BRAID. A plaited, twisted or woven trimming.

BRAIDING MACHINE. (*Machine à lacets*, Fr.; *Bortenwerkerstuhl*, Ger.) This being employed, not only to manufacture stay-laces, braid, and upholsterers' cord, but to cover the threads of caoutchouc for weaving brace-bands, deserves a description in this work. Three threads at least are required to make such a knitted lace, but 11, 13, or 17, and even 29 threads are often employed, the first three numbers being

204

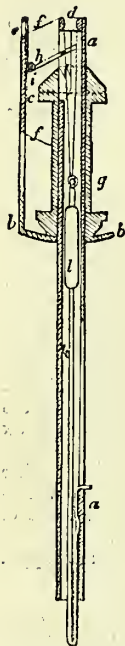

205

preferred. They are made by means of a frame of a very ingenious construction, which moves by a continuous rotation. We shall describe a frame with 13 threads, from which the structure of the others may be readily conceived. The basis of the

machine consists of four strong wooden uprights, *A*, *figs.* 204, 205, 206, occupying the four angles of a rectangle, of which one side is 14 inches long, the other side 18 inches, and the height of the rectangle about 40 inches. *Fig.* 204 is a section in a horizontal plane, passing through the line *a b* of *fig.* 205, which is a vertical section in a plane passing through the centre of the machine *c*, according to the line *c d*, *fig.* 204. The side *x* is supposed to be the front of the frame; and the opposite side, *y*, the back, *B*, six spindles or skewers, numbered from 1 to 6, placed in a vertical position upon the circumference of a circle whose centre coincides with that of the machine at the point *c*. These six spindles are composed—1, Of so many iron shafts or axes *D*, supported in brass collets *E* (*fig.* 205), and extended downwards within 6 inches of the ground, where they rest in brass steps fixed upon a horizontal beam. 2, Wooden heads, made of horn-beam or nut-tree, placed, the first upon the upper end of each spindle, opposite the cut-out beam *F*, and the second opposite the second beam *G*. 3, Wooden-toothed wheels, *H*, reciprocally working together, placed between the beam *G* and the collet-beam *E*. The toothed wheels and the lower heads for each spindle are in one piece.

206

The heads and shafts of the spindles No. 1 and 6 are one-fifth stronger than those of the other spindles; their heads have five semi-circular grooves, and wheels of 60 teeth, while the heads of the others have only four grooves, and wheels of 48 teeth; so that the number of the grooves in the six spindles is 26, one-half of which are occupied with the stems of the puppets *I*, which carry the 13 threads from No. 1 to 13.

The toothed wheels, which give all the spindles a simultaneous movement, but in different directions, are so disposed as to bring their grooves opposite to each other in the course of rotation.

x, the middle winglet, triple at bottom and quintuple at top, which serves to guide the puppets in the direction they ought to pursue.

r, three winglets, single at top and bottom, placed exteriorly, which serve a like purpose.

m, two winglets, triple at bottom and single at top, placed likewise exteriorly, and which serve the same purposes as the preceding; *n*, are iron pins inserted in the cut-out beam *G*, which serve as stops or limits to the oscillations of the exterior winglets.

Now, if by any moving power (a man can drive a pair) rotation be impressed upon the large spindle No. 1, in the direction of the arrow, all the other spindles will necessarily pursue the rotatory movement indicated by the respective arrows. In this case the 13 puppets working in the grooves of the heads of the spindles will be carried round simultaneously, and will proceed, each in its turn, from one extremity of the machine to the opposite point, crossing those which have a retrograde movement. The 13 threads united at the point *x*, situated above the centre of the machine, will form at that point the braid, which after having passed over the pulley *o*, comes between the two rollers *p q*, and is squeezed together, as in a flattening-mill, where the roller *p* receives its motion from the toothed wheel of the spindle No. 3, and from the intermediate wheels, *r*, *s*, *t*, as well as from the endless screw *z*, which drives at proper speed the wheel *w*, fixed upon the shaft of the roller *p*.

The braid is denser in proportion as the point *x* is less elevated above the tops of the puppets, but in this case, the excentric motion of these puppets is much more sensible in reference to that point towards which all the threads converge than when it is elevated. The threads, which must be always kept equally stretched by means of a weight, as we shall presently see, are considerably strained by the traction occasioned by the constantly excentric movement of the puppets. From this cause, braiding machines must be worked at a moderate velocity. In general, for fine work, 30 turns of the large spindle per minute are the utmost that can safely be made.

The puppet or spindle of this machine, being the most important piece, I have represented it in section, upon a scale one-fourth of its actual size, *fig.* 206. It is formed of a tube, *a*, of strong sheet iron well brazed; *b* is a disc, likewise of sheet iron, from which a narrow fillet *c*, rises vertically as high as the tube, where both are pierced with holes, *d e*, through which the thread *f* is passed, as it comes from the bobbin, *g*, which turns freely upon the tube *a*. The top of this bobbin is conical and toothed. A small catch or detent *h*, moveable in a vertical direction round *i*, falls by

its own weight into the teeth of the crown of the bobbin, in which case this cannot revolve; but when the detent is raised so far as to disengage the teeth, and at the same time to pull the thread, the bobbin turns, and lets out thread till the detent falls back into these same teeth.

A skewer of iron wire, *k*, is loaded with a small weight, *l*, melted upon it. The top of this skewer has an eye in it, and the bottom is recurved, as is shown in *fig. 206*, so that supposing the thread comes to break, this skewer falls into the actual position in the figure, where we see its lower end extending beyond the tube *a*, by about $\frac{1}{4}$ of an inch; but as long as the thread is unbroken, the skewer *k*, which serves to keep it always tense during the excentric movement of the puppet, does not pass out below the tube.

This disposition has naturally furnished the means of causing the machine to stop whenever one of the threads breaks. This inferior protrusion of the skewer pushes in its progress a detent, which instantly causes the band to slide from the driving pulley to the loose pulley. Thus the machine cannot operate unless all the threads be entire. It is the business of the operative, who has 3 or 4 under her charge, to mend the threads as they break, and to substitute full bobbins for empty ones, whenever the machine is stopped.

BRAN (*Son*, Fr.; *Kleie*, Ger.) The husky portion of ground wheat, separated by the boulder from the flour. It is advantageously employed by the calico printers, in the clearing process, in which, by boiling in bran-water, the colouring matters adhering to the non-mordanted parts of maddered goods, as well as the duu matters which cloud the mordanted portions, are removed. A valuable series of researches by M. Daniel Kœchlin-Schouch, justified the following conclusions:—

1. The dose of two bushels of bran for 10 pieces of calico is the best, the ebullition being kept up for an hour. A boil for the same time in pure water had no effect in clearing either the grounds or the figures.

2. Fifteen minutes boiling are sufficient when the principal object is to clear white grounds, but in certain cases 30 minutes are requisite to brighten the dyed parts. If, by increasing the charge of bran, the time of the ebullition could be shortened, it would be, in some places, as Alsace, an economy; because in the passage of the 10 pieces through a copper or vat heated with steam, 1 cwt. of coal is consumed in fuel, which costs from $2\frac{1}{2}$ to 3 francs, while 2 bushels of bran are to be bought for 1 franc.

3. By increasing the quantity of water from 12 to 24 hectolitres with 2 bushels of bran, the clearing effect upon the 10 pieces was impaired. It is therefore advantageous not to use too much water.

4. Many experiments concur to prove that flour is altogether useless for the clearing boil, and that finer bran is inferior for this purpose to the coarser.

5. The white ground of the calicoes boiled with wheat bran is distinguishable by its superior brightness from that of those boiled with rye bran, and especially with barley bran; the latter having hardly any effect.

6. There is no advantage in adding soap to the bran boil; though a little potash or soda may be properly introduced when the water is calcareous.

7. The pellicle of the bran is the most powerful part; the flour and the starch are of no use in clearing goods, but the mucilage, which forms one-third of the weight of the bran, has considerable efficacy, and seems to act in the following way:—In proportion as the mucilaginous substance dissolves the colouring and tawny matters upon the cloth, the husky surface attracts and fixes upon itself the greater part of them. Accordingly, when used bran is digested in a weak alkaline bath, it gives up the colour which it had absorbed from the cloth.

From bran, Pélégot obtained 8·0 per cent. of cellulose. Millon succeeded in extracting considerable quantities of glutinous substances from the bran with acetic acid and alcohol. He found in 100 parts, starch, dextrine, and sugar, 50·0; sugar, 1·0; gluten, 14·9; fat, 3·6; cellulose, 9·7; salts, 5·7; water, 13·9; and of odorous and resinous matters, 1·2 per cent.

BRANCH COAL. A term applied in Yorkshire to cannel and other kinds of coal, which occurs in layers traversing the ordinary coal of the district. The *branching coal* of South Wales derives its name from the peculiar swelling which takes place in the operation of coking, after which it becomes very light.

BRANDS. Imperfectly carbonised pieces of wood taken from a charcoal heap.

BRANDY. (*Eau de vie*, Fr.; *Branntwein*, Ger.) The name given in this country to ardent spirits distilled from wine, and possessing a peculiar taste and flavour, due to a minute portion of a volatile oil. Each variety of alcohol has an aroma characteristic of the fermented substance from which it is procured; whether it be the grape, cherries, sugar-cane, rice, corn, or potatoes; and it may be distinguished even as procured from different growths of the vine. The brandies of

Languedoc, Bordeaux, Armagnac, Cognac, Aunis, Saintonge, Rochelle, Orleans, Barcelona, Naples, &c., being each readily recognisable by an experienced dealer.

Aubergier showed by experiments, that the disagreeable taste of the spirits distilled from the *marc* of the grape is owing to an essential oil contained in the skin of the grape; and found that the oil, when insulated, is so energetic that a few drops are sufficient to taint a pipe of 600 litres of fine-flavoured spirit. See FUSEL OIL.

The most celebrated of the French brandies, those of Cognac and Armagnac, are slightly rectified to only from 0.935 to 1.922: they contain more than half their weight of water, and come over therefore highly charged with the fragrant essential oil of the husk of the grape. When, to save expense of carriage, the spirit is rectified to a much higher degree, the dealer, on receiving it at Paris, reduces it to the market proof by the addition of a little highly flavoured weak brandy-and-water; but he cannot in this way produce so finely-flavoured a spirit as the weaker product of distillation of the Cognac wine. If the best Cognac brandy be carefully distilled at a low heat, and after distillation the strong spirit be diluted with water to restore it to its original strength, it will be found that the brandy has suffered much in its flavour.

Genuine French brandy evinces an acid reaction with litmus-paper, owing to a minute portion of vinegar; it contains, besides, some acetic ether, and, when long kept in oak casks, a little astringent matter.

The constituents of brandy are *alcohol, water, volatile oil, acetic acid, acetic ether, colouring matter, and tannin.*—Pereira.

Pale brandy acquires the slight colour which it possesses from the cask in which it is kept. *Brown brandy* is coloured by *caramel*. Brandy is sold of various strengths, but it is usually about 10 per cent. under proof. The quantities of brandy imported, and its computed value, have been as follow:—

	1867 Proof Galls.	1868 Proof Galls.	1869 Proof Galls.	1870 Proof Galls.	1871 Proof Galls.
Quantity . . .	4,849,832	4,062,885	3,937,266	7,942,965	5,228,568
	£	£	£	£	£
Value	1,376,360	1,309,413	1,249,579	2,153,699	1,895,378

For the last three years the returns are given, showing the quantity retained for home consumption:—

	1870 Proof Galls.	1871 Proof Galls.	1872 Proof Galls.
Imports	9,942,965	5,372,486	3,519,413
Home consumption . .	3,526,132	3,715,675	3,944,725

The duty on brandy was reduced in 1860 to 8s. 6d. per gallon.

BRANDY, BRITISH. Dr. Ure gave the following formula for its preparation:—Dilute pure alcohol to the proof pitch; add to every hundred pounds weight of it from half a pound to a pound of argol, dissolved in water, a little acetic ether, and French wine vinegar, some bruised French plums, and flavour stuff from Cognac; then distil the spirit with a gentle fire in an alembic furnished with an agitator. British brandies are now sold as pure grain spirits, flavoured and coloured with caramel. See ALCOHOL.

BRASS. (*Laiton, cuivre jaune, Fr.; Messing, Ger.*) An alloy of copper and zinc. The brass of the ancients appears, in very early times, to have chiefly consisted of a mixture of copper and tin, and to have consequently, been a species of bronze or bell metal. See ALLOYS.

Brass was formerly manufactured by cementing granulated copper, called *bean-shot*, or copper clippings, with calcined calamine (native carbonate of zinc) and charcoal in a crucible, and exposing them to bright ignition. Three parts of copper were used for 3 of calamine and 2 of charcoal.

James Emerson obtained a patent, in 1781, for making brass by the direct fusion of its two metallic elements, and it is now usually manufactured in this way.

It appears that the best proportion of the constituents to form fine brass is 2 equivalents of copper = 63½ + 1 of zinc = 32.3; or very nearly 2 parts of copper to 1 of zinc.

In the process of alloying two metals of such different fusibilities as copper and zinc, a considerable waste of the latter metal by combustion might be expected; but in reality, their mutual affinities seem to prevent the loss, in a great measure, by the speedy absorption of the zinc into the substance of the copper. Indeed, copper plates and rods are often *brassed* externally by exposure, at a high temperature, to the fumes of zinc, and afterwards laminated or drawn. The spurious gold wire of

Lyons is made from such rods. Copper vessels may be superficially converted into brass by boiling them in dilute muriatic acid containing some tartar and zinc amalgam.

The first step in making brass is to plunge slips of copper into melted zinc till an alloy of somewhat difficult fusion be formed, to raise the heat, and add the remaining proportion of the copper.

The brass of the first fusion is broken to pieces, and melted with a fresh quantity of zinc, to obtain the finished brass. Each melting takes from 8 to 9 hours. The metal is now cast into plates, about 40 inches long by 26 broad, and from one-third to half an inch thick. The moulds were formerly slabs of granite mounted in an iron frame. Granite appears to have been preferred as a mould, because it preserves the heat, whilst, by the asperities of its surface, it keeps hold of the clay lute applied to secure the joinings.

The modern method of making brass, by the direct mixture of the component metals, is largely practised at Birmingham in small square furnaces, built of fire-brick, and measuring from 10 to 12 inches in the side, and about 2 feet in depth. Crucibles of Stourbridge fire-clay, or, rarely, of plumbago, are placed on the iron bars at the bottom of the furnace, and packed round with coke. The ingot copper is first introduced into the crucible, and when this is melted the proper proportion of zinc is cautiously added, the mixture being stirred with an iron poker to ensure union of the metals. As soon as the mixture is thoroughly effected, the crucible is withdrawn, and the molten brass is cast, either into moulds of sand, or into iron ingot moulds, slightly oiled inside, and dusted over with charcoal powder. In the manufacture of the variety of brass called 'Muntz's metal,' an alloy extensively made for sheathing the bottoms of ships, the mixture of metals is generally effected in a reverberatory furnace, instead of in crucibles. See MUNTZ'S METAL.

The cast plates of brass are usually rolled into sheets. For this purpose they are cut into ribands of various breadths, commonly about $6\frac{1}{2}$ inches. The cylinders of the brass rolling mill are generally 46 inches long and 18 inches in diameter. The ribands are first of all passed through the cylinders cold; but the brass soon becomes too hard to laminate. It is then annealed in a furnace, and, after cooling, is passed afresh through the rolls. After paring off the chipped edges, the sheets are laminated, two at a time; and if they are to be made very thin, even 8 plates are to be passed through together. The brass in these operations must be annealed 7 or 8 times before the sheet arrives at the required thickness. These successive heatings are expensive; and hence manufacturers have been led to try various plans of economy. The annealing furnaces are of two forms, according to the size of the sheets of brass. The smaller are about 12 feet long, with a fire-place at each end, and about 13 inches wide. The arch of the furnace has a cylindrical shape, whose axis is parallel to its small side. The hearth is horizontal, and is made of bricks set on edge. In the front of the furnace there is a large door, which is raised by a lever, or chain and counterweight, and slides in a frame between two cheeks of cast-iron. This furnace has, in general, no chimney, except a vent slightly raised above the door, to prevent the workmen being incommoded by the smoke. Sometimes the arch is perforated with a number of holes. The sheets of brass are placed above each other, but separated by parings, to allow the hot air to circulate among them, the lowest sheet resting upon bars of cast-iron placed lengthwise.

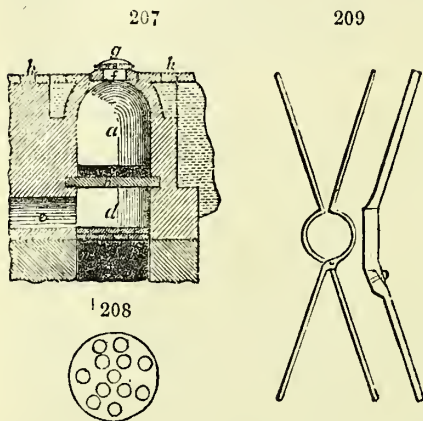

The larger furnaces are usually 32 feet long, by $6\frac{1}{2}$ feet wide, in the body, and 3 feet at the hearth. A grato 13 inches broad extends along each side of the hearth, through its whole length, and is divided from it by a small wall, 2 or 3 inches high. The vault of the furnace has a curvature, and is pierced with 6 or 8 openings, which allow the smoke to pass off into a low bell-chimney above. At each end of the furnace is a cast-iron door, which slides up and down in an iron frame, and is poised by a counterweight. On the hearth is a kind of railway, composed of two iron bars, on which the carriage moves with its load of sheets of brass.

These sheets, being often 24 feet long, could not be easily moved in and out of the furnace; but as brass laminates well in the cold state, they are all introduced and moved out together. With this view an iron carriage is framed with bars, which rest on four wheels. Upon this carriage, of a length nearly equal to that of the furnace, are laid the sheets, with brass parings between them. The carriage is then raised by a crane to a level with the furnace, and entered upon the grooved bars which lie upon the hearth. That no heat may be lost, two carriages are provided, the one being ready to put in as the other is taken out; the furnace is meanwhile uniformly kept hot. This method, however convenient for moving the sheets in and out, wastes a good deal of fuel in heating the iron carriage.

The principal places in which brass is manufactured on a large scale, in England, are Bristol and Birmingham, and at Holywell, in North Wales.

At the brass manufactory of Hegermühl, upon the Finon Canal, near Potsdam, the following are the materials of one charge:—41 pounds of old brass, 55 pounds refined copper (*Garkupfer*) granulated, and 24 pounds of zinc. This mixture, weighing 120 pounds, is distributed in four crucibles, and fused in a wind furnace with pitcoal fuel. The waste, upon the whole, varies from $2\frac{1}{2}$ to 4 pounds.

Fig. 209 represents the furnace as it was formerly worked with charcoal; *a*, the laboratory, in which the crucibles were placed. It was walled with fire-bricks. The

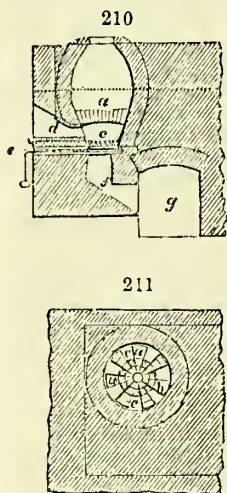

foundations and the filling-in walls were formed of stone rubbish, as being bad conductors of heat; sand and ashes may be also used; *b*, cast-iron circular grating plates, pierced with 12 holes (see *fig. 208*), over them a sole of loam, *c*, is beaten down, and perforated with holes corresponding to these in the iron discs; *d*, the ash-pit; *e*, the *bock*, a draught flue which conducts the air requisite to the combustion, from a sunk tunnel in communication with several melting furnaces. The terrace or crown of the furnace, *f*, lies on a level with the foundry floor, *h h*, and is shut with a tile of fire-clay, *g*, which may be moved in any direction by means of hooks and eyes in its binding iron ring.

Fig. 209 the tongs for putting in and taking out the charges, as viewed from above and from the side.

The following description of a Continental brass manufactory, by Dr. Ure, it has been thought advisable to retain, with only a few verbal alterations.

Figs. 210, 211, represent the furnaces more recently constructed for the use of pitcoal fuel; *fig. 210* being

In this furnace the crucibles are not surrounded with the fuel, but receive the requisite melting heat from the flame proceeding from the grate upon which it is burnt. The crucibles stand upon seven arches *a*, which unite in the middle at the keystone, *b*, *fig. 211*; between the arches are spaces, through which the flame rises from the grate, *c*; *d*, is the fire door; *e*, a sliding tile or damper for regulating or shutting off the air-draught; *f* an inclined plane, for carrying off the cinders that fall through the grate, along the draught tunnel *g*, so that the air in entering below may not be heated by them.

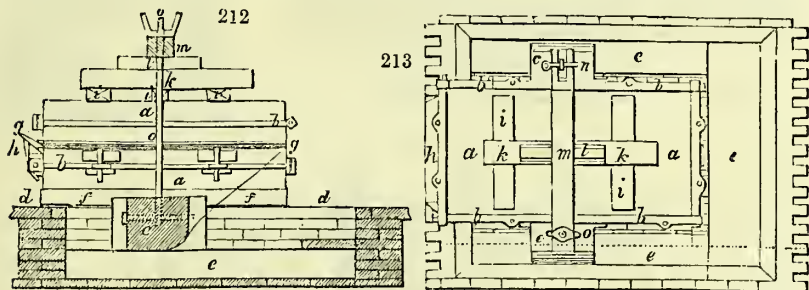

The crucibles are 16 inches deep, $9\frac{1}{2}$ wide at the mouth, $6\frac{1}{2}$ at the bottom; with a thickness in the sides of 1 inch above and $1\frac{1}{2}$ below; they stand from 40 to 50 meltings. The old brass, which fills their whole capacity, is first put in and melted down; the crucibles are now taken out and charged with the half of the zinc in pieces of from 1 to 3 inches in size, covered over with coal-ashes; then one-half of the copper is introduced; again dust; and thus the layers of zinc and copper are distributed alternately with coal-ashes betwixt them, till the whole charge becomes finally fused. Over all, a thicker layer of carbonaceous matter is laid, to prevent oxidation of the brass. Eight crucibles filled in this way are put into the furnace between the 12 holes of the grate; and over them are laid two empty crucibles to be heated for the casting operation. In from $3\frac{1}{2}$ to 4 hours the brass is ready to be poured. Fifteen English bushels of coals are consumed in one operation; of which six are used at the introduction of the crucibles, and four gradually afterwards.

When sheet brass is to be made, the following process is pursued:—

An empty crucible is taken out of the furnace through the crown with a pair of tongs, and kept red hot by placing it in a hollow hearth surrounded with burning

coals; into this crucible the contents of four of the melting pots are poured; the dross is raked out with an iron scraper. As soon as the melting pot is emptied, it is immediately re-charged in the manner above described, and placed in the furnace. The surface of the melted brass is swept with the stump of a broom, and then stirred about with the iron rake, to bring up any light foreign matter to the surface, which is then skimmed with a little scraper; the crucible is now seized with the casting tongs, and emptied in the following way:—

The mould or form for casting sheet brass consists of two slabs of granite, *a a*, figs. 212, 213. These are $5\frac{1}{2}$ feet long, 3 feet broad, 1 foot thick, and, for greater security,

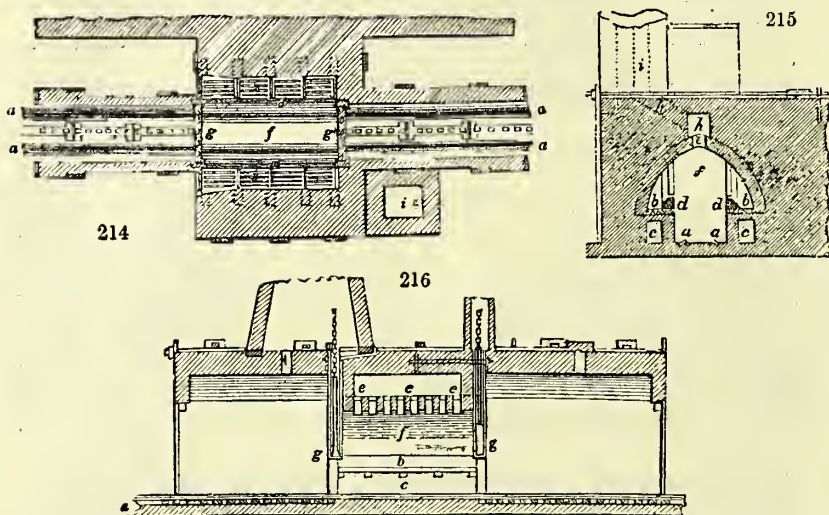

girt with iron bands, *b b*, 2 inches broad, $1\frac{1}{2}$ thick, and joined at the four corners with bolts and nuts. The mould rests upon an oaken block, *c*, $3\frac{1}{2}$ feet long, $2\frac{1}{6}$ th broad, and $1\frac{1}{4}$ thick, which is suspended at each end upon gudgeons, in bearing blocks, placed under the foundry floor, *d d*, in the casting pit, *e e*. This is lined with bricks; and is $6\frac{3}{4}$ feet long, $5\frac{1}{2}$ broad, and 2 deep; upon the two long side walls of the pit are laid the bearing blocks which support the gudgeons. The swing blocks are 10 inches long, 18 inches broad, 15 inches thick, and somewhat rounded upon their back edge, so that the casting frame may slope a little to the horizon. To these blocks two cross wooden arms, *f f*, are mortised, upon which the under slab rests freely, but so as to project about 5 inches over the block backwards, to secure an equipoise in the act of casting. *g g* are bars, placed at both of the long sides, and one of the ends, between the slabs, to determine the thickness of the brass plate. Upon the other slab the gate *h* is fastened, a sheet of iron 6 inches broad, which has nearly the shape of a parallel trapezium (lozonge), and slopes a little towards the horizon. This serves for setting the casting pot upon in the act of pouring, and renders it more convenient to empty. The gate is coated with a mixture of loam and hair. The upper slab is secured to the under one in its slanting position by an *armour* or binding. This consists of tension bars of wood, *i, k, l, m*, of the iron bars *n*, (3 to $3\frac{1}{2}$ inches broad, $1\frac{1}{2}$ inch thick, see the top view, fig. 213) of a rod with holes and pins at its upper end, and of the iron screw spindle *o*. The mode in which these act may be understood from inspection of the figure. In order to lift the upper slab from the under one, which is effected by turning it round its edge, a chain is employed, suspending two others, connected with the slab. The former passes over a pulley, and may be pulled up and down by means of a wheel and axle, or the aid of a counterweight. Upon each of the two long sides of the slab are two iron rings, to which the ends of the chains may be hooked. The casting faces of the slab must be coated with a layer of finely ground loam; the thinner this is the better.

When calamine is employed, $\frac{1}{2}$ cwt. of copper, $\frac{3}{4}$ cwt. of calamine, and $\frac{1}{3}$ rd the volume of both of charcoal mixed, are put into seven crucibles, and exposed to heat during 11 or 12 hours; the product being from 70 to 72 lbs. of brass.

Brass-Plate Rolling.—At Hegermühl there are two re-heating or annealing furnaces, one larger, 18 feet long, and another smaller, $8\frac{1}{2}$; the hot chamber is separated from the fireplace by iron beams, in such a way that the brass castings are played upon by the flames on both their sides. After each passage through the laminating rolls, they are heated anew, then cooled and laminated, until they have reached the proper length. The plates are smeared with grease before rolling.

Fig. 214 shows the ground plan of the furnace and its railway; fig. 215, the cross section; and fig. 216 the section lengthwise; *a a*, the iron way bars or rails upon the floor of the foundry for enabling the wheels of the waggon to move rapidly backwards and forwards; *b b*, the two grates; *c c*, the ash-pits; *d d*, the fire beams;

e e e, vents in the roof of the hot chamber *f*; *g, g*, two plates for shutting the hot chamber; *h*, the flue; *i*, the chimney. After rolling, the sheets, covered with black oxide of copper, are plunged for a few minutes into a mother-water from the alum

works, then washed in clean water, and lastly, smeared with oil, and scraped with a blunt knife.

For musical purposes, the brass wire of Berlin had acquired great and merited celebrity; but that of Birmingham and of Cheadle is now preferred by foreigners.

The Table on the opposite page, for the compilation of which we are indebted to Mr. Robert Mallet, F.R.S., presents, in a very intelligible form, the chemical and physical conditions of the various kinds of brass.

It is known that common brass, containing from 27·4 to 31·8 per cent. of zinc and from 71·9 to 65·8 per cent. of copper, is not malleable while hot, but that articles of it must be made by casting. As it would be of great advantage in many branches of industry to have an alloy of this kind that could be worked while hot, like malleable iron, the information that such an alloy exists must be welcome to artists.

By melting together 33 parts of copper and 25 parts of zinc, there was a loss of 3 parts, thus making 60 per cent. copper and 40 per cent. zinc. It differs from the English specimens by containing a larger proportion of zinc, and possesses, according to M. Machts, the proprietor of a brass foundry in Hanover, the precious property of malleability in a higher degree than the English specimens.

A piece of 'yellow metal,' similar in colour to this alloy, was found on analysis to contain 60·16 copper and 39·71 zinc, which is the composition of malleable brass. It also showed great density or solidity.

An alloy was prepared by melting together 60 parts copper and 40 parts zinc, which had the following properties:—The colour was between that of brass and tombak, it had a strong metallic lustre, a fine close-grained fracture, and great solidity (density). Its specific gravity at the temperature of 10° C. was 8·44; by calculation it ought only to have been 8·08; thus showing that in the formation of the alloy a condensation must have taken place. Calculation shows that the alloy may be considered as a determinate chemical combination, for the results of the analysis very nearly accord with the assumption that it may be considered as composed of three atoms by weight of copper and 2 atoms by weight of zinc (3Cu + 2Zn). The hardness of the alloy is the same as that of fluor spar; it can be scratched by apatite (phosphate of lime), consequently its hardness is = 4. The alloy is harder than copper, very tough, and is, in a properly managed fire, malleable; so much so that a key was forged out of a cast rod.

These important properties of this alloy warrant an expectation of its application to many purposes in the arts, and it would appear that they depend on its definite chemical proportions.

We learn some further particulars from the 'Gewerbeverein,' of Lower Austria. The commission obtained from an English specimen 65·03 of copper and 34·76 zinc.

	Chemical Constitution	Composition by Weight per Cent. ¹ E, signifies earthy; CC, coarse crystalline; FC, fine fibrous; C, conchoidal; V, vitreous; VC, vitreco-conchoidal; TC, tabular crystalline.

Elsner analysed a malleable brass, and found it to contain 61·16 copper and 39·71 zinc. These numbers approximate to the composition Cu^2Zn^2 (59·4 per cent. copper and 40·6 zinc).—*Liebig and Kopp's Report*.

The alloy noticed in the preceding paragraphs is identical with that known as 'Muntz's patent sheathing' (see table on preceding page).

The chief properties of value in brass, are its colour, hardness (which is superior to that of copper), and power of taking delicate impressions when cast in a mould.

The malleability of brass varies greatly with its chemical composition, and with the temperature at which it is worked. As a rule, the malleability diminishes with the increase in the quantity of zinc.

The effect of the admixture of foreign metals on brass is somewhat similar to that produced by them in copper. Antimony is most injurious, as it renders the metal brittle and liable to crack at the edges in rolling.

Lead also has a hardening effect on brass, and is useful for all work that requires to be turned or filed; as the addition of about two per cent. causes the turnings to break short, and thus prevents the tool from becoming clogged. The same effect is produced in brass for engraving by the addition of a small quantity of tin.

Brass is apt to undergo a gradual molecular change, especially if subjected to vibration, and thus becomes extremely brittle. Hence, it happens that brass chains used for suspending heavy objects, like chandeliers, occasionally snap without any external violence.

Thin sheet brass may be readily stamped into shape, and in this way ornamental brass objects are now extensively made: the sheet brass being subjected to heavy blows delivered by steel dies. The metal requires, however, to be frequently annealed during the stamping, and the film of oxide which is formed on the surface by the annealing, requires to be removed by dipping in aquafortis; the objects are then washed with water, and lacquered. By varying the strength of the aquafortis, the colour of the brass may be considerably modified.

The surface of brass work requires to be protected from the action of the air, by a coating of a less oxidisable metal, or a resinous varnish or lacquer. The metal is first brought up to a clean face by the process of 'dipping' or immersion into weak nitric acid, whereby the adherent scale or oxide formed during annealing is removed. By varying the strength of the acid employed, and repeating the dipping, the metal may be made to assume a 'matt,' dead, or frosted appearance. After dipping, the metal is washed in water, and dried by imbedding it in hot sawdust. The lacquer, which is an alcoholic solution of shellac, more or less coloured with dragon's blood, according to the tint desired in the finished work, is brushed over the article when in a heated state, and dried over a stove. The colour in the lacquer helps to produce a higher or more golden tint than that due to the metal alone.

