. Few persons without experience have any idea of the remarkable ranges at which signals made by motions are visible to the naked eye, or the wonderful gain had by the use of a simple poeket-telescope. Signaling at 5 miles is held by experienced signalists to be at very short range. Messages have been sent 10 miles by means of a pocket-handkerehief attaehed to a 12-foot rod. With the flags and staffs in use in the Signal Corps of the U. S. army communieation is said to have been had at 25 miles' distance, and detached words are reported to have been read at a distance of 40 miles.

It is well known that the suceess of modern military operations depends very largely upon celerity of movement and the eoneentration of the largest force at a given point. The greatly increased aeeuracy and range of small-arms and artillery have made it imperatively necessary that there should be rapid and sure means of intercommunication between the various component parts of an army, and that there must be prompt transmission of information both on the march and on the field of battle. The conditions neeessary to meet these requirements are well provided for by the Signal Corps of the U. S. army as at present organized. The system of military signals of which Maj. Albert J. Myer was the originator proved to be a great advance over the crude and unwieldy methods previously in use. Its value was speedily demonstrated by actual test almost immediately after the apointment of Myer as first signal officer of the army in 1860, and at the close of the civil war its usefulness as an auxiliary arm on the field of battle and on the march was not only recognized by giving it a plaee in the permanent military establishment, but the record whieh the corps made during the war has been utilized by the military powers, and the Myer system serves as a basis upon which rests modern military signaling. In Aug., 1861, a eamp was formed at Georgetown, D. C., where signal-parties were instructed and equipped to attend eaeh army that took the field; but it was not until Mar. 3, 1863, that the Signal Corps was given a separate and systematic organization. It was to consist of 1 colonel, 1 lieutenant-colonel, 2 majors, 1 captain, and 8 lieutenants for each army-corps, and for each officer there was allowed a sergeant and 6 privates. The corps was authorized for the duration of the civil war, and appointments were to be made on the reeommendation of examining boards.

The Signal Corps served with the greatest efficiency on all fields during the civil war, and even on naval vessels, notably with Farragut in the fight at Mobile Bay. At the close of the war it was again reorganized. The aet of July 28, 1866, provides that there should be one chief signal officer, with the rank of colonel, but it made no provision for a corps other than by a limited detail of six officers and not to exeeed 100 men from the Engineer battalion. The school of instruetion was established at Fort Whipple, now Fort Myer, Virginia, and here for many years signal instruction was given to offieers of the army and the navy and to the enlisted men of the Signal Corps. In 1870 a meteorologieal division was added to the signal servicc, to provide for taking meteorological observations, with a view to giving notiee by telegraph and signals of the approaeh and force of storms, and for twenty-one years this work formed a most important part of the duties of the serviee, gaining for it a worldwide reputation by the skill with which its weather forecasts were produced and their great reliability.

On July 1, 1891, however, that branch of the service was constituted the weather bureau and transferred to the Department of Agriculture. See WEATHER SIGNALS.

The Signal Corps of the U. S. army is constituted under a law which took effect July 1, 1891, and which provides that in addition to the chief signal officer (who has the rank of brigadier-general), the commissioned force shall consist of 1 major, 4 captains, and 4 first lieutenants, who shall receive the pay and allowances of mounted officers of like grades in the army. The enlisted force of the Signal Corps of the army shall consist of 50 sergeants, of which ten shall be of the first class, with the pay of hospital stewards. In time of war the ten officers and fifty enlisted men would have to be largely supplemented from the army, in order to man the various appliances that constitute its equipment, its present number having already been found too small. At present a number of the sergeants are employed as operators on the military telegraph lines throughout the republic and at the various department headquarters, and the rest are at the School of Instruction for Military Signaling at Fort Riley, Kansas.

This course of instruction extends over six months, and consists of both theoretical and practical instruction in the general principles of signaling, and requires a thorough knowledge of all the codes likely to be used in active service, including the international and nautical codes used by the U. S. navy, thus assuring, when necessary, signal communication between the land and naval forces and merchant marine. Instruction is also given in cryptography, and the class is required to devise plans of cipher and by practice to become skilled in enciphering and deciphering messages. Theoretical and practical instruction is also given in electricity, topography, photography, and the operation of the field telegraph and captive balloon trains. Practice in signaling extends over various ranges up to 12 miles with the flag, torch, and flash-lantern, and with the field-telegraph kit, both insulated cable and the bare-wire system being used. The course of instruction to operators consists largely in practice with the Morse system until each of the sergeants can send and receive thirty-five words a minute, and transcribe twenty-five words a minute on the typewriter, together with the regulations for transmission of messages and keeping the accounts of the various military lines, on which a considerable amount of commercial work is done.

The means of communication by day used by the corps are flags, heliograph, and the field telegraph and telephone trains; and by night the torch, flash-lantern, rockets, bombs, and searchlight. The method of visual signaling by flags consists in waving a flag to the right for a dot, to the left for a dash, and to the front for the space in the American Morse code. Thus the motions

Right, right, front, right represent C.
Right, front, right represent O.
Right, front, right, right represent R.
Right, right, front, right, right represent Y.
Right, right, right, front, right represent Z.
Right, front, right, right, right represent &.

Each motion embraces an arc of ninety degrees, starting from and returning to the vertical. The long dash (letter

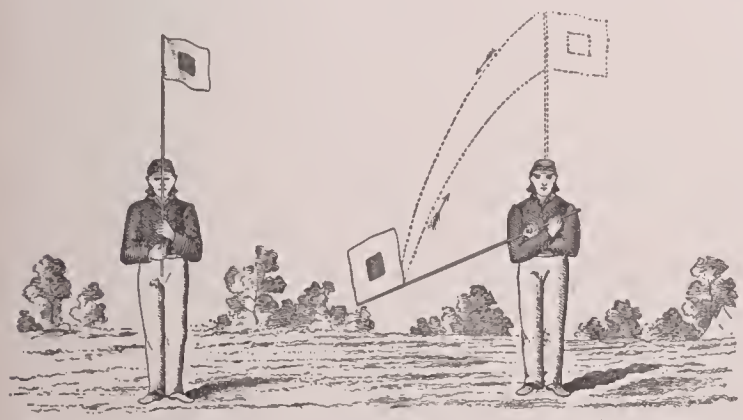

FIG. 1.—First position. First motion—"one"—"1" or dot (-).

"L" and numeral "naught") is distinguished from the "T" dash by a slight pause at the lowest point of dip, and with this exception there is no pause whatever between the motions required for any single letter. A slight pause is made between letters. At the end of each word, abbreviation, or conventional signal the space signal, or "front" motion, is made, preceded and followed by a pause equivalent to that made between letters.

The U. S. naval code for visual and telegraphic signaling uses three signals, numbered 1, 2, and 3, by combinations of which all the letters and numerals are expressed. In flag-signaling 1 is made by a motion to the right, 2 by one to the left, and 3 by one to the front (see figures); with a whistle or flash-light 1 is one toot or short flash, 2 two toots or short flashes, and 3 a blast or long flash. The alphabet and numerals are as follows:

A 22, B 2112, C 121, D 222, E 12, F 2221, G 2211, H 122, I 1, J 1122, K 2121, L 221, M 1221, N 11, O 21, P 1212, Q 1211, R 211, S 212, T 2, U 112, V 1222, W 1121, X 2122, Y 111, Z 2222. 1–1111, 2–2222, 3–1112, 4–2221, 5–1122, 6–2211, 7–1222, 8–2111, 9–1221, 0–2112.

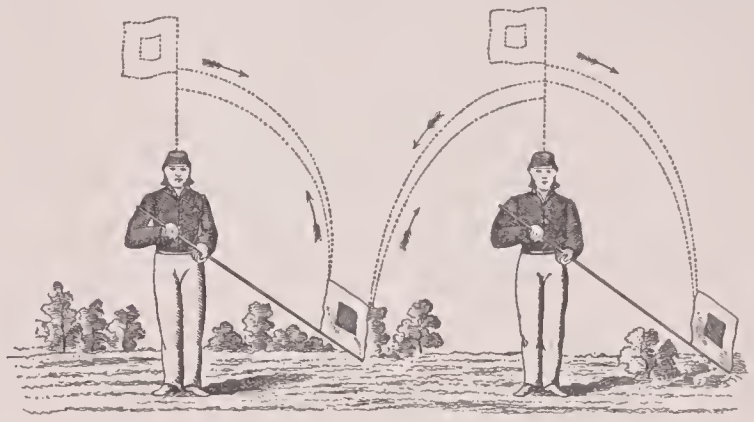

FIG. 2.—Second motion—"two" "Two—one"—"21" (— -). —"2" or dash (—).

When signals are communicated in the presence of the enemy they must be transmitted in cipher. The composition of cipher codes is facilitated by the use of a simple device called the cipher disk (see Fig. 4). This consists of several concentric disks, each carrying letters of the alphabet or numbers arranged in irregular sequence. To encipher a message the disk is clamped in any desired position, and the letters or symbols on one of the outer disks are used, each standing for the letter opposite it on the inner disk.

The field-telegraph train used in the U. S. army consists of a battery wagon and three sections, each of which includes a lance-truck and a wire-wagon.

The Japanese Signal and Telegraph Corps, the day following the battle at Ping Yang, in Korea, 1894, ran into that city a flying telegraph line extending from Seoul, the distance being 70 miles. This shows what modern war requires, and the necessity of a specially trained corps for these purposes.

The balloon-train is another factor of the utmost value in modern war tactics. The ability to discover the movements and position of an enemy is an absolute necessity, and these can be accurately ascertained by an operator in a balloon about 2,500 or 3,000 feet above the surface of the earth, who can scan the country for miles around with a good telescope, and telephone at once whatever he may see to the surface of the earth. The balloon-train at Fort Riley consists of three wagons for the carriage of tubes of compressed hydrogen and one wagon for the balloon and appliances.

When the balloon is inflated the manœuvering-bar is at-

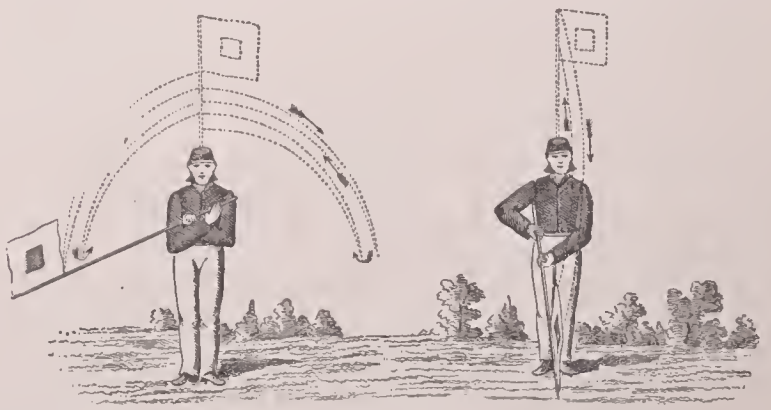

FIG. 3.—"One—two—one—two." "Three"—"3"—or "front." —"12 12" (- — - —).

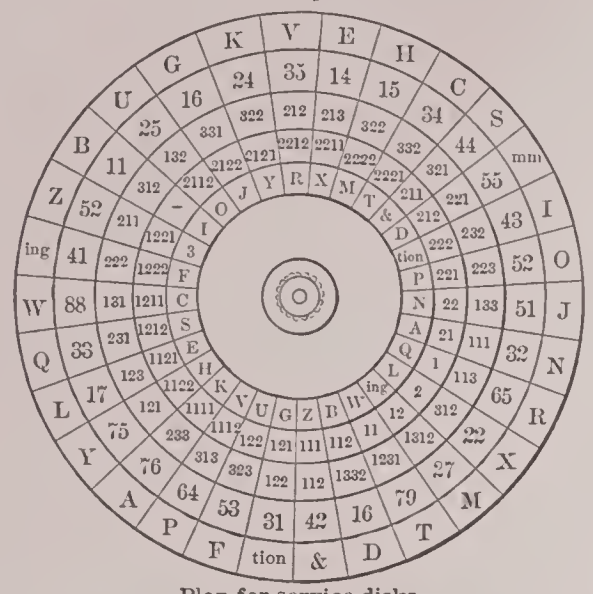
tached to the end of the cable on the drum of the balloon-wagon, and the necessary amount of cable is paid out. The height of the balloon above the ground is of course regulated by the length of cable paid out, and the observer in the car, having a field telephone kit, can direct the manipulation of the balloon itself as occasion may require.

The equipment of the car consists of an aneroid barometer, prismatic compass, telescope, field-glasses, note-book and pencil, telephone, maps of the country, and a camera. The operator is thus fully prepared for photographic work and observation. It may be thought that a balloon would present a good target to the enemy, but the experiments at Shoeburyness with an old captive balloon showed that it is almost impossible to hit such an object with long-range musketry fire or by artillery fire, especially if it be kept moving, which it always would be.

The advantage that a force possessing a balloon-train has over a less-favored enemy is manifest. All the great nations have equipped their armies with captive balloon-trains,

Fig. 4.—Cipher disk.



Plan for service disks.

Vertical section exhibiting plan for four disks.

and the individual processes of manipulation are regarded as military secrets. The French claim to possess a dirigible balloon, and if its practicability be established the machine should prove a most powerful engine of war.

It will be seen from the foregoing that the system of signaling used in the U. S. army—which is practically the invention of one man, Gen. A. J. Myer—has developed into a military science. In most of the foreign armies the signal service has been dignified by a separate corps organization, and where not separately organized they form a distinct division of some corps already in existence, such as the engineer, and the practical exigencies of war have in war served to make them independent in all but name. In Great Britain the signaling operations are entirely under the jurisdiction of the Royal Engineers Telegraph Corps, which consists of 6 officers and 245 men. In the Austrian army this duty is performed by a regiment having charge of railways and telegraph. In the Russian army there are 7 field-telegraph boards, each board consisting of 3 divisions, with the strength of 1 officer and 38 men. In the German army there are 7 field and 4 semi-permanent telegraph divisions, each field division being composed of 4 officers and 148 men. Belgium, Holland, Spain, and Italy have all given special attention to the organization of telegraph and signal trains in connection with their military establishments.

In addition to the military telegraph lines under charge of the chief signal officer of the U. S. army, there are thirty-three military posts and stations whose telegraphic connections with the great commercial systems of the U. S. are over prominent lines, constructed and operated by the Signal Corps of the army. There is at present hardly a military post which has not a telegraph station either within its limits or at some convenient point speedy of access. In addition to the regular telegraph service attention is being given to suitable equipment of its flying telegraph-trains in all phases, from the connection, by means of such lines, of army headquarters with the permanent lines of the U. S., to the provision for temporary telegraphic or telephonic communication between army, division, or even brigade headquarters, with all essential points, whether in camp or on battle-line.

H. H. C. Dunwoody.

Signature: in the old system of medicine, some physical peculiarity of a drug which was supposed to indicate its use. Thus, because the euphrasy or eye-bright has a flower with an eye-like mark, it is good for the vision; the rock-liverwort was thought to be shaped like the liver, hence it is good for diseases of that organ. This belief prevailed not only among herbalists and pretenders, but among the best-trained physicians of the time.

Sign-language: See Deaf-mutes.

Signorelli, seĕn-yō-rel'leĕ, Luca: painter; b. at Cortona, Italy, about 1441; pupil of Piero della Francesca. In 1472 he was painting at Arezzo, in 1474 in Città di Castello. He afterward went to Rome, and in the Sistine chapel painted two frescoes representing incidents in the history of Moses. These were completed by 1484, when he returned to Cortona, and painted an altarpiece for the chapel of Sant' Onofrio in the Cathedral of Perugia. In 1490 he painted the *Circumcision* in the Church of San Francesco at Volterra and an altarpiece in the Duomo, and the next year returned to Cortona and took office as a councilor. The eight frescoes in Mont' Oliveto, near Sienna, were commissioned in 1497, but the greatest works of this master are the frescoes of the chapel of the Madonna di San Brizio in the Cathedral of Orvieto. These were undertaken after Signorelli's sixtieth year. The four great compositions with life-size figures represent *Antichrist*, *Hell*, *The Resurrection*, and *Paradise*. These, with the decorative designs around them, were all executed by Signorelli and his assistant Girolamo Genga within three years and three months. Signorelli painted innumerable altarpieces and frescoes besides the works mentioned. He signed his name in several manners: Lucas Signorellius Corthonensis, also in a Greek form, Λουκᾶς ὁ Κορτιός, also Lucas Coritius, also Lucas Ægidii Signorelli Cortonensis. He was the first of the whole cycle of Italian painters in his mastery of drawing the human figure, and of his use of it in his compositions for its own sake. His frescoes at Orvieto greatly impressed Michelangelo, whose *Last Judgment* testifies to the influence Signorelli had over him. Signorelli died at Cortona in 1523. He had lived there in splendor and luxury, more like a nobleman than a painter, according to Vasari. His son Antonio and his nephew Francesco Signorelli were painters also. Luca Signorelli is well represented in European galleries. For further information, see Vasari; Crowe and Cavalcaselle's *History of Painting in Italy* (1864–71); Robert Vischer, *Luca Signorelli* (Leipzig, 1879); and Kugler's *Handbook*, edited by Sir H. A. Layard (1887). W. J. Stillman.

Sig'ourney: city; capital of Keokuk co., Ia.; on the Skunk river, and the Chi., Mil. and St. P. and the Chi., Rock Is. and Pac. railways; 25 miles E. of Oskaloosa, 28 miles W. of Washington (for location, see map of Iowa, ref. 6–I). It is in a coal-mining region, has important manufactories, and contains a public high school, a national bank with capital of $50,000, 2 State banks with combined capital of $100,000, and a monthly and 3 weekly periodicals. Pop. (1880) 1,735; (1890) 1,523; (1900) 1,952.

Sigourney, Lydia Howard (*Huntley*): poet; b. at Norwich, Conn., Sept. 1, 1791; established a select school for young ladies at Norwich 1809, and at Hartford 1814; published a volume of *Moral Pieces in Prose and Verse* (1815), and was thenceforth through a long life one of the most popular of American poets. She published fifty-nine volumes of poems, essays, and letters, chiefly on moral or religious themes. She married Charles Sigourney, a merchant at Hartford, in 1819; visited Europe 1840; d. at Hartford, June 10, 1865. Among her works were *Letters to Young Ladies* (1833); *Zinzendorff, and other Poems* (1835); *Pocahontas, and other Poems* (1841); *Pleasant Memories of Foreign Lands* (1842): *Past Meridian* (1854); and a posthumous autobiography, *Letters of Life* (1866). Two volumes of her selected poems appeared in London 1841, and a choice edition, illustrated by Darley, was published at New York 1848. Revised by H. A. Beers.

Sigwart, Christoph, von, Ph. D., Dr. Theol., LL. D.: b. at Tübingen, Würtemberg, Mar. 28, 1830; educated there and became professor in a seminary 1859 and Professor of Philosophy in the University of Tübingen 1863. He is a corresponding member of the Academy of Sciences of Berlin. His principal works are *Spinozas neuentdeckter Tractat von Gott, etc., erläutert* (1866); *Logic* (vol. i., 1873; vol. ii., 1878; 2d ed. vol. i., 1889: vol. ii., 1893; English translation 1894); *Vorfragen der Ethik* (1886); *Die Impersonalien, Eine logische Untersuchung* (1888). J. M. B.

Sihon, or **Sihun**: See Syr-Darya.

Sikes, Olive (*Logan*): actress and author; daughter of a theatrical manager; b. at Elmira, N. Y., in 1841; made her *début* on the stage in Philadelphia 1854; went to England 1857, in which year she was married to Henry Delille, from whom she obtained a divorce in 1865; became a contributor to English and French papers; published two novelettes (1860); reappeared on the stage at Wallack's, New York, in 1864, in *Eveleen*, a play written by herself; retired in 1868, and devoted herself principally to lecturing on woman's rights and on other social topics, magazine-writing, and newspaper correspondence. In 1871 she became the wife of William Wirt Sikes. Among her publications are *Photographs of Paris Life* (1861); *Château Frissac* (1865); *John Morris's Money* (1866); *Apropos of Women and Theatres* (1869); *Before the Foot-lights* (1870); *The Mimic World* (1871); *Get thee behind me, Satan* (1872); and *They Met by Chance*, a novel (1873). Revised by H. A. Beers.

Sikes, William Wirt: journalist and author; b. at Watertown, N. Y., in 1836. He learned type-setting in his boyhood, and wrote for the newspapers. He was afterward editorially connected with the Utica *Herald*, *The Chicago Times* and *Evening Journal*, and the New York *Sun*. While in Illinois he was appointed State inspector of canals. He removed to New York in 1867, and in 1871 was married to Olive Logan. From 1876 to 1883 he was U. S. consul at Cardiff, Wales. He published *One Poor Girl: the Story of Thousands* (1869); *British Goblins: Welsh Fairy Mythology* (1879); *Rambles and Studies in Old South Wales* (1881); and *Studies of Assassination* (1881). D. in London, England, Aug. 19, 1883. H. A. Beers.

Sikhs, seeks [from the Punjaubi word *sikha*, or *sikh*, a disciple]: the disciples or followers of Nanak, a religious reformer, who was born in the village of Talwandi, now called Nankana, on the bank of the river Ravi, near Lahore, in A. D. 1469. They form the principal native element of the province of the Punjaub.

The history of Nanak is recorded in what are known as the *Janam Sakhis*, or biographical sketches. According to these ancient records Nanak was a Hindu by birth, of the Khattri càste, and the son of a village official. In his early years he sought the society of ascetic monks. At the age of fifteen he misappropriated the money which his father had given him for trade, and gave it to religious mendicants. This induced his father to send him to a relative at Sultanpur, in order that he might be weaned from his affection for a monkish life; but he still continued to give all his earnings to poor mendicants, and reserved but a bare pittance for himself. While in the service of a Mohammedan in Sultanpur, Nanak believed that he received ecstatic visions and divine inspirations. When engaged in religious exercises he was translated bodily, so he said, to the gates of paradise, and received a golden goblet of *amrita*, or the "water of life." Then God said to him, "Nanak, I am with thee, and whosoever shall follow thee shall be happy indeed." Nanak recovered from the trance, and when he awoke he uttered those words which have become the keynote of his religious system: "In religion there is no Hindu, and there is no Moslem." He soon began to show evidences of supernatural power, and many miracles are credited to him. He was accepted by the people as a religious guide. His employer was among his first converts, and the eclectic character of his system made Nanak acceptable to Hindus and Moslems alike.

He next proceeded to Benares, the sacred city of the Hindus, in order to be brought in contact with the teachings of the Brahmans. Here he succeeded in converting to his views a large number of Hindus, and not a few Moslems. Among those who joined him from the ranks of Islam was the Sheik Farīd, who afterward became a valuable assistant in enabling Nanak to combine in his religious system the ideas of the Hindu and of the Moslem. Nanak was, upon his return from Benares, captured among the prisoners taken by the Emperor Baber, and it is said the Mogul ruler was much attracted by the teacher's piety. After his release Nanak renewed his missionary work, and many people joined him. He is said to have visited Mecca, and to have acknowledged Mohammed as a God-sent messenger. He returned to his native river to die (1538 A. D.), after having named Angad as his successor, the *guru* or teacher of the Sikhs.

Nanak was an uneducated man, but a book was compiled by one of his successors (by Arjun, the fifth *guru*, it is said), which claims to record the opinions and teachings of Nanak. This sacred book, known as the *Adi Granth*, which is written in the Punjaubi language, is kept in the Golden Temple of Amritsar, and is guarded and preserved with great honor by a corps of priests and choristers. It is called by the people the *Granth Sahib*. An English translation by Dr. Ernest Trumpp has been published in London.

Sikhism may be generally characterized as a pantheistic system, similar to Hinduism, but rejecting caste distinctions and the practice of idolatry. It contains in itself the mystic elements of ancient Hinduism, and the more modern teachings of the Moslem Sufis. The line of teachers who succeeded Nanak is as follows: Angad, who died in A. D. 1552; Amar-Das, 1574; Ram-Das, 1581; Arjun, 1603; Har-Govind, 1638; Har-Raie, 1660; Har-Kisan, 1664; Tegh-Bahadur, 1675; Govind Singh, 1708. Govind Singh welded the Sikhs into a great military power. He established the Khālsa, or brotherhood, by which he enrolled the followers of Nanak into an army of fighting men, and conferred upon each member the title of Singh, or lion. After a turbulent reign he was slain by an Afghan follower, and in his dying moments refused to name a successor. He said the *Granth Sahib* was enough to guide them for all time. The Sikhs were little heard of after Govind's death, but the falling power of the moguls, and the repeated invasion of India, first by Nadir Shah and then by Ahmad Shah, the Afghan, favored the revival of the followers of Govind Singh as a military power. In 1763 40,000 Sikhs defeated the Afghan governor of Delhi. In 1785 the Sikhs formed a confederacy, with annual durbars at Amritsar, and are said to have numbered more than 70,000 horsemen. Under the vigorous rule of Runjeet Singh (*q. v.*) they became an important nation. After his death the Punjaub was ruled by a durbar, or council, of Sikh nobles, during the minority of Runjeet Singh's son, Maharajah Dhuleep Singh. Eventually Dhuleep Singh abdicated in favor of the British, and embraced Christianity. He died in Paris in 1894. The Sikhs are considered admirable soldiers, and there are about 14,000 serving under British colors. Among the leading Sikh princes are the maharajahs of the semi-independent states of Patiala, Kashmir, and Kapurthala.

Thomas P. Hughes.

Si-kiang, sĕē'kyaang': a river of China (*q. v.*).

Sik'kim: feudatory state of British India, occupying the upper part of the Tista river basin on the southern slope of the Himalaya Mountains, with Tibet on the E. and N., Nepal on the W., and the British district of Darjiling on the S. It is about 70 miles long N. and S., and 50 miles broad. Area, 2,600 sq. miles. It is governed by a maharajah, aided by a British political resident who has entire charge of the foreign affairs. It is a mountainous, elevated, and healthful territory, producing rice, maize, millet, tea, oranges, cloths, and copper. Pop. (1891) 30,458. The people are Buddhist. The principal towns are Tumlong and Gamtak. See Edgar, *Report on a Visit to Sikkim* (1874); Strahan, *Report on Explorations in Sikkim* (1889). M. W. H.

Silao, sĕē-laa'ō: town of the state of Guanajuato, Mexico; on the Mexican Central Railway, and 237 miles by this route from Mexico city; head of a branch road to Guanajuato, 14 miles (see map of Mexico, ref. 6–F). It is on the plateau, 5,910 feet above the sea; is the center of a rich wheat and maize district; and has factories of cottons and woolens. Silao is the ancient Indian town of Cillan. Pop. about 15,000. H. H. S.

Sile'nus [= Lat. = Gr. Σειληνός]: in mythology, son of Hermes or Pan, and the childhood instructor and constant companion of Dionysus. In Asia Minor he was originally the god of flowing water, and so he always carried a skin of water; but in Greece he was degraded to a mere δαίμων, and was represented as a drunken, jolly, fat old fellow with bald head, flat nose, and abundant hair all over his body, and carrying always a skin filled with wine. J. R. S. S.

Sile'sia: province of Prussia, S. of the provinces of Brandenburg and Posen, bounded E. by Poland, S. by Moravia and Bohemia, and W. by Saxony. Area, 15,557 sq. miles. Along the southern and western boundaries the province is mountainous and rugged, but the whole central part is flat, traversed by the Oder and its tributaries. The soil is generally fertile and well cultivated. Grain, flax, hemp, oil-plants, tobacco, beets, and hops are extensively cultivated. An excellent breed of sheep yields a very fine wool, and important manufactures of linen and woolen fabrics are carried on. The mineral wealth is considerable,

lead, copper, and coal being abundant. Pop. (1895) 4,415,309. Capital, Breslau.

Silesia was from the sixth century inhabited partly by German, partly by Slavonic tribes, and formed a fief or—as it was divided between several dukes—several fiefs, first of the Polish, then of the Bohemian crown. In 1537 the Duke of Liegnitz and the Elector of Brandenburg made an agreement that if either of the two reigning lines became extinct its possessions should fall to the other. In 1675 the ducal family died out, but the German emperor refused to acknowledge the validity of the agreement of 1537, and incorporated Liegnitz and the other ducal possessions as a lapsed fief of Bohemia into the Austrian empire. In 1740 the duchies were seized by Prussia. (See FREDERICK II. of Prussia and SEVEN YEARS' WAR.) Under the Prussian Government the province has developed greatly, and forms one of the richest provinces of the kingdom.

Revised by M. W. HARRINGTON.

Silesia, Austrian: province of Austria, between Prussia, Moravia, and Galicia. Area, 1,987 sq. miles. The northern part is covered by the Sudetic Mountains; the rest is flat, though high. The climate is somewhat rigorous, but healthful. Good crops of rye, barley, and oats are raised, cattle, sheep, and bees are extensively reared, and copper, lead, iron, and coal are mined. Pop. (1891) 605,649, of whom four-fifths are Roman Catholics. Capital, Troppau. M. W. H.

Silhouette [from Étienne de Silhouette, French Minister of Finance in 1759, either because of his excessive public economy, causing his name to be applied to things cheap, or because of his making such figures as a diversion]: a figure drawn in outline and filled in solid, usually with black, without other details than those of the outline; much like a shadow. By extension the term is used when there is some slight delineation of the parts within the bounding line.

Sil'ica or **Silicic Acid** [*silica* is Mod. Lat., from Lat. *si'lex, si'licis*, flint]: a compound (SiO_2) of SILICON (*q. v.*) with oxygen. It was first pointed out by Smithson in 1811 that this substance is a weak acid, and shortly afterward Berzelius showed that it is one of the most important and widely distributed acids of the mineral kingdom. It occurs in nature partly free, partly in combination in the silicates. Free silica is either crystallized or amorphous. The crystallized varieties contain no water, have the specific gravity 2·66 or 2·3 according to the form, and are insoluble or difficultly soluble in alkalies. The amorphous varieties contain water, have the specific gravity 2·1 to 2·2, and are dissolved by alkalies. The principal form in which silica occurs is QUARTZ (*q. v.*).

Tridymite crystallizes in the same system as quartz, but has a lower specific gravity, 2·3, and constitutes an undoubted allotropic form of silica. It was discovered by von Rath.

Amorphous Forms of Silica.—Silica when precipitated from solution, and when fused, as with the oxyhydrogen flame, assumes the density 2·225, and in this form is highly soluble in caustic alkalies—to a small extent in many saline solutions, and even in pure water. This is the form in which silica is left in the decomposition of many natural silicates by alkaline waters, and it is therefore present in most soils. All amorphous varieties of mineral silica are called opal. Among these are OPAL and HYALITE (*qq. v.*). Mixtures of the crystallized and amorphous varieties of silica also occur in nature. Among these are AGATE, CHALCEDONY, CHERT, FLINT, and CARNELIAN (*qq. v.*). An analysis of a very pure opal by von Rath gives the formula $3SiO_2.H_2O$, with the density 1·99, corresponding to 9·84 per cent. of water. Some of these hydrates, however, contain as much as 13, 16, and even 21 per cent. of water, and some opals as low as 5 or 6 per cent. only. This indefinite character of opal is probably due sometimes to admixture with quartz or other forms of silica, a variable insoluble residue being generally left on boiling with an alkali.

The relations of silica to life upon the land are very important. Of the animal kingdom it is but a very trifling constituent, but to many plants silica has the same relation that tricalcic phosphate has to most animals—that is, silica is the main material of the plant-skeleton. Of the ashes of plant-stems, particularly, silica is often found to be a large constituent; thus in ash of rye-straw is found 65 per cent., of potato-stems 36 per cent., and of wheat-straw as much as 73 per cent. Hence the importance of the existence in soils of silica in such form that it may pass in solution into the roots—namely, in the form of soluble silica, or more probably that of hydrated silica.

Silicic hydrates may be obtained artificially by several methods. If solutions of soluble glass (see GLASS) are treated with acids, hydrate of silica precipitates in gelatinous form. This, if well washed and dried over oil of vitriol, gives, according to Doveri, a product of the composition $3SiO_2.2H_2O$, which was converted at 212° F. into $3SiO_2.H_2O$, the same as von Rath's native opal, referred to above. Hydrates may also be obtained by the action of the gaseous fluoride of silicon on water. Fuchs obtained thus the above trisilicic monohydrate, and another, a tetrasilicic monohydrate ($4SiO_2H_2O$). Ebelman also obtained a definite hydrate ($2SiO_3.3H_2O$) as a transparent solid glass by the action of air upon silicic ether. By DIALYSIS (*q. v.*) Graham obtained a solution of 5 per cent. of silica in pure water, which may be boiled rapidly down to 14 per cent. if no gelatinization is allowed on the edges. This solution is tasteless, with a feeble acid reaction. In the course of a few days it passes spontaneously into a transparent jelly. Addition of a little muriatic acid or an alkali tends to preserve it. Carbonic acid coagulates it, also alkaline and earthy carbonates in minute proportion. Added to a solution of gelatin, this precipitates, together with the silica, about in equal parts. This solution evaporates to a lustrous transparent glass of composition $SiO_2.H_2O$, containing 22 per cent. H_2O.

Silicate Cotton: See MINERAL WOOL.

Silicide of Carbon: a very hard crystalline substance first obtained about the year 1890 by E. G. Acheson, of Chicago, while experimenting for the production of diamonds in the electric furnace. Under the supposition that he had formed a compound of carbon and corundum, he gave it the name "carborundum," by which it is commercially known. Chemical analysis, however, shows that it has the following composition: Silicon, 69·10; carbon, 30·20; with about seven-tenths of 1 per cent. of oxide of iron, alumina, and lime, which may be regarded as impurities and as imparting color, which varies from nearly white to a deep emerald green and blue. The composition may thus be expressed by SiC, the elements being united atom to atom.

The crystallization is rhombohedral, usually with a broad development of the basal plane, forming hexagonal plates confusedly aggregated and very small, but with brilliant surfaces, an adamantine luster, and transparent. Specific gravity about 3. It is a good conductor of heat, is not fusible before the blowpipe, and is insoluble in acids.

The most important physical characteristic, industrially, is its extreme hardness, which appears to be between that of the sapphire, which it scratches, and the diamond. It is used as a substitute for emery or corundum, and is made into wheels, whetstones, and polishing-cloths. It is manufactured by exposing a mixture of sand and carbon to the heat of a powerful electric current for eight hours. The result is a mass of crystals of small size, which is crushed and the powder digested with dilute sulphuric acid to remove soluble impurities.

See Acheson, *Carborundum, its History, Manufacture, and Uses*, in *Jour. Frank. Inst.* (Philadelphia, Sept., 1893); Schützenberger, *Contribution to the History of Carbosiliceous Compounds* (*Comptes Rendus*, May, 1892); *Carborundum*, etc., *The Electrical Engineer*, xv., p. 227 (Mar., 1893); *Science*, xxii., 141 (Sept. 15, 1893).

W. P. BLAKE.

Sil'icon [Mod. Lat., from Lat. *si'lex, si'licis*, flint]: an element which, next to oxygen, is the most abundant one in the solid part of the earth's crust. Quartz, sandstones, and other forms of SILICA (*q. v.*) contain over 45 per cent. of their weight of silicon. Granite and gneiss-rocks average 35 per cent. of silicon, slates 30 per cent., and trap-rocks 23 per cent. Silicon was first obtained by Berzelius in 1823 from the silicofluoride of potassium by the action of fused potassium thereon. It appears, when thus obtained, as an amorphous powder of a dull-brown color, which smears the fingers like lampblack. It does not conduct electricity; is not acted on by mineral acids, except hydrofluoric, but dissolved by potash solution. Heated in air or oxygen, it burns brilliantly, forming silica, SiO_2. Silicon may be obtained in this form also by the action of potassium or sodium on gaseous fluoride or vaporous chloride of silicon; also by the electrolysis of fused silicofluorides, and by heating sand (silica) with metallic magnesium. A second allotropic form of silicon is obtained by exposure of the above to strong heat, which causes it to become denser and pass into graphitoid silicon. This form was obtained in hexagonal tabular crystals by Wöhler by fusing silicofluoride

of potassium with an excess of metallic aluminium, and, after the action, dissolving out the aluminium from the metallic button obtained, with acids. Molten zinc dissolves silicon, and, on cooling, the latter crystallizes out in needles. The preparation of needle-formed silicon is accomplished by heating to a high temperature a mixture of silicofluoride of potassium, metallic sodium, and granulated zinc. After the silicon has crystallized out, the zinc is dissolved by hydrochloric acid, and the crystals of silicon left behind. This form of silicon is also obtained by passing vapor of chloride of silicon over fused aluminium. Another form is fused silicon, which was obtained by Deville by heating above the melting-point of steel. This is dark steel-gray, and hexagonal in crystallization. Deville and Caron obtained cast ingots weighing nearly a pound. In this modification it will not burn, even in oxygen gas at a white heat.

The allotropic forms of silicon offer a remarkable parallelism with those of carbon; and, indeed, there are no elements, of such widely different functions in nature, which present so many analogies as carbon and silicon, the first being a characteristic element of the organic kingdom, and the last of the inorganic. Silicon is more electro-positive or basylic than carbon, at least at high temperatures, and will even decompose potassium carbonate when fused with it, setting carbon free, with vivid incandescence, potassium silicate being formed. It is therefore a more powerful agent in smelting reduction than carbon, and if it were cheaply procurable would have valuable practical applications in this way. Silicon combines with iron at high temperatures, and pig irons often contain it. Revised by Ira Remsen.

Silis'tria (anc. *Durostorum*): town; in Bulgaria; on the Danube; about 70 miles N. W. of Varna (see map of Turkey, ref. 3–E); carries on a large trade in wheat and lumber. It is specially important as one of the strongest fortresses on the Danube. Until the conclusion of the Russo-Turkish war (1878) it was for almost 500 years the main bulwark of the Ottoman empire on its northeast European frontier. The Russians besieged it in vain in 1773, 1810, and 1854. In 1828–29 12,000 Ottomans withstood for months the whole army of Marshal Diebitch, but July 1 the town was forced to surrender, and the fortifications were demolished. Though not captured by the Russians in 1877–78, the demolition of its principal redoubt, Arab Tabia, was one of the stipulations of the Congress of Berlin (1878). Pop. (1893) 11,710. At a village 6 miles S. E. from Silistria the treaty of Kaĭnardji was signed (July 21, 1774), the conditions of which were the most disastrous up to that time imposed on the Ottoman empire. E. A. Grosvenor.

Sil'ius Ital'icus: poet: full name Tiberius Catius Silius Italicus, which is found only in one inscription (*Corpus VI.*, 1984). Born in 25 A. D., at what place it is not known, he acquired some reputation as a pleader at the bar, was consul in 68, and was proconsul in Asia, probably under Vespasian. Possessed of ample means, he purchased numerous villas, including one that had been Cicero's, filled them with books and works of art, and devoted himself to literature and philosophy. The latter part of his life was spent in retirement on the Campanian shore, near the tomb of Vergil, of whom, as well as of Cicero, he was an ardent admirer. Among his friends were the Stoics Epictetus and Cornutus, and he ended his life in true Stoic fashion by voluntary starvation in 101, being afflicted with an incurable disease. His epic poem, entitled *Punica*, in seventeen books, is the longest of the Roman epics, and also the dullest, evincing, as the younger Pliny says, more industry than talent. The subject is the second Punic war, and the two great heroes are Scipio and Hannibal. Livy is his principal source for the facts and Vergil for the phraseology, while various incidents are imitated also from Homer. Of late Silius has found few readers, and has been seldom edited. The best text is given by L. Bauer (2 vols., Leipzig, 1890–92). Of earlier editions may be mentioned that of Ruperti (2 vols., Göttingen, 1795–98). Another work, entitled *Homerus Latinus*, a Latin version or epitome of the *Iliad*, in 1,070 hexameters, is generally ascribed to Silius, and was probably composed at a much earlier period than the *Punica*, and not later than the time of Nero. At the beginning and end are found acrostica, Italicvs scripsit. This has been edited by F. Plessis (Paris, 1885). See also R. Döring, *Ueber den Homerus Latinus* (Strassburg, 1884) and *De Silii Italici epitomes re metrica et genere dicendi* (Strassburg, 1886). M. Warren.

Silk [O. Eng. *seolc*; akin to Russ. *shelkŭ*, Mongol. *sirgek*, and obtained from a different source from Germ. *seide*]: a fine, soft, strong, elastic, and lustrous filament or fiber produced by the larvæ of certain bombycid moths which feed on the leaves of the mulberry (*Morus alba*) and other trees, and are known as silkworms. (See Silkworm.) The name silk is also applied to the textile fabrics woven from these filaments or threads. The finest silk is the product of the *Bombyx mori* or silkworm proper, which feeds on the mulberry. Some of the other varieties of silkworms, which are found in a wild state, produce what is commonly known as wild silk, a rather coarse filament possessing few of the properties of the mulberry-fed silk. Tussah silk, produced by the oak-feeding worm, is woven by the natives of India and China into a cloth of primitive make; and of late years, owing to the improvements made in the mode of treating it and depriving it of its gum, it has found a more extended consumption in Europe. The extreme fineness of silk adapts it for articles in which appearance has to be combined with lightness and durability. So great is the fineness of the thread formed in the cocoon that several of them have to be reeled together into one single thread. This fineness varies, even in the same cocoon, and reaches as low as $\frac{1}{400}$th of an inch in diameter, while the length of the worm's secretion is very great compared with its weight, exceeding 1,000,000 yards to the pound.

Preparation of Silk.—The secretion which the full-grown silkworm emits comes out through two separate seric tubes which combine in the worm's "spinner" under its lower lip. The cocoon is formed in six or eight days, and in about three weeks the worm undergoes all the transformations into chrysalis and butterfly. The best cocoons are carefully selected and retained for seed—i. e. for the hatching of the moths which are to lay the eggs for the following year. The chrysalides in the other cocoons have to be killed in order to prevent the piercing of the cocoon by the moth, which would make it unfit for reeling. The smothering of the chrysalis can be accomplished in hot-air ovens, with damp air or with dry air, by steam, and by exposure to the hot sun. It has also been attempted with carbonic acid, sulphur fumes, etc. The cocoons are then ready for reeling, and have to be separated in groups in order to obtain as much uniformity as possible in color and quality of the silk to be reeled. Stained cocoons and others having imperfections are grouped separately. Before reeling the cocoons are cleaned by removing the frame which the worm builds before lining it with the valuable fiber, and which is the floss or loose silk. The reeling has to be done very carefully, and female labor is mostly employed in doing it. The value of the product, its fineness, its uniformity, are all dependent on good reeling. While the filament in the cocoon is a continuous and independent thread, the glutinous or gummy substance which makes the cocoon a kind of homogeneous mass has to be softened or dissolved in order to permit of the free unwinding of the cocoon thread. The reeling of the silk is done while the cocoons float in a pan of hot water, the temperature of which is between 194° F. and the boiling-point, the spinner touching them lightly with a small broom in order to find the end of the threads that have to be spun together. According to the thickness of the silk to be obtained, from two to six cocoons or more are reeled together into a single thread. Attached to these threads is still sufficient of the gum to cause them to be glued together with a slight pressure of the fingers and a light twist. The combined thread is then carried on to the reel. New cocoons have to be taken and their ends joined to the continuous thread when the first cocoons give out or cease to spin. The thread produced by reeling is known as *raw silk*, and comes in commerce in large skeins or hanks.

Principal Countries producing Raw Silk.—These are Italy and France in Europe; China, Japan, India, and Asiatic Turkey in Asia. Silk is also produced in Spain, Austria-Hungary, Greece, European Turkey, Russia, Persia, Central Asia, etc., but on a smaller scale than in the countries first named. Notwithstanding all the efforts made to introduce sericulture in the U. S., very little raw silk is produced there at a profit. The opening up to commerce of the ports of the far East greatly increased the supply of raw silk available for Europe and America, and as this supply has been increasing at a steady rate, there has been a tendency toward a lower level of prices. The production of raw silk of the world in 1893 and 1894 may be estimated to have averaged about 30,000,000 lb. per annum. Of this China and Japan supplied more than half. Italy produces

about one-sixth of the entire world's supply, France much less. Raw silk is graded in regard to its commercial value; French and Italian is the higher priced, that produced in Asiatic Turkey, Japan, and that part of China known as the Canton district follows, and common China silk shipped through Shanghai represents the inferior grade.

Conditioning.—The raw silk reeled in Japan and China on the European system is classified as filature. Native-reeled silk can be rereeled; these are known as rereels. The fineness of raw silk is expressed by a number, which indicates the weight for a certain number of yards. This weight is expressed in *deniers* (old style *pennyweight*), and is called its title (French, *titre*; Italian, *titolo*). Of this there are several standards, the most used being the Milan legal standard and the Lyons standard, the first numbering 1 for each unity of weight of ½ decigram for 450 meters, while the Lyons standard, which is also known as the international, numbers the same unity of weight for every 500 meters. As, however, uniformity in fineness is not obtainable, the "number" of raw silk is usually expressed between limits. Thus if raw silk is numbered 9/11 deniers, it means that for every unity of length it weighs between 9 and 11 times the unity of weight, averaging 10 deniers. A scientific method of assaying silk has been found necessary, in order to establish its title, the amount of moisture it contains, etc. This is commonly called conditioning. Nearly every European city in the industries of which silk plays any part has a conditioning establishment. A certificate is given for each separate parcel, which gives it a sort of legal status, and is sufficient for commercial purposes. Nearly all the silk exported to the U. S. from Europe is accompanied by a certificate of conditioning, while much of the Asiatic silk imported is conditioned in the U. S.

Waste Silk.—Under this general name may be included everything that in the course of the manufacture, from the cocoon to the finished fabric, is eliminated through one reason or another. This includes the pierced cocoons which have been used for seed, and all others that are unadapted for reeling. In reeling the raw silk only about 70 per cent. of the silk in the cocoon is utilized, the rest going as waste. Waste is also made at every subsequent process of manufacture. All this waste is the raw material for a subsidiary but important industry, that of making the yarn that is commonly called spun silk, which can be used for many purposes, as it possesses all the luster of silk. Spun silk is used as filling in silk fabrics; it can be used in combination with wool, cotton, and other fibers, in mixed goods. Spun silk is also much used in the manufacture of velvets and plushes.

Treatment of Raw Silk.—Raw silk has to be thrown before it becomes fit for further process of manufacture. Only for a few special tissues can it be woven as it is. The throwing consists in twisting several threads into one thicker thread. It includes various operations, such as rereeling, doubling, cleaning, spinning, doubling again, twisting, and, if the silk has to be dyed, reeling again into skeins. Thrown silk is known as *tram* if to be used for the filling and as *organzine* if to be used for the warp. The tram, being less exposed to friction and to rough handling during the weaving, is less strong than the organzine; it has a smaller number of raw silk threads, and is given less twist in the throwing than is the case with organzine.

Boiling and Dyeing.—Combined with the silk is always present a certain amount of gum, which to some extent impairs its brilliancy. This can be eliminated by boiling the silk with soap, the operation being called "boiling off." Boiled silk is as near as possible the purest silk obtainable for commercial purposes. The loss in weight caused by the boiling may be as high as 25 per cent., but there is a proportionate gain in the brilliancy of the fiber. Boiled silk is used in the richer tissues, in which great luster has to be combined with strength and softness of the fiber. For some tissues only a partial boiling is necessary, while for others all the original stiffness of the fiber is required. The operation of boiling usually precedes the dyeing. The dyeing of silk is a very delicate operation, and while the desired shade has to be produced on the fiber, this must not lose its brilliancy. Silk takes the dye as easily as wool, and more readily than any of the vegetable fibers. Silk can also be bleached by being exposed to the action of sulphur fumes. The loss in weight which silk sustains through the boiling can be regained in the operation of dyeing. The dyer can even increase the weight of the silk by what is called loading, but the increase in weight is often obtained at the expense of the strength of the fiber. This operation is based on the property possessed by silk of absorbing and retaining other substances. The substances available are white sugar, tannic acid, compounds of tin, lead, iron, and other metals. The excessive loading of silk is intended to deceive the consumer, and such addition is extensively made to black silks, the *charge* sometimes more than doubling the weight. Silk that is not loaded is commonly known as pure dye. The silk is usually dyed in the skeins before being woven. The tissues can be dyed after they have been woven, but usually only the lower-priced and lighter tissues are so treated. The operation is called piece-dyeing, as distinguished from skein or yarn dyeing.

Fabrics of Silk.—The natural qualities of silk make it possible to obtain with this fiber greater diversification in the tissues that can be woven with it than is the case with any other fiber. The weaving is preceded by the operations of winding, spooling, warping, etc., which make the yarn ready for the loom. Improvements in machinery have made it possible to weave almost any fabrics on power-looms, and the greater proportion of the silk tissues now produced are so woven, although some of the richer fabrics require so much care that they can be produced only on hand-looms. In the U. S. the looms are nearly all driven by power, but in Europe there are still many hand-looms. Tissues can be classified into two distinct families. Plain tissues are in one color only, and show no elaborate pattern, the variety in them being obtained by the different arrangement of the warp and filling threads as regards each other. Fancy tissues include all those in the making of which enter more than one color, all figured tissues that show a design. When one color is used for the warp and another for the filling in a plain tissue, the two colors combine, producing a peculiar effect of reflex, known as changeable (French, *glacé*). Plain silk cloth can be embossed, producing figures in relief; for this purpose only the lighter silk tissues are used. Another peculiar effect that can be produced on silk fabrics, and which is commonly called *moiré*, is obtained by exerting strong pressure on the surface of a grained silk fabric (gros-grain) which becomes flattened at certain spots, producing a design. In the weaving of tissues various kinds of raw silk are employed, according to the cloth that has to be woven. The sort of warp that is used for some fabrics is not suitable for others, and the number of twists per yard of length which have to be given to the organzine also varies. In the tissues produced the weave varies according to the position of the single warp and filling threads relatively to each other. Satin has a smooth surface, formed by well-twisted warp threads. Taffeta is relatively light tissue, plainly woven. Pongee is still lighter, and was first imported from China; it is woven in the U. S. and Europe in several varieties, known under different names. The Japanese export large quantities of light silk fabrics, which are known as habutai and kaiki. Grained surfaces are represented by gros-grain and other tissues. A good gros-grain has to be carefully woven to insure the regularity of the grain. Surah represents the twilled weaves. Ribbed fabrics are also plentiful in silk goods, and are known under various names, according to the thickness of the ribs. Tulle, gauze, grenadine, and veil are transparent fabrics, the weaving of which requires special care, and the threads for which have to be specially thrown, as some of these require thread more twisted than is the case with other goods. Under the name of armures are known fancy weaves, which show a special effect or design, usually very small, and formed by the threads themselves without the aid of a change in color. Damask, brocade, and damassé are figured fabrics in which a design is produced while they are being woven. Silk can be woven alone and in combination with other fibers. Good wearable tissues are obtained by weaving together silk and wool. Some dress fabrics are made with silk warp and wool filling. Others have wool warp and silk filling. The principal representative of these is bengaline, which is a silk and wool poplin. To the bengaline family also belong crystal weaves, being large fancy ribbed goods in silk and wool mixtures. Other silk and wool mixtures, known under the names of Ottoman and others, show more or less large ribs, and are principally used for cloaking purposes. Silk is also much used in combination with cotton for making cheaper goods, which are used for linings, for umbrellas, and other purposes. The cheaper satins are made of silk and cotton, and are known as cotton-back satins (the silk showing on the satin face, the cotton on the back) to distinguish them from the all-silk satins.

After the tissues have been woven they have to be "finished." This is usually done in separate establishments, and is the final operation of manufacture. The finisher passes the tissues over rollers. Some tissues have to be "sized," a pasty or starchy substance being added in the finishing process, which is sprinkled over or otherwise transferred on the tissues while they travel on the rollers.

Silk-printing.—Silks are printed—a colored design is produced on them—by means of engraved rollers. The cloth travels in a continuous strand, and as it passes under each engraved roller it receives the impression for one color of which the design is composed. There are two different systems of printing. In the chemical process the pieces are treated as if they were to be dyed in one color, except that care is taken to prevent the fixation of the color on certain points; on these portions, either at once or in the later handling, other colors appear, thus forming the design. The other process, which may be called the mechanical, consists in transferring every color, ready prepared, and in the form in which the fiber will take it, on the surface of the cloth by means of the rollers. The printing is done on a machine which can give as many different colors as it has engraved rollers, some machines having as many as twelve rollers. In Europe some printing is done by hand with the old-fashioned blocks, but hand-printing is, as a rule, only resorted to for the more delicate and elaborate designs. Lyons, France, has been for a long time the center of the silk-printing industry. Since about 1880 silk-printing has become an important branch of the silk industry of the U. S.

Sewing-silk and Machine Twist.—The invention of the sewing-machine called for the manufacture of a special kind of sewing-silk. This is called machine twist. The making of sewing-silk may be called a continuation of the process of throwing. This branch of the industry was the first to be established in the U. S., where it has reached its full development, importations being very small and insignificant.

The *principal silk-manufacturing countries* are France, with a product having a value of about $100,000,000 per annum, and the U. S., with a product valued at about $80,000,000 per annum. Switzerland and Germany follow with products exceeding $20,000,000 per annum. Great Britain has an important silk-manufacturing industry, which, however, has made little progress since 1860. It is the largest importer of silk-manufactures, purchasing over $50,000,000 worth yearly, and exporting only a comparatively small amount. The U. S. imports over $30,000,000 worth per annum, and exports very little. With its large home production, the U. S. is now the largest consumer of manufactured silks. France, Switzerland, and Germany, on the other hand, export more than they import. Italy has made good progress since 1870, but has more importance as a producer of raw silk than of silk-manufactures. Japan has made great progress since 1880 as a silk-manufacturing country, and in 1899 exported over 21,000,000 yens' worth of goods.

History.—After wool and linen, silk seems to have been, in the remote East, one of the earliest of textile industries. The Chinese records agree that Hwang-Ti, Emperor of China, charged his first or principal wife or queen, Si-Ling-Chi, to examine some silkworms and test the practicability of using the thread from the cocoons. In her zeal she collected large numbers of the worms, fed them herself, and discovered not only the means of rearing them, but also the method of reeling the silk and of employing it to make garments. The period when this beneficent discovery was made is left as vague as the rest of the Chinese chronology, and European writers have differed in regard to the date all the way between 2700 B. C. and 1700 B. C. Other particulars in the long and useful reign of Hwang-Ti render it probable that he ruled over China during the greater part of the century 1800 to 1700 B. C. The Chinese say that Si-Ling-Chi was deified for this meritorious act, and that she has ever since received divine honors under the name of "the goddess of silkworms." The wild silkworms—or at least some of the numerous genera and species of the *Bombycidæ*—were found in great numbers in other countries of Southern or Eastern Asia; they inhabited the jungles of India, Pegu, Siam, and Cochin-China; but for many centuries the only use made of their cocoons was by carding and spinning the silk, very much as spun silk is now produced. Meanwhile the Chinese kept their methods of rearing silkworms and reeling silk a profound secret for nearly 2,000 years. During this period silk-culture had made a little progress westward; some of the nations of Central Asia who were under the sway of the Chinese were rearing silkworms under rather rigid restrictions; and Persia was for nearly 1,000 years the common carrier of silk between China and the West, without knowing how silk was made. Aristotle was the first European to learn the true origin of the wrought silk brought to him from Persia on the return of the victorious army of Alexander. He described the silkworm as a horned insect, passing through successive transformations, and producing *bombykia*, the name he gave to the silk. The prevalent theory of the origin of silk among the Greeks and Romans for at least 500 years after this time is given with all seriousness by Ammianus Marcellinus, in the first century after the Christian era, in the passage in which he represents the *Seres*, or silk-growers, as "a sedate and gentle people, passing their happy days in the most perfect tranquillity and delightful leisure, amid shady groves, fanned by gentle breezes; these groves produce fleeces of downy wool which, after being sprinkled with water, is combed off in the finest threads and woven into *sericum*" (the Latin name of silk). Vergil also says in reference to silk, "Velleraque ut foliis depectant tenuia Seres" (The Seres comb the delicate fleeces from the leaves). Probably both writers had confounded the gathering of the silk-cotton from the silk-cotton tree (*Bombax*) of the East with the production of silk.

Silk-culture in Europe.—In Aristotle's time Pamphila and her associates in the island of Cos (or possibly Ceos, the modern *Zea* in the Ægean Sea) had imported silk goods, or possibly raw silk, from Persia, and, unraveling it, had woven from the single and delicate threads a silken gauze, which from its transparency received the name of "woven wind." Her example was followed somewhat later by the Roman ladies, who used the silk only for the warp of these delicate tissues, while the weft or filling was of fine threads of linen or cotton. The Phœnicians of Tyre, Sidon, and Berytus also procured raw silk from the Persians, and wove silk goods for Corinth and Rome. The latter city under the emperors indulged freely in the costly luxury of silk attire. It became the favorite dress of both sexes, and sumptuary laws were passed to restrict its use to women, and to the wealthy among these, under the reigns of Tiberius, Vespasian, and Diocletian. Silk in its raw state was still imported through the Persians, and continued to be till the time of Justinian in the sixth century of the Christian era. That emperor, having engaged in war with Persia, found his supply of silk cut off and the manufacturers in great distress. Two Nestorian monks then arrived at Byzantium from China, bringing with them the seeds of the mulberry, and communicated to him their discovery of the mode of rearing silkworms. The exportation of the eggs of the silkworm or of the unreeled cocoons from China was at this time forbidden under the pain of death; but, stimulated by the persuasions and liberal promises of Justinian, the two monks returned to China, and in 555 came back, by way of Persia and Bokhara, to Byzantium, bringing with them a quantity of silkworm eggs concealed in the hollows of their pilgrims' staves. From this small beginning the culture of silk spread rapidly over Greece and Syria. It was introduced into Spain and Portugal in 711 by the Saracens, into Sicily and Naples in the twelfth century, and probably in the thirteenth into Genoa and Venice. It was not generally extended throughout Italy and Piedmont till the sixteenth century. It did not take root in France till the latter part of the sixteenth century and the beginning of the seventeenth, but during the latter century it made great progress there, as well as in Belgium and Switzerland. The manufacture of silk had begun earlier in France and Germany, and to some extent in England. It is worthy of notice that from the sixth to the seventeenth century the choicest silks, under the names of *samite* (*examitum*, or six-threaded), *cendal*, *siglatoun* or *cyclatoun*, *dysaspres* or *diaper*, *escaraments*, *bauderquin* or *baldaquin*, and cloth of gold, were woven first for the churches and cathedrals and for the hierarchy of the Church, next for kings and emperors, and finally for the higher nobility and the wealthier knights of the age of chivalry. Up to the close of the twelfth century silks—some of them with raised woven figures of Oriental patterns, but the best embroidered by hand with years of labor—were brought first from the East, from Persia and China, and later from Greece, where the art of weaving and embroidering these rich textiles was kept secret; still later from Spain, where the Saracens had introduced these arts; and from about the middle of the twelfth century from Sicily, where the Saracens had at first transported their skill

from Spain, but were superseded by Greek silk-weavers whom Roger, King of Sicily, had brought as captives from Corinth, Thebes, and Athens to his own island. Some of these early silks surpass in beauty any of the productions of the manufacturers of modern times. In another hundred years the manufacture of silk had extended to Lucca, and thence, about sixty years later, to Venice, Florence, Milan, Genoa, and Bologna. The manufacture of silk goods was brought from Lucca to Lyons probably as early as the fifteenth century, but it made little progress until silk-culture and the production of the cocoons and raw silk were established at the beginning of the seventeenth century. In England the manufacture had made a little progress in the fifteenth and sixteenth centuries, but all attempts at silk-culture had failed. In Austria, Germany, Switzerland, and the Netherlands there were manufactories of silk, but very little silk was grown.

In America.—The first attempts to introduce silk-culture into America were made very early. James I. having been foiled in his efforts to establish the rearing of silkworms in England, and having learned that the climate of Virginia was favorable for silk-culture, sent over, in 1622, silkworm eggs, white mulberry-trees, and some printed instructions. Large bounties were offered for the production of raw silk, and fines were imposed on every planter who failed to plant a certain number of mulberry-trees, but the enterprise was neglected by the company and thrown upon the planters before it was fully established, and hence failed. Some silk was exported to England for several years, but after a time the attention of the planters was turned wholly to tobacco. At the time when the colonies of Georgia and the Carolinas were founded, the effort was made to revive the culture of silk there, and under vigorous protection and encouragement from England it was for a period of perhaps twenty-five or thirty years very successful. The first shipment of silk from Georgia consisted of 8 lb., and was made in 1735. From this small beginning there was a steady increase to 1759 or 1760. After 1760 the culture of silk declined; probably the next year's yield was not more than $80,000.

The culture was not attempted in Connecticut till about 1760, but it was carried on there more persistently and extensively than anywhere else in North America. For many years the silk produced in Connecticut amounted to $100,000 or $200,000 per annum, but was seldom exported, being mostly made up into sewing-silk and into woven fabrics by home manufacture. The rearing of silkworms was also attempted with some success from 1869 to 1875 in Pennsylvania, New Jersey, New York, Rhode Island, and Massachusetts. In most of these States it had been given up during the Revolutionary war, and was not revived again till about 1825 or 1826. New machinery for reeling, throwing, and weaving silk was invented and put into operation; and as the supply of American-grown silk was not sufficient to meet the demand, a moderate quantity was imported. But the imports of manufactured silks continued to increase. The history of silk-culture in the U. S. has been one of ceaseless efforts toward a goal that has not yet been reached. Silk-manufacture, however, has developed into a staple industry. In 1830 an effort was made to introduce the so-called Chinese mulberry (*Morus multicaulis*) in the place of the white mulberry (*Morus alba*) on which the silkworms had been fed hitherto. Speculation came in and in 1839 twigs of the *Morus multicaulis* less than 2 feet in length and of the size of a pipe-stem were sold for $2, $3, or $5. In the autumn of 1839 the bubble burst, ruining thousands. In 1844 a severe winter destroyed most of the trees, and blighted in the Northern States generally the white mulberry; and for the second time the rearing of silkworms was practically abandoned in the U. S.

Yet great good resulted, in the end, from this apparent disaster. The men who had devoted so much attention to silk-culture, finding the rearing of silkworms unprofitable, turned their energies to the manufacture of silk. From the beginning of the nineteenth century there had been some importation of raw silk, mostly for the fringe and dress-trimming manufacturers, and to some extent also for exportation; in some years it had amounted to $100,000, $200,000, and in one year to $600,000. As yet there was little done save in sewing-silks, dress-trimmings, and a few styles of ribbons; but in the next decade (1850–60) the demand for sewing-machine silk and twist began to increase, and by this time it was found that the best brands of American sewing-silks fulfilled all requirements in quality, evenness, strength, and color. Pongees, Japanese silks, and other mixed goods were made of as good quality as the imported; handkerchiefs, ribbons, and a few pieces of broad goods were put upon the markets, and were creating a demand for more. After years of experiment the spun silks made from silk waste, pierced cocoons, etc., were coming into use, and greatly reducing the cost of those goods of which they could form a part. As yet (in 1860) American silk-manufacturers had received no protection or aid from the Government; but in 1861 the exigencies required the raising of a large revenue, and a duty of 40 per cent. *ad valorem*, which was afterward raised to 60 per cent., was imposed on manufactured silk, while raw silk was admitted free. In 1840 some machinery was taken from Connecticut to Paterson, and gave rise to an industry that has been steadily growing and has caused Paterson to be called the Lyons of America, since it is the principal silk-manufacturing center in the U. S.

In the U. S. nearly everything that is known in the line of silk-manufactures can be produced, although foreign goods find a market either on account of their novelty, as Europe retains the supremacy in designing and in fashion, or because the lower wages paid in other countries enable foreign manufacturers to sell some lines of goods cheaper than they can be produced in the U. S., notwithstanding the import duty.

SILK INDUSTRY IN THE U. S., CENSUS OF 1890.

STATES.	Establishments.	Capital.	Average number of hands employed.	Wages paid during the year.	Net value of finished goods.
California	9	$112,283	214	$83,566	$266,312
Connecticut	35	9,037,042	5,081	2,006,804	8,123,561
Illinois	10	422,096	805	295,636	785,845
Maryland	4	50,400	75	24,233	100,361
Massachusetts	20	3,353,296	3,216	1,296,399	4,611,959
New Jersey	132	16,809,927	17,917	7,176,180	25,405,982
New York	185	11,165,918	13,151	5,584,399	17,736,315
Ohio	3	37,830	40	13,685	33,927
Pennsylvania	66	9,362,063	9,522	2,981,334	11,404,223
Rhode Island	3	122,256	194	61,978	135,000
All other States	5	534,426	698	156,104	551,114
Totals	472	$51,007,537	50,913	$19,680,318	$69,154,599

The values of the principal items in the production, as given in the census of 1890, are: Ribbons, $17,081,447; dress goods, figured and plain, $15,183,134; machine twist and sewing-silk, $7,068,213; upholstery goods, $7,630,536; dress and cloak trimmings, $4,403,757; tailors' linings, $3,011,437; other broad goods, $1,928,036; handkerchiefs, $1,913,224; fringe, knitting, embroidery, and floss silk, $1,849,631; hosiery and knit goods. $1,150,172; velvets and plushes, $3,141,026; braids and bindings, $2,771,382; tie silks and scarfs, $919,919; laces, $261,750; military trimmings, $232,600; other goods, $602,330.

To meet the requirements of the increasing production of silk-manufactures the imports of raw silk in the U. S. have been increasing steadily. This progression is shown by the following table, giving the imports of raw silk in fiscal years:

YEAR.	Pounds.	Value.
1843	17,898	$53,350
1850	* 120,010	401,385
1860	* 297,877	1,340,676
1870	583,589	3,017,958
1880	2,562,236	12,024,699
1885	3,424,076	12,421,739
1890	5,943,366	23,285,099

* Estimated from current prices.

Artificial Silk.—In 1888 public attention was called to a chemically prepared substance called artificial silk. This is a pure cellulose obtained by treating wood-pulp, cotton, or other fibers with acids; run through a fine funnel it can be formed into a filament that is almost as fine as silk, possesses all its brilliancy, and can be dyed very readily; it is, however, easily set on fire. F. Sansone.

Silk-cotton: the cottony down of many malvaceous trees of Africa, India, and South America, of the genera *Bombax*, *Eriodendron*, *Chorisia*, etc. *Eriodendron anfractuosum* is the common silk-cotton tree of the West Indies. The trees are mostly very large, with very soft wood.

Silk, Vegetable: See Fiber.

Silkweed, or Milkweed: a plant of the genus Asclepias (*q. v.*).

Silkworm: the silk-producing larva of a bombycid moth. The silkworm proper, *Bombyx mori*, feeds upon the mulberry, and was originally derived from the northern or mountainous provinces of China, though the wild worm has not been rediscovered. The moth is white, with the fore wings falcate, and the hinder pair not reaching the tip of the abdomen, and antennæ well pectinated. The caterpillar is hairy when hatched, with a large head. When fully fed it is naked, not very thick-bodied, cylindrical, with a tubercle on the second thoracic ring and a long horn on the tail. It is 3½ inches long, and of an ashy or cream color. In almost every batch of worms raised in India there will be seen, after the first moult has occurred, some dark-colored worms, which at first glance appear to be a distinct species, but they are actually types of the original species. The silkworm is an annual, though some allied species yield two or three broods in the warmer parts of India. It moults four times, but occasionally only three times. The eggs are about the size of mustard-seeds, and the larvæ of the first age are one or two lines long, and of a dark color. In five days begins the second stage. In the third stage the worm is naked, whitish, and lives six days before attaining the fourth. The fifth stage is the longest, lasting nine days; and at this time the worm is very voracious. It then ceases to eat, and in about thirty-six days after hatching it begins to make its cocoon, which is spun from the large silk-glands opening in the under lip (labium). See SILK.

In the rearing of the silkworm the work-room should be well ventilated and warmed, with racks containing frames from 1 to 1¾ yards in breadth, with a border to prevent the worms from falling, and lined with paper on the bottom. The eggs laid before the end of winter are hung up in woolen cloths in a cool, dry place exposed to the N. As soon as the buds of the mulberry-tree begin to unfold the eggs are spread out on sheets of paper in very thin layers, placed for three or four days on a table in a room having a southern aspect, but out of the direct rays of the sun. The temperature of the room is gradually raised to 25° C., and maintained till all the eggs are hatched. The larvæ are fed six to eight times a day on chopped leaves. The worms are removed to new food by nets placed upon the old food, the worms ascending through the meshes to the fresh leaves placed above. When fully fed the worms ascend into sprigs of heather placed at intervals on the tables. Here they spin their cocoons, some of which are white, producing the best silk, while most of them are yellow. See the illustration given in the article ENTOMOLOGY.

Of the diseases which affect the silkworm, muscardine was until lately the most prevalent, the losses in France being estimated at one-sixth of the profits. When affected, the worm changes to a duller white, its movements are slower, it becomes soft, and soon dies. Seven or eight days after death it turns hard and reddish, and in a day after the whole body becomes floury. The disease was found by Bassi, an Italian, to be due to the attacks of a fungus, *Botrytis bassiana*. But still more destructive is the disease called *pebrine*, in allusion to the dark spots peppering (whence the term *poivrine*, *pebrine*) the skin of the worm. This disease was probably unknown before 1842. Quatrefages believes that the disease is not a new one, but was confounded with muscardine; he compares it with the Asiatic cholera, and states that it is an hereditary epidemic, and that it may become accidentally contagious and infectious. It originates from the presence of exceedingly minute corpuscles, probably a parasitic fungus, which multiply by self-division and infest the tissues and viscera of the larva, pupa, and adult, as well as the scales of the latter. The disease first showed itself in France, and spread eastward until it reached China, and, in 1865, Japan. It was also a little later introduced into the establishment of Prof. Trouvelot, at East Medford, Mass., and carried off from $5,000 to $10,000 worth of worms of *Telea polyphemus*, the silkworm which he then had under domestication. Pebrine differs from muscardine in being hereditary. Another disease is called *flacherie*, where the worms become enfeebled by the fermentation of the food in the stomach, resulting in the development of vibrios or fermentation-fungi. This disease is also hereditary, but, like muscardine, more or less accidental, and not an epizoötic, as pebrine is, and does not affect the eggs.

Alarmed by the fearful ravages of pebrine, silk-raisers turned their attention to the importation of other silkworms. Of these the tussah and arrinda moths are the most manageable and promising. The tussah moth (*Antheræa mylitta*) has a closed cocoon, spun from an unbroken thread. It is semi-domesticated in India, and the silk is an article of commerce. It spins a hard, most durable silk of a dark-brownish color. While the tussah moth can not be reared in Europe, the related yama-mai (*Antheræa yama-mai*) of Japan, does well in France in the open air.

The AILANTUS SILKWORM (*q. v.*) can be reared in Europe and the U. S., and is double-brooded. Though the cocoon is open at one end, the thread with care can be unwound; in one case an unbroken thread 800 yards long was unreeled. The silk, however, like that of the tussah moth, is coarse, ill-colored, and can not be placed in competition with the most inferior mulberry silk.

A similar article is furnished by the American silkworm (*Telea polyphemus*). The thread is coarser than that of the *Bombyx mori*, but has a rich gloss, and can be used very extensively in commerce. The thread of which the closed cocoon is spun is unbroken, and can be readily unwound. Its larva feeds on the oak, and is thick, fleshy, striped obliquely with white on the sides, with angulated segments, on which are tubercles giving rise to a few short hairs. The pupa is very thick, and the cocoon is regularly oval-cylindrical. The moths leave the cocoons late in May, appearing until the middle of June. They then lay their eggs, generally singly, on the under side of the leaves. In ten or twelve days the caterpillars hatch. The worm moults five times, the first four moults occurring at intervals of ten days, while about twenty days elapse between the fourth and fifth moults. It spins its cocoon late in September, and in six or eight days after beginning it assumes the pupa state, and in this condition passes the winter. A. S. PACKARD, Jr.

Sill, EDWARD ROWLAND: poet and scholar; b. at Windsor, Conn., Apr. 29, 1841. He graduated at Yale in 1861; taught school in Ohio; was principal of the high school at Oakland, Cal., 1871–74; Professor of English Literature in the University of California 1874–82, when he returned to Ohio. He was the author of *The Hermitage and Other Poems* (New York, 1867) and *The Venus of Milo and Other Poems* (1883). D. at Cleveland, O., Feb. 27, 1887. A selection of his *Poems* was published in 1888. H. A. B.

Sill, JOSHUA WOODROW: soldier; b. at Chillicothe, O., Dec. 6, 1831; graduated at the U. S. Military Academy July 1, 1853, and was appointed a second lieutenant in the ordnance corps. After a brief service at the Watervliet arsenal he was recalled to West Point, where he served until 1857 as Assistant Professor of Geography, History, and Ethics; subsequently in command of Vancouver ordnance dépôt, Washington, and Leavenworth dépôt, Kansas. In Jan., 1861, he resigned from the army, and became Professor of Mathematics and Civil Engineering in the Brooklyn Polytechnic Institute. On the outbreak of the civil war he was tendered the colonelcy of a New York regiment, and proceeded to Ohio, where he served as assistant adjutant-general of the State in organizing volunteers, and in the field at the battle of Rich Mountain. In Aug., 1861, he accepted the colonelcy of the Thirty-third Ohio Volunteers, and was engaged in the occupation of Bowling Green, Ky., and Nashville, Tenn., Feb., 1862, and in Gen. Mitchel's expedition to Huntsville, Ala., and seizure of the railroad from Stevenson to Decatur, thus regaining control of Northern Alabama; most of this time he was in command of a brigade. In July, 1862, he was commissioned brigadier-general of volunteers, and commanded a division in the Army of the Ohio at the battle of Perryville, Oct. 8, and subsequent pursuit of the Confederate army. In the battle of Murfreesboro, Dec. 31, 1862, he was killed at the head of his brigade.

Revised by JAMES MERCUR.

Silliman, BENJAMIN, M. D., LL. D.: chemist; b. at North Stratford (now Trumbull), Conn., Aug. 8, 1779; son of Gold Selleck Silliman (1730–90), a lawyer and colonel of Connecticut cavalry during the Revolution; graduated at Yale College 1796; was a tutor there 1799–1802, studying law in the meantime; was admitted to the bar 1802, and in the same year chosen Professor of Chemistry in Yale College; spent a part of the years 1802–04 at Philadelphia, preparing for his professorship under the guidance of Dr. James Woodhouse, of the University of Pennsylvania; gave his first full course of lectures on chemistry at Yale in the winter of 1804–05; spent fourteen months in England, Scotland, and Holland 1805–06, engaged in the prosecution of his studies; made a geological survey of a part of Connecticut, the first exploration of the kind in America; published a memoir, with an analysis, of the fragments of the celebrated Weston meteorite of Dec. 14, 1807; aided Dr. Robert Hare in his ex-

periments with the compound blowpipe, with which instrument he demonstrated the fusibility of several bodies never before fused; secured for Yale College the valuable mineralogical and geological cabinet of Col. George Gibbs 1812; founded in 1818 *The American Journal of Science and Arts*, of which he was sole editor until 1838, and senior editor, along with his son, 1838–46; was the first to notice and record the effect of a powerful battery in volatilizing carbon and transferring it from the positive to the negative pole in the state of vapor; was an eloquent lecturer in scientific topics before popular audiences, having been perhaps the first to give such courses in the principal cities of the U. S.; made a second visit to Europe 1851; resigned his professorship 1853, and was made professor emeritus, but at the request of his colleagues continued to lecture on geology until June, 1855, when he retired from active labors. D. at New Haven, Nov. 24, 1864. He was the author of *Journal of Travels in England* (New York, 2 vols., 1810; 2d ed. New Haven, 3 vols., 1820); *Elements of Chemistry* (1830); *A Narrative of a Visit to Europe* (2 vols., 1853); and several minor publications; he also edited Henry's *Chemistry* (1814) and Bakewell's *Introduction to Geology* (1829). An interesting *Life* was prepared from his MS. reminiscences, diaries, and correspondence, by Prof. G. P. Fisher (2 vols., New York, 1866).

Silliman, Benjamin, M. D., LL. D.: scientist; son of Benjamin Silliman, chemist; b. at New Haven, Conn., Dec. 4, 1816; graduated at Yale College 1837; became associate editor of Silliman's *Journal of Science* 1838, and associate proprietor (with Prof. James D. Dana) 1846; was an instructor in chemistry, mineralogy, and geology in Yale College 1838–46; became Professor of Applied Chemistry 1846, and successor to his father in the chair of Chemistry 1854, which position he held in the medical department till his death. In 1847, in connection with Prof. John P. Norton, he established the Yale Scientific School, which has since grown into the Sheffield Scientific School. He was also Professor of Medical Chemistry and Toxicology in the University of Louisville, Ky., 1849–54; visited Europe with his father in 1851; was a director in the departments of chemistry, mineralogy, and geology in the Crystal Palace world's fair at New York 1853, and prepared (with Charles R. Goodrich) *World of Science, Art, and Industry* (New York, 1853) and *Progress of Science and Mechanism* (1854), in which the results of the exhibition were recorded; was for many years secretary of the American Association for the Advancement of Science, in which capacity he edited the volumes of *Proceedings*: wrote *First Principles of Chemistry* (1846: revised ed. 1856); *Principles of Physics* (1858; revised ed. 1868); and *American Contributions to Chemistry* (1875); contributed many papers to scientific societies, besides the large number published in his own *Journal*; was a popular lecturer on scientific subjects. D. at New Haven, Jan. 14, 1885.

Silo: See Ensilage.

Silo'am [= Lat. = Gr. Σιλωάμ, from Heb. *Shilo'ah*, liter., a sending (of water), aqueduct: Arab. *Silwan*]: (1) a fountain and pool in Jerusalem, on the southern edge of Ophel, 1,708 feet S. S. W. of the Fountain of the Virgin, with which it is connected by a winding tunnel. The fountain proper, hewn out of solid rock, is about 6 feet wide. Like the Fountain of the Virgin, it is intermittent. The lower basin is 52 feet long, 18 broad, and 19 deep, but now holding only 3 or 4 feet of water. It was once arched over. Jewish writers say it furnished the water used in sacrifice on the last great day of the Feast of Tabernacles. Jesus alludes to the practice of sending a Levite with a golden pitcher to get it (John vii. 37–39). This most famous of all the pools in or about Jerusalem is mentioned only three times in the Bible (Isa. viii. 6; Neh. iii. 15; John ix. 7), but frequently by Josephus. In the tunnel alluded to, cut in the solid rock, there was discovered in the summer of 1880 a Hebrew inscription. Prof. A. H. Sayce made the first intelligible copy (Feb., 1881). It is thus translated by Canon S. R. Driver: "Behold the piercing through! And this was the manner of the piercing through: Whilst yet the miners were lifting up the pick, each towards his fellow, and whilst yet there were 3 cubits to be cut through, there was heard the voice of each calling to his fellow, for there was a fissure in the rock on the right hand. And on the day of the piercing thus the miners smote each so as to meet his fellow, pick against pick; and there flowed the water from the source to the pool, 1,200 cubits, and 100 cubits was the height of the rock over the head of the miners." (*Heb. Text of the Books of Samuel*, p. xvi.) This inscription is proof that the excavation was begun at each end, probably simultaneously. The inscription is undated, but the shape of the letters apparently shows that it dates from at least Hezekiah's time; and it is certainly one of the oldest known Hebrew inscriptions. 2 Kings xx. 20, 2 Chron. xxxii. 30 may allude to the excavation. See the discussion by A. H. Sayce in *Records of the Past*, new series. i., 168, *seq.*, and S. R. Driver, *l. c.*, pp. xiv., *seq.* In 1889 a second conduit, some 20 feet below the ground, was discovered leading from the Pool of Siloam to another reservoir which once existed below. To it Isa. viii. 6 is supposed to refer. It was to Siloam that Jesus once sent a blind man to wash (Luke iv. 18). (2) The name of a little straggling, dirty village occupying an old quarry on the east side of the Kedron, overlooking the Pool of Siloam.

Samuel Macauley Jackson.

Sil'phium [Mod. Lat., from Lat. *sil'phium* = Gr. σίλφιον, an umbelliferous resin-bearing plant, perhaps the asafœtida]: a genus of perennial plants of the family *Compositæ*, comprising twenty species, many of which are found in abundance in the U. S. on the prairies and in the Southern States, also in other parts of North America. They are very hardy and coarse, bear large flower-heads, and exude a plentiful resin-like juice, whence the commonest species (*S. laciniatum*) has received the name of rosin-weed. The stem sometimes exceeds 10 feet in height. Both the resin and the leaves are much employed by farriers for asthma in horses, and a tincture has sometimes been found useful as a tonic and diaphoretic. This species is known by the names of Compass-plant (*q. v.*), pilot-weed, and polar-plant, from the fact that its leaves have a tendency to stand with one surface facing the E. and the other the W.; the plane of the leaf, which is usually vertical, is thus N. and S. The prairie burdock (*S. terebinthinaceum*) and the singular cup-plant (*S. perfoliatum*) belong to this genus. Revised by Charles E. Bessey.

Compass-plant (much reduced).

Silu'rian Period [*Silurian* is from Lat. *Si'lures*, name of a people in ancient Britain]: the division of geologic time preceded by the Cambrian period and followed by the Devonian. The name was first applied by Murchison to a rock series occurring in England and Wales in a district formerly occupied by the Silures. In the original description of Silurian and Cambrian rocks a large series was included under both designations, and a long dispute followed. Partly as a means of settling this dispute, but also on paleontologic grounds, the name Ordovician was proposed by Lapworth as the name of a period between the Silurian and Cambrian, and this proposition has received much favor; but the prevailing usage in Great Britain and North America refers the disputed series to the Silurian period, constituting it a minor division under the title Lower Silurian. The Silurian rocks of the U. S. are well developed in the basin of Lake Ontario and in the Champlain-Hudson valley, extending thence southwestward along the Appalachian chain through Pennsylvania, Maryland, Virginia, Tennessee, and Georgia into Alabama. In New England are several outlying areas, in which the rocks are metamorphic. In Ohio, Indiana, Kentucky, and Tennessee are broad areas laid bare by the erosion of the crest of the Cincinnati arch, and a still greater area follows the western coast of Lake Michigan and sends an arm up the Mississippi valley into Minnesota. Other areas are found in Missouri and Texas. The hydraulic cement and salt of New York and the fossil iron ores of the Appalachian chain from New York to Alabama, besides sandstones and limestones of architectural importance, are derived from formations of this period. See Cambrian Period and Geology, and for the flora of this period see Plants, Fossil, and consult Murchison's *Siluria* (1854); Lapworth's *Tripartite Classification of the Lower Paleozoic Rocks* (*Geol. Mag.*, vol. vi., 1879); Sedgwick's *Synopsis of the English Series of Stratified Rocks Inferior to the Old Red Sandstone* (*Proc. Geol. Soc.*, London, vol. ii., 1838).

G. K. Gilbert.

Silu'ridæ [Mod. Lat., named from *Silu'rus*, the typical genus, from Lat. *silu'rus* = Gr. *σίλουρος*, a kind of river-fish, perhaps the sheat]: an extensive family of fishes of the order *Nematognathi*, comprising the catfishes of Europe and North America. The skin is naked; the operculum developed; barbels, especially maxillary ones, well developed; gill-openings confluent below, the membrane being free at its posterior margin; the anterior vertebræ co-ossified and much modified; the inferior pharyngeal bones distinct. Most of the species live in fresh water, but some are found in warm seas. *Silurus glanis* is the sheat-fish found in the rivers of Central and Northern Europe. Among the North American species are the common catfishes or bullheads of the genus *Amiurus*, the stonecats of the genus *Noturus*, and the channel-cats of the genus *Ictalurus*.

Silva, Antonio José, da: dramatist; b. in Rio de Janeiro, Brazil, May 8, 1705. He went to Portugal when a child; was educated at Coimbra, and became a lawyer in Lisbon. He soon became known as the author of numerous comedies, which won great applause and are still regarded as among the finest in the Portuguese language. Silva's mother, who was of Jewish descent, was accused of Judaism, and was imprisoned by the Inquisition; later, suspicion fell on the poet and his wife, they were twice incarcerated, and finally all three were burned at Lisbon, Oct. 13, 1739. H. H. S.

Silva Lisbo'a, Balthazar, da: historian; b. in Bahia, Brazil, Jan. 6, 1761. He studied law at Coimbra, Portugal; held various judicial positions at Bahia and Rio de Janeiro, and in 1823 was imprisoned for a short time on account of his political utterances. His principal published work is *Annaes do Rio de Janeiro* (7 vols., 1834). D. in Rio de Janeiro, Aug. 14, 1840.—His brother, José da Silva Lisboa (b. in Bahia, July 16, 1756; d. in Rio de Janeiro, Aug. 20, 1835), was a well-known statesman, leader of the imperialists in the Brazilian parliament, senator from 1826, and the author of numerous works on history and political economy. He was created viscount of Cayrú in 1830. H. H. S.

Silver [O. Eng. *seolfor*, *seolubr*: Germ. *silber* < O. H. Germ. *silbar*: Goth. *silubr*; source obscure. Lat. *argentum*, Gr. *ἄργυρος*, Sanskr. *rajata-* is another widespread name of the same metal]: one of the precious metals, known from remote ages, and much used for ornaments, household vessels, and for money. Among the alchemists it was known as *luna*. Its chemical symbol, Ag, is derived from the Latin name. It is the whitest of the metals, and takes a brilliant mirror-like polish. In hardness it is intermediate between gold and copper, and it is very malleable and ductile. It may be beaten into foil or leaves 0·00001 of an inch in thickness. A grain of the metal may be drawn out into a wire 400 feet in length. If repeatedly heated it becomes brittle. The specific gravity of silver ranges from 10·1 to 11·1, according to its condition and purity. Karsten found the gravity of fused silver to be 10·4382; G. Rose gives 10·57 for hammered silver, and 10·92 for precipitated silver. The metal fuses readily on charcoal before the blow-pipe or in a crucible in a forge or furnace. It expands forcibly upon cooling, and thus solid pieces will float in molten silver as ice floats in water. It may be vaporized by the burning lens or by the oxyhydrogen blowpipe or strong electrical currents. The vapors are white. When pure the molten metal absorbs from twenty to twenty-two times its bulk of oxygen, according to various authorities, but the presence of a small percentage of copper or lead greatly diminishes or prevents this absorption. The absorbed gas is given off at the moment of solidification, and with considerable force. If the surface of a globule or bar of silver has cooled while the interior is fluid, the expansion breaks the crust and more or less of the fused metal is projected through the cracks, and forms an arborescent growth generally known as sprouting, and, when it is projected with violence, as spitting. This mechanical projection of a portion of a globule of silver cooling upon a cupel is a frequent source of loss in assaying. The absorption of oxygen and the subsequent spitting may be prevented to a great extent by the use of charcoal powder upon the melted metal. Absorption of oxygen is also prevented by fusing it under a layer of salt. The use of niter in the crucible causes a large absorption of the gas. The vapor of water is decomposed by silver at a white heat, oxygen being absorbed and hydrogen liberated. Silver is a good conductor of heat and of electricity. It is capable of being welded, alloys freely with gold, copper, and several other metals, and crystallizes in forms of the monometric system, generally in octahedra.

Silver is abundantly distributed in nature, particularly among the metallic minerals. Malaguti and Durocher give a table of 122 assays, chiefly of metalliferous minerals exclusive of silver ores proper in most of which silver was found in traces or appreciable quantities. It exists in sea-water in the ratio of 1 milligramme to 100 kilogrammes. Assuming that there is 1 centigramme of silver per cubic meter of water, it has been calculated that the oceans contain not less than 2,000,000 tons of silver. The metal has been found in small quantity also in rock-salt in the mines of the department of Meurthe-et-Moselle, France. All native gold contains from ·016 to 16 per cent. of silver, but generally from 5 to 13 per cent.; California gold averages about 12 per cent. of silver. It occurs also nearly pure in masses and irregular grains, but it is not so generally distributed in this form as gold, and is seldom found in placers or alluvial deposits, being confined rather to the vicinity of the outcrops of veins. It is usually in irregular, ragged masses, or in thin sheets coating surfaces of the veinstone, or filiform, as if drawn out into wire. This wire-like form of silver is of frequent occurrence in the cavities of veins. The filaments sometimes reach the length of a foot or more, but are generally much curled up and interwoven or matted together, looking like bunches of hair or wool. Specimens of this description occur in the ore of the Rainbow lode, Walkerville, Montana, and in the Silver King mine, Pinal, Arizona. At Kongsberg, in Norway, the metal has been found massive and in large and perfect crystals, which retain their whiteness without tarnishing in a remarkable degree. One mass taken from these mines and preserved in the Royal Museum at Copenhagen weighs upward of 500 lb. Large amounts of native silver have been obtained in Mexico and South America. One mass in Peru is said to have weighed 800 lb. Large masses have been reported from the northern portion of the Mexican state of Sonora. It is not uncommon, though not in large masses, in the upper portions of the silver-bearing veins of the Western States and Territories of the U. S. It is found also in a vein upon Silver islet in Lake Superior, and associated with the native copper of the Keweenaw Point mines. Some of these specimens are remarkable for being completely joined to the copper, without any intermingling of the metals; half of a mass may be silver and the other half copper.

Specimens of silver when taken from mines are usually tarnished a dull brown, or even black, this color being caused generally by the presence of sulphurous vapors either from the constituents of the vein or the combustion of powder. Such vapors rapidly tarnish silver. Silverware and silver-plate are rapidly tarnished and turned black by the gases of bilge-water, and also by the tainted atmosphere about drains and vaults, and the sulphurous gases from burning coal. The peculiar whiteness of the Norwegian native specimens is supposed to be due to the presence of a portion of mercury. Native silver is rarely pure. The cupriferous variety sometimes contains 10 per cent. of copper. With gold the proportions are variable. (See Gold.) The *electrum* of Pliny contains one-fifth of silver. The pale gold of Transylvania contains from 35 to 38 per cent. of silver. The native alloy in the great Comstock lode of Nevada contains about 43 per cent. of silver, as shown by Attwood, the rest being gold. It is usual to estimate that of the $550,000,000 in value, in round numbers, produced from the lode $250,000,000, or a little less than half, was gold. Gold predominated at the surface, particularly at Gold Hill and Cedar Hill, at the two ends of the lode. Native amalgams have been found in Chili, containing from 52 to 64 per cent. of silver. The metal is also found combined with sulphur, antimony, arsenic, tellurium, etc., and with chlorine, bromine, and iodine, giving a great variety of interesting species. The chief ores are the sulphide, containing 86 per cent. of silver; the brittle or antimonial sulphide, with 68·5 per cent. of silver; gray silver ore, with 23 per cent. of silver; dark-red silver ore, with 60 per cent.; and the light-red silver ore, with 64 per cent. This last is generally known as ruby silver, from the brilliant ruby red of the crystals by transmitted light. In the upper portions of silver-bearing veins, where air and moisture have had access, a certain amount of decomposition has taken place among the minerals, especially if they consist of the above-mentioned species, and new combinations have been formed, which may be called secondary ores. These are generally oxides, chlorides, bromides, and iodides, and are more earthy and highly colored than those in the deeper parts of the vein, being intermingled with oxides of copper, lead, and iron. They are also softer than the un-

changed ores below, and are more easy to work. Such ores are known in Mexico as *colorados*, especially if red, and in Peru as *pacos*. The ores from a greater depth in the mine, which have not been acted upon by the air, are more compact, brilliant, and darker in color, and are called *negros*. The green bromide ores are known in Zacatecas, Mexico, as *plata verde*. Chloride of silver is common in the upper portions of rich silver-bearing veins, and usually forms thin dark-colored crusts or films upon the gangue. It is easily identified by its wax-like hardness, and by giving a globule of silver when fused in the flame of a candle.

A large class of the metallic minerals contain silver in varying proportions, especially galena and blende, which are rarely free from a portion of silver. The greater portion of the silver produced in Europe is extracted from argentiferous galena. The galenas of England and of the Hartz Mountains carry from ·03 to ·05 per cent., and those of Tuscany from ·03 to ·07 per cent. The galena ores of the U. S., with the exception of those of the Mississippi valley, nearly all contain silver in larger quantities, the percentage ranging from ·10 to 1·85 and 3·0, but the quantity of these rich ores is seldom large in the Eastern States. Some of the Wood river and Kootenay lead ores carry 100 oz. to the ton, but 30 to 60 oz. to the ton of lead ore is a very fair yield. Formerly lead ores containing less than 10 oz. could not be profitably worked for silver, but since the discovery by Pattinson, of England, in 1829 of the process which bears his name, the cost of separating silver from lead has been greatly cheapened. Lead containing only 3 oz. of silver to the ton can now be worked with profit, and in smelting operations on a large scale where lead ores are used as a flux even a small amount of contained silver is incidentally important.

The antiquity of silver coinage is very great. The most ancient coins known were struck in silver by Phidon, King of Ægina, B. C. 869. After the conquest of Egypt by Cambyses, about 540 years before Christ, a great improvement appears to have been made in the purification of silver, for that which was produced under Aryandes was celebrated for its purity and fineness. The alloy in the Greek silver coinage generally appears to have been lead, which had not been removed for want of the requisite skill in refining. The Athenian currency was noted for its purity, and Xenophon mentions the profit with which it could be exported. Silver currency was adopted by the Roman republic about 269 B. C., and its standard was as high as the Greek, but it rapidly fell. Under Vespasian the alloy was one-eighth, under the Antonines one-fourth, under Severus about one-half, after which there does not appear to have been a fixed standard. (*King.*) After the loss of Spain, from which the chief supply of silver was drawn, the silver currency vanished, and was replaced by *billon* denarii, having only one-fourth part of silver. According to Pliny, Antony alloyed denarii with iron, apparently to harden the coin. The denarii of Justinian and the Italian Goths weigh about 15 grains troy, and are the reputed direct antecedents of the Anglo-Saxon silver penny.

Silver was largely used by the Romans for household plate and table decoration. It was elegantly chased and embossed in the *repoussé* style by Grecian artists. The wealthy Romans vied with each other in possessing the most massive dishes. Of such dishes, weighing 100 lb. or more, there were 150 in Rome before the first civil war. Pliny cites the existence of one dish weighing 500 lb., with eight plates to match, weighing together 250 lb. The old chased plate of the Grecian artists was valued as a curiosity in Pliny's time. The ornamentation of silver, known as niello-work, originated in Egypt, and was revived and carried to great perfection by the Florentine silversmiths. Cellini gives a recipe for the fusible argentiferous compound used to fill the engraved design. This art was applied to the decoration of armor as early as the days of Homer. Agamemnon's breastplate was thus inlaid. In mediæval times massive plate was in great favor, and the chief form of investment for the noble-born and wealthy. Its extensive use for ecclesiastical decoration is also to be noted. In 1899 7,657,770 oz. of silver were sent out from the mints of the U. S. in the form of bars for industrial uses. The total annual consumption of silver in the industrial arts approximates $53,000,000 coining value, and is increasing.

In modern times solid silverware has been to a great extent replaced by nickeliferous alloys and britannia ware, covered with a layer of pure silver by the galvanoplastic method. Silver may, by this method, be deposited to any desired thickness, thus giving all the appearance of solid silver, and its utility for most purposes. The annual consumption of the metal for this purpose alone is very large. Silver thus deposited is pure, but solid silverware and silver coin contain a portion of alloy, generally copper. In the U. S. and in France the standard fineness is one-tenth of alloy, or 900 parts of silver and 100 of copper, the mixture being denominated ·900 fine. In Great Britain the standard is higher, being 925 of silver and 75 of copper, or ·925 fine. This is the fineness of "sterling silverware."

The value of silver relatively to other objects obviously depends upon two chief conditions—the demand and the supply. The demand is seriously affected by legislation, as, for example, by the demonetization of silver. The variations in the demand are sufficiently indicated by the preceding references to its use in historic times. The supply is also variable, and at times excessive. The production of silver in the large way, owing to its mode of occurrence and mineralization, is more dependent upon the use of mechanical power (steam or water) than upon the labor of men, and generally it requires a heavy plant and large capital. There may therefore be a large production of silver in sparsely populated regions and within a short period of time. With gold, however, the bulk of the product is derived from placers. It is so much more generally distributed in the earth that an unlimited number of men may be engaged together in its production. No expensive preparations or chemical operations are required to obtain gold in a merchantable form.

The value of silver relatively to gold has greatly changed within historic times, and it has been different in various countries. Commerce has tended to equalize this difference. King justly observes that in the ancient world silver was to the same extent the peculiar production of Europe that gold was of Asia. It follows naturally that the estimation of silver relatively to gold was higher in Asia than in Europe—a condition prevailing until within a recent period. Sir Isaac Newton in 1717 showed that the ratio in weight of equal values of the two metals, silver and gold, in China and Japan was as 9 : 1, while it was as 15 : 1 in Europe. Perhaps the earliest recorded ratio is found inscribed at Karnak, the tribute-lists of Thutmosis (1600 B. C.) giving 13·33 : 1. The same ratio is shown by cuneiform inscriptions on plates found in the foundations of Khorsabad and on ancient Persian coins. It was reported by Xenophon (400 B. C.) as the ratio in Asia. Toward the Christian era gold fell in value relatively to silver. As early as about 189 B. C. the Romans coincided with the Greeks in estimating the value of gold compared with silver as 10 : 1. Upon Cæsar's return to Rome gold became so abundant that the ratio for a time was as $7\frac{1}{2}$: 1. A century later the ratio was as $12\frac{1}{2}$: 1, where it remained for 150 years or more. When guineas were first coined in 1663 the value of fine gold compared with that of fine silver was rated in the English mint at about 14 : 1. In 1805 the ratio was nearly as 15 : 1, and in other countries gold was rated higher. In the Middle Ages the ratio varied from 9 : 1 to 12·8 : 1. At the date of the discovery of America the ratio was about 11·30 : 1, since which, up to the discovery of gold in California and Australia, it gradually rose to 15·83 : 1 in the year 1850. In 1870 and 1871 the average commercial ratio was 15·57 : 1, and in 1873 as 15·92 : 1, with a gradual increase to 26·49 : 1 in 1893, 32·56 : 1 in 1894, and 34·36 : 1 in 1899.

The annual production of gold and silver in the world, stated in kilogrammes, with the ratio of silver to gold by weight, is shown in the following table:

YEARS.	ANNUAL PRODUCT, KILOG.		Ratio of silver to gold, by weight.
	Gold.	Silver.	
1871 to 1875, mean	173,904	1,969,425	11·3
1876	165,956	2,323,779	14·0
1877	179,445	2,388,612	13·3
1878	185,847	2,551,364	13·7
1879	167,307	2,507,507	15·0
1880	163,515	2,479,998	15·2
1881	158,864	2,592,639	16·3
1882	148,475	2,769,065	18·6
1883	144,727	2,746,123	19·0
1884	153,193	2,788,727	18·2
1885	159,289	2,993,805	18·8
1886	159,741	2,902,471	18·2
1887	159,155	2,990,398	18·8
1888	159,809	3,385,606	21·2
1889	185,809	3,901,809	21·0
1890	181,256	4,180,532	23·1
1891	189,824	4,479,649	23·6
1892	196,234	4,945,237	25·1
1893	236,570	5,031,488	21·3

The lowest, highest, and average price of bar-silver in London per ounce, British standard, 0·925 fine, since the year 1871, and the equivalent value in U. S. gold coin taken at the average price are shown in the following table:

YEARS.	Lowest (pence).	Highest (pence).	Average (pence).	Average.
1871	60·188	61·000	60·500	$1·326
1872	59·250	61·125	60·313	1·322
1873	57·875	59·138	59·250	1·298
1874	57·250	59·500	58·313	1·278
1875	55·500	57·625	56·875	1·246
1876	46·750	58·500	52·750	1·156
1877	53·250	58·250	54·813	1·201
1878	49·500	55·250	52·563	1·152
1879	48·875	53·750	51·250	1·123
1880	51·625	52·875	52·250	1·145
1881	50·875	52·875	51·938	1·138
1882	50·000	53·375	51·813	1·136
1883	50·000	51·188	50·625	1·110
1884	49·500	51·375	50·750	1·113
1885	46·875	50·000	48·563	1·065
1886	42·000	47·000	45·375	0·995
1887	43·250	47·125	44·625	0·978
1888	41·625	44·563	42·875	0·940
1889	42·000	44·375	42·688	0·936
1890	43·625	54·625	47·750	1·046
1891	43·500	48·750	45·063	0·988
1892	37·875	43·750	39·813	0·876
1893	30·500	38·750	35·625	0·782
1894	27·000	29·916	28·875	0·635

The world's production has increased from 41,260,000 oz. in 1870 to 167,224,243 oz. in 1899. The production in the U. S. was approximately 12,375,360 oz. in 1870 and 54,764,500 oz. in 1899. The production for 1893 was more than 60,000,000 oz., the maximum for the U. S. See the reports of the director of the U. S. mint; Soetbeer's tables; *The Mineral Industry*, vol. ii.; and the annual circulars by W. J. Valentine, San Francisco, and by Pixley & Abell of London.

WILLIAM P. BLAKE.

Chemistry of Silver Compounds.—Silver forms a number of compounds of practical importance and scientific and technical interest.

Silver chloride, or *chloride of silver*, AgCl, is an important substance, which is found native as horn-silver. The insolubility of silver chloride causes its production, by adding a solution of a chloride, to be an excessively delicate test of the presence of silver in a solution. Gay-Lussac's volumetric method of silver-assay, in use in all U. S. mints, depends on the use of a standard solution of common salt to precipitate the silver as chloride. Silver chloride melts at about 500° F. to a clear liquid. On exposure to light and moisture it becomes darker. When any organic matter is present, as when the chloride is applied to paper, this action of light is far more powerful. Photographic methods are chiefly founded upon these kinds of changes of the halogen compounds of silver by light, the dark compound formed under the influence of the light being insoluble in hyposulphite of soda and other fixing agents, while the unchanged chloride, iodide, or bromide of silver remains soluble, and is therefore easily removed from the paper, leaving the picture, composed of the changed dark-colored compound, attached thereto. *Silver bromide*, or *bromide of silver*, AgBr, constitutes the mineral bromyrite or bromargyrite. It is found as an ore in Mexico and Chili, and at Huelgoat in Brittany. At some of the Chilian mines, as in Chanarcillo and in Copiapo, another silver mineral is much more abundant than either the chloride or bromide, which is a combination of the two in varying proportions, called embolite. *Silver iodide*, or *iodide of silver*, AgI, forms the mineral iodyrite, found in Mexico, Chili, Spain, and Arizona. It is sulphur-yellow when pure, and very soft and sectile. Bromide and iodide of silver, when precipitated, are much more sensitive to light than the chloride.

Silver nitrate, or *nitrate of silver*, $AgNO_3$, known also by its ancient name of *lunar caustic*, is manufactured on a large scale, owing to its important applications in medicine and in the arts of photography and electro-plating. It crystallizes very easily, and is largely introduced into commerce in crystalline form, though the lunar caustic for medicinal use is generally fused and cast into sticks or pencils. It is soluble in its own weight of cold water.

Silver sulphide, or *sulphide of silver*, Ag_2S, in pure state, constitutes the mineral argentite or silver-glance. This is, with lead-gray, a regular crystallization, but is often cryptocrystalline or amorphous. The hardness is about that of gypsum, and it has a high degree of sectility, the mineral often cutting almost like metallic lead. It contains, when pure, 87 per cent. of silver, being the richest of all silver ores. It is common among the ores of the celebrated Comstock lode, as well as in many other localities in the U. S. Sulphide of silver forms, in combination with other metallic sulphides, a large number and variety of argentiferous minerals and ores. With sulphide of arsenic it forms the mineral proustite ($3Ag_2S.As_2S_3$), containing 65·4 per cent. of silver. This is a magnificent carmine-red mineral, of adamantine luster when crystallized, the crystals being rhombohedral. Pyrargyrite ($3Ag_2S.Sb_2S_3$), containing 59·8 per cent. of silver, is also a splendid red rhombohedral mineral, of a darker shade of color than pronstite, hence sometimes called dark-red silver ore. Ruby silver ore is also a name applied to both the arsenical and the antimonial species. Proust first showed the true difference between them, as implied in the above formulas in 1804. Proustite is abundant in Mexican, Peruvian, and Chilian mines, but rare in the Comstock lode and most North American silver-districts. It was found, however, very fine and in immense masses, with pyrargyrite, in the Poorman lode in Idaho. Stephanite ($5Ag_2S.Sb_2S_3$), containing 68·5 per cent. of silver, is an iron-black ore, right-rhombic in crystallization, found sparingly in the Comstock lode and in many other North American regions. It is sometimes called brittle silver ore.

Revised by IRA REMSEN.

Silver City: city; capital of Grant co., N. M.; on the Ateh., Top. and S. Fé Railroad; 48 miles N. W. of Deming (for location, see map of New Mexico, ref. 13-Q). It is in an agricultural and stock-raising region; is principally engaged in mining gold, silver, and copper; and contains a smelter, several reduction-mills, flour-mills, a national bank with capital of $50,000, and two weekly newspapers. Pop. (1880) 1,800; (1890) 2,102; (1900) 2,735.

Silver Coinage in the United States: The question whether it is the wiser policy of the U. S. Government to admit the coinage of silver in unlimited quantities at the established ratio with gold, or to restrict the minting of the cheaper metal, has for many years constituted an important issue in party politics. A brief summary of the principal arguments advanced on each side of the question is presented in the following paragraphs:

Free Coinage of Silver.—The advocates of this measure point to the necessity of increasing the supply of currency. Both the national banking system and the policy of buying limited quantities of silver bullion and issuing gold-notes for the purchase-money have failed to furnish an adequate currency. Moreover, the latter policy has been objectionable to bimetallists and monometallists alike, the former party desiring unlimited coinage for both metals, the latter fearing that it would lead to the establishment of silver as the sole standard. In the opinion of the free-silver party, the opposition of the monometallists, and of those bimetallists who would defer the adoption of the double standard till other nations agree to accept it, is based upon merely theoretical grounds, and is at variance with the world's experience. It was not till 1873 that the U. S. Government prohibited the coinage of silver money as full legal tender, and for several years it was evident that the majority of the people strongly desired to return to the old system. The Mint Act of 1792 opened the mints of the Government to the unlimited coinage of both gold and silver at the ratio of 15 to 1. There was no fear of a gold or silver inundation, and though the French Government, in 1803 and 1804, adopted the ratio of 15½ to 1, thus causing the exportation of gold from the U. S., the silver dollar never lost in purchasing power. In 1834 and 1837 the ratio was changed to 16 to 1, which overvalued gold in respect to silver. As a result, but little silver came to the U. S. mints, and the metallic money was principally gold; yet no one complained, except the advocates of the bank, who, in their opposition to the attempt to supersede the bank-note circulation by gold, denounced the latter metal as bitterly as the national banks have since denounced silver. Thus the disparity between the legal and market ratios caused no complaint on either of these occasions, and nothing like an excessive influx of the cheaper metal resulted. As to the argument that the greater value of gold per weight makes it preferable in large transactions, and therefore more suitable for rich nations, while silver is better adapted for the poorer nations, it has lost all force since the expedient of representing gold and silver coins by certificates has been devised. Certificates representing the gold and silver coin in the treasury are accepted by the people in preference to specie.

From the tables submitted to the committee on coinage, weights, and measures, by the director of the mint in his hearings before that body on Jan. 27, 1892, it appears that at the ratio of 15½ to 1 there is about an equal amount of the two metals in circulation. The output of gold and silver from the mines since 1873 shows also about the same ratio in the respective weights of the metals produced. Nor does the fact that in the latter part of this period the ratio has exceeded this in favor of silver invalidate the argument, for the per cent. of increase when compared to the whole stock of gold and silver is too small to be taken into account, and, moreover, is probably but temporary. Since the ratio of the world from 1803 to the demonetization of silver in 1873 was 15½ to 1, and even since the latter date has been about the same, and since the debts of the world, both public and private, have been contracted at this ratio, it is a gross injustice to the producing classes, which at last liquidate these debts, to readjust the ratio so as to conform to the demonetized price of silver as compared with gold. Measured by commodities, gold has risen 50 per cent. since the demonetization of silver in the U. S. in 1873. Silver, as compared with gold, has not fallen more than 30 per cent. Silver, therefore, as measured by commodities, has not fallen, but, on the contrary, the weight of testimony shows that there has been a slight appreciation of silver in spite of its demonetization.

The Secretary of the Treasury, Mr. Windom, in his annual report for 1889, page 73, arguing against the proposition to put more silver in the dollar, says: "The paramount objection to this plan, however, is that it would have a decided tendency to prevent any rise in the value of silver. Seizing it at its present low price, the law would in effect declare that it must remain there forever, so far as its uses for coinage are concerned." In all the centuries of the past no difficulty has been encountered in the question of using both gold and silver as money. For nearly a hundred years the two metals were at par at the French ratio of 15½ to 1. This condition remained till the U. S. and Germany demonetized silver, or, more correctly speaking, the par remained, notwithstanding the demonetization by the U. S. and Germany, till France suspended the coinage of silver. Had France continued the coinage, the par no doubt would still exist. To demonetize silver and thus cause a greater demand for gold, to compel gold to rise 50 per cent. and then insist that silver shall be coined at a ratio to meet the rise in gold, is a legislative confiscation of the rights of debtors. If this policy were generally adopted it would in effect demonetize at least 30 per cent. of the silver stocks of the world; in other words, it would eliminate about one billion two hundred million in value of silver now in circulation. It would also demonetize 30 per cent. of all the future productions of this metal. A restoration of silver by its enlarged demand and consequent enlarged value is demanded. The free use of silver will lessen the demand for gold and increase the demand for silver, thus causing gold to fall and silver to rise, and in this way the par of the two metals can be brought about without injustice to creditors or debtors.

R. P. Bland.

Objections to the Free Coinage of Silver.—Some of the principal objections to the free coinage of silver will appear from the following paragraphs: By the Coinage Act of 1873 the standard silver dollar of 412½ grains was dropped out of the monetary system of the U. S. The act was not passed surreptitiously, as has sometimes been asserted by the silver-money men. It was recommended by the Secretary of the Treasury in three successive messages, the bill was printed thirteen times, considered through five sessions of Congress, and the debates concerning it occupy 140 pages of the *Congressional Record*. Nor did it drive silver out of circulation, because there were no silver dollars in circulation, very few having been coined since 1834 owing to the fact that it had been cheaper to coin gold than silver. Nor was it an attempt to injure the debtor class for the benefit of the creditor class, because at the time the silver dollar was worth 102 cents in gold and no debtor would choose to pay in silver. It is necessary to state these facts in order to show that free coinage of silver can not be demanded on the ground of an original injustice committed in 1873.

From 1873 to 1878 no silver dollars existed in the financial system of the U. S. In 1878 the silver-money men succeeded in passing the Bland-Allison bill restoring the silver dollar as legal tender, but providing for only a limited coinage, so that gold still remained the standard. In 1890 the Sherman act provided for the purchase of a larger amount of silver, 4,500,000 oz. per month, but at the same time declaring it to be the policy of the U. S. Government to maintain all dollars at a parity. Here also there was no adoption of free coinage. In 1893 the Sherman act was repealed so far as the purchasing clause was concerned, and in 1894, the President vetoed the bill for the coinage of the seigniorage. The U. S. since 1873 has therefore rested officially on the gold basis, and for the purpose of maintaining this basis it sold $162,500,000 worth of bonds during 1894 and 1895. On this statement of facts we have the following conclusions:

(1) Free coinage of silver can not be demanded as a matter of justice. Since 1873 all contracts have been entered into on the gold basis, and no injustice has been committed by the Government toward the debtor class.

(2) It is impossible for the Government to maintain the price of silver. Notwithstanding the coinage of $400,000,000 under the Bland act, and the purchase of $152,000,000 under the Sherman act, the price has fallen from $1.29 per ounce to 65 cents per ounce (1895). The fall in the price of silver is due, therefore, to the increased production of silver, not to its demonetization.

(3) Free coinage of silver would not restore its value. Even if it drove all the gold out of circulation the demand for silver as a circulating medium would be limited. If the value of silver went up temporarily an enormous stimulus would be given production, so that the supply would increase and the price would come down. The U. S. would also get silver from other nations who would be glad to unload on it.

(4) Free coinage of silver would therefore not establish bimetallism, but would drive gold out, bring the U. S. to the silver basis and result in inflation of prices. It is said that this inflation would benefit the debtor class who have suffered so grievously during the last twenty years by the fall of prices. It is not probable that such relief would be attained. The first result of free coinage would probably be contraction of the currency by the loss of gold and sinking of values due to panic. All mortgages due would be foreclosed and the land thrown on the market, or the mortgages renewed only on a gold basis. On the other hand, the creditor class would be injured, and in that class are included all depositors in savings-banks, all beneficiaries of trust funds, and all small investors. All men living on fixed salaries would be injured, because the cost of living would go up. Finally, the laboring class would suffer from increased cost of living and because during inflation wages rise more slowly than prices.

Free coinage of silver would seem to be a very hazardous experiment, bringing more hardship and injustice than it remedies. It would remove the U. S. from the ranks of the great commercial nations with the gold standard. It would destroy public credit and lead to partial repudiation of debt. It would drive away the foreign investor of capital and retard the national development. Owing to the apparently unlimited supply of silver it would make the standard of value very uncertain, thus embarrassing all commercial dealings.

R. Mayo-Smith.

Silver Creek: village; Chautauqua co., N. Y.; on Lake Erie, at the mouth of Silver creek, and on the Lake Sh. and Mich. S., the N. Y., Chi. and St. L., and the W. N. Y. and Penn. railways; 9 miles E. N. E. of Dunkirk, 31 miles S. S. W. of Buffalo (for location, see map of New York, ref. 6–B). It is in an agricultural and grape-growing region, and contains manufactories of milling machinery and a weekly newspaper. Pop. (1890) 1,678; (1900) 1,944.

Silvering: See Mirrors.

Silver-plating: See Electro-plating.

Silverside, or **Silver Fish**: See Atherina.

Silver Stick: in the British court, a title borne by the lieutenant and the standard-bearer of the corps of gentlemen-at-arms; also by the field officer commanding any of the guard regiments. See Gold Stick.

Silverton: town; capital of San Juan co., Col.; on the Animas river, and the Denver and Rio Grande and the Silverton railways; 285 miles W. S. W. of Pueblo, 494 miles S. W. of Denver (for location, see map of Colorado, ref. 5–B). It has an elevation of 9,400 feet above sea-level; is surrounded by high mountains, including the noted Sultan Mountain about 2 miles distant; and contains gold and silver mines, smelting-works, a national bank with capital of $50,000, a State bank, and two weekly newspapers. Pop. (1880) 264; (1900) 1,380.

Silvestre, sēēl'vest'r', Theophile Louis: writer on art; b. at Fossat, in the department of Ariège, France, Oct. 12,

1823; was educated in the University of Pamiers and the College of Toulouse, and began to study law and medicine in Paris, but finally devoted himself entirely to the study of art. In 1855–56 he published *Histoire des Artistes vivants*, which attracted much attention (3d ed. 1878). Afterward he visited England, published *L'Art, les Artistes, et l'Industrie en Angleterre* (1859), and lectured on art in various cities in Belgium, etc. Among his other works are *L'Apothéose de M. Ingres* (1861); *Eugène Délacroix* (1864); and *Théodore Rousseau* (1868). D. in Paris, June 20, 1876.

Silvia, Saint, of Aquitania, in the south of France: sister of Rufinus, consul 392 A. D. Her learning is highly praised by Palladius in his *Historia Lausiaca*, and to her is ascribed an interesting but incomplete description of a visit to the Holy Land, *Peregrinatio ad loca sancta*, discovered in a manuscript of the eleventh century at Arezzo, and edited for the first time by J. F. Gamurrini (Rome, 1887), also by J. Pomialowsky (St. Petersburg, 1889). M. W.

Simaruba'ceæ: a family of dicotyledonous trees or shrubs. The leaves are alternate and without glands, and each ovary-cell has only one ovule. The species are mostly inhabitants of warm regions, and the bitter bark of some yields Quassia (*q. v.*).

Simbirsk': government of European Russia; on the Volga, S. of Kazan, E. of Nijni-Novgorod. Area, 19,110 sq. miles. The surface is level and the soil fertile. Agriculture, breeding of cattle and horses, fisheries, and manufactures of coarse woolen and linen fabrics are the principal branches of industry. Rye, wheat, buckwheat, hemp, flax, and tobacco are the common crops. Pop. (1897) 1,550,458.

Simbirsk: capital of the government of Simbirsk, European Russia; on the Volga, in lat. 54° 19′ N. (see map of Russia, 7–G). It manufactures leather, soap, and candles, and has an important annual fair, held in February. In 1864 and 1865 the town was almost destroyed by fires. Pop. (1897) 41,702.

Simcoe: a lake of Ontario, Canada; situated between Lake Ontario and Georgian Bay; 30 miles long and 18 miles wide, and about 126 feet above Lake Huron, into which it discharges itself through Lake Gougichin, the Severn, and Georgian Bay. Its area is 160 sq. miles. The banks are generally clothed to the water's edge with wood, fine whitefish are taken in its waters, and of its many islands, one, Snake island, is a Chippewa Indian reservation.

Simcoe, post-village: capital of Norfolk County, Ontario, Canada; on the river Lynn, 7 miles N. W. of Port Dover; a junction of the "loop-line" and the Georgian Bay and Lake Erie Branch of the Grand Trunk Railway (see map of Ontario, ref. 5–C). It has a fine court-house and jail and some manufacturing interests, and is in a fertile region. Pop. (1891) 2,674.

Sim'eon [from Heb. *Sihm'ōn*, liter., hearing with acceptance]: the second son of Jacob and Leah (Gen. xxix. 33). He was cursed by the dying Jacob, and Moses passed by the tribe in silence (Deut. xxxiii.). The tribe of Simeon numbered 59,300 at the Exodus, but only 22,200 at the entrance into Canaan (Num. i. 23; cf. xxvi. 14). Its territory was scattered, comprising districts wholly within the territory of the tribe of Judah, and tracts in Mt. Seir and Gedor. The tribe sank into obscurity.

Simeon, Charles: clergyman; b. at Reading, England, Sept. 24, 1759; educated at Eton and at King's College, Cambridge, where he obtained a fellowship 1782, taking holy orders in the same year. He was appointed vicar of Trinity church, Cambridge, Jan., 1783, a post which he retained through life; and was distinguished as a leader of the Evangelical party in the Church of England. He was active in the promotion of missionary enterprise, founding the Church Missionary Society, and organized a successful scheme for the purchase of advowsons or presentations to benefices in the Church of England, in order to secure their being conferred upon evangelical preachers, the fund established by him still having control of some sixty livings. His religious gatherings in Cambridge, known as conversation parties, were famous. D. at Cambridge, Nov. 13, 1836. He published a translation of Claude's *Essay on the Composition of a Sermon*, to which he added notes and a hundred skeleton-sermons, and subsequently published such outlines (2,536 in number) upon the entire Bible, *Horæ Homileticæ* (London, 1819–28, 17 vols.). His *Works* were edited by Rev. T. H. Horne in 21 vols. (1832–33), the best known being the several series of skeleton-sermons. His *Life* was written by Rev. William Carus (1846). See Abner W. Brown, *Recollections of Simeon's Conversation Parties* (1862), and H. C. G. Moule, *Charles Simeon* (1892). Revised by S. M. Jackson.

Simeon Styli'tes: pillar-saint; b. at Sisan in the northern part of Syria about 390; grew up in solitude as a shepherd in the mountains of Amanus, but in his sixteenth year entered a monastery at Teleda, where he distinguished himself by the severity of his ascetic practices. Finding the rules of the monastery too lenient, he afterward removed to Telanessa, in the vicinity of Antioch, where he built a hut and determined to live as an anchorite; but soon his fame for holiness attracted swarms of visitors, and in order to escape their intrusion he placed himself on the top of a column, where he spent his days and nights, always standing, never resting, exposed to the severities of the climate, nourished by what was brought to him, and occupied in religious exercises. The first column he occupied was only ten feet high, but the last was sixty feet, with a platform four feet in diameter, and here he is said to have lived for about thirty years. He died Sept. 2, 459, and was buried in Antioch; and his example, which gained for him much admiration and even power during his lifetime, found many imitators after his death. The so-called pillar-saints, air-martyrs, or stylites were numerous in the Eastern countries, and did not wholly disappear until the twelfth century. Wulfailich, near Treves, on the Moselle, in Rhenish Prussia, about 550, was the only stylite in the West. Simeon's biography was written by his disciple Antonius, contained in the first volume of *Acta Sanctorum*, and by a contemporary admirer, Cosmas, presbyter of Thanir in Cœlesyria, contained in Asseman's *Acta Martyrum*. Evagrius, in his history of the Christian Church, translated into English in Bohn's Ecclesiastical Library, devotes a chapter (i., 13) to him, and describes (14) a visit he paid to the church which inclosed Simeon's pillar. Count de Vogüé, in his *Syrie Centrale* (Paris, 1865–77, i., 141–154), describes his visit to the ruins of the same church, now called House of Simeon, which confirms Evagrius. Revised by S. M. Jackson.

Simfero'pol, or **Simpheropol** (Gr. Συμφερόπολις, Union City): town of European Russia, in the Crimea; capital of the government of Taurida; railway station on the line from Lozovaia to Sebastopol (see map of Russia, ref. 11–D); beautifully situated on the Salghir, in a picturesque valley surrounded with gardens and orchards. It consists of a modern part, built by the Russians, and the old Tartar town, with its mosques, Tartar schools, and bazaars. Pop. (1897) 48,821.

Simi'idæ [Mod. Lat., named from *Si'mia*, the typical genus, from Lat. *si'mia*, ape, monkey]: a family of mammals of the order *Primates* and sub-order *Anthropoidea*, containing the mammals most closely related to man. The form is considerably like that of man, but the anterior limbs are very elongate and the posterior relatively short; the spinal column has a slight sigmoid curve; the lumbar as well as the dorsal neural spines are directed more or less backward; the sacrum is large and solid, composed of four or five vertebræ, and tapers gradually backward; there is no tail; the sternum is broad and short. By all these characters the species are approximated to man. To this group belong two types—one containing large, robust species—i. e. the chimpanzee, gorilla, and orang utan, constituting the sub-family *Simiinæ*—and the other comparatively small, slender species—i. e. the gibbons, or sub-family *Hylobatinæ*. The *Simiidæ* are peculiar to the Old World (the monkeys of the New World belonging to two different families—the *Cebidæ* and *Mididæ*), and are confined to tropical Africa and Asia. See Chimpanzee, Gibbon, Gorilla, and Orang Utan.

Simile: See Rhetoric.

Sim'la: district and town in the Punjaub, British India; on the southern slopes of the Himalayas (see map of N. India, ref. 4–E.); acquired by the British after the Gurkha war (1816) from the Rajah of Bassahir (Bisser). Area of district, 18 sq. miles. Pop. 45,000. The town, 170 miles N. of Delhi, is the permanent abode of numerous Europeans, and during the summer the headquarters of the Government of British India, and the temporary home of Europeans from every part of British India. The houses are not massed together, the town being built according to the cottage system; the lowest house stands at 6,617, the highest at 8,008 feet. The annual mean temperature has been calculated at 57·8°. There are fine warehouses, good hotels, and eight schools for European children—excellent insti-

tutions which are in a flourishing condition. Splendid entertainments and balls are given by the viceroy and high functionaries who pass the summer here. Simla has a theater, a concert-room, Episcopal churches, and one Roman Catholic church. Pop. 13,000. See *Gazetteer of the Simla District* (1888–89). Revised by M. W. Harrington.

Simmons, Edward Emerson: genre and portrait painter; b. at Concord, Mass., Oct. 27, 1852; pupil of Boulanger and Lefebvre, Paris; member of the Society of American Artists (1888); honorable mention, Paris Salon, 1882; third-class medal, Paris Exposition, 1889; Temple silver medal, Pennsylvania Academy, Philadelphia, 1889. One of his best works is *The Carpenter's Son* (1890). He lived for several years at St. Ives, Cornwall, England, and painted there, exhibiting at the Royal Academy, London, and in Paris and New York. He visited the U. S. and painted portraits in New York and Boston in 1891 and 1892.

Simmons, Franklin: See the Appendix.

Simms, William Gilmore: novelist; b. at Charleston, S. C., Apr. 17, 1806; studied law, and was admitted to the bar 1827, but abandoned that profession for literature and journalism, publishing in the same year two volumes of *Poems*; became in 1828 editor of the Charleston *City Gazette*, a political journal of Union proclivities, which was discontinued during the nullification excitement of 1832, leaving him in poverty; resided at Hingham, Mass., 1832–33; wrote there his longest and best poem, *Atalantis, a Story of the Sea* (New York, 1833), and his earliest novel, *Martin Faber, the Story of a Criminal* (New York, 1833); returned soon afterward to South Carolina and settled at Woodlands, near Medway; wrote a series of romances founded on Revolutionary incidents in South Carolina, including the *Partisan* (1835); romances of colonial life, of which *The Yemassee* (1835) is considered the best; published 11 volumes of novelettes, collected tales, and essays; 2 volumes of *Views and Reviews in American History, Literature, and Fiction* (1845–46), collected from a large number contributed to the leading magazines and periodicals; a *History of South Carolina* (1840), a *Geography of South Carolina* (1843), and *South Carolina in the Revolution* (1854). He was several years a member of the South Carolina Legislature, and filled other political offices. D. at Charleston, S. C., June 11, 1870. His best works of fiction were republished in 19 vols. (London, 1853–59; new ed. 17 vols., 1865), under the title *Revolutionary and Border Romances of the South*, with illustrations by Darley. A copious selection of his *Poems* appeared in 1864. See the *Life* by George W. Cable in American Men of Letters Series (Boston, 1888).

Simon, Sir John: surgeon and sanitarian; b. in England in 1816; was made professor in King's College, London; surgeon to King's College Hospital and to St. Thomas's Hospital; was the first medical officer appointed to the general board of health of the privy council, in which capacities his annual reports on sanitary science, dealing with important questions of the day in medicine, have been of great value. His *Physiological Essay on the Thymus Gland* (1845) gained the Astley Cooper prize of £300. He has received honorary degrees from the Universities of Munich, Dublin, Oxford, and Cambridge. Among his works are *Aims and Philosophic Method of Pathological Research* (1848) and *Lectures on General Pathology* (1850). He has contributed largely to the *Cyclopædia of Anatomy and Physiology* and to scientific and medical periodicals, and edited (with a prefatory memoir) Dr. J. H. Green's *Spiritual Philosophy, founded on the Teachings of the late Samuel Taylor Coleridge* (2 vols., 1865). Revised by S. T. Armstrong.

Simon, sĕĕ'mōñ', Jules François Suisse: statesman and political writer; b. at Lorient, department of Morbihan, France, Dec. 31, 1814; succeeded Cousin as Professor of Philosophy at the Sorbonne in 1839, but was dismissed in 1851 on account of his opposition to the *coup d'état*; lectured in 1855 and subsequently on philosophy in various cities in Belgium; was elected a member of the Legislative Assembly for the department of Loire in 1863; offered a strong opposition to the policy of Napoleon III., the plebiscite of 1870, the declaration of war against Prussia, etc., and was a member of the Government for the national defense established on Sept. 4, 1870, and of the Government of Thiers, Feb. 19, 1871–May 24, 1873, as Minister of Public Education. During his term of office he carried through important reforms, but provoked the hostility of the clericals by his efforts to establish compulsory education. On Dec. 13, 1876, he became premier, but difficulties with the president caused his resignation in May, 1877. He was chosen senator for life in Dec., 1875, and was elected a member of the French Academy in the same year. D. June 8, 1896. His writings are distinguished by clearness and precision, and some are the result of very comprehensive studies. Among them are *Histoire de l'École d'Alexandrie* (2 vols., 1844); *Le Devoir* (1854); *La Religion naturelle* (1856; translated into English by I. W. Cole, London, 1857); *La Liberté* (2 vols., 1859); *L'Ouvrière* (1863); *Le Travail* (1866); *La Politique radicale* (1868); *Le Libre échange* (1870); *Souvenirs du 4 Septembre* (1874); *Dieu, Patrie, Liberté* (1883); *Thiers, Guizot, Rémusat* (1885); and *La Femme du XX^e siècle* (1891). F. M. Colby.

Simon, Richard: biblical critic; b. at Dieppe, France, May 13, 1638; entered the Congregation of the Oratory in 1659, but left it again in 1678; was for a short time priest at Belleville, but retired in 1682 to his native city; devoted himself exclusively to literary pursuits. D. at Dieppe, Apr. 11, 1712. His writings—*Fides Ecclesiæ Orientalis* (1671); *Histoire critique du Vieux Testament* (1678; Eng. trans., *A Critical History of the Old Testament*, London, 1682); *Histoire critique de la Créance et des Coutumes des Nations du Levant* (1684); *Histoire critique du Texte du Nouveau Testament* (1689; Eng. trans., *A Critical History of the Text of the New Testament*, 1689); *Histoire critique des Principaux Commentateurs du Nouveau Testament* (1692); *Nouvelles Observations sur le Texte et les Versions du Nouveau Testament* (1695)—form the first and, both on account of the consistency of the ideas and on account of the learning of his arguments, one of the most powerful manifestations of that theological standpoint afterward known as rationalism. They were violently attacked by the Port-Royalists, Bossuet, and other theologians. See his *Life*, by A. Bernus (Lausanne, 1869). Revised by S. M. Jackson.

Simone da Pesaro: See Cantavius, Simone.

Simonians: See Simon Magus.

Simonides, sī-mon'i-dēez (Σιμωνίδης), or **Semonides** (Σημωνίδης), commonly called **of Amorgos**, though b. at Samos: Greek iambic poet who flourished about 625 B. C. He is known chiefly by a satirical poem—a manner of "Mirror of Women"—in which various types of women are represented as descended from various animals and from earth and sea. Only one type of the sex receives his commendation, the "bee-woman"; the rest are handled without mercy and with a kind of personal spite. The remains of Simonides were edited by Welcker (1835), and by Bergk in his *Poetæ Lyrici Græci*, vol. ii., p. 441 fol. (4th ed.).

B. L. Gildersleeve.

Simonides (Gr. Σιμωνίδης): one of the greatest lyric poets of Greece; b. at Iūlis, in the island of Ceos, about 556 B. C.; d. about 468 B. C. His sunny temper and his easy philosophy of life made him welcome wherever his vocation took him, whether he sojourned with the Pisistratidæ at Athens or among the Scopadæ and Aleuadæ of Thessaly. After Marathon, this encomiast of tyrants and oligarchs won the prize over Æschylus for his elegy on those who had fallen in the great battle, and his distich on the dead of Thermopylæ is the most famous in the range of literature. In Sicily he served as mediator between Thero and Hiero (476), and was a special favorite at the brilliant courts of Syracuse and Agrigentum. It was at the court of Hiero that he came into collision with his great rival, Pindar, who claimed for himself a loftier spirit and a truer inspiration; and the very wit and grace of Simonides, his ready sympathy with the spirit of the age, the mundane tone of his poetry, his almost sophistic dexterity have justified the claims of Pindar in the eyes of modern critics. Of his many lyrical poems a fragment remains to warrant what the ancients say of the perfection of his style in everything that he touched, of the exquisite tenderness of his dirges, in which he surpassed all rivals, and of his unequaled command over the resources of the epigram. His fragments were edited by Schneidewin (Brunswick, 1835), and by Bergk in his *Poetæ Lyrici Græci*, vol. iii., pp. 384–535 (4th ed.). B. L. Gildersleeve.

Simon Magus: a Samaritan of the apostolic age; b., Justin Martyr says (*Apol.*, i., 26), at Gitton, which has been identified with *Kuryet Jît*, a village near Nablus. He is described in Acts viii. 9–24 as a sorcerer, called by the people "that power of God which is called great," who was apparently converted by the preaching of Philip, and sought to purchase with money the power of imparting the Holy Ghost; whence the expression *simony*. Of his subsequent

history the ancient accounts are utterly discordant. The Simonians, one of the earliest of the Gnostic sects, lasting for several centuries, took their name from him, and he became a sort of archetype of heresy.

Simonoseki: another spelling of SHIMONOSEKI (*q. v.*).

Simony: in canon law, the buying or selling of ecclesiastical offices or benefices. It received its name from Simon Magus, who wished to buy of the apostles, for gold, the power of conferring the Holy Ghost (Acts viii. 18–24). By all Christian denominations simony is considered and denounced as a great crime, but it has been nevertheless, at various periods, an almost universal practice.

Simoom [from Arab. *samūm*, a sultry pestilential wind, deriv. of *samma*, to poison]: a hot, scorching wind which rises in the sandy deserts when intensely heated by the sun, and blows, loaded with fine sand and dust, over Palestine, Syria, and Arabia. It generally occurs at the time of the equinoxes, and lasts for several hours. It is much dreaded, as it often proves fatal to animal life, partly on account of its heat, which rises to 126°, partly on account of the suffocating dust with which it is filled. Similar winds are the khamsin in Egypt, the samiel of Turkey, the sirocco of Italy, the solano of Spain, the harmattan of Guinea and Senegambia, etc.

Simplicidenta'ti [Mod. Lat.; Lat. *sim'plex*, *sim'plicis*, simple, single + *denta'tus*, toothed, deriv. of *dens*, *den'tis*, tooth]: a sub-order of rodents. See RODENTIA.

Simpli'cius: a Neo-Platonic philosopher, native of Cilicia; flourished in the first half of the sixth century A. D. Nothing is known of his personal history except that he had as teachers Ammonius and Damascius, that he taught at Athens, and that he was one of the philosophers who, after the edict of Justinian (A. D. 529) closing the schools of philosophy at Athens, emigrated, at the invitation of King Khosru Nushirvan (Khosroes) to Persia, where their high hopes were doomed to disheartening disappointment, and whence, with the aid of the friendly king, they soon returned to Athens, to enjoy liberty of thought indeed, but not liberty to teach. Simplicius is known principally as a scholarly and conscientious commentator on Aristotle. Of his commentaries we still possess those on the *Categories*, the *Physics*, the *De Cœlo* (see *Philological Museum*, vol. ii., pp. 588, *seq.*), and the *De Anima* of Aristotle, and one on the *Enchiridion* of Epictetus. Besides these, he is known to have written one on Aristotle's *Metaphysics*. Like most philosophers of his school, he makes no claim to originality. Adopting unquestioningly the doctrines of Plato, he endeavors to bring those of Aristotle into harmony with them by showing that, however much they may conflict in appearance, they do not do so in reality. He was a great admirer of Chaldæan and Orphic lore. THOMAS DAVIDSON.

Simplon, Fr. pron. săñ'plōñ' (Ital. *Sempione*, Germ. *Simpeln*): village and mountain-pass near the boundary between Valais and Piedmont; famous for the military road which Napoleon I. built here from 1800 to 1806. That much-admired piece of engineering, extending from Brieg to Domo d'Ossola, 42 miles long and 30 feet wide, with several long tunnels, 611 bridges, and 10 houses of refuge, was, after the Brenner Pass, the first carriage-road across the Alps. The culminating point is 6,218 feet above the sea. Near by, at the base of Monte Leone (10,977 feet), a hospice has been erected for the gratuitous accommodation of travelers. The scenery on the southern slope is grand and severe in the extreme.

Simpson, ALEXANDER RUSSELL: obstetrician and gynæcologist; b. at Bathgate, Scotland, Apr. 30, 1835. He was educated at Edinburgh University, where he graduated M. D. in 1856. Afterward he studied on the Continent, and on his return to Edinburgh was assistant to Sir James Y. Simpson from 1858 to 1865. He practiced in Glasgow from 1865 to 1870, when he returned to Edinburgh University to fill the chair of Professor of Midwifery and the Diseases of Women and Children. He was president of the Obstetrical Society of Edinburgh 1876–77, 1882–83, and 1892–93; president of the Medico-Chirurgical Society of Edinburgh 1890–91; and president of the Royal College of Physicians of Edinburgh 1892–93. He was editor of *Sir James Y. Simpson's Clinical Lectures on the Diseases of Women* (Edinburgh, 1872); author of *Contributions to Obstetrics and Gynæcology* (Edinburgh, 1880), and of many papers and lectures published in the Edinburgh *Medical Journal* and *British Medical Journal*. S. T. ARMSTRONG.

Simpson, Sir GEORGE: b. at Lochbroom, Ross-shire, Scotland, about 1796; accompanied the Earl of Selkirk, who employed him in the establishment of his Red river colony, to Canada 1820; pushed his settlements northward to Athabasca Lake in rivalry with the Hudson Bay Company, and after the two companies had coalesced (1821) received the appointment of governor of Rupert's Land and of general superintendent of the affairs of the Hudson Bay Company. He planned the successful expedition under his nephew, Thomas Simpson, 1836–39, which traced the coast of the Arctic Ocean from the mouth of Mackenzie river to Point Barrow, and from the mouth of Coppermine river to the Gulf of Boothia. He made an overland journey around the world 1841–42, of which he published a *Narrative* (2 vols., London, 1847); was knighted in 1855. D. at Lachine, near Montreal, Canada, Sept. 7, 1860.

Simpson, JAMES HERVEY, A. M.: soldier; b. in New Jersey, Mar. 9, 1813; graduated at the U. S. Military Academy July 1, 1832, and was assigned to the artillery; was mainly in garrison until 1838, when transferred to the topographical engineers with rank of first lieutenant (captain 1853, major 1861, lieutenant-colonel of engineers 1863), and was thenceforward engaged on the survey and improvement of lakes and harbors, and on lighthouse and Coast Survey duty until 1858; was then appointed chief topographical engineer with the army in Utah, and opened a wagon-route from the valley of Great Salt Lake across the Great Basin of Utah, by which the journey to the Pacific coast was shortened some 200 miles: a report of which he submitted early in 1861. In the early days of the civil war he served as mustering officer in Ohio and chief engineer of department of the Shenandoah. He was appointed colonel of the Fourth New Jersey Volunteers Aug. 12, 1861, and in the Virginia Peninsular campaign led his regiment in the action at West Point and in the battle of Gaines's Mill, where he was taken prisoner and held until Aug., 1862. On his release he resigned his volunteer commission, and thereafter served as chief engineer of the department of the Ohio and had general charge of fortifications in Kentucky till the close of the war. In Aug., 1865, he was detailed as chief engineer of the Department of the Interior on proposed change of route of the Union Pacific Railroad, W. from Omaha, and served as Government commissioner of that road until 1868; subsequently engaged in the regular line of duty with his corps, in which he attained the rank of colonel in 1867; was brevetted colonel and brigadier-general; retired 1880. D. at St. Paul, Minn., Mar. 2, 1883. Revised by JAMES MERCUR.

Simpson, Sir JAMES YOUNG, M. D., D. C. L.: obstetrician; b. at Bathgate, Scotland, June 7, 1811; educated at the University of Edinburgh and at the medical school of the same institution, taking his degree 1832; lectured there on pathology 1836; became Professor of Midwifery 1840; introduced the use of chloroform as an anæsthetic 1847; became president of the Royal Society of Physicians at Edinburgh 1849, and of the Medico-Chirurgical Society 1852; foreign associate of the French Academy of Medicine 1853; received the Montyon prize for his introduction of anæsthesia 1856; was made a knight of a Swedish order about 1854; was created a baronet 1867, and enjoyed an enviable reputation, not only as a skillful medical practitioner but as an eminent antiquarian. D. in Edinburgh, May 6, 1870. In 1871 his principal works were collected under the titles *Selected Obstetrical Works*, *Anæsthesia and Hospitalism*, and *Clinical Lectures on the Diseases of Women*; and his *Archæological Essays* appeared in 1872.
Revised by S. T. ARMSTRONG.

Simpson, JOHN PALGRAVE: author; b. at Norfolk, England, in 1805; was educated at Corpus Christi College, Cambridge; traveled for several years on the Continent, and published *Second Love* (1846); *Gisela* and *Letters from the Danube* (1847); *Lily of Paris; or, The King's Nurse*, and *Pictures from Revolutionary Paris* (1848). After his return to England, in 1850, he wrote with success for the stage—*The World and the Stage*, *Sibylla; or, Step by Step*, etc.—in all about forty pieces of various kinds. He also published a *Life* of Karl Maria von Weber. D. in London, Aug. 19, 1887. Revised by H. A. BEERS.

Simpson, MATTHEW, D. D., LL. D.: bishop; b. at Cadiz, Harrison co., O., June 20, 1810; graduated at Madison College, Pennsylvania, 1829, and was tutor in the same institution 1829–32; studied medicine and received the degree of M. D. 1833; was licensed the same year in the ministry and joined the Pittsburg Conference of the Methodist Episcopal

Church; became vice-president and Professor of Natural Science at Allegheny College 1837; president of Indiana Asbury University at Greencastle, Ind., 1839; editor of *The Western Christian Advocate* 1848, and was elected bishop 1852. He was an intimate friend of President Lincoln, at whose request he devoted much of his time during the civil war to the maintenance of public sentiment in behalf of the Union by addresses in many Northern cities, being also employed by the Government in several important confidential commissions. In 1863–64 he made an extended tour of inspection of the missions of his Church in Syria and the East generally, and traveled through several countries of Europe upon a similar errand. He visited the Mexican missions 1874, and the European mission conferences 1875, and on his return became a resident of Philadelphia. Author of *A Hundred Years of Methodism* (1876); *Cyclopædia of Methodism* (1878); *Yale Lectures on Preaching* (1879); and *Sermons* (1885). D. in Philadelphia, June 18, 1884. See his *Biography*, by G. R. Crooks (New York, 1890).

Revised by A. Osborn.

Simpson, Thomas: mathematician; b. at Market-Bosworth, Leicestershire, England, Aug. 20, 1710; was in early life a weaver, but became an accomplished mathematician by private study; was for some years a teacher in Derby and in London; became Professor of Mathematics in the Royal Military Academy at Woolwich 1743, and a fellow of the Royal Society 1745; and published many ingenious papers on pure mathematics and physical astronomy. He published works on fluxions, the laws of chance, doctrine of annuities, algebra, geometry, and trigonometry. D. at Market-Bosworth, May 14, 1761.

Simrock, Karl: poet and author; b. at Bonn, Germany, Aug. 28, 1802; studied jurisprudence in his native city and in Berlin; entered the Prussian civil service, but was dismissed in 1830 on account of a song he wrote on the revolution of July in Paris; devoted himself to literature, and studied especially the old German language and literature, of which he was appointed professor at Bonn in 1850. His chief poetic work is *Wieland der Schmied* (1835), one of the best epic poems of modern German literature, in which the old hero-legend is successfully revived. He translated with excellent taste and remarkable skill the *Nibelungenlied* into modern German (1827); several works of the minnesingers; the *Edda* (1851); *Beowulf* (1859) and *Heliand* (1856); Shakspeare's *Sonnets* (1867); Tegnér's *Frithiof's Saga* (1863); and many other mediæval works of poetry. He also published a *Handbuch der deutschen Mythologie* (1864); *Die Rheinsagen* (1836); *Deutsche Volksbücher* (1839–67); *Quellen des Shakspeare* (1831), and other works. D. at Bonn, July 18, 1876.

Revised by Julius Goebel.

Sims, George Robert: journalist and dramatist; b. in London, Sept. 2, 1847; was educated at Bonn; entered journalism, and contributed to the press the *Dagonet Ballads* (1879); *Three Brass Balls* (1880); *The Social Kaleidoscope* (1880); *Ballads of Babylon* (1880); *The Theatre of Life* (1881); *How the Poor Live* (1883); *Stories in Black and White* (1885); *Mary Jane's Memoir* (1887), etc. His letters to the London *Daily News* on the condition of the poor attracted much attention, and led, in part, to the appointment of a royal commission. Has written with success for the stage—*The Lights o' London* (1882); *The Romany Rye* (1883), etc.

H. A. Beers.

Sims, James Marion, M. D., LL. D.: surgeon; b. in Lancaster co., S. C., Jan. 25, 1813; graduated at South Carolina College, Columbia, 1832; studied medicine at Charleston and Philadelphia, graduating M. D. at Jefferson Medical College 1835; in 1836 entered upon the practice of his profession at Montgomery, Ala.; in 1845 called attention to his new theory of the nature and origin of trismus nascentium, and also to the subject of vesico-vaginal fistula, inventing instruments and an operation for the cure of that lesion. He urged the use of metallic sutures in every department of general surgery. In 1852 he published a full account of his discovery in *The American Journal of Medical Sciences*. In 1853 he settled permanently in New York. His investigations of the diseases peculiar to women early led him to perceive the importance and necessity of establishing a great permanent woman's hospital in New York, and a temporary hospital was opened in May, 1855. Dr. Sims was elected attending surgeon, with Drs. Mott, Francis, Stevens, Green, and Delafield as a consulting board. In 1857–58 he obtained from the Legislature a charter for the Woman's Hospital of the State of New York, and the city of New York granted a site on which a hospital was built. In 1861 Dr. Sims went to Europe, and he operated in Dublin, in London, in Paris, and in Brussels. He received decorations from the French, Italian, Spanish, Portuguese, and Belgian Governments as a public benefactor. In 1868 he returned to New York. In 1870, on the breaking out of the Franco-German war, he organized in Paris the Anglo-American Ambulance Corps, took charge of it as surgeon-in-chief, and went with it to Sedan. Soon after this Dr. Sims returned to New York. To his labors and discoveries are mainly due the establishment of the science of gynæcology as a new department in medicine, recognized by a special professorship in all well-organized medical colleges. Dr. Sims was a corresponding member of many learned societies in the U. S. and Europe, notably of London, Edinburgh, Berlin, Christiania, etc., and of the Royal Academy of Medicine of Brussels. He was elected president of the American Medical Association at its meeting at Louisville, Ky. D. in New York, Nov. 13, 1883. There is a monument of him in Bryant Park, New York. See his autobiography, *The Story of my Life*, edited by his son, H. Marion Sims, M. D. (1884).

Sims, Winfield Scott: See the Appendix.

Simulation: See Feigned Diseases.

Sinai, sī′nā, or sī′nī [from Heb. *Sīnay*: cf. *Sīn*, the wilderness of Sin, liter., clay]: (1) a triangular peninsula of Arabia Petræa, between the Gulfs of Suez and Akabah. Its apex points S.; its base is 150 miles across from gulf to gulf; its western side 186 miles long, its eastern side 133, and its area about 11,500 sq. miles. First comes the wedge-like protrusion of the limestone plateau known as the Desert of the Wandering, then a sandstone belt, and finally the mountain-masses of granite and porphyry, flanked right and left by narrow strips of lowland bordering the gulfs. These mountains may be divided into three groups, the highest peaks of which, respectively, are Serbal (6,734), Catharine (8,526), and Shomer (8,449). The ancient Egyptians called this peninsula "the land of the gods." Its solitary grandeur impresses all travelers alike. Mines of iron, copper, and turquoise were once worked here. It is still the home of about 5,000 Bedouin. The curious inscriptions, found mostly on the western side of the peninsula, are generally in the Nabatæan character, and the Nabatæans were, about the beginning of the Christian era, the chief traders between Egypt and Assyria. They were an Arab people living on the east and southeast of the Holy Land. Some of the inscriptions are Greek and a few Coptic. With them are rude drawings. The whole was probably the work of caravans between 200 B. C. and 400 A. D., and of no more importance than such scratchings usually are.—(2) Used in the Old Testament interchangeably with Horeb to designate the Mountain of the Law. Lepsius and others have tried to identify it with five-peaked Serbal, the most picturesque of all the mountains of the peninsula: but the true Sinai is a gigantic mass, about 2 miles long from N. to S., and about half a mile wide from E. to W. Its southeastern peak, called Jebel Musa, is the traditional scene of the giving of the Law; but there was not open space enough on the south side of the mountain to accommodate the Hebrew host. Its northwestern peak, called Sufsafeh, overlooks three wadies (Rahah, Deir, and Leja), which might easily have held 3,000,000 or 4,000,000 people; and there is no other such spot anywhere in the whole peninsula. Here the Israelites encamped for a year, and here the Law was given. The watershed at the foot of Sinai is 5,140 feet above the sea, Jebel Musa 7,359, Sufsafeh a little lower. The famous convent of St. Catharine, in whose library Tischendorf discovered the Sinaitic Codex of the Scriptures (in 1844), and Mrs. Agnes Smith Lewis the oldest text of the Syriac Gospels (in 1893), is on the east side of the mountain.

Revised by S. M. Jackson.

Sinaitic Inscriptions: See Codex Sinaiticus.

Sinaloa, sē̆e-nă̆a-lō′ă̆ă (sometimes written Cinaloa): a northwestern maritime state of Mexico, bounded by Sonora on the N. W., Chihuahua and Durango on the N. E., Tepec on the S. E., and the Pacific and the Gulf of California on the S. W. (see map of Mexico, ref. 4–D). Area, 36,184 sq. miles. The eastern and northeastern parts are covered with spurs and terraces of the Sierra Madre, which have a true mountainous character, and sometimes attain 6,000 feet in altitude; on their slopes are extensive oak forests, and the valleys are very fertile. The coast belt is low, and in parts unhealthful; there are many lagoons near the gulf. Several rivers cross the state, flowing down from the Sierra

Madre, but none of them is navigable. The greater part of the state is in the temperate zone; in general, however, the climate of the coast belt is essentially tropical, and the higher lands have a mild and equable climate (*tierra templada*). The rainy season (June to September) is well marked in the highlands, but in parts of the coast belt the rainfall is insufficient for agriculture and the vegetation is scanty. The state is rich in gold and silver, and mining is the most important industry; agriculture is generally on a small scale, sufficing only for home consumption. There are considerable manufactures of cotton cloths, etc. Pop. (1893) estimated, 245,733; a large proportion are Indians or mixed races. Capital, Culiacan; chief port, Mazatlan. Sinaloa, the ancient capital (96 miles N. N. W. of Culiacan, on the river Sinaloa), had formerly 10,000 inhabitants, now reduced to 3,000. HERBERT H. SMITH.

Sinapis: See MUSTARD.

Sinclair, Sir JOHN: author; b. at Thurso Castle, Caithness, Scotland, May 10, 1754; educated at the Universities of Edinburgh, Glasgow, and Oxford; became a member of the Faculty of Advocates at Edinburgh 1775; was called to the bar at Lincoln's Inn 1782; published *History of the Public Revenue of the British Empire* (3 vols., 1785–89); was made a baronet in 1786; built up the port of Thurso; was influential in reviving the fisheries and in establishing the Scottish Society of Wool-growers (1791) and Board of Agriculture (1793), of which associations he was the first president; maintained an extended correspondence with Gen. Washington; sat in Parliament with brief interruptions from 1780 to 1811; compiled *A Statistical Account of Scotland, drawn up from the Communications of the Ministers of the Different Parishes* (Edinburgh, 21 vols. 8vo, 1791–99); wrote in all 39 volumes and 367 pamphlets, covering almost the whole range of literature, being aided therein during his later years by his daughter CATHARINE, who became eminent as a novelist. D. in Edinburgh, Dec. 21, 1835. —His eldest son, Sir GEORGE, b. in Edinburgh, Oct. 23, 1790, was for some years a member of Parliament, and wrote several works against Roman Catholicism. D. in Edinburgh, Oct. 9, 1868.—Another son, JOHN, b. in Edinburgh, Aug. 20, 1797, was archdeacon of Middlesex from 1842; published *Memoirs* of his father (2 vols., 1837), and *Sketches of Old Times* (1875). D. in London, May 22, 1875.

Sinclair River: See ST. CLAIR RIVER.

Sindh, Sind, or **Scinde**: western province of British India; adjoining Baluchistan; part of the Bombay Presidency; on the lower Indus, W. of Rajputana and N. of the Runn of Kuch. Area, 47,789 sq. miles, or including the tributary state of Khairpur, which forms a part of it administratively, 54,435 sq. miles. It occupies the Indus delta, and is for the most part monotonous, nearly treeless, with many dead and few live watercourses. The desert of Thar occupies its eastern part and that of Shikarpur the northwest. The soil is sandy or clayey, and is much impregnated with salt and alkali. It lacks the monsoons, and rain in some parts is almost unknown. The Indus bears to it the same important relation that the Nile does to Egypt. The climate is generally hot and the extremes great. It is considered unhealthful, and is especially subject to fevers and cholera. Only 7 or 8 per cent. of the land is cultivated, and nearly all of this has to be irrigated. The canals have a total length of about 6,000 miles. There are two annual crops; those of the spring are chiefly cereals, legumes, and oil-seeds. The second harvest yields millet, rice, and cotton. The fruits are numerous and excellent. The fauna includes the tiger, hyæna, wolf, fox, onagra, wild boar, antelope, and deer. Fishing is an important industry, and dried fish are exported. The population in 1891 was 2,871,774 for the districts of Sindh and 131,937 for Khairpur, an increase since 1881 of nearly 20 per cent. in the districts, but a decrease for Khairpur. The inhabitants are mostly Mohammedans, including the indigenous Sindhis, formerly Hindus, now Sunnites. These form about half of the population; they are tall, robust, apathetic, and lazy, are without caste, have a pure Neo-Sanskrit language of great interest, with a small literature, chiefly theological and from Arabic sources. The capital is Karachi or Kurrachee; pop. (1901) 115,407. A railway extends from this place up the Indus to the Punjaub, with a branch from Shikarpur into Baluchistan. This is a very ancient country historically. It was probably visited by the Persians under Scylax, and by one of the generals of Alexander the Great. It probably formed a part of the Græco- or Indo-Bactrian kingdom. The sacred city of Patala was once its capital, and it is supposed that Haidarabad, a later capital, occupies its site. It has undergone remarkable political revolutions, and the variations in the course of the Indus have made its physical changes quite as remarkable. It contains numerous ruins of towns and cities, often in localities now entirely uninhabitable because of lack of water. It became a British province in 1843. See Ross, *The Land of Five Rivers and Sindh, Sketches Historical and Descriptive* (1883). MARK W. HARRINGTON.

Sin'dia, or **Scindia**: the dynastic name of the most powerful of the native Mahratta princes of India, having their capital at Gwalior. The family took its rise in the person of RANOJI SINDIA, a low-caste retainer of the Mahratta peishwa, who rose to a high rank in the body-guard, and in 1743 received as a fief half of the province of Malwa.—His son, MADHOJI SINDIA (d. 1794), joined the Mahratta confederacy; fought against the Afghans at the great battle of Paniput (1761); became a useful ally of the Emperor of Delhi; expelled the Sikhs from Central India, and became virtual ruler of the empire; fought against the British 1779–82; was confirmed in his possessions by the treaty of 1783; captured Gwalior 1784; seized on Delhi and Agra; reduced the Rajput states, and formed a vast army, well disciplined by French adventurers.—His grand-nephew and successor, DAULAT RAO SINDIA, ruled from 1794 to 1827; waged war with varying success against the rival family of Holkar; was defeated by Sir Arthur Wellesley (afterward Duke of Wellington) at Assaye, and by Lord Lake at Laswari, and submitted to British influence, but retained his capital and a portion of his territories.—BAJI RAO SINDIA (1843–86) was a loyal ally of the British during the mutiny of 1857–59.

Si-ngan-foo, sē'ng'ăn'foo', or **Si-an-foo** (sometimes SI-GAN-FOO): city of China; capital of the province of Shensi, and the capital of the empire during some of its most famous dynasties—e. g. the early Han (202 B. C.–24 A. D.), the T'ang (618–905 A. D.), and the Sung (960–1127). It is splendidly situated in the basin of the Wei, the most important affluent of the Yellow river, and is commercially of great importance. Its walls, which have a circuit of 24 miles, are well built, and its pavilioned gates surpass in magnificence those of Peking. It is the seat of a Roman Catholic bishopric, and contains the oldest mosque in China, founded about 1,100 years ago. In 1868–71 the city and surrounding country suffered much from the Mohammedan rebellion. Pop. about 200,000. Here in 1857 was found an immense tablet covered with inscriptions in Chinese and Syriac, and dated 827 A. D., recording the establishment of Christianity in this neighborhood by the Nestorians in the fourth century. See Yule's *Book of Ser Marco Polo* (2d ed. 1876). R. L.

Singapore': an island at the extremity of the Malayan Peninsula. It contains the town of Singapore, founded by the Malays 1283, ceded to the British by the Sultan of Johor 1819, and rendered a free port in order to strike a blow at the Dutch; became in 1853 the capital of the Straits Settlements (see map of East Indies, ref. 6–B). The area of the island is 207 sq. miles; the surface varies from 20 to 30 feet above the sea-level; low hills are numerous, varying from 50 to 200 feet; Bukemata, a hill in the center of the island, has a height of 517 feet. The climate is agreeable to Europeans; the mean annual temperature is 80·7° F.; during the day the heat is intense; the atmosphere is very moist, there being usually a fall of rain every week. The drainage of the town, formerly as bad as possible, has been considerably improved. The seamen's hospital is an excellent building, well adapted for its purpose and well attended to. The population of the island was 184,554 in 1891, of whom 121,908 were Chinese, 35,992 Malays, 16,035 natives of India, and 2,769 whites. The city was once a dreaded lurking-place for pirates, but developed into a great commercial center of the Malayan Archipelago, doing in 1893 a total business in native produce and foreign goods of $232,430,724. Numerous harbors on the Malayan Peninsula, especially Pulo-Penang, in Borneo, in Sumatra, in Siam, and Cochin-China, formerly traded exclusively through Singapore, but afterward established direct connections. The city had 110,000 inhabitants in 1891. The port has excellent docks and is strongly fortified. It has considerable trade with the U. S., and is connected by telegraph with Madras, Java, Australia, and Japan. See STRAITS SETTLEMENTS. Revised by M. W. HARRINGTON.

Singer, OTTO: See the Appendix.

Singhalese: the people and language of CEYLON (*q. v.*).

Single Tax: a term which has come into use since 1887 to denote the proposal, theory, or movement which aims at the collection of all public revenues from one single source, what in political economy is termed "rent," the value of land itself, irrespective of the value of any improvement in or on it; or, to adopt another form of statement, a proposal or movement which aims at the appropriation of economic rent, the "unearned increment of land values" to public uses, by means of taxation.

These two forms of statement, though often indiscriminately used, since the practical method of reaching the single tax from existing conditions is "to abolish all taxation save that on land values," are suggestive of two different points of view—the fiscal and the moral—that of governmental expediency and that of social justice. Although social justice must really include governmental expediency, the argument for the single tax may perhaps be most concisely put by presenting it first from the narrower and then from the wider of these standpoints.

From the fiscal side, the single tax offers the cheapest and in all respects the best mode of raising public revenues. Every owner of a valuable estate has the power of raising revenue from those who use it. He may, as was largely the custom of feudal landlords, require from his tenants a multiplicity of payments, conditioned on what they may do or have—as on the building or repairing of houses, the growing of crops, the engaging in certain occupations, the possession of certain amounts or forms of wealth, the bringing in or taking out of goods; or even on such occurrences as births, deaths, or marriages. But reason and experience both show that the largest revenue can be raised with the least trouble and expense by substituting for such small exactions one single charge or rent, and this has become the custom of enlightened landlords. Now the taxing power of the state is simply that of the superior landowner or "over-lord" of a certain area. It exists only within that area, and, as in the case of the individual landlord, is limited by what people are willing to pay for the privilege of living in it. For though the state still retains the power of seizure and punishment, which once belonged to the larger landlords (the "right of pit and gallows"—i. e. of life and death—having in Scotland been taken from them only in comparatively recent times), this avails nothing in the raising of permanent revenues. If taxes be imposed beyond a certain point in any given area, men will refrain from coming into it, those already there will leave if they can, and those who can not leave will become impoverished and finally starve and die. There are many instances of populous cities reduced to ruins and fertile districts to deserts by ill-laid and excessive taxation.

Thus the same principles that enable the individual landlord to raise the largest revenue with the least waste, cost, and trouble, by a single rent-charge, apply in the case of public revenues; and the common-sense way for the state or any of its subdivisions to obtain revenues is by a single tax on the value of land. The attempts of governments to raise revenues by other taxes are really as stupid and barbarous as would be the resort of an individual landlord to petty feudal exactions. Such taxes invite evasion, fraud, and perjury; they require an expensive array of tax-gatherers, and even then can not be fairly assessed or fully collected. They check production, lessen accumulation, and take from the people much more than the state receives. The waste involved in the more important of them is not merely in the expenses of trying to collect them and of trying to evade them. Taxes on imports, taxes on internal production or exchange, taxes on capital in any of its forms, nearly all license taxes, and all that part of real-estate taxes that rests on buildings and improvements do not really fall on those who pay them to the state, but with added interest and profits finally fall upon the ultimate user or consumer. These taxes are really of the nature of that most destructive of fiscal devices, the farming of revenue.

Since a tax on the value of land is not a tax on land, but on an advantage accruing on specially desirable land, which can in no case go to the land-user as user, it can not check production, or lessen the return from use or improvement, or be shifted from shoulder to shoulder, increasing in weight as it goes. Avoiding all the waste, loss, and fraud of indirect taxes, it also avoids the evasions and injustice that attend attempts to tax incomes of all kinds, and is of all possible taxes that which may be most cheaply, certainly, and equitably obtained. It can not be evaded. It must fall on the owner, wherever he may be, taking from him, not in proportion to anything his labor or capital may have contributed to the general wealth, but only in proportion to the unearned income which the adjustments of the state give him the special privilege of receiving. Land can not be concealed or removed, and its value can be ascertained with greater ease and certainty than any other value. A small sign on each separate piece of land, giving boundaries, area, and valuation, would bring public knowledge and opinion to the aid and correction of the assessment, while under a proper system the collection would involve little more than the clerical labor of receiving. In the U. S., as taxes are levied on land-values for state and local purposes in the tax on real estate, and as the percentage needed for national purposes could be collected by the same system, the substitution of this one method of raising public revenues for the complicated system in use would involve no new machinery, but only the abolition of many offices and the great lessening of corruptive and demoralizing agencies.

From the Moral Side.—The perfection of the single tax as a fiscal measure does not, however, account for the rapid spread of the idea and the ardor it excites. These come from its moral side, in which it is apprehended as the easy, yet, under the conditions of the times, the only possible way of relieving undeserved poverty, establishing social justice, and avoiding that monstrous inequality in the distribution of wealth that is so rapidly developing destructive tendencies in modern civilization. The argument from this side may thus be briefly stated:

The equal right to land flows from the right to life, and is the corollary of the right of property, or exclusive right of the producer to the product. In the rude stage of social life, where a simple industry seeks to satisfy primary needs from the spontaneous offerings of nature, the equal right to the use of land and the exclusive right to the products of labor are secured when all have free access to the land ranged over by the tribe, and each may dispose of what his efforts obtain. But as society begins to take settled form, the division of labor begins to separate occupations, and a higher use of land calls for the use of capital, social order, industrial necessities, and the recognition of the right of property, all require such exclusive possession of land as shall assure to him who plants that he may reap, and to him who builds that he may enter in. This need becomes wider as civilization advances and improvements become more costly and industry more complex.

But no matter how far civilization advances, the exclusive right of property need never interfere with the equal right to the use of land. For these rights are correlative, the one involving the other, and the denial of one being really a denial of the other. Thus to deny to a man his equal right to the use of land is to deny him the benefits of his own labor, and to compel him to yield that labor or its products without due return. So far from the right of property making it necessary to attach to land that right of ownership which by natural law attaches to things temporarily drawn from land by labor, such treatment of land is as truly a denial of the right of property as making property of men. Between chattel slavery, the rude method of appropriating labor, and industrial slavery, the more civilized method, the difference is only of form. In the one, the man himself is treated as the property of another; in the other, the land on which the man must live is treated as the property of another. The result in either case is robbery, and robbery that may go to the same pitch. To the chattel slave must be left enough of his earnings to support life. Are there not to-day in so-called free countries great bodies of men who think themselves fortunate to get this?

In the relations of individuals with each other we find no difficulty whatever in combining exclusive possession with equal rights to use. A man may leave a horse, a ship, a building, or anything else incapable of division, to his children or to others equally; or such equal rights may be acquired in daily transactions without difficulty being encountered. Where a right to use can not be divided, its value may. So the exclusive possession of land called for by social advance need involve no denial of the equal right to use. That equality may be secured in a way permitting the best use of land by requiring from him who is accorded exclusive possession of any piece of land a contribution to common uses equivalent to any advantage it gives over that obtainable from the best land that others are free to use. There is nothing new in this. The principle lay at the base of feudal tenures, and is applied partially in Chicago, where the equal right of the whole community to the use of a cer-

tain piece of land now covered with very valuable buildings, the property of individuals, is recognized by the appropriation of the ground-rent to municipal expenses; and there are similar examples in many other cities. The special advantage attaching to the possession of any piece of land is always exactly measured by ground-rent, since it is what gives value to land itself. By taking that, and that alone, for common needs, the equal right to land and the exclusive right of property may both be secured in any stage of civilization, however advanced, and the society placed on the only enduring basis, that of exact justice between man and man.

Fiscal considerations and moral considerations both point to a complementary relation between the need for public revenues and the value of land. If we consider the appearance, growth, and direct cause of the two phenomena, this conclusion becomes irresistible; and the same recognition by which we see that the milk secreted in the mother's breast is intended for the sustenance of the babe shows us in land-values the intended provision for public revenues.

In that primitive social condition in which land may be left to free access, the state exists only in the rudimentary form of patriarchal authority or an occasional council, and there is no need for regular public revenues. The division of labor, which is the mark and measure of civilization, does not yet require that some men shall devote themselves to public service; there are no courts or schools to maintain; no roads to make; no public buildings to erect; no streets to pave and clean and sewer; none of the public needs of civilization to provide for. In this social condition land has no value whatever, for land has no original value, such as attaches from the first to things produced by labor. But the same advance in civilization that brings the need for public revenue attaches value to land; and while, by lessening the cost of production, it tends steadily to lessen the value of products of labor, it as steadily tends to increase land-values. When a few self-contained families roamed over Manhattan Island there was no need for public revenue and no value to land. In New York to-day immense public revenues are needed to meet legitimate public wants, and land has such an enormous value that the most costly and towering buildings are not so valuable as the bare land they cover.

This we may see wherever civilization centers. The same social advance which by increasing public needs calls for larger public revenues, correspondingly, and even more than correspondingly, increases the value of land. The reason is that the integration of individuals, in which civilization consists, besides increasing the power of individual exertion to satisfy desires, develops in the society itself an additional power of satisfaction which tends to localization, not merely bringing out important differences in the original qualities that adapt land to the satisfaction of human desires, but, in places where exchanges center, attaching enormous value to mere standing-room. It is not only that all public improvements, material, political, and even moral, increase this "unearned increment"; it also grows by private improvement, for the erection of a beautiful dwelling, the opening of a good hotel, or well-appointed store, or of a mine or factory, or even improvement in the personal qualities or conditions which make people more desirable neighbors, localize an advantage that becomes tangible in land-values. The adoption of the single tax itself, while it would destroy speculative rent, would by promoting general prosperity tend to vastly increase the aggregate of economic rent, the value attaching to land itself.

"Rent" is not produced by land, which is but the passive factor in production; nor yet is it produced by the landlord, who as landlord contributes no more to production than could a sun-lord or air-lord. The active factor in all production is human exertion or labor, of which capital (wealth applied in further production) is a subdivision. In the most primitive form of industry the whole product goes to labor as wages. In the next higher form it is distributed between the economic terms labor and capital, in wages and interest; but in that still higher form of industry which comes at the point in social development when a value begins to attach to land, the distribution of the product is into wages, interest, and rent. This distribution is a matter of natural law, and there is no possible device of human law or of individual ingenuity by which rent can be made to increase wages or interest. If it be turned over to a laborer or a capitalist, he becomes in receiving it a landlord to that extent, and may at any time separate what he receives of it from what he receives as laborer or as capitalist, for there is no true rent until, and so long as, some one stands willing to pay for the privilege of using land.

Thus economic rent, the "unearned increment," is a natural growth, born of civilization and increasing with its advance; belonging to the society itself as distinguished from its individual members, by the same right of property which gives to the individual the ownership of his product. It is the natural provision for the natural need of public revenues; a fund secreted by the social organism to meet the wants, analogous to those of the physical body for sustenance, which come with its definite appearance and grow with its growth.

To see this is to see more. For that civilization develops a fund belonging to the social all and not to the social each, shows that the wider and closer co-operation of man with his fellows, to which all increase in his knowledge and powers is due, should bring a greater and greater equality of condition, and thus that our highest moral perceptions are not mocked by, but correspond to, the design of that Originating Intelligence manifest in the phenomena of nature. Now good and evil lie not in things, but in their uses, whatever is potent for good being correspondingly potent for evil. Thus the neglect or perversion of the natural provision by which the advance of civilization tends to bring about a higher and higher equality in human conditions must turn that advance toward a more and more monstrous inequality.

In the perversion of the great law of rent lies the explanation of those threatening facts obvious throughout modern civilization to-day. Rejecting what rightfully belongs to it, the state is driven by its need for public revenues to ignore the moral right of property and to take what rightfully belongs to individuals, by taxes that necessarily fall most heavily on those least able to bear them, that check production, render distribution inequitable, foster monopolies, create artificial crimes, put a premium on fraud and perjury, corrupt government, and debauch morals. But worse than this: what the state refuses to take must go to mere landowners, thus not only creating a class of idle rich, who become demoralized and demoralizing social factors, but by attaching a premium to the forestalling of land and developing speculative rent turn the very forces of invention and improvement which directly increase the productive power of labor into agencies which degrade and impoverish the laboring masses, by creating an artificial scarcity in the indispensable natural element of all production and all life.

This is why those who apprehend the single tax from the moral side see in it the easy yet only possible way of saving our civilization from otherwise certain destruction, and turning its advance to nobler heights than have yet been more than dreamed of. To them the single tax means the abolition of all real taxes; the taking for society of the provision made in the natural order for its needs; the conforming of the most fundamental of all social adjustments to the moral laws of the Creator.

HENRY GEORGE.

Sing Sing: village; Westchester co., N. Y.; on the Hudson river, and the N. Y. Cent. and Hud. River Railroad; 31 miles N. of New York. Its name was changed to Ossining in March, 1901. Its streets and avenues, rising one above another to the height of from 200 to 300 feet, afford views of the lovely scenery of the Hudson. The river is wider at this point than at any other; the broad Tappan Zee and Haverstraw Bay are separated by the long peninsula known in Revolutionary times as Teller's Point (where the Vulture waited for Arnold and André), and now, as Croton or Underhill's Point, famous for its vineyards. The Croton aqueduct crosses the Kill Brook by a magnificent stone arch of 88 feet span and 70 feet above the stream, and beneath this arched bridge is a second one for highway uses. Among the articles manufactured here are porous plasters, pills, baking-powder, self-feeding cotton-gins, cotton-gin saws, gas and water pipes, steam-engines, files, wrenches, carriages, and sleighs. A soldiers' monument was unveiled here May 30, 1887. The village contains several churches, 4 boarding-schools for boys, 2 being under military discipline, a boarding and day school for young ladies, 2 public schools, several private schools, a public library (founded in 1838), 4 other libraries, one of the most noted prisons in the U. S., gas and electric lights, electric street-railways, a national bank with capital of $100,000, a savings-bank with deposits of over $1,379,000, and a monthly, a bi-monthly, and 2 weekly periodicals. Pop. (1880) 6,578; (1890) 9,352; (1900) 7,939.

M. F. ROWE, EDITOR OF "REPUBLICAN."

Sinim: the name used in the Bible for the Seres, or ancient Chinese. See CHINA.

Sink-hole: a hollow of the land drained at the bottom. Districts underlain by limestone or gypsum are often drained through subterranean channels, and the surface waters find their way to these channels through vertical crevices which are sometimes opened out into shafts of some size. The washing of soil, etc., into such shafts usually produces a funnel-shaped cavity, and this is known in the U. S. as a sink-hole or limestone-sink, and in England as a swallow-hole. Such hollows are abundant in the great Appalachian valley, which is underlain by limestone from Pennsylvania to Alabama. The word sink is sometimes inappropriately applied to drainless hollows which receive the water of streams, and discharge it to the air by evaporation. See PLAYA. G. K. GILBERT.

Sinking Fund: See FINANCE (*Public Loans*).

Sinnett, ALFRED PERCY: journalist; b. in London, 1840; the son of E. W. Sinnett, a journalist; joined the staff of the London *Globe* in 1859; afterward edited *The Daily Press* at Hongkong; returned to England in 1868; went to Allahabad, India, in 1871, as editor of *The Pioneer*; joined the Theosophical Society in 1879, and, returning again to England in 1882, expounded theosophy to the British public in two widely circulated volumes, *The Occult World* (1881) and *Esoteric Buddhism* (1883). H. A. BEERS.

Sino'pe (Gr. Σινώπη, Turk. *Sinûb*): town; in Asia Minor, in the vilayet of Castamouni (see map of Turkey, ref. 4–G). Situated on a peninsula with a splendid harbor, it was the most important of the Greek colonies on the Black Sea. It was the capital of the kingdom of Pontus. Mithradates the Great was born here (134 B. C.). During the Middle Ages it belonged to the empire of Trebizond, and was captured by Mohammed II. (1470). In its harbor the Ottoman fleet was defeated with a loss of 4,000 men and twelve ships by the Russian admiral Nachimoff (Nov. 30, 1853). This event decided France and Great Britain to interfere, and brought on the Crimean war. The town is well fortified, and has an arsenal and shipyard. It exports dried fruits, fish, skins, nuts, and tobacco. Pop. (1889) 7,162, of whom 2,840 are Greeks. E. A. GROSVENOR.

Sinters [loan-word from Mod. Germ. *sinter* < O. H. Germ. *sintar*: O. Eng. *sinder* (the spelling *cinder* due to influence of Fr. *cendre* < Lat. *cinis*)]: a general designation for mineral substances deposited as incrustations or porous and cellular masses from the waters of mineral springs. The principal kinds are siliceous and calcareous sinters. Some siliceous sinters are classed by Dana with the crypto-crystalline varieties of quartz. They proceed from waters containing silica itself in solution, or sometimes, doubtless, soluble silicates of bases which are decomposed by the carbonic acid of the air. The great mass of siliceous sinters are composed of hydrates of silica. Fiorite, michaelite, and geyserite are names that have been given to some of these. Calcareous sinters are also called calcareous tufas. They are similar in nature and origin to the material of STALACTITES (*q. v.*).

Sintra: See CINTRA.

Sinus: See FISTULA.

Sion, Mount: See ZION.

Sioot, or **Siut**: See ASSIUT.

Siouan (soo'ăn) **Indians**: that linguistic stock or family to which the "Sioux" and cognate tribes of North America belong. According to Trumbull, Sioux, the popular appellation of the tribes which call themselves Dakota, Lakota or Nakota, is an abbreviation of Nadowessioux, which is a corruption of Nadowe-ssi-wag, "the snake-like ones" or "enemies" (derived from the Algonquin word *nadowe*, a snake). The characteristic languages are eminently vocalic and abound in inflections; agglutination and juxtaposition are also found.

Tribes.—The family comprises a number of tribes commonly arranged in ten groups, as follows: 1. (*A*) *Dakota* and (*B*) *Assiniboin*. The former includes the six Dakota sub-tribes, (*a*) Santee, comprising the Mde-wa-ka^{n}-to^{n}-wa^{n} (Spirit-lake village) and Waqpe'kute ("to shoot among deciduous trees"); (*b*) Sisseton (Sisito^{n}wa'^{n}); (*c*) Wahpeton (Wa-qpeto^{n}wa^{n}, "dwellers among deciduous trees"); (*d*) Yankton (Ihañkto-wa^{n}, "end village"); (*e*) Yanktonnai (Ihañkto^{n}wa'^{n}na, "little end village"), divided into Upper Yanktonnai (including the Cut Head band or Pa-baksa gens) and Lower Yanktonnai; and (*f*) Teton (Ti'to^{n}-wa^{n}, "dwellers on the prairie"), in seven divisions, namely, Brulé (Sitea^{n}xu, "burned thighs"), including Upper or Highland Brulé and Lower or Lowland Brulé; Sans Ares (Ita'zipteo, "without bows"); Blackfeet (Sihasapa); Minneconjou (Miniko'oju, "planting beside streams"); Two Kettles (Oo'heno^{n}-pa, "two boilings"); Oglala (o-gla'la, "she poured out her own"), including the Wazaza and the Loafers (Waglu'xe, "inbreeders"); and Huñkpapa (Unepapa or Uncapapa). The tribal organization of the Assiniboin is uncertain; they are called Hohe (rebels) by the Dakota. 2. *Dhegiha* (or *Cegiha*), consisting of the tribes known as (*a*) Omaha (Uma^{n}ha^{n}, "upstream people"); (*b*) Kwapa or Quapaw (Uka'qpa, "downstream people," the Arkansa or Arkansas of early writers); (*c*) Ponka or Ponca; (*d*) the Osage (Waeaea, etc.), divided into Little Osage (Ütsĕhta, "campers on the lowland") and Big Osage (Pahe'tsi, "campers on the mountain"), and the "Arkansaw band" (Santsu'kci$_{n}$, "campers in a highland grove"); and (*e*) the Kansa (Kaw, Ka^{n}ze, referring to the wind). 3. *Tciwere*, comprising (*a*) the Iowa (Pa'qotce, "dusty noses" or "dusty heads"); (*b*) the Oto (Watota, "lovers of sexual pleasure"); and (*c*) the Missouri. 4. *Winnebago*, including only the Winnebago tribe (who call themselves Hoteañgara, "people of the parent speech"). 5. *Mandan*, consisting of the Mandan tribe. 6. *Hidatsa* (Minnetaree or Gros Ventres of the Missouri), consisting of (*a*) the Hidatsa and (*b*) the Crow (Absoroka or Absaruqe, etc.) tribes. 7. *Tutelo* (Yesa^{n}), comprising the Tutelo, Sapona, and cognate tribes. 8. *Biloxi* (calling themselves Tanĕksha^{n}yadi), including the Biloxi and very probably the Paskagula or Pascagoula tribes. 9. *Catawba* (Flatheads), comprising the Catawba, Woccon, and cognate tribes (? Eutaw, ? Chickoree, ? Nachees, etc.). 10. The "Virginia group," composed of the Mannahoak, Monacan, and cognate eastern tribes and confederacies (mainly extinct).

Habitat.—Excepting the Biloxi, Paskagula, Tutelo, Sapona, Catawba, and Woccon tribes, the territory of the Siouan Indians was mainly in one body, extending from about 53° N. in the Hudson Bay Company territory to about 33°, including a considerable part of the watershed of Missouri river and that of the upper Mississippi. The detached portion of Siouan territory on the E. was occupied by Catawba, Biloxi, etc. It comprised a portion of the present States of Virginia, North Carolina, and South Carolina. Contrary to current opinion, the general trend of Siouan migration has been westward.

General Characteristics.—The Dakota tribes were warlike. They were hostile not only to the white people and Indians of other families (especially the Ojibwa and Pawnee), but also to the Crow, Hidatsa, Mandan, Omaha, and other tribes of their own family. Many of the Dakota have come under the influence of Christianity, and are advancing toward civilization. The Omaha and the Ponka have been warlike, but they have never fought against the U. S.; this might be said also of the southern tribes of this family.

Sociology.—The civil and religious institutions are determined by kinship as expressed in terms of consanguinity and affinity. The unit of the social organization is the *gens*, which is usually characterized by one or more taboos. The religious and the legislative, executive, and judicial functions are not differentiated, being exercised by chiefs whose tenure of office is limited by age or other physical incapacity, or by misconduct. The chiefship descends from father to son, unless the ambition and influence of a near relative displace him. With some exceptions descent is in the male line, although the entire system of consanguinity and affinity bears traces of a period in which descent was in the female line. A plurality of wives is deemed essential to the amassing of wealth, which is one avenue to power; divorce is optional with the husband. Civil government, personal conduct, property rights, corporations or organized bodies of persons, war, and international relations are regulated by laws and compacts. Indirectly related to the civil government are two kinds of associations for religious, industrial, and other purposes, the first being the feasting organizations and the second the brotherhoods or dancing societies, to some of which the shamans belong. Murder and rape, as a rule, are punished or avenged by death at the hands of kindred of the victim.

History.—The Dakota were mentioned in the *Jesuit Relations* as early as 1639–40. In 1658 they had thirty towns W. N. W. from the mission St. Michel of the Potawatami; in 1689 they were on the upper Mississippi near St. Croix river. In the nineteenth century the Teton Dakota went into the Black Hills region, previously occupied by the Crow tribe.

The Yankton and Yanktonnai passed from the upper Mississippi into the upper Missouri country prior to 1800. In 1862 the Santee and other Dakota joined in a formidable uprising in which over 1,000 whites were killed. Spotted Tail, Red Cloud, Crazy Horse, Sitting Bull, American Horse, and Even-his-horse-is-feared (popularly called Man-afraid-of-his-horses) are among the most famous Dakota chiefs and warriors of the nineteenth century. An outbreak of serious proportions was narrowly averted during the ghost-dance excitement at Pine Ridge agency in the winter of 1890–91. In all, over 850 Dakota are located in Canada and over 27,500 in the U. S., chiefly in North and South Dakota, Montana, and Nebraska.

Hennepin (1680) described the Assiniboin as dwelling N. E. of the Issati (Isanyati, Santee, or Mdewakantonwan), who were on Knife Lake, Minnesota. The Jesuit map of 1681 placed them on Lake of the Woods, then called Lake Assinepoualacs. They were near this lake in 1766, when they were said to have 1,500 warriors. In 1829 they were W. of the Dakota and N. of the Missouri and Assiniboine rivers, with a population of 8,000. Drake (1848) numbered them at 10,000 before the smallpox epidemic of 1838; that epidemic carried off 4,000. Since 1843 they have been decreasing in numbers. In 1890 there were about 3,000, mostly in Canada; some 700 were at Fort Peck reservation, Montana.

According to tribal traditions, the Omaha, Ponka, Kwapa, Osage, and Kansa tribes were originally one people, dwelling on the Ohio and Wabash rivers. A separation took place as early as 1500, as it preceded de Soto's discovery of the Mississippi; those who went down the Mississippi became the Kwapa, and those who went up the river the Omaha; the Ponka settled on Niobrara river. The Omaha subsequently occupied the country between Covington, Neb., on the N. and Nemaha river on the S., ranging W. as far as the Ponka and Pawnee habitats. About the beginning of the nineteenth century they were near Omaha, Neb. In 1890 they numbered nearly 12,000. They are citizens of the U. S. and of Nebraska.

Although archaic, the name Ponka does not appear in history till 1700. The Ponka were met by Lewis and Clark in 1804, when they had been reduced by the smallpox to about 200. In 1829 they numbered 600; in 1842, 800; and in 1871, 747. Prior to that time they had been friends of the Dakota; but a cession of lands to the Sioux reservation made the tribes enemies. The warfare continued until the forcible removal of the Ponka tribe to the Indian Territory in 1877. A commission appointed in 1880 visited both settlements of the Ponka, and their investigations resulted in legislation in favor of the tribe. Those who agreed to remain in the South are said to be prospering. In 1890 they numbered over 600, while those in Nebraska numbered 217.

The Kwapa were found in 1541 by de Soto on the Mississippi, above the St. Francis, apparently near the site of the present New Madrid. La Salle (1681) found them in three villages along the Mississippi. The earliest mention of "Akansa" is by La Métairie in 1682. Saint-Cosme says the greater part of the Kwapa died of the smallpox in Oct., 1699. Gravier (1701) mentions five villages, the Imaha (equivalent to Omaha in meaning), which he terms "the largest village of the Akansa confederation," being the *highest up* the Arkansas, while Sibley (1805) says the Arkansa were in three villages about 12 miles above Arkansas Post. The Kwapa subsequently affiliated with the Caddo, though of another linguistic family. In 1877 the Kwapa were on their reservation in the Indian Territory, but most of them later removed to the Osage country. Their total number in 1890 was 232.

The Osage were mentioned by Marquette (1673) as the Ouchage and Autrechaha. In 1829 Porter gave their number as 5,000, and described their country as beginning 25 miles W. of the Missouri line, running to the Mexican line (of that date), being 50 miles wide. Schoolcraft said that in Apr., 1853, they numbered 3,788. In 1894 they were on the Osage reservation, Oklahoma; in 1890 they numbered 1,581.

After the cession of Louisiana to the U. S., a treaty with the Kansa tribe was made by the Government. They were then on Kansas river, at the mouth of the Saline, and numbered about 1,500, in 130 earth lodges. In 1825 they ceded their lands on the Missouri, retaining a reservation on Kansas river. In 1846 they again ceded their lands, and a reservation was assigned them on Neosho river, in Kansas. This was soon after sold, and a new reservation acquired in Indian Territory. In 1890 they numbered 214.

In 1761 Jefferys located the Iowa Indians on the east side of Missouri river, W. of the heads of Des Moines river, above the Oto and below the Maha (Omaha). Drake (1848) said that in 1805 they numbered 800, and dwelt 40 leagues up Des Moines river, on the southeast side. Part of the Iowa afterward removed to the Sac and Fox reservation in what is now Oklahoma, but the rest remain on the Great Nemaha reservation, Kansas. Their number in 1890 was 273.

The Oto was the third tribe to separate from the Winnebago, the Iowa being the first and the Missouri the second. In 1673 they were placed by Marquette between 40° and 41° N. lat., W. of Missouri river, E. of the Maha (Omaha) and S. E. of the Pana (Pawnee or Ponka?); in 1680 they were 130 leagues from the Illinois, almost opposite the mouth of Miskoncing (Wisconsin) river; and in 1687 they were on Osage river. Iberville (1700) located the Iowa and Oto with the Omaha, between Mississippi and Missouri rivers, about 100 leagues from the Illinois tribe. In 1833 Catlin found the Oto and Missouri together in the Pawnee country. In 1894 they were with the Missouri on the Ponka, Pawnee, and Oto reservation, Oklahoma. Together with the Missouri, they numbered nearly 400.

The name Missouri first occurs about 1687. Their village was placed by Bourgmont (1723) 30 leagues below Kansas river, and 60 leagues below the principal Kansa village. The tribe formerly dwelt at the mouth of Missouri river, but gradually ascended that stream. About 1798 or 1800 they were dispersed by the Sac and Fox and other Indians; five or six lodges joined the Osage tribe, two or three took refuge with the Kansa, and most of the remainder amalgamated with the Oto. In 1805 Lewis and Clark found the Missouri in villages S. of Platte river, numbering 300 souls. They were with the Oto in 1829, when they numbered 80, and followed them to Indian Territory in 1882.

The Winnebago are closely related to the Iowa, Oto, Missouri, and Mandan. The earliest mention of the name is in the *Jesuit Relation* of 1640. Nicollet found them on Green Bay, Wisconsin, in 1639. Kelton says that they derived their popular name from their former residence on Winnebago Lake, called by the Algonquin tribes near it *Winibi*, dirty water. In 1811 Pike named seven Winnebago villages. In 1822 the Winnebago population was estimated at 5,800, with 900 warriors. By treaties in 1825 and 1832, they ceded all their land S. of Wisconsin and Fox rivers for a reservation on the Mississippi above the Oneota. One of their villages in 1832 was at Prairie la Crosse. During their third visitation of smallpox, in 1836, more than one-fourth of the people perished. In 1837 they relinquished their title to the country E. of Mississippi river, and in 1840 removed to the Territory of Iowa. In 1846 they surrendered their reservation for one above Minnesota river, and in 1856 removed to Blue Earth, Minn., and thence to a new reservation on the Omaha lands above Fort Randall, where they occupy lands allotted in severalty. In 1890 there were 1,215 here, with nearly 1,000 elsewhere, chiefly in Wisconsin.

The Mandan settled about 1750 on Missouri river, near the mouth of Heart river, in nine villages; they afterward ascended the river to a point 1,430 miles above its mouth. In 1837 the Mandan were almost destroyed by the smallpox, there being left only thirty-one (according to one account, though others vary from 125 to 145) out of 1,600. About 1872 a reservation was set apart for the Mandan, Hidatsa, and Arikara, in Dakota and Montana, along Missouri and Yellowstone rivers. In 1890 the Mandan numbered 252.

The Hidatsa were formerly known as the Minnetaree or Gros Ventres of the Missouri, and so were often confounded with the Minnetaree or Gros Ventres of the Plains, or the Atsina, of the Algonquian family. In 1796 there were three villages of this tribe on Knife river, in what is now North Dakota. The largest, Hidatsa, gave its name to the tribe. After the smallpox epidemic of 1837, the villages united. In 1845 the Hidatsa tribe (and about the same time the Mandan) moved up the Missouri and established a permanent village 30 miles by land and 60 by water from their old home. They were joined by the Arikara in 1862. In 1890 the Hidatsa on Fort Berthold reservation numbered 522.

The real name of the Crow tribe, which is Absaroka or Absoruqe (Hoffman), does not mean "crow," but refers to a species of hawk. When met by Lewis and Clark the Crow were in four "bands." In 1817 Brown located them on Yellowstone river. The Indian *Report* of 1842 gave their number as 4,000, inhabiting the head waters of the Yellowstone. They were later gathered on the Crow reservation, Montana, and in 1890 numbered 2,287.

The Tutelo or Yesan was the leading tribe of the seventh group of Siouan Indians. To this group belonged the

Sapona and probably the Occanecche or Akenatzy, Keyauwee, Shoccorie, Stenkenock, and Meipontsky tribes. The Tutelo were first referred to by Capt. John Smith. They were in Southern Virginia in 1671, according to Batt; in North Carolina in 1714, according to Lawson. They and the Sapona returned to Virginia, and in the eighteenth century, with the Nottoway and Meherrin, migrated into Pennsylvania and subsequently joined the Six Nations. At the close of the Revolutionary war the Tutelo followed the Six Nations into Canada, settling on Grand river reservation, Ontario. The tribe was nearly exterminated by smallpox in 1848, and the last survivor died in 1870.

In 1669 the Biloxi had one village on Biloxi Bay, near the Gulf of Mexico; thirty years later there were three villages, Biloxi, Paskagula, and Moctobi. In 1804 the Biloxi were on Red river, and in 1828 they were reduced to twenty families on Neches river, Texas. In 1894 about twenty-five of the tribe survived in Lecompte, Rapides parish, La.

Of the Catawba tribes, those mentioned earliest were the Wateree and St. Helena, seen by Juan Pardo's expedition in 1567. In the earlier part of the next century the Catawba proper (who were called Flatheads) were on Catawba creek, in Botetourt co., Va., and may have occupied the adjoining county, Roanoke, where there is now a settlement bearing their name. About 1660 they migrated to South Carolina. Lawson (1701–02) spoke of the Kataba on Catawba river, South Carolina, as Esaw, and distinguished them from the Kadapaw on Lynches creek. Adair states that in 1743 the Catawba had 400 warriors; Ramsay (1795) that in 1780 they numbered 490 with 150 warriors. In 1780 they withdrew before Cornwallis to Virginia, where some of them joined the American army, returning to establish themselves in two new villages. About 1841 they sold to the State of North Carolina 14 sq. miles of their territory, reserving only 1 sq. mile and a tract of land on the east side of Catawba river. At that time, as also in 1890, they numbered about 120.

The Mannahoak confederacy of Virginia consisted of about a dozen tribes, of which the names of eight have been preserved. Their habitat was between tide-water and the Blue Ridge. Of the Monacan confederacy of Virginia five tribes were named by Capt. John Smith, Lederer, and Jefferson. Both confederacies are extinct.

For a description of the manners, customs, etc., of the Siouan Indians (with others), see INDIANS OF NORTH AMERICA.

Ethnology, 1894); *Indian Linguistic Families*, by J. W. Powell (in 7th Ann. Rep. Bur. Am. Ethnology); *Information respecting the Indian Tribes of the United States*, by H. R. Schoolcraft.

JAMES OWEN DORSEY.

Sioux (soo) **City**: city; capital of Woodbury co., Ia.; at the junction of the Big Sioux and Missouri rivers; on the Chi., Mil. and St. P., the Chi., St. P., Minn. and Om., the Ill. Cent., the Sioux City and North., the Sioux City and Pac., the Sioux City, O'Neill and W., and the Union Pac. railways; 80 miles S. of Sioux Falls, S. D., and 100 miles N. by W. of Council Bluffs (for location, see map of Iowa, ref 4–C). It is the second city in size in the State, has a large frontage on the Missouri river and a picturesque residence quarter on high bluffs, and is an important commercial center. It is the gateway to South Dakota, the upper Missouri region, and the Black Hills mining and grazing country.

Public Interests.—The city has all the modern improvements: water-works (cost $1,000,000); 51 miles of electric and 3 miles of elevated railway; gas and electric lights; over 40 miles of sewers; 25 miles of paved streets; city-hall and public library (cost $80,000); police building ($30,000); county court-house; U. S. Government building ($250,000); Y. M. C. A. building ($60,000); 2 hospitals; a Union dépôt ($600,000); and a bridge across the Missouri river ($1,000,000). There are over 40 churches, several of which cost from $50,000 to $75,000 each; 30 public-school buildings (cost over $650,000), including a high-school building that cost $130,000: the University of the Northwest, and 3 daily and 13 weekly papers.

Business Interests.—The census returns of 1890 showed 195 manufacturing establishments (representing 50 industries), with a combined capital of $4,938,606, employing 2,997 persons, paying $1,862,612 for wages and $10,329,994 for materials, and turning out products valued at $14,164,667. In 1895 there were 5 meat-packing houses with a capacity for slaughtering and packing 13,000 hogs, 3,000 cattle, and 1,600 sheep per day. Over $6,000,000 was invested in manufacturing. The principal productions were stoves, engines, shoes, flour, soap, starch, wagons, plows, tile, brooms, furniture, and clothing. The jobbing trade amounts to about $30,000,000 per annum. There were 17 banks of all kinds, having a combined capital of $3,575,000 and a surplus of $940,000, and 2 loan and trust companies.

History.—The city was settled by traders in 1849, was an important Government post during the early Indian troubles, and was the outfitting point for the Black Hills expeditions. It achieved great fame from its corn palaces, beautiful structures decorated with grains, grasses, and other products of the soil. Five were built, in which annual fairs and festivals were held, lasting a month. Since the palaces were abandoned annual interstate fairs have been held at Riverside Park, a beautiful retreat in the suburbs, with ample grounds and a race-track.

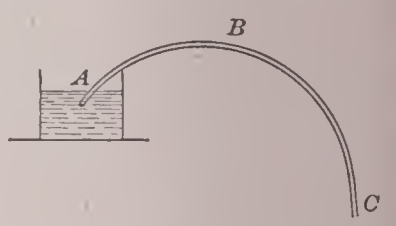
Pop. (1880) 7,366; (1890) 37,806; (1900) 33,111.

ORA WILLIAMS, MANAGING EDITOR OF "JOURNAL."

Sioux Falls: city (incorporated as a town in 1877, as a city in 1883); capital of Minnehaha co., S. D.; on the Big Sioux river, and the Burl., Cedar Rap. and N., the Chi., Mil. and St. P., the Chi., St. P., Minn. and Om., the Great N., and the Ill. Cent. railways; 90 miles N. of Sioux City, Ia. (for location, see map of South Dakota, ref. 7–G). It is in an agricultural and stone-quarrying region; has large stock-raising interests; derives great power from the river, which falls nearly 100 feet in a series of cascades within a distance of half a mile; and contains water-works, sewers, and gas and electric-light plants. The streets are paved with jasper, quarried near the city, and many buildings are constructed with the same stone. There are 30 churches, 7 public-school buildings, public-school property valued at over $175,000, Sioux Falls University (Baptist), All Saints' School (Protestant Episcopal), a Norwegian-Lutheran college, a business college, the State School for Deaf Mutes, the South Dakota penitentiary, 4 national banks with combined capital of $450,000, 3 State banks with capital of $200,000, and 2 daily, 7 weekly, and 3 monthly periodicals. Sioux Falls is the seat of the Protestant Episcopal bishopric of South Dakota and of the Roman Catholic bishopric of Sioux Falls. Pop. (1880) 2,164; (1890) 10,177; (1900) 10,266.

CHARLES M. DAY, EDITOR OF "ARGUS-LEADER."

Siphon [from Lat. *si'pho*, *sipho'nis* = Gr. *σίφων*, reed, pipe, tube, siphon]: a bent tube for conveying water from a reservoir, A, to a lower level, C, over an elevation, B, which is not more than 33 feet higher than A. To put the siphon into action the air must be exhausted, and then the atmospheric pressure on the surface of the water at A causes the water to rise and flow over, with a velocity depending upon the difference of level between A and C. The siphon is used for emptying casks, and sometimes on pipe-lines for water-works, but in the latter case a pump is placed at B, in order to remove the air which otherwise accumulates there and diminishes the flow. See HYDRAULICS.



M. M.

Siphonap'tera [Mod. Lat., from Gr. *σίφων*, tube + *ἄπτερος*, wingless]: an order of insects which contains the fleas. See ENTOMOLOGY.

Siphona'ta [Mod. Lat., deriv. of *sipho* = Gr. *σίφων*, tube]: one of the two divisions into which the lamellibranch molluscs (clams, etc.) were formerly divided, the name being given in allusion to the fact that the posterior edges of the mantle were united with a tube (familiar in the so-called "head" of the common clam). See LAMELLIBRANCHIATA.

Siphonoph'oræ [Mod. Lat., from Gr. *σίφων*, tube + *φορός*, bearing]: a group of HYDROZOA (*q. v.*) characterized by the formation of free-swimming colonies, the individuals of which have become highly differentiated. These individuals are each modified jellyfishes, and are connected by a tube, whence the name. In a typical form the following individuals may occur: (1) A float, to suspend the colony, occurring

at the end of the tube; (2) swimming bells; (3) feeding polyps; (4) digestive polyps; (5) reproductive polyps; (6) sensory polyps; (7) tentaeles; (8) covering scales, which cover and proteet some of the others. Of these the swimming and reproductive individuals retain most clearly the medusan features. Usually one or more of the individuals may disappear, while in many forms the tube may be eontraeted into a disk. The siphonophores, of whieh there are many speeies, vary greatly in size and appearanee. Some are but an ineh or two in length, while others are 2 yards or over. Some are perfeetly transparent and eolorless, while others (e. g. *Physalia* and *Velella*) are brilliantly eolored with blues, reds, and greens. Many of the species are armed with powerful batteries of nettle-cells, and contaet with them will eause severe pain in man. Most of the speeies inhabit tropical seas. See Haeckel, *Zoölogical Reports* of the Challenger expedition, vol. xxviii. (1889), and papers by Gegenbaur, Huxley, Claus, and Fewkes. J. S. Kingsley.

Siphonosto'mata: See Copepoda.

Sipuncula'cea, or **Sipunculoi'dea** [Mod. Lat., named from *Sipun'culus*, the typieal genus, from Late Lat. *sipunculus*, for Lat. *siphun'culus*, dimin. of *si'pho*, *sipho'nis*, tube. See Siphon]: a group of marine worms in whieh the body is usually elongate and cylindrieal, without traees of segmentation, and without bristles or other appendages. The mouth is at the anterior end of the body, and this region can be inverted into the rest by the aetion of retraetor muscles. The mouth is usually surrounded by tentaeles. Internally, all traees of segmentation are lost, and the viseera are suspended in an extensive body-eavity. The intestine is usually coiled upon itself, and the vent is dorsal, near or in front of the middle of the body. There are one or two exeretory organs (nephridia), and the genital produets, whieh arise at the origin of the retractor muscles, and whieh are set free in the body-cavity, pass out through the nephridia. A eirculatory system is well developed, and the tentaeles subserve respiratory purposes. There is a metamorphosis in development, the larva being strikingly like that of the true annelids. These worms burrow in the sand or inhabit tubes, dead shells, etc. Over 100 speeies are known. See Selenka, *Sipunculiden*, in Semper's *Philippinen Reise* (1883); Andrews, *Anat. Sipunculus.*, Studies Johns Hopkins Laboratory, iv. (1890); Hatsehek, *Entwickelung*, in *Arbeiten d. zool. Inst. Wien*, v. (1884). J. S. Kingsley.

Sirbonian Bog, or **Sirbonic Lake**: formerly a long, narrow body of water, separated from the Mediterranean by a low strip of shore, and extending eastward from Pelusium in Egypt. It is now dry and eovered with sand. At the beginning of the Christian era Strabo (*Geogr.*. i., 3, 4) spoke of it as a marsh, and just previously Diodorus reported that it was overgrown with reeds and papyrus. These statements do not agree with the further statements of Strabo (xvi., 2, 33, and 42, 43) that it was a deep body of heavy water into which one could not dive, and that asphalt or bitumen rose to the surfaee near the middle of it, whenee it was gathered by men on rafts. One of the prineipal routes to Asia led along the narrow neek between sea and lake, but it was dangerous at eertain states of wind and tide. Artaxerxes is said to have lost a part of his army when attempting the passage. The route of the Exodus proposed by Brugseh included the erossing of the bog by the Israelites, but the discovery of the site of Pithom overthrew his theory by loeating the initial stages of the itinerary about midway of the isthmus. Charles R. Gillett.

Sir-Darya: See Syr-Darya.

Sire'don [Mod. Lat., from Gr. σειρηδών, late collateral form of σειρήν, siren]: a name at first applied to the axolotl of Mexico, but now extended to inelude the large larvæ with external gills of several species of salamanders belonging to the genus *Amblystoma*.

Siren [Mod. Lat., from Gr. σειρήν, siren. So named because supposed to have a singing voiee]: a genus of tailed amphibians of the southern parts of the U. S. The only species is *Siren lacertina*, the mud-eel of the Carolina rieeswamps. It has two weak fore legs, no hind limbs, permanent gill-tufts, as well as lungs, is 2 feet long, and blaek. It is eonsidered venomous by the Negroes. *Pseudobranchus striatus* is a smaller but very similar animal.

Sirene: See Acoustics.

Sire'nia [Mod. Lat., from Gr. σειρήν, siren. So called from a fancied resemblance of the dugong to the fabled sirens]: an order of mammals, containing speeies familiarly known as sea-cows. They are adapted for habitual life and progression in the water, but less modified than the eetaceans. The form is fish-like, the skull short and head small in proportion to the body; front limbs are present as flippers, hind limbs are absent; the body ends in a transversely flattened tail, whieh may be rounded, as in the manatee, or, as in the dugong, forked like the flukes of a whale. The brain essentially resembles that of the higher mammals, but is notable for the compression and elevation of the cerebrum, the upturned bulbous olfactory nerves, and the depression of the eerebellum. Molar teeth, adapted for the trituration of herbage, are in the sides of both jaws; the neek is moderate, and the seeond vertebra has a distinet odontoid proeess; the heart is deeply fissured between the ventrieles. The speeies are all herbivorous, and feed upon the vegetation growing on the banks of estuaries and rivers, as well as seaweed. When at rest they remain upraised from the bottom of the water by their tail, but with the head downward, and the back eonsequently arehed; at intervals of about one minute to one minute and a quarter they rise to breathe, and the valves of the nose open and shut as they come to the surfaee and go downward again. The order is now represented by two families—*Trichechidæ*, ineluding the manatees, and *Halicoridæ*, containing the dugongs. Up to the end of the eighteenth century a third family (*Rhytinidæ*) existed in the North Pacifie (Bering Sea), but its only living species was in a short time exterminated by the attaeks of man. The earliest extinet representatives of the order yet known are of Eoeene age, and sinee then several peeuliar forms have flourished and died out. See Dugong and Manatee. Revised by F. A. Lucas.

Sirenoi'dea: same as Dipnoi (*q. v.*).

Sirens [plur. of *Siren* = Lat. = Gr. Σειρήν, plur. αἱ Σειρῆνες, the Sirens]: in Greeian mythology, maidens who lived on an island between Seylla and the island of Ciree, and by their ravishing songs eharmed mariners to their ruin, for whoso heeded their singing saw nor wife nor home again. It was fated that the Sirens should die as soon as any one should pass by without heeding their singing. Odysseus eseaped their allurements only by stuffing his eompanions' ears with wax and having himself seeurely tied to the mast. The Argonauts eseaped them beeause they were eharmed by the superior singing of Orpheus. The Sirens were ehanged for one reason or the other to sunken roeks loeated at Pelorum, or Sorrento, or Capri, or the Sirenusæ. In earliest times they were represented as birds with the heads of maidens, and later as ereatures with the body of a maiden and the legs and wings of a bird. J. R. S. Sterrett.

Si'rius [= Lat. = Gr. Σείριος]: the dog-star, a star of *Canis major*, the brightest star in the heavens. It may be seen in the S. in the winter evenings. From the expressions of several aneient writers it is sometimes elaimed to have been red in aneient times, though now a brilliant white, but the question of its former color is not yet settled. It was formerly believed to exereise a powerful and, to some extent, a baleful influence upon human affairs.

Revised by S. Newcomb.

Siroc'co [= Ital., from Arab. *shoruq*, deriv. of *sharq*, sunrise, east, deriv. of *sharaqa*, rise; ef. Saracen]: a hot, relaxing wind which rises in the Sahara, then blows aeross the Mediterranean, where it occasionally beeomes filled with moisture, and finally over Sieily, Southern Italy, Malta, ete. It generally oeeurs in spring and autumn, lasts for one or two days, though sometimes for a whole week, and is very injurious to vegetable and animal life, causing general exhaustion, great prostration, and mental depression.

Sisal' Hemp [named from *Sisal*, a port of Yueatan]: the fiber of various species of Agave (*q. v.*). Sisal hemp is produeed in eonsiderable quantities in Yucatan and at Key West, Fla., and adjaeent islands. It makes exeellent eordage, superior to that of true hemp, but it is ehiefly made into hammoeks of great strength and durability.

Sis'co, or **Cisco**: any one of several fishes of the genus *Coregonus*, natives of the Great Lakes of North Ameriea. The prineipal speeies are the *C. artedi* (also ealled herring), and the *C. hoyi* of the deep waters of Lake Michigan. They are reeognizable by their herring-like form, terminal mouth, with the lower jaw longest, short intermaxillary bones, and the long and narrow suborbital bones. They are small, rarely weighing as mueh as a pound. The *C. artedi* inhabits the shoaler waters. It is in some places excessively abundant.

Sis'cowet, Siskowit, or **Siskawitz** [from native (Amer.-Ind.) name]: a variety of the great lake-trout (*Salvelinus namaycush*, var. *siskawitz*), found in Lake Superior. It is similar to the namaycush, but is less elongated, and becomes extremely fat.

Sisen'na, Lucius Cornelius: historian; b. about B. C. 119; was prætor B. C. 78; defended Verres in 70, and died B. C. 67 in Crete, being at the time legate of Pompey in the war with the pirates. Having been an actor in public affairs, he was well fitted to relate the events of his own time (including the Social war and the civil wars of Sulla) in his work entitled *Historiæ*, written in an archaic style. Cicero says of him (in his book on *Laws*) that he surpassed all previous Latin historians, and Sallust highly praises his diligence. Sisenna translated also into Latin the Milesian tales (Μιλησιακά) of Aristides. Whether the Sisenna who wrote commentaries to several plays of Plautus is the same is disputed. Only fragments of the *Historiæ* remain, collected by Peter in *Hist. Roman. Fragmenta*, pp. 175–189.

Revised by M. Warren.

Siskin [from Dan. *sisgen*, or Swed. *siska*; Germ. *zeisig*, from Sloven. *čižek*: Polish *čyžŭ*, siskin]: an Old World bird, *Spinus* or *Chrysomitris spinus*, of the family *Fringillidæ*. The male is a prevailing olive green above and yellowish white below, streaked with black on the back and sides, and with a black throat and crown. It is a favorite cage-bird. The pine-siskin (*S. pinus*) and the American goldfinch are related North American species.

Sismon'di, Jean Charles Léonard Simonde, de: historian and political economist; b. at Geneva, Switzerland, May 9, 1773; educated in the college of his native town, and was a clerk in a large counting-house in Lyons; political disturbances drove his family into exile, and he lived in England and later in Italy for several years; settled finally in his native town in 1800; devoted himself to studies and literary work, though at the same time participating very actively in politics; married in 1819 an English lady. D. near Geneva, June 25, 1842. His first work was a treatise on political economy. *De la Richesse commerciale* (1803), based on the ideas of Adam Smith, which, however, he afterward abandoned, and even opposed, in his *Nouveaux Principes d'Économie politique* (2 vols., 1819) and *Études sur les Sciences sociales* (3 vols., 1836). His acquaintance with Madame de Staël, Benjamin Constant, Guizot, etc., turned his attention from political economy to history, and it was as an historian that he acquired his great celebrity. His *Histoire des Républiques italiennes du moyen âge* (16 vols.) appeared at Zurich in 1807–18; *La Littérature du Midi de l'Europe* (4 vols., 1813) was translated into English by Thomas Roscoe in 1823. Of his principal work, *Histoire des Français* (31 vols., 1821–44), he gave an abstract, *Précis de l'Histoire des Français* (2 vols., 1839). See *Sismondi, Fragments de son Journal et de sa Correspondance avec Mlle. de Sainte-Aulaire* (1863), *Lettres inédites à Madame d'Albany* (1864), and another collection of *Lettres Inédites* (1878).

Sistan: See Seistan.

Sisterhoods: in the religious sense, unions of women devoted by public vows to religious work. They are in idea nearly as old as monasticism, for female branches of all the principal monastic orders were organized by the original founders, whose members are called nuns, and are technically spoken of as female religious. A distinction should be made, however, between a sister and a nun, for the former, unlike the latter, is not shut up in a convent, nor given up to contemplation and ascetic practices. Sisterhoods in the strict sense are modern, for the first one, still the most famous of all, was founded by St. Vincent de Paul in 1629, and is known variously as Daughters or Sisters of Charity, Gray Sisters, and Sisters of St. Vincent de Paul. (See article Charity, Sisters of.) There are now many sisterhoods, all doing similar work. One of them, the Irish Sisters of Charity, founded in 1815, uses an adaptation of the Jesuit rule. The vows of all are the monastic ones of poverty, celibacy, and obedience. To these are added, in some cases, other obligations. The sisters wear a distinctive dress, and have houses to live in and start from on their daily round of labor.

Protestant women, although equally devoted to the relief of suffering, do not, as a rule, favor sisterhoods. They prefer to work independently. Besides, they resent the implication of the vow as to "chastity," that the married relation is in any sense derogatory, instead of being in every respect an honor and glory to woman, and that it is a hindrance to spiritual life, whereas it is a divinely ordered help. Protestant sisterhoods date from the revival of what is called "Catholic" teaching in the Church of England. The first sisterhood in the Church of England was founded by Dr. Pusey in 1845. The Society of the Holy Trinity was founded at Devonport in 1847, and many others have since been organized. One of the largest is Sisters of the Poor, founded in 1851. The saintly Sister Dora (Dorothy Pattison, 1832–78) belonged to the Sisterhood of the Good Samaritans.

The first Protestant sisterhood in the U. S., the Sisterhood of the Holy Communion, was founded by Rev. Dr. W. A. Muhlenberg in New York in 1852. It took charge of St. Luke's Hospital in that city in 1859, and St. Johnland in 1866. The Sisterhood of St. Mary was founded in New York in 1865. There were in 1895 nineteen sisterhoods in the Protestant Episcopal Church, four being branches of English ones.

The Protestant sisterhoods differ somewhat in methods and objects, but agree in promoting a combination of piety and good works. They pay particular attention to the inner life, and strive to put the spiritual force thus gained to practical account. In dress their members resemble those in the Roman Catholic Church, except that they do not cover up the hair. They take vows, but not irrevocable ones, although it is very seldom that a woman leaves a sisterhood. For the allied order of Deaconesses, see Deaconess.

Sadlier's Catholic Directory (New York) annually gives the figures for the Roman Catholic sisterhoods in the U. S. and Canada, and the *Catholic Directory*, published in Dublin, those for Great Britain and Ireland. For the sisterhoods in the Church of England, see the yearly list in the *Kalendar of the English Church* (London). For those in the Protestant Episcopal Church see the *Living Church Quarterly* (Milwaukee, Wis.). On the general subject, see Mrs. Jamieson, *Sisterhoods of Charity* (London, 1855); Mary Goodman, *Sisterhoods in the Church of England* (1863; 2d ed. 1865); J. M. Ludlow, *Woman's Work in the Church* (1865); W. A. Muhlenberg, *Evangelical Sisterhoods* (New York, 1867); C. E. Stephen, *The Service of the Poor* (London, 1870); H. C. Potter, *Sisterhoods and Deaconesses at Home and Abroad* (New York, 1871); C. C. Grafton, *Vocation; or, The Call of the Divine Master to a Sister's Life* (1886).

Samuel Macauley Jackson.

Sisters of Charity: See Charity, Sisters of.

Sisters of Mercy: a Roman Catholic religious sisterhood, founded at Dublin, Ireland, in 1827, by Miss Catherine McAuley. The rule is similar to that of the Presentation nuns. Originally each convent was independent, but offshoots from the parent house, especially outside of Ireland, are usually subject to it. These religious women are always under the jurisdiction of the bishop in whose diocese they are located. They were introduced into the U. S. in 1843, at Pittsburg. Their convents are more than 200 in number, and the sisters are chiefly occupied in the conduct of parochial schools, private academies, hospitals, and homes for the aged. See *Life of Mother Catherine McAuley, Leaves from the Diary of a Sister of Mercy*, and *Hoffman's Catholic Directory* for 1895.

J. J. Keane.

Sisto'va: town and fortress; in Bulgaria, on the Danube, between Nicopolis and Rustchuk (see map of Turkey, ref. 3–D). It manufactures leather and cotton goods and carries on a large trade in wheat and wine. The treaty of Sistova was signed here between the Ottoman empire and Austria (1791), and the Russians crossed here in 1877. Pop. (1893) 13,212.

E. A. G.

Sis'yphus (Gr. Σίσυφος): in Grecian mythology, son of Æolus, father of Glaucus, grandfather of Bellerophon, and king and founder of Corinth. Because of his wickedness Zeus sent Death to take him to Hades; but Sisyphus bound Death and held him long time prisoner, so that no one died until Death was finally released by Ares. For this reason (though other reasons also are given) Sisyphus, when finally he had come to the house of Hades, was doomed to roll to the top of a high mountain a huge rock, which always broke away from him just as the top was being reached.

J. R. S. Sterrett.

Sit'ka (formerly New Archangel): capital of Alaska Territory, on Baranof island, near the Pacific coast, in lat. 57° 2′ N. (see map of Alaska, ref. 4–H). It has a harbor that is deep and commodious, but is difficult of ingress and egress. It was founded by the Russians in the eighteenth

century, and was long the headquarters of the Russian-American Fur Company, but consisted, when transferred to the U. S. in 1867, of only about 100 log huts. Since then several large edifices have been built, and the presence of a detachment of U. S. troops until 1877 did much to contribute to the prosperity of the place. A noteworthy relic is the Greek church of St. Michael, built in 1816. The Presbyterian mission established an industrial school there in 1878; also a hospital and a museum. Pop. (1890) 1,190; (1900) 1,396. M. W. Harrington.

Sitt'idæ [from *Sitta*, the typical genus]: a family of birds containing the nuthatches. See Nuthatch.

Sitting Bull (Indian name, Tatanka Yotanka): Sioux chief and medicine-man; b. on Willow creek, Dakota, 1837; became the leader of the unruly members of his tribe, who raided settlements of whites and small reservations of Indians—massacred whites at Spirit Lake, Iowa, and in Minnesota 1862, and were driven by Gen. Sully into the Big Horn region and to the Yellowstone 1864. They were defeated in a battle on the Muscle Shell river 1868; were placed on a reservation in the Black Hills, from which they were driven by miners, 1876; refused to be transported to the Indian Territory; resisted and slew a party of troops under Gen. Custer. On being pursued by Gen. Terry, Sitting Bull and some of his followers escaped into Canada. He surrendered on a promise of pardon 1880, and returned to Dakota, but continued to ferment trouble among the Sioux, and in 1890 the military authorities determined to arrest him. He was attacked Dec. 15 in his camp near Grand River, North Dakota, and during the fight that ensued was killed.

Siut: See Assiut.

Śiva, or **Shiva** [Sanskr., the gracious or blessed one]: a Hindu god, usually spoken of as the "Destroyer and Regenerator," the third member of the Hindu Trimurti or triad of divinities, of which Brahmā, the "creator," and Vishnu, the "preserver," are the first and second respectively. He appears, however, under a great variety of names, attributes, and functions. As the Destroyer he is represented by Rudra. As the Regenerator or Reproducer his symbol is the linga or phallus, and under this he is now usually worshiped. (See Linga.) He also represents the contemplative and ascetic side of Hinduism. He is represented as sitting absorbed in thought, naked, and smeared with funereal ashes, with matted hair, and wearing a necklace of human skulls and bones. He has three eyes, and fire from them consumes those who dare to interrupt his devotions. His worship is called *Saivism*, or *Sivaism*, and his worshipers *Saivas*.

Sivas' (anc. *Sebasteia*, Σεβάστεια): town; in Asia Minor, in the vilayet of Sivas, on the Kizil Irmak (see map of Turkey, ref. 4–G). Though situated in the center of an extensive and fertile plain at the juncture of natural routes, lack of roads nullifies these advantages, and the town is poverty-stricken and lifeless; hundreds of the natives work in distant places, above all in Constantinople, and thus support their families. It manufactures excellent carpets and woolen and linen goods. Pop. (1889) 39,368, of whom 23,619 are Mussulmans and 14,439 Armenians. E. A. G.

Sivathe'rium [Mod. Lat.; Eng. *Siva*, i. e. *Çiva*, the Hindu god + Gr. θηρίον, wild animal]: an extinct genus of ruminating animals from the Siwalik Hills, India, remarkable for their size and peculiar horns. *S. giganteum* nearly equaled the elephant in size, and was armed with two pairs of horns, a small pair springing from the anterior part of the head, and a much larger pair from the top. The bony cores of these horns, the only part preserved in the fossil state, show that these animals belonged to the hollow-horned type of ruminants. The front pair were divergent, apparently nearly straight, and simple. The posterior pair were branching, and had at least three points. The American antelope or prong-buck is the only living hollow-horned ruminant with branching horns. It is also the only one known to shed its horns. The posterior horns of *Sivatherium* seem to have closely resembled in structure those of the prong-buck, and may have been deciduous. The bones of the skeleton of *Sivatherium* were massive, like those of oxen. The nose was probably more or less movable, as evinced by the short projecting nasals. Falconer and Cautley supposed the animal to have possessed a true proboscis, but Dr. Muric concludes, from a study of the remains and a comparison with allied forms, that the nose was similar to that of the saiga of Tartary. O. C. Marsh.

Si'wah (anc. *Am'mon*, or *Ammo'nium*, Egypt. *Amun*): an oasis in Northwestern Egypt, 360 miles W. of Cairo, and 160 miles S. of the Mediterranean. Area, 6 sq. miles. The eastern part of the oasis is very fertile and rich in springs; in the northern part some limestone hills are found. In ancient times the place was celebrated as the seat of the temple of Jupiter Ammon, of which remains are extant, and of the Fountain of the Sun, whose waters were cold at noon and hot at midnight. The temple was immensely rich and guarded by strong fortifications. Cambyses attempted in vain to capture it. Alexander visited it, and was hailed by the priests as a son of the god. The Emperor Justinian built a Christian church here. The oasis is inhabited by about 3,350 Berbers and Negroes, who profess Mohammedanism, and speak a peculiar dialect much mixed with Arabic. The town of Siwah is in lat. 29° 12′ N., lon. 25° 30′ E., near the site of the ancient temple.

Revised by M. W. Harrington.

Six Nations: See Iroquoian Indians.

Six-principle Baptists: a sect of American Christians who take as their creed the six principles laid down in Heb. vi. 1, 2, viz.: (1) repentance, (2) faith, (3) baptisms (of repentance, of fire, and of Christ's sufferings), (4) laying on of hands, (5) the resurrection, (6) the eternal judgment. They especially insist upon the laying on of hands, and refuse to commune with those who do not practice it. They are Arminians, and neither educate nor adequately support their ministry. They are found in Rhode Island, Massachusetts, New York, and Pennsylvania. They were first organized in 1652 by William Wickenden, Chad Brown, and Gregory Dexter, at Providence, R. I., and once composed the most numerous and influential section of American Baptists. In 1900 they reported eighteen organizations and 937 communicants. Revised by W. H. Whitsitt.

Sixth: in music, an interval comprising five degrees of the diatonic scale. See Interval.

Sixtus: the name of five popes. (See Pope.) Sixtus IV. (Francesco della Rovere), b. 1414, entered the Franciscan order, attracted notice by his eloquence and learning, became the close friend of Cardinal Bessarion, through whose influence, it is said, he was chosen pope 1471. His pontificate was marked by munificence in founding and improving useful institutions, and in the patronage of arts and letters, but his nepotism caused great scandal, his connivance in the Pazzi conspiracy against the Medici was most dishonorable, and the war with Florence which he entered into was inglorious for the Holy See and disastrous for Italy. D. in Aug., 1484. Sixtus V. (Felice Peretti), one of the ablest of the Roman pontiffs, was born near Montalto, Dec. 18, 1521; entered the order of the Franciscans in 1534; became a teacher of canon law at Rimini and at Sienna, acquired great reputation as a preacher, and became a cardinal in 1570. Arrived at this point, his ambition seemed to go no further. He was not anxious either to exercise influence on the papal government or to procure lucrative positions for his relatives. He lived quietly, and gave the impression of being a man easy to lead. After the death of Gregory XIII. (1585) the cardinals, thinking he would be a mild and indulgent pope, elected him to the Holy See, but to their astonishment he threw off all concealment of the natural energy of character, and at once began vigorous measures of reform. In all theological controversies he was cautious and tried to remain neutral. His great idea was to raise the papal see once more to its former splendor, and although his negotiations with the Emperor Rudolph II. of Germany and Stephen Báthori, King of Hungary, led to no permanent result, they show his ambition and his talent. He pronounced the ban upon Henry III. of France; and when that monarch was assassinated by the Dominican monk Jacques Clement he openly approved of the deed. The celebrated aqueduct Acqua Felice, the great dome of St. Peter's church, the obelisk in front of this church, and the library buildings of the Vatican, are among the public works that he successfully executed. He also suppressed the banditti, encouraged commerce and manufactures, and enforced the law in his states. He died suddenly at Rome, Aug. 27, 1590. See Ranke's *History of the Popes*. F. M. Colby.

Sjöberg, syö'bärg, Erik (pseudonym *Vitalis*): poet; b. in Södermanland, Sweden, Jan. 14, 1794. The son of a laborer, his life was a hard struggle with poverty and disease. He was a master of satire, and his ridicule of the excesses of the Phosphorists had a wholesome influence upon Swedish literature. His style strongly resembles that of Byron. During the last years of his life he was a sincere Christian, and de-

voted himself to the study of Thomas à Kempis. D. at Upsala, Mar. 14, 1828. The complete works of Vitalis were published at Stockholm in 1873. D. K. DODGE.

Skagerrak', or **Skager-Rack**: an arm of the North Sea, 80 miles broad, extending between Norway and the Danish peninsula of Jutland, and connecting the German Ocean with the Cattegat or Kattegat. The current generally sets E. along the coast of Jutland, where the depth varies between 30 and 40 fathoms, and W. along the Norwegian coast, where the depth generally is 200 fathoms. There is neither haven nor good anchorage on Jutland, but good harbors abound on the opposite coast.

Skaneateles, skăn-ĕe-ăt'lĕez: village (settled in 1796, incorporated in 1833); Onondaga co., N.Y.; at the outlet of Lake Skaneateles; on the Skan. Railroad; 7 miles E. by N. of Auburn, 18 miles W. S. W. of Syracuse (for location, see map of New York, ref. 4–F). It is in an agricultural and teasel-growing region; derives good power for manufacturing from the lake; contains flour-mills, woolen-mills, iron-works, hydraulic lime-kilns, printing-paper mill, carriage-factories, Union School and Academy, public library (founded in 1877), a State bank with capital of $60,000, a savings-bank, and two weekly newspapers, and is a popular summer resort. Pop. (1880) 1,669; (1890) 1,559; (1900) 1,495.

EDITOR OF "FREE PRESS."

Skate: a name given to certain species of fish of the family RAIIDÆ (*q. v.*). See also RAIÆ.

Skeat, skēt, WALTER WILLIAM: clergyman and philologist; b. in London, England, Nov. 21, 1835; educated at King's College School and at Sir R. Cholmeley's school, Highgate; graduated at Cambridge University 1858; became a fellow of Christ's College 1860; took orders in the Church of England; curate 1860–64; became lecturer on mathematics at Christ's College Oct., 1864, and subsequently lecturer on English; was in 1873 one of the founders of the English Dialect Society. A prolific and useful writer and editor, he has published some forty works, among which are the following for the Early English Text Society: *Lancelot of the Laik, a Scotch Metrical Romance* (1865); *Parallel Extracts from 29 MSS. of Piers the Plowman* (1866); *The Romans of Partenay or Lusignan, otherwise known as the Tale of Melusine* (1866); *Pierce the Ploughman's Crede* (1867); *The Vision of William concerning Piers the Plowman* (3 parts, 1867–73); *The Romance of William of Palerne, or William and the Werwolf* (1867); *The Lay of Havelok the Dane* (1868); *The Bruce, by Master John Barbour* (part i., 1870); *Joseph of Aramathie, or the Romance of the Seint Graal* (1871); and Chaucer's *Treatise on the Astrolabe*. For several of these he prepared introductions, notes, and glossarial indexes. For the Philological Society he edited a *Mœso-Gothic Glossary* (1868), for the Oxford University Press 2 vols. of *Specimens of English Literature* and several of Chaucer's *Canterbury Tales*, and completed for the Cambridge University Press the *variorum* edition of the *Anglo-Saxon Gospels* left unfinished by John Mitchell Kemble. In a new edition of Chatterton's *Poems* he settled the question of authenticity by showing the precise sources of Chatterton's diction; is author of a *Handlist of some Cognate Words in English, Latin, and Greek* (1871); *Questions for Examination in English Literature* (1873); an *Etymological Dictionary of the English Language* (1882); *The Principles of English Etymology* (2 vols., 1887–91); an edition of *Chaucer's Minor Poems* (1888); and *Complete Works of Geoffrey Chaucer* (6 vols., 1894).

Revised by BENJ. IDE WHEELER.

Skeleton [= Mod. Lat., from Gr. σκελετόν (sc. σῶμα, body), dried body, mummy, skeleton, liter., neut. of σκελετός, parched, dried up, deriv. of σκέλλειν, dry, parch]: in its broadest sense, the structures serving to support and protect the more delicate tissues of the body of an animal. Among the invertebrates the skeleton is often represented by calcareous or siliceous plates or masses developed in connection with the integument, hence known as the exoskeleton, as distinguished from the more highly specialized supporting apparatus developed within the connective tissue as the cartilage or the true osseous substance which constitutes the endoskeleton. Ignoring the feeble attempts at the formation of a connective-tissue skeleton which are found among the lower animals, as the *Vermes* and the *Mollusca*, a true skeleton, composed of cartilaginous or osseous pieces forming a definite framework throughout the body, may be said not to exist except in vertebrated animals.

In addition to the endoskeleton, many vertebrates also possess in connection with the integument supplementary protecting structures which constitute an exoskeleton. Conspicuous examples of such structures are seen in the external skeletal plates of the sturgeon, the tortoise, or the armadillo. In other animals, again, a partial bony support is formed within the substance of certain organs, as, for example, the bony plates within the heart-walls of ruminants, the osseous rods within the tongue of certain lizards, or the slender bone within the male copulative organ of many carnivora, rodents, bats, and some monkeys. Such osseous structures occurring within the substance of the viscera constitute the splanchno-skeleton.

The first framework formed within the immature animal is the primary cartilaginous skeleton which is developed by the specialization of parts of the connective tissue of the embryo. This framework of cartilage in a general way outlines the bony skeleton, although much simpler than the latter in its details. Among the higher vertebrates the cartilaginous structures are only temporary, and after affording support to the delicate softer tissues of the developing organs for a limited time are replaced by the permanent bony skeleton. While such substitution is almost complete among the higher animals, some of the lower vertebrates, as the sharks, retain the primary cartilaginous framework throughout life as their permanent skeleton. Usually, however, after a time, at certain points called centers of ossification, the cartilage becomes invaded by true bone-producing tissue, and the substitution of osseous for cartilaginous structures is effected. For the details of the process of bone-formation, see the article HISTOLOGY.

Every vertebrate, whether fish, amphibian, reptile, bird, or mammal, possesses in the spine or vertebral column a fundamental axis in regard to which the remaining portions of the endoskeleton are symmetrically arranged. This axis is not necessarily bony in character, since in some fishes it never develops beyond the cartilaginous condition. In the lanceolet, or amphioxus, it never attains even to the cartilaginous stage, but represents the primitive embryonic axis, the notochord. See EMBRYOLOGY.

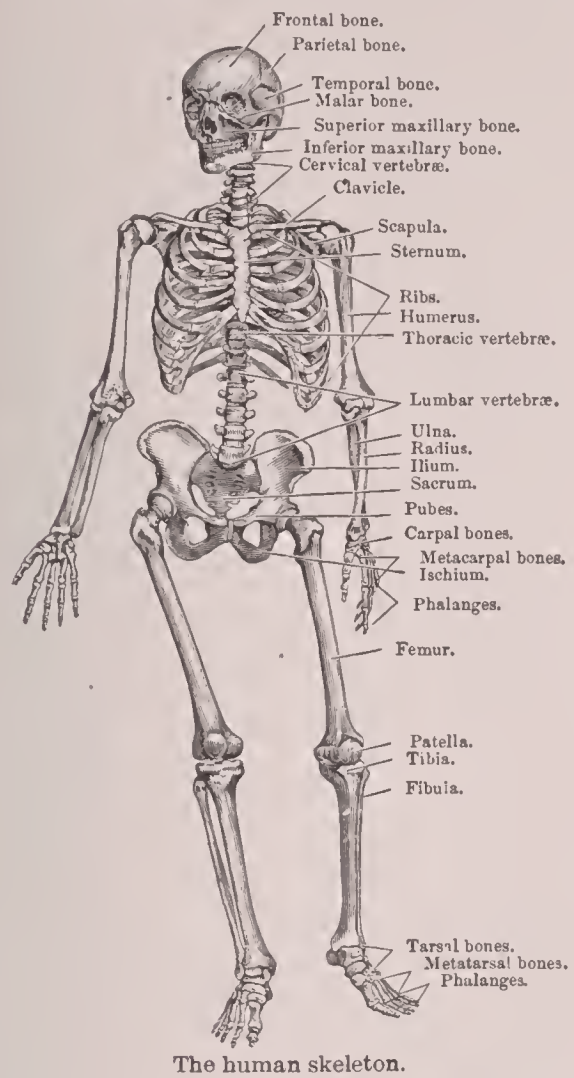
The vertebrate axis is formed by a series of disks, the bodies of the vertebræ extending from the base of the skull to the caudal pole and including a variable number of segments, as few as fifteen or as many as 365. From this fundamental axis two series of very unequal dorsal and ventral arches extend. The dorsal arches are formed by the union of short vertebral plates—the laminæ—which thus form a tube extending from the cephalic to the caudal pole of the animal. This tube is the vertebral canal and contains the spinal cord. At its anterior, or cephalic extremity, the tube usually widely expands into the cranial cavity containing the brain. The brain-case, or cranial portion of the skull, may be considered in a qualified sense as being composed of enlarged and modified vertebral segments. The dorsal or vertebral canal is distinguished therefore as containing and protecting the great cerebro-spinal nervous axis.

The ventral arches proceeding from the vertebral axis, on the other hand, are less constant, varying greatly in their number and position. The ventral arches are principally represented by the ribs, thoracic or abdominal, and by the variable series of branchial bows, or gill-arches, placed at the base of the head. The ventral arches inclose the thoracic and abdominal organs, affording them protection and support.

The osseous framework of man, in common with that of other high vertebrates, consists of two parts—the axial and the appendicular skeleton. The former includes the more constant and essential portions of the vertebrate framework, namely, the vertebral column, the skull and the ribs, with the breast-bone. The appendicular skeleton depends for its development upon the presence of limbs, since it includes the bones of the extremities, together with those forming the skeletal connection between the framework of the limbs and the spine. These connections are known respectively as the shoulder-girdle and pelvic girdle.

The shoulder-girdle in man consists of the collar-bone or clavicle, and the shoulder-blade or scapula, by means of which the bones of the upper limb are indirectly connected to the axial skeleton, an arrangement favoring the great latitude of motion enjoyed by the upper extremities. The pelvic girdle is much more fixed, consisting of the hip-bones or innominata, which give firm support to the thigh-bones and transmit the weight of the upper portions of the body. In animals, as the whales, where the hind limbs are wanting, the pelvic girdle, and hence the pelvis, is absent.

The individual osseous pieces composing the skeleton are so related that usually more or less extended movement is possible between the several bones. These latter are united by fibro-elastic bands—the ligaments—and the structures of the joints. The opposed surfaces of bones may be so intimately united that only a thin membrane intervenes. This may undergo absorption at a later period, in which case the earlier distinct bones become fused and the original line of articulation disappears. The bones of the roof of the skull afford examples of such union, followed by the obliteration of former lines of contact or the sutures.



The human skeleton.

The more usual relation between the bones allows of a certain amount of movement, the surfaces of contact and motion being inclosed within the structures of the joints. The articulations at the shoulder, the elbow, the knee, and the hip afford striking examples of the wide latitude of movement enjoyed by the bones of the extremities. For the details of the joints, see articles JOINT and SYNOVIAL MEMBRANES.

In addition to affording support and protection to the tissues and the organs of the body, the skeleton supplies the points of attachment for the numerous voluntary muscles. These latter, with very few exceptions, have at least one extremity, and more usually both ends, attached to portions of the skeleton, acting upon the more movable parts from the fixed points. The leverage afforded by the long bones of the extremities is an important factor in many movements essential to the proper use of the limbs.

The exact number of separate bones composing the human skeleton varies with age, since many bones which at middle life consist of a single piece in early infancy are represented by several distinct segments, as instanced in the sacrum and innominate bones forming the pelvis. Again each fully formed bone in very many cases is the product of the fusion of several segments, which before maturity become united by the substitution of true osseous tissue for the layer of cartilage connecting the pieces. Thus the thighbone or femur represents the fusion of at least five distinct segments, the union not being fully completed until about the twentieth year. The adult human skeleton consists of 206 distinct bones, as follows:

The spine, including 24 vertebræ, the sacrum, and the coccyx	26
The ribs, 12 pairs, the sternum, and the hyoid	26
The skull, 22, together with the 6 ear-bones	28
The upper extremities, each 32	64
The lower extremities, each 31	62

At birth their number is 278; at the age of twenty-five, 224; and in advanced old age, 194. About 660 segments are needed in the formation of the 206 permanent bones.

Notwithstanding the great diversity in size, shape, and proportions, the general groups of long, short, broad, and irregular bones suffice for the usual purposes of classification of the constituents of the skeleton. A description of the individual bones is contained in the article OSTEOLOGY, while their chemical composition and structural peculiarities are given in the articles BONE and HISTOLOGY respectively. See also FOOT, HAND, and SPINAL COLUMN.

G. A. PIERSOL.

Skeleton Leaves: See CELLULOSE.

Skelton, JOHN: poet; b. probably in Norfolk, England, about 1455; graduated at Cambridge about 1482; was laureated at Oxford University about 1490; was ordained deacon 1498 and priest 1499; was tutor to Prince Henry (afterward Henry VIII.); held a nondescript position at court, by some considered equivalent to king's jester, by others to poet-laureate; became rector of Diss, Norfolk, and curate of Trompington, Cambridge, 1504; subsequently became royal orator; was suspended from his benefice by the Bishop of Norwich, having concealed the fact of his marriage; incurred the resentment of his former patron, Cardinal Wolsey, by his satirical verses; was obliged to take sanctuary at Westminster, and died there June 21, 1529. Skelton was one of the earliest English poets whose writings are easily intelligible to modern readers. Most of his verses are coarse, but were highly esteemed by Erasmus and the wits of the day. His best-known poems are *Philip Sparrow* and *Colin Clout*; he also wrote Latin epigrams. The only good edition of his complete *Works* is that of Rev. Alexander Dyce.

Skelton, Sir JOHN: See the Appendix.

Skene, skeen, ALEXANDER JOHNSTON CHALMERS, M. D.: gynæcologist; b. in the parish of Fyvie, Aberdeenshire, Scotland, June 17, 1837; studied medicine at King's College, Scotland, the University of Michigan, and at Long Island Medical College, where he graduated in 1863; served as acting assistant surgeon in the Union army 1863–64; returned to Brooklyn in the latter year, and was appointed adjunct professor and instructor in medicine in Long Island Medical College; subsequently was appointed Professor of Gynæcology in that institution, and for a time occupied the same chair in the Post-Graduate Medical School, New York. He is a member of various domestic and foreign scientific societies. His best-known works are *Diseases of the Bladder and Urethra in Women* (New York, 1878) and *Diseases of Women* (New York, 1888). D. July 4, 1900.

Skene, PHILIP: soldier; b. in London, England, in Feb., 1725; entered the British army 1739; served in the taking of Portobello and Cartagena in South America, at the battles of Fontenoy and Culloden, and in the American campaigns against Ticonderoga and Havana; received in 1759 a large grant of land on Lake Champlain, and with a view to strengthening the hold of the British on Canada founded Skenesboro (now Whitehall), N. Y.; was made governor of Crown Point and Ticonderoga, with rank of colonel in the army; was arrested as a loyalist in Philadelphia June, 1775, and exchanged Oct., 1776; accompanied Burgoyne in his invasion of Northern New York; was taken prisoner at Saratoga; was attainted by the Legislature of New York 1779, his estate being confiscated; was granted a pension by the British Government, and spent the remainder of his life in England. D. near Stoke Goldington, Bucks, June 10, 1810.

Skene, WILLIAM FORBES, LL. D.: historian; b. at Inverie, Kincardineshire, Scotland, June 7, 1809; educated at the High School and University of Edinburgh, also at that of St. Andrews, and in Germany; became a lawyer, a distinguished archæologist, an officer of several learned societies; and in 1881 historiographer for Scotland. He was the author of *The Highlanders of Scotland, their Origin, History, and Antiquities* (2 vols., 1837), and editor of *The Dean of Lismore's Book, a Selection of Ancient Gaelic Poetry* (1861); *Chronicles of the Picts and Scots and other Early Memorials of Scottish History* (1868); *The Four Ancient Books of Wales* (2 vols., 1868); *The Coronation Stone* (1869); *John of Fordice's Chronicles of the Scottish Nation* (2 vols., 1871); and *Celtic Scotland* (3 vols., Edinburgh, 1876–80).

Skepticism: See SCEPTICISM.

Skimmer, or **Scissors-bill**: any bird of the genus *Rhynchops*. These birds skim over the sea with the lower mandi-

ble, which is much longer than the upper and compressed like a knife-blade, cutting through the water. They are related to the terns, but belong to a distinct family. The black skimmer (*R. nigra*) is black above, white below. The spread of wing is 3½ to 4 feet; length, 16 to 20 inches. It ranges northward to New Jersey, but *R. albicollis* is Indian and *R. flavirostris* African. F. A. L.

Skin: See HISTOLOGY.

Skin Diseases: diseases affecting the skin. These diseases appear as primary or secondary eruptions. The following are the primary forms: (1) The *macule* or *spot*, a change of the normal color of the skin without elevation, arises from hyperæmia, hæmorrhage, or inflammation, sometimes from anomalies of the distribution of the coloring granules of the skin. (2) The *papule* or *pimple*, a projection above the surface, varying in size from that of a millet-seed to that of a lentil, is produced by diseases of the cutaneous glands, inflammation, and new growths of the papillary layer. (3) The *tubercle* is a solid projection of the size of a lentil up to that of a hazel-nut. (4) The *wheal* is slightly raised above the surface, and greatly exceeds the thickness in horizontal extension, varying in size from that of a finger-nail to that of the palm of the hand. (5) The *tumor* forms a solid projection of the size of a walnut to that of a man's fist. (6) *Vesicles* are elevations of the epithelial layer of the skin produced by a transparent or milky fluid, corresponding in size to that of papules, and as such never being of a long duration; while (7) *blebs* surpass the size of vesicles up to that of a goose's egg, and (8) *pustules* always contain pus, and therefore form superficial abscesses of the skin. Vesicles, blebs, and pustules almost always are surrounded by inflammatory areas.

Secondary forms of eruptions are (1) the *excoriation*, a flat abrasion of the epithelial layer of the skin, arising from destruction and rupture of primary eruptions, very often through scratching with the finger-nails. They always heal without the formation of a scar. (2) The *ulcer* presents a loss of substance penetrating into the derma, which heals slowly and with formation of a cicatrix. (3) *Fissures* are elongated cracks in the skin on parts liable to much stretching. (4) *Scales* are produced by detached epidermis. (5) *Crusts* result from drying of an exuded fluid or of extravasated blood. (6) *Scars* or *cicatrices* are connective-tissue formations which replace deeper losses of substance of the derma.

The causes of diseases of the skin are either rooted in the whole organism, or they are local ones, by which the skin is primarily or chiefly attacked; hence the division into symptomatic and idiopathic affections of the skin. Certain rashes occur in variola, scarlet fever, measles, syphilis, in typhoid fever, in purulent infection of the blood, so-called pyæmia, in scrofulosis, scorbutus, etc. Moreover, diseases of internal organs may involve the skin, especially affections of the intestinal tract, of the liver and spleen, of the internal genital organs, of the urinary apparatus, of the nerve-centers. There are, lastly, normal processes—dentition, menstruation, pregnancy—which lead to various kinds of cutaneous affections. Besides general injurious influences—heat and cold, dryness and moisture, different arts and trades—merely local diseases are caused by the operation of caustic substances, neglect of cleanliness or exaggerated washing and rubbing with strong kinds of soap, long-continued pressure upon certain parts, and parasitic organisms which penetrate the skin. The scratching of the patient himself who suffers from itching is an important cause for producing mechanically lesions of the skin. Thus parasites give rise to such affections by irritating the skin directly or by exciting the sensibility of the cutaneous nerves by producing the sensation of itching.

The changes of the skin, by too great an afflux of blood (hyperæmia) or lack of blood (anæmia), as such do not produce diseases of their own, being always of a transient character or rooted in diseases of the whole organism, and are therefore omitted in the following enumeration.

1. *Diseases due to Perverted States of the Secretions of the Cutaneous Glands.*—The sweat-glands of the skin (see HISTOLOGY) produce a fluid, the perspiration, which contains 99·3–99·5 per cent. of water, the residue consisting of solid matters, among which are chloride of sodium, phosphate of lime, hydrochlorate of ammonia, and traces of iron and of fatty matters. Even in the normal state each individual diffuses a special odor. There are persons with a peculiar rancid odor of their perspiration, a disease called *bromidrosis*, either universal or local—for instance, lasting in the armpits, on the feet—in spite of the most scrupulous cleanliness. This disease is always dependent on too copious perspiration (*hyperidrosis*), and curable by repeated treatment with diachylon ointment. The secretion of a colored perspiration is termed *chromidrosis*. The sebaceous glands, which secrete a fatty mass, may produce the sebum in excessive quantity, there being no impediment to its secretion —the so-called *seborrhœa*. The disease is very common on the scalp (dandruff), and always leads to loss of the hair. It yields readily to certain preparations of tar, and a new growth of hair can very often be obtained. If, on the contrary, the excretion of the sebaceous mass be interfered with, the result is its accumulation within the glands or their ducts, the so-called flesh-worm—*comedones*. In the mass of a flesh-worm there is often found a mite, the *Acarus folliculorum*. The flesh-worms, again, are the most common causes of pimples, as they act upon their neighborhood like foreign bodies.

2. *Diseases due to Inflammation.*—Inflammatory affections of the skin may be acute or chronic. The acute contagious inflammations, so-called *exanthemata*, are due to diseases which attack the whole organism, are attended with febrile symptoms, present certain definite appearances on the surface of the body, and run a course the duration of which can be computed beforehand. In these diseases—*measles*, *scarlet fever*, and *smallpox*—the sympathy of the entire organism is manifested by symptoms of various kinds, both while the rash is present and also after its disappearance. The acute, non-contagious inflammations have a definite typical course, as their symptoms succeed one another in regular order. If the inflammation be manifested mainly by redness, with a slight exudation of the fluid part of the blood, fugitive rashes are produced, which, when spread over large parts of the surface are termed *erythema*, but when presenting isolated red spots are termed *roseola*. Extended and isolated superficial inflammations, accompanied with stinging or itching sensation, receive the name of *urticaria*, the latter being always characterized by the development of wheals. Diseases of this kind often are produced by disturbances of the stomach or by local irritations of the skin. They usually disappear after a short time without special treatment, but are very liable to recurrences. Lastly, there exist acute inflammations with accumulation of fluid beneath the epidermis, leading to the formation of vesicles and blebs, with short duration and no liability to return. The *herpes zoster* (shingles) is the most important of the forms of HERPES (*q. v.*). Shingles attack the individual, in most instances, only once during life. The chronic inflammations, such as PSORIASIS, LICHEN (*qq. v.*), and *pityriasis rubra*, are characterized by a tendency to repeated relapses and the protracted course which they run. Psoriasis is a very common disease, characterized by white, rough patches on a dark-red ground, dispersed all over the body, mainly on the elbow and knee. The patches are not liable to any further change, such as suppuration and ulceration; they leave no scars, though they are sometimes followed by persistent pigmentation. Sensations of pricking or itching are complained of only when the patches first come out; afterward there are no subjective symptoms. The disease occurs often on otherwise healthy and strong individuals.

A second group of inflammatory affections is characterized by intense itching, and besides the primary form of eruption they irresistibly provoke scratching in consequence of the itching; this, again, gives rise to further changes in the skin known as excoriations. To this group belong ECZEMA (*q. v.*) and *prurigo*.

A third group of chronic inflammatory diseases embraces those pimply and pustular affections which arise from inflammation of the hair-sacs and sebaceous glands. They include *acne*, *sycosis*, and *rosacea*. Acne on the face, the chest, and the back—one of the most disfiguring diseases—is always produced by accumulation of sebaceous masses in the glands (flesh-worms), and is entirely curable by repeated emptying of the glands.

To the fourth group of chronic inflammations belong the eruptions in shape of blebs, termed PEMPHIGUS (*q. v.*). Chronic inflammations of the skin of very variable but characteristic forms are produced by a general disease, *syphilis*; here the skin is merely symptomatically attacked, besides different other organs. With traumatic lesions of the skin, as well as with its inflammatory diseases, hæmorrhage is very often combined. Hæmorrhage is furthermore a symptom of universal disease in *scorbutus* and in *purpura rheumatica*. See PURPURA.

3. *Diseases due to Hypertrophy.*—Too copious production of any tissue of the skin may be a consequence of a chronic inflammatory process, or it may occur without the symptoms of irritation as a consequence of anomalous congenital productivity. The *corn* and the *tyloma*, for instance, are products of a long-continued local irritation of the skin, but instances are known in which tyloma, the hardening and hypertrophy of the skin of the palms and the soles, must be considered as a congenital disease. The Elephantiasis (*q. v.*), an immense hypertrophy of all constituting tissues of the skin, is doubtlessly due to chronic inflammation of the lymphatics; while Ichthyosis (*q. v.*), the exuberant growth of epidermis, is due to the congenital hypertrophy of the papillæ. *Warts* and *papillary growths* of the skin may be produced by either kind—local irritation as well as anomalous function of papillæ. *Horns* of the skin, hypertrophy of the nails and the hairs—*polytrichia*—always are dependent on congenital anomalies in the formation of the tissues of the skin. The pigment-granules of the rete mucosum are very often hypertrophied, leading to formation of brown spots, *ephelides* (freckles), *chloasma* (liver-spots), while long-continued irritation of the skin leads to universal dark discoloration—*melasma*.

4. *Diseases due to atrophy* are based on the same principles as hypertrophy. Inflammation often produces first hypertrophy, afterward ulceration, loss of substance, and atrophy. Hypertrophy of the pigmentum is not rarely combined with its partial atrophy in *vitiligo*, *leukopathia*, etc. Merely to atrophy are due the senile changes of the skin, the white color of the hairs, the early falling out of the hairs without visible cause, the localized atrophy of hairs in *alopecia areata*. (See Baldness.) A plain atrophy is also the *xerodermia*. Very little can be done with regard to the cure of these diseases.

5. *Diseases due to New Growths.*—New growths or tumors either belong to the connective-tissue formations of the skin, the derma, or are products of an anomalous epithelial growth. Tumors of the former kind may be benign or innocent, viz., painless, not ulcerating, not recurring after extirpation, and not infecting the organism, such as *fibroma*, a variety of which is the formation of scars without preceding lesion, the so-called *cheloid*; furthermore, *papilloma*, growth of the papillary layer, embracing most of the *warts* and *nævi*; lastly, *angioma*, erectile tumors produced by copious new formation of blood-vessels. Or the connective-tissue tumors are malignant, viz., painful, ulcerating, producing new growths around the first-formed tumor, and easily recurring after extirpation, even leading to secondary formations of identical tumors in the lungs, the liver, etc., such as *sarcoma*, one variety of which, the *pigmented* or *melanotic sarcoma*, forms the most malignant kind of tumors of the organism. Cancer is considered to be essentially an epithelial formation, which always is malignant. In all tumors the radical extirpation is the only reliable means of curing the disease, very often of saving the life of the patient.

6. *Diseases due to Anomalies of Innervation.—Neuroses.*—Many of the already named diseases of the skin can be looked upon as being disturbances of the nerves in the first instance (*urticaria*, *herpes zoster*, *leprosy*, *atrophy of pigment*). Disturbances in the property of sensation of the skin are lowered sensibility—*anæsthesia*—and excited sensibility—*hyperæsthesia*. To the latter kind belongs the itching of old persons, *pruritus senilis*.

7. *Diseases due to Parasites.*—The Scabies (*q. v.*) is produced by the presence of the itch-insect within the epidermis. The disease is readily curable by local application of preparations of sulphur. Analogous is the action of the flea, the bed-bug, and the louse. By vegetable parasites are produced slightly scaling and itching brown spots, *pityriasis versicolor*; furthermore, *herpes tonsurans* (ringworm), a very common disease, appearing first in the shape of small vesicles or ring-like red eruptions, which, when situated on the parts provided with hairs, lead to baldness; lastly, Favus (*q. v.*), a disease kindred to ringworm. If the parasites are killed locally, a perfect cure can be obtained; but on the scalp and the beard, where the parasites advance deeply into the root-sheaths of the hairs, these diseases usually are very obstinate.

Revised by G. H. Fox.

Skink: any one of the lizards of the family Scincidæ (*q. v.*).

Skin-moths: beetles of the family *Dermestidæ*, which attack skins, etc., and are often very destructive in museums. The most notable species are (1) *Dermestes lardarius*, (2) *Dermestes vulpinus*, and (3) *Anthrenus museorum*. The first is for the most part blackish, with a broad brownish-gray band on the elytra, relieved by three black spots on each side. Both the imago and the larva are very destructive. The second is totally black above, but the sides of the thorax and the under part of the body are covered with white scales. It is less common and less generally distributed than the preceding, but almost equally to be dreaded. Both the preceding attain about a quarter of an inch in length. The third species has three transverse waved lines on the elytra. It is often very destructive to museum specimens, and especially to collections of pinned insects. It has become a household pest, and is known as buffalo-bug or carpet-beetle. It is only about a tenth of an inch in length. All these species may be killed by applications of benzine, and camphor and turpentine are also used. Specimens for museums should be prepared for resistance to the attacks of these insects by applications of arsenic, carbolic acid, corrosive sublimate, and benzine.

E. A. Birge.

Skinner, Charles Rufus: See the Appendix.

Skinner, John Stuart: editor; b. in Maryland, Feb. 12, 1788; was admitted to the bar 1809: settled at Baltimore 1813; was postmaster of that city 1822–37; began in 1819 the publication of *The American Farmer*, the first periodical exclusively devoted to agriculture in the U. S.; afterward edited several other periodicals of similar character, including *The Turf Register* and *The Plough, Loom, and Anvil*; was the first organizer of agricultural shows and fairs in the Middle and Southern States; wrote several works on farming and sporting topics, and was third assistant postmaster-general 1841–45. D. in Baltimore, Mar. 21, 1851.

Skinner, Stephen, M. D.: etymologist; b. in London, England, in 1623; graduated at Christ Church, Oxford, 1646; studied philology and medicine on the Continent, especially at Heidelberg; became a physician at Lincoln; was an earnest student of many languages, and devoted his life to the preparation of a vast work on English etymology, which he left incomplete at his death, which occurred at Lincoln, Sept. 5, 1667. Fortunately his MSS. fell into the hands of Thomas Henshaw, who edited them under the title *Etymologicon Linguæ Anglicanæ* (London, folio, 1671), a work of great value to the critical student of English.

Skipjack: any one of several fishes having a tendency to leap from the water, as the Bonito (*q. v.*), the Bluefish (*q. v.*), the Saury (*q. v.*), and a fresh-water herring, *Clupea chrysochloris*.

Skipper: (1) the Saury (*q. v.*); (2) any one of several small dark-colored butterflies of the family *Hesperiidæ*.

Skirret: the *Sium sisarum*, an umbelliferous parsnip-like plant, a native of Asia, long cultivated in Europe, and rarely in the U. S., for its root, which is very nutritious and palatable. Skirret affords a good percentage of alcohol when distilled, owing to the large amount of sugar present.