Brass work is bronzed in several different ways: the most usual are, immersion in a solution of arsenious acid, in hydrochloric acid, or in bichloride of platinum. The former is chiefly employed for cheap work, such as common gas fittings, while the latter is used for blacking or bronzing telescopes, mathematical instruments, and similar fine work. The effect, in either case, is the production of a film of dark coloured metal on the surface of the brass, namely, arsenic in the former, and platinum in the latter case. This operation is performed after dipping, and before lacquering.

Another method now extensively used, is to apply a coating of a solution of corrosive sublimate (bichloride of mercury) in water, mixed with vinegar. A film of mercury is thus formed on the surface of the brass.

For the method of covering brass with a film of tin, see PIN MANUFACTURE.

BRASS FOIL. Dutch leaf, called *Knitter* or *Rausegold* in Germany, is made from a very thin sheet brass, beat out under a hammer worked by water-power, which gives from 300 to 400 strokes per minute, from 40 to 80 leaves being laid over each other. By this treatment it may be reduced to leaves not more than $\frac{1}{50000}$ th of an inch thick. The metal employed is one rich in copper.

BRASS, YELLOW. The following Table exhibits the composition of several varieties of this species of brass. No. 1 is a cast brass of uncertain origin; 2, the brass of Jemappes; 3, the sheet brass of Stolberg, near Aix-la-Chapelle; 4 and 5, the brass for gilding, according to D'Arcet; 6, the sheet brass of Romilly; 7, English brass wire; 8, Augsburg brass wire; 9, Brass wire of Neustadt-Eberswald, in the neighbourhood of Berlin:—

Tombak, or Red Brass, in the cast state, is an alloy of copper and zinc, containing not more than 20 per cent. of the latter constituent. The following varieties are distinguished:—1, 2, 3, tombak for making gilt articles; 4, French tombak for sword-handles, &c.; 5, tombak of the Okar, near Goslar, in the Hartz; 6, yellow tombak of Paris, for gilt ornaments; 7, tombak for the same purpose from a factory in Hanover; 8, chrysochalk; 9, red tombak from Paris; 10, red tombak of Vienna.

Mr. Holtzapffel, in his 'Mechanical Manipulation,' has given some very important descriptions of alloys. From his long experience in manufacture, no one was more capable than Mr. Holtzapffel to speak with authority on the alloys of copper and zinc; and from his work, the following particulars have been obtained:—

The red colour of copper slides into that of yellow brass at about 4 or 5 ounces of zinc to the pound of copper, and remains little altered unto about 8 or 10 ounces; after this it becomes whiter, and when 32 ounces of zinc are added to 16 of copper, the mixture has the brilliant silvery colour of speculum metal, but with a bluish tint.

The alloys—from about 8 to 16 ounces to the pound of copper—are extensively used for dipping, a process adopted for giving a fine colour to an enormous variety of furniture work. The alloys with zinc retain their malleability and ductility well unto about 8 or 10 ounces to the pound; after this the crystalline character slowly begins to prevail. The alloy of 2 zinc and 1 copper may be crumbled in a mortar when cold. In the following list, the quantity of zinc employed to 1 lb. of copper is given:—

- 1 to 1½ oz. gilding metal for common jewellery.
- 3 to 4 oz. Bath metal, pinchbeck, Mannheim gold, Similor; and alloys bearing various names, and resembling inferior jewellers' gold.
- 8 oz. Emerson's patent brass.
- 10½ oz. Muntz's metal, or 40 zinc and 60 copper. 'Any proportions,' says the patentee, 'between the extremes, 50 zinc and 50 copper and 37 zinc and 63 copper, will roll and work well at a red heat.'
- 16 oz. soft spelter solder, suitable for ordinary brass work.
- 16½ oz. Hamilton and Parker's patent mosaic gold.

Brass is extensively employed for the bearings of machinery. Several patents have been taken out for compositions varying but slightly. The following, for improvements in casting the bearings and brasses of machinery, appears important:—Mr. W. Hewitson, of Leeds, directs, in his patent, that the proper mixture of alloy, copper, tin, and zinc, should be run into metal or 'chill' moulds, in place of the ordinary moulds. In large castings, it is found more especially that the metals do not mix intimately in cooling, or, rather, they arrange themselves into groups when cast in sand, and the bearings are found to wear out more quickly; but if the bearings are cast so that the alloy comes in contact with metal, the mixture is more intimate, and the bearings last longer than if cast in dry or green sand moulds.

Mr. Hewitson generally only applies these chill-metal surfaces of the moulds to these parts of a brass, or bearing, that are to receive the shaft or bear the axis of a machine. The chills are preferred of iron, perforated with holes ($\frac{1}{16}$ th to $\frac{1}{8}$ th inch)

for the passage of air or vapours; the surface should be thinly coated with loam, and heated to about 200°.

Fenton's patent metal consists of copper, spelter, and tin: it has less specific gravity than gun-metal, and is described as being 'of a more soapy nature,' by which, consequently, the consumption of oil or grease is lessened.

Many of the patentees of bearing metals assure us, that the metals they now use differ very considerably from the statement in their specifications. Surely this requires a careful examination.

We exported of our BRASS MANUFACTURES, in 1864, as follows:—

	Cwts.	£
Brass wire of all sorts, and manufactures of wire	10,950	54,648
Brass tubing	8,077	41,554
Wrought brass of all other sorts, not being ordnance, } and not otherwise described	23,646	137,811
In the same year we imported:—		
Brass manufactures, unenumerated	4,643	49,802
Brass, old, fit only to be re-manufactured	3,085	6,325

BRASS COLOUR, for staining glass, is prepared by exposing for several days thin plates of brass upon tiles in the *leer*, or annealing arch, of the glass house, till they are oxidised into a black powder, aggregated in lumps. This being pulverised and sifted, is to be again well calcined for several days more, till no particles remain in the metallic state, when it will form a fine powder of a russet-brown colour. A third calcination must now be given with a carefully regulated heat, its quality being tested from time to time by fusion with some glass. If it makes the glass swell and intumescence, it is properly prepared; if not, it must be still further calcined. Such a powder communicates to glass greens of various tints, passing into turquoise.

When thin narrow strips of brass are stratified with sulphur in a crucible, and calcined at a red heat, they become friable and may be reduced to powder. This being sifted and exposed upon tiles in a reverberatory furnace for 10 or 12 days, becomes fit for use, and is capable of imparting a chalcedony—red or yellow—tinge to glass by fusion, according to the mode and proportion of using it.

The glassmakers' red colour may be prepared by holding small plates of brass in a moderate heat in a reverberatory furnace till they are thoroughly calcined. When the substance becomes pulverulent, and assumes a red colour, it is ready for immediate use.

Brass colour, as employed by the colourmen to imitate brass, is of two tints—the red or bronze, and the yellow, like gilt brass. Copper filings mixed with red ochre, or bole, constitute the former; a powdered brass, imported from Germany, is used for the latter. Both must be worked up with varnish after being dried by heat, and then spread flat with a camel-hair brush evenly upon the surface of the object. The best varnish is composed of 20 ounces of spirits of wine, 2 ounces of shellac, and 2 ounces of sandarach, properly dissolved. (See VARNISH.) Only so much of the brass powder and varnish should be mixed at a time as is wanted for immediate use. See BRONZE POWDER.

BRASSES, COAL, or BRASS OF COAL, or BRASSEY COAL. Names given to iron pyrites found in the coal-measures. In 1872 it was estimated that the following quantities were produced and used:—

NORTHUMBERLAND and DURHAM	3,250 tons.
YORKSHIRE	3,700 „
LANCASHIRE	2,400 „
STAFFORDSHIRE	3,700 „

These sulphur ores are employed in Yorkshire, Lancashire, and on the Tyne, in the manufacture of the protosulphate of iron (copperas.) For this purpose they are extended in wide-spread heaps, and thus exposed to atmospheric influences. The result is the conversion of the sulphur into sulphuric acid, which re-uniting with the iron forms the sulphate of the protoxide of iron, which is dissolved out and crystallised. The presence of iron pyrites in coal (Brasses), often gives the tendency to spontaneous combustion. A large number of the ships which are sent from South Wales to Chili, with coals, which are used for smelting the copper ores of that country, take fire when they reach the tropics. This arises mainly from carelessness. In the first place, the coals are not carefully selected. They are bought cheaply, and being small, are put on board the ships, without being washed or picked, and frequently damp. During the voyage, decomposition goes on, and by the time they reach the warmer latitudes, a temperature sufficiently high to occasion actual com-

bustion is produced. By carefully washing the coal and drying it, these casualties might be almost entirely prevented. Brass is a name given to an iron ore found in the coal-measures of South Wales, which is not a pyritic ore, although for a long period mistaken for it. See COAL BRASS.

BRASSIL. A name given to iron pyrites in Derbyshire, 'a hard substance, and fiery, but yields no metal.'—Hodson, *Complete Derbyshire Miner*.

BRASSING IRON. Iron ornaments are covered with copper or brass by properly preparing the surface, so as to remove all organic matter, which would prevent adhesion, and then plunging them into melted brass. A thin coating is thus spread over the iron, and it admits of being polished or burnished. The electro-magnetic process is now employed for the purpose of precipitating brass on iron. This process was first mentioned in Shaw's 'Metallurgy,' in 1844, where he remarks: 'In depositing copper upon iron, a solution of the cyanide or acetate of copper should be employed. The only value of these salts is, that the surface of iron may be immersed in their solutions without receiving injury by the corrosion consequent upon the deposition of a film of metal by chemical action.' The following solutions are recommended by Dr. Woods, in the 'Scientific American,' for coating iron with copper, zinc, or brass, by the electrotype process:—

To make a *Solution of Copper or Zinc*.—Dissolve 8 ounces (troy) cyanide of potassium and 3 ounces of cyanide of copper or zinc in 1 gallon of rain or distilled water. These solutions to be used at about 160° F. with a compound battery of from 3 to 12 cells.

To prepare a *Solution of Brass*.—Dissolve 1 lb. (troy) cyanide of potassium, 2 ounces of cyanide of copper, and 1 ounce of cyanide of zinc, in one gallon of rain or distilled water; then add two ounces of muriate of ammonia. This solution is to be used at 160° F. for smooth work, and from 90° to 120°, with a compound battery of from 3 to 12 cells. See ELECTRO-METALLURGY.

BRATTICE. The division made in a shaft of a colliery is so called. It is used to ensure an up and a down-cast current of air. Brattices may be also used in any of the levels for the same purpose. They may be of metal, of wood, or tarred canvas. Mining engineers speak of a *natural brattice*, i.e. one independent of any artificial arrangement—when the currents separate naturally in a shaft or a level—and thus produce a natural ventilation.

BRAUNITE. A sesquioxide of manganese, composed when pure of nearly 70 per cent. of manganese, and 30 per cent. of oxygen.

BRAZILIAN ARROWROOT. See ARROWROOT.

BRAZIL NUTS. The hard-shelled fruit of the *Bertholletia excelsa*, which is roundish and about six inches in diameter, contains about two dozen of the elongated wrinkled triangular seeds—these are the 'nuts' of the shops. See PARA NUTS.

BRAZIL WOOD. (*Bois de Pernambouc*, Fr.; *Brasilienholz*, Ger.) This dye-wood gives its name to the part of America whence it was first imported. It has also the names of Pernambuco, Wood of St. Martha, and of Sapan, according to the places which produce it. Linnæus distinguishes the tree which furnishes the Brazil wood by the name of *Cesalpinia crista*. It commonly grows in dry places among rocks. Its trunk is very large, crooked, and full of knots. It is very hard, susceptible of a fine polish, and sinks in water. It is pale when newly cleft, but becomes red on exposure to the air. The following is a very exact description of the tree producing this wood:—

The *ibiripitanga*, or Brazil wood, called, in Pernambuco, *pao da rainha* (Queen's wood), on account of its being a Government monopoly, is now rarely to be seen within many leagues of the coast, owing to the improvident manner in which it has been cut down by the Government agents, without any regard being paid to the size of the tree or its cultivation. It is not a lofty tree. At a short distance from the ground, innumerable branches spring forth and extend in every direction in a straggling, irregular, and unpleasing manner. The leaves are small and not luxuriant; the wood is very hard and heavy, takes a high polish, and sinks in water; the only valuable portion of it is the heart, as the outward coat of wood has not any peculiarity. The name of this wood is derived from *brasas*, a glowing fire or coal; its botanical name is *Cesalpinia Brasileto*. The leaves are pinnated, the flower white and papilionaceous, growing in a pyramidal spike; one species has flowers variegated with red. The branches are slender and full of small prickles. There are nine species. See Bell's 'Geography.'

The species *Brasileto*, which is inferior to the *crista*, grows in great abundance in the West Indies. The demand for the *Brasileto*, a few years ago, was so great, owing to its being a little cheaper than the *crista*, that nearly the whole of the trees in the British possessions were cut down and sent home, which Mr. Bell very justly terms improvidence. It is not now so much used, and is consequently scarcer in the English market.

The wood known in commerce as *Pernambuco* is most esteemed, and has the greatest quantity of colouring matter. It is hard, has a yellow colour when newly cut, but turns red by exposure to the air. That kind termed *Lima wood* is the same in quality. *Sapan wood* grows in Japan, and in quality is next the two named above. It is not plentiful, but is much valued in the dyehouse for red of a certain tint; it gives a very clear and superior colour. The quantity of ash that these two qualities of wood contain is worthy of remark. *Lima wood*, as imported, gives the average of 2.7 per cent., while *Sapan wood* gives 1.5 per cent.; in both, the prevailing earth is lime. The quantity of moisture in the wood averages about 10 per cent.; that in the ground wood in the market about 20 per cent.

Sapan wood is yielded by *Cesalpinia Sapan*, and *Lima wood* by *C. echinata*.

Brazil wood has different shades of red and orange. Its goodness is determined particularly by its density. When chewed, a saccharine taste is perceived. It may be distinguished from red saunders wood by its colouring water, which the latter does not.

BRAZIL WOOD DYES. Boiling water extracts the whole colouring matter of Brazil wood, and if the ebullition be long enough continued, it assumes a fine red colour. The residuum appears black. In this case an alkali may still extract much colouring matter. The solution in alcohol or ammonia is still deeper than the preceding.

The decoction of Brazil wood, called juice of Brazil, is observed to be less fit for dyeing when recent than when old, or even fermented. By age it takes a yellowish-red colour. For making this decoction, Helot recommends the use of the hardest water; but it should be remarked that this water deepens the colour in proportion to the earthy salts which it contains. After boiling this wood reduced to chips, or what is preferable, to powder, for three hours, this first decoction is poured into a cask. Fresh water is poured on the wood, which is then made to boil for three hours, and mixed with the former. When Brazil wood is employed in a dyeing bath, it is proper to enclose it in a thin linen bag.

Wool immersed in the juice of Brazil wood takes but a feeble tint, which is speedily destroyed; it must therefore receive some preliminary preparations.

The wool is to be boiled in a solution of alum, to which a fourth or even less of tartar is added, for a larger proportion of tartar would make the colour yellowish. The wool is kept impregnated with it, for at least eight days, in a cool place. After this, it is dyed with the Brazil juice with a slight boiling. But the first colouring particles that are deposited afford a less beautiful colour; hence it is proper to pass a coarser stuff previously through the bath. In this manner a lively red is procured, which resists pretty well the action of the air.

Brazil wood is made use of for dyeing silk the colour known as false crimson, to distinguish it from the crimson made by means of cochineal, which is much more permanent.

The silk should be boiled at the rate of 20 parts of soap per cent., and then alumed. The aluming need not be so strong as for the fine crimson. The silk is refreshed at the river, and passed through a bath more or less charged with Brazil juice, according to the shade to be given. When water free from earthy salts is employed, the colour is too red to imitate crimson; this quality is given it by passing the silk through a slight alkaline solution, or by adding a little alkali to the bath. It might, indeed, be washed in a hard water till it had taken the desired shade. They thus become permanent colours. But what distinguishes them from madder and kermes, and approximates them to cochineal, is their re-appearing in their natural colour, when they are thrown down in a state of combination with alumina, or with oxide of tin. These two combinations seem to be the fittest for rendering them durable. It is requisite, therefore, to enquire what circumstances are best calculated to promote the formation of these combinations according to the nature of the stuff.

The astringent principle, likewise, seems to contribute to the permanence of the colouring matter of Brazil wood; but it deepens its hue, and can only be employed for light shades.

To make deeper false crimsons, a dark red juice of logwood is put into the Brazil bath after the silk has been impregnated with it. A little alkali may be added, according to the shade that is wanted.

To imitate poppy or flame colour, an arnotto ground is given to the silk, deeper even than when it is dyed with earthamus; it is then washed, alumed, and dyed with juice of Brazil, to which a little soap water is usually added.

The colouring particles of Brazil wood are easily affected and made yellow by the action of acids.

The colouring particles of Brazil wood are also very sensible to the action of alkalis,

which give them a purple hue; and there are several processes in which the alkalis, either fixed or volatile, are used for forming violets and purples. But the colours obtained by these methods, which may be easily varied according to the purpose, are perishable, and possess but a transient bloom. The alkalis appear not to injure the colours derived from madder, but they accelerate the destruction of most other colours.

In England and Holland the wood-dyes are reduced to powder by means of mills erected for the purpose.

The bright fugitive red, called fancy red, is given to cotton of Nicaragua, or peach wood, a cheap kind of Brazil wood. See PEACH WOOD.

The cotton being scoured and bleached, is boiled with sumach. It is then impregnated with a solution of tin (at 5° B., according to Vitalis). It should now be washed slightly in a weak bath of the dyeing wood; and, lastly, worked in a somewhat stale infusion of the peach or Brazil wood. When the temperature of this is lukewarm, the dye is said to take better. Sometimes two successive immersions in the bath are given. It is now wrung out, aired, washed in water, and dried.

M. Vitalis says, that his solution of tin is prepared with two ounces of tin and a pound of aqua regia, made with two parts of nitric acid at 24° B. and three parts of muriatic acid at 22°.

For a rose colour, the cotton is alumed as usual, and washed from the alum. It then gets the tin mordant, and is again washed. It is now turned through the dye-bath, an operation which is repeated if necessary.

For purple, a little alum is added to the Brazil bath.

1. For amaranth, the cotton is strongly galled, dried, and washed.
2. It is passed through the black eask (*tonneau noir*), till it has taken a strong grey shade. See BLACK DYE.
3. It receives a bath of lime water.
4. Mordant of tin.
5. Dyeing in the Brazil wood bath.
6. The last two operations are repeated.

Dingler has endeavoured to separate the colouring matter of the different sorts of Brazil wood, so as to obtain the same tint from the coarser as from the best Pernambuco. His process consists in treating the wood with hot water or steam, in concentrating the decoction so as to obtain 14 or 15 pounds of it from 4 pounds of wood, allowing it to cool, and pouring into it two pounds of skim milk; agitating, then boiling for a few minutes, and filtering. The dun colouring matters are precipitated by the coagulation of the caseous substance. For dyeing, the decoctions must be diluted with water; for printing, they must be concentrated so that 4 pounds of wood shall furnish only 5 or 6 pounds of decoction, and the liquor may be thickened in the ordinary way. These decoctions may be employed immediately, as by this treatment they have acquired the same property as they otherwise could get only by being long kept. A slight fermentation is said to improve the colour of these decoctions; some ground wood is put into the decoction to favour this process.

Gall-nuts, however, sumach, the bark of birch or alder, renders the colour of Brazil wood more durable upon alumed linen and cotton goods, but the shade is a little darker.

In dyeing wool with Pernambuco Brazil wood, the temperature of the bath should never be above 150° F., since higher heats impair the colour.

According to Dingler and Kurrer, bright and fast scarlet reds may be obtained upon wool, by preparing a decoction of 50 pounds of Brazil wood in three successive boils, and setting the decoction aside for 3 or 4 weeks in a cool place; 100 pounds of the wool are then alumed in a bath of 22 pounds of alum and 11 pounds of tartar, and afterwards rinsed in cold water. Meanwhile, we fill two-thirds with water a copper containing 30 pails, and heated to the temperature of 150° or 160° F. We pour in 3 pailfuls of the decoction, heat to the same point again, and introduce 30 pounds of wool, which does not take a scarlet, but rather a crimson tint. This being removed, 2 pails of decoction are put in, and 30 pounds of wool, which becomes scarlet, but not so fine as at the third dip. If the dyer strengthens the colour a little at the first dip, a little more at the second, and adds at the third and fourth the quantity of decoction merely necessary, he will obtain an uniform scarlet tint. With 50 pounds of Pernambuco, 1,000 pounds of wool may be dyed scarlet in this way, and with the deposits another 100 may be dyed of a tile colour. An addition of weld renders the colour faster, but less brilliant. See WELD.

Karkutsch says the dye may be improved by adding some ox-gall to the bath.

In dyeing cotton, the tannin and gallic acid are two necessary mordants; and the colour is particularly bright and durable when the cloth has been prepared with the oily process of Turkey red.

It is said that stale urine heightens the colour of Brazil dyo when the ground wood is moistened with it.

Chevreul obtained the colouring matter from Brazil wood in the following manner : Digest the raspings of the wood in water till all the colouring matter is dissolved, and evaporate the infusion to dryness, to get rid of a little acetic acid which it contains. Dissolve the residue in water, and agitate the solution with litharge, to get rid of a little fixed acid. Evaporate again to dryness ; digest the residue in alcohol ; filter and evaporate, to drive off the alcohol. Dilute the residual matter with water, and add to the liquid a solution of glue, till all the tannin which it contains is thrown down ; filter again, and evaporate to dryness, and digest the residue in alcohol, which will leave undissolved any excess of glue which may have been added. The last alcoholic solution, being evaporated to dryness, leaves *brazilin*, the colouring matter of the wood, in a state of considerable purity.

BRAZIL. A term given to a hard coal, approaching Anthracite in character, in South Staffordshire.

BRAZILIN and **BRAZILIEN** are two colouring matters which have been separated from Brazil wood, by Chevreul and Preisser. They are probably identical. See Watt's ' Dictionary of Chemistry.'

BRAZING. See **SOLDERS** and **SOLDERING**.

BREAD. One of the most important, if not altogether the most important, article of food, unquestionably, is bread ; and although rye, barley, oats, and other cereals, are sometimes used by the baker, *wheat* is the grain which is best fitted for the manufacture of that article, not only on account of the larger amount of gluten, or nitrogenous matter, which it contains, and than can be found in other edible grains, but also on account of the almost exact balance in which the nitrogenous and non-nitrogenous constituents exist in that cereal, and owing to which it is capable of ministering to all the requirements of the human frame, and of being assimilated at once and without effort by our organs, whence the name of ' staff of life,' which is often given to it, wheat being, like milk, a perfect food.

Although gluten is one of the most important constituents of wheat, the nutritive power of its flour, and its value as a bread-making material, should not be altogether considered as dependent upon the quantity of gluten it may contain, even though it be of the best quality. Doubtless a high per-centage of this material is desirable, but there are other considerations which must be taken into account ; for, in order to become available for making good bread, flour, in addition to being sound and genuine, must possess other qualities beyond containing merely a large amount of gluten. Thus, for example, the *blé rouge glacé d'Auvergne*, which contains hardly 45 per cent. of starch, and as much as 36 per cent. of gluten, though admirably adapted for the manufacture of macaroni, vermicelli, semolina, and other *pâtes d'Italie*, is totally unfit for making good bread ; the flour used for making best white loaves containing only from 13 to 18 per cent. of gluten, and from 60 to 70 per cent. of starch.

Bread is obtained by baking a dough, previously fermented either by an admixture of yeast or leaven, or it is artificially rendered spongy by causing an acid, muriatic or tartaric, to react upon carbonate or bicarbonate of soda, or of ammonia, mixed in the doughy mass ; or, is in Dr. Daughlish's process, which will be described further on, by mixing the flour which has to be converted into dough, not with ordinary water, but with water strongly impregnated with carbonic acid.

Although a history of bread making cannot be given in the present article, a few words on the subject, reproduced from a former edition of this work, will not be deemed uninteresting.

Pliny informs us, that barley was the only species of corn at first used for food ; and even after the method of reducing it to flour had been discovered, it was long before mankind learned the art of converting it into cakes.

Ovens were first invented in the East. Their construction was understood by the Jews, the Greeks, and the Asiatics, among whom baking was practised as a distinct profession. In this art, the Cappadocians, Lydians, and Phœnicians, are said to have particularly excelled. It was not till about 580 years after the foundation of Rome that these artisans passed into Europe. The Roman armies, on their return from Macedonia, brought Grecian bakers with them into Italy. As these bakers had handmills besides their ovens, they still continued to be called *pistores*, from the ancient practice of bruising the corn in a mortar ; and their bakehouses were denominated *pistorie*. In the time of Augustus there were no fewer than 329 public bakehouses in Rome ; almost the whole of which were in the hands of Greeks, who long continued the only persons in that city acquainted with the art of baking good bread.

In nothing, perhaps, is the wise and cautious policy of the Roman government more remarkably displayed than in the regulations which it imposed on the bakers within the city. To the foreign bakers who came to Rome with the army from Macedonia,

a number of freedmen were associated, forming together an incorporation from which neither they nor their children could separate, and of which even those who married the daughters of bakers were obliged to become members. To this incorporation were entrusted all the mills, utensils, slaves, animals, everything, in short, which belonged to the former bakehouses. In addition to these, they received considerable portions of land; and nothing was withheld which could assist them in pursuing, to the best advantage, their highly prized labours and trade. The practice of condemning criminals and slaves, for petty offences, to work in the bakehouse, was still continued; and even the judges of Africa were bound to send thither, every five years, such persons as had incurred that kind of chastisement. The bakehouses were distributed throughout the fourteen divisions of the city, and no baker could pass from one into another without special permission. The public granaries were committed to their care; they paid nothing for the corn employed in baking bread that was to be given in largess to the citizens; and the price of the rest was regulated by the magistrates. No corn was given out of these granaries except for the bakehouses, and for the private use of the prince. The bakers had besides private granaries, in which they deposited the grain which they had taken from the public granaries for immediate use; and if any of them happened to be convicted of having diverted any portion of the grain to another purpose, he was condemned to a ruinous fine of five hundred pounds' weight of gold.

Most of these regulations were soon introduced among the Gauls; but it was long before they found their way into the more northern countries of Europe. Borrichius informs us that in Sweden and Norway, the only bread known, so late as the middle of the 16th century, was unleavened cakes kneaded by the women. At what period in our own history the art of baking became a separate profession, we have not been able to ascertain; but this profession is now common to all the countries in Europe, and the process of baking is also nearly the same.

The French, who particularly excel in the art of baking, have a great many different kinds of bread. Their *pain bis*, or brown bread, is the coarsest kind of all, and is made of coarse groats mixed with a portion of white flour. The *pain de méteil* is a bread made with rye and barley flour, to which wheat flour is sometimes added also. The *pain bis blanc*, is a kind of bread between white and brown, made of white flour and fine groats. The *pain blanc*, or white bread, is made of white flour, shaken through a sieve after the finest flour has been separated. The *pain mollet*, or soft bread, is made of the purest flour without any admixture. The *pain chaland*, or customers' bread, is a very white kind of bread, made of pounded paste. *Pain chapelé*, is a small kind of bread, with a well-beaten and very light paste, with butter or milk. This name is also given to a small bread, from which the thickest crust has been removed by a rasp. *Pain cornu* is a name given by the French bakers to a kind of bread made with four corners, and sometimes more. Of all the kinds of small bread this has the strongest and firmest paste. *Pain à la reine*, queen's bread, *pain à la Ségovie*, *pain chapelé*, and *pain cornu*, are all small kinds of bread, differing only in the lightness or thickness of the paste. *Pain de gruau* is a small very white bread made now in Paris, from the flour separated after a slight grinding from the best wheat. Such flour is in hard granular particles.

In England, however, we have but few varieties of bread, the loaves known under the names of *bricks*, *Coburg*, *cottage*, and *French rolls*, being all made of the same dough; the only difference is in the *shape* given to them, their various flavours depending on the way in which they are affected by the heat of the oven in the baking. These loaves are crusted all over because they are deposited in the oven separate from each other, or baked in moulds made of tinned iron. The *batch* bread, the more usual variety, is crusted only at the top and bottom, because the loaves, which have a cubic form, touch each other in the oven; those, however, which lie round the oven have a crust on three of their sides. The *cottage* and *French rolls* are generally made of best flour,—known under the name of whites;—but *batch* bread is made of best flour and of *households*, or flour of second quality, and of *seconds*, which is flour of a third quality—that is, of flour containing more bran than the other kinds just enumerated.

We have also 'rye bread,' which is generally made of nothing else than ordinary wheat flour and bran.

Dr. Ure, in the former edition of this Dictionary, truly remarked, 'The object of baking is to combine the gluten and starch of the flour into a homogeneous substance, and to excite such a vinous fermentative action, by means of its saccharine matter, as shall disengage abundance of carbonic acid gas in it for making an agreeable, soft, succulent, spongy, and easily digestible bread. The two evils to be avoided in baking are, hardness on the one hand and pastiness on the other. Well-made bread is a chemical compound, in which the gluten and starch cannot be recognised

or separated, as before, by a stream of water. When flour is kneaded into a dough, and spread into a cake, this cake, when baked, will be horny if it be thin, or if thick, will be tough and clammy; whence we see the value of that fermentative process, which generates thousands of little cells in the mass or crumb, each of them dry yet tender and succulent through the intimate combination of the moisture. By this constitution it becomes easily soluble in the juices of the stomach, or, in other words, light of digestion. It is, moreover, much less liable to turn sour than cakes made from unfermented dough.

‘Rye, which also forms a true spongy bread, though inferior to that of wheat, consists of similar ingredients—namely, 61·07 of starch, 9·48 of gluten, 3·28 of vegetable albumen, 3·23 of uncrystallisable sugar, 11·09 of gum, 6·38 of vegetable fibre; the loss upon the 100 parts amounted to 5·62, including an acid whose nature the analyst M. Einhof, did not determine. Rye flour contains also several salts, principally the phosphates of lime and magnesia. This kind of grain forms a dark coloured bread, reckoned very wholesome; comparatively little used in this country, but very much in France, Germany, and Belgium.

‘Dough, fermented with the aid either of leaven or yeast, contains little or none of the saccharine matter of the flour, but, in its stead, a certain portion, nearly half its weight, of spirit, which imparts to it a vinous smell, and is volatilised in the oven, whence it might be condensed into a crude, weak alcohol, on the plan of Mr. Hick’s patent, were it worth while. But the increased complexity of the baking apparatus will probably prove an effectual obstacle to the commercial success of this project, upon which a few years ago upwards of 20,000*l.* sterling were foolishly squandered.

‘That the sugar of the flour is the true element of the fermentation which dough undergoes, and that the starch and gluten have nothing to do with it, may be proved by decisive experiments. The vinous fermentation continues till the whole sugar is decomposed, and no longer; when, if the process be not checked by the heat of baking, the acetous fermentation will supervene. Therefore, if a little sugar be added to a flour which contains little or none, its dough will become susceptible of fermenting, with extrication of gas, so as to make spongy succulent bread. But since this sponginess is produced solely by the extrication of gas and its expansion in the heat of the oven, any substance capable of emitting gas, or of being converted into it under these circumstances, will answer the same purpose. Were a solution of bicarbonate of ammonia obtained by exposing the common sesquicarbonate in powder for a day to the air, incorporated with the dough, in the subsequent firing it will be converted into vapour, and, in its extrication, render the bread very porous. Nay, if water highly impregnated with carbonic acid gas be used for kneading the dough, the resulting bread will be somewhat spongy. Could a light article of food be prepared in this way, then, as the sugar would remain undecomposed, the bread would be so much the sweeter and the more nourishing. How far a change propitious to digestion takes place in the constitution of the starch and gluten during the fermentative action of the dough has not been hitherto ascertained by precise experiments.

‘Dr. Colquhoun, in his able essay upon the art of making bread, has shown that its texture, when prepared by a sudden formation and disengagement of elastic fluid generated within the oven, differs remarkably from that of a loaf which has been made after the preparatory fermentation with yeast. Bread which has been raised with the common carbonate of ammonia, as used by the pastrycooks, is porous no doubt, but not spongy with vesicular spaces, like that made in the ordinary way. The former kind of bread never presents that air-cell stratification which is the boast of the Parisian baker, but which is almost unknown in London. It is, moreover, very difficult to expel by the oven the last portion of the ammonia, which gives both a tinge and a taste to the bread. The bicarbonate would probably be free from this objection, which operates so much against the use of the sesquicarbonate.’—*Ure*.

The conversion of flour into bread includes two distinct operations: namely, the preparation of the dough and the baking. The preparation of the dough, however, though reckoned as one, consists, in fact, of three operations: namely, *hydrating*, *kneading*, and *fermenting*.