Skit'tagetan Indians [*Skittagetan* is derived from Skiteiget, the name of a chief, and was first employed by Gallatin in 1848]: a linguistic family, also well known as the Haida. They are in two divisions, the Haida proper and the Kaigani. The former are confined to the Queen Charlotte islands, Northwestern America; the Kaigani, who form an offshoot of the Haida proper, emigrated to Forrester and Prince of Wales islands, probably since 1750. In the Haida division there are thirteen villages, besides eleven that have been abandoned, and in the Kaigani division there are seven occupied villages and three abandoned ones. Five other villages, which can not be identified with any of the preceding ones, were named by Krause in 1885.

General Characteristics.—Investigations into the native languages by Dr. Franz Boas render it quite probable that the family should be merged into the neighboring Koluschan family. (See Koluschan Indians.) They are larger, better proportioned, and of lighter complexion than the Salish and other southern coast-tribes. The Haida are essentially maritime Indians, and derive their subsistence from the rivers and sea. Shellfish are much used, as are all edible roots and berries. The first rude beginnings of agriculture are discernible among them in the cultivation, from a remote period, of tobacco, either the true plant or one of the several substitutes employed. The dog was their only domesticated animal. The Haida live in permanent villages, but they scatter more or less at different seasons in pursuit of food. The houses, which are the large structures common to the northwest coast, are occupied communally, several

related families dwelling under one roof, the household being governed by an elder or sub-chief. There is nothing in the nature of a confederacy of the several villages. The chieftaincy was hereditary, and, as descent was through the female line, it passed, on the death of a chief, to his eldest brother, or, there being no brother, to his sister's son. Customs came to have the force of laws, and persons were restrained from injury to the person or property of a fellow tribesman by the custom of reprisals. In some respects, apparently, the tribes of the northwest coast, especially the Haida, had advanced beyond the condition of the eastern Indians, as partially shown by the extent to which they possessed personal property, and by the establishment of personal ownership in land. The Haida appear to have been of martial character, internal warfare having been common, as also forays upon distant tribes for the purpose of procuring slaves. The institution of hereditary slavery seems to have been intimately woven into the social system of the Haida, and slaves were regular objects of barter. The Haida are skillful workers in wood, and to some extent in metal, particularly copper. Their great skill at carving is seen, perhaps at its best, in the well-known carved totem-posts which adorn each village. Tattooing was formerly universal; labrets were worn by the females. The institution of the potlatch—the free distribution of property on certain ceremonial occasions—exists among the Haida, as among all the tribes of the northwest.

Population.—Dawson estimates the present number of the Haida to be from 1,700 to 2,000; Petroff gives the number of the Kaigani as 788. These figures indicate a marked decrease of population since 1850.

Authorities.—H. H. Bancroft, *Native Races* (1882), iii., 564, 604; J. C. E. Buschmann, *Spuren der aztek. Sprache* (1859), 673; Dawson, *Queen Charlotte Islands* (1880); A. Gallatin, in Schoolcraft's *Indian Tribes* (1853), iii., 402; Krause, *Tlinkit Indianer* (1885), 304; L. H. Morgan, *Ancient Society* (1878), 176; I. Petroff, Tenth Census, Alaska (1884), 32; Poole, *Queen Charlotte Islands* (1872), 195, 309; H. R. Schoolcraft, *Indian Tribes* (1855), v., 489; Tolmie and Dawson, *Comparative Vocabularies* (1884), 15, 26. See Indians of North America.

James Owen Dorsey.

Skittles: See Bowls and Bowling.

Sko'beleff, Michael Dmitrievitch: Russian general; b. in 1841; served in the army against the Polish insurrection in 1863; was called to join the general staff in 1866; and in 1869 was sent to Turkestan, where he secured much valuable geographical information, which he afterward employed to great advantage in the expedition against Khiva in 1873. In this expedition he won great distinction. He afterward crushed the rebellion in Khokand, and became governor of the territory he had subdued. In the Russo-Turkish war he showed a degree of valor and skill in marked contrast to the inefficiency at the Russian military headquarters. He commanded the left wing at Plevna, captured the so-called Shipka army, Jan. 9, 1878, and took Adrianople. D. suddenly in Moscow, July 7, 1882. See Ossipovitch, *Michael Dmitrievitch Skobeleff* (Hanover, 1887).

Skoke: See Garget-root.

Skowhe'gan: town; capital of Somerset co., Me.; on the Kennebec river, and the Maine Central Railroad; 35 miles N. by E. of Augusta, and 50 miles W. of Bangor (for location, see map of Maine, ref. 6–C). It derives excellent water-power from the river, which has here a perpendicular fall of about 30 feet, and has manufactories of woolen goods, scythes and edged tools, shoes, oilcloth, pulp, lumber, and flour. There are electric-light and power plants, water-works, 7 churches, free public library (founded in 1867), 2 national banks with combined capital of $275,000, a savings-bank, and 2 weekly newspapers. The town was originally known as Canaan; was incorporated under the name of Milburn in 1823; has been called Skowhegan since 1836. It was enlarged by the annexation of the town of Bloomfield in 1861. Pop. (1890) 5,068; (1900) 5,180, village 4,266.

J. O. Smith, editor of "Somerset Reporter."

Skua, or **Skua-gull**: See Jaeger.

Skull [M. Eng. *skulle*, loan-word from Scandin.; cf. Icel. *skāl*, bowl: Germ. *schale*; cf. *hirnschale*. Eng. *scale* (of balance) is a doublet, of native origin]: the hard framework of the head of vertebrates. It consists of two portions, the cranium which forms the protecting case for the brain, and the facial structures. These may all consist of cartilage throughout life, as in the sharks, or entirely of bone, as in adult birds and mammals, or of both bone and cartilage, as in many fishes and amphibians. In the lower forms no separate cranial elements can be recognized, the brain-case forming a continuous structure, with openings here and there for the passage of nerves, blood-vessels, etc. In the higher vertebrates distinct elements or bones can be recognized in the cranium, and these arise either by ossification of the cranial cartilage or by the formation of bone in the membranes outside the cartilage cranium. A similar distinction can be drawn between the cartilage-bones and the membrane-bones of the face. For the details of the bones of the skull, reference should be made to works upon comparative anatomy. The following are the bones more frequently found in the skull, arranged according to their origin and position:

Cranium.
- Cartilage-bones:
  - Floor. Basioccipital, basisphenoid, presphenoid.
  - Sides. Exoccipital, bones of the ear-capsule (otic), orbitosphenoid, alisphenoid.
  - Roof. Supraoccipital (part).
  - Front. Mesethmoid, lamina cribrosa.
- Membrane-bones:
  - Floor. Parasphenoid.
  - Sides. Temporal or squamosal, parietal, supra- and post-orbital.
  - Roof. Supraoccipital (part), frontal, pre- and post-frontal.

Face.
- Cartilage-bones: Palatine, pterygoid, quadrate, and articular.
- Membrane-bones: Premaxillar, maxillar, vomer, nasal, lachrymal, jugal, and quadratojugal, and in the lower jaw the dentary, splenial, and angular.

It is rarely that all these bones are present in one and the same form. Usually there is an over-development (hypertrophy) of one and an under-development (atrophy) of its neighbors, or a fusion of two or more may occur. Still other bones may exceptionally appear (e. g. in the suspensory apparatus of fishes), which are properly not to be regarded as belonging to the skull. Although the subject of an enormous amount of study, the skull is yet far from thoroughly known. The best general account will be found in Parker and Bettany's *Morphology of the Skull* (London, 1877).

In the human skull but twenty-two bones exist, eight in the cranium and fourteen in the face. This is largely due to the fusion of bones distinct in the embryo as well as in the adult of lower forms.

J. S. Kingsley.

Skull-cap [so called from the helmet-like appendage to the upper lip of the calyx]: any one of a genus (*Scutellaria*) of perennial herbs found over a wide range of climates in America, especially in Mexico and the sub-tropical regions, though several species grow in northern parts of the U. S. and in Europe. They derive their name from an envelope around the fruiting calyx, have little aroma, and—especially for the cure of hydrophobia—enjoy a popular reputation which is entirely undeserved.

Skunk [from Abenaki (Amer.-Ind.) *segan'ku*, skunk]: a musteloid carnivorous mammal of the sub-family *Mephitinæ*. The body is moderately elongated and arched backward; the legs comparatively short; the feet sub-plantigrade; the tail rather long and very bushy; the color is particolored, black and white being contrasted. Their anal glands, according to Chatin, are essentially like those of the badgers and ratels, and are in a single pair and of large dimensions; their outer walls are formed by a thick fleshy tunic formed of two layers of interlaced fibers, capable of sudden strong compression of the receptacles; these are enormous reservoirs, with a dense resisting fibrous coat, always containing a considerable quantity of the follicular product. The glandular substance is not spread all over the central pouch, but is restricted to a particular portion, and contrasts by its dark color with the white ground of the envelope of the pouch. The receptacles contain a nauseous liquid, which the animal, on being alarmed, discharges with such force that the jet is carried to a distance of from 8 to 12 feet. The voiding of the liquid must be sudden; and it does not suffice that the receptacle is large and powerfully muscular; the offensive liquid must be directed far backward, so as to flow as little as possible upon the rectal muscular membrane; so the opening is large and upon the summit of an umbilicated papilla, around

which rests a cutaneous fold which in a measure directs the discharge. The skunks are distributed throughout America, North as well as South, except the coldest parts, and are found in no other portion of the world. The species are all active carnivorous animals, feeding on small quadrupeds and birds as well as reptiles. They burrow in the ground, and in the northern parts of North America remain torpid during the winter. They bring forth from six to nine young at a birth. The mephitic fluid has been employed medicinally to some extent as an antispasmodic in hysteria, asthma, etc. The bite of the animal is in some quarters much dreaded, and is said to induce hydrophobia. *Mephitis mephitica* is the common large skunk; *Mephitis putorius* is the little striped skunk; *Conepatus mapurito* is about the size of *Mephitis mephitica*, and extends into the southwestern parts of the U. S. (Texas, etc.), from Mexico. Although they vary much in color, they can generally be distinguished as follows: The common species is black, with the crown white and with two white streaks diverging thence; the little striped skunk is black, with a spot on the forehead and one on each temple, and a number of white but interrupted longitudinal streaks on the back; *Conepatus mapurito* is black, but with a broad white dorsal median band.

Revised by F. A. Lucas.

Skunk-cabbage: the *Symplocarpus fœtidus*, a large marsh-plant of the arum family, common in the U. S. from Maine to South Carolina, distinguished by the unpleasant smell of its large, broad, and veiny leaves. It is a monocotyledon, producing early in the spring its four-petaled flowers in a globular cluster upon a short stem within a shell-shaped spathe or hood, of a dark purplish, or with yellow and purple stripes and spots, variegated with patches of red or green. The fruit is oval and fleshy, inclosing large purple seeds. The roots and leaves have been used as stimulants. Revised by Charles E. Bessey.

Skye: an island of Scotland, the largest of the Inner Hebrides, belonging to the county of Inverness, from the mainland of which it is separated by the channel of Kyle Rhea, half a mile broad. Area, 535 sq. miles. The surface is mountainous and rugged; the coast-line is steep, abrupt, and wild, but often strikingly picturesque on account of its peculiar basaltic formations, its caves, and waterfalls. The soil is not unproductive, but, on account of the extreme dampness of the climate, it is unfit for agriculture. The name of the island, *Skye*, means cloud in the old Scandinavian tongue, and is very appropriate, as the days during the year on which no rain falls are very few. Turnips and potatoes grow well, however, and sheep-breeding is carried on with some success. Fishing is the principal occupation, and large quantities of salt and dried cod, herring, ling, and saithe are exported. The inhabitants, who are of Gaelic descent, interspersed with Norse settlers, and who still use the Gaelic language, are poor, and their number decreases, as many emigrate. Pop. (1851) 21,521; (1891) 15,705.

Skylark: the *Alauda arvensis*, an Old World bird, noted for its song. It has the feathers of the occiput slightly prolonged, the first primary very small, the second and third (which exceed the fourth) equal, and the external tail-feathers margined with white; the upper parts are variegated with blackish and reddish gray; the lower parts white on the abdomen, but with the neck, breast, and sides tinged with reddish and spotted with brown. The length is about 7 inches, the tail being 3. The skylark is found all over Europe, as well as in Northern Africa and the corresponding zones of Asia. It frequents meadows, and does not perch. It feeds chiefly on the seeds of various plants and larvæ. Its nest is formed on the ground. It lays four or five eggs of a whitish gray. It is almost equally esteemed for the delicacy of its flesh and the melody of its song.

Sky'ros, or **Scyros**: Greek island; in the Ægean Sea; N. E. of Eubœa. It consists of two mountains, the valley between forming a narrow isthmus. It has two good harbors, is well watered, and has fine forests of oak and pine. Its silver-mines and marble-quarries are no longer worked. The inhabitants are supported by their vineyards and flocks of sheep and goats. Here, according to mythology, Theseus was killed, and here Achilles concealed himself before the Trojan war. Pop. 3,188. See Sporades.

E. A. G.

Sladen, Douglas B. W.: See the Appendix.

Slags [from Swed. *slagg*, dross, slag, or Dutch *slagge*; cf. Germ. *schlacke*, dross, slack, borrowed from like source; akin to *schlagen*, strike—i. e. the splinters struck off in forging]: the imperfect glassy or vitrifiable compounds which are produced during the reduction of metallic ores by various fluxes. The slags produced in metallurgical operations should have the following properties: They should fuse at the right temperature; be of such fluidity and specific gravity as to allow the metal or matte (*regulus*) produced to sink readily through them; have such a composition that they will not attack the desired product or the furnace-walls, and will not allow undesirable bodies to separate from themselves; must be able to take up foreign substances, and must be in sufficient quantity to protect the desirable products from the hurtful influence of the blast or other agencies. It is seldom the case that all of these conditions can be fulfilled, and therefore the efforts of the smelter must be directed to securing as advantageous a combination as possible. The slags of ordinary occurrence are silicates, combinations of silicic acid with bases already present in the charges or formed during the operation; but they frequently contain earthy sulphides and fluorides, as well as particles of metal and matte. Sometimes they may be looked upon as single chemical compounds, at other times they appear to consist of mixtures, but in normal slags the amount of silicic acid is always within certain limits.

Frequently, by judicious mixture of ores, the proper slag can be obtained without adding any flux; at other times a basic flux, like limestone, will be absolutely necessary. Occasionally there will be an excess of alumina, and it is then to be regarded as playing the part of an acid, but aluminates without silicates do not occur as slags. The most infusible silicates, like silicate of zinc or tin, can be made to fuse when combined with other silicates. A slag should not fuse before the desired effect has been produced in the furnace, such as the reduction of an oxide, absorption of carbon by iron, sulphurization of metals, etc. Slags are often affected by the manner in which they solidify; rapid cooling producing a glassy, brittle slag, while slow cooling tends to produce a stony, tough slag, provided the chemical constitution is right. For this reason the slags when used for paving or building are slowly cooled. Slags have also been used to manufacture cement and alum, for fertilizers, and for ornament. The slag from the basic Bessemer-steel process is used as a substitute for phosphates.

The color of slags is very various. Generally a dark slag will owe its color to metallic oxides, dark green or black indicating iron oxides, and dark brown manganese; light green indicates protoxide of iron; red or reddish brown, suboxide of copper. Some very dark slags from iron furnaces, however, owe their color probably to sulphur, and contain little iron oxide. The peculiar blue of some blast-furnace slags has been referred to the presence of vanadium, molybdenum, cobalt, and titanium. While each or all of these may be present in blue slags, and may possibly cause their color, especially the cobalt oxide, Bontemps has shown that oxide of iron alone can impart all colors to glass; while Fournet refers the blue shades of most of these slags to their physical constitution. The blue color of old zinc retorts has been also referred to the presence of titanium; and Wöhler considered that certain blue slags from blast-furnaces owed their color to a compound like ultramarine, but containing sulphide of calcium in place of sulphide of sodium. Among the minerals closely imitated by certain slags in composition and crystalline form may be mentioned amphibole, pyroxene, wollastonite, diopside, gehlenite, and labradorite. Revised by C. Kirchhoff.

Slander: See Libel and Slander.

Slate [M. Eng. *slat*, *sclat*, from O. Fr. *esclat*, a shiver, splinter, deriv. of *esclater*, shiver, chip (> Fr. *éclater*, burst, break forth)]: a rock, consisting largely of silicate of aluminum, which is easily split into slabs or plates. It is supposed to have been formed by the consolidation, under heat and pressure, of clay deposited in still water. It is known also as clay-slate and argillite. It weighs from 170 to 180 lb. per cubic foot, and its most extensive use is for roofs. The output of slate in the U. S. in 1892 was valued at $4,117,125, of which $2,333,000 worth was quarried in Pennsylvania and $1,014,000 worth in Vermont. In 1893, owing to business depression, the output was much less. See Merrill's *Stones for Building and Decoration*, and articles on *The Strength and Weathering Qualities of Roofing Slates*, in *Transactions of the American Society of Civil Engineers* for Sept., 1892, and Dec., 1894. M. M.

Slater: town; Saline co., Mo.; on the Chi. and Alton Railroad; 12 miles W. of Glasgow, 96 miles E. of Kansas

City (for location, see map of Missouri, ref. 3-F). It is in an agricultural region, and contains 2 State banks with combined capital of $150,000, a high school, and a daily and 3 weekly papers. Pop. (1880) 771; (1890) 2,400; (1900) 2,502.

Slater, Samuel: manufacturer; b. at Belper, Derbyshire, England, June 9, 1768; was apprenticed at the age of fourteen to Jedidiah Strutt, partner of Arkwright in the business of cotton-spinning; saw in a newspaper in 1789 the law passed by the U. S. Congress in that year for the encouragement of manufactures, and a notice of the bounty offered by the Pennsylvania Legislature for the introduction of the Arkwright patents into the U. S., the communication of the models of the new machinery to foreign countries being then forbidden by English law under severe penalties. Believing himself able to construct new machinery from memory, he sailed for New York. He entered into a contract with William Almy and Smith Brown, of Pawtucket, R. I., to construct and work the new cotton-spinning machinery, and started at Pawtucket, Dec. 21, 1790, a mill with three carding-machines and seventy-two spindles, which was the virtual beginning of the manufacture of cotton in the U. S. He erected cotton-mills at Oxford (now Webster), Mass., in 1812, to which he added woolen-mills 1815–16, the nucleus of the village of Slatersville. D. at Webster, Mass., Apr. 21, 1835. See Rev. George S. White's *Memoir of Samuel Slater* (Philadelphia, 1836; 2d ed. 1846).—His nephew, John Fox Slater (1815–84), became a manufacturer, and in 1882 gave $1,000,000 for the education of freedmen in the South.

Slatington: borough (incorporated in 1864); Lehigh co., Pa.; on the Lehigh river, and the Lehigh Val. and the Phila. and Reading railways; 16 miles N. W. of Allentown, the county-seat (for location, see map of Pennsylvania, ref. 5-I). It has 9 churches, 14 public schools, including a high school with college preparatory department, extensive slate-quarries, rolling-mills, steam-boiler works, large school-furniture factory, a national bank with capital of $100,000, and a weekly newspaper. Pop. (1880) 1,634; (1890) 2,716; (1900) 3,773.

Editor of "News."

Slave Coast: old geographical name for that part of the coast of Upper Guinea which is about the Bight of Benin, so named because formerly a favorable place for obtaining slaves. It is now in part Dahomey, under French protection, and in part (to the E.) the territory of the Royal Niger Company. See Dahomey and Niger Territories.

Slave Lake and River: See Great Slave Lake.

Slavery [deriv. of *slave*, of like source with Germ. *sklave* < M. H. Germ. *sklave*, *slave*, Dutch *slaaf*, Fr. *esclave*, originally a Slave, a Slavonian. The word acquired its meaning in Italy in the eighth or ninth century]: a state of bondage in which one human being is in complete subjection to the will of another. In its usual sense it is restricted to chattel slavery, in which the slave may be bought and sold like ordinary property, and it thus excludes the milder forms of bondage, such as serfdom or villanage. In its origin it was the sign of advancing civilization, in that it arose from the practice of sparing the lives of captives, who in the period of primitive savagery were generally slain by their captors. The arts of production must have reached the point at which a man's labor produced a surplus over what was necessary for his own support, for among barbarians clemency toward captives sprang from the perception that an economic benefit might be gained by their enslavement. The slavery of the industrial classes has characterized the early history of all civilized races, and as forcing men to labor, despite the natural reluctance inherent in barbarous tribes, seems to have been a necessary element of progress. It existed among all the races of antiquity of whom there is historic record, but in some its rigors were mitigated by peculiar laws and customs, as among the Hebrews, whose slaves became free after seven years had elapsed from the beginning of their servitude, while every fiftieth year, on the occasion of the jubilee, all slaves were emancipated.

Greek Slavery.—The Homeric poems bear witness to the antiquity of the practice of holding slaves among the Greeks. In the historic period the supply seems to have been kept up by capture in war, and by purchase from the slave-owners of Asia Minor and Thrace. Kidnapping, the sale of children by their parents, and enslavement for debt were also sources of supply. The rearing of slaves was never an abundant source in Greece, as it was cheaper to purchase those who had already reached the age of labor. They were employed in domestic service, in agriculture, and even in commerce, manufactures, and occupations in which the risk and responsibility were great. As to the relative numbers of the slaves in Greece reliable statistics are lacking, but it is probable that in the cities they were greatly in excess of the free population. It is estimated that in Attica the slaves bore to the free native population the ratio of three to one, and in Sparta the Helots are said to have numbered 220,000, while the Spartans numbered only 32,000. Their treatment differed greatly in the different cities. In Sparta the Helots suffered cruel treatment at the hands of their masters, despite their kinship of race, while the Athenian masters were noted for their mildness. By the Athenian law a slave who had just grounds for complaint against his master could demand to be sold; he had a right to asylum in the temples and sacred places, and his death could be avenged like that of a free citizen. He could purchase his freedom with the money that he had saved during servitude, and could be liberated by the act of his master. As a reward for fidelity or honorable services emancipation was frequent. No consciousness of the injurious moral effects of slavery seems to have been felt by the greatest thinkers of classic Greece. Aristotle and Plato both regarded the institution as necessary, the former holding it to be beneficial to both parties if practiced with justice.

Roman Slavery.—In Rome slavery became more highly developed, and formed a more essential part of the social and political system than in any other ancient state. As in Greece, the sources of supply were wars and commerce with the slave-producing countries of the East, the latter being by far the more important source in the latter years of the republic and under the empire. The proportion of slave to free population is estimated by Blair at three to one in the period from the middle of the second century B. C. to the reign of Alexander Severus (222–235 A. D.), and the number of slaves owned by a single master was often very large. A freedman in the reign of Augustus is said to have left by his will over 4,000, and families of 200 or 300 slaves were not uncommon. As to the legal status of the slave, he was under the complete dominion of his master, against whom he had no legal redress. The marriage of slaves had no legal recognition, and their union (*contubernium*) was terminable at the will of the master; nor could a slave legally acquire property, though it became customary to permit him to enjoy a share of his earnings, known as his *peculium*. In general, punishments for crime were more severe against slaves than against free men. Their harsh treatment is attested by several servile insurrections, of which the most formidable were that of Eunus in Sicily in 133 B. C. and that of Spartacus in 73 B. C. By the second century, however, when the period of conquest had closed and the policy of the state aimed at peaceful development within existing limits, a greater humanity began to display itself in dealing with the slaves. This was furthered by the spread of Christianity, which, though it did not expressly forbid slavery or brand it as a crime, rested upon premises which must lead inevitably to its destruction. Accordingly, when the Teuton invaders settled within the Roman empire, they found the condition of slavery greatly modified. A system of caste or heredity in occupation had developed in both private and public business. The *coloni* on the landed estates were personally free, but could not leave the lands of the proprietors, and the prædial slaves in the course of time approached the condition of the *coloni*. Upon contact with the Roman civilization the Germanic tribes were naturally affected by the system of agricultural labor which they found in operation. Almost the only form of slavery known among them had been the slavery of the cultivator of the soil, and this gradually conformed to the condition of the Roman agricultural laborer. The resulting system was serfdom (see Serf), the effect of which was to lower somewhat the position of the old *colonus* while it raised that of the class of agricultural laborers as a whole.

Mohammedan Slavery.—During the Middle Ages slavery was still practiced, but among Christian races the enslavement of Christians was opposed by the Church. No such scruple applied to the enslavement of Mohammedan captives, many of whom were held as slaves throughout Europe, while numerous Christian slaves were left in the hands of the Turks and Saracens in the course of the many conflicts between Christianity and Mohammedanism. Many Moslem slaves were introduced into Europe by the great commercial cities of Italy, which carried on an extensive slave-trade with the East. On the other hand, the corsairs of Barbary carried off thousands of Christians into slavery, even pene-

trating into the interior of Spain and Southern France, and seizing the peasants in their homes. Charles V. is said to have set free 20,000 Christian slaves after his expedition against Tunis in 1535, and 12,000 Christian galley-slaves were liberated after the battle of Lepanto in 1571. White slavery still exists among the Mohammedans, but the slaves are on the whole humanely treated. The traffic in black slaves, however, is marked by every form of atrocity, and has continued despite the prohibition of the Porte.

Negro Slavery.—Though black slaves were to be found in Europe in the time of the Roman empire, African slavery on an extensive scale was not practiced by Europeans till after the discovery of America, when a great demand arose for Negro labor in the West Indian colonies of Spain. The Portuguese, who had introduced slaves into Europe some fifty years before, had at first a virtual monopoly of the slave-trade, but the English subsequently took part in supplying the Spanish demand. The rise of the North American colonies opened up another source of profit to the slave-traders. The first slaves sold to the English colonists were brought by a Dutch vessel to Jamestown in 1619, but the English afterward supplied the greater number, and continued the trade throughout the eighteenth century, despite the increasing opposition to it on both sides of the Atlantic. The Quakers had from the first opposed it, but they lacked numbers and influence. Encouraged, however, by Lord Mansfield's decision in the Somerset case in 1772, the enemies of slavery at last succeeded, through the labors of Clarkson, Sharp, Wilberforce, and others, in bringing the matter before Parliament. After repeated failures to secure legislation against the slave-trade, they triumphed at last under the Grenville and Fox ministry, and an act abolishing the slave-trade was passed in 1807. They then turned their attention to the suppression of slavery itself. On Aug. 28, 1833, a law was enacted fixing Aug. 1, 1834, as the date for the emancipation of all slaves within the British empire, and providing for the payment of £20,000,000 to the masters, who, however, were to retain their slaves as apprentices till Aug., 1840. The apprenticeship system was found to work badly, and was discontinued in 1838.

In the U. S. the slave-trade was forbidden by law in 1808. For many years before that time the abolition of slavery had been favored, not only by the Quakers, but by some of the leading statesmen. Franklin, Jefferson, Madison, and Jay were among the advocates of emancipation, and in the North this policy was so far carried out that by 1821 slavery had ceased to be a power in that region. The ordinance of 1787 prohibited slavery in the Northwest Territory. In the South, however, Eli Whitney's invention of the cotton-gin caused an ever-increasing demand for slave-labor, and the Southern States were growing more tenacious of slavery while the abolition sentiment was developing in the North. The more moderate opposition to slavery confined itself to attempts to restrict its sphere, and did not aim at unconditional abolition, but the latter policy was favored by radical reformers like Benjamin Lundy and William Lloyd Garrison, who represented a small and discredited but aggressive party. The story of the contest on the slavery question belongs to the history of the U. S., and is discussed under that title. In the Missouri Compromise (*q. v.*), in the struggle over the Wilmot Proviso, resulting in the formation of the Free-soil Party (*q. v.*), in the Kansas-Nebraska difficulty (see Kansas), and finally in the formation of the Republican Party (*q. v.*), the question of the extension of slavery became the leading issue in national politics. When civil war followed the secession of the Southern States from the Union, the expediency of the emancipation of the slaves as a war measure began to be seriously considered, and on Jan. 1, 1863, President Lincoln issued a proclamation granting immediate and unconditional emancipation. F. M. Colby.

Slave-trade: dealing in slaves; in particular, the business of capturing or purchasing human beings, transporting them to another country, and selling them as slaves.

Slavery as a status is repugnant to the principles of the modern international law. In the Congresses of Vienna, 1815, Aix-la-Chapelle, 1818, and Verona, 1822, the contracting parties agreed to unite in suppressing the slave-trade. Several states forbade their subjects to engage in it; such were Denmark, Great Britain, and the U. S. Nevertheless it may exist, if recognized by the laws of individual states, within their jurisdiction only. The traffic in slaves carried on in the ships of such states could not be restrained without their consent, expressed by treaty. Accordingly, under the influence of the agitation carried on by Zachary Macaulay, Sir Thomas Fowell Buxton, Wilberforce, and others, the British Government, in the early part of the nineteenth century, began to make treaties with a number of states for the suppression of the slave-trade. To be effective, these treaties required one of two provisions: either (1) a reciprocal right to search the merchant ships of the contracting parties, or (2) co-operation by their naval forces. Such treaties were made by Great Britain with a great variety of powers, Spain and Portugal, the chief offenders, among them. As these treaties proved ineffective, they were amended or superseded by further negotiations. Most of these conceded to British cruisers the right to search ships flying the flag of the other nationality on suspicion of being engaged in the slave-trade, with provision for trial, either by mixed courts or by a court of the defendant. Two treaties with France and the U. S. bound the parties to maintain squadrons on the coast of Africa. The gradual success of these efforts has been in its field almost complete.

It was very natural that the efforts of Great Britain to draw the U. S. into an agreement to permit a mutual right of search should have been unsuccessful, for in the earlier half of the nineteenth century the memory of British pretensions in searching U. S. ships for British seamen and then impressing them was still fresh. The first treaty which concerned the slave-trade between the two countries is that of 1814. In it (Art. X.) both parties agreed to "use their best endeavors" to bring about its abolition, but no definite plan was arranged. By several acts during 1818, 1819, and 1820 the penalties for engaging in the slave-trade were increased; authority was given for the maintenance of ships on the African station; and for all persons under the jurisdiction of the U. S. the slave-traffic was declared to be piracy, that is, to be put into the same category with piracy by statute, and visited with the same penalty. Statutory piracy does not, however, warrant arrest and trial at the hands of any state, so that these statutes alone proved insufficient, and the British Government earnestly tried to persuade the U. S. to consent to a reciprocal right of search. This the latter steadily refused. The national sentiment against it was too strong; but the detestation of the slave-trade was strong also, and led to a resolution of the House, in 1823, in favor of an international agreement making it piracy. Nothing came of this, nor of negotiations in England the next year which provided a modified right of search, but the cases to be tried in the defendant's courts. In fact, it was not until 1842 that any joint arrangement was made, and this, avoiding the reciprocal right of search, provided that each country should maintain a squadron on the African coast, the two to act in concert. Finally, in 1862, the mutual right of search within certain limits, and under conditions, was conceded. Mixed courts were established at the Cape of Good Hope, Sierra Leone, and New York. The limits were extended a little by an additional article in 1863, and in 1870 the mixed courts were abolished, the ordinary prize-courts of the two countries taking cognizance of slave-trading cases.

It has been said that the slave-traffic off the African coast has been for the most part broken up, but the vast interior is given over to it, the hunting being carried on largely by Arab adventurers, and a market being found in the Mohammedan countries in the northeastern quarter of the continent. To check this traffic the civilized powers have addressed themselves, still under the lead of Great Britain. Thus in 1877 a convention was signed between Great Britain and Egypt, by which the slave-trade into or across the latter country was prohibited, with penalties for the parties implicated; the tribal wars having the making and selling of slaves as their object were to be discouraged; and a mutual right of search was granted on the Red Sea, the Gulf of Aden, the African and Arabian coasts, and in Egyptian waters. Another treaty with Portugal, in 1879, was aimed at the slave-trade within Portuguese jurisdiction in South Africa, and in 1884–85 the Berlin Congo conference decreed the abolition of the slave-trade within the Congo Free State. To make this abolition effectual, an important "General Act" was agreed upon in 1890, the parties to it including Turkey, Persia, the Congo Free State, Zanzibar, all the European maritime powers, and the U. S. This act begins by declaring the "most effective means of counteracting the slave-trade in the interior of Africa to be"—

(1) A civilized protectorate over the administration of the African territories.

(2) The establishment of strong stations by each power in its own territory to repress slave-hunting.

(3, 4, 5) The development of the country—Central Africa—by roads, railways, steamboat service supported by fortified posts, and telegraph lines to unite them.

(6) The organization of expeditions and flying columns to protect the communications and "support repressive action."

(7) The restriction of the importation of modern firearms and ammunition throughout the entire region in which the slave-trade is carried on.

This is a most attractive programme, if it can be carried out. Without good weapons the Arabs and their slave-hunting auxiliaries would not venture to attack the native tribes. Armed boats on the great lakes and fortified stations on the great highways would break the trade up effectively, while the growth of missions, of civilization, and of civilized trade would narrow its operations. To the carrying out of this programme the signatories pledged themselves with much detail and many provisions. At sea also, along certain stretches of coast, on the Indian Ocean and off Madagascar, the powers agreed to combine to put down slave-trading in small vessels.

Finally, those of the signatory powers whose domestic institutions recognized slavery agreed to forbid the importation of slaves, their transit, their departure, and the trade in them; while Zanzibar, Persia, and Turkey have bound themselves to assist actively in the suppression of this traffic. The provisions of the act to secure all these objects run through 100 articles. THEODORE S. WOOLSEY.

Slavic Languages: a group of Indo-European languages which embraces Russian, Polish, Servian, etc. 1. Whether there ever was a unitary Slavic language is still a problem of philology. Theoretically, it is proper to speak, within the field of the Indo-European languages, of a unitary Slavic type, intimately related to the Baltic; and these two are often grouped as a Lithu-Slavic or Balto-Slavic branch of Indo-European, just as Sanskrit and Iranian are comprehended under Indo-Iranian. And the branch thus constituted undoubtedly stands in many characteristic phenomena nearer to the Indo-Iranian than to the Germanic, Celtic, Italic, or Greek. The Balts (i. e. the Lithuanians, Letts, and Prussians) have in common with the Slavs as against the remaining Indo-Europeans a richly developed vocabulary, similar formative suffixes, and noun and pronoun declensions closely related, especially in the formation of the so-called compound declension of the adjective with the pronoun stem *ja-*; e. g. τοῦ ἀγαθοῦ is in Lith. *gero-jo* (gen. of *geras*, good, and *jis*, he), in Slav. *dobra-jego*. In conjugation there are fewer points of contact, but the Lith. infin. in *-tė*, *-ti*, and the Slav. in *-ti* come close together: *dûti*, *dati*; likewise the supines in *-tum* : *tŭ* : *dûtum*, *datŭ*. In the consonant system Baltic shares with Slavic the loss of aspirates: Lat. *fero*, Gr. φέρω, Lith. *beriu*, Slav. *berą*; Lat. *fumus*, Gr. θυμός, Lith. (pl.) *dumai*, Slav. *dymŭ*; also the change of the palatal explosives to spirants somewhat as in Indo-Iranian: Gr. ἑκατόν, Lat. *centum*, Goth. *hunda-*, Lith. *szimtas* (*sz* = Slav. *š*), Slav. *sŭto*; Lat. *hiems*, Gr. χειμών, Lith. *žiema*, Slav. *zima*; Gr. γιγνώσκω, Lat. (*g*)*nosco*, Lith. *žinoti*, Slav. *znati*. In syntax may be noted as common to both the use of the genitive object in negative sentences, e. g. Lith. *nesa jis ne* (nec scit eum) *reg nej pažysta jos*; *bet jus jį pažystate*, Slav. *jako ne viditĭ jego ni znajetĭ jego*, *vy že znajete i*. Here *jos* and *jego* are objects in the genitive. (quia non videt eum vos autem eum cognoscetis)

2. The Slavic type differs from the Baltic in two marked peculiarities: (*a*) the change of diphthongs into monophthongs; (*b*) by the finely organized laws of palatalization, i. e. by the regular change of *k*, *g*, *ch* to *č*, *ž*, *š* before the palatal vowels *e*, *ē*, *ĭ*, *i*, and by the later change of *k*, *g*, *ch* to *c*, *z*, *s* before the vowels *ē*, *i* which result from *oi*, *ai*. Here follow illustrations of both these typical phenomena: (*a*) Lith. *ai* corresponds to Slav. *ê* (a long, broad sound); *baisus*, terrible: *bêsinŭ*, angry; *dailinti*, decorate: *dêlati*, carve; *mainyti* : *mêniti*, exchange; *raižyti* : *rêzati*, cut. Lith. *au* corresponds to Slav. *u* (orig. long); Lith. *ausis* : Slav. *ucho*, ear; *draugas* : *drugŭ*, friend; *jaunas* : *junŭ*, youth; *kaupas* : *kupŭ*, heap. Sometimes Lith. *au* corresponds to Slav. *y* (a deep guttural long *ŭ*); Lith. *au* is here plainly a resultant of *eu*; *krauti* : *kryti*, cover; *grauszti* : *grysti*, gnaw; *mauti* : *myti*, wipe; *raudoti* : *rydati*, moan. Lith. *ei* and *iė* correspond to Slav. *i*; *eiti* : *iti*, go; *miėlas* : *milŭ*, dear; *teisus* : *tichŭ*, still; *piėtūs* plur. dinner-time: *pišta* (from *pitja*), food. (*b*) The Slavic palatalization may be illustrated by the following parallels: Lith. *keturi* : Slav. *četyre*, four; *kibiras* : *čibĭrŭ*, jug; *kirwarpa* : worm-hole : *čirvĭ*, worm, cf. Lith. *kirmis*: Lat. *vermis* for **kvermis*; *geidauti*, yearn : *o-židati*, wait for; *gerti*, *geriu*, drink : *žrĕti* (for *žerti*), *-žirą*, devour; *sarginti*, nurse : *stražiti* (for *storžiti*), watch over; vocat. *nebage* : *nebože* (from *nebogŭ*, poor). While this form of palatalization shows itself in all the Slavic languages and dialects, and consequently is their common property, dating from the time of their linguistic unity, there has been developed in one of the Baltic languages, viz., the Lettic, after the time of the division into the three chief branches, Lithuanic, Lettic, and Prussian, a phenomenon analogous to the Slavic palatalization, so that a *c* and *dz* correspond to the Slavic *č* (from *k*) and *ž* (from *g*); e. g. Slav. (Serv.) *čitavŭ*, whole : Lett. *ceeli*, firm (Lith. *kiėtas*); Slav. *čirta*, mark : Lett. *cērtu*, cut, but Lith. *kertu*; Slav. *čirvĭ* : Lett. *cērms*, worm, but Lith. *kirmis*; Slav. *živŭ* : Lett. *dzīws*, vivus, but Lith. *gywas*. With the primitive Slavic phenomena of palatalization belongs also the change *ch* (= Gr. χ) > *š*. The Slav. *ch* is, however, itself a product of *s*. Cf. Slav. *suchŭ* : Lith. *sausas*, to which the verbum causat. is Lith. *sausinti* : Slav. *sušiti*; Lith. *dausos* plur. air : Slav. *duchŭ*, but Lith. *dausinti* : Slav. *dušiti*.

A later palatalization, but one which nevertheless falls within the boundaries of the Slavic group, is the change of *k* > *c*, *g* > *dz* (*z*), *ch* (*s*) > *s* or *ś*, which occurs in the special case where a guttural comes before an *ê* or *i*, resulting from original *ai*, *oi*. Cf. Goth. *hails*, which would be **kailas* in Lith. if it existed, and Slav. *cělŭ*, salvus; Lith. *kaina* (: Lat. *poena*) and Slav. *cêna*, price; Lith. *gailus*, sharp : Slav. *dzělŭ*, violent. This appears prominently in suffixes and case-endings or verb inflexions; nom. plur. of *stogas*, roof, Lith. *stogai* : Slav. *stodzi* from *stogŭ*; dat. sing. Lith. *rankai* from *ranka*, hand : Slav. *rącê* from *rąka*; imper.-optat. from *teka*, flow : *tĭci-tĭcête*. The commonest appearance is in the Slav. suffixes *-ĭcĭ*, *-ĭca*, *-ĭce*, *-ica*, which are used so widely as to give the impress of peculiarity to the entire body of the language. The corresponding Lith. suffixes show always *k*. Cf. Slav. *vĕnĭcĭ*, garland: Lith. *wainikis*; Slav. *junĭcĭ*, steer : Lith. *jaunikis*.

3. Another strong characteristic of the Slavic as against the Baltic type is the uniform loss of final *-s*. And as final *-ŭ* (< I.-E. *-ŏ*, *-ŭ*) and *-ĭ* (I.-E. short *-ĭ*) became silent at an early date, present Slavic word-forms often appear mutilated to the extent of the entire final syllable. Cf. Slav. *drugŭ* (now *drug*) : Lith. *draugas* (usually *draugs*); Slav. *osilŭ* (now *osel*, *osieł*, *osał*) : Lith. *asilas*; cf. also the casus obliqui, Slav. gen. sing. *nošti* (< *notji*) : Lith. *naktiės*, Slav. acc. sing. *nošti* : Lith. *naktĭ*. But as an offset to its poorer noun declension, Slavic has a fuller and clearer development of verb forms—a difference which constitutes one of the most difficult problems of philology. Cf. Lith. 2 pers. pres. *teki*, 3 pers. *teka* : Slav. *tečeši*, *tečetĭ*, pl. *tekątĭ*; Slav. aorist formation *tekŭ-tekomŭ*, *têchŭ-têchomŭ*, *tekochŭ-tekochomŭ* and imperf. *tečaachŭ-tečaachomŭ* (also *tecêchŭ-tecêchomŭ*): Lith. perf. *tekėjau* and habitual imperf. *tekėdavau*. Lith. opt. *tekėtumbei* (: supine *teketum* + *bei*) corresponds with change of category to Slav. condit. *teklŭ bi*. On the other hand, the Slavic language type lacks all except a few traces of the *s*-future : *tekėsiu* must be expressed in Slav. either by the pres. *teką* (compounded with various prepositions to complete its meaning) or by the inf. *tešti* (= *teiji*, *teći*, *teči*, *teci*) with the vb. *choštą*, will, *imamĭ*, have, or *bądą*, become. This last-mentioned distinction between the two language types is closely connected with the fine distinctions of the Slavic verb as regards the aspects of time-duration, which are not developed to the same degree in Baltic. In contrast to the Slavic use of the opt. as impv., *tĭci-tĭcête* (where *i* and *é* are parallel to Gr. opt. endings *-οις*, *-οιτε*), Lithuanian has a new formation from the true infinitive stem with *-k* : *tekėk*, *tekėkite*. A trace of the optative remains in *te-tekiė*.

4. The separation of the Slavic from the Baltic must have been many centuries before our era. Many new acquisitions of sounds and vocabulary fall in the subsequent period of separation. The lexicographical material common to Slavic and Baltic shows no great or long-continued advance in culture from the primitive Indo-European period. The common Slavic vocabulary, on the contrary, is characterized by a great wealth of words important for the history of culture, and testifies to so long a period of common development and so rich and varied a community of life that the separation of the Slavs into various branches and peoples must be a comparatively very recent matter, and a result merely of local expansion. Especially worthy of notice is the borrowing of culture-words from the Teutonic, usually

in the Gothic form, during this period of primitive Slavic unity, doubtless during its closing centuries, e. g. *kŭnędzĭ*, prince, from Goth. *kuningas*; *cêsarĭ*, emperor, from Goth. *kaisar*; *brŭnja*, coat-of-mail, from Goth. *brunjô*; *cęla*, coin, from *kinlus*; *chorągy*, flag, from Goth. *hrunga*, pole: *kolĭlŭ*, kettle, from Goth. *kalilas*; *skldędzĭ*, shilling, from Goth. *skillingas*; *šlêmŭ*, helmet, from Goth. *hilms* ($h > š : k > c$), and many others.

The undivided Slavic people, apparently with the principal designation of *Slovêne* (sing. *Slovêninŭ*), inhabited the region of the Vistula (upper and lower) and of the upper Dniester and Dnieper, extending to the outer fringe of the Carpathian Mountains. They are first mentioned in classic literature by Pliny, Tacitus, and Ptolemy under the name of *Venedæ* (Οὐενέδαι). The name *Sclavêni* (*Sclavini*) is first met with in Jordanes (who also uses *Venêlhæ*) and Procopius in the sixth century: Σκλαβηνοί. The movements of the neighboring peoples—the Germanic Bastarnians, Goths, and Herulians on the W., and the Huns, Avars, Bulgars, and Chazars on the E.—pushed the habitat of the politically unorganized Slavs sometimes to the E. and N., sometimes to the W. and S. Jordanes and Procopius still locate the mass of the Slavic people eastward of the Vistula and northward of the Danube. But they soon spread to the W. beyond the Vistula and Oder and to and across the Elbe, and also to the S. across the Danube into the regions of the Hæmus, the Adriatic, and the Alps. Their migration into Pannonia began under pressure of the Huns, but became greater under pressure of the Avars.

5. Without doubt the separation of the Slavs into several linguistic groups preceded their final dispersion and in many ways determined its directions, as the present relative positions of the Slavic peoples seem to agree entirely with the philological classification and grouping of their languages, so that the settlements of the Slavs in historic times seem simply to reproduce on a larger scale the grouping of the prehistoric Slavic microcosm; e. g. the languages of the northwestern Slavs, including the now extinct Elban and Pommeranian, the Polish, Lusatian-Servian, Čech (Czech), and Slovakian, lead to the assumption that they lived in prehistoric times in the same relative positions, but within narrower limits. In all Northwest Slavic languages, primitive Slavic $t'j > c$, $d'j > dz$ ($> z$), e. g. *svêl'ja* > *sv'ieca*, *med'ja* > *m'edza* (> *m'eza*, *meze*). Yet it can not be said that the Northwest Slavic languages form a distinct unity as contrasted with all East and South Slavic languages, a view long held, however, under the influence of Dobrowský's classification; e. g. the treatment of the nasalized vowels forms a break in this assumed Northwest Slavic unity: the Polish, Pommeranian, and Elban retained the nasalization till the latest historic times (cf. Pol. *pięć*, *mięso*, *dąb*, *ząb*; Polab. (as written) *mangsi*, *mangsee*, *jansmin*, *tielang*, *pangt*, *gunsik*, *dumb*, *gunss*, etc.), while in Lusatian-Servian and Čecho-Slovakian nasalization has disappeared since the earliest historic times. Neither can we set up a dual division into Polish-Polabian and Lusatian-Servian–Čecho-Slovakian; for prim. Slav. *borda*, beard > Pol. *broda* : Lus.-Serv. *broda* : Čecho-Slov. (as also in South Slav. dialects) *brada*, etc., while Polab. gives *or* in *korwo*, *bordzya*, *chorna*, *vorno*, *ggorch*. No more can the South Slavic languages (Slovenian, Servo-Croatian, Bulgarian) be forced into a group with the Russian dialects, for while $t'j >$ Russ. *č*, $d'j > ž$ (rarely *dž*), e. g. *sv'ěča*, *m'eža*, in the South the Bulgarians say *svešla*, *mežda* (earlier *svêšt'a*, *mežd'a*); the Servo-Croatians *sveća* (*svieća*, *svića*, *ć* = *l'* or *tj*), *megja* (*gj* = *dj*, a palatal *d* with very weak assibilation) and *meja*; the Slovenians *sveča* (also *sveća*), *meja*. Hence the assumption of an original prehistoric bifurcation of all Slavic languages can not stand. But neither will a triad succeed. We see, rather, a continuous interrelation of each two or more neighboring languages, giving rise not infrequently to transition phenomena and transition dialects, which still furnish many problems for Slavic philology. In many cases the connecting links have disappeared, as, e. g., in Eastern Germany between Polabian and Casubian, in Lower Austria and Northern Styria between Čecho-Slovakian and Slovenian, in Pannonia between various Slovenian dialects, in Dacia between Slovenian and Russian.

6. The Slavic overflow into Central and Southeastern Europe came to a close in the first decade of the sixth century. The patriarchal organization of the Slavs and their division into very small disunited tribes allowed them to make no immediate political impression on their better organized and more cultured neighbors, to whom they were hostile not only by difference of language, but also by their persistent clinging to heathenism. The so-called Bavarian geographer gives the names of over fifty-five Slavic tribes scattered in larger or smaller areas over Germany, and his list could be somewhat increased from other sources. Their Christian neighbors sought at once both to convert and to subjugate them. Missionary efforts lasted during the seventh and eighth centuries, and first bore fruit in Dalmatia, Carantania, and Pannonia. In the meantime the Slavs learned the new forms of political and national life from those around them. Samo tried in the seventh century to unite the Slavic portions of Bohemia, Saxony, Thuringia, Bavaria, and the Alps, and a strong Slavic principality, which later became a kingdom, long existed in Dalmatia. Still more powerful was a state founded in Moravia, including parts of Northern Hungary, which gave rise to an event of the utmost importance for the history of the world. In answer to a request of Rostislav, who wished to free his kingdom from ecclesiastical dependence upon the Frankish, the learned and zealous Constantine and his older brother, Methodius, were sent from Constantinople as missionaries to the Slavs. Constantine (later called Monk Cyril) founded a literary language for all the Slavs—the so-called Church Slavonic or Old Bulgarian (or Old Slovenian), which served for many centuries as the organ of the Church and of Christian civilization for more than half the Slavic race. It was written in two alphabets, the Glagolitic, still universally retained for Constantine's writings, and the Cyrillic, which arose soon after, apparently in Bulgaria, and, because of its greater simplicity and its close resemblance to the liturgical Greek uncial (while the Glagolitic is based chiefly on the cursive minuscule), displaced the earlier alphabet. With some modernization under Peter the Great, it is still the alphabet of Great and Little Russian, Bulgarian, and Servian, while the Croatian, Slovenian, Slovakian, Čech, Lusatian-Servian, and Polish use the Latin alphabet. The Glagolitic prevailed from the tenth to the twelfth centuries in all western Slavic countries (Moravia, Pannonia, Dalmatia, Macedonia, Bosnia, and Servia), but later was restricted to Northern Dalmatia, Croatia, the coast-land, Istria, and the Quarnero islands. In these lands it is still used in Old Slovenian books printed in Rome for the Catholic Church service. Toward the end of the fifteenth century it was used for public notices, laws, communion-books, and even in private correspondence, and, with the rise of Protestantism, to spread Protestant doctrine in Istria, Croatia, the coast-land, and Dalmatia.

In Slavic philology Church Slavonic plays much the same part as Gothic in Germanic philology. It has the important advantage of having received a fixed literary form 300 years earlier than any other dialect. Its oldest form, represented by monuments going back to the tenth century, shows so ancient and so transparent an organization that it frequently furnishes the key to modern Slavic problems. Its importance to philological investigation is further aided by its use of an alphabet extraordinary for its fine phonetic discriminations. The first scientific grammar was written by Abbé Joseph Dobrowský, the founder of Slavic philology, in 1822—*Institutiones linguæ slavicæ, veleris dialecti*. Other works have appeared, as follows: Alexander Vostokov, a *Razsuždenie* (consideration) of this language (Moscow, 1820—demonstrates the presence of nasalization in Church Slavonic), edition of Ostromir's *Evangelium*, the oldest dated (1075) monument (1842); Kopitar, *Glagolita Clozianus* (1837); Miklosich, *Vergleichende Grammatik der slavischen Sprachen* (of which he made Church Slavonic the basis), appearing in parts as follows: *Lautlehre* (1st ed. 1852, 2d ed. 1879), *Stammbildungslehre* (1875), *Wortbildungslehre* (at first called *Formenlehre*; 1st ed. 1856, 2d ed. 1876), *Syntax* (2d ed. 1883); Schleicher, *Formenlehre der kirchenslavischen Sprache* (1852). See also the Slavic parts of Schleicher's *Compendium* and Brugmann's *Grundriss*. To the grammar belong also the following: Leskien, *Handbuch der Altbulgarischen Sprache* (2d ed. 1886); Jagić, editions of the *Codex Assemanianus* (1865), *Codex zographensis* (1879), *Codex Marianus* (1883), articles in the *Archiv für slavische Philologie*, etc.: also the writings of the Russian savants Sreznevskij, Sobolevskij, Brandt, Fortunatov, and others. The study centering on this language has raised a whole series of questions with reference to which the scientific and grammatical treatment of the separate Slavic languages must be largely shaped, both in form and content. Especially has the question of the habitat of the Church Slavonic called forth differences of opinion that have been

reflected in the names given it. At the outset Dobrowský recognized in it a southern dialect, which he called at first Old Servian, later Bulgaro-Servian or Macedonian. Kopitar advanced the hypothesis of a Pannonian-Carantanian origin, which Miklosich followed with slight modifications. From these two scholars comes the name Old Slovenian. Šafařík defended the Old Bulgarian hypothesis, more on historical than on linguistic grounds. The name Old Slovenian is still used because in native sources the language was so called, *slověnĭskŭ* (*slovenica lingua*), but it is now known to have been a South Slavic dialect spoken somewhere in Macedonia in the ninth century, having the most points of contact not with modern Slovenian, but with Bulgarian, and some also with the present Servo-Croatian dialects. In location it probably formed a frontier between Bulgarian and Servo-Croatian; not necessarily in Northern Macedonia, however, for Constantine Porphyrogenitus speaks of Servians near Saloniea. Aside from its philological importance, Church Slavonic is indispensable for the history of mediæval literature, serving beside the Christian Greek and Latin as the third international literary language. From the tenth century to the seventeenth a wealth of patristic literature, including lives, legends, and homilies, was assiduously translated—from the tenth to the fourteenth centuries especially in the South, but later also in Russia. It was also the state language in Bulgaria, Servia, Bosnia, Russia (including Lithuania), Moldavia, and Wallachia; and while its supremacy, like that of Latin in the West, ceased with the end of the seventeenth century, yet even to-day the Russian literary language rests on centuries of Church Slavonic traditions as to forms, vocabulary, and orthography. See Russian Language.

Individual Slavic Languages.

7. The southern Slavs, who in Byzantine times migrated in larger or smaller bands into the regions of the Hæmus, the Adriatic, and the Alps, are all called by Byzantine historians (Procopius, Menander, Theophanes, Theophylactus) by the name Σκλαβηνοί, equivalent to Slav. *Slovêne*, adj. *slověnĭskŭ*, a name continually met with in all historical periods in the Slavic South. The Bulgarians were originally called *Slovêne* both by themselves and others, and their language *slověnĭskŭ*. The inhabitants of Styria, Carinthia, Carniola, and the coast around Trieste and Gorz are still called *Slovenci*, and their language Slovenian. The republic of Ragusa also, in spite of the identity of its language with the inland Servo-Croatian, held in its rich poetical literature of the fifteenth to the eighteenth centuries to the name of "Slovinian." Hence the Byzantine name Σκλαβηνοί must have designated the whole of the southern Slavs. These tribes have never attained to a political or cultural unity. In Carinthia, Styria, and Carniola they early submitted to the Germans, and their closely resembling dialects formed the basis of the present Slovenian language. The dialect of Carniola forms the basis of the literary language. Slovenian was first treated grammatically by Kopitar (1808), later by Metelko, Dainko, Murko, and more recently by Miklosich, Levstik, and Šuman. A complete dictionary is (1895) being edited by Pleteršnik.

Nearest related to the Slovenian is the language of Slavonia in the old sense of the term, that is, of the region between the Save, Drave, and Mur (including scattered areas N. of the Mur in South Hungary). It probably extended formerly much farther toward the E., but the populations driven out of the Balkan Peninsula by the Turks entered the present Slavonia in such numbers that the Old Slovenian of the former kingdom of Slavonia is now restricted to the counties of Warasdin, Kreuz (Križevci), Agram, nearly to Belovar and Wirowitic. Since the end of the seventeenth century, this region has been known as Croatia and its language as Horvatian. Its literature began with the Protestant movement, and furnished in the seventeenth and eighteenth centuries a series of important prose works (also dictionaries by Belostenec and Habdelič). It continued as a literary language until the rise of Illyrianism in Agram, after 1830, led to its displacement by the richer and more extended Servo-Croatian. As a popular dialect it still continues. It is often called the *kaj* dialect, from its use of the word *kaj* (quid?).

8. The Croatians proper and Servians extend farther south, roughly from the river Kulpa throughout Istria, the islands, the Croatian coast, Dalmatia, Montenegro, and throughout the interior (Bosnia, Herzegovina, Old Servia, Servia), and northward beyond the Save throughout Slavonia, Syrmia, and Southern Hungary. The popular language deviates more or less from the literary dialect according to locality. That of Southwestern Servia and Herzegovina, together with the Bezirk of Ragusa, is nearest in character to the literary dialect. Montenegrin offers many peculiarities in pronunciation and syntax. As a result of ecclesiastical and political separation, the Servians and Croatians, so nearly related in language, have had a very diverse historical development. Though both were originally converted by Rome, and both accepted the Slavic liturgy in the ninth century, the separation of the Church into Eastern and Western soon afterward divided them into two hostile camps, Servia holding firmly to Constantinople and to Church Slavonic, while in the west the influence of Rome in ecclesiastical and public matters constantly increased. Not only in the old Romance cities of Dalmatia, but in the independent principality of Croatia, Latin was the ruling language in Church and state, though Church Slavonic still had a limited use in private congregational matters. After the end of the fourteenth century the popular language was used with Latin characters, at first in prose works for Christian instruction, but by the end of the fifteenth century for a poetical literature which reached its richest development in Ragusa in the seventeenth century. In 1595 Faustus Verantius (Vrančić) treated the "Dalmatinian" (for so he called it) lexicographically and proved the Slavic loan-words in Hungarian. In 1604 appeared the first grammar of the "Illyrian" language by Bartholomew Kašić, and in 1649 a valuable dictionary by Jacobus Micalia. The literary life of Dalmatia spread to Bosnia in the sixteenth century—at least among Catholic adherents—and in the seventeenth and eighteenth books were printed in the popular language for circulation in Bosnia, with both the Cyrillic and Latin alphabets. The true founder of the popular language as a literary dialect for the Servians is Vuk Stef. Karadžić, who published much popular material, principally songs, in the second and third decades of the nineteenth century, and based the Cyrillic orthography on phonetic principles. Since this Servian dialect of Vuk is the same as the Dalmatian of the fifteenth to the eighteenth centuries (later used also in Bosnia), which, as above mentioned, was introduced into Agram in 1835 under the name of Illyrian, these two long separated branches have at last been united again into the Servo-Croatian literary language. Though this still preserves a dualism in name (Servian and Croatian), and in the use of different alphabets (Cyrillic and Latin), it is one in grammar and vocabulary. Vuk prepared a small grammar and an excellent dictionary (2d ed. 1852). The great *Academic Dictionary of the Croatian or Servian Language*, begun by G. Daničić (1882), is being published by the South Slavic Academy in Agram.

9. Most peculiar in its development has been the language of the Bulgarians, who borrowed their name from their Turkish conquerors, the Bulgars. They live, to the number of about 3,000,000, E. of the Servians on the lower Danube, in the Balkan and Rhodope Mountains, in Roumelia nearly as far as Adrianople, and in a large part of Macedonia. They were originally composed of seven Slovenian tribes, whose branches may have extended to the south as far as Greece, and northward as far as Eastern Pannonia and Transylvania; the resulting dialectal differences are not yet wholly obliterated. Besides the use of a post-positive article, Bulgarian has lost the true Slavic declension, replacing it by prepositions with the general case, which gives it a strange appearance in comparison with all other, even southern, Slavic dialects, with which in other ways it has many points of contact. This phenomenon probably dates back to the fourteenth century, and may have been partly due to the influence of Roumanian, in which it certainly developed much earlier. The Slavic conjugation, however, except for the loss of the infinitive, has been retained in Bulgarian in its old form, agreeing with the eastern Servo-Croatian dialects even in the formation of the future by means of the auxiliary *štă* (from *chošta*), and with all South Slavic dialects in the use of the conjunction *da* with object clauses (instead of *že iž* in Northwest Slavic, and *čto- što* in Russian). As noted above, Bulgaria was for a long time the center of Church Slavonic literary activity (under the Emperor Simeon, 927 A. D., and his immediate successors). As a result, the popular language does not appear in literature before the seventeenth century, and must be gathered from fragments found scattered through the Church Slavonic texts. The language was made known to the literary world by Vuk Stef. Karadžić and Kopitar, having been scarcely known to Dobrowský, and has been investigated

scientifically by Miklosich, Hattala, Biljarskij, Kalina, Lavrov, Drinov, Conev, and Miletič. The first dictionary was by Duvernois.

10. Characteristics common to all South Slavic languages are: (*a*) The hard pronunciation of the vowel *e*, so that the syllables *te*, *de* are as hard in sound as *ta*, *da*; (*b*) the phonetic blending of *i* and *y* into a medial hard *i* (e. g. *biti* and *byti* are homonyms; the pronoun *ti* represents both *tibi* and *tu*); (*c*) *or* and *ol* + cons. > *ra*, *la* (e. g. *grad*, *glad*), *er* and *el* + cons. > *rê*, *lê*; (*d*) the use of *r̥* (vocalic or syllabic) e. g. *nrtev*, *mrtav*. *mrtuv*, while *l̥* > Sloven. *ol* + cons. (with *l* usually silent): Servo-Cro. *u* (< carlier *ul*) : Bulg. *l̥*, e. g. Sloven. *volk* (pron. *vôk*), S.-C. *vuk*, Bulg. *vlk* (written *vlŭk*); (*e*) *ę* > *e* (sometimes pronounced very broad, and after palatals even equivalent to *a*), while *ǫ* > Sloven. *ô* (close and somewhat long): S.-C. *u* : Bulg. *ŭ* (sometimes *ă* or even *o*), e. g. Sloven. *môž*: S.-C. *muž* : Bulg. *mŭž* (*măž*, *mož*—*ž* final = *š*); (*f*) the softening influence of final *-ĭ* on *t* and *d* has disappeared, e. g. prim. Slav. *mostŭ*, *kostĭ* > *most*, *kost*, both with hard *t*.

11. The ancient line of contact between the southern and northwestern (Čecho-Slovakian) Slavs must have run originally through Pannonia along the line of Buda-Pest-Oedenburg, and along the portion of the Alps that divides Styria from Austria. It was obliterated by the founding of Ostmark and the occupation of Pannonia by the Magyars. It is noteworthy, however, that the Slovaks of Northern Hungary (along the Tatra Mountains from Moravia to beyond the boundaries of Galicia) still call their language Slovenian (*slovenský jazyk*) and themselves Slovaks (*Slovák*). The Čecho-Slovakians (Čechs, Moravians, North Hungarians) entered their present abodes either from the north through the opening of the Oder valley between the Sudetes and the Beskides, or have spread from Pannonia. They number about 7,000,000, of whom 2,000,000 are in Hungary. Their language, whose monuments date from the twelfth century, may be characterized as follows: (*a*) *e* and *i* have a softening influence (in contrast with South Slavic hard *e* and *i*), especially in Slovakian, e. g. *budete* is pronounced nearly *bud'et'e*, the dat. *ti* (*tibi*) is distinct in pronunciation from nom. *ty* (*tu*), *biti* is distinct from *byti*; (*b*) final *-ĭ* also has a softening influence, e. g. *kosť* is distinguished from *most*; (*c*) *ĭr* + cons. > *r̥* (e. g. *prst*, *srdce*, *zrno*), which is lengthened in Slovakian, e. g. *kŕmiť*, feed, *pŕliť*, burn, *pŕš*, rain, *sŕňa*, fawn; (*d*) in Čech, medial *-ŭ-* and *-ĭ-* > *-e-*, e. g. *den*: Ch. Slav. *dĭnĭ*, day, *sen* : Ch. Slav. *sŭnŭ*, somnus; (*e*) nasal *ǫ* > *u* (while *ę* + soft sound > Čech *i̯e* (lengthened to *í*), *ę* + hard sound > *a* (< *i̯a*); (*f*) the Old Slovenian vowel *ê* fluctuates between *ie* and *i̯e*. Čech *ie*, if lengthened, > *í*, and Slovak. *i̯e* tends to become *e*, e. g. Čech *pěna* (*ě* = *i̯e* short) : Slovak. *pena*; (*g*) as in all Northwest Slavic, *t'j*, *d'j* > *c*, *dz* (*z*), e. g. *svíce* : Slovak. *svieca*, *ryzý* : Slovak. *rydzi*; (*h*) as in all Northwest Slavic, the original consonant groups *dl*, *tl* are retained, e. g. *krydlo*, *mydlo* (: Russ. *krylo*, *mylo*), *pletla*, *bodla* (S. Slav. *plela*, *bola*); (*i*) epenthetic *l* is lost, e. g. *zemiak*, potato, *konopě* (Slovak. *konopa* : S. Slav. *konoplja*); (*j*) *g* > *h*, e. g. *noha*, *mnoho*, but remains in the Slovak. *druzgati*, *miazga* (*mliazga* : Sloven. *mézga*), *rázga* (Čech *rozha*); (*k*) in adjective declension *o* + *e* > *é* in all N. W. Slav. (: S. Slav. *ō* : Russ. *oe*), e. g. *dobré* : S. Slav. *dobrō* : Russ. *dobroe*. The demonstrative pronoun is *ten* instead of S. Slav. *tè- ta- taj* : Russ. *toj- tot*; likewise *jenž* instead of *iže*.

While Čech had, by the thirteenth and fourteenth centuries, developed a rich mediæval literature, literary activity among the Slovaks began among the adherents of Protestantism, who, making use of the rich Hussite and Brethren literature (in Čech), also made literary use of the Čech in preference to their own Slovakian dialect. Later, however, the claims of the Slovakian dialect were asserted under Catholic influences, with the final result that in 1850 the Slovakians adopted as their literary language the dialect recommended by Hodža and Hattala—a separation weakening to both the Slovakians themselves and to Bohemian literature, for the divergences between the two dialects were not sufficient to warrant it. Slovakian grammar has been treated by Bernolák (also author of a large dictionary), L. Štur, and Hattala. The eastern population of Moravia is almost more Slovakian than Čech as regards dialectic peculiarities, as shown by Prof. Bartoš's *Dialectologie moravská* (part i., 1886). Čecho-Slovakian literary activity (as also the scientific study of the dialects) began in Bohemia, as noted above, with such poetical works as the *Romance of Alexander* and the prolix *Legend of Catharine*. The language of these monuments is called Old Bohemian, principally because of its use of certain ancient forms (e. g. simple and *s*-aorist, and pluperfect). From the end of the fourteenth century various theological themes were treated by Old Bohemian prose-writers, beginning with Huss, and especially under the Bohemian Brethren. Huss laid the foundations of present Slavic orthography by indicating the palatals with diacritical marks over *c*, *s*, *z* (now *č*, *š*, *ž*). In 1533 and frequently thereafter appeared a grammatical publication (*Orthography and Etymology*) by Beneš Optat and Václav Philomathes. Jan Blahoslav annotated this work, and in 1571, the year of his death, finished an appendix, which was first published by H. Jireček, Vienna, 1857. After their terrible reverses at the beginning of the seventeenth century, the Bohemian people began to recover under the Empress Maria Theresa and the Emperor Joseph II., and to take up again their much-neglected language. This was the time of the beginning of Dobrowský's work. With him begins not only the comparative grammar of the Slavic languages, but also the scientific regeneration of Bohemian grammar (e. g. the correction of the orthography in several points, the division of the verb into six classes, according to formation of infinitive, etc.). After his death (Jan. 6, 1829), Bohemian study made progress chiefly in historical and dialectological directions (under Šafařík, J. Jireček, Šembera, and others) until the studies carried on by Gebauer (part i. of *Phonology*, 1894). Invaluable, even after the work completed by Kott, is the dictionary of Josef Jungmann (5 vols., 1835–39). As a result of the preponderating influence of the dialect of Prague, the language of Bohemia is subject to few dialectic variations; that of Moravia is less uniform.

12. North of the Čecho-Slovakians, and once their immediate neighbors, are the formerly powerful Lusatian-Servians or Wends, numbering now about 150,000 around Bautzen in Saxony and Cottbus in Brandenburg. Their language falls into two dialects, Upper and Lower. The German annalists, especially Thietmar of Merseburg, give many accounts of their conflicts with the Germans in the tenth to twelfth centuries. They appear under many names, apparently tribal designations, as Dalemėnei, Siusli, Chutici, Coledici, Mileieni, Lusiei, Selpuli, Sorowe, etc. Formerly they extended as far as the Poles on the E., the Polabians on the N., and the Czechs on the S., touching the Germans only on the W.; to-day they are hemmed in by the Germans on every side. The language of this people, first aroused to literary life by Protestantism (the New Testament was translated by Jaknbiea in 1548, a song-book and shorter catechism appeared in 1574), has received grammatical treatment by Tieinus (Upper Lusatian-Servian), 1679, Matthaei (Upper Lusatian-Servian), 1721, Hauptmann (Lower Lusatian-Servian), 1761, and in this century the Upper Lusatian-Servian by Seiler, Jordan, and Pfuhl, the Lower Lusatian-Servian by Mucke (*Historische und vergleichende Laut- und Formenlehre der Niedersorbischen Sprache*, Leipzig, 1891), and Zwahr (dictionary, 1847). In dialectic characteristics Lusatian-Servian is intermediate between Czech and Polish.

13. The Poles, in the earliest Slavic sources also called Ljachen, have from the earliest times dwelt E. of the Wends on the upper side of the Riesengebirge and Sudetes, on the outermost fringe of the Tatra and Beskides Mountains, and over the wide plains of the Oder and Vistula. Before the sixth century their ancestors and those of the later Polabians may have dwelt together in the present home of the Poles, which falls mostly within the original European habitat of the Slavs. The most ancient Russian chronicles mention as tribes the Poljans, Mazovšans, Ljutic, and Pommeranians; the Bavarian geographer mentions that *Lendizi*, which is the same name as the *Ljadskaja zemlja* of the Russian chronicle. The Uuislans (Vislans) and Sleenzans (Slenzans) and some others mentioned in the same authority are doubtless Poles. Formerly the Poles were neighbors to the Pommeranians on the N., the Kriwič, of White Russian stock, on the E., and the Lusatian-Servians and Polabians on the W.; but the Germanization of the Slavic territory between the Elbe and Oder brought them into contact on the N. and W. with the Germans, by whom the development of their political power was constantly repressed in those quarters. In the east, however, they developed their political and cultural supremacy at the expense of the Little and White Russians. They number at present about 13.000,000, being next to the Russians the most numerous Slavic people. Their unity of culture and language was furthered by their long political independence and religious unity.

The Polish language is characterized most strongly among all the living Slavic languages by retention of the original Slavic nasalization; cf. prim. Slav. *dąbŭ-dąba-dąbu*, Polish *dąb-dębu*; prim. Slav. *rąka-rąką-rąkŭ*, Polish *ręka-rękę-rąk*. The Polish is rich, almost too rich, in sibilants, the original Slav. groups *te-ti*, *de-di* being assibilated: *cie* (i. e. *će*), *ci* (i. e. *ći*), *dzie* (i. e. *dźe*), *dzi* (i. e. *dźi*); so also *s*, *z*, before palatal vowels become *ś*, *ź*; *siano* (i. e. *śano*) *ziemia* (i. e. *źeḿa*). Polish differs widely from Čech in the treatment of the old Church Slav. vowel *ê*, making it now *ie* (before soft sounds), now *ia* (before hard); thus *wiatr* (Čech. *vítr*, genit. *větru*), but *wierny*, *wierzyć* (Čech. *věřiti*). Polish forms from *or* + cons. and *oł* + cons. not *ra-ła*, like Čecho-Slovak. and South Slav., but *ro-ło*, like Lusatian-Servian; *er* + cons. and *el* + cons. do not yield *rê* + cons., *lê* + cons. as in Cech and South Slav., but *re* + cons., *le* + cons., e. g. Cech *březa* or *bříza*, Pol. *brzoza*. Polish has no *ŗ-*, *ļ-* sonans. In the umlaut of *ie* > *io* Polish is akin to Russian. Polish has retained *ł* (hard) and *l* (palatal), whereas Čech has in recent centuries entirely relinquished *ł*. Beside other peculiarities of the Polish is to be noted its constant accentuation of the penultimate syllable, as distinguished from Čech and Lusatian-Servian, which accentuate the first; also its lack of distinctions in quantity as contrasted with the many long syllables, notably final ones, in Čech.

14. The Casubian was regarded by Kryński, Biškupski, and Pobłocki as a dialect of Polish, but by most scholars has been more correctly regarded as the last remnant of the language of those Slavs who formerly extended throughout Pommerania and beyond the Oder to the Elbe. The Casubians of to-day (also called Slowincians or Slowiencians) are a poor fishing people around the Gulf of Dantzic and in some places in the provinces of West Prussia (Putzig, Neustadt, Karthaus, Dantzic, Berent, Konitz, Schlochau) and Pommerania (Lauenburg, Stolp, Bütov), and number over 150,000. A comparison of their language (treated by Cenowa, Hilferding, Biškupski, and others) with Polabian (as set forth by Schleicher) shows conclusively that Polabian and Pommeranian had much in common that can not be found in Polish. A most serviceable dictionary of Casubian by Ramult was published by the Cracow Academy in 1893.

15. For an account of the Russian dialects, see Russian Languages. V. Jagić.

Slavo'nia [= Late Lat., deriv. of *Sla'vus*, Slav; cf. O. Bulg. *Slovie'ninŭ*: Russ. *Slavya'ninŭ*, Slav, Slavonian; perhaps connected with O. Bulg. *slovo*, word, *slava*, glory]: a territory of Austria-Hungary, forming with Croatia a province attached to Hungary; bounded N. by the Drave and S. by the Save, and E. by the Danube. Area, 9,106 sq. miles. A branch of the Carnian Alps enters Slavonia from the W., and traverses it in its whole length, forming the watershed between the Drave and the Save, and terminating somewhat abruptly on the banks of the Danube. These mountains, which nowhere rise above 2,700 feet, are rich in copper, iron, lead, and beautiful marble, and their slopes are clothed with fine timber-yielding forests, vineyards which produce a sweet, strong, richly flavored wine, and orchards in which apples, pears, cherries, and peaches, figs, oranges, and walnuts ripen to perfection. Along the rivers extend low, rather marshy, but very fertile plains, where large crops of wheat and maize are raised and immense herds of cattle and swine reared. Of manufactures there are almost none; some linen fabrics are made from the excellent flax and hemp which are raised, but only for home use. The inhabitants, who call themselves *Slavonatz* and their country *Slavonska*, are at once warlike and dreamy, fond of music, poetry, and dancing, excelling in all kinds of horsemanship, and preferring the life of the shepherd to that of the tiller of the soil. They are deeply attached to their fatherland and proud of their nationality, and of late political ideas and passions have begun to play a conspicuous part in their lives. See Croatia.

Revised by M. W. Harrington.

Slavs [from Germ. *Sklave*, *Slave*, from the Slavic forms. See Slavonia]: a race of Indo-European relationship, characterized chiefly by their speech and constituting three-tenths of the population of Europe, and divided into three main branches—Eastern, Western, and Southern. To the first belong the Russians and Ruthenians; to the second, the Poles, the Czechs, the Slovaks, and the Wends; to the third, the Bulgarians, the Servians and Croatians, and the Slovenes. For the Slavic population of Austria-Hungary, Prussia, and Russia, see the articles on those countries.

No information is given, even by legends, as to the first appearance of the Slavs in Europe. In the fourth century they were found in great numbers in the neighborhood of the Carpathians, and that is supposed to have been one of their earliest homes. Thither point the legends of many Slavonic peoples, especially the Poles and Czechs, and thence the Slavonic settlers appear to have spread northward to the Baltic and southward to the Adriatic. The earliest authentic records of the Slavs are given by Procopius, Jordanes, Agathias, the Emperor Maurice, and other writers during the second half of the sixth century. These authors all lived in Byzantium or in Italy, and were personally acquainted only with the Southern Slavs, who dwelt on the lower Danube and spread through ancient Mœsia and Pannonia. The Northern Slavs they knew by report only. No political unity seems ever to have existed among these early Slavs, but their different bodies consolidated at various periods between the seventh and eleventh centuries into monarchies, of which most have virtually disappeared. To the early Slavs, Jordanes and some other writers give the name of Wends, by which name the Slavonic inhabitants of Lusatia are still known to their German neighbors. This designation, under various kindred forms, appears to have been applied to Slavs by foreigners, just as that of Welsh (*Wälsche*) was given by the Teutonic to the Latin-speaking peoples.

Of the ancient Slavs little information can be obtained except from the writings of Greeks, Germans, Arabs, and other foreigners. They appear to have differed but little in the various lands which they occupied, everywhere bearing the character of being a brave and hardy race, given to agriculture, and of a peaceable nature, except where they were influenced by more martial neighbors. Some modern writers suppose that the Slavs formed into clans, others that the foundation of Slavonic society was the family community. Among the Western Slavs, at least, a cluster of such communities formed a *jupa*, or district, at the head of which was a *jupan*, or chief, and in its center a *grad*, or town. The mode of life among all the Slavonic tribes was patriarchal, the father ruling his family with despotic power. Polygamy prevailed among them in heathen times, and also a kind of suttecism, but women do not seem to have occupied an altogether degraded position. Of Slavonic heathenism not much is known, but its deities appear to have been for the most part personifications of nature-forces. Vague recollections survive of Svarog, the heaven-god, answering to the Greek Ouranos, the Vedic Varuna. He appears to have given place, in some parts, to a solar deity, Dazhbog, together with whom, as the representative of the sun, a Khors is mentioned. Another solar deity was Volos or Velcs, the special protector of cattle, surviving in Christian times as St. Blasius or Vlasy. Kupalo and Garilo are supposed to have been representatives of the summer sun, the fertilizer of the earth. Fire is said to have been worshiped under the name of Ogon, answering to the Vedic Agni, and there was a wind-god, Stribog; but the chief deity of the Northeastern Slavs was Perun, the thunder-god, answering to the Teutonic Thor, and supposed to be the European representative of the Vedic Parjayna. Among the Western Slavs other deities were worshiped, such as Radigost and Sviatovit, and the three-headed Triglaf, of whose images detailed accounts are given by old writers. These Western Slavs appear to have had temples and priests, but it is doubtful whether this was the case among their Eastern brethren. Of inferior deities the memory is still preserved in the belief of the common people of all Slavonic lands in Rusalkas, Vilas, and many other supernatural beings supposed to haunt woods, waters, and pastures. The Western Slavs appear to have been the first to accept Christianity, many of the Moravians, for instance, having been converted as early as the seventh century, their religious teachings coming from the West; but the submission of the great body of Slavs dates from the mission of the Greek monks Cyril and Methodius in the ninth century. See Slavic Languages. Revised by M. W. Harrington.

Sleep [O. Eng. *slēp*: O. Sax. *slāp*: O. H. Germ. *slāf* (> Mod. Germ. *schlaf*): Goth. *slēps*; cf. Lat. *la'bi*, *lapsum*, glide, slide, fall down, whence Eng. *lapse*]: a condition of the organism, normal, and occurring generally periodically, in which there is a more or less complete suspension of consciousness and the power of voluntary motion. It is somewhat difficult to analyze the various phenomena which go to make up the condition called sleepiness. The most

prominent sensations are an impression of weight in the upper eyelids, and of a general relaxation of the muscles of the body; but there is besides an internal feeling of supineness and torpor, to describe which is by no means easy. Along with this languor there is a general obtuseness of all the senses, which increases the separation of the mind from the external world. The liveliest scenes cease to engage the attention, and the most exciting conversation no longer interests. For a time, indeed, such circumstances may dissipate the inclination for sleep, but eventually nature obtains the ascendency and consciousness is lost. Before this event there is usually yawning—a phenomenon strongly indicative of a wearied attention—the head nods and droops upon the breast, and the body assumes that position which is most conducive to muscular inactivity. The order in which the muscles lose their power is in general well marked, and bears a distinct relation, as Cabanis has pointed out, to the importance of their functions. The muscles which move the arms and legs become relaxed before those which support the head, and the latter before those which maintain the erectness of the back. This, however, is not always the case.

During sleep the respiration is slower, deeper, and usually more regular than during wakefulness. The vigor of the process is lessened, and therefore there is a diminution of the pulmonary exhalations. Owing to the general muscular torpor which prevails, mucus may accumulate in the bronchial tubes and require to be expectorated on awakening. The circulation of the blood is slower. The heart beats with more regularity, but with diminished force and frequency. As a consequence, the blood is not distributed to distant parts of the body so thoroughly and rapidly as during wakefulness, and accordingly the extremities readily lose their heat. Owing to the reduction in the activity of the respiratory, circulatory, and heat-producing functions, the temperature of the whole body falls, and coldness of the atmosphere is less easily resisted. The functions of the several organs concerned in digestion indirectly have their activity increased during sleep. The blood which is thus diverted from the brain goes, as Durham has shown, to the stomach and other abdominal viscera, and hence the quantities of the digestive juices are augmented, and the absorption of the nutritious elements of the food promoted. The urine is excreted in less quantity during sleep than when the individual is awake and engaged in mental or physical occupation, because the wear and tear of the system is at its minimum.

The nervous system continues in action during sleep, though generally with somewhat diminished power and sensibility. The reflex functions of the nerve-centers are still maintained, and thus various movements may be executed without consciousness being awakened. Somnambulism is a condition of exaltation in the functions of nerve-centers, without the controlling influence of the cerebrum being brought into action; but aside from this rather abnormal phenomenon, there are others which are entirely within the range of health. Thus, if the position of the sleeper becomes irksome, it is changed; if the feet become cold, they are drawn up to a warmer part of the bed; and cases are recorded in which individuals have risen from bed and emptied a distended bladder without awaking, as well as performing many other complicated and apparently volitional acts.

The ability to be readily roused through the senses constitutes one of the main differences between sleep and stupor. Relative to the different faculties of the mind as affected by sleep great variations are observed. It has been thought by some authors that several of them are really exalted above the standard attained during wakefulness, but this is probably a wrong view. The predominance which one or two mental qualities apparently assume is not due to any absolute exaggeration of power, but to the suspension of the action of other faculties which, when we are not asleep, exercise a governing or modifying influence. Thus, for instance, as regards the imagination, which appears to be most lively in dreams, we find that, when we carefully study its manifestations in our own persons, although there is often greater brilliancy in its vagaries, uncontrolled as it is by the judgment, the pictures to which it gives rise are usually incongruous and silly in the extreme. Even though the train of ideas excited in the dream seems to be rational and coherent, we are fully conscious on awakening that we are capable of doing much better by intentionally setting the brain in action and governing it by our will and judgment. Owing to the fact that these two faculties of the mind are incapable of acting normally during sleep, the imagination is left absolutely without controlling influence. Indeed, we are often cognizant in those dreams which take place when we are half awake of an inability to direct it.

That the imagination may in its flights during sleep strike upon fancies which are subsequently developed by the reason into lucid and valuable ideas is very probable. It would be strange if, from among the innumerable absurdities and extravagances to which it attains, something fit to be appropriated by the mind should not occasionally be evolved, and there are many instances of the starting-point of important mental operations having been taken during sleep.

As regards the memory in dreams, it is undoubtedly exercised to a considerable extent. In fact, whatever sign of activity the mind may then exhibit is based upon events the recollection of which has been retained. But there is more or less error mingled with a small amount of truth. The unbridled imagination of the sleeper so distorts the simplest circumstances as to render their recognition a matter of no small difficulty, and thus it scarcely if ever happens that events are reproduced during sleep exactly as they would be recalled by the mind of the individual when awake. Frequently, also, recent events which have made a strong impression on our minds are forgotten, as when, for instance, we dream of seeing and conversing with persons not long dead. Yet there are many instances on record of knowledge which had passed out of the mind being reacquired during sleep.

During sleep the power of bringing the judgment into action is suspended. We do not actually lose the power of arriving at a decision, but we can not exert the faculty of judgment in accordance with the principles of truth and correct reasoning. An opinion may therefore be formed during sleep, but it is more likely to be wrong than right; and no effort that we can make will enable us to distinguish the false from the true, or to discriminate between the possible and the impossible.

As regards the will, very opposite opinions are entertained relative to its activity. In the course of his remarks on sleep, Darwin repeatedly alleges that during this condition the action of the will is entirely suspended, but he falls into the singular error of confounding volition with the power of motion. Thus he says: "When by one continued posture in sleep some uneasy sensations are produced, we either gradually awake by the exertion of the volition or the muscles connected by habit with such sensations alter the position of the body; but when the sleep is uncommonly profound and these uneasy sensations great, the disease called incubus or nightmare is produced. Here the desire of moving the body is painfully exerted, but the power of moving it, or volition, is incapable of action until we are awake."

Dugald Stewart contends that during sleep the power of volition is not suspended, but that those operations of the mind and body which depend on volition cease to be exercised. In his opinion, the will loses its influence over all our powers both of mind and body in consequence of some inexplicable physical alteration in the system.

It seems, therefore, that during sleep the three great functions of the mind are differently affected. (1) Feeling, embracing sensation and emotion, is suspended in part so far as the first is concerned, but is in full action as regards the second. We do not see, hear, smell, taste, or enjoy the sense of touch in sleep, although the brain may be aroused into activity, and we may awake through the excitations conveyed to it by the special senses. The emotions have full play, unrestrained by the will, and governed only by the imagination. (2) The will or volition is entirely suspended. (3) The thought or intellect is variously affected. The imagination is active, and the memory may be exercised to a great extent, but the judgment, perception, conception, abstraction, and reason are weakened, and sometimes altogether lost.

As to the immediate causes of sleep, it was formerly almost uniformly attributed to an increase in the amount of blood in the brain, but others hold that sleep is the direct consequence of a diminished amount of blood in the cerebral blood-vessels, and that unless this diminution takes place sleep is impossible.

Revised by J. Mark Baldwin.

Sleeper: any one of several sharks or fishes: (1) Either one of the nurse-sharks. (See Nurse-shark.) (2) In some of the West Indian islands a gobioid fish of the sub-family *Eleotridinæ*; these rarely exceed a foot in length, and are of an elongated form, with two separated dorsal fins, the first of which has six slender spines, and thoracic ventral fins, which have each a spine and five rays.

Sleep of Plants: the nocturnal condition of many plants. Many leaves assume a particular position at nightfall or when placed in a darkened room, as is notably the case with certain sorrels (*Oxalis*), clovers (*Trifolium*), sensitive plants (*Mimosa*), and other *Leguminosæ*. Many flowers close at night and open again in the morning, as of species of *Portulaca* and *Oxalis*, and the dandelion and many other *Compositæ*.

C. E. B.

Sleepy Eye: village; Brown co., Minn.; on Sleepy Eye Lake, and the Chi. and N. W. Railway; 48 miles W. of Mankato (for location, see map of Minnesota, ref. 10–D). It is in an agricultural region, and contains 6 churches, a State high school, 2 parochial schools, 6 warehouses and grain elevators, flour-mill, brewery, creamery, electric lights, a State bank with capital of $25,000, a private bank, and two weekly newspapers. The place was named in honor of Ish-a-humbak, an Indian chief who was friendly to the whites during the massacre of 1861, the name meaning "Man whose eyes have appearance of sleep." Pop. (1880) 997; (1890) 1,513; (1900) 2,046.

Editor of "Dispatch."

Sleidan, Johann, whose true name was Philippsohn: historian; b. at Sehleiden, 42 miles S. W. of Cologne, 1506; studied at Louvain and Paris and jurisprudence at Orleans; was secretary to Cardinal du Bellay, minister to Francis I., King of France (1536–41), although at Louvain he had imbibed Protestant opinions; was the representative of Francis I. at the Diet of Regensburg; led a wandering life till 1543 when he settled in Strassburg, which thenceforth was his home. He was appointed historiographer by the princes of the Smalkaldian League; represented Strassburg at the Council of Trent (1551), and on his return became Professor of Law. D. in Strassburg, Oct. 31, 1556. His fame rests upon his great history, *De statu religionis et reipublicæ Carolo Quinto Cæsare commentarii* (Strassburg, 1553–56; best ed. by Chr. C. am Ende, 3 vols., Frankfort, 1785–86), which gives a history of the Reformation from 1517 to 1556, resting on documentary evidence. It remains "the most valuable contemporary history of the Reformation, and contains the largest collection of important documents." It was translated into French (Geneva, 1557; new trans. The Hague, 1767), Italian (Florence, 1557), English (*A famouse cronicle of oure time, called Sleidanes commentaries*, etc., translated by John Daus, London, 1560; same, edited by Edmund Bohun, under title *The General History of the Reformation, etc., 1517–1556, with continuation to 1563*, 1689), and German (Frankfort, 1567, n. e. Halle, 1770–73, 4 parts). Another famous work, often reprinted, was his *De quatuor summis imperiis, Babylonico, Persico, Græco, et Romano* (Strassburg, 1556; n. e. Amsterdam, 1705; Eng. trans. *The Key of History*, London, 1627, new trans. 1695; French trans. Geneva, 1563). His *Opuscula* appeared at Hanau, 1608. See his *Life* by H. Baumgarten (Strassburg, 1878), who also edited his correspondence (*Sleidans Briefwechsel*) 1881.

Samuel Macauley Jackson.

Slemmer, Adam J.: soldier; b. in Montgomery co., Pa., in 1828. He graduated from the U. S. Military Academy July 1, 1850, and was appointed brevet second lieutenant in the artillery; first lieutenant 1854. Detailed for duty at West Point in 1855, he served as Assistant Professor of Geography and History a year, and of Mathematics 1856–59. In the latter year he was ordered to Fort Moultrie, S. C., and in 1860 was transferred to Florida, where, in 1861, he commanded the small body of U. S. troops in Pensacola harbor, occupying with them Fort Barrancas and the neighboring feeble barracks. When intelligence of the surrender of the Pensacola navy-yard to the Confederates reached him, he transferred (Jan. 10) his command to Fort Pickens, opposite, which action prevented the seizure of that important work. In May, 1862, he was attached to Gen. Buell's army, and participated in the siege of Corinth and in the subsequent movement to Louisville, Ky., and to the relief of Nashville, Tenn. He was commissioned a brigadier-general of volunteers Nov. 29, 1862, and engaged in the battle of Murfreesboro Dec. 31, where he was severely wounded and incapacitated from further active service in the field. He was promoted lieutenant-colonel Fourth Infantry Feb., 1864, and in Aug., 1865, he was mustered out of the volunteer service, and breveted colonel and brigadier-general. D. at Fort Laramie, Kansas, Oct. 7, 1868.

Sleswick: another spelling of Schleswig (*q. v.*).

Slickensides: a peculiar polished and striated surface found commonly on the wall-rocks of mineral veins or faults, and where slate, shale, coal, and other fine materials have been crumpled and folded by pressure. Not unfrequently a foreign body, such as a concretion, shell, or nut lying in an argillaceous rock of which the particles have been moved on each other with great force, shows the polished striated surface to which this name has been given.

Slidell', John: statesman; b. in New York about 1793; graduated at Columbia College 1810; settled at New Orleans, where he became a distinguished lawyer; U. S. district attorney 1829–33; member of Congress 1843–45; appointed minister to Mexico 1845, but not received by the Mexican Government; was U. S. Senator 1853–61, but withdrew in consequence of the secession of his State, which he had done much to promote. Sailing from Charleston as commissioner of the Confederate government to France, he and his associate, James M. Mason, ran the blockade and embarked at Havana on the British steamer Trent. On Nov. 8, 1861, Capt. Wilkes, of the U. S. frigate San Jacinto, stopped the Trent, seized the two commissioners, and brought them back to the U. S., where they were held prisoners at Fort Warren in Boston harbor. Bitter denunciations of the seizure appeared in the British press, and the attitude of the British Government was for the moment very threatening, but the U. S. disavowed the act of Wilkes and released the prisoners Jan. 1, 1862, thus putting an end to the difficulty. After the war Slidell settled in London, where he died July 29, 1871.

Slide-rule: an instrument for solving arithmetical problems where approximate results are sufficiently accurate. The form invented by William Oughtred (1573–1660) is best known, and the more precise one introduced by Edwin Thacher in 1885 is much used by engineers. The principle is that of logarithms, the divisions on one scale being those of the logarithms of numbers from 1 to 100, or from 1 to 1,000, while the numbers themselves are marked at the divisions of the other; by sliding one scale along the other the products and quotients of two numbers may be read off by inspection.

Mansfield Merriman.

Sli'go: county in the province of Connaught, Ireland, bordering N. on the Atlantic. Area, 721 sq. miles. The surface rises from the coast toward the E. and N. E., reaching 1,778 feet in the Ox Mountains. The western part is level, the soil mostly consisting of a light sandy or gravelly loam, interspersed with patches of bog. There are, however, districts with a deep and rich soil well adapted for tillage. Agriculture is the principal occupation, especially cattle-breeding and dairy-farming. Some coarse woolen stuffs are manufactured, and fishing is carried on. Two members are returned to the House of Commons. Pop. (1891) 98,013. Principal town, Sligo, at the mouth of the Garvogue, 137 miles by rail N. W. of Dublin, at the head of the Bay of Sligo (see map of Ireland, ref. 6–F). It has a good harbor, and exports cattle, grain, butter, etc. Sligo has a Roman Catholic cathedral and a modern town-hall. Pop. (1891) 10,110.

Slime-moulds: the *Mycetozoa* or *Myxomycetes*, a group of organisms of doubtful affinity; when referred to the animal kingdom called by the former name, when to the vegetable kingdom by the latter. They have hitherto been commonly regarded as plants, but are more probably related most closely to the rhizopods among animals. In their growing stage they consist of a naked mass of protoplasm of indefinite size and shape, and here their resemblance to the rhizopodous infusorians is evident; but in their reproductive stage they are definitely circumscribed masses of dry spores, here reminding one of some of the puff-balls

(*Gasteromyceteæ*) among the higher fungi. This latter resemblance, which is now known to be altogether superficial, caused the earlier botanists to group the slime-moulds with the higher fungi. They have been studied almost exclusively by botanists, who have written nearly all the literature relating to them, and as a consequence the treatment accorded them here is necessarily botanical rather than zoölogical.

The vegetative or growing stage of a slime-mould, known as the plasmodium (Fig. 1), varies in size from minute amœba-like masses to those as large as one's hand or larger. They may be flattish and continuous or loosely reticulated, and in consistence they vary from extreme wateriness to a considerable toughness and firmness. They are usually yellowish or reddish. Numerous nuclei are present, although not easily demonstrated.

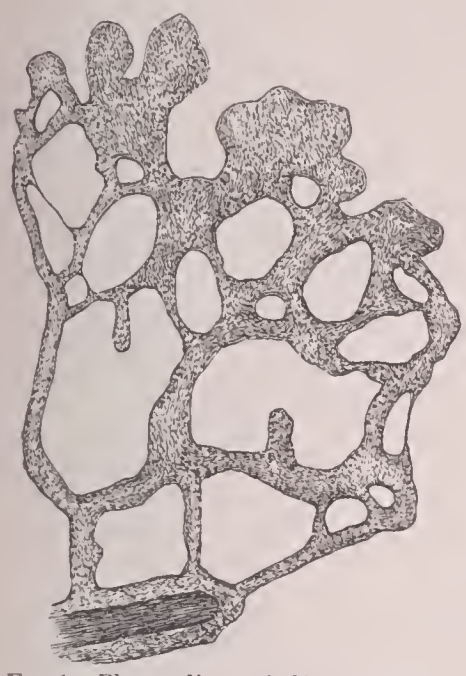

Fig. 1.—Plasmodium of *Chondrioderma difforme* (× 50).

Plasmodia are mostly saprophytic in habit, and are to be found in decaying bark and wood. They move freely with an amœboid motion, and thus come to the surface or move from place to place. Hofmeister observed the rapidity of the mass-movement of the plasmodium of *Didymium serpula* to be at the rate of about 3 mm. per minute. In this way they are able to move considerable distances during favorable (damp and quiet) weather. They are often found upon living stems and leaves, to reach which they must have moved a foot or more from the decaying matter in which they grew.

When they have reached maturity they come to the surface, and, losing water by evaporation, they divide their protoplasm into minute rounded portions, each of which secretes a wall of cellulose around itself, thus constituting a spore. At the same time the general contour of the plasmodium assumes a definite and in some cases a uniform outline which is characteristic of this stage, while its hardened boundary is known as the peridium. Internally other changes have taken place. The protoplasm usually secretes a more or less extended mass of filaments—the capillitium—which serves to give strength to the sporangium. The substance of the filaments is cellulose, or nearly allied to it, and is often incrusted or combined with lime.

Fig. 2.—*Ceratiomyxa mucida*, natural size.

The spores germinate by the bursting of their walls and the escape of the protoplasm as amœba-like bodies, each at length provided with a cilium, which grow in size and coalesce into plasmodia. At one time it was thought that this coalescing partook of the nature of conjugation in some of the green algæ (*Conjugatæ*), but this has been shown to be erroneous. It is not primitive sexuality, but the simple fusion of two or more soft masses of protoplasm.

About 400 species of proper slime-moulds have been recognized, and if some closely related forms (*Monadineæ*) are added the number will be increased by about fifty. They are classified almost entirely upon characters derived from their spore - bearing stage.

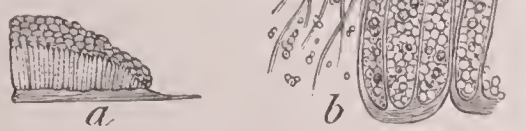

Fig. 3.—*Clathroptychium rugulosum*; natural size at *a*, enlarged at *b*.

Rostafinski in 1875 made a thorough revision of the group, and proposed an arrangement based largely upon the color of the spores. This was followed by Berlese. Zopf made many changes in the system, abandoning the color of the spores for the principal characters. Massee adopted a modification of Zopf's system. The following arrangement is based upon Schroeter's, with some changes.

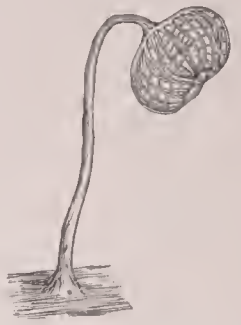

Fig. 4.—*Dictydium cernuum*, empty sporangium enlarged fifty times.

Class Myxomyceteæ. Plasmodium terrestrial and saprophytic, its surface eventually forming a membrane (peridium), its interior developing (1) spores, and mostly (2) a filamentous framework (capillitium). Spore-bearing stage ("fruit") either (1) of irregular shape, plasmodium-like (a plasmodiocarp), or (2) sporangia of uniform and regular shape, which may be (*a*) single (an orthosporangium) or (*b*) coalesced into a compound body (an æthalium). From a millimeter to many centimeters in extent.

Order Ceratiales (Ectosporeæ). Spores external.

Family *Ceratiomyxaceæ*. Spores borne singly on pedicels. The genus *Ceratiomyxa* of Schroeter (*Ceratium* of other authors) is the sole representative of this family (Fig. 2).

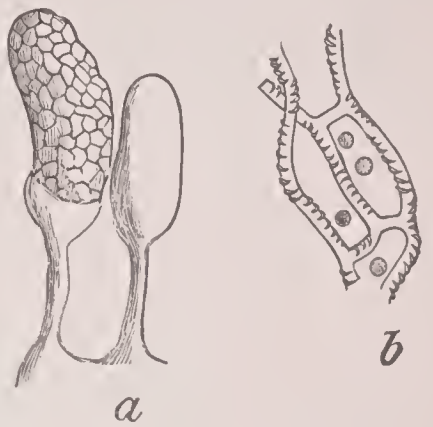

Fig. 5.—*Arcyria punicea*, at *a* enlarged twenty times; *b*, threads of capillitium, enlarged 175 times.

Order Cribrariales (Endosporeæ). Spores internal, no capillitium.

Family *Liceaceæ*. Peridium uniformly thickened (no network), when ripe irregularly torn. "Fruit" a plasmodiocarp, sporangium, or æthalium. The four genera *Licea*, *Protodermium*, *Tubulina*, and *Lindbladia* are represented by species of mostly small organisms.

Family *Clathroptychiaceæ*. Peridium with internal thickenings, the thin parts breaking away when ripe, forming irregular projections. "Fruit" consisting of numerous sessile, globose, or cylindrical sporangia coalesced into an æthalium.

Fig. 6.—Plasmodiocarp of *Hemiarcyria serpula*, enlarged six times.

Two genera—*Enteridium* and *Clathroptychium* (Fig. 3)—represent this family.

Family *Cribrariaceæ*. Peridium with internal thickenings, the thin parts breaking away when ripe, forming a network. Orthosporangia stipitate.

The two genera are *Dictydium* (Fig. 4) and *Cribraria*.

Order Trichiales (Endotricheæ). Spores internal, capillitium present, peridium or capillitium sometimes with incrustations of lime.

Family *Trichiaceæ*. Without lime (except in *Perichæna*), capillitium of tubes, free or combined into a network, the tubes mostly with rough prickly, plicate, or spirally thickened walls; no columella. "Fruit" an orthosporangium, rarely an æthalium or a plasmodiocarp.

Arcyria (Fig. 5), *Lycogola*, *Trichia*, and *Hemiarcyria* (Fig. 6) are the most common genera in the U. S.

Family *Reticulariaceæ*. Without lime, capillitium of solid filaments combined into an intricate network; columella present. Sporangia naked, many coalesced into an æthalium.

Fig. 7.—*Comatricha typhina*, enlarged five times.

The three genera are *Reticularia*, *Amaurochæte*, and *Siphoptychium*.

Family *Stemonitaceæ*. Without lime, capillitium a net of solid filaments springing from the columella. Sporangia simple.

The commonest genera are *Lamproderma*, *Comatricha* (Fig. 7), and *Stemonitis*.

Family *Spumariaceæ*. With lime in the peridium or columella (not in capillitium); capillitium a net of much-

branched threads extending from the columella to the peridium. Sporangia single or coalesced into an æthalium.

Diachea and *Spumaria* (Fig. 8) are the genera.

Fig. 8.—*Spumaria alba*, natural size.

Family *Didymiaceæ*. With lime (mostly in crystals in the outer wall of the peridium); capillitium of delicate tubes or filaments, without lime, extending from the columella or base of the sporangium to the peridium. Columella none or short, hemispherical, or orbicular. "Fruit" an orthosporangium or a plasmodiocarp.

The more important genera are *Didymium* and *Chondrioderma* (Fig. 9).

Family *Physaraceæ*. With lime in granules; capillitium a net of hyaline, thin-walled, broad tubes, usually filled with lime; columella usually wanting. "Fruit" mostly an orthosporangium, less commonly a plasmodiocarp or an æthalium.

The common genera of this large family are *Tilmadoche*, *Leocarpus*, *Physarum* (Fig. 10), *Badhamia*, and *Fuligo* (Fig. 11).

Allied to the slime-moulds proper are two other groups, the *Acrasieæ* and *Phytomyxineæ* —classes they may conveniently be called— which are to be regarded as simpler and lower than the foregoing. They may be noted as follows:

Class Acrasieæ. With no true plasmodium, the amœboid swarm-spores not fusing; saprophytic; in fruit consisting of rounded heaps of free spores.

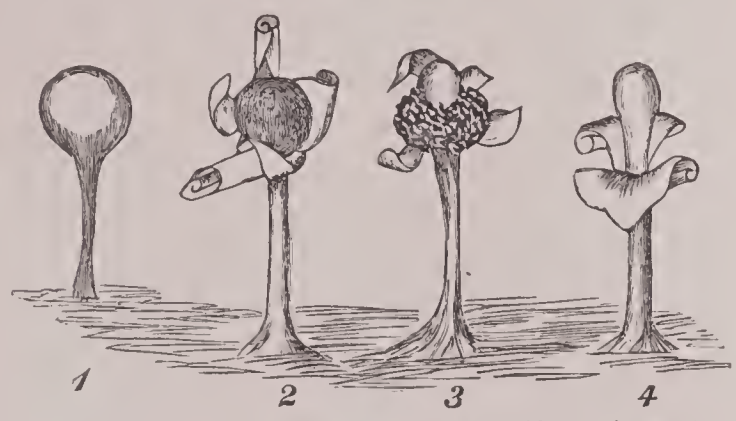

Fig. 9.—*Chondrioderma floriforme*, enlarged fifteen times: 1, unopened; 2, 3, ruptured, showing spores; 4, showing columella.

Several genera of these low organisms, falling into two groups, are known. They occur upon manure and other decaying matter.

Fig. 10.—*Physarum sinuosum*, natural size.

Class Phytomyxinæ. With a true plasmodium, parasitic in the cells of higher plants, in fruit dividing into a mass of spores. The organisms here brought together are but obscurely known. *Plasmodiophora brassicæ* (Fig. 12) occurs in the roots of cabbage, causing club-root. *Phytomyxa leguminosarum* causes the root-tubercles of clover and many other leguminous plants.

Zopf has added many other organisms to the slime-moulds, such as *Vampyrella*, *Bursulla*, *Colpodella*, *Protomonas*, *Protomyxa*, etc., whose animal nature has never been seriously doubted and whose affinities to the higher slime-moulds are evident.

Fig. 11.—*Fuligo septica*, reduced one-half.

As to their place in nature, the writer must agree with de Bary in placing them "outside the limits of the vegetable kingdom." If plants, they are so unlike all others that they must be regarded as belonging to a different genetic line. To set them off in a group by themselves would be merely an evasion of the question. Divesting one's self of prejudice and rightly estimating the value of their resemblance to and their differences from plants, one is compelled to admit that their resemblances to any plants are merely superficial (e. g. to some puff-balls), while their differences are profound. On the

Fig. 12.—*Plasmodiophora brassicæ*: I, cabbage-root, swollen, natural size; II, cells of affected cabbage, × 50; III, spores, × 620; IV, spores germinating; V, amœboid masses.

other hand, in their structure, both in the vegetative and reproductive stages, they exhibit such striking similarity to the lower protozoans that one can not avoid the conclusion that their real relationship is with these lower animals rather than with plants. Among investigators who have placed the slime-moulds outside the vegetable kingdom are the following: de Bary (1858), Haeckel (1866), Allman (1879), Kent (1880), Zopf (1887), Rolleston and Jackson (1887), Bennett and Murray (1889), Lister (1890). On the other hand, those who have devoted themselves to a study of these organisms, systematically or descriptively, generally regard them as plants—e. g. Rostafinski (1875) probably, Cook (1877), Berlese (1888), Schroeter (1889), McBride (1892), Massee (1892).

Massee, *A Monograph of the Myxogastres* (1892). Charles E. Bessey.

Sling: a simple contrivance for hurling missiles, consisting of a small disk of leather pierced by a hole and suspended by one, two, or three strings, say a yard long. A stone or other missile was placed upon the leathern disk, and then whirled rapidly about for a time, when one of the strings was dropped from the hand at the proper instant, and the missile sent with great force through the air. The Greek light-armed troops in the Persian wars and afterward used the sling, often with a plummet of lead. These bullets are well known to antiquaries. They frequently bear the word ΔΕΞΑΙ, "Take this," or some similar word. The Persians, Achæans, Acarnanians, and especially the Balearic islanders, were famous slingers. The sling was also used by several half-savage peoples, as the Tahitians.

Slivinski, Joseph: See the Appendix.

Sliv'no, or **Selim'nia** (Bulg. *Sliven*): town in Bulgaria (see map of Turkey, ref. 3-D); commanding on the S. the important pass in the Balkans called the Iron Gate; carries on an active trade in wool and arms. Pop. (1893) 23,210.

Sloane, Sir Hans: physician and naturalist; b. at Killyleagh, County Down, Ireland, Apr. 16, 1660. He went to Jamaica in 1687 as physician to the Duke of Albemarle, and after his return published a work on the natural history of the island (2 vols. folio, 1707–25). Subsequently he was appointed physician-general of the British army 1719, and physician to the king 1727. He was a prominent member of the Royal Society, succeeding Sir Isaac Newton as president in 1727; most of his numerous scientific publications are embodied in the *Philosophical Transactions* of that society. He was an indefatigable collector of objects of natural history, antiquities, coins, etc., and books, and being wealthy, he was able to amass a large and very valuable museum. D. in London, Jan. 11, 1752. In accordance with the terms of his will, his museum and library were sold to the Government for £20,000—a price which was no more than equal, it was said, to the intrinsic value of the coins alone. This collection became the basis of the British Museum. H. H. S.

Sloat, John Drake: naval officer; b. in New York in 1780; entered the U. S. navy as a midshipman 1800; was engaged in the action between the United States and the Macedonian Oct. 25, 1812; served in the expedition against West Indian pirates 1824–25; was commander of the Pacific squadron 1844–46; was next placed in charge of the Norfolk navy-yard; superintended the construction of the Stevens battery at Hoboken; became commodore (retired list) July 16, 1862, and rear-admiral in July, 1866. D. at New Brighton, Staten Island, N. Y., Nov. 28, 1867.

Slocum, Henry Warner: soldier; b. at Pompey, Onondaga co., N. Y., Sept. 24, 1827; graduated at the U. S. Military Academy July 1, 1852; appointed second lieutenant of artillery; first lieutenant 1855. After a brief campaign in Florida against the Seminoles, he served in garrison at Fort Moultrie, South Carolina, until Oct. 31, 1856, when he resigned from the army to practice law at Syracuse, N. Y.; was a member of the New York State Legislature in 1859. On May 21, 1861, he was appointed colonel of the Twenty-seventh New York Volunteers, which regiment he led in the battle of Bull Run July 21. Early in August he was commissioned brigadier-general of volunteers; in September was assigned to command of a brigade in Franklin's division of the Army of the Potomac, and in the Virginia Peninsular campaign of 1862 was engaged in the siege of Yorktown and action of West Point, succeeding to command of the division May 15, on Franklin's assignment to the Sixth Corps. At the battle of Gaines's Mill, June 27, his command was sent to Porter's relief at a critical period, and rendered important service; at the battle of Glendale, June 30, it held the right of the main line, as at Malvern Hill July 1. He was made a major-general of volunteers July 4, and engaged in the second battle of Bull Run, at South Mountain, and at Antietam. In October he was assigned to the command of the Twelfth Corps, which he led at the battle of Chancellorsville and at Gettysburg, where he commanded the right wing of the army. Transferred, he served in the department of the Cumberland until Apr., 1864, when, his corps being consolidated with the Eleventh, he was assigned to the command of a division and of the district of Vicksburg. In Aug., 1864, he succeeded Gen. Hooker in command of the Twentieth Corps, which was the first to occupy Atlanta, Ga., Sept. 2. In Sherman's march to the sea he commanded the left grand division of that army. In Sept., 1865, he resigned, and resumed the practice of his profession in Brooklyn, N. Y., declining in 1866 the appointment of colonel of infantry in the regular army. He was elected to the Forty-first, Forty-second, and Forty-eighth Congresses; president of board of public works, Brooklyn, N. Y., 1876–78. D. in Brooklyn, N. Y., April 14, 1894.

Slocum, William Frederick: See the Appendix.

Sloe: the fruit of the blackthorn (*Prunus spinosa*), a small thorny plum-tree of Europe, sparingly naturalized in the eastern parts of the U. S. The black austere fruit is used for preserves, for making a factitious port wine, and for dying black. The unripe fruit yields German acacia, a substitute for gum-arabic, and the wood is made into walking-sticks. Some botanists regard the sloe as the original form of the cultivated plum. There is a double-flowered form in cultivation. Revised by L. H. Bailey.

Sloth [M. Eng. *slouthe* < O. Eng. *slwæð*, deriv. of *slāw*, slow]: any one of several species of the family *Bradypodidæ*, notable for sluggishness. The form somewhat recalls that of the *Primates* (man and monkeys) in the freedom of the members from the common abdominal integument, the length of the limbs, and especially of the fore ones, and the atrophy of the tail. The skull is oblong and compressed, with the rostral portion much abbreviated; the intermaxillary bones much reduced; malar bones disconnected from the zygomatic processes of the squamosal bones, and each with a supratemporal process; the lower jaw has a gutter-like symphysis; molar teeth $\frac{5}{4}$, simple and rounded: pelvis moderate; posterior limbs shorter than the anterior; toes in reduced numbers, two or three (fully developed) in front and three behind. The species differ considerably in other characters. All are confined to South and Central America. Numerous peculiar characters in addition to those

The sloth.

mentioned are exhibited by the skeleton, one of the most remarkable features being the number of cervical vertebræ. Almost without other exceptions (the manatees form one) mammals have seven cervical vertebræ; but in the sloths some (the *Bradypodinæ*) have as many as nine, while one (*Cholopus hoffmannii*) has only six, although its near relations (e. g. *Cholopus didactylus*) have seven. The species are ill adapted for progression on the ground, the feet being bent inward, but are admirably fitted for life in trees. Unlike all other mammals, they cling to the branches by their feet with the back downward, and thus they progress, feed, and sleep. They rarely or never voluntarily descend to the ground, but when one tree is denuded of its leaves proceed from it to a contiguous one by means of interlocking or neighboring boughs. *Bradypus* and *Arctopithecus* belong to the sub-family *Bradypodinæ*, and *Cholopus* to the sub-family *Cholopodinæ*. Revised by F. A. Lucas.

Slovak' Language: See Slavic Languages.

Slovak Literature [*Slovak* is from Slov. *Slowak*; cf. Slavonia]: the body of literary productions in the language or dialect of the Slovaks, who, with the Moravians, belong to the Czech branch of the Slavic family. The Slovaks dwell in the mountainous northwest corner of Hungary, but extend beyond the Hungarian boundary into Moravia; besides, there are oases of Slovaks all through Hungary, hemmed in and intellectually as well as politically oppressed by the Magyars. According to the census of 1880, their number was 1,855,400, more than two-thirds professing the Roman Catholic faith, the rest belonging to the Augsburg Confession.

The Slovak dialect, which according to the consensus of the most eminent Slavists exhibits an earlier form of Czech, just as Slovene is older than Servian-Croat, produced some weak specimens of literature in the Middle Ages; but the Reformation, introduced from Bohemia in the sixteenth century, interrupted a national literary development, and established Czech (in the narrow sense) as the literary language among the Slovaks. For nearly 300 years their own dialect was almost extinct; a considerable number of Slovak authors arose in the eighteenth century, but all of them employed the Czech language, as Matthew Bel (1684–1749), especially famous as historian of Hungary; Daniel Krman (d. 1740); Stephen Leška (d. 1818), editor of the first Slovak newspaper; Georg Palkovič, and others.

At the end of the eighteenth century Catholic writers originated a literature of their own in the revived Slovak dialect, as distinctly separated from the Czech language. (See Czech Literature.) Anton Bernolak especially was instrumental in the separation; he endeavored to settle definitely the Slovak language by his grammar, *Grammatica Slavica* (Pressburg, 1790; Germ. transl., Buda, 1817), and his *Lexicon Slavicum Bohemico-Latino-Germanico-Hungaricum* (6 parts, Buda, 1825–27).

The attempt to revive the old Slovak literary language

was strongly opposed by the Magyars and the Czechs alike, but Slovak literature nevertheless developed. Poets of repute were active: Holly wrote an epic on Svatopluk in twelve books in classical style and meter and a Cyrillo-Methodiad in six books. He died in 1849, just at the great outbreak of the Hungarian revolution against the house of Hapsburg. Ljudevit Štur (b. 1815; d. 1856), studied in Pressburg and Halle, wrote some German pamphlets against the Magyars as the oppressors of the Slovak people, and edited in 1845–48 the Slovak newspaper *Slovenské Novini* with the literary supplement *Orol Tatranski*. The revolution drove him from Hungary, and he fled to Vienna, where he became one of the fiercest agitators against the Magyars, while his great countryman Kossuth, entirely Magyarized, led the Hungarian revolution against Austria. By his paper and personal influence Štur raised Slovak to the standard of the literary language of his people. He also wrote in Czech a critical work on the character of Slavic popular poetry (Prague, 1853), and left a manuscript in German *Das Slaventhum und die Welt der Zukunft*, the first great Slavophil work, translated by W. Lamanskij into Russian (Moscow, 1867).

A number of other poets have gained a good reputation in Slovak literature, which seems firmly established, even if the process of Magyarization should succeed in obliterating the nationality of the people.

The most important and influential modern educator, grammarian, and framer of the Slovak language is Martin Hattala, born in 1821, at Trstená, Hungary. Originally a Catholic priest, he wrote a *Grammatica linguæ Slovenicæ* (Schemnitz, 1840), which secured for him a call as Professor of Slavic Languages to Prague. His principal merit is the elaboration of the Slovak language in phonetics, form, syntax: *Phonology of the Old and New Czech and Slovak Languages* (Prague, 1854); *Comparative Grammar of the Czech and Slovak Languages* (Prague, 1857); *Antibarbarus of the Czech Language* (Brus jazyka českého, Prague, 1877); text-books for Slovak schools, etc. His polemical writings against Schleicher, and his defense of the genuineness of the Königinhof Manuscript (*Rukopis Kralodvorský*) are noteworthy. Besides him three men eminently contributed to the definite settlement of Slovak language and literature: J. Vietorin, by his *Grammatik der slovakischen Sprache* (4th ed. by Loos, Budapest, 1876); J. Loos, by his *Wörterbuch der slovakischen, ungarischen und deutschen Sprache* (Budapest, 1871); and Šembera, by his excellent treatment of Czech-Slovak dialectology (*Základové dialektologie česko-slovenske*, Vienna, 1864).

The chief collections of Slovak popular poems are by Šafařik (2 vols., Pest, 1823–27); Kollar (2 vols., Buda, 1834–35; *Narodnie Zpievanky*); and by the Slovak Matica (suppressed by the Magyars) *Sborník Slovenských národních piesní* (Collection of Slovak National Songs, 2 vols., 1870–74).

HERMANN SCHOENFELD.

Slove'nian Language: See SLAVIC LANGUAGES.

Slovenian Literature: the literature produced by that branch of the Slavic family which inhabits the southern portion of Carinthia and Styria, all Carniola (except the great German speech-island around Gottschee), Görz and Gradiska, a small part of Istria, the region around Radkersburg in Hungary and around Cividale in Italy—total population (1895), about 1,300,000.

This literature is most closely related to that of the Servo-Croats. It is written in a language the oldest form of which is held by some of the greatest and most authoritative scholars—Kopitar, Miklosich, Daničić and Jagić—to be the mother language of Palæo-Slavonic, as preserved to us. Great zeal has been exhibited in fixing the grammatical structure of the language. This labor has been performed by scholars like Kopitar, Metelko, Murko, Janečić, Lewstik, and, best of all, Šuman (*Slovenska slovnica*, Klagenfurth, 1884).

The only literary monument of Old Slovenian is the liturgical manuscript of Freising (Bavaria). It is in Latin script, and belongs to the tenth century (ed. by Kopitar in *Glagolita Klozianus*, Vienna, 1836). Then, until the middle of the sixteenth century, there was nothing that can be classed as literature. With the Reformation literary interest revived. The Carinthian reformer Primus Truber (1508–86) and his associates translated the New Testament into Slovenian in 1557. The first complete edition of the Bible on the Protestant side appeared first in 1584 in Tübingen. Other spiritual and church books, too, were composed by Truber, but he was driven into exile, and the incipient reformatory movement suppressed by the counter-reformation. Literary activity again practically ceased until the end of the eighteenth century. Only meager grammatical and bibliographical work was produced. The first Slovenian grammar appeared in 1584, the first dictionary in 1592.

Toward the end of the eighteenth century, however, self-consciousness began to awaken among the Slovenes, as well as in the entire South Slavonic world, stimulated especially by the longing for liberty and by the Roman Catholic Church. On the Catholic side a complete Bible translation, pre-eminently by Japel and Kumerdey, was issued 1791–1802. Secular literature, too, began to flourish; Valentin Vodnik (1758–1819) was its founder. When Carinthia was incorporated into the Illyrian provinces by Napoleon and belonged to France (1810–14), he published his *Ilirja oživlena* (Illyria revived), which cost him his position as inspector of schools when Austria regained her provinces. He also wrote valuable poems (*Pesni*, 3d ed. Laibach, 1869), and edited the first Slovenian newspaper (1797–1800). The greatest modern Slovenian poet, however, is Francis Preširn (1800–49); his poems are mostly lyrics (complete edition, *Pesmi Franceta Preširna*, Laibach, 1866; German trans. by Samhaber, *Preširenklänge*, Laibach, 1880).

Since the middle of the nineteenth century national life has steadily developed, and the political revival has been accompanied by an increase of literary productions of a varied character. Levstik, Valjaveč, and Stritter are very good national poets. The Matica Slovenska (Slovenian Literary Society) is the center of the literary movement. The periodical *Ljubljanski Zvon* (The Laibach Bell) is the great organ in which the national productions mostly appear.

The principal collections of Slovene folk-song are *Slovenske pesmi krajnskago naroda* (5 vols., Laibach, 1839–44); *Narodne pešni ilirske* (Styria, Carinthia, West Hungary), by Stanko Vrac (Agram, 1839); *Volkslieder aus Krain*, trans. by A. Grün (Count Auersperg), Leipzig, 1850; *Cvetje slovenskega naroda*, by A. Janečić (Klagenfurth, 1852). See Child, *Ballads*.

BIBLIOGRAPHY.—Kleinmayr gives an excellent sketch of Slovene literature, *Zgodovina slovenskega slovstva* (Klagenfurth, 1881); see also Pypin and Spasovič, *Istorija slavjanskich literatur* (St. Petersburg, 1865; German by Tr. Peeh, Leipzig, 1880–84). HERMANN SCHOENFELD.

Slows: See MILK-SICKNESS.

Sloyd: See MANUAL TRAINING.

Slug [from M. Eng. *slugge*, slothful; cf. Eng. *slack*, *slouch*, and *sluggard*]: any one of various naked terrestrial molluses, mostly members of the family *Limacidæ* (see PULMONATA). The name is sometimes applied to other molluses, and occasionally, but wrongly, to certain insects which occur as pests in gardens and greenhouses.

The red slug.

Slug-worms, popularly but incorrectly called **Slugs**: the larvæ of certain of the saw-flies (*Tenthredinidæ*), belonging to the *Hymenoptera*. They are slug-like in form. In the U. S. the pear, rose, vine, raspberry, walnut, linden, and other trees are infested with the larvæ of species of *Selandria*, which are often very destructive. Decoctions of tobacco or quassia, whale-oil soap, a weak solution of carbolic acid, and petroleum are among the substances recommended for showering shrubs and trees infested with slug-worms. For small trees and shrubs hand-picking is generally sufficient.

Smalcald: See SCHMALKALDEN.

Small, ALBION W.: See the Appendix.

Small, JOHN: soldier; b. at Strathardle, Scotland, in 1726; served in the Scotch brigade, in the Dutch service, in the pursuit of the Jacobites of Scotland 1747, at Ticonderoga 1758, at Montreal 1760, and in the West Indies 1762; was in the battle of Bunker Hill; raised a corps of Highlanders in Nova Scotia, the Eighty-fourth Battalion, known as the "Royal Emigrants," which he commanded as major in the campaigns of New Jersey and Pennsylvania; became lieutenant-colonel 1780, lieutenant-governor of Guernsey 1793, and major-general 1794. D. at Guernsey, Mar. 17, 1796.

Small-arms: the projectile arms which since the invention of gunpowder have replaced the bow and arrow and cross-bow. The original firearms, bombards, were not portable, and it was not until the early part of the fifteenth century that lighter pieces came into use; even these, at first, required for their transportation and service several men, and were fired in the field from a tripod and from the fortress walls on a rest. Of such guns the Duke of Orleans was reported to possess 4,000 in 1411; three years later they were employed at the siege of Arras, and in 1471 a number were introduced into England by some Flemings that accompanied Edward IV. on his return from Flanders in that year. These hand-cannon, as they were called, could be carried by two men, had a straight stock of wood about 3 feet long, and were fired by a match applied on top of the breech.

The first improvement was the removal of the vent to one side and the addition of a pan to hold the priming; a sight on the breech was also added. The trigger of the cross-bow suggested to the English a similar arrangement for bringing the lighted match to the priming; the gun, after this modification, was called a matchlock.

In Italy and Spain successive improvements received the names of hacquebutte, arquebuse, and mousquet; the stock was made curved, permitting aim to be taken from the shoulder instead of firing from the chest as formerly, and the weight was reduced to about 15 lb. The former tripod had now been replaced by a forked rest which the soldier carried as a cane. Grose, in his *Military Antiquities*, describing the English musketeer, says: "He had besides the unwieldy weapon itself his coarse powder for loading, in a flask; his fine powder for priming, in a touch-box; his bullets in a leathern bag, with strings to draw to get at them; whilst in his hand were his musket-rest and his burning match, and when he had discharged his piece he had to draw his sword in order to defend himself." In the Spanish army the mousqueteers wore a broad belt across the breast to which wood cases containing the proper charge of powder were attached; also a ball-pouch and a priming-flask. Six yards of slow-match for firing was wound about the stock. At the battle of Pavia the Spanish had a force of 2,000 arquebusiers and 800 mousqueteers, whose fire proved decisive in determining the issue of the battle, the balls readily penetrating the best armor of the knights.

Fig. 1.—Mousqueteer of 1525.

In the wheel-lock, snaphance, firelock, and finally the flintlock, names each marking an advance in design or construction, the match was replaced by some arrangement of flint and steel; the last-named piece was adopted by France in 1671, an example followed by all other nations within twenty years. In the flintlock the weight was brought down nearly to that of the modern rifle; in other respects too it marked the top wave of progress, and without material improvement remained during 150 years the arm of the infantry soldier, until early in the nineteenth century the invention of the percussion-cap, made of practical value about 1820, led to the gradual substitution in the next two decades of the percussion-musket.

Up to this date military small-arms were smooth-bores, and fired spherical balls between one-half and nearly three-fourths of an inch in diameter, and while the rifling principle had been known and used for many years, it was not introduced for soldiers until early in the nineteenth century; to these rifles was then applied the percussion-cap. The breech-loading principle was also made a partial success for military arms at the same time, and some few soldiers were armed with them. In Prussia, where the needle-gun had been adopted, the issue began in 1841. Used with great success in the war with Austria in 1866, its merits were generally acknowledged, and in a few years different breech-loaders replaced in every country the muzzle-loading rifle, the change being induced not merely by the qualities of the arms themselves, but in consequence of the introduction of the metallic cartridge, which, combining the cap, powder, and bullet in one receptacle, also served as a gas-check and prevented leakage at the breech, the main defect at first of the new guns.

Fig. 2.—Hall's breech-loading musket, patented 1811.

In the U. S. the first successful breech-loader was invented by Hall in 1811. Two years later he proposed its manufacture on the principle, which had previously failed in France, of interchangeable parts, and in 1817, a board of officers reporting favorably, he was employed to superintend at the U. S. arsenal, Harper's Ferry, the establishment of the necessary machinery and the manufacture of the gun. The system of interchangeable parts has since prevailed in the U. S. and has been adopted in Europe, but the arm itself met with only a qualified success. Part of the cavalry was armed with the carbines, but upon the death of the inventor in 1844 their manufacture was discontinued.

In 1854 Congress made an appropriation for breech-loading rifles, and a board of officers recommended those of Sharps and Symmes for trial. Three years later another board reported in favor of the Burnside rifle, an opinion confirmed by a third board in the following year, but without recommending the adoption of the arm for service.

The civil war caused a suspension of experiments, all the energies of the ordnance department being then given to the production in sufficient quantities of the arms then in use. From Government and private factories and from abroad nearly 4,000,000 small-arms were obtained, including nineteen varieties of breech-loading carbines and eight of rifles, those of Burnside, Sharps, Maynard, and Henry (the latter a magazine-arm) being the best known.

Fig. 3.—Springfield.

Fig. 4.—Remington locking rifle, model 1871.

Fig. 5.—Russian Berdan.

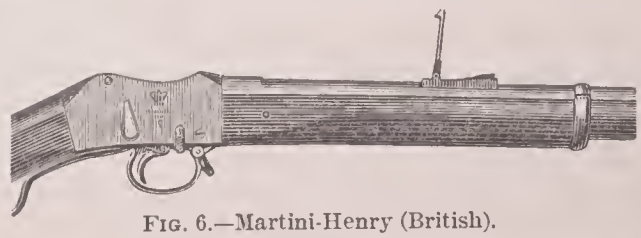

Fig. 6.—Martini-Henry (British).

Fig. 7.—Mauser (German).

After the war, boards of officers were convened in 1866,

1869, and 1872; they mentioned favorably the Peabody, Remington, Sharps, and Springfield, and finally recommended the adoption of the latter arm.

The same decade witnessed the adoption abroad of arms that remained for nearly twenty years in the hands of troops, and which, while differing in many particulars, can be placed in two general classes dependent upon the method of breech-closure—viz., by a hinged block and by a sliding bolt. Of the first class the Remington, the Springfield of the U. S., and the Martini-Henry of Great Britain, and of the second class the Mauser of Germany and Berdan of Russia, are the best known. As these, with those of other countries, marked the highest development of the single-loading rifled breech-loader, their principal features are given in the accompanying table.

TABLE I.—SMALL-ARMS OF DIFFERENT NATIONS, 1874.

NATION.	Name of gun.	When adopted.	Caliber, inch.	WEIGHT OF—				Initial velocity, foot-second.
				Gun, pounds.	Bullet, grains.	Powder, grains.	100 cartridges, pounds.

Since 1885 there has been a great improvement in small-arms, the most important being the substitution of magazine-arms for the single-loaders (see MAGAZINE-GUNS), the decrease in the caliber of the barrel, and the adoption of smokeless powder in place of the powder formerly used.

As magazine systems were gradually developed the necessity of meeting the increased expenditure of ammunition with an augmented supply of cartridges became evident, but as the soldier's load was already at the limit considered practicable, this could only be accomplished by diminishing the weight of a single round, and that only by decreasing the diameter of the bullet and consequently of the bore of the rifle. This has resulted in the adoption in different countries of calibers between 0·315 and 0·256 inch, a decrease that probably has not yet reached its limit.

When gunpowder was used in these small bores, the fouling soon became excessive, unduly impairing the accuracy of fire. To overcome this trials were made which have led to the introduction of the so-called SMOKELESS POWDERS (*q. v.*). Many of these powders have been successfully developed and are in general use; their range of chamber-pressure varies from 14 or 15 tons per square inch, as with the powders used in the French Berthier and the Schmidt, to 20 tons in the Belgian Mauser and 21 tons in the German infantry rifle. This necessitates a strength and stiffness in the breech-mechanism of the new rifles that the old arms did not require, and also a corresponding increase of strength in the barrel. The modern barrels are therefore generally made of a superior grade of steel and of a little greater thickness of metal. Being of less interior diameter and also somewhat shorter, their weight, as compared with the old, has been diminished. With the augmented pressure also comes a great gain in the initial velocity, necessitating, in order to secure steadiness of flight for the bullet, a more rapid twist to the rifling, which now makes in all the new guns one turn in about 8 or 10 inches, instead of 18 to 24 inches as formerly. The majority of the barrels are rifled with four grooves (though some have only three and others six or seven), of a depth varying in the different countries from 0·003 to 0·006 inch, and more frequently of a width two or three times that of the lands.

As leaden bullets fired with high velocities through such barrels will not follow the rifling, but will strip and override the lands, it became necessary that the surface of the projectile be made of some harder metal; but to retain the high specific gravity of the lead, with the consequent ability of the ball better to overcome the resistance of the air, the greater portion of the bullet is made of a lead slug and then coated or jacketed with a covering, about 0·02 inch thick, of some harder metal, as steel, copper, nickel, or German silver. These bullets have a length of about four calibers, are without the cannelures or lubricant of the lead ball, and weigh on the average about 220 grains.

The weights of the smokeless powder-charges vary with the particular powder, averaging about 30 to 40 grains.

The penetration of the bullet at all distances has been increased by the alteration in its shape, by its harder surface, and also, except at the extreme ranges where the air-resistance has overcome much of the velocity, by its more rapid initial movement. At the shorter ranges, 200 to 300 yards, protection is now obtained by about 0·2 inch of steel plate and about 0·3 inch of wrought iron. The penetration into earth at these distances is about 25 inches, into pine about 30 inches. As they have not been used to any extent in warfare their effect upon the living human body is yet to be fully determined; probably if striking no bone the bullets will inflict wounds on three or four men in file, but wounds less serious than those from the heavier lead ball.

With the greater number of the modern guns and powders the velocities are about 2,000 feet per second, running up for the smaller calibers, as the new guns of Italy, Holland, Roumania, and Norway, to about 2,300 feet per second. This gives a dangerous space in front of the muzzle of fully 600 yards, a maximum even exceeded by the extremely reduced calibers just mentioned, and a flatness of trajectory at all ranges compensating for errors when estimating the distance of the objective that would produce a miss with the old weapons.

The recoil is less than half that of the old single-loader.

The sights on all modern military arms are designed primarily for use in battle, rather than on the target-range; they are strong and simple in construction, with an open leaf that allows an unobstructed view when aiming, and generally without any arrangement giving drift or windage correction. The lowest adjustment is 300 meters (or yards), the leaf for that range being turned down on the base. Above that, on the leaf, the graduations are placed only for 100-meter (or yards) intervals, and with many of the sights it is impossible to obtain any closer adjustments than given by these limits, the slide engaging in notches that occur only at the graduation-marks. These latter generally extend up to 1,800 or 2,200 yards.

For the familiar triangular bayonet all nations except Russia have substituted knives with blades from 9 to 12 inches long and about an inch wide. The guards are short and usually straight, the handles of wood and steel, and about 4 inches long. The weights of the complete bayonets are from 8 to 15 oz.

The heat produced by discharge is much in excess of that formerly evolved; the barrels can not be freely handled after ten or twenty shots have been quickly delivered. To overcome this difficulty, the Germans have enveloped the barrel in a metallic case, and the Swiss have covered it with wood until it appears entirely surrounded by the forestock, but most of the other countries have limited the wooden hand-guard to the space back of the rear sight or else extending it only as far forward as the lower band. The latter provision is probably the best, affording all the protection required when firing or when carrying the piece afterward.

The breech-block of the single-loader has been replaced by a bolt having a sliding and generally also a turning movement. When closed it sustains the shock of discharge; moving it extracts the empty cartridge-case and recocks the piece for firing. In all countries these arms are also magazine-guns, that for the U. S., Fig. 8, having been chosen in

FIG. 8.—U. S. magazine rifle, model 1892.

the autumn of 1892. This arm was selected only after an examination lasting nearly two years, careful consideration being given not only to the rifles used by the troops of Austria, Belgium, Denmark, Great Britain, France, Germany, Japan, Portugal, Roumania, Russia, and Switzerland, but also to those presented by the leading gun-inventors of the U. S. and Europe. The rifle finally chosen was the invention of Capt. O. Krag, director of the royal small-arms factory at Kongsberg, Norway, and E. Jörgensen, an armorer there employed.

The accompanying table gives the rifles and their ammunition forming (1895) the infantry armament of various countries.

TABLE II.—SMALL-ARMS OF DIFFERENT NATIONS, 1895.

NATION.	Name of gun.	Type.	Magazine.	Cartridges in magazine.	BARREL.		GROOVES.				WEIGHT.				Kind of powder.	Initial velocity.
					Length, inches.	Caliber, inch.	Number.	Depth, inch.	Width in terms of lands.	Twist, inches.	Gun, pounds.	Bullet, grains.	Powder, grains.	100 cartridges as carried, pounds.

* Nearly equal.

These pieces mark the culmination of a progress extending over forty years, beginning with a small-arm that could deliver about two shots per minute and had a range of about 200 yards. Twenty years later, the muzzle-loading smooth-bore having given place to the rifled breech-loader, the number of shots and the effective range were increased tenfold; and then the small-caliber magazine-rifle succeeded, with a range of about 4,000 yards and capacity in expert hands of firing nearly forty shots per minute. STANHOPE E. BLUNT.

Smalley, GEORGE WASHBURN: journalist; b. at Franklin, Mass., June 2, 1833. He graduated at Yale 1853; studied at the Harvard Law School, and practiced law at Boston until the outbreak of the civil war, when he became war correspondent for *The New York Tribune*; he became a member of its editorial staff in 1862. In 1866 he reported for the *Tribune* the Austro-Prussian war. In 1867 he took up his abode in London, and his letters formed a familiar and popular feature of the *Tribune's* foreign correspondence until 1895, when he became the U. S. correspondent of the London *Times*. H. A. BEERS.

Smalley, JOHN, D. D.: clergyman; b. at Lebanon (now Columbia), Conn., June 4, 1734; graduated at Yale College 1756; was ordained minister of the Congregational Church at New Britain, Conn., 1758. D. at New Britain, June 1, 1820. He was a prominent teacher of theology and a noted divine of the New England school. He published several collections of sermons; among them, those on *Natural and Moral Inability* (1769). Revised by G. P. FISHER.

Small Fruits: a term applied in the U. S. to the strawberry and various fruits which grow upon bushes, as raspberries, blackberries, gooseberries, and currants. Omitting the strawberry, the term corresponds with bush-fruits, used in England. Grapes and mulberries, and even cherries, are sometimes improperly classed with the small fruits.

Smallpox [*pox* = *pocks*, pustules], or **Vario'la** [Mod. Lat., dimin. of Lat. *va'rius*, various, diversified]: a specific, contagious eruptive fever, characterized by the development of papules, vesicles, and pustules, and the formation of persistent pitted scars. Smallpox was unknown to the early Greek writers on medicine, but is mentioned in the oldest books of India—the Vedas. The Vedas describe inoculation with the secretion of the smallpox pustule as producing a mild form of the disease, and thereby preventing its occurrence in the dangerous natural form. The first accurate description of smallpox is that by an Arabian medical writer of the ninth century—Rhazes. Smallpox was known in Europe in the sixth century, and in the sixteenth century it was carried by the Spaniards to America. It was most intelligently studied, and its treatment admirably described, by Sydenham and Morton in England, in the seventeenth and eighteenth centuries.

The manifestations of smallpox are general illness, violent pains in the back and head, high temperature, followed in three or four days from the onset by an eruption of papules (pimples), which in about four days more become vesicles, and then pustules. The pustules may break down into ulcers, which destroy the entire thickness of the skin, and when healed leave pits of scar-tissue, which may never be obliterated, and which have an appearance that can not be mistaken. There are two forms of smallpox, which are not only distinct in appearance but quite different in severity. The first is called the discrete form; the second the confluent form. In discrete smallpox the pustules are separate and distinct; in confluent smallpox the pustules run together, and form larger and more serious ulcers than are found in the discrete form. Confluent smallpox is of a very severe type, or perhaps it would be better to say that severe attacks of smallpox are likely to have confluent lesions of the skin. The general symptoms of smallpox are a sense of illness, often a chill, elevation of temperature, eruption of papules, a moderate fall of temperature, the development of pustules accompanied by a second rise of temperature, after which the symptoms depend upon the progress of the disease toward death or recovery.

The papules of smallpox usually appear first on the face, and especially on the chin, and afterward on the neck and chest; later on the body and the extremities. The eruption occurs not only on the skin, but also on the mucous membrane of the respiratory and digestive apparatus, where it is of the vesicular type. It is found in the nose, in the mouth, in the throat, in the larynx, and elsewhere, producing symptoms dependent upon the situation and severity of the local conditions. Delirium often occurs in smallpox, and especially in that grave form called hæmorrhagic or "black" smallpox, which is very much like what is known as spotted fever (cerebro-spinal meningitis). Like all contagious diseases, smallpox has what is called a period of incubation, following the time of exposure to the contagium and preceding the time in which there are recognizable evidences of the disease. The length of this period is variously estimated at from seven to twenty-one days. Smallpox is both contagious and infectious; that is, it may be derived from direct association with a person having the disease, or by contact with articles which have been on or about a person suffering with smallpox. The disease has appeared after articles used by the sick have been handled, even after these articles had been removed to a long distance, and after a long time had elapsed. The nature of the smallpox contagium is absolutely unknown; no disease-germ peculiar to smallpox has ever been discovered, although it has been most diligently sought after. Apparently the disease is contagious in all its stages, and it is undeniable that some peculiar virus which is capable of being transferred by the air may give rise to it; unborn children have developed the disease, showing that it is transmissible through the blood of a mother. Previous to the introduction of processes of VACCINATION (*q. v.*), smallpox was one of the most dreaded of diseases, and in Europe millions of persons lost their lives from its ravages. Since the general use of vaccination, and probably partly on account of advancing intelligence and improved hygienic conditions among all classes of society, the ravages of smallpox have diminished to such an extent that only at long intervals and in few localities does

it appear in the form of an epidemic. The treatment of smallpox is principally what is called symptomatic, that is, addressed to the individual conditions incident to the disease. Violent medication has been entirely abandoned. The patient is isolated, given digestible food, plenty of water, and cool and antiseptic applications are made to the skin. CHARLES W. DULLES.

Smallwood, WILLIAM: soldier; b. in Kent co., Md., about 1732; raised a battalion of Marylanders 1776, which he commanded as colonel, and half of which perished in the battle of Long Island under another commander; was engaged in the battle of White Plains; was appointed brigadier-general Oct. 23, 1776; accompanied Gen. Sullivan in the Staten Island expedition 1777; raised a new battalion of militiamen from the Western Shore of Maryland, and led it at the battle of Germantown; was made major-general Sept. 15, 1780; was with Gates in his Southern campaign, but left after the defeat at Camden, refusing to serve under Steuben; was member of Congress 1785, and Governor of Maryland 1785–88. D. in Maryland, Feb. 14, 1792.

Smalt: See COBALT.

Smart, BENJAMIN HUMPHREY: grammarian and metaphysician; b. in England about 1785; was for more than fifty years from 1815 a successful teacher of elocution in London; was a voluminous writer upon grammar, logic, rhetoric, and metaphysics, in which last department he claimed to "assert, correct, and carry onward the philosophy of Locke." Among his works were *A Grammar of English Pronunciation* (1810); *Rudiments of English Grammar Elucidated* (1811); *A Grammar of English Sounds* (1813); *Practical Logic* (1829); *Accidence of Grammar*, *Principles of Grammar*, *Manual of Rhetoric and Logic*, *The Practice of Elocution*, and *Historico-Shakspearian Readings*, the five latter being issued as a complete series in 1858; *Outlines of Sematology* (1831), with a *Sequel* (1837) and an *Appendix* (1839), the three works being issued together as *The Beginnings of a New School of Metaphysics* (1839); *The Way out of Metaphysics* (1844); *The Metaphysicians, a Memoir of Franz Carvel, Brushmaker, and of Harold Fremdling, Esq.* (1857); *Thought and Language* (1855); and *An Introduction to Grammar on its True Basis* (1858). Smart also published in 1836 a *Pronouncing Dictionary*, based upon that of John Walker, issued an epitomized edition of the same in 1840, and an *Appendix* in 1846 (revised editions 1860), which figure among the authorities upon pronunciation most frequently cited in the later editions of Webster's and Worcester's dictionaries. D. about 1872. Revised by B. I. WHEELER.

Smart, CHRISTOPHER: poet; b. at Shipbourne, Kent, England, Apr. 11, 1722; educated at Pembroke College, Cambridge, where he became a fellow 1745; settled in London as a writer, becoming intimate with Pope, Johnson, and Garrick; was noted for improvidence and a convivial disposition, which made him the inmate of an insane asylum and later of the king's bench prison for debtors, where he died May 18, 1770 or 1771. He translated the *Works of Horace* into English prose (2 vols., 1756), and into verse (1767); published *The Hilliad, an Epic Poem* (1753), being a satire on Sir John Hill, noted for his quarrels with Fielding and with the Royal Society, and *The Parables of Christ done into Verse* (1765); but his most remarkable production was the *Song to David*, written in a madhouse, published in 1763, and reprinted in full in Chambers's *Cyclopædia of English Literature*. See *With Christopher Smart*, in Browning's *Parleyings with Certain People of Importance*.
Revised by H. A. BEERS.

Smart, HENRY: organist and composer; b. in London, Oct. 26, 1813; after studying law took up music; in 1831 was organist of the parish church of Blackburn, and there composed his first important work, an anthem. In 1836 went to London, where he remained, playing, teaching, and composing. His works include an opera, *Bertha* (1855); cantatas, *The Bride of Dunkerron*, Birmingham festival, 1864; *King René's Daughter* (1871), *The Fisher Maidens*, both for female voices; and an oratorio, *Jacob*, Glasgow festival, 1873. D. July 6, 1879. D. E. HERVEY.

Smeaton, JOHN: civil engineer; b. at Austhorp, near Leeds, England, May 28, 1724; invented in 1751 an instrument for measuring a ship's progress; made several valuable inventions in hydraulic machinery, for which he received the Copley medal (1759); was noted as the builder of the Eddystone lighthouse (1756–59), an account of the construction of which he published (1791); constructed Ramsgate harbor (1749–74), the Forth and Clyde Canal, and many other important improvements. D. Oct. 28, 1792.

Smectym'nuus: a name compounded of the initials of the authors of a celebrated tract entitled *An Answer* (1641), written in reply to Bishop Hall's *Episcopacy by Divine Right Asserted* (1641). The names of its five writers are Stephen Marshall, Edmund Calamy, Thomas Young, Matthew Newcomen, and William Spurstowe.

Smeerenberg: See the Appendix.

Smell, Organ of: See HISTOLOGY (*Organs of Special Sense*).

Smelt [in allusion to the cucumber-like odor of the typical species]: a small salmoniform fish belonging to the genus *Osmerus*, or a related genus, of the family *Argentinidæ*, and esteemed as food. These fishes have the teeth of the lower jaw stronger than those of the upper, and fang-like ones on the vomer and front of the tongue, and normally inhabit salt water. *Osmerus eperlanus* is the European species; *O. mordax*, the eastern North American, known also as frost-fish; *O. thaleichthys*, the California smelt. *Hypomesus pretiosus* is the surf-smelt of California and northward. The silver-sides (*Atherinidæ*), structurally very unlike the *Argentinidæ*, are also loosely called smelts, as the California *Atherinopsis californiensis*. Among other fishes locally and improperly known by the name are the cyprinoid *Hybognathus regius*, the spawn-eater, and the Pacific tomcod.

Smelting [from M. Dutch *smelten*: O. H. Germ. *smelzen* (> Mod. Germ. *schmelzen*), melt; cf. Gr. μέλδειν, melt, but probably not akin to Eng. *melt*]: in the more extended use of the term the entire process of reducing metals from their ores by fusion; in a more limited sense those particular metallurgical processes in which an ore or a product of other operations, such as roasting, treatment with acids, etc., is finally reduced to pure metal or some intermediate product. The fusions are conducted in shaft-furnaces, reverberatory furnaces, or crucibles. Metals ready for use or sale may be produced from ores by a single smelting operation, as iron; or they may require a series of smeltings, alternated with roastings, as copper when made from sulphuretted ores. The smelting process may be simply reducing, or oxidizing and reducing, or may be designed to volatilize certain bodies, to oxidize others, and to reduce still others. Charcoal, coke, and anthracite are the fuels generally used in shaft-furnaces and for heating crucibles, and bituminous coal and wood for reverberatory furnaces; but peat, gas obtained from different materials in special generators and peculiarly constructed fireplaces, natural gas, petroleum, and waste gases from furnaces are used.

To remove earthy matters and foreign oxides, and to facilitate the collection of the reduced metals, slags are produced, and, according to the nature of the effect to be obtained and the substance to be removed by scorification, the charges are so constituted as to yield more or less acid or basic slags by judicious mixture of the ores treated or by addition of various fluxes. Sometimes it is desirable to liberate some sulphur to combine with the metals and form a *matte* or *regulus*, and then iron pyrites is added. The general products of smelting are slag and metal, or slag and *matte*, or sometimes all three at once. The slags may have to be subjected to a reducing smelting to obtain the metal retained in them, the metal to an oxidizing and scorifying smelting to purify it, and the matte to Bessemerizing, to an oxidizing smelting, or, after roasting, to a reducing and scorifying smelting, during which some metals are partly removed by volatilization, as antimony, arsenic, and zinc; others by oxidation and scorification, as iron, zinc, and tin, while the desired metal is obtained in a nearly pure state or as a concentrated matte.

Shaft-furnaces are mainly employed for reducing fusions with coke, charcoal, and anthracite, although by a proper construction, good management of fluxes, and preparation of the ores, etc., a partial oxidizing action can be produced. The fusion is almost invariably effected by the aid of a blast. Reverberatory furnaces, with wood, coal, natural or producer gas, or petroleum, are generally used for oxidation; a very effective reducing action can also be obtained in them by excluding the air and keeping the hearth full of reducing gases. In crucibles the results of smelting depend entirely on the nature of the charge, oxidation and scorification being produced by certain fluxes: reduction by adding carbonaceous matters; scorification alone by using a simple

flux like borax; precipitation by adding metallic iron or some substance which will yield iron by reduction; sulphurization by adding metallic sulphides, or alkaline sulphates with a reducing agent and a simple flux.

Revised by C. Kirchhoff.

Smer'dis (in Gr. Σμέρδις): brother of Cambyses, who, because envious of the strength of Smerdis, sent him back to Susa from Egypt. Shortly afterward Cambyses, having dreamed that Smerdis was seated on the royal throne, sent and had him put to death secretly. A rebellion broke out in Susa because of the tyranny of Cambyses, who was still absent in Egypt, and the brother of the governor of the royal palace, because he resembled much the dead Smerdis, was declared to be the real Smerdis, and proclaimed king. In haste Cambyses began the journey home to defend his throne, but he died on the way, and though the nobles soon discovered the fraud that had been practiced on them, still the false Smerdis was able to hold the throne for seven months. He was finally murdered by the nobles, who elected Darius Hystaspis king. J. R. S. Sterrett.

Smet, Peter John, de: missionary; b. at Termonde, Belgium, Dec. 31, 1801; was trained in the seminary at Mechlin; sailed with five fellow students to the U. S. in 1821; became a Jesuit; assisted in founding the University of St. Louis, Mo., 1828; in 1838 was sent to labor with the Pottawattomies, on Sugar creek, and in 1840 was transferred to the Flathead mission, in the Rocky Mountains. Father de Smet acquired a singular power of restraint over nearly all the Indian tribes, from the Sioux westward. He became procurator of the Indian missions, several times visited Europe in behalf of his missions, and wrote several works in French and English, among them *Letters and Sketches, and Residence in the Rocky Mountains* (Philadelphia, 1843); *Oregon Missions and Travels over the Rocky Mountains in 1845–46* (New York, 1847); *Western Missions and Missionaries* (1863), and many letters published in the *Annals* of the Roman Propaganda. He was a chaplain in the Utah expedition. D. in St. Louis, May 23, 1872.

Revised by S. M. Jackson.

Smew: a merganser, *Mergellus albellus*, inhabiting the northern parts of the Old World. It is distinguished by the short narrow bill (considerably shorter than the head), whose margins are beset with short approximated lamellæ. In the male the ground-color is white (whence one of the popular names, white nun); black pervades around and in front of the eyes, at the occiput under the crest, at the front of the back, on the tail, and on the wings, but the scapulars and middle wing-coverts, as well as secondaries and tertials, are white; in the female the head is of a reddish brown; the length is about 17 inches. Like its relatives, it is an excellent swimmer and diver. It makes a nest near the water, and lays therein from eight to ten eggs. T. G.

Smilax [= Lat. = Gr. σμῖλαξ, yew. also (with distinguishing adjectives) a kind of bean, a kind of bindweed]: a large genus of monocotyledonous plants of the sub-family *Smilaceæ* and family *Liliaceæ*. They consist of herbaceous or shrubby plants, generally more or less climbing, with reticulated leaves and bisexual or polygamous flowers, a six-parted perianth, six stamens, a free three-celled ovary, with one or several seeds in each cell, three stigmas, and a roundish berry. There are about 200 known species scattered over the globe, though most numerous in the temperate and tropical parts of Asia and America. True sarsaparilla and China root are among the products of the genus, the former from *S. officinalis*, *S. papyracea*, and *S. syphilitica*, of the West Indies and South America, and the latter from *S. china* of Japan, China, and the East Indies. The U. S. has numerous species, none of them important. The so-called China brier is the most widely known of them. It is very frequent in the southern parts of the U. S., and extends northward to New Jersey. It has large, tuberous, brownish-red root-stocks, which contain a considerable amount of starch. Formerly the Seminoles used the root-stocks for food in times of scarcity, either separating the starch or cooking the whole root. At present a kind of beer is made from them with molasses, parched corn, and sassafras. Several plants of this genus are fine in hothouse and garden culture. The related climbing plant which under the name of smilax is cultivated by florists is the *Myrsiphyllum asparagoides*. It comes from the Cape of Good Hope, and is more closely allied to the asparagus. It has a fine thread-like stem, sometimes 20 feet long, and elegant, strongly colored leaves which do not easily fade. Revised by Charles E. Bessey.

Smiles, Samuel: author; b. at Haddington, Scotland, in 1812; educated for the medical profession; practiced some years as a surgeon at Leeds; became editor of the Leeds *Times*; was secretary to the Leeds and Thirsk Railway 1845–52, and to the Southeastern Railway 1852–66. Among his numerous works are *Self-Help, with Illustrations of Character and Conduct* (1860); *Workmen's Earnings, Strikes, and Savings* (1861); *Lives of the Engineers, with an Account of their Principal Works* (4 vols., 1861–65); *Character* (1871); *Thrift* (1875); *The Huguenots in England and Ireland* (1868); *The Huguenots in France after the Revocation of the Edict of Nantes* (1874); *Life of a Scotch Naturalist* (1876); *George Moore, Merchant and Philanthropist* (1878); *Life of Robert Dick, Geologist and Botanist* (1878); *Duty, with Illustrations of Courage, Patience, and Endurance* (1880); *Men of Invention and Industry* (1884); *A Publisher and his Friends: John Murray* (1891); *Jasmin, the Barber-poet* (1891); *Josiah Wedgewood* (1894). Most of his works have been republished in the U. S.

Smiley, William Henry: See the Appendix.

Smillie, George Henry: landscape-painter; son of James Smillie (1807–85), engraver; b. in New York, Dec. 20, 1840; pupil of James M. Hart; National Academician 1882; member of the American Water-color Society. Studio in New York.—His brother, James David, also a landscape-painter, was born in New York, Jan. 16, 1833; studied under his father; became a National Academician 1876; member American Water-color Society. Studio in New York.

Smirke, Robert, R. A.: painter; b. at Wigton, near Carlisle, England, in 1752; was brought up to the business of a painter of coach-panels; was admitted as a student at the Royal Academy 1771; became an academician 1791, his presentation picture being *Don Quixote and Sancho Panza*; painted many scenes illustrating the Bible, Milton, Thomson, and *The Arabian Nights*; was one of the contributors to Boydell's *Shakspeare*, and brought out a magnificent edition of his daughter Mary's translation of *Don Quixote*, with 74 engravings (4 vols., London, 1818). D. in London, Jan. 5, 1845.

Smirke, Sir Robert, R. A.: architect; eldest son of Robert Smirke; b. in London, England, in 1780; educated as an architect in England and on the Continent; was gold medalist at the Royal Academy 1799; published *Specimens of Continental Architecture* (1806); was architect of the new Covent Garden theater 1808–09, of the mint 1811, the post-office 1823–29, the Union, United Service, and Carlton clubs, most of them being examples of the so-called classical school, and built many other important private and public edifices. His fame rests chiefly upon the British Museum, built by him at intervals from 1823 to 1847. He was knighted 1831, and was thirty years treasurer of the Royal Academy. D. at Cheltenham, Apr. 18, 1867.

Smirke, Sydney, R. A.: architect; son of Robert Smirke; b. in England, 1799; studied architecture; gained the gold medal of the Royal Academy 1819; assisted his brother in designing the Oxford and Cambridge University Club-house in Pall Mall, London, 1835–37; superintended the restoration of the Temple church, of which he published an account (1842); in 1847 succeeded his brother as architect to the British Museum, in which capacity he built the reading-room 1855, the Roman, Assyrian, and other galleries, and was the architect of several other public edifices and of many splendid country-seats. His last achievement was the new Royal Academy in Burlington House, begun 1867 and completed 1874. He was chosen R. A. 1860; became Professor of Architecture at the Academy 1861, and its treasurer 1862; subsequently trustee of that institution and of the Soane Museum. D. Dec. 11, 1877.

Smith, Adam: economist and philosopher; b. at Kirkcaldy, Fifeshire, Scotland, June 5, 1723. His education was carried forward in the grammar school of Kirkcaldy, the University of Glasgow, and Baliol College, Oxford, with a view to his taking orders in the English Church. In Glasgow he gave chief attention to mathematics and natural science, but at Oxford he turned to the study of languages, and took especial pains to master English. Abandoning all thought of the clerical office, he returned to his native place, and in 1748 took up his residence in Edinburgh. There he first came before the public, delivering lectures on rhetoric and belles-lettres under the patronage of Lord Kames. In 1751 he was made Professor of Logic in the University of Glasgow, and the following year became Professor of Moral

Philosophy in the same institution. He resolved the science of morals into four parts, and accordingly discussed in his lectures, first, natural theology; second, ethics; third, justice with reference to specific rules and precepts; and fourth, political expediency as affecting the honor, power, and prosperity of the state. His lectures were delivered extemporaneously, and were, for both matter and style, very popular. His first published work was the *Theory of Moral Sentiments*, issued in 1759. It called forth a high encomium from Hume, and brought Smith at once a wide reputation. Incidentally, this publication led to his being selected, four years afterward, to accompany the young Duke of Buccleugh on his travels. He carefully improved the opportunity thus presented to become acquainted with the internal policy of other states, and to confer with distinguished economists on the Continent. He returned to England in 1766, and for ten years lived with his mother in partial retirement at Kirkcaldy. There he devoted himself to the earnest study of subjects which had occupied his attention for nearly twenty years. The result was given to the world in 1776 in his great work entitled *An Inquiry into the Nature and Sources of the Wealth of Nations.* Many principles laid down in that work were no doubt derived from the French economists, but the completeness of their compilation and the clearness with which they are set forth in this treatise fairly entitle Adam Smith to be regarded as the father of modern political economy. His book will continue to be, as it has been hitherto, a standard of reference. Smith's biographer thus defines the main feature of this work: "Its great object is to demonstrate that the most effectual plan for advancing a people to greatness is to maintain that order of things which nature has pointed out, by allowing every man, as long as he observes the rules of justice, to pursue his own interest in his own way, and to bring both his industry and his capital into the freest competition with those of his fellow citizens." After residing two years in London, he was appointed a commissioner of customs for Scotland, and removed to Edinburgh, where he spent the remainder of his life. In 1787 he was elected lord rector of the University of Glasgow. D. in Edinburgh, July 17, 1790. After his decease most of his manuscripts were destroyed, as he had directed, but a few were published in 1795 under the title *Essays on Philosophical Subjects.* Revised by J. Mark Baldwin.

Smith, Alexander: poet; b. at Kilmarnock, Scotland, Dec. 31, 1830; was pattern-designer for a lace-factory at Glasgow; published a volume of poems, *A Life Drama* (1853), which attracted great attention; was appointed secretary of the University of Edinburgh 1854; wrote *Sonnets of the War*, along with Sydney Dobell (1855); *City Poems* (1857); *Edwin of Deira* (1861); and the prose works *Dreamthorp* (1863); *A Summer in Skye* (1865); *Alfred Hagart's Household* (1866); and *Miss Oona McQuarrie* (1866). D. at Wardie, near Edinburgh, Jan. 5, 1867. Smith has been classed with Bailey, the author of *Festus*, and others of "the spasmodic school" satirized in Aytoun's *Firmilian.* A *Memoir* by P. P. Alexander was published along with a posthumous volume of miscellanies entitled *Last Leaves* (1868). Revised by H. A. Beers.

Smith, Andrew Jackson: soldier; b. in Bucks co., Pa., Apr. 28, 1815; graduated at the U. S. Military Academy; appointed in the army a second lieutenant of the First Dragoons July, 1838, of which regiment he became major in May, 1861 (known as the First Cavalry Aug., 1861), and July, 1866, colonel of the Seventh Cavalry. Prior to 1861 he served almost continually with his regiment on the frontier. In Oct., 1861, he was commissioned colonel of the Second California Cavalry, and Mar. 17, 1862, a brigadier-general of volunteers. He was engaged in the assault of Chickasaw Bluffs (Dec. 27–29, 1862), and later in the assault and capture of Arkansas Post (Jan. 11, 1863). In command of a division of the Thirteenth Army-corps, he took part in the siege and assaults of Vicksburg and in the subsequent capture of Jackson, Miss. In the Red river campaign he commanded the force (composed of detachments of the Sixteenth and Seventeenth corps) which captured Fort De Russy, and was engaged in the battle of Pleasant Hill. Next ordered to Missouri, he aided in driving Price from that State, then was called to re-enforce Gen. Thomas at Nashville, and engaged in the battle of Nashville and pursuit of Hood's army. Recalled to Gen. Canby's command in Feb., 1865, he commanded the Sixteenth Corps in the reduction and capture of Mobile, Ala. In Jan., 1866, he was mustered out of the volunteer service, and in May, 1869, resigned his commission in the regular army. The brevets of colonel, brigadier-general and major-general were bestowed on him for gallantry at Pleasant Hill, La., Tupelo, Miss., and Nashville, Tenn. He was reappointed colonel of cavalry Jan. 22, 1889, by act of Congress and retired. D. Jan. 30, 1897.

Smith, Buckingham: bibliographer and historian; b. on Cumberland island, Ga., Oct. 31, 1810; graduated at the Cambridge Law School 1836; was elected to the territorial legislature at Florida; was secretary of legation at Mexico 1850–52, and at Madrid 1855–58; and subsequently settled in Florida, where he was a judge and a member of the State Senate. He made special and important researches in Mexican history and antiquities, Indian philology, and the early Spanish expeditions in North America. Besides aiding Bancroft, Sparks, and Parkman in their researches, he edited translations of the *Narrative of Cabeza de Vaca* (1851); *Letter of Hernando de Soto and Memoir of Hernando de Escalante Fontaneda* (1854); and translated, with copious notes, *Narratives of the Career of Hernando de Soto in the Conquest of Florida* (1868). In 1864 he published *An Inquiry into the Authenticity of Documents concerning a Discovery of North America claimed to have been made by Verrazano.* D. in New York, Jan. 5, 1871. A portion of his library was secured for the New York Historical Society. Herbert H. Smith.

Smith, Charles Emory, LL. D.: journalist; b. at Mansfield, Conn., Feb. 18, 1842; graduated at Union College in 1861; became editor of the Albany *Express* in 1865, of *The Albany Journal* in 1870, and of the Philadelphia *Press* in 1880. He was president of the New York State Press Association in 1874, and U. S. minister to Russia 1890–92. In Apr., 1898, he was appointed Postmaster-General.

Smith, Charles Ferguson: soldier; b. in Philadelphia, Pa., Apr. 24, 1807; graduated at the U. S. Military Academy in 1825, entering the army as a lieutenant of artillery. From 1829 to 1842 he served at the Military Academy in various capacities. In the Mexican war, as captain of artillery, he served with distinction, and received the brevets of major, lieutenant-colonel, and colonel. Appointed lieutenant-colonel of the Tenth Infantry in 1855, he commanded the Red river expedition in 1856, engaged in the Utah expedition in 1857–61, for a time was in command of the department of Utah, and was in command of the city and department of Washington Apr. 10–28, 1861. On Aug. 31, 1861, he was appointed a brigadier-general of volunteers, and ordered to Kentucky. In September he became colonel of the Third Infantry. In the operations about Forts Henry and Donelson he acquired a high reputation. In the fight for the possession of the latter stronghold he led the division which had held the left of the investing lines of the Union army, and which stormed and captured all the high ground on the Confederate right, which commanded Fort Donelson. Gen. Smith was then selected to command the movement up the Tennessee, and on Mar. 21 was promoted to be major-general of volunteers. D. at Savannah, Tenn., Apr. 25, 1862.

Smith, Charles Forster: professor of Greek: b. in Abbeville co., S. C., June 30, 1852; educated at Wofford College, Harvard and Leipzig Universities; Ph. D., Leipzig, 1881; Professor of Greek and German, Wofford College, 1875–79; Assistant Professor Ancient Languages, Williams College, 1881–82; Professor of Modern Languages, Vanderbilt University, 1882–83; Professor of Greek, Vanderbilt University, 1883; Professor of Greek, University of Wisconsin, 1894; author of *Thucydides: Book III. and Book VII.* of College Series of Greek Authors; vice-president American Dialect Society 1891.

Smith, David Eugene: See the Appendix.

Smith, Sir Donald Alexander, D. C. L.: member of Canadian Parliament; b. in Morayshire, Scotland, in 1821, and educated there. He was for many years in the service of the Hudson Bay Company, and is resident governor and chief commissioner of that corporation in Canada; is president of the Bank of Montreal, and a director of the Canadian Pacific Railway. He was appointed a member of the Executive Council for the Northwest Territories in 1870; represented Winnipeg and St. John in the Manitoba Assembly 1871–74; Selkirk in Dominion Parliament 1871–78; and Montreal West in that body 1887–95. He was knighted in 1886. Neil Macdonald.

Smith, Edmund Kirby: soldier; b. at St. Augustine, Fla., May 15, 1824; graduated at the U. S. Military Acad-

emy in 1845, and entered the army as brevet second lieutenant of infantry. In the war with Mexico he distinguished himself, and was breveted first lieutenant and captain for gallantry at Cerro Gordo and Contreras. From 1849 to 1852 he was Assistant Professor of Mathematics at West Point. Transferred to the Second Cavalry in 1855 with the rank of captain, he served on frontier duty, and was severely wounded in a fight with the Comanche Indians in Texas, May 13, 1859. In Jan., 1861, he became major of his regiment, but resigned Apr. 6; was soon after appointed a brigadier-general in the Confederate army, and served under Gen. Joseph Johnston in Virginia. At the battle of Bull Run, July 21, 1861, he arrived on the field with Elzey's brigade toward the close of the action, but was soon disabled by a shot, when Elzey assumed command. Made major-general in 1862, he was transferred to East Tennessee, and placed in command of that department. Under Bragg he led the advance in the invasion of Kentucky; he routed the Union forces at Richmond, Ky., Aug. 30, and advanced to Frankfort. Promoted to the grade of lieutenant-general, he was engaged at the battle of Perryville, Oct. 10, and in the battle of Murfreesboro, Dec. 31, 1862–Jan. 3, 1863. He was soon after made general, and in command of the Trans-Mississippi department, opposing Banks in the Red river campaign, and engaged in the battle of Jenkins's Ferry, Apr. 30, 1864. He was the last to surrender the forces under his command, May 26, 1865. He filled the positions of president Pacific and Atlantic Telegraph Company 1866–68, president Western Military Academy 1868–70, chancellor of the University of Nashville, Tennessee, 1870–75; and Professor of Mathematics in the University of the South from 1875 till his death at Sewanee, Tenn., Mar. 28, 1893.

Revised by JAMES MERCUR.

Smith, ELI, D. D.: missionary; b. at Northford, Conn., Sept. 15, 1801; graduated at Yale College 1821, at Andover Seminary 1826; went to Malta as superintendent of a missionary printing establishment 1826; traveled with Dr. Anderson through Greece 1829, and with Dr. Harrison G. O. Dwight, of Constantinople, through Armenia, Georgia, and Persia 1830–31—a tour which resulted in the establishment of the important Armenian and Nestorian missions of the American Board; visited the U. S. and published *Missionary Researches in Armenia* (2 vols., Boston, 1833); settled at Beyrout 1833; accompanied Dr. Edward Robinson in his geographical explorations of Palestine, to which he largely contributed, 1838 and 1852; revisited the U. S. 1839 and 1845; introduced an elegant font of Arabic type, cast under his supervision at Leipzig, for the mission press, 1839, and was engaged from 1847 upon a new translation of the Bible into Arabic, completed by Dr. C. V. Van Dyke. D. at Beyrout, Jan. 11, 1857. Revised by G. P. FISHER.

Smith, ELIZABETH OAKES (*Prince*): author; b. at Cumberland (then North Yarmouth), Me., Aug. 12, 1806; resided from infancy in Portland, Me.; married there in 1823 Seba Smith, editor and humorist, whom she aided in his journalistic enterprises; obtained a considerable local reputation as a writer of prose and verse, but never appeared publicly as an author until after the loss of her husband's fortune in 1839; settled in New York 1842. Her contributions to the magazines were partially collected in several volumes, of which the best known was *The Sinless Child and Other Poems* (1843). She also published two tragedies, *The Roman Tribute* and *Jacob Leisler* (1853); *Riches without Wings* (1838); *The Western Captive* (1850); *Woman and her Needs* (1851); *The Newsboy* (1855); *The Two Wives* (1870); *Kitty Howard's Journal* (1871); and other books. She lectured before lyceums, occasionally preached, and was a prominent advocate of woman's rights. D. at Hollywood, N. C., Nov. 8, 1893. Revised by H. A. BEERS.

Smith, ERMINNIE ADELLE (*Platt*): scientist; b. at Marcellus, N. Y., Apr. 26, 1837; educated at Mrs. Willard's seminary at Troy, N. Y.; married Simeon H. Smith, of Jersey City, in 1855; while educating her sons in Europe studied in Germany mineralogy, geology, crystallography, and other branches of science; also visited and investigated the amber-fisheries on the coast of the Baltic Sea. She was the first woman elected fellow of the New York Academy of Sciences, and the first woman appointed an officer in the American Association for the Advancement of Science, being at the time of her death secretary of the section of anthropology. In 1880 Mrs. Smith became one of the salaried members of the bureau of ethnology, Smithsonian Institution, and was detailed to study the language, customs, myths, and peculiarities of the Iroquoian Indians. She spent two summers among the Tuskaroras in Canada, who adopted her as a member of the tribe, and compiled an Iroquois-English dictionary. In 1885 she was appointed by Gov. Abbett commissioner of the department of woman's work to represent the State of New Jersey at the New Orleans Exposition. D. in Jersey City, June 9, 1886. J. W. POWELL.

Smith, FRANCIS HENNEY, A. M.: soldier; b. at Norfolk, Va., Oct. 18, 1812; graduated at the U. S. Military Academy in 1833, and entered the army as a brevet second lieutenant of artillery; second lieutenant Nov. 30, 1833. In 1836 he resigned from the army, and in 1837 was appointed Professor of Mathematics at Hampden-Sidney College, Virginia. Upon the organization of the Virginia Military Institute at Lexington, Va., in 1839, he was appointed its superintendent and principal professor (of mathematics), the duties of which positions he performed until Jan. 1, 1890. Emeritus professor until his death. Soon after the outbreak of the civil war the professors and assistants went into the Confederate army, and Smith, as colonel of a Virginia regiment, was stationed at the city of Norfolk and in command of the fort on Craney island. The institute was subsequently reopened. He was the author of various educational works. D. at Lexington, Mar. 21, 1890.

Smith, FRANCIS HOPKINSON: landscape-painter and author; b. in Baltimore, Md., Oct. 23, 1838. He is by profession a civil engineer, and has built a number of public works, some for the U. S. Government. As a painter he is self-taught, paints principally in water-color, and is a member of the American Water-color Society. He is an accomplished writer of fiction and descriptive articles, and well known as an illustrator. His water-colors of scenes in Venice are freely and cleverly painted. W. A. C.

Smith, Sir FRANCIS PETTIT: inventor; b. at Hythe, England, Feb. 9, 1808; constructed in 1834 a model of a steam-vessel to be propelled by a screw driven by a spring; made a larger boat on the same principle, which he successfully tested in the English Channel 1837; constructed for the British navy the screw steamer Archimedes of 237 tons, 90 horse-power (finished 1840), the success of which led to the rapid introduction of screw-vessels into the navy and the mercantile marine. He was knighted in 1871. D. in London, Feb. 11, 1874.

Smith, GEORGE: Assyriologist; b. in London, England, Mar. 26, 1840. He became interested in Assyriology by having to engrave some cuneiform signs for publication. Appointed to a position in the Assyrian department of the British Museum he rapidly became, by his industry, insight, and remarkable memory one of the greatest promoters of Assyriology. In connection with Sir Henry Rawlinson he edited vols. iii.–iv. of *The Cuneiform Inscriptions of Western Asia* (1870, 1875), a monumental work. In 1872 he discovered among the clay books in the British Museum fragments of a story of the Deluge similar to the biblical version. *The Daily Telegraph* newspaper then sent him to Nineveh to make further search for clay books in the ruins of Asshurbanipal's palace. This expedition was successful, and was followed by two others for the museum. On the third expedition he died of fever at Aleppo, Aug. 19, 1876. The Deluge story proved to be part of a great poem written on twelve tablets. The whole was published, so far as recovered, in *The Chaldæan Account of Genesis*, of which there have been several editions. His other works are *Assyria, from the Earliest Times till the Fall of Nineveh* (London, 1875); *Assyrian Discoveries* (1875), an account of his own travels and researches; *The Assyrian Eponym Canon* (London, 1876); *History of Babylonia*, ed. by A. H. Sayce (1877); *History of Sennacherib*, ed. by A. H. Sayee (London, 1878), a work similar to the *History of Asshurbanipal*; and numerous articles in the *Transactions of the Society of Biblical Archæology*, etc. D. G. LYON.

Smith, GEORGE ADAM, D. D.: clergyman and author; b. in Calcutta, India, Oct. 19, 1856; was educated at the University and New College, Edinburgh, and the Universities of Tübingen and Leipzig; traveled twice extensively in Egypt and the Holy Land; was assistant in Brechin Free church 1880; in charge of the chair of Hebrew in Free Church College, Aberdeen, 1880–82; first minister of Queen's Cross church, Aberdeen, 1882–92; since 1892 Professor of Hebrew and Old Testament Exegesis in Free Church College, Glasgow. Dr. Smith has published *The Book of Isaiah* in *The Expositor's Bible* (London and New York, vol. i.,

1888; 7th ed. 1894; vol. ii., 1890; 3d ed. 1894); *The Preaching of the Old Testament to the Age* (London and New York, 1893); *The Historic Geography of the Holy Land* (London and New York, 1894); with Bartholomew, the Scottish cartographer, *Historical Atlas of the Holy Land* (1895); and many articles for reviews. C. K. Hoyt.

Smith, Gerrit: philanthropist; b. at Utica, N. Y., Mar. 6, 1797; son of Peter Smith, a proprietor of vast tracts of land in Central and Northern New York; graduated at Hamilton College 1818; took up his residence at Peterboro, Madison co., N. Y., devoting himself to the management of his great landed estate; became a member of and liberal contributor to the Colonization Society 1825, but withdrew from it 1835, when he connected himself with the American Anti-Slavery Society, of which he was thenceforth one of the leading members; was elected to Congress 1852, but resigned after a single session; was a liberal contributor to the Free-soil campaign in Kansas; gave pecuniary aid to John Brown 1859 when preparing the attack on Harper's Ferry, though, it is believed, without a knowledge of that project; was nominated for Governor of New York in 1840 and in 1858, at the latter time on a platform of abolition and prohibition; joined Horace Greeley in signing the bail-bond of Jefferson Davis 1867; wrote, printed, and distributed many pamphlets on slavery and other reforms, built a non-sectarian church at Peterboro, in which he sometimes preached. D. in New York, Dec. 28, 1874. Author of *Speeches in Congress* (1855); *Sermons and Speeches* (1861); *The Religion of Reason* (1864); *The Theologies* (1866); and *Nature the Base of a Free Theology* (1867). See his *Biography*, by Frothingham (New York, 1878).

Smith, Goldwin, LL. D., D. C. L.: author; b. at Reading, England, Aug. 13, 1823; educated at Eton and at Oxford, where he graduated in 1845, and became a fellow of University College in 1847; called to the bar in 1847, but never practiced law. In 1850 he was appointed by the Government assistant secretary of the royal commission on the state of Oxford University; was secretary of the second Oxford commission; a member of the popular education commission in 1858; Regius Professor of Modern History in Oxford University 1858–66, and Professor of English and Constitutional History in Cornell University 1868–71. He ably championed the cause of the U. S. Government during the civil war; visited the U. S. in 1864 to deliver a series of lectures, and was given the degree of LL. D. by Brown University. In 1871 he removed to Toronto, Canada; was for a time a member of the senate of Toronto University; edited *The Canadian Monthly* 1872–74, and subsequently founded *The Week* and *The Bystander*, the latter of which is not now published. Since his removal to Canada he has persistently advocated the annexation of that country to the U. S. In addition to numerous magazine articles he has published the following among other works: *Lectures on the Study of History* (1861); *Irish History and Irish Character* (1861); *The Empire* (1863); *Three English Statesmen* (1867); *Cowper* (English Men of Letters Series, 1880); *A Trip to England* (1888); *Jane Austen* (Great Writers' Series, 1890); *Canada and the Canadian Question* (1891); *The Moral Crusader, William Lloyd Garrison* (1892); *The United States* (1893); *Bay Leaves: Translations from the Latin Poets* (1893); *Essays on Questions of the Day* (1894); and *Guesses at the Riddle of Existence* (1896).

Smith, Green Clay: soldier; b. at Richmond, Ky., July 2, 1830; served as a volunteer in the Mexican war, gaining the rank of lieutenant of cavalry; graduated at Transylvania University 1850, and at Lexington, Ky., Law School; became a lawyer at Covington; was a member of the Kentucky Legislature 1861, and a decided Union man; became colonel of the Fourth Kentucky (Union) Cavalry Mar., 1862, and brigadier-general of volunteers June, 1862; resigned Dec. 1, 1863; was a member of Congress 1863–66; a delegate to the Baltimore convention 1864; Governor of Montana Territory 1866–68; entered the Baptist ministry, and was ordained in 1869. Presidential candidate on the Prohibition ticket 1876. D. in Washington, D. C., June 29, 1895.

Smith, Gustavus Woodson: soldier; b. in Scott co., Ky., Jan. 1, 1822; graduated from the U. S. Military Academy July 1, 1842; appointed to the Engineer Corps, and for two years engaged in the construction of fortifications of New London harbor; Assistant Professor of Engineering at West Point 1844–46; commanded the sappers, miners, and pontoniers during the siege of Vera Cruz and during the subsequent operations of the war with Mexico, receiving the brevets of first lieutenant and captain for gallantry at Cerro Gordo and Contreras. He was principal Assistant Professor of Engineering at West Point 1849–54, when he resigned from the army. He was subsequently employed in the construction of various Government buildings and in the iron-works of Cooper & Hewitt at Trenton, N. J. In 1858 he became street commissioner of New York city; early in 1861 he entered the Confederate army, and in August was appointed a major-general. On May 31, 1862, Gen. Johnston having been severely wounded that day at Fair Oaks, Gen. Smith succeeded to the temporary command of the Army of Northern Virginia, and subsequently commanded at Petersburg, Va. In 1864–65 he was commander of the State forces of Georgia, and was captured at Macon, Ga., Apr. 20, 1865. From 1866 to 1870 he was in charge of the Southwest Iron Company's works at Chattanooga, Tenn., and from 1870 to 1876 was insurance commissioner of Kentucky. D. in New York, June 24, 1896. He was the author of many works on life-insurance and on Confederate battles and leaders.

Smith, Hannah: author; b. at Wellington, Shropshire, England. Under the pseudonym of *Hesba Stretton* she has been a prolific author of novels and stories, including *Jessica's First Prayer* (1866); *The Clives of Burcot* (1867); *Paul's Courtship* (1867); *Hester Morley's Promise* (1878); and *Bede's Charity* (1882). H. A. B.

Smith, Henry Boynton, D. D., LL. D.: theologian; b. at Portland, Me., Nov. 21, 1815; graduated at Bowdoin College 1834; was a tutor there 1836–37, and again 1840–41, between which periods he studied theology at Andover, Bangor, Halle, and Berlin; was pastor of the Congregational church at West Amesbury, Mass., 1842–47; Professor of Mental and Moral Philosophy at Amherst College 1847–50; was Professor of Church History in Union Theological Seminary, New York, 1850–54, and of Systematic Theology 1854–74; after that professor emeritus; was moderator of the General Assembly of the (New School) Presbyterian Church 1863–64; delivered at the meeting of that body at Dayton, O., an address on *Christian Union and Ecclesiastical Reunion*, which was directed toward that union with the "Old School" Church which was afterward consummated, and for which he prepared an essay on the doctrinal basis, *The Reunion of the Presbyterian Churches* (1867); was appointed delegate in 1867 to the meeting of the Evangelical Alliance in Amsterdam, for which he prepared a report *On the State of Religion in the United States*; was the founder and editor of *The American Theological Review* (1859–71), consolidated with *The Presbyterian Review* in 1862, and united with *The Princeton Review* in 1872; aided Prof. R. D. Hitchcock in the *Life, Character, and Writings of Edward Robinson* (1864). He published in 1859 a *History of the Church of Christ, in Chronological Tables* (folio); was translator in part, and editor, of Gieseler's *Church History* (4 vols., 1859–63; vol. v. published posthumously in 1880); editor of revised translations of Hagenbach's *History of Christian Doctrine* with large additions (2 vols., 1861–62), and Stier's *Words of the Lord Jesus* (1864–65). D. in New York, Feb. 7, 1877. In that same year his friend Dr. Prentiss edited a collection of his discourses and essays entitled *Faith and Philosophy*. In 1881 his *Memoirs* appeared, edited by his wife, and a briefer biography, by his pupil Prof. Lewis French Stearns, appeared in Boston, 1892. Another pupil, Prof. William S. Karr, of Hartford, edited his *Apologetics* (1882), his *Introduction to Christian Theology* (1883), and his *System of Christian Theology* (1884).
Revised by S. M. Jackson.

Smith, Sir Henry George Wakelyn, usually known as Sir Harry Smith: soldier; b. at Whittlesea, Cambridgeshire, England, in 1788; entered the army as second lieutenant in the rifle-brigade in 1805; served as assistant quartermaster-general in the campaign of Waterloo; commanded a division in the Kaffir war 1834–35; was appointed adjutant-general to the forces in India 1839; was distinguished at the battles of Gwalior and Maharajpur, being knighted for the latter service 1844; took a prominent part in the war against the Sikhs in the Punjaub; was sent to the relief of Ludhiana, and took Aliwal at the point of the bayonet Jan. 28, 1846, capturing sixty-seven guns; re-enforced Lord Gough in time to enable him to win the decisive battle of Sobraon, Feb. 10, 1846; received the thanks of Parliament on the proposal of the Duke of Wellington, and was made a baronet; became governor of the Cape of Good Hope 1847; conducted the Kaffir war of 1851–52, and was made lieutenant-general 1854. D. in London, Oct. 12, 1860.

Smith, Hoke: lawyer and journalist; b. at Lincolnton, Lincoln co., N. C., Sept. 2, 1855; son of H. H. Smith, a native of New Hampshire, and for several years a professor in the University of North Carolina; educated at the University of Georgia; went to Atlanta 1872 to study law; also taught school at Waynesboro, Ga.: admitted to the bar at Atlanta 1873; canvassed Northern Georgia 1877, urging the removal of the State capital from Milledgeville to Atlanta; organized and became president of the Atlanta *Evening Journal* Company 1887; made the paper very popular in the State through his advocacy in its columns of a low tariff. Was Secretary of the Interior 1893–96.

Smith, Horace: humorist and poet; b. in London, England, Dec. 31, 1779; became a member of the Stock Exchange, in which business he acquired a fortune; was associated with his brother James in writing for several periodicals and in the production of a celebrated volume of poetical parodies entitled *Rejected Addresses* (1812); was author of numerous novels which had but moderate success, and of an anonymous volume of humorous prose sketches, *The Tin Trumpet* (1836). A collection of his poems was published at London in 1846. D. at Tunbridge Wells, July 12, 1849. A selection from the poetical works of both brothers, including the *Rejected Addresses*, and accompanied by a *Memoir*, was published by Epes Sargent (New York, 1857).

Smith, Horace: See the Appendix.

Smith, James: signer of the Declaration of Independence; b. in Ireland about 1720; was taken to Pennsylvania by his parents, who settled on the Susquehanna 1729; was educated at the College of Philadelphia; became at first a surveyor near Shippensburg, afterward a lawyer at York; raised in 1774 the first volunteer company in the State for the purpose of resistance to Great Britain; was a member of the convention called to consider the expediency of abstaining from importing English goods, and one of the committee to prepare instructions for the representatives; published an *Essay on the Constitutional Power of Great Britain over the Colonies in America*, which gave a powerful impulse to the Revolution; was elected to the Continental Congress 1775–78; signed the Declaration of Independence, and was elected to the General Assembly of Pennsylvania 1780. D. at York, July 11, 1806. He was a man of great wit, and his odd gestures and drawling utterance added to the effect of his droll speeches.

Smith, John: adventurer; b. at Willoughby, Lincolnshire, England, in Jan., 1579; spent four years of his early manhood in military service in the Netherlands; was afterward, according to his own account, engaged in wars against the Turks in Hungary and Transylvania, but there is reason to believe that his wonderful adventures in the East are wholly or in part fictitious. Returning to England, by way of Barbary, he was induced by Capt. Bartholomew Gosnold to take part in the colonization of Virginia (1606), then being carried into effect, and brought to bear with such effect his military renown upon the directory of the "London Company" that his name was placed on the secret list of seven persons appointed members of the council. During the long voyage to Virginia (1607) Smith was placed under arrest on an accusation of sedition, and, though liberated on arrival at Jamestown, Va., where the colony was located, he was excluded from his place in the council. He accompanied Capt. Newport in his voyage of exploration up James river as far as the present site of Richmond; was on their return admitted as a member of the council; took part in the disturbance which resulted in the removal from office of Wingfield, the president of the colony, against whom he successfully brought a suit for slander; was intrusted with the command of several expeditions into the interior, partly for the purpose of exploration, but chiefly with the object of obtaining food. He repressed with severity the projects of some of the settlers to return to England; upon which charge he caused Capt. George Kendall to be condemned and executed. Upon one of these expeditions, in Dec., 1607, Smith was taken prisoner, and detained for some time, though kindly treated by the Indian chieftain Wahunsenacawh (incorrectly called by many writers the "emperor" Powhatan). The famous incident of the preservation of his life by Pocahontas (or Amonate) was related of this captivity, but there is little doubt that the whole adventure is fictitious. On being carried back to Jamestown by the Indian chieftain, Smith was tried by his fellow councilors for the death of two of his companions, said to have been killed by the Indians through his imprudence, and was condemned to be executed the next day, but his life was saved by the opportune arrival of Capt. Newport with re-enforcements and provisions. In the following year Smith made two extended surveys of Chesapeake Bay and its tributary waters, of which he made a map; became president of the council Sept., 1608; had several skirmishes with hostile Indians, who at one time meditated the destruction of Jamestown. His departure from Virginia, to which he never returned, took place in Sept., 1609, and was attributed by himself to his having been burned by an explosion of gunpowder, but another account states that he was sent to England a prisoner. In 1614 he explored with two ships fitted out by some London merchants a large portion of the North American coast, to which he gave the name of New England, and of which he formed a tolerably accurate map, and made a handsome profit by fishing and fur-trading. In 1615 he undertook another voyage to New England for the purpose of founding a colony, but was captured by a French man-of-war and taken to Rochelle. Afterward he claims to have been engaged in "sea-fights for the French against the Spaniards," and to have experienced several remarkable adventures. About 1616 he received the title of admiral of New England, and was thenceforth much engaged in promoting American colonization by means of a series of publications on America, written either by or for him, in which romantic versions of his career in many lands were put forth; but many of the details are contradicted by conclusive proofs, and his several books and pamphlets are not consistent with one another upon some important points. D. in London, June 21, 1631, and was buried in the choir of St. Sepulchre's church. Under the name of *Thomas Watson*, Smith sent from Virginia *A True Relation of such Occurrences and Accidents of Note as hath happened in Virginia, etc.* (London, 4to, 1608), which was printed in black letter, accompanied by a map, and is the earliest tract published on the subject. It was reprinted, with an introduction and notes, by Charles Deane (Boston, 1867). He was also author of *A Map of Virginia, with a Description of the Country, the Commodities, the People, Government, and Religion, etc.* (Oxford, 1612); *A Description of New England, or the Observations and Discoveries of Captain John Smith (Admiral of that Country) in the North of America in the Year of our Lord 1614, etc.* (London, 1616; reprinted in vol. vi., 3d series of the *Collections* of the Massachusetts Historical Society, and in Force's *Tracts*; *New England's Trials, etc.*, 1620 and 1622); *The Generall Historie of Virginia, New England, and the Summer Isles* (1626)—a work including the substance of its predecessors; two treatises on seamanship (1626 and 1627); *The True Travels, Adventures, and Observations of Captain John Smith in Europe, Asia, Africa, and America from 1593 to 1629, etc.* (1630); and *Advertisements for the Unexperienced Planters of New England, etc.* (1631; reprinted at Boston, 1865); and was engaged at the time of his death upon a *History of the Sea*, no part of which has been preserved. The *Generall Historie* and *True Travels* were republished together at Richmond (2 vols., 1829). A *Letter of John Smith to Lord Bacon*, written in 1618 to recommend to the chancellor's attention the fisheries of New England, was first printed in the New York *Historical Magazine* for 1861. There are biographies by George S. Hillard (in Sparks's Series, vol. ii.), W. G. Simms (1846), and George C. Hill (1858). Much light was thrown upon his career by the Hakluyt Society's publication of Strachey's *History of Travails into Virginia Britannia* (1849) from the original MS., and by Charles Deane's notes to his edition of Wingfield's *Discourse of Virginia* (Boston, 1859), in which publications the falsity of the Pocahontas legend was first exposed. In Bryant and Gay's *Popular History of the United States* (vol. i., 1876) judicious use has been made of the materials above mentioned.

Revised by C. K. Adams.

Smith, John Lawrence, M. D., M. N. A. S.: chemist; b. near Charleston, S. C., Dec. 17, 1818; graduated at the University of Virginia, and at the Medical College of the State of South Carolina 1840; acted as civil engineer on the Charleston and Cincinnati Railroad; pursued his professional studies in France and Germany; began in 1844 the practice of medicine at Charleston, S. C., where he delivered lectures on toxicology; mining engineer (1846–51) to the Turkish Government; aided in the development of cotton-growing in Asia Minor; was instrumental in the discovery of deposits of emery and corundum in the U. S.; invented in 1851 the inverted microscope; was elected in that year

Professor of Chemistry in the University of Virginia; removed to Louisville, Ky.; became a professor in the Medical University of that city; was U. S. commissioner to the Universal Exposition of Paris (1867), Vienna (1873), and Philadelphia (1876); was in 1872 president of the American Association for the Advancement of Science; was a member of the National Academy of Science and of numerous associations; received from the Emperor Napoleon III. the cross of the Legion of Honor; was author of a report to the U. S. Government on *The Progress and Condition of Several Departments of Industrial Chemistry* (1867), as seen at the Paris Exposition, and *Mineralogy and Chemistry* (Louisville, 1873). D. in Louisville, Ky., Oct. 12, 1883.

Smith, John Pye: clergyman and author; b. at Sheffield, England, May 25, 1774; studied at the Independent Academy at Rotherham; became a Dissenting (Independent) minister, and in 1800 resident classical tutor in the theological academy at Homerton; exchanged that post in 1813 for the divinity tutorship, which he filled until 1843; was again classical tutor, and also principal, from the latter date until 1850. For forty-three years he was pastor of the Gravel Pits Chapel, Homerton; took great interest in science, and was elected a fellow of the Royal Society. D. at Guildford, Surrey, Feb. 5, 1851. He was the author of *The Scripture Testimony to the Messiah* (2 vols., 1818–21); *The Mosaic Account of the Creation and Deluge illustrated by the Discoveries of Modern Science* (1837); *Scripture and Geology* (1839); and other works. See *Memoirs of the Life and Writings of John Pye Smith*, by J. Medway, 1853.

Smith, John William: legal writer; b. in London, England, Jan. 2, 1809; educated at Trinity College, Dublin; began practice as a special pleader 1831, and was called to the bar at the Inner Temple May 3, 1834; was made a revising barrister in 1840. He was gifted with a remarkable memory, and powers of nice discrimination and lucid exposition. D. in London, Dec. 17, 1845. Besides a *Compendium of Mercantile Law* (1834) and *A Selection of Leading Cases in Various Branches of the Law* (2 vols., 1837–40; 9th ed. 1889), which are of the highest authority, he wrote *An Elementary View of the Proceedings in an Action at Law*, *Law of Landlord and Tenant*, and other less important works. See *Memoirs* in *Blackwood's Magazine* (Feb., 1847), *Law Magazine* (Feb., 1846), and *Albany Law Journal* (Dec., 1872).

F. Sturges Allen.

Smith, Joseph, Jr.: Mormon prophet; b. at Sharon, Vt., Dec. 23, 1805; removed while a child, with his parents, to Palmyra, N. Y., where he grew up almost without education, leading an idle and rather disreputable life. According to his own account, he began to have visions at the age of fifteen, and on Sept. 21, 1823, the angel Moroni appeared to him, announcing that God had a work for him to perform, and that buried in the earth in a certain spot a few miles distant was a record inscribed upon gold plates, giving an account of the early inhabitants of America and of their fate; and with this record would be found a kind of spectacles through which alone the writing could be read. Four years after, the angel placed the plates in his hands, together with the spectacles. Smith described the plates as being about 8 inches long, 7 wide, and connected by rings so as to form a volume about 6 inches thick. The plates were inscribed on both sides with hieroglyphic characters in a language no longer extant, but which he was able to decipher and understand by the use of the miraculous spectacles, which he called the Urim and Thummim. Smith professed to have dictated in English the contents of these plates to Oliver Cowdery, who acted as his amanuensis, the plates themselves mysteriously disappearing as they were successively transcribed. The manuscript thus prepared was printed at Palmyra in 1830 under the title, *The Book of Mormon, an Account written by the Hand of Moroni upon Plates taken from the Plates of Nephi. By Joseph Smith, Jr., Author and Proprietor*; and to it was prefixed a certificate signed by Cowdery and two others to the effect that they had seen and handled the plates. Subsequently, all three of the witnesses fell out with Smith, and declared the whole matter to be a hoax. Smith had been joined by Sidney Rigdon, a printer by trade, who had also aspired to found a new religion, and the two gained a small body of followers, and in 1831 went to Kirtland, O., where they built a temple and set up a fraudulent bank. They were driven away by the citizens in 1838. Smith had in the meantime fixed upon a place in Missouri as the site of his New Jerusalem, and here his adherents had begun to gather; but becoming obnoxious to the surrounding inhabitants, they abandoned their settlement, and took refuge in Hancock co., Ill., where in 1840 they established themselves in a fine location at the bend of the Mississippi, calling their new home Nauvoo; the town increased so rapidly that in six years the population numbered 15,000. Here Smith soon began to put forth, as occasion demanded, a succession of new revelations, among others one establishing polygamy as an essential feature of the Church of the Latter-Day Saints, and combining in his own person all civil, military, municipal, and sacerdotal authority. A newspaper was set up to oppose him; the presses were destroyed by Smith and his adherents May 6, 1844; warrants were issued for his arrest and that of his brother Hyrum and some others; they refused to obey the writs; the State militia were called out; the Mormons armed themselves, and a conflict was imminent. The Governor of Illinois at length induced the Smiths to surrender and submit to trial, guarantying their personal safety in the interval. They were committed to jail at Carthage, the county-town, and a guard was placed for their protection. On the evening of May 27 a mob assembled, dispersed the guard, and began firing into the door and window of the jail. Hyrum Smith was shot dead; Joseph returned the fire with a revolver until his charges were exhausted, when he endeavored to make his escape by the window, but was shot in the attempt, and fell dead to the ground. See Mormons and Rigdon, Sidney. Revised by S. M. Jackson.

Smith, Joshua Toulmin: author; b. in Birmingham, England, May 29, 1816; educated in the public schools of Birmingham; devoted himself to the Scandinavian languages and literature, in which he became proficient; resided in the U. S. 1837–42; published at Boston his *Northmen in New England, or America in the Tenth Century* (1839), which was chiefly a translation from the *Antiquitates Americanæ* (1837); devoted himself, on his return to England, to the study of constitutional and Old Saxon law; was called to the bar 1849; wrote several able legal treatises, especially *The Parish, its Obligations and Powers, its Officers and their Duties* (1854); illustrated in several publications the antiquities of Birmingham, and undertook the preparation for the Early English Text Society of a *History of English Guilds*, a work of immense labor, which, as well as a projected *History of Birmingham*, was left incomplete at the time of his death, which occurred at Lancing, Sussex, Apr. 28, 1869. The *History of English Guilds*, edited by his daughter, Lucy Toulmin Smith, appeared in 1870.

Smith, Judson, D. D.: clergyman; b. at Middlefield, Mass., June 28, 1837, graduated at Amherst College 1859, and at the Oberlin Theological Seminary 1863. He was Professor of Latin in Oberlin College 1866–70, and of Ecclesiastical History in Oberlin Theological Seminary 1875–84. In 1884 he was made a secretary of the A. B. C. F. M., Boston, Mass. He is the author of two volumes of historical lectures (privately printed) and of various articles in reviews and other journals, and since 1882 has been one of the editors of the *Bibliotheca Sacra*. G. P. Fisher.

Smith, Munroe, J. U. D.: professor of Roman law; b. in Brooklyn, N. Y., Dec. 8, 1854; A. B., Amherst, 1874; LL. B., Columbia, 1877; studied at Berlin, Leipzig, and Göttingen Universities 1877–80 (J. U. D., Göttingen); lecturer on Roman Law, Columbia College, 1880–91; Professor of Roman Law and Comparative Jurisprudence since 1891; instructor in history 1880–83; Adjunct Professor of History 1883–91; contributor to *Johnson's Universal Cyclopædia*, *The Nation*, etc., and managing editor *Political Science Quarterly* 1886–93. C. H. Thurber.

Smith, Nathan Ryno, M. D., LL. D.: surgeon; b. at Cornish, N. H., May 21, 1797; graduated at Yale College 1817; took the degree of M. D. at New Haven 1823; was Professor of Anatomy and Surgery in the University of Vermont in 1825; on the organization of the Jefferson Medical College in Philadelphia, became the Professor of Anatomy, but in 1827 accepted the chair of Surgery in the University of Maryland; in 1838 became Professor of Practical Medicine in the Transylvania University, Lexington, Ky.; in 1840 returned to the University of Maryland; invented a method of lithotomy, an excellent suspensory apparatus for fractured inferior extremities, and wrote *Surgical Anatomy of the Arteries* (1832) and other medical works. D. in Baltimore, Md., July 3, 1877. Revised by S. T. Armstrong.

Smith, Richard Somers: soldier and educator; b. in Philadelphia, Pa., Oct. 30, 1813; graduated at the U. S.

Military Academy July 1, 1834; assigned to the Second Infantry as brevet second lieutenant, but served on topographical duty until 1836, when he resigned to follow the profession of civil engineering. In 1840 he was reappointed in the army, with rank of second lieutenant of infantry; first lieutenant 1846; transferred to the Fourth Artillery 1848. He was Assistant Professor of Drawing at the Military Academy 1840–55; resigned from the army, and was Professor of Mathematics and Drawing in the Brooklyn Polytechnic Institute, which position he retained until 1859. From 1859 to 1861 he was a director of the Cooper Union; on May 14 of the latter year he re-entered the army, with rank of major, and was assigned to the Twelfth Infantry. He served on mustering and disbursing duty until the latter part of 1862, when he rejoined his regiment, and was engaged in the battle of Chancellorsville May 2–4, 1863. Soon after this (May 30) he relinquished his commission to accept the presidency of Girard College, Philadelphia, and held that position until 1868. He was Professor of Civil Engineering in the Polytechnic College of the State of Pennsylvania 1868–70; Professor of Mathematics 1870–73; and 1873–77 at the head of the department of drawing at the U. S. Naval Academy at Annapolis. In 1857 Columbia College conferred upon him the degree of A. M. He was the author of *A Manual of Topographical Drawing* (Philadelphia, 1854) and *Manual of Linear Perspective* (1857). D. at Annapolis, Md., Jan. 23, 1877.

Smith, Richmond Mayo, Ph. D.: economist; b. at Troy, O., Feb. 9, 1854; A. B., Amherst College, 1875; studied at the Universities of Berlin and Heidelberg 1875–77; assistant in history, Columbia College, 1877–78; adjunct professor 1877–83; Professor of Political Economy and Social Science, Columbia College, since 1883; member of the National Academy of Science; honorary fellow Royal Statistical Society; member of the International Statistical Institute; author of *Statistics and Economics* (1888); *Emigration and Immigration* (1890); and numerous magazine articles.

Smith, Robert: mathematician; b. in England in 1689; took orders in the Church of England; succeeded his cousin and friend, Roger Cotes, as Professor of Astronomy at Cambridge 1716; edited Cotes's works with commentaries; published *A Complete System of Optics* (2 vols., 1738) and *Harmonics, or the Philosophy of Musical Sounds* (1749), and succeeded Bentley as master of Trinity College 1742. D. at Cambridge, Aug., 1768. By his will he left £2,000 to Trinity College and £2,500 to the university for the support of the astronomical professorship and the maintenance of two annual prizes (since called the Smith prizes) for proficiency in mathematics and natural philosophy.

Smith, Robert: brother of Gen. Samuel Smith; b. at Carlisle, Pa., Nov., 1757; served as a volunteer at Brandywine; graduated at Princeton 1781; studied law, which he practiced with distinction at Baltimore; was for some years a member of the Maryland Legislature; was Secretary of the Navy in the cabinet of President Jefferson 1802–05, Attorney-General Mar.–Dec., 1805, and Secretary of State under President Madison 1809–11; was for several years president of the American Bible Society and of the Maryland Agricultural Society, and provost of the University of Maryland. Author of an *Address to the People of the United States* (1811). D. in Baltimore, Nov. 26, 1842.

Smith, Robert Barnwell: See Rhett.

Smith, Robert Payne, D. D.: clergyman and author; b. in Gloucestershire, England, Nov., 1818; graduated with honors at Oxford 1841; took orders in the Church of England; became sub-librarian of the Bodleian Library, Oxford, 1857; canon of Christ Church and Regius Professor of Divinity, Oxford, 1865; Dean of Canterbury, in succession to Henry Alford, 1871. He published (in Latin) a *Catalogue* of the Syriac MSS. in that library; edited and translated from the Syriac the *Commentary* of Cyril of Alexandria on Luke (1858); translated from the same language the *Ecclesiastical History* of John of Ephesus (1860); commenced in 1868 for the delegates of the Clarendon Press a *Syriac Lexicon*, based on that of Castell (10th fasciculus 1895); is author of *The Authenticity and Messianic Interpretation of the Prophecies of Isaiah vindicated in a Course of Sermons preached before the University of Oxford* (1862); *Prophecy a Preparation for Christ* (1865), being the Bampton lectures for that year; *Exposition of the Historical Portions of the Writings of Daniel* (1886); and the commentary on Jeremiah in the series known as *The Speaker's Commentary*, on Isaiah in the *Commentary* of the Society for the Promotion of Christian Knowledge, on Samuel in *The Pulpit Commentary*, and on Genesis in *Bishop Ellicott's Commentary*. He visited the U. S. as a delegate to the general conference of the Evangelical Allianee in Oct., 1873. He was a member of the Old Testament revision eompany. D. Apr. 1, 1895.

Revised by S. M. Jackson.

Smith, Samuel: soldier; b. at Lancaster, Pa., July 27, 1752; removed in childhood to Baltimore; was some years in his father's counting-house; became a captain in Smallwood's Maryland regiment Jan., 1776: participated in the battles of Long Island, Harlem, and White Plains, and in the retreat through New Jersey; beeame major in Gist's battalion Dec. 10, 1776, and lieutenant-colonel 1777; was at the attack on Staten Island and at the battle of Brandywine; was placed by Washington in command of Fort Mifflin, which he gallantly defended from Sept. 26 to Nov. 11, when he was severely wounded and forced to remove to the Jersey shore; received the thanks of Congress and an elegant sword; was at Valley Forge and at the battle of Monmouth, after which he resigned his commission in the army, but continued to serve as colonel of militia; was a member of the Maryland constitutional eonvention 1776; member of Congress 1793–1803 and 1816–22; U. S. Senator 1803–15; and again 1822–33, serving much of the time as chairman of the finance committee, and occasionally as president *pro tempore* of the Senate; was major-general of militia at the defense of Baltimore against the British 1814; quelled a formidable mob in 1835, and was thereupon elected mayor. D. in Baltimore, Apr. 22, 1839.

Smith, Samuel Francis, D. D.: author and editor; b. in Boston, Mass., Oct. 21, 1808; graduated at Harvard 1829; studied theology at Andover Seminary; became a Baptist clergyman 1832; edited *The Baptist Missionary Magazine* at Boston 1832–33; was a prominent contributor to Dr. Lieber's *Encyclopædia Americana*; was pastor of a church at Waterville, Me., and Professor of Modern Languages in Waterville College 1834–42; pastor at Newton, Mass., 1842–54; edited *The Christian Review* 1842–49, and for many years was editor of the publications of the Baptist Missionary Union. He published (with Rev. Baron Stow) *The Psalmist* (1843); edited a volume of *Lyric Gems* (1844); wrote a *Life of Rev. Joseph Grafton* (1845); and is author of many well-known songs and hymns, including *My Country, 'tis of Thee* and *The Morning Light is Breaking*. On Apr. 3, 1895, he was given a very enthusiastic reeeption in Music Hall, Boston, and in many parts of the country the public-school children observed the day by singing his famous song. D. suddenly in Boston, Mass., Nov. 16, 1895.

Smith, Samuel Stanhope, D. D., LL. D.: educator; son of Rev. Dr. Robert Smith (1723–93); b. at Pequea, Pa., Mar. 16, 1750; graduated at Princeton 1769; was edueated at, and became a teacher in, his father's classical academy, pursuing meanwhile the study of theology; was tutor at Princeton 1770–73; was ordained to the Presbyterian ministry 1774; labored as a missionary in Western Virginia; was the first president of Hampden-Sidney College 1775–79; became Professor of Moral Philosophy at Prineeton 1779, also Professor of Theology 1783; vice-president of the college 1786, and president 1795; was a member of the committee appointed to draw up a system of government for the Presbyterian Church 1786; was an eloquent and effective pulpit orator and distinguished for courtly manners; published *An Essay on the causes of the Variety of Complexion and Figure of the Human Species* (Philadelphia, 1787); *Sermons* (Newark, N. J., 1799); *Lectures on the Evidences of the Christian Religion* (Philadelphia, 1809); *Lectures on Moral and Political Philosophy* (2 vols., Trenton, N. J., 1812); and *Comprehensive Views of Natural and Revealed Religion* (New Brunswick, N. J. (1815); completed the *History of the United States* (Philadelphia, 1816–17) begun by his brother-in-law, Dr. David Ramsay, and published a number of separate sermons and discourses. He married a daughter of his predecessor, Dr. Witherspoon; resigned the presidency on aceount of ill health 1812. D. at Princeton, Aug. 21, 1819. Two volumes of his *Sermons* were published posthumously in Philadelphia, 1821, preceded by a brief memoir.

Revised by S. M. Jackson.

Smith, Seba: journalist and humorist; b. at Buckfield, Me., Sept. 14, 1792; graduated at Bowdoin College 1818; became a journalist at Portland, editing successively the *Argus*, *Family Recorder*, and *Daily Courier*; married Miss Elizabeth Oakes Prince 1823; won a wide reputation as a

humorist by his *Letters of Major Jack Downing* (1833); lost his property 1839; settled in New York 1842; devoted himself successfully to literature, as did also his wife (see SMITH, ELIZABETH OAKES): published *Dewdrops of the Nineteenth Century* (1846); *My Thirty Years out of the Senate* (1859): *Powhatan, a Metrical Romance* (1841); *New Elements of Geometry* (1850); and *Way Down East, or Portraitures of Yankee Life* (1855); besides a vast number of uncollected verse and prose essays which appeared in various periodicals. D. at Patchogue, L. I., July 29, 1868.

Revised by H. A. BEERS.

Smith, SYDNEY: clergyman and author; b. at Woodford, Essex, England, June 3, 1771; was educated at Oxford, where in 1792 he became a fellow of New College; resided a few months in Normandy, where he mastered the French language, and in 1794 became curate of a lonely parish on Salisbury Plain. In 1796 he went to Edinburgh, where he remained five years, officiating in an Episcopal chapel; became intimate with Brougham, Jeffrey, and other brilliant young men, who in 1802 started *The Edinburgh Review*, Smith acting as original editor and contributing seven articles to the first number. Soon after this he went to London, where he became a popular preacher, and in 1804–06 delivered courses of lectures on moral philosophy, contributing also to *The Edinburgh Review* until 1827. In 1806 he was presented with the living of Foston-le-Clay, in Yorkshire, worth £500 a year, but situated in a desolate region. In 1809 he went to Heslington, near York, leaving Foston in charge of a curate, hoping to exchange it for a more desirable benefice. Not succeeding in this, he returned in 1814, built a comfortable rectory, in which he lived until 1828, when the chancellor, Lord Lyndhurst, appointed him canon of Bristol, and gave him the rectory of Combe-Florey. In 1831 he was made resident canon of St. Paul's, upon which he took up his abode in London, where he passed the remainder of his life in the discharge of his official duties, in literary labor, and in the pleasures of society, in which he was a great favorite for his wit and rare conversational powers. D. in London, Feb. 22, 1845. Among his most characteristic productions are his *Letters on the Subject of the Catholics, to my brother Abraham, who lives in the Country, by Peter Plymley* (1807–08; published anonymously), which had a large share in bringing about Roman Catholic emancipation. He published several volumes of sermons, many occasional discourses, and political and social essays. His early lectures on moral philosophy were edited by Francis Jeffrey, and published under the title *Elementary Sketches of Moral Philosophy* (1849). Several volumes of selections from his various works have appeared, the best of which is *Wit and Wisdom of Rev. Sydney Smith*, accompanied by a biographical sketch and notes, by Evert A. Duyckinck (1856). His memoirs have been written by his daughter, the wife of Sir Henry Holland (1855). Also see *Life and Times of Sydney Smith* (London, 1884), by Stuart J. Reid.

Smith, Rev. WALTER C.: See the Appendix.

Smith, WILLIAM: geologist; b. at Churchill, Oxfordshire, England, Mar. 23, 1769; in the practice of his profession as mineral surveyor was led to notice and make maps of the succession of geological strata; he published a *Tabular View of the Order of the Strata, and their Imbedded Organic Remains, in the Neighborhood of Bath* (1799); *Mineral Survey, or Delineations of the Strata of England and Wales* (1815, with sixteen colored maps); *Strata identified by Organized Fossils* (1816–19); *Stratigraphical System of Organized Fossils* (1817); issued between 1819 and 1824 no less than twenty-one colored geological maps of English counties; delivered lectures in most of the provincial towns of England; superintended the model farm of Sir John V. B. Johnstone at Hackness, Yorkshire, 1828–34; received from the Geological Society of London the first Wollaston medal for his important discoveries, and in his later years received a pension of £100 a year. He discovered and was first to apply the principle of the classification and correlation of formations by means of their contained fossils, and has hence been called "the father of English geology." D. at Northampton, Aug. 28, 1839. Revised by G. K. GILBERT.

Smith, Sir WILLIAM: editor and author; b. in London, England, May 20, 1813; graduated in London University; studied law at Gray's Inn, but never practiced; was for some years Professor of Greek, Latin, and German in the Independent colleges of Highbury and Homerton, and on their consolidation as New College, St. John's Wood, accepted the professorship of the Greek and Latin Languages and Literature; became classical examiner in the University of London in the year 1853, and editor of *The Quarterly Review* in 1867. He is widely known by his exeellent series of classical dictionaries, having published those upon *Greek and Roman Antiquities* (1840; 2d ed., enlarged and revised, 2 vols., 1891), *Biography and Mythology* (1849), and *Geography* (1852–57), as well as by his *Dictionary of the Bible* (1860–63) and *Dictionary of Christian Antiquities.* He prepared numerous classical schoolbooks, an *English-Latin Dictionary* (1870), a *Biblical and Classical Atlas* (1875), and a series of *Students' Manuals* of ancient and modern history, etc. He was knighted in 1892. D. Oct. 7, 1893. Revised by A. GUDEMAN.

Smith, WILLIAM ANDREW, D. D.: preacher and educator; b. at Fredericksburg, Va., Nov. 29, 1802; became a preacher of the Methodist Episcopal Church South; in 1846 became president of Randolph-Macon College; in 1866 resigned, and after serving as pastor two years became president of Central College; was a leading member of every General Conference from 1832 to 1866; was appointed at the General Conference of 1866 one of the commissioners on the part of the Southern Church to settle the property question with the Northern Church; wrote *Lectures on the Philosophy and Practice of Slavery* (Richmond, 1860), which may be considered as the fullest and ablest presentation of the pro-slavery view of the question. D. at Richmond, Va., Mar. 1, 1870. Revised by A. OSBORN.

Smith, WILLIAM FARRAR: soldier; b. at St. Albans, Vt., Feb. 17, 1824; graduated at the U. S. Military Academy July 1, 1845; appointed brevet second lieutenant of topographical engineers; served as Assistant Professor of Mathematics at West Point, on several surveys, and on lighthouse-construction duty; in July, 1861, was appointed colonel of the Third Vermont, and was engaged in the first battle of Bull Run on the staff of Gen. McDowell. Commissioned brigadier-general of volunteers (Aug. 13), he served in the defenses of Washington until Mar., 1862, and in the Virginia Peninsular campaign of 1862; promoted to be major-general of volunteers July 4, 1862, he led his division in the Maryland campaign, at South Mountain, and Antietam. In Nov., 1862, he was assigned to the command of the Sixth Corps, and engaged at Fredericksburg; transferred to Ninth Corps Feb., 1863. In Oct., 1863, he became chief engineer of the department of the Cumberland and in November of the division of the Mississippi. In Mar., 1864, he was confirmed as major-general of volunteers, and in May assigned to the Eighteenth Corps; on special duty under orders of the Secretary of War Nov., 1864–Dec., 1865. In Nov., 1865, he resigned his volunteer commission, and in Mar., 1867, his commission as major of engineers in the regular army. He was breveted from lieutenant-colonel to major-general; president of the International Telegraph Company 1864–73; appointed police commissioner New York city 1875; president of the board Dec., 1875–Mar., 1881; civil engineer in service of the U. S. since 1881; by act of Congress of Feb., 1889, reappointed major U. S. army, and was retired Mar. 1, 1889.

Smith, WILLIAM LOUGHTON, LL. D.: b. in Charleston, S. C., 1758; educated in England and Switzerland; returned to Charleston in 1783; was a member of Congress 1789–97; an able supporter of the administration of Washington and Adams, and an active opponent of Jefferson, against whom he published a pamphlet; was minister to Portugal 1797–1800, and to Spain 1800–1801. D. in South Carolina in 1812. Author of a volume of *Speeches*, published in London 1794, an *Address* (1794) to his constituents on the difficulties pending with England, a *Comparative View of the Constitutions of the States* (Philadelphia, 1796), and various other political pamphlets.

Smith, WILLIAM ROBERTSON, D. D., LL. D.: theologian and Orientalist; b. at Keig, Aberdeenshire, Scotland, Nov. 8, 1846; studied at Aberdeen, Edinburgh, Bonn, and Göttingen; was appointed Professor of Hebrew in the Free Church College at Aberdeen in 1870; made an extensive journey in Arabia in 1879–80, which he described in a series of exceedingly interesting letters to *The Scotsman.* In 1881 he was removed from his office by an extraordinary act of the General Assembly on account of his critical views of the Old Testament published in the *Encyclopædia Britannica.* In 1883 he was appointed Professor of Arabic in the University of Cambridge; in 1886 librarian to the university, but exchanged the position for the Adams Arabic professorship in 1889, succeeding William Wright. He was associated with

Prof. T. S. Baynes in editing the *Encyclopædia Britannica* from 1881 till Prof. Baynes's death (1887), when he became sole editor, and finished the work the next year. He was extraordinarily learned and versatile. D. at Cambridge, Mar. 31, 1894. Besides numerous contributions to scientific journals, he published *The Old Testament in the Jewish Church* (London, 1881; 2d ed. 1892); *The Prophets of Israel, and their Place in History to the Close of the Eighth Century B. C.* (1882); *Kinship and Marriage in Early Arabia* (1885); *The Religion of the Semites* (1889; new ed. 1894).

Revised by S. M. Jackson.

Smith, Sir William Sidney: sailor; b. at Westminster, England, in 1764; entered the navy at the age of twelve as midshipman under Lord Rodney; was captain in the Swedish service in the naval war with Russia, and received a Swedish order of knighthood for gallantry in action; served with distinction under Lord Hood at Toulon Dec., 1793; was taken prisoner by the French at Havre 1796, and confined two years in the Temple, Paris, whence he escaped 1798; was given command of a squadron in Turkish waters the same year; captured a French flotilla at St. Jean d'Acre Mar. 16, and successfully defended that fortress against Napoleon May, 1799; proceeded to Egypt; negotiated the treaty of El Arish Jan., 1800; was wounded at the battle of Alexandria 1801; destroyed the Turkish fleet at Abydos 1807; was knighted 1815; became admiral 1821, and lieutenant-general of marines 1830. D. in Paris, May 26, 1840. See his *Life*, by Sir John Barrow (London, 1848).

Smith College: an institution for the higher education of women, at Northampton, Hampshire co., Mass. It was founded in 1871 by Miss Sophia Smith, of Hatfield, Mass., who bequeathed funds to furnish women—in her own words—"with means and facilities for education equal to those which are offered in our colleges for young men," with the ultimate purpose that a woman "may be better qualified to enjoy and do well her work in life, whatever that work may be." Rev. L. Clark Seelye, D. D., LL. D., elected in 1873, has been the only president of the college since its foundation. The college was opened for students in 1875, and the first class numbered fourteen. The curriculum comprises three courses—classical, literary, and scientific—each occupying four years. The institution has also schools of music and art, the course in the former requiring three years and in the latter four years for completion. The college is entirely unsectarian in management and instruction, but students and teachers meet daily for worship, and the study of the Bible is a part of the course. The buildings number eighteen. They comprise College Hall (assembly hall, lecture-rooms, reference library, and offices), Lilly Hall of Science, music hall, Hillyer art gallery (with studios and extensive collections), observatory, botanical plant house, alumnæ gymnasium (the gift of the graduates), president's house, and ten dwelling-houses for students. These buildings are clustered toward the front of the grounds, which stretch a considerable distance in the rear and are ample for outdoor exercise and recreation. The faculty, inclusive of the president, number (1900) seventy-four; undergraduates, 1,131.

E. A. Grosvenor.

Smith's Falls: post-village; Lanark County, Ontario, Canada; on Rideau Canal, and on the Canadian Pacific Railway, at the junction of the Perth Branch (see map of Ontario, ref. 2–H). The chief industry is the manufacture of stoves and agricultural implements. Pop. (1891) 3,864.

Smithson, James: scientist; b. in England about 1765; was a natural son of Hugh Smithson, first Duke of Northumberland; was educated at Oxford, graduating in 1786 under the name of Lewis Macie; was chosen a fellow of the Royal Society in the following year; devoted himself to science, especially in the fields of chemistry and mineralogy, and published many papers in the scientific periodicals. He was a friend and associate of many of the most learned men of his day, not only in Great Britain, but upon the Continent. He lived usually in Paris, where he was an intimate of Arago, and was a familiar figure in the scientific circles of other European capitals. Sometime between 1791 and 1803 he took the name of Smithson. D. in Genoa, Italy, June 27, 1829. For an account of his munificent bequest to the U. S. and its employment in the maintenance of a national scientific institute, see Smithsonian Institution.

Smithsonian Institution: an establishment in Washington, D. C., for the advancement of learning under the patronage of the Government of the U. S., organized in 1846. Its founder was James Smithson (see Smithson, James), whose will was found to contain the following clause in relation to a residuary bequest: "I bequeath the whole of my property to the United States of America, to found at Washington, under the name of the Smithsonian Institution, an establishment for the increase and diffusion of knowledge among men." It is almost certain that he knew Joel Barlow in Paris, and very probable that he was familiar with his plan for a realization of Washington's project for a great national institution of learning in the Federal city. The phrase "an institution for the increase and diffusion of knowledge" occurs in Washington's farewell address (Sept. 19, 1796).

In 1835 the U. S. legation in London was notified that his estate, amounting in value to about £100,000, was held in possession of the accountant-general of the British court of chancery.

As soon as the facts became public great opposition to the acceptance of the gift arose in Congress. Eminent statesmen, led by Calhoun and Preston, argued that it was beneath the dignity of the U. S. to receive presents, and that the donor was seeking immortality for too moderate an equivalent. The acceptance of the gift was ardently advocated by others under the leadership of ex-President John Quincy Adams. Richard Rush was finally appointed agent to prosecute the claim. He proceeded to London, entered suit in the court of chancery in the name of the President of the U. S., and, owing to the generous tolerance of the British authorities, brought the matter to a conclusion in less than two years. The decision was favorable. The legacy was received by Mr. Rush in the form of 104,960 sovereigns, which were delivered by him Sept. 1, 1838, to the Philadelphia mint, and immediately recoined into U. S. money, producing $508,318.46, the first installment of the legacy. This

Smithsonian Institution, Washington, D. C.

was soon after increased to $515,169, and in 1867 by a residuary legacy of $26,210.63 to $541,379.63, the total sum derived from the founder's beneficence, which by careful management had been in 1867 increased to $650,000. At one time in the early history of the institution a large portion of its fund was in certain State bonds which became worthless: Congress appropriated money to make good the loss, and the permanent fund is held as a deposit at 6 per cent. in the U. S. treasury.

During the eight years that passed before any use was made of the money public opinion had an opportunity to shape itself, and the organization in Washington in 1840 of the National Institution (afterward the National Institute), which was intended by its promoters to become the nucleus for the development of Smithson's idea, gave opportunity for much experimental study in administration. The National Institute, which was for two or three years the largest and most active scientific society on the continent, developed many features which were ultimately adopted for the Smithsonian Institution and experimentally demonstrated that others were impracticable. It languished and died soon after the organization of the Smithsonian Institution, which it had hoped to incorporate with itself.

Administration.—The Smithsonian Institution was formally established by the act of Congress approved Aug. 10, 1846. As defined in the act of establishment it is composed of the President of the U. S., who is presiding officer *ex officio*, the Vice-President, the members of the cabinet, and the chief justice, and the "establishment" thus constituted is made responsible for the duty of "the increase and diffusion of knowledge among men."

In addition to the "establishment" the act provides for a "board of regents," by whom the business of the institution is administered, and which is composed of the President of the U. S., the chief justice of the Supreme Court, three members of the Senate, three members of the House of Representatives, and six citizens appointed by joint resolution of the Senate and House of Representatives, no two of whom may be from the same State, though two must be residents of the District of Columbia.

The presiding officer of the regents is the Chancellor, whom they elect from their own number. This position is customarily held by the Chief Justice. The executive officer is the secretary of the institution, who is also elected by the regents. The duties and responsibilities of the secretary are such as in other institutions usually belong to the office of director, but the name of "secretary" is that which in Washington designates the highest grades of executive responsibility. The secretary makes all appointments on the staff of the institution, is responsible for the expenditure and disbursement of all funds, is the legal custodian of all its property, and *ex officio* its librarian and the keeper of its museum. He presents to the regents an annual report upon the operations, expenditures, and conditions of the establishment, which is transmitted by the board to Congress for publication. By special act of Congress of 1884 an acting secretary is provided in case of the absence or disability of the secretary, the designation being left with the chancellor of the institution. There is at present but one assistant secretary, who is in charge of the National Museum.

The annual meeting of the regents is held in January; their executive committee of three members meets quarterly.

The first meeting of the board of regents took place Sept. 7, 1846, and before the end of the year the policy of the regents was practically determined upon, for, after deciding upon the plan of the building now occupied, they elected to the secretaryship Prof. Joseph Henry, and thus approved his plan for the organization of the institution which had already been submitted to them. Eminent alike as a man of science and an administrator, Henry for more than thirty years directed the activities of the organization.

Objects of the Institution.—These as defined by Henry are, first, to increase knowledge by original investigations and study either in science or literature; and, second, to diffuse knowledge not only through the U. S., but everywhere, and especially by promoting an interchange of thought among those prominent in learning in all nations. No restriction is made in favor of any one branch of knowledge.

The leading features of the plan of Prof. Henry were, in his own words, "to assist men of science in making original researches, to publish them in a series of volumes, and to give a copy of them to every first-class library on the face of the earth." Probably there is not a scientific investigator in the U. S. to whom a helping hand has not at some time been extended by the institution, and the hand has often reached across the Atlantic. Books, apparatus, and laboratory accommodation have been supplied to thousands, and each year a certain number of money grants have been made. Not less important has been the personal encouragement afforded and advice given in the tens of thousands of replies written each year in response to inquiries.

Publications.—The publications of the establishment, which are regularly distributed to about 4,000 institutions, are as numerous as those of a great publishing-house, and are practically all given away. In addition to the annual report, which contains in its appendix articles of popular interest in regard to scientific progress, there are two series printed at the cost of the Smithson fund: (1) The *Smithsonian Contributions to Knowledge*, 28 volumes in quarto, containing nearly 15,000 pages and many fine plates. (2) The *Smithsonian Miscellaneous Collections*, in 35 octavo volumes, aggregating about 22,000 pages. Besides these there are the series of *Bulletins* of the National Museum, 50 in number, beginning in 1875; the *Proceedings* of the National Museum, including already 1,100 separate papers, embraced in 17 annual volumes, beginning with 1878; the *Annual Reports* of the Bureau of Ethnology, beginning in 1879 and forming a series of 12 illustrated volumes in royal octavo; and the *Bulletin* of the bureau, of which 26 numbers have appeared. The value of the books distributed since the institution was opened can not be much less than $1,000,000, estimating at standard publishers' rates.

In return for its own publications, and by purchase, the institution has received the great collection of books which form its library, and which is one of the richest in the world in the publications of learned societies. This includes more than 300,000 titles, the greater portion of which, by permission of Congress, have been placed in the National Library at the Capitol, where they are kept by themselves as the Smithsonian Deposit. The working libraries of the National Museum and the Bureau of Ethnology are distinct from the general Smithsonian Library, and separately administered.

System of Exchanges.—The Smithsonian system of international exchanges, begun in 1852, had for its object the free interchange of scientific material between scientific institutions and investigators in the U. S. and those in foreign lands, and its results have affected beneficially the libraries of most of the learned institutions in America. In 1867 Congress assigned to the institution the duty of exchanging fifty copies of all public documents for similar works published in foreign countries. Finally, in 1889 a definite treaty, made previously at Brussels, was formally proclaimed by the President of the U. S., wherein the U. S. Government, with a number of others, undertook the continuation of the exchange service on a more extensive basis. Out of this has grown the Bureau of International Exchanges, for the maintenance of which Congress partially provides by annual appropriation. From 1852 to 1893 the Smithsonian exchange service handled 1,175,000 packages. The number of correspondents upon its lists is about 24,000.

The National Museum.—The Smithsonian is by law the custodian of the National Museum, of which the secretary of the institution is the legal keeper. This museum is supported entirely by the Government, but previously part of its maintenance was from the Smithson fund. It is the only lawful place of deposit of "all objects of art and of foreign and curious research, and all objects of natural history, plants, and geological and mineralogical specimens, belonging, or hereafter to belong, to the U. S., which may be in the city of Washington in whosesoever custody." The nucleus of these collections consists in the specimens brought home by the Wilkes and other early exploring expeditions, but for many years the museum was supported entirely at the expense of the Smithson fund, and a considerable portion of the collections is the property of the institution. See NATIONAL MUSEUM OF THE UNITED STATES.

Bureau of Ethnology.—The Bureau of American Ethnology is an outgrowth of activities begun in the early days of the history of the institution, and has for its object the investigation of the languages, habits, customs, and classification of the North American Indians. In 1879 a special appropriation was made by Congress for this work, which is (1895) still in progress under the direction of Maj. John W. Powell, who has been the director of the bureau from the start. With the aid of a well-trained staff, he has rescued from destruction a vast amount of important material in regard to the early inhabitants of the continent, priceless

not only to students of American ethnology, but in the study of mankind as a whole.

Astrophysical Observatory.—Under the immediate direction of the present secretary an astrophysical laboratory has been established, in which important investigations upon the constitution of the sun are being carried on.

The National Zoölogical Park established by Congress in 1890, under the direction of the institution, occupies a tract of 166 acres, on Rock creek, 2 miles N. of the center of the city. The grounds are nearly twice as extensive as those of any other zoölogical park, and are possessed of admirable natural advantages, but the appropriations for the development of the park have not been sufficient to allow of any satisfactory progress.

The American Historical Association is by law affiliated with this institution, and transmits its annual reports to Congress through the secretary.

The institution supports a table at the International Zoölogical Station in Naples for the benefit of American naturalists.

An important feature of the institution's work has been its participation in the various expositions. It was represented at Philadelphia in 1876, Berlin 1880, London 1883, New Orleans 1885, Cincinnati 1889, Madrid 1892, and Chicago 1893, and on each occasion received awards of the most commendatory nature.

There is an assembly-hall in the museum building, in which meetings of scientific bodies of national scope are held. There the National Academy of Sciences holds its annual meeting every April, and the American Historical Association its December meeting. Here also each year a course of popular scientific lectures is delivered under direction of the scientific societies of Washington.

The office of secretary has been held by three men: Joseph Henry, elected in 1846, Spencer Fullerton Baird, in 1877, and Samuel Pierpont Langley, in 1888. Each in addition to his general administrative work in the institution has made some feature of the general plan peculiarly his own. Secretary Henry, besides establishing the general policy of, gave especial attention to, the publications, the system of international exchanges, the library, and the development of that great system of meteorological observation and weather prediction which has since been transferred to another department of the Government, and now constitutes the Weather Bureau.

Secretary Baird continued the development of the museum, which had been under his special charge during his twenty-seven years of service as assistant secretary, secured the erection of the new museum building, gave much attention to explorations, and carried on, in connection with his special work as U. S. commissioner of fisheries, a most extensive biological investigation of the waters of North America.

To Secretary Langley is due the establishment of the National Zoölogical Park, and of the astrophysical observatory, and a new system of encouragement of original research in the physical as well as in the biological sciences. Under his administration also important donations and bequests have been added to the permanent fund of the institution. The limit of $1,000,000, which may by law be permanently deposited in the U. S. treasury at 6 per cent., has nearly been reached, and Congress has recognized the authority of the institution to receive and administer other funds, beyond the above-named limit, thus making it possible for it to undertake the administration of financial trusts for any purpose within the scope of its general plan, preserving in connection with each fund the name of the person by whom it was established. This privilege has already been accepted by several benefactors. The Hodgkins fund, derived from the gift of Thomas G. Hodgkins, is being thus administered, in addition to the Hodgkins medal, which is to be awarded from time to time for important discoveries in regard to atmospheric air. The Avery fund, the bequest of Robert P. Avery, provides for special investigations in the fields of magnetism, electricity, etc.

Buildings.—The building occupied by the institution and bearing its name is an ornate structure of Seneca brownstone, occupying a prominent place in the Mall which extends from the Capitol to the Washington Monument—in a square known as the Smithsonian Grounds. It was planned by James Renwick, Jr., and was in construction from 1847 to 1855. The temporary wooden structure occupied by the astro-physical observatory stands in the rear of the Smithsonian building, and the National Museum building, of brick, 325 feet square, is at its eastern end. The Bureau of Ethnology occupies rented quarters in the city, and the offices of the Zoölogical Park are in the park grounds.

G. Brown Goode.

Smith'sonite: the mineral *zinc carbonate* ($ZnCO_3$), named after Smithson, who was the founder of the Smithsonian Institution. It crystallizes in rhombohedrons of glassy luster, white when pure, with the hardness of apatite, and density when pure and normal = 4·455 at 0°; Naumann and Levy both give 4·45. It occurs abundantly at Lancaster, Pa., near Bethlehem, Pa., and at Perkiomen, Pa.

Smith-Stanley, Edward Geoffrey: See Derby.

Smock, John Conover: See the Appendix.

Smoke [O. Eng. *smoca*: Dutch, *smook*: Germ. *schmauch*. Perh. cf. Gr. σμύχειν, smolder]: the product of an imperfect combustion. If coal, which is chiefly composed of carbon, hydrogen, nitrogen, and oxygen, be burned perfectly, the result will be carbonic acid, steam, and nitrogen, which substances will escape through the chimney-top and blend with the atmosphere under the form of invisible and incombustible gases and vapor. But as the combustion of coal in the way in which it is generally burned is very imperfect, inflammable gases and vapors and large quantities of fine particles of carbon issue together with the above substances, form soot and black and brown smoke, contaminate the air, and cause a considerable loss of fuel. As coal-smoke is a great nuisance, and in large towns and manufacturing districts even a serious evil, much attention has been paid to the matter of burning it. This is attended with great practical difficulties, arising from the necessity of preventing the smoke from cooling and of supplying the combustible gases and vapors with the necessary amount of oxygen in order to make them burn with flame; but these difficulties are nevertheless not greater than may be generally overcome, as they have been in many single cases. See Combustion.

Smokeless Powders: explosives acting without the production of smoke. They may be divided into three classes: 1. Those composed of cellulose nitrate, either the insoluble or soluble variety, or both. 2. Those composed of the constituents of 1 mixed with nitroglycerin or other organic nitrates. 3. Those composed of the constituents of 1 mixed with nitro-derivatives of hydrocarbons, such as pieric acid and the picrates. Each of these varieties may contain oxidizing agents like barium or potassium nitrates and retarding agents such as tannin or lycopodium.

Among the best-known and most successful of these powders are of the first class indurite, used by the U. S. navy, and B. N., used by the French; of the second class ballistite, used by the Italians, and cordite, used by the British; and of the third class Peyton powder.

These powders are more or less smokeless because the products of their combustion are wholly gaseous, whereas 55 per cent. of the products of the combustion of ordinary gunpowder is finely divided solids. This property of smokelessness is the feature of these powders which has attracted the widest popular attention; but though it is a desirable property, and one which has modified strategy and tactics, the most valuable property common to these powders is the high velocities which they impart to projectiles and which greatly exceed those which it is possible to secure with black gunpowder.

In order not to endanger the gun it is essential that the pressure developed by the burning powder shall be within prescribed limits. The best powder is that one which gives the maximum initial velocity with the minimum chamber pressure; which gives uniform results when used under uniform conditions; and which undergoes no change, either chemical or physical, under the exposure incident to the military and naval service. The best record thus far reported for any powder is from the firing trials of indurite made at Indian Head proving-ground, Maryland, when 26 lb. of this powder, fired in the 6-inch service-gun, imparted to a 100-lb. projectile an initial velocity of 2,469 feet per second, while it exerted but 13·96 tons pressure on the gun. Repeated rounds gave remarkably uniform results. See Explosives.

Charles E. Munroe.

Smolensk': government of European Russia, S. W. of Moscow, and traversed by the Dwina, which runs to the Gulf of Riga, and the Dnieper, which flows to the Black Sea. Area, 21,638 sq. miles, consisting generally of extensive plains interspersed with morasses. The climate is cold, but healthful; the soil is fertile and well cultivated, yielding

large crops of rye, the principal product, and of hemp and flax. Tobacco and hops are also cultivated. On its extensive pastures large numbers of fine cattle are raised, while its vast forests, abounding with game, furnish a large amount of valuable timber. Much attention was formerly paid to the raising of bees, and honey and wax were exported. Copper, iron, and salt are found in considerable quantities. Its manufactures are unimportant. Pop. (1897) 1,550,973.

Smolensk: town; capital of the government of Smolensk, Russia; on the Dnieper; 250 miles W. S. W. of Moscow (see map of Russia, ref. 7-D). It is surrounded by massive walls, that are rapidly falling into decay, and has a magnificent cathedral, an episcopal palace, monasteries, several good educational institutions, including a military school, manufactures of linen, carpets, leather, and soap, and a considerable export trade in grain and flax. Pop. (1897) 46,889.

Smollett, Tobias George: novelist; b. at Dalquhurn House, Cardross, Scotland, in 1721; lost his father in early childhood; was educated at Dumbarton school by the care of his grandfather, Sir James Smollett, of Bonhill, a member of the Scottish Parliament; studied also at Glasgow, where he served an apprenticeship to a surgeon; went to London at the age of nineteen, carrying a tragedy entitled *The Regicide*, which he unsuccessfully offered to the theatrical managers; accepted the position of surgeon's mate in the navy; participated in the unfortunate expedition against Cartagena 1741; resided for some time in Jamaica; returned to England 1746; married in 1747, Miss Anne Lascelles, whom he had known in Jamaica; published in 1748 with great success his first novel, *The Adventures of Roderick Random*, in which he made good use of his West Indian experiences; visited Paris 1750; published *The Adventures of Peregrine Pickle*-(4 vols., 1751); after endeavoring to obtain medical practice at Bath, settled at Chelsea 1753, in which year he wrote *The Adventures of Ferdinand, Count Fathom*; published a translation of *Don Quixote* (1755); issued *A Compendium of Authentic and Entertaining Travels* (7 vols., 1757), in which he embodied his own experiences at Cartagena; edited for some time a Tory organ, *The Critical Review*; was fined and imprisoned three months for a libel on Admiral Knowles (1759); wrote in fourteen months a *Compleat History of England, deduced from the Descent of Julius Cæsar to the Treaty of Aix-la-Chapelle* (4 vols., 1757–58), to which he subsequently added a *Continuation from 1748 to 1760* (4 vols., 1763), of which the later volumes have been often reprinted as a supplement to Hume; translated *Gil Blas* (4 vols., 1761); wrote in prison his *Adventures of Sir Launcelot Greaves* (1762); edited *The Briton*, a newspaper in defense of Lord Bute (1762–63); aided Thomas Francklin and other writers in bringing out a translation of the *Works of Voltaire* (37 vols., 1761–70); made a journey through France and Italy 1763–66, which furnished materials for a work of *Travels* (2 vols., 1766); satirized Bute and the elder Pitt in his *Adventures of an Atom* (1769); went for his health to Italy 1769, and wrote on the journey *The Expedition of Humphrey Clinker* (3 vols., 1771), his best novel. D. at Monte Novo, near Leghorn, Italy, Sept. 17, 1771. Smollett ranks with Richardson and Fielding as one of the standard novelists of the eighteenth century, founders of the English school of prose fiction. He was greatly influenced by Cervantes, Le Sage, and the whole group of Spanish "rogue" or *picaro* novelists. His stories are narratives of low life, travel, and broadly comic adventure, vigorous and racy, but coarse to the verge of brutality. In the persons of Commodore Trunnion, Jack Rattlin, Tom Bowling, and other nautical characters he introduced into fiction the now familiar figure of the British tar. Many complete editions of his novels and poems have been published. Biographies were written by Dr. Robert Anderson (1796), Dr. John More (1797), Thomas Roscoe (London, 1840; New York, 1857), and D. Hannay (Great Writers' Series, 1887). Revised by H. A. Beers.

Smolt: See Salmon.

Smuggling [like Germ. *schmuggeln*, from Low Germ. *smuggeln*; connected with root *smug-* of Germ. *schmiegen*, snuggle up to, and O. Eng. *smūgan*, creep]: the (statutory) offense either of bringing into a country articles entirely prohibited, or of defrauding the customs revenue by secretly importing goods upon which duties are laid without paying such duties or without paying the full amount required by law. In Great Britain the offense includes the exporting of goods with like intent, and (as often defined) the introduction of any articles into consumption without paying the duties chargeable upon them. As the whole subject of the customs revenue is the creature of statute, the offenses which consist in its evasion or violation are also of a statutory origin. In Great Britain and Ireland smuggling is especially restrained by the Customs Laws Consolidation Act of 1875 (39 and 40 Vict., c. 36).

Smuggling in the U. S.—In the U. S. the regulation of this offense belongs exclusively to the jurisdiction of the national legislature and judiciary, being included in the power of Congress to regulate all foreign commerce. The body of the existing law is contained in the *Rev. Stat. of the United States*, especially in tit. xxxiv., chap. 10, §§ 3058 to 3094 (although some provisions are scattered through other chapters relating to the imposition and collection of duties), and in the *Supp. of the Rev. Stat. of the United States*, p. 32, *seq.*, where smuggling is defined as "the act, with intent to defraud, of bringing into the United States, or, with like intent, attempting to bring into the United States, dutiable articles without passing the same, or the package containing the same, through the custom-house, or submitting them to the officers of the revenue for examination."

Penalties.—The following penalties may be enforced for various acts which are collectively embraced in the general description of smuggling: (1) The guilty person is liable to a fine of not more than $5,000 and not less than $50, or to imprisonment for not more than two years, or to both. (2) The goods fraudulently introduced or attempted to be introduced are to be seized, and, if condemned by the court, are to be forfeited and sold. (3) The vessel in which the goods are thus imported may be likewise seized, condemned, and forfeited if the owner or managing agent was consenting to and guilty of the offense. (4) Any vehicle, conveyance, team, beast, etc., by means of which goods are wrongfully brought into the country by land may also be seized and forfeited; but no such conveyances belonging to and used by common carriers, whether persons or corporations, are liable to forfeiture unless the owner, superintendent, or agent in charge is consenting or privy to the illegal importation. (5) Various pecuniary penalties may be visited upon the owners or masters of vessels for certain specific violations of the law, such as resisting or hindering the revenue officers and the like; which penalties are made liens upon, and may be summarily enforced against, the vessels themselves. Cases involving any of the foregoing forfeitures or pecuniary fines are reported to the proper U. S. district-attorney, and it is his duty to prosecute the delinquent or to procure a condemnation of the property in the national courts.

Detection of Smuggling.—The customs officers are clothed with very large powers in order to detect and punish any fraudulent importation or concealment, or failure to pay the full duties required by the law. They may board and search all vessels lying in port, and all those bound to the U. S. while not more than 4 leagues from the coast. They may also search all persons coming into the country, all trunks, boxes, or other baggage, papers, envelopes, all conveyances and means of transport, stores, warehouses, and other buildings—in short, all places or things where the goods themselves or the evidence of their wrongful importation may possibly be concealed. Finally, by means of an order of the court they may obtain an inspection of the books of account and business papers of merchants and others suspected of or charged with the wrongful non-payment of duties. When the property seized is condemned and sold, the proceeds, after paying the costs and expenses, are distributed, part to the U. S., part to the principal customs officers of the district, and part to the informer if there was any distinct from the officer himself who detected the offense and procured the seizure. Revised by F. Sturges Allen.

Smuts [: Germ. *schmutz*, dirt; Dutch, *smet*]: the *Ustilagineæ*, an order of minute parasitic fungi principally attacking the higher plants, and often producing serious injuries to farm and garden crops (Fig. 1). In some portions of England they are known as dust-brands. They consist of slender, branching, colorless threads, which grow through the tissues of their hosts, following the intercellular spaces, or actually penetrating and even filling the cell-cavities. After a period of growth, the threads produce spores in great numbers, forming dark, dusty masses, which have suggested the popular name of these organisms.

No sexual organs are known in any of the smuts, and it is probable that in this group of plants the structural degradation due to excessive parasitism is so great that these organs have been lost. This degradation is shown in the soft-

walled cells composing the filaments, and also in the distorted and irregular spore-bearing masses (Fig. 2) which may be

Fig. 1.—Smut on Indian corn, reduced one-half.

regarded as crushed and distorted spore-sacs (*asci*). The spores arise within these crushed masses as rounded bodies,

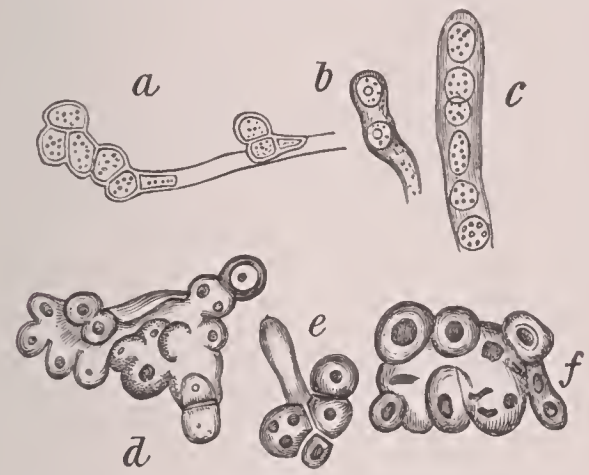

Fig. 2.—Formation of spores: *a b c*, in *Ustilago maydis*; *d e*, *U. antherarum*; *f*, *U. flosculosorum*, magnified 900 times.

which soon acquire a dark-colored, thick, smooth, or roughened wall. At maturity the spores are set free by the deliquescence of the cell-walls of the spore-bearing masses. In a few cases the spores are borne singly, and rarely they appear to be in little distorted ascus-like cells (Fig. 2, *c*).

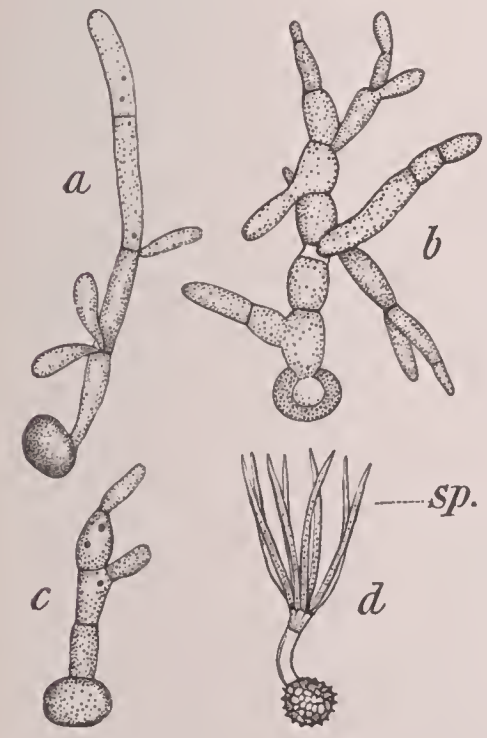

Fig. 3.—Germination of smut spores: *a*, *Ustilago avenæ*, × 1,000; *b*, *U. tritici*, × 800; *c*, *U. hordei*, × 700; *d*, *Tilletia tritici*; *sp.*, the sporidia, × 200.

The production of spores usually takes place in those parts of the parasite which have penetrated the flowering or fruiting portions of the host, and which as a consequence are generally much distorted (Fig. 1). The spores are distributed by winds, after the rupture of the epidermis of the host and the escape of the surplus moisture.

Germination takes place by the protrusion of a short filament (Fig. 3) known as the *promycelium*, upon which are borne minute spores (the *sporidia*), which are so minute that they may readily be dispersed by the wind. The parasite gains access to the embryo host plant by penetrating the tender walls of the epidermal cells, and it appears that in many, if not all, cases it is impossible for such penetration to take place when the host has made a considerable growth.

The smuts are divided by Schroeter into two families, as follows:

I. *Ustilaginaceæ*, with septate promycelium, bearing lateral sporidia. About 150 species, nearly all of which (143) belong to the genus *Ustilago*.

Wheat Smut (*U. tritici*), called also the "loose smut" of wheat, injures the heads of unripe wheat by destroying the kernels, and turning them into black dusty masses of spores (Fig. 4). The spores are very small (about 5·5 by 6·5μ), ovoid or elliptical, and minutely verruculose.

Oat Smut (*U. avenæ*) affects unripe heads of the cultivated oat, destroying them before the ripening of the crop. The spores are larger than the preceding (about 7μ or 6·5 by 8μ), globose or ovoid, and faintly verruculose.

Barley Smut (*U. hordei*) likewise destroys the unripe heads of barley. The spores are nearly of the same size as in the oat smut (about 7μ), globose and smooth.

Fig. 4.—Head of wheat affected by *U. tritici*, reduced to one-half natural size.

The three foregoing species have generally been confounded under the name of *U. carbo*, or *U. segetum*, but investigations by Jensen, confirmed by Kellerman, prove them to be distinct. These experimenters have found that these smuts may be greatly reduced by immersing the grains for eight to fifteen minutes in water heated to 56° C. (133° F.), then drying before sowing.

Maize Smut (*U. maydis*) is parasitic upon Indian corn, causing swellings and distortions of the kernels (Fig. 1), and sometimes, also, similarly affecting the staminate flowers, and even the leaves and stems. The spores are large (8 to 13μ), globose and echinulate.

Other species occur on sorghum (*U. sorghi*), foxtail grass (*U. neglecta*), and many other grasses, sedges, knotweeds, etc.

II. *Tilletiaceæ*, with non-septate promycelium, bearing terminal sporidia. About 170 species, distributed among 9 genera, of which the principal are *Tilletia* (33 species), *Entyloma* (41), *Urocystis* (27), *Thecaphora* (18), *Sorosporium* (23).

Bunt, or Stinking Smut (*Tilletia tritici* and *T. fœtens*).—These two species, which differ in the first having reticulated spores and the second smooth ones, are parasitic upon wheat, filling the kernels at maturity with a mass of closely packed, fetid spores (Fig. 5). Both are common in the U. S., Europe, and most other wheat-growing countries. Bunt may be prevented by the hot-water treatment referred to above.

Fig. 5.—*a*, head of wheat affected with bunt; *b*, kernels filled with spores, × one-half; *c*, spores of *T. tritici*, × 200; *d*, spores of *T. fœtens*, × 200.

Onion Smut (*Urocystis cepulæ*) attacks the leaves of cultivated onions, often seriously damaging the crop in the eastern parts of the U. S.

Literature.—In addition to the standard works on fungi, the reader is referred to the following: J. B. de Toni, *Ustilagineæ*, in Saccardo's *Sylloge Fungorum*, vol. vii. (1888);

J. Schrocter, *Die Pilze Schlesiens* (1889); C. B. Plowright, *A Monograph of the British Uredineæ and Ustilagineæ* (1889); Kellerman and Swingle, *Report on the Loose Smut of Cereals*, in *Second Annual Report* of the Experiment Station of the Kansas Agricultural College (1889).

CHARLES E. BESSEY.

Smyr'na [= Lat. = Gr. Σμύρνα. Cf. σμύρνα, myrrh]: city; in the vilayet of Aidin, Asia Minor; in lat. 38° 25′ N. and lon. 24° 50′ E., at the eastern extremity of the Gulf of Smyrna (see map of Turkey, ref. 5–D). It presents a magnificent appearance as seen from the water, spreading along the bay and up the slope of Mt. Pagus. A fine quay over 3 miles in length, along which the tramway runs, lines the shore, and in front is a spacious and sheltered harbor. Were it not for the hundreds of camels constantly traversing the quay, Smyrna with its modern edifices would be taken at first glance for a city of Western Europe. It still justifies its poetical names of Crown of Ionia, Eye of Anatolia, Pearl of the East. The slow deposits of the river Hermus and the quantities of rubbish thrown into the water threaten its existence as a port.

Its origin is lost in myths. According to tradition, Tantalus, about 1500 B. C., was its founder. Its name is said to be derived from Smyrne, the Amazon, the wife of Theseus. Colonized by the Grecks soon after the Trojan war, it was constantly fought over by the Æolians and the Ionians, and ultimately remained in the possession of the latter. Taken and dismantled by Alyattes, King of Sardis (628 B. C.), it was rebuilt according to the order of Alexander the Great by Antigonus and Lysimachus. It rapidly developed, and has since that time been the chief commercial city of Asia Minor. Here was one of the Apocalyptic churches. Captured by the Seljuk pirate Tzachas (1080), Smyrna suffered greatly, but was soon retaken by the Greeks. The Seljuk prince of Aïdin conquered it (1313), but a crusading fleet drove out the Moslems. The Roman Catholic faith was introduced in 1346, and the city has contained ever since many members of that communion. Tamerlane, after defeating Bayezid I. at Angora (1401), filled up the port, carried the place by storm and butchered the inhabitants. Since 1424, when it was conquered by Murad II., it has remained in the undisturbed possession of the Ottomans save that it was sacked by the Venetians in 1473. The site of the city, though always near the bay, has changed many times. Smyrna has often suffered from earthquakes, notably in 177 (after which it was rebuilt by Marcus Aurelius), 1688, 1778, and 1880; and from plague, as in 1812 and 1837.

The streets run generally parallel with or at right angles to the shore. The houses are built of wooden beams encased in stone, as safer in fire and earthquake. There are several free hospitals, each prominent nationality having its own, and numerous churches of the leading Christian faiths, as well as a synagogue and several mosques. The schools are excellent, especially those maintained by the Roman Catholic and Protestant missionaries. Educational advantages are nowhere greater in the Ottoman empire. Six newspapers are published. Smyrna is the western terminus of the great inland commercial routes and of two railways that run eastward into the interior of Asia Minor. It is the chief mart for European commerce in Anatolia. The principal imports are sugar, coffee, cotton, silk and woolen goods, worked leather, nails, machinery, earthenware, building-stone, lumber, cordage, etc.; the exports, dried fruits, raw silk and cotton, opium, wheat, rice, valonia, oil, sesame, goatskins, carpets, wax, emery, cheese, beans, bones, mohair, etc. The exports average about $20,000,000 annually in value, and the imports about $15,000,000.

Smyrna possesses some remarkable ruins, as the Genoese castle on the summit of Mt. Pagus, the theater lower down, the stadium and scant remains of the temple of Diana. Pop. (estimated 1893) 225,000, of which about half are Greeks, the rest being Turks, Armenians, Europeans, and Jews. The Levantines, offspring of marriages between Europeans and natives, are numerous. E. A. GROSVENOR.

Smyrna: town; Kent co., Del.; on Duck creek, and the Phila., Wil. and Balt. Railroad; 36 miles S. W. of Wilmington, 60 miles S. of Philadelphia (for location, see map of Delaware, ref. 4–N). It is in an agricultural and fruit-growing region; is engaged in ship-building and the manufacture of agricultural implements, fruit-baskets, sashes, doors, and other articles; and contains a public high school, two national banks, and a weekly paper. Pop. (1880) 2,423; (1890) 2,455; (1900) 2,168.