When the baker intends to make a batch of bread, his first care is, in technical language, *to stir a ferment*. This is done, in London, by boiling a few potatoes, in the proportion of 5 lbs. or 6 lbs. of potatoes per sack of flour (which is the quantity we shall assume it is desired to convert into bread), peeling them, mashing and straining them through a cullender, and adding thereto about three-quarters of a pailful of water, 2 or 3 lbs. of flour, and one quart of yeast. The water employed need not be warmed beforehand, for the heat of the potatoes is sufficient to impart a proper temperature (from 70° to 90° F.) to the liquid mass, which should be well stirred up with the hand into a smooth, thin, and homogeneous paste, and then left at rest.

In the course of an hour or two, the mass is seen to rise and fall, which swelling

and heaving up is due to carbonic acid, generated by the fermentation induced in the mass, which may be thus left until wanted. In about three hours, this fermenting action will appear to be at an end, and when it has arrived at that stage, it is fit to be used. The ferment, however, may be left for six or seven hours and be still very good at the end of that time, but the common practice is to use it within four or five hours after its preparation. After this the ferment rapidly becomes sour.

The next operation consists in '*setting the sponge.*' This consists in stirring the ferment well, adding thereto about two gallons of lukewarm water, and as much flour as will make, with the ferment, a rather stiff dough. This constitutes '*the sponge.*' It is kept in a warm situation, and in the course of about an hour fermentation again begins to make its appearance, the mass becomes distended or is heaved up by the carbonic acid produced, the escape of which is impeded by the toughness of the mass. This carbonic acid is the result of the fermentation induced under the influence of water, by the action of the gluten upon the starch, a portion of which is converted thereby into sugar, and then into alcohol. A time, however, soon comes when the quantity of carbonic acid thus pent up becomes so great that it bursts through, and the sponge collapses or drops down. This is called the *first sponge*.—But as the fermentation is still going on, the carbonic acid soon causes the sponge to rise again as before to nearly twice its volume, when the carbonic acid, bursting through the mass, causes it to fall a second time; and this constitutes what the bakers call the *second sponge*. The rising and falling might then go on for twenty-four hours; but as the alcoholic would pass into the acetous fermentation soon after the second rising, the baker always interferes after the second, and very frequently after the first sponge. The bread made from the first sponge is generally sweeter; but unless the best flour is used, and even then, the loaf that is made from it is smaller in size and more compact than that which is made with the *second sponge*. In hot weather, however, as there would be much danger of the bread turning sour, if the sponge were allowed to '*take a second fall,*' the first sponge is frequently used. The next process consists in '*breaking the sponge,*' which is done by adding to it the necessary quantity of water and of salt,—the quantity of the latter substance varying from $\frac{1}{2}$ lb. to $\frac{3}{4}$ of a pound per bushel of flour; that is, from $2\frac{1}{2}$ lbs. to $3\frac{3}{4}$ lbs. per sack of flour (new flour, or flour of inferior quality, always requires, at the very least, $3\frac{1}{2}$ lbs. per sack, to bind it, that is to say, to render the dough sufficiently firm to support itself while fermenting.) Salt acts, to a great extent, like alum, though not so powerfully. As to the quantity of water to be used, it depends also a great deal on the quality of the flour, the best quality absorbing most; though, as we shall have occasion to remark, the baker too often contrives to force and keep into bread made from inferior flour, by a process called *under baking*, the same amount of water as is normally taken up by that of the best quality. Generally speaking, and with flour of good average quality, the amount of water is such, that the diluted sponge forms about 14 gallons of liquid. The whole mass is then torn to pieces by the hand, so as to break any lumps that there may be, and mix it up thoroughly with the water. This being done, the rest of the sack of flour is gradually added and kneaded into a dough of the proper consistency. This kneading of the dough may be said to be one of the most important processes of the manufacture, since it not only produces a more complete hydration of the flour, but, by imprisoning a certain quantity of air within the dough, and forcibly bringing into closer contact the molecules of the yeast or leaven with the sugar of the flour, and also with a portion of the starch, the fermentation or rising of the whole mass, on which the sponginess of the loaf and its digestibility subsequently depend, is secured. When by forcing the hand into the dough, the baker sees that, on withdrawing it, none of the dough adheres to it, he knows that the kneading is completed. The dough is then allowed to remain in the trough for about an hour and a half or two hours, if either *brewers'* or *German yeast* have been employed in making the sponge;—if, on the contrary, *patent yeast* or *hop yeast* have been used, three or even four hours may be required for the dough to rise up, or, as in technical language, to *give proof*. When the dough is sufficiently '*proofed,*' it is weighed of into lumps, shaped into the proper forms of 4 lbs. 4 oz. each, and exposed for about one hour in an oven to a temperature of about 570° F., the heat gradually falling to 430 or 420° F. The yield after baking is 94 quartern (not 4-lb.) loaves, or from 90 to 92 really 4lb. loaves, as large again as they were when put into the oven in the shape of dough.

The manner in which yeast acts upon the flour—is, as yet, an unsolved mystery, or at any rate an, as yet, unsatisfactorily explained action; for the term '*catalysis,*' which has sometimes been applied to it, explains absolutely nothing.

A yeast, or fermenting material, may be prepared in various ways; but only three kinds of yeast are used by bakers: namely, *brewers' yeast*, or *barm*,—*German yeast*,—and *patent*, or *hop yeast*.

The most active of these ferments is the first, or *brewers' yeast*; it is, as is well

known, a frothy, thickish material, of a brownish or drab colour, which, when recent, is in a state of slight effervescence, exhales a sour characteristic odour, and has an acid reaction.

When viewed through the microscope, it is seen to consist of small globules of various size, generally egg-shaped. They were first described by M. Desmayères.

The best, and in fact the only, brewers' yeast used in bread-making is that from the ale breweries; porter yeast is unavailable for the purpose, because it imparts to the bread a disagreeable bitter taste.

German yeast is very extensively used by bakers. It is a pasty but easily crumbled mass, of an agreeable fruity odour, and of a dingy white colour. German yeast will remain good for a few weeks, if kept in a cool place. When in good condition, it is an excellent article; but samples of it are occasionally seized on bakers' premises, of a darker colour, viscid, and emitting an offensive cheesy odour: such German yeast, being in a putrefied state, is, of course, objectionable.

The so-called '*patent yeast*' is the cheapest and at the same time the weakest of these ferments; very good bread, however, is made with it, and it is most extensively used by bakers. It is made either with or without hops: when with hops, it is called *hop yeast*, and is nothing more than a decoction of hops to which malt is added while in a scalding hot state; when the liquor has fallen to a blood heat, a certain quantity of brewers' or German yeast is thoroughly mixed with it, and the whole is left at rest. The use of the hops is intended to diminish the tendency of this solution to become acid.

Potato yeast is a kind of '*patent yeast*' in general use. See YEAST.

The theory of panification is not difficult of comprehension. 'The flour,' says Dr. Ure, 'owes this valuable quality to the gluten, which it contains in greater abundance than any of the other *cerealia* (kinds of corn). This substance does not constitute, as has been heretofore imagined, the membranes of the tissue of the perisperm of the wheat; but is enclosed in cells of that tissue under the epidermic coats, even to the centre of the grain. In this respect the gluten lies in a situation analogous to that of the starch, and of most of the immediate principles of the vegetables. The other immediate principles which play a part in *panification* are particularly the starch and the sugar; and they all operate as follows:—

'The diffusion of the flour through the water *hydrates* the starch, and dissolves the sugar, the albumen, and some other soluble matters. The kneading of the dough, by completing these reactions through a more intimate union, favours also the fermentation of the sugar, by bringing its particles into close contact with those of the leaven or yeast; and the drawing out and laminating the dough softens and stratifies it, introducing at the same time oxygen to aid the fermentation. The dough, when distributed and formed into loaves, is kept some time in a gentle warmth, in the folds of the cloth, pans, &c., a circumstance propitious to the development of their volume by fermentation. The dimensions of all the lumps of dough now gradually enlarge, from the disengagement of carbonic acid in the decomposition of the sugar, which gas is imprisoned by the glutinous paste. Were these phenomena to continue too long, the dough would become too vesicular; they must, therefore, be stopped at the proper point of sponginess, by placing the loaf lumps in the oven. Though this causes a sudden expansion of the enclosed gaseous globules, it puts an end to the fermentation, and to their growth; as also evaporates a portion of the water.

'The fermentation of a small dose of sugar is, therefore, essential to true bread making; but the quantity actually fermented is so small as to be almost inappreciable. It seems probable that in well-made dough the whole carbonic acid that is generated remains in it, amounting to one-half the volume of the loaf itself at its baking temperature, or 212° F. It thence results that less than one-hundredth part of the weight of the flour is all the sugar requisite to produce well-raised bread.

'Although the rising of the dough is determined by the carbonic acid resulting from the decomposition of the sugar, produced by the reaction of the gluten on hydrated or moist flour, considering that the quantity of sugar necessary to produce fermentation does not amount, probably, to more than one-hundredth part of the weight of the flour employed, and perhaps to even considerably less than that,—the saving and economy which are said to accrue to the consumer from the use of unfermented bread (which is bread in which the action of yeast is replaced by an artificial evolution of carbonic acid, by decomposing bicarbonate of soda with muriatic acid, as we said before) is therefore much below what it has been estimated (25 per cent.!) by some writers; and is certainly very far from compensating for the various and serious drawbacks which are peculiar to that kind of bread, one of which—and it is not the least—is its indigestibility, notwithstanding all that may have been said to the contrary.

'In a pamphlet, entitled, "Instructions for making Unfermented Bread, by a Phy-

sician," published in 1846, the formula recommended for bread made of wheat meal is as follows:—

Wheat meal	3 lbs. avoirdupois.
Bicarbonate of soda	4½ drachms troy.
Hydrochloric acid.	5 fluid drachms and 25 minims, or drops.
Water	30 fluid ounces.
Salt	$\frac{2}{3}$ of an ounce troy.

'Bread made in this manner,' says the author, 'contains nothing but flour, common salt, and water. It has an agreeable, natural taste, keeps much longer than common bread, is *much more digestible*, and much less disposed to turn acid,' &c.

Liebig, in his 'Letters on Chemistry,' very judiciously remarks, 'that the intimate mixture of the saliva with the bread, whilst masticating it, is a condition which is favourable to the rapid digestion of the starch; wherefore the porous state of the flour in fermented bread accelerates its digestion.'

Now, it is a fact, which can be readily ascertained by anyone, that unfermented bread is permeated by fluids with difficulty. It will not absorb water, hence its heavy and clammy feel; nor saliva, hence its indigestibleness; nor milk, nor butter. Unfermented bread will neither make soup, nor toast, nor poultice. When a slice of ordinary bread is held before a bright fire, a portion of the moisture of the bread, as the latter becomes scorched, is converted into steam, which penetrates the interior of the mass, and imparts to it the sponginess so well known in a toast properly made; but if a piece of unfermented bread be treated in the same manner, the steam produced by the moisture, not being able to penetrate the unabsorbent mass, evaporates, and the result is an uninviting slice, toasted, but hard inside and out, and into which butter penetrates about to the same extent as it would a wooden slab of the same dimensions.

'Fermentation,' says Liebig, 'is not only the best and simplest, but likewise the most economical way of imparting porosity to bread; and besides, *chemists, generally speaking, should never recommend the use of chemicals for culinary preparations*, for chemicals are seldom met with in commerce in a state of purity. Thus, for example, the muriatic acid which it has been proposed to mix with carbonate of soda in bread is *always very impure*, and *very often contains arsenic*. Chemists never employ such an acid in operations which are certainly less important than the one just mentioned, without having first purified it.'

In order to remove this ground of objection, tartaric acid has been recommended instead of muriatic acid for the purpose of decomposing the carbonate of soda; but in that way, another unsafe compound is introduced, since the result of the reaction is tartrate of soda, a diuretic aperient, and consequently very objectionable salt, for it is impossible to say what mischief the continuous ingestion of such a substance may eventually produce; and whatever may be the divergence of opinion,—if there be such a divergence,—as to whether or not the constant use of an aperient, however mild, may be detrimental to health, it surely must be admitted that, at any rate, it is better to eschew such, to say the least of it, suspicious materials; and that, at any rate, if deprecating their use be an error, it is an error on the safe side;—after all, a bakehouse is not a chemical laboratory.

Before leaving this question of unfermented bread, we must not omit to speak of a remarkable process invented by Dr. Daughlish, and which has lately excited some attention. Without discussing the value of the idea which is said to have led Dr. Daughlish to invent the process in question, we shall simply describe Dr. Daughlish's method of making bread, and give his own version of its benefits:—

'Taking advantage of the well-known capacity of water for absorbing carbonic acid, whatever its density, in quantities equal to its own bulk, I first prepare the water which is to be used in forming the dough, by placing it in a strong vessel capable of bearing a high pressure, and forcing carbonic acid into it to the extent of say ten or twelve atmospheres' (about 150 to 180 lbs. per square inch); 'this the water absorbs without any appreciable increase in its bulk. The water so prepared will of course retain the carbonic acid in solution so long as it is retained in a close vessel under the same pressure. I therefore place the *flour and salt*, of which the dough is to be formed, also in a close vessel capable of bearing a high pressure. Within this vessel, which is of a spheroidal form, a simply-constructed kneading apparatus is fitted, worked from without through a closely-packed stuffing box. Into this vessel I force an equal pressure to that which is maintained on the aerated water-vessel; and then, by means of a pipe connecting the two vessels, I draw the water into the flour, and set the kneading apparatus to work at the same time. By this arrangement the water acts simply as limpid water among the flour, the flour and water are mixed and kneaded together into paste, and to such an extent as shall

give it the necessary *tenacity*. After this is accomplished the pressure is released, the gas escapes from the water, and in doing so raises the dough in the most beautiful and expeditious manner. It will be quite unnecessary for me to point out how perfect must be the *mechanical* structure that results from this method of raising dough. In the first place, the mixing and kneading of the flour and water together, before any vesicular property is imparted to the mass, render the most complete incorporation of the flour and water a matter of very easy accomplishment; and this being secured, it is evident that the gas which forms the vesicle, or sponge, when it is released, must be dispersed through the mass in a manner which no other method—fermentation not excepted—could accomplish. But besides the advantages of kneading the dough before the vesicle is formed, in the manner above mentioned, there is another, and perhaps a more important one, from what it is likely to effect by giving scope to the introduction of new materials into bread making,—and that is, I find that powerful machine-kneading, continued for several minutes, has the effect of imparting to the dough tenacity or toughness. In Messrs. Carr and Co.'s machine, at Carlisle, we have kneaded some wheaten dough for half an hour, and the result has been that the dough has been so tough, that it resembled birdlime, and it was with difficulty pulled to pieces with the hand. Other materials, such as rye, barley, &c. are affected in the same manner. So that by thus kneading, I am able to impart to dough made from materials which otherwise would not make light bread, from their wanting that quality in their gluten which is capable of holding or retaining, the same degree of lightness which no other method is capable of effecting. And I am sanguine of being able to make from rye, barley, oatmeal, and other wholesome and nutritious substances, bread as light and sweet as the finest wheaten bread. One reason why my process makes a bread so different from all other processes where fermentation is not followed is, that I am enabled to knead the bread to any extent without spoiling its vesicular property; whilst all other unfermented breads are merely *mixed*, not kneaded. The property thus imparted to my bread by kneading, renders it less dependent on being placed immediately in the oven. It certainly cannot *gain* by being allowed to stand after the dough is formed, but it bears well the necessary standing and waiting required for preparing the loaves for baking.

‘There is one point which requires care in my process, and that is,—the *baking*: as the dough is excessively cold; first, because *cold* water is used in the process; and next, because of its sudden expansion on rising. It is thus placed in the oven some 40° Fahr. in temperature lower than the ordinary fermented bread. This, together with its slow springing until it reaches the boiling point, renders it essential that the *top* crust shall not be formed until the very last moment. Thus, I have been obliged to have ovens constructed which are heated through the bottom, and are furnished with the means of regulating the heat of the top, so that the bread is *cooked through the bottom*; and, just at the last, the top heat is put on and the top crust formed.

‘With regard to the *gain* effected by saving the loss by fermentation, I may state what must be evident, that the weight of the dough is always exactly the sum of the weight of flour, water, and salt put into the mixing vessel: and that, in all our experiments at Carlisle, we invariably made 118 loaves from the same weight of flour which by fermentation made only 105 and 106. Our advantage in gain over fermentation can only be equal to the *loss* by fermentation. As there has been considerable difference of opinion among men of science with respect to the amount of this loss—some stating it to be as high as 17½ per cent., and others so low as 1 per cent.—I will here say a few words on the subject. Those who have stated the loss to be as high as 17½ per cent. have, in support of their position, pointed to the extra yield from the same flour of bread when made by non-fermentation, compared with that made by fermentation. Whilst those who have opposed this assertion, and stated the loss to be but 1 per cent. or little more, have declared the gain in weight to be simply a gain of extra water, and have based their calculations of loss on the destruction of material caused by the generation of the necessary quantity of carbonic acid to render the bread light. Starting then with the assumption that light bread contains in bulk half solid matter and half aëriiform, they have calculated that this quantity of aëriiform matter is obtained by a destruction of but *one* per cent. of solid material. In this calculation the loss of carbonic acid, by its escape through the mass of dough during the process of fermentation and manufacture, does not appear to have been taken into account. All who have been in any way practically connected with bakeries well know how large this loss is, and how important it is that it should be taken into account, that our calculations may be correct.

‘One of the strongest proofs that the escape of gas through ordinary soft bread dough is very large arises from the fact, that when biscuit dough, in which there is a mixture of fatty matter, is prepared by my process, about half the quantity of gas only is needed to obtain an equal amount of *lightness* with dough that is made of flour

and water only, the fatty matter acting to prevent the escape of gas from the dough. Other matters will operate in a similar manner—boiled flour, for instance, added in small quantities. But the assumption that light bread is only half aëriiform matter is altogether erroneous. Never before has there been so complete a method of testing what proportion the aëriiform bears to the solid in light bread as that which my process affords. The mixing vessel at Messrs. Carr and Co.'s works, Carlisle, has an internal capacity of ten bushels. When $3\frac{1}{2}$ bushels of flour are put into this vessel, and formed into spongy bread dough, by my process, it is quite full. And when flour is mixed with water into paste, the paste measures rather less than half the bulk of the original dry flour. This will, therefore, represent about $1\frac{3}{4}$ bushel of solid matter expanded into 10 bushels of spongy dough, showing in the *dough* nearly 5 parts aëriiform to 1 solid; and in all instances, if the baking of this dough has not been accomplished so as to secure the loaves to 'spring' to at least double their size in the oven, they have always come out heavy bread when compared with the ordinary fermented loaves. This gives the relative proportion of aëriiform to solid in light bread at least as 10 to 1, and at once raises the loss by fermentation from 1 to 10 per cent., without taking into account the loss of gas by its passage through the mass of dough.

'Of the quality and properties of the bread manufactured by my process, there will shortly be ample means of judging. I may be allowed, however, here to state, what will be evident to all, that the absence of everything but flour, water, and salt, must render it absolutely pure;—that its sweetness cannot be equalled, except by bread to which sweet materials are superadded;—that, unlike all other unfermented bread, it makes excellent toast; and, on account of its high absorbent power, it makes the most delicious sop puddings, &c., and also excellent poultice. Sop pudding and poultice made from this bread, however, differ somewhat from those made from fermented bread, in being somewhat richer or more glutinous. This arises from the fact of the gluten not having been changed, or rendered soluble, in the manner caused by fermentation; but that this is a good quality rather than a bad one is evident from the fact, that the richer and purer fermented bread is, the more glutinous are the sop, &c., made from it; and the poorer and more adulterated with alum it is, the freer the sop, &c., are of this quality.'

Such then is Dr. Dauglish's plan; and it is impossible to deny that it possesses great ingenuity.

From the fact that, in all his experiments at Carlisle, Dr. Dauglish invariably made 118 loaves from the same weight of flour which, by fermentation, made only 105 or 106, to argue that the *gain over fermentation* can only be equal to the *loss by fermentation*, is to draw a somewhat hasty conclusion; for the gain may be, and is probably due, not to the preservation in the bread of what is generally lost by fermentation, but simply to a retention of water.

It is of course certain that the production of the porosity required in bread produced by the carbonic acid and alcohol evolved by fermentation, entails the loss of a portion of the valuable constituents of the flour, but the amount of that loss should not be estimated, I think, from the proportions which the aëriiform bear to the solid matter of the loaf *after it is baked*.

In effect, the fermentation induced in bread differs from that produced at the distillery, in as much as, instead of the fermenting material being sheltered from the air by an atmosphere of carbonic acid, the dough is on the contrary thoroughly permeated by, and retains a considerable quantity of atmospheric air introduced into it by the kneading process, and owing to the presence of which, in fact, the acetous fermentation is carried on to a certain extent, within the dough, simultaneously with the alcoholic fermentations, so that even the 10 parts of aëriiform matter to 1 of solid matter in a quartern loaf, are not altogether carbonic acid resulting from the fermentation, but are carbonic acid from that source mixed with the atmospheric air with which the dough is permeated. On the other hand, the aëriiform matter thus imprisoned in the dough, expands to at least twice its volume when exposed to the temperature of the oven, and accordingly the bread after breaking becomes as bulky again as the dough from which it was made, and this doubling of the volume being due to the expansion of the gases, and not to the fermentation, bears no proportion whatever to the amount of the sugar of the flour employed in the production of the alcohol and carbonic acid evolved. Moreover, as a quartern loaf, for example, measures about 9 inches by 6.5 inches by 5 inches, making a total of about 292 cubic inches, if we take nine-tenths of that to be aëriiform matter, we have 262.8 inches as the aëriiform cubic contents of the quartern loaf.

It is ascertained beyond doubt by numerous experiments, that genuine, properly manufactured new bread contains, on an average, 42.5 per cent. of water, and 57.5 of flour, and consequently a quartern loaf weighing really four pounds, would consist of 11,900 grains of water and 16,000 grains of solid matter, 422.5 grains of which are

salt and inorganic matter, the rest, 15677·5 grains, being starch and gluten. Now a quarter loaf measuring about $9 \times 6\cdot5 \times 5$ inches gives a total of 292 cubic inches. Assuming with Dr. Daughlish, nine-tenths of that to be aëriform matter, we have 262·8 inches of aëriform cubic contents of a quarter loaf, but as the gases expanded in the dough to double their volume during its being baked into a loaf, we must divide by 2 the 262·8 inches above alluded to, which gives 131·4 as the number of cubic inches of aëriform matter contained in the dough before it went into the oven. Again, assuming with Dr. Daughlish that these 131·4 cubic inches consist altogether of carbonic acid resulting from the fermentation of the flour, they would represent in weight only 62 grains of that gas, and as 1 equivalent=198 of sugar produces 4 equivalents=88 of carbonic acid, it follows that, at most, about 140 grains of sugar or solid matter out of the 15677·5 of flour in the quarter loaf would have disappeared, which loss is less than 1 per cent., from which, however, it is necessary to make a considerable reduction, since a large quantity of air is mixed with that carbonic acid, and expanded with it in the oven. Unless, therefore, it can be satisfactorily proved that the unfermented bread manufactured by Dr. Daughlish's process is more nutritious, weight for weight, or more digestible, or possesses qualities which unfermented bread has not, or is sold at a reduced price proportionate to the quantity of water thus locked up and passed off for bread, the benefits and advantages will be all on the manufacturer's side, but the purchasers of the unfermented bread will make but a poor bargain of it.

Of all the operations connected with the manufacture of bread, the most laborious, and that which calls most loudly for reform, is that of kneading. The process is usually carried on in some dark corner of a cellar, where the temperature is seldom less than 60° F., and frequently more, by a man, stripped naked down to the waist, and painfully engaged in extricating his fingers from a gluey mass into which he furiously plunges alternately his clenched fists, heavily breathing as he, struggling, repeatedly lifts up the bulky and tenacious mass in his powerful arms, and with effort flings it down again with a groan fetched from the innermost recesses of his chest, and which almost sounds like an imprecation.

We know, on very good and unexceptionable authority, that a certain large bakery on the borders of a canal actually pumped the water necessary for making the dough directly and at once from the canal, and this from a point exactly contiguous to the dischargings of the cesspool of that bakery! And let us not imagine that this is a solitary instance of horrible filth. The following memoranda recorded by Dr. Wm. A. Guy, in his admirable lecture on 'The Evils of Night-work and Long Hours of Labour,' delivered on Thursday, July 6, 1848, at the Mechanics' Institution, Southampton Buildings, will serve to illustrate the condition of the bakehouses:—

1. Underground, two ovens, no daylight, no ventilation, very hot and sulphurous.
2. Underground, no daylight, two ovens, very hot and sulphurous, low ceiling, no ventilation but what comes from the doors. Very large business.
3. Underground, no daylight, often flooded, very bad smells, overrun with rats, no ventilation.

After mentioning several other establishments in the same, or even in a worse, condition than those just enumerated, Dr. Guy adds:

'The statements comprised in the foregoing memoranda are in conformity with my own observations. Many of the basements in which the business of baking are carried on are certainly in a state to require the assistance of the Commissioners of Sewers, and to invite the attention of the promoters of sanitary reform.'

If we reflect that bread, like all porous substances, readily absorbs the air that surrounds it, and that, even under the best conditions, it should never, on that account, be kept in confined places, what must be the state of the bread manufactured in such a villanous manner, and with a slovenliness greater than it is possible for our imagination to conceive? What can prove better the necessity of Government supervision than such a fact? The heart sickens at the revolting thought, but after all there is really but little difference between the particular case of the bakery on the border of a canal above alluded to, and the mode of kneading generally pursued, and to which we daily submit.

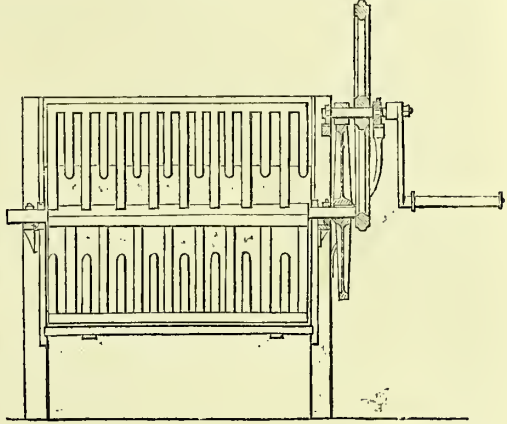

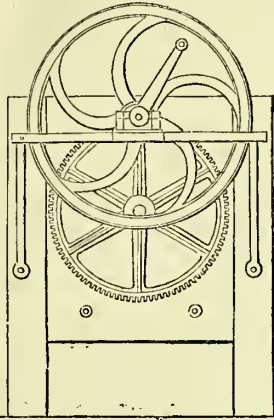

In the sitting of the Institute of France, on the 23rd of January, 1850, the late M. Arago presented and recommended to the Académie the kneading and baking apparatus of M. Rolland, then a humble baker of the 12th Arrondissement, which, it would appear, fulfils all the conditions of perfect kneading and baking.

'The kneading machine (*pétrin mécanique*) of M. Rolland,' says Arago, 'is extremely simple, and can be easily worked, when under a full charge, by a young man from 15 to 20 years old: the necessity for horse-labour or steam-power may thus be obviated. The machine (*figs. 217 to 220*) consists of a horizontal axis traversing a trough, containing all

the dough requisite for one baking batch, and upon which axis a system of curvilinear blades, alternately long and short, are placed in such a manner that, while revolving, they describe two quarters of cylindrical surfaces with contrary curves, so that the convexity of one of these surfaces, and the concavity of the other, is turned towards the bottom of the trough. The axis has a fly-wheel, and is set in motion by two small cog-wheels connected with the handle, as represented in the following figures:—

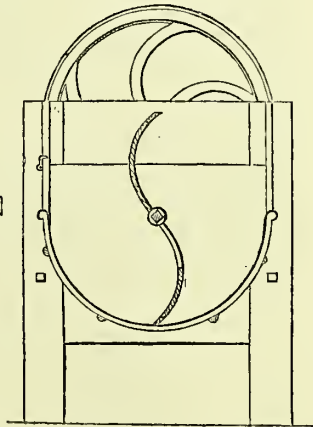

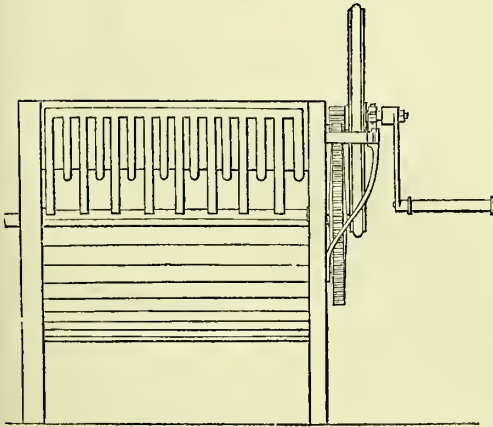

217

218

219

220

The action of the kneading machine is both easy and efficacious. In 20, and if necessary in 15, or even 10 minutes, a sack of flour may be converted into a perfectly homogeneous and aerated dough, without either lumps or clods, and altogether superior to any dough than could be obtained by manual kneading. The time required in kneading varies according to the greater or less density of dough required; and the quantity of dough manufactured in that space of time varies, of course, also with the dimensions of the kneading-trough; for instance, in the trough provided with 16 blades, one sack and a half of flour can be kneaded at once; in that of 14 blades one sack, and in that of 12 blades two-thirds of a sack.

M. Rolland gives the following instructions for the use of the machine, in order to impart to the dough the qualities produced by the operations known in France under the names of *frasage*, *contrefrasage*, and *soufflage*, which we shall presently describe, and to which the bread manufactured in that country mainly owes, in the words of Dr. Ure, 'a flavour, colour, and texture, never yet equalled in London.'

The necessary quantity of leaven or yeast is first diluted with the proper quantity of water, as described before; and in order to effect the mixture, the crank should be

made to perform 50 revolutions alternately from right to left.—*Frasage* is the first mixture of the flour with the water. The flour is simply poured into the kneading-trough, or, better still, when convenience permits it, it is let down from a room above through a linen hose, which may be shut by folding it up at the extremity.

Three-fourths only of the flour should at first be put into the trough; the first revolutions of the kneader should be rather rapid, but during the remainder of the operation the turning should be at the rate of two or three revolutions a minute, according to the density of the dough to be prepared. The dough thereby having time to be well drawn out between the blades, and to drop to the bottom of the trough. From 24 to 36 revolutions of the crank will generally be sufficient; but in order to obtain the dough in the condition which the *frasage* would give it in the usual way, it will be necessary to make about 250 revolutions of the crank alternately from right to left, about the same number of turns.

Contrefrasage is the completion of the process of mixing; and, in order to perform that operation, the last fourth part of the flour must now be added, the crank turned 150 revolutions, to wit, 75 turns rather slowly, alternately from right to left, and the remainder at the rate of speed above mentioned.

The operation of *Soufflage* consists in introducing and retaining air in the paste. To effect this, the kneader should be made to perform, during nearly the whole time occupied in the operation, an almost continuous motion backwards and forwards, by which means the dough is shifted from place to place; five revolutions being made to the right, and five to the left, alternately, taking care to accelerate the speed a little at the moment of reversing the direction of the revolving blades.

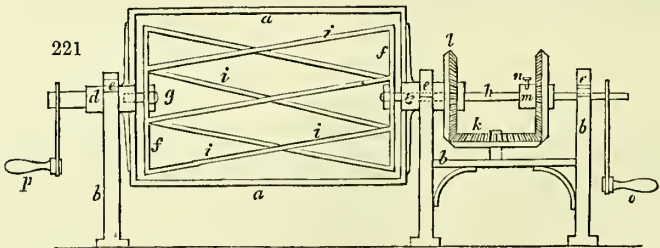

All these operations are accomplished in twenty or twenty-five minutes.

Of course, the reader should not imagine that these numbers must be strictly followed, they are given merely as a guide indicative of the *modus operandi*.

The kneading being completed, the dough is left to rest for some time, and then divided into lumps, of a proper weight, for each loaf. The workman takes one of these lumps in each hand, rolls them out, dusts them over with a little flour, and puts each of them separate in its *panneton*; he proceeds with the rest of the dough in the same manner, and leaves all the lumps to swell, which, if the flour have been of good quality, will take place at a uniform rate. They are then fit for baking, which operation will be described presently.

Another kneading trough, said to be very effectual, is that for which Mr. Edwin Clayton obtained a patent in August 1830. It consists of a rotatory kneading trough, or rather barrel, mounted in bearings with a hollow axle, and of an interior frame of cast iron made to revolve by a solid axle which passes through the hollow one; in the frame there are cutters diagonally placed for kneading the dough. The revolving frame and its barrel are made to turn in contrary directions, so as greatly to save time and equalise the operation. This double action represents kneading by the two hands, in which the dough is inverted from time to time, torn asunder, and reunited in every different form. The mechanism will be readily understood from the following description:—

Fig. 221 exhibits a front elevation of a rotatory kneading trough, constructed

according to improvements specified by the patentee, the barrel being shown in section; *a* is the barrel, into which the several ingredients, consisting of flour, water, and yeast, are put, which barrel is mounted in the frame-work *b*, with hollow axles *c* and *d*, which hollow axles turn in suitable bearings at *e*; *f* is the revolving frame which is mounted in the interior of the barrel *a*, by axles *g* and *h*. The ends of this revolving frame are fastened or braced together by means of the oblique cutters or braces *i*, which act upon the dough when the machine is put in motion, and thus cause the operation of kneading.

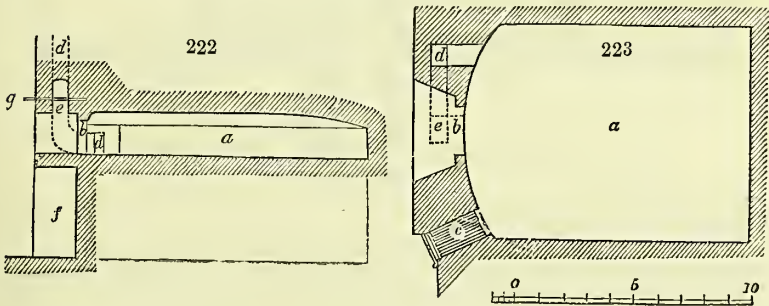

Either the barrel may be made to revolve without the rotatory frame, or the rota-

tory frame without the barrel, or both may be made to revolve together, but in opposite ways. These several motions may be obtained by means of the gear-work, shown at *k*, *l*, and *m*, as will be presently described.

If it be desired to have the revolving motion of the barrel and rotatory frame together, but in contrary directions, that motion may be obtained by fastening the hollow axle of the wheel *m*, by means of a screw *n*, to the axle *h* of the rotatory frame *f* tight, so as they will revolve together, the other wheels *k* and *l* being used for the purpose of reversing the motion of the barrel. It will then be found that by turning the handle *o*, the two motions will be obtained.

If it be desired to put the rotatory frame *f*, only into motion, that action will be obtained by loosening the screw *n* upon the axle of the wheel *m*, when it will be found that the axle *h* will be made to revolve freely by means of the winch *o*, without giving motion to the wheels *k*, *l*, and *m*, and thus the barrel will remain stationary. If the rotatory action of the barrel be wanted, it will be obtained by turning the handle *p*, at the reverse end of the machine, which, although it puts the gear at the opposite end of the barrel into motion, yet as the hollow axle of the wheel *m* is not fastened to the axle *h* by the screw *n*, these wheels will revolve without carrying round the frame *f*.

The Hot-water Oven Biscuit-baking Company possesses also a good machine with which 1 cwt. of biscuit dough, or 2 cwts. of bread dough, can be perfectly kneaded in

10 minutes. The machine is an American invention, and of extraordinary simplicity, for it is in reality nothing more than a large corkscrew, working in a cylinder, by means of which the dough is triturated, squeezed, pressed, torn, hacked, and finally agglomerated as it is pushed along. The dough as it issues from that machine can at once be shaped into loaves of suitable size and dimensions. A machine capable of doing the amount of work alluded to does not come to more than from 6*l.* to 7*l.*; the other forms of kneading machines are likewise inexpensive, so that, in addition to the economy of time which they realise, there does not seem to be any excuse for retaining the abomination of manual kneading.

Among superior and very desirable apparatus for bread-making, there are at any rate three which fulfil the desiderata above alluded to, in the most complete and economical manner. One of them is M. Mouchot's aërothermal bakery; the second is A. M. Perkins' hot-water oven; the third is Rolland's hot-air oven, with revolving floors: all three are excellent.

Before proceeding to explain them, a plan and longitudinal section of an ordinary London baker's oven is given (*figs.* 222 and 223), that the reader may be the better able to judge of the vast improvement realised by the other ovens.

a, the body of the oven; *b*, the door; *c*, the fire-grate and furnace; *d*, the smoke flue; *e*, the flue above the door, to carry off the steam and hot air, when taking out the bread; *f*, recess below the door, for receiving the dust; *g*, damper plate to shut off the steam flue; *h*, damper plate to shut off smoke flue, after the oven has come to its proper heat; *i*, a small iron pan over the fire-place *c*, for heating water; *k*, ash-pit below the furnace.

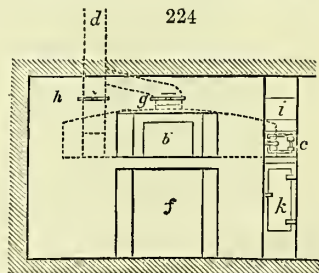

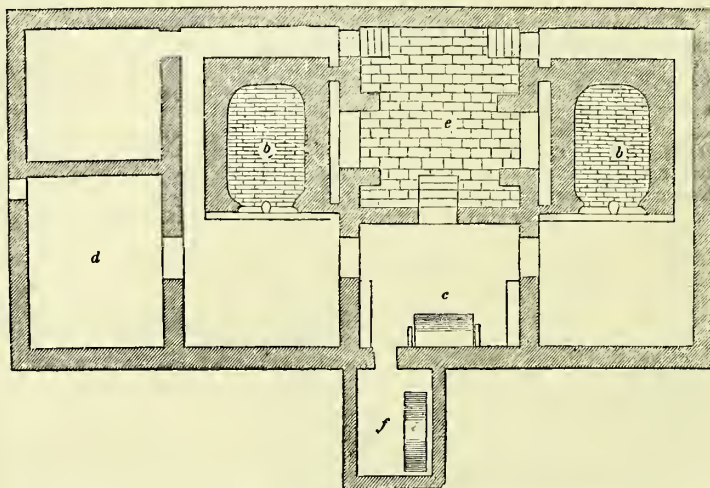

Fig. 224 is the front view; the same letters refer to the same object in all the figures.

The flame and burnt air of the fire at *c*, sweeping along the bottom of the oven by the right-hand side, are reflected from the back to the left-hand side, and thence escape by the flue *d*. Whenever the oven has acquired the proper degree of heat, the fire is withdrawn, the flues are closed by the damper plate, and the lumps of fermented dough are introduced.

225

We shall now give a description not only of the oven, but of the improved bakery, *boulangerie perfectionnée*, of M. Mouchot.

Fig. 225 is a ground plan of the aërothermal bakehouse: the granaries being in the upper storeys, are not shown here. *b b* are the ovens; *c*, the kneading machine; *d*, the place where the machinery is mounted for hoisting up the bread into the store

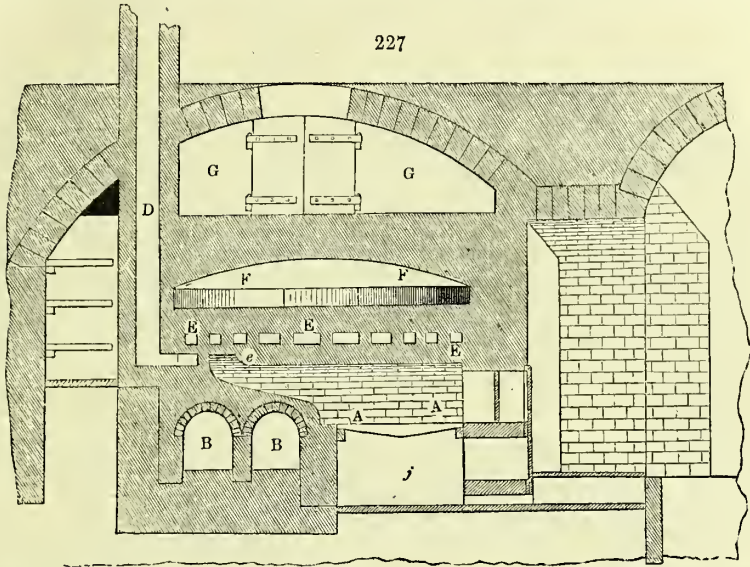

226

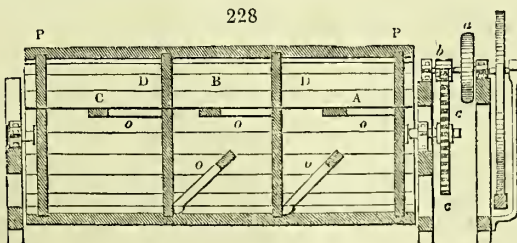

room above; *e*, a space common to the two ovens, into which the hot air passes; *f*, the place of a wheel driven by dogs, for giving motion to the kneading machine.

Fig. 226 is a longitudinal section of the oven; *A*, the grate where coke or even pit-coals may be burned; *B B*, void spaces which, becoming heated, serve for warming small pieces of dough in; *cc* are flues for conducting the smoke, &c., from the fire-

place; *D*, seen in *fig. 227* (a transverse section through the middle of the oven), is the chimney for carrying off the smoke transmitted by the flues; *EE*, void spaces immediately over the flues, and beneath the sole *FF*, of the oven. By this arrangement the air, previously heated, which arrives from the void spaces *B* through the flues *cc*,

gets the benefit of the heat of the flame which circulates in these flues, and, after getting more heated in the spaces *EE*, ascends through channels into the oven *FF*, upon the sole of which the loaves are to be baked or laid. The hot air is admitted into it through the passages *aa*, being drawn from the reservoirs *BB*, and also by the passage *dd*, drawn from the reservoirs *EE*. The sole is likewise heated by contact with the hot air contained in the space *EE*, placed immediately below it. The hot air, loaded with moisture, issues by the passage *bb*, and returns directly into the reservoir *BB*. *GG*, an enclosed space directly over the oven, to obstruct the dissipation of its heat; *g*, vault of the fire-place. *Fig. 228*, the kneading machine, a longitudinal section passing through its axis; *PP*, the contour of the machine, made of wood, and divided into three compartments for the reception of the dough. The wooden bars *oo* are so placed in the interior of the compartments, as to divide the dough whenever the cylinder is made to revolve. One portion, *D*, of the cylinder may be opened and laid over upon the other by means of a hinge joint, when the dough and flour are introduced. *A, B, c*, the three compartments of the machine, two for making the dough, and one for preparing the sponge, called *levain*, or leaven, by the French. *aa* is the pulley which receives its motion from the engine, and transmits it to the cylinder through the pinion *b*, and the spur-wheel *e*; *dd*, the fly-wheel to regulate the motion; *g*, a brake to act upon the fly *d*, by means of a lever *h*; *i*, the pillar of the fly-wheel.

There is a ratchet-wheel counter for numbering the turns of the kneading machine, but it cannot be shown in this view; *n*, cross-bars of wood, which are easily removed when the cylinder is opened; they divide the dough.

Each of the three compartments of the *kneader* (*fig. 228*) is furnished at pleasure

with two bars fixed crosswise, but which may be easily removed, whenever the cylinder is opened. These bars constitute the sole agents for drawing out the dough. In a continuous operation, the leaven is constantly prepared in the compartment A; with which view there is put into it—

125	kilogrammes	of	ordinary	leaven	or	yeast,
67	,,	flour.
33	,,	water.

—
In all, 225 kilogrammes.

The person in charge of the mechanical kneader shuts down its lid, and sets it a-going. At the end of about seven minutes he hears the bell of the counter sound, announcing that the number of revolutions has been sufficient to call for an inspection of the sponge, in regard to its consistence. The cylinder is therefore opened, and after verifying the right state of the leaven, and adding water to soften, or flour to stiffen it, he closes the lid, and sets the machine once more in motion. In 10 minutes more the counter sounds again, and the kneading is completed. The 450 kilogrammes of leaven obtained from the two compartments are adequate to prepare dough enough to supply alternately each of the two ovens. For this purpose 75 kilogrammes of leaven are taken from each of the two compartments A and A', and placed in the intermediate compartment B. The whole leaven is then $75 + 75 = 150$ kilogrammes; to which are added 100 kilogrammes of flour and 50 of water = 150, so that the chest contains 300 kilogrammes. There is now replaced in each of the cavities A and A' the primitive quantity, by adding 50 kilogrammes of flour and 25 of water = 75.

The cylinder is again set a-going; and, from the nature of the apparatus, it is obvious that the kneading takes place at once on the leavens A and A', and on the paste B; which last is examined after 7 minutes, and completed in 10 more = 17, at the second sound of the counter-bell.

The kneader is opened, the paste on the sides and on the bars is gathered to the bottom by means of a scraper. The whole paste of the chest B being removed, 150 kilogrammes of the leaven are taken, to which 150 kilogrammes of flour and water are added to prepare the 300 kilogrammes of paste destined for the supply of the oven No. 2. These 75 kilogrammes of leaven from each compartment are placed as before, and so on in succession.

The water used in this operation is raised to the proper temperature, viz. 25° or 30° C. (77° or 86° F.) in cold weather, and to about 68° F. in the hot season, by mixing common cold water with the due proportion of water maintained at the temperature of about 160° F., in the basis F, placed above the ovens.

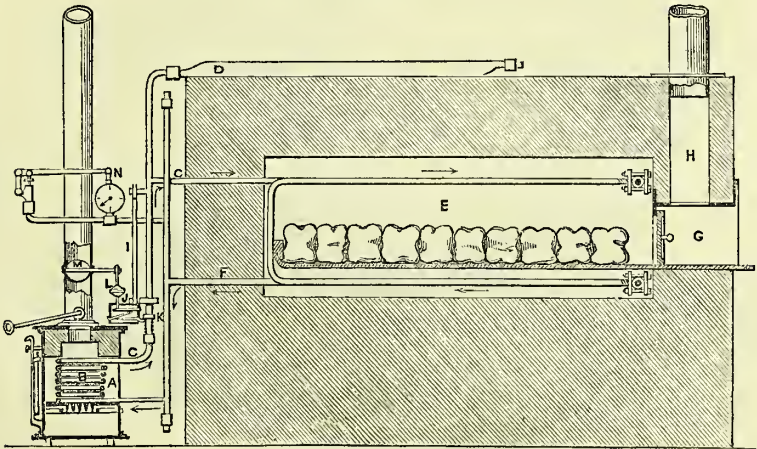

Through the water poured at each operation upon the flour in the compartment B, there is previously diffused from 200 to 250 grammes of fresh leaven, as obtained from the brewery, after being drained and pressed (*German yeast*). This quantity is sufficient to raise properly 300 kilogrammes of dough. As soon as this dough is taken out of the kneader, as stated above, and while the machine goes on to work, the quantity requisite for each loaf is weighed, turned about on the table D, to give it its round or oblong form, and there is impressed upon it with the forcarm, or roller, the cavity which characterises cleft loaves. All the lots of dough of the size of one kilogramme, called cleft loaves (*pains fendus*), are placed upon a cloth, a fold of which is raised between two loaves, the cloth being first spread upon a board; which thus charged with 10 or 15 loaves is transferred to the wooden shelves G G, in front of the oven. The whole of them rise easily under the influence of the gentle temperature of this antechamber or *fournil*. Whenever the dough loaves are sufficiently raised here, they are put into the oven, a process called *enfournement* in France; which consists in setting each loaf on a wooden shovel dusted with coarse flour, and placing it thereby on the sole of the oven, close to its fellow, without touching it. This operation is made easy, in consequence of the introduction of a long-jointed gas-pipe and burner into the interior of the oven, by the light of which all parts of it may be minutely examined. The oven first is kept moderately hot, by shutting the dampers; but whenever the thermometer attached to it indicates a temperature of from 300° to 290° C. (572° to 554° F.), the damper or registers are opened, to restore the heat to its original degree, by allowing of the circulation of the hot air, which rises from the lower cavities around the fire-place into the interior of the oven. When the baking is completed, the gas-light, which had been withdrawn, is again introduced into the oven, and the bread is taken out; called the process of *défournement*. If the temperature have been maintained at about 300° C., the 300 kilogrammes of dough, divided into loaves of one kilogramme ($2\frac{1}{5}$ lbs. avoirdupois), will be baked in 27 minutes. The charging having lasted 10 minutes, and the discharging as long, the baking of each

batch will take up 47 minutes. But on account of accidental interruptions, an hour may be assigned for each charge of 260 loaves of 1 kilogramme each; being at the rate of 6,240 kilogrammes (or 6.75 tons) of bread in 24 hours.

Although the outer parts of the loaves be exposed to the radiation of the walls, heated to 280° or 300° C., and undergo therefore that kind of *caramelisation* (charring) which produces the colour, the taste, and the other special characters of the crust, yet the inner substance of the loaves, or the crumb, never attains to nearly so high a temperature; for a thermometer, whose bulb is inserted into the heart of a loaf, does not indicate more than 100° C. (213° F.)

Perkins' hot-water oven is an adaptation of that distinguished engineer's stove, which, as is well known, is a mode of heating by means of pipes full of water, and hermetically closed; but with a sufficient space for the expansion of the water in the pipes. As a means of warming buildings, the invention has already produced the very beneficial effects which have gained for it an extensive patronage. There is no doubt but that this novel application entitles the inventor to the warmest thanks of the public. The following figure (229), represents one of these ovens. A, stove; B, coil of iron pipe placed in the stove; C, C, flow-pipe; D, expansive tube; E, oven charged with loaves, and surrounded with the hot-water pipes; F, return hot-water pipe; G, door of the oven; H, flue for the escape of the vapours in the oven; I, rigid bar of iron supporting the regulating box; J, J, regulating box, containing three

229

small levers; K, nut adjusted so that if temperature of the hot-water pipe is increased beyond the adjusted point, its elongation causes the nut to bear upon the levers in the box J, which levers, lifting the straight rod I, shut the damper M of the stove; N is an index indicating the temperature of the hot-water pipes.

The oven is first built in the ordinary manner of sound brickwork, made very thick in order to retain the heat. Then the top and bottom of the internal surfaces are lined with wrought-iron pipes of one inch external diameter, and five-eighths of an inch internal diameter, and their surface amounts in the aggregate, to the whole surface of the oven. These pipes are then connected to a coil in a furnace outside the oven. The coil having such a relative proportion of surface to that which is in the oven, that the pipes may be raised to a temperature of 550° F., and no more. This fixed and uniform temperature is maintained by a self-regulating adjustment peculiar to this furnace, which works with great precision, and which cannot get out of order, since it depends upon the expansion of the upper ascending pipe close to the furnace acting upon three levers connected with the damper which regulates the draught. The movable nut at the bottom of that expanding pipe being adjusted to the requisite temperature, that precise temperature is uniformly retained. The smallest fluctuation in the heat of the water which circulates in the pipes instantly sets the levers in motion, and the expansion of one thirty-sixth part of an inch is sufficient to close the damper.

It will be observed that if the pipes be heated to 550° F. the brickwork will soon attain the same temperature, or nearly so, and accordingly the oven will thus possess double the amount of the heating surface of ordinary ovens applicable to baking.

The baking temperature of the oven is from 420° to 450° F., which is ascertained by a thermometer with which the oven is provided.

With respect to Rolland's oven, Messieurs Boussingault, Payen, and Poncelet, in their report to the Institute of France; Gaultier de Glaubry, in a report made in the name of the Committee of Chemical Arts to the Société d'Encouragement; and the late M. Arago, represented that oven as successfully meeting all the conditions of salubrity, cleanliness, and hygiene. Wood, coals, ashes are likewise banished from it, and neither smoke nor the heated air of the furnace can find access to it. As in Perkins', the furnace is placed at a distance from the mouth of the oven, but instead of conveying the heat by pipes, as in the hot-water oven, it is the smoke and hot air of the furnace which, circulating through fan-shaped flues, ramifying under the floor and spreading over the roof of the oven, impart to it the requisite temperature. The floor of the oven, on which the loaves are deposited, consists of glazed tiles, and it can thus be kept perfectly clean. The distinctive character of M. Rolland's oven, however, is that the glazed tiles just spoken of rest upon a revolving platform which the workman gradually, or from time to time, moves round by means of a small handle, and without effort.

Figures 230 to 239 represent the construction and appearance of M. Rolland's oven on a reduced scale.

230

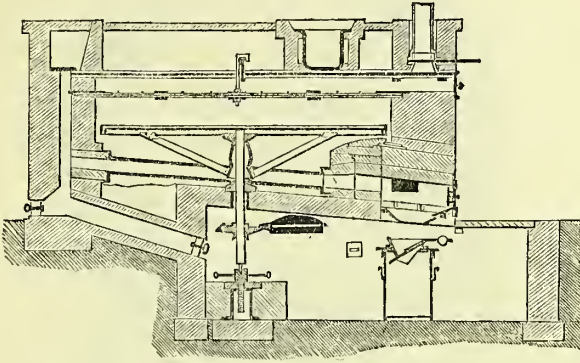

When the oven has to be charged, the workman deposits the first loaves, by means of a short peel, upon that part of the revolving platform which lies before the mouth of the oven, and when that portion is filled, he gives a turn with the handle, and proceeds to put the loaves in the fresh space thus presented before him, and so on until the whole is filled up. The door is then closed through an opening covered with glass, and reserved in the wall of the oven, which is lighted up with a jet of gas, or by opening the door from time to time the progress of the baking may be watched; if it appears too rapid on one point, or too slow on another, the journeyman can, by means of the handle, bring the loaves successively to the hottest part of the oven, and *vice versa*, as occasion may require. The oven is provided with a thermometer, and, in an experiment witnessed, the temperature indicated 210° C. = 420° F., the baking of a full charge was completed in one hour and ten minutes, and the loaves of the same kind were so even in point of size and colour that they could not be distinguished from each other.

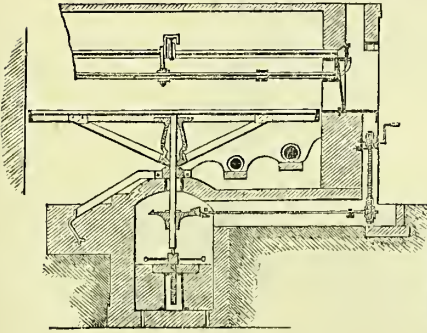

The top of the oven is provided with a pan for the purpose of heating the water necessary for the preparation of the dough, by means of the heat which in all other plans (Mouchot's excepted) is lost. The workman should take care to keep always some water in that pan, for otherwise the leaden pipe would melt and occasion dangerous leaks. For this and other reasons, the safest plan, however, would be to

replace this leaden pipe by an iron one. The said pan should be frequently scoured, for, if neglected, the water will become rusty and spoil the colour of the bread. Bread baking may be considered as consisting of four operations: namely, heating

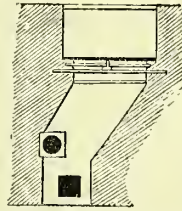

231

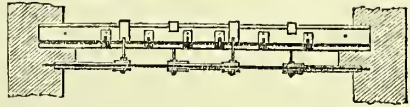

232

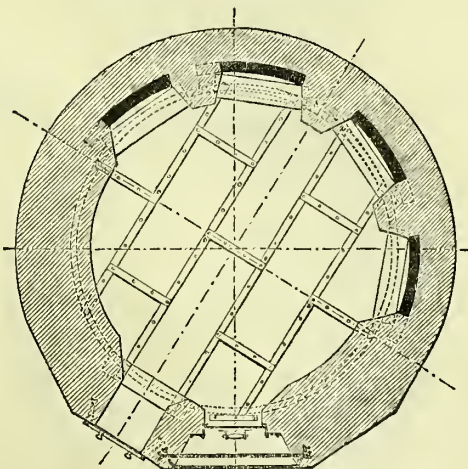

233

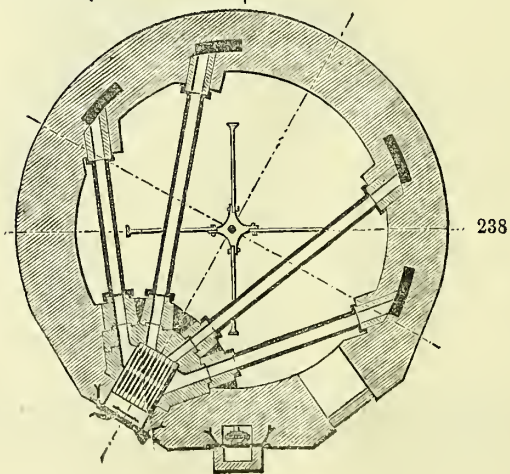

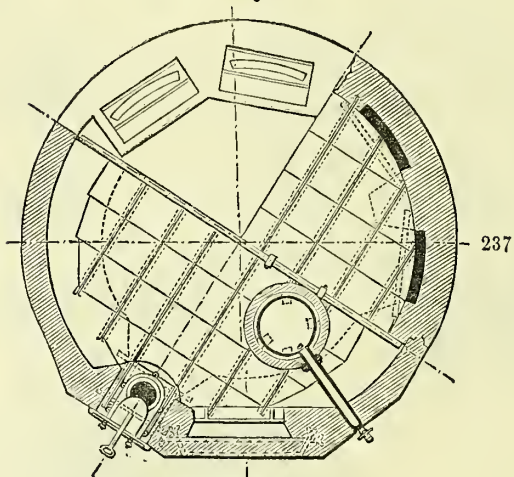

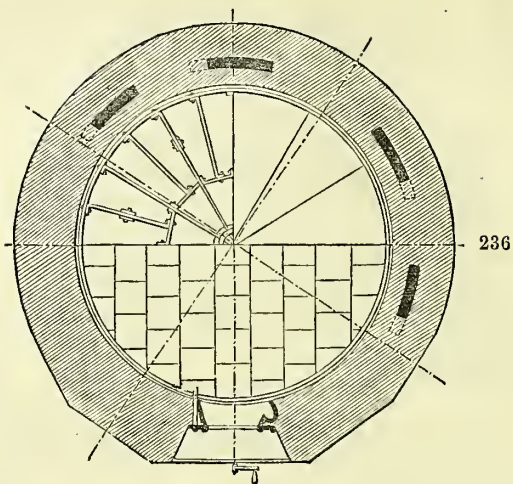

234

235

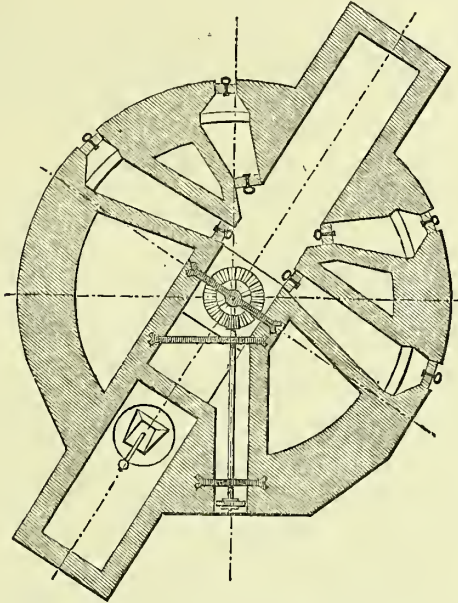

the oven, putting the dough into the oven, baking, and taking the loaves out of the oven. The general direction given by M. Rolland for each of these operations are as follows:—

In order to obtain a proper heat and one that may be easily managed, it is necessary to charge the furnace moderately and often, and to keep it in a uniform state.

239

When the fire is kindled, the door should be kept perfectly closed, in order to compel the current of air necessary to the combustion to pass through the grate, and thence through the flues under and the dome over the oven. If, on the contrary, the furnace door were left ajar, the cold air from without would rapidly pass over the coals without becoming properly heated, and passing in that condition into the flues would fail in raising it to the proper temperature. In order that the flame and heated products of the combustion may pass through all the flues, it is, of course, necessary to keep them clear by introducing into them once a month a brush made of wire, or

240

whalebone, or those which are now generally used for sweeping the tubes of marine tubular boilers, and the best of which are those patented and manufactured by Messrs. Moriarty of Greenwich, or How of London. The vertical flues which are built in the masonry are cleared from without or from the pit, according to the nature of the plan adopted in building the oven. These flues need not be cleaned more often than about once in three months.

Sweeping between the floors should be performed about every fortnight.

In case of accident or injury to the thermometers, the following directions, which indeed apply to all ovens, may enable the baker to judge of the temperature of his oven. If, on throwing a few pinches of flour on the tiles of the oven, it remains white after the lapse of a few seconds, the temperature is too low; if, on the contrary, the flour assumes a deep brown colour, the temperature is too high; if the flour turns yellowish, or looks slightly scorched, the temperature is right.

The baking in Rolland's oven takes place at a temperature varying from 410° to 432° F. according to the nature and size of the article intended to be baked. During the baking, the revolving floor is turned every ten or twelve minutes, so that the loaves not remaining in the same place the baking becomes equal throughout.

As to the hot-water oven, a few establishments only have as yet adopted it in England;

one of them is the 'Hot-water Oven Biscuit-baking Company,' on whose premises fancy biscuits only are baked; and another establishment is that of a baker of the name of Neville, carrying on his business in London. With respect to M. Mouchot's system, it is not even known in this country, otherwise than by having been alluded to in one or two technological publications or dictionaries.

The quantity of bread which can be made from a sack of flour depends to a great extent upon the quantity of gluten that the flour of which it is made contains, but the wheat which contains a large proportion of nitrogenous matter does not yield so light a flour as those which are poorer. From a great number of determinations it is found that the amount of gluten contained in the flour to make best white bread ranges from 10 to 18 per cent., that of the starch being from 63 to 70 per cent., the ashes ranging from 0.5 to 1.9 per cent.

In the ordinary plan of bread making, London bakers reckon that 1 sack of such a flour, weighing 280 lbs., will make 94 real 4-lb. loaves (not quartern) of pure genuine bread, although a sack of such flour may yield him 94 or even 95 quartern (not 4-lb.) loaves.¹

From this account it may be easily imagined that if the baker could succeed in disposing at once of all the loaves of his day's baking either by sale at his shop, or, still better, by delivery at his customers' residences, such a business would indeed be a profitable one commercially speaking, for on that day he would sell from 28 to 34 lbs. of water at the price of bread, not to speak of the deficient weight.

As to those bakers who, by underbaking, or by the use of alum, or by the use of both alum and underbaking, manage to obtain 96, 98, 100, or a still larger number of loaves from inferior flour, or material, their profit is so reduced by the much lower price at which they are compelled to sell their sophisticated bread, that their tamperings avail them but little; their emphatically hard labour yields them but a mere pittance, except their business be so extensive that the small profits swell up into a large sum, in which case they only jeopardise their name as fair and honest tradesmen.

Looking now at the improved ovens, of which we have been speaking merely in an economical point of view, and abstractedly from all other considerations, the profits realised by their use appears to be well worth the baker's attention. But as with the improved ovens the economy bears upon the wages and the fuel, the advantages are much less considerable in a small concern than in a large one. Thus the economy which, upon 12 sacks of flour per week, would scarcely exceed 20 shillings upon the whole, would, on the contrary, assume considerable proportions in establishments baking from 50 to 100 sacks per week.

The richness or nutritive powers of sound flour, and also of bread, are proportional to the quantity of gluten they contain. It is of great importance to determine this point, for both of these objects are of enormous value and consumption; and it may be accomplished most easily and exactly by digesting in a water-bath, at the temperature of 167° F., 1,000 grains of bread (or flour) with 1,000 grains of bruised barley malt, in 5,000 grains, or in a little more than half a pint, of water. When this mixture ceases to take a blue colour from iodine (that is, when all the starch is converted into a soluble dextrose), the gluten left unchanged may be collected on a filter cloth, washed, dried at a heat of 212° F., and weighed. The colour, texture, and taste of the gluten ought also to be examined, in forming a judgment of good flour or bread.

The question of the relative value of white and brown bread, as nutritive agents, is one of very long standing, and the arguments on both sides may be thus resumed.

The advocates of brown bread hold:—

That the separation of the white from the brown parts of wheat grain, in making bread, is likely to be baneful to health;

That the general belief that bread made with the finest flour is the best, and that whiteness is a proof of its quality, is a popular error;

That whiteness may be, and generally is, communicated to bread by alum, to the injury of the consumer;

That the miller, in refining his flour, to please the public, removes some of the ingredients necessary to the composition and nourishment of the various organs of our bodies; so that fine flour, instead of being better than the meal, is, on the contrary, less nourishing, and, to make the case worse, is also more difficult of digestion, not to speak of the enormous loss to the population of at least 25 per cent. of branny flour,

¹ It is absolutely necessary thus to establish a distinction between four pounds and quartern loaves, because the latter very seldom indeed have that weight, and this deficiency is, in fact, one of the profits calculated upon; for although the Act of Parliament (Will. IV. c. xxxvii.) is very strict, and directs (sect. vii.) that bakers delivering bread by cart or carriage shall be provided with scales, weights, &c., for weighing bread, this requisition is seldom, if ever, complied with.

There are of course a few bakers whose quartern loaves weigh exactly four pounds, but many are from four to six ounces short.

containing from 60 to 70 per cent. of the most nutritious part of the flour, a loss which, for London only, is equal to at least 7,500 sacks of flour annually ;

That the unwise preference given so universally to white bread, leads to the pernicious practice of mixing alum with the flour, and this again to all sorts of impositions and adulterations ; for it enables the bakers who are so disposed, by adding alum, to make bread manufactured from the flour of inferior grain to look like the best and most costly, thus defrauding the purchaser and tampering with his health.

On the other side, the partisans of white bread contend, *of course*, that all these assertions are without foundation, and their reasons were summed up as follows in the *Bakers' Gazette*, in 1849 :—

‘The preference of the public for white bread is not likely to be an absurd prejudice, seeing that it was not until after years of experience that it was adopted by them.