Smyth, CHARLES PIAZZI, LL. D.: son of Admiral W. H. Smyth; astronomer; b. in Naples in 1819; was employed for some time under Sir T. Maclear in the observatory of the Cape of Good Hope; was appointed royal astronomer for Scotland in 1845, which position he resigned in 1888; made a valuable series of observations from the Peak of Teneriffe 1856; published *Teneriffe, an Astronomer's Experiment, or Specialties of a Residence above the Clouds* (1858); in 1859 visited the Russian observatories (see his *Three Cities in Russia*, 2 vols., 1862), and made a thorough examination of the Great Pyramid of Egypt, which he considers to have been built under divine inspiration as a standard of a system of weights and measures. This theory is set forth and defended in three works—*Our Inheritance in the Great Pyramid* (1864), *Life and Work at the Great Pyramid* (3 vols., 1867), and *Antiquity of Intellectual Man* (1868). He composed a comprehensive star catalogue and ephemeris of selected observations of the same stars, published in the Edinburgh Observatory's publications (1877–86). D. Feb. 21, 1900.

Smyth, EGBERT COFFIN, D. D.: educator; son of Rev. William Smyth (1797–1868), Professor of Mathematics in Bowdoin College; b. at Brunswick, Me., Aug. 24, 1829; graduated at Bowdoin College 1848, and at Bangor Theological Seminary 1853. In 1854 he was made Professor of Rhetoric and Oratory in Bowdoin College; in 1856 he succeeded Rev. Dr. Roswell D. Hitchcock as Professor of Natural and Revealed Religion in the same institution; and in 1863 was appointed Professor of Ecclesiastical History in Andover Theological Seminary. Since 1878 he has been president of the faculty there. He is one of the board of trustees of Bowdoin College, and was for a number of years a member of the prudential committee of the American Board of Commissioners for Foreign Missions. He translated (with Prof. C. J. H. Ropes) Uhlhorn's *Conflict of Christianity with Heathenism* (1879), has published many addresses, sermons, and scholarly articles, and was one of the founders and editors of *The Andover Review*. Revised by G. P. FISHER.

Smyth, HERBERT WEIR: Greek scholar; b. at Wilmington, Del., Aug. 8, 1857; A. B., Harvard, 1878; Ph. D., Göttingen, 1884; instructor in Williams College 1883–85; in Johns Hopkins University 1885–88; appointed Professor of Greek in Bryn Mawr College 1888; secretary of American Philological Association. He has published *Der Dipthong EI im Griech.* (1884); *Sounds and Inflections of the Greek Dialects*, vol. i., *Ionic* (1894); and various papers on philological subjects in *The American Journal of Philology*, *Transactions of the American Philological Association*, and *The Classical Review*. C. H. THURBER.

Smyth, JOHN: clergyman; b. in England about 1552: graduated at Cambridge 1575; became a fellow; took orders in the Church of England; was reproved by the heads of the university in 1586 for having advocated a Judaic observance of Sunday, but persisted in his teachings; connected himself with the Puritans; was minister at Gainsborough to a congregation with which he emigrated to Amsterdam in 1606; was converted to Baptist principles by Mennonite theologians; caused an Anabaptist separation among the Puritan refugees in Holland, and maintained controversies with Ainsworth, Robinson, and others. D. at Amsterdam in Aug., 1612. He was the author of *A True Description of the Visible Church* (1589); *The Difference of the Churches of the Separation* (1608); *Parallels, Censures, Observations*, etc. (1609); *The Character of the Beast*, etc. (1609); and a *Declaration of the Faith of the English People remaining at Amsterdam* (1611), etc.

Revised by W. H. WHITSITT.

Smyth, NEWMAN, D. D.: brother of Egbert Coffin Smyth; b. at Brunswick, Me., June 25, 1843; graduated at Bowdoin College 1863, and at Andover Seminary 1867; was acting pastor in Providence, R. I., 1868; was in Europe 1868–69; was pastor of the First Congregational church in Bangor, Me., 1870–75, of the First Presbyterian church in Quincy, Ill., 1876–82, and in 1882 became pastor of the First church (Congregational) in New Haven, Conn. He was assistant teacher in the Naval Academy in Newport immediately after his graduation, and was first lieutenant of the Sixteenth Regiment of Maine Volunteers in the last year of the civil war. He has published *The Religious Feeling* (1877); *Old Faiths in New Light* (1877; revised ed. 1887); *The Orthodox Theology of To-day* (1881); *Dorner on the Future State* (1883); *The Reality of Faith* (1884)—a series of sermons; *Personal Creeds*, etc. (1890); *Christian Ethics* (1892); and various articles in reviews. Revised by G. P. FISHER.

Smyth, William Henry: sailor and hydrographer; b. at Westminster, England, Jan. 21, 1788; entered the navy in 1805; made surveys of Sicily, the shores of the Adriatic, and Sardinia; became rear-admiral in 1853 and hydrographer to the admiralty in 1857. Author of *The Mediterranean* (1854). D. near Aylesbury, England, Sept. 9, 1865.

Snail [O. Eng. *snægel* : Icel. *snigill* : dial. Germ. *schnegel*; cf. Germ. *schnecke*, snail < Teuton. **snag-*, crawl]: a name given to the terrestrial shell-bearing gasteropod molluscs generally, and frequently extended to the similar forms inhabiting the waters. The terrestrial snails are divisible into three categories—viz.: (1) Pulmonata (*q. v.*), including the inoperculate forms as well as allied forms living in the water, and also the slugs; (2) certain operculigerous forms (*Cyclostomidæ*, *Aciculidæ*, etc.) which are closely allied to the aquatic *Littorinidæ*, etc.; and (3) other operculigerous types (*Helicinidæ*, *Proserpinidæ*, etc.) which are representatives of another group, the *Diotocardia*. It is thus seen that the form of the shell and even the presence or absence of a shell are of very inferior systematic significance, and entirely subordinate to differences in structure of the animal. Those differences are chiefly exhibited by the modifications of the nervous system, the heart, the dentition of the lingual ribbon, and the organs of generation. See, further, Gasteropoda. Revised by J. S. Kingsley.

Snake-bird: See Darter.

Snake-bites: See Poison of Serpents.

Snake-eels: marine eels constituting the genus *Ophisurus*, allied to the common eel, but found only in warm latitudes. They are remarkable for the absence of the caudal fin, the end of the tail being much like that of a snake.

Snakefish: a name given on some parts of the English coast to the *Cepola rubescens*, otherwise called Bandfish (*q. v.*), and in parts of the West Indies and Bermuda to the *Synodus* (or *Saurus*) *lacerta*.

Snake Indians: See Shoshonean Indians.

Snake Plains: a region in Idaho through which Snake river flows in a deep cañon, covered by successive eruptions of basaltic lava which came from fissures and deluged an area of not less than 250,000 sq. miles, including parts of Oregon and Washington. In Idaho the lava occurs in horizontal sheets resting on older volcanic rocks, and the streams from the mountains flow beneath it, forming "lost rivers." I. C. R.

Snake River: a river which rises in the high mountains of Western Wyoming, N. of Yellowstone Lake, in two main branches, known as the North and South Forks, flows westward across Idaho, and then northward, forming the boundary between Idaho and Oregon for 200 miles, and the boundary between Idaho and Washington for 30 miles. It then turns westward and joins the Columbia in Washington near Pasco. Its length is between 800 and 1,000 miles. At the junction of the North and South Forks the elevation is 4,800 feet, and at its union with the Columbia 340 feet. Throughout a large part of its course it is a rapid stream, flowing in cañons from 1,000 to 3,000 feet deep, and is interrupted by magnificent cataracts. From the Idaho-Washington boundary to its mouth it has been navigated by small steamers. It flows through an arid region, the drainage of which has been rejuvenated on account of vast overflows of volcanic rock and probably also by reason of recent elevations, and the gorge it has cut is still narrow and steep-sided. Its tributaries also flow in cañons, making traveling near its course difficult. Israel C. Russell.

Snakeroot: any one of many plants believed to be efficacious in the cure of snake-bites. In the U. S. the name is applied to the following among others: (1) The black snakeroot or sanicle (*Sanicula marilandica*), a common umbelliferous plant, with a root of an aromatic taste, of some value as an antispasmodic. (2) *Eryngium yuccæfolium*, buttonsnake-root, or rattlesnake-master, is diaphoretic and expectorant. (3) The Seneca snakeroot (see Senega). (4) *Liatris spicata*, (5) *L. squarrosa*, and (6) *L. scariosa*, called also buttonsnake-root, blazing-star, rattlesnake-master, etc., showy composite-flowered plants, with stimulant and diuretic properties. (7) *Eupatorium ageratoides*, common in the Northern States and a good tonic, is called white snakeroot. (8) *Aristolochia serpentaria*, the well-known Virginia snakeroot, has valuable stimulant and tonic powers and a pleasant fragrance. (9) *A. reticulata* of the Southwest has properties similar to those of Virginia snakeroot, and produces much of the snakeroot of commerce. (10) *Cimicifuga racemosa*, or black snakeroot, is a valuable sedative and expectorant. (11) *Asarum canadense*, or wild ginger, is called snakeroot and Canada snakeroot in New England. It is fragrant, with properties much like those of *Aristolochia serpentaria*, but is much more pungent.

Snakes: See Serpents.

Snakestone: a small piece of stone, bone, or other substance which is placed upon the bite of a poisonous serpent for the purpose of absorbing or charming away the poison. The vulgar in almost all countries have faith in this and other like means of cure, such as the madstone, which is applied to the bite of a rabid dog. In India, snakestones are often used, and there are several apparently well-authenticated instances of their seeming efficacy. It is possible that some of these stones may have a strong absorptive power for the snake poison, for they are often porous, and the unlimited faith which the bitten persons have in this means used for cure is doubtless a powerful adjuvant.

Snake-wood: the name of a number of trees (see Letter-wood); also of the root and wood of *Strychus colubrina* and *S. nux-vomica*, esteemed as a remedy for snake poison.

Snapdragon: any plant of the genus *Antirrhinum*, family *Scrophulariaceæ*. The snapdragons are annuals and perennials, and many fine flowering varieties are cultivated, mostly belonging to *A. majus* and *A. orontium*, Old World plants of easy culture. L. H. B.

Snapper: any one of several fishes of the family *Lutjanidæ*. The species inhabit warm seas; they are carnivorous, with short intestines and few pyloric cæca; vomerine teeth and canines, no incisors or molars, and a continuous dorsal fin. The red snapper (*Lutjanus aya*), common on the Gulf coast of the U. S. in deep water, is an important food-fish. The mangrove snapper, or gray snapper (*L. griseus*), ranges from the West Indies N. to New Jersey, and is especially abundant along shore among mangroves. The name is improperly applied to the rosefish (*Sebastes marinus*), the bluefish, and several other fishes. See Fisheries.

Snapping Turtle: in the U. S., any one of several species of tortoises. (1) The common snapping turtle of the Northern and most of the Southern States is the *Chelydra serpentina*. This has the head moderately large, and covered with a soft skin, and the marginal scales of the shell are in a single row. It is said that it sometimes (though very rarely) attains a length of about 4 feet and a weight of 50 lb. It is found from Canada southward, and from the Atlantic seaboard westward to the plains. (2) A species which in some parts of the Southern States at least replaces the *Chelydra serpentina* is the *Macrochelys lacertina*. This animal has the head very large and broadly triangular, and it is covered with numerous horny plates; the marginal scales of the shell are in two rows. It reaches a very large size, sometimes weighing as much as 100 lb. It is confined to the Southern States, extending from Florida to Western Texas, and northward up to Missouri. It is perhaps more generally known as the alligator snapper. Both of these species belong to the family *Chelydridæ*, and are distinguishable from all the other turtles of the U. S. by the long and imperfectly retractile neck and tail, and the cruciform plastron or lower shell. Their popular name is due to the habit of snapping at food or enemies. Their bite is severe, and it is difficult to relax their hold. They are by many esteemed for food, especially for making soup. They have a rather strong musky odor. In the early summer they lay from twenty to forty eggs in a hole dug by themselves. (3) In some sections of the U. S. the name is also applied to the soft-shell turtles, or *Trionychidæ*, which snap abruptly at food or other objects. Revised by F. A. Lucas.

Sneezewood: the beautiful and durable timber of the *Ptæroxylon utile* (family *Sapindaceæ*), a tree of South Africa. When sawing or rasping it, joiners are much troubled by the sneezing which its fine dust provokes. Its wood is very inflammable, even when green.

Sneezing, or **Sternutation** [from Lat. *sternuta're*, intensive of *sternu'ere*, *sternu'tum*, sneeze; cf. Gr. πταρνύναι, sneeze]: a convulsive movement by which the lungs and chest-walls are expanded and then suddenly contracted, forcing the breath out violently through the nose. It is produced by reflex action, there being some irritation of the pituitary membrane of the nose which originates the action. The sneezing tends to remove the irritating substance from the nose. There are a large number of irritating substances

whose presence in the nostrils will induce sneezing. When it is a symptom of cold, it indicates that catarrhal inflammation has induced a state of things similar to that produced by a foreign substance in the nose. In children measles may begin with this symptom, and influenza is also frequently so initiated. Revised by W. Pepper.

Snell, Willebrord (also known as Snellius): astronomer and mathematician; b. in Leyden in 1591; succeeded his father as Professor of Mathematics at the University of Leyden in 1613. He discovered the law of the refraction of light. (See Optics.) He was also the first to calculate the size of the earth by measuring trigonometrically an arc of a meridian. The method he employed in this undertaking he described in his *Eratosthenes Batavus, sive de Terræ Ambitus vera Quantitate* (Leyden, 1617). He also wrote *Cyclometria, sive de circuli dimensione* (Leyden, 1621), and other works. D. in Leyden, Oct. 30, 1626.

Snera: See Mogador.

Snider, Denton Jaques: See the Appendix.

Snider Rifle (so called from its inventor): a rifle, the essential features of which are that the breech-block revolves around an axis on the right of and parallel to the axis of the bore, and the firing-pin passes obliquely from the nose of the hammer through the breech-block to the center of the base of the cartridge. This was the first form of breech-loader adopted by the British Government, which in 1866 directed that the old Enfield muzzle-loaders should be altered to breech-loaders upon this system. See Small-arms.

Snipe [M. Eng. *snipe* : Dutch, *snep*, *snip* : Germ. *schnepfe*, snipe : Swed. *snäppa*, sandpiper]: any bird of the family *Scolopacidæ*, which includes those known as shore-birds or sandpipers. (See Sandpiper.) More commonly the name is restricted to the marsh-haunting species of the genus *Gallinago*, about twenty in number, which are distributed over the greater part of the globe, but more particularly in temperate regions. They have a straight bill, considerably longer than the head, grooved to the end, which is slightly expanded, well supplied with nerves and used in probing the mud for worms. The eye is placed far back, over the ear. The plumage is streaked with shades of buff and brown, black and white, and blends completely with the ground. The tail-feathers vary from twelve to twenty-six. The American snipe (*Gallinago delicata*) is found in suitable places over the greater part of the U. S., breeding in the northern portions and thence northward. In winter it migrates, occurring as far S. as Brazil. It is sometimes called English snipe; but that bird, although very similar, is a distinct species (*Gallinago gallinago*), which does not reach North America, although occasionally found in Greenland. The jack-snipe of Europe (*G. gallinula*) is the smallest of the group; the great snipe of eastern South America (*G. gigantea*) is the largest. F. A. Lucas.

Snipefish: another name of the Bellows-fish (*q. v.*).

Snoho'mish: city; capital of Snohomish co., Wash.; on the Snohomish river, and the Everett and Monte Cristo, the Gt. North., and the Seattle, Lake Shore and East. railways; 9 miles from Puget Sound; 38 miles N. N. E. of Seattle (for location, see map of Washington, ref. 3–D). It is in an agricultural, mining, and lumbering region, has regular steamboat communication with Seattle, and contains a county court-house (cost $30,000), 3 graded public schools, 5 churches, about 20 sawmills and shingle-mills, 2 sash and door factories, Masonic and Odd Fellows' halls, water-works, electric lights, street-railways, 2 national banks with combined capital of $100,000, and 2 tri-weekly and 3 weekly newspapers. Pop. (1880) 149; (1890) 1,993; (1900) 2,101.

Editor of "Eye."

Snoilsky, snoil'skĕ, Karl Johan Gustaf, Count (*Sven Tröst*): poet; b. in Stockholm, Sweden, Sept. 8, 1841. He made his first appearance in print, with several other young poets, in the publication of the Upsala society Namnlösa sällskapet (1860). His earliest collection of poems, *Smådikter* (1861), is characterized by great warmth and originality, especially in the descriptions of Italian life and scenery. His sonnets (1871) and his translation of Goethe's ballads (1876) are among the best of their kind in recent Swedish literature. His later poems, *Nye dikter*, etc. (1881), are more national in spirit, and display a deep sympathy for the unfortunate and oppressed classes of society. For a number of years he has served with distinction in the Swedish diplomatic corps. See C. D. af Wirsén, *Om Karl Snoilskys skaldskap i Svea* (1882). D. K. Dodge.

Snorri Stur'luson [usually written Snorre Sturlason]: the most celebrated historian of old Iceland. He was born in 1178, and belonged to the numerous and powerful clan of the Sturlungs. He was fostered by the prominent chief Jon Loptson, at whose home he acquired the book-knowledge of his day, and he became particularly familiar with the old poetry and saga literature of Iceland and Norway. At the age of twenty Snorre married a wealthy woman, and by this marriage he became one of the most powerful chiefs of Iceland and was able to attend the Althing at the head of about 900 armed men. He was made speaker of laws (*lögsögumaðr*) several times, and for several years he was the richest and most influential man in the whole land. He became involved in the bloody feuds which in his time split the Sturlungs into warring factions, and he was continually implicated in litigation with his relatives and others in regard to property and inheritances. In 1218 he made his first visit to Norway, and was received into the household of the young king, Hakon Hakonson. In 1219 he visited the lagman Eskil in Sweden, and there he must have obtained that thorough knowledge of Sweden and Swedish affairs which appears in his writing. In 1220 he returned to Iceland, after having previously promised to work for the subjugation of Iceland to Norway. As he made no progress in the realization of this plan, he was suspected of faithlessness by the rulers of Norway, and his enemies in Iceland took advantage of this circumstance to bring about his ruin. After endless feuds in his own country, Snorre had to go a second time to Norway in 1237, but he lost the good will of King Hakon and was compelled to return to Iceland. On his arrival there he got into trouble with his son-in-law, Gissur Thorvaldson, who, at the instigation of King Hakon, murdered him on Sept. 22, 1241, at his home at Reykholt, where ruins of his splendid mansion are still to be seen. Snorre became Iceland's most distinguished sagaman, and he enjoys some reputation as a skald. As a writer of history he ranks with Herodotus or Thucydides. His *Heimskringla*, embracing an elaborate history of the kings of Norway to the death of Magnus Erlingson in 1177, is famous throughout the world. An English translation of this work was published by Samuel Laing in London in 1844, and a revision of Laing's translation by Rasmus B. Anderson appeared in London and New York in 1889. The *Younger Edda* also bears Snorre's name, and is to a great extent his work. See Edda and Icelandic Literature.

Rasmus B. Anderson.

Snow [O. Eng. *snaw* : O. H. Germ. *snēo* (> Mod. Germ. *schnee*) : Goth. *snaiws*; cf. Lith. *snĕgas* : Russ. *sniegŭ* : Ir. *sneachd* : Lat. *nix*, *nivis* : Gr. *νίφα* (acc.) < Ind-Eur. *sneighos* : *snoighos* : snow]: the aggregations of minute spicules of ice into which the excess of vapor in the atmosphere is condensed when the temperature is at or below the freezing-point of water. These aggregations, called snowflakes, though assuming a great variety of crystalline forms, usually present the outline of a hexagon or a six-pointed star. (See the illustration in the article Ice.) In high and middle latitudes the ground is covered with snow each winter, but within the tropical regions no snow falls at or near the level of the sea, for the temperature of the lower atmosphere is always sufficient to melt it, even if it is formed in the upper air. In the northern hemisphere the limit of the fall of snow at the sea-level is an irregular line passing mainly between 25° and 40° N. lat.; in the southern it is more regular, lying in the continents between lats. 37° and 38°. In general, this line is nearest to the equator in the regions most exposed in winter to the polar winds, as on the eastern coast of Asia and of North America. As the heat of the air decreases upward, the formation of snow is always possible upon high mountains, even under the equator. At the summit of the Andes and the Himalayas, for example, the moisture condensed during the rainy season falls in the form of snow, while it rains on the slopes and plains below. Thus in all latitudes from the equator to the poles the tops of high mountains are covered with a layer of permanent snow, which the summer heat is not sufficient to melt. The lower limit of perpetual snow, called the *snow-line*, varies in altitude in the different portions of the globe. Within the tropics it is found about 3 miles above the level of the sea; in temperate latitudes it descends to a little less than 2 miles; and at the northern limits of the continents it is about half a mile, or even less, above the level of the sea; while on the arctic islands vast fields of snow remain permanently very near the seashore.

The height of the snow-line, as observed in different latitudes, is given in the following table:

Latitude.	New World.	Feet.	Latitude.	Old World.	Feet.
75° N.	North Greenland	2,300	75° N.	Bear Island	600
54°	Unalashka	3,500	71°	Mageroe, Cape North	2,300
48°	Mt. Baker, Ore.	about 8,000	67°	Sulitelma, Lapland	3,800
43°	Rocky Mountains	12,500	61°	Scandinavian Alps	5,300
39°	Rocky Mountains	14,500	50°	Altai Mountains	7,000
38°	Sierra Nevada	11,000	46°	Alps, north side	8,900
19°	Popocatepetl, Mexico	14,900	46°	Alps, south side	9,200
5°	Tolima, Colombia	15,300	43°	Caucasus	11,000
1° S.	Andes of Ecuador	15,700	35°	Hindu Kush	13,000
17°	Andes of Bolivia, west side	18,500	31°	Himalaya, south side	16,200
17°	Andes of Bolivia, east side	15,900	31°	Himalaya, west side	18,600
33°	Andes of Central Chili	14,700	12°	Abyssinian Mountains	14,000
42°	Andes of Patagonia	6,000	3° S.	Kilimá Njaro	16,000
54°	Andes of Straits of Magellan	3,700	44°	New Zealand Alps	7,500

This table shows that though the height of the snow-line decreases toward the poles, its greatest altitude is not at the equator, but near the tropics, and that it is also subject to great irregularity of elevation.

Two conditions regulate the altitude of the snow-line—the quantity of fallen snow, and the amount of heat to melt it. Thus in the sub-tropical zones, which have less snow and no less summer heat, the snow-line is higher than at the equator. In similar latitudes the coast-regions, exposed to moist winds, have a lower snow-line than the interior of the continents with their scanty snows, dry atmosphere, and hot summers. The peaks of the Sierra Nevada bear perpetual snow 3,500 feet lower than the Rocky Mountains in the same latitude. The southern slope of the Himalayas, which condenses the vapors brought by the warm monsoons, has a snow-limit, on an average, 2,000 and in some places 4,000 feet lower than the northern slope on the dry and sunny plateau of Tibet. In the Alps the line of snow is somewhat higher on the southern slopes, exposed to the warm summer wind from Italy. In passing from the dry climate of Central Chili to the rainy region farther S., the snow-line descends from 14,700 feet to 6,000. A vast amount of snow in the latter region, and a wet, cloudy summer, account for the change. In the Rocky Mountains, in a latitude corresponding to that of the Patagonian Andes, the snow-line has an altitude of 12,500 feet—that is, full 6,000 feet higher. See Glaciers. Revised by M. W. Harrington.

Snow, Francis Huntington: See the Appendix.

Snowball: the *Viburnum opulus*, a cultivated shrub of the family *Caprifoliaceæ*, called also Guelder rose. To this species belongs the high-bush cranberry of the U. S., whose fruit is edible. The species is native to Europe and North America. The snowball is a variety with handsome globular cymes of sterile flowers. The Japanese snowball is *V. tomentosum* (*V. plicatum* of nurseries). Revised by L. H. Bailey.

Snowberry: the *Symphoricarpos racemosus*, a handsome shrub (family *Caprifoliaceæ*), common in the U. S. in many parts, and half naturalized in European shrubberies. Its persistent, white, inedible berries are well-known and familiar objects. The name is also given to *Chiogenes hispidula* (family *Ericaceæ*), a creeping woody plant, whose leaves and white edible berries have the taste of the checkerberry (*Gaultheria*). It is common in the northern parts of the U. S. and Canada. Revised by Charles E. Bessey.

Snowbird: any one of several species or varieties of the genus *Junco*. These belong to the family *Fringillidæ*, and have a small conical bill, the wings rather short, the middle toe shorter than the short tarsus, the outer toe rather longer than the inner, and extending to the claw of the middle one, and the tail nearly as long as the wings, slightly emarginate, and decidedly rounded; the color is blackish or ash above, white on the belly, and not developed in streaks anywhere; the outer tail-feathers are white. The several forms generally rather exceed 6 inches in length, of which the tail forms a little more than half. They are distributed over different regions of the U. S., seven species and four sub-species being generally recognized, although the differences between some of them are very slight. Of these, the form *hyemalis* is the only Eastern type, the others being found in the West. They are mostly birds of passage in the Eastern and Middle States, for while some breed in the mountains from North Carolina to New York, the majority go North to breed while yet snow may be on the ground, and return in the late fall. They feed on seeds and berries. The nests are built on the ground; they lay about four eggs, about three-quarters of an inch long, and of a yellowish white dotted with reddish brown. The name is sometimes applied to the snow-bunting (*Plectrophenax nivalis*), a pretty little finch found in high northern latitudes and seen in the northern parts of the U. S. in winter, sometimes in vast flocks. The back is gray, tail and wings black and white, under parts white. In breeding-plumage the back and bill are black, and there is more white in the plumage than in winter.

Revised by F. A. Lucas.

Snow-bunting: See Snowbird.

Snowden, James Ross: numismatist; b. at Chester, Pa., 1810; educated at Dickinson College; studied law and settled at Franklin, Pa.; was Speaker of the Pennsylvania House of Representatives 1842–44; State treasurer 1845–47; treasurer U. S. mint 1847–50, and director of the mint 1853–61; wrote the articles on U. S. coinage in *The National Almanac* (1863), also in Bouvier's *Law Dictionary* (1868); published seven annual *Reports* on the mint, and many addresses and pamphlets on coinage, currency, and allied subjects; was author of two beautifully illustrated volumes descriptive of the ancient and modern coins in the U. S. mint (Philadelphia, 1860), and of the medals and other objects of interest in the same collection (1861); of a volume on *The Mint at Philadelphia* (1861); *The Coins of the Bible and its Money Terms* (1864); and *The Cornplanter Memorial, an Historical Sketch of Gy-ant-wa-chia, "the Cornplanter," and of the Six Nations of Indians* (Harrisburg, 1867). D. at Hulmeville, Pa., Mar. 21, 1878.

Snowdrop: the *Galanthus nivalis* (family *Amaryllidaceæ*), a small herb much cultivated in gardens for its snow-white flower, appearing in earliest spring. A native of the Alps, it is naturalized in Northern Europe, and is becoming so in the U. S. A larger species, *G. imperatri*, is also grown.

Snowdrop-tree: either the *Halesia tetraptera* or the *H. diptera* (family *Styracaceæ*), small trees or large shrubs native in the southern parts of the U. S. They bear showy-white clusters of flowers, which appear in spring somewhat before the leaves. They are very fine in cultivation. A third species is *H. parviflora*, from Florida. By some recent authors the genus is called *Mohrodendron*.

Snowflake: the *Leucolum vernum*, *L. æstivum*, and the *L. aulumnale*, European herbs of the family *Amaryllidaceæ*, cultivated also in gardens in the U. S. They are hardy bulbous plants with white flowers. The bulb of the first-mentioned species has long been employed in the Old World as an emetic, and probably all have aero-narcotic powers.

Snow-goose: a goose of the genus *Chen*, the *Chen hyperborea*. Its popular name was given it both on account of the pure white plumage of the adult and because of its northern habitat. The forehead is frequently of a light-rusty color and the ends of the primaries dark. The snow-goose reaches a length of 2½ feet and a weight of 5 or 6 lb., breeds in the far north, and during migration is common in the interior of the U. S. and on the Pacific coast. It is rare on the Atlantic coast and is accidental in Europe.

F. A. L.

Snow Hill: city (chartered in 1894); capital of Worcester co., Md.; on the Pocomoke river, and the Phila., Wil. and Balt. Railroad; 5 miles from Chincoteague Sound, and 20 miles S. S. E. of Salisbury (for location, see map of Maryland, ref. 5–H). It has regular steamboat communication with Baltimore; ships large quantities of oysters, fruit, and vegetables to the Northern markets; and contains 8 churches, 2 graded public schools, a national bank with capital of $50,000, and 2 weekly periodicals. There are manufactories of cotton goods, whips, baskets, feed, lumber, and shooks, and a canning factory. Pop. (1890) 1,483; (1900) 1,596.

Snuff: See Tobacco.

Snyder, Zachariah Xenophon: See the Appendix.

Snyders, Frans: painter; b. at Antwerp, 1579. He was a pupil of Peter Breughel, the younger, and afterward of Hendrik van Balen. He became a friend of Rubens. He began by painting still life only, but when he returned to his native city in 1609 after a visit to Italy, he began to produce pictures of the chase, in which he depicted the struggles of eager hounds with savage beasts at bay, introducing the human figure also. Rubens, whom he followed, sometimes made use of his services as an assistant. Snyders is celebrated as a fruit-painter. The Louvre possesses a *Concert of Cats* by him, and the gallery of the Prado at Madrid has many pictures of his, as also the National Gallery in London and the galleries of St. Petersburg, Antwerp, Munich, Dresden, Brussels, and other European cities. D. at Antwerp, Aug. 19, 1657. W. J. Stillman.

Soane, Sir John, F. R. S.: originally called Swan; architect; b. at Reading, England, Sept. 10, 1753; son of a bricklayer; was sent to Italy for three years (1777–80) as a traveling student at the cost of the Royal Academy; appointed architect to the Bank of England 1788; executed plans for the country-seats of many of the opulent gentry, a volume of which was printed in 1788; became clerk of the works to St. James's Palace and the houses of Parliament 1791, and Professor of Architecture at the Royal Academy 1806; published a volume of his plans of *Public and Private Buildings* (1828) and a *Description* (1827) of his own house and museum in Lincoln's Inn Fields, where he died Jan. 20, 1837. This house, with its art and antiquarian museum, he bequeathed to the nation. Among its treasures are pictures by Hogarth, Reynolds, and Turner, and models by Flaxman.

Soap [M. Eng. *sōpe* < O. Eng. *sāpe*: Germ. *seife* < Teuton. **saipjō*, whence Lat. *sāpō* > Fr. *savon*: Ital. *sapone*]: any salt of the fatty acids with a metallic base, usually a soda or a potash. All the true Oils and Fats (*qq. v.*) are decomposed by the alkaline hydrates, by certain metallic oxides, and also by acids, high steam, and hot water. In the decomposition of fats by alkalies the products formed are glycerin and the alkali salts of the fatty acids which were contained in the fats. This process is known as *saponification*. As a rule, soaps produced from soda are *hard soaps*, while those produced from potash are *soft soaps*. Castor oil, however, forms with potash a hard and brittle soap. A fundamental distinction between the hard and soft soaps is found also in the fact that in the former the glycerin is removed in the mother liquor or spent lye, while in the latter it remains mingled with the semi-fluid mass. Moreover, it is not possible to dry the potash soaps, owing to the very hygroscopic character of the base, while soda soaps may be so completely dried as to admit of grinding to powder.

Saponification takes place slowly in the cold, much more quickly by aid of heat, and the presence or absence of air is immaterial. The result depends on the nature of the fat or oil as well as on the base; e. g. if the fat is complex—containing, for example, stearin, palmitin, olein, etc.—then as many new salts are formed as there are fatty acids to combine with the base.

In the production of soap by the action of caustic potash on stearin (glyceryl stearate) the products are glycerin and potassium stearate; thus:

Stearin.	3 molecules pot. hydrate.		Glycerin.	3 molecules of potassium stearate.	
$(C_{18}H_{35}O)_3$	K_3		$(C_3H_5)'''$	$(C_{18}H_{35}O)_3$	
$(C_3H_5)'''$ O_3 +	H_3	O_3 =	H_3	K_3	+ O_3

Formerly in North America and Russia much larger quantities of potash were obtained in clearing up forests than now, and hence potash soaps were produced in proportionate quantity. These were, especially in Germany, converted into hard or soda soaps by utilizing the property of the potassium-salts in decomposing common salt or sodium sulphate, forming potassium chloride or sulphate and soda soap. Moreover, the enormous production of caustic soda at a cheap rate consequent on the adoption of Leblanc's soda-process, stimulated by the great demand for bleaching-powders, of which sodium salts are a by-product, has well-nigh put an end to the use of potash in producing soap, excepting as an element of domestic economy in those regions where potash is still a common product. Thus in Canada and in some other parts of North America "pot-ashes" and "pearlashes" are still articles of considerable importance.

As a technical art, soap-boiling depends on the use of caustic lyes of a suitable strength for the saponification of fats, oils, and resins. The lye of the soap-boiler is a dilute alkaline liquor prepared by the action of slaked lime (calcium hydrate) on a boiling solution of 3 parts of potassium carbonate in 12 parts of water, or the same quantity of sodium carbonate (soda-ash) in half this quantity of water. "The manufacturer nowadays buys solid caustic soda or potash from the alkali-works. The sodium aluminate obtained by the decomposition of cryolite is used in the U. S. under the name *Natrona refined saponifier* for soap-manufacturing purposes" (*Wagner*).

The manufacturer of hard soap, having provided a stock of alkaline liquors (lyes) of various strengths, charges his soap-pan with a quantity of neutral fat or oil, and adds weak liquors of about 1·050° density. Soap-pans are made of iron plates riveted at the joints, and of various sizes, from 10 to 15 feet in diameter and of proportionate depth, set over fire-chambers, or more frequently heated by steam, either in jackets or injected from numerous small holes pierced in pipes introduced into the liquors. They vary in capacity, of course, but many hold from 20 to 30 tons of soap. As the temperature rises and the oil and alkali liquor mingle, a uniform milky emulsion is formed in which neither oily globules nor water are visible on cooling a portion of the fluid. The operator watches for this change, and adds more solution of alkali or water, as the case may require, until the emulsion forms and all alkaline taste has disappeared, using the tongue as a test. Stronger liquors are then added gradually to complete the displacement of the glycerin, which was begun by the weak liquors, and the boiling continues until a strong alkaline taste is detected. The workman then adds more fat or oils, and repeats the use of stronger lyes until gradually the soap-pan is nearly filled, taking care that at the last there shall be no excess of alkali. During this series of operations he often also adds a portion of resin, which by virtue of its constitution undergoes a kind of saponification with alkalies, and adds to the product more than its value in weight and volume. Then comes the next important stage of the soap-boiling operation, in which, by the addition of salt, the emulsion of oils and alkali is decomposed, the salt taking the water and causing the precipitation of the newly formed soap in a curdy or granulated state, floating on the dense spent lyes in which is found the glycerin and salt, but no alkali. This mother liquor, after the separation of the soap is complete, is withdrawn and rejected as having no value. The imperfectly developed soap is subjected a second time to a like series of operations as at first; it is brought by boiling to a homogeneous state, more oils or fats and strong alkaline liquors are added until the whole has a decided alkaline taste, and more salt is then added to cause the separation of the soap from the alkaline solution, and the whole mass is kept boiling for some time until all the fats, etc., are completely saponified. This completes the chemical part of the operation if the soap contains no rosin, and after allowing time for subsiding of the dregs the "curd" is transferred by skimmers to the "frames," where it cools and becomes solid preparatory to cutting up for use. If the soap contains rosin it requires a further treatment before framing—viz., the curds, after removal of the spent liquor and dregs, are melted with more water and boiled by steam or fire or both. A homogeneous compound results, containing an indefinite quantity of water, which is permitted to rest for two or three days, when it separates into a stratum of a definite compound containing about 65 per cent. of fat acids, 6·5 of soda, and 28·5 of water, and resting on a lower stratum of an indefinite compound containing much more water and the dregs or sediments of the operation. This lower stratum, called nigre, contains also an excess of alkali, and forms with the addition of fat and salt the staple of another "boil" for more soap. The nigre which accumulates with each boil is used as a mottling for clouded soaps, or may otherwise be worked up in subsequent operations. A strong preference at one time existed for mottled soaps, founded on the fact that in such soaps no excess of water could exist. The substances which impart the mottled appearance, being heavier than soap, were held in suspension only in consequence of its thick and pasty condition. It is, however, possible so completely to simulate the appearance of genuine mottled soap, by adding mineral and other colors during the process of hardening to soaps containing much more than the normal quantity of water, that this sign has lost its value, and such mottlings are justly re-

garded as only evidence of impurity from the introduction of bodies foreign to soap. Good hard white soap contains fatty acids, 61·0; soda, 6·2; water, 32·8.

The soaps vary chiefly with the fats or oils from which they are produced, and may be considered as forming two principal classes—viz., soaps made from vegetable oils and those from animal oils and fats.

A. Vegetable Hard Soaps.—*Marseilles or Castile Soap.*—In Southern Europe soap is largely made of olive oil mixed with about 20 per cent. of rape-seed oil. This soap is noted for its firmness, freedom from the depraved animal odors found too often in tallow soaps, and in general for its excellent qualities. Without the addition of rape-seed oil the soap from olive oil is so hard as to crumble when cut, and is difficult to dissolve in water. This soap has a peculiar mottling—like granite, and not in streaks of color, as in the imitations made from animal fats. The best olive-oil soap is made in Spain and Portugal, also in Provence and Aix, from oil hot-pressed from the olives after the virgin and table oils have been extracted: 100 parts of new and good oil produce 175 parts of finished soap when no rape oil is used, by which the product is reduced to 170 parts or less. The richness of olive oil in margarin or palmitin is the reason for the superior quality of the soap it produces. The marbling of the Marseilles soap is due to iron, which is sometimes added as sulphate, and is changed to sulphide by the alkaline sulphide present in the soda. By exposure to the oxidizing influence of air the dark stains of ferric sulphide are changed to a reddish color. Dr. Normandy found the foreign castile (or Marseilles) soap (sp. gr. = 1·0705) to contain fatty acids, 76·5; soda, 9; water and coloring-matter, 14·5 = 100. The English imitation (sp. gr. = 0·9669) gave fatty acids of pasty consistence, 75·2; soda, 10·5; water with a little coloring-matter, 14·3 = 100.

Cocoanut-oil Soap.—Marine Soap.—The soap made from the oil of the cocoanut is remarkable for its extreme hardness, and consequently for the very large amount of water it can hold without becoming soft. It has a disagreeable odor, which is with difficulty removed. The oil requires for its saponification a very strong lye, and is aided by the use of potash. This soap is not easily decomposed by weak saline liquors, and is hence used to wash in salt water, whence its name of marine soap. This quality of carrying a large amount of water has led to the use of cocoanut-oil soap as a means of mottling weak soda soaps from tallow, etc. Such soap can be made to hold up manganese oxide, ultramarine, etc., in connection with far more water than can be introduced into a genuine castile soap.

Rosin Soap.—Common Yellow Soap.—Rosin boiled with alkaline liquors, whether caustic or carbonated, is converted into a soapy emulsion. It is not a true soap, but from its plastic, viscid nature it is found to be a good vehicle for diluting true soaps from tallow or other fats. The process of manufacture for rosin soap varies from that of soap from oils or fats alone by the omission of the last boiling. By itself, rosin does not form a hard soap, and unless it is thoroughly treated by strong liquors it leaves on the hands or any surface washed with it a resinous varnish and offensive odor of rosin. It forms, when carefully prepared and not in excessive quantity, a very serviceable soap, which quickly forms an excellent lather and is very cheap.

Castor-oil soap and *palm-oil soap* are both soda soaps, although the oil of the castor-bean forms a hard soap with potash, and is remarkable, like the cocoanut-oil soap, for the large quantity of water which may be combined with it—as much as 70 per cent. The palm oil is saponified like tallow soap; it is used chiefly as an addition to yellow rosin soap, as the unbleached oil has a decided yellow color, and its strong and rather agreeable odor serves to disguise the disagreeable odor of rosin soap, which also acquires in addition a certain transparency, due to the palm oil.

B. Tallow and other Animal-fat Soaps.—Under the heads of fats and oils is given nearly all that is needful to say of hard soaps from animal fats and oils. The old German hard soap was prepared from crude tallow by lye of ashes or potashes, giving an imperfect soap, which in the subsequent boiling is converted into soda soap by salt, which, being at the same time supplied with an excess of alkali, produces a neutral soda soap, and is then boiled down to curd with salt. This art long preceded the knowledge of chemical principles underlying it. The indications of saponification, advancing by all the grades of the process, are so distinct that no thought was entertained at first of working with weighed quantities. All that was required was to add more lye or more fat, according to appearance, until the proper state had been attained. In all respects the teachings of this empiric experience led to the same result which chemical knowledge has since illustrated and confirmed. The use of crude tallow has been abandoned in favor of purified grease, and the abundance of pure caustic soda renders useless the old methods of leaching ashes for potash lye or of boiling up soda-ash with lime. Experiment shows that 100 lb. of tallow produce 150 to 155 lb. of perfect curd soap, weighed as soon as it is cut; if more is obtained it is because water is added.

Oleic Soap, or Red Soap.—This soap, resulting from the lime-saponification of animal fats in the stearic-acid manufacture, is an important product wherever the manufacture of stearin candles is carried on. As the glycerin has already been removed, the saponification of the oleic acid is readily effected even by alkaline carbonates. It is also mingled with neutral fats, and saponified by soda-lye of 18° B. A patented process for producing soap from red oil depends on treating the oleic acid in a steam-heated copper while agitated by a steam-twist with carbonate of soda, etc., in equivalent proportion in the state of fine powder, added in successive portions, with or without rosin, according as a coarser soap or a fine toilet-soap is required. The relative proportions of oleic acid, water, and rosin in this soap being adjusted at the beginning, there is no waste lye; the soap is said to come quickly, does not shrink by air-drying, and is in all respects represented as an excellent soap.

Soft Soap.—In domestic economy it is a practice in New England and New York to saponify the drippings of the kitchen, chiefly beef and mutton suet, with the crude potash of commerce in the cold. The following empirical receipt has become traditional for domestic soft soap: Fat, 12 lb.; potash, 9 lb.; water, 12 gal. The fat and alkali are placed together in a cask, and the water is added, 3 gal. at a time, boiling hot, once in twenty-four hours, until all is used. The process of saponification sets in soon, but is not completed until after many days, and is hastened by frequent stirring with a strong stick. When saponification is complete all lumps of unaltered fat disappear, the soap has a silky luster when stirred, and the consistency of a jelly, trailing off in slender threads from a stirrer, and is a powerful detergent for all the coarser purposes of the household. Such a soap is obviously an impure potash-fat soap in caustic lye, and not an actual soap; all the glycerin of the fats is of course present also in this crude product. If an attempt is made to purify it by separation of the glycerin and excess of alkaline lye by solution of salt, it results simply in the production of hard soda soap, on principles already explained.

In the manufacture of soft soap by boiling, caustic lyes are made from leached ashes or American potashes, exactly as when soda-lyes are used, and of graded strength, 9°–11° solutions being first used with gentle heat. The fatty bodies used are kitchen drippings, tallow, fish oil, linseed, rape-seed, and other drying oils. As soon as the complete combination is effected, and the thick fluid falls in strings from the stirrers with a shining appearance and somewhat turbid, the clarification begins with the gradual addition of a stronger lye at regular intervals until the soap passes from its turbid state to a clear, transparent slime. The boiler judges by empirical rules the state of progress toward completion of the saponification. If a drop from the middle of the pan when cooled on a plate of glass remains clear, the soap is complete; a gray margin indicates a want of lye in proportion to its breadth; and if this deficiency is great, the specimen is fluid and slimy. If the proper quantity of lye has been exceeded, the soap is said to be overdone, which is indicated by a gray skin spreading over the whole drop, instead of forming a ring or rim only; the soap is then granular, and when wet easily detached from the glass (*vitreous*). An excess of water is driven off by evaporation with a brisk fire and beating the froth as it rises with stirrers. As the soap thickens the froth subsides, the soap sinks and becomes darker, white bubbles are borne on the surface overlapping each other, called laminations by the workman; and the noise occasioned by this action has led to the saying, "the soap talks." As some kinds of oil, like that of hemp-seed, impart an esteemed greenish color to soft soap, while other varieties of soap are yellow, the greenish tint is artificially imparted to the yellowish soap by indigo. The detergent power of soft soap is very great, owing largely to its strong alkaline condition, and is hence

much esteemed in scouring wool, coarse linens, and for other like uses in the dyehouse. As it normally retains as inseparable from it the excess of alkali, the free glycerin and other impurities, there is no guaranty, as in the case of hard soaps, for its purity. Hence many methods have been practiced for reducing its cost—as, for example, the so-called bone soap, formed by the addition of the gelatin from ground bones, dissolved or partially decomposed by potash. In another plan hydrochloric acid is used to dissolve out the mineral matter of bones, leaving the gelatin, which, when carefully washed free of acid, is added during saponification to the fat. The soap with bones is called "Liverpool poor man's soap"; it is an open fraud, since gelatin and phosphate of lime can act only as useless diluents of soap. But this fraud is harmless compared with the use of the intestines of animals, skin, sinews, hoofs, hair, decomposed fish, and other animal refuse. Even naphtha, a non-saponifiable oil, and dextrin are sometimes employed in a like manner. Soft soap contains, according to quality, fatty acids, 50 to 40 parts; potash, 9·5 to 11·5 parts; and water, 38·5 to 50·5 parts in 100.

Silicated soaps contain either soluble silica or sand and powdered pumice, fuller's earth, and alumina. These substances act only mechanically as detergents, and may be permitted when a proper reduction in price is allowed. Sand soap, such as is used for scouring floors, contains as much as 75 per cent. of its weight of sand, and the French *savon-ponce* (pumice-soap) has from 20 to 26 per cent. of ground silica or pumice. These comparatively worthless mechanical mixtures have been replaced by soap in which soluble glass, or silicate of sodium, is employed with advantage. This feeble alkaline compound has by itself a considerable detergent power, and when mixed with ordinary soap an article of greatly reduced price and useful for many domestic and manufacturing operations is produced. These silicated soaps are quite strongly alkaline, owing to the nature of the soluble glass; this excessive alkalinity is reduced for some purposes by combining, with the soap, rosin or fatty acids, as in the ordinary process of soap-making. Carbonic-acid and sulphurous-acid gases are likewise passed into the liquid for the purpose of partially neutralizing the excess of alkalinity.

Toilet-soaps are made from very pure and sweet materials—sweet almond oil, beef-marrow, refined sweet lard, saponified without heat and perfumed with various essential oils. Very pure curd soap is also used for the foundation of toilet-soaps, for which purpose the soap is reduced to thin shavings, melted over a water-bath with rose and orange-flower water and common salt—24 lb. of soap, with 4 pints each of rose and orange-flower water, and about half a pound of salt. When cold next day, it is cut in small bits and dried in the shade, again melted down with the same proportion of orange and rose water, strained, cooled, and dried again. The heavy animal odor is thus removed, when it is powdered and left in a clean place exposed to air for some days. After this, it is ready to receive the desired perfume, and may be colored with aniline tints, ultramarine, etc., and moulded in forms for use. *Shaving-cream* is made by beating up lard with once and a half its weight of potash-lye, and perfuming and coloring as desired. *Glycerin soap* is prepared by mixing pure glycerin with a toilet soap, or with the transparent soap produced from its solution in alcohol. It mollifies the skin in cold weather.

Properties of Soap.—Besides its detergent properties every kind of soap in use contains a variable quantity of water, partly in chemical combination; and its power of absorbing water is also very various, being from 7½ per cent. in hard soda soaps to 162 per cent. in soft potash soaps of oleic acid when previously dried by artificial heat. Soap is perfectly soluble in alcohol, as also in hot water, both solutions becoming of the consistency of a jelly on cooling. In this state, mixed with camphor and oil of rosemary, the alcoholic tincture of soap is familiar as opodeldoe, or *linimentum saponis compositum* of the *Pharmacopœia*. Tincture of white soap is readily decomposed by salts of calcium and magnesia, and is familiar to the chemist, when made of normal strength, as the most convenient test for the hardness of natural waters (Clark's test). Potash soap is more soluble in water than soda soap. The sodium stearate is hardly affected when placed in 10 parts of water, while potassium stearate thus treated forms a stiff jelly. Sodium oleate dissolves in 10 parts of water—potassium oleate in 4 parts, and it forms a jelly even with 2 parts. Cold water partially decomposes the alkaline oleates, palmitates, and stearates (common soap), the neutral salts being resolved into alkali, which dissolves, and the free acid, which precipitates. This explains why in using soap, even with pure water, its transparency is always disturbed, while the alkaline property, and consequent detergent power, of soapsuds is due to the liberation of a portion of caustic potash or soda, which attacks and removes the grease of foul linen, etc.

The value of soap depends mainly on the amount of dry soap (the real soap or alkaline salt of the fatty acids) in any given specimen. The loss in weight of a given amount of soap cut in thin shavings, when completely desiccated in a drying oven, at 212° F., is hygroscopic water, which should not for best hard white soap exceed 20 per cent., for mottled soap 25 per cent., and for yellow soap 30 per cent. The fat acids vary from 60 to 70 per cent., and the alkalies from 7 to 9 per cent., according to quality. As before mentioned, soaps made from cocoanut oil contain normally much more water, and in the yellow soaps from 10 to 20 per cent. of the fatty acids are replaced by rosin.

Soap was not known to the ancients. It is first mentioned by Pliny, who refers to it as something used by the Romans for the purpose of beautifying the hair. Geber in the second century states that soap was prepared from various kinds of tallow with potash and lime. It is stated further that soap is used as a medicine, and that by means of it all dirt could be removed from the body and clothes. For more details respecting the manufacture of soap, consult Richardson and Watts, *Chemical Technology*; Muspratt's *Chemistry*; Watts, *Dictionary of Chemistry*; Ad. Wurtz, *Dictionnaire de Chim.*; R. S. Cristani's *Soap and Candles*; Dussance's *Manufacture of Soap*; Thorpe, *Dictionary of Applied Chemistry*. Revised by IRA REMSEN.

Soapberry: the fruit of the *Sapindus saponaria* and *S. inæqualis*, West Indian trees of the family *Sapindaceæ*. The pulp is a powerful detergent, much stronger than ordinary soap, and the hard shining seed has been exported and used for making buttons, which are very durable. In the southern parts of the U. S. there grows another soapberry-tree, *Sapindus marginatus*, which is sometimes 40 feet high. There are various tropical species which have a fruit with an edible pulp, but the seed is often poisonous. These trees have no practical importance. Revised by L. H. BAILEY.

Soapstone: See STEATITE.

Soapwort: a name sometimes applied in a general way to the plants of the family *Sapindaceæ*, on account of the soapy quality of the fruits of many species. It is also the name for plants of the genus *Saponaria* (family *Caryophyllaceæ*) and other plants of the same family, which are sometimes utilized for their detergent powers. There are in many parts of the world vegetables which are excellent substitutes for soap. In some instances this cleansing power depends upon the prineiple saponine, found in plants of widely diverse families. The root and leaves of common soapwort contain saponine, and are often used for washing. The root has also medicinal properties. Revised by CHARLES E. BESSEY.

Soccage, or **Socage**: See TENURE.

Socialism [from Lat. *so'cius*, sharing, associated, (as noun) fellow, partner, companion]: a conscious endeavor to substitute organized co-operation for existence in place of the present anarchical competition for existence; or the system of social organization calculated to bring this about. This definition, though it gives, perhaps, adequate expression to the active and practical side of socialism, leaves out of account altogether its theoretical basis. From this point of view socialism is an attempt to lay the foundation of a real science of sociology, which shall enable mankind, by thoroughly understanding their past and present, to comprehend, and thus, within limits, to control the movement and development of their own society in the near future. Consequently socialism in its wide sense is not, as is still commonly thought, a mere aspiration for a better state of society, still less only a series of proposals to mitigate the evils arising from the present social arrangements. Modern scientific socialism essays to give an intelligible explanation of the growth of human society, and to show that as each step in the long course of development from the institution of private property, through chattel slavery, serfdom, and wagedom, was inevitable, so the next step from capitalism to socialism is also inevitable. The object which socialists have in view in their propaganda is that this, the final trans-

formation, should be made consciously by an organized, educated, and intelligent people, instead of unconsciously, and therefore tempestuously, by groups of discontented, embittered, and ignorant workers. Agitation against the injustice of the present system of production, therefore, is only valuable in so far as it educates men and women to appreciate the tendency of the time, and in this way leads them to organize for the attainment of the definite end which the evolution of economic forms has made ready. Whether the great change will be brought about peaceably or forcibly has no bearing upon socialism in itself, but depends upon the stage of development which has been reached in each civilized country, and the attitude which the dominant class may adopt in relation to the demands that the economic situation impels the producing class to make.

The Early Communal System.—All authorities on the early history of our race are agreed that the primitive forms of human society were founded upon communism, or common ownership, alike of the means of production and of the products; the personal relations between the members of these communities being regulated by kinship, and not by property or residence. In these circumstances equality of social condition was the rule within the limit of the gens or tribe; women were supreme in the communal household, their children belonging to their own gens; and though the power of man to produce wealth was then very small, and scarcity or famine was not uncommon, it was impossible in these circumstances for one portion of the little community to be foodless while another portion was in possession of a superfluity of the necessaries of life. Examples of this form of society are still to be found in their pristine completeness, as well as in process of disintegration, in many parts of the world. According to socialistic theories, the same law applies to human society that has been found to govern development in other portions of inorganic and organic nature. This law, which has been formulated in the philosophic guise of unification, differentiation, and reintegration, may be traced throughout the vegetable and animal kingdoms. First there is the simple organism, then its division in the form of germination or otherwise, and lastly its reappearance in a form similar to the first. In the case of human society in its slow upward progress private property acts as the differentiating force, and the early communal society embraced within itself all the possibilities of the future, as the acorn possesses within itself, in suitable surroundings, the potentiality of the oak. With the institution of private property the entire break-up of the communal form and all that this involved became sooner or later inevitable. But during the period of communism all the inventions and discoveries which form the foundation of the modern system of machine production were placed at the disposal of mankind. The domestication of animals, the growth of cereals, the wheel, the potter's wheel and pottery, the canoe and sail, weaving, dyeing, the use of the stencil-plate, the mining and smelting of metals—each and all of these were in use under communism. The tribes benefited by the increased power to produce wealth thus very slowly obtained; but the very names of the inventors and discoverers are forgotten, and the circumstances in which they lived prevented them from deriving any individual or personal advantage from their superior ingenuity. At the same period of social growth, exchange, in its modern sense, was unknown, and considerable works were carried out in various directions as portions of the organized industry of the little communities, those who were engaged in work which could give no immediate return in food or clothing being supplied by the labor of other members of the community.

Slavery and Serfdom.—As the power of man to produce wealth increased further progress in wealth-production was hampered by these communal forms, and by the necessity incumbent upon each member of the tribe to perform his share of the communal duty. When, also, it was discovered that the captives from neighboring tribes could produce by their labor more than was necessary to maintain themselves in health and strength, there was a strong economic reason for keeping them alive, in the service of the conquering tribe or its chiefs, in place of butchering them on the spot or reserving them for cannibal banquets. (See SLAVERY.) Despite the evil features of slavery thus established it was an inevitable stage in development, and the strongest minds in the period of its economic supremacy could scarcely imagine that any organized human society could continue if slavery ceased; the slaves themselves, though in such cities as Athens, Corinth, or Rome vastly more numerous than their masters, scarcely thought of achieving their freedom. But with the growth of private property, the break-up of the old ties of kin, the increase of wealth, and the establishment of locality and residence as the basis of representation in the ancient oligarchies, miscalled sometimes democracies, the division into classes and castes took shape, and those class-struggles began in earnest which, in one shape or another, have since recorded the history of civilization. At the same time the extension of trade marked the rise of the merchant class on the shores of the Mediterranean and elsewhere, whose full influence was not to be felt until many centuries later.

Rome was, speaking in general terms, the last of the great slave-supported civilizations, and never, since private property was established, did the permanence of any empire seem so completely assured. But slavery became economically unprofitable. The great slave-worked estates in Italy and other countries, which had built up the wealth of the Roman nobles, had fallen into economic decay. Barbarians from without and insurrections from within broke down the fabric of Roman domination, and the second great form of human subordination to the possessors of property was established. Serfdom arose as slavery disappeared and the feudal system, with its complementary institutions, municipal and sacerdotal, obtained control over Western Europe. As slavery had become economically unprofitable, so, in turn, serfdom, with the various classes which it supported, gradually ceased to afford sufficient outlet to the social and economic forces that invention and the greater knowledge of the planet called into being.

Rise of the Modern Wage-system.—By degrees free individual owners and craftsmen formed the mass of the working population in the European nations which had grown up on the ruins of the Roman empire, although this enfranchisement took place at widely different dates in the various countries. It is from this period that the more direct analysis of modern society from the socialist standpoint begins. Throughout history, side by side with the class-struggles, the ideas of collectivism, derived from the old communistic societies, and of complete individualism, the direct outcome of private property, had been in more or less acknowledged conflict. With peasant cultivators in the country and free craftsmen in the cities the individual form of private property received its highest development. At no period can it be said that this personal independence for the producing class was universal in any community; at all times the propertyless retainers, wage-earners, or serflike dependents accompanied the dominant form. But at the end of the feudal period in Great Britain the individual peasants and individual craftsmen were sufficiently numerous to give the tone to the whole industrial system. The man who worked upon the land and the man who worked at his trade were both, in the main, owners of their soil, their tools, their products which they produced for their own use or for that of their neighbors in the immediate locality. Owing to a series of historic and economic causes, these free individual owners and craftsmen were gradually deprived of their private property and independence, and were driven to produce as wage-earners in the employment of others. The only freedom left to the propertyless man was that of selling his power to labor to some one else who paid him for his service, and used him in conjunction with others to produce goods, no longer primarily for use but for exchange. In the whole previous history of mankind production for exchange and profit had been the exception; now it became the rule. The personal relations which, in the main, had dominated over the old civilizations were transformed by degrees into mere pecuniary relations, and thenceforth pecuniary considerations became supreme in society.

Characteristics of the Modern Competitive System.—This economic change, though eventually complete, was of course gradual, and at first its effect was not perceived. Instead of individual production, generally for individual use or with a view to the local market, only the surplus coming into exchange after personal wants were satisfied, production itself assumed a social form, and the local market widened into the national and international market. A class had arisen out of the downfall of the feudal system unlike any class which history before had noted. The members of this class were free in the eye of the law, and possessed, nominally at least, full liberty to do what they pleased; but in practice, having no property of any kind, they were compelled to sell the sole possession left to them, the power to labor in their bodies,

to those who were in a position to purchase this their only commodity by the payment of daily or weekly wages. The payment of wages by no means began with the decay of feudalism; that form of remuneration for services rendered has itself a history extending over many centuries. But the difference between the wage-earner who accepted wages from others in the intervals between laboring for himself and the wage-earner for life, between the independent property-owner and the propertyless hind or "hand," is a difference not only of degree but of kind. The former was, on the whole, economically free, however badly he might be paid in mere money; the latter is economically a mere dependent, no matter to what point his wages may temporarily rise. These wage-earners employed by a master who had accumulated capital by commerce, the slave-trade, or piracy, worked together in co-operation in the workshop. They produced, primarily in social combination, articles of social use, for a social purpose, in the shape of exchange. But these workers had no share in the ownership of the raw material, no say in the quantity or quality of the articles produced, no control over the finished product, which belonged to the master. They received in the shape of wages that which represented on the average their cost of subsistence, in accordance with the standard of life of their class, so long as their employer required their services. What then had happened? A great and crucial change had been brought about. The individual form of production had been transformed into a social form of production; but the form of the ownership of the articles thus socially produced, as well as the control over their exchange, remained in the hands of the individual master or employer. Society at this stage—and the process can be traced at various periods in the development of all civilized nations—passed from an economical condition in which production as well as appropriation and exchange were in the main individual, to a condition of society in which production became social, but appropriation and exchange remained at the entire disposal of individuals. This manifestly involves a direct economic antagonism, and that initial antagonism lies at the root of all the antagonisms of the modern system of capitalist and wage-earning production for exchange and profit. Competition now ruled the market. Competition by free, propertyless wage-earners below; competition for increased profit by capitalists and employers above. The latter were driven by the very necessities of their existence to sweep aside the old local restrictive laws of the Middle Age period; and, as they gained strength, they were likewise impelled to substitute their own commercial control in politics for that of the classes which had hitherto been supreme. From this time forward all improvements and inventions went into the hands of the capitalist class and were shared by them, though much against their will, with the landlords.

Such was the course of events in Great Britain, where the economic transformation was soonest effected, the removal of the people from the individual or collective ownership of the soil having first been carried out. Geographical position and the character of the people favored this earlier development in England, but all civilized countries have followed, or are following, along the same road. Not, however, until the end of the eighteenth century, when steam and the great machine industry became the dominant factors in production, was it possible for the owners of the capital and machinery to obtain complete control over the wage-earners, and to marshal the industrial army under their management in disciplined array. With the factory industry, founded on the inventions of Watt, Hargreaves, and others, it may be said that the last great system of human slavery was firmly established, and wherever it has been allowed to flourish unchecked it is unquestionable that the cruelty and physical degradation by which it has been invariably accompanied fully equal, if they do not surpass, in horror the records of the old chattel slavery and serfdom. The British official blue-books show, indeed, that at the end of the eighteenth century and the beginning of the nineteenth, when unrestricted freedom of contract prevailed between the owners of the means of production and the workers, women and children, to say nothing of men, were treated with more entire disregard for common humanity than were slaves or serfs at any time whatever. Similar causes have produced like effects in other countries, and the condition of the working population in the great cities on both sides of the Atlantic, as set forth in official reports, proves that comparatively little has been done to remedy the evils which are inherent in the competitive system of wage-earning. At the same time the limited market of the Middle Ages has been converted into a universal international market. Even the nations that resorted to the most stringent restrictive tariffs have been unable to extricate themselves from the great market of the world, which capitalism has steadily extended since the discovery of America. Commercial wars have but served to expand the ever-widening circle of international commerce, and the demand for fresh markets to meet the growing output of commodities, due to the increasing power of machinery, has been the means of pushing expeditions into the remotest parts of Asia and Africa. Capitalism, therefore, in pursuing its inevitable course and in working out the law of its being, like the great slave-supported civilizations of antiquity and the feudalism—by no means confined to its European manifestation—which followed, has unconsciously prepared the way for a closer understanding between the inhabitants of this planet than had ever before been possible. The long slow movement of economic development which arises out of the institution of private property is thus approaching its close, and we are on the threshold of the greatest and most crucial transformation that the world has ever seen. To convince the dominant classes in every country that such a transformation is inevitable, while educating and organizing the producing classes, so that they may consciously and intelligently take advantage of the opportunities which they inherit from the long martyrdom of man to the forms of production and exchange—such is the task of the advocates of socialism.

It has been seen that when European society in the Middle Ages changed from the form of production by individual free men for individual use, only the surplus coming into exchange, to the form of production in which groups of wage-earners worked in social organization under employers, all the goods being made for the express purpose of exchange, no similar change was made in the ownership of these products. That remained in the hands of an individual as before, who competed with other individuals, similarly placed in economic control of nominally free workers for the sale of his products. That which distinguishes this capitalist system of production from all previous systems is that it is carried on primarily for profit and exchange. Goods are of no immediate use to those who produce them. They are made to go upon the market under the control of the employer who in order to keep his business going must sell them for cash in competition with others, who likewise sell for cash; and, in practice, he can only hold his place by steadily increasing his turnover. Cheapness being the determining force in the bitter commercial conflict of the markets of the world, each producer or manufacturer is compelled to cut down his cost of production to the lowest point possible in order that he may be able to undersell his rivals and thus enlarge the scope of his trade and therewith his personal profit. So early as the middle of the seventeenth century the great economist Sir William Petty could speak of "the trade of the world" as falling to the seller of the cheapest products. Assuming free competition to exist, this is even more true now than it was then.

Economic Antagonisms under the Modern Industrial System.—What, however, is the law which governs the exchange of commodities under the capitalist system of free competition—commodities being articles of recognized social use in the social conditions of the time, produced primarily for the purpose of profit and exchange? Such exchange is on the average conducted on an equality, and the relative value of commodities so brought forward for exchange is governed by the amount of social labor which it takes to produce them, or which is incorporated in them. It is impossible to tell whether a bushel of wheat is the product of the best or the worst land, or whether a bale of cloth has been made by hand or by the most improved or by inferior machinery. Neither is it possible to establish directly how much social labor is embodied in the articles so brought forward for exchange. This can only be arrived at indirectly, by way of such exchange and through the higgling of the market. But the amount of social labor necessary on the average to produce the two articles exchanged comes behind both parties to the transaction and settles the terms on which business will be done. Any reduction in the average amount of social labor incorporated in either of the commodities will reduce its value to a proportional extent relatively to the other. Gold in present conditions being, when dug from the bowels of the earth, a representative of incorporated social labor value, serves as a medium of exchange

and also as a standard of value for the various commodities; the ups and downs of value due to variations of demand and supply at particular periods are averaged over the whole, and do not disturb the level of exchange on the basis of incorporated social labor.

The free laborers without private property who are obliged to sell their labor-power as a commodity in order to live exchange it on the same basis as other commodities. Its value is regulated by the amount of social labor which, on the average, is necessary to keep the laborers alive on the ordinary standard of life in their trade in the country where they reside. This amount they receive from the employer in the form of money-wages, with which they in turn buy their food, clothing, housing, and the like. So far the exchange is conducted on the principle of all exchange of commodities. But the special commodity which the wage-earner sells—his power to labor, namely—produces in the course of the day or week or month considerably more value than the worth of the wages which he is paid. From this surplus labor-value incorporated in commodities the employer derives his profit, the landlord his rent, the commission-agent his brokerage, the banker his interest, and so on. It is the unpaid labor of the wage-earners—the labor which they give in excess of the value of the wages they receive—that enables the capitalist class and their associates to pile up riches and capital. Although individual capitalists may run risks, there can be no risk for the class as a whole. A profit for them as a class is absolutely certain; but in order to enhance this profit in circumstances where they are pressed by the competition of their fellows, individual capitalists, and not unfrequently the whole class, have naturally endeavored to reduce wages, to lengthen hours of labor, to introduce improved machinery, and to turn out as much goods as cheaply as possible, so as to obtain by their superior cheapness (due to the lessened amount of social labor embodied in a given quantity) a larger sale. The wage-earners being obliged, until their combinations are very strong and even afterward, to compete with one another for the sale of their sole commodity, labor-power, which will not keep unless rapidly sold, often accept lower rates of wages because they must do this or starve. The success of the employer seems a necessity of existence to them, and a large employer of labor for profit is often regarded as a public benefactor; but it is manifest that the interests of the wage-earning class and the capitalist class can not by any possibility be in reality identical, though it may be and is to the temporary interest of a particular set of wage-earners that their own individual employer should be successful. Those who are contributing of their vital strength and health in the form of unpaid labor to build up fortunes for others are, of necessity, whether they themselves recognize it or not, in a position of direct class antagonism to those others, however much this antagonism may be disguised or glossed over; but this class antagonism between wage-earners and capitalists or, to use the wider French terms, between proletariat and bourgeoisie, is itself the direct result and the inevitable human expression of the conflict already noted in its earlier and simpler strife between the social form of production and the individual form of appropriation and exchange.

Out of these two initial antagonisms, however, others arise in their turn. The factory industry, for example, and the mining industry, and agriculture carried on upon a large scale with machinery, call for the most thorough organization, and anything in the shape of unpunctuality or dereliction of duty on the part of the employees is severely fined. It is absolutely essential, from the profit-making point of view, that there should be no waste of time in business hours, and that the whole of the plant, mechanical and human, should work on with unvarying regularity, as if the various parts were dovetailed into one another. This perfection of organization and machine-like co-operation has been secured under the capitalist system to a degree which beforehand would have seemed quite impossible, and great works employing thousands of men and women produce from year's end to year's end with scarcely a break. This complete organization in the factory, the workshop, and the like finds its correlative opposite in the utter anarchy of the exchange at the time when competitive capitalism is in full swing. Each factory at that period is concerned solely with its own output, each mine or each farm with its own product; the object of all being to turn out as much as they can upon the market as quickly as possible, with a view to obtaining as large a profit as may be while trade is flourishing. No one takes the least account of the proceedings of his neighbor, being too deeply engaged in fighting for his own hand. Thus the complete organization of production in the factory leads to complete anarchy in the exchange. Further, in order to continue his operations successfully, each manufacturer or producer of any kind must convert his finished goods or products into money before he can begin again, credit merely disguising this operation. He can not exchange his products direct for the products of his brother producers, even for the purposes of his own consumption. They must be converted into money first in every case. If the circulation of the commodities be in any way impeded, then it at once appears that there is a difficulty in this way of conducting business—that money can not at once be realized for these goods which have been thus thrown upon the market. Money, in fact, then becomes temporarily a means for hindering exchange instead of for facilitating it, and it is apparent that in such conditions there is a clear antagonism between commodities and gold, or its equivalent in convertible paper. Again, the tendency of modern society to gather the population into great towns having no rural interests has developed another antagonism, as a partial result of those already specified, between town and country. The interests of the two are frequently found to be antagonistic instead of harmonious, and one of the great problems of the future will be to restore or to bring about a co-operative agreement between these two great departments of human life and industry. Moreover, the capitalist system of production has developed an antagonism between the sexes, and even between parents and their children. This antagonism arises, like all the rest, from economic causes. The family, in its ancient sense, has been disrupted, and men are met in the whirl of competition for wages by women who, owing to a variety of causes, compete with them on a lower standard of life for a lower rate of wages. Children, in like manner, are in many countries brought in to compete against men and women. A man's foes in this instance are literally they of his own household; though in this as in other cases the workers themselves do not perceive the mischief which is being done to themselves, and at the same time to the whole community. Of the antagonism between skilled and unskilled labor, between casual, unorganized workers and trade-unionists, between employed and unemployed, it is unnecessary to speak; these struggles are too apparent to all who study the history of society in the nineteenth century.

The Cause of Commercial Crises.—Ever since the capitalist system became the predominant form of production in civilized countries, ups and downs of trade, periods of inflation alternating with periods of depression, have been the rule. So much is this the case that they are taken for granted by men of business, who base their calculations upon such variations, but are seldom able to grasp the causes of them. (See Commercial Crises.) These sudden collapses of trade are generally regarded as being as much beyond human control as an eclipse or an earthquake, a tornado or a long frost. They are, nevertheless, indisputably the result of social causes, which, when they are understood, can be regulated and controlled. The most remarkable feature in all the successive cataclysms from 1815 to 1893, before as after the universal use of steam-vessels, railways, and telegraph cables, was that they were preceded and accompanied by an excess of products in every department. In all previous economic epochs, as in barbarous countries at the present time, general depression of trade has arisen from drought or from flood, from bad harvest or from pestilence among men or cattle; in any case from an insufficient supply of necessaries. Only among the most civilized peoples does an excess of what the world requires become an immediate cause of stagnation, and the reason why thousands of workers in all countries are prevented from earning their livelihood. At this time the power of man to produce wealth in every department of industry, including agriculture, is far greater than it has ever been before. Hence this enhanced productive capacity seems in some way to have become at intervals a serious hindrance to production and exchange. Whence does this arise? The control of all the great means and instruments of production, the direction of the huge industrial machines, the arrangement of the amount of labor to be devoted to great public works or to the output of commodities, the initiation of fresh enterprises and the adoption of new inventions—all this rests with the capitalist class and the managers whom they employ. When, owing to various causes, a time of good trade begins, all the financiers, employers, manufacturers, mine-owners, and so forth, hasten with one accord

to take advantage of the days of prosperity rendered the brighter by contrast with the previous gloom. The unemployed workers, who are an unfortunate necessity for the due functioning of the capitalist system, are absorbed into activity, the demand for goods from every quarter increases, prices (not values) rise all along the line, great works, such as railways and canals, are again undertaken, huge vessels are laid down in all the ship-building yards, demand in one direction enhances demand in another, wages are paid on an almost unexampled scale, and goods are turned out in greater abundance than ever before. But at the very moment when the expansion is at its height the collapse begins. Suddenly a difficulty arises in disposing of one set of goods for money, a large capitalist has to press his bills or his commodities upon the market in order to realize their value for immediate cash. Others pursue the same course. There is a general rush to sell. The antagonism between gold and commodities is felt in earnest. Prices fall more rapidly than they had risen. Workmen are discharged, factories are shut down or run on short time, furnaces are blown out, shipping-yards are closed, railways are suspended. A crisis has begun; the incapacity of the capitalist class to handle effectively the machinery of modern civilization is proclaimed to the world, and bankruptcy and stagnation at once follow. The social form of production revolts against the individual form of the exchange.

Tendencies toward the Socialization of the Means of Production.—At this point socialism comes in and, having completed its analysis, shows how the antagonisms inherent in the capitalist system must be solved by making exchange social, as production is social; by establishing co-operative production and distribution in the place of competitive wagedom and competitive capitalism. That which in itself is desirable from the *a priori* point of view, society is even now anarchically and unconsciously working up to. The entire series of differentiations arising out of the establishment of private property having been passed through, the complete reintegration of collectivism or communism on a higher plane is even now in progress, without the vast majority even of intelligent and educated men being in the least aware of it. Socialism is asserting itself in modern society by reason of economic causes, as capitalism owed its predominance before to the action of the same causes.

Thus the capitalist class in all civilized countries have championed competition and unlimited right of free contract between the wage-earners and their employers; but the hideous results of this scramble in the shape of physical degeneration, with accompanying mental and moral degradation, alarmed even the modern state, and laws have been passed to limit the freedom of the masters and servants alike in order to check in some degree this serious deterioration. At the same time, and as if in spite of themselves, modern statesmen, while upholding stoutly the doctrine that everything is best done by private effort, have been impelled to set on foot a number of public services, national and local, whose duties are continually extending in the face of all the protests raised by the older school of economists. Moreover, there is a growing feeling in every civilized nation that the hours of labor as well as the wages of the workers in these public services should no longer be governed by the law of competition for subsistence wages, but that the governments and municipalities should assure to their servants a day's work of no more than reasonable length in proportion to the intensity of their toil, and wages adequate to obtain for them a decent standard of life. This view, though still far removed from socialism, is manifestly a portion of a movement which is leading toward it. The public services are, in short, being transformed in the interests of the workers with the assent of the whole community. In like manner the public health, the improvement of the conditions and surroundings of the workers of the cities in particular, in order to secure to the working population a better physical development and some enjoyment of life—this also has become a matter of general concern to which national laws and state and municipal ordinances give expression. Such measures as these may be reckoned as conscious though small endeavors on the part of society to correct the evils of existing anarchy and to prepare the way for a better system.

Far more important, however, are the unconscious strivings toward the new period. On the one hand, the formation of companies, consisting of many bondholders and shareholders, to carry out great public works, and the transformation of private concerns engaged in all the departments of production and distribution into similar companies, form a distinct move in the direction of socialization. The individual employer is merged in a multitude of shareholders, and the pecuniary relation becomes the sole and only tie between employers and employed. This company form is manifestly an unconscious step toward socialism, seeing that these great organizations and corporations, whether for production or for distribution, are controlled and directed by managers and boards of directors who, regarding the matter solely from the economic point of view, might as easily be appointed by the workers to carry on the business in the interest of the community and the workers themselves as be nominated in the way they are to-day by shareholders who, in the majority of cases, have no direct knowledge of the affairs from which they derive an income, and perhaps have never been within hundreds or thousands of miles of the place where "their" factories, or mines, or works, or railways, or lands are situated. So soon as this economic possibility is generally recognized the final change has begun; but at the same time that this modification from the individual form into the company form of ownership and appropriation is taking place, the private firms and the companies are alike abandoning competition for combination. Banks are being consolidated, nationally and internationally; shipping companies are agreeing not to compete; joint-stock associations form trusts and "rings." In the U. S., where unregulated competition attained perhaps its highest pitch of development, this form of industrial and financial monopoly has unquestionably become more striking than anywhere else. This process is going on in all civilized countries. Moreover, the introduction of improved processes of manufacture, which was formerly hastened by individual anxiety to compete on better terms, is now hindered by the disinclination of monopolists to disturb vested interests with which they are well content. Thus the capitalist system of production no longer favors human progress, but heads back the economic evolution, and brings about periods of recurrent anarchy in every department of industry. Capitalism therefore is making plain the way before the face of socialism by its unconscious but inevitable institution of monopoly. The other human side of this great economic antagonism is likewise unconsciously organizing its forces to capture these monopolies. Throughout the civilized world the workers are beginning to see that whatever be their nationality, whether they are men or women, skilled or unskilled, their true interest lies in the thorough combination of labor with a view to the final overthrow of the wage system. Socialism is accepted only by the minority, but its principles are spreading daily, and ere long it will be universally recognized by the toilers that mere strikes, however well organized, are almost as hopeless a method of struggling against the domination of capital as was the old plan of machine-breaking. The machines were used against the interests of the workers; therefore they, in their ignorance, tried to destroy them, instead of combining to capture them. The great monopolies are in like manner used against the workers; therefore they, in their ignorance, attempt to strike against them, instead of using the political machinery at their command to obtain possession of and manage them. But with national and international organization come also education and full appreciation of the facts of their social surroundings. Then the producers, who will constitute practically the whole community, can move forward in fraternal solidarity and educated comprehension to take advantage of the economic conditions which have been prepared for them. Each nation must of course follow the route marked out for it by its previous economic history and its geographical position. It seems certain, however, that no matter by what means it may triumph socialism will begin with the public services and the more highly developed company forms, and proceed until production is last organized on the land which has not yet reached the company form in any country.

With the establishment of national and eventually of international socialism, mankind resumes the definite control over the means and instruments of production, and masters them thenceforward for all time instead of being overmastered by them. By such co-operative industry, whose power over nature is increased by each fresh invention and discovery, a carapace of repression is lifted off from the faculties of each individual, and wealth being made as plentiful as water by light wholesome labor, all freely contribute to increase their own happiness as well as that of their fellows. Human nature assumes a new and higher character in a

society in which the surroundings are such that life is not as to-day a constant struggle against the pressure of want and the temptations of misery. Instead of the personal, limited, introspective individual ethic is the social, altruistic, broad ethic in which the duty toward society necessarily involves the highest duty toward a man's self. Woman, relieved of economic and social subjugation, will assume her place as the social equal of man. So far, therefore, from individual initiative and personal freedom in the highest sense being limited and stunted, human beings will have the opportunity for attaining to a level of physical, moral, and mental development such as the world has never seen. The golden age of human society is, indeed, not in the past but in the future.

Such is a statement, obviously abstract and incomplete, of the theories of scientific socialism. There have been various schools of socialists, but the theories above set forth are accepted by the overwhelming majority of socialists in all civilized countries, and the differences which arise are chiefly on points of tactics; though in this respect an exception must be made with regard to Christian socialists who connect their socialist theories with the founder of the Christian Church. The utopian socialism which has striven, and even now attempts, to establish little oases of co-operation amid the existing wilderness of competition and monopoly, is slowly merging itself in the worldwide sweep of scientific collectivism. That such great thinkers and writers, however, as Saint-Simon, Robert Owen, and Fourier should in part have taken this view only shows how difficult it is for the highest minds to grasp the tendency of the facts around them until the time is ripe for the complete analysis of the fully developed economic forms. The anarchists, who sometimes call themselves socialists, are so fearful that universal co-operation and collectivism will crush the freedom of the individual that they not unfrequently drift into the advocacy of sheer reaction, and preach the gospel of wholesale destruction, which is really the creed of individualism run mad. It is needless to say that this revolt against all authority, even that which is voluntarily accepted for the purpose of securing the full advantage of organized industrial co-operation, is in direct opposition to socialism, though often confounded with it. The destruction or transformation of class government and the abolition of wagedom, which socialists look forward to as the next stage in the development of human society, will give free outlet to the individual; while the attempt to secure the supremacy of the individual by mere individual effort, if it could be realized and made effective, would but deprive mankind of the vast collective powers of production which are now available. Socialism and anarchism are directly opposed, alike as to theory and tactics; their only point of agreement is that both are in antagonism to our present society.

Socialism manifests itself in the shape of an organized disciplined party chiefly in Germany, where its development since 1870 has been remarkable. In that country the socialists form now a recognized political force, and their action is in the main guided by the views set forth in this article. If they continue to progress in the future at the same rate as in the past, there is every reason to believe that within the next generation they will be the dominant party in the state, and thus able to give full expression to their opinions. It is most probable, however, in spite of appearances, that the lead of the international socialist movement will be with the English-speaking peoples, whose greater economic development and superior adaptability in politics, together with their geographical extension, give them opportunities such as the Germans can never possess. In France the movement has advanced since about 1890 with amazing rapidity and the country which was the first to manifest to the world a genuine rising of the modern proletariat will have its full share in moulding the great international socialist movement. All through Europe and at length in the U. S. socialism is recognized even by the dominant classes as a coming power. The doctrines of human solidarity, of international fraternity, and worldwide co-operation for the benefit of the present and future generations, appeal to the sentimental aspirations of the large number who have little inclination to examine into the scientific theories on which those doctrines are based; who, moreover, having formed a high opinion of human intelligence, are apt to resent any attempt to demonstrate that men and women have hitherto been little better than sentient automata in their social and economic relations. Now, also, that socialism is translating itself into action in the direction of palliatives of existing evils, and recent international socialist congresses, as well as the proceedings of recognized socialists on public councils and boards, have shown that definite, practical efforts are being made to hasten on the attainment of complete emancipation for all, men and women of all nationalities and of every creed are led to investigate the causes of the class-war which is raging around them in the midst of profound peace, and to believe that socialism furnishes the only possible solution of the conflict. H. M. Hyndman.

Social War [*social* is from Lat. *socia'lis*, pertaining to comrades or allies, deriv. of *so'cius*, fellow, comrade, ally]: in Roman history, the name applied to the war (B. C. 90–89) between Rome and her Italian allies. The latter, who had for nearly two centuries shared the burdens and dangers of the republic, now justly demanded admittance to the privilege of the franchise. After the assassination of M. Livius Drusus (91 B. C.), who desired to grant citizenship to the Italians, the allies, including the Marsi, the Peligni, the Lucanians, the Samnites, and many others, rose in arms and proclaimed a new republic. A bloody war followed, and notwithstanding the great victories of Sulla, Marius, L. Cæsar, and others, the Romans were compelled to make many concessions, and in the end the Italians received the franchise, though they did not gain their due share of political influence on account of the restriction that forbade their voting in any but a specified number of tribes. Over 300,000 men are said to have been slain in this war.

Society Islands: a group of islands in the South Pacific Ocean, the principal part of what is officially known as the French establishments in Oceania, which also includes the Marquesas, Tuamotu, Gambier, and Tubuai groups and Rapa island. The Society islands lie between lat. 16° and 18° S. and lon. 148° and 155° W. They consist of one large island, Tahiti (*q. v.*), and a number of small isles, comprising altogether an area of 636 sq. miles, with 16,000 inhabitants. The islands are mountainous. In the center some of them rise to the height of 6,000 or 8,000 feet, but they all have a belt of low land extending between the foot of the mountains and the sea, and they are generally surrounded by coral reefs. The soil is very fertile and the climate delightful. All tropical fruits grow luxuriantly, and European fruits which have been introduced succeed well. The inhabitants are Polynesians; most of them are Christians. The chief town and port, and capital of the colony, is Papeete. The chief exports are mother-of-pearl, copra, cotton, and vanilla. Sugar and coffee also are produced. Revised by M. W. Harrington.

Society of Friends: See Friends, Society of.

Society of Jesus: See Jesuits.

Socin, sō'săn', Albert: Orientalist; b. at Basel, Switzerland, Oct. 13, 1844; studied at Basel, Göttingen, Leipzig, and Berlin; Professor of Oriental Languages at Basel, Tübingen, and Leipzig successively; author of *Die Gedichte des Alkama Alfahl* (1862); *Baedeker's Palestine and Syria* (1876); *Arabische Grammatik*, 1885 (Eng. trans); 2d ed. 1893; *Die neuaramäischen Dialekte* (1882); *Arab. Sprichwörter und Redensarten* (1882); *Die Genesis übersetzt* (with Kautrich), 2d ed. 1891; *Kurdische Sammlungen* (1887–90). B. I. W.

Socin'ians and Socin'ianism: the historical designations of the advocates and doctrines of the most thoroughly organized system of anti-Trinitarianism that has ever existed. In the U. S. the names are seldom used, having long since given place to Unitarians and Unitarianism, names of much wider scope.

I. History.—The Trinitarian doctrine, as defined in the Nicene and Athanasian creeds (see article God), a gradual development of three centuries, was held almost universally after the time of Justinian as a fundamental element of Christianity by the ancient churches, Eastern and Western, and by all the churches springing immediately out of the Reformation. At the era of the Reformation the first anti-Trinitarians were certain individuals who appeared at different points, chiefly among the German Anabaptists. Among these were Martin Cellarius (b. in Stuttgart, 1499, educated at Wittenberg, at first a disciple and coadjutor of Luther, d. at Basel, 1546), John Denk (d. at Basel, 1528), Lewis Hetzer (at first a fellow laborer of Zwingli, executed for polygamy at Constance, 1529), and John Campanus (studied at Wittenberg, and died after long imprisonment at Cleves, 1574). One of them, named Spiritus, supposed by Dr. Rees to have been Adam Pastor, a Frisian Anabaptist,

first carried Unitarian doctrine to Poland in 1546, which afterward became the seat of the denomination. Servetus in 1531 published his first work, *De Trinitatis Erroribus.* In 1532, at Haguenau, he published his *Dialogorum de Trinitate, Libri duo*, and at Vienna, in 1553, his *Christianismi Restitutio.* He was then imprisoned by the Roman Catholics for heresy. Escaping, he went to Geneva, where he was burned as a blasphemer and disturber of the peace. His heresy was neither Arian nor Socinian, but apparently a more consistent assertion of the deity of Christ than that of his enemy, Calvin.

In Italy, where during the preceding century religious faith had been generally superseded among the educated by a semi-pagan humanism, many prominent persons, affected by the religious excitement of the Reformation, adopted rationalistic views. In the second quarter of the sixteenth century, at Vincenza, a small town in the district of Venice, a society existed consisting of persons denying the divinity of Christ and related doctrine. It was dispersed in 1546, previous to which, it is said, Bernard Ochinus and Lælius Socinus joined it. The latter, born in Sienna in 1525, was educated as a lawyer, but devoted his life and great talents to theological speculations. He has been correctly designated "the spiritual father of Socinianism," while his nephew, Faustus Socinus, was "the founder of the sect." He remained ostensibly a member of the Reformed Church at Zurich, although by personal influence, wide correspondence, and extensive journeys disseminating his opinions. He visited Poland in 1551, and again in 1558, and died in Zurich in 1562. His nephew, Faustus Socinus (1539–1604), filled with his uncle's spirit, but with a much more elaborate and consistent system of theology, settled first in Basel, was called into Transylvania to assist Blandrata in his controversy with Francis David, and settled permanently in Poland 1579. After the removal of Spiritus to Poland in 1546, Francis Lismanin, a Corsican monk and confessor of the queen, Bona Sforza, had been converted to Unitarianism in 1551. He was soon re-enforced by Peter Conezius and George Blandrata, a native of Piedmont, who through the influence of Lismanin was appointed physician to the queen. At this time all the Protestant synods held in Poland embraced promiscuously the ministers of all the Reformed societies, whether Lutheran, Calvinistic, or anti-Trinitarian. In 1565 the latter were expelled from communion, and forced to form an independent ecclesiastical organization. The Unitarian Church thus formed comprised persons of very dissimilar opinions. "They all concurred in maintaining the supremacy of the Father, but with respect to Jesus Christ, some thought him to be a God of inferior nature, derived from the Supreme Deity; others held the doctrine of Arius, conceiving him to have been the first created Spirit, who became incarnate with a view to effecting the salvation of mankind; while a third party believed him to be a human being. These last were divided into two classes—the one believing the miraculous conception of Jesus; the other considering him to have been the son of Joseph as well as of Mary." Socinus held that although a man only, he was entitled to divine honors, since his exaltation at the right hand of God and assumption of the government of the Church, while others, pre-eminently Francis David, denied this.

From the advent of Faustus Socinus these various elements were, through his superior genius, wrought into a homogeneous ecclesiastical organization, and brought into substantial agreement with the theological views of his uncle; and ultimately the denomination and system of theology took their historical designation of "Socinian" from these great leaders, but during their earlier history they were called Pinczovians, from Pinczow, the place of their first settlement, and afterward Racovians, from Racow, a town built for them by a Polish nobleman, and their metropolis of learning and influence. They flourished exceedingly for the greater part of a century, converting to their views many of the Polish nobility; they established colleges which attained great reputation, attracting multitudes of Roman Catholic and Protestant youth, and they produced a number of theological speculators and polemics of great learning and ability, whose works attained a vast circulation. In 1563 Blandrata went into Transylvania to attend the prince, John Sigismund II., as a physician, where he succeeded in bringing over to his own opinions Francis David, at that time superintendent of the Reformed churches. These together secured a large following, but the prosperity of the sect was greatly impaired by the bitter controversy which subsequently arose between Blandrata and David, the former affirming and the latter denying that divine honors are to be paid to Christ. David was condemned by the diet held at Weissenburg in 1579, and died in prison in November following. After a long struggle with their opponents the Socinians were suppressed in Poland in 1658, the centennial of Blandrata's arrival. Those who refused to renounce their opinions went into Transylvania, Hungary, and Prussia, and the majority into Holland, where they were merged with the Mennonites and Low Arminians. Of churches of their order in Transylvania there were 108 in 1887, with nearly 60,000 registered members.

A first catechism was written by George Schoman (d. 1591). Faustus Socinus (d. 1604) left another incomplete. Valentine Schmalz and Jerome Moscorovius produced the *Racovian Catechism*, the standard of the Socinian churches. It appeared in Polish in 1605, and was published in German 1608, and in Latin 1609. An English edition, produced in Amsterdam 1652, was ordered to be burned the same year by the English Parliament. It was again translated and published in English in 1818, with a history of the Polish Socinians by Dr. Thomas Rees. After their expulsion from Poland, Andrew Wissowatius and other learned men, finding refuge in Holland, collected their more important writings and published them in 8 vols. folio, comprising the works of Socinus, Crelius, Schlichtingius, and Wolzogenius; to which a ninth volume has been added, containing the writings of Przipcovius and Andrew Wissowatius, and a tenth volume, containing the works of Brenius. This collection is known as the *Bibliotheca Fratrum Polonorum.*

II. Doctrine. 1. *The Scriptures.*—Socinians admit that a supernatural revelation is essential as a means to effect the salvation of men. They regard Christianity as a new law, revealed and executed by Jesus Christ. This revelation is contained in the Scriptures of the Old and New Testaments, and especially in the latter. These are authentic, sufficient, and perspicuous. Yet, as they can contain no elements inconsistent with reason, they are to be interpreted in a sense agreeable to reason; which rule of interpretation in their hands led practically to the conclusion that although containing a divine revelation, and virtually infallible, they contain minor errors.

2. *Theology.*—(1) The divine unity is inconsistent with personal distinctions. (2) Free self-determination is more fundamental in the divine nature than either justice or love. (3) By the act of creating the world, God has voluntarily limited his omnipresence as to his essence, and by creating free agents he has voluntarily limited his power and his knowledge, because free will is self-determined, and future contingent events are not the objects of knowledge. (4) "There is no such justice in God as requires absolutely and inexorably that sin be punished. There is, indeed, a perpetual and constant justice in God, but this is nothing but his moral equity and rectitude, by virtue of which there is no depravity or iniquity in any of his works." (Socinus, *Prælect. Theol.*, c. xvi.) Hence he can pardon any repentant and reforming sinner without a satisfaction to justice. (5) The Holy Ghost is the impersonal power and efficacy of God.

3. *Anthropology.*—The guilt of Adam's sin is not imputed. Man was created naturally mortal, and since the time of Adam has gradually acquired an hereditary tendency to sin, which of itself does not involve guilt. Responsibility is limited by ability. Man, animated by the promises of God, is able to turn unto God; and when he does so turn and believe, God seals his promises more and more on his heart by the Holy Spirit. *Rac. Cat.*, sec. 5, ch. x.

4. *Christology and Soteriology.*—(1) Christ, as to his essential nature, is strictly human, but miraculously generated by the power of the Holy Ghost in the womb of the Virgin. Hence he was from birth without sin. At his baptism he was supernaturally sealed with the Holy Ghost, and qualified and endowed with authority for his office as Prophet, Priest, and King. He was also taken up to heaven and admitted to the vision of God, and instructed in divine things. While on earth he revealed the will of God to his disciples with divine authority. After his death he was raised to the throne of God, endowed with the divine attributes of omniscience, omnipotence, and supreme dominion. He is the rightful object of divine worship and of invocation. He saves his people as Prophet and King, the office of Priest being merged in the other two. He will judge the world at the last day, and raise believers to share in his own glory. (2) As God's justice demands no satisfaction, Christ's death

saves us as an exhibition of divine love; it subdues obduracy, confirms hope by sealing God's promises; it was the necessary means to his resurrection, by which he brings life and immortality to light by an ocular demonstration.

5. *The Church and Sacraments.*—The Church they defined as the company of those who believe saving doctrine. As to what this doctrine is, they allowed, within the limit of the recognition of the divine mission of Christ, the largest freedom of opinion. Socinus discarded the term "sacrament," and held that the Supper was the only sacred rite which Christ intended to be permanently observed. The authors of the *Racovian Catechism* in its final form teach that baptism and the Lord's Supper are the two Christian rites. These they regard as only memorials and symbols and badges of church membership. They pronounce infant baptism an error, but advise its toleration.

In his practical ethics Faustus Socinus was exceedingly humane—opposed to war and capital punishment. The system of Socinus was remarkable for its radical departure from the traditional theology. Even the English Unitarians of the eighteenth century, who were Socinian rather than Arian, were much more cautious and conservative than Socinus, while the early Unitarians in the U. S. were generally Arians, regarding Jesus as a being *sui generis*, and only a little less than God.

LITERATURE.—See, as above mentioned, the *Bibliotheca Fratrum Polonorum*; Dr. Toulmin's *Life of Socinus*; Dr. Thomas Rees's *Racovian Catechism, with History of Unitarianism in Poland* (London, 1818); *De Tribus Elohim* of Hieron. Zanchius (1516–91); *Socinianismi Confutatio* (Amsterdam, 1664) of John Hornbeck; *Vindiciæ Evangelicæ* of Dr. John Owen (Oxford, 1665; vol. xii. of Goold's Edinburgh edition of Owen's *Works*); Dorner's *History of the Development of the Doctrine of the Person of Christ* (English trans. 1861–63, div. 2, vol. ii.); Principal Cunningham's *Historical Theology* (1862, vol. ii.). Revised by JOHN W. CHADWICK.

Soci'nus, FAUSTUS and LÆLIUS: See SOCINIANS.

Sociol'ogy [Fr. *sociologie*, from Lat. *so'cius*, companion (whence by deriv. *soci'etas*, society) + Gr. λόγος, discourse]: the science or natural philosophy of society. More definitely, sociology is the general and fundamental science of society, which occupies itself with the elements and first principles of social phenomena, and leaves to ethnology, demography, political economy, comparative jurisprudence, the theory of the state, the comparative study of religions, and other special social sciences a detailed investigation of particular groups of social facts, all of which have their ultimate interpretation in the underlying and co-ordinating principles of sociology.

HISTORY OF SOCIOLOGICAL THEORY.—To some extent society was studied scientifically and philosophically in ancient times. The *Republic* and the *Laws* of Plato and the *Politics* of Aristotle abound in scientific generalizations. Later, Hobbes, in the *Human Nature* and in the *De Corpore Politico*, entered upon an interpretation of society in terms of its internal forces or motives; and Montesquieu, in *L'Esprit des Lois*, laid the foundations of an interpretation in terms of external conditions or environment. But there was no true science of society until the nineteenth century. Auguste Comte, who coined the word sociology, was the first to put together in one conception all the necessary elements of such a science. Plato and Aristotle had not separated the science from the art of politics nor from ethics. Neither Hobbes nor Montesquieu nor the economists had studied society comprehensively in all its aspects, and, notwithstanding the influence of Hume (to whom, as Huxley has pointed out, Comte was indebted for whatever is scientifically valid in his notions of causation), the explanations of society were still to a great extent theological and metaphysical. Comte insisted that society must be viewed as a whole, indivisible and organic, and he desired to found a science of social phenomena in their co-ordinated entirety. This comprehensive sociology he desired to make positive, basing it on a wide observation of facts and freeing it altogether from theology, metaphysics, the revolutionary spirit, and the art of politics. Comte's conception was incomparably superior to his performance. Both together made for a time so little impression upon thought that the very name sociology was well-nigh forgotten when Herbert Spencer took it up, and by making a voluminous treatise on sociology an integral part of his system of *Synthetic Philosophy*, established for both the conception and the name an enduring place in the circle of the sciences.

Spencer had worked out his scheme of thought before he knew anything of Comte's, and his sociology has nothing in common with Comte's beyond the general idea and the name. It is an application of the philosophy of evolution to society. Society, like the material world and the living organism, undergoes integration and differentiation. It passes from homogeneity and indefiniteness to heterogeneity and definiteness of organization. Comte used the term social statics in a merely rhetorical way, as a name for social order, and social dynamics as a name for progress. Spencer uses the terms in the physicist's sense. Social statics is an account of social forces in equilibrium, social dynamics an account of disturbing and evolutionary changes. Actually the static and the dynamic tendencies are themselves balanced, and the result in society as in the solar system and in the living body is a moving equilibrium. On the physical side therefore Spencer's explanation of society is more profound and scientific than Comte's. At the same time his conception of society as organic is more definite. Without adopting Hobbes's conceit of the leviathan, he finds in society a division of labor not only among individuals, but among groups and organizations of individuals. There is a sustaining system made up of industrial groups, a distributing system of commercial activities, and a regulating system of political and religious agencies. In working out this analogy, however, Spencer, while avoiding the fancifulness of Hobbes, fails to rise to the thought of Plato, who found in this functional organization of society the basis and the true type of the ethical life, and so prepared the way for the conception of society as a means to the perfection of human personality.

The biological-organic conception of society has been made much of by two later sociologists of distinction, namely, A. Schäffle, in the *Bau und Leben des socialen Körpers* (Tübingen, 1875), and Guillaume de Greef, in his *Introduction à la Sociologie* (Brussels, 1886–89), and in a less degree by Lester F. Ward in his *Dynamic Sociology* (New York, 1883). All these writers, however, lay especial stress on the psychical phenomena of society. Ward argues that at a certain stage the natural evolution of society passes over into an artificial and teleological evolution in which society consciously determines its own destinies. De Greef asks what fact distinguishes society from other organisms, and answers that it is contract, including all understandings and alliances. The Platonic or moral-organic conception of society is elaborated with ability by John S. Mackenzie in *An Introduction to Social Philosophy* (London, 1890).

Much of the best work in sociology has been directed upon a more profound study of fundamental social processes. Gabriel Tarde (*Les Lois de l'Imitation*, Paris, 1890), finds the elementary and distinctively social phenomenon in imitation; Ludwig Gumplowicz (*Der Rassenkampf*, Innsbruck, 1883, and *Grundriss der Sociologie*, Vienna, 1885) finds it in the conflicts, amalgamations, and assimilations of heterogeneous ethnical groups. J. Novicow, of Odessa (*Les Luttes entre les Sociétés humaines*, Paris, 1893). has studied exhaustively the phenomena of conflict and alliance; and Émile Durkheim (*De la Division du Travail social*, Paris, 1893) has shown that the division of functions creates not only economic solidarity, but, through reactions upon law and morals, a social and ethical solidarity. Of all these writers it is Tarde, undoubtedly, who has perceived the true and ultimate nature of social facts. Phenomena of any kind, as he points out, can be known only because they repeat themselves. In physics we study repetition under a variety of forms; in biology under the form of heredity, or the transmission of life and characteristics from cell to cell; in sociology under the form of imitation, or the transmission of impulse, feeling, and idea from individual to individual, from group to group, and from generation to generation.

Systematic sociology, however, is not an abstract science, tracing the operation of particular social forces through all their ramifications. On the contrary, it is a concrete science, descriptive, historical, and explanatory, concerning itself with the organization, activities, and evolution of those bands, hordes, tribes, and nations into which the animal and human populations of the world are distributed. Sociology is the fundamental social science, or the science of social elements and first principles, because it includes the elementary and preliminary descriptive matter which is presupposed by all the special social sciences, whether abstract or concrete.

Descriptive Sociology. — Systematic sociology begins with analysis, classification, and generalization. It is necessary to observe the elements that are combined in social phenomena, to know the conditions under which they are brought together, and to examine the groupings and organizations that result. The elements of society are all included under the term population, which must be studied under its outward aspect of numbers, reproduction, increase, density, migrations, and the intermingling of races and nationalities; and under its subjective aspect of sympathies, antagonisms, tolerances, habits, and traits of character. These internal or subjective elements of society are combined in the subjective aspect, or internal constitution, of society itself— that is to say, in the common sympathy and purpose, the accepted tradition, the public opinion, the general will; in a word, in the social mind. Society as subjective, the social mind, projects itself and realizes itself outwardly in an external organization, which is twofold in form. There is a series of groups which are alike in all important respects, and merely repeat themselves to make up the larger aggregates. This series, which may be called the social composition, includes the family, the horde, the tribe, the town, the county, the commonwealth, and the nation. The other form of organization may be called the social constitution. Its basis is a division of labor, and it consists of associations engaged in different activities, some economic, some political, some cultural, but all co-ordinated in one complex system of mutual helpfulness.

Population.—The study of population in its outward or physical aspect begins with the facts of aggregation or grouping. Animal life and human population are massed in dense aggregates in certain places, in less dense aggregates elsewhere. Comparatively few individuals among animals or men live strictly isolated lives. This physical aggregation is the indispensable preliminary condition to the evolution of society. That there may be communication, companionship, and mutual aid, there must be propinquity and contact. These are ensured by the unequal distribution of food-supplies, the varying degrees of temperature and moisture, the topography and other physical circumstances, making life in some places easier than in others.

Looking still at the outward facts and neglecting for a time the internal factors of sympathy and social instincts, we observe that aggregation is of two forms. Individuals descended from a common ancestry are often found living near each other in and about the place of their birth, as in an isolated village, whose inhabitants have married in-and-in for generations and have never separated. This may be called a genetic aggregation. Other individuals born in many different places, perhaps in widely remote parts of the world, are found assembled and carrying on their life-activities in one place, as in a great modern city like London or New York. This may be called a congregate aggregation. The patriarchal theory of the origin of society assumed that genetic aggregation was the original form. The social-contract theory, logically carried out, would assume that congregate aggregation was the original form. Actually no large community is a genetic aggregation only, or a congregate aggregation only. The vital and mental energies evolved in regions where resources are on the whole abundant expend themselves not only in maintaining the food-supplies by industry, and in perpetuating population by reproduction, but in ceaseless motion, travel, exploration, and colonizing; while on the other hand, from regions where the life-struggle is becoming severe, population moves to more favored areas where the opportunities are greater. Migration is thus a normal phenomenon. Every community loses in this way individuals born within it and receives individuals born elsewhere. Every community thus has a mixture of population elements, which may be called its demotic composition. At the same time every community except colonies, and new cities in the first generation or two of their existence, is perpetuated mainly by its own birth-rate rather than by immigration. Society, therefore, we may say, is normally autogenous. It is for this reason that the assimilation of the foreign-born goes on with astonishing rapidity, even in a country like the U. S., which received from 1820 to 1890 an immigration of 15,427,657 souls.

Turning to the internal or psychical factors of society, the most elementary phenomena of social psychology are simple activities of feeling, perception, and will that involve two or more individuals, namely: (1) Mutual perception and communication, by motions, tones, or speech; (2) recognition of fellow beings of one's own kind or species as like one's self and unlike all other objects; (3) imitation; (4) conflict; (5) toleration; (6) mutual aid, alliance; (7) mutual pleasure, play, festivity. These mutual feelings and activities constitute association as distinguished from the merely physical phenomenon of aggregation. An important question to be answered through the study of these phenomena is that of the relation of the social to the individual instincts. The notion which Hobbes converted into a classical doctrine, that individual instincts only are primitive and that "the state of nature" which preceded society was "a state of war," of each individual against every other, is not supported by the results of modern research. Among the lowest forms of life creatures do not prey upon their own kind, but upon other species. Even the amœba, a mere drop of structureless sarcode, discriminates between fellow amœbæ swimming near and such favorite food-objects as desmids and diatoms. This recognition of kind and of accompanying acts of imitation begins when a sentient creature identifies the feeling of touching a fellow creature as like the feeling experienced when it touches one part of its own body with another part. Such feelings can not be associated with nutrition because, even though one pseudopodium of an amœba encountering another should coalesce with it, nutrition would not follow. Therefore, at the dawning of consciousness fellow creatures of the same species can not regard each other as food-objects. On the contrary, they necessarily imitate one another in capturing non-related food-objects, since the touch of a moving part of one is to another a stimulus like the touch of a moving part of itself against itself, and starts like motions. Consequently these beginnings of social feelings and social actions are as primitive as the individual instincts. Among the lowest animal forms, as among civilized men, the struggle for food is normally a rivalry or competition rather than a "war."

Under the pressure of scarcity, however, conflict may at any time break out. Cannibalism has doubtless everywhere had its origin in starvation. Toleration is then re-established by force, not by moral feeling, nor by a conscious calculation of expediency. The very strong kill off the very weak. The very strong are overborne by the numerical superiority of the individuals of average power. The latter are too nearly equal for one to hope to vanquish another, and their resulting toleration is an equilibrium of strength, which is tested from time to time, and so maintained, by frequent acts of aggression and revenge. Toleration being established, fellow-feeling, sympathy, and imitation can work themselves out, step by step, with the evolution of intelligence, in the positive forms of mutual aid, alliance, and mutual pleasure. Mutual aid begins in accidental helpfulness and protection, and is perpetuated consciously when its benefits are perceived. Social pleasures are observed among nearly all the higher animals, as among men. Among the birds and the more intelligent mammals infancy and youth are a continuous playtime. In social pleasures the higher sympathetic feelings, which presently become the strongest social bonds, are developed, and the cultural activities are born. Mutual aid is the foundation of political alliance and of economic organization. Toleration is the foundation of justice. Imitation is the foundation of diversified desires and individual industry.

Association reacts on the associated individuals, developing in them a social nature; but owing to differences of circumstance and of heredity the development does not go on equally, or at the same rate, in all parts of the population, and social classes result. In a majority of individuals fellow-feeling, imitativeness amounting to industry, tolerance amounting to justice, helpfulness, and companionableness, are ruling qualities. This class is the normally social. In other individuals these qualities are deficient or absent, but are simulated. Pretending to have the social nature and appealing to those in whom it is real, these pseudo-social characters, if not aggressively anti-social, make up the pauper class. Yet others, whether simulating the social nature or not, having become aggressively anti-social, are the criminal class.

The Social Mind.—The foregoing mental and moral elements of society are combined in products which we call by such terms as the common feeling, the moral sense, the public opinion, the general will, of the community, and which it is convenient for the sociologist to name collectively the social mind or the social consciousness: but care is necessary to avoid associating false conceptions with these terms. They do not stand for mere abstractions. The social mind

is a concrete thing. It is more than any individual mind and dominates every individual will. Yet it exists only in individual minds, and we have no knowledge or evidence of any consciousness but that of individuals. There is no real paradox here, however. The social mind is the phenomenon of many individual minds in interaction, so playing one upon another that they simultaneously feel the same emotion, arrive at one judgment, and perhaps act in concert. It is therefore, as Tarde has called it (*La Logique Sociale*, Paris, 1894), a social logic, binding the products of individual logic into more complex wholes.

The social integration of desire, belief, and will, which constitutes this logic, is effected sympathetically or rationally; passionately and violently, or deliberatively. One mode is seen in popular fads or crazes, panics, emotional revivals, mobs, lynchings, riots, violent revolutions. The other is seen in the proceedings of a parliamentary body, the execution of legal justice, the movements of a disciplined army. The proportion of rational or deliberative action depends on the mental evolution of the population, its temperament, and the amount of its criminality. The greater the criminality, the less the rationality and the greater the violence.

In discussion and deliberation society arrives at self-consciousness. Each individual concerned makes his neighbor's thought the object of his own thought at the same instant that he makes his own thought such an object; he judges the two to be identical, and then acts with a full belief that his fellows have come to like conclusions and will act in like ways.

The primary products of the social mind are social choices and values. These are further combined with reference to the phases and interests of life into standards of living and of industry, rules and methods of art, laws of conduct, political policies, religious faiths, scientific doctrines, ethical ideals, all of which, handed on from one generation to another, become traditions. The three primary traditions are: (1) The economic, consisting of the whole body of knowledge and usage pertaining to material well-being; (2) the juridical, consisting of the customary and positive law; (3) the political, consisting of the political history, policy, and aspirations of a state. Secondary traditions are the lingual, the æsthetic, the religious, the scientific, and the ethical.

All values, standards, codes, faiths, and traditions exist in individual minds only. Durkheim's argument, that they are independent objective realities because they can be committed to writing, is a fallacy, since the written page is meaningless apart from the living knowledge of the reader. But they exist in a multitude of interacting minds simultaneously, and are therefore objective as well as subjective to each individual. Upon each mind as it unfolds they are imposed from without, and sanctioned by penalties for disregard or disobedience that range from ridicule, disapproval, and boycotting to collective force or vengeance.

Through the channels of these different traditions the mental life of society flows in an ever-changing distribution. At one time society is religious, at another time creative and artistic, at yet another time scientific. One generation is absorbed in political concerns, another in business affairs. Always, however, a tendency toward the establishment of a normal equilibrium may be observed. At any given moment desires and beliefs assume unlike forms and find varied expression in different parts of the population. The social codes and faiths are mutually dependent. This is the social logic in its highest manifestation.

The social mind not only creates codes and faiths and imposes them upon individuals; it reflects upon the groupings of individuals which grow up more or less unconsciously, and upon various relations of mutual aid. Sanctioning some groupings and relations, opposing others, it shapes the social structure or organization.

The Social Composition.—In the social structure by composition small groups are combined into larger groups, and these again into groups yet larger. Each group, whether small or large, contains both sexes and more than one generation. Each, therefore, might live independently of the others, perpetuate itself, and grow to larger dimensions. Each group is made up of elements that are less like each other than one group, as such, is like another group of similar composition. For example, father, mother, and child in the family are more unlike than are two families of the same kind or type. The inhabitants of a town in which are found different nationalities perhaps, different ages, different abilities, characters, and tastes, are more unlike among themselves than are neighboring towns one to another. Each group has much the same characteristics and lives in much the same way as any other group of similar dimensions and composition. Such groups therefore supplement or mutually aid each other only in power and mass, not by division of labor.

The unitary group in societies of the higher animals, or of men, is the family, which may be a temporary or an enduring union of one male with one female and their offspring, or of one male with two or more females (polygyny), of one female with several males (polyandry), or of several males with several females (punaluan or communistic marriage).

Human societies composed of families grouped in larger aggregates are of two types, the ethnical and the demotic. Ethnical societies are genetic aggregations; a real or fictitious blood-kinship is the chief social bond. Demotic societies are congregate aggregations. They are groups of people bound together by habitual intercourse, mutual interests, and co-operation, with little or no regard to origins or to genetic relationships. Ethnical societies are the earlier. Demotic societies have been developed out of the ethnical. Among ethnical societies many are metronymic, kinship being traced through the mother-name only. Others are patronymic, with the kinship traced through the father-name only. Metronymic relationships are the earlier.

The smallest ethnical society, whether metronymic or patronymic, is the horde, which is a group of from three or four up to twenty or thirty families, dwelling together in a camp or village. The Bushmen, Fuegians, and Inuits afford examples. The next larger group is the tribe, an organization large enough to have been formed, and probably having had its origin in fact, in an alliance of several hordes for defense or aggression. Horde and tribe are often confounded in ethnological writings with the clan or gens, which is a totally different organization from either. The horde, and likewise the tribe, includes and claims all of its descendants, whether through its daughters or through its sons, who dwell together in the parent camp. The clan, on the contrary, is a partly natural, partly artificial brotherhood and sisterhood, which rigidly excludes all of the descendants of its sons if metronymic, or all the descendants of its daughters if patronymic. A clan therefore can never be perfectly identified with a horde or with a tribe. It may be a section of a tribe, or its membership may be scattered through many hordes or through several tribes.

Related tribes bound together by clanship ties and speaking dialects of the same language, when they unite in a military or political federation are a folk or ethnic nation. Such were the allied six tribes of the Iroquois, and such were the confederated Franks, the Lombards, and the Angles.

In demotic society the smallest community is the deme, village, or township. Townships are combined into counties, counties into commonwealths, commonwealths into federal states.

The social composition is effected by the deliberate action of the social mind under the pressure of external necessities, especially those of defense and aggression. When integration has been accomplished the social mind puts its own impress on each component group and moulds it into conformity with a certain type. Thus in a given community every variety of the family may have existed at the outset or may from time to time appear; but the social mind gives approval and sanction to some one type, as the monogamic or the polygamous, and prohibits or discountenances all others. In like manner in the commonwealth each component town, and in the federal state each component commonwealth, is compelled to conform to a type or standard. Psychologically, therefore, the social composition may be described as a mutual toleration and alliance of the unlike among the individual elements of a society, supplemented by an alliance of the like and non-toleration of the unlike among its component groups.

The Social Constitution.—The social structure by constitution is a co-ordination of associations, any one of which may or may not include both sexes in its membership, but in any case does not include them both for purposes of marriage and reproduction. Accordingly, the constituent associations of society are mutually dependent, and each presupposes the social composition. Each association is composed of individual elements that on the whole are more alike than associations themselves are to one another. The members

of a given trade-union are more alike with reference to the purpose which unites them than one trade-union is like another; otherwise the differing members would connect themselves with other unions. The members of a given church are more alike in feeling and belief than one church is like another. The members of trade-unions collectively or of churches collectively are more alike than trade-unions in general are like churches in general. Each association does a specific work; it may be said to have a functional purpose. Combination among associations is therefore a co-ordination, and mutual aid among them is not through mere increase of mass and power, but by a division of labor.

The social constitution is analogous to that of a biotic organism, as Spencer has shown; but the analogy is of limited value for scientific purposes until supplemented by a close study of those features of social organization that are distinctive. Of these the most important is a more perfect actual or potential duplication in the social organization of the organs or agencies for performing every essential function. Though in the animal many vital organs are duplicated, there neither is nor can be any complete duplication of the alimentary, the circulatory, or the nervous system. Public association or the state can at need assume every social function. Voluntary association can do the same. It is as if the cerebral nervous system, on the one hand, had the emergency power to organize from the body-tissues a new alimentary and circulatory system, and the sympathetic nervous system, on the other hand, could at will assume the functions of the brain and spinal cord. This power of public and of private association to assume each other's functions is maintained, because at all times some duplication is in fact kept up in every essential class of social services. The error of attributing to the state defensive and juridical functions only, and to private associations economic and cultural functions only, is being constantly repeated in political and economic writing. The fact is that the state performs always important economic functions of production, transportation, exchange and finance, and cultural functions, religious or educational, and that private associations, such as political parties, political clubs, revolutionary societies, and private tribunals to achieve political or juridical ends, are among the most important voluntary organizations known. The socialists, therefore, are right in saying that the state could, if necessary and desired, carry on all social undertakings, and the individualists are right in saying that society could get on, and in a way achieve its ends, without the organized state; but both are wrong in supposing that either thing will happen under a normal social evolution. The actual distribution of functions between public and private agencies is a varying one, always changing with changing circumstances. Consequently, movements tending to increase public activity on the one hand or to enlarge the opportunities for private initiative on the other hand will be self-limiting so long as conditions are normal. They should be regarded as tendencies toward equilibrium. Whatever belittles the state or destroys popular faith in its power to perform successfully any kind of social service—whatever impairs the popular habit of achieving ends by private initiative and voluntary associations, by so much endangers society, checks its development, and prevents the full realization of its ends.

The supreme end of society is the protection and perfecting of sentient life. The end of human society is the evolution of the rational and spiritual personality of its members. The associations directly concerned in this function are the cultural, namely, the religious, the scientific, the ethical, and the æsthetic, the educational organizations, and what is called polite society. Economic, legal, and political organization exists (in a functional sense) for the sake of cultural organization and activity. The social mind always has perceived this truth, and by means of its sanctions has endeavored to mould the social constitution into accordance with it. Associations and relationships sanctioned by the social mind are known as institutions, and they are fostered or abolished always with a view to cultural as well as to protective ends. For both ends specialization and division of labor are necessary. Society is obliged to tolerate and promote differentiation in its constitution while it maintains the homogeneity of its composition. Psychologically, therefore, the social constitution may be described as an alliance of the like and non-toleration of the unlike in each simple association, supplemented by toleration and co-ordination of the unlike in complex association—that is to say, in the relations of each association to other associations and to society at large.

Historical Sociology.—The stages of sequence in social evolution have corresponded roughly to the four stages of synthesis above described. Concourse, fellow-feeling, social instincts, and mutual aid had their origins in animal society, and it was by means of them that animal life was developed into various types. The first stage of association, therefore, was zoögenic. In the second stage the evolution of speech and the genesis of a varied tradition made the social mind self-conscious, and transformed the anthropoid into man. Society then was anthropogenic. The third stage, in which the social mind, acting on spontaneous forms of alliance, created clan, tribe, folk, and nation, was ethnogenic. In the fourth stage a wonderful development of the social constitution, with division of labor, has made possible a high utilization of resources, a rapid multiplication of population, and a democratic evolution of the social mind. Society has become demogenic.

Zoögenic association is as old as sentient life. All biological speculations that ignore the social factor in the struggle for existence are imperfect, and without appeal to it the evolution of animal intelligence can not be explained at all. Long before man appeared on the earth sympathy was highly developed, the art of communicating feelings and simple ideas, by tones and gestures, was practiced by millions of creatures, family relationships were established, and bonds of mutual aid, companionship, and pleasure held together swarms, flocks, troops, bands, and herds. Even the beginnings of tradition had appeared. Association had become the most important defense and help in the life-struggle. The survival of the fittest was the survival of the social.

Anthropogenic Association.—Therefore nothing could be more unscientific than a theory of human origins through the evolution of a single pair of anthropoid apes into man and woman. If science abandons the dogma of special creation, it must abandon also the dogma of a first pair. There could have been no continuity of animal and human descent without a continuity of animal and human society. If anthropoid apes became simian men, a whole community or many communities underwent the transformation. John Fiske's theory (*Outlines of Cosmic Philosophy*, Boston, 1874) that the prolongation of infancy, as an incident of the physical evolution of man, by holding the family together for a relatively long period prepared the way for more extended social relations, reverses the probable order of cause and effect. Increasing social intercourse stimulated and developed the cerebral nervous system. Cerebral development entailed the prolongation of infancy, which, in turn, by delaying the use of arms and legs and jaw, altered the proportions of the skeleton and the facial angle.

These changes, it is probable, took place step by step with the evolution of speech and of tradition. Many evidences point to communal festivity, with its attendant rhythmical gesticulation and some approach to song, as the means by which, under the influence of mental exaltation, conventionalized sounds were so definitely associated with feelings and ideas as to constitute the beginnings of speech. (See Language.) Industrial traditions had their beginnings among animals. Most characteristic of the beginnings of human society were the primitive explanations and traditions of life, death, and causation, known as Animism (*q. v.*), and the ghost-theory. See also Anthropology.

Ethnogenic Association.—There is no reason to doubt that the earliest hordes of men were composed of family groups. Among the higher mammals the troop, band, or herd is subdivided into pairs, families, or studs, and it would be astonishing to find that the same thing was not true of the primitive hordes of men. At the same time the relations of the sexes may have been of the loosest description. Writers on the history of marriage have too often made the mistake of assuming that the two things must be inconsistent. The living together of man and woman does not always preclude irregular indulgence on the part of either. Festival occasions are still, in many parts of the world, opportunities for conduct closely approaching promiscuity by men and women who, none the less, live habitually in family relations. The trading of wives also, and the lending of wives to guests, are customs of friendship and hospitality in many communities.

It is probable, further, that, as a rule, the domestic group was a simple pairing or monogamous family, in which male jealousy and power played the important part ascribed to

them by Darwin and Sir Henry Sumner Maine, and that polyandry and polygyny were exceptional deviations from the mean type. The argument for a primitive polyandry is based on the fact that primitive kinships were metronymic, and the attempt to explain it by uncertainty of paternity. Another explanation is quite as good. A family established by the forcible appropriation of the woman and maintained by masculine power is dissolved the moment the man tires of his captive and deserts her. Her offspring, knowing only the mother that cares for them, will take her name. That primitive family unions were commonly of such brief duration and followed by such consequences is extremely probable. See MARRIAGE.

The family, as a rule, was exogamous—that is, the sons preferred to take wives from other households instead of from among their sisters. This is a preference that had its beginnings in animal life, as Westermarck has shown, and is to be accounted for by the influence of novelty upon the sexual passion, supplemented by natural selection. When several hordes dwell in such proximity that some intercourse, friendly or hostile, is possible, the preference may extend to the women of other hordes, and especially if the practice of obtaining them by force, theft, or stratagem causes them to be prized as trophies of prowess or cunning. The hordes, then, like the households, may become exogamous.

Brothers and sisters by blood are a natural property-holding and defensive group, spontaneously aiding each other to redress wrongs inflicted by other groups. In pursuing its interests and redressing its wrongs, it seeks the aid and protection of supernatural power. In the animistic stage of culture some natural object, plant, or animal, which is regarded with superstitious veneration, becomes the special guardian of the household. Believing that a mysterious kinship can be established through touch, by imitation, and in other ways, the members of the fraternal circle do not doubt that they may become akin to the object of their worship, and to make sure that they always bear its protection with them they mutilate or mark themselves or their clothing or belongings with a sign or rude image of the sacred object. Soon every practice of the kindred circle is thought of as sanctioned by its totemic deity, and any deviation from established custom is looked upon as a sacrilege, sure to be followed by dire penalties. In this way exogamy becomes a binding obligation and incest a sin.

For a long period each little fraternity of uterine brothers and sisters in each succeeding generation is likely to have its own totemic deity; but sooner or later, under the influence of their mother and her relatives, or through reasoning that they are descended from their mother's totemic deity, a circle of brothers and sisters is sure to adhere to the mother totem and worship, instead of adopting a new one. From that moment the totemistic circle begins to enlarge. In the second generation it necessarily includes brothers and sisters, mothers, daughters and sons, uncles and aunts, nephews, nieces, and cousins. Since kinship is reckoned through mothers, but not through fathers, the circle will claim and include the children born of its daughters, and will exclude those begotten by its sons. Children of sons will belong to the kindreds of their mothers; and since in the household exogamy has become superstitiously associated with totemistic worship, and what was originally an instinct has developed into the idea that men must not take wives of their own totem, the wider totemistic circle also must be exogamous. The kindred has become a clan.

Though the clan can never be perfectly identified with the horde, and if neighboring hordes are exogamous each clan will have members in several different hordes, there are two ways in which a majority of the members of a horde may belong to the same metronymic clan. Men may go to live in the residences of their wives—beena-marriage. In this case clanswomen with their children and unmarried male kinsmen may live together in one place, and their husbands, belonging to many different clans, will be an unimportant minority. If, however, men steal or buy their wives (baal-marriage), who then follow the residences of the husbands, the children of a metronymic clan will be dispersed through many hordes, and each horde will be made up of members of many clans. Nevertheless it may happen that divorced wives and their children return in such numbers to their parent hordes that the clan is always tending toward identity with the horde. A cluster of neighboring hordes may thus be transformed into a cluster of horde-clans.

When neighboring clan-hordes draw together into a tribal organization, the lines of demarkation between hordes as such may disappear or cease to have importance, while the clanship lines remain sharply defined. Composed of hordes the tribe is constituted of clans, mutually dependent because exogamous. If a clan, becoming large, subdivides, the tradition of original unity is often preserved in the phratry, a fraternity of clans. If a tribe subdivides, individuals from each of its clans go into the new tribe. The household is the economic organization of the community, developing and handing on the economic tradition. The phratry is the religious organization, guarding the religious tradition. Its secret societies of medicine-men are the germ of a priestly and professional class. The clans are the juridical organization, developing and applying a customary law which regulates property rights, marital rights and limitations, feuds, and vengeance. The sachems, elected by clansmen and clanswomen, are the first lawyers and judges. The tribe is the military organization. Its council is composed of the leaders or chiefs of the volunteer war-parties put forward by each clan. In the tribal council a military tradition is evolved. True political organization begins only when tribes confederating become a folk or ethnic nation. Then for the first time the juridical power and the military power are combined in one governmental system, as different expressions of a single sovereignty.

Patronymic societies exhibit the same forms and stages of organization as metronymic, with the exception of differences that necessarily follow from kinship through fathers. The change from mother-kinship to father-kinship may occur at any stage of social integration; in the horde or in the folk. It is effected by economic circumstances or evolution. If the family can survive only through the industry and protection of the father, as among the Esquimaux, who depend on the arduous and dangerous chase of the walrus, it will hold together long enough for children to grow up under paternal authority and take the father-name. When under different conditions wealth in flocks and herds begins to be important, men appropriate it and desire to transmit it to sons instead of to sisters' children. Patronymic kinship prepares the way for an advance in culture from animism to ancestor-worship, which in turn greatly strengthens paternal power. With baal-marriage and patronymic kinship the horde and the clan can become nearly identical, compact, and powerful. In horde, clan, and tribe chieftaincy can become hereditary. Chieftains can become the founders of a nobility, and the chief military leader of a folk, becoming a true king by uniting supreme religious and judicial authority with his military functions, can found a royal family. Kings and chieftains receiving from their followers large shares of the booty of war, and privileges in the tribal land, enrich their favorites, who in turn, attaching to themselves the broken and ruined men of shattered clans and tribes, become the "cow noblemen" and systematic marauders of that barbaric feudalism which in time seriously undermines the kinship or gentile organization of society and prepares the way for another system. See, further, ETHNOLOGY.

Demogenic Association.—In ethnogenic association the social constitution is incidental to the social composition. In demogenic association the state has become supreme. It subordinates and rearranges the social composition and perfects the social constitution.