‘The adoption of white bread, in preference to any other sort, by the great body of the community, as a general article of food, is of itself a proof of its being the best and most nutritious.

‘The finer and better the flour, the more bread can be made from it. Fifty-six pounds of fine flour from good wheat will make seventy-two pounds of good, sound, well-baked bread, the bread, having retained sixteen pounds of water. But bran, either fine or coarse, absorbs little or no water, and adds no more to the bread than its weight.’

And, lastly, in confirmation of the opinion that white bread contains a greater quantity of nutriment than the same weight of brown bread, the writer of the article winds up the white bread defence with a portion of the Report of the Committee of the House of Commons, appointed in 1800, ‘to consider means for rendering more effectual the provisions of 13 Geo. III., intituled “An Act for the better regulating the Assize and making of Bread.”’

In considering the propriety of recommending the adoption of further regulations and restrictions, they understood a prejudice existed in some parts of the country against any coarser sort of bread than that which is at present known by the name of ‘fine household bread,’ on the ground that the former was less wholesome and nutritious than the latter. The opinions of respectable physicians examined on this point are,—that the change of any sort of food which forms so great a part of the sustenance of man might for a time affect some constitutions ; that as soon as persons were habituated to it, the standard wheaten bread, or even bread of a coarser sort, would be equally wholesome with the fine wheaten bread which is now generally used in the metropolis ; but that, in their opinion, the fine wheaten bread *would go farther* with persons who have no other food than the same quantity of bread of a coarser sort.

It was suggested to them that if only one sort of flour was permitted to be made, and a different mode of dressing it adopted, so as to leave in it the fine pollards, 52 lbs. of flour might be extracted from a bushel of wheat weighing 60 lbs., instead of 47 lbs., which would afford a wholesome and nutritious food, and add to the quantity 5 lbs. in every bushel, or somewhat more than $\frac{1}{4}$ th. On this they remarked, that there would be no saving in adopting this proposition ; and they begged leave to observe, if the physicians are well founded in their opinions, that bread of coarser quality will not go equally far with fine wheaten bread, and increased consumption of wheaten bread would be the consequence of the measure.

From the baker's point of view, it is evident that all his sympathies must be in favour of the water-absorbing material, and therefore of the fine flour ; for each pound of water added and retained in the bread which he sells represents this day so many twopences ; but the purchaser's interest lies in just the opposite direction.

The question, however, is not, in the language of the Committee of the House of Commons of those days, or of the physicians whom they consulted, whether a given weight of wheaten bread *will go farther* than an equal weight of bread of a coarser sort ; nor whether a given weight of pure flour is more nutritious than an equal weight of the meal from the same wheat used in making brown bread. The real question is,—*Whether a given weight of wheat contains more nutriment than THE FLOUR obtained from that weight of wheat.*

The inquiry of the Committee of the House of Commons, and the defence of white bread *versus* brown bread, resting as it does, in this respect, upon a false ground, is therefore perfectly valueless ; for whatever may have been the opinion of respectable physicians and of Committees, either of those days or of the present times, one thing is certain—namely, that bran contains only 9 or 10 per cent. of woody fibre, that is, of matter devoid of nutritious property ; and that the remainder consists of a larger proportion of gluten and starch, fatty, and other highly nutritive constituents, with a few salts, and water, as proved by the following analysis by Millon :—

Composition of Wheat Bran.

Starch	52.0
Gluten	14.9
Sugar	1.0
Fatty matter	3.6
Woody „	9.7
Salts	5.0
Water	13.8

100.0

And it is equally certain that wheat itself—the whole grain—does not contain more than 2 per cent. of unnutritious, or woody matter, the bran being itself richer, weight for weight, in gluten than the fine flour; the whole meal contains, accordingly, more gluten than the fine flour obtained therefrom. The relative proportions of gluten in the whole grain, in bran, and in flour of the same sample of wheat, were represented by the late Professor Johnston to be as follows:—

Gluten of Wheat.

Whole grain	12 per cent.
Whole bran	14 to 18 „ „
Fine flour	10 „ „

Now, whereas a bushel of wheat weighing 60 lbs. produces, according to the mode of manufacturing flour for London, 47 lbs.—that is, 78 per cent. of flour, the rest being bran and pollards; if we deduct 2 per cent. of woody matter, and $1\frac{1}{2}$ per cent. for waste in grinding at the mill, the bushel of 60 lbs. of wheat would yield 58 lbs., or at least $96\frac{2}{3}$ per cent., of nutritious matter.

It is, therefore, as clear as anything can possibly be, that by using the whole meal instead of only the fine flour of that wheat, there will be a difference of about $\frac{1}{6}$ th in the product obtained from equal weights of wheat.

In a communication made to the Royal Institute nearly four years ago, M. Mège Mourière announced that he had found under the envelope of the grain, in the internal part of the perisperm, a peculiar nitrogenous substance capable of acting as a ferment, and to which he gave the name of ‘céréaline.’ This substance, which is found wholly, or almost so, in the bran, but not in the best white flour, has the property of liquefying starch, very much in the same manner as diastase; and the decreased firmness of the crumb of brown bread is referred by him to this action. The coloration of bread made from meal containing bran is not, according to M. Mège Mourière, due, as has hitherto been thought, to the presence of bran; but to the peculiar action of cerealin; this new substance, like vegetable casein and gluten, being, by a slight modification, due perhaps to the contact of the air, transformed into a ferment, under the influence of which the gluten undergoes a great alteration, yielding, among other products, ammonia, a brown-coloured matter analogous to umine, and a nitrogenous product capable of transforming sugar into lactic acid. M. Mège Mourière having experimentally established, to the satisfaction of a committee consisting of MM. Chevreul, Dumas, Pelouze, and Peligot, that by paralysing or destroying the action of cerealin, as described in the specification of his patent, bearing date June 14, 1856, white bread, having all the characters of first-quality bread, may be made, in the language of the said specification, ‘with using either all the white or raw elements that constitute either corn or rye, or with such substances as could produce, to this day, but brown bread.’

Cerealin, according to M. Mège Mourière, has two very distinct properties:—the first consists in converting the hydrated starch into glucose and dextrine; the second, which is much more important in its results, transforms the glucose into lactic, acetic, butyric, and formic acid, which penetrate, swell up, and partly dissolve the gluten, rendering it pulpy and emulsive, like that of rye; producing, in fact, a series of decompositions, yielding eventually a loaf having all the characteristics of bread made from inferior flour.

In order to convert the whole of the farinaceous substance of wheat into white bread, it is therefore necessary to destroy the cerealin; and the process, or series of processes, by which this is accomplished, is thus described by M. Mège Mourière in his specification:—

‘The following are the means I employ to obtain my new product:—

‘1st. The application of vinous fermentation, produced by alcoholic ferment or yeast, to destroy the ferment that I call “céréaline” existing, together with the frag-

ments of bran, in the raw flour, and which in some measure produces the acidity of brown bread directly, whilst it destroys indirectly most part of the gluten.

'2ndly. The thorough purification of the said flour, either raw or mixed with bran, (after dilution and fermentation,) by the sifting and separating of the farinaceous liquid from the fragments of bran disseminated by the millstone into the inferior products of corn.

3rdly. The employing that part of corn producing brown bread in the rough state as issuing from the mill after a first grinding, in order to facilitate its purification by fermentation and wet sifting.

'4thly. The employing an acidulated water (by any acid or acid salt) in order to prevent the lactic fermentation, preserving the vinous fermentation, preventing the yellow colour from turning into a brown colour (the ulmic acid), and the good taste of corn from assuming that of brown bread. However, instead of acidulated water, pure water may be employed with an addition of yeast, as the acid only serves to facilitate the vinous fermentation.

'5thly. The grinding of the corn by means of millstones that crush it thoroughly, increasing thereby the quantity of fowl parts, a method which will prove very bad with the usual process, and very advantageous with mine.

'6thly. The application of corn washed or stripped by any suitable means.

'7thly. The application of all these contrivances to wheat of every description, to rye, and other grain used in the manufacture of bread.

'8thly. The same means applied to the manufacture of biscuits.

'I will now describe the manner in which the said improvements are carried into effect.

'First Instance. *When flour of inferior quality is made use of.*—This description of flour, well known in trade, is bolted or sifted at 73, 74, 75, or 80 per cent. (a mark termed *Scipion mark* in the French War Department), and yields bread of middle quality. By applying to this sort of flour a liquid yeast, rather different from that which is applied to white flour, in order to quicken the work and remove the sour taste of bread, a very nice quality will be obtained, which result was quite unknown to everybody to this day, and which none ever attempted to know, as none before me was aware of the true causes that produce brown bread, &c.

'Now, to apply my process to the said flour (of inferior mark or quality) I take a part of the same—a fourth part, for instance—which I dilute with a suitable quantity of water, and add to the farinaceous liquid 1 portion of beer yeast for 200 portions of water, together with a small quantity of acid or acid salt, sufficient to impart to the said water the property of lightly staining or reddening the test-paper, known in France by the name of *papier de tournesol*. When the liquid is at full working, I mix the remaining portions of flour, which are kneaded, and then allowed to ferment in the usual way. The yeast applied, which is quite alcoholic, will yield perfectly white bread of a very nice taste; and I declare that if similar yeast were ever commended before, it was certainly not for the purpose of preventing the formation of brown bread, the character of which was believed to be inherent to the nature of the very flour, as the following result will sufficiently prove it, thus divesting such an application of its industrial appropriation.

'Second Instance. *When raw flour is made use of.*—By raw flour, I mean the corn crushed only once, and from which 10 to 15 per cent. of rough bran have been separated. Such flour is still mixed with fragments of bran, and is employed in trade to the manufacture of so-called white flour and bran after a second and third grinding or crushing. Instead of that, I only separate, and without submitting it to a fresh crushing, the rough flour in two parts, about 70 parts of white flour and 15 to 18 of rough or coarse flour, of which latter the yeast is made; this I dilute with a suitable quantity of water, sufficient to reduce the whole flour into a dough, say, 50 per cent. of the whole weight of raw flour. To this mixture have been previously added the yeast and acid, (whenever acid is applied, which is not indispensable, as before stated), and the whole is allowed to work for 6 hours at a temperature of 77° F. for 12 hours at 68°, and for 20 hours at 59°, thus proportionally to the temperature. While this working or fermentation is going on, the various elements (*céréaline*, &c.) which by their peculiar action are productive of brown bread, have undergone a modification; the rough parts are separated, the gluten stripped from its pellicles and disaggregated, and the same flour which, by the usual process, could have only produced deep brown bread, will actually yield first-rate bread, far superior to that sold by bakers, chiefly if the fragments of bran are separated by the following process, which consists in pouring on the sieve, described hereafter, the liquid containing the rough parts of flour thus disaggregated and modified by a well-regulated fermentation,

'The sieve alluded to, which may be of any form, and consist of several tissues of

different tightness, the closest being ever arranged underneath or the most forward, when the sieve is of cylindrical or vertical form, is intended to keep back the fragments of bran, which would by their interposition impair the whiteness of bread, and by their weight diminish its nutritive power. The sifted liquid is white, and constitutes the yeast with which the white flour is mixed after being separated, so as to make a dough at either a first or several workings, according to the baker's practice. This dough works or ferments very quickly, and the bread resulting therefrom is unexceptionable. In case the whiteness or neatness of bread should be looked upon as a thing of little consequence, a broader sieve might be employed, or even no sieve used at all, and yet a very nice bread be obtained.

'The saving secured by the application of my process is as follows:—By the common process, out of 100 parts of wheat, 70 or 75 parts of flour are extracted, which are fit to yield either white or middle bread; whilst, by the improved process, out of 100 parts of wheat 85 to 88 parts will be obtained, yielding bread of superior quality, of the best taste, neatness, and nutritious richness.

'In case new yeast cannot be easily provided, the same should be dried at a temperature of about 86° F., after being suitably separated by means of some inert dust, and previous to being made use of it should be dipped into 10 parts of water, lightly sweetened, for 8 to 10 hours, a fit time for the liquid being brought into a full fermentation, at which time the yeast has recovered its former power. The same process will hold good for manufacturing rye bread, only 25 per cent., about, of coarse bran are to be extracted. For manufacturing biscuits, I use also the same process, only the dough is made very hard and immediately taken into the oven, and the products thus obtained are far superior to the common biscuits, both for their good taste and preservation. Should, however, an old practice exclude all manner of fermentation, then I might dilute the rough parts of flour in either acidulated or non-acidulated water, there to be left to work for the same time as before, then sift the water and decant it, after a proper settling of the farinaceous matters of which the dough is to be made; thus the action of the acid, decantation, and sifting, would effectively remove all causes of alteration, which generally impair the biscuits made of inferior flour.

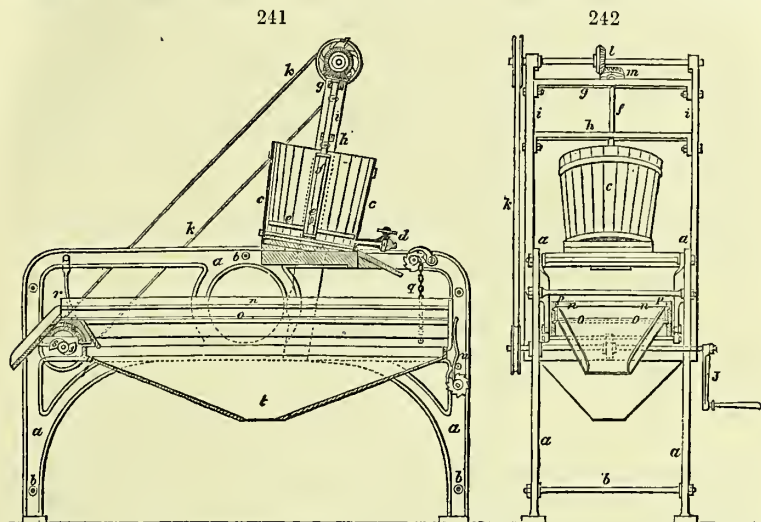

'The apparatus required for this process is very plain, and consists of a kneading trough, in which the fowl parts are mixed mechanically, or by manual labour, with the liquid above mentioned. From this trough, and through an opening made therein, the liquid mixture drops into the fermenting tub, deeper than wide, which must be kept tightly closed during the fermenting work. At the lower part of this tub a cock is fitted, which lets the liquid mixture down upon an incline plane, on which the liquid spreads, so as to be equally distributed over the whole surface of the sieve. This sieve, of an oblong rectangular form, is laid just beneath, and its tissue ought to be so close as to prevent the least fragments of bran from passing through; it is actuated by the hand, or rather by a crank. In all cases that part of the sieve which is opposite to the cock must strike upon an unyielding body, for the purpose of shaking the pellicles remaining on the tissue, and driving them down towards an outlet on the lower part of the sieve, and thence into a trough purposely contrived for receiving the waters issuing from the sieve, and discharging them into a tank.

'The next operation consists in diluting those pellicles, or rougher parts, which could not pass through the sieve, sifting them again, and using the white water resulting therefrom to dilute the fowl parts intended for subsequent operations. The sieve or sieves may sometimes happen to be obstructed by some parts of gluten adhering thereto, which I wash off with acidulated water for silk tissues, and with an alkali for metallic ones. This washing method I deem very important, as its non-application may hinder a rather large operation, and therefore I wish to secure it. This apparatus may be liable to some variations, and admit of several sieves superposed, and with different tissues, the broadest, however to be placed uppermost.

'Among the various descriptions and combinations of sieves that may be employed, the annexed figures show one that will give satisfactory results.

'*Fig. 241* is a longitudinal section, and *fig. 242* an end view, of the machine from which the bran is ejected. The apparatus rests upon a cast-iron framing *a*, consisting of two checks, kept suitably apart by tie pieces *b*; a strong cross-bar on the upper part admits a wood cylinder *c*, circled round with iron, and provided with a wooden cock *d*. The cylinder *c* receives through its centre an arbor *f*, provided with four arms *e*, which arbor is supported by two cross-bars *g* and *h*, secured by means of bolts to the uprights *i*. Motion is imparted to the arbor *f* by the crank *j*, by pulleys driven by the endless straps *k*, and by the toothed wheel *l*, gearing into the wheel *m*, which is keyed on the upper end of the arbor *f*. Beneath the cylinder *c*, two sieves *n* and *o* are borne into a frame *p*, suspended on one end to two chains *q*,

and on the other resting on two guides or bearings *r*, beneath which, and on the crank shaft, are cams *s*, by which that end of the frame that carries the sieves is alternately raised and lowered. A strong spring *u* is set to a shaft borne by the framing *a*, whilst a ratchet wheel provided with a clink allows the said spring,

according to the requirements of the work, to give more or less impulse or shaking as the cams *s* are acting upon the frame-sieve carrying the sieve. Beneath the said frame a large hopper *t* is disposed, to receive and lead into a tank the liquid passing through the sieves. The filter sieve is worked as follows:—After withdrawing, by means of bolting hutches, 70 per cent., about, of fine flour, I take out of the remaining 30 per cent. about 20 per cent. of groats, neglecting the remaining 10 per cent., from which, however, I could separate the little flour still adhering thereto, but I deem it more available to sell it off in this state. I submit the 20 per cent. of groats to a suitable vinous fermentation, and have the whole taken into the cylinder *c*, there to be stirred by means of the arbor *f* and the arms *e*; after a suitable stirring, the cock *d* is opened and the liquid is let out, spread on the uppermost sieve *z*, which keeps back the coarsest bran. The liquid drops then into the second sieve or filter *o*, by which the least fragments are retained; the passage of the liquid through the filters is quickened by the quivering motion imparted by the cams *s* to the frame carrying the sieve.

The advantages resulting from such a process are obvious: first, it would appear—and those experiments have been confirmed by the committee of the Académie des Sciences, who had to report upon them—that no less than from 16 to 17 per cent. of white bread of superior quality can be obtained from wheat, which increase is not due to water, as in other methods, but is a true and real one, the Commissioners having ascertained that the bread thus manufactured did not contain more water than that made in the usual way, their comparative examinations in this respect having given the following results:—

Loss by drying in Air.

	Crumb	Crust
Old method	37·8 . . .	12·0 per cent.
New method	37·5 . . .	14·0 „
Difference	00·3 . . .	2·0 „

Another experiment by Peligot:—

Loss by drying in Air at 248° F.

	Crumb and Crust
New method	34·9 per cent.
Old method	34·1 „
Difference	00·8 „

Since the enrolment of his Specification, however, M. Mège Mouriès has made an improvement, which simplifies considerably his original process, according to which the destruction of the cerealin, as we saw, was effected by ordinary yeast; that is to say, by alcoholic fermentation. The last improvement consists in preventing cerealin from becoming a lactic or glucosic ferment, by precipitating it with common salt, and not allowing it time to become a ferment. In effect, in order that cerealin may produce the objectionable effects alluded to, it must first pass into the state of ferment, and, as all nitrogenous substances require a certain time of incubation to become so,¹ if, on the one hand, cerealin be precipitated by means of common salt, the glucosic action is neutralised; whilst, on the other hand, the levains being made with flour containing nocerealin—that is to say, with best white flour—if a short time before baking households or seconds are added thereto, it is clear that time will be wanting for it (the ferment) to become developed or organised, and that, under this treatment, the bread will remain white.

The application of these scientific deductions will be better understood by the following description of the process:—

100 parts of clean wheat are ground and divided as follows:

Best whites for leaven	40.0
White groats, mixed with a few particles of bran	38.0
White groats, mixed with a larger quantity of bran	8.0
Bran (not used)	15.5
Loss	0.5
	102.0

These figures vary, of course, according to the kind of wheat used, according to seasons, and according to the description of mill and the distance of the millstones used for grinding.

'In order to convert these products into bread,' says M. Mège Mouriès, 'a leaven is to be made by mixing the 40 parts of best flour above alluded to, with 20 parts of water, and proceeding with it according to the mode and custom adopted in each locality. This leaven, no matter how prepared, being ready, the 8 parts of groats mixed with the larger quantity of bran above alluded to, are diluted in 45 parts of water in which 0.6 parts of common salt have been previously dissolved, and the whole is passed through a sieve which allows the flour and water to pass through, but retains and separates the particles of bran. The watery liquid so obtained has a white colour, is flocculent, and loaded with cerealin; it no longer possesses the property of liquefying gelatinous starch, and weighs 38 parts (the remainder of the water is retained in the bran, which has swelled up in consequence, and remains on the sieve). The leaven is then diluted with that water, which is loaded with best flour, and is used for converting into dough the 38 parts of white groats above alluded to; the dough is then divided into suitable portions, and after allowing it to stand for one hour, it is finally put in the oven to be baked. As the operations just described take place at a temperature of 25° C. (= 77° F.), the one hour during which the dough is left to itself, is not sufficient for the cerealin to pass into the state of ferment, and the consequence is the production of white bread. Should, however, the temperature be higher than that, or were the dough allowed to be kept for a longer time before baking, the bread produced, instead of being white, would be so much darker, as the contact would have lasted longer. By this process, 100 parts in weight of wheat yield 136 parts of dough, and, finally, 115 parts in weight of bread' instead of 100, which the same quantity of wheat would have yielded in the usual way. This is supposing that the grinding of the wheat has been effected with close set millstones; if ground in the usual manner, the average yield does not exceed 112 parts in weight of bread.

The substances which are now almost exclusively employed for adulterating bread are, *water*, alone or incorporated with rice, or *water* and *alum*: other substances, however, are or have been also occasionally used for the same purpose.

This retention of water into bread is secured by underbaking, by the introduction of rice, of potatoes, and other feculæ, and of alum.

Underbaking is an operation which consists of keeping in the loaf the water which otherwise would escape while baking; it is, therefore, a process for selling water at the price of bread. It is done by introducing the dough into an oven unduly heated, whereby the gases contained in the dough at once expand, and swell it up to the ordinary dimensions, whilst a deep burnt crust is immediately afterwards formed;

¹ Communication of M. Mège Mouriès to the Académie des Sciences, January 1858.

which, inasmuch as it is a bad conductor of heat, prevents the interior of the loaf from being thoroughly baked, and at the same time opposes the free exit of the water contained in the dough, and which the heat of the oven partly converts into steam; while the crust becomes thicker and darker than it otherwise should be, a sensible loss of nutritive elements being sustained, at the same time, in the shape of pyrogenous products, which are dissipated.

The proportion of water retained in bread by underbaking is sometimes so large, that a baker may thus obtain as much as 106 loaves from a sack of flour.

The addition of boiled rice to the dough is also pretty frequently used to increase the yield of loaves; this substance, in fact, absorbs so much water that as many as 116 quartern loaves have thus been obtained from one sack of flour.

From a great number of experiments made with a view to determine the normal quantity of water contained in the crumb of genuine bread, it is ascertained that it amounts, in new bread, from 38 at least to at most 47 per cent.

The quantity of water contained in bread is easily determined, by cutting a slice of it, weighing 500 grains, for example, placing it in a small oven heated, by a gas-burner or a lamp, to a temperature of about 220° F., until it no longer loses weight, the difference between the first and last weighing (that is to say, the loss) indicating, of course, the amount of water.

Alum, however, is the principal adulterating substance used by bakers, *almost without exception, in this metropolis*; as was proved by Dr. Normanby in his evidence before the Select Committee of the House of Commons, appointed in 1855, under the presidency of Mr. W. Scholefield, to inquire into the adulteration of food, drinks, and drugs, which assertion was corroborated and established beyond doubt by the other chemists who were examined also on the subject.

The introduction of alum into bread not only enables the baker to give to bread made of flour of inferior quality the whiteness of the best bread, but to force and keep in it a larger quantity of water than could otherwise be done. We shall see presently that this fact has been denied, and on what grounds.

The quantity of alum used varies exceedingly; but no appreciable effect is produced when the proportion of alum introduced is less than 1 in 900 or 1,000, which is at the rate of 27 or 28 grains in a quartern loaf. The use of alum, however, has become so universal, and the Act of Parliament which regulates the matter has so long been considered as a dead letter, from the trouble, and chance of pecuniary loss which it entails on the prosecutor should his accusation prove unsuccessful, that but few, and until quite lately none, of the public officers would undertake the discharge of a duty most disagreeable in itself and at the same time full of risk.

When alum is used in making bread, one of the two following things may happen: either the alum will be decomposed, as just said, in which case the alumina will, of necessity, be set free as soon as digestion will have decomposed the organic matter with which it was combined; and thus it is presumable that either alum will be re-formed in the stomach, or that, according to Liebig, the phosphoric acid of the phosphates of the bread, uniting with the alumina of the alum, will form an insoluble phosphate of alumina, and the beneficial action of the phosphates will, consequently, be lost to the system; and since phosphoric acid forms with alumina a compound hardly decomposable by alkalis or acids, this may, perhaps, explain the indigestibility of the London bakers' bread, which strikes all foreigners. — *Letters on Chemistry.*

The last defence set up in behalf of alumed bread to be noticed is, that, with certain descriptions of flour, bread cannot be made without it; that by means of alum a large quantity of flour is made available for human food, which, without it, must be withdrawn, and turned to some other less important uses, to the great detriment of the population, and particularly of the poor, who would be the first to suffer from the increase of the price of bread which such a withdrawal must fatally produce.

The process usually adopted for the detection of alum is that known as Kuhlmann's process, which consists in incinerating about 3,000 grains of bread, porphyrising the ashes so obtained, treating them by nitric acid, evaporating the mixture to dryness, and diluting the residue with about 300 grains of water, with the help of a gentle heat; without filtering, a solution of caustic potash is then added, the whole is boiled a little, filtered, the filtrate is tested with a solution of sal-ammoniac, and boiled for a few minutes. If a precipitate is formed it is *not alumina*, as hitherto thought and stated by Kuhlmann and all other chemists, but *phosphate of alumina*,—a circumstance of great importance, not in testing for the presence of alumina, but for the determination of its amount, as will be shown further on, when entering into the details of the modifications which it is necessary to make to Kuhlmann's process.

In a paper read in April 1858, at the Society of Arts, Dr. Odling stated that out of

46 examinations of ashes furnished him by Dr. Gilbert, and treating them by the above process, he (Dr. Odling) obtained, to use his own words, 'in 21 instances, the celebrated white precipitate said to be indicative of alumina and alum, so that had these samples been in a manufactured instead of the natural state—had the wheat, for example, been made into flour—I should have been justified, according to the authority quoted, in pronouncing it to be adulterated with alum. But a subsequent examination of the precipitates I obtained, showed that in reality they were not due to alumina at all. M. Kuhlmann's process, as above described, is possessed of rare merits: it will never fail in detecting alumina when present, and will often succeed in detecting it when absent also. The idea of weighing this *olla podrida* of a precipitate, and from its weight calculating the amount of alum present, as is gravely recommended by great anti-adulteration adepts, is too preposterous to require a moment's refutation.'

In order, however, to render the process for the detection of alum in bread free from objections, the following method is recommended. It requires only ordinary care, and it is perfectly accurate:—

Cut the loaf in half; take a thick slice of crumb from the middle, carefully trimming the edges so as to remove the crust, or hardened outside, and weigh off 1,500 or 3,000 grains of it; crumble it to powder, or cut it into slices, and expose them, on a sheet of platinum foil turned up at the edges, to a low red heat, until fumes are no longer evolved, and the whole is reduced to charcoal, which will require from twenty to forty minutes, according to the quantity; transfer the charcoal to a mortar, and reduce it to fine powder; put now this finely-pulverised charcoal back again on the platinum foil tray, and leave it exposed thereon to a dark cherry-red heat until reduced to grey ashes, for which purpose gas-furnace lamps will be found very convenient. Only a cherry-red heat should be applied, because at a higher temperature the ashes might fuse, and the incineration be thus retarded. Remove the source of heat, drench the grey ashes with a concentrated solution of nitrate of ammonia, and carefully reapply the heat; the last portions of charcoal will thereby be burnt, and the ashes will then have a white or drab colour. Drench them on the tray with moderately strong and pure hydrochloric acid, and after one or two minutes' standing, wash the contents of the platinum foil tray, with distilled water, into a porcelain dish; evaporate to perfect dryness, in order to render the silica insoluble; drench the perfectly dry residue with strong and pure muriatic acid, and, after standing for five or six minutes, dilute the whole with water, and boil; while boiling, add carefully as much carbonate of soda as is necessary nearly, but not quite, to saturate the acid, so that the liquor may still be acid; add as much pure alcohol-potash as is necessary to render it strongly alkaline; boil the whole for about three or four minutes, and filter. If now, after slightly supersaturating the strongly alkaline filtrate with pure muriatic acid, the further addition of a solution of carbonate of ammonia produces, either at once or after heating it for a few minutes, a light, white, flocculent precipitate, it is a sign of the presence of alumina, the identity of which is confirmed by collecting it on a filter, putting a small portion of it on a platinum hook, or on charcoal, heating it thereon, moistening the little mass with nitrate of cobalt, and again strongly heating it before the blowpipe; when if, *without fusing*, it assumes a beautiful blue colour, the presence of alumina is corroborated. If the operator possesses a silver capsule, he will do well to use it instead of a porcelain one for boiling the mass with pure caustic alcohol-potash, in order to avoid all chance of any silica (from the glaze) becoming dissolved by the potash, and afterwards simulating the presence of alumina, though, if the boiling be not protracted, a porcelain capsule is quite available. It is, however, absolutely necessary that he should use *potasse à l'alcohol*, for ordinary caustic potash *always* contains some, and occasionally considerable quantities of alumina, and is totally unsuited for such an investigation. Even *potasse à l'alcohol* retains traces of silica, either alone or combined with alumina; so that for this, and other reasons which will be explained presently, an extravagant quantity of it should not be used.

Lastly, carbonate of ammonia is preferable to caustic ammonia for precipitating the alumina, since that earth is far from being insoluble in caustic ammonia.

The liquor from which the alumina has been separated should now be acidified with hydrochloric acid, and tested with chloride of barium, which should then yield a copious precipitate of sulphate of barytes.

The only precipitate which can, under the circumstances of the experiment, simulate alumina, is the phosphate of that earth, which behaves with all reagents as pure alumina. Such a precipitate, therefore, if taken account of as pure alumina, would altogether vitiate a quantitative analysis if the amount of alum were calculated from it; but the proof that a certain quantity of alum had been used in the bread from which it had been obtained would remain unshaken; since alumina, whether in that state

or in that of its phosphate, could not have been found except a salt of alumina—to wit, alum—had been used by the baker. When, therefore, the exact amount of alumina has to be determined, the precipitate in question should be submitted to further treatment in order to separate the alumina; and this can be done easily and rapidly by dissolving the precipitate in nitric acid, adding a little metallic tin to the liquor, and boiling. The tin becomes rapidly oxidised, and remains in the state of an insoluble white powder, which is a mixture of peroxide of tin and of phosphate of tin, at the expense of all the phosphoric acid of any earthy phosphate which may have been present. The whole mass is evaporated to dryness, and the dry residue is then treated by water and filtered, in order to separate the insoluble white powder, and the filtrate which contains the alumina should now be supersaturated with carbonate of ammonia. If a precipitate is formed, it is pure alumina. The white insoluble powder, after washing, may be dissolved in hydrochloric acid, and after diluting the solution with water, the tin may be precipitated therefrom by passing through it a stream of sulphuretted hydrogen to supersaturation, leaving at rest for ten or twelve hours, filtering, boiling the filtrate until all odour of sulphuretted hydrogen has disappeared; an excess of nitrate of silver is then added, and the liquor filtered, to separate the chloride of silver produced, and *exactly* neutralising the filtrate with ammonia; and if a lemon-yellow precipitate is produced, immediately soluble in the slightest excess of either ammonia or nitric acid, it is basic phosphate of silver (3AgO), PhO^3 , the precipitate obtained in the first instance being thus proved to be phosphate of alumina. The pure alumina obtained may now be collected on a filter, washed with boiling water, thoroughly dried, and then ignited and weighed. One grain of alumina represents 9·027 grains of crystallised alum.

In testing bread for alum, it should be borne in mind, however, that the water used for making the dough generally contains a certain quantity of sulphates, and that a precipitate of sulphate of barytes will therefore be very frequently obtained, though much less considerable than when alum has been used. Some waters called 'selenitous' contain so much sulphate of lime in solution, that if they were used in making the dough, chloride of barium would afford, of course, a considerable precipitate. For these reasons, therefore, the separation and identification of alumina are the only reliable proofs; because, as that earth does not exist normally in any shape in wheat or common salt otherwise than in traces, the proof that alum has been used becomes irresistible when we find, on the one hand, alumina, and, on the other, a more considerable amount of sulphate of barytes than, except under the most extraordinary circumstances, genuine bread would yield.

Sulphate of copper, like alum, possesses the property of hardening gluten, and thus, with a flour of inferior quality, bread can be made of good appearance, as if a superior flour had been used.

The use of sulphate of copper in bread is said to have originated about 25 or 30 years ago with the bakers of Belgium.

M. Kuhlmann, Professor of Chemistry at Lille, having been called upon several times by the courts of justice to examine, by chemical processes, bread suspected of containing substances injurious to health, collected some interesting facts upon the subject, which were published under the direction of the central council of salubrity of the department du Nord.

For some time public attention has been drawn to an odious fraud committed by a great many bakers in the north of France and in Belgium,—the introduction of a certain quantity of sulphate of copper into their bread. When the flour was made from bad grain, this adulteration was very generally practised, as was proved by many convictions and confessions of the guilty persons. When the dough does not rise well in the fermentation (*le pain pousse plat*), this inconvenience was found to be obviated by the addition of blue vitriol, which was supposed also to cause the flour to retain more water. The quantity of blue vitriol added is extremely small, and it is never done in presence of strangers, because it is reckoned a valuable secret. It occasions no economy of yeast, but rather the reverse. In a litre (about a quart) of water, an ounce of sulphate of copper is dissolved; and of this solution a wine-glassful is mixed with the water necessary for 50 quartern or 4-pound loaves.

Lime water has been recommended by Liebig as a means of improving the bread made from inferior flour, or of flour slightly damaged by keeping, by warehousing, or during transport in ships; and this method, at the meeting of the British Association at Glasgow, in 1855, was reported as having been tried to a somewhat considerable extent by the bakers of that town, and with success; the bread kneaded with lime-water, instead of pure water, being of good appearance, good taste, good texture, and free from the sour taste which invariably belongs to alumed or even to genuine bread;—admitting all this to be true, still we should deprecate the use of lime-water in bread, because it cannot be done with impunity; however small the dose of additional matter

may be considered when taken separately, it is always large when considered as portion of an article of food like bread, consumed day after day, and at each meal, without interruption. To allow articles of food to be tampered with, under any circumstances, is a dangerous practice, even if it were proved that it can be done without risk, which, however, is not the case; and Liebig himself has said that chemists should never propose the use of chemical products for culinary preparations.

The quantity of ashes left after the incineration of genuine bread, varies from 1·5 at least to at most 3 per cent.; and if the latter quantity of ashes be exceeded, the excess may safely be pronounced to be due to an artificial introduction of some saline or earthy matter.

As to the addition to bread of potatoes, beans, rice, turnips, maize, or Indian corn, which has occasionally been practised to a considerable extent, especially in years of scarcity, it is evident that they are actually permitted under the Act of Parliament, Will. IV. cap. 27. sect. 11.

In his 'New Letters on Chemistry,' Liebig makes the following remarks on the subject:—

'The proposals which have hitherto been made to use substitutes for flour, and thus diminish the price of bread in times of scarcity, prove how much the rational principles of hygiene are disregarded, and how unknown the laws of nutrition are still. It is with food as with fuel. If we compare the price of the various kinds of coals, of wood, of turf, we shall find that the number of pence paid for a certain volume or weight of these materials is about proportionate to the number of degrees of heat which they evolve in burning. . . . The mean price of food in a large country is ordinarily the criterion of its nutritive value. . . . Considered as a nutritive agent, rye is quite as dear as wheat; such is the case also with rice and potatoes; in fact, no other flour can replace wheat in this respect. In times of scarcity, however, these ratios undergo modification, and potatoes and rice acquire then a higher value, because, in addition to their natural value as respiratory food, another value is superadded, which in times of abundance is not taken into account.

'The addition to wheat flour of potato starch, of dextrine, of the pulp of turnips, gives a mixture, the nutritive value of which is equal to that of potatoes, or perhaps less; and it is evident that one cannot consider as an improvement this transformation of wheat flour into a food having only the same value as rice or potatoes.'

The detection of potato starch, of beans, peas, Indian corn, rice, and other feculæ, which is so easily effected by means of the microscope in flour, is exceedingly difficult, if not impossible, in bread. Bread which has been made with flour mixed with Indian corn is harsher to the touch, and has frequently a slight yellowish colour, and when moistened with solution of potash of ordinary strength, a yellow or greenish-yellow tinge is developed.—The late Dr. A. N. See TOAST, LEAVEN.

Wo exported in 1871 the following quantities of BREAD and BISCUITS:—

BREAD-FRUIT TREE. (*Artocarpaceæ*, *Æpros*, *bread*; *χαρπύς*, *fruit*.) The *A. incisa*, the true bread-fruit tree, is a native of the South Sea Islands, inhabiting such places as are hot and damp. The tree is about twelve inches diameter, and grows to the height of forty feet. The fruit is about the size of a melon, and the seeds are large nut-like bodies. The fleshy receptacle is the valuable part of the fruit. It is very white, and of the consistence of new bread. When washed it becomes excellent food, tasting like wheaten bread, only a little sweeter.

A cloth is made of the fibres of the inner bark; the wood is used for building houses and boats. The leaves are used as towels and table-cloths, and to wrap provisions in. The male catkins serve as tinder, and the juice is employed as birdlime, and to mend the cracks in the water vessels of the natives. See *COW TREE*, *JACK TREE*, *UPAS TREE*.

BRECCIA. An Italian term used for a rock composed of angular fragments of stone, cemented together by an earthy or a mineral substance. It corresponds to the 'brockrans' of the Cumberland miners.

BRECCIATED AGATE. An agate composed of fragments of jasper, blood-stone, &c., cemented by chalcedony.

BREEZES. (*Braise*, Fr.) The dust of coke or charcoal. The coke burner applies this term to the small residual coke obtained in coke burning. The sifted ashes removed from houses is called *breeze*, and sold under that name to brickmakers and others.

BREEZE OVEN. An oven for the manufacture of small coke. Mr. Joseph Davis, of Birmingham, has patented (*Specification*, A.D. 1856, No. 1,425) a breeze oven, many of which are in use in South Staffordshire. The 'thick coal' of South Staffordshire is employed in this oven. The slack is screened, and the finer part is burnt on the grate adjoining the boiler, the remainder is converted into 'breezes.' Mr. Davis's specification will most completely illustrate and explain the character of this oven:—

This invention consists of a coke oven, constructed, arranged, and used as hereinafter described, and illustrated in the accompanying drawings, for the manufacture of the small coke called *breezes*, for economising of heat, and for the suppression or partial suppression of smoke.

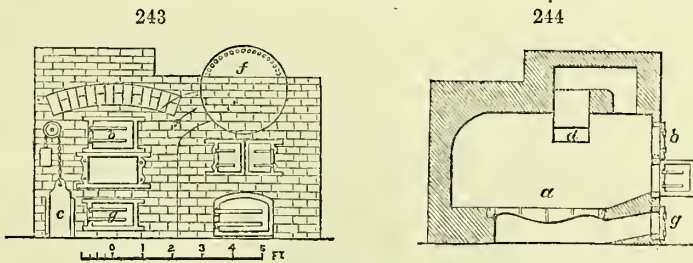

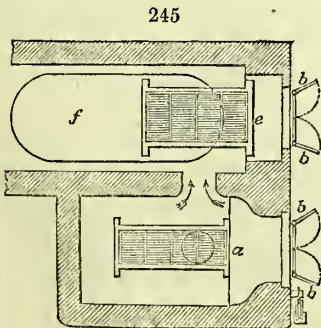

Fig. 243 of the accompanying drawing represents in elevation, fig. 244 in vertical section, and fig. 245 in plan, a coke oven, combined with the furnace of a steam-boiler, constructed according to this invention.

The said coke oven consists of a chamber or furnace, *a*, provided with doors, *b, b*, by which said doors the coal to be coked is introduced and the admission of air regulated. The draught may be further regulated by means of the damper, *c*. The oven, *a*, is also provided with flues, *d*, in which flues dampers may be situated. The heated air and flame from the oven, *a*, may be conducted therefrom either into a stack or chimney, or into the furnace or fireplace, *e*, of a steam-boiler, *f*, or the said heated air and flame may be conducted elsewhere, where they can be applied to heating or other useful purpose. When the flame and heated air from the coke oven, *a*, are conducted into the furnace, *e*, of a steam-boiler,

f, they may be delivered at or near the bridge of the said furnace, when they will effect the suppression or partial suppression of the smoke from the said furnace. The heat from the coke oven, *a*, also increases the production of steam in the boiler, *f*,

When the coal in the oven, *a*, has been converted into the small coke, called breezes, the combustion is stopped by the closing of the doors, *b b*, damper, *c*, and the door, *g*, of the ash-pit; and the breezes are cooled by the introduction of a jet of water into the said oven, the said water being directed upon the breezes; or the said breezes may be withdrawn from the oven in a heated state, and afterwards cooled by water of otherwise. Although I prefer to place the coke oven on the side of the boiler, as represented, yet it may be placed under the boiler, or in any other convenient situation.

Although I have only represented in the accompanying drawing the combination of a coke oven for manufacturing breezes with a steam-boiler, yet the said oven may be combined with any other furnace for the purpose of increasing its heat and suppressing or partially suppressing its smoke; but I believe the nature of my said invention will be sufficiently understood by the description herein given, and illustrated in the accompanying drawing.

The size and form of the ovens may be varied to suit the quantity of breezes to be manufactured, and the particular purposes to which the flame and heated air from the said ovens are to be applied.

BREMEN BLUE and GREEN. Pigments containing a basic carbonate of copper with alumina and carbonate of lime. According to one method, blue vitriol (sulphate of copper) is dissolved in 10 parts of water, and a little aquafortis added; the liquid is allowed to stand for a week, and is then filtered; after addition of lime-water, it is precipitated by a solution of pearlash. By Gentele's method, these pigments are prepared from common salt and blue vitriol. A blue or a green colour is produced, according as the pigment is mixed with water or with linseed oil.

BREWING. (*Brasser*, Fr.; *Brauen*, Ger.) The art of making beer, or an alcoholic liquor, from a fermented infusion of some saccharine and amylaceous substance with water.

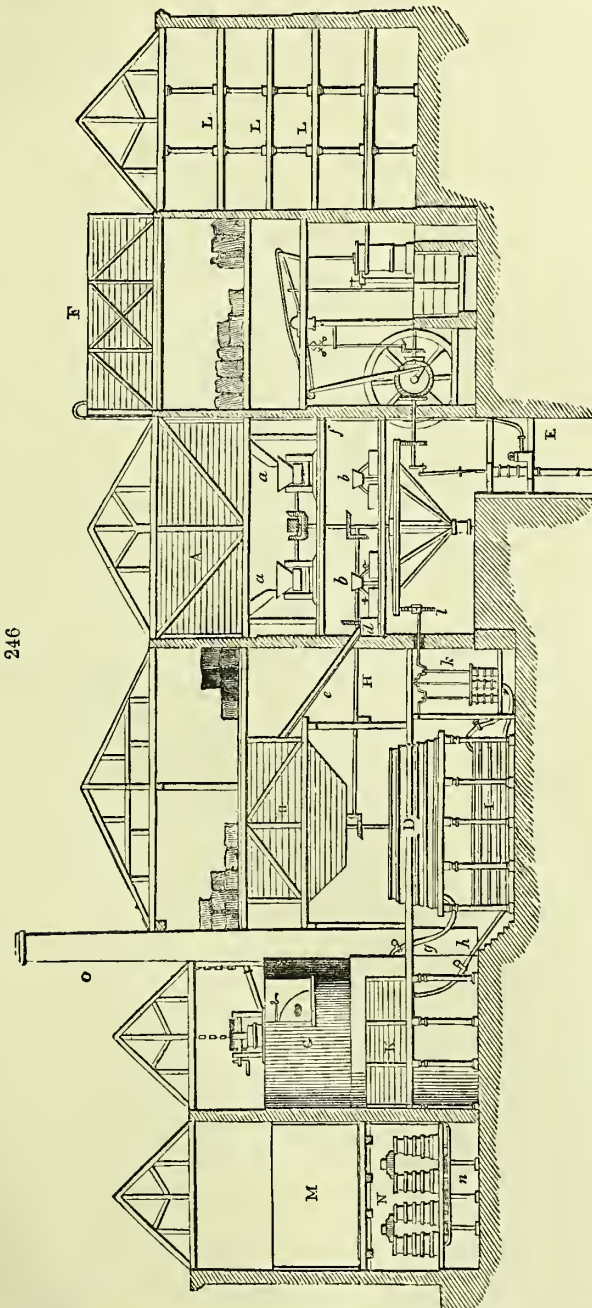

Figs. 246 and 247 represent the arrangement of the utensils and machinery in a porter brewery on the largest scale, in which it must be observed that the elevation *fig. 247*, is in a great degree imaginary as to the plane upon which it is taken, but the different vessels are arranged so as to explain their uses most readily, and at the same time to preserve, as nearly as possible, the relative position which is usually assigned to each in works of this nature.

The malt for the supply of the brewery is stored in vast granaries or malt-lofts, usually situated in the upper part of the buildings. Of these, we have been able to represent only one, at *A*, *fig. 246*: the others, which are supposed to be on each side of it, cannot be seen in this view. Immediately beneath the granary *A*, on the ground-floor, is the mill; in the upper storey above it, are two pairs of rollers (*figs. 246, 248, and 249*), under *a a*, for bruising or crushing the grains of the malt. In the floor beneath the rollers are the mill-stones *b b*, where the malt is sometimes ground, instead of being merely bruised by passing between the rollers, under *a a*.

The malt, when prepared, is conveyed by a trough into a chest *d*, to the left of *b*, from which it can be elevated by the action of a spiral screw, *fig. 250*, enclosed in the sloping tube *e*, into the large chest or bin *B*, for holding ground malt, situated immediately over the mash-tun *D*. The mash-tun is a large circular tub with a double bottom; the uppermost of which is called a false bottom, and is pierced with many holes. There is a space of about 2 or 3 inches between the two, into which the stop-cocks enter, for letting in the water and drawing off the wort. The holes of the false bottom, if of wood, should be burned, and not bored, to prevent the chance of their filling up by the swelling of the wood, which would obstruct the drainage: the holes should be conical, and largest below, being about $\frac{2}{3}$ ths of an inch there, and $\frac{1}{4}$ th at the upper surface. The perforated bottom must be fitted truly to the sides of the mash-tun, so that no grains may pass through. The mashed liquor is let off into a large back, from which it is pumped into the wort-coppers. The mash-tun is provided with a peculiar rotatory apparatus for agitating the crushed grains and water together, which we shall presently describe. The size of the wort-copper is proportional to the amount of the brewing, and it must, in general, be at least so large as to operate upon the whole quantity of wort made from one mashing; that is, for every quarter of malt mashed, the copper should contain 140 gallons. The mash-tun ought to be at least a third larger, and of a conical form, somewhat wider below than above. The malt is reserved in this bin till wanted, and is then let down into the mashing-tun, where the extract is obtained by hot water supplied from the copper *C*, seen to the left of *B*.

The water for the service of the brewery is obtained from the well *E*, seen beneath the mill to the right, by a lifting pump worked by the steam-engine; and the forcing-pipe *f*, of this pump conveys the water up to the large reservoir or water-back *F*, placed at the top of the engine-house. From this cistern, iron pipes are laid to the copper *C* (on the left-hand side of the figure), as also to every part of the establishment where

cold water can be wanted for cleaning and washing the vessels. The copper *g* can be filled with cold water by merely turning a cock; and the water when boiled therein,

is conveyed by the pipe *g* into the bottom of the mash-tun *D*. The water is introduced beneath a false bottom, upon which the malt lies; and, rising up through the

holes in the false bottom, it extracts the saccharine matter from the malt; a greater or less time being allowed for the infusion, according to circumstances. The instant the water is drawn off from the copper, fresh water must be let into it, in order to be ready for boiling the second mashing, because the copper must not be left empty for a moment, otherwise the intense heat of the fire would destroy its bottom. For the convenience of thus letting down at once as much liquor as will fill the lower part of the copper, a pan or second boiler is placed over the top of the copper, as seen in *fig. 252*; and the steam rising from the copper communicates a considerable degree of heat to the contents of the pan, without any expense of fuel. This will be more minutely explained hereafter.

During the process of mashing, the malt is agitated in the mash-tun, so as to expose every part to the action of the water. This is done by a mechanism contained within the mash-tun, which is put in motion by a horizontal shaft above it, *n*, leading from the mill. The mash machine is shown separately in *fig. 251*. When the operation of mashing is finished, the wort or extract is drained down from the malt into the vessel *i*, called the *underback*, immediately below the mash-tun, of like dimensions, and situated always on a lower level, for which reason it has received this name. Here the wort does not remain longer than is necessary to drain off the whole of it from the tun above. It is then pumped up by the three-barrelled pump *k*, into the pan upon the top of the copper, by a pipe which cannot be seen in this section. The wort remains in the pan until the water for the succeeding mashes is discharged from the copper. But this delay is no loss of time, because the heat of the copper, and the steam arising from it, prepare the wort, which had become cooler, for boiling. The instant the copper is emptied, the first wort is let down from the pan into the copper, and the second wort is pumped up from the under-back into the upper pan. The proper proportion of hops is thrown into the copper through the near hole, and then the door is shut down and screwed fast, to keep in the steam, and cause it to rise up through pipes into the pan. It is thus forced to blow up through the wort in the pan, and communicates so much heat to it, or to water, called *liquor* by the brewers, that either is brought near to the boiling point. The different worts succeed each other through all the different vessels with the greatest regularity, so that there is no loss of time, but every part of the apparatus is constantly employed. When the ebullition has continued a sufficient period to coagulate the grosser part of the extract, and to evaporate part of the water, the contents of the copper are run off through a large cock into the *jack-back* *k*, below *e*, which is a vessel of sufficient dimensions to contain it, and provided with a bottom of cast-iron plates, perforated with small holes, through which the wort drains and leaves the hops. The hot wort is drawn off from the jack-back through the pipe *h* by the three-barrelled pump, which throws it up to the coolers *L L L*; this pump being made with different pipes and cocks of communication, to serve all the purposes of the brewery, except that of raising the cold water from the well. The coolers, *L L L*, are very shallow vessels, built over one another in several stages; and that part of the building in which they are contained is built with lattice-work or shutter flaps, on all sides to admit free currents of air. When the wort is sufficiently cooled to be put to the first fermentation, it is conducted in pipes from all the different coolers to the large fermenting vessel or gyle-tun *m*, which, with another similar vessel behind it, is of sufficient capacity to contain all the beer of one day's brewing.

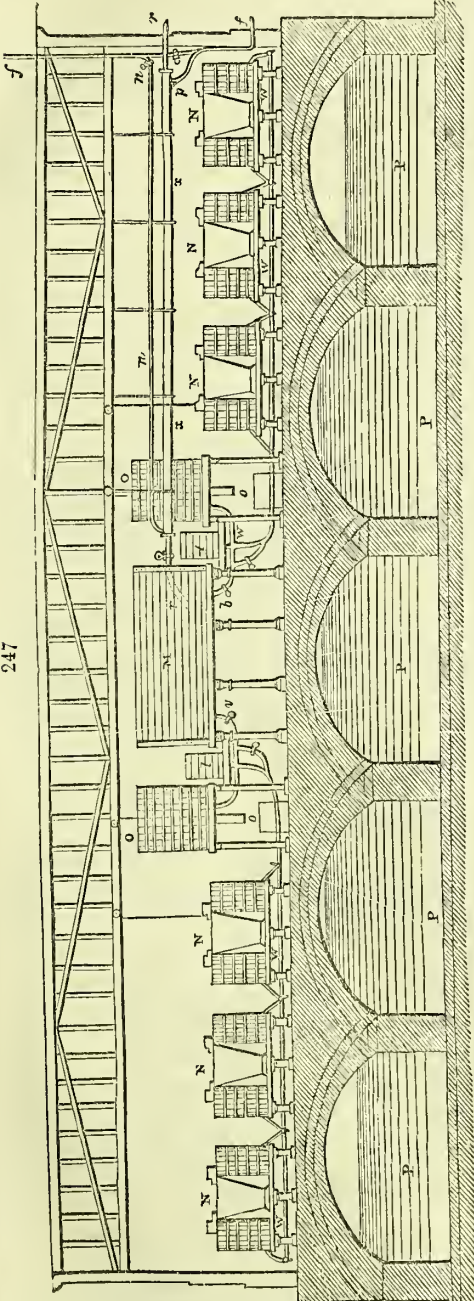

Whenever the first fermentation is concluded, the beer is drawn off from the great fermenting vessel *m*, into the small fermenting casks or cleansing vessels *n*, of which there are a great number in the brewery. They are placed four together, and to each four a common spout is provided to carry off the yeast, and conduct it into the troughs *u*, placed beneath. In these cleansing vessels the beer remains till the fermentation is completed; and it is then put into the store-vats, which are casks or tuns of an immense size, where it is kept till wanted, and is finally drawn off into barrels, and sent away from the brewery. The store-vats are not represented in the figure: they are of a conical shape, and of different dimensions, for fifteen to twenty feet diameter, and usually from fifteen to twenty feet in depth. The steam-engine, which puts all the machine in motion, is exhibited in its place on the right side of the figure. On the axis of the large fly-wheel is a bevelled spur-wheel, which turns another similar wheel upon the end of a horizontal shaft, which extends from the engine-house to the great horse-wheel, set in motion by means of a spur-wheel. The horse-wheel drives all the pinions for the mill-stones *b b*, and also the horizontal axis which works the three-barrelled pump *k*. The rollers *a a* are turned by a bevel wheel upon the upper end of the axis of the horse-wheel, which is prolonged for that purpose; and the horizontal shaft *n*, for the mashing engine, is driven by a pair of bevel wheels. There is likewise a sack-tackle, which is not represented. It is a machine for drawing up the sacks of malt from the court-yard to the highest part of the building, whence

the sacks are wheeled on a truck to the malt-loft A, and the contents of the sack are discharged.

The horse-wheel is intended to be driven by horses occasionally, if the steam-engine should fail; but these engines are now brought to such perfection that it is very seldom any resource of this kind is needed.

Fig. 247 is a representation of the fermenting-house at the brewery of Messrs. Whitbread and Company, Chiswell Street, London, which is one of the most complete in its arrangement in the world: it was erected after the plan of Mr. Richardson, who conducts the brewing at these works. The whole of fig. 247 is to be considered as devoted to the same object as the large vessel m and the casks n, fig. 246. In fig. 247, r r is the pipe which leads from the different coolers to convey the wort to the great fermenting vessels or squares m, of which there are two, one behind the other; ff represent a part of the great pipe which conveys all the water from the well E, fig. 246, up to the water cistern F. This pipe is conducted purposely up the wall of the fermenting-house, fig. 247, and has a cock in it, near r, to stop the passage. Just beneath this passage a branch-pipe p proceeds, and enters a large pipe x x, which has the former pipe r within-side of it. From the end of the pipe x, nearest to the squares m, another branch n n proceeds, and returns to the original pipe f, with a cock to regulate it. The object of this arrangement is to make all, or any part, of the cold water flow through the pipe x x, which surrounds the pipe r, formed only of thin copper, and thus cool the wort passing through the pipe r, until it is found by the thermometer to have the exact temperature which is desirable before it is put to ferment in the great square m. By means of the cocks at n and p, the quantity of cold water passing over the surface of the pipe r can be regulated at pleasure, whereby the heat of the wort, when it enters into the square, may be adjusted within half a degree.

When the first fermentation in the squares m m is finished, the beer is drawn off from them by pipes marked z, and conducted by its branches w w, to the different rows of fermenting-tuns, marked n n, which occupy the greater

the beer is drawn off from them by pipes marked z, and conducted by its branches w w, to the different rows of fermenting-tuns, marked n n, which occupy the greater

part of the building. In the hollow between every two rows are placed large troughs, to contain the yeast which they throw off. The figure shows that the small tuns are all placed on a lower level than the bottom of the great vessels *m*, so that the beer will flow into them, and, by hydrostatic equilibrium, will fill them to the same level. When they are filled, the communication-cock is shut; but, as the working off the yeast diminishes the quantity of beer in each vessel, it is necessary to replenish them from time to time. For this purpose, the two large vats *o o* are filled from the great squares *m m*, before any beer is drawn off into the small casks *x*, and this quantity of beer is reserved at the higher level for filling up. The two vessels *o o* are, in reality, situated between the two squares *m m*; but I have been obliged to place them thus in the section, in order that they may be seen. Near each filling-up tun *o* is a small cistern *t*, communicating with the tun *o* by a pipe, which is closed by a float-valve. The small cisterns *t* are always in communication with the pipes which lead to the small fermenting vessels *n*; and therefore the surface of the beer in all the tuns, and in the cisterns, will always be at the same level; and as this level subsides by the working off of the yeast from the tuns, the float sinks and opens the valve, so as to admit a sufficiency of beer from the filling-up tuns *o*, to restore the surfaces of the beer in all the tuns, and also in the cistern *t*, to the original level. In order to carry off the yeast which is produced by the fermentation of the beer in the tuns *o o*, a conical iron dish or funnel is made to float upon the surface of the beer which they contain; and from the centre of this funnel a pipe, *o*, descends, and passes through the bottom of the tun, being packed with a collar of leather, so as to be water-tight; at the same time that it is at liberty to slide down, as the surface of the beer descends in the tun. The yeast flows over the edge of this funnel-shaped dish, and is conveyed down the pipe into a trough beneath.

Beneath the fermenting-house are large arched vaults, *p*, built with stone, and lined with stucco. Into these the beer is let down in casks when sufficiently fermented, and is kept in store till wanted. These vaults are used at Mr. Whitbread's brewery, instead of the great store-vats of which we have before spoken, and are in some respects preferable, because they preserve a great equality of temperature, being beneath the surface of the earth.

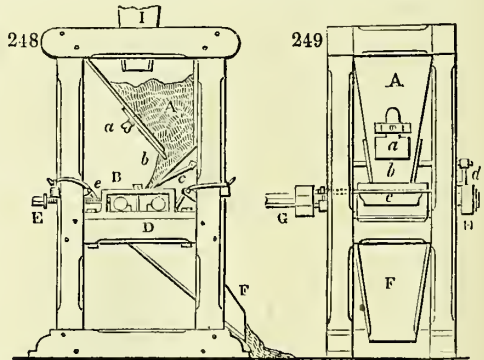

The kiln-dried malt is sometimes ground between stones in a common corn-mill, like oatmeal; but it is more generally crushed between iron rollers, at least for the purpose of the London brewers.

The Crushing Mill.—The cylinder malt-mill is constructed as shown in *figs. 248, 249*. *r* is the sloping-trough, by which the malt is let down from its bin or floor to the hopper *A* of the mill, whence it is progressively shaken in

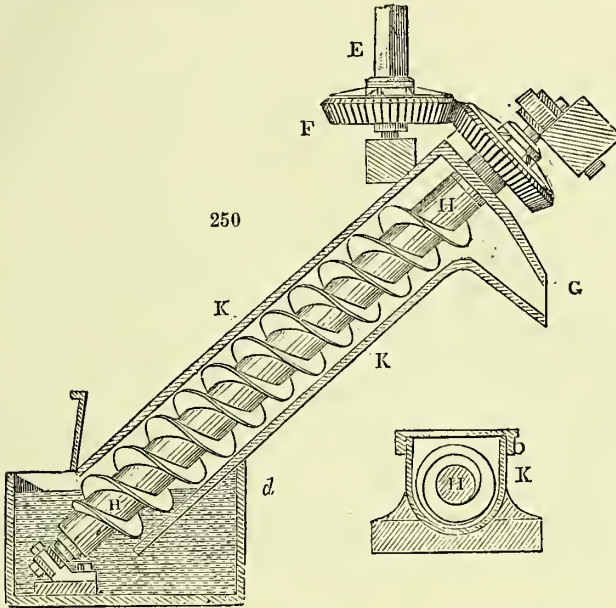

between the rollers *B D*. The rollers are of iron, truly cylindrical, and their ends rest in bearers of hard brass, fitted into the side frames of iron. A screw *e* goes through the upright, and serves to force the bearer of the one roller towards that of the other, so as to bring them closer together when the crushing effect is to be increased. *g* is the square end of the axis, by which one of the rollers may be turned either by the hand or by power; the other derives its rotatory motion from a pair of equal-toothed wheels *h*, which are fitted to the other end of the axes of the rollers. *d* is a catch which works into the teeth of a ratchet-wheel on the end of one of the rollers (not shown in this view). The lever *c* strikes the trough *b* at the bottom of the hopper, and gives it the shaking motion for discharging the malt between the rollers, from the side sluice *a*. *e e*, *fig. 248*, are scraper-plates of sheet iron, the edges of which press by a weight against the surfaces of the rollers, and keep them clean.

Instead of the cylinders, some employ a crushing mill of a conical-grooved form, like a coffee-mill upon a large scale.

Fig. 250 is the screw by which the ground or bruised malt is raised up, or conveyed from one part of the brewery to another. *x* is an inclined box or trough, in the centre of which the axis of the screw *h* is placed; the spiral iron plate or worm, which is fixed projecting from the axis, and which forms the screw, is made very nearly to

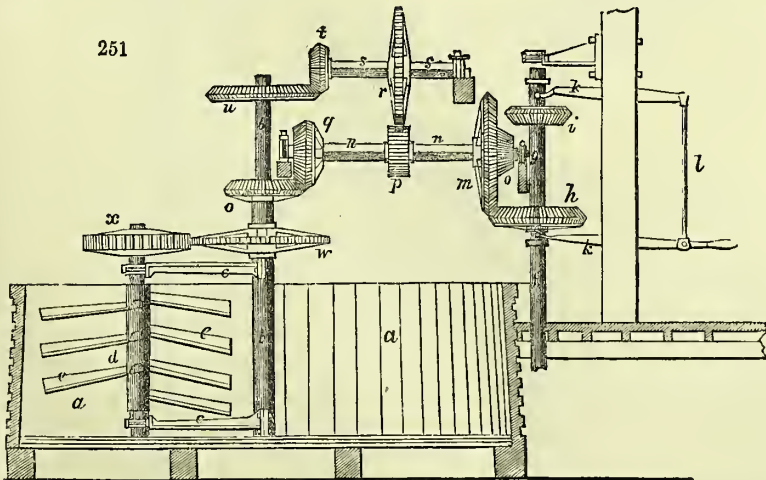

fill the inside of the box. By this means, when the screw is turned round by the wheels *E F*, or by any other means, it raises up the malt from the box *d*, and delivers it at the spout *G*.

This screw is equally applicable for conveying the malt horizontally in the trough *K*, as slantingly; and similar machines are employed in various parts of breweries for conveying the malt wherever the situation of the works require.

Fig. 251 is the mashing-machine. *a a* is the tun, made of wood staves hooped together. In the centre of it rises a perpendicular shaft *b*, which is turned slowly round

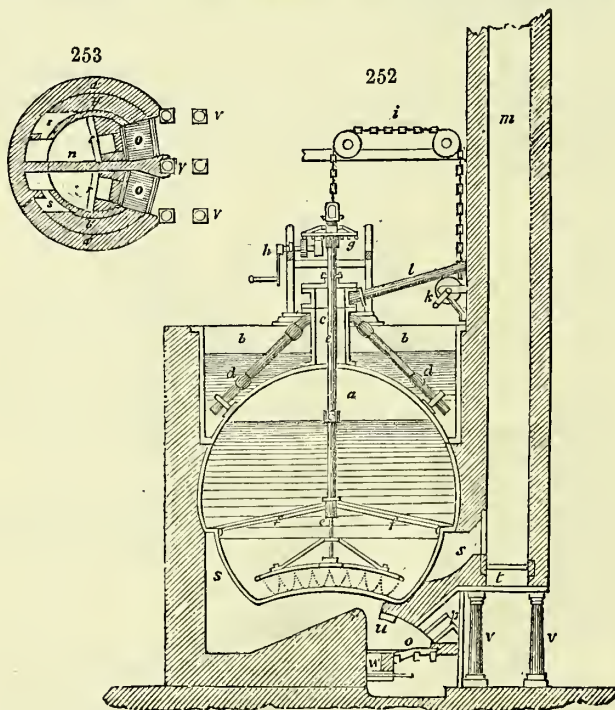

by means of the bevelled wheels *t u* at the top. *c c* are two arms projecting from that axis, and supporting the short vertical axis *d* of the spur-wheel *x*, which is turned by the spur-wheel *w*; so that, when the central axis *b* is made to revolve, it will carry the thick short axle *d* round the tun in a circle. That axle *d* is furnished with a number of arms, *e e*, which have blades placed obliquely to the plane of their

motion. When the axis is turned round, these arms agitate the malt in the tun, and give it a constant tendency to rise upwards from the bottom.