A tribal confederation seldom establishes itself permanently upon the territory where it originates. It moves on to conquer richer regions, and, if successful, reduces their inhabitants to slavery or serfdom. Increasing then in wealth, it attracts to itself strangers from far and near, who presently become so large an element in the population that it is no longer possible to organize legal and military administration on the clanship and tribal basis. Legal rights and membership in the state are made to depend on civic association within territorial limits. Society enters upon civilization.

Civilization exhibits three stages. Egypt and Babylonia did not get beyond the first, Greece and Rome did not complete the second. The modern Western nations have entered fairly upon the third. In the first stage all the energies of society are concentrated upon the task of political integration and defense. To this everything else is sacrificed or subordinated, and government is absolute. This work completed, the liberated national energies expend themselves in criticism, in the struggle for personal freedom, and in the effort to combine liberty with stability through the constructive evolution of municipal and constitutional law. Greece failed in legal construction, and Rome sacrificed

spontaneity to system. The civilizations of Greece and Rome, like those of the Eastern nations, were unstable, because they were surrounded by a worldwide environment of barbarism and savagery. The modern Western civilizations are stable because they simultaneously grew to great and powerful statehood in an environment of civilization, which for ages had lain between them and the more remote barbarism of Africa and Asia. Consequently there was no necessity for an extreme sacrifice of personal initiative and the lesser interests of life. The second stage also with them was no partial evolution. The Renaissance, the Protestant Reformation, the American and the French revolutions were but so many phases of a thoroughgoing criticism and reconstruction of the social constitution on lines of legality and free association. By means of this strong but elastic union of voluntary and flexible organization with law, the magnificent development of modern industry and a consequent multiplication of population without parallel in history have been made possible.

Spencer's generalization that societies are military or industrial in type is therefore neither adequate nor altogether accurate, in the form in which he has stated it. Militarism and industrialism are stages rather than types, and between them lies the stage of critical and legal reconstruction, which is the cause, rather than the effect, of industrial evolution.

The development of the fundamental social interests thus reverses the order of their genesis. Society is first economic, then juristic, then political. Perfecting then the political system, it works back through law to the economic foundations. Not so in its cultural interests. The order of their genesis—religious, scientific, ethical—is the order of their development. The political era is also the great religious period; society is theocratic. Then the social mind goes forward to critical and scientific activity while it applies itself to legal construction, and it is only by the aid of science and criticism that legal construction is accomplished. Finally, when it works back to industrial problems it advances to a serious study of ethical principles and ideals, and only as it does so can it hope to adjust the complicated relations of economic life. Future society, increasingly economic, will be also increasingly ethical.

Explanatory Sociology.—The details of explanatory sociology are yet to be worked out, but certain principles are established. The interpretations of social structure and evolution must be in terms of natural causation; but psychological phenomena, no less than physical, are natural, and society must be explained in terms of motives and choices, as well as in terms of outward forces.

The initial causes of society are physical. Aggregation and association are brought about by geographical and organic conditions; but association furthers survival and happiness, and the associated individuals, becoming consciously and fully aware of the benefits of society, attempt to defend and improve it. The unconscious natural process thus becomes conscious and artificial. Relations and activities are valued, choices are made, policies are devised, and institutions founded. The process does not end here, however. Natural selection works among policies, laws, and institutions, as among individuals. Some fail to benefit the community, and disappear. Those that survive are not always the ones that were supposed to be most promising at their inception.

The further task of sociology, therefore, is to discover the details and laws of these complicated processes. It must try to formulate, first, the laws of the purely physical and unconscious causation that occurs in society; second, the laws of conscious social choice; and, third, the laws that govern the natural selection and survival of arrangements, laws, and institutions.

Society has often been described as an organism. Being essentially psychical it is more and higher than an organism. It is also more than a multitude of individual minds. It is a psychological organization of conscious organisms.

Socorro: See the Appendix.

Soco'tra: an island in the Indian Ocean, off the eastern coast of Africa; in lat. 12° 39′ N., lon. 54° 1′ E., 140 miles N. E. of Cape Guardafui; controlled by Great Britain. Area, 1,384 sq. miles. The island produces good tobacco and dates and the best aloes known, and has superior sheep and goats. There is considerable trade with Muscat. Pop. about 10,000.

Socrates, sok′rā-tēēz: philosopher; son of Sophroniscus and Phænarete; b. at Athens in 470 B. C. (or 469, in May or June); drank the cup of poison 399 B. C. (in April or May?). His father was a sculptor, and Socrates in his early years worked at the same occupation. He alludes to his mother (*Theætetus*) as a midwife, and likens to her art his own skill in drawing out ideas by conversation. In his youth he learned geometry and astronomy and practiced gymnastics. He is reported by Plato (*Phædo*) as having studied the work of Anaxagoras on *Nature*, probably under the instruction of Archelaus, the disciple of Anaxagoras; and according to Xenophon (*Mem. I.* and *IV.*) he had a critical knowledge of the writings of the early wise men, as well as of the Ionic school of philosophy. He probably met Parmenides when about twenty years of age, and mastered the Eleatic view of negative dialectic (which proved its theories by showing up the contradictions of its opponents), and was thoroughly instructed in the doctrine of the Sophists—possibly may have received direct instruction from Prodicus. It is said that having early lost the patrimony inherited from his father, the wealthy Crito assisted him in his education, and employed Evenus to instruct him in poetry, Theodorus in geometry, and Damo in music, and that the celebrated Aspasia had a share in his culture. He married, and had three sons. Xantippe, his wife, has come down in history as the typical scold. Socrates is represented as using the violence of her temper as a means of cultivating his patience. He took part in three military campaigns with his fellow citizens—that of Potidæa (432 B. C.), wherein he saved the life of the young Alcibiades, who was wounded; that of Delium (424 B. C.), in which he saved the life of Xenophon, and himself received assistance against his Bœotian pursuers from Alcibiades in the disastrous retreat which followed, and wherein his own cool bravery was conspicuously manifested; and that of Amphipolis (422 B. C.). He proved himself to have an extraordinary capacity to endure cold, heat, and fatigue. He walked barefoot upon the ice and snow of Thrace in his usual clothing, while others were clad in furs. By this time he had become noted for his peculiar mode of instruction by means of conversations which he held with people of all classes at the public resorts. Aristophanes in *The Clouds* held him up to ridicule as the arch-Sophist, as a dreamer morally worthless and physically incapable (as Grote remarks) nearly at the time when Socrates was exposing his life for his country on the battle-fields of Delium and Amphipolis. The personal appearance of Socrates was such as to shock the Athenian sense of the beautiful; with a turned-up nose, projecting eyes, bald head, thick lips, round belly, he resembled a satyr or Silenus; he wore a miserable dress, and would frequently stand still in sudden fits of abstraction, rolling his eyes, staring on vacancy. Aristophanes found in him the choicest subject for comedy. Modern historical criticism has justified in large measure the poet, and pointed out his patriotic desire to save his native city from the decline in morals and political ideas which he saw impending from the prevalent tendency to reflection and sentimentalism—the cultivation of independent subjectivity or individualism (the right of private opinion) as contradistinguished from implicit, unreflecting obedience to customs and laws. This he traced, correctly enough, partly to the teachings of the Sophists or private teachers of culture, among whom Socrates was acknowledged to belong by his contemporaries, notwithstanding his radical differences from them in doctrine. In common with Socrates, the Sophists cultivated reflection—to make up the mind on internal personal grounds. Dialectics was the art of the advocate and orator, so much needed before the courts and popular assemblies of Athens—the art to make the worse appear the better reason; an art which could be applied to good purposes or to bad ones, and not in itself a corrupt art. It was the same art that is cultivated in the debating societies and moot-courts of young lawyers of our own time. Plato and Aristotle were the first to bring the name "Sophist" into odium as a perverted species of philosophizing. Aristophanes condemned equally all species of philosophic reflection. Isoc-

rates called Plato a Sophist, and Aristotle calls Aristippus, the disciple of Socrates, a Sophist. Socrates was selected as representative of his profession by Aristophanes because of the notoriety of his personal appearance and his missionary habit of practicing his art among all classes without price. In *The Clouds* it is portrayed as teaching a vain and profitless semblance of wisdom, corrupting in its influence upon youth, and undermining all true discipline and morality. Twenty-four years after the appearance of *The Clouds*, Meletus, a poet, seconded by Anytus, an influential demagogue, and Lycon, an orator, hung up an indictment against Socrates accusing him of being "guilty of crime—first, for not worshiping the gods whom the city worships, but introducing new divinities of his own; next, for corrupting the youth. The penalty is death." Lycon is said to have felt aggrieved at what Socrates had said of the orators (see his attack on orators in Plato's *Gorgias*); Meletus, for his treatment of the poets; Anytus, a rich leather-dealer, had been driven from Athens during the rule of the Thirty, and as Socrates was supposed to sympathize with the tyrants, and especially with Critias, the most detested of them all (having taught him when a young man), his feeling toward the accused may be explained. Moreover, a son of Anytus had become interested in the conversations of Socrates, and the latter had interceded with the father to educate his son for something better than a leather-seller. To produce aspiration for a career above the family vocation was "corrupting the youth." Socrates had cross-examined with his dialectic skill and bitter irony most of the celebrated statesmen, orators, poets, Sophists, and artisans of Athens. None had forgotten their humiliation at his hands; a few had sought help and instruction from him afterward, but most of them avoided his presence and desired revenge. Very many of these were to be found among the 500 (557 according to Diogenes Laertius) judges who sat at his trial. In his defense before his judges he was so bold and free-spoken that he produced a very unfavorable impression, and was accordingly adjudged to be guilty by a small majority. According to custom, he was allowed to name the punishment he preferred to substitute for the penalty of Meletus; he gave it as his opinion that he deserved to be subsisted in the Prytaneum at public expense for the rest of his life as a benefactor of the state, but upon the solicitation of his friends agreed to ask a fine of thirty *minæ*. This haughtiness so incensed the judges that they voted by a majority of eighty votes for his death. The execution was delayed for thirty days, until the return of the sacred ship from Delos. Socrates refused to avail himself of the means of escape from prison offered him by Crito, thus attesting his law-abiding character. He drank the cup of hemlock with perfect composure after a conversation with his friends upon the immortality of the soul, being assured that he was merely setting out upon a happy journey, and that by his death he attested the steadfastness of his convictions to his disciples, and thereby accomplished far more than by living.

As to the best authority regarding the actual teachings of Socrates there has been much dispute. He has left behind no writings of his own, and we know him chiefly through his two disciples, Xenophon and Plato. It is supposed that the *Memorabilia* of the former give us a more accurate picture of his method and ethical doctrines, while the *Dialogues* of the latter present us with highly idealized portraitures, and offer us the further-developed doctrines of Plato through the mouth of Socrates. Aristotle testifies that to Socrates belongs the honor of the invention of induction and accurate definition of terms. His dialectic rests on induction. More important even than this was his practical application of the Delphian precept, "Know thyself," as the condition of virtue. Aristotle (*Nich. Eth.*) says that his fundamental idea is the union of theoretical insight and practical virtue. That virtue is a knowing is a very radical statement, and altogether incomprehensible unless one considers its relation to the time in which it was uttered. Relieved of its exaggeration, perhaps, it means only that self-consciousness is essential to responsible action. It expresses the transition from the morality of custom and habit, mere conventional use and wont, to morality as conscious right conduct, resting on reflection and moral principles. In this, therefore, Socrates is the most significant personage in the ethical history of the race. All beyond him lies in the region of unsophisticated use and wont, or prescriptive ethics, like that of the Chinese and other Oriental civilizations; on the hither side the chief interest is the ever-widening influence of the individual consciousness of moral necessity, the long and gradual discipline of mankind into independent, responsible wills, endowed with "rights of conscience." In the ante-Socratic principle the individual takes the impulse of his volition from external phenomena—from auspices or auguries, nothing being undertaken without them. Individual conscience and personal decision date from the epoch of Socrates, and their growth from that time is the progress of the world-history. The new principle in its appearance with Socrates is as yet undeveloped, and involved with much that is foreign to it and contradictory of it. His dæmon (*δαιμόνιον*) or "genius" is a relic of the old, and is akin to those immediate stages of psychical life which we know under the names somnambulism, dreaming, premonition, hypnotism, and is a return of the conscious mind to its fœtal stage of existence, to instinct—the transplanting, as it were, of the augury from external appearance to internal impression. On the other hand, it was related to the consciousness of principles, and as such formed a factor of what we call conscience. There is no individual responsibility without conscious determination of the will, and even the perverse action of the conscious will is higher than mere unconscious action: a wicked man is a higher order of being and more precious in the sight of God than a good, obedient ox or horse. Socrates seems to have exaggerated this view so far as to make all virtue to be correct knowledge, and all vice to be ignorance, thus ignoring the will altogether. This, however, is not surprising when we consider the novelty and the greatness of his insight into knowledge as a factor of true moral action. Nor, if we consider the ultimate consequences of perfect insight, can we regard him as wrong in holding that ignorance is the occasion of all wickedness, although we insist that moral responsibility implies knowledge of the right, and assert that wickedness is perversity of will in the face of better knowledge. See Moral Philosophy.

The panegyrics pronounced upon the character of Socrates are not surpassed. That of Alcibiades in Plato's *Symposium* is perhaps the finest—that of Xenophon, more sober and weighty: "Knowing him to be such a man as I have described—so pious toward the gods as never to undertake anything without first consulting them; so just toward men as never to do the slightest injury to any one, while he conferred the greatest benefits on all who came in contact with him; so temperate and chaste as never to prefer pleasure to what was right; so wise as never to err in judging of good and evil, nor needing the aid of others in order properly to discriminate between them; so able to discourse upon and accurately define the subjects we have mentioned; so skillful in penetrating the hidden characters of men and seizing the fittest time to reprove the erring and turn them to the paths of virtue—I can not but regard him as the most excellent and happy of mankind." The sources of information as to his life are Xenophon's *Memorabilia*; Plato's works, especially the *Apology*, *Phædo*, and *Symposium*; Aristotle's *Metaphysics* and *Ethics*; Diogenes Laertius (book ii.); and, among others of modern writers, the essays of Schleiermacher, Boeckh, Van Heusde, Hegel, Forchhammer, Brandis, Rötscher, and Grote are important. Zeller's *Socrates and the Socratic Schools* is the best work accessible in English.

William T. Harris.

Soda [from Ital. *soda*, liter., fem. of *sodo* (collat. form of *solido*, solid) < Lat. *soldus*, collat. form of *so'lidus*, solid]: in chemistry, a hydrous oxide of the metal Sodium (*q. v.*), Na_2O; in commerce, however, the compound formed by the action of water upon this oxide, and generally designated, even by chemists, hydrate of soda or sodium hydrate. The carbonates of sodium also are often called soda commercially. Sodium hydrate, NaOH, or caustic soda, is prepared commercially from the carbonate by the action of lime. Three parts of crystallized carbonate (*sal-soda*) are dissolved in five times as much boiling water, and one part of quicklime, slaked and mixed to a cream with three parts of water, is gradually added, with continued ebullition. The caustic solution is then decanted after settling, and boiled down rapidly with the access of air. From the residue pure caustic soda may be dissolved out by alcohol, which is then distilled off; but for most commercial, manufacturing, and medical uses the residue is merely melted and cast into sticks, which are preserved in bottles. Much caustic soda is also made by heating or boiling together the Greenland mineral cryolite with hydrate of lime. The compound is white, opaque, crystalline, and melts below incandescence. It is used largely, in the form of solution or soda-lye, for making soap.

Revised by Ira Remsen.

Soda-ash: crude soda, as first produced before having gone through any refining processes. Previous to the French Revolution of 1789 the only source of the alkali-soda was from the ashes of marine and seashore plants, or kelp. The trade in kelp ceasing during the Revolution, the Committee of Public Safety in France called upon chemists to find some new source of soda, all the potash attainable being needed for gunpowder. Nicolas Leblanc, a surgeon and chemist, obtained the prize offered. His method consists in converting common salt first into sulphate by means of sulphuric acid, and then heating this together with charcoal and carbonate of calcium, which gives (theoretically) a mixture of carbonate of sodium and sulphide of calcium. This process is carried on, particularly in England, in large chemical works, all the soda used for making soap, glass, and many other products being thus procured. For details of the process reference must be made to the standard works on chemical technology, as, for example, the *Dictionary of Applied Chemistry*, by T. E. Thorpe.

The crude soda-ash, sometimes called black ash, as it leaves the furnace is a very complex mixture of substances, containing chiefly carbonate of sodium, caustic soda (hydrate), carbon, carbonate of calcium, and sulphide or oxysulphide of calcium. It is treated with hot water or steam on a furnace-hearth to break it up, and then the carbonate is leached out with hot water in an apparatus contrived to accomplish much work with little water. The great defect of Leblanc's system as originally carried out was the loss of all the sulphuric acid or of the sulphur used in making it. Hence other methods of obtaining carbonate of soda from salt have been much sought after. One in successful operation, known as the Solvay or ammonia-soda process, consists of decomposing concentrated brine with a strong solution of bicarbonate of ammonia, which engenders chloride of ammonium and nearly insoluble bicarbonate of soda. The chloride of ammonium is readily reconvertible into bicarbonate. to be used over again. With respect to Leblanc's method, however, it may be noticed that by Chance's process, patented in 1888, the sulphur can be economically recovered from the exhausted black ash. Revised by Ira Remsen.

Soda-water: See Aërated Waters and Solution.

So'dium [Mod. Lat., from Eng. *soda*. See Soda]: one of the elements of matter, a very important and remarkable metallic substance which was first obtained in 1807 by H. Davy by the electrolysis of caustic soda (hydrate). Its occurrence in nature is chiefly as common salt (chloride of sodium) in the ocean, and as a constituent of silicates, chiefly the feldspars albite and oligoclase, on the land. It is also found in natron, an impure sodium sesquicarbonate, containing besides sodium sulphate and chloride. A cubic foot of ocean-water contains about 6,440 grains, not far from 1 lb. avoirdupois, of metallic sodium, and a cubical tank 14 feet on each side filled with sea-water will contain more than 1 ton of this alkali-metal. A cubic foot of rock-salt contains over 52 lb. of sodium. Sodium is a metal probably more abundant in its occurrence than iron, and probably not necessarily much more difficult or expensive to obtain in approximate purity than the latter metal, and yet, by reason of the fewer uses developed for it, the cost of sodium is much greater than that of iron. Sodium is one of the elements most essential to animal life, being a constituent of all blood. It is also found in the vegetable organisms that dwell in the ocean and along its coasts, but plants dwelling on land above the sea-level contain potassium more abundantly than sodium.

Preparation.—Gay-Lussac and Thénard first prepared sodium in quantity by the action of metallic iron at an intense heat on fused caustic soda, but a much better method is that of Brunner, which consists in distilling a mixture of charcoal and carbonate of sodium, the transformation being essentially as follows:

$$Na_2CO_3 + C_2 = 2Na + 3CO;$$

a current of carbonic oxide gas resulting, which sweeps along with it the metallic sodium in vapor. The latter is condensed by passing the gases through a thin, flat cast-iron condenser of peculiar form, which becomes, and remains throughout, hot enough to prevent the metal from solidifying within it, and thus clogging it up. It is so contrived also that a sharp-pointed iron rod may be driven in through it into the retort to clear it out when in danger of choking up and thus leading to a dangerous explosion. The sodium trickles out of the condenser in melted form, and is prevented from taking fire and burning in the air by being received in a vessel of melted paraffin. The vessel should be double, each part having a close-fitting lid to be applied in case the paraffin should kindle. Care must be taken that the carbonate of sodium and charcoal are free from silica and phosphates, which energetically attack the iron of the retort and perforate it from the inside. Deville introduced the admixture of powdered chalk with the mass, to prevent its passing into liquid fusion, but this may introduce silicates, and an excess of coarsely powdered charcoal has been used instead.

A method for the preparation of sodium on a large scale has been devised by Castner. This consists essentially in the reduction of sodium hydroxide (caustic soda), by heating it with an intimate mixture of finely divided iron and carbon. The mass is prepared by mixing the iron with molten pitch, allowing it to cool, breaking it into pieces, and heating it to a comparatively high temperature without access of air. The reaction is believed to take place as represented in this equation:

$$3NaOH + FeC_2 = 3Na + Fe + CO + CO_2 + 3H.$$

Sodium is a brilliant silver-white metal, of the softness of wax within the normal range of temperatures, but becoming somewhat harder at 20° below zero. It melts at 204° F., and has the specific gravity 0·972 at 15°. It crystallizes in octahedrons of the dimetric or tetragonal system. Its vapor, unlike that of potassium (which is green), is colorless. When exposed to the air, it rapidly absorbs oxygen, and moisture if present, forming either anhydrous oxide (Na_2O) or caustic soda (NaOH). When water touches it there is an intense reaction, with evolution of hydrogen gas and caustic soda. If the quantity of water is small, the heat produced is so high that the metal takes fire, and burns with a yellow flame and high heat.

In the preservation of sodium it must be kept immersed under the surface of some liquid which is free from oxygen, the heavy oils of coal-tar being better for this purpose, apparently, than rectified petroleums, which seem to absorb oxygen slowly and transmit it to the sodium, which thus becomes soon encrusted with a product not yet examined. The addition of a small percentage of amyl alcohol to the oil prevents tarnishing of the metal.

Sodium Salts.—The most important salts or compounds of soda are the acetate, borate, carbonates, hypochlorite, hyposulphite, nitrate, phosphates, silicates, sulphate, sulphite, and tungstate. *Acetate of Sodium.*—This is a commercial article, prepared on a large scale by the manufacturers of wood-vinegar or pyroligneous acid. It is a white salt in prismatic crystals, which effloresce in the air, soluble in three parts of cold water. Heat converts it into a mixture of carbon and carbonate. It is used in medicine and as the source of commercial acetic acid by distilling with sulphuric acid. *Borates of Sodium.*—Of these the most important is Borax (*q. v.*). *Carbonates of Sodium.*—Of these there are two of great importance—the neutral or normal carbonate, commercially sal-soda or washing-soda, and the bicarbonate, commercially cooking-soda. *Sal-soda*, $Na_2CO_3 + 10H_2O$, crystallizes in large, transparent crystals, which are monoclinic. This salt effloresces in the air very rapidly, falling down to a white powder, which contains but half as much water as before. It dissolves in twice its weight of cold water. On exposure to a gentle heat it loses all water, and becomes dry anhydrous carbonate. This latter is a product of enormous value in the arts, used chiefly in the manufacture of glass and soap. *Cooking-soda* (*disodium dihydrogen dicarbonate*), $HNaCO_3$, is made by exposing the last compound to an atmosphere of carbon dioxide, which is absorbed, with evolution of heat and separation of water. It is sometimes called soda saleratus. Commercial bicarbonate of soda is a white granular powder, which requires thirteen times its weight of water for solution. It is largely used in medicine and in cookery. For *hypochlorite of soda*, or *Labaraque's liquor*, used as a disinfectant, see Hypochlorites; *nitrate of sodium*, see Saltpeter, Chili; *phosphates of sodium*, see Phosphoric Acid; *silicates of sodium*, see Glass.

Sulphate of sodium, or Glauber's Salt (*q. v.*), $Na_2SO_4 + 10H_2O$, forms large transparent monoclinic crystals. It occurs native in mineral springs, and as the mineral species mirabilite. Glauber's salt is highly efflorescent, falling to a white powder in the air, and in time losing all its water of crystallization. It dissolves in three times its weight of cold and in its own weight of boiling water. It has a remarkable propensity to form supersaturated solutions. For *sulphite of sodium*, see Sulphurous Acid; *tungstate of sodium*, see Tungsten. Revised by Ira Remsen.

APPENDIX.

Ramsauer, raam'sow-*er*, JEAN: educator; pupil and colleague of Pestalozzi; b. in Hérisau, Switzerland, in 1790. At the age of ten he became dependent upon charity, and was placed in a family living near Burgdorf. Madam von Werth sent him to the school opened at Burgdorf by Krüsi, which was soon afterward united to that conducted by Pestalozzi, and when the Burgdorf institute opened in Oct., 1800, Ramsauer was the first boarding pupil received. As he was poor, he worked for his support, studying when he was at leisure. He found favor with Pestalozzi, who appointed him, at the age of twelve, assistant to the teacher at the head of the communal school, and Ramsauer discharged his duties efficiently. In the same year he became teacher of the lower class in the institute itself. He followed Pestalozzi to Münchenbuchsee, but when Pestalozzi went to Yverdun Ramsauer remained at Münchenbuchsee with Fellenberg. In 1805 Pestalozzi called him to Yverdun. At the age of twenty, after the departure of Joseph Schmid, he became master in the institute, and had charge of the instruction in drawing, gymnastics, and geometry, and from 1812 to 1815 he served as Pestalozzi's secretary. Owing to difficulties with Schmid, he left the institute in 1816, and became teacher to the young princes of Oldenburg. He remained in this position until 1835. He also founded an institution for young girls in Oldenburg. He died in Oldenburg, 1848. He was the author of several text-books, but his most interesting writings are his *Autobiography* and *Memorabilia*, which contain very valuable anecdotal reminiscences of Pestalozzi. His judgment of the philosophical and social sides of Pestalozzi's character is of little value, since after he left the institute he became a pietist, and his standpoint in writing makes him incapable of understanding the great pedagogue. C. H. THURBER.

Ramsay, FRANCIS MUNROE: naval officer; b. in the District of Columbia, Apr. 5, 1835. Entering the Naval Academy in 1850, he became lieutenant in 1858, lieutenant-commander in 1862. During the civil war he took part in the fight at Haines's Bluff, on the Yazoo river, and subsequently destroyed the Confederate navy-yard and some vessels on that stream. He was in the engagement at Liverpool Landing in 1863, commanded a battery before Vicksburg in the same year, and commanded a division of the Mississippi squadron 1863–64. He had charge of expeditions on the Ouachita, Atchafalaya, and Black rivers in 1864, and gave fight to the enemy at Simmsport, La. Commanding the gunboat Unadilla of the North Atlantic squadron 1864–65, he engaged in the bombardment of Fort Fisher, and was honorably mentioned in the official report for skill, good judgment, and bravery. Subsequently he participated in engagements at Fort Anderson and at other forts on the Cape Fear river; was made commander in 1866, was fleet captain and chief of staff of the South Atlantic squadron 1867–69, became captain in 1877, and had charge of the torpedo station 1878–80; was superintendent of the Naval Academy; became commodore in 1889, rear-admiral in 1894, and was placed on the retired list in 1897.

Range-finders and Position-finders: instruments used in the military service for quickly locating the position of the target fired at with respect to the gun. The distinction between the two names should be clearly understood. A *range-finder* determines the distance or range to the target, but does not give the direction, and it can therefore only be used at or very near the gun itself, since the range determined from some other or distant point might not be, and in general would not be, the same as the range from the gun. A *position-finder* measures both the range in yards to the target and its direction in degrees and minutes of azimuth, the meridian in passing through the vertical axis of the instrument being taken as the origin of direction, and the zero line of direction being the line of sight through the point, looking south. The *position-finder* may be located at or near the gun, or at a very considerable distance from it, without affecting the accuracy of the results, except that when used at a distance from the gun it is necessary to use in conjunction some form of replotting device, in order quickly to transform the readings given by the position-finder into the corresponding ranges and azimuths from the gun. Several different forms of replotting devices are in use, most of them being simple in construction, and in the most improved types of position-finders now in service the replotting is done by an automatic mechanical attachment, which makes the required transformation without appreciable error or loss of time.

Of the two kinds of instruments used range-finders alone are used with infantry, cavalry, and field and siege artillery, while the position-finder is exclusively used with the seacoast armament and guns of fixed position.

A number of different range-finders have been tried in the naval service, but up to the present time no instrument of this kind has been developed which successfully overcomes the many practical difficulties incident to service on shipboard. Position-finders are not needed in the naval service.

RANGE-FINDERS.—All range-finders may be classed under three general heads, viz.: (1) acoustic range-finders, (2) stadias, and (3) topographical range-finders. The first two classes are comparatively unimportant, since the instruments are few in number and limited in their use to conditions that seldom obtain in service. In the third class are included all range-finders whose construction and operation are based upon the usual topographical methods of solving a plane triangle.

1. *Acoustic Range-finders.*—After the flash of a gun or bursting shell is seen a certain time-interval must elapse before the sound of the explosion is heard, and any device which will measure this interval accurately may be used as a range-finder in determining the distance from the observer to the gun or bursting shell. Sound travels at the rate of 371 yards per second through air at normal temperature of 50° F. This rate increases or decreases 1 foot for each degree above or below 50° F.

The wind, humidity of the air, and barometric pressure all affect the *intensity* of sound, but do not appreciably affect its *velocity*. An acoustic range-finder is therefore a simple form of time-keeper or seconds-reckoner. It is small and cheap, and under certain favorable conditions is fairly accurate. The two best-known instruments of this class are the Boulengé and the Redier. The first named consists of a glass tube 6 inches long filled with benzine, and containing a silver traveler or indicator formed of two flat disks connected by a central wire, the whole inclosed in a neat wooden case. The diameter of the indicator-disks is slightly less than that of the tube, so as to equalize the errors caused by the expansion of the liquid and the increased velocity of sound due to rise in temperature. When the tube is held vertically the indicator travels along the graduated range-scale at a uniform rate of speed. In use the instrument, with the indicator at zero, is held horizontally in the hand, back of the hand up. When the flash of an enemy's gun is seen the hand is instantly turned until the tube is vertical; then when the report is heard the hand is quickly replaced in its original position. The range in yards is read directly from the scale. The Redier range-finder resembles an ordinary stop-watch in appearance and operation. The two hands are placed at zero, and secured by a small spring catch. The slightest pressure on this spring releases the mechanism, and the hands then continue to revolve rapidly, the long hand twelve times as fast as the short one, until the pressure is removed,

when both are instantly stopped and the number of revolutions made by each is registered by the dial of the watch. The range in yards, which corresponds to the interval of time during which the pressure was applied to the spring catch, is taken from a specially prepared table.

Both these range-finders are simple, convenient, and inexpensive, and are sufficiently accurate for service within the limits of the method; but the method itself is at fault, since in the confusion of the battle-field it could scarcely ever be used.

2. *Stadias.*—The *stadia* as a surveying instrument is well known. Used as a range-finder it determines the distance to a target by measuring the angle subtended by a known height at a known distance. The height of the target (such as a mounted or foot soldier) is supposed to be known, and forms the base of a triangle whose apex is at the eye of the observer. The intervening distance is ascertained by a micrometer measurement of the apex angle. This is done either by the vertical movement of a micrometer wire placed between the lenses of the eyepiece of the observing telescope, or by a fixed, graduated scale similarly placed. It is necessary, in using such an instrument, to refer to a specially prepared table of distances in order to find the range corresponding to any scale of micrometer reading. As the exact height of the object observed can never be known, and as they require a separate table of ranges for each different object, range-finders of the stadia class are of little practical value.

3. *Topographical Range-finders.*—At least nine-tenths of all field range-finders now in use belong to the class known as topographical range-finders. The number of these is so great and the essential differences in construction are so small that no attempt will be made to describe more than a few of the typical ones. The principle of construction common to all is dependent upon the well-known property of plane triangles—that when three elements are known the other three can always be determined. The solution of the triangle is, however, in all cases mechanical.

There are three types of topographical range-finders in service, viz.: Those requiring a short fixed base, such as Clerk's, Guthrie's, Adee's, Berdan's, and Mallock's; those similar to a theodolite, as Nolan's; and those of the nature of a sextant, like Watkin's, Weldon's, Goulier's, Gautier's, Labbez's, Dredge-Steward's, etc.

Those of the first type find the distance by the amount of displacement of the object as seen from either end of a short fixed base-line within the instrument itself. Mirrors have generally been used in instruments of this type, and the greatest difficulties encountered have been due to the necessity of exactly superimposing the direct and the reflected images and the loss of light by reflection. The Mallock, which is the most promising instrument of the type, has two sets of mirrors, one set at each end of a tube $2\frac{1}{2}$ or 5 feet long. The two mirrors composing each set are placed at an angle of 45 degrees. It is proposed to use prisms instead of mirrors in this instrument, which will no doubt greatly increase the accuracy. The Nolan range-finder is the best example of an instrument of the second type. It consists of two separate telescopes placed on gun-carriages or tripods some distance apart. The telescopes measure the angle subtended at the object by the distance between the telescopes, and the ranges are found from a special calculating disk. Range-finders of the third type all use a base of some considerable length, and require at least two observers working in conjunction. They are all subject to errors of parallax, but in the hands of skilled observers and under favorable conditions the results are sufficiently accurate to meet service requirements.

The Watkin range-finder has been the English service instrument for many years. It is, in reality, a convenient form of sextant, in which the horizon-glass is movable and the index-glass is fixed. To save the trouble of direct measurement, the true base is measured by means of a subsidiary base 18 feet long, and after adjusting a sliding pivot to the true base on a graduated bar the range is given automatically on a drum-scale, the movement of which alters the position of the index-glass sufficiently to measure the angle at the end of the base opposite the right angle. The instrument is better adapted for use with field artillery than for the infantry or cavalry, since the equipment of the two stations is too bulky and elaborate to be carried with foot troops or by one man. It is, however, easy of adjustment, and the most accurate and satisfactory type of its kind yet developed.

The Weldon range-finder is the simplest instrument of the kind in use. It consists of three accurately ground prisms set in one case, the whole being so small that it may be carried in the vest-pocket. Two observers similarly equipped are necessary, and the range is found by measuring the distance between the observers and multiplying this distance by the fixed multiplier of the instrument. Two of the prisms reflect the angles of a right-angled triangle, the perpendicular of which is fifty times the base (the angles being 90°, 88° 51′, and 1° 9′). The third reflects an angle of 74° 53′, and is used for measuring the true base by means of a subsidiary base one-fourth its length. With this instrument one interior angle and one exterior angle of the triangle are laid off, and not two interior angles, as with the Watkin.

A most ingenious topographical range-finder of the first type has recently been introduced for trial in the naval service. It is the invention of Capt. B. A. Fiske, U. S. N., and deserves especial mention because it is the first electrical instrument of the kind ever used. The principle of the Wheatstone bridge is applied in recording the angle through which the telescope at each end of the base-line is moved, a sensitive galvanometer being employed in obtaining a balance in the bridge to ascertain the range-reading. As installed on shipboard, the Fiske range-finder consists essentially of two specially mounted telescopes, one at each end of a fixed base-line (approximately the length of the vessel), a galvanometer and plotting station below deck, and the necessary battery power and wires connecting the telescopes with the galvanometers. At least three operators are necessary to find the range. As each observer at the telescope follows the target a sliding contact is moved along a wire of uniform resistance, thus changing the resistance in a particular branch of the Wheatstone bridge. To ascertain the range, the operator at the plotting station moves each plotting arm until the needle of the corresponding galvanometer stands at zero. The intersection of the two arms determines the range to the target. The mechanical and electrical details are carefully worked out in this instrument, and when in proper adjustment its results are exceedingly accurate.

Position-finders.—With the long ranges, flat trajectories, and enormous cost of modern seacoast ordnance, the use of some quick, accurate, and reliable means of determining the exact position of the target with respect to the gun becomes a necessity. The gun itself has developed into a machine of almost scientific accuracy when the conditions under which it is fired are once known. Two consecutive shots, for instance, from the Jubilee gun in England at a range of 11 miles fell within 30 yards of each other. But in order to utilize to the best advantage the accuracy of the gun and its carriage, it is necessary for the gunner to be constantly informed as to the distance to the target and its direction from him. Since the natural target of the coast artillery gunner is an enemy's vessel, and since this target will generally be in more or less rapid motion according to the kind of vessel and the character of the water approaches to the battery, the element of time becomes a vital one. The loss of a few seconds in determining the range will often mean the loss of a shot. The position-finder is therefore the basis upon which every system of modern artillery-fire control rests.

The comparative efficiency of the many different systems of coast defense possessed by the different powers of the world may be measured by the character and accuracy of the position-finding instruments in use by each.

Only two classes of such instruments are in general use at the present day, the essential difference being in the length and position of the working base-line and in the number of stations and observers necessary. The first class, known as *horizontal-base position-finders*, are used where the site of the fortification is low, and when the water approaches are such that the enemy can be seen simultaneously by the two observers at the opposite extremities of a base-line of considerable length. The second class are called *vertical-base* or *depression position-finders*, from the fact that the working base is vertical, being the height of axis of the telescope at the moment of taking an observation above the level of the sea, and the angles through which the telescope is moved in following the target are all angles of depression. Instruments of the second class are so much simpler in construction and operation, and possess such manifest advantages from a service point of view, that they are used in all cases where the fortification and its surround-

ings are such as to afford sufficient altitude for their installation.

The Horizontal-base Position-finder.—To constitute a horizontal-base position-finder three separate stations and operators are neeessary. Two of these stations, ealled the *observing stations*, are each equipped with a special quiek-reading theodolite, for determining the azimuth of the target, and a telephone or telegraph, and are situated at eaeh extremity of a earefully measured base-line. The third, or *replotting station*, is usually near the gun, is equipped with suitable replotting apparatus, and must be in eonstant eleetrical communieation with eaeh of the other stations and with the gun. The length of the base-line is generally a thousand yards or more, and its direction is as nearly as possible perpendieular to the principal line of approaeh to the battery.

To find the position of a target, eaeh observer directs his telescope upon it, and telephones the azimuth angle read to the operator at the replotting station. The latter first plots the position with respeet to the two base-end stations by means of two pivoted arms of the plotting-board, and then immediately replots it with respeet to the gun by means of a third pivoted scale-arm, the pivot of whieh represents the plotted position of the gun with respeet to the two observing stations. The third arm gives the range in yards and the direetion in degrees and minutes of azimuth from the gun to the target, and these are, of eourse, the data the gunner must have in order to train his gun on the target. When the target can be seen through the sights on the gun the direction may be determined by the gunner himself, and in this ease the replotter only transmits the range scale-reading.

With trained observers, a base-line of suitable length, and with targets fixed in position, these instruments give exeeedingly aeeurate and satisfactory results. They possess the great comparative advantage of not being affeeted by tidal ehange, curvature, refraetion, wave-action, and indistinetness of water-line. They are also eheap, and may be easily installed for temporary or permanent use. With a moving target, however, such as a vessel in motion, or where a number of sueh targets are approaching a gun at the same time, instruments of this type are not equal to the problem of position-finding then presented. The length and eomplexity of the lines of eommunieation, the difficulty of securing simultaneous readings on the part of both observers, and the still greater difficulty of getting both to observe the same target—all combine to diseredit the results obtained. The length of time consumed and the number of men necessary are also serious objections. Exeept in England, the horizontal-base position-finder is still largely used abroad, but in England and the U. S. it is used only to a limited extent, and in eertain special cases as already indieated.

Depression Position-finders.—A depression position-finder is a single-station, self-contained instrument, requiring but one man to operate it. The observer, through a powerful telescope, follows the target, keeping the horizontal wire eoincident with the water-line and the vertical wire upon any desired point of the object. The range in yards and the direetion in degrees and minutes are read direetly from the dials of the instrument. Like all range-finding instruments, its operation depends upon the quick mechaneal solution of a triangle. In this instance the triangle is right-angled, the vertical height of the instrument above sea-level constituting one side and the range to the objeet another side, the angle at the base being the angle of depression through which the telescope has moved in locating the target. It follows, therefore, that all ranges found by a depression instrument must lie either wholly or in part over the surface of water, and that the object observed must have a water-line. Means must be provided for compensating for changes in tide, since a rise or fall of the tide necessarily shortens or lengthens the working base of the position-finder. It is also found necessary to provide eorrections for the effeets of curvature of the earth and of atmospheric refraetion. All these correetions are applied meehanieally and automatieally, the exact amount of each for each division of the range-scale having been carefully eomputed during construction.

The position-finder is permanently installed upon a concrete foundation, in an underground protected cell, a complete view of harbor being afforded through a long, narrow, horizontal window. The pedestal is provided with leveling-screws, and the observer must be careful to see that the table remains level while in use. The instrument is usually installed at some eonsiderable distanee from the battery whose fire is to be directed and eontrolled from it. The electrieal eommunications eonneeting the two are laid in underground conduits. Sinee it is neeessary to transmit to the gun-layer, not the range and the direetion of the target from the instrument, but its range and direetion from the gun itself, each depression position-finder has used in eonnection with it some form of replotting apparatus. In the most improved instruments the replotting is done automatieally, so that the observer has nothing to do but to follow and loeate his target through the telescope and then read the correct range and direction from the gun from the proper dials.

At least one eomplete position-finder is provided for each independent battery or group of guns. A gun-group is usually composed of two or three guns mounted in eontiguous emplaeements. The right or middle gun of the group is designated the *directing gun*. The information from the position-finder is transmitted to each gun of the group. The gun-commander of the direeting gun lays his gun aeeordingly, but eaeh of the other gun-eommanders makes a slight eorreetion in direction to eompensate for the displaeement of his gun. The range given is correet for all. In what is known as "predieted firing," whieh is now generally employed by heavy artillery against moving targets, the observer at the position-finder elosely follows the target for a given interval of time, noting earefully its change in range and direction during this interval. With these data he quiekly prediets the ehange for a like interval (say two minutes) in advance and sets his instrument accordingly. He at once transmits to the guns the training for the predieted position, and the guns are laid to strike the point. The observer now, after making a slight correction to eompensate for the time of flight of the projectile, watehes the target as it enters the field of his telescope, and eloses the firing circuit or gives the eommand "fire" the instant the image crosses the vertieal wire.

With a trained observer (who is generally a eommissioned offieer or an intelligent non-commissioned offieer) at the position-finder, and with well-drilled men at the guns, it is possible by this method to follow an approaching vessel from the time she enters the zone of fire 10,000 yards away, keeping the guns constantly laid to strike her at any desired point of the course. It is this ability on the part of the defense to direet the fire of their guns with seientifie aeeuraey upon the hostile ship long before the latter can return the fire that eonstitutes the greatest advantage possessed by shore defenses over a naval adversary. Only when the battle-ship has approaehed sufficiently near to bring her rapid-fire armament into aetion ean she hope to disable the position-finding serviee.

The two most successful position-finders of the depression elass are the Watkin in England and the Lewis in Ameriea. The former is the invention of Major Watkin, of the Royal Artillery, who is also the inventor of the English service field range-finder, already mentioned. The Watkin position-finder was first introdueed into the eoast defenses of Great Britain about 1880, but so jealously have the details of eonstruction been guarded by the War Office that no representative of a foreign government has ever been permitted to inspect the instrument or to witness its operation and no description of it has ever been published. The invention was not patented, the rights being purchased outright by the Government for a very large sum. All the English eoast defenses, including those of the colonies, are now supplied with these instruments. In 1898 and 1899 an additional number of the most improved model were installed in the new fortifications at Gibraltar.

The position-finder which is now in use in all the coast defenses of the U. S. is the invention of Lieut. Lewis, of the Sixth U. S. Artillery. While similar to the Watkin in many of the essential principles of construetion, the Lewis instrument has been developed independently, and is believed to be superior to the former in several respects, particularly in the completeness of the automatic replotter, in the correction for abnormal refraetion, and in the known aeeuracy of its work. Two types of the Lewis position-finder are manufactured and in service, being known as type A and type B. The first type is intended for permanent installation at some considerable distance from the gun. It consists essentially of a speeial metal table 45 inches in diameter resting upon a hollow east-iron pedestal, which is provided with means of leveling, and pivoted in the eenter of which is a substantial traversing arm that carries the telescope and the elevating range and replotting mechan-

ism. The complete instrument, weighing about 650 lb., is mounted upon a concrete foundation in an underground cell. The type B instrument is portable, weighing about 18 lb., and somewhat resembles an ordinary engineer's transit in the ease and quickness of its adjustment. It is intended

Lewis position-finder, type A.

to be an emergency or breakdown instrument to be used at the gun in case of damage to the main position-finder or to the electrical lines of communication. Several alternate mountings are prepared for it along the gun-parapet, and when necessity arises for immediate use it takes but a few minutes to mount and adjust the instrument. The larger type A position-finder is, however, more accurate, and is chiefly depended upon in controlling the fire of the battery.

I. N. Lewis.

Rankine, John, LL. D.: law-writer and educator; b. in Scotland, Feb. 18, 1846: after receiving his early education at Sorn and the academies of Ayr and Edinburgh, he took courses at the Universities of Edinburgh and Heidelberg; then read law; was called to the Scottish bar in 1869; was made advocate-depute in 1885, and queen's counsel in 1897. He made a special study of Scotch law, and particularly the law of real estate, and was appointed Professor of Scotch Law in the University of Edinburgh in 1888. His publications include *The Law of Landownership in Scotland* (3d ed. 1891) and *The Law of Leases in Scotland* (2d ed. 1893). He is editor of *Erskine's Principles of the Law of Scotland* (18th and 19th eds.), and other minor works.

F. Sturges Allen.

Rapallo, Charles A.: b. in New York city, Sept. 15, 1823; received his early education under his parents' supervision, and at the age of twenty-one, without having attended school or college, was admitted to the New York bar; rapidly became prominent in the practice of his profession, and acquired a wide practice in matters relating to State, trust, and corporation law; in 1870 was elected as chief justice of the court of appeals under the amended constitution, and in 1884 was re-elected for a further term of fourteen years. His decisions are the most highly respected of those in the State reports, and are scattered through fifty-seven volumes of *Reports*. D. Dec. 28, 1887.

F. Sturges Allen.

Rathbun, Richard, M. S., D. Sc.: naturalist; b. in Buffalo, N. Y., Jan. 25, 1852. As a boy he developed an interest in the fossil remains of Western New York, and was curator of paleontology in the Buffalo Society of Natural Sciences 1869–71. He then entered Cornell University, and devoted much of his time to the special study of the Devonian fossils collected in Brazil by the C. F. Hartt expeditions, and in 1873 moved to the Museum of Comparative Zoölogy in Cambridge, Mass., to complete his studies on them, also serving as assistant in zoölogy in the Boston Society of Natural History 1874–75. Meanwhile he began the study of marine animals at Eastport, Me., under Prof. Edward S. Morse, and was a volunteer zoölogical assistant in the summer expeditions of the U. S. Fish Commission in 1874–75. In Nov., 1875, he went to Brazil as assistant geologist on the geological commission of Brazil, under the direction of Prof. Charles F. Hartt, and remained there until Feb., 1878. On his return to the U. S., he was appointed scientific assistant of the U. S. Fish Commission, in connection with the seacoast investigations and the study of marine invertebrates, continuing in that capacity until 1887, when he was appointed assistant in charge of the division of inquiry respecting food-fishes in the U. S. Fish Commission, which place he then held until 1897, when he became assistant secretary of the Smithsonian Institution. Since 1883 he has been curator of the department of marine invertebrates in the U. S. National Museum, which relation since 1887 has been an honorary one. During the winter of 1892–93 he served as the U. S. representative on the joint commission with Great Britain relative to the preservation of the fisheries in the waters contiguous to the U. S. and Canada. The honorary degree of M. S. has been conferred upon him by the Indiana University, and that of D. Sc. by Bowdoin College. Dr. Rathbun is a member of various scientific societies, and has written many papers for the Government publications of the various departments with which he has been connected.

Marcus Benjamin.

Ratich (known also as **Ratichius** and **Ratke**), Wolfgang: educator, chronologically the first of the pedagogical innovators; b. in Wilster, Holstein, Oct. 18, 1571; studied theology at the University of Rostock; devoted himself specially to the study of languages, since defective pronunciation prevented his preaching; made a journey to England in 1600, and went thence to Amsterdam, where he remained eight years to learn Arabic and mathematics. Here he conceived the idea of reforming the methods of instruction in use in his time. After an unsuccessful effort to interest Prince Maurice of Orange, he went to Germany and settled in Frankfurt in 1611. In 1612 he addressed a memoir to the imperial Diet, in which he promised by the aid of God and for the good of all Christendom to point out a way of teaching in a short time and in an easy manner, to both young and old, Hebrew, Greek, Latin, and the other tongues. This memoir attracted some attention, and two professors in the University of Giesen, Helwig and Jung, were commissioned to examine his method, and expressed approval, as did also four professors in the University of Jena who later examined it at the suggestion of the reigning Duchess of Weimar. There were plenty to oppose his plans, however, and some even declared that the pompous promises of his programme were only airy persiflage. In 1614 he went to Augsburg, by invitation, to reform the schools of the city, being accompanied by Helwig and Jung, who separated from him, however, at the end of the year, and he was forced to abandon the Augsburg experiment. During the following years he traveled from place to place, and finally, in 1618, was placed, by the Prince of Anhalt-Köthen, at the head of a model school, where he remained eighteen months. The prince, enraged that he had been made the dupe of a man whom he had come to regard as an impostor, cast him into prison at the end of that period, where he remained eight months, being released only after he had made a written declaration that he had promised more than he could perform. From Köthen he went to Magdeburg, where he was authorized by the burgomaster to open a school, but was driven out mainly in consequence of theological difficulties. Countess Anna Sophia of Rudolstadt welcomed him to her estates, and recommended him to the Swedish chancellor Oxenstiern, who instigated an examination into his method, but before anything could come of it Ratich was attacked by apoplexy, which brought on paralysis, and in 1635 he died at Erfurt. Ratich seems to have been a difficult person to get on with, and he was also lacking in the power of putting his theories into practice, nor was he entirely exempt from the charge of charlatanism. His programme of studies embraces only languages and mathematics. He was a most zealous Lutheran and narrow in his theological ideas. His pedagogical teachings were influenced by the writings of Bacon. He must be given credit for a number of new and correct ideas, which may be

summed up very briefly as follows: 1. Follow the order of nature. 2. Do one thing at a time. 3. Repeat the same thing often. 4. Begin with the native tongue. 5. Do everything without force. 6. Learn nothing by heart. 7. Give children frequent recreation. 8. Uniformity and harmony in everything (by which he seems to mean something similar to what we know to-day as correlation). 9. First the thing and then the nature of the thing (by which he meant the modern inductive or scientific method). 10. Everything by experience and induction. He wrote a considerable number of educational works. See Von Raumer, *Geschichte der Pädagogik*; Williams, *History of Modern Education*: Compayré, *History of Pedagogy*. C. H. THURBER.

Rattigan, Sir WILLIAM HENRY, LL. D.: East Indian lawyer and judge; b. in Delhi, India, Sept. 4, 1842; was educated at the high school in Agra and afterward at King's College, London; then took up the study of law and was called to the English bar in 1873. He is a barrister and advocate of the high court of the Northwest Provinces, India, and has been a number of times judge of the chief court of Punjaub, and was a member of the supreme legislative council of India 1892–93. He has made a special study of the science of jurisprudence as applicable to the government of India, and has published *The Science of Jurisprudence* (2d ed. 1892); *Private International Law* (1895); *Digest of the Customary Law for Punjaub* (5th ed. 1895): *De Jure Personarum, or the Roman Law of Persons* (1873); and he has translated the second volume of *Savigny's System of Modern Roman Law* (1884). He resides at Lahore, in the Punjaub, India. F. STURGES ALLEN.

Raymond, JEROME HALL, Ph. D.: educator; b. in Clinton, Ia., Mar. 10, 1869; A. B., Northwestern University, 1892, having previously spent two years in travel and study in Europe and the Orient; A. M., same, 1893; Ph. D., University of Chicago, 1895; lecturer in history and secretary of the Chicago Society for University Extension, 1892–93; Professor of History and Political Science, Lawrence University, 1893–94; lecturer in sociology and secretary of class study department, University of Chicago, 1894–95; assistant in Sociology, same, 1895; Professor of Sociology and secretary of the university extension department, University of Wisconsin, 1895–97; president of West Virginia University, Morgantown, W. Va., since 1897.

Read, DAVID BREAKENRIDGE: author; b. in Augusta, Ontario, June 13, 1823; admitted to the bar in 1845, and settled in Toronto. He was elected mayor of Toronto in 1858, and the same year was made a queen's counsel. He has contributed largely to various magazines, and has devoted much time to historical subjects. Among his works are *The Lives of the Judges of Upper Canada* (1888); *The Life and Times of General John Graves Simcoe* (1890); *The Life and Times of Major-General Sir Isaac Brock, K. B.* (1894); *The Rebellion of 1837* (1897).

Read, OPIE PERCIVAL: author and editor; b. in Nashville, Tenn., Dec. 22, 1852; after receiving education in his native State, and serving as a newspaper reporter in Franklin, Ky., edited the Little Rock *Gazette*, was on the staff of the Cleveland *Leader*, and in 1883 founded the *Arkansaw Traveler*. Among his publications are *Up Terrapin River* (1889); *A Kentucky Colonel* (1889); *Emmett Bonlore* (1891); *Miss Madam, and other Sketches* (1893); *A Tennessee Judge* (1893); *Wives of the Prophet* (1894); *My Young Master* (1896); and *Bolanyo* (1897).

Reade, JOHN: author; b. in Ballyshannon, Ireland, Nov. 13, 1837; went to America in 1856, and took up journalism in Montreal. In 1870 he published a small volume of poetry, *The Prophecy of Merlin, and other Poems*. In 1877 he was made an honorary member of the Literary and Historical Society of Quebec, and in 1895 he contributed an article to the memorial biographies of the Historical Genealogical Society of New England. In 1896 he was elected a fellow of the Royal Society of Literature of Great Britain.

Recording Apparatus, Psychological: The quantitative relations of mental states are measured by means of apparatus based on the laws of physics and physiology. Since it is impossible to measure sensations, thoughts, feelings, or emotions directly, the investigator must gauge them in terms of their causes and effects. All psychological measurements, therefore, are measurements of either the stimuli (or physical causes) which produce the mental state or the (physiological) motor effect which the mental state produces. The stimulus may be measured with respect to its duration, intensity, or spatial extent. The motor effect is generally measured with reference to its variation in extent or intensity from moment to moment.

1. *General Apparatus.*—Records are obtained by two methods. In the first, an index or pointer moves along a scale, and stops at a number representing the measurement desired. This is the principle of the apparatus whose names end in *-meter* or *-scope*. The index is usually constructed so as to stop at the point desired, while the mechanism either proceeds, as in the chronoscope, or returns to its starting-point, as in the dynamometer. A number of records can thus be obtained in rapid succession. An electric current is often used to start the mechanism or stop the index.

In the second or graphic method, a quill point moves back and forth on a cylinder covered with paper; as the cylinder rotates, a record or curve is obtained in two dimensions, one of which represents time (Fig. 1). This principle

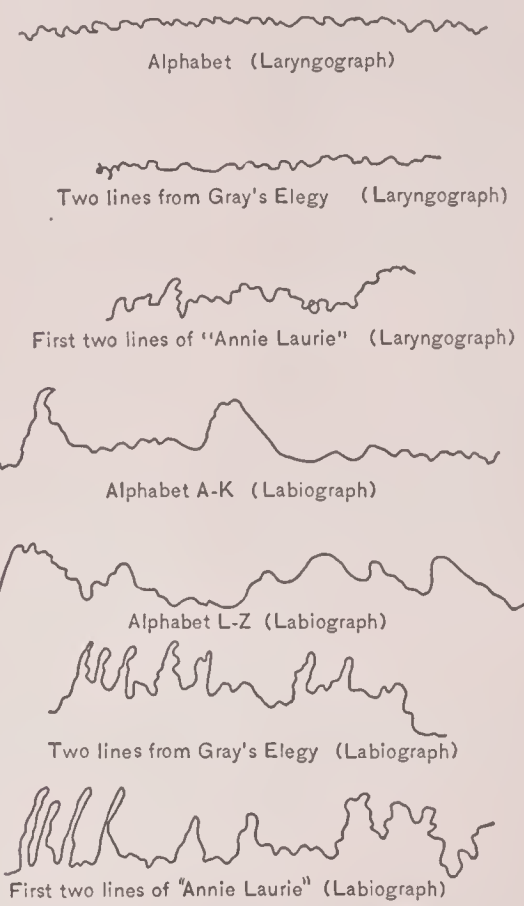

FIG. 1.—Laryngograph and labiograph tracings.

is involved in the apparatus whose names end in *-graph*. The quill may be attached directly to the special apparatus, as in the ergograph, or the record may be transmitted by air-pressure or an electric current. For air-pressure transmission the *Marey tambour* is used. This consists of two drums of wood or metal, connected by a firm rubber tube, each drum having one elastic rubber head. The movement to be recorded takes the form of an inward pressure on the elastic head of the first or exploring tambour; this compresses the air in the tube and in the second or receiving tambour, and the elastic head of the latter is raised. A quill extends over the receiving tambour, rising and falling with the movement of the head. This principle is used in the sphygmograph and similar apparatus. The electric mode of transmission is illustrated in the *Deprez signal*. Here the quill is fastened to the armature of an electromagnet. When the circuit is made, the quill is drawn to the magnet; when the circuit is broken, it is released and drawn away by a spring. A record of the points of time at which the circuit is made and broken is thus obtained on the paper. This is the principle of the chronograph.

Numerous devices are used for holding and running the recording cylinders. The *kymograph* consists of a clockwork, which turns the cylinder, and several convenient adjustments for altering the rate of rotation, the angle of its axis, and its position along the axis. The *polygraph* is used for obtaining several records simultaneously. Near the cylinder is a firm, upright rod, to which a number of receiving tambours may be clamped; their quills record at different heights on the cylinder, but at identical points of its circumference. A time record is generally included among the data, giving the duration of the phenomena

even if the cylinder does not rotate uniformly. The records are obtained on glazed paper that has received a uniform coating of lampblack or candle-black; they are made permanent by bathing the paper in some fixing solution.

2. *Apparatus for Measuring the Duration of Mental Processes.—Reaction Time.*—Reaction time is measured by means of the chronoscope or chronograph. See CHRONOSCOPE, CHRONOGRAPH. For discussion of the different mental processes involved, see PSYCHOMETRY.

The chronoscopes used for psychological measurement differ somewhat from the physical chronoscopes. The *Hipp chronoscope* (Fig. 2), the most common form, is a clock whose hands are connected with the works by making an electric circuit and disconnected by breaking it. There are two dials, each divided into 100 parts; the hand on the upper dial makes a circuit in one-tenth of a second, the lower in ten seconds; by reading the two together, the time is indicated in thousandths of a second (called σ, sigma; $1{,}000\,\sigma = 1$ sec.). In practice the clockwork is first started; then some mechanism gives the stimulus and starts the hands at precisely the same instant; when the given mental act is completed, the subject presses a reaction key, which stops the hands; the reaction time is the entire time during which the hands have moved. A simpler form of chronoscope is the *d'Arsonval chronometer*. This has but one dial, marking hundredths of a second; it is portable and almost noiseless; once wound it continues to go till run down. The arrangement for starting and stopping the hand is essentially the same as in the Hipp. The *pendulum chronoscope* is a pendulum which swings along a scale indicating the time occupied in swinging. The pendulum is held at the upper end of the arc by an electro-magnet and released when the stimulus is given; when the subject reacts, another electro-magnet draws a pointer to the scale and holds it, while the pendulum continues its course. The position of the pointer indicates the reaction time.

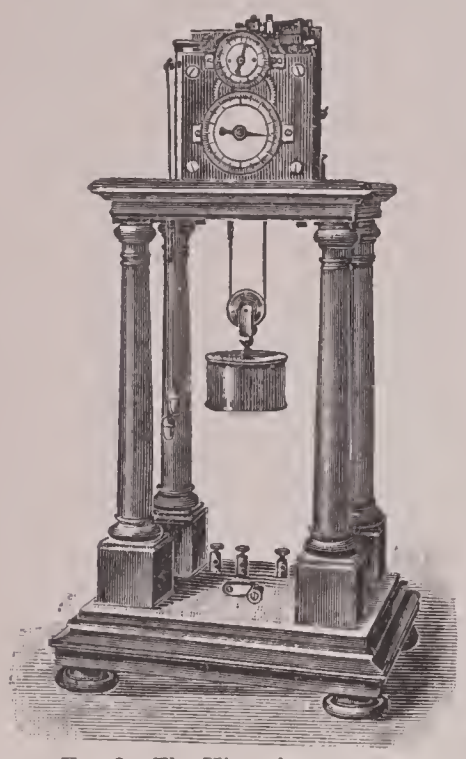

FIG. 2.—The Hipp chronoscope.

The *chronograph* used in psychological experiment is some form of revolving cylinder, such as the kymograph or polygraph, described above. The time is measured by a tuning-fork, metronome, or seconds pendulum, and recorded by means of tambours or an electric circuit. The tuning-fork gives the most accurate results. An electro-magnet near one prong of the fork draws that prong; this breaks the circuit, and the prong, released, flies back, makes the circuit again, and so on. The fork is thus kept in vibration, and as the circuit is made and broken with each vibration it is recorded on the cylinder by the Deprez signal. When the circuit is finally broken by the reaction movement, the record ceases, though the fork continues to vibrate. A continuous time record may be obtained by a quill attached directly to a prong of the fork.

The reaction-time apparatus includes also the *stimulus releaser* and the *reaction key*. For visual stimuli, such as light, colors, letters, and words, a screen with an aperture is attached to a pendulum; as the latter swings, the stimulus, behind it, is exposed for a time to view; the instant this exposure begins, the chronoscope or chronograph circuit is made. The two apparatus are combined in the pendulum chronoscope. Instead of a pendulum a heavy falling screen with an aperture may be used to expose the stimulus. For sensations of sound a bell or hammer is struck, and this completes the circuit which starts the time apparatus. For sensations of touch a blunt point is pressed against the skin, and this movement completes the circuit.

The most common form of *reaction key* is for the hand; it is similar to a telegrapher's key; the circuit is broken (or made) by pressing a knob at the end of a lever. For reacting with the vocal organs a lever is fastened to the jaw or pressed against the teeth; when the mouth is opened to speak a circuit is broken. In another form the mouth is placed at the large end of a funnel; a puff of air is sent through, moving a tongue at the other end and breaking the circuit. For reaction with choice a complex key is used, with a lever for each finger; if one stimulus appears, the thumb lever is pressed; if another stimulus, the forefinger lever, and so on, as agreed on beforehand.

Least Duration.—The least duration of stimulus consistent with a given kind of perception is measured as follows: A disk with alternate sectors of black and white is rotated on a color-wheel (described below); when the speed is increased beyond a certain rate the flickering ceases, and we see a uniform gray; from the rate of speed and width of the sectors the duration of the separate stimuli is calculated. Or, using a screen with aperture, swinging with a pendulum, and taking a printed word as stimulus, the speed of the pendulum is increased or the width of the aperture diminished, till the word is no longer distinguishable; the least time of exposure at which the word can be read is thus determined.

Time Relations of Different Senses.—The relation between simultaneous perceptions of visual and auditory stimuli is measured by the *complication pendulum*. This consists of a disk with a scale, over which swings a pointer attached to a pendulum. Concealed behind the disk is a bell, which can be adjusted so as to strike as the pointer passes any given point on the scale. The subject notes the point at which the bell seems to strike; in general, he indicates a point *before* that at which the bell actually strikes.

Appreciation of Time.—To measure the least perceptible difference between two periods of "empty" time, the *time-sense apparatus* is used. It consists of a disk with circular scale. Three levers, which project from the disk, may be placed at any points on the scale. Another disk, with a single pointer, rotates over this, and the pointer strikes the three levers in turn, making an electric circuit, and causing a bell or hammer to strike each time. The position of two levers being fixed, the third is varied until the time between the second and third taps is just noticeably different from the time between the first and second.

3. *Apparatus for Measuring the Intensity and Quality of Sensation.*—The least sensation is measured by the least stimulus that will produce a sensation (this is called the *threshold of sensation*); the least difference of sensation, by the least change in stimulus that will produce a different sensation (called *threshold of difference*). Where measurements of the quality of sensation are possible, as in sight and hearing, they are of the same character. For determinations of the threshold of sensation, see PSYCHO-PHYSICS.

Sense of Pressure.—The threshold of difference is measured with a set of *test-weights*. Jastrow's test-weights are cylinders of the same size and appearance, whose weight may be regulated as desired by pouring in shot. One cylinder, called the standard, is placed on the subject's hand; it is then replaced by another, and he compares the two. The standard is next compared with another in the same way, and so on, until we find the one least different from the standard which the subject observes to be different. Verdin's æsthesiometer (described below, under *Space Apparatus*) has a scale showing the amount of pressure exerted when it is applied to the skin.

Heat and Cold Sensations.—The threshold of difference in these two senses is determined by the *thermæsthesiometer*. One form of this apparatus consists of two tubes filled with water, whose temperature is measured by a thermometer and regulated by spigots. One tube is maintained at constant temperature, while the other is heated or cooled until a difference between the two is observed. Münsterberg's æsthesiometer (described below) is also adapted for this investigation.

Pain-sense.—The threshold of pain, threshold of difference for pain, and greatest endurable pain are measured by

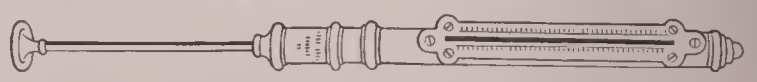

FIG. 3.—The temple algometer.

the *algometer*. This consists of a piston-rod which works against a heavy spring. At the end of the rod is a button-like tip, covered with flannel. This is pressed against the skin with increasing force, till it becomes painful; the

amount of pressure is indicated on a scale. One form of algometer is used on the temple (Fig. 3), another on the palm of the hand.

Muscle or Joint Sense.—The threshold of difference is measured with the test-weights, as in the sense of pressure; in investigating the muscle-sense, however, the weights are grasped and lifted by the subject, instead of resting on the palm of his hand.

Sense of Bodily Movement.—The sense of passive movement is investigated with the *rotation table.* This is a long board on which the subject lies, and which rotates freely in the horizontal plane. A fixed scale over which a pointer moves indicates the amount of rotation, and the beats of a metronome, or electric contacts at various points on the scale, record its rate. The apparatus measures the least perceptible movement, and demonstrates the relativity of these sensations.

Taste and Smell.—Taste has been but little investigated; the means used are solutions of sugar, quinine, tartaric acid, salt, etc. The substance is diluted in water until it can no longer be distinguished, or solutions of different strength are compared. For smell, the *olfactometer* is used. Zwaardemaker's olfactometer consists of a pair of horizontal tubes, turned upward at one end for insertion in the nostrils; a board conceals the other end from the subject's sight. Over this end are fitted in turn various tubes with odoriferous substances. The strength of the odor varies with the distance that the odor-tubes project out beyond the tubes of the olfactometer, and this furnishes a measure for the thresholds of sensation and difference.

Hearing.—The threshold of difference is determined by dropping a ball from varying heights on to a wooden stand; the ball is held by a clamp and released automatically; the length of fall is determined by a scale on the rod to which the clamp is fixed. Instead of a ball, a shot is sometimes used; it adheres to the lower side of an electro-magnet, and drops when the circuit is broken. The *sound pendulum* consists of a swinging metal rod, tipped with a hard rubber ball, which strikes against an ebony block at the lowest point of its arc. A clamp holds the ball at any desired point of the arc and releases it. The intensity of the sound is calculated from the length of arc, which is measured by a scale on the arm bearing the clamp.

Quality or pitch differences give rise to another set of problems in sound. The lowest audible pitch (see Acoustics) is determined by means of large tuning-forks; a fork is fitted with an adjustable weight, by which its rate may be varied from 16 to 24 vibrations per second; the rates for various positions of the weight are indicated on the fork. *Appunn's reed*, or *lamella*, is a blade surmounted by a flat bulb, and held below by a clamp; the length of the blade, and consequently its rate of vibration, is varied by adjusting the clamp. The highest audible pitch is determined by the *Galton whistle.* This is a very short pipe, whose length may be diminished to zero by a screw piston. A sound is made by squeezing a bulb attached to the pipe; the pitch is measured by the length of pipe, as indicated by a fine scale. Another means of determining the highest audible pitch is a set of steel cylinders, which, when struck with a steel hammer, give very high notes, the highest in the series being inaudible. To determine the threshold of pitch difference, tuning-forks of nearly the same pitch are compared, or a standard fork is compared with an adjustable one. The *Savart wheel* consists of a disk with a large number of teeth cut uniformly on the circumference; when placed on an axis and rotated against a tongue, it produces a tone which varies in pitch with the rate of speed. Pitch intervals and overtones are investigated with the *sonometer.* This is a long sounding-board, over which two wires are stretched; on the board are marked off various fractions of the length, and the interval through which the pitch is raised when the wire is held or dampened at these points.

Vision.—The threshold of light-difference is found by comparing different shades of gray on the *color-wheel.* This apparatus has an axle, on which black, white, and colored disks or sectors may be clamped and rotated rapidly by means of a series of geared wheels or a motor. The disks used are slit along one radius, so they can be fitted into one another, giving sectors of different colors or shades. The adjustable color-wheel has an axle in three parts, one within another; disks may be fitted to each, interlocking as in the simple color-wheel; but by moving a lever the proportion of each disk showing may be altered while they are rotating. To find the threshold of difference one black and one white disk are fitted together in a certain ratio, which is slowly altered until a difference is noted. The shade of gray is measured in terms of the proportion of black and white in the circumference. Another method used in this problem is to compare the shadows from two lights, one of which is varied in intensity or distance.

The thresholds of color-sensation and color-difference, and various phenomena of saturation, color-mixing, contrast, etc., are investigated by means of color-mixers. (See Complementary Colors.) There are several forms, including the color-wheel just described. The *reflection color-mixer* consists of a clear pane of glass, standing perpendicular to a black velvet surface. Strips of differently colored paper are placed on the velvet each side; the subject looks through the glass at an angle and sees the reflection of one strip over the image of the other. The intensity of the reflected color, and hence the character of the mixture, alters with the angle of regard. Another form is Hering's *binocular color-mixer.* Glasses of different colors are placed before the two eyes, which are directed upon three white spots; the left spot is seen with the left eye alone and in the color of the glass before that eye; the right spot similarly with the right eye; the central spot is seen with both eyes, and gives a binocular mixture of the two colors, which can be compared with each separately. For other tests of color-vision see Sensation, Complementary Colors, and Color-blindness.

4. *Apparatus for Measuring the Perception of Space and Space Relations.*—Besides the thresholds of space and space-difference, there is a threshold of direction obtained by comparing two lines or pairs of points differing slightly in direction.

Touch and Pressure.—The several threshold values are determined by means of points pressed on the skin (see Touch): for these investigations the æsthesiometer is used. *Verdin's æsthesiometer* (Fig. 4) consists of a long horizontal

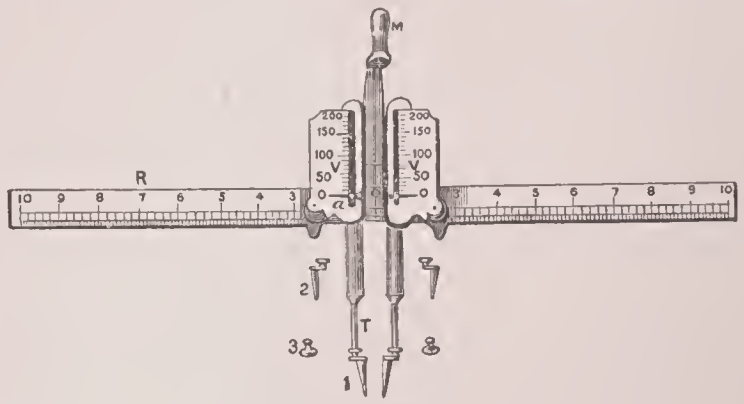

Fig. 4.—Verdin's æsthesiometer.

beam, on each half of which slides a vertical rod tipped with a rounded ivory point; the distance apart of the two points is indicated by a scale on the beam. The lower part of each rod holds a piston, which works against a spring; when the points are pressed on the skin the spring is forced up, the amount of pressure being indicated on another scale. *Jastrow's æsthesiometer* is a simplified form without the spring; the instrument is held by a handle which slides on a vertical rod; when the points touch the skin the handle moves down, avoiding any additional pressure by the operator. *Münsterberg's æsthesiometer* is a flexible rod, at one end of which is a handle, at the other a sheath, by means of which various contact pieces may be attached. Among the contact pieces used are points arranged in various figures, continuous squares and circles, and surfaces of various sizes, for investigating the thresholds of sensation and difference; a set of small pans is used for investigating the temperature senses. For reaction-time experiments a circuit is made, when the skin is touched, by the bending of the flexible rod.

Heat and Cold.—Besides the application of Münsterberg's æsthesiometer just noted, the space relations of the temperature senses are investigated by moving a hot or cold point along the skin. A brass cylinder tapering at one end to a fine point is used. Two cylinders are necessary, one being kept in hot or cold water while the other is in use, with frequent changes on account of the loss or gain of temperature from the skin. This apparatus is used for mapping out the position of the hot and cold spots. The thermæsthesiometer (described above) is also used for this investigation. When an area of the skin has been searched thoroughly with one

of these apparatus, and all the hot and cold spots marked in distinctive inks, a permanent record may be made by laying a *transfer-frame* of transparent paper over the area, and marking the spots, which are visible through the paper. Thus we may compare the distribution of the spots in different areas, or in the same area at different times.

Muscular Sense.—Cattell's apparatus for measuring the appreciation of small differences of movement consists of a carriage which travels freely on a track. One finger is inserted into a loop attached to the carriage, and the latter is moved a certain distance; the carriage is then brought back and the subject endeavors to make another movement of the same length. The distance traveled each time is indicated by a pointer on a scale.

Sense of Position.—For investigating the subjective estimate of bodily position the *tilt-board* is used. This is a long, flat board (like the rotation table) placed across a sawhorse, so as to swing vertically. The subject is strapped to the board with bandaged eyes; it is then swung into any position, and he makes a judgment as to the angle. The actual angle is shown by a scale and a plumb-line or pointer.

Hearing.—Our auditory space-perception consists chiefly of estimates of direction. It is investigated by means of a graduated horizontal circle in the plane of the ears, with other arcs in various planes. A sound is made with a telegraphic sounder at different points on these circles, and the subject's estimate compared with its actual direction.

Vision.—The space threshold is measured by means of a series of alternate black and white strips of the same width. The distance of the strips from the eye, or their width, is varied, till they are barely distinguishable. (See VISION.) The threshold of difference is determined by numerous methods. Münsterberg's *eye-measure* (Ger. *Augenmaass*) consists of a long black surface, across which extend three movable white strips. Two of the strips are placed a certain distance apart, and the subject endeavors to place the third so as to make an equal distance. A concealed scale indicates the actual distances. Other forms of apparatus are similar in principle. In some, the strip or point moves automatically, and is merely stopped by the subject at the point desired. To measure discrimination of *depth* a different instrument is necessary. Cattell's apparatus consists of a box with eye-holes at one end and threads within, stretched vertically across. These threads can be placed at various distances from the eye, the distance being measured on a scale. The subject judges their absolute or relative distance with one eye or with both together.

Near the periphery of the eye the power of space discrimination falls off considerably and the color-sense is entirely lost. These phenomena are measured by means of the perimeter; this consists, essentially, of a fixation point for the eye, and a circular scale rotating about the line of direct vision. To determine the peripheral limits of any color a small piece of colored paper is placed at the end of the scale and gradually approached to the center of vision until the color is correctly distinguished; this is repeated for as many points of the periphery as desired. To determine the peripheral variations of the space threshold the colored piece is replaced by a white surface having two black dots a small distance apart; the piece is moved in till the spots are distinguished as two. The *campimeter* is similar to the perimeter; instead of a circular scale, a large flat sheet of white paper is used; the color-limits, etc., are marked directly on this. For locating the blind spot, see VISION.

5. *Motor Recording Apparatus.—Movement in General.*—Apparatus for measuring the extent of movement have already been described; its duration and rate are measured by a simple application of the kymograph; its force may be noted by the pressure exerted against a spring. There are various apparatus for measuring one or more of these data. Delabarre's apparatus for finding the components of movement along vertical and horizontal axes consists of a vertical and a horizontal string, each attached to the finger and passing over a pulley; at the other end they are attached to recording quills, which are pulled one way by the finger, the other by an elastic. The *dynamometer* is used to determine the maximum force of a muscle, or to compare movements of the same estimated force. It is an oval of flexible steel, which can be compressed at the sides or pulled apart at the ends; the amount of force exerted in either case is indicated on scales by a pointer, which stops at the highest point reached. The hand dynamometer is grasped in the hand and squeezed; a larger form is used for the arm and other muscles. In the *dynamograph* the force exerted is recorded on a revolving cylinder by means of tambours. This shows the rate and variation, as well as the amount of force exerted. Mosso's *ergograph* measures the work done by a single muscle, and its rate of fatigue and exhaustion. The forearm is placed on a cushioned board and held immovable by two sets of clamps; the second and fourth fingers are held fast in tubes, and the middle finger is attached to a string bearing a heavy weight: in raising and lowering the weight this finger moves alone without bringing any other muscle into play. The recording part of the ergograph consists of a carriage, to which the string from the finger is attached; it moves on two rods; from this carriage another rod extends, with a quill which marks on a revolving cylinder. The *myograph* measures the form and rate of simple muscular contraction. It consists of a bridge placed over the muscle in question and bound fast. A rod extends down and rests on the muscle. When the muscle contracts the rod is pressed up, and this acts on a tambour, which records the movement in the manner already described.

Involuntary Movements.—Jastrow's *automatograph* consists of a pane of glass resting on three perfectly spherical balls, which rest on another pane, which is set firmly and carefully leveled before the experiment. The hand rests lightly on the upper pane, which moves without friction with the movements of the hand. A rod extending out from this pane bears a hard rubber pencil, which moves over a flat sheet of blackened paper. When the eyes are closed the hand makes slight involuntary movements, differing according to the nature of the thoughts, and these movements are recorded on the blackened paper. This is a scientific application of the popular planchette.

Speech.—The form of movement of various organs in speech is measured and recorded by apparatus which are applied to the proper organs in the same way as the myograph, and which work on the same principle. The *labiograph*, *laryngograph*, and *palatemeter* measure the movements of the lips, larynx, and palate respectively. (See tracings in Fig. 1.) By means of the polygraph (described above) these records may be obtained simultaneously.

Physiological Processes.—The rate and form of certain physiological processes furnish a measure of the condition and changes of consciousness. A record of these processes under normal conditions may be compared with other records, taken during hard thinking or strong emotion, or after intellectual effort, fatigue, etc. The rate and intensity of the heart-beat is measured by the *cardiograph*; the *sphygmograph* measures the rate and form of the pulse (see SPHYGMOGRAPH): the *pneumograph* measures the movements of the thorax in breathing. These are similar in principle to the myograph. In one form of pneumograph a flexible rubber bottle is bound to the chest: it is compressed by the expansion of the chest in breathing, and the pressure recorded by a tambour. The *plethysmograph* is used to measure changes in the volume of the arm, due to changes in the blood-supply. It consists of a vessel, G (Fig. 5), into which the arm is inserted; the opening about the arm is then closed, and the vessel filled with water. Any increase in volume of the arm forces the water out into a second jar and causes the weight N to fall, and *vice versa*; these changes are registered on a scale.

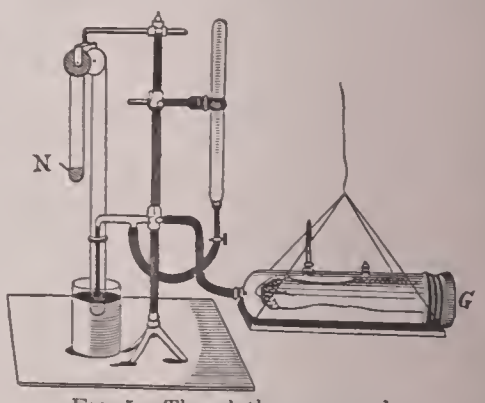

FIG. 5.—The plethysmograph.

6. *Apparatus for Measuring the Intellectual Functions.—Attention.*—If the attention be maintained at a maximum, this maximum will rise and fall at intervals. The rate of fluctuation is measured for vision by means of the *Masson disk*. This is a white surface, along one radius of which is a black line of uniform thickness but broken into segments; when the disk is rotated the inner segments of the line, being broader in proportion to the whole circumference than the outer segments, will give a darker gray. The breadth of the line is such that four or five rings are always distinguishable with close attention; the ring next beyond alter-

nately appears and disappears; the alternating intervals are measured by the chronograph. For hearing, the ticking of a watch at the farthest audible distance is used, or the faint sound of sand dropping continuously on a metallic surface.

Memory.—Ebbinghaus has measured the falling off in accuracy of memory trains and their latent force by means of nonsense syllables. Having memorized a series of these of given length after a certain number of repetitions, he observed the number of errors made in repeating the series after the lapse of one day, two days, etc. The number of repetitions required to relearn the series furnished a measure of the latent force of memory. Memory of intensity and intensity-difference has been measured in several of the senses for short intervals. The apparatus is the same as that used for the threshold for intensity-difference. Memory of visual size has been measured by means of a series of squares, circles, or lines of nearly the same dimensions. One of these, the standard, is shown and removed; after an interval another is shown. The falling off in accuracy is shown by the increase of the threshold value as the time is lengthened.

Perception of Motion.—A series of instantaneous pictures appearing in rapid succession will give the effect of continuous motion. The rate of change necessary to accomplish this is measured by the apparatus described above under least duration, or by a stroboscope whose speed is variable and measurable. (See STROBOSCOPE.) Other forms of apparatus having the same principle as the stroboscope are the zoetrope or zoötrope, vitascope, mutascope, and kinetoscope.

Illusions.—The well-known optical illusions of the size of angles, relation of horizontal to vertical lines, relation between filled and empty space, etc., may be measured by constructing variable figures, and altering their form until the illusion is allowed for and apparently corrected. Baldwin's two-square illusion apparatus is an example of this. It consists of a small and a large square, with a line connecting the mid-points of their sides; along this line moves a pointer, which the subject stops (by pressing a key) when the middle of the line appears to be reached; this judgment is affected by the size of the squares; the amount of error is indicated on a concealed scale, and constitutes a measure of the illusion. The illusion of weight as affected by size is measured by comparing a series of objects, of different weights and sizes but of uniform material, with a standard weight of different material. The subject determines which one of the series is apparently equal to the standard.

Imagination.—Scripture's apparatus for measuring the intensity of imagination consists of a telescope tube, through which the subject observes a screen of white paper. The latter is illuminated faintly in front and by a variable flame behind. The subject is asked to imagine threads like the cross-hairs of a telescope on the white surface, and to describe their changes as the illumination is increased. On the back of the paper, unknown to him, is a real line, which he finally sees and compares with his imagined lines. When they are equal in intensity the intensity of the real line furnishes a measure of the intensity of his imaginations.

7. *Apparatus for Anthropometrical Measurements.*—Measurements of height, weight, diameter of chest, etc., are performed in the usual way. The capacity of the lungs is measured by means of a *spirometer.* One form of spirometer consists of an inverted jar resting in water and counterbalanced by weights. When air is blown through a tube into this jar the latter is lifted, the amount of air sent in being indicated on a scale. The subject takes a full breath and breathes out through the tube. The dimensions of the head are measured by means of the *craniometer.* One form of this apparatus is the hatter's *conformateur*, which is set on the head and indicates the outline of the largest horizontal area of the head. The *pupillometer* is used to measure the diameter of the pupil of the eye. The *ophthalmometer* determines the curvature of the cornea. The dynamometer, color-blindness tester, perimeter, Galton's whistle, and reaction-time apparatus are also employed in anthropometrical tests.

LITERATURE.—Most of the apparatus are described in articles in psychological magazines on the investigations for which they are used. See also Sanford, *A Course in Experimental Psychology* (Boston, 1898); catalogue issued by the psychological laboratory of Harvard University (Cambridge, 1893); and catalogues of various instrument-makers —Verdin, Koenig, Rothe, Zimmermann, Petzold, Cambridge Scientific Instrument Company, Queen, Biddle, J. D. Brown, Meyrowitz, and Garden City Model Works.

HOWARD C. WARREN.

Reed, HUGH: soldier and author; b. in Richmond, Ind., Aug. 17, 1850; graduated at the U. S. Military Academy in 1873; promoted to second lieutenant, serving on garrison and frontier duty; was attached to the Signal Service, being Professor of Military Science and Tactics in the training-school at Fort Whipple 1878–79, at the Southern Illinois Normal University 1880–83, and on garrison and frontier duty 1883–84, having been appointed inspector-general on the staff of Gov. Porter, of Indiana, in 1881; on leave of absence since 1884, because of poor health; has invented a metallic shelving and a folding cash-box. He compiled *A Calendar of the Dakota Nation* (1877, afterward included in the fourth annual report of the bureau of ethnology of the Smithsonian Institution), and has published *Signal Tactics* (1880); *Cadet Regulations* (1881); *Upton's Infantry Tactics*, abridged and revised (1882); *Artillery Tactics*, abridged and revised (1882); *Military Science and Tactics* (1882); *Standard Infantry Tactics* (1883); and *Broom Tactics, or Calisthenics in a New Form* (1883).

Registration of Titles (to land): The recording, in a hall or office of public records, of deeds and other instruments conveying, granting, or creating titles to or liens or charges upon property is of comparatively recent date, and the registration of titles, as distinct from such recording of instruments merely, is even more recent, and as yet practiced only with regard to real property.

Owing to the essential peculiarities of real property and its tenure, and owing to the fact that it may be subject to varied interests and rights in different persons simultaneously, some or all of whom may not be in physical possession of the property, the recording of deeds of real estate, mortgages upon real estate, etc., becomes of peculiar importance, because in the absence of such registration the difficulty of determining the actual status of the title to the property and its condition as regards liens and incumbrances is very difficult as well as uncertain, and may require the expenditure of so large a sum as to interfere materially with commerce in real estate. In the absence of special legislation protecting purchasers or mortgagees, they must make such investigation into the title of property intended to be purchased at their own risk, and this investigation has to be repeated in each transaction involving title to the property in question. This investigation is still necessary, to some extent, under any system of registration of titles, but its difficulty and the risk of error are mostly done away with.

The registration of titles differs from the recording of deeds and other instruments, in that, while the law may provide for the recording, conveying, or granting titles to or interests in real estate without providing that such recording shall afford any special protection to the person recording them, the acts providing for the registration of titles secure to the party in whose name the title is registered a certificate or other instrument which in effect guarantees to him the title to the property.

In England there is still (1899) no general law requiring the registration of titles, and no law for the voluntary registration which is observed. The matter of statutory regulation of the recording of deeds and registration of titles practically dates from the reign of Henry VIII., when an act was passed providing for the recording of bargains and sales of freeholds. Similar acts for the recording of conveyances were discussed in Parliament under the Commonwealth, but none of them became a law. Later, in 1669, the matter was again actively mooted, and in a report of a committee of the House of Lords it was stated that the depreciation of land was partially caused by the uncertainty of titles, and a system of *registration of titles* was advocated as a remedy for this.

In England a bill for a general system of registration was introduced into Parliament in 1758, but this too failed to become a law, and the subject was practically dropped, until it arose again in 1830, and again in 1857, in which years royal commissions brought in reports favoring a system for the registration of titles, and as a result of the report of these commissions in 1857 there was passed in 1862 an act (25 and 26 Vict., chap. 53) for the facilitation of the proof of title to and the conveyance of real estate. This act provided for the establishment of an office for the land reg-

ister in London. It left the registration of title optional, and no title could be registered unless it were such as a court of equity would consider to be a good marketable title. The effect of registration was to make the title indefeasible, and a land certificate was delivered to the person registered as owning the title, and the deposit or indorsement of the certificate constituted an effectual sale or mortgage of the land. The expense and delay involved in making registration of title under the provisions of this act, however, were very great, the average expense of searching and registration being said to be about $1,000, and requiring never less than five or six months to consummate, and usually longer than that. Neither did the registration have the desired effect of cheapening or rendering more expedient subsequent conveyances or mortgages. This act proving a failure, in 1875 the Land Transfer Act of 38 and 39 Vict., chap. 87, was passed, providing for the registration of any person as the owner of land upon his satisfying the register that he had a *prima facie* fee in the property, and was in possession in this right. Such a registration of title did not bear upon or affect any adverse claim or interest, except that the lapse of time would perfect the registered title.

The act also provided for the registration of "qualified titles" in cases where the title could be made out only for a limited period or subject to exceptions, the registration in this case excepting from its effect the rights or interests respecting which the title was uncertain. This act failed, and in a report of the select committee of the House of Commons its failure was attributed to the absence of power to remove from the register a title which had been once placed upon it; the disinclination of solicitors to recommend to their clients compliance with the act, fearing a curtailment of their profits; a general distrust of land registration arising from the failure of the previous act; the disinclination of the public and the legal profession to familiarize themselves with the new system; and the prejudice against departing from established usage. In 1888 an act entitled the Land Charges and Registration Act (51 and 52 Vict., chap. 51) made further changes in the system of registration, intended to improve it and make its observance more popular, but to little effect. A bill for the compulsory registration of titles was introduced in 1895, but failed to become a law. In 1897 an act entitled the Land Transfer Act was passed. This act amended the law of 1875, and also provided that where real estate is vested in any person without a right in another person to take a right by survivorship it shall, on his death, notwithstanding any testamentary disposition, devolve to and become vested in his personal representative or representatives from time to time as if it were a chattel real vesting in them or him, and this provision was made to apply to any interest in any real estate over which the testator had a joint power of appointment.

It also provided for a probate and letters of administration of estates having real estate only, and vested the real estate in the personal representative as trustee, subject to the powers, rights, duties, and liabilities imposed in the act, for the benefit of all persons by law beneficially interested in the estate; and these persons have the same power of requiring a transfer of real estate as persons beneficially entitled to personal estate have of requiring a transfer of their interest in the personal estate.

It provided that in the administration of the assets of a person dying after the commencement of the act his real estate should be administered in the same manner, and subject to the same liabilities for debts, costs, and expenses, as if it were personal estate. If the personal representative fails, on request of the person entitled to the land, to convey the land to that person, the beneficiary may apply to the court, which, if it thinks fit, may, upon such application and after notice to the personal representatives, order that the conveyance be made, or, in the case of unregistered land, that the person entitled to be registered as proprietor, sole or joint, be registered as such. The act also repeals the act of 32 Henry VIII., chap. 9, which prohibits sales or other disposition of land where the grantor or his predecessor entitled had not been in possession for one whole year previous to the disposition so made.

Besides these general provisions, which vitally modify the previous real-estate law of England, it made special provisions for the regulation of the conduct of official searchers, the payment of indemnity to persons injured by the registration of title, etc. The act of 1897 went into effect on Jan. 1, 1898.

Except for these acts the evidence of possession of title in England remains subject to the common-law regulations, by which the delivery of the deed is effectual as a mortgage, and may even constitute a conveyance in equity. The titles to land are involved, and the transfer or conveyance of real estate causes so large an expense as to constitute a great obstacle to the sale of land in small parcels.

In the U. S. statutes providing for the registration of titles as such have been adopted in California, Illinois, and Ohio, where the acts of adoption provided for the establishment of systems essentially the same as the Torrens system; but in the States of Illinois and Ohio the act was adjudged as unconstitutional, as attempting to confer judicial power upon the registration office. Subsequently, however, in Illinois, an act was passed to remove the unconstitutionality of the statute. In Massachusetts an act for the registration of titles to land was passed, and went into effect Oct. 1, 1898, which provides for a court of registration, consisting of two judges, sitting at Boston, with the right to adjourn to such other place as may seem convenient. Under it only estates in fee simple may be registered, and this is done upon an application to the court and a formal notice to the occupants of the land adjoining the owners. The decree of the court confirms the title, orders its registration, and can not be opened except within one year if the registration is obtained by fraud, and not even for that reason against an innocent purchaser for value. The decree is registered in the county in which the land is situated, and a certificate of registration is issued to the owner, evidencing his ownership. After registration no voluntary conveyance or instrument of transfer, except a will and a lease for not over seven years, binds the land; but it constitutes merely a contract between the parties, which entitles the transferee to re-registration, upon which the new certificate is issued in place of the old one which is surrendered. In the other States of the U. S. a system of recording of deeds as distinguished from registration of titles prevails.

The system of registration of title has been adopted in Germany, part of Switzerland, Austria-Hungary, Australasia, and the larger part of Canada. In New South Wales and Victoria the Torrens system (see Torrens System) of land registration has been used since 1862; in South Australia since 1858; in Queensland since 1861; in Tasmania since 1863; in New Zealand and British Columbia since 1870; in Western Australia since 1874; in India since 1884; and in Manitoba since 1883. The German method of registration of title is very peculiar. The state undertakes to keep an account, similar to a ledger account, for each piece of property individually owned, correctly and in such form that any ordinarily intelligent person can, without an examination of any deed or other instrument, ascertain the owner of the property and the debts and other incumbrances which are a charge upon it. In Prussia transfers are made by word of mouth, without any deed or conveyance, and both parties may appear before a registrar and declare their contract, and the purchaser is then registered as the owner. See Recording of Conveyances.

For full account of the system of registration of title in Central Europe see 2 *Jour. Com. Leg.* 112 (June, 1897); see also the *Report of the American Bar Association for 1890*. Reid, Alexander Peter, M. D.: b. in London, Ontario, Oct. 22, 1836; graduated in medicine at McGill University in 1858. He also took the degree of M. D. at the University of New York in 1865. He was instrumental in establishing the Halifax Medical College, of which he was president for several years. In 1878 he was appointed superintendent of the Nova Scotia Hospital for the Insane, where he remained until he was transferred to the superintendency of the Victoria General Hospital, Halifax, in 1892. Among his published writings are *Strychnia*; *Ascent of Man, or Stirpiculture*; *Poverty Superseded, or New Political Economy*.

Religious Societies: This term is rather loosely applied to various associations of individuals who have voluntarily united for the purpose of worshiping together, observing other religious rites and ceremonies, and administering to their common welfare. Such societies may be, and in the U. S. often are, incorporated as religious bodies, and are then called religious corporations. The term *religious so-*

ciety is distinct in meaning from *ecclesiastical corporation* as used in the English law, the latter being a religious body composed entirely of spiritual persons, such as bishops, certain deans, prebendaries, archdeacons, parsons, and vicars, who constitute sole corporations, and certain other deans and chapters, and formerly monks, abbots, etc., who constitute corporations aggregate.

The term religious corporation as here used implies some special privilege or power had by reason of its religious character; but where there are general corporation laws, as there now are in most of the States of the U. S., there is nothing in the nature of them which prohibits a body of men from organizing as a corporation under them unless such organization be expressly prohibited. All religious corporations in the U. S., however, are merely civil corporations, having the same rights and privileges as any other civil corporation, except where special privileges are given as mentioned above, the most important privileges so given being partial or entire exemption from taxation and the power of taking property in perpetuity for religious uses. As in the case of other corporations, the rights of property and of contract of such corporations are subject to the general law equally with other civil corporations, and the acts of its members are equally subject to the control of the courts.

The term religious society as here and generally used is not synonymous with the term *church*. Although the two bodies may coexist and the membership in each may be identical, they are distinct from and independent of each other; and a religious society may exist without a church and a church without a religious society. A religious society, however, usually does include or have associated with it a church consisting of members professing a common religious belief and worshiping together, and a congregation consisting of the church and such other persons as usually and statedly worship with the church, and a board of trustees acting for the church, the congregation, or the religious society as beneficiaries.

In such a case the church is governed by its own rules and regulations, and has the power to control and direct its members, and enforce strict observance and adherence to the church regulations, doctrines, and standards and subordination to the ecclesiastical courts, subject, however, to appeal to the civil courts in any matters involving property rights. For the purposes of such appeal property rights are construed to include the right to exercise the functions of an office, the right to membership in the church, and in general the right to have the rules and regulations of the church fairly and correctly enforced. The discipline of a church does not affect the membership of the disciplined person in the corporation, which has not the power to try its members or to deprive them of their membership for moral delinquency, and excommunication from the church does not affect membership in the religious corporation. The religious corporation, on the other hand, usually owns the property which is used by the church, and attends to and assumes the financial management and responsibility incidental to the conduct of the church and congregation. The minister, or person who administers the religious rites of the church, or the rector, priest, or pastor, as he may be designated, although having for his duties the conduct and care (*cure*) of the church, is usually hired by the corporation or society, and the church or congregation, in calling a minister, does not bind the corporation or society; and he should not be so called until the society has regularly and legally agreed to employ him. When he has been employed by the society and accepted such employment, the failure of the trustees of the church to apply the revenues of the church to the payment of his salary does not affect his right to recover it from the corporation by an action at law.

Organization and Membership.—Most of the States of the U. S. have passed laws for the incorporation of religious societies, but they are so varied and specific in their provisions that no general statement of their details can be made. Where no certificate is required, a religious corporation *de facto* may be created by the use and assumption of corporate powers by any body of competent persons. Where a certificate of incorporation is required by the statute, it must be accepted by the society or body of persons acting as such at a regular meeting, and the assent of the members as individuals is not a sufficient acceptance. If any specified forms are prescribed by the statute, they must be strictly observed in order to effect a valid incorporation. In the absence of statutes prescribing qualifications for membership the incorporating body may impose such qualifications as they see fit, provided the requirements be not inconsistent with the general law of the land; but in those States in which special provision is made for the incorporation of religious societies it is usually required that the persons intending to become members shall be adults professing a common religious belief. It is usual for the society also to require, as a condition of membership, public confession of the faith of the church associated with the society and submission to its decisions; but a society may be so formed that merely stated attendance at the religious service of the society or the renting of a pew may suffice to entitle a person to membership in the society.

Property and Pecuniary Liabilities.—In some States of the U. S. the incorporation of a religious society is required as a condition of its receiving the title to property, while in others this is not required; in others the formation of religious corporations is prohibited, as in the States of Virginia and West Virginia, where the law provides for passing the title to property to unincorporated religious societies. The vesting of the title to the property in a religious corporation which has been created by a special charter or under the provisions of a general incorporation act, or the vesting of it in a body of unincorporated trustees for the benefit of an unincorporated society, creates a trust that the property so held shall be devoted to the religious purposes contemplated; and the courts will interfere by injunction to restrain the diversion of such property to other than the religious uses for which it was acquired, except so far as the doctrine of *cy pres* may be applied. (See Cy Pres.) Property conveyed to the society for use in the support of any specified form of worship or other religious purpose can not be diverted from the specified use, even by a majority vote of the corporation; and, in the event of any change or modification of the tenets of the church or in its method of worship making it impossible to carry out the terms of the trust, a court of equity will appoint a trustee or trustees to effect their fulfillment. Trusts devoting property to the support of a specified form of religious doctrine are enforced mainly in those States which recognize and sustain charitable uses; but in some States, as Minnesota and Michigan, they are held to be invalid.

In case of a division in a religious society made under adequate authority a division of the common property ordinarily accompanies it; but members seceding from the organization forfeit their property rights in it, and the title to the entire property remains in the hands of those members acting in accordance with the purposes and objects for which the society was formed.

The power of a religious society to take and hold property under a will depends upon the statutes by which the subject is regulated more or less completely in the various States.

F. Sturges Allen.

Rensselaer Polytechnic Institute: a school of science and engineering situated in Troy, N. Y. It was founded by Stephen Van Rensselaer in 1824 as Rensselaer School. This name was changed in 1832 by legislative act to Rensselaer Institute. In 1850 the present name was assumed. The institution is the first school of civil engineering established in any English-speaking country. Lectures on land surveying and civil engineering were given as early as 1828, and the degree of C. E. was first conferred in 1835. The curricula were completely reorganized in 1849–50, and soon afterward the courses were extended to four years. While the courses offered lead to the degrees of C. E. and B. S., the school is more widely known as a school for civil engineering. The course in natural science is identical with that in civil engineering for the first two years, but the last two years are, to a large extent, taken up with the study of chemistry, assaying, geology, mineralogy, and metallurgy. The course in engineering is a very general one, and includes the study of the design and construction of bridges and other structures, water-works, sewers, steam-engines, electric motors, dynamos, etc., the location and construction of roads and railroads, and the assay of ores. There are in all six buildings. The main building is 155 × 50 feet, and the others grouped about it, except the Alumni building, are of proportionate size. The Alumni building, a beautiful three-story structure, is in the business center of the city, and contains the administrative offices of the institu-

tion. The library consists of 6,500 volumes and many pamphlets. Fifteen professors instruct a student body of about 140 (1900). The school has 1,303 graduates, of whom 873 are living. In Troy and its near neighborhood there are engineering works of all kinds, and manufacturing plants of great diversity, which afford to sudents opportunities for practical observation and investigation. John Hudson Peck, LL. D., has been president since 1888.

Requests, Courts of: in English law, courts of special jurisdiction, analogous in their functions to modern courts of equity or chancery courts, constituted for the decision of civil actions, and especially the recovery of small debts. Various courts differently constituted, and with different powers, have been called by this name, the origin of some of which are obscure, The most important of these is what is commonly called the *king's court of requests*.

Courts of Requests other than the King's Court.—Besides the king's court of requests there were established various other courts so called, the most noted of which were the court of requests in the city of London, commonly called the "court of conscience, New Guild Hall," which was established Feb. 1, 1518 (Henry VIII.). This court, which probably owed its origin to Cardinal Wolsey, had jurisdiction extending only over the recovery of small debts, not exceeding forty shillings, in disputes between citizens and tradesmen of London; and its judges were "two aldermen and four ancient discreet commoners." It appears to have been established originally as an experiment to last for two years only, but maintained its successful existence until abolished altogether, with all other similar courts, by the Small Debts Act of 9 and 10 Victoria, ch. 95, and the order of council of May 9, 1847, by virtue of which the jurisdiction of these courts was transferred to the county courts. The London court of requests was first given legal validity by the act of Parliament, 1 James I., ch. 14, in the year 1604. No other similar court was established by statute before the reign of William and Mary, when by the act 1 William and Mary, Session I, ch. 18, courts of conscience were established for Gloucester and Bristol. These courts, although essentially the same as the king's court of requests, were not recognized by that title in this statute. Another similar court was established by the act 22 George II., ch. 47, creating a small-debt court for Southwark under the style of "The court of requests for the town and borough of Southwark"; and in the following year a court of requests for the city and liberty of Westminster was authorized, and subsequently a number of smaller courts were established in various parts of the country. The East India Company at a later date established similar courts of requests in each of the three presidencies governed by that company.

The King's Court of Requests.—The origin of the king's court of requests has not been definitely settled, but it undoubtedly was established as a definite tribunal during the reign of Henry VII., as the books of the court show it to have been active from the eighth year of his reign, and the judges of the court were nominated from that time forward. The judges even then, however, were not more than a standing committee of the chance attendants at the bar of the king's council; but this committee, at first forming but a numerically unimportant portion of the judges of the court of requests, eventually absorbed the whole of its active jurisdiction. This court, as established during the reign of Henry VII., was a court for civil causes corresponding to the star chamber, which had cognizance of criminal matters; and the members of the court were furnished from the star chamber. The Lord Privy Seal, who was an official of the star chamber, was president of the court of requests, which was at first called the court of poor men's causes. The court was evidently established at an interval between the sittings of Parliament and was never placed upon a statutory basis; but it gradually developed from a tribunal constituted by a more or less shifting committee to an itinerant council which attended the royal progresses into a court with a fixed place of sitting and permanent professional judges. It has been claimed by some historians that it was established to enhance the royal prerogative, but the history of the court seems to preclude this origin; and it appears that it was borrowed from a similar institution in France where the king was looked upon as a dispenser of patriarchal justice to his subjects. The judges of the courts were called masters of requests. Originally the court sat without regard to the law terms of the common-law courts, but about the year 1497 this custom began to undergo a change, and in the years 1522–23 the vacations of the law courts were observed by the king's court of requests, and about the year 1516–17 the court appears to have been assigned a permanent seat of judgment at the Whitehall in Westminster.

By reason of the summary and informal method of procedure of the king's court of requests it was opposed by the common-law judges and the practitioners in the common-law courts, and its constitutionality was constantly and bitterly contested. The judges of the common-law courts acknowledged the *de facto* existence of the court of requests, but the exercise of its authority by the masters of requests was frowned upon by the common-law courts, and in the time of Elizabeth the defendants began boldly to defy the court, relying upon the support of the common-law judges, who opposed and prevented the execution of its judgments by injunction and writs of *habeas corpus*. The court of requests, however, was sustained by the favor of the royal court and by those who favored the exaltation of the royal prerogative, but the assaults upon it were re-enforced by the authority of Coke, who in 1606 was made lord chief justice of common pleas, and assumed an attitude antagonistic to the royal prerogative and assertive of the independence of the bench. The reason for the energy and persistence of this attack by the common-law judges has been assigned to the alleged use of torture by the court of requests, but the real reason was probably that the court of requests interfered with the profits of the common-law judges and the common-law practitioners, by removing from the common-law courts a large number of cases from which fees would otherwise have been received both by the judges and the pleaders at the bar.

Some authorities believe the court of requests to have been virtually abolished by the statute 16 Charles I., ch. 10, passed in 1640, entitled "An act for the regulating the privy council, and for taking away the court commonly called the star chamber"; but, as the court of requests is not mentioned directly or indirectly in this act, it is more probable that it was not then abolished, but merely ceased to exercise its prerogatives at the time of the establishment of the protectorate under Cromwell. Petitions are in existence, dating at the time of the restoration, for appointments as masters of requests, or for confirmation of appointments alleged to have been made; but after the establishment of the Commonwealth the court did not again exercise any active jurisdiction.

For a full discussion of the origin, jurisdiction, and abolishment of these courts see vol. xii. of the publications of the Selden Society, and the authorities there referred to.

F. Sturges Allen.

Resistance of a Ship: the resistance which must be overcome in order to propel a ship through the water. This is but a special case of the more general problem of the resistance to the motion of a solid in a liquid, to which we may first refer.

It is shown in hydrostatics, for a body wholly or partially immersed in a liquid, and at rest relative to it, that the horizontal resultant of all forces between the liquid and the body is zero, and that the vertical resultant equals the weight of the body. If, however, there is relative motion between the liquid and the body, these conditions no longer hold, and we find in general a force acting between the liquid and the body in such direction as to oppose the movement, and tending thus to reduce the relative motion to zero. The force thus developed has in general a vertical as well as a horizontal component, and while the former is usually omitted, it may in special cases reach an amount requiring recognition.

The development of resistance thus appears as the result of a change in the nature and amount of the distributed system of surface forces acting between the body and the liquid. When the two are relatively at rest these forces are all normal to the surface. When motion is instituted they are no longer normal, but oblique. They may, however, be resolved into two systems, one composed of normal forces and the other of tangential forces. The former will differ from the normal system when at rest, and the latter is an entirely new development. The total resistance opposed to the motion will be the total longitudinal component of these two systems of forces. We thus reach an analysis of resistance based upon an examination of the modified systems of surface forces, and from this standpoint we should naturally distinguish two subdivisions or kinds of resist-

ance—(*a*) that due to the normal component system, and (*b*) that due to the tangential component system. These may be termed the normal and the tangential resistances.

Turning now from the body to the water, we find, consequent upon the relative motion, a certain number of resulting forms of disturbance. These may be classified under four heads: (1) The particles constituting a certain portion of the water, in their motion relative to the body, follow smoothly curved flowing or stream-line paths. (2) The particles constituting a certain other portion of the water, especially when the contour of the body is blunt at the stern, are thrown into large eddies and whirls, forming a series of more or less imperfect vortices left behind as the body proceeds on its way. (3) The particles constituting that part of the water which flows very near the surface of the body are acted on by the more or less pronounced roughness or irregularity of its surface, and by molecular forces as well. They are thus thrown into a series of minute vortices and whirls, constituting a kind of skin of eddying water surrounding the body as it moves through the liquid. (4) There will be formed a series of waves or surface disturbances more or less pronounced, according to the circumstances of the case. Subdivisions (1) and (4) are not independent. though they are frequently referred to as though they were. The more common but not altogether satisfactory method of analyzing resistance proceeds on the assumption that these various manifestations or disturbances correspond each to a particular kind of resistance. We have thus stream-line resistance, eddy resistance, skin or frictional resistance, and wave resistance. The skin resistance corresponds to the resistance due to the tangential system of forces, while the other three correspond to the resistance due to the normal system of forces, as referred to above.

The typical case for the exhibition of eddy or head resistance is with a small plane moving at right angles to itself, and immersed so far below the surface that there shall be no sensible wave disturbance. In such case experiment shows that the resistance may be expressed in the form

$$R_1 = f_1 \frac{\sigma}{2g} A v^2,$$

where R_1 = resistance, f_1 = an empirical coefficient, σ = density, A = area, v = velocity, g = aeceleration due to gravity. With the foot, second, and pound as units, the value of f_1 is found from 1·1 to 1·7, the latest experiments pointing to the lower values as the more correct. Where the direction of the plane is oblique, or at any angle θ to the direction of motion, experimental results differ and various formulas have been proposed for the longitudinal resistance. Joessel's formula, which is perhaps the most correct, is as follows:

$$R = f_1 \frac{\sin^2 \theta}{\cdot 39 + \cdot 61 \sin \theta} \frac{\sigma}{2g} A v^2,$$

in which f_1 would have the same value as above.

The typical case for the exhibition of skin or tangential resistance is with an immersed plane moving in the direction of its length. An extensive experimental investigation by William Froude between 1870 and 1874 shows that this resistance may be expressed by an equation in the form

$$R = f_2 A v^n,$$

in which, with the same units as above, f_2 varies according to the nature of the surface and the length of the plane, being naturally greater as the surface is rougher, and less as the plane is longer. For a varnished surface the values vary from about ·0040 for 2 feet length to ·0030 for 50 feet length. For medium sand the values for the same lengths vary from about ·009 to ·005. The exponent n also varies from about 1·83 to 2, being usually taken at the lower figure for smooth surfaces.

Wave-making resistance is due to the fact that the energy involved in a train of waves is not propagated on as fast as the geometrical contour, and the maintenance of a system of waves of fixed configuration requires, therefore, a constant supply of energy which must be provided by the ship. The wave-formation thus drains energy constantly from the ship, and the operation results in the development of a resistance to the movement.

The wave-making resistance of a ship-formed body is usually considered of the form

$$R = A l u^4$$
$$\text{or } R = B l u^4 + C u^6,$$

where A, B, and C are constants, l is linear function of the ship, and u is the speed.

For a ship-formed body the eddy resistance is usually negligible, so that the skin and wave-making resistances are alone of importance. The term *residual resistance* is often used to imply all of the resistance left after subtracting the skin resistance. As we have just seen, this will be chiefly wave-making resistance.

The satisfactory determination of the values of the coefficients in the above equations for wave-making resistance has not yet been effected, and in consequence the determination of residual resistance by formula is attended with some uncertainty. The most satisfactory way in which the problem can be approached for purposes of ship design is by means of the experimental canal and the law of comparison. By the aid of this law the experimental data for models are made available for ships of the same geometrical character but of varying sizes, there being a particular ratio between the speeds of the model and ship at which this relation holds. Such speeds are known as "corresponding," and are intended to be those for which the two forms would be surrounded by wave systems of like configuration. They are defined as speeds in the direct ratio of the square roots of similar linear dimensions of the two forms. The statement of the law is, then, that for similar ships at corresponding speeds the residual resistances are in the direct ratio of the volumes, or in the ratio of the cubes of their similar linear dimensions. The use of this law depends wholly on the separation of the total resistance into two parts, the skin and the residual. The former is computed for both model and ship by formula as above. The skin resistance for the model being subtracted from the total amount as determined by experiment, the remainder is the residual resistance for the model at the model speed. This multiplied by the ratio of the volumes gives the residual resistance of the ship at the desired speed. This added to the computed skin resistance gives the total resistance desired.

Still more directly the law of comparison is frequently considered to relate to the whole resistance instead of to the residual only, and hence the step from the resistance of the model to that of the ship requires simply the application of this law.

The law of comparison is sometimes considered as an exact relation between the residual resistances of similar forms at corresponding speeds. This, however, is not the case. It applies to all resistance due to stream-line deformation, including that due to the formation of waves, but is only exact on the supposition of a liquid without viscosity, and of the absence of all discontinuity of flow such as would be caused by breaking waves or eddies. As these conditions are the further from being fulfilled, the less exactly will the law of comparison apply. The confidence felt in the results of its use is therefore dependent on experience rather than abstract theory. This appeal to experience shows that the law, while not quite exact, furnishes a remarkably close and satisfactory approximation, and in the present condition of the science undoubtedly furnishes the most reliable method of treating the residual resistances of bodies moving in a liquid.

This field of hydromechanics has naturally received much attention from the theoretical as well as from the experimental side, and many important investigations have been made. From the nature of the case, however, these are necessarily limited to specially simple or regular forms of bodies, such as the sphere or cylinder, to an ideal constitution of the liquid, and to the supposition that the motion takes place at an indefinite distance from the surface, so that all superficial disturbance is eliminated. These restrictions so far remove the problem from the actual case that while such investigations have their interest, and furnish valuable indications regarding the nature of the relation between the surrounding conditions and the resulting resistance, yet for quantitative measurement entire dependence must be placed on experimental investigation, and its results as expressed by empirical formulas. Further progress in this field seems to be dependent on a wider provision of experimental data, coupled with its systematic and exhaustive analysis in the light of the highest results of theoretical investigation.

For more detailed information on this subject, reference may be made to the following papers and works: William Froude, Reports to British Association for the Advancement of Science, 1872, 1874; R. E. Froude, *Transactions of*

the Institute of Naval Architects (vol. xxii., p. 220); Pollard and Dudebout, *Théorie du Navire* (Paris, 1893); Taylor, *Resistance of Ships and Screw Propulsion* (New York, 1893); Durand, *The Resistance and Propulsion of Ships* (New York, 1898). W. F. DURAND.

Restraint of Trade, Contracts in: This term is technically used to designate those contracts which impose such hindrance or obstruction to the free and uninterrupted pursuit of trade and business as to conflict with public policy, and for that reason to be illegal and void, although the term has a wider general meaning, making it applicable to any contract which hinders or interferes with freedom of trade, whether to such a degree as to render it illegal or not. What shall constitute such restraint of trade as to render a contract illegal or void is so far dependent upon the conditions and circumstances connected with each contract as to render any more than a general statement of the matter impossible.

A contract in restraint of trade may exercise such restraint either in restricting the territory within which the business or occupation may be carried on by one or more parties to the contract, or it may entirely restrain one or more parties from pursuing a given occupation or occupations.

A certain degree of hindrance or impairment of freedom of trade may be imposed in a contract without rendering the contract invalid as against public policy, so that, generally speaking, such restraint may be imposed as is necessary to afford a fair protection to the interests of the one in whose favor the restraint is imposed. Whatever restraint is imposed beyond the needs of such protection becomes void, so that restraining covenants must be limited in regard to the territory to which they apply. Certain contracts, such as those for the sale of secret processes of manufacture which it is agreed shall be communicated for the exclusive use of the buyer, or the sale of a patent right for the life of the patent, may impose an unlimited restraint of time and place; and, generally speaking, where the restraint imposed is reasonably limited as to space, it may be imposed without limit as to the duration of time. Where, however, no space-limit is imposed, but the prohibition or restraint becomes general, the duration or length of time for which the restraint is to continue may be void. Contracts illegal because in restraint of trade most frequently are those involving the sale of a good-will of the firm or business concern to those intending to operate the same trade, or business, or calling within the same territory as that in which the vendor previously operated it.

Except in the instances above mentioned—the sale of secret processes, patent rights, etc.—it may be comprehensively stated that a general covenant in restraint of trade without qualifications is void because unreasonable and contrary to public policy; but if some qualification be placed upon the restraint, either at the time or place, so that the restraint is partial only, the question of reasonableness is raised, which can be legally settled only by a jury or court.

Another form of contract involving illegal restraint of trade which is very common and of great commercial importance at present are those contracts intended to establish a monopoly or form a combination of the capital or goods of two or more persons or corporations in such way as to restrict trade or to prevent competition in the sale of commodities.

The determination of the question whether a contract is in restraint of trade or not is chiefly governed by the specific circumstances under which the restraint originates and is exercised, and anything more than a very general statement of the principles of law governing the subject is impossible. A rule or statement which has met with favor is that "contracts in restraint of trade are in themselves, if nothing more appear to show them reasonable, bad in the eye of the law; but if from the peculiar circumstances of each case they appear to be reasonable, and they are founded upon a good consideration, the contracts are valid."

Thus for certain purposes, such as the prohibition of the practice of medicine, a restraint extending over a district within 12 miles of a place by a doctor selling the good-will of his practice within that place is considered valid, and in another case a contract not to engage in a certain business within 60 miles of a place within ten years was considered valid.

The tendency of the recent decisions to relax the rigor of the general doctrine that all contracts in restraint of trade are void is especially noticeable in the treatment of combinations effected for the sole purpose of creating monopolies or enhancing the price of commodities of which the public must have a constant supply. Such combinations are called TRUSTS (*q. v.*).

As to what is held to be legally an unlimited restraint of trade in respect of space there is some dispute, it being still a mooted question in England as to whether there exists an inflexible rule that contracts the restraint of which extends throughout England are null and void. In the U. S. it was early held that a covenant not to pursue an occupation within a State was in total restraint of trade and void, but subsequently it was held by the U. S. Supreme Court that a restraint coextensive with the limits of the State was not necessarily void.

See Parsons, *The Law of Contracts*; Patterson, *The Law of Contracts in Restraint of Trade*; Edison *On Contracts*; Matthews, *Covenants in Restraint of Trade*.

F. STURGES ALLEN.

Rhodesia: that part of Africa bounded N. by the Congo Free State and German East Africa, E. by the Central Africa Protectorate and Portuguese East Africa, S. by the South African Republic and the 22d parallel, and W. by German and Portuguese West Africa. It embraces the whole sphere of operations of the British South Africa Company, and is divided by the Zambesi into Northern and Southern Rhodesia. Northern Rhodesia includes the whole of British Central Africa except the Central Africa Protectorate. (See NYASSALAND.) It has about 600,000 inhabitants, and in 1899 is very little developed, though the northern part is said to be healthful and suitable for cattle-raising, while wheat and European vegetables are also grown. Here is the Stevenson road, between Lakes Nyassa and Tanganyika, built for wagon traffic and placed in excellent order in 1898. Southern Rhodesia is far more developed. Its area is 174,728 sq. miles. Matabeleland occupies about a third and Mashonaland nearly two-thirds of it, and the population, estimated at 460,000, is nearly equally divided between them. Railroads connect Cape Town with Buluwayo, the chief town of Matabeleland, and Beira, on the Indian Ocean, with Salisbury, the chief town of Mashonaland and the capital of Rhodesia. The area of the gold-fields of Southern Rhodesia is estimated at nearly 6,000 sq. miles, and now that mining machinery may be carried into the country by rail rapid development is expected. Other mineral resources are large, and much of the country is well adapted for farming. Salisbury, Buluwayo, and Umtali have nearly all the conveniences and improvements of flourishing cities, including banks and hospitals. They are now within twenty-four days' travel of London, and are connected with Europe by telegraph. C. C. A.

Rice, ALLEN THORNDIKE: editor; b. in Boston, Mass., June 18, 1853; graduated at Oxford, England, in 1875, afterward entering Columbia's law school, New York city; purchased the *North American Review* in 1876, and became its editor; organized and directed the Charnay expedition, which, under the auspices of the U. S. and France, made archæological investigations in Central America and Mexico; purchased a controlling interest in *Le Matin*, Paris, in 1884; was nominated for Congress by the Republicans in 1886, but was defeated; was first to recommend the Australian system of voting for adoption in the U. S., which system, owing to his advocacy of ballot reform, was incorporated in the platforms of the Republican and United Labor parties in 1887. He edited *Reminiscences of Abraham Lincoln* (1886), and contributed to *Ancient Cities of the New World* (1887). D. in New York city, May 16, 1889.

Rice, EDWIN WILBUR, D. D.: clergyman and author; b. in Kingsborough, N. Y., July 24, 1831; graduated at Union College in 1854, afterward studying law and theology; became a missionary of the American Sunday-school Union in 1859, and was ordained a Congregational minister in 1860; became superintendent of the Sunday-school Union's missions in Milwaukee in 1864, and assistant secretary of missions and assistant editor of its periodicals in Philadelphia in 1871, and has been editor of its publications since 1879; received the degree of D. D. from Union College in 1884; inaugurated and edited the lesson-papers that have been issued by the Sunday-school Union since 1872, and has prepared the series of *Scholar's Handbooks on the International Lessons*. He has edited the *Sunday-school World*, the *Youth's World*, the *Union Companion*, and other publications; contributed to Schaff's *Bible Dictionary*, edited

Kennedy's *Four Gospels* and Hood's *Great Revival of the Eighteenth Century*, and has independently published *Pictorial Commentary on Mark* (1881); *Historical Sketch of Sunday-schools* (1886); *The People's Commentary on Matthew* (1887); *The People's Lesson-book on Matthew* (1888); and *Stories of Great Painters* (1888).

Richard, Édouard, Lit. D.: lawyer and historian; b. in Princeville, province of Quebec, Mar. 14, 1844; was educated at the College of Nicolet and at McGill University; was called to the bar in 1868, and practiced his profession at Arthabaskaville for seven years; in 1872 was elected to the House of Commons for Megantic as a Liberalist, and retained his seat until 1878; was sheriff of the Northwest Territory 1878–83, in which last year he resigned his office and took up his residence at Winnipeg. He has made an exhaustive study of the history of the Acadians and published *Acadia* (2 vols., 1895), a history of the settlement of the Acadians. In 1897 he was sent to Paris by the Government to continue his historical researches.

F. Sturges Allen.

Richards, Henry Charles, F. S. A.: lawyer and politician; b. in Hackney, a suburb of London, England, Apr. 10, 1851; was educated at the City of London School and College, when he took up the study of law in connection with a clerkship in a law office; received the Bacon scholarship at Gray's Inn in 1879, was called to the bar in 1881, and has since been created queen's counsel. He entered actively into political affairs, and early in the practice of his profession became prominent as counsel for the local government, being retained as junior counsel to the post-office on his circuit, counsel to the Postmaster-General at the central criminal court in 1887, chairman of the city branch of the Church Defense Institution in 1877, and is now (1899) chairman of the City Church and Churchyard Society, which society he formed in 1880; was elected as Conservative candidate for Northampton in 1883 against Mr. Bradlaugh, and has been elected a Conservative member of Parliament for East Finsbury since 1895. He was retained in the Tower Bridge case, and in many cases for and against the London school board, and is an authority on the powers and duties of officers of charity, charitable and church organizations, and the law of compensation for damages arising out of municipal torts; and he has published several works on these subjects, including *Parish Councilor and Church-Wardens' Manual* and *The Law of Compensation*.

F. Sturges Allen.

Richards, Theodore William, A. M., Ph. D.: chemist; b. in Germantown, Pa., Jan. 31, 1868. He is the son of William T. Richards, the marine artist, and Anna Matlack Richards, the authoress of a volume of sonnets entitled *Letter and Spirit*. He graduated at Haverford College in 1885. He then entered Harvard University, where he took the degree of A. B. in 1886, and received those of A. M. and Ph. D. in 1888. Meanwhile he had been made an assistant in the department of chemistry in Harvard, and in 1894 was made assistant professor of that branch there. Prof. Richards has devoted himself chiefly to a study of the atomic weights of the elements, and is the author of nearly fifty papers in his specialty, most of which have been contributed to the *Proceedings* of the American Academy and to the *American Chemical Journal*.

Marcus Benjamin.

Richardson, Ernest Cushing, A. M., Ph. D.: librarian; b. in Woburn, Mass., Feb. 9, 1860; graduated at Amherst, and at Hartford Theological Seminary in 1883; was assistant librarian at Amherst in 1879; assistant librarian, librarian, and associate professor at Hartford Theological Seminary 1882–90, and became librarian of Princeton in 1890; received the degree of A. M. from Amherst in 1883 and from Princeton in 1896, and Ph. D. from Washington and Lee University in 1887; is a member of the American Library Association. His publications include *Bibliographical Synopsis of the Ante-Nicene Fathers* (1887); *Eusebius's Life of Constantine*, in the *Nicene and Post-Nicene Fathers* (1890); *Jerome and Gennadius: Lives of Illustrious Men*, in the same (1892); and *Hieronymus und Gennadius, De viris illustribus* (1896). Since 1896 he has furnished the annual review of the literature of American history to the Leipzig *Jahresberichte*.

Richardson, Hugh: jurist; b. in London, England, July 21, 1826; admitted to the bar in 1847. He began to practice his profession in Woodstock, Ontario, and in 1872 became chief clerk of the Department of Justice of Canada. In 1876 he was sent to the Northwest Territories, where he became judge of the Supreme Court of the Territories in 1887. He served as administrator of the Government during 1897 and 1898.

Richey, Matthew Henry: statesman; b. in Windsor, Nova Scotia, June 10, 1828; admitted to the bar in 1850. He practiced in Halifax, and became one of the examiners of candidates for admission to the bar. He was made queen's counsel in 1873, and later was elected vice-president of the Dominion Law Society. He was mayor of Halifax 1864–67 and 1875–78. He held a seat in the House of Commons in 1878 and 1882, and in 1883 was appointed lieutenant-governor of Nova Scotia, serving the full term of five years. He was president of the Nova Scotia Historical Society, and in 1884 received the honorary degree of D. C. L. from Mt. Allison University.

Richmond, Borough of: one of the boroughs of the city of New York as constituted under the charter of Jan. 1, 1898. It comprises the whole of Staten Island, and is coterminous with Richmond County. Pop. (1900) 67,021. For the new government, see New York, City of, in the Appendix.

Rideing, William Henry: author; b. in Liverpool, England, Feb. 17, 1853; early removed to Chicago, Ill., where he began writing for the press, devoting himself entirely to literature after 1874; traveled abroad extensively; was special correspondent of the Wheeler surveying expedition in 1878; edited the London, England, *Dramatic Notes* 1881–83, and on returning to the U. S. settled in Boston, and was attached to the staff of the *Youth's Companion*; was made managing editor of the *North American Review* in 1888, and resigned in 1897, and became associate editor in 1898. He is the author of *Pacific Railways Illustrated* (1878); *A-Saddle in the Wild West* (1879); *Stray Moments with Thackeray* (1880); *Boys in the Mountains* (1882); *Boys Coastwise* (1884); *Thackeray's London* (1885); *Young Folks' History of London* (1885); *A Little Upstart* (1885); and *The Boyhood of Living Authors* (1887).

Riggs, Kate Douglas (*Wiggin*): author; b. in Philadelphia, Pa., Sept. 23, 1857; received education at the public schools of Hollis, Me., and at the Abbott Academy, Andover; removed to Los Angeles in 1876 and there studied kindergarten methods, which she taught in Santa Barbara College; founded in San Francisco the first free kindergarten W. of the Rocky Mountains, afterward, with others, organizing the California Kindergarten Training-school; married Samuel Bradley Wiggin in 1880, removing with him to New York city, where he died, and in 1895 she married George Christopher Riggs. She is the author of *Kindergarten Chimes* (1888); *The Story of Patsy* (1889); *The Birds' Christmas Carol* (1889); *A Summer in a Cañon* (1889); *Timothy's Quest* (1890); *The Story-Hour*, in connection with her sister, Nora A. Smith (1890); *The Relation of the Kindergarten to the Public School* (1891); *Children's Rights* (1892); *A Cathedral Courtship* (1893); *Penelope's English Experiences* (1893); *The Kindergarten* (1893); *Polly Oliver's Problem* (1893); *The Village Watch-Tower* (1895); *Froebel's Gifts*, in connection with her sister (1895); *Nine Love-Songs and a Carol* (1896); *Froebel's Occupations* and *Kindergarten Principles and Practice*, both in connection with her sister (1896); and *Penelope's Progress* (1898).