The motion of the axle *d* is produced by a wheel, *x*, on the upper end of it, which is turned by a wheel, *w*, fastened on the middle of the tube *b*, which turns freely round upon its central axis. Upon a higher point of the same tube *b* is a bevel wheel *o*, receiving motion from a bevel wheel *g*, fixed upon the end of the horizontal axis *n n*, which gives motion to the whole machine. This same axis has a pinion *p* upon it, which gives motion to the wheel *r*, fixed near the middle of a horizontal axle, which, at its left-hand end, has a bevel pinion *t*, working the wheel *u*, before mentioned. By these means, the rotation of the central axis *b* will be very slow compared with the motion of the axle *d*; for the latter will make seventeen or eighteen revolutions on its own axis in the same space of time that it will be carried once round the tun by the motion of the shaft *b*. At the beginning of the operation of mashing, the machine is made to turn with a slow motion; but, after having wetted all the malt by one revolution, it is driven quicker. For this purpose, the ascending-shaft *f g*, which gives motion to the machine, has two bevel wheels *h i*, fixed upon a tube *f g*, which is fitted upon a central shaft. These wheels actuate the wheels *m* and *o*, upon the end of the horizontal shaft *n n*; but the distance between the two wheels *h* and *i* is such that they cannot be engaged both at once with the wheels *m* and *o*; but the tube *f g*, to which they are fixed, is capable of sliding up and down on its central axis sufficiently to bring either wheel *h* or *i* into gear with its corresponding wheel *o* or *m*, upon the horizontal shaft; and as the diameters of *n o* and *i m* are of very different proportions, the velocity of the motion of the machine can be varied at pleasure, by using one or other. *k* and *l* are two levers, which are forked at their extremities, and embrace collars at the ends of the tube *f g*. These levers being united by a rod, *l*, the handle *k* gives the means of moving the tube *f g*, and its wheels *h i*, up or down, to throw either the one or the other wheel into gear.

Figs. 252, 253 represent the copper of a London brewery. *Fig. 252* is a vertical section; *fig. 253*, a ground plan of the fire-grate and flue, upon a smaller scale: *a* is the close

copper kettle, having its bottom convex within; *b* is the open pan placed upon its top. From the upper part of the copper, a wide tube, *c*, ascends, to carry off the steam generated during the ebullition of the wort, which is conducted through four downwards-

slanting tubes, *d d* (two only are visible in this section), into the liquor of the pan *b*, in order to warm its contents. A vertical iron shaft or spindle, *e*, passes down through the tube *c*, nearly to the bottom of the copper, and is there mounted with an iron arm, called a *rouser*, which carries round a chain hung in loops, to prevent the hops from adhering to the bottom of the boiler. Three bent stays, *f*, are stretched across the interior, to support the shaft by a collet at their middle junction. The shaft carries at its upper end a bevel wheel *g*, working into a bevel pinion upon the axis *h*, which may be turned either by power or by hand. The *rouser* shaft may be lifted by means of the chain *i*, which, going over two pulleys, has its end passed round the wheel and axle *k*, and is turned by a winch: *l* is a tube for conveying the waste steam into the chimney *m*.

The heat is applied as follows:—For heating the colossal coppers of the London breweries, two separate fires are required, which are separated by a narrow wall of brickwork, *n*, *figs.* 252, 253. The dotted circle *a' a'*, indicates the largest circumference of the copper, and *b' b'* its bottom; *o o* are the grates upon which the coals are thrown, not through folding doors (as of old), but through a short slanting iron hopper, shown at *p*, *fig.* 252, built in the wall, and kept constantly filled with the fuel, in order to exclude the air. Thus the low stratum of coals gets ignited before it reaches the grate. Above the hopper *p*, a narrow channel is provided for the admission of atmospheric air, in such quantity merely as may be requisite to complete the combustion of the smoke of the coals. Behind each grate there is a fire bridge, *r*, which reflects the flame upwards, and causes it to play upon the bottom of the copper. The burnt air then passes round the copper in a semicircular flue, *s s*, from which it flows off into the chimney *m*, on whose under end a sliding damper-plate, *t*, is placed, for tempering the draught. When cold air is admitted at this orifice, the combustion of the fuel is immediately checked. There is, besides, another slide-plate at the entrance of the slanting flue into the vertical chimney, for regulating the play of the flame under and around the copper. If the plate *t* be opened, and the other plate shut, the power of the fire is suspended, as it ought to be, at the time of emptying the copper. Immediately over the grate is a brick arch, *u*, to protect the front edge of the copper from the first impulsion of the flame. The chimney is supported upon iron pillars, *v v*; *w* is a cavity closed with a slide-plate, through which the ashes may be taken out from behind, by means of a long iron hook.

We have thus given the general plan and requisites for a brewery on a large scale. We need scarcely say those arrangements will vary in every establishment, according to the requirements and facilities of the locality, and the various modes of operation. The few simple utensils required may be easily recapitulated:—

1. A mill for crushing the malt.
2. An iron pan for heating water.
3. A mash-tun or open tub fitted with a false bottom, a strainer, or with some other means of allowing the wort to run off freely, keeping back the grains.
4. An iron or copper pan for boiling the wort.
5. A shallow vessel or cooler, over which is placed the hop-jack or sieve for straining out the spent-hops.
6. A gyle tun or open tub for commencement of the fermentation.
7. A barrel or cask in which the cleansing is completed.

The first necessity is a plentiful supply of pure water, which it should be the chief aim in all arrangements to render available at the least labour and cost, as on its proper and judicious application greatly depends the regulation of the temperature in the various operations; and the most scrupulous cleanliness in every part is of the utmost importance. The fermenting rooms and store-cellars should be placed below the ground level, for the purpose of attaining a low and equable temperature; and for this purpose also the double stone fermenting square is highly esteemed. It consists of an inner cubical vessel, containing from fifteen to thirty barrels; each side formed by one slab of fine slate. This is placed in an exterior square or shell of inferior stone, leaving a space between the inner and outer squares, which can be filled with hot or cold water at pleasure. The inner or fermenting square has a man-hole, with a raised rim, in the slab forming the top, on which also are raised four other fine slate slabs, which form a cistern for the expansion and overflow of the beer and yeast during the process of the fermentation, and from which the yeast is readily removed at its close.

The process of brewing may be classed under three heads: the mashing, the boiling, and the fermentation.

For the principle which should guide the brewer in the conduct of these operations, we refer to the article BEER, where it will be seen that the ultimate success of the entire series depends greatly on the regulation of the temperature, the duration, and the proper management of the initial process of malting.

The Mashing.—Upon this very important process information, the result of Dr. A.

Schwarzer's researches, is perhaps the most valuable and precise of the present day, and it would be well if every brewer were familiar with them.

In the *Brewers' Journal*, January 15, 1871, this information is fully detailed, but as the number may not easily be obtainable, it is here reinserted:—

'As a general rule, the larger the quantity of diastase and the greater the heat up to a certain point, the more rapid is the transformation of the gummy portion of the starch into sugar.

'At a temperature of about 167° Fahr., and especially at 177° or 178°, however, a diminution takes place in the action of the diastase, which increases with the further increase of the temperature; and if the heat be raised for a certain time to about 190°, the action of the diastase ceases altogether.

'If also an extract of malt be heated to 190° before the starch is added, a diminution in the action occurs, which is the more determined according to the length of time at which the heat has been maintained.

'The quantity of diastase thus rendered inactive may be ascertained by comparing the action of a certain amount of the overheated extract, with that of a like quantity at the temperature of 145°. Observation must be taken of the time which elapses before all reaction ceases to be exhibited by the iodine test; and the same test must be applied to the action of the extract submitted to the lower temperature.

'Two per cent. of an extract of malt, not weakened by heating, effects the transformation more rapidly than four times that percentage kept at the heat of 178° for one hour, or than twenty per cent. of the same extract maintained for the same period at a temperature of 190°. In the last case scarcely one-tenth of the diastase originally developed in the malt remains in the extract.

'With minute quantities of diastase the action proceeds more rapidly at first with a temperature of 190°, but afterward more slowly than at 145°.

'When the iodine test shows no discolouration, the saccharification is practically terminated, and the continuance of the action of the diastase yields an infinitesimal quantity of sugar.

'If, in one hour, and until the iodine shows no discolouration, fifty per cent. of sugar is formed, and if, during the next three hours, only two per cent. is produced, it is certain that the iodine test shows practically the action is finished.

'The cause of this feeble saccharification after the iodine test ceases to act, does not, however, arise from the exhaustion of the energy of the diastase, because if a new amount of starch be added, it will be rapidly transformed.

'At all temperatures from 167° to 32°, even though employing very different proportions of diastase, from fifty to fifty-three per cent. of sugar is invariably produced from the starch in the extract.

'Admitting that the starch is transformed into an equivalent of sugar, and an equivalent of dextrine, analysis shows that the sugar to be obtained from the extract amounts to 52.6 per cent. of the extract.

'The amount of sugar obtained in practice differs so little from this rate that the small difference may fairly be supposed to arise from errors in the quantities and interruptions in the action of the diastase.

'At temperatures exceeding 167° the quantity of sugar produced falls off in proportion.

'At 190°, after the iodine test ceases to act, the amount of sugar formed in the extract may fall off to twenty-seven per cent.; and even if the extract is heated to that temperature before the addition of the starch gum, and the greatest care be taken to prevent cooling during the experiment, very little change indeed will be observed in the percentage.

'If all these facts be taken into account, it seems certain, that the action of the diastase at temperature below 167° is very different from what it is under greater heats.

'The amount of sugar equal to twenty-seven per cent. which is the minimum value at which the iodine test ceases to exhibit any change, agrees exactly with the transformation of starch into an equivalent of sugar and an equivalent of dextrine.

'A fact deserving of notice is, that between the temperatures of 167° and 190° the difference in the amount of sugar formed is more than twenty per cent.

'In maintaining the extract of malt at 190° for a long period, it is so greatly altered that when the heat is afterward lowered, the amount of sugar is not, or scarcely at all, increased; but if, on the contrary, a solution of starch which contains about twenty-seven per cent. of sugar, be heated to 190°, and afterwards submitted to the action of diastase, not heated and enfeebled at a lower temperature, the percentage may be carried to fifty-two per cent.

'During fermentation, the diastase continues to effect the transformation of starch; and it is not improbable that yeast acts in the same manner as the former.'

With these very important facts before us, it is comparatively easy for the brewer to determine his rule or mode of operation in the process of mashing.

As the heats approaching to 167° tend to detract from the energy of the diastase, such must of course as much as possible be avoided, it being known with equal certainty that when malt-wort is allowed to drop its temperature to a heat approaching 140°, it is liable to acetancy, and more readily so, as the temperature recedes below 140°; about 120° being the most favourable to the change.

Therefore it is advisable that the wort should reach the copper before such a temperature is attained; still further it is ascertained that the value of the desired transformation in the malt-wort is best obtained with a temperature of about 151°, also that saccharification is promoted by agitation, and that the stronger the extract is, the less is the danger of acetification.

Therefore, in the first place, the brewer has to obtain a mash of 151° temperature or thereabouts; but he must do it with liquor as far removed below 167° as possible, and when the goods are thoroughly mashed, 151° of heat should be maintained during their clarification; the wort should then be run from the mash-tun into a copper suitably warmed beforehand, and should then be slowly and carefully heated up to boiling, just by the time the subsequent exhaustion of the malt is completed by the 'sparging.'

In practice the following method will be found extremely easy, and safe in operation:—

Some time before commencing the mash, a sufficiency of boiling water is run into the tun to make it as hot as possible, and immediately before commencing the brewing this hot water is let off again into the underback, or the copper; this being done, the mashing liquor having previously been very carefully prepared, is let into the tun under the false bottom, to the quantity of about one and a half barrels to the quarter of malt, where it arrives at about 164° temperature; when a sufficiency has been let in, the grist is then added and thoroughly mashed, the infusion will then be about 150°, the temperature of reserve mashing liquor has been raised, and when the malt is effectually mashed, a further quantity of about half a barrel per quarter is run in at 166°, and thoroughly mixed up with the mash: the object of the additional liquor is to raise the heat of the mash to about 152°, after which settling and clarification are requisite; this usually occupies about two hours.

The tun having been thoroughly heated before the admission of the mash, it does not abstract the heat from the infusion, either during the operation or when it is completed, but materially assists to maintain the heat for a very considerable time; with a well-protected and covered tun it will do it for four hours if required, without allowing the temperature to drop a single degree.

This is of the greatest importance, for the wort leaves the mash-tun at about 151°; and as it is passed from vessel to vessel is immediately preceded by the hot water from the vessel before it; thus, in turn, each vessel is thoroughly warmed, and we need hardly say most thoroughly cleansed, and being prepared in this way enables the operator to get the wort into the copper before it can fall even to 146° or 147°, leaving the mash in the tun at such heat that all danger of acetification is entirely removed.

As the full value of the mash cannot be obtained by one maceration, recourse is now had to 'sparging,' and to do this properly requires a little careful thought and more careful management.

In the operation of mashing every possible care should be taken that the infused malt—called 'goods'—when drained should lay perfectly level, otherwise the sparging liquor, in running off, will form for itself courses through those portions of the mash that offer the least resistance, and as a consequence some parts of the 'goods' will have treatment in excess of what is desirable, while other portions will be kept with an imperfect sparge.

The liquor for sparging should be of such a heat that it will, on penetrating the 'goods,' raise their temperature gradually from, say 148° or so, to 167° or 168° at the close, this will generally be found sufficient to dissolve out of them all the tractable portions of dextrine, &c. that are of any real value.

It is advisable during the operation to allow the infused malt to drain two or three times that the act of compression may express from them those portions of sweet wort detained in the texture of each individual grain; this will enable the brewer to obtain the whole of the value that is producible from his malt, which may on that account be treated with less pressure in the grinding; care in this latter particular will considerably facilitate all subsequent operations, and give a brilliancy and superior quality to the beer unattainable by other means.

In drawing the wort from the mash-tun, no mechanical means should be neglected that would aid in discharging it clear and bright into the copper, for all flocks and

particles of malt that are taken there, very materially interfere with the action and value of the hops upon the wort; but chemical agencies for this purpose should be avoided where possible.

With regard to temperature, the brewer must not only regulate the heat of the water for the first mash by the colour, age, and quality of the malt, whether pale, amber, or brown, but he should also mark the temperature of the atmosphere, as influencing that of the malt, and the absorption of the heat by the utensils employed; remarking that well-mellowed and brown malt will bear a higher mashing heat than pale or newly dried.

The following table of Mashing Heats is by Levesque:—

Table of Mashing Temperatures.

Temp. of the Air	Brown Malt		Time of Standing	Temp. of the Air	High-dried		Time of Standing	Temp. of the Air	Amber ⁷		Time of Standing	Temp. of the Air	Pale Malt		Time of Standing		
	Heat of Mash, 146° to 148°				Heat of Mash, 145° to 147°				Heat of Mash, 144° to 146°				Heat of Mash, 143° to 145°

Heat of the Tap, 144° to 146°.				Heat of the Tap, 143° to 145°.				Heat of the Tap, 142° to 144°.				Heat of the Tap, 141° to 143°.					

The first column gives the temperature of the air at the time of mashing.

The second column shows the heat of the water, the quantity used, and the resulting heat of the mash—noting, that if the water has been let into the mash-tun at the boiling point, and allowed to cool down, or the vessel has been thoroughly warmed before the commencement of the process, the heat may be taken several degrees lower.

The third column shows the time for the standing of the mash, but this will be modified, as before stated, by the quality of the extract required.

The bulk of the materials used must also enter into the consideration of the temperature, as a large body of malt will attain the required temperature with a mashing heat lower than a small quantity; the powers of chemical action and condensation of heat being increased with increase of volume.

Donovan, speaking of the temperature to be employed in mashing, lays down the following as a general rule:—For well dried pale malt the heat of the first mashing liquor may be, but should never exceed, 170°; the heat of the second may be, 180°; and, for a third, the heat may be, but need never exceed, 185°.

The quantity of water, termed liquor, to be employed for mashing, depends upon the greater or less strength to be given to the beer; but in all cases, from one barrel and a half to one barrel and three firkins is sufficient for the first stiff mashing, but more liquor may be added after the malt is thoroughly wetted.

The grains of the crushed malt, after the wort is drawn off, retain from thirty-two to forty gallons of water for every quarter of malt. A further amount must be allowed for the loss by evaporation in the boiling and cooling, and the waste in fermentation, so that the amount of liquor required for mashing will, in some instances, be double that of the finished beer, but in general the total amount will be reduced about one-third during the various processes.

The following example has been given of the proportions for an ordinary quality of beer:—

Suppose thirteen imperial quarters of the best pale malt be taken to make 1,500 gallons of beer, the waste may be calculated at near 900 gallons, or 2,400 gallons of water will be required in mashing.

As soon as the water in the copper has attained the heat of 160° in summer, or 167° in winter, 600 gallons of it are to be run off into the mash-tun (which has pre-

viously been well cleansed or scalded out with boiling water), and the malt gradually but rapidly thrown in and well intermixed, so that it may be uniformly moistened, and that no lumps remain. After continuing the agitation for about half an hour, more liquor, to the amount of 450 gallons, at a temperature of 180°, may be carefully and gradually introduced (it is an advantage if this can be done by a pipe inserted under the false bottom of the mash-tun), the agitation being continued till the whole assumes an equally fluid state, taking care also to allow as small a loss of temperature as possible during the operation, the resulting temperature of the mass being not less than 148°, or more than 152°.

The mash is then covered close, and allowed to remain at rest for an hour, or an hour and a half, after which the tap of the mash-tun is gradually opened, and if the wort that first flows is turbid, it should be carefully returned into the tun until it runs perfectly limpid and clear. The amount of this first wort will be about 675 gallons.

Seven hundred and fifty gallons of water, at a temperature of from 180° to 185°, may now be introduced, and the mashing operation repeated and continued until the mass becomes uniformly fluid as before, the temperature being from 160° to 170°. It is then again quickly covered and allowed to rest for an hour, and the wort of the first mash having been quickly transferred from the underback to the copper, and brought to a state of ebullition, the wort of the second mash is drawn off with similar precaution, and added to it. A third quantity of water, about 600 gallons, at a temperature of 185° or 190°, should now be run through the goods into the mash-tun by the sparging process, or by any means that will allow the hot liquor to percolate through the grains, displacing and carrying down the heavier and more valuable products of the two first mashings. The wort is now boiled with the hops from one to two hours.

By the mashing process before described, the malt is so much exhausted that it can yield no further extract useful for strong beer or porter. A weaker wort might be, no doubt, still drawn off for small beer, or for contributing a little to the strength of the next mashing of fresh malt. But this, we believe, is seldom practised.

The wort is then transferred into the copper, and made to boil as soon as possible, for if it remains long in the underback, it is apt to become acescent. The steam, moreover, raised from it in the act of boiling serves to screen it from the oxygenating or acidifying influence of the atmosphere.

Until it begins to boil, the air should be excluded by some kind of cover.

Dr. Piesse, in 1840, read a paper before the Chemical Society, showing that much extract was left in the malt after brewing, and that it was this matter which was convertible into sugar, which gave its feeding qualities to 'grains.'

It was shown that the malt, after the first wort was drawn off still contained a portion of starch which was not converted into sugar, and that the presence of diastase was necessary to effect this conversion. As diastase is very soluble, there was none of course left in the infused malt.

It is, therefore, recommended by Dr. Piesse, that malt containing diastase should be added to the second wort.

In brewing thirty quarters, I should take twenty-nine quarters for the first mash and add the remaining quarter to the second, by which all the starch, it was contended, would be converted into sugar. To prevent the access of air, which tends to induce acidity, to the wort, it is suggested that a board the size of the back in which it is contained should float on the surface of the fluid. (*Transactions of the Chemical Society*, 1841.)

BRICK. (*Brique*, Fr.; *Backstein*, *Ziegelstein*, Ger.) A solid rectangular mass of baked clay, employed for building purposes. Brickmaking is exceedingly ancient: the tower of Babel was built with bricks, as we are told in Scripture, and also the city of Babylon. Over the ruins of Babylon, and the sites of the other great cities of the ancient monarchies, we still discover bricks of various kinds. Some are merely sun-dried masses of clay; others are well burnt; and others, again, are covered with a vitreous glaze. The Egyptians were great brick-makers; and the Romans were celebrated for their bricks and tiles, large quantities of them having been employed in the construction of their different military stations in England. Subsequently, the same bricks have at times been used on later structures, as for instance, in St. Alban's Abbey, which contains a large quantity of bricks from ruins of the Roman buildings of Verulamium. The Lollards' Tower of Lambeth Palace, built in 1454, and the older portions of Hampton Court Palace, built in 1514, are good examples of the English brick architecture in mediæval times.

The natural mixture of clay and sand, called *loam*, as well as *marl*, which consists of lime and clay with little or no sand, are the materials usually employed in the manufacture of bricks.

There are few places in this country which do not possess alumina in combination with silica and other earthy matters, forming a clay from which bricks can be manufactured. That most generally worked is found on or near the surface in a plastic state. Others are hard marls on the coal-measure, New Red Sandstone, and Blue Lias formations. It is from these marls that the blue bricks of Staffordshire and the fire bricks of Stourbridge are made. Marl has a greater resemblance to stone and rock, and varies much in colour; blue, red, yellow, &c. From the greatly different and varying character of the raw material, there is an equal difference in the principle of preparation for making it into brick; while one merely requires to be turned over by hand, and to have sufficient water worked in to make it subservient to manual labour, the fire-clays and marls must be ground down to dust, and worked by powerful machinery, before they can be brought into even a plastic state. Now these various clays also shrink in drying and burning from 1 to 15 per cent., or more. This contraction varies in proportion to the excess of alumina over silica, but by adding sand, loam, or chalk, or (as is done by the London brick-makers) by using ashes or breeze—as it is technically called—this can be corrected. All clays burning red contain oxides of iron, and those having from 8 to 10 per cent. burn of a blue, or almost a black colour. The bricks are exposed in the kilns to great heat, and when the body is a fire-clay, the iron unites with a portion of the silica, forming a fusible silicate of protoxide of iron, which melts into an external glaze. Bricks of this description are common in Staffordshire, and, when made with good machinery (that is, the clay being very finely ground), are superior to any in the kingdom, particularly for docks, canal or river locks, railway-bridges, and viaducts. In Wolverhampton, Dudley, and many other towns, these blue bricks are commonly employed for paving purposes. Other clays contain lime and no iron; these burn white, and take less heat than any other to burn hard enough for the use of the builder, the lime acting as a flux on the silica. Many clays contain iron and lime, with the lime in excess, when the bricks are of a light dun colour, or white, in proportion to the quantity of that earth present; if magnesia, they have a brown colour. If iron is in excess, they burn from a pale red, to the colour of cast iron, in proportion to the quantity of that metal.

There are three classes of brick earths:—

1st. Plastic clay, composed of alumina and silica, in different proportions, and containing a small per-centage of other salts, as of iron, lime, soda, and magnesia.

2nd. Loams, or sandy clays.

3rd. Marls, of which there are also three kinds: clayey, sandy, and calcareous, according to the proportions of the earth of which they are composed, viz., alumina, silica, and lime.

Alumina is the oxide of the metal aluminium, and it is this substance which gives tenacity or plasticity to the clay-earth, having a strong affinity for water. It is owing to excess of alumina that many clays contract too much in drying, and often crack on exposure to wind or sun. By the addition of sand, this clay would make a better article than we often see produced from it. Clays contain magnesia and other earthy matters, but these vary with the stratum or rock from which they are composed. It would be impossible to give the composition of these earths correctly, for none are exactly similar; but the following will give an idea of the proportions of the ingredients of a good brick earth: silica, three-fifths; alumina, one-fifth; iron, lime, magnesia, manganese, soda, and potash forming the other one-fifth.

The clay, when first raised from the mine or bed, is, in very rare instances, in a state to allow of its being at once tempered and moulded. The material from which fire-bricks are manufactured has the appearance of ironstone and blue lias limestone, and some of it is remarkably hard, so that in this and many other instances in order to manufacture a good article, it is necessary to grind this material down into particles as fine as possible.

Large quantities of bricks are made from the surface marls of the New Red Sandstone and Blue Lias formations. These also require thorough grinding, but from their softer nature it can be effected by less powerful machinery.—*Chamberlain*.

Recently, some very valuable fire-bricks have been made from the refuse of the China Clay Works of Devonshire. The quartz and mica left after the *Kaolin* has been washed out are united with a small portion of inferior clay, and made into bricks. These are found to resist heat well, and are largely employed in the construction of metallurgical works. See CLAY.

The general process of brick-making consists in digging up the clay in autumn; exposing it, during the whole winter, to the frost and the action of the air, turning it repeatedly, and working it with the spade; breaking down the clay lumps in spring, throwing them into shallow pits, to be watered and soaked for several days. The next step is to temper the clay, which is generally done by the treading of men or oxen. In the neighbourhood of London, however, this process is performed in a

horse-mill. The kneading of the clay is, in fact, the most laborious but indispensable part of the whole business; and that on which, in a great measure, the quality of the brick depends. All the stones, particularly the ferruginous, calcareous, and pyritous kinds, should be removed, and the clay worked into a homogeneous paste with as little water as possible.

Mr. F. W. Simms, C.E., communicated to the Institution of Civil Engineers, in April and May, 1843, an account of the process of brick-making for the Dover Railway. The plan adopted is called slop-moulding, because the mould is dipped into water before receiving the clay, instead of being sanded as in making sand-stock bricks. The workman throws the proper lump of clay with some force into the mould, presses it down with his hands to fill the cavities, and then strikes off the surplus clay with a stick. An attendant boy, who has previously placed another mould in a water trough by the side of the moulding table, takes the mould just filled, and carries it to the floor, where he carefully drops the brick from the mould, on its flat side, and leaves it to dry; by the time he has returned to the moulding table, and deposited the empty mould in the water trough, the brickmaker will have filled the other mould for the boy to convey to the floor, where they are allowed to dry, and are then stacked in readiness for being burned in clamps or kilns. The average produce is shown in the following Table:—

Force employed	Area of Land		Duration of Season	Produce per Week	Produce per Season
	Roods	Perches	Weeks	Bricks	Bricks
1 moulder . 1 temperer . 1 wheeler . 1 carrier boy 1 picker boy	2	14½	22	16,100	354,200

It appears that while the produce in sand-stock bricks is to that of slop-bricks, in the same time, as 30 to 16, the amount of labour is as 7 to 4; while the quantity of land, and the cost of labour per thousand, are nearly the same in both processes. The quantity of coal consumed in the kiln was at the rate of 10 cwt, 8 lbs. per 1000 bricks. The cost of the bricks was 2*l.* 1*s.* 6*d.* per thousand. The slop-made bricks are fully 1 pound heavier than the sand-stock. Mr. Bennett states that at his brick-field at Cowley, the average number of sand-stock bricks moulded per day was 32,000; but that frequently so many as 37,000, or even 50,000, were formed. The total amount in the shrinkage of his bricks was $\frac{1}{13}$ ths of an inch upon 10 inches in length; but this differed with the different clays. Mr. Simms objects to the use of machinery in brick-making, because it causes economy only in the moulding, which constitutes no more than about one-eighth of the total expense.

The principal machines which have been worked for this purpose are three—1st, the pug-mill; 2nd, the wash-mill; 3rd, the rolling-mill.

The pug-mill is a cylinder, sometimes conical, generally worked in a vertical position, with the large end up. Down the centre of this is a strong revolving vertical shaft, on which are hung horizontal knives, inclined at such an angle as to form portions of a screw, that is, the knives follow each other at an angle forming a series of coils round this shaft. The bottom knives are larger, and vary in form, to throw off the clay, in some mills vertically, in others horizontally. Some have on the bottom of the shaft one coil of a screw, which throws the clay off more powerfully where it is wished to give pressure.

The action of this mill is to cut the clay with the knives during their revolution, and so work and mix it, that on its escape it may be one homogeneous mass, without any lumps of hard untempered clay; the clay being thoroughly amalgamated, and in the toughest state in which it can be got by tempering. This mill is an excellent contrivance for the purpose of working the clay, in combination with rollers; but if only one mill is worked, it is not generally adopted, for, although it tempers, mixes, and toughens, it does not extract stones, crush up hard substances, or free the clay from all matters injurious to the quality of the ware when ready for market. This mill can be worked by either steam, water, or horse-power; but it takes much power in proportion to the quantity of work which it performs. If a brick is made with clay that has passed the pug-mill, and contains stones, or marl not acted on by weather, or lime-shells, (a material very common in clays), or any other extraneous matter injurious to the brick, it is apparent from the action of this mill that it is not removed or reduced. The result is this, the bricks being when moulded in a very soft state of tempered material, or mud, considerably contract in drying, but the stones or hard substances not contracting, cause the clay

to crack ; and even if they should not be sufficiently large to do this in drying, during the firing of the bricks there is a still further contraction of the clay, and an expansion of the stone from the heat to which it is subjected, and the result is generally a faulty or broken brick, and on being drawn from the kilns, the bricks are found to be imperfect.

The clay, being sufficiently kneaded, it is brought to the bench of the moulder, who works it into a mould made of wood or iron, and strikes off the superfluous matter. The bricks are next delivered from the mould, and ranged on the ground ; and when they have acquired sufficient firmness to bear handling, they are dressed with a knife, and stacked or built up in long dwarf walls, thatched over, and left to dry. An able workman will make, by hand, 5,000 bricks in a day.

The different kinds of bricks made in England are principally *place bricks*, *grey and red stocks*, *marl facing bricks*, and *cutting bricks*. The place bricks and stocks are used in common walling. The marls are made in the neighbourhood of London, and used in the outside of buildings, they are very beautiful bricks, of a fine yellow colour, hard, and well burnt, and, in every respect, superior to the stocks. The finest kind of marl and red bricks, called cutting bricks, are used in the arches over windows and doors, being rubbed to a centre, and gauged to a height.

Bricks, in this country, are generally baked either in a clamp or in a kiln. The latter is the preferable method, as less waste arises, less fuel is consumed, and the bricks are sooner burnt. The kiln is usually 13 feet long, by 10½ feet wide, and about 12 feet in height. The walls are one foot two inches thick, carried up a little out of the perpendicular, inclined towards each other at the top. The bricks are placed on flat arches, having holes left in them resembling lattice-work ; the kiln is then covered with pieces of tiles and bricks, and some wood put in, to dry them with a gentle fire.

This continues two or three days before they are ready for burning, which is known by the smoko turning from a darkish colour to semi-transparency. The mouth or mouths of the kiln are now dammed up with a *shinlog*, which consists of pieces of bricks piled one upon another, and closed with wet brick earth, leaving above it just room sufficient to receive a fagot. The fagots are made of furze, heath, brake, fern, &c., and the kiln is supplied with these until its arches look white, and the fire appears at the top ; upon which the fire is slackened for an hour, and the kiln allowed gradually to cool. This heating and cooling is repeated until the bricks are thoroughly burnt, which is generally done in 48 hours. One of these kilns will hold about 20,000 bricks.

Clamps are also in common use. They are made of the bricks themselves, and generally of an oblong form. The foundation is laid with *place brick*, or the driest of those just made, and then the bricks to be burnt are built up, tier upon tier, as high as the clamp is meant to be, with two or three inches of breeze or cinders strewed between each layer of bricks, and the whole covered with a thick stratum of breeze. The fire-place is perpendicular, about three feet high, and generally placed at the west end ; and the flues are formed by gathering or arching the bricks over, so as to leave a space between each of nearly a brick wide. The flues run straight through the clamp, and are filled with wood, coals, and breeze, pressed closely together. If the bricks are to be burnt off quickly, which may be done in 20 or 30 days, according as the weather may suit, the flues should be only at about six feet distance ; but if there be no immediate hurry, they may be placed nine feet asunder, and the clamp left to burn off slowly.

The following remarks by Mr. H. Chamberlain, on the drying of bricks, have an especial value from the great experience of that gentleman, and his careful observation of all the conditions upon which the preparation of a good brick depends.

‘The drying of bricks ready for burning is a matter of great importance, and requires more attention than it generally receives. From hand-made bricks we have to evaporate some 25 per cent. of water before it is safe to burn them. In a work requiring the make of 20,000 bricks per day, we have to evaporate more than 20 tens of water every 24 hours. Hand-made bricks lose in drying about one-fourth of their weight, and in drying and burning about one-third. The average of machine bricks—those made of the stiff plastic clay—do not lose more than half the above amount from evaporation, and are, therefore, of much greater specific gravity than hand-made ones.

‘The artificial drying of bricks is carried on throughout the year uninterruptedly in sheds having the floor heated by fires ; but this can only be effected in districts where coal is cheap. The floors of these sheds are a series of tunnels or flues running through the shed longitudinally. At the lower end is a pit, in which are the furnaces the fire travels up the flues under the floor of the shed, giving off its heat by the way, and the smoke escapes at the upper end, through a series of (generally three or four)

smaller chimneys or stacks. The furnace end of these flues would naturally be much more highly heated than the upper end near the chimneys. To remedy this, the floor is constructed of a greater thickness at the fire end, and gradually diminishes to within a short distance of the top. By this means, and by the assistance of dampers in the chimneys, it is kept at nearly an equal temperature throughout. Bricks that will bear rapid drying, such as are made from marly clays or very loamy or siliceous earths, will be fit for the kiln in from 12 to 24 hours. Before the duty was taken off bricks, much dishonesty was practised by unprincipled makers, where this drying could be carried on economically. Strong clays cannot be dried so rapidly. These sheds are generally walled round with loose bricks, stacked in between each post or pillar that supports the roof. The vapour given off from the wet bricks, rising to the roof, escapes. This system of drying is greatly in advance of that in the open air, for it produces the ware, as made, without any deterioration from bad weather; but the expense of fuel to heat these flues has restricted its use to the neighbourhood of collieries. In 1845 attention was turned to the drying of bricks, and experiments carried out in drying the ware with the waste heat of the burning kilns. The caloric, after having passed the ware in burning, was carried up a flue raised above the floor of the shed, and gave off its spent heat for drying the ware. Although this kiln was most useful in proving that the waste heat of a burning kiln is more than sufficient to dry ware enough to fill it again, it was abandoned on account of the construction of the kiln not being good.