Rimsky-Korsakow, Nicolaus Andrejewitch: musician; b. in Tichwin, Russia, in 1844, and was at first intended for a military career. After several years' service in the imperial army as an officer of marines, he took up the study of music, and in 1871 was appointed Professor of Composition in the conservatory of St. Petersburg, and succeeded Balakirew as director of the free music school. He produced two operas at the Russian Opera-house in 1873 and 1880. He has also composed *Sadko*, a legend for orchestra; a symphony, *Antax*; some string quartets; a symphonietta in A minor; a third symphony; a fantasia for violin and orchestra; a capriccio for orchestra; and a number of piano pieces. He is one of the brightest leaders of the Neo-Russian school.

D. E. Hervey.

Ritter, Frederic Louis: musician; b. in Strasbourg in 1834, and when sixteen years old was sent to Paris to continue studies already begun at home. After two years he returned home, and was appointed Professor of Music in the Protestant seminary at Fénéstrange, and also conductor of the Société des Concerts at Bordeaux. He went to the

U. S. in 1856, and after a short residence in Cincinnati he settled in New York in 1862, and was elected conductor of the New York Harmonie Society, for which he composed several meritorious choral works. In 1867 he was appointed Professor of Music at Vassar College, Poughkeepsie, retaining that position until his death. In 1878 the University of New York conferred the degree of doctor of music upon him. He wrote a *History of Music*; *Music in England*; *Music in America*; *Practical Method for the Instruction of Chorus Classes*; and other literary works. His compositions include several cantatas, three symphonies, several overtures, a piano concerto, several string quartets, a symphonic poem entitled *Stella*, after Victor Hugo, many songs, and some small orchestral pieces. He died suddenly in Antwerp, July 6, 1891. D. E. Hervey.

Ritual Law: an ecclesiastical law; the law governing the ritual or sacred offices of the Church. The term is applied broadly to include the rules governing the sacred offices and the manner of celebrating religious services in the church of any denomination, but usually and more specifically to such laws relating to an established Church, as in Great Britain.

The ritual laws or rules of a church organization or body in the U. S. have no force as public laws, and can not be enforced except by exercising the discipline provided for their enforcement by the rules, express or customary, of each particular organization, in much the same manner as the rules of a club or social organization may be enforced. A person disciplined has a right to appeal to the courts of the law to enforce his legal rights in the organization and protect him from any discipline or punishment which violates either the law of the land or his rights and privileges under the rules and regulations of the church organization to which he belongs.

In Great Britain there is a common law of the Church, which exists and is a part of the general common law of the land, and is of binding authority as well in the temporal as in the ecclesiastical courts. It is a part of the canon law, and rests for its authority upon immemorial usage. It may be proved either by reports of adjudged cases or by public custom, or be deducible from principles and analogy, or shown by having received legislative recognition. Until the passing of the judicature acts the enforcement of the ritual law was vested primarily in the ecclesiastical courts, of the decisions of which, however, there are no published reports, with one recent exception. See Law and Canon Law.

See Phillimore, *Ecclesiastical Law of the Church of England*; Hoffman, *Ritual Law of the Church*; Stubbs, *Constitutional History of England*. F. Sturges Allen.

Roberts, Charles George Douglas: author; b. in Douglas, New Brunswick, Jan. 10, 1860; graduated at the University of New Brunswick in 1879, taking his degree of M. A. in 1881. He taught for some time in New Brunswick, and later in Nova Scotia, where in 1895 he resigned his position as Professor of Literature in King's College University, Windsor, to devote his time to writing. He is a fellow of the Royal Society of Canada, and was one of the literary judges at the World's Fair, Chicago. Among his works are *Orion and other Poems* (1880); *In Divers Tones* (1888); *The Canadian Guide-book* (1891); *Ave: an Ode for the Shelley Centenary* (1892); *Earth's Enigmas*, a volume of prose sketches (1896); *The Book of the Nations* (1897); *The Forge in the Forest* (1897); *History of Canada* (1897); and *The Heart of the Ancient Wood* (1900).

Roberts, Howard: sculptor; b. in Philadelphia, Pa., Apr. 9, 1843; studied art at the Pennsylvania Academy and in Paris. His statue of Robert Fulton is in the Capitol in Washington. Among his more noted works are a statuette of *Hester and Pearl*, from Hawthorne's *Scarlet Letter*; *La première pose*; *Hypatia*; *Lucille*; and *Lot's Wife*.

Robertson, Henry, LL. B.: lawyer; b. in Whitchurch, Ontario, May 31, 1840; was educated at local public schools and graduated at the University of Toronto in 1861, in which year he was called to the bar, and began the practice of his profession at Collingwood; was created queen's counsel in 1890; in 1882 was elected grand master of Odd Fellows; in 1887–88 was grand master of Freemasons; in 1891 grand master of Knights Templars. He has published a *Digest of Masonic Jurisprudence* (2d ed. 1889).

Robertson, John Ross: journalist; b. in Toronto, Ontario, Dec. 28, 1841; entered upon the printing business in 1861, served as reporter for various Toronto papers, and in 1876 established the *Evening Telegram*, which he still owns and conducts. He was president of the Canadian Copyright Association for the years 1888–96. In 1896 he took a seat in the House of Commons.

Robinson, Christopher: lawyer; b. at Beverly House, Toronto, Jan. 21, 1828; was educated at Upper Canada College and at King's College, Toronto, and at Trinity University; read law and was called to the bar in 1850; took up the practice of his profession in 1852; was appointed reporter to the court of queen's bench in 1856, retaining the position until 1872, when he became editor of the *Law Reports*; in 1885 resigned his editorship, being selected bencher of the Law Society of Upper Canada. He has devoted himself exclusively to his profession, and been connected as counsel in many of the cases of great public interest, including the libel suit of the Queen against Wilkinson, the case for the arbitration respecting the boundaries of the province of Manitoba, the prosecution of Louis Riel, the Bering Sea arbitration, etc.

Rockall Islet: a small steep rock, only about 70 feet high and 300 feet in circumference, rising above a bank of small extent from the abysmal waters of the North Atlantic, about 260 miles N. of Ireland, 57° 36′ N. lat., 13° 14′ W. lon. The rock has often been mistaken for a ship. The bank on which it stands is about 100 miles from N. to S. and 50 miles from E. to W., with less than 100 fathoms of water over it. It has high repute as a fishing-ground, and is frequented by fishermen from Grimsby and the Faeroes. Mr. Cristy Miller called attention to the eligibility of Rockall as the site of a meteorological station, but investigations in 1897 seemed to show that it would hardly be available, on account of the difficulty of surmounting the steep rock.

Roe, Charles Francis: soldier: b. in New York city, May 1, 1848; graduated at the Military Academy in 1868, and was appointed second lieutenant in the First Cavalry; was transferred to the Second Cavalry in 1870, and mustered out in the same year; re-entered the service as second lieutenant in the Second Cavalry in 1871, and served as adjutant 1876–78; advanced to first lieutenant in 1880, serving as adjutant until 1886; resigned in 1888 to engage in the real estate business in New York city; joined the National Guard in 1889, becoming captain of Troop A of the First Brigade, and in 1895, when a squadron was formed, was unanimously elected major; commanded Troop A during the switchmen's strike in Buffalo in 1892, and during the Brooklyn trolleymen's strike in 1895; became major-general of the New York State National Guard in 1898, and in the same year was appointed brigadier-general in the volunteer army in the Spanish-American war, resigning at the close of hostilities.

Roe, Francis Asbury: naval officer; b. in Elmira, N. Y., Oct. 4, 1823. He became a midshipman in 1841, and left the service for nearly a year in 1848; served on a mail-steamer of the New York and West India line 1851–52; in the North Pacific exploring expedition he was attached to the Porpoise; was commissioned master and lieutenant in 1855, and served in the Coast Survey 1857–58; commanded the Pensacola, of Farragut's squadron, and manœuvred that ship in passing Forts Jackson and St. Philip; was advanced to lieutenant-commander in 1862. Serving on the Katahdin 1862–63, on the Mississippi river, he successfully defended Baton Rouge from attack, and engaged in destroying the Confederate ram Arkansas. He commanded the Sassacus of the North Atlantic blockading squadron in 1864, and did effective service on the coast of North Carolina, participating in the defeat of the Confederate ram Albemarle, in which engagement he heroically rammed the ironclad and captured her consort, the Bombshell. He was advanced to commander in 1866, and commanded the Tacony on a mission to Mexico, when he averted a bombardment of Vera Cruz; was made fleet captain of the Asiatic station in 1867, serving at that post until 1871; was advanced to captain in 1872, and made commodore in 1880; was governor of the naval asylum at Philadelphia 1883–84; became rear-admiral in 1884, and was retired in 1885.

Roe, Henry: Archdeacon of Quebec; b. in Henryville, Quebec, Feb. 22, 1829; educated at Bishop's College, Lennoxville, which has conferred upon him the degrees of B. A. (1845), M. A. (1867), D. D. (1879), honorary D. C. L. (1896). He was ordained priest of the Church of England in 1853, and has spent most of his life in mission work. From 1873

to 1891 he was a leading member of the faculty of Bishop's College, from which he retired to resume his mission work. He was appointed Archdeacon of Quebec in 1888. Among his published works are *The Ritual Question* (1858); *The Place of Giving in the Christian Economy* (1880); *Blessed are the Peacemakers* (1886); *The Things which Make for Peace* (1895); *The Continuity of the Church of England and the Papal Encyclical Apostolic Curæ* (1897).

Rogers, Franklin Whiting: artist; b. in Cambridge, Mass., Aug. 27, 1854; became an art-pupil of J. F. Cole in 1874, afterward studying under W. M. Hunt and Thomas Robinson; has given special attention to the portrayal of dogs, among his noted pictures being *The Two Friends*; *Steady*; *Resignation*; *Loo*; and *Mischief*.

Rogers, Robert Vashon, LL. D.: lawyer and law-writer; b. in Kingston, Ontario, in 1843; educated at private schools and at Queen's University, graduating in 1861; was called to the bar in 1865, when he took up the practice of his profession. He is now (1899) a law lecturer in Queen's University. He has published *Wrongs and Rights of a Traveler by Boat, by Stage, by Rail* (1875); *The Law and Medical Men* (1884); and various legal text-books.

Rogers, William A.: astronomer and physicist; b. in Waterford, Conn., Nov. 13, 1832; graduated at Brown University in 1857; became a teacher in Alfred Academy and subsequently Alfred University. In 1870 he was appointed assistant in the Harvard College Observatory, and it is with this appointment that his scientific career may be said to have begun. In 1875 he was promoted to an assistant professorship at Harvard College, and in 1886 was called to the chair of Physics and Astronomy in Colby University, which position he held up to the time of his death, in Waterville, Me., Mar. 1, 1898. As an astronomical observer Prof. Rogers was untiring, and the annals of the Harvard Observatory from 1871 to 1883 contain many voluminous and important memoirs from his pen. During the later years of his life he turned his attention more particularly to physics, and in the department of metrology especially he became an authority. To the question of the accurate comparison of the yard and meter, in which he became interested about 1880, he gave much of his time for nearly twenty years, and it was in connection with this problem that his well-known studies of the microscope, the dividing engine, the comparator, and the interferometer were made. He was a member of the American Academy of Arts and Sciences, Fellow of the Royal Microscopical Society of London and of the National Academy of Sciences, and he was twice chairman of a section of the American Association for the Advancement of Science. His most important scientific work was done, perhaps, at the Harvard Observatory, where for many years he took a prominent and laborious part in the celebrated "zone observations" carried on in conjunction with other astronomical stations by that institution. E. L. N.

Romero, Matias: statesman; b. in Oaxaca, Mexico, Feb. 24, 1837. He served as minister to the U. S. for more than twenty years, his last term extending over sixteen years. He was admitted to the Mexican bar in 1857; in the revolution of that year was made the private secretary of Juarez, then a cabinet officer; in 1859 was sent to Washington as secretary of the Mexican legation, and was subsequently *chargé d'affaires* until 1863, when he returned home, and, taking a colonelcy on the staff of Diaz, aided in overthrowing French power in Mexico; late in the same year returned to Washington as minister, holding that position until 1868, when he took the Mexican Treasury portfolio, in which capacity he served under Presidents Juarez and Diaz, having between his terms of such service been a member of the Congress; in 1880 became Postmaster-General, from which office he was retired by Gonzales; in 1881 accompanied Gen. Grant through Mexico; was again sent to Washington as minister during President Garfield's administration, when important boundary questions were amicably adjusted by him; resigned his ministerial post at the expiration of Gonzales's term as president, but was reappointed by Diaz in 1884, and served until his death. The Mexican legation was raised to the grade of an embassy just before the death of Señor Romero, and a day had been fixed when he was to present his credentials as an ambassador. His diplomatic services to the U. S. and to his own country were considered exceptionally beneficial. Among his published works are *Coffee Culture on the Southern Coast of Chiapas*; *Historical Sketch of the Annexation of Chiapas and Soconusco to Mexico*; and the first volume of a work entitled *Mexico and the United States*, dealing with political, commercial, and social relations. D. in Washington, D. C., Dec. 30, 1898.

Roosa, Daniel Bennett St. John, A. M., LL. D.: physician; b. in Bethel, N. Y., Apr. 4, 1838; entered Yale in 1856, but left on account of poor health; studied chemistry in New York city; graduated at the medical department of the University of New York in 1860; became a resident physician in the New York Hospital in 1862; studied in Europe in 1863, paying special attention to ophthalmology and otology; settled to practice in New York city in 1864; was Professor of Diseases of the Eye and Ear in the medical department of the University of the City of New York 1863–82, also in the University of Vermont 1875–80; was one of the founders of the Manhattan Eye and Ear Hospital, and became Professor of Eye and Ear Diseases in the New York Post-graduate Medical School and president of the faculty; was president of the International Otological Society in 1876, and of the New York State Medical Society in 1879; received from Yale the honorary degree of A. M., and from the University of Vermont that of LL. D. Besides several translations from the German, he has published *A Vest-pocket Medical Lexicon* (1865); *Treatise on the Ear* (1866); *A Doctor's Suggestions* (1880); and *On the Necessity of Wearing Glasses* (1887).

Root, Elihu: b. in Clinton, N. Y., Feb. 15, 1845; graduated at Hamilton College in 1864; studied law at Hamilton College and the University Law School in New York, and began practice in New York city in 1867. He has had a remarkable career in winning decisions in his litigation, having been the leading counsel for Judge Hilton in the Stewart case, in the Fayerweather contest will case, the Sugar Trust, and others; in 1879 was an unsuccessful candidate for judge of the court of common pleas; was U. S. district attorney 1883–85; in 1893–94 was one of the active members of the committee of thirty in resisting the Republican machine in New York County; was chairman of the judicial committee in the Constitutional Convention of New York in 1894. He became Secretary of War in Aug., 1899. He has been president of the New England Society: member of the Century, Metropolitan, University, and Players' Clubs and other similar organizations. F. Sturges Allen.

Root, George Frederick: song-composer; b. in Sheffield, Mass., Aug. 30, 1820, and in early life was much influenced by the English singers Henry Russell and John Philip Knight. He took some lessons from A. N. Johnson and Dr. Lowell Mason. In 1860 he settled in Chicago. He had already published several songs, including *Hazel Dell* (1853), and *Rosalie, the Prairie Flower*, to which he signed the name Wurzel, the German for Root. When the civil war broke out Root began the series of war-songs by which he is best known. *The First Gun is Fired*; *The Battle-Cry of Freedom*; *Tramp, Tramp, Tramp*; *Lay Me Down and Save the Flag*; and *Just before the Battle, Mother*, are some of these that were familiar to every soldier. He also composed several light cantatas for Sunday and day schools and many miscellaneous songs. D. on Bailey's island, on the coast of Maine, Aug. 6, 1895. D. E. Hervey.

Roraima, Mount: the highest of a number of isolated sandstone plateau-topped mountains discovered by Robert Schomburgk on the boundary line he surveyed between Venezuela and British Guiana. Roraima is 9,000 feet high, and its upper 2,000 feet was long supposed to be a perpendicular wall. Everard im Thurn, in Dec., 1884, found on one face a narrow ledge that afforded a pathway to the summit. The soft sandstone of the plateau at the top had been carved by denudation into many remarkable forms. The precipitation is very large. There are no trees, and the general character of the plants is dwarfish and almost alpine. Sir Joseph Hooker and others had thought the flora on the plateau would be found to be different from that of the plain, and to some extent this was found to be true. Other explorers have since visited the top of Roraima, and a black butterfly, spiders, frogs, lizards, and a small mammal have been found there.

Rosenthal, Albert: artist; son of Max Rosenthal; b. in Philadelphia, Jan. 30, 1863; studied art under his father and at the Pennsylvania Academy; devoted himself to etching, his work becoming widely known; has etched many portraits of historical American characters.

Rosenthal, Max: artist; b. in Turek, Russian Poland, Nov. 23, 1833; studied lithography, drawing, and painting in Paris, completing his studies in Philadelphia, Pa., in

1849: made the chromo-lithographic plates for *Wild Scenes and Wild Hunters*, believed to be the first book illustrated by that process in the U. S.; sketched and lithographed the interior of the old Masonic Temple in Philadelphia, producing the largest chromo-lithograph in the country at that time, the plate being 22 by 25 inches; accompanied the Army of the Potomac during the civil war, making many drawings; made lithographs of many distinguished Americans up to 1884, when he gave his attention to etching, executing numerous portraits of American and British officers; is a member of the Pennsylvania Academy and a founder of the Sketch Club. Among his celebrated pictures are *Storm Approaches*, after the painting by Henry Mosler; *Doris, the Shepherd Maiden*; *Marguerite*; and illustrations for several of Longfellow's poems.

Rosenthal, Moriz: pianist; b. in Lemberg, Austria, Dec. 18, 1862; began study of the piano when a child. In 1875 his parents settled in Vienna, where he took lessons from Rafael Joseffy. In 1876 he moved to Bucharest, where he was named pianist to the Roumanian court at fourteen years of age. In 1878 he began a concert tour, including Weimar, Paris, and St. Petersburg, and then returned to Vienna and continued his studies. In 1882 he began another concert tour which included New York, where he played two piano ensemble pieces with Joseffy, who had preceded him there. He returned to Europe, and again visited New York in 1896 and began a concert tour, but was taken ill in Chicago and had to give it up. In 1898 he again went to the U. S. and played throughout the entire season in various places. D. E. Hervey.

Rosenthal, Toby Edward: artist; b. in New Haven, Conn., Mar. 15, 1848; first studied art in San Francisco, then in Munich and other places in Europe; gained medals in Munich in 1870 and 1883, and in Philadelphia in 1876; has spent his professional life chiefly in Europe. Besides numerous portraits, he has painted *Spring's Joy and Sorrow*; *Morning Prayers in Bach's Family*, purchased by the Saxon Government; *Elaine*; *Young Monk in Refectory*; *Forbidden Longings*; *Who Laughs Last Laughs Best*; *A Mother's Prayer*; *Trial of Constance de Beverley*; *A Dancing Lesson during the Empire*; and *Out of the Frying Pan into the Fire*, popular and frequently engraved.

Ross, Alexander Milton, M. D.: b. in Belleville, Ontario, Dec. 13, 1832; went to New York while a boy, and worked in a newspaper office. He studied medicine and received his degree in 1855, and afterward became a member of the College of Physicians and Surgeons in Ontario and Quebec. After several years' service as surgeon in the U. S. army and in Mexico, he returned to Canada and devoted himself to the classification of the fauna and flora of Canada. Among his works are *Recollections of an Abolitionist* (1867); *Birds of Canada* (1872); *Butterflies and Moths of Canada* (1873); *Flora of Canada* (1873); *Forest Trees of Canada* (1874); *Ferns and Wild Flowers of Canada* (1877); *Mammals, Reptiles, and Fresh-water Fishes of Canada* (1878); *Vaccination a Medical Delusion* (1885); *Medical Practices of the Future* (1887). D. in Detroit, Mich., Oct. 27, 1897.

Rosseau, ros'sō', Rodolphe: French advocate and consulting lawyer; b. in Maubege, Mar. 24, 1849; called to the bar in Paris in 1868, and acted as justice of the peace of the third and tenth arrondissements 1879–90: during the Universal Exposition of 1889 was vice-president of the Congress of Societies, and afterward was made its general secretary. He pleaded a number of important cases for the societies or the administrations for which he was counsel, such as the state railways, telephone companies, cable from Paris to New York, submarine telegraph, etc., but he is best known by his writings on matters of jurisprudence, of which some of the more important are *Du trafic des billets de complaisance d'après la loi civile et la loi pénale* (2d ed. 1876); *Traité théorique et pratique de la correspondance* (1877); *Des Sociétés commerciales françaises et étrangères* (2d ed. 1876); *Dictionnaire théorique et pratique de procedure civile, commerciale, criminelle et administrative* (1879–80); *Questions nouvelles sur les sociétés commerciales* (1882); *Répertoire alphabétique de la doctrine et de la jurisprudence des dix dernières années en matière de sociétés commerciales* (1889); *Loi du I^er^ aout, 1893, sur les sociétés par actions* (1893). F. Sturges Allen.

Rosser, Thomas Lafayette: soldier; b. in Campbell co., Va., Oct. 15, 1836; entered the U. S. Military Academy in 1856, but before graduating resigned and entered the Confederate service as first lieutenant of artillery; was promoted to captain in 1861, and to lieutenant-colonel of artillery in 1862, when he was placed in command of a regiment of cavalry and attached to the Army of Northern Virginia; was advanced to brigadier-general in 1863, and given command of the Virginia cavalry in the Shenandoah Valley, serving under Gen. Jubal Early and winning distinction; became major-general in 1864. After the war he turned his attention to engineering, and had charge of the Dakota, Yellowstone, and Missouri divisions of the Northern Pacific Railway 1870–79; has been chief engineer of the Canadian Pacific Railroad, president and general manager of the New South Mining and Improvement Company, and consulting engineer of the Charleston, Cincinnati and Chicago Railroad Company. He served in the Spanish-American war in 1898.

Round, William Marshall Fitts: author; b. in Pawtucket, R. I., Mar. 26, 1845: received academic education, and entered the medical school of Harvard, which he left on account of ill health before graduating; was U. S. commissioner to the Vienna Exposition, having charge of the New England department; on his return made a study of prison reform, becoming corresponding secretary of the Prison Association of New York in 1883; was instrumental in organizing the National Prison Association of the U. S., was made its secretary, and was sent as a delegate from the U. S. to the international penitentiary congress in Rome 1886; formed the general scheme for the Burnham Industrial Farm. His publications include *Achsah: a New England Life Study* (1876); *Child Marion Abroad* (1876); *Torn and Mended* (1877); *Hal: the Story of a Clodhopper* (1878); and *Rosecroft* (1880).

Routhier, Adolfe Basile, Lit. D., LL. D.: judge and author; b. in St. Placide, province of Quebec, May 8, 1839; was educated at the College of Ste. Thérèse and at Laval University; studied law, and was called to the bar in 1861, taking up the practice of his profession at Kamouraska; was appointed puisne judge of the Supreme Court of the Province of Quebec in 1873, sitting in the Saguenay district until 1889, when he was transferred to the district of Quebec; was appointed judge of the court of vice-admiralty, Quebec, 1897. Before his appointment as judge he published, besides other books, the *Causeries du Dimanche* and *Portraits et Pastels Littéraires*, the latter under the name of Jean Piquefort. He has also published *À Travers l'Europe*; *En Canot*; *Les Echos*; *À Travers l'Espagne*; *Les Grandes Drames*; *Conferences et Discourses*; *De Québec à Victoria*.

Rowland, Henry Augustus, Ph. D.: physicist; b. in Honesdale, Pa., Nov. 27, 1848; graduated at Rensselaer Polytechnic Institute, Troy, N. Y., as a civil engineer, and in 1871 was employed in surveying for a railroad in Western New York; taught for a time in Wooster University, and in 1872 became instructor in physics in Rensselaer Institute, and in 1874 assistant professor; spent the year 1875 studying with Helmholtz in Berlin and examining European physical laboratories; Professor of Physics in Johns Hopkins University since 1876. He attended the electrical congress in Paris in 1881, and because of services there on the jury of the electrical exhibition was made a chevalier of the Legion of Honor. He is a permanent member of the international commission for establishing electrical units, is a corresponding member of the British Association for the Advancement of Science, is one of the twelve foreign members of the Physical Society of London, is an associate of the American Academy of Arts and Sciences and of the National Academy of Sciences. He is the author of many papers and addresses, some of the most important being *On Magnetic Permeability* (1873); *On the Magnetic Permeability and Maximum Magnetization of Nickel and Cobalt* (1874); *Studies on Magnetic Distribution* (1875); *On a Magnetic Effect of Electric Connection* (1876); *Research on the Absolute Unit of Electrical Resistance* (1878); *On the Mechanical Equivalent of Heat* (1880); *On Concave Gratings for Optical Purposes* (1883); *On the Relative Wavelengths of the Lines of the Solar Spectrum* (1886); *Photographs of the Normal Solar Spectrum* (1886).

Rug: a carpet-like textile, usually oblong, made in one piece, and used principally for floor service. The most artistic rug-makers of the world are the Persians, who learned the art of weaving such fabrics from the Babylonians many centuries before Christ; but whether the Babylonians or the Egyptians were the first to make rug carpets is not known.

1. Turkish.

2. Persian.

3. Indian.

RUGS.

Persian rugs were early used by the patricians of Greece and Rome, and were introduced into Spain by artisans from Shiraz, and they were distributed by the argosies of Venice throughout Europe, adorning the palaces and castles of the Middle Ages; they were spread over the rushes that covered the floor of Queen Elizabeth's presence-chamber. The work on these Oriental fabrics is still done by hand, and while the varieties do not greatly differ in the mode of weaving, each rug has its individuality, no two being exactly alike; hence their commercial value. They are woven on rude looms, the variations of design being infinite. Machinery has not yet been introduced for their manufacture, but latterly such patterns as have found favor abroad have been reproduced in certain districts. The Persian rug remains the most original and durable of all such fabrics, and is the parent stock of all the rugs made in the world, at least to the west of China, where such textiles, resembling those of India, have an unknown origin. Many of the rugs of Persia, especially the finer grades, are not intended to be laid on the floor, but to cover divans or tables, or to hang as tapestries and portières. Such are often made of silk. The colors formerly employed in the rugs of Persia were imperishable, fabrics a hundred or more years old showing no deterioration in tint. The introduction of aniline dyes at one time threatened to ruin the manufacture of textile fabrics in Persia, but the law against the employment of such dyes enacted by the Persian Government was rigorously enforced.

The Turkoman rugs, in some respects unsurpassed for texture and peculiar beauty of design, are not made within the Shah's dominions, but over the border, although they are included commercially among the Persian rugs, as the Turkomans were until recently subject to Persia. The prevailing color of the Turkoman rugs being red, the weavers have shown a disposition to use aniline dyes. Such dyes can easily be detected by the application of a wet cloth to the suspected tint.

In the making of Persian rugs tufts of colored woolen yarn are knotted into the warp with the fingers, and when a row of tufts has been knotted it is pressed down even and hard with a comb-like apparatus, the warp being wool or linen, and sometimes cotton.

The rugs of Feraghan and Teheran have a loose texture and a velvety pile of medium thickness, the center being generally of a mixed pattern of small, irregular figures surrounded by a rich border, though it is sometimes of a uniform color, red or blue. The rugs of Khorassan are of a richer texture than those of Feraghan, the patterns being celebrated for realistic flowers. In texture the Kerman rugs are more valuable than those of Khorassan and Feraghan, the designs including figures of men, animals, and flowers. The Shiraz rug, which resembles the Kerman, has a heavy pile. Undyed camels' hair is used in Southern Persia for the groundwork and border of rugs. The fabric made in Kurdistan is esteemed the best of Persian rugs, a common pattern representing flowers interwoven with the groundwork in impressionist style, the borders being designed to direct attention to the central ornamentation. There is a species of rug peculiar to Kurdistan, its texture suggesting knitted rather than woven work. It is called ghileem, or dorü. The pattern is identical on both sides, thus allowing the use of either side. The colors are firm and brilliant, and the designs often of extraordinary beauty. The lightness and flexibility of these rugs qualify them for use as portières or as covers for tables or sofas, and render them easy for transportation. The ghileems of Shuster are preferable for portières, while the Garrouste ghileems are more suitable for curtain-hangings. Those of Lauristan and Zerend are preferable for carpetings, while those of Kermanshah are famous for the originality and beauty of their patterns. The silk rug, once common in Persia, has been revived for foreign markets.

One of the choicest rugs made in the East is known to Americans as the Khiva, often called the Bokhara. They are made by the Turkomans. The colors are chiefly various shades of maroon, red, and blue, interwoven with a creamy white, the pattern consisting almost invariably of a many-angled conventional figure. The rugs of Daghestan have a closer pile than most Persian fabrics, with a surface rich and smooth. The Samarcand rug has a rich and heavy pile, soft as silk, the prevailing tone being a golden brown or a mellow gray. The figures of men and animals are never seen on Turkish rugs. Rugs made by the Uruks resemble the Kurdistan ghileems in texture, but are coarser, the designs being usually in stripes.

The Abnákee rug is the product of an American industry located at Pequaket, N. H. These rugs usually have plain centers of solid color, terra-cotta, old pink, tan, dark blue, gobelin blue, yellow, or olive, with borders worked in two or three harmonious colors, the designs ranging from the Saracenic, Gothic, and classic to conventionalized floral patterns and to Aztec and savage ornament. The rugs are all wool and hand-made. Each maker works an individual cipher on the rug woven. The cipher woven on the label of the Abnákee rugs is an Indian totem that appears on a treaty between the Abnákees and the English.

Rummell, Franz: pianist; b. in London, England, Jan. 11, 1853, the son of a German merchant; studied in Brussels under Brassin, and became one of the teachers in the conservatory there; made his first appearance as a pianist in Antwerp in 1872. In 1877–78 he made a concert tour through Holland with Minnie Hauck and Ole Bull, and made his first visit to the U. S. in 1878, his second in 1886, and his third in 1898, each time giving many concerts with great success. He is married to an American woman and resides in Berlin. D. E. Hervey.

Russell, Henry: singer and song-composer; b. in Sheerness, England, Dec. 24, 1813; studied in Bologna in 1825 and went to New York in 1832, remaining seven years, during which he married, and his son, W. Clark Russell, the sea-novelist, was born in New York. During his American visit he composed and sang many of the songs which made him famous. He composed more than 800 songs, to many of which he wrote also the words. Perhaps the best known is *A Life on the Ocean Wave*. His singing was intensely descriptive, and he always played his own accompaniments. He died in London, Dec. 6, 1900. In addition to his songs, he published a memoir in 1846 and a treatise on singing in 1860. His latest composition is a song, *Our Empress Queen*, which was written for Queen Victoria's jubilee in 1887. D. E. Hervey.

Russell, James Earl, Ph. D.: educator; b. in Hamden, N. Y., July 1, 1864; A. B., Cornell University, 1887; Ph. D., University of Leipzig, 1894; teacher and principal in secondary schools 1887–93; Professor of Philosophy and Pedagogy, University of Colorado, 1895–97; Professor of History of Education and dean of Teachers' College, Columbia University, since 1897. He is the author of *Extension of University Teaching in England and America* (1895); *German Higher Schools*; *The History, Organization, and Methods of Secondary Education in Germany* (1898).

Russell, William Eustis: lawyer; b. in Cambridge, Mass., Jan. 6, 1857; graduated at Harvard in 1877; admitted to the bar in 1880; elected to the Cambridge common council in 1881, alderman in 1883 and 1884, mayor in 1885, 1886, and 1887; defeated as a candidate for Governor of Massachusetts in 1888 and 1889, but elected in each of the next three years, and resumed his law practice after his third term; appointed as one of the board of Indian commissioners Nov., 1894. D. at Little Pabos, Canada, July 16, 1896.

Russia, History of: The last year of Czar Alexander III. witnessed one of the distressing famines which sometimes afflict the country. In 1893 there was a tariff war with Germany. (See Agrarianism.) Nicholas II. has maintained the old traditions and policy, while showing evidence of somewhat more liberal opinions. Conjointly with Germany and France, Russia applied pressure to Japan in 1895, after the Japanese victories over China. (See Japan.) The coronation of the czar in 1896 was the occasion of elaborate ceremonies.

Russia has of late years become allied with France, and has steadily pushed her colossal Trans-Siberian railway and her Asiatic schemes. Her influence is felt in China, where an agreement with England as to spheres of influence gives to the Russians the predominance in the north. The work of Russianizing Manchuria by railway and fortresses has begun. At home the Russianizing of Finland is (1899) in progress.

The repression of the Jews, of non-Russian bodies like the Finns, and of the Nihilists presents one side of Russian endeavor. Great interest attaches to the peace proposals made by the czar in 1898, which resulted in the international conference at The Hague in 1899.

Edmund K. Alden.

Rylance, Joseph Hine, D. D.: clergyman; b. near Manchester, England, June 16, 1826; graduated at King's Col-

lege, London, in 1861; after serving as curate in London, removed to the U. S. in 1863, becoming rector of St. Paul's church, Cleveland, O.; was rector of St. James's, Chicago, 1867–71, in the latter year becoming rector of St. Mark's, New York city; received the degree of D. D. from Western Reserve College in 1867; belongs to the school of Christian rationalists. Among his works are *Preachers and Preaching* (1862); *Essays on Miracles* (1874); *Social Questions: Lectures on Competition, Communism, Co-operation, and Christianity and Socialism* (1880); and *Pulpit-talks on Topics of the Times* (1881).

Sadlier, Anna Theresa: author; daughter of Mary Anne Sadlier; b. in Montreal, Canada, Jan. 19, 1854; received education in New York city, and graduated at the convent of Ville Marie, near Montreal, in 1871. Besides contributing freely to the Roman Catholic press, translating numerous tales and poems from the French and Italian, and compiling *Gems of Catholic Thought* (1882), she has written *The King's Page* (1877); *Seven Years and Mair* (1878); *Women of Catholicity* (1885); and *The Silent Woman of Alood* (1887).

Sadlier, Mary Anne (*Madden*): author; b. in Cootehill, Ireland, Dec. 31, 1820; was educated privately; removed to Montreal, Canada, in 1844; has translated considerably from the French, and has written a number of stories for Roman Catholic Sunday-schools. Her publications include *Alice Riodan, or the Blind Man's Daughter* (1851); *New Lights, or Life in Galway* (1853); *The Blakes and Flanagans* (1855); *The Confederate Chieftains, a Tale of the Irish Rebellion of 1741* (1859); *Bessy Conway, or the Irish Girl in America* (1862); *The Daughter of Tyrconnell* (1863); *Maureen Dhu, the Admiral's Daughter* (1870); and *Purgatory, Doctrinal, Historical, and Political* (1886).

St. Ignatius College: a Catholic institution of learning in Chicago, Ill., chartered in 1870, and conducted by the Fathers of the Society of Jesus. It has four departments—collegiate, academic, commercial, and preparatory. Courses in the collegiate department lead to the usual degrees. The degree of bachelor or doctor of philosophy is granted only to masters of arts after successful post-graduate courses in philosophy and science. All courses include religious instruction. Non-Catholics are admitted. The college has no endowment, and is entirely dependent on tuition fees. The material equipment is good. In addition to a library of 20,000 volumes, a smaller select library for students, a scientific library, chemical and physical laboratories, apparatus and dynamo rooms, music-rooms, and lecture-halls, there are valuable mineralogical and zoölogical museums. Since the college is intended only for day scholars, there are no dormitories, and students living at a distance are not encouraged to take lodgings in the city, unless they are of mature age and steady disposition. Twenty-two professors and instructors make up the faculty. The attendance in the different departments is (1899): collegiate, 143; academic, 214; commercial, 90; preparatory, 30; total, 477. Rev. James F. X. Hoeffer, S. J., is president.

Sajous, saa'zhoo', Charles Eucharist: physician; b. in Paris, Dec. 13, 1852; early removed to the U. S., receiving private education; attended lectures in the medical department of the University of California and at Jefferson College, Philadelphia, receiving his diploma in 1878; became Professor of Anatomy and Physiology in the Wagner Free Institute of Science and lecturer on diseases of the nose and throat in the Philadelphia School of Anatomy; was made clinical chief in the throat department of Jefferson College hospital, and finally lecturer in the college proper; has invented numerous instruments widely used in nose and throat treatment. Besides many articles contributed to medical journals, he has published *Curative Treatment of Hay-fever* (1885); *Diseases of the Nose and Throat* (1886); and in 1888, assisted by sixty-six associate editors, prepared the large *Annual of the Universal Medical Sciences*.

Salvador: A financial crisis in 1897–98 was largely the result of the low price of coffee, which inflicted great hardship upon the planters. Four of the six banks in San Salvador suspended payments. The large resources of the country promise prosperity. With a population of 89 to the square mile, which is 14 times the density in Guatemala and 20 times the average density in the Central American republics, and with a very productive soil and an enlightened policy, the prospects of the state are regarded as excellent. The people are frugal and industrious. The imports from the U. S. in 1900 were $679,440 (gold); from England (1899) $910,222. The exports to the U. S. were $738,674; to England (1899) $474,669. Germany and France also have important trade relations with Salvador. Complaint has been made that goods from the U. S. are not adequately packed for the rough usage received from Colon and beyond. The chief imports are cotton goods, spirits, ironware, flour, and silk goods and yarn. The chief exports are coffee, tobacco, indigo, and balsams. C. C. A.

Salzmann, Christian Gotthilf: educator; b. in Rohrborn, near Erfurt, Saxony, June 1, 1774. After attending the gymnasium at Langensalza and the University at Jena, he entered the ministry, and remained in it for several years, meantime engaging in literary work. At the same time he entered into relations with Basedow and his associates in the Philanthropinum at Dessau, and in 1781 went to Dessau to take charge of the religious instruction in the institute. Here he continued his literary labors, and also conceived the idea of founding an institute of his own. In the latter enterprise he enlisted the interest of Duke Ernest II. of Saxe-Gotha, and in 1784 opened an educational institution in Schnepfenthal, which, though never a large school, became one of the famous schools of Europe. D. in Schnepfenthal, Oct. 31, 1811. Among the most important of his numerous writings are a romance, *Karl von Karlsburg* (1780–86), which it is said occupies in his life a position analogous to that of *Leonard and Gertrude* in the life of Pestalozzi; *Volks- und Jugendschriften* (12 vols., 1845–46); *Pädagogische Schriften* (2 vols., 1887). Salzmann belonged to the so-called philanthropic school of pedagogy of the eighteenth century, of which school he is one of the principal representatives, and, on the whole, the most meritorious one. In his writings one finds most of the principles of which Pestalozzi later made use, and Salzmann's works may yet be read with profit by modern educators. C. H. Thurber.

Sampson, William T.: naval officer; b. in Palmyra, N. Y., Feb. 9, 1840; graduated at the Naval Academy, Annapolis, in 1860. During his first cruise he was promoted master, and on July 16, 1862, was commissioned lieutenant. He was on the practice-ship John Adams the following year, and at the Naval Academy in 1864. In 1865, while executive officer of the ironclad Patapsco, of the South Atlantic blockading squadron, he was ordered by the admiral to enter Charleston harbor and destroy the submarine mines and torpedoes placed there, and the Patapsco was destroyed in the attempt. He was assigned to the Colorado, flag-ship of the European squadron, 1865–67, being commissioned lieutenant-commander July 25, 1866; was at the Naval Academy until 1871, and the following year was ordered to special duty on the Congress. He commanded the Alert 1874–75, receiving the commission of commander Aug. 9, 1874; returned to the Naval Academy for two years, and was in command of the Swatara, of the Asiatic station, 1879–82. After serving at the Naval Observatory for three years he was put in charge of defenses in 1885, and the next year was made superintendent of the Naval Academy, where he remained until 1890. He served as delegate to the international maritime conference in Washington in 1889. He was promoted captain Mar. 26, 1889. In 1890 he was put in command of the San Francisco, and in 1893 became chief of the Bureau of Ordnance, which position he held until 1897, when he was ordered to the command of the Iowa. He was president of the board of inquiry regarding the cause of the destruction of the Maine in the harbor of Havana, Feb. 15, 1898. At the outbreak of the war with Spain he was made acting rear-admiral in command of the North Atlantic squadron sent to blockade the Cuban ports. He was commissioned commodore July 3, 1898, and rear-admiral Aug. 10 of the same year.

Samuels, Arthur Warren, LL. D.: Irish lawyer and publicist; b. in Ireland, May 19, 1852; was educated at the royal school in Dungannon, and at Trinity College, Dublin, subsequent to which he read law, and was called to the Irish bar in 1877; during his college and post-graduate course he devoted himself especially to the study of classics, modern literature, history, and political economy, and received the gold medal of the Historical Society. He was Professor of Personal Property at King's Inns 1891–94, in which latter year he was made queen's counsel; was called to the English bar in 1896. He has been prominent in the various movements set on foot for the procuring of Irish private bill procedure reform, and for reforms of Irish financial matters. He has published numerous articles and pam-

phlets on the Irish financial question and procedure in the Irish courts, including *The Fiscal Entity Question*; *The Financial Report, and What it Finds*, etc.

F. Sturges Allen.

Sanborn, John Benjamin: soldier; b. in Epsom, N. H., Dec. 5, 1826; was educated at Dartmouth; studied law, and was admitted to the bar in 1854, after which he settled in St. Paul, Minn.; as adjutant-general and quartermaster-general of Minnesota, was active in organizing and equipping military forces at the outbreak of the civil war, and became colonel of the Minnesota volunteers in 1862; was noted for gallantry in the many actions in which he participated; on the recommendations of Gens. Grant and McPherson, was promoted to brigadier-general in 1863; conducted a campaign against the Indians of the Southwest in 1865, terminated hostilities with the Comanches, Kiowas, Cheyennes, Arapahoes, and Apaches, and freed all lines of communication to Colorado and New Mexico; under the appointment of President Johnson, settled the difficulties growing out of the war between the Cherokees, Choctaws, Chickasaws, Creeks, and Seminoles and their slaves, and made the slaves of these tribes free; was designated by Congress one of an Indian peace commission in 1867; has several times been a member of the General Assembly of Minnesota, serving in both houses.

Sanborn, Katharine Abbott: author; b. in Hanover, N. H., in 1839; after teaching English literature in various seminaries, held that chair in Smith College, resigning in 1886; has lectured on literary history and kindred subjects, published articles on education, and served as a newspaper correspondent in New York city; has edited holiday books and calendars. Her books, published under the name of Kate Sanborn, include *Home Pictures of English Poets* (1869); *Round Table Series of Literature Lessons* (1884); *The Vanity and Insanity of Genius* (1885); *Wit of Women* (1886); and *A Year of Sunshine* (1887).

Sanday, William, D. D., LL. D.: Church of England clergyman; b. in Holme Pierrepont, near Nottingham, England, Aug. 1, 1843; graduated B. A. at Oxford 1865; was fellow of Trinity College 1866–73; rector of Barton on the Heath, Warwickshire, 1873–76; principal of Bishop Hatfield's Hall, Durham, 1876–83; became Ireland Professor of Exegesis of Holy Scripture, Oxford, 1882; Lady Margaret Professor of Divinity and canon of Christ Church, Oxford, 1895. He is the author of *Authorship and Historical Character of the Fourth Gospel* (London, 1872); *The Gospels in the Second Century* (1876); *Appendices to the Greek Testament* (1889); *The Oracles of God* (1st and 2d ed. 1891); *Inspiration* (Bampton lectures, 1893; 3d ed. 1896); *The Conception of Priesthood in the Early Church and in the Church of England* (1898). He contributed the commentary on Romans and Galatians to Bishop Ellicott's *Commentary* (1878); was joint editor of the *Variorum Bible* (1880) and of *Old Latin Biblical Texts* (1886). S. M. J.

Sandham, Alfred: author; b. in Montreal, Nov. 19, 1838; for many years secretary of the Canadian Young Men's Christian Association; has devoted most of his leisure time to numismatics and book-illustrating. Among his published works are *Ville Marie, or Montreal, Past and Present*; *Coins, Tokens, and Medals of Canada*; *Medals Commemorative of the Visit of the Prince of Wales to Canada*; and *The Trade Tokens of Montreal.*

Sandham, Henry: artist; b. in Montreal, May 24, 1842; began his art studies under leading Canadian artists; studied in Europe, and on returning to America in 1880 made his home in Boston. He is well known as an illustrator of books and magazines. Among his paintings are *Battle of Lexington*; *March of Time*; and *Founding of Maryland.*

San German: a town of Southwest Puerto Rico, situated in an elevated position above the river Guanajibo, in a district that has more than 20,000 fairly well-to-do inhabitants. The town has a seminary, a hospital, and a Dominican convent. The surrounding farm-lands have been very productive, but have somewhat deteriorated, owing to imperfect tillage.

Sangster, Margaret Elizabeth (*Munson*): b. in New Rochelle, N. Y., Feb. 22, 1838. She was educated at Paterson, N. J., and at Williamsburg, N. Y.; was associate editor of *Hearth and Home* 1871–73, of the *Christian at Work* 1873–79, and afterward of the *Christian Intelligencer*; was editor of *Harper's Young People* 1882–89, and became editor of *Harper's Bazar* in 1889. Her principal published books are *Poems of the Household* (1882) and *Home Fairies and Heart Flowers* (1887).

Santa Clara: a province of Cuba (usually called in Cuba *Las Villas*, from Las Cinco Villas, the five towns that were first founded in it). It is one of the richest regions in Cuba, and contains some of the largest sugar plantations and factories. All the special products of Cuba thrive there, and fruits of the temperate zone are cultivated on the mountain slopes. Pop. (1899) 356,536.

Santa Clara: a city; capital of Santa Clara province, Cuba. Popularly known as Villa Clara. Connected with Havana, 248 miles distant, by rail. The city has many cultured inhabitants, and its situation is charming. Gold, plumbago, and copper have been found in the neighborhood, and an excellent quality of asphaltum is exported. The city suffered greatly in the insurrection of 1895. Pop. (1899) 13,763.

Sartain, Emily: artist; daughter of John Sartain; b. in Philadelphia, Pa., Mar. 17, 1841; studied and practiced engraving under her father, afterward studying painting at the Pennsylvania Academy and in Paris, devoting herself chiefly to portraiture; was awarded a medal for her *Reproof* at the Centennial Exhibition in 1876, and the Mary Smith prize at the Philadelphia Academy in 1881 and 1883; was art editor of *Our Continent* 1881–83, and became principal of the Philadelphia School of Design for Women in 1886.

Sartain, Samuel: engraver; son of John Sartain; b. in Philadelphia, Pa., Oct. 8, 1830; has chiefly devoted himself to engraving portraits and other illustrations for books, having begun work at the age of sixteen under his father's direction. Among his noted prints are *Clear the Track*; *Christ Blessing Little Children*; *One of the Chosen*; *Christ Stilling the Tempest*; *The Song of the Angels*; and *Evangeline.*

Sartain, William: artist; son of John Sartain; b. in Philadelphia, Pa., Nov. 21, 1843; studied and practiced engraving under his father, producing some notably good plates; studied painting privately and at the Pennsylvania Academy 1867–68, and afterward in Paris; returned to the U. S. in 1877, settled in New York city, and became an associate of the National Academy of Design; is one of the founders of the Society of American Artists; paints both landscape and figure subjects. Among his paintings are *Tombs of the Saints at Bouzareah*; *Italian Boy's Head*; *Italian Girl's Head*: *Narcissus*; *A Nubian Sheik*; *A Quiet Moment*; and *A Chapter of the Koran.*

Satterlee, Henry Yates, D. D.: clergyman; b. in New York city, Jan. 11, 1843; graduated at Columbia College in 1863, at the General Theological Seminary of New York city in 1866, in which year he was ordained deacon in the Protestant Episcopal Church, and became priest in 1867; after serving as assistant rector at Wappingers Falls 1865–75, became its rector; took charge of Calvary church, New York city, in 1882; received the degree of D. D. from Union College in 1882; declined the assistant bishopric of Ohio in 1888; has been active in the interests of the Episcopal Church, especially in the home and foreign missionary work.

Satterlee, Walter: artist; b. in Brooklyn, N. Y., Jan. 18, 1844; studied art privately and at the National Academy, of which he became an associate in 1879; gained the Clark prize at the Academy in 1886. His oil-paintings include *Contemplation*; *Extremes Meet*; *The Convent Composer*; *Good-bye, Summer*; *The Cronies*; and *Fortune by Tea-Leaves.* Among his water-colors are *Solitaire*; *Old Ballads*; *Two Sides of a Convent-Wall*; *The Net-mender*; and *The Lightened Load.* He has frequently sketched illustrations for books.

Sauer, Emil: pianist; b. in Hamburg, Germany, Oct. 8, 1862, and received his first lessons in music from his mother, herself an accomplished musician. When fourteen years old Anton Rubinstein heard him play, and recommended him to study under his brother, Nicholas Rubinstein, under whom he made rapid progress. He made his first appearance in public in 1878 in Germany, and in 1879 went to London. Up to 1883 he made several concert tours. In 1884 he studied again, under Liszt, in Weimar, and in 1885 made his *début* in Berlin. Since then he has played in all the great European capitals. His first appearance in the U. S. was on Jan. 10, 1899, in the Metropolitan Opera-house, New York. D. E. Hervey.

Saunders, Alvin: b. in Fleming co., Ky., July 12, 1817; accompanied his father to Illinois in 1829, where he worked on a farm and received a common-school education; removed to that part of Wisconsin Territory which is now Iowa in 1836, and studied law, but did not practice, engaging in business as a merchant and banker; was a member of the convention that framed the constitution of Iowa in 1846, a State Senator for eight years, a commissioner to organize the Pacific Railroad Company, and was Governor of Nebraska Territory from 1861 until 1867; served in the U. S. Senate 1877–83. D. Nov. 1, 1899.

Saunders, Thomas Bailey: English lawyer and philosophical writer; b. in Alice, Cape Colony, South Africa, Dec. 2, 1860; received his university education at King's College, London, and University College, Oxford, and was made a fellow of King's College, London; spent some years in Germany, and then, returning to England, read law, and was called to the bar at the Inner Temple in 1886; practiced for a time, but gave up the practice of his profession for literature, and devoted himself to the study of philosophical and literary subjects: was appointed secretary of the statutory commission for the reorganization of the University of London in 1898. He has published *Translation of Schopenhauer's Essays*; *The Wisdom of Life*; *Studies in Pessimism*; *The Art of Literature*; *On Human Nature, etc.* (1889–96); *Goethe's Maxims and Reflections* (1893); *The Life and Letters of James Macpherson* (1894); and a *Version of Professor Harnack's Christianity and History* (1896). F. Sturges Allen.

Sauret, sō′rā′, Emile: violinist; b. in Dun-le-roi, France, May 22, 1852, and took up the study of the violin at a very early age, so that when eight years old he played in concerts in Germany, and in 1862 in London. In 1866 he met Wieniawski. Later he traveled with Titiens, Mario, and Bottesini, and made extended tours through Germany, Russia, Austria, Italy, and the U. S. in 1872, 1874, and 1877. He then settled in Berlin, remaining there ten years. He married the pianist Teresa Carreño, being her first husband, but the marriage was soon dissolved and he married again. Saurct's own compositions are very many, and entirely for the violin. D. E. Hervey.

Saussier, sō′syā′, Felix Gustave: soldier; b. in Troyes, Aube, France, Jan. 16, 1828; passed from the military school at St.-Cyr into the infantry Oct. 1, 1850; lieutenant Feb. 25, 1854; captain Aug. 1, 1855; major Oct. 10, 1863; lieutenant-colonel Mar. 6, 1867; after serving in the Crimea, in Italy, in Mexico, and in Africa, was made colonel Dec. 23, 1869; commanded a regiment of infantry in the siege of Metz in 1870, and, having been made a prisoner, escaped and rejoined the Army of the Loire; promoted to be general of brigade Jan. 5, 1871. Elected to represent Aube in the National Assembly, Nov. 16, 1873, he was relieved from his command and took a prominent part in the discussions relating to reorganization of the army. He was called in May, 1876, to the command of a brigade, and on July 6, 1878, was made general of division, and served in Tunis and Algeria. On Mar. 24, 1884, he became commander-in-chief of the army and military governor of Paris. He retired, under the age limit, Jan. 16, 1898, and was appointed a permanent member of the supreme council of war.

Sauzet, sō′zā′, Marc: French deputy and lawyer; b. in Tournon, Ardèche, Feb. 18, 1852; took up the study of law, and received his doctor's degree; was made an advocate of the court of appeals, and a fellow in 1881 of the faculty of law of Lyons, and in 1891 of that of Paris; he was elected as a Republican member of the legislature in 1893 over the Marquis of Tourette, the Conservative candidate. He has been a constant contributor of articles to the *Revue Critique de Législation et de Jurisprudence*, including important studies entitled *Sur la Responsabilité des patrons*; *Le Livret et les Assurances des ouvriers*; *La Personnalité civile des Syndicats*; *La Juridiction des Conseils des Prud'hommes*, etc. (1883–91). F. Sturges Allen.

Savart, Félix: French physician and physicist; b. in Mézières, June 30, 1791; in 1816 he received the degree of M. D. from the University of Strassburg; in 1819 he went to Paris, where he prosecuted extensive researches on the vibrations of solid, liquid, and gaseous bodies, the mechanism of speaking, and the constitution of the organ of hearing; in 1827 was made member of the Académie des Sciences. In 1838 he succeeded Ampère in the chair of Physics at the Collège de France, Paris. His writings appeared as articles in the *Annales de physique et de chémie;* an outline was published in 1827 entitled *Analyse des travaux de M. Savart.* His principal invention was the toothed wheel which bears his name. (See Recording Apparatus, Psychological.) D. in Paris, Mar. 16, 1841.

Scadding, Rev. Henry, D. D.: author; b. in Dunkeswell, England, July 29, 1813; received part of his education at Upper Canada College, where his work earned for him a free course at an English university. He graduated at St. John's College, Cambridge, in 1837, and returned to Canada the following year. There he was engaged in teaching and in organizing the first free church in Toronto. He took his M. A. in 1840, and when he returned to Cambridge in 1852 received the degree of D. D. His publications have been chiefly historical. Among them are *Shakespeare—The Seer—The Interpreter* (1864); *Truth's Resurrections* (1865); *The First Bishop of Toronto, a Review and a Study* (1868); *Early Pioneer Life in Canada* (1887); *Seneca's Prophecy and its Fulfillment*, etc. (1897).

Scalchi, skaal′kee, Sofia: singer; b. in Turin, Italy, June 8, 1852, of a musical family; made her *début* in opera in her fifteenth year, and after singing in the principal Italian cities made a tour of Great Britain; then went to St. Petersburg for five consecutive seasons. Next she sang in Madrid, Vienna, and Warsaw. Then she went to Rio de Janciro, and finally to New York, where she has sung season after season, first in the Academy of Music and then in the Metropolitan Opera-house. She is married to Count Lolli, but retains her well-known name for the public. Her voice is a rich and pure contralto, and she has a very large repertory of operas. D. E. Hervey.

Schaeffer, Nathan C., D. D., Ph. D., LL. D.: educator; b. in Maxatawney township, Berks co., Pa., Feb. 3, 1849; educated in Maxatawney Seminary (now Keystone State Normal School), Franklin and Marshall College, Theological Seminary, Mercersburg, and the Universities of Berlin, Tübingen, and Leipzig; taught in Mercersburg College and Franklin and Marshall College; was for sixteen years principal of the Keystone State Normal School; superintendent of public instruction, State of Pennsylvania, since 1893. C. H. Thurber.

Schalk, Franz: conductor; b. in Vienna in 1863, and entered the conservatory when twelve years old, taking up the violin, and proceeding to counterpoint and composition; made his *début* as a violinist in 1881. In 1888 he was called to Graz, Bohemia, as kapellmeister, remaining eight years, and was then engaged as conductor at the Landes theater, in Prague, as the successor of Anton Seidl. Next he conducted opera and concerts in Berlin. In the summer of 1898 he was engaged by Maurice Grau to conduct the German presentations of opera in New York and London for the season. He signed a ten-year contract, beginning Sept. 1, 1899, with Count Hochberg, director of the Berlin Opera. D. E. Hervey.

Schleswig-Holstein: The Prussian legislature in 1898 voted an appropriation to build further defenses to protect the low western coast of Schleswig and its islands from the invasion of the North Sea. One of the largest features of the work is a breakwater between the small island of Oland and the mainland, which with other works is expected to keep the sea within bounds for many miles. The new works are to give complete protection to the Halligen islands, which rise only a few feet above high water. The encroachments of the sea had compelled the inhabitants to live in small cabins on artificial mounds, and many had sought refuge on the mainland. Since the Middle Ages the sea has gnawed the coast away to a depth of 20 miles, and the existing islands are merely the ruins of what was a part of the mainland. In six hundred years Schleswig has thus lost a third of its area.

Schmid, Joseph: educator, pupil and collaborator of Pestalozzi; b. in Tyrol in 1786, his people being honest peasants. In 1801, at an uncle's expense, he was placed in Pestalozzi's institute at Burgdorf, where after two years he became teacher of mathematics. He followed the school in its changes until it settled at Yverdun, gradually winning the highest place in Pestalozzi's esteem and a dominant influence in the direction of the school. He published a considerable number of works devoted to the application of Pestalozzi's ideas to the teaching of mathematics. In the difficulties that broke out in the school between Pestalozzi and his teachers, Schmid remained faithful to his master;

but finally, in 1810, he withdrew from the institute, publishing soon afterward a brochure in which he publicly explained the reasons which had led him to this step. The publication of this work has been characterized as an act of black ingratitude toward Pestalozzi, but it seems that Pestalozzi did not so regard it, and those who speak of it in such unqualified terms certainly never have read it. After traveling in Austria, South Germany, and Switzerland, Schmid became head of a public school in Bregenz, Bavaria, and in 1815 re-entered the Yverdun institute, now threatened with ruin, and from that time to 1827 his work was most intimately united with that of Pestalozzi in the institute. After the death of Pestalozzi Schmid lived in Paris, engaging in various professional and literary projects, but occupying no prominent position. D. in Paris, Feb. 14, 1851. Schmid was the most famous of Pestalozzi's assistants, and about his connection with and influence upon the institute at Yverdun a vast amount of controversy has taken place. That he was a man of great sincerity and enthusiasm there can be little question. He was almost totally uneducated, in the accepted sense of the term. Had he been favored with opportunities for a liberal education, no doubt much of the rudeness and lack of taste with which he has been charged, perhaps justly, would have disappeared. But at any rate he enjoyed the confidence and esteem of Pestalozzi in a far higher measure than any other of his associates. C. H. Thurber.

Schmidt, Karl: educator; b. in Osternienburg in 1819; studied in the gymnasium in Koethen and at the Universities of Halle and Berlin; became in 1845 professor at the gymnasium in Koethen, and then was for a time pastor, but returned and taught in the gymnasium from 1850 to 1863. In the spring of 1863 he was nominated director of primary education in the duchy of Saxe-Gotha, and also director of the Teachers' Seminary in Gotha. The energy with which he set to work to reform the schools of the duchy undermined his health, and he died in Gotha, Nov. 8, 1864. He was the author of a considerable number of pedagogical works, the most important of which is his *Geschichte der Pädagogik* (History of Pedagogy), first published in four volumes in 1862, and in several revised editions since that time. C. H. Thurber.

Schönefeld, Henry: musician; b. in Milwaukee, Wis., Oct. 4, 1857, and began the study of music at the age of seven years. He became proficient on both violin and piano, and when he was fifteen he had composed a trio for piano, violin, and violoncello. In 1874 he went to Leipzig and stayed there three years, studying and composing. Then he went to Weimar, and returned to his native country in 1879, settling in Chicago. At the competition of 1897 at the National Conservatory of Music, New York, he won the prize of $500 for a symphony, which was performed by the orchestra, conducted by himself. He has composed much for orchestra, piano, violin, and voices, both solo and concerted. D. E. Hervey.

School Diseases: a term used rather loosely to indicate diseases prevalent among school-children; more accurately used to denote diseases caused or specially aggravated by the conditions of school life. As it is impossible to determine how many of the former are included in the latter, and as disease among school-children, whatever the cause, affects the welfare of the school, the investigations thus far made have generally had regard to school diseases in the broader sense.

Contagious Diseases.—The school does not cause contagious diseases, but it spreads them. Observation has given manifold evidence of this, and statistics could be cited if it were necessary. For example, Körösi found during the three quarters of the year when the school was in session an average of 4,000 to 4,400 cases of measles per month, but for the vacation month of August only 780 cases; for the month of September, the first of the school year, only 639, and only 1,695 for October. Taking the four quarters of the year, there were for the three months of vacation only 3,054 cases, while for the first quarter of the year there were 11,865; for the second, 13,258; for the third, 13,147. In part this might be accounted for by the influence of the seasons; but further proof of the causal relation between school attendance and the spread of measles was found in the fact that when the time of vacation was changed, as occurred one year on account of the cholera, the period of minimal number of cases of the diseases was altered correspondingly. Similar statistics could be cited for other contagious diseases. Scarlet fever and diphtheria especially are spread by the school. But while the conditions of school life favor the spread of such diseases, with competent medical supervision the school affords also favorable opportunity for checking disease. With all the children collected inspection is easy, and cases are detected and isolated in the early stages that otherwise might pass unnoticed until a whole neighborhood was exposed to infection. In regard to the period that children suffering from different diseases should be excluded from the school there is some difference of opinion. The only safe rule is that no child recovering from a contagious disease should be readmitted except upon a certificate by competent medical authority that all danger of communicating the disease is over. Conservative authority places the minimum for several of the more common diseases as follows: Whooping-cough, 30 days; mumps, 3 weeks; rash, 14 days; scarlet fever, 6 weeks; diphtheria, 7 weeks; in all cases reckoning from the first appearance of the disease. In case of measles, scarlet fever, and diphtheria, as well as smallpox, the brothers and sisters of the patient should also be excluded from the school; some authorities demand this in case of whooping-cough and certain other diseases. In cases of diphtheria, as the Klebs-Loeffler bacillus, the recognized cause of the disease, may remain in the nose or nasopharynx for some time after convalescence, no child should be readmitted until after culture tests indicate that danger of communicating the disease is over.

Some only of the States have special laws concerning contagious diseases in the school, and legislation varies in the different States. The Massachusetts law represents a minimum demand. It is as follows:

"The school committee shall not allow a child who has not been duly vaccinated to be admitted to or connected with the public schools."

"The school committee shall not allow any pupil to attend the public schools while any member of the household to which such pupil belongs is sick of smallpox, diphtheria, or scarlet fever, or during a period of two weeks after death, recovery, or removal of such sick person; and any pupil coming from such household shall be required to present to the teacher of the school the pupil desires to attend a certificate from the attending physician or board of health of the facts necessary to entitle him to admission in accordance with the above regulation." The Ohio law rightly includes in the list that excludes from the school, "measles, whooping-cough, or other dangerous communicable diseases." As regards tuberculosis, now recognized as a contagious disease, there is no special school legislation, and authorities differ; but there appears to be ample reason for excluding pupils suffering from this disease, although provision should sometimes be made for their instruction in special classes.

Chronic Diseases.—The first investigation of the health of a large number of school-children was made by Hertel, and the results published in 1881. This embraced reports of 3,141 boys and 1,211 girls in the higher schools of Copenhagen, mostly from the well-to-do classes. Printed lists of questions, inquiring in regard to the age of the pupils, class, number of hours of school work, home study, state of health, hours of sleep, capacity, etc., were distributed, and answered by parents and teachers. The result showed 31·1 per cent. of the boys and 39·4 per cent. of the girls to be suffering from chronic diseases, not including defects of sight and hearing. Children suffering from acute diseases were reckoned among the well. In 1882 commissions were appointed both in Denmark and Sweden to study the subject. The two commissions worked by much the same plan, and the results, so far as disease is concerned, were as follows: The Danish commission reported on the health of 17,595 boys and 11,646 girls, partly from the higher schools, partly from the people's schools, including pupils from schools in the country as well as from Copenhagen. Of the total number of boys 29 per cent. were found ill; of the girls, 41 per cent. The report of the Swedish commission concerned the health of more than 18,000 pupils of the higher schools. Axel Key, a distinguished Swedish physician, prepared the report for this commission, and he gives the following statistics: The reports of 11,210 pupils of the higher boys' schools were studied. Of these 44·8 per cent. were afflicted with chronic disease. The largest percentage of illness was found on the classic side. Here the percentage of illness amounted to one-half, 50·2 per cent. In the common course, as it is called, the percentage was 40·9; in the real course, 39·6. In the other schools the proportion was similar. Of 3,072

pupils in the higher girls' schools the percentage of illness was 61·7. The main features of the curves of disease found by these different investigators is significant. The Danish commission found that upon entering school 20 per cent. of the boys were ill. The curve of illness rises rapidly to 28 per cent. in the eighth year, then slowly to the tenth year; then there is a small plateau between the tenth and eleventh years; then a rise till the twelfth year, when the maximum is reached with 31 per cent. Then there is a slight fall till the sixteenth year, then a slight rise again. The same general course of the curve appears more or less marked in each investigation. The curve for girls is similar in its main features. Whatever the cause, it is a noteworthy fact that half of the girls (51 per cent.) were chronically ill in the thirteenth year, when just on the threshold of puberty.

These investigations in Scandinavian schools are based on 50,000 children, and, while these results might not be paralleled in other countries, they suggest grave questions in regard to the conditions of school life. Scrofula, anæmia, and habitual headache were the most frequent diseases, according to the Danish commission. In Sweden, anæmia, headache, and nose-bleeding formed the majority among the boys. Among the girls, anæmia, headache, loss of appetite, spinal curvature, and nervous diseases were frequent. These are, with the exception of scrofula—of which a large percentage was found by the Danish commission, although but few cases by the Swedish commission—diseases that might naturally be expected to be caused by the conditions of school life. How far the school was responsible is not evident; but it does seem clear that the conditions of school life, together with the home study and inadequate supply of sleep, were largely responsible. The Swedish commission found, further, that the time devoted to sleep decreased from nine hours to seven hours, or a trifle more in the highest classes. Prof. Key found in Stockholm that those children who slept less than what he deems a normal period (namely, ten to eleven hours for younger children, eight to nine hours for older ones) showed in the upper classes 5 per cent., in the lower 8 per cent., more cases of illness than the others. The children investigated by the commissions were also weighed and measured, and it appeared that in general periods of maximum rate of growth are periods of maximum power to resist chronic diseases. This is specially noteworthy, according to Key, at the beginning of puberty. With the marked increase in the rate of growth at this time, there was a decided decrease in the percentage of disease. Unfortunately, no similar investigation of the health of large numbers of school-children has been made in the U. S.; but in regard to the point last mentioned corroborative evidence has been furnished by Dr. Hartwell's study of the death-rates of Boston school-children. He has found the death-rate least at those periods when the growth-rate is greatest.

The number of pupils with defective vision has been found to be very large. The first test of the vision of a large number of school-children was made by Dr. Cohn in Breslau some thirty years ago. He found an average of about 30 per cent. of myopic eyes, and did not make tests for astigmatism. Many other investigations made since in Germany and other European countries have shown a large number of children with defective vision. Key in Sweden found that among pupils who took the Latin course the percentage of near-sighted pupils increased from 6·1 per cent. in the lowest classes to 37·3 in the highest. The Danish commission found an increase in the classical course from 14·7 per cent. in the lowest class to 45·5 per cent. in the highest. Tests made in the London elementary schools, under the direction of Carter, showed only 39 per cent. with normal vision, and it was found that more than half of the defectives suffered from astigmatism. The number of children with defective eyes in the U. S. seems to be less than in Germany, but a number of investigations have been made in the U. S., and a large percentage of defective eyes has been found. Allport, for example, who has tested the eyes of 23,000 children in the Minneapolis schools, found more than 30 per cent. defective, exclusive of those already wearing glasses. Special stress has been placed upon the fact that the percentage of myopia seems to increase from the lower to the higher grades of the school. Especially the Continental investigators have found that the number of emmetropic or normal eyes decreases from the lower to the higher grades: that likewise the number of hypermetropic eyes (the hypermetropic eye being merely an undeveloped eye, and regarded by some as the normal condition of the eye in infancy) decreases from grade to grade; and that, conversely, the number of myopic eyes increases from the lower to the higher grades. While this seems to be demonstrated for the German schools, it is not universally true. Carter, for example, did not find any such progressive increase in the London elementary schools. Two theories are in conflict as to the cause of myopia (or, more accurately, two classes of theories): one, the older and more widely accepted, lays the blame chiefly upon the school and unhygienic conditions of work; the other, which has recently come into prominence, finds the cause in innate structural peculiarities of the eye. The former is held by Cohn and others; the latter by Stilling, Schnabel, Carter, and others. Both innate structural peculiarities and the school must probably be looked upon as causes. Which is chief we can not say. But the influence of the school as one factor can hardly be denied, in view of the great increase in myopia from the lower to the higher grades. The evidence, of course, is not conclusive. The crucial test would be to investigate the eyesight of a large number of children outside the school. If a similar progressive increase in myopia were found among them, the result would indicate that some other cause than the school must be sought. If no such increase were found, then it would appear that the conditions of school life were the chief cause. It is needless to say that it is difficult to make such an investigation. Some data of this kind have been obtained. The examination of German recruits indicates that those who have been to school least show a smaller percentage of defective eyes. But which of the various theories in regard to the cause of myopia will be substantiated by further investigation remains to be seen. The effect of recent studies and discussions, however, has been to modify opinion very largely in regard to the influence of the school in producing this defect. How far innate structural peculiarities are the cause of myopia, and to what extent it may be caused without such predisposition, is not clear. For practical purposes it does not matter. It does appear that something can be done to retard the development of myopia, and there is no reason to relax stringent hygienic rules in regard to care of the eyes in school.

The number of school-children with defective hearing is also large. Many investigations have been made in different countries. An examination of the hearing of children in the Prussian secondary schools showed only about 2 per cent. with defective hearing; but the tests were made by the teachers, and the pupils in these schools are largely a select class. Most investigators have found 20 per cent. or more of the children defective in one or both ears. Bezold, perhaps the best authority on the subject, in a test of 1,918 children in Munich, found 25·8 per cent. with defective hearing. Studies in the U. S. and in Europe have shown a large percentage of defective teeth among school-children. Pedley in England found among 3,145 children that 77·5 per cent. had defective teeth. Röse, in an investigation of the teeth of German school-children, found the number with defective teeth varied from 79 per cent. to 98·7 per cent. as the regions were rich or lacking in lime. At the international dental congress in Copenhagen a few years ago a report was made to the effect that the number of school-children suffering from defective teeth in civilized countries amounts nowhere to less than 80 per cent., and rises to 98·5 per cent. The prevalence of nasal diseases in the school has been shown by Bresgen, Kafemann, Chappell, and others. Dr. Chappell tested 2,000 children in New York city, 645 of them from a grammar school, the remainder from asylums and other places. Of these children, 1,231 were found to have some nasal defect; 60 were suffering from adenoid growths. The frequency of this disease did not seem to be determined by social conditions. There were as many cases among the children of the grammar school as among those from the asylums; but the cases were more frequent among the boys than among the girls. Of 1,292 boys 49 had adenoids. Among the 708 girls there were only 11 cases. Knowledge of this disease is of special importance to the teacher, as the adenoid often causes deafness and also interferes with the nutrition of the brain, causing inattention, loss of memory, and stupidity. Many cases of marked improvement in mental ability following the removal of the adenoid growth have emphasized the necessity of special examination of dull pupils that show the characteristic symptoms, among which are impaired nutrition, the dull, sleepy, inquiring look, and the habit of keeping the mouth open.

Nervous Diseases.—The most important investigations of nervous disorders among school-children have been made in European countries. From investigations of 100,000 English school-children Warner has found 11·8 per cent. of the boys and 8·8 per cent. of the girls suffering from nervous disorders of various kinds. A still higher percentage has been found by several Continental investigators. There is some evidence of a decided increase from the lower to the higher grades. Nesteroff, for example, found in a Moscow gymnasium that the number suffering from nervous disorders was much larger in the higher grades, in case of the day pupils the increase being from 8 per cent. in the preparatory class to 69 per cent. in the highest class. The number of cases studied, however, was relatively small, and the conditions perhaps unusual. Many of the nervous disorders of school-children are neuroses of development, and would occur whether or not the pupils went to school; but such disorders are often aggravated by the conditions of school life, and in some cases can be directly traced to the school as a cause. Of special disorders it may be said that idiocy, insanity, epilepsy, and other more pronounced forms of nervous disease are relatively rare among school-children. Children afflicted with these diseases are usually kept at home or sent to special institutions. In all cases they should be excluded from the school. Headache in its various forms has been found very common among school-children. Virchow as long ago as 1869 noticed its frequency, and many investigators since have found from 11 per cent. to 80 per cent. of the children suffering from it. Some investigators, holding the school directly responsible, have called the disorder *cephalalgie scolaire*; but it is often incident to some neurosis of development, and diseases of the nose, ears, teeth, and eyes are frequent causes. Investigation of several forms of nervous disorder—especially chorea, stuttering, and hysteria—among school-children indicate the danger of spreading such diseases by psychic contagion. Especially is this true of certain forms of hysteria. A number of epidemics of this order have been reported where it became necessary to close the school. The studies and observations made indicate the necessity of excluding from the school pronounced cases of stuttering, chorea, hysteria, and epilepsy.

Among the most important of recent studies of school life in relation to health should be mentioned that made by Dr. Schmid-Monnard, who has investigated the growth and health of children at Halle, in Germany. More than 8,000 children were studied by him—5,100 boys, 3,500 girls. Some of the children attended school, some did not. Among the conclusions from his study in regard to the influence of school life on the physical condition and health of the children are the following: That in the first period of school life directly after entering school there is a retardation of the rate of growth both in the weight and height; that acute diseases appear most frequently in the first school years, and that, in general, they are more frequent and more permanent with boys from the less well-to-do families; that acute diseases occur more frequently where there are unsatisfactory arrangements for lighting and ventilation; that the amount of chronic disease is greater among girls than among boys; that the number of pupils with chronic disease increases in the course of the year, more sick children leaving the school on an average than entering it; that chronic diseases are specially frequent where instruction extends over the whole day, and where the pupils have little or no free time for going out of doors; that the amount of chronic disease goes hand in hand with the amount of work and with unfavorable division of the work, also with shortening of the time of sleep and with increase of the elective work of the pupils—hours in music and the like; that in the thirteenth and fourteenth years of life there is a decrease in the amount of disease among the boys and girls of the middle schools which have little home work, but no such decrease is found in the higher boys' and girls' schools with greater amount of work.

Thus there is considerable evidence to show that the school is a factor of considerable importance in determining the growth of school-children. It appears that the rate of increase in weight is affected more by the school than growth in height, the latter being determined chiefly by other factors. It seems natural enough that this should be so, because the increase in weight is so largely dependent on nutrition and the like, and the conditions of school life affect nutrition; and then, too, the conditions are less favorable for exercise. It appears also that prolonged school work is detrimental to health. This has been well shown, too, by Schmid-Monnard's results, since he found that the percentage of disease among children who attended school in the afternoon as well as in the forenoon was much greater than in case of those who had no afternoon school work.

No extended investigations concerning the health of school-children have been made in the U. S., but observation and the minor investigations that have been made indicate that a large percentage have defective senses or suffer from chronic diseases. It appears from observation and special investigation both in the U. S. and in Europe that one-third of the pupils in school are likely to have defective eyes, that a fourth are likely to have defective hearing, and that from 12 to 50 per cent., according to grade and locality, suffer from nervous and other disorders. The question of the responsibility of the school for this large amount of disease has been much discussed. The tendency in so many cases for the curve of disease to rise rapidly immediately after the children enter school, and then continuously from the lower to the higher grades, is noteworthy; but it is not clear that the curve of disease would not have risen if the children had not attended school. It is impossible justly to divide the responsibility between the home and the school. But this is unessential. The school is clearly one factor; and the chief causes of ill health in the school appear to be, on the one hand, uncleanliness and bad air, and, on the other, bad methods of study and instruction. The competition, the marking system, examinations, punishments, and the hurry and strain often induced by teachers who feel compelled to produce certain prescribed results—all these things tend to produce nervous disorders and to lay the foundation for other diseases.

Whatever the cause of the illness among school-children, the fact remains that a large proportion of them are sickly, and this makes special regard for hygiene necessary. Courses of instruction, periods of study, and methods adapted to pupils who are strong and well may be injurious to the weak. To determine the fitness of individual children for school work, to test physical and mental ability for certain tasks, and to judge of the effect of given conditions upon the health, demands some degree of expert knowledge. To meet this demand two plans are advocated by different authorities. One is to require special knowledge of school hygiene as a part of the professional equipment of teachers, requiring perhaps from a physician a certificate of health when children enter school, but leaving the general supervision of the health of the school to the teacher. The other plan provides for systematic medical inspection by regular physicians.

Medical supervision of the schools has been strongly advocated by physicians for many years. Dr. Hermann Cohn, of Breslau, has fought for it for twenty years. In 1877 the hygienic congress in Nuremberg advocated it, and many scientific and medical congresses since that time have taken similar action. Medical supervision has been tried in Sweden, France, Belgium, Austria, and several other countries, in the German cities of Leipzig, Karlsruhe, Dresden, Wiesbaden, Darmstadt, Berlin, etc., and in some American cities. The duties of a school physician, as they are prescribed by law in some European countries, illustrate the scope of the plan. The law in Austria-Hungary, for example, requires the school physician to investigate the school buildings, walls and surroundings, playgrounds, the floors, doors, windows, stairways, corridors, and the like. He tests further the air and the drinking-water, has charge of disinfecting the school when necessary, and so on. When the children enter the school he tests their health, giving a physical examination, noting the condition of the heart and lungs, any tendency to spinal curvature, any symptoms of contagious diseases, nerve signs, and the like. He tests the eyes and ears, and examines the teeth, hair, skin, etc. Further, when the physician has reason to suspect that the pupils live in an unhealthy home, or are not properly fed, he causes the director of the school to look after the parents or guardians in this respect. He has supervision of the plays and sports of the pupils, baths and swimming-tanks, etc.; and he reports each year to the director in regard to the hygienic condition of the pupils.

The advantages of having a school physician have been shown in many places; but frequently the success has been only partial, because physicians busy with their regular practice, or lacking knowledge of school hygiene, have been employed; and often the number of children—4,000 or more in Berlin—allotted to one physician has been too

large. In no country has the problem of health supervision been satisfactorily solved. There is a growing demand, however, for greater regard for hygiene in the schools. Periodic tests of the physical condition of the pupils are now deemed necessary by the best authorities. Tests of the senses are being made. A new law in Connecticut requires that the eyes of all school-children shall be tested. As the state requires children to attend school, it is maintained that it should safeguard their health. Hence it seems essential both that teachers should be instructed in school hygiene by prescribed courses in all training schools and that there should be medical inspection by competent physicians.

WM. H. BURNHAM.

School Gardens: As early as the fourteenth century institutions were found in a few cities of Italy (for instance, in Salerno and Venice) in which plants from all the parts and climates of the world were raised or cultivated for purposes of education and the enhancement of science; but these institutions, called *botanical gardens*, did not come into general use until natural science experienced the revival that astonished the world by its suddenness and brilliant results. The wealthy cities of Italy, led by Ferrara, vied with each other, early after the revival, in establishing such gardens. The universities of France and Spain followed this example. It is true the establishment of a botanical garden in Paris at the close of the sixteenth century had its cause in the trivial desire to furnish new floral designs to the embroiderers of court gowns. Not until 1626 was the garden transformed into an institution for scientific purposes, in which most plants of the world were raised. Later it received the name "Jardin des Plantes." In Germany a lively interest in botanical gardens was manifested during the closing decades of the sixteenth century. Their establishment was usually contemporaneous with the foundation of universities. At present no German university is without a botanical garden that furnishes the material for instruction in botany, biology, and physiology, and such gardens are frequently also used as experimental stations for raising and cultivating agricultural plants.

In view of these facts, it seems curious that it did not occur to any one to demand such gardens for lower schools. The first who expressed the idea was Comenius, who said that every school should have a garden in which "the pupils may let their eyes 'graze,' by watching the trees, flowers, and herbs." He recognized in the school garden the means of awakening and promoting the desire for knowledge. Pestalozzi also demanded that the young, purely for purposes of education, should be occupied in field and garden. Fröbel laid much stress upon having gardens for the infants' pleasant occupation. He even called his institutions for infants *Kindergärten* (children's gardens). But the school garden as a means for instruction in horticulture, agriculture, and natural history (chiefly botany) in the lower schools is an idea of rather recent origin, and one that is not well understood even at the present day.

Sweden, of all civilized countries, is the one in which the school garden is found in general use. The leading authorities in that country have recognized the fact that the elementary school may lend its aid in upbuilding national wealth by offering practical instruction in some branches of horticulture and agriculture. In 1876 Sweden had 1,602 school gardens; in 1881 this number had increased to 2,000. At present it is safe to say that there is scarcely an elementary school in Sweden without a garden.

The considerable wealth of the rural population of Belgium arises from the cultivation of vegetable gardens for the markets of the numerous cities of that densely populated country, a state of affairs which is chiefly attributable to the establishment of school gardens and the systematic and practical knowledge gained in them by the children.

Since 1885 France has given special attention to the introduction of instruction in agriculture into primary schools. In Switzerland, since 1885, the federal Government has made appropriations annually for maintaining school gardens. In the latter country the utilitarian view has been kept in the background and pedagogical considerations have dictated both the establishment and management of these gardens. Austria, in 1869, by imperial law, introduced instruction in agriculture into the normal schools, and ordered the establishment of school gardens for every country school, and in 1870 decreed that instruction in natural history in the elementary schools should be given in connection with practical exercises in the school gardens. This made the establishment of such gardens a necessity, and the result of the movement in Austria has been most gratifying. The states of Bavaria and Oldenburg have been particularly prominent in encouraging school gardens in the German empire; but such gardens are now common everywhere in Germany. While in the U. S. vast amounts of money are appropriated yearly for use, in one way or another—largely by scattering seeds—for promoting interest in agriculture, the matter of direct education of the pupils, through the school, to a greater knowledge, interest, and capacity in relation to agricultural activities has been astonishingly neglected. "Much the largest class of the workers of this country is engaged in agriculture. The environments of their children are rural. The rural school should aim especially to make country life more attractive and beautiful, and should pay more attention to rural industries. Every normal school should have, as a means of instruction, a school garden, planned and conducted not merely to teach the pure science of botany, but also the simple principles of the applied science of agriculture and gardening, and every rural school should also have its garden, through which the training of the normal school may reach the home." See *Report of the U. S. Commissioner of Education, 1889–90*, vol. i.; *Educational Review*, Mar., 1889; *Report of the Committee of Twelve on Rural Schools*.

C. H. THURBER.

School Hygiene: the art of fostering the normal functioning and development of the child's organism so far as determined by the conditions of school life. According to this broad conception school hygiene is concerned with every aspect of the school—even curricula, methods, and discipline—so far as it may affect health. It is based upon general hygiene and upon the physiology and psychology of development. Child hygiene differs from adult hygiene because the child's body is a growing organism. Its special characteristic is that it considers the effect of school environment and all educational conditions and methods with regard to their effect on a growing organism. The child is a different creature from the adult. The proportions of the body are different in the two. The pulse-rate is not the same; respiration is not the same; the constituents of the body are not the same. Besides the more obvious physical differences there are great differences in the nervous system, both anatomical and functional, a large part of the child's brain, as shown by the investigations of Flechsig, being "unripe" at birth. In general the child's organism is uneven, unstable, provisional. Many errors in hygiene have resulted from ignoring the obvious differences between the child and the adult.

It is just because a child's organism is in process of development that such questions as that of the period of study, amount of sleep, posture during school exercises, care of the eyes, and the like are of special importance. Thus domestic hygiene and school hygiene are the most important chapters of special hygiene. And during the last thirty years the whole environment of the child in school has been studied with regard to health, and a very rich literature has accumulated relating not only to school sanitation, but also to the wider field of school hygiene, including studies of growth and development, the senses, mental activity, and the hygiene of instruction in the different school subjects.

The Schoolhouse.—The site for the schoolhouse should be chosen carefully. The grounds should be well drained, free from foreign admixtures, pervious to water and air, the soil natural, not worked over by the hand of man. The best soils are gravel, sand, sandy clay, and marl containing lime and dolomite. The more sand the soil contains and the less of clay the more suitable it is. The ground should be level, there should be some slope to facilitate drainage, the space should be as large as possible but free, and, if possible, somewhat elevated in order to admit light from all sides. There should be no large amount of ground-water, and tests by expert chemists and others should be made if there are no adequate reports in regard to the nature of the soil. The locality should be removed from high buildings, noisy industries, disagreeable exhalations, markets, hotels, barracks, and the like. In the country a site should be chosen where there are no swamps, ponds, or standing water in the neighborhood. The size of the ground depends upon the kind of school, but in determining it space should be provided for a playground, at least 3 square meters for each child; and if there is no gymnasium, for a covered open space. The yard should be so paved that it will dry very quickly after a rain. An ideal ground contains a school garden as well as playgrounds. In choosing the site the question of lighting the rooms as well as ventilation should be considered. All the schoolrooms must have sufficient light. The best frontage for the schoolrooms is toward the southeast, east, and northeast; toward the south is good in winter; toward the west is not so favorable, being in summer too hot, and exposed to rain and snow. Position toward the north and northwest is deemed unfavorable on account of the cold and tendency to moisture. But such rooms can be used for drawing, and as anterooms and the like.

The plan of the schoolhouse must be determined by considerations of climate, locality, kind of school, etc. In general it may be said that school buildings should not be more than two, or at the most three stories high. In case of very large buildings they may advantageously be built around large open quadrangles like those of the Lycée Janson de Sailly in Paris. The entire building should be undercellared, and the cellar should be thoroughly ventilated, the floor cemented or asphalted, and isolating layers should be used to prevent moisture. The lower floor should be at least a foot and a half above the surface of the ground. The walls should contain vertical air-chambers, and the floors and ceiling sound-deadening layers. The roof should be fire-proof; the halls large; the stairways wide, light, ventilated, broken by landings, and of fire-proof material when possible. The steps should not be more than 8 inches high, and hand-rails should be provided on both sides. The material for the building should be dry, solid, and as little hygroscopic as possible, and the woodwork sound and well seasoned. The doors should be noiseless, open outward, and the windows large and simple in their adjustment. Ample fire-escapes in large buildings must be provided. Every new building should be thoroughly dry before it is occupied by the children. It is recommended that a new schoolhouse should not be used for at least six months after completion. The surroundings of the schoolhouse should be arranged with regard to keeping the house as clean as possible. The approach should be of concrete or paved, and according to some of the newer plans the entrance is through a court covered with gravel or concrete, in order that as little dust as possible may be carried into the building by the pupils. Separate, well-ventilated rooms should be furnished for wraps, umbrellas, etc., and where possible individual lockers. Outbuildings and water-closets should be the best possible and thoroughly ventilated, the plumbing the same for the schoolhouse as for other buildings.

The size of the separate schoolrooms must be determined by the number of pupils and the grade. The length of the room must be determined by the possibilities of seeing clearly what is written on the blackboards and hearing by the teacher and pupils. For ordinary purposes of instruction in the lower grades, the length may be about 30 feet; the breadth not more than 20 feet, in order to insure sufficient light; the height at least 12 or 14 feet. The walls should be smooth in order to retain as little dust as possible; the ceiling smooth and of pure white color; the floor of the best possible material, at least hard, splinterless, oiled boards, in order that they may be easily cleaned.

The Air.—A large number of investigations in different localities in Europe and in the U. S., notably in the cities of Boston, Philadelphia, and Buffalo, have shown that the air of schoolrooms is usually bad. There is a consensus of opinion in regard to the ill effects of bad air. Both statistics and observation have given evidence that continued sojourn in rooms where the air is vitiated is very injurious to health; and, further, there is evidence that bad air greatly decreases the ability to do mental work. The various impurities which are likely to be found in the air of a schoolroom may be roughly classified as follows: First, CO_2 when in excess of 4 parts in 10,000; second, solid particles of dust from the hair, clothes, wood, coal, chalk, and the like; third, organic matter from the lungs, skin, etc.; fourth, living micro-organisms of various kinds; fifth, bad odors, especially from clothing, bodies, mouths, and teeth of the children; sixth, small quantities of carbon monoxide and other impurities from the heating apparatus. There is no consensus of opinion at present in regard to which of these various impurities is the chief cause of the ill effects experienced in unventilated rooms. The CO_2 used to be regarded as the injurious element. It is still taken as the most convenient gauge of the other impurities, but is not itself deemed injurious in the small quantities in which it is found, even in the worst-ventilated rooms. That it is not poisonous in small quantities has been shown by numerous experiments, notably by that of Haldane and Smith, who confined a person in an air-tight chamber 6 ft. 2 in. high, 2 ft. 11 in. wide, and 3 ft. 11 in. long. When a person remained in this chamber until the CO_2 was from 10 to 20 times as great as in the most crowded and worst-ventilated public buildings, and when the air was vitiated to such an extent as completely to prevent a match from burning, it had no appreciable effect upon the subject of the experiment. Again, the organic matter supposed to be contained in expired air was deemed specially injurious. In 1887 Brown-Séquard and D'Arsonval reported experiments which seemed to demonstrate the existence of a volatile organic poison in expired air. This injected into rabbits caused death. Further experiments seemed to corroborate this view. But recent experiments by Lehman and Jessen, by Haldane and Smith, and others, notably those by Dr. Bergey, working under the direction of Drs. Billings and Mitchell, have made it doubtful whether there is any organic matter in exhaled breath that is harmful. The Brown-Séquard and D'Arsonval experiments, upon which recent theories in regard to expired air have been based, have been repeated by these investigators with negative results. There is plenty of organic matter in schoolroom air from the skin, etc.; but what has been supposed a chief source of such impurity—namely, the expired air—it now seems that we may rule out. Other impurities, especially some which have often been neglected—such as dust, bacteria, and bad odors, together with excessive moisture and the products of overheating and the diminution of oxygen—are probably the chief sources of danger and of discomfort in unventilated rooms; and, consequently, it appears that some of the principles upon which our theories of ventilation have been based are doubtful, and most of the handbooks on school hygiene need to be revised, in the light of these recent investigations.

Heating and Ventilation.—The problem of ventilation can not be considered apart from that of heating. Both are technical subjects of great complexity. (See VENTILATION.) But the general principles that specially concern school heating and ventilation may be stated briefly. The method of heating must be determined largely by local conditions. But whether it be by stove, hot-air furnace, hot water, or by steam, the aim is to furnish and distribute an amount of heat sufficient to warm all parts of each schoolroom, and with constant change of air to maintain a uniform temperature of 68° or 70° F. The air brought into the schoolroom must be pure, the sources of contamination reduced to a minimum, and the air of the room constantly diluted to a degree well within the limits of danger to health.

Considering recent studies and the views of experts, the general rules that lie at the foundation of school ventilation may be summarized as follows:

(1) While at present there is some doubt about the injurious elements in expired air, there is no reason to diminish the present standards of air-supply. From 2,000 to 3,000 cubic feet of fresh air per pupil should be brought into the schoolroom each hour; 30 cubic feet per minute is the minimum. The cubic air-space per pupil should be 200 to 300 cubic feet; never less than 200 cubic feet.

(2) Sources of contamination that have often been disregarded—dust, bad odors, excess of moisture, overheating, and the like—appear to be of very grave significance. The CO_2 is the most convenient gauge of the various impurities. The maximum limit of impurities is represented by 10 parts of CO_2 in 10,000. All practicable means of removing the sources of contamination of the air should be adopted. One of the most important means of avoiding these sources of danger, however, is a good system of heating and ventilation.

(3) The system of heating and ventilation should be determined beforehand, and incorporated in the plan of the building. The Massachusetts law provides that architects or others who prepare plans for or superintend the construction of buildings of this class shall include in them the plans for the ventilation, all of which shall be filed with the inspector of the district in which the building is located. The plans, after having been approved, can not legally be changed without obtaining a new certificate of approval. The contractor should sign a contract like the following:

"To guarantee to furnish at least 30 cubic feet of fresh, properly warmed and circulated air per minute for each pupil, allowing (any given number, say 50) pupils to each room, and to remove an equal quantity of vitiated air per minute for each pupil. To maintain a temperature of at least 70° in each room in the coldest weather, the temperature not to vary more than 3° between any two points in the room on the same level at the same time. The whole to be done subject to the approval of the State inspector of public buildings for the district in which the building is situated; said inspector to examine and give a written approval of the work before more than half the contract price is paid to the contractor or his agent."

(4) The ventilation should not be subsidiary to the system of heating. It may be either by the so-called gravity system, usually by aspirating chimneys, or mechanical means may be used to exhaust the air. The latter method has the advantage of permitting a regulation of the amount of air exhausted.

(5) The fresh air must be warmed before being introduced into the schoolroom. The temperature of this fresh air as it comes into the room should not, as a rule, much exceed 100° F. This indirect system of heating may be combined with a direct system where climatic conditions make this necessary.

(6) The warm-air supply ducts should be large, at least 1 square foot in area for 10 pupils.

(7) In regard to the introduction and exhaustion of the air, every room presents its own problem, but there is a general consensus that in an ordinary schoolroom the inlet should be about 7 or 8 feet above the floor on an inner wall or corner of the room, and that the outlet should be near the floor on the same side.

(8) The attempt should be made to supply adequate means of ventilation without opening windows; but investigations indicate that, except with the best systems of ventilation, it is impossible to have pure air in a schoolroom without draught ventilation from windows and doors. This, however, should be at recess, and chiefly at the close of school. The importance of this draught ventilation is emphasized by recent investigations, which indicate the necessity of removing the dust.

(9) The same principles should be followed in heating and ventilating a small schoolhouse of one room as in case of larger buildings. The stove should be surrounded with an air-space inclosed by a jacket of sheet iron. Fresh air should be introduced into this space through a flue connecting with the outer air. The bad air should be exhausted by an outlet into the chimney near the floor.

(10) As many teachers are obliged to teach in schoolhouses that have no proper means of heating and ventilation, they should learn to make the best of bad conditions. This can be done by greater regard for cleanliness, and by considering the general laws of air-currents. Each room presents each day a new problem in ventilation, to be solved only by considering many factors—as the position of the windows in relation to the heating apparatus, the direction of the wind, the humidity of the atmosphere, the difference between the outdoor and indoor temperature. If the conditions are so bad that the room can not possibly be ventilated properly, then the way to keep the pupils in good health and to make them do the maximum amount of work is to have frequent recesses, during which the room is flooded with fresh air by opening the windows.

(11) The best possible system of heating and ventilation is desirable for pedagogical as well as hygienic reasons; but even this is not enough to make the schoolroom atmosphere hygienic unless great care is also taken for the highest degree of cleanliness of the children, of the furniture, the blackboards, the books, etc., and for removing dust, avoiding overheating, bad odors, etc.

(12) All the essentials of hygiene in regard to the air-supply must be regarded.

Lighting.—Dr. Cohn maintains that too much light can not be had in a school, and Javal insists that the schoolroom should be flooded with light. The amount of light usually deemed sufficient is indicated by the norms of different countries. It is usually required that the window-surface in a schoolroom should be from one-quarter to one-sixth of the floor-space. Dr. Billings maintains that the ratio should be 1 square meter of window-surface to 4 square meters of floor-surface. It is necessary also that there should be plenty of light at each desk irrespective of this ratio. Hence photometric determinations are often required. Photometers have been invented by Weber and others by which the amount of light at any pupil's desk can easily be determined. The standard of measurement is the "meter-candle"—that is, the amount of light cast on a paper exposed to a normal candle at a distance of 1 meter; spermaceti candles weighing one-sixth of a pound are taken as normal. Dr. Cohn's standard, that the minimum brightness on dull days for any seat should be 10 normal meter-candles, may be adopted, but tests have shown that to enable the eye to read as readily as in clear daylight an illumination of 50 meter-candles is necessary. To insure sufficient light it is necessary to follow Javal's rule, that if the schoolhouse is near other buildings the distance of the latter should be equal to twice their height, and the French norm, that the height of the windows in a schoolroom should be equal to two-thirds the width of the floor, is a safe one. It should at least be required that each pupil can see some portion of the sky from his seat.

Most writers on school hygiene favor unilateral lighting, or at least demand that the greater part of the light should come from one side, and it is necessary that the seats should be so arranged that this light come from the left. The objection to bilateral lighting from the left and rear can be met by the use of suitable curtains. With the unilateral lighting the bottom of the windows should be about a meter above the floor, and they should be as near together as possible and should extend to the top of the room. The ideal plan advocated by some is to have a glass roof. The color of the light determines to considerable degree the effect upon the eye. Blue has been found by many a most agreeable color, and every-day experience indicates that blue, gray, and light shades of lavender and green are pleasant to the eye. The whole subject of the influence of light of different colors upon the eye has not been accurately studied; but, as regards the practical point for school hygiene, opinion seems to favor use of gray or a light shade of blue-gray or greenish gray for the walls of the schoolroom. Indirect sunlight is the best kind of light, but it should be regulated by suitable curtains, and these should always be arranged to run up from the bottom as well as to let down from the top. Artificial light should also be indirect and thoroughly diffused throughout the room. The electric light is best; but whenever work in drawing or the like must be done by artificial light, individual lights at each desk are necessary, because the draughtsman depends upon the shadows, and these are lacking when there is only general diffused artificial light. The amount of light actually found in schoolrooms is often deficient. Careful measurements in different German schools showed that a large number of the pupils sat at desks with very inadequate light, and in some classrooms the light in the dark places was found less than 1 meter-candle on dull days. Most of the new school buildings in the U. S. are well lighted, but in many of the older buildings the light is often far from adequate.

Cleanliness.—Recent studies indicate the prime importance of cleanliness in the school. The subject has been put on a scientific basis by bacteriological study in the schools, for dust offers a favorable medium to the bacteria. Meyrich, a teacher in a Leipzig school, has tested the dust by exposing a plate with a suitable medium for five minutes during the period of instruction, the children remaining in the room, and counting the micro-organisms that developed in seventy-two hours in a temperature equal to that of the schoolroom. The number that developed in the schoolroom cultures was enormous as compared with the number that developed under similar conditions from Herr Meyrich's private rooms. The investigation was carried out with German thoroughness. Tests were made to determine the number of micro-organisms in the dust that was swept up. Meyrich estimated that there were at least a million micro-organisms to a gramme of dust. The fine dust that settles on the seats and furniture was also tested, and the number to a gramme was estimated at 4,354,635. Now from these tests it appears than an enormous number of micro-organisms adhere to the dust and pass into the air. The significance of the figures cited is seen by comparison with the number found in mountain or sea air. It is said that in tests of the air on the high mountains in Switzerland Freudenreich often had to seek through two or three cubic meters of air before he found a single bacterium. The studies of other investigators have shown that the number of micro-organisms stands in inverse ratio to the adequacy of the means of ventilation, the cleanliness of the room, and the cleanliness of the children.

Hygiene now demands regard for cleanliness in the whole planning, construction, and management of the schoolhouse. It is not satisfied with diluting the bad air to a certain standard of CO_2, but it requires the removal as far as possible of all sources of contamination. It is necessary not only to observe the obvious rules of cleanliness as regards frequent sweeping with moist sawdust, wiping furniture with moist cloths, cleaning of floors and windows, and the like, and special care of outhouses, but the books when used by different classes should be disinfected periodically. Investigations by Lion have shown that large numbers of micro-organisms are likely to be found on books, especially on the dirty pages, and that many varieties can live for a long time on paper. Tests by the same investigator and by others indicate that the best means of disinfection is by the use of formalin. The children also must be clean. Sometimes the presence of a single child with dirty clothing vitiates the air of a whole room, and the best system of ventilation is insufficient with a roomful of dirty children. The most efficacious means of cleanliness is the school bath. School baths, usually shower-baths, have been introduced into schools in Berlin, Frankfort, Breslau, Cologne, and several other German cities, and one or two cities in the U. S. have new buildings provided with them. The experience with them has generally been reported as satisfactory, and many officials are demanding that they be placed in all new schoolhouses.

School Furniture.—In most schools the larger part of the time is spent in sedentary occupations; consequently, school seats and desks are the most important articles of school furniture. During the last fifty years there has been a vast improvement in school seating. Before the appearance of Barnard's classic work on *School Architecture* (1848) the principle followed in choosing and arranging school seats and desks seems to have been one in the interest of discipline by the teacher. In some of the schoolhouses a row of desks was placed around the three sides of the room, and inside a plank served for a seat, so that the pupils sat facing the wall with their backs to the teacher. In others the pupils were boxed up so that when sitting only their heads were visible. Barnard was the first in the U. S. to prepare a scale for seats and desks adapted to the height of pupils at different ages. This was based on measurements of children begun as early as 1838. In Germany, during the sixties, Fahrner, Prof. Hermann Meyer, and others explained the principles that must determine the making of hygienic seats. And since that time there has been a perfectly definite conception of the essential features. The fundamental rule, as formulated by Uffelmann, is that the school seat and desk in all parts should be adjusted to the corresponding measurements of the child's body when clothed. Measurements have been made by Fahrner, Cohn, Geissler and Uhlitzsch, and others to determine the height of children at different ages, and the relative length of different parts of the body, with the special purpose of finding the proper dimensions for seats and desks, and tables based on such measurements have been made by different authorities.

The determination of average height for different ages is not sufficient, as is seen by noting the great range of individual variation found by different investigators. For example, the tallest boy over fourteen measured by Geissler and Uhlitzsch was 176 cm. in height; the shortest of the same age, 97 cm.; the tallest girl, 167 cm.; the shortest of the same age, 109 cm. And, moreover, such differences between the sexes are found that the same scale of measurements should not be used for both. The ideal is to have the seat adapted to the individual child, the seat and desk fitting him like his clothes. An attempt, often very crude, has been made during the last few years to attain this ideal by providing adjustable seats and desks. Many of these have been placed upon the market, each one of the many patterns having some good features, but none of those yet devised being altogether satisfactory. The determination of the proper kind of seat and desk is a problem by no means simple. The seats should be so adjusted that the body may be held in equilibrium with the minimum muscular effort, so that a pupil while writing would retain his position if the desk were suddenly snatched away. Under these conditions the spine is in normal position, there is no abnormal pressure on the abdomen, and with a suitable desk the eyes may be kept at proper distance from the paper. There is a definite conception in regard to the essential features of a seat and desk that will render this position natural. The main points are as follows: (1) The height of the seat should equal the length of the child's leg from the bend of the knee to the sole of the foot. (2) The width of the seat should equal about three-quarters the length of the upper leg. (3) The seats should have a backrest for the small of the back above the hip-bones opposite the last lumbar vertebra. This is specially important. (4) There should be a support for the back under the shoulders. (5) The seats should be sufficiently large to enable the child to change position, and the front edge of the seat should be a little higher than the back and rounded off. (6) The dimensions of the desk should be sufficient for the accommodation of books and the like. (7) The slope should be about 45 degrees for reading and 15 degrees for writing. (8) The *difference*, or distance from the seat to the edge of the desk, should be such that the child, when sitting erect, can easily place both arms on the desk without lowering or raising the shoulders. A convenient rule is that the difference should equal the distance from the seat-bone to the elbow plus 1·5 cm. (9) The distance of the seat from the desk may be zero, plus, or minus. For convenience in taking the seat and in standing a plus distance is required; for writing a minus distance of 2 inches is necessary. Such are the essential features, and there is practically a consensus of all authorities in regard to them. To insure them, both seat and desk must be adjustable to different heights. And it is of prime importance not only to have the seat of the right height, but also to have the correct difference and the proper distance, since upon these chiefly depends a correct sitting posture. That the distance may be plus for reading and minus for writing, it is necessary to have either a movable seat or a sliding desk. For obtaining a slope of 45 degrees for reading and 15 for writing, the desk must be adjustable to different angles; and an ideal seat would have a backrest adjustable to the individual, such as some teachers' chairs are provided with. In a word, the seat and desk should be automatically adjustable as regards height, difference, distance, back-rest, and desk-slope. While there is a consensus of opinion in regard to these essentials, and the best adjustable seats and desks on the market, although not altogether satisfactory, are still a vast improvement upon the ordinary means of seating, still in most schools the majority of children are misfitted, and frequently are required to sit in seats which are far from hygienic.

Hygiene of Instruction.—School hygiene in the broad sense, or pedagogical hygiene, is concerned, on the one hand, with school sanitation—heating, lighting, ventilation, drainage, etc., and the general principles of somatic hygiene; on the other, with mental hygiene and the hygiene of the nervous system, including not only the hygiene of the brain, but also that of its tools, the senses and motor organs. The hygiene of instruction comes under this second head, and presupposes good sanitation and observance of the general principles of somatic hygiene. It has to do with the

conditions that favor the normal functioning of the child's psycho-physic mechanism so far as they are determined by methods of study, school programmes, manner of teaching, text-books, and the like. The studies in somatic and cerebral hygiene throw light directly upon this subject; but these investigations should be supplemented by special observation and systematic study of children while at work upon their different school subjects. Upon the results of such studies, and upon the principles of somatic and cerebral hygiene, the hygiene of instruction is based. This newer branch of hygiene points out that every subject of instruction and every pedagogical method have important hygienic aspects that must be studied before their true value can be estimated. It is, however, in the deepest harmony with true pedagogy, for the aim of both alike is the normal guidance of development.

The first principle of the hygiene of instruction is that the sequence of the different forms of instruction and training should be adapted to the sequence of the stages of the child's development. The great difference between the child and the adult is due to the fact that the child's organism is in process of growth and development. We know only in a general way what the course of development is. We can not give a series of pictures even of the physical child at the different stages of its career. A new physiology is needed which shall show the sequence of the different stages of growth and their relation to the development of organic, sensory, and motor functions. But some very important studies have been made in recent years in regard to physical growth by numerous investigators in Europe, and by Bowditch, Peckham, Porter, Boas, West, and others in the U. S. For the period of school life it appears that from six or seven to ten or eleven in girls, and to twelve or thirteen in boys, is likely to be a period of decrease in the rate of growth; from the eleventh or twelfth year in girls to the fifteenth, and from the twelfth or thirteenth to the sixteenth or seventeenth in boys, is one of rapid growth. But even here so many conditions affect growth—heredity, food, climate, care, exercise, etc.—that it is not easy to interpret data. And when we come to consider the nervous system, we know relatively little about its development. We can distinguish three periods in the development of the brain after birth. Those for boys are as follows: During the first seven or eight years the brain attains almost its maximum weight. The next period, until the age of fourteen, is one of moderate growth and development. The third, from fourteen to twenty-five, is characterized especially by development of function. We know too in a general way that the order of development is from the fundamental to the accessory. The nerve-centers that function the larger and more central organs are developed first; those that function the smaller and more peripheral ones later. Again we find that development is by parts, not uniform, and we have reason to believe also that different nerve-centers have nascent periods when their functional development proceeds at a relatively rapid rate. Not all parts of the nervous system develop at the same time, any more than all parts of the skeletal structure are growing equally at the same time. Beyond such general statements we can not go very far. But even the relatively meager and general knowledge we now possess is of vital importance. If once for all one grasps the point of view of development, it changes one's whole attitude toward the child. Even the obvious facts of physical growth are of great practical significance. In general such studies have emphasized the danger of any premature or unrelated developments. Instruction or training of any organ or faculty before the nerve-centers involved are ripe for it is not only questionable pedagogically, but likely to be injurious to health. And, on the other hand, unduly delayed training is loss of opportunity, and may mean arrest of development.

There is a general consensus that children should not begin school work before the age of six or seven. Some physiologists—Mosso, for example—would not have intellectual work begun before the age of ten. For the younger children the school day should be short, not exceeding two or three hours for children under ten, four for children between ten and twelve, and five for those twelve to fourteen years of age. In regard to the length of each period of study practice differs greatly. At the London Congress of Hygiene and Demography, in 1891, a resolution was passed to the effect that until the matter has been further studied no school period should exceed three-quarters of an hour in length, and that each period should be followed by a quarter of an hour for rest. The numerous studies of fatigue in school-children (see MENTAL HYGIENE) throw light on this problem. It appears that the matter is largely relative to the age and ability of the individual, the kind of work, the time of day, the work that has preceded and is to follow, the character of the teacher, etc. A much shorter period is required for the younger pupils; a longer one may sometimes be an advantage for older ones. Chiefly regard must be had for individual peculiarities. In general the amount of time devoted to recess in the U. S., especially in the secondary schools, is too small. In Germany, in the secondary schools, at least forty minutes for recess in a five-hour session is prescribed by law, and after many years of experience there seems to be no tendency to decrease the amount. Where possible the recess should be spent in free play out-of-doors. Gymnastics is not to be regarded as a means of recreation, but as an important subject demanding its own place in the curriculum. Hence gymnastic exercise should not take the place of the outdoor recess. The question of one session a day, or two, must be determined largely by local conditions. Some observations indicate that the afternoon session is of little value, and it interferes with exercise out-of-doors. But if the one-session plan is adopted, care must be taken that the pupils eat their breakfasts, opportunity for a wholesome lunch should be provided, and recesses should be given as in the German schools.

Such are some of the important chapters in school hygiene, a subject which has so developed in recent years that it now affords opportunity for research to many experts, and whose contributions are already so important that no teacher should be ignorant of their practical bearings. It remains to be noted that all the demands of hygiene are interrelated. The best of schools can not keep children from being ill if the homes are unhealthy. Healthy homes can not keep children well if the schools ignore hygiene. And it is necessary to regard all the essentials of hygiene in the school.

LITERATURE.—Baginsky and Janke, *Handbuch der Schulhygiene zum Gebrauche für Ärzte, Sanitätsbeamte, Lehrer, Schulvorstände, und Techniker* (Stuttgart, 1898); Barnard, *School Architecture* (6th ed. School Laws: As used in the American decisions and statutes, the term *school laws* generally designates those which relate to and regulate the conduct of the common or public school existing under the laws of the State and maintained at the expense of the public. Most of these laws are purely statutory and constitutional, but they have a general resemblance, due to similarity of subject-matter, and their enforcement is covered by certain general principles applicable to the various laws in the different States which are of the same nature.

Laws as to Teachers.—In most of the States the statutes provide that a teacher shall, before entering upon his duties, obtain from a designated official a certificate of his qualifications to teach. It is held that only average qualifications are required, and only reasonable attention to the discharge of his duties, and that the teacher's certificate is *primâ facie* evidence of these. It is generally held that the contract for enrollment as a teacher of one who does not hold such a certificate is void, and that any service rendered by an uncertificated teacher under such a contract does not create a right to be paid. The right of the teacher to payment, however, is not affected by the inadvertent withholding of a certificate to which he was entitled, and it has been held that a teacher whose certificate has been maliciously or wantonly withheld or revoked has a right of action against the parties refusing to issue it to him. The laws usually provide that the teacher shall be employed by school directors or trustees in a certain prescribed manner, but the individual members of the board have not the power of binding the board or the district which they represent by their individual acts when not convened as a board, and any contract made by one or more members of the directors or trustees when not thus convened is void unless it be subsequently ratified by the board in legal session. The statutory regulations as to the manner of the making of the contract for the employment of teachers must be strictly complied with. The board of directors or trustees may in good faith make contracts for the employment of teachers for a term extending beyond their own term of office; but if it can be shown that this action was taken with the intention of forestalling their successors or the subsequent action of the board, the contract is voidable if the teacher be in complicity with them in this intent.

The rights of the teacher to compensation are governed by the same rules as those which govern the rights of any other person employed to render services for a given period. The contract can not be nullified or the term of service shortened by abolishing or removing the school where the teacher was to have taught, or in any other way rendering it impossible for him to perform his services. The teacher may also recover damages to the amount of his stipulated wages, subject to mitigation, by proof either of earnings or of their possibility, if he be discharged without sufficient cause.

Generally speaking, the same person can not be at once a teacher and a school trustee, and if he be employed as a teacher he forfeits and vacates his office of trusteeship.

The authorities have a lawful right to discharge a teacher for incompetency, neglect of duty, immoral conduct, or any other cause for which the teacher is responsible, and which prevents him from properly performing his duties. If the contract of employment, however, provides that he may be discharged if he does not give satisfaction, the employing authorities may discharge him at pleasure. In some States the statutes provide that a teacher can not be dismissed, even for cause, except upon notice and being given opportunity for trial.

The Rights of Pupils, and School Regulations.—The public schools must provide accommodations and instruction for all children of legal school age whose parents reside within the school district. If the parents reside without the school district the children may be prohibited from attending the school if the school authorities see fit.

The fourteenth amendment of the Constitution of the U. S., which provides that no State shall deny to any person within its jurisdiction the equal protection of the laws, does not prohibit the establishment of separate schools or systems of schools for white and colored children, provided the schools afford equal privileges and educational facilities to white and colored pupils; but if such schools are not provided the colored pupils can not be legally excluded from the other schools, and a writ of mandamus will be issued to compel the reception of pupils who are so deprived of their educational privileges.

The relation existing between the teacher and the pupil and the right of the teacher to enforce the lawful rules and regulations adopted for the conduct and government of the school are governed both by the common law and by the statute law. The teacher has a right to maintain reasonable discipline and compel obedience to reasonable regulations in any lawful manner, and to this end he may, in the absence of statutory prohibition, inflict corporal punishment upon the pupil. It is held that the teacher is *in loco parentis* to the pupil, and by virtue of this has, by way of delegation, the power of imposing such restraint and administering such punishment as may be required for proper exercise of the duties of his office. A mistake of judgment on the part of the teacher in the exercise of this right of correction, if his acts be done in good faith and do not inflict lasting injury, does not give rise to an action for damages for the injury suffered from such punishment; but punishment can not be legally inflicted except by way of correction of some specific offense committed by the pupil in violation of a reasonable rule or regulation, for which violation he is given to understand that the punishment is inflicted.

Exclusion from the school or suspension of school privileges may be resorted to as a means of enforcing discipline and compliance with the school rules and regulations, and the power of expulsion or suspension has been in some States conferred upon the school directors; but this power is inherent in the teacher, and may be exercised by him whenever necessary to the preservation of the interests of the school, unless he be deprived of it by statute or by legal action of the proper authorities. The teacher's power of punishment extends not only to acts committed during school hours, but also to acts detrimental to school discipline while going to or returning from school, and in some cases even to acts done at other times. The power of making rules and regulations may be vested in the trustees or in the school directors by a statute, but rules made under such power must be reasonable. In the absence of such rules established by the trustees or other proper authority, the teacher is vested with the right to make and establish such rules and regulations as may be necessary and proper for the good conduct of the school; and in either case he has the authority to enforce such rules as may be necessary to the actual administration of the affairs of the school, provided they do not conflict with any express rules of the trustees. The question of what constitutes reasonableness in a rule is a matter which varies so widely with circumstances and the statutory regulations as not to admit of any exact definition. It may be stated, however, that a rule requiring scholars to be vaccinated under penalty of exclusion; a rule requiring the pursuance of particular studies; a rule making it the duty of the teacher to keep a record of the standing of each pupil, and that this shall be forwarded to the parent and signed and returned by them; a rule authorizing the expulsion of a scholar for absence, even under the direction of the parent and the spiritual adviser of the child, in order to attend religious services; a rule providing that the pupils absent six half-days in four consecutive weeks without satisfactory excuse shall be suspended, are all reasonable and proper. Among rules which have been held to be unreasonable are one requiring that pupils shall be suspended for failing to bring into the schoolroom each day a stick of wood for the fire; a rule that a scholar living with his parents shall not go to a party; a rule requiring a pupil to pay for damage done to school property, under penalty of expulsion, etc. A general statement has been made that "any rule of the school not subversive of the rights of the children or parents, or in conflict with humanity and the precepts of divine law, which tends to advance the object of the law in establishing public schools, must be considered reasonable and proper."

The right of the school authorities to require the reading of the Scriptures in school has in some cases been held as unconstitutional, on the ground that it is sectarian instruction. The decision of the question depends upon the construction of the State constitution and its legislative acts,

but such a rule is generally sustained as being constitutional.

The rules and regulations affecting the subject of textbooks, school districts, formation of schools, and other matters affecting the physical property and being of the school, are so specific in their nature as not to admit of treatment in a work of this character.

F. Sturges Allen.

Schools of Fine Arts: Instruction in the fine arts follows a well-determined course in all the prominent art schools in Europe and the U. S. The pupil is first taught to exercise the eye and the hand by copying drawings or by drawing from simple objects cast in plaster. This is the elementary stage, and is often learned outside the classrooms. Drawing from plaster casts from various portions of the human figure taken from the antique statues is then followed by drawing from casts of the whole figure. Large sheets of white paper and charcoal or crayon are the materials generally employed. From this the pupil advances to drawing in the same manner from the nude model. Good instruction prescribes a long drill in drawing from the life, and painting from life follows. When the pupil has attained proficiency he may undertake creations of his own. In sculpture the instruction is similar, except that modeling is begun sooner after drill in drawing than painting. During the practice in drawing and painting from life the student attends courses in composition, makes trial sketches, and receives instruction in perspective and anatomy. In the summer vacations he is at liberty to make studies from nature out of doors; and while some landscape-painters have never attended any other school than that of nature, most of those in modern times who have achieved prominence have studied drawing and painting from the human figure. This study, it is agreed, is the best for the development of the artistic faculties; and while methods vary somewhat under different masters, it is and has been since the Italian Renaissance the basis of all art instruction.

In New York, the art center of the U. S., the most popular school for instruction in the fine arts, and the one with the widest reputation throughout the county, is that of the Art Students' League. It was established in 1878, and is maintained by art students of New York for the purpose of giving academic instruction in drawing, painting, modeling, and composition. Its studios and offices are in the building of the American Fine Arts Society, No. 215 West Fifty-seventh Street, the league being joint owner of the edifice with the Society of American Artists and the Architectural League of New York. The Art Students' League is incorporated, and is governed by a board of control, elected annually by its members. The average attendance in all the classes is from 1,000 to 1,200 pupils. Several distinguished artists have been or are now in the lists of instructors. Among those who have retired are William M. Chase, Augustus St. Gaudens, J. Alden Weir, H. Siddons Mowbray, George de Forest Brush, and J. Carroll Beckwith. In the season of 1899–1900 the life classes were taught by Kenyon Cox, George B. Bridgman, and Joseph de Camp. No examination is required for the antique classes, but applicants for admission to the life classes must submit a drawing of a full-length nude figure from cast or life. The fees for instruction in the various classes range from $4 to $12 a month. Four scholarships and three cash prizes are awarded annually.

The National Academy of Design has maintained a school for instruction in the fine arts since 1825. The classes are taught by prominent instructors chosen by the council from the body of Academicians and Associates. The Academy building, at the corner of Twenty-third Street and Fourth Avenue, New York, having been vacated in 1899, the schools are now established in a large and commodious building on the Academy's property on Cathedral Heights, corner of Amsterdam Avenue and 109th Street. The season, as in most of the principal art schools in the U. S., runs from the first of October to the latter part of May. The "schools committee" consists of H. Bolton Jones, J. Carroll Beckwith, and H. Siddons Mowbray. The life classes are taught by Edgar M. Ward and George W. Maynard. The painting classes in still life are under Francis C. Jones, etching is taught by James D. Smillie, and lectures on perspective are given by Frederick Dielman, president of the Academy. The antique classes are free, and are instructed by F. C. Jones and E. M. Ward. The Suydam and Elliott medals in silver and bronze and the Cannon, Hallgarten, and Baldwin money prizes are awarded annually. A high standard is maintained in the various classes, and the school equipment, while always adequate, is constantly being added to. A department of medal and coin engraving is among the new features in contemplation. The average attendance of pupils is about 300.

The New York School of Art resembles somewhat in its organization the Art Students' League. Douglas John Connah is the director and William M. Chase the chief instructor. The schoolrooms are at No. 57 West Fifty-seventh Street, and the average attendance of pupils is about 350. The life classes are under the instruction of William M. Chase, J. Carroll Beckwith, Frank V. Du Mond, D. J. Connah, and F. Luis Mora. The monthly fees range from $5 to $15. The Julian scholarship, entitling the holder to one year's tuition in the Académie Julian, Paris, and four other scholarships are awarded each year. The Shinnecock Summer School of Art, at Shinnecock Hills, near Southampton, Long Island, is closely allied with this school. Mr. Chase is its president and instructor and Mr. Connah its director. Open-air classes in painting from the model and landscape are held daily. The fees are $20 a month, or $65 for the season, from June 1 to Sept. 1. The attendance averages 125 in all the classes.

The Cooper Union for the Advancement of Science and Art, founded and endowed by Peter Cooper in 1857, maintains in its building at Astor Place, New York, free art classes for women and free night classes for men. R. Swain Gifford is the art director of the women's classes, and other instructors are Douglas Volk, Willard L. Metcalf, Miss Elizabeth A. Talbot, J. H. Twachtman, and Frederick Dielman. Miss Mary A. Vinton is the principal. Instruction is given in oil-painting, antique and life drawing, design, pen-and-ink illustration, miniature-painting, etc. The average attendance is about 300. Pupils are selected from the applicants, who must be at least sixteen and not over thirty-five years of age. In the night classes for men the same system is observed, and applicants must be at least fifteen years of age. The instruction in these classes covers mechanical drawing, architectural drawing, cast drawing, decorative designing, modeling, and perspective. Young women are admitted to the classes in perspective and in elementary architectural drawing. Pupils in all the classes at the Cooper Union have free access for study to the Museum for the Arts of Decoration, of which Miss Sarah Cooper Hewitt is chairman of the committee of management, and which possesses a valuable collection of casts, stuffs, costumes, embroideries, metal-work, and other objects of art. The reading-room and library of the Cooper Union are also open to students. The Pratt Institute in Brooklyn has art classes for men and women under the direction of Arthur W. Dow, and special attention is given in this institution to composition and to teaching industrial art. At the Metropolitan Museum of Fine Arts in New York free lectures on art subjects are delivered each winter by prominent artists under the auspices of Columbia University. Many small art schools and private classes in drawing, painting, and modeling exist in New York, and a few prominent artists take pupils in their own studios.

The Pennsylvania Academy of Fine Arts, Philadelphia, is the oldest art institution in the U. S., having been founded in 1805, and its art schools date from the same year. The schools are managed by a faculty whose members consist of officers of the institution and instructors of the classes. Edward H. Coates is president of the Academy, Harrison S. Morris is the managing director, and John H. Packard, M. D., is chairman of the faculty. The classes include drawing and painting from the antique and from life, modeling, perspective, composition, etc., and among the instructors are William M. Chase, Charles Grafly, Miss Cecilia Beaux, Henry J. Thouron, Thomas P. Anschutz, and Hugh H. Breckenridge. The Academy disposes of a traveling scholarship of $800 providing for a year's study abroad, of the Toppan, Stewardson, and other money prizes, the value of which is from $50 to $200. They are awarded at the opening of the spring exhibition of students' work. The fees for instruction range from $10 to $30 for each of two terms of seventeen weeks. A student's ticket entitles the holder, during and after attendance at the schools, to the use of the galleries, special exhibitions, the library, the print collection, and the courses of lectures given from time to time under the auspices of the Academy.

The school of drawing and painting connected with the Museum of Fine Arts, Boston, was established in 1876. Miss

Elizabeth Lombard is the manager. The committee in charge is composed of directors of the museum, prominent Boston artists, and patrons of the fine arts. Among the instructors are Edmund C. Tarbell, Frank W. Benson, Philip Hale, Bela L. Pratt, and Mrs. William Stone. The last named conducts a class in decorative design. Diplomas are given, upon application, to those students who have fulfilled the requirements of the committee. The fees are $45 for each of the first two terms of twelve weeks and $35 for the third term of nine weeks, but pupils who have paid the fees for the first two terms of any one year are entitled to free instruction for the third term of that year. The school awards ten scholarships annually and the Paige traveling scholarship providing $800 a year for two years to be spent in study abroad. The Hamblen scholarship gives the holder, who must be a young woman, a year's tuition and $100. The Sears and Thayer money prizes are worth from $25 to $75 each. The number of pupils in the school is limited to 200. In Boston also is the Cowles Art School, which has flourishing classes under a corps of competent instructors.

The art schools of the Art Institute of Chicago, of which Charles L. Hutchinson is president and W. M. R. French director, has a large annual enrollment of pupils, the total, including 300 Saturday special students, children and schoolteachers, reaching 1,800. The standard of the work is high and the facilities open to students include the collections of the institute, the passing exhibitions, the library, and courses of lectures. The schools are housed in the fine building of the institute and date from 1866. The instructors include Frederick W. Freer, Lorado Taft, Albert Herter, of New York, John H. Vanderpoel, and Miss Pauline A. Dohn. The school of architecture is an important department and has as instructors, besides others, Louis J. Millet, Walter F. Shattuck, William K. Fellows, and Albert Fleury. The fees for tuition are $75 per year, or less, and in 1897–98 the total received amounted to more than $34,000.

The St. Louis School of Fine Arts, St. Louis, Mo., is, with the art museum, a department of Washington University. The director is Halsey C. Ives, and among the instructors are Edmund H. Wuerpel, Robert P. Bringhurst, Charles Percy Davis, and Lawrence Ewald. The average of students enrolled in the classes is 350. Instruction is given in drawing, painting, modeling, composition, architectural and mechanical drawing, perspective, and anatomy. The fees are $25 for each of the three terms, or smaller charges for single classes. There are classes for public-school teachers and in design as applied to glass, mosaic, etc. The schools are housed in spacious quarters and the facilities include the collections of the museum, the library, and courses of lectures.

The Art Academy of Cincinnati is a department of the Cincinnati Museum Association, and is well endowed. The building is upon a hilltop in Eden Park, Cincinnati, O., and a summer school of art is also maintained for a term of ten weeks from June to September. The director is A. T. Goshorn, and the instructors include Prof. Thomas Noble, principal, Vincent Nowottny, J. H. Sharp, L. H. Meakin, and O. W. Beek. The average attendance of pupils is about 450. Besides the instruction in drawing, painting, and modeling there are classes in wood-carving, painting on porcelain, and photography. The fees for a year's instruction range from $5 to $25. The collections and library of the museum are accessible to students.

Some other schools of fine arts in the U. S. are those of the Corcoran Art Gallery, Washington, D. C., with 250 pupils; the Minneapolis Academy of Fine Arts, the Pittsburg School of Design for Women, and the academies at San Francisco, Cleveland, Buffalo, and Worcester, Mass. At Columbia University, New York, there is a fine school of architecture in which Profs. William R. Ware and A. D. F. Hamlin are the chief instructors. At Harvard and Princeton Universities lectures on the fine arts are regularly given, and in the scientific schools connected with these institutions there is instruction in free-hand drawing. At Yale University is the well-known Yale School of Fine Arts. It was founded under the Street endowment in the sixties, and gives complete instruction in the various branches of the fine arts. Prof. John F. Weir is the director and Prof. John H. Niemeyer one of the principal instructors. Women are admitted to any of the classes. Money prizes and the English traveling scholarship with an income of $2,000 for two years' study abroad are in the gift of the school. The Fine Arts building is on the college campus, and besides the schoolrooms contains several galleries which hold a valuable permanent collection of ancient and modern paintings as well as casts from the antique.

The American Academy at Rome, whose foundation in 1895 was largely due to the efforts of Mr. Charles F. McKim, of New York, occupies the Villa dell' Aurora, Rome, Italy, and has painters, sculptors, and architects sent from the U. S. as resident students. The recipients of the Columbia University and University of Pennsylvania scholarships in architecture, the Lazarus, Rhinehart, and other scholarships in painting and sculpture, are among the students. These scholarships are awarded by committees of artists, architects, and laymen residing in New York, Baltimore, and Philadelphia, and annual exhibitions of the work sent home by the students at the Villa dell' Aurora are held in one of the galleries of the Metropolitan Museum, New York.

The most noted school of fine arts in Europe is the École des Beaux-Arts, Paris, where many prominent art instructors in the U. S. received their education. Its school of architecture is easily the first in the world. The instructors in drawing and painting are leading masters in the French school of painting, and lectures are given by famous critics of art. The school is under the control of the French Government. An annual competition, or *concours*, is held in painting, sculpture, architecture, and engraving, and the winners of the first prizes, or *grands prix*, are sent at the public expense for from three to five years' further study at the French Academy at Rome. In Paris also are numerous art schools such as the Académie Julian, which has a large following of American students and numbers its pupils by hundreds, and *ateliers* or students' classes conducted—often without compensation, though pupils pay the expenses of rent, models, and heating—by prominent painters and sculptors. In Great Britain the chief art school is that of the Royal Academy, London. The Kensington Museum schools afford instruction in decorative and applied arts. There are art academies at Glasgow, Edinburgh, Dublin, Manchester, and other large cities. The Royal Academy schools at Munich, Bavaria, are the most famous in Germany, and during the period from 1870 to 1885 there were many American students there. Other noted German art schools are at Berlin, Düsseldorf, and Dresden. The Antwerp Academy is a famous school in Belgium, but its attraction for foreign students, like that of Düsseldorf, has long since departed. There is a flourishing art school at Brussels. In Italy the Academy of Saint Luke, and the schools at Florence, Turin, Venice, and Naples are the most prominent. At The Hague, Vienna, St. Petersburg, Madrid, and other European capitals there are art academies each with a large attendance of pupils. Something like our American summer schools are the painters' colonies in France, England, and Italy in the country districts. In these colonies, however, there are generally more artists with established reputations than there are pupils. Where the climate permits, many of these artists work the year round out of doors. Such art colonies in France are at Grez, Barbizon, and Marlotte, near the forest of Fontainebleau, at Giverny on the Normandy coast, and Pont-Aven and Concarneau in Brittany. In England there are painters and pupils at St. Ives and Newlyn on the Cornish coast, and in Italy at the island of Capri. Similar colonies in the summer season in the U. S. are at Windsor, Vt.; Easthampton, Long Island; Gloucester, Mass.; Mount Desert, Me.; and at various mountain villages in the Eastern and Middle Atlantic States.

WILLIAM A. COFFIN.

School Statistics: Of the earlier periods, no trustworthy school statistics are available. The social consciousness was late in awakening to the necessity of recording accurate information in regard to schools. With the development of the modern national systems of education, attention has been more and more directed to this point by Government officials. In the U. S. the State superintendent publishes an annual or biennial report upon the school system of the State, in which a large amount of statistical matter is included; but in few States have such reports been issued consistently over a long period of years. The same is true of the city superintendents. The U. S. Bureau of Education was established for the purpose of collecting statistics and disseminating information. This bureau, however, does not possess any authority to compel statistical returns, and, as a consequence, many of the blanks it sends out for information are not returned. This branch of its work has been developed with continually increasing efficiency, however, and new items are added almost yearly to the list of those subjects on which statistics are collected. In the matter of

educational reports, there is as yet no uniformity concerning returns which are of importance, and therefore there are few subjects upon which information may be found in all of the State and city reports. The adoption of a uniform system for educational reports would be of great service. The following items are taken for the U. S. from the *Report of the United States Commissioner of Education*, covering the years 1898–99.

For foreign countries, returns, unless other authority is given, are taken from the *Statesman's Year-book* for 1899.

The German Empire.

The total number of children of school age in 1890 was 8,694,887.

No official statistics of the number of schools, pupils, teachers, etc., are issued for the entire empire: but particulars on these heads will be found under some of the separate states. The number of elementary schools was estimated in 1891 at 56,560, of pupils attending them 7,925,000, and of teachers 120,030. The immediate expenditure on elementary schools was about 242,400,000 marks, of which 69,305,000 marks came from state funds (Brachelli, *Statistische Skizze des Deutschen Reichs*, 7th ed.). In 1897 the number of secondary schools was as follows:

Gymnasia	439	Realschulen	198
Progymnasia	92	Höhere Bürgerschulen	2
Realgymnasia	198	Other public schools	32
Realprogymnasia	93	Private schools	56
Oberrealschulen	40		

Elementary Schools in France (including Algeria).

C. H. Thurber.

Schreiner, Olive (Mrs. Cronwright): pseudonym "Ralph Iron"; b. in Cape Town, in the early sixties; daughter of a Lutheran minister and sister of the Hon. W. P. Schreiner. She went to England when twenty years old and there published her first novel, *The Story of an African Farm*. She has since published *Dreams* (5th ed. 1893), *Dream Life and Real Life* (1893), *Trooper Peter Halket of Mashonaland* (1897), and *An English South African's View of the Situation* (1899).

Schreiner, W. P.: South African lawyer and politician: b. in Cape Colony about 1855; was educated at South African College, Cape Town, and Downing College, Cambridge, England, where he was senior in the law tripos of 1882; read law, and was called to the bar at the Middle Temple. He became prominent in Mr. Rhodes's second ministry in 1893, when he was made attorney-general; in 1896 was made a delegate to conduct negotiations as to railway and customs difficulties between Cape Town and the Orange Free State; was a witness before the British South African committee in the House of Commons in 1897; premier of the Cape Parliament in 1898. F. Sturges Allen.

Schürer, Emil, D. D.: Protestant German theologian; b. in Augsburg, May 2, 1844; studied at Erlangen, Berlin, and Heidelberg; became tutor at Leipzig 1869; professor extraordinary 1873; ordinary professor at Giessen 1878, at Kiel 1890, at Göttingen 1895. He is the author of the *Lehrbuch der Neutestamentlichen Zeitgeschichte* (Leipzig, 1874), which in much enlarged form was republished under the title

Geschichte des jüdischen Volks im Zeitalter Jesu Christi (1886–90, 2 vols.; 3d ed., in 3 vols., 1898–99); English translation, *A History of the Jewish People in the Time of Jesus Christ* (Edinburgh, 1885–91, 6 vols.). In 1876 he founded the *Theologische Litteraturzeitung* (Leipzig), and has ever since been its editor, but since 1881 in connection with Prof. A. Harnack, now of Berlin University. S. M. J.

Schweinitz, Emil Alexander, de, M. D., Ph. D.: chemist; b. in Salem, N. C., Jan. 18, 1865; son of Bishop E. A. de Schweinitz; graduated at the University of North Carolina in 1882, where he remained as an instructor until 1884, when he went to Germany and studied chemistry in the University of Göttingen, where in 1886 he received the degree of Ph. D. On his return to the U. S. he became connected with the chemical laboratory of the U. S. Agricultural Department in Washington, and is now director of the biochemic laboratory of that department. For some years he has held the chair of Chemistry in the Columbian University Medical School, and is now dean of that institution. He is a member of numerous scientific societies, including the American and German Chemical Societies, and in 1896 he was president of the Washington Chemical Society. He represented the U. S. at the tuberculosis congress held in Berlin in 1899. He was a member of the jury of hygiene at the Tennessee Centennial Exposition, and received the honorary degree of M. D. from Columbian University in 1894. He is the author of many papers, most of which have been along the lines of biochemistry. Marcus Benjamin.

Schytte, Ludwig: pianist; b. in Aarhuus, Jutland, Denmark, Apr. 28, 1848: after studying chemistry, devoted himself to music in his twenty-second year; studied under several teachers of piano, then under Gade in composition. In 1884 he was in Berlin, and in 1885 was appointed teacher of the highest class in Horak's music academy in Vienna. Here he became associated with Moriz Rosenthal, who plays many of his compositions. These enjoy considerable popularity, but are mostly for the very advanced pianist, abounding in difficulties. D. E. Hervey.

Scots Law, or **Law of Scotland**: The municipal law of Scotland consists, like that of most other countries, partly of statutory or written law, which is embodied in the statutes and decisions of the courts, and partly of the customary or unwritten law, which derives its validity from presumed or tacit consent.

In their earliest form the laws of Scotland are closely analogous to those of Anglo-Saxon England and the other Teutonic nations of Northern Europe. Its present form is the result of modifications due chiefly to the intimate connection which existed for several centuries between Scotland and the Continent of Europe, especially France; and the union of Scotland and France, arising out of the French connection, resulted in a large infusion of the Roman civil law of marriage, guardianship, contract, and the like, and the adoption of several peculiarly French judicial arrangements, such as the constitution of the college of justice, and the model of the parliament of peers, the institution of a public prosecutor of crimes, and the adoption of much of the legal and official terminology common to the legal and judicial systems of the Continent. These peculiarities were also heightened by the custom of the Scotch lawyers of going to the universities of Italy and Holland for legal instruction.

The modifications of the laws of Scotland arising from the union of Scotland and England are most perceptible in the different departments of the mercantile law and in the law of evidence; and the assimilation of the laws of the two countries is continually going on.

The statute law of Scotland may be divided into two distinct, and in many respects dissimilar, portions, the first consisting of those enacted by the Parliament of Scotland from the time of James I. down to the union with England in 1707, and the second of those enacted by the Parliament of Great Britain subsequent to 1707. The public general statutes enacted by the Parliament of Great Britain are presumed to apply to the whole United Kingdom, but this presumption may be overcome by express provision, or by implication. In those cases where an enactment applicable to Scotland is expressed in the English legal terminology, in its interpretation the Scotch words most closely analogous should be applied. The unwritten or customary law of Scotland is commonly held to include the laws made prior to the reign of James I., it being held that these "have gradually lost their statutory force, by their not having been preserved from interpellation by any public record."

The ordinances made by the court regulating the forms of proceeding to be observed in questions of practice commonly called the law of sederunt are also generally considered to be a part of the written law of Scotland, the Court of Sessions having had a delegated power from Parliament to "make such acts, statutes, and ordinances as they shall think expedient for ordering of process and hasty expedition of justice."

The most ancient of the written laws of Scotland are contained in the books of *regiam majestatem*, now considered to be a private transcription of Glanvil's treatise on the laws of England, altered so as to adapt them to recognized practice in Scotland, but feigned to have been compiled by order of David I.; the burgh laws enacted by David I., the statutes of William, Alexander II., David II., and the three King Roberts, all of which were collected and published by Sir John Scheene, clerk register in the beginning of the seventeenth century.

The decisions of the Court of Sessions are commonly considered to be a part of the customary law, and only binding upon the litigating parties; but where they embody a ground of judgment and not a mere *obiter dictum*, the judgment of a superior court is binding in a similar case upon an inferior or co-ordinate court unless itself modified by the statute.

The civil and canon laws, although they have had a very great influence upon the laws of Scotland, are not deemed to be properly parts of its written law. Nevertheless, their influence was such that the powers exercised by the sovereigns and judges of Scotland have been justified upon the ground that they were conformable to the civil or canon laws; and until the time of the Reformation, when a statute was passed rescinding so much of the constitution of Scotland as was repugnant to the Protestant doctrine, they were of great weight in matters of interpretation or the adjudication of the unwritten law. From the time of the Reformation the canon law has been little respected, and it does not now obtain except where it has been acknowledged by a statute or a decision of the courts, or has been adopted in the canons of a provincial council. The Roman law, however, still continues to have great weight in all cases where it is not contrary to statute or custom, and where its application accords with the genius of the Scots law.

For a full treatment of the history and specific provisions of the law of Scotland, see Lorimer's *Handbook of the Law of Scotland* (6th ed. 1894); Erskine's *Principles of the Law of Scotland* (19th ed. 1895); Bell's *Principles of Law* (1890).

F. Sturges Allen.

Scots Money: a term applied specifically to the money used in Scotland before her union with England. When money is mentioned in the acts of Parliament of Scotland or in judicial or public proceedings prior to the union, and for some time after that, Scots money is meant, unless the contrary be expressly stated. This money is one-twelfth the value of sterling money. The following is a table showing the relative value of Scots money and sterling money:

Scots.	Sterling. £	s.	d.
1 doyt, or penny	0	0	$0\frac{1}{12}$
1 bodle, or twopence	0	0	$0\frac{2}{12}$
1 plack, groat, or fourpence	0	0	$0\frac{4}{12}$
1 shilling	0	0	01
1 merk, or 13*s.* 4*d.* (two-thirds of a pound)	0	1	$1\frac{4}{12}$
1 pound	0	1	8
100 pounds	8	6	8

F. Sturges Allen.

Scott, Colin Alexander, Ph. D.: educator; b. near Ottawa, Ontario, Feb. 11, 1861; studied in New York city grammar schools, College of the City of New York 1878–79, Toronto Normal School 1880; graduated at Queen's University, Kingston, with honors in chemistry and biology, in 1886; fellow in psychology, Clark University, 1895–97; Ph. D., Clark University, 1897; supervisor and teacher of drawing, Kingston public schools, 1886–87; science master, Ottawa Collegiate Institute, 1887–95; head of department of psychology and child-study, Chicago Normal School, since 1896. He is author of *Sex and Art* and *Old Age and Death* (*American Journal of Psychology*, 1896); *Psychology and Adolescence* (N. E. A. *Proceedings*, 1897); and various poems and magazine articles; as an artist has been an exhibitor at Royal Canadian Academy, Boston Art Club, Art Institute, Chicago, etc. C. H. Thurber.

Scott, Rev. Frederick George: author; b. in Montreal, Apr. 7, 1861; educated at Bishop's College, Lennoxville, and at King's College, London. He entered the ministry in 1886, and ten years later became curate of St. Matthew's, Quebec. Besides a novel, *Elton Hazelwood* (1893), he has published three volumes of poetry: *My Soul's Quest, and other Poems* (1888); *My Lattice, and other Poems* (1894); and *The Unnamed Lake, and other Poems* (1897).

Scott, Sir John, K. C. M. G., D. C. L.: English lawyer; b. in Wigan, Lancashire, in 1841, his father being a solicitor of that place; was educated at Bruce Castle School, Tottenham, and at Pembroke College, Oxford, receiving his degree of bachelor of arts in 1865, and of master of arts in 1868; read law in the Inner Temple, and was called to the bar in 1865, and took up the practice of his profession on the northern circuit. He was appointed a judge and afterward vice-president of the international court of appeal in Egypt 1874–82; judge of the high court at Bombay 1882–90; and was judicial adviser of the Khedive of Egypt 1890–98. He has received decorations of several honorary societies, including the grand cordon of the Medjidieh and the grand cordon of the Osmanieh. In 1898 he was appointed deputy judge-advocate-general to the royal forces of Great Britain. He was knighted in 1894. F. Sturges Allen.

Scott, Julian: artist; b. in Johnson, Vt., Feb. 14, 1846; entered the Union army at the outbreak of the civil war; studied art at the National Academy in 1863, and afterward under Emmanuel Leutze; became an associate of the Academy in 1871, and was made life fellow of the American Geographical Society in 1873. Among his paintings, which chiefly portray army life, are *Rear-Guard at White Oak Swamp*; *Battle of Cedar Creek*; *The Recall*; *Battle of Golding's Farm*; *On Board the Hartford*; *Old Records*; *Duel of Burr and Hamilton*; *Reserves Awaiting Orders*; *In the Cornfield at Antietam*; *Charge at Petersburg*; *The War is Over*; and *The Blue and the Gray*. D. July 4, 1901.

Screw Propeller: an appliance whereby may be obtained the thrust necessary for the propulsion of a ship through the water. Geometrically, a screw propeller may be defined as consisting of one or more blades having on the rear or driving side an approximately helical surface, such blades being joined to a common boss or central portion through which they receive their motion of rotation in a transverse plane relative to the ship. Fig. 1 shows a four-bladed right-hand propeller. A propeller is said to be *right-hand* or *left-hand* according as it turns with or against the hands of a watch when viewed from aft and driving the ship ahead. The *face* or *driving-face* of a blade is the rear face. It is that face which acts on the water, and which in return receives the excess of pressure which gives the driving thrust. The *back* of a blade is on the forward side. The *leading* and *following edges* of a blade are respectively the forward and after edges. The *diameter* of a propeller is the diameter

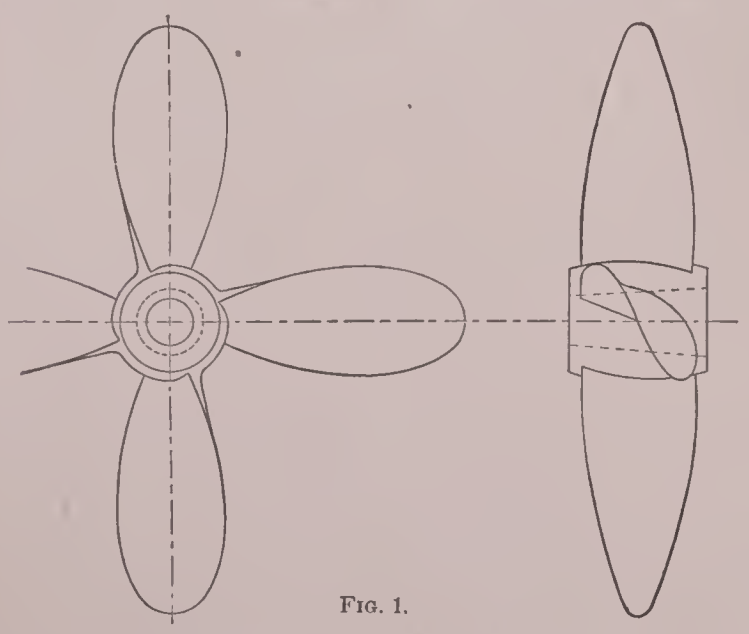

Fig. 1.

of the circle swept by the tips of the blades. The pitch is the axial distance between two successive convolutions of the helical surface. In an actual propeller the term should be understood as strictly referring to a small element of the driving-face only. With this understanding the pitch may be defined as the longitudinal distance which the ship would be driven were such element to work on a smooth, unyielding surface, as the corresponding helical surface of a fixed nut. Pitch is thus seen to be purely a geometrical function of the propeller. Its value may vary from point to point over the entire driving-face, or it may be constant. In the latter case the propeller is said to be of uniform pitch. If it increases as we go from the hub toward the outer circumference, the pitch is said to increase radially. If it is greater on the following than on the leading edge, the pitch is said to increase axially. The latter mode of variation is usually implied by the simple term *increasing* or *expanding pitch*. The *pitch ratio* is the ratio of pitch to diameter. The *slip* of a propeller is the difference between the distance which the ship would go were the propeller to work with its face on a smooth, unyielding surface and the distance traveled in the actual case. For one revolution the former distance is the pitch as above defined. The *slip ratio* is the slip for one revolution divided by the pitch. The *area*, *developed area*, or *helicoidal area* of a blade is the actual surface of the driving-face. For the propeller it is, of course, the sum of the areas of the blades. The *projected area* is, correspondingly, the area of the projection, on a transverse plane, of one blade or of all the blades. The *disk area* is the area of the circle swept by the tips of the blades. The *boss* or *hub* is the central body to which the blades are all united, and which in turn is attached to the shaft.

Returning now to the geometry of the propeller, we will consider the principal forms which may be produced. Taking

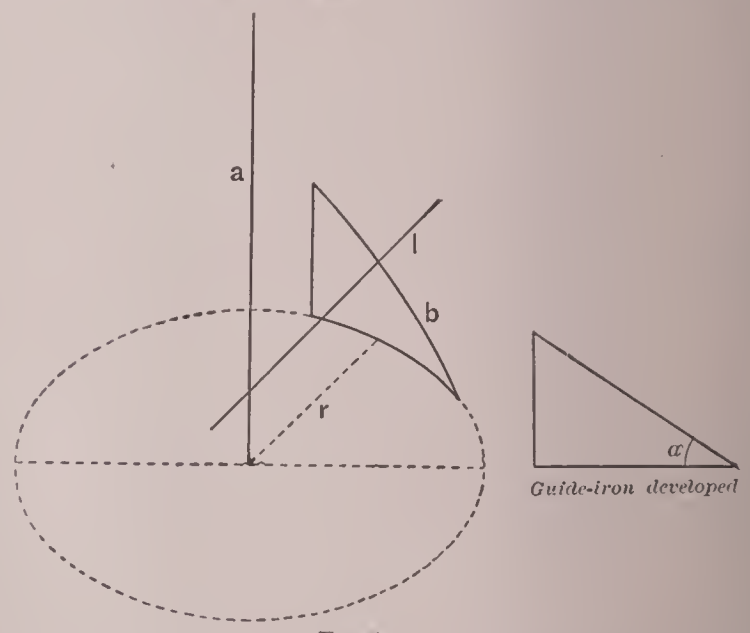

Fig. 2.

the common helical surface of uniform pitch as standard, we may generate such a surface by a line, l, Fig. 2, moving so as to touch the axis a and the guide b, and remain always at a fixed angle of 90 degrees with the axis. The guide b, or *guide-iron*, as it is termed, lies in the surface of a cylinder of which a is the axis. The surface of this cylinder being developed, we have the actual or developed form of the guide-iron. In the present case this will be a straight line inclined to the transverse, or development of the circumference, at an angle α, and if r is the radius of the cylinder containing the guide-iron the pitch p will have the value $p = 2\pi\ r \tan \alpha$. The surfaces for most of the forms of propellers may be generated by variations in the generatrix l, or in the guide-iron b, or in the duplication of the latter. The variations found in l are as follows: (1) Straight and at right angles to a; (2) straight and inclined to a; (3) bent or curved in an axial plane; (4) bent or curved in a transverse plane. The developed guide-iron may have its edge either straight or curved. The curvature is usually such that the angle α, and hence the pitch, increases from the forward to the after edge. Where two guide-irons are used corresponding to different values of the pitch near the hub and tip, there will be a continuous radial change in the pitch. We may have also other forms of helicoidal surface which can not be generated by a rigid line in any manner. We may most readily conceive of such a surface as made up of the summation of an indefinite number of guides, b, and thus as generated by a variable guide moving radially, and perhaps angularly and longitudinally as well, and taking at the same time the successive shapes and inclinations as determined by the nature of the pitch at the successive radial locations. In this way any form of blade and any distribution of pitch, no matter how complex, may be geometrically determined,

and by the use of a reasonable number of guides actually produced in the form of a pattern, or moulded direct in the foundry.

It is thus possible to form an indefinite variety of propellers as regards shape of blade and distribution of pitch, and to use either two, three, or four, or even more blades for a propeller. But few among this great variety of forms are, however, in practical use. The propeller of uniform pitch with blades at right angles to the axis, generated as described above, is most commonly met with. Instead of making a right angle with the axis, the blades are often bent back from the plane of rotation. The surface for such a blade may be generated by inclining the generatrix at an appropriate angle, usually from 5 to 15 degrees from the perpendicular. The pitch, instead of being uniform, is often caused to vary over the surface of the blade according to some more or less definite law. The most common variation of pitch is an increase from the forward or leading edge to the after or following edge. Such a surface may be generated by giving to the edge of the developed guide-iron an appropriate curvature, as noted above. The pitch may also be given a radial variation, in such case being usually made less near the hub than at the tip of the blade. As noted above, such a surface requires two guide-irons, one near the hub and the other near the tip, each adapted to the pitch at that part of the blade. In some cases the distribution of pitch is still more complex. For a certain distance from the hub outward, for example, the pitch may remain constant, then increase rapidly by some 15 or 20 per cent., and then decrease again to a smaller value near the tip. In such case the surface can not be generated by a rigid line, but, as noted above, may be considered as an aggregate of an indefinite series of guide-irons varying in such manner as to give the distribution of pitch desired.

There is at present little or no scientific foundation for the various departures from a uniform pitch. Theoretical examination can not settle the question of the best distribution of pitch, and it has not yet been made the subject of experimental investigation. So far as experimental results seem to indicate, the uniform pitch is quite as efficient as other distributions more or less irregular in character.

In modern practice the screw propeller is usually of either three or four blades. There is little scientific ground for choosing between the two, except that for the same work under the same conditions the propeller of three blades will be necessarily some 10 per cent. greater in diameter than that of four. The actual area of the blades, or *helicoidal area*, is usually made a certain fraction of the *disk area*, or area of the circle swept by the tips of the blades. This proportion is usually found between ·25 and ·35 for three blades and between ·35 and ·50 for four blades. The shape of the blades has undergone considerable modification in the course of the development of the typical modern screw propeller. The earlier forms of blades were more or less trapezoidal in form, widening toward the tips and with only slightly rounded corners. The modern form of blade is distinctly oval or elliptical in form, as shown in Fig. 1.

Fig. 1 shows the propeller cast entire, or with the blades fast to the hub. Most large propellers in modern practice are made with blades and hub cast separately. The blades are then attached to the hub by bolts, or by some form of dovetailed and keyed joint. This type of construction has advantages where a large number of propellers are to be made, but its chief feature lies in the readiness with which a broken or damaged blade may be removed and replaced by a new one, instead of by a new propeller entire, as would be necessary with the solid type of construction. When the blades are bolted to the hub, it is also usually so arranged that they may be twisted about a radial axis a little way on either side of a mean position, thus effecting within moderate limits any desired change of pitch.

It should be noted that such a rotation is in the nature of a distortion, and does not equally affect the pitch, so that if it is normally uniform it will not so remain after the change, and the surface will have undergone geometrically an entire change of character. The amount of variability is slight, with the usual amounts of rotation, so that the method is available as a practicable way of effecting moderate changes in the effective or average pitch of the propeller.

Propulsive Action.—The fundamental problem in propulsion is to find a thrust whereby we may overcome the resistance which the ship meets when moving through the water. The action of a screw propeller in developing this propulsive thrust may be viewed from two standpoints, as follows:

We know that the production of a change of momentum requires the action of a force and the expenditure of energy, and that conversely the matter acted on will react on the agent producing the change of momentum, such reaction being, in fact, the resistance opposed to the change of momentum. If, therefore, we provide an agent attached to the ship which shall produce a change of momentum in matter of any kind, such change of momentum being directed astern, or at least having a sternward component, there will result on the agent a reaction having a forward component, such reaction being then available as a propulsive thrust.

Viewed from this standpoint it is the office of the propeller to act on the water as a convenient medium, and to impart to it an accelerated motion having at least a sternward component. It will then receive the corresponding forward reaction, and thus will be developed the propulsive thrust desired.

Turning now to the second view, it is a fact of common experience that no body can be moved through a liquid without experiencing a resistance. Let us then consider the pair of bodies formed by the ship and propeller, the latter being given motion relative to the former. Such motion will meet with a resistance which is simply the resultant of the distributed systems of pressures and tangential forces acting on the surface of the moving body. This resistance, as a resultant force, is not, in general, in a line directly opposed to the direction of motion. Especially with the form given to the propeller-blade, as shown in section in Fig. 3, the resulting total resistance has a direction somewhat as indicated by A B, lying only slightly inclined to C B, the perpendicular to the surface. The force A B which thus acts on the blade has a longitudinal component D B, which acts directly as a propulsive thrust. The mathematical investigation of the action of the screw propeller from the first standpoint would require a determination of the relation between the propeller and its motion, on the one hand, and the amount of water acted on and the sternward acceleration imparted to it, on the other. The investigation from the second standpoint would require a determination of the relation between the propeller and its motion, on the one hand, and the resulting distributed system of surface forces, or at least the resultant total resistance, both in direction and amount. None of these determinations in general terms is possible, with any satisfactory degree of accuracy, and it thus follows that, from the standpoint of pure mathematics and mechanics, the investigations are necessarily limited to ideal cases, which are of interest and value as giving the results for certain hypothetical or limiting conditions, but which require to be modified by factors derived from experimental investigation before they can be made of use for purposes of design. By this combination of theoretical and experimental investigation a fairly satisfactory working theory of the propeller has been derived. It thus appears that we may take the thrust developed by the propeller as directly proportional to the square of the diameter, the square of the pitch, and the square of the revolutions; as increasing with the slip ratio rather more slowly than in direct proportion; as decreasing with increase of pitch ratio rather more rapidly than in inverse proportion; as increasing with increased area of blade very slowly beyond the usual area proportions; and as varying with the shape of blade nearly in the ratio of the moment of inertia of the blade area about the axis of rotation.

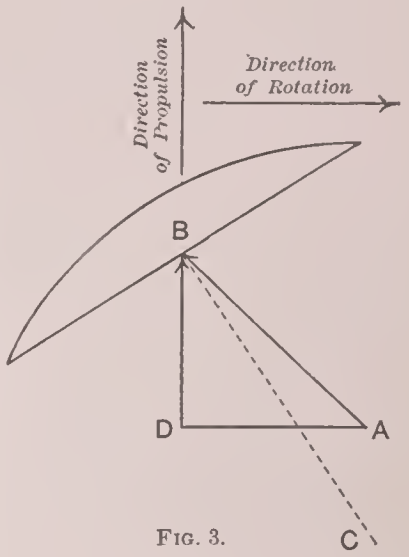

Fig. 3.

The product of the thrust by the distance traveled gives the useful work, while the total work will equal the useful work divided by the efficiency. The latter term, which in engineering always means a proportion of returns to expenses, means here, of course, the ratio between the return in the shape of useful work and the expense in the shape of total work furnished to the propeller.

The efficiency is chiefly dependent on the pitch ratio and

slip. Under favorable circumstances it is found between ·65 and ·70. For a pitch ratio of about 1 the highest efficiency, with normal area and shape of blade, corresponds to a slip ratio of about 18 per cent.; for a pitch ratio of about 2 the highest efficiency corresponds to a slip ratio of about 23 per cent.

Fig. 4 shows three efficiency curves derived from experimental results, and corresponding to pitch ratios as indicated. All propeller efficiency curves show the same leading

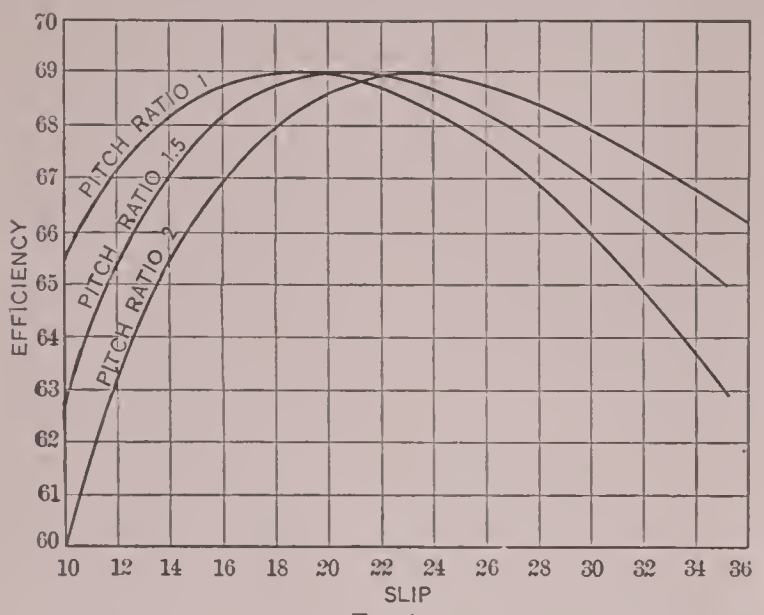

Fig. 4.

characteristics. The value falls off from the maximum much more rapidly for a decrease of slip than for an increase, while for a considerable range of slip variation the change in efficiency is but slight, thus making possible a fairly good economic performance, even with some uncertainty in the conditions.

At excessively high rotative and peripheral speeds such as are occasionally met with in cases of advanced practice, especially when combined with a large slip, a phenomenon has recently presented itself to which the term *cavitation* is applied. In the case of a moving immersed body, the water behind the body closes in and fills up the open space in the wake which the motion would tend to form. The water thus closes in by virtue of the static pressure head, and its velocity will depend on such pressure, and hence on the depth. If the velocity of the body be sufficiently high, it will exceed the rate at which the water can flow in behind it, and thus will be formed an open or partly vacuous space in the wake of the moving body. This result is occasionally reached with propeller-blades at very high speeds, and it is found, under such circumstances, that but little additional thrust is gained by an increase in revolutions, while the efficiency undergoes serious loss.

It is always desirable, therefore, to avoid the conditions giving rise to the phenomenon of cavitation. This can usually be attained by appropriate design. In some cases the difficulty has been obviated by the use of two or three screws on one shaft, and two or more shafts, thus subdividing the power among several screws, for which the conditions will be less trying than with one or two of larger diameter.

Reaction between the Ship and Propeller.—The action of the propeller as discussed above involves the slip ratio as one of the determining conditions. Considering the propeller as working in undisturbed water, the meaning of this term is without ambiguity. In the actual case, however, the propeller works behind a ship, and in the wake produced by its motion through the water. The constitution of this wake must be briefly noted. The surface of the ship through molecular forces, and by reason of its slight irregularities, sets in forward motion a thin layer of water, of which that near the surface moves with nearly the velocity of the ship itself, while as the distance from the surface is increased the velocity rapidly decreases. The water thus acted on by the skin of the ship is finally found at the stern, where, influenced still further by wave and stream-line motion, it forms the so-called wake. The forward velocity in the wake at different points in a transverse plane at the stern is quite variable, rising as high as 50 or 75 per cent. of that of the ship at points near the stern-post at the surface, and decreasing both outward and downward to nothing as the outlying water is reached. For single-screw ships the average value in that part of the wake influenced by the propeller is usually found between 10 and 20 per cent. of the speed of the ship. For twin-screw ships the propellers are located somewhat outside the strongest part of the wake, and the average value for that part influenced by them is usually found between 6 and 10 per cent. of the speed of the ship.

It follows that the actual propeller works in a stream of water flowing forward relative to the surrounding body of still water with an average velocity from 5 or 6 to 20 per cent. or more of the velocity of the ship. It is clear that the performance of the propeller will depend fundamentally upon the water in which it works and on which it acts, rather than upon the outlying body of undisturbed water. Hence the value of the slip as related to the thrust developed and to the efficiency must be reckoned relative to the wake, and not to the outlying undisturbed water. The slip relative to the outlying water is, however, of importance in the process of design, so that we have thus two different slips to be taken into consideration. Their relation may be seen as follows: Taking all velocities relative to the outlying still water, let u be the velocity of the ship and v that of the wake, both in feet per minute. Then $(u - v)$ is the speed of the propeller through the wake. Also let p denote the pitch of the propeller and N the revolutions per minute. Then, if there were no slip, pN would be the speed through the water in which the propeller works. The difference $pN - u$ is called the apparent slip, and is evidently the slip relative to the outlying still water. The difference $pN - (u - v)$ or $(pN + v) - u$ is the true slip, or the slip relative to the water in which the propeller works. The difference between the two is readily seen to be the wake velocity, as we should expect—the true slip being greater than the apparent by the amount of this difference. When the term slip is used in a loose or popular way, it is usually the apparent slip which is intended. When it is used as one of the conditions controlling the performance of a propeller, the true slip is implied. The statements made above regarding the relation of the slip of the propeller to its performance refer solely to the true slip.

The ship is thus seen to exercise, through the wake which it causes, a modifying influence on the performance of the propeller. On the other hand, the propeller, by the nature of its action, exercises an influence over the resistance of the ship. This arises in the following manner: As we have already seen, the action of the propeller is to produce an acceleration in the water acted on. In the actual propeller this is produced partly in front of the propeller and partly in and aft of the propeller. That part of the acceleration produced in front of the propeller arises from a defect of pressure extending some little distance forward, and in answer to which the water flows aft toward the propeller and in the direction of decreasing pressure with increasing velocity. It follows that extending throughout the water for some little distance forward of the propeller is a region of decreased liquid pressure. This will result in a decreased forward pressure on the stern of the ship, and in a virtual increase in the resistance to be overcome. (See Resistance.) Somewhat more popularly the action of the propeller may be likened to a pump drawing water away from the ship and delivering it sternward with an accelerated velocity. This results in the same decrease of liquid pressure about the stern, and in the increase of resistance as before.

The true resistance to the motion of a ship is considered as the tow-line resistance—that is, the resistance measured by the pull on a tow-line necessary to move the ship at the given speed. The actual resistance, including this effect due to the propeller, is known as the augmented resistance, and the increase chargeable to the action of the propeller is correspondingly termed the augmentation of resistance.

The actual thrust developed by the propeller must, of course, equal the augmented resistance. The augmentation effect implies, therefore, a loss in efficiency corresponding to the increase in thrust which must be developed, as compared with the true or tow-line resistance.

On the other hand, the location of the propeller in the wake enables it to regain part of the energy spent in forming the wake, and thus to develop the necessary thrust with a lesser expenditure of power than if it worked in the outlying still water. This action is known as the *wake-return*, and implies a gain in efficiency due to the location of the propeller within the wake. Experiment shows that for all normal conditions the loss due to augmentation and the

gain due to the wake increase and decrease together, and at all times very nearly balance each other, leaving the net work of the propeller nearly the same as that which would be required to move the ship at the same speed by means of a tow-line. The power required for the latter is known as the *effective horse-power*, and is usually from 50 to 60 per cent. of the indicated horse-power. The remaining 50 to 40 per cent. represents the power lost in the friction of the engine and line-shaft, and in the propeller as an instrument of propulsion.

Number and Location of Propellers.—The number of propellers fitted will depend on the desired subdivision of power, the available draught, and the desired number of revolutions of the engines. In many cases the total power is more than is readily transmitted with one shaft, and thus two or more shafts and propellers are fitted. Considerations of safety against breakdown and increase of manœuvring power point also toward subdivision of the power and two or more propellers. Again, the draught may be so limited, or the power so great, that a single screw would be of too large a diameter for the needed immersion of the blades. In such cases, also, two or more propellers may be fitted, thus reducing the diameter to a value suited to the draught of the ship.

The location of the propeller depends on the question of augmentation of resistance, on its relation to the wake, and on structural considerations. If single it is usually placed directly aft of the stern-post, at such distance as the necessary structural arrangements make convenient. Twin screws are located one on each side, close about the stern-post or slightly forward, usually, though not always, in the same transverse plane.

With the cut-up form of stern commonly found on torpedo-boats, fast yachts, etc., the propeller or propellers come entirely underneath the structure of the boat. This favors a full and free flow of water to the propeller, and tends to decrease augmentation of resistance.

Materials.—For the material of screw propellers cast iron, cast steel, brass, gun-metal, and the various bronzes are used. Cast iron is the cheapest, but, being relatively weak and brittle, the blades are necessarily thicker and less efficient than with steel or bronze. The strength available is usually from 20,000 to 25,000 lb. per square inch of section.

Cast steel is stronger than cast iron, its ultimate strength in castings suitable for propeller-blades ranging from 50,000 to 60,000 lb. per square inch of section. The sections may therefore be made thinner, and a better efficiency obtained in so far as dependent on this feature. The surface is naturally not as smooth as that of cast iron, but with improved methods of production the difference in this feature is insignificant.

Bronzes have naturally a smoother surface, and seem, furthermore, to have a lower coefficient of skin resistance. This, added to their strength and good casting qualities, makes possible a relatively smooth, thin blade with sharp edges, all of which are features favorable to good efficiency. The strength available with the best bronzes varies from 40,000 to 60,000 lb. per square inch of section. With ordinary gun-metal from 25,000 to 35,000 lb. per square inch of section may be allowed, while with common brass not more than 20,000 to 25,000 lb. should be depended upon. Of these various alloys, manganese bronze is probably more used than any other, because of its better combination of desirable qualities, resistance to corrosion, etc. Its greater relative cost restricts its use, however, to war-ships, yachts and launches, ocean-liners, and other cases where the importance of a saving in propulsive efficiency is considered worth obtaining at a slight increase in first cost.

The durability of propeller-blades is, in the order, bronze, cast iron, cast steel. The last two usually deteriorate by general corrosion and local pitting, the average life being usually from five to ten years. The life of bronze blades is practically indefinite, or at least as great as that of the ship itself.

Field of Employment.—For the propulsion of war-ships of all classes and of all vessels engaged in deep-sea navigation, the screw propeller may be said to be exclusively employed. It is also used on all tugboats, fast yachts, launches, and like craft, and its use is rapidly extending for bay and river steamers, a field long held by the paddle-wheel as peculiarly its own.

For more detailed information on this subject, reference may be made to the following papers and works: William Froude, in *Transactions Inst. of Naval Architects, London* (vol. xix., p. 47); R. E. Froude, *ibid.* (vol. xxiv., p. 231; vol. xxvii., p. 250; vol. xxx., pp. 390, 406; vol. xxxiii., p. 265); A. G. Scripture, Edward Wheeler, Ph. D. (Leipzig): psychologist; b. in Mason, N. H., May 21, 1864; studied at the College of the City of New York and the Universities of Leipzig, Berlin, and Zurich; was fellow at Clark University 1891–92. In 1892 he was made instructor in experimental psychology at Yale University, and in 1898 was appointed director of the psychological laboratory there. His principal works are *Arithmetical Prodigies* (1891); *Thinking, Feeling, Doing* (1895); *The New Psychology* (1897); and various articles in psychological magazines. He is editor of the annual *Studies from the Yale Psychological Laboratory*, containing results of the investigations made there. He has devised numerous psychological apparatus, including a pendulum chronoscope. Howard C. Warren.

Sea Laws: This term is used in general to designate the laws relating to maritime or admiralty matters; but it is more usually and specifically used to designate what are technically known as the *rules of the road*. In the first and broad sense of the word it includes the general admiralty laws regulating the rights of merchants in time of war and peace, the rights of masters of ships and of seamen, the rights of belligerents and neutrals in time of war, etc. For full treatment of these subjects, see Admiralty, Masters of Ships, Rules of the Road, Belligerents, Neutrals, etc.
F. Sturges Allen.

Sea Letter, or **Sea Brief**: a document which is required by the law of nations to be found on board of every neutral ship as one of its papers evidencing its title to neutrality. It specifies the nature and quantity of the cargo, the port whence it was shipped, and the port of its destination. It is analogous to the passport of an individual. See Chitty's *Treatise on the Law of Nations.* F. Sturges Allen.

Search-light: an electric arc-lamp in combination with mirrors or lenses so adjusted as to project the light in a nearly cylindrical beam. The apparatus as a whole comprises the following chief items: (1) The lamp and its focusing mechanism; (2) the projecting mirrors or lenses; (3) the means for controlling the lamp as a whole, and thus for directing the beam where desired.

The lamp is of the ordinary arc type, but must be provided with means for adjusting the arc at the principal focus of the mirror. This may be done automatically, or by direct hand control, or by a combination of the two. The last method may be preferred, as no form of automatic control can be depended on to take care of all contingencies which may arise in the nature of the arc or form of the carbon-points. At the same time, the best forms of regulators will satisfactorily control the arc under all ordinary circumstances, thus dispensing with the close attention necessary with hand control alone.

The lamp may be either inclined or horizontal. With the former the rays of light readily reach the mirror, but a small change in the location of the arc removes it from the principal optical axis of the mirror, and may cause loss of light in the reflected beam. With the latter, the larger positive carbon facing the mirror, the light is to some extent intercepted by the negative carbon; but changes in the location of the arc do not remove it from the optical axis, and only a slight loss in concentration results from a moderate lack of adjustment in the focus. The chief advantage of the horizontal lamp seems to be in its readier adaptation to automatic control than that of the inclined lamp. Both types of lamp are employed in standard forms of search-light.

The optical part of the apparatus consists of a concave mirror, of which there are three types: parabolic in form and of polished metal; parabolic in form and of glass silvered on the convex side; spherical in form and of glass silvered on the convex side. Polished metal is used only for the cheaper kinds of search-lights, because at best its surface is a poorer reflector than silvered glass, and it tarnishes persistently, especially when exposed to sea-air. To some extent there is a tendency in the trade to imply by the term *search-light* an apparatus fitted with a metal mirror, and by *projector* one fitted with a mirror of silvered glass. The Schuckert mirror is of glass, parabolic in form, and silvered on the convex side, the glass being of uniform

thickness. This makes a most excellent reflector, but is difficult to form accurately. The Mangin mirror, which has on the whole met with most favor, is of glass with spherical surfaces, the back surface having the greater radius, as shown in Fig. 1. By this combination of reflection and refraction the aberration is very closely corrected, and a cylindrical beam with a deviation of less than 2 degrees is projected. As between the parabolic and spherical mirrors, the former has the important advantage of a shorter focal distance for the same diameter. In consequence of this the mirror subtends a larger angle at the arc, and thus receives a larger proportion of the light given off, and thus throws a beam of greater intensity, other conditions being equal. The mirror with spherical surfaces has, however, the important advantage of being much more readily ground and polished with geometrical accuracy, and it is this advantage which has led to its more general use.

FIG. 1.

For mounting the lamp and mirror they are placed in a cylinder hung on pivots in a supporting frame, as shown in Fig. 2. The front of the cylinder is covered by thin plane glass for purposes of protection. This frame turns about a vertical pivot in the supporting base of the apparatus, and by a combination of these two movements the motions of the beam of light are under complete control. These movements may be either controlled at the light by hand, or from a distance by mechanical transmission, or in the larger sizes by distant electrical control of motors in the base of the apparatus. The usual range of sizes for search-lights is from 2,000 to 10,000 candle-power, requiring from 10 to 100 amperes of current at a potential difference of about 50 volts. The diameters of mirror and barrel vary, correspondingly, from 8 or 10 to 30 inches.

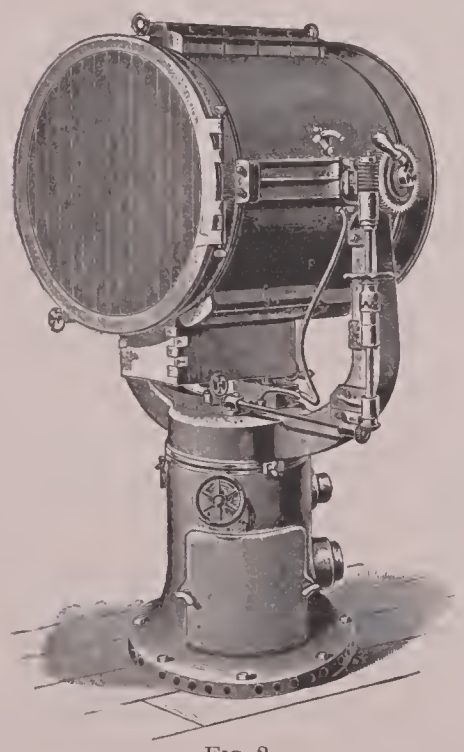

FIG. 2.

The search-light is chiefly useful as an aid to navigation, its immediate purpose being to assist in picking up buoys or range-marks, or in detecting the vicinity of other ships, or of reefs, rocks, and other dangers to navigation. To this end great concentration of light is necessary in order to illuminate the object sufficiently to make it visible at the maximum distance possible, and this is furnished by the arc-lamp and mirror as described. If desired, the lamp may usually be moved slightly out of focus, thus giving a spreading beam and serving for purposes where a more general illumination of lesser intensity is suitable. In the larger and more complete forms one or more lenses are usually provided for producing at will the angle of dispersion or divergence which may be desired. Search-lights are also of high importance as a part of the defensive equipment of war-ships. Against night torpedo-boat attacks they are considered as one of the chief items of defense, rendering them visible at a distance of a mile or more, and thus exposing them to attack from the rapid-fire battery.

On the larger war-ships four, and sometimes more, search-lights are installed at various points, intended to provide defense on all sides, and duplication in case of injury from gun-fire. For navigational purposes alone one light is usually sufficient, located on the pilot-house or bow, and intended especially to project its beam directly ahead and across the bows on either side. W. F. DURAND.

Seaver, EDWIN PLINY, A. M., LL. B.: educator; b. in Northborough, Mass., Feb. 24, 1838; graduated at the Bridgewater (Mass.) Normal School 1857; A. B. and A. M., Harvard College, 1864; LL. B., Harvard Law School, 1868; tutor and assistant professor, Harvard College, 1865–74; head master of English High School, Boston, 1874–80; superintendent of public schools, Boston, since 1880; author of several mathematical text-books.

Seawell, MOLLY ELLIOT: author; b. in Gloucester co., Va., Oct. 23, 1860; was educated chiefly at home; won a short-story prize in 1890, and a $3,000 prize for a story in the New York *Herald* in 1895; she is the author of *Midshipman Paulding* (1891); *Paul Jones* (1892); *Decatur and Somers* (1893); *The Berkeleys and their Neighbors* (1894); *A Strange, Sad Comedy* (1895); *The Sprightly Romance of Marsac* (1896); *The History of Lady Betty Stair's Suitors* (1897); *A Virginian Cavalier* (1898); *The Rock of the Line* (1898); and *The Loves of the Lady Arabella* (1898).

Securities: This term is strictly used to designate property held to secure the payment of a debt or obligation of another; but the term is commonly applied to those forms of property in which investments are usually made, consisting of a debt or obligation of another and stocks in corporations evidenced by bond or bond and mortgage, stock certificate, or instrument of such other form as may be used in any particular case.

Growth of Investment Securities.—The rapid and very great increase in personal property which has taken place during the nineteenth century, and especially in the last fifty years, and its accumulation in the hands of private individuals and corporations, has led to a corresponding increase in the demand for proper security for suitable investment for such funds. On the other hand, the rise and development of the modern industrial system, the invention and development of valuable patents, the establishment of great centers of manufacturing industry with establishments employing enormous fixed capital invested in manufacturing plants, the creation of systems of railway communication, the incurring of enormous national debts by nations in carrying on wars or other operations requiring unusual expenditure of money—these have all added to the forms of securities which are offered to investors with a rapidity equal to the growth in the demand. This has led to a complicated system of securities which admit of a general legal classification, but are confusingly various and different in their details as to names by which they are designated, the methods under which they may be legally issued, the degree of security given by them, the rights of the holders, etc.

The subject of the investment of funds in securities by trustees, charitable institutions, and public corporations, such as savings-banks, trust companies, banks, etc., the investment of whose funds affects the public interest, is specifically and carefully regulated by statute to secure the honest and safe disposition of the funds invested.

The chief securities of Great Britain in which such funds may be invested are the parliamentary stocks of public funds or Government securities of the United Kingdom; real or heritable securities; the stock of the Bank of England and the Bank of Ireland (which are authorized investments for trustees) and the stock of other banks (which are not authorized investments for trustees); Indian stock issued by the Secretary of State in council of India, under the authority of act of Parliament and charged on the revenues of India; securities the interest of which is for the time being guaranteed by Parliament; consolidated stock created by the metropolitan board of works or by the London county council, and debenture stocks created by the receiver for the metropolitan police district; debenture or rent-charge or guaranteed or preference stock of railway companies incorporated by special act of Parliament (only those which have not passed a dividend of less than 3 per cent. per annum on the ordinary stock for the ten years last past being authorized investments for trustees); stock of railway and canal companies leased in perpetuity for a term of not less than 200 years at a fixed rental to another such company as immediately above mentioned; debenture stock of railway companies in India, the interest of which is paid or guaranteed by the Secretary of State in council of India;

annuities of the Eastern Bengal, the East India, and the Sindh, Punjaub and Delhi railways, which are charged on the revenues of India, and also deferred annuities comprised in the registry of holders of India, class D, and annuities comprised in the register of annuitance, class C, of the East Indian Railway Company; the stock of railway companies in India upon which a fixed or minimum dividend is paid or guaranteed by the Secretary of State in council of India, or upon the capital of which the interest is so guaranteed; debenture or guarantee or preference stock of companies in Great Britain and Ireland, especially for the supply of water and incorporated by special act of Parliament or by royal charter (only those which have not passed a dividend of 5 per cent. on their ordinary stock for ten years last past being authorized investments for trustees); nominal or inscribed stock issued by the corporation of a municipal borough (authorized investments for trustees being limited to those which at the last census returned a population exceeding 50,000), and those issued by any county council under the authority of an act of Parliament or a provisional order; nominal or inscribed stock issued by commissioners incorporated by act of Parliament for the supply of water, and having compulsory power of levying rates (authorized investments for trustees being limited to those cases where the rates may be levied over an area having at the last census a population exceeding 50,000, and where the rates levied for each of the ten years last past shall not have exceeded 80 per cent. of the amount authorized to be levied); local loans stock issued under the Local Loans Act of 1887 (3 per cent. stock); exchequer bills; mortgages of freeholds and copyholds; nominal debentures or stock issued under the Local Loans Act.

All of the above, except as noted, are authorized investments for trustees in their discretion, subject to the necessity of obtaining any consent which may be required with reference to the investment of the funds by the instrument, if any, creating the trust.

In the U. S. the securities which are commonly offered for investment of trust funds consist of first mortgages upon real property, municipal bonds, tax certificates, U. S. Government bonds, railway bonds which have not defaulted in payment of interest for a given period, railway stocks which have not passed a dividend for a certain number of years as fixed by statute, trust company stock, savings-bank deposits, canal company bonds. In most, if not all, of the States special legislation has been passed prescribing the forms of personal securities in which trustees may invest their trust funds without being liable for negligence in the event of the money so invested being lost. These laws are various in their provisions, those in some States prescribing a larger list of securities than those in others, but all agreeing in imposing restrictions as to passing of dividends, location of corporation, especially municipal corporations, the proportion of loan to the total value of property, etc.

Besides the securities above, which are those ordinarily used for the permanent and safe investments, there are many other forms of securities of much less stability, such as mining stocks and the stocks of industrial corporations. These and other stocks, such as those of gas companies, water companies, etc., whose value depends upon public franchises which are of a precarious nature or whose value may be destroyed by a grant of other similar franchises, are subject to great fluctuations due to depression in trade, threatened adverse legislation, exhaustion of natural resources, or the like, and are a dangerous form of investment for funds, where a safe and permanent investment is desired. Their value can not be ascertained except by a minute and careful investigation of the assets and resources of the company by which they are issued, and in the case of industrial corporations a thorough investigation of the trade in which the corporation is engaged; and the making of such investigation is but a small safeguard against future fluctuations in price.

Securities may be generally classified as to their character into bonds and other debentures or evidences of debt which are secured by a lien or charge upon property, these being subdivided into those which are secured by a lien upon real estate and those which are secured by a lien upon chattels; bonds and other debentures, or evidences of debt, which are not secured by any lien or charge upon property; and stock certificates or other evidences of ownership of property. They may be classified as to the nature of the corporation or person or other party issuing them into public securities (such as tax certificates, municipal bonds, Government bonds, etc.) and private securities (such as railroad bonds, mortgage bonds, stock certificates, etc.). Securities are generally classified, with respect to the place of issue, as foreign and domestic; with respect to the markets in which they are sold, as domestic and international; with respect to liability (stocks), as limited, unlimited, and non-liability stocks; and with respect to their negotiability or necessary method of sale, as registered, or inscribed, and unregistered.

Debentures.—Broadly speaking, a document which either creates a debt or acknowledges it is called a debenture. In this sense the term is applied to every document, whether payment or discharge of the debt is secured by a charge upon property, or by priority to other creditors, or not. In many cases the debentures are so secured, but the rights of the holders of debentures must be ascertained in every case from the instrument, setting forth the terms upon which it is issued. The term is chiefly used in Great Britain, in the U. S. such instruments being generally called mortgage bonds, or by the specific name designating the particular class of debentures. Debentures so called in England consist chiefly of those issued under acts of Parliament in the nature of mortgage debentures, debentures issued by local authorities under the Local Loans Act, and debentures of private companies or corporations registered under the companies acts. The debentures issued by virtue of the acts of Parliament often confer certain special privileges on the holders, and those issued by private corporations are usually secured by mortgage upon some particular property, or by a charge upon the entire property of the corporation. This latter charge, called a *floating charge*, leaves the company free to manage its own affairs according to the ordinary course of business, and to sell or dispose of its property by sale or mortgage in so doing; but upon the default of the interest or principal, or in the event of an attempt or agreement to wind up the company, the holders of the debentures have the right to enforce their security against the entire property of the company as it then exists, subject to such charges as the company may have placed upon it as a company while a going concern. The debentures issued by countries other than England, except in some special cases, such as the Daira bonds of Egypt, do not customarily give any special privilege to the holder, but are merely governmental promises to pay certain sums at certain times with interest.

Where the debenture is secured by a charge upon the property of the company, so that the company may not treat or use the specific property as free from incumbrances, there must be a mortgage or trust deed made for this purpose; and if the security be upon movable goods, the mortgage or trust deed must be registered as a bill of sale, except in the case of an incorporated company, when it need not be so registered. In the U. S. mortgages against land must be registered to be good against *bona-fide* purchasers for the value, and the necessity for the recording of mortgages or bills of sale of personal property is determined by the specific laws of each State in question.

There is a class of debentures the principal of which is made payable only in the default of payment of interest or winding up of the company issuing the debentures, and these are frequently called *perpetual debentures*. Sometimes the government or corporation issuing debentures reserves the right to redeem them on or before a certain date, or upon the happening of a given event at the borrower's option. As respects the general requirements of a debenture, as regards its being payable at a certain date, registration, negotiability, etc., the laws apply in each case which govern the particular class of instruments to which the debenture in question belongs. Debentures payable to bearer are now subject in Great Britain to a stamp duty of 10 shillings to £100, to be paid by the borrower, and registered debentures are subject to a stamp duty payable on transfer by the transferrer.

Debenture stock, so called, consists of two different kinds: First, that which is issued by British railway companies or other companies whose charter is subject to the Companies Clauses Act of 1863. It places a charge upon the entire property both for principal and interest, and has priority for payment of interest over the payment of dividends or interest on any ordinary shares or stocks. Such debenture stock invests in its holders the right, in the event of interest remaining unpaid for thirty days after it becomes payable, of obtaining the appointment of a receiver in England or Ireland, or a judicial factor in Scotland, and arrears

may be recovered by an action against the company. On the other hand, the principal paid in upon the debenture stock by the purchasers or holders of it does not become payable under any circumstances, neither does the property of the company under any conditions fall into their possession, and the company itself has not the power to redeem the debenture stock, except by a special act of Parliament authorizing this to be done. Such debenture stock has many of the characteristics of the preferred stock, or *preference stock*, as it is called in England, but is most closely analogous to a perpetual annuity, the payment of which may be enforced against the assets of the company, as above mentioned.

The other class of debenture stock is that issued by companies incorporated under the companies acts, and is in the nature of perpetual debentures, secured by a charge against the entire assets of the company both for principal and interest. Stock of this kind is usually issued in the form of so-called perpetual debentures, making the principal payable only upon the default in payment of interest or a winding up of the company. The stock certificates are usually registered, and may be issued to borrower; and it may be provided that any portion of the stock may be transferred, or that any portion not less than a fixed sum, such as £1, may be transferred. Generally speaking, the holder of this form of stock is secured, and stands in the same position as regards the company issuing the stock as the holder of ordinary debentures.

Public and Private Securities.—Public securities are constituted by the obligations given to secure the payment of government or public loans which are usually classed as either external or internal, an *external loan* being that which is raised in part or entirely outside of the country, its principal and interest being payable abroad as well as at home; and *internal loans* being those which are raised, or at least are payable, principal and interest, within the country borrowing. The foreign holder of an internal loan is legally required to present his bond or security within the home country for payment in the same manner as a citizen owner, but not infrequently foreign countries borrowing upon internal loans arrange for the payment of the interest and principal of their loans abroad through private or public banks; but this arrangement is terminable at the option of the borrowing government.

The processes of issuing public loans are generally either by public issue at or above a fixed minimum price or at a fixed price, or by direct sale in gross to one or more banking or financial concerns which hold or dispose of the securities in the same way as any other securities purchased by them. In the case of issues either at a minimum price or at a fixed price, the public or investors compete for the issue either by offer of a price equal to or above the minimum; or, in the case of a fixed price, by application for the securities in excess of the amount really wanted. In the case of issuances at a minimum price, allotments of issues are usually made by filling all tenders above a certain price in full, and filling all tenders at a certain price by a percentage of the amount of the tender. In the case of tenders at a fixed price, the usual method of allotment is based upon a percentage of the amount of the bid, it being quite a general custom for applicants to bid for nominal amounts very much in excess of the amount really desired. Where, however, government loans are issued with the idea of encouraging small lenders or purchasers, a common plan, as in France in the case of the *credit foncier*, is to fill all small tenders in full and to prorate the rest of the loan among the larger applicants.

Government loans may be evidenced either by registered stock or bonds or by bonds payable to bearer, with coupons attached, which latter in effect constitute drafts or checks for the amount of the interest as they become due at the quarterly or semi-annual payments.

Private securities are simply those issued by individuals or private corporations, include those of every description, and each class is governed by rules and laws applicable to itself, which can not be given here except as under other subdivisions of this article.

Domestic and Foreign Securities.—Domestic securities, as respects any particular transaction or body of transactions, are those securities which are issued within the country where the transaction takes place or where the investor is situated.

Foreign securities are those which are issued in countries foreign to the country of the investors. The investing of capital in the securities of foreign countries takes place mostly in those countries which are comparatively old and where capital seeking investment is forced to look to other places and parts for investment more profitable than those afforded to it in the place where the capital is present. The United Kingdom of Great Britain is the largest purchaser of securities of foreign countries, and the total amount there invested in foreign securities was estimated in 1893 to have been about the sum of $8,500,000,000. Of this amount about $1,250,000,000 is in private investments and the rest in foreign government securities or public corporations operating in foreign countries. About $1,125,000,000 is in colonial government securities; about $2,265,000,000 in foreign stocks; about $600,000 in American railroads; about $1,300,000 in the railways of all other countries; and the rest in miscellaneous securities.

Domestic and International Securities.—Domestic securities are those which are ordinarily dealt in only in the country in which they are issued.

The term international securities is customarily used to designate stocks and shares which are simultaneously dealt in upon the markets of different nations, as upon the London market, the exchanges of Germany, New York, etc. The distinguishing feature of such bonds is the opportunity which it affords to the holder or owner to realize upon them in whichever market may be most profitable or best suited for his purpose. Such bonds consist chiefly of the more important and stable railroad stocks, and especially of government bonds, such as those of the French and Italian Governments, and some other governments which are mostly or widely purchased outside of the countries in which they are issued. The bonds of any one government issued have a special market where they are most dealt in, depending more or less upon the political relations, the government securities being mostly held by those countries which are, or are supposed to be, most favorable to the country issuing the bonds. Thus at present (1899) France is one of the largest holders of the Russian bonds formerly held in Berlin, Frankfort, and other German markets, which bonds were previously held in English markets; so also the securities of the South Austrian Railway were formerly so commonly dealt in upon the markets of Vienna, Berlin, Paris, and London as to be a favorite medium of remittance between these markets, and this is now true of the shares of a number of American railroads. As distinguished from these securities which have an international market, the British colonial stocks have their market almost entirely confined to London, and even there they are sometimes not freely salable. These international securities, so called, also furnish an opportunity to the broker for what is called an *arbitrage business*, which enables a large part of the remittances between countries to be conducted without the actual remittance of any form of cash, the effect of which is to equalize the scarcity or plentifulness of money, or, as it is called, the ease of the money market in the countries between which arbitrage dealings are freely conducted. See ARBITRAGE.

Liabilities of Shareholders in Corporations or Companies.—The liabilities of the stockholders of a corporation or company vary according to the laws of the jurisdiction under the laws of which the corporation or company is incorporated or organized, and according to the nature of the particular corporation issuing the shares and the circumstances under which the shares are held or purchased. Companies in this respect are broadly divided into those in which there is an unlimited liability, those in which there is a limited liability, and those in which there is no liability. Corporations in which the stockholders have unlimited liability are now comparatively rare. Those having a limited liability are usually in the nature of banks or banking corporations, where a common provision is that the shareholders, in the event of the winding up of the company or its insolvency, shall be liable up to the face value of the shares which they hold, and in the case of unpaid shares they are also liable, as in the case of any other company, for the difference between the face value of the shares and the amount which has been paid in to the company upon them. This matter is fully treated under the titles of CORPORATIONS and JOINT-STOCK COMPANIES.

Registered and Unregistered Securities.—Unregistered securities are made payable to bearer, and may be transferred either with or without indorsement: and, as respects the liability of the principal upon such securities to the holder of them, they bear many analogies to negotiable bills

and notes. Registered or inscribed stock must be transferred upon the books of the company or party by whom they are issued, in order to constitute a complete sale as to the company, upon a written assignment. This interferes with the freedom of transfer of the securities, and causes greater publicity as to facts of ownership, and for that reason registered stocks are less common in the U. S. and on the Continent of Europe than they are in England, where this interference is less objected to. If an unregistered security be lost, a new bond or certificate can not generally be obtained by the owner except upon giving bonds to secure the issuer against loss; but in the case of the loss of a registered security a new bond or certificate may be readily obtained by the last registered owner in the absence of notice of an unregistered sale.

The Purchase of Listed Securities.—The stocks or bonds or other securities listed upon any stock exchange may be purchased through a broker who is a member of the exchange upon the floor of the exchange in the ordinary course of business by the payment to the broker of such per cent. of the value of the securities to be purchased as may be required either by the broker or by the custom of the exchange and his commission, which latter varies, being usually in the U. S. about one-eighth of 1 per cent. Securities listed on the stock exchange may be sold without accrued interest, when the purchaser receives interest upon the bond or other security only from the time of his purchase; or with accrued interest, when he receives interest from the date of the last payment of interest or the date when the interest was last payable, and this amount is included in the purchase price of the bond or other security to him. In the case of purchase of shares of stock issued by a new company, or of bonds issued by a public or private corporation, the stock or bonds may be sold either through brokers who have not already purchased them, or, where purchased direct from the corporation or party issuing them, by a letter of application and a letter of allotment. A *letter of application* consists of a form which is usually a mere request signed by the subscriber for the allotment for the specified face value of the issue, and is accompanied by a check for payment to the usual amount required in such cases, usually either 5 or 10 per cent. of the amount subscribed for; a *letter of allotment* is in the nature of an ordinary letter, which specifies the price or amount of bonds or shares to be issued to the applicant, the amounts payable, and the dates upon which the payments fall due, and also a receipt for the amount already received from the subscriber. The letters of application and allotment taken together constitute a contract for a valuable consideration, which may be enforced against the subscriber, and he becomes liable for the entire face value of the stock or bonds for which he has so subscribed, and may be compelled to complete his purchase by an action at law. When a part only of the purchase price is paid by the purchaser to the broker who retains the purchased securities and carries them for his customer, the securities are said to be purchased upon a margin, which is the difference between the amount paid toward the purchase price of the security and the purchase price itself. The amount of margin usually required upon the purchase of ordinary stocks or bonds is 10 per cent., varying to as high as 25 per cent. or more, according to the nature of the security purchased, especially as regards its fluctuations in value upon the market. The margin upon which a security is purchased must be kept up by additional deposits if the security depreciate in value; and if it appreciate in value the purchaser may ordinarily demand and receive the excess of his margin so arising over 10 per cent. on the market value. Purchases for investment are not usually made upon a margin, but this form of purchase is customary where stocks are purchased for speculative purposes only. Where the margin is of an inconsiderable amount such transactions are carried on by brokers outside of the stock exchanges, commonly called in the U. S. curbstone brokers and bucket-shop brokers. If in a margin transaction the securities be not actually purchased by the broker the transaction is a gambling transaction, and the purchaser may recover his margin or not, although there be a nominal loss, according to the gambling laws of the jurisdiction where the transaction takes place. A good delivery upon the stock exchange is made when it is such in respect to time, place, and subject of delivery that it can not be refused by the purchaser. A purchaser of securities may reject the security when delivered, upon the ground of its not being a good security, if the security is mutilated or has any other defect upon its face, or if it is marked by the absence of the necessary revenue stamps or absence of proper coupons or irregularity in number, or if the bond be payable only to bearer and the name of the owner is retained upon the bond or other document. In the case of dispute as to what constitutes a good delivery, a decision of the committee or governing board of the stock exchange upon which the security is purchased is conclusive upon the parties. F. STURGES ALLEN.

A., Williams College, 1883; principal of schools in New York State 1871–83, 1886–87; principal of Ferry Hall Seminary and Professor of Pedagogy, Lake Forest University, Lake Forest, Ill., 1887–94; student in the University of Berlin 1894–95; Professor of Pedagogy, New Jersey State Normal School, Trenton, N. J., since 1895. He is the author of *Grubé's Method of Teaching Arithmetic*; *The Grubé Idea*; *The German Common-School System.*

Seguin: the name of a talented musical family of England and the U. S., famous as singers. The first of the name was ARTHUR EDWARD SHELDEN, b. in London, Apr. 7, 1809; his voice was a deep bass, and he began singing in 1828; he continued with great success in concerts and opera. On Oct. 15, 1838, he appeared in New York in Rooke's opera *Amilie*, and formed the Seguin Opera Company, which met with great success all over the country. He died in New York, Dec. 9, 1852. His wife, ANN CHILDE, first appeared as a singer in 1828 at the same performance as her future husband. After her husband's death she retired from the stage and taught music in New York until her death, in Aug., 1888.—Their son EDWARD made his first appearance in Covent Garden, London, with the Pyne and Harrison English Opera Company. He went to New York in Dec., 1860, and sang with the Richings, Parepa-Rosa, Kellogg, Hess, and Emma Abbott companies. His voice was also a deep bass. He died Oct. 9, 1879. His wife, ZELDA HARRISON, whom he married in 1867, was an admired contralto singer, and sang in the same companies with her husband.—The elder Seguin's younger brother, WILLIAM HENRY, b. in 1814, had a light bass voice, and was an admired concert singer. He died in London, Dec. 28, 1850. His wife, Miss GOOCH, a soprano singer, survived him only a few years.
D. E. HERVEY.

Selfe, Sir WILLIAM LUCIUS, K. B.: English judge; b. in London, June 11, 1845; received his college education at Rugby and at Corpus Christi College, Oxford, taking his degree of bachelor of arts in 1868; he then read law in the Inner Temple, and was called to the bar in 1870; he then took up practice as conveyancer and equity draughtsman, and afterward was engaged in the preparation and publication of statutes, including *The Statute Law Revision Bills*; *Revised Edition of the Statutes*; *Chronological Table and Index to the Statutes*; and was also employed as parliamentary draughtsman. He was principal secretary to Lord Chancellor Earl Cairns in 1880, and was appointed judge of the county courts in 1882, sitting in the circuit for East Kent; has been chairman of the East Kent quarter sessions since 1893, and was appointed member of the county-court rules committee in 1894. F. STURGES ALLEN.

Selfridge, THOMAS OLIVER: naval officer; b. in Boston, Mass., Apr. 24, 1804. He entered the Naval Academy in 1818, becoming lieutenant 1827; served in the Mediterranean, the West Indies, and Brazil; became commander 1844; was with the East India squadron 1845–46, on the flag-ship Columbus, and with the Pacific squadron during the Mexican war; took part in the capture of Mazatlan and Guaymas, being so badly wounded at the latter place that he turned over command of his ship and went home; was with the Gulf squadron a short time in 1861, and in 1862–65 had charge of the Marc island navy-yard; was made captain 1855, commodore 1862, rear-admiral 1866; was president of the examining board 1869–70, and lighthouse inspector at Boston; also member of the examining board 1870–71. He is the senior officer of the retired list.—His son, THOMAS OLIVER, also a naval officer, was born in Charlestown, Mass., Feb. 6, 1837. Graduating at the Naval Academy in 1854, he became lieutenant 1860; was attached to the Cumberland when that vessel was sunk by the Merrimac in Hampton Roads; was advanced to lieutenant-commander 1862, serving on the Cairo, which was destroyed by a torpedo in Yazoo river; at the capture of Vicksburg he had charge of a siege-

battery, of the Manitou and the Conestoga, and commanded the Osage in the Red river expedition, inflicting heavy loss on the Confederates at Blair's Plantation; in the bombardments of Fort Fisher he had charge of the Huron, and led a division of landing sailors against the fort: was made commander 1869; between that year and 1873 was engaged in surveying for a canal across the Isthmus of Darien; in 1876 was a member of the international congress at Paris on the question of that canal; commanding the Enterprise, he surveyed the Amazon river 1877–80; was commissioned captain 1881; during subsequent service at the Newport torpedo station he invented a device for protecting ships from torpedoes; was in the Asiatic squadron 1887; became commodore 1894, rear-admiral 1897, and retired 1898.

Sembrich, Marcella: singer; b. in Lemberg, Galicia, in 1858. The name by which she is known is that of her mother's family, her maiden name being Praxede Marcelline Koschanska. Her father was a violinist, and she began the study of the pianoforte at four years of age, and the violin at six. At twelve she went to the conservatory in Lemberg and studied under Wilhelm Stengel, to whom she was afterward married. She became a fine player on both piano and violin. Liszt heard her play both instruments, and then asked her if she could also sing, and on her reply in the affirmative sent her to Madame Marchesi at Paris, by whose advice she began vocal study. She made her *début* in Athens in May, 1877, in *I Puritani*, and since then has been successful everywhere. She made her first appearance in New York Oct. 24, 1883, in *Lucia*, in the Metropolitan Opera-house. She has sung in London and all European capitals. Her voice is a wonderfully flexible and pure soprano, highly cultivated, and her repertory of operas is very large.

D. E. Hervey.

Senn, Nicholas: surgeon; b. in Buchs, Switzerland, Oct. 31, 1844; early removed to the U. S., settling at Ashford, Wis.; was educated at the Fond du Lac grammar school and at Chicago Medical College, where he graduated in 1868; removed to Milwaukee in 1874, and became a recognized authority on intestinal diseases; became Professor of the Principles and Practice of Surgery in the College of Physicians and Surgeons of Chicago in 1885, and Professor of the Principles of Surgery and Surgical Pathology in Rush Medical College 1888; removed to Chicago in 1891; was made surgeon-general of Wisconsin before his removal, and organized the associations of military surgeons of the National Guard of both Wisconsin and the U. S., serving as president of both bodies; was a delegate to the international medical congress at Berlin in 1890; was in the field as a surgeon during the Spanish-American war in 1898. He has published *Four Months among the Surgeons of Europe* (1887); *Experimental Surgery* (1892); *Surgical Bacteriology* (1894); *Pathology and Surgical Treatment of Tumors* (1896); *Principles of Surgery* (1897); and *Tuberculosis of the Genito-Urinary Organs*.

Separation (of husband and wife): in law, the cessation of cohabitation of husband and wife, whether by mutual consent or by act of law. When used alone the word generally denotes a voluntary cessation of the marriage relation made in pursuance of a contract between the husband acting for himself and trustees representing the wife. Such a contract does not affect the validity of the marriage or the legitimacy of children born of the husband and wife during the time of any such contract, since they may at any time agree to live together as husband and wife. In case of an agreement for total separation, however, the husband forfeits his right to bring an action for criminal conversation with the wife, but not his right to proceedings for divorce for adultery on her part.

Separation deeds are now legalized in Great Britain by recent legislation; but an agreement between husband and wife made in contemplation of *future* separation, intended to hold good whenever they shall choose to live separately, is void as being against public policy.

Separation *by law* is usually termed separation *a mensa et thoro*, and is a species of divorce not dissolving the marriage relation, and much less extensive in its effects than a divorce *a vinculo matrimonii*, or one annulling the marriage.

See Alimony and Divorce. See also Bishop's *Commentaries on the Law of Marriage and Divorce*; Schouler's *Treatise on the Law of Domestic Relations*; J. Carter Harrison's *Epitome of the Laws of Probate and Divorce*; John A. Gemmill's *Divorce Practice in Canada*.

F. Sturges Allen.

Service: In law the word *service* is used to designate several very diverse matters, including—(*a*) The acts performed by a person in fulfilling the terms of his employment by another. The term also here includes the acts or deeds to which a parent is entitled at the hands of his child, a husband at the hands of his wife, etc. The rights and duties of persons in such relations and the extent and nature of their service required to be rendered are treated under the titles Contracts, Bailments, Married Women, Damages, Parent and Child, Guardian and Ward, etc. (*b*) The acts which the tenant holding under a lord was bound to perform in fulfillment of the terms and conditions upon which he held his fee or estate. These services were divided into *free* and *base* service in respect to their quality, and into *certain* or *uncertain* service in respect of quantity and time of performance. (See Feudal Tenure.) (*c*) In civil law, a servitude. (*d*) In practice law, such a delivery of a paper, or communication of its contents, as to charge another with legal notice of it. The term is also used with a similar meaning in relation to other matters requiring the delivery or other communication of papers or other matter necessary to render them effective or to give them their proper legal effect.

The most important matters to which service in this last sense of the word pertains is the service of process in actions or proceedings at law, the term *process* here including all those writs, papers, and notices which are necessary or proper to the beginning of an action, suit, or proceeding in law or equity, and the conduct of it to a termination which shall be binding upon the parties to it. No valid suit or proceeding can be maintained against any person or his property except by making legal service of notice of such proceeding upon him, actually or constructively; but what shall constitute such service varies greatly with the nature of the action or proceeding and the purpose to be accomplished by the service. The right to be served with notice of a proceeding as a condition to its validity is recognized at the common law and secured by constitutions and decisions of the courts. When, however, a person has been served with valid notice of an action or proceeding, all subsequent steps and proceedings legally taken are binding upon him so long as no material modification of the original purpose of the action or proceeding is made.

Who may Make Service.—The service of process issued from the court is ordinarily required to be made by the sheriff, as the officer of the court. Where this is the case the service must be made by the sheriff to whom it is addressed, either personally or by his lawfully authorized deputy, and must be made within the limits of the county or district over which his jurisdiction extends. If the sheriff be a party in interest in the action or proceeding there is usually a provision for the substitution of some other person or officer to make such service in his stead. In the case of the federal courts of the U. S., service which is ordinarily made by the sheriff in the State courts is made by a marshal or his deputies, and in the case of actions or proceedings before justices of the peace by a constable. The service of papers subsequent to that which is necessary to the valid beginning of an action or proceeding may frequently be made by an indifferent person, or even by a party in interest; and in those States having a code practice it is usually provided that any person upward of a certain age, as eighteen or twenty-one years, not a party to the action or proceeding or otherwise interested in it may make a valid service of the summons or other paper by which the action or proceeding is instituted, the summons in such cases being a mere notification from the plaintiff or his attorney, and not, properly speaking, a process of court. The statutes may prescribe the age of a person qualified to serve the summons; but in the absence of this it is generally held that he must not be under twenty-one years of age. Lawful service can not be made by a deputy other than one appointed according to the provisions of the law.

Time, Place, and Manner of Service.—In general, service of process or of a notice or other paper in an action or proceeding may be made at any time of the day or night, and on any day except such as are *dies non juridicus*, either at common law or by statute. At the common law legal service can not be made on Sunday; and in addition to this various legal holidays are provided by statute in the States and by Federal statutes, upon which valid service of certain process can not be made. It is also a general rule of the common law that service must not be made at such a time as to interfere unreasonably with the right of a per-

son to celebrate the rites of his religion, or be made in any other way intended to be grossly offensive or prejudicial to the person upon whom service is made, by exposing him to public infamy or the like; and service willfully so made will, generally speaking, be set aside as void and against public policy. Service made without the jurisdiction of the court having jurisdiction in the action or proceeding is invalid, and where a particular method of service is prescribed by court such method must be strictly followed.

The fact that a person is a non-resident does not affect the validity of the service upon him if he be personally served within the jurisdiction of the court in which the action or proceeding is brought; but a substituted service by publication or other reasonable notice prescribed by law may be made so as to be effectual against a non-resident in a proceeding *in rem* or *quasi in rem*, such as an attachment of property, an action for divorce, or the like; and a judgment or conclusion or order of court based upon a service legally so made is binding against the persons served within the limits of the State in which the judgment or order is made. Such a substituted service, however, in order to make valid a judgment affecting the property or person of the defendant, must be accompanied either by his appearance in court or by the seizure of his property within the jurisdiction of the court. In the case of divorce proceedings some of the States recognize the validity of a divorce granted upon such substituted service where the defendant has not appeared in the action, and even where notice of such action was not brought to his knowledge. In other cases it has been held that a decree of divorce rendered without actual service upon the defendant, or without his appearance, is void of effect beyond the jurisdiction of the court in which the decree is rendered.

Service of process issued against a State as a party of record to the action should be made upon the Governor or other chief executive magistrate and the attorney-general. A corporation at the common law was served by proper delivery of the writ or summons to one or more of its officers, and in the case of the corporation not appearing by a writ of distraint against its property; so that a corporation could not be compelled to appear, either at law or in equity, if it had no property upon which distraint could be levied. Service of process and of other papers upon corporations is now regulated by statutes, which provide, in general, that service upon an officer, or upon some designated agent, shall be effectual as service upon the corporation. These provisions are generally made applicable to municipal corporations, such as cities, towns, villages, and counties, service ordinarily being required to be made upon the chief executive officer of the municipality, and in the event of his absence upon the next officer in order of official rank. Service upon foreign corporations, in the absence of special statutes, is governed by the same rules and regulations as that governing service upon domestic corporations; but it is now usually provided that no foreign corporation shall be recognized as having any legal existence in a State unless it shall have, among other things, designated some person within the State upon whom legal service may be made upon the corporation. A partnership is served by service on one of its members, in which case the action or proceeding is binding against all of the copartnership property, and personally also against the member of the copartnership who is served. This rule as to service of copartners is a specific application of the rule that where an action is brought against several defendants jointly service upon one or more of the defendants only will not sustain a judgment *in personam* against those who are not served. Infants, or those who are not of legal age, must be served not only by a personal service upon the infant himself, but also upon some person legally acting as his guardian or next of kin. As regards service upon husband and wife, the common-law rule that valid service of a summons or other process issued against them as husband and wife might be made by service upon the husband alone has been changed in the U. S. by statute, so that the wife must be served in all cases in order to create a foundation for an effectual judgment or conclusion of court affecting the property rights of the wife.

Exemptions from Service.—Certain persons, such as ambassadors and public ministers from foreign nations, are exempt from the jurisdiction of the courts of the country to which they are sent, and are privileged from service of process issued from its courts; but this exemption does not now extend to consuls. Domestic public officers, such as members of Congress and of State Legislatures, judges, some persons in military service, and election officers, are generally exempt from service of process during the session of the executive body or the actual performance of their duties. A similar rule applies to witnesses or other persons who are in the actual performance of their duties, or acting in compliance with process already served upon them; so that they have the right not only to be exempt from service during their actual attendance or compliance to the process to which they are already subject, but they are also privileged for a reasonable time before and after actual attendance, for the purpose of enabling them to come and go to and from the place where attendance is required. The exemption here not only includes freedom from all kinds of civil process, but also from arrest and criminal proceedings. If such a person, however, after the time of his discharge from process, delays unreasonably or deviates from a direct course or journey in return, he waives his privilege.

Persons without the jurisdiction in which service must be made can not be legally served if decoyed into the jurisdiction in order to enable service to be made upon them, such service being fraudulent and invalid.

Return of Process.—When process has been served due return must be made in order to render it effectual to sustain a judgment or other conclusion based upon it; and, in general, a similar proceeding must be had in the case of all other legal notices or papers required to be served in an action or proceeding. In the case of process served by a sheriff or public officer, the return usually consists in the indorsement in writing, on the back of the writ or other process, of the particulars constituting legal service. In the case of papers served by indifferent parties or private individuals, the return is replaced or constituted by the individual's affidavit of service setting forth the facts required by law to constitute effectual service. It is not necessary that the return should be made in any exact language, but any statement that shows that the statutory requirements have been complied with is sufficient. See FOREIGN CORPORATIONS, CITIZEN, DOMICILE, JURISDICTION, SHERIFF.

F. STURGES ALLEN.

Settlement of Decedents' Estates: This term is used in law to designate the legal disposition of the estates left by deceased persons. Such estates are settled in various ways, depending upon the question as to whether or not the deceased person provided for the disposition of his property.

If the decedent left a will, the proper and necessary method of settlement is to have the will probated, either by the party in possession of the will or by the party entitled to it, and to whom it may be surrendered. A will is said to be *probated* or admitted to probate when it has been established by the testimony of subscribing witnesses, or as many of them as are necessary for that purpose, at the time the will is admitted to record; and it is said to be *admitted to record* when a copy of it, with a copy of the order of the court admitting the same to probate, is recorded in the State and county wherein it was admitted to probate.

The decedent who has made a will is called a *testator* if a male person, or a *testatrix* if a female person. If the maker of a will has appointed a person to carry his will into effect and settle his estate (called an *executor* or *executrix* if a male or a female person respectively), such person is usually vested with such control over and title to the decedent's estate as is specially provided for in the will; and if the will requests that he be not required to give a bond or other security for the proper performance of his trust under the terms of the will, he is customarily not required to give any such security. If, however, the beneficiaries under the will can show any good reason to the court why such a bond should be required, it is at the discretion of the court to require it. If no executor or executrix is appointed by the will, *letters of administration with the will annexed* may be issued to an administrator (called an administrator with the will annexed), who is required to give a bond, and is appointed to settle the estate of the decedent. Such an administrator is also appointed in the event of the executor appointed under a will refusing to serve. If an estate has been previously settled in part by an executor or administrator who becomes for subsequent causes unable to perform the duties of his office, a person is appointed to settle the estate called an *administrator de bonis non*, or if he be appointed upon a will an administrator *de bonis non* with the will annexed. If the

decedent left no will, the court will appoint a person called an *administrator* or *administratrix* to settle the estate, which is called an intestate estate.

In general, the right to administer the estate of a decedent belongs to the oldest and nearest male relative, first to the next of kin, and afterward to the collateral relatives. The term *next of kin* is generally considered to include only those relatives who come within the provisions of the statutes of distribution; but in the construction of wills and settlements the rule is established in Great Britain that the term should be interpreted in ulterior limitations to mean nearest of kin without regard to the statute of distribution. In the U. S., generally, a wife is not included among the next of kin of her husband, or a husband among the next of kin of his wife; but in the construction of wills the term will be interpreted according to the evident intent of the testator.

The duties and rights of executors and administrators in any particular jurisdiction, or in administering any particular estate, are usually particularly prescribed by statute, as well as the procedure to be followed in securing their appointment and discharge; and the statutes must be consulted for specific provisions relating to the subject. See also PROBATE COURT, COURTS, ESTATE, etc.

F. STURGES ALLEN.

Sgambati, sgaăm-baa'tee, GIOVANNI: pianist; b. in Rome, Italy, May 18 (or 28 ?), 1843, the son of an Italian father and an English mother. The boy showed early evidences of musical talent, and after study went to Rome when twelve years old and passed the examination for the Academy of St. Cecilia. In 1866 he settled permanently in Rome. Both Liszt and Richard Wagner took much interest in him. He had become an excellent pianist, and made concert tours in England, Germany, Denmark, and Russia. In 1877 he was appointed Professor of the Pianoforte in the newly founded Liceo di Santa Cecilia, Rome, and has received several decorations from the court. He has composed much piano music, several quintets, a nonet, a concerto in G minor, a suite in B, a symphony in D, and other works in the higher forms, being one of the few Italian musicians who have attempted composition in the classical style. D. E. HERVEY.

Sharp, WILLIAM: author and critic; b. at Garthland Place, Scotland, 1856. He was educated at the University of Glasgow; has been an extensive traveler, having visited the U. S. several times. He was intimate at the exclusive home of the Rossettis in his youth, and in 1882 published the biography of Dante Gabriel Rossetti, which was followed by a biography of Browning. *The Human Inheritance, Transcripts from Nature, and other Poems* (1882), his first volume of verse, has been followed by *Earth's Voices* (1884); *Romantic Ballads* (1888); *Sospiri di Roma* (1891); *Flower of the Vine* (1892); *Vistas* (1894), etc. *Sospiri di Roma* and *Flower of the Vine* have been reprinted in America. He edited the Canterbury Poets Series, and has published several novels.

Sharpless, ISAAC, Sc. D., LL. D.: educator; b. in Chester co., Pa., Dec. 16, 1848; studied at Westtown boarding-school; S. B., Harvard University, 1873; Sc. D., University of Pennsylvania, 1883; LL. D., Swarthmore College, 1889; teacher in Westtown boarding-school 1873–75; tutor, Haverford College, 1875–79; Professor of Mathematics and Astronomy, Haverford College, 1879–85; dean, Haverford College, 1885–87; president of Haverford College since 1887. He is author of text-books on astronomy and geometry; *English Education* (International Educational Series); *A Quaker Experiment in Government*; and numerous papers and addresses.

Shattuck, AARON DRAPER: artist; b. in Francestown, N. H., Mar. 9, 1832; studied art in Boston and at the National Academy of Design; became an Academician in 1861; invented a stretcher-frame with keys for tightening canvases. His paintings include *Study of Grasses and Flowers*; *White Mountains in October*; *Sunday Morning in New England*; *Granby Pastures*; and *Peaceful Days.*

Shaw, ANNIE CORNELIA: artist; b. in West Troy, N. Y., Sept. 16, 1852; studied art in Chicago, where she was elected an associate of the Academy of Design 1873, and became an Academician in 1876. Her best-known paintings are *An Illinois Prairie*; *Ebb Tide on the Coast of Maine*; *Returning from the Fair*; *In the Rye-Field*; *Close of a Summer Day*; *A July Day*; *Fall Plowing*; *Ashen Days*; and *The Russet Year.*

Shaw, CHARLES LEWIS: lawyer and journalist; b. in Perth, Ontario, Feb. 7, 1862, and there received his early education; graduated at Trinity University, Toronto, in 1881; subsequently studied law, was called to the bar, and practiced his profession in Winnipeg; edited the *Nor'wester* and the *Saturday Night*; accompanied Lord Wolseley on the Nile expedition in 1884; was present at the battle of Berber. He has published *Random Reminiscences of a Nile Voyageur*; *Campaigning in the Sudan*; and various short stories. Since 1897 he has edited the *Rat Portage Miner.*

Shaw, EDWARD RICHARD, Ph. D.: educator; b. in Bellport, Long Island, N. Y., Jan. 13, 1856; B. L., Delaware College, 1878; Ph. B., Lafayette College, 1881; A. M., Lafayette College, 1886; Ph. D., University of the City of New York, 1890; traveled and studied school systems in Europe, 1891, 1894, 1896; principal, Union School, Greenport, Long Island, N. Y., 1881–83; principal, high school, Yonkers, N. Y., 1883–92; Professor of Institutes of Pedagogy, School of Pedagogy, New York University, since 1892; dean of the School of Pedagogy, New York University, since 1894. He is author of *Three Studies in Education* (1899); numerous text-books, editions of school texts, magazine and periodical articles, etc.

Shaw, GEORGE BERNARD (*Corno di Bassetto*): author; b. in Dublin, Ireland, July 26, 1856; after receiving slight education, removed to London in 1876, where he in time became celebrated as a critic of the fine arts; became an active agitator of socialism in 1883. His publications include four early novels—*The Irrational Knot*, *Love among the Artists*, *Cashel Byron's Profession*, and *An Unsocial Socialist* (1880–83); *Plays, Pleasant and Unpleasant* (1898); and *The Perfect Wagnerite* (1898). He has edited the *Fabian Essays*, various socialistic tracts, contributed weekly articles on music to the London *Star* and to the *World* from 1888 to 1894, and has since furnished articles on the drama to the *Saturday Review.*

Shelley, HARRY ROWE: organist; b. in Connecticut, June 8, 1858, and when fourteen years old was organist of the Central church, New Haven; entered Yale College and studied music under Prof. Stoeckel; then removed to Brooklyn, N. Y., and studied under Dudley Buck, and later studied in London and Paris. Since his return he had been continuously organist in Brooklyn until May, 1899, when he was appointed organist of the Fifth Avenue Baptist church, New York. He has composed many popular songs and part songs, some orchestral music, *Vexilla Regis* and *The Inheritance Divine*, two sacred cantatas, much organ music, and has edited and compiled several volumes of anthems and pieces for the organ. D. E. HERVEY.

Shepard, IRWIN, A. B., Ph. D.: educator: b. in Marcellus, N. Y., July 5, 1843; educated first in common schools of New York, and later of Michigan; attended the State Normal School, Ypsilanti, Mich., 1860–61; served in the army 1862–65, being granted a congressional medal of honor for gallantry in action in a sortie from Fort Saunders on the night of Nov. 23, 1863; studied at Olivet College 1866–71; A. B., Olivet, 1871; A. M., Olivet, 1874; Ph. D., Olivet, 1893; superintendent of schools, Charles City, Ia., 1871–75; principal of high school, Winona, Minn., 1875–78; superintendent of schools, Winona, 1878–79; president of State Normal School, Winona, 1879–98; secretary of National Educational Association, annually elected 1893–98, and elected permanent secretary 1898; editor of *Proceedings of the National Educational Association.*

Sherwood, MARY ELIZABETH (*Wilson*): b. in Keene, N. H., about 1830; is a patron of literature and art, and is a leader of society; has given public readings. She is the author of *The Sarcasm of Destiny* (1877); *Home Amusements* (1881); *Amenities of Home* (1881); *A Transplanted Rose* (1882); *Manners and Social Usages* (1884); *An Epistle to Posterity* (1897); and *Here, There, and Everywhere* (1898).

Sherwood, WILLIAM H.: pianist; b. in Lyons, N. Y., Jan. 31, 1854; at first a pupil under his father, William Mason, Jan Pychowski, and others in New York; went to Berlin in 1872, and from 1873 to 1875 was organist in the English chapels in Berlin and Stuttgart; studied also with Liszt in Weimar. On returning home he settled in Chicago, and made his first public appearance at the Centennial Exhibition in Philadelphia in 1876. He is one of the founders of the American College of Musicians. He is a fine pianist of the Rubinstein-Liszt school, and has played successfully in many cities. D. E. HERVEY.

Shinn, George Wolfe: clergyman; b. in Philadelphia, Pa., Dec. 14, 1839; was educated at public schools, at the Virginia Theological School, and graduated at the Philadelphia Divinity School in 1863; entered the ministry of the Protestant Episcopal Church, holding rectorates in Philadelphia, Shamokin, and Lock Haven, Pa., Troy, N. Y., and finally became rector of Grace church, Newton, Mass. Besides editing for ten years the *Teacher's Assistant* and a *Prayer-Book and Hymnal for the Sunday-School*, he has published *Manual of Instruction upon the Collects, Epistles, and Gospels for the Christian Year* (1874); *Manual of the Prayer-Book* (1875); *Manual of Church History* (1876); *Stories for the Happy Days of Christmas Time* (1879); *Questions about our Church* (1880); and *Questions that Trouble Beginners in Religion* (1882).

Ship-canals: The Nicaragua Canal Company having ceased operations in 1893, owing to lack of funds, Congress in 1895 appointed a commission of three well-known engineers, known as the Ludlow commission, to report on the feasibility and cost of completing the company's project. After examining the route and the company's engineering data, the commission reported that, while the project was feasible, they could not indorse some important features of the company's plans. Their estimate of the cost of completing the canal was $133,472,893, as against the company's estimate of about $67,000,000. The commission suggested that a more thorough examination might disclose alternative routes free from the objections they urged to the company's route, and they advised the appropriation of $350,000 for further examination and the preparation of final plans and estimates. This recommendation was adopted. A new commission, consisting of Rear-Admiral John G. Walker, Prof. Lewis M. Haupt, C. E., University of Pennsylvania, and Col. P. C. Hains, U. S. A., spent several months in a personal examination, and in Dec., 1897, placed in the field a well-equipped force of 250 men, including 80 engineers, a geologist, a hydrographer, 10 boring outfits, and complete apparatus for determining rainfall, evaporation, flow of streams, and all other phenomena affecting the construction and operation of the canal. An official abstract of the commission's complete report was made public on May 31, 1899. The commission adopted and made estimates for the route from Brito, on the Pacific, to Lake Nicaragua, known as the Childs route, and from the lake to Greytown, on the Atlantic, known as the Lull route, and expressed the belief that the canal may be built across the isthmus on this route for a cost not exceeding $118,113,790. Col. Hains concurred generally in the views of the other members, but his estimate of the cost was $134,818,308. Upon an earlier preliminary report of the commission the Senate had passed a bill authorizing the expenditure of $115,000,000 for building the canal. About the same time the latest official facts with regard to the progress of the Panama Canal began to attract much attention.

In Oct., 1894, a new company was formed to complete the Panama Canal. Its cash capital, all paid in, was $13,000,000. The company determined to make a complete study of the engineering features, and also to begin work on a scale large enough to determine exactly what sort of material would be encountered in completing the excavations and building the dams and locks. At the outset the company abandoned the De Lesseps idea of a sea-level canal and substituted a system of locks. A force of several thousand men was put upon the work at several points, including the Culebra cut. It was evident that the floods of the Chagres river afforded sufficient water for the canal, and an investigation was begun to ascertain the average amount of the Chagres discharge and the possibility of storing it in suitable reservoirs that would both feed the summit-level and hold back the waters in time of flood. This investigation was conducted by 150 engineers and their assistants, and the surveys occupied four years and cost $1,200,000. The work was carried out to the smallest details, including the plans and drawings for every culvert and bridge. At the request of the company, an international technical commission had been appointed to pass upon these surveys and plans. The commission was composed of ten eminent engineers of the U. S., Great Britain, Germany, Russia, and France, and included Gen. H. L. Abbot, Corps of Engineers, U. S. A., and the engineering directors of the Kiel and Manchester Canals. This body was organized in 1896, spent two years in its investigations, and on Dec. 2, 1898, presented a unanimous report indorsing the plans and estimates of cost of the new company. It declared that the work on the canal was then two-fifths completed, that the cost to complete it under the new plans would be $87,000,000, and adding 20 per cent. for contingencies $102,400,000, and the time required for completion would be from eight to ten years.

The prevailing belief in the U. S. that there is need for only one canal and that only one will be built, and the favorable report of the international commission on the Panama project, resulted in a general expression of opinion throughout the country that nothing further should be done to promote the Nicaragua scheme until the whole question of the best canal route under the existing circumstances had been submitted to a competent tribunal. President McKinley was accordingly authorized to appoint a new commission for this purpose. Its members are Rear-Admiral Walker, Col. Hains, and Prof. Haupt (members of the Nicaragua commission which had just handed in its report); ex-Senator Samuel Pasco, of Florida; Alfred Noble, C. E., who was also on the Ludlow commission; George S. Morrison, C. E., of New York; Prof. William H. Burr, of Columbia University; Lieut.-Col. Oswald H. Ernst, U. S. A.; and Prof. Emory R. Johnson, of Pennsylvania.

Robert M. Caffall, chief engineer of the Florida Transpeninsular Ship-canal, reported in 1898 that the most feasible route on the lock system (a tide-water canal being out of the question) was from St. Augustine to the St. John's river, up that river 10 miles, thence to Orange Lake, and thence to the Gulf S. of Wacassassee Bay; total length, 108 miles.

The receipts of the Suez Canal in 1898 were $17,581,200. The cost of maintaining the canal was about $50,000 less than usual. The surplus of receipts over expenditures was $9,757,800. Among the 3,503 vessels passing through the canal were 69 petroleum-ships, many of them carrying oil in bulk. For years the company would not permit these vessels to enter the canal, believing the carrying of oil in bulk to be dangerous.

The patronage of the Kaiser Wilhelm Canal is growing. The number of vessels passing through in the year 1895–96 was 19,960; in the year 1896–97, 23,108. Of these 20,307 were German vessels.

The business of the Manchester Canal is very slowly increasing. The total tonnage in 1896 was 1,828,237; in 1897, 2,065,815. The canal is not deep enough to accommodate many of the larger vessels now building. C. C. Adams.

Shipman, Nathaniel: jurist; b. in Southbury, Conn., Aug. 22, 1828; graduated at Yale College in 1848, then studied law and was admitted to the Connecticut bar in 1850; practiced law in Hartford for twenty-three years; made U. S. district judge in 1873; retained this position until 1892, when he was made circuit judge, which position he still (1899) holds; member of Connecticut House of Representatives 1857.

Shippard, Sir Sydney Godolphin Alexander, D. C. L., M. A., F. R. G. S., K. C. M. G.: South African judge and jurist; b. about 1840; he was educated at King's College School and Oriel and Hartford Colleges, Oxford, after which he read law and was called to the bar at the Inner Temple in 1867; he was attorney-general of Griqualand West 1873–77; was acting recorder of the high court of Griqualand 1877; judge of the Supreme Court of Cape Colony 1884–85; a British commissioner on the Angra Pequena and West Coast claims commission 1884–85, and deputy high commissioner and resident commissioner for the Bechuanaland protectorate and the Kalahari 1885–95. His writings consist chiefly of his judgments while acting as judge of the Supreme Court of Cape Colony. He was knighted in 1887.
F. Sturges Allen.

Ship's Papers: the papers or documents which are required by law to be carried by a vessel to show her ownership, nationality, and cargo, and to show that she has complied with the revenue and navigation laws of the country under whose laws she is registered. These papers are commonly divided into those required by the common law of the country to which the vessel belongs (as the license, clearance papers, crew list, shipping articles, certificate of registry or enrollment, etc.); and those required by international law to be carried by neutral ships to show their title to neutrality, as the parts of property in the ship, the charter-party, bills of sale and of lading, invoices, log-book, bill of health, etc.

Although the absence of any one of the papers proper to

be carried by a ship is not conclusive evidence against the neutrality or other character of good faith of the ship, its absence renders the character of the vessel suspicious; and when the absence is traced to willful destruction (or, as it is technically called, spoliation), the presumption of guilt is nearly conclusive as a ground of condemnation against a ship otherwise entitled to the privileges of a neutral. The use of false or pretended papers is also practically conclusive evidence against the good character of a vessel, and is sufficient to avoid an insurance unless it is expressly stipulated between the insurer and the insured that such papers may be carried. F. STURGES ALLEN.

Shoup, FRANCIS ASBURY: soldier; b. in Laurel, Ind., Mar. 22, 1834; graduated at the U. S. Military Academy in 1855; resigned from the service in 1860; after admission to the Indianapolis bar removed to Florida in 1861. Under orders of the Governor of Florida, he erected a battery at Fernandina; was appointed lieutenant in the Confederate army; was commissioned major of artillery in 1861, and served with Gen. Hardee in the trans-Mississippi department, afterward with Gen. A. S. Johnston at Shiloh; was inspector of artillery under Gen. Beauregard, served as chief of artillery under Gen. Hindman, commanded a division at the battle of Prairie Grove, and was made brigadier-general in 1862. He commanded a Louisiana brigade at Vicksburg, receiving the first attack of the Union forces; surrendered and was exchanged, becoming chief of artillery under Gen. Joseph Johnston; constructed the defensive works on Chattahoochee river; became chief of staff to Gen. J. B. Hood in 1864; after being relieved at his own request, submitted to the Confederate Congress a pamphlet arguing for the enlistment of Negroes in the Confederate army. He became Professor of Applied Mathematics in the University of Mississippi in 1866; studied for the ministry, took orders in the Protestant Episcopal Church, and held rectorates in Nashville, Tenn., Jackson, Miss., and New Orleans; was Professor of Metaphysics in the University of the South. He published *Infantry Tactics* (1862); *Artillery Division Drill* (1864); *Elements of Algebra* (1874); and *Mechanism and Personality* (1889). D. in Columbia, Tenn., Sept. 1, 1896.

Shurtleff, ROSWELL MORSE: artist; b. in Rindge, N. H., June 14, 1838; studied drawing in Buffalo and Boston; enlisted in the army at the outbreak of the civil war; after the war furnished drawings to various periodicals and engravers, subsequently devoting himself entirely to painting, both in oil and water-color; became an associate of the National Academy in 1880. Among his best oil-paintings are *The Wolf at the Door*; *A Race for Life*; *On the Alert*; *Autumn Gold*; *Gleams of Sunshine*; and *A Song of Summer Woods*. His water-colors include *Harvest Time*; *Basin Harbor*; *Lake Champlain*; *The Morning Draught*; and *A Mountain Pasture*.

Siberia: Since the building of the Trans-Siberian Railroad began Russian peasants have been removing in vast numbers to Siberia. This is partly due to the large numbers who have insufficient lands in Russia. The immigration is promoted in every way by the Government. It amounted in 1896 to 200,000 souls, and in 1898 to nearly 400,000. The peasants are settling on the agricultural lands of Western Siberia, and also far E. in the Amur province, and even across the border in Northern Manchuria. As the railroad has advanced its freight and passenger business has much surpassed expectations, and in 1899 the Government opened a further credit of £42,626,889 to improve the western and central sections, the disbursement to extend over a series of years and to include the laying of new and heavier rails and increasing the speed of trains. The rails in 1899 had been laid beyond Irkutsk and Lake Baikal. Of the 490,000 tons of freight carried in 1898 more than 320,000 tons were cereals. The Russo-Chinese Bank, established in 1896 for the development of commercial relations between Russia and China, obtained a permit from the Chinese Government to build a railroad through Manchuria, and a company, nominally Chinese, was organized to construct the road, which is now building. The line leaves the Trans-Siberian at Nertschinsk E. of Lake Baikal and is to terminate at Vladivostok, the route being comparatively straight and passing through Tsitsikar. A branch will extend S. to Port Arthur. The Amur section of the main road presents large technical difficulties, and its completion may not be hastened now that connection with Vladivostok through Manchuria is assured. The railroad is giving a great impetus to Siberian agriculture, mining, and other industries. Before the central section was opened in 1897 there was no important movement of raw product east. Since then meat and other produce have been shipped in large quantities to Tomsk, Krasnoyarsk, Irkutsk, and other cities. The new leather-works in the government of Tomsk will tan most of the skins from the Western Siberian steppes. Oil-refining is making rapid progress. In 1897 more than 2,500 tons of butter was exported to Western Europe, and wheat-raising has greatly increased.

The prospect of the completion of the railroad is changing Vladivostok from merely a naval station and naval port to a busy center of trade. In 1898 there was not an unoccupied stone building or dwelling in the town, which then had about 15,000 inhabitants. Seven-eighths of the business men are Russians. The harbor will be kept open in winter by means of an ice-breaker. The imperial Government is expending 2,000,000 rubles improving the port of Alexandrovski, on the mainland opposite the island of Saghalien, so that Russian squadrons may recoal there. A survey has been made of the navigability of the rivers in the Amur district, and it is found that the Amur is navigable for about 2,000 miles; the Shilka and Ingoda, 660; the Sungari and its tributaries, 1,320; the Ussuri, 660; and the Selenga, 660. The streams in the Amur basin are deepest. The Government is developing steam-navigation on Baikal, one of the largest fresh-water lakes. It has very few good natural harbors. In 1899 Vice-Admiral Makarov was instructed to attempt, with his ice-breaker, to open the route in the Kara Sea and to keep it open for the steamers engaging that summer in the trade between Siberia and Europe. It is hoped, with the use of these machines, to keep the ice from greatly impeding navigation on this Arctic route and enable vessels to make two round trips in the season. The attempts to establish a commercial route between Western Europe and Western Siberia began in 1870, and the results have been encouraging. As yet the Yenisei has been a more prominent factor than the Ob in these enterprises. In July, 1899, a commission appointed by the czar was devising plans to abolish the Siberian exile system.
C. C. ADAMS.

Sicard, MONTGOMERY: naval officer; b. in New York city, Sept. 30, 1836; graduated at the Naval Academy in 1855, became master 1858, and lieutenant 1861; participated in the bombardment and passage of Forts St. Philip and Jackson and the Chalmette batteries 1862, and took part in the destruction of the Confederate flotilla; passed the Vicksburg batteries 1862; was promoted to lieutenant-commander the same year, serving in the South Atlantic blockading squadron 1864–65; engaged in the several attacks on Fort Fisher 1864–65, and took part in the bombardment of Fort Anderson; served at the Naval Academy, in the North Atlantic squadron, and in the Pacific fleet 1865–71; was made commander 1870; was on ordnance duty at New York and at Washington 1870–78, when he joined the North Atlantic squadron, and in 1879 was assigned to special duty at Washington; was in charge of the Boston navy-yard 1880, and made head of the ordnance bureau at Washington 1881, and advanced to captain; was subsequently stationed at the Brooklyn navy-yard, commanded the North Atlantic squadron, and was made rear-admiral 1897; became president of the naval strategy board 1898, and was retired the same year. D. in Westernvill, N. Y., Sept. 14, 1900.

Sicily: In 1895 Dr. Olinto Marinelli made a study of the distribution of population in relation to distance from the sea. He drew lines of equal distance from the coast at intervals of 5, 10, and 20 kilometers, etc. He ascertained the number of inhabitants in each zone and distinguished three principal zones, viz.: the coast zone, within 5 kilometers (3·1 miles) of the shore, containing 702 persons to the square mile; an intermediate zone, between 5 and 10 kilometers, with 262 to the square mile; and the inland region, with 199 to the square mile. Elevation, malaria, history, water, soil, and other factors influence the distribution of population. Sicily is the largest producer of sulphur, but consumption for years did not keep pace with production, and the closing of many mines in the past decade brought much suffering upon working people. The most important sulphur-mining district is in the center of Sicily, near Caltanissetta, where there are 567 mines, more than one-third of which are not now in operation. The U. S. consumes about one-third of the Sicilian sulphur product, and increased demand in the U. S. has improved the industry. About half the imports

to the U. S. are used in the preparation of wood-pulp for paper-making. The fruit industry has been considerably crippled by new tariffs imposed by the U. S. C. C. A.

Sierra Leone: A protectorate was declared in 1896 over a large area of the Hinterland, fertile and rich country, producing rice, rubber, kola, gum, kernels, and palm-oil in abundance. The area is 30,000 sq. miles. A railroad is in operation from Songotown to Freetown (30 miles), and across the Ribbi river to Rotofunk (30 miles), and 80 miles, to Bo, are under construction. The road and telegraph were opened on Apr. 4, 1899, between Freetown and Waterloo. The cost of the road will be $1,500,000. The colony had only a small public debt before borrowing money to build this line, which is expected to brighten the commercial prospects. The imports from the U. S. in 1897 were leaf tobacco, flour, kerosene, and lumber, valued at $230,000; exports to the U. S. were hides, kolanuts, coffee, and ginger, valued at $25,652. C. C. A.

Siloti, Alexander: pianist; b. near Charkow, Southern Russia, Oct. 10, 1863. From 1875 to 1882 he was a pupil in the conservatory in Moscow, where he studied under Nicholas Rubinstein, Tschaikowski, and others. The following three years he studied with Liszt, remaining with that master until his death, though he had already played in public as early as 1880. His first professional visit to the U. S. was in 1898, making his first appearance in Brooklyn in January, and in New York at the Waldorf-Astoria and in Mendelssohn Hall on Feb. 9 and 16. He is one of the young Russian school, and is possessed of a wonderful technic and an unusual stretch of hand. He reconstructed Tschaikowski's symphonic poem *Vovoyode*, after the composer had destroyed it. D. E. Hervey.

Simmons, Franklin, A. M.: sculptor; b. in Webster, Me., Jan. 11, 1842; during the civil war made many life-size medallions of members of the cabinet and officers of the army and navy, which were cast in bronze, most of them being purchased by the Union League of Philadelphia; settled permanently in Rome, Italy, in 1868; received the honorary degree of A. M. from Bates College and from Colby University. His sculptures include statues of Roger Williams, William King, Oliver P. Morton, and Henry W. Longfellow; *Medusa*; *Jochebed with the Infant Moses*; *Grief and History*, surmounting the naval monument at Washington; *Galatea*; *Penelope*; *Washington at Valley Forge*; and *The Seraph Abdiel*, from *Paradise Lost*. His portrait busts embrace those of Abraham Lincoln, William T. Sherman, David D. Porter, James G. Blaine, and Gen. Grant.

Sims, Winfield Scott: inventor; b. in New York city, Apr. 6, 1844; graduated at the Newark, N. J., high school in 1861; served in the Thirty-seventh New Jersey Regiment during the civil war, afterward applying himself to the invention of electric apparatus, producing various devices in electro-magnets; constructed an electric motor for light work in 1872, weighing 45 lb. and having a battery of 20 half-gallon Bunsen cells, by means of which he was able to propel an open boat 16 feet long, with six persons on board, at the rate of 4 miles an hour; was first to apply electricity for the propulsion of torpedoes, his device of a torpedo being a submarine boat with a cylindrical hull of copper and with conical ends, furnished with a screw propeller and a rudder, the power being electricity generated on shore or on shipboard, by means of which the torpedo is propelled, guided, and exploded; subsequently devised a boat with a speed of 18 miles an hour, and to carry a 250-lb. charge of dynamite.

Singer, Otto: musician; b. in Sora, Saxony, July 26, 1833; educated in Dresden, and later in Leipzig until 1865, and after a short residence in Weimar with Liszt went to New York in 1867. In 1873 he went to Cincinnati as assistant musical director, under Theodore Thomas, of the first May Musical Festival, in that year. He composed the cantata *The Pilgrim Fathers* for the festival of 1876, and *Festival Ode* for the opening of the music-hall in 1878. He remained with the Cincinnati College of Music until 1892, when he returned to New York, where he died Jan. 3, 1894. He was an earnest and aggressive disciple of Liszt and Wagner both in his compositions and piano performances. He conducted various singing societies, and in addition to the cantata mentioned he composed some sonatas for the pianoforte and a concerto. D. E. Hervey.

Skelton, Sir John, K. C. B., LL. D.: historian: b. in Edinburgh in 1831; educated at St. Andrews and Edinburgh Universities; practiced as a lawyer from 1854 to 1868, when he was appointed secretary of the board of supervision, of which he was made chairman in 1892; was first vice-president of the local government board for Scotland, retiring in 1897, in which year he was knighted; published in 1876 a treatise on pauperism, and in 1890 a manual on public health; wrote for the Scotch magazines under the signature "Shirley." Among his published works are *Nuga Critica*, essays (1862); *A Campaigner at Home* (1865); *The Impeachment of Mary Stuart* (1876); *Essays in Romance* (1878); *Crookit Meg* (1880); *Maitland of Lethington and the Scotland of Mary Stuart* (1887); *Mary Stuart* (1893); *Table-Talk of "Shirley"* (1895 and 1897). D. in Edinburgh, July 20, 1897.

Skinner, Charles Rufus, A. M., LL. D.: educator; b. in Union Square, N. Y., Aug. 4, 1844; educated in common schools, at Mexico Academy, and Clinton Liberal Institute; prepared for Hamilton College, but did not enter; A. M., Hamilton College, 1889; LL. D., Colgate University, 1895; member of board of education, Watertown, N. Y., 1874–83; member of New York Assembly from Jefferson County, 1877–81; Representative in Congress for Jefferson, Lewis, and Herkimer Counties, 1881–85; deputy State superintendent of public instruction, New York, 1886–92; supervisor of teachers' institutes and training classes, New York State, 1892–95; elected State superintendent of public instruction, New York, 1895, and re-elected in 1898; president of the National Educational Association 1896–97; author of *Arbor Day Manual*, and numerous addresses and reports on educational subjects.

Sladen, Douglas Brooke Wheelton: author: b. in London, England, 1856. Having received education at Cheltenham and Oxford, in 1879 he went to Australia, where he became Professor of History in the University of Sydney, and published a number of volumes of poetry, among them being *Frithjof and Ingebjorg* (1882); *Australian Lyrics* (1883, 1888); *A Poetry of Exiles* (1884); *A Summer Christmas* (1885); *In Cornwall and Across the Sea* (1885); *Edward, the Black Prince*, a drama (1886); and *The Spanish Armada* (1888). Returning to London, he produced anthologies of Australian and Canadian poets. He has visited nearly every part of the world, and has been an indefatigable writer. Among his prose works are *The Japs at Home* (1894); *On the Cars and Off*, sketches of Canadian travel (1894); and *A Japanese Marriage*, a novel (1895). He has done much toward the permanent establishment of the London Authors' Club, of which he is honorary secretary.

Slivinski, Joseph: pianist; b. in Warsaw, Dec. 15, 1865; pupil at the conservatory, and later in Vienna under Leschetizki, and next under Anton Rubinstein in St. Petersburg. He is a fine pianist. He made a professional visit to the U. S. in 1894.

Slocum, William Frederick, LL. D.: educator; b. in Grafton, Mass., in 1851; A. B., Amherst College, 1874; studied in Germany 1874–75; B. D., Andover Theological Seminary, 1878; LL. D., University of Nebraska, 1894; LL. D., Amherst College, 1893; pastor of Congregational churches—Amesbury, Mass., 1878–83, Baltimore, Md., 1883–88; president of Colorado College, Colorado Springs, Col., since 1888; president of State board of charities and corrections and State board of pardons of Colorado, and writer on sociological and educational subjects.

Small, Albion Woodbury, Ph. D.: educator; b. in Buckfield, Me., May 11, 1854; prepared for college at Portland, Me., high school; A. B., Colby University, 1876; student in Newton Theological Institution 1876–79; student in University of Berlin 1879–80, University of Leipzig 1880–81; Ph. D., Johns Hopkins University, 1889; Professor of History and Political Economy, Colby University, 1881–88; reader in history, Johns Hopkins University, 1888–89; president of Colby University 1889–92; head Professor of Sociology, University of Chicago, since 1892. He is author of *Outline of the French Revolution*; *Introduction to the History of European Civilization*; *The Beginnings of American Nationality*; *Introduction to the Science of Sociology*; *Introduction to the Study of Society* (with George E. Vincent); and many sociological monographs; editor of *American Journal of Sociology*.

Smeerenberg: a former remarkable village on Amsterdam island, off the northwest coast of Spitzbergen, whose ruins still testify to the great extent of the whaling and fishing interests in those waters in the seventeenth century.

The town contained the principal establishments for trying out oil, cooperage, etc. The place was within 10 degrees of the north pole. Hundreds of ships and more than 10,000 men visited it annually. There were many shops, bakeries, and drinking-places, and brick houses for the laborers. The failure of the shore fisheries about 1640 drove the Dutch to more remote waters, and Smeerenberg was gradually abandoned. About 1,000 fishermen were buried in its cemetery. See Greely's *Handbook of Arctic Discoveries.*

Smiley, William Henry, A. B.: educator; b. in Maplewood, Mass., Apr. 28, 1854; prepared for college at Melrose, Mass., high school; A. B., Harvard University, 1877; master of New Salem Academy, New Salem, Mass., 1877–80; instructor in St. John's School, Boston, 1880–82; instructor in Jarvis Hall, Denver, Col., 1882, and master there 1883–86; instructor in Denver high school, district No. 1, 1886–92, and principal there since 1892; author of articles in educational journals; president of the secondary department of the National Educational Association in 1895.

Smith, David Eugene, Ph. D.: educator; b. in Cortland, N. Y., Jan. 21, 1860; graduated at Cortland State Normal School; Ph. B. 1881, Ph. M. 1884, Ph. D. 1887, Syracuse University; honorary M. Pd., State Normal College, Ypsilanti, Mich., 1898; practiced law 1882–84; teacher of mathematics, Cortland State Normal School, 1884–91; Professor of Mathematics in the Michigan State Normal College 1891–98; principal of the State Normal School, Brockport, N. Y., since 1898. He is author of translation of Klein's *Famous Problems of Geometry* (1897); translation of Fink's *History of Elementary Mathematics* (1899); *History of Modern Mathematics* (1896); joint author of *Beman and Smith's Series of Mathematics* (1896–).

Smith, Horace: English magistrate, law-writer, and litterateur; b. in London, Nov. 18, 1836; educated at King's College, London, and Trinity Hall, Cambridge; called to the bar in 1862, and in 1881 made recorder of Lincoln, having held in the intermediate time the positions of counsel to the mint, revising barrister on the midland circuit, and secretary to the Oxford bribery commission. He is best known for his treatise on the *Law of Negligence* (2d Am. ed. 1887); *Manual of the Law of Landlord and Tenant* (joint author with Thomas S. Sowden, 1871); and as the editor of *Addison on Contracts*; *Addison on Torts*; *Roscoe's Criminal Evidence*; and *Russell on Crimes.* He has published also several volumes of poems and interludes.

Smith, Rev. Walter C., M. A., LL. D.: poet; b. in Aberdeen, Scotland, in 1825; educated at Aberdeen University and New College, Edinburgh; ordained minister of the English Presbyterian church in Islington, London, in 1850; afterward a minister of the Free Church of Scotland in Orwell (Kinross), Roxburgh (Edinburgh), Tron (Glasgow), and High church (Edinburgh). In 1867 he was arraigned for heresy alleged to be expressed in his lectures on the "Sermon on the Mount," but the General Assembly dismissed the charges. In 1893 he was moderator of the Assembly. He is best known as a poet, his chief works being *The Bishop's Walk* (1861); *Hymns of Christ and the Christian Life* (1867); *Olrig Grange* (1872); *Borland Hall* (1874); *Hilda* (1878); *Raban* (1881); *North-Country Folk* (1883); *Kildrostan* (1884); *Thoughts and Fancies for Sunday Evenings* (1887); *A Heretic* (1891).

Smock, John Conover, Ph. D.: geologist; b. in Holmdel, N. J., Sept. 21, 1842; graduated at Rutgers College in 1862, and was tutor in chemistry there 1865–67; became Professor-elect of Mining and Metallurgy in 1867, holding the chair 1871–75, meantime studying at the Berg-Akademie and at the University of Berlin; was assistant in charge of the New York State Museum 1885–89; received the degree of Ph. D. from Lafayette College in 1882; was manager of the American Institute of Mining Engineers 1875–77; was associated with Prof. George H. Cook in preparing the annual reports of the Geological Survey of New Jersey for 1871–84, and in the volumes on *The Geology of New Jersey* (1868), and the *Report on Clay Deposits*; issued, as a bulletin of the State museum, *On Building-Stones in New York* (1888).

Snider, Denton Jaques; author; b. in Mt. Gilead, O., Jan. 9, 1841; graduated at Oberlin College in 1862; after teaching for a time, became a traveling lecturer on general literature. Among his works are *A System of Shakespeare's Dramas* (1877); *Delphic Days* (1880); *A Walk in Hellas* (1882); *Agamemnon's Daughter* (1885); *An Epigrammatic Voyage* (1886); *Commentary on Goethe's "Faust"* (1886); and *Commentary on Shakespeare's Tragedies* (1887).

Snow, Francis Huntington, LL. D.: educator; b. in Fitchburg, Mass., June 29, 1840; prepared for college at Fitchburg high school; graduated at Williams College 1862, Andover Theological Seminary 1866; A. B. 1862, A. M. 1865, Ph. D. 1881, Williams College; LL. D. 1890, Princeton; has rendered consecutive service to the University of Kansas, Lawrence, Kan., since Sept., 1866, as follows: Professor of Mathematics and Natural Science 1866–70, Professor of Natural History 1870–89, Professor of Botany and Entomology and president of the university faculties 1889–90, chancellor of the university since 1890. He is author of a large number of scientific and educational papers and addresses. In 1886 the State of Kansas appropriated $50,000 for the erection of a natural history building, to furnish a suitable home for the collection of birds, insects, and fossils which had been secured through the personal efforts of Mr. Snow in summer expeditions to Western Kansas, Colorado, and New Mexico. This building was named the Snow Hall of Natural History.

Snyder, Zachariah Xenophon, Ph. D.: educator; b. in Reagantown, Pa., Aug. 31, 1850; prepared for college in Mount Pleasant (Pa.) Classical Institute; graduated A. B. and S. B. at Waynesburg College, Pennsylvania, 1876; received Ph. D. degree 1887. After graduation taught in public schools; instructor in mathematics, Waynesburg College, 1881–82; superintendent of public schools, Greensburg, Pa., 1884–88; superintendent of public schools, Reading, Pa., 1888–90; president of State Normal School, Indiana, Pa., 1890–92; president of Colorado State Normal School, Greeley, Col., since 1892. He is author of educational essays and addresses, several printed in the *Proceedings* of the National Educational Association.

Sobat River: a right tributary of the White Nile, S. of Fashoda, very little known, except in its lower course, until 1898. A reconnoissance by Anglo-Egyptian gunboats showed the river to be a good navigable stream. At a distance of 212 miles from its junction with the White Nile it becomes two rivers, that flowing from the E. being called Adura (in its upper reaches, the Baro), and the S. river, shown on the maps as the Juba, being known locally as the Pibor. The gunboats ascended the Adura 30 miles, and natives say it is navigable for a greater distance. The Pibor is navigable for 75 miles. The Sobat flows through an immense alluvial plain, swampy near the river, with flat grasslands stretching to the horizon beyond. There are no hills, but extensive woods vary the landscape. The river current is 2½ miles an hour, the depth is more than 20 feet throughout, and the width is from 150 to 200 yards. C. C. A.

Socor'ro: town of Colombia; in the department of Santander, of which it was formerly the capital; on a plateau, 40 miles S. S. W. of Bucaramanga; 4,120 feet above the sea (see map of South America, ref. 2–C). It was founded in 1540 on the site of an Indian city, and was removed to its present site in 1681. In 1781 it was the center of a formidable revolt, and it was the first place in New Granada to declare for independence in 1810. Hand-woven mantles and "Panama" hats are exported. Pop. about 18,000. H. H. S.

Socorro: city; capital of Socorro co., N. M.; on the Rio Grande river, and the Atch., Top. and S. Fé Railroad; 75 miles S. by W. of Albuquerque; 178 miles N. of El Paso, Tex. (for location, see map of New Mexico, ref. 12–R). It is engaged in mining and smelting gold, silver, and lead, raising cattle, sheep, and goats, agriculture, fruit-culture, and lumbering; and contains 6 churches, 3 public-school buildings of brick (cost $25,000), State School of Mines (cost $50,000), 2 national banks with combined capital of $100,000, and 2 weekly newspapers. The city has an excellent climate that is highly recommended for persons in the early stages of consumption. When discovered by the Spaniards, the site was occupied by an Indian pueblo. The place was settled by Franciscan fathers, was destroyed and abandoned in 1650, and was again settled in 1765, 1794, and 1804. Pop. (1880) 1,272; (1890) 2,295; (1900) 1,512.