Another system of drying is in close chambers, by means of steam, hot water, or by flues heated by fire under the chambers. I will, therefore, briefly describe the steam-chamber as used by Mr. Beart. This is a square construction or series of tunnels or chambers, built on an incline of any desired length; and at some convenient spot near the lower end is fixed a large steam-boiler, at a lower level than the drying chamber. From the boiler the main steam pipe is taken along the bottom or lower end of the chamber, and from this main, at right angles, runs branch pipes of four inches diameter up the chamber, two feet apart, and at about three feet from the top or arch. From there being so close and shallow a chamber between the heating surface of the pipes and the top, and so large an amount of heating surface in the pipes, the temperature is soon considerably raised. At the top and bottom ends are shutters or lids, which open for the admission of the green ware at the upper end, and for the exit of the dry ware at the lower end of the chamber. Over the steam-pipes are fixed iron rollers, on which the trays of bricks, as brought from the machine, are placed, the insertion of one tray forcing the tray previously put in further on, assisted in its descent by the inclination of the construction. The steam being raised in the boiler flows through the main into those branch pipes in the chamber, and from the large amount of exposed surface becomes condensed, giving of its latent heat. From the incline given to the pipes in the chamber, and from the main pipe also having a fall towards the boiler, the whole of the warm water from the condensed steam flows to the boiler to be again raised to steam, sent up the pipes, and condensed intermittently. The steam entering at the lower end of the chamber, it is of course warmer than the upper end. Along the top end or highest part of the chambers is a series of chimneys and windguards, through which the damp vapour escapes. The bricks from the machine enter at this cooler end charged with warm vapour, and as the make proceeds are forced down the chamber as each tray is put in. Thus, those which were first inserted reach a drier and warmer atmosphere, and, on their arrival at the lower end, come out dry bricks, in about 24 hours, with the strongest clays. In some cases the waste steam of the working engines is sent through these pipes and condensed. Bricks will dry soundly without cracking, &c., in these close chambers, when exposed to much greater heat than they would bear on the open flue first described, or the open air, from the circumstance of the atmosphere, although very hot, being so highly charged with vapour. In practice, these steam-chambers have proved many principles, but they are not likely to become universal, for they are very expensive in erection on account of the quantity of steam-pipes, and involve constant expense in fuel, and require attention in the management of the steam-boiler; but their greatest defect is the want of a current of hot air through the chamber to carry off the excess of vapour faster than is now done. The attaining a higher degree of temperature in these chambers is useless, unless there is a current to carry off the vapour. Why should this piping be used, or steam at all, when we have a large mass of heat being constantly wasted, night and day, during the time the kilns are burning? and after the process of burning the kiln is completed, we have pure hot air flowing, from 48 to 60 hours, from the mass of cooling bricks in the kilns, free from carbon or any impurities; this could be directed through the drying chambers, entering in one constant flow of hot, dry air, and escaping in warm vapour. The waste heat during the process of burning can be taken up flues under the chamber, and thereby all the heat of our burning

kilns may be economised and a great outlay saved in steam-pipes, boilers, and attention. It must not be forgotten, also, that so large an atmospheric condenser as the steam-chamber is not heated without a considerable expenditure in fuel. This drying by steam is a great stride in advance of the old flued shed; but practical men must see the immense loss incurred constantly from this source of the spent heat of the burning kilns, and that by economising it, an immense saving will be effected in the manufacture. The kilns are constructed as near the lower end of these chambers as convenient.

A kiln for attaining the object of the one built in 1846 by Mr. Chamberlain is worked at Epsom; but with this difference, that the smoke is consumed. The drying shed is kept quite close, that the hot flues may raise the temperature so high as to dry the ware. In this kiln the heated gases escape from the top, after passing up through the ware, into flues, and are carried to the ground, and thence into the drying shed, which is a very large construction in proportion to the size of the kiln, and holds nearly sufficient ware to fill four kilns. In this shed the heat passes up a hollow wall, about six feet high, and after running through the length of the shed on one side, returns down similar flues on the opposite side of the shed, and is again carried to the kiln, through the bottom of which it passes in two close flues between the three kiln-furnaces, with the exception of small apertures, through which the heat enters to consume the smoke. From these return flues the spent gases rise up a shaft at the end of the kiln. One result of carrying these return flues through the kiln, is the attaining a great draft or suction in the flues to carry off vapour.

The common brick kiln is a rectangular building, generally open, but sometimes arched over. In the side walls and opposite to each other, are built fireplaces, or holes for the insertion of the fuel. The furnaces are formed in the setting of the kiln with unburnt bricks, and above these the kiln is filled as above described. In these kilns, from the raw ware forming the furnace, the flash of the flame, from the fires of the walls, too often vitrifies and destroys the nearest bricks. In the open kiln, as the fire or heat reaches to the top, the fireman soils or earths it down, which throws the draft to another part more backward; and, as it continues to rise, he proceeds with this operation until all the top is earthed in; he then continues the firing until the whole has sunk, by the contraction of the clay in the fire, to the desired depth. The fire-holes are then stopped up with mud, and the kiln is left to cool gradually. If the air were admitted too rapidly while the kiln was at this intense heat, it would cause bricks, made with strong clays, to fly to pieces like glass; it is, in fact, the process of annealing. Cooling too quickly also affects, in many clays, the colour of the bricks.

Temporary kilns are constructed in the country, with unburnt bricks, and called clamps. In Staffordshire, the bricks are burnt in small round kilns, called ovens which hold from 7,000 to 8,000 bricks each; these are burnt from fire in the walls round the ovens, and the raw ware is set in, so as to form a flue from each fire, to direct the flame to the centre. These ovens burn very quickly, and a most intense heat can be obtained in them. Mr. Chamberlain must be again quoted on the burning of bricks:—

‘I will now more fully describe a principle of burning which I have had in practice for the last six years, and which I can therefore recommend with great confidence. The great object in brick-making is to attain a sufficient heat to thoroughly burn the ware with as small a consumption of coal as possible; and with nearly an equal distribution of the heat over all parts, so that the whole of the ware, being subjected to the same temperature, may contract equally in bulk, and be of one uniform colour throughout. The advantage is also gained of burning in much less time than in the old kilns, which, on an average, took a week; and the management is so simplified that any man, even though not at all conversant with the manufacture, after he has seen one kiln burnt, will be able to manage another; and the last, though not least, advantage is, that of delivering up to us the waste heat at the ground level, or under the floor of the kiln, to be used in drying the green ware, or in partially burning the next kiln.

‘Hitherto the heat has been applied by a series of fireplaces, or flues and openings round the kiln, each exposed to the influence of the atmosphere; and in boisterous weather it is very difficult to keep the heat at all regular, the consequence of which is, the unequal burning we often see. The improvements sought by experimentalists have been the burning the goods equally, and, at the same time, more economically. These are obtained by the patent kilns, as improved by Mr. Robert Scrivener, of Shelton, in the Staffordshire Potteries. The plan is both simple and effective, and is as follows:—A furnace is constructed in the centre of the kiln, much below the floor level, and so built that the heat can be directed to any part of the kiln at the pleasure

of the fireman. First, the heat is directed up a tube in the centre to the top of the oven or kiln, and, as there is no escape allowed to take place there, it is drawn down through the goods by the aid of flues in connection with a chimney. Thus, all the caloric generated in the furnace is made use of, and, being central, is equally diffused throughout the mass; but, towards the bottom, or over the exit flues, the ware would not be sufficiently burnt without reversing the order of firing. In order to meet this requirement there is a series of flues under the bottom, upon which the goods are placed, with small regulators at the end of each; these regulators, when drawn back, allow the fire to pass under the bottom, and to rise up among the goods which are not sufficiently fired, and thus the burning is completed. By means of these regulators the heat may be obtained exactly the same throughout; there is, therefore, a greater degree of certainty in firing, and a considerable saving of fuel, with the entire consumption of the smoke. From the fire or draught being under command, so as to be allowed either to ascend or descend through the ware during the time of burning or cooling, the waste caloric can be economised and directed through the adjoining kiln in order to partially burn it, or be used in drying of the raw wares on flues or in chambers. I have found the saving of fuel in these kilns, over the common kiln, 50 per cent.; and to give an idea of the facility with which they can be worked, it is common for my men to fill the kiln, burn, cool, and discharge it in six days.' See **KILN**.

In France attempts were long ago made to substitute animals and machines for the treading of men's feet in the clay kneading pit; but it was found that their schemes could not replace, with advantage, human labour where it is so cheap, particularly for separating the stones and heterogeneous matter, from the loam. The more it is worked, the denser, more uniform, and more durable, the bricks which are made of it. A good French workman, in a day's labour of 12 or 13 hours, it has been said, is able to mould from 9,000 to 10,000 bricks, 9 inches long, $4\frac{1}{2}$ inches broad, and $2\frac{1}{2}$ thick; but he must have good assistants under him. In many brick-works near Paris, screw presses are now used for consolidating the bricks and paving tiles in their moulds. M. Molerat employed the hydraulic press for the purpose of condensing pulverised clay, which, after baking, formed beautiful bricks; but the process was too tedious and costly. An ingenious contrivance for moulding bricks mechanically is said to be employed near Washington, in America. This machine moulds 30,000 in a day's work of 12 hours, with the help of one horse, yoked to a gin-wheel, and the bricks are so dry when discharged from their moulds, as to be ready for immediate burning. The machine is described, with figures, in the 'Bulletin de la Société d'Encouragement,' for 1819.

Mechanical Brick Moulding.—Messrs. Lyne and Stainford obtained, in August 1825, a patent for a machine for making a considerable number of bricks at one operation. It consists, in the first place, of a cylindrical pug-mill of the kind usually employed for comminuting clay for bricks and tiles, furnished with rotatory knives, or cutters, for breaking the lumps and mixing the clay with the other materials of which bricks are commonly made. Secondly, of two movable moulds, in each of which fifteen bricks are made at once; these moulds being made to travel to and fro in the machine for the purpose of being alternately brought under the pug-mill to be filled with the clay, and then removed to situations where plungers are enabled to act upon them. Thirdly, in a contrivance by which the plungers are made to descend, for the purpose of compressing the material and discharging it from the mould in the form of bricks. Fourthly, in the method of constructing and working trucks which carry the receiving boards, and conduct the bricks away as they are formed.

Fig. 254 exhibits the general construction of the apparatus; both ends of which being exactly similar, little more than half the machine is represented. *a* is the cylindrical pug-mill, shown partly in section, which is supplied with the clay and other materials from a hopper above; *b b* are the rotatory knives or cutters, which are attached to the vertical shaft, and, being placed obliquely, press the clay down towards the bottom of the cylinder, in the act of breaking and mixing it as the shaft revolves. The lower part of the cylinder is opened; and immediately under it the mould is placed in which the bricks are to be formed. These moulds run to and fro upon ledges in the side frames of the machine; one of the moulds only can be shown by dots in the figure, the side rail intervening: they are situated at *c c*, and are formed of bars of iron crossing each other, and encompassed with a frame. The mould resembles an ordinary sash window in its form, being divided into rectangular compartments (fifteen are proposed in each) of the dimensions of the intended bricks, but sufficiently deep to allow the material, after being considerably pressed in the mould, to leave it, when discharged, of the usual thickness of a common brick.

The mould being open at top and bottom, the material is allowed to pass into it, when situated exactly under the cylinder; and the lower side of the mould, when so

placed, it is to be closed by a flat board *d*, supported by the truck *e*, which is raised by a lever and roller beneath, running upon a plain rail with inclined ends.

The central shaft, *f*, is kept in continual rotatory motion, by the revolution of the upper horizontal wheel *g*, of which it is the axis; and this wheel may be turned by a horse yoked to a radiating arm, or by any other means. A part of the circumference of the wheel *g*, has teeth, which are intended at certain periods of its revolution to take into a toothed pinion, fixed upon the top of a vertical shaft *h h*. At the lower part of this vertical shaft there is a pulley *i*, over which a chain is passed that is connected to the two moulds *c*, and to the frame in which the trucks are supported; by the rotation of the vertical shaft, the pulley winds a chain, and draws the moulds and truck frames along.

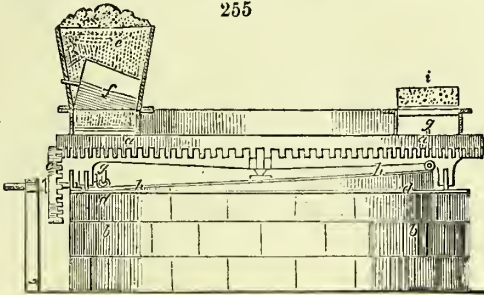

The clay and other material having been forced down from the cylinder into the mould, the teeth of the horizontal wheel *g*, now come into gear with the pinion upon *h*, and turn it and the shaft and pulley *i*, by which the chain is wound, and the mould at the right hand of the machine brought into the situation shown in the figure; a scraper or edge-bar under the pug-mill having levelled the upper face of the clay in the mould, and the board *d*, supported by the truck *e*, formed the flat under-side.

The mould being brought into this position, it is now necessary to compress the materials, which is done by the descent of the plungers *k k*. A friction-roller *l*, pendant from the under side of the horizontal wheel, as that wheel revolves, comes in contact with an inclined plane, at the top of the shaft of the plungers; and, as the friction-roller passes over this inclined plane, the plungers are made to descend into the mould, and to compress the material; the resistance of the board beneath causing the clay to be squeezed into a compact state. When this has been effectually accomplished, the further descent of the plungers brings a pin, *m*, against the upper end of a quadrant catch-level, *n*, and, by depressing this quadrant, causes the balance-lever upon which the truck is now supported to rise at that end, and to allow the truck with the board *d* to descend, as shown by dots; the plungers at the same time forcing out the bricks from the moulds, whereby they are deposited upon the board *d*; when, by drawing the truck forward out of the machine, the board with the bricks may be removed, and replaced by another board. The truck may then be again introduced into the machine, ready to receive the next parcel of bricks.

By the time that the discharge of the bricks from this mould has been effected, the other mould under the pug cylinder has become filled with the clay, when the teeth of the horizontal wheel coming round, take into a pinion upon the top of a vertical

shaft, exactly similar to that at *h*, but at the reverse end of the machine, and cause the moulds and the frame supporting the trucks to be slidden to the left end of the machine; the upper surface of the mould being scraped level in its progress, in the way already described. This movement brings the friction-wheel, *o*, up the inclined plane, and thereby raises the truck, with the board to the under side of the mould, ready to receive another supply of clay; and the mould at the left-hand side of the machine being now in its proper situation under the plungers, the clay becomes compressed, and the bricks discharged from the mould in the way described in the former instance; when this truck being drawn out, the bricks are removed to be dried and baked, and another board is placed in the same situation. There are boxes, *p*, upon each side of the pug cylinder containing sand, at the lower parts of which

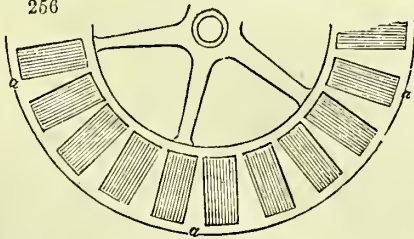

255

small sliders are to be opened (by contrivances not shown in the figure) as the mould passes under them, for the purpose of scattering sand upon the clay in the mould to prevent its adhering to the plungers. There is also a rack and toothed sector, with a balance-weight connected to the inclined plane at the top of the plunger-rods, for the purpose of raising the plunger after the friction-roller has passed

over it; and there is a spring acting against the back of the quadrant-catch, for the purpose of throwing it into its former situation, after the pin of the plunger has risen. An effective machine for brick-making is that patented by Mr. Edward Jones, of Birmingham, in August 1835. His improvements are described under four heads: the first applies to a machine for moulding the earth into bricks in a circular frame-plate horizontally, containing a series of moulds or rectangular boxes, standing radially round the circumference of the circular frame, into which boxes successively the clay is expressed from a stationary hopper as the frame revolves, and after being

256

so formed, the bricks are successively pushed out of their boxes, each by a piston acted upon by an inclined plane below. The second head of the specification describes a rectangular horizontal frame, having a series of moulding boxes placed in a straight range, which are acted upon for pressing the clay by a corresponding range of pistons fixed in a horizontal frame, worked up and down by rods extending from a rotatory crank shaft, the moulding boxes being allowed to rise for the purpose of enabling the pistons to force out the bricks when moulded, and leave them upon the bed or board below. The third head applies particularly to the making of tiles for the flooring of kilns in which malt or grain is to be dried. There is in this contrivance a rectangular mould, with pointed pieces standing up for the purpose of producing air-holes through the tiles as they are moulded, which is done by pressing the clay into the moulds upon the points, and scraping off the superfluous matter at top by hand. The fourth or last head applies to moulding chimney-pots in double moulds, which take to pieces for the purpose of withdrawing the pot when the edges of the slabs or sides are sufficiently brought into contact.

Fig. 255 represents, in elevation, the first-mentioned machine for moulding bricks. The moulds are formed in the face of a circular plate or wheel, *a a*, a portion of the upper surface of which is represented in the horizontal view, fig. 256. Any convenient number of these moulds are set readily in the wheel, which is mounted upon a central pivot, supported by the masonry *b b*. There is a rim of teeth round the outer edge of the wheel *a a*, which take into a pinion, *c*, on a shaft connected to the first mover; and by these means the wheel *a*, with the moulding boxes, is made to revolve horizontally, guided by arms with anti-friction rollers, which run round a horizontal plate, *a a*, fixed upon the masonry.

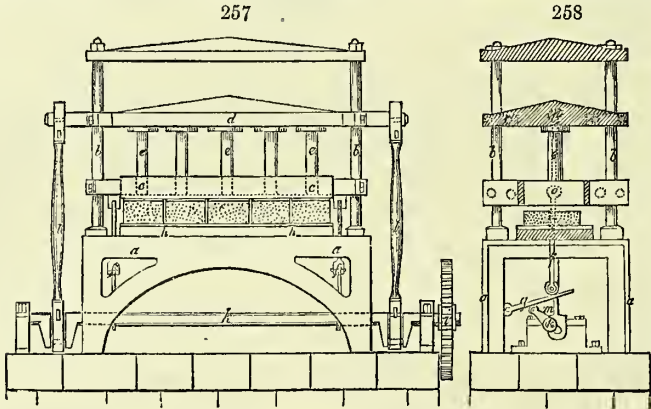

A hopper, *e*, filled with the brick earth, shown with one of the moulding boxes in section, is fixed above the face of the wheel in such a way, that the earth may descend

from the hopper into the several moulding boxes as the wheel passes round under it, the earth being pressed into the moulds, and its surface scraped off smooth by a conical roller, *f*, in the bottom of the hopper.

Through the bottom of each moulding box there is a hole for the passage of a piston-rod, *g*, the upper end of which rod carries a piston with a wooden pallet upon it acting within the moulding box; and the lower end of this rod has a small anti-friction roller, which, as the wheel *a* revolves, runs round upon the face of an oblique ring or inclined way, *h h*, fixed upon the masonry.

The clay is introduced into the moulding boxes from the hopper fixed over the lowest part of the inclined way *h*; and it will be perceived that as the wheel revolves, the piston-rods, *g*, in passing up the inclined way, will cause the pistons to force the new-moulded bricks, with their pallet, or board, under them, severally up the mould, into the situation shown at *i*, in *fig. 256*, whence they are to be removed by hand. Fresh pallets being then placed upon the several pistons, they, with the moulds, will be ready for moulding fresh bricks, when, by the rotation of the wheel, *a*, they are severally brought under the hopper, the pistons having sunk to the bottoms of their boxes, as the piston-rods passed down the other side of the inclined way *h*.

The second head of the invention is another construction of apparatus for moulding bricks, in this instance in a rectangular frame. *Fig. 257* is a front elevation of the machine; *fig. 258*, a section of the same taken transversely. *a a* is the standard frame-work and bed on which the bricks are to be moulded. Near the corners of this standard frame-work, four vertical pillars, *b b*, are erected, upon which pillars

the frame of the moulding boxes, *c*, slides up and down, and also the bar, *d*, carrying the rods of the pistons, *e e e*. These pistons are for the purpose of compressing the clay in the moulding box, and therefore must stand exactly over and correspond with the respective moulds in the frame *a*, beneath.

The sliding frame, *c*, constituting the sides and ends of the moulding boxes, is supported at each end by an upright sliding rod, *f*, which rods pass through guides fixed to the sides of the standard frame, *a a*, and at the lower end of each there is a roller, bearing upon the levers, *g*, on each side of the machine, but seen only in *fig. 258*, which levers, when depressed, allow the moulding boxes to descend and rest upon the bed or table of the machine *h h*.

In this position of the machine resting upon the bed or table, the brick-earth is to be placed upon, and spread over, the top of the frame *c*, by the hands of workmen, when the descent of the plunger or pistons *e e e* will cause the earth to be forced into the moulds, and the bricks to be formed therein. To effect this, rotatory power is to be applied to the toothed wheel *i*, fixed on the end of the main driving crank-shaft *k k*, which on revolving will, by means of the crank-rods *l l*, bring down the bar *a*, with the pistons or plunger *e e c*, and compress the earth compactly into the moulds, and thereby form the bricks.

When this has been done, the bricks are to be released from the moulds by the moulding frame, *c*, rising up from the bed, as shown in *fig. 257*, the pistons still remaining depressed, and bearing upon the upper surfaces of the bricks. The moulding frame is raised by means of cams, *m*, upon the crank-shaft, which at this part of the operation are brought under the levers *g*, for the purpose of raising the cams and the sliding rods *f* into the position shown in *fig. 258*.

The bricks having been thus formed and released from their moulds, they are to be removed from the bed of the machine by pushing forward, on the front side, fresh boards or pallets, which of course will drive the bricks out upon the other side, whence they are to be removed by hand.

There is to be a small hole in the centre of each pallet, and also in the bed, for the purpose of allowing any superfluous earth to be pressed through the moulding boxes when the pistons descend. And in order to cut off the projecting piece of clay which would be thus formed on the bottom of the brick, a knife-edge is in some way connected to the bed of the machine, and as the brick slides over it, the knife separates the protuberant lump; but the particular construction of this part of the apparatus is considered to be of little importance, and the manner of effecting the object is not clearly stated in the specification.

Fig. 259 represents Mr. Hunt's machine. The principal parts consist of two cylinders, each covered by an endless web, and so placed as to form the front and back of a hopper, the two sides being iron plates, placed so that when the hopper is filled with tempered clay from the pug-mill, the lower part of the hopper, and consequently the mass of clay within it, has exactly the dimensions of a brick. Beneath the hopper an endless chain travels simultaneously with the movement of the cylinders. The pallet-boards are laid at given intervals upon the chain, and being thus placed under the hopper, while the clay is brought down with a slight pressure, a frame with a wire stretched across it is projected through the mass of clay, cutting off exactly the thickness of the brick, which is removed at the same moment by the forward movement of the endless chain. This operation is repeated each time that a pallet-board comes under the hopper.

259

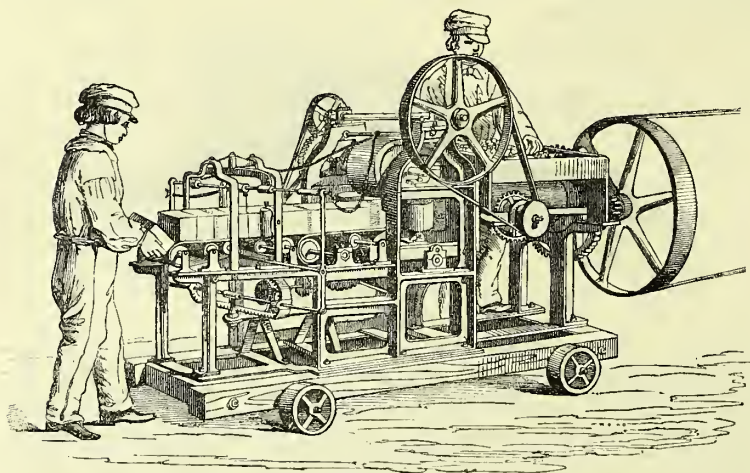

There are numerous machines in use for the manufacture of bricks. For the manufacture of perforated bricks, Mr. Beart's machine is the most generally employed. Mr. Chamberlain thus describes it:—'The most universally used die-machine which has been extensively worked up to the present time is Mr. Beart's patent for perforated bricks. This gentleman, who is practically acquainted with these matters, in order to remedy the difficulties I have mentioned in expressing a mass of clay through a large aperture or die, hung a series of small tongues or cores, so as to form hollow or perforated bricks. By this means the clay was forced in its passage through the die into the corners, having the greater amount of friction now in the centre. Still, the bricks came out rough at the edge with many clays, or with what is termed a jagged edge. The water-die was afterwards applied to this machine, and the perforated bricks, now so commonly used in London, are the result. In Mr. Beart's machine, which is a pug-mill, the clay is taken after passing through the rolling-mill, and being fed in at the top, is worked down by the knives. At the bottom are two horizontal clay-boxes, in which a plunger works backwards and forwards. As soon as it has reached the extremity of its stroke, or forced the clay of one box through the die, the other box receiving during this time its charge of clay from the pug-mill, the plunger returns and empties this box of clay through a die on the opposite side of the machine. The result is, that while a stream of clay is being forced out on one side of the machine the clay on the opposite side is stationary, and can, therefore, be divided into a series of five or six bricks with the greatest correctness by hand. Some of these machines have both boxes on one side and the plungers worked by cranks. This machine cannot make bricks unless the clay has previously passed through rollers, if coarse; for anything at all rough, as stone or other hard substance, would hang in the tongues of the die. But the clay being afterwards pugged in the machine is so thoroughly tempered and mixed, the bricks when made cannot be otherwise than good, provided they are sufficiently fired. As to the utility of hollow or perforated bricks, that is a matter more for the consideration of the

architect or builder than for the brick-maker. Perforated bricks are a fifth less in weight than solid ones, which is a matter of some importance in transit; but it takes considerably more power to force the clay through those dies than for solid brick-making. In the manufacture of perforated bricks, there is also a royalty or patent-right to be paid to Mr. Beart.'

Mr. Chamberlain's own machine is in principle as follows (*fig. 260*):—The clay is fed into a pug-mill, placed horizontally, which works and amalgamates it, and then forces it off through a mouth-piece or die of about 65 square inches, or about half an inch deeper and half an inch longer than is required for the brick, of a form similar to a brick on edge, but with corners well rounded off, each corner forming a quarter of a 3-inch circle, for clay will pass smoothly through an aperture thus formed, but not through a keen angle. After the clay has escaped from the mill it is seized by four rollers, covered with a porous fabric (moleskin), driven at a like surface speed from connection with the pug-mill. These rollers are two horizontal and two vertical ones, having a space of 45 inches between them; they take this larger stream of rough clay, and press or roll it into a squared block, of the exact size and shape of a brick edgewise, with beautiful sharp edges, for the clay has no friction, being drawn through by the rollers instead of forcing itself through, and is delivered in one unbroken stream. The rollers in this machine, perform the functions of the die in one class of machinery, and of the mould in the other. They are, in fact, a die with rotating surfaces. By hanging a series of mandrels or cores between these rollers, or by

260

merely changing the mouth-piece, we make hollow and perforated bricks, without any alteration in the machine.

Messrs. Bradley and Craven, of Wakefield, have invented a very ingenious brick-making (*fig. 261*) machine:—

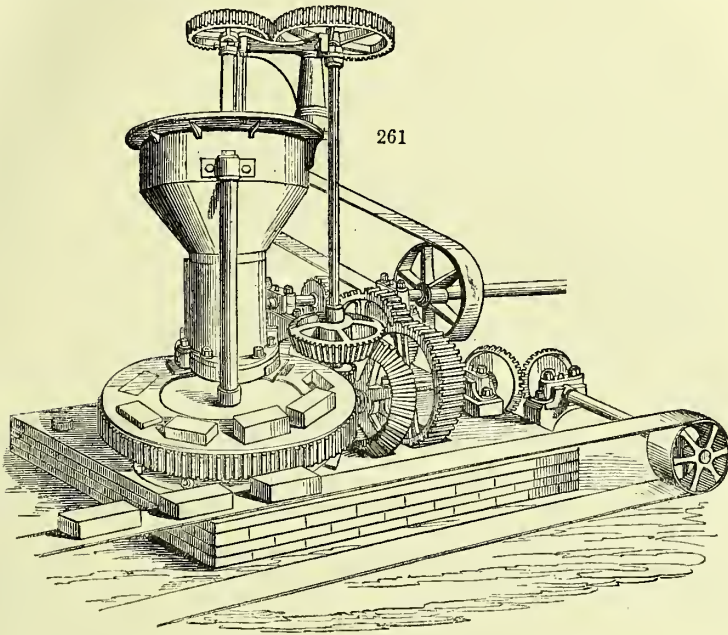

It consists of a vertical pug-mill of a peculiar form, and greatly improved construction, into the upper part of which the clay is fed. In this part of the apparatus the clay undergoes the most perfect tempering and mixing, and on reaching the bottom of the mill, thoroughly amalgamated, is forcibly pressed into the moulds of the form and size of bricks required, which are arranged in the form of a circular revolving table.

As this table revolves, the piston-rods of the moulds ascend an incline plane, and gradually lift the bricks out of the moulds, whence they are taken from the machine by a boy, and placed on an endless band which carries the bricks direct to the waller, thus effecting the saving of the floor room.

The speed of the several parts of the machine is so judiciously arranged, that the operations of pugging, moulding, and delivering proceed simultaneously in due order, the whole being easily driven by a steam-engine of about six-horse power, which, at the ordinary rate of working, will make 12,000 bricks per day; or, with eight-horse power, from 15,000 to 18,000.

In consequence of the perfect amalgamation of the clay, and the great pressure to which it is subjected in the moulds, the bricks produced by this machine are perfect;

and from the stiffness of the clay used, less water has to be evaporated in the drying, thus saving one half the time required for hand-made bricks, and avoiding the risk of loss from bad weather.

The following remarks by Dr. Ure are deserving of attention :—

‘The brick kilns and clamps round London and other large cities, which are fired with the breeze rubbish collected from dust-holes that contain the refuse of kitchens, &c., emit, in consequence, most unpleasant effluvia ; but brick kilns fired with clean coke or coal give out no gases of a more noxious nature than common household fires. The consideration of this subject was closely pressed upon my attention on being consulted concerning an injunction issued by the Chancellor against a brick clamp in the Isle of Wight, fired with clean coke-cinders from the steam-engine furnace at Portsmouth Dockyard. The bricks, being of the description called sand stock, were of course made in moulds very slightly dusted with sand, to make them fall freely out. The sand was brought from Portsmouth Harbour, and, on being subjected to a degree of heat more intense certainly than it could suffer in the clamp, was thought to give out traces of hydrochloric acid.

‘As it is well known to the chemist that common salt strongly ignited in contact with moist sand will emit hydrochloric acid, there was nothing remarkable in the above observation ; but I ascertained that the sand with which the moulds were strewed would give out no hydrochloric acid at a heat equal at least to what the bricks were exposed to in a clamp 10 or 12 feet high, and fired at its bottom only with a layer of cinders 3 or 4 inches thick. But I further demonstrated that the entire substance of the brick, with its scanty film of sand, on being exposed to ignition in a suitable apparatus, gave out—not hydrochloric or any other corrosive acid, but ammonia gas. Hence, the allegations that the clamp sent forth a host of acid gases to blight the neighbouring trees were shown to be utterly groundless ; on the contrary, the ammonia evolved from the heated clay would act beneficially upon vegetation, while it was too small in quantity to annoy any human being. A few yards to leeward of a similar clamp in full activity, I could perceive no offensive odour. All ferruginous clay, when exposed to the atmosphere, absorbs ammonia from it, and of course emits it again on being gently ignited.’

Floating bricks are a very ancient invention ; they are so light as to swim in water ; and Pliny tells us that they were made at Marseilles, at Colento, in Spain, and at Pittane, in Asia. This invention, however, was completely lost until M. Fabroni published a discovery of a method to imitate the floating bricks of the ancients.

According to Posidonius, these bricks were made of a kind of argillaceous earth, which was employed to clean silver plate. But as it could not be our tripoli, which is too heavy to float in water, M. Fabroni tried several experiments with mineral agaric, guhr, lac-lunæ, and fossil meal, which last was found to be the very substance of which he was in search. This earth is abundant in Tuscany, and is found near Casteldelpiano, in the territories of Sienna. According to the analysis of M. Fabroni, it consists of 55 parts of siliceous earth, 15 of magnesia, 14 of water, 12 of alumina, 3 of lime, and 1 of iron. It exhales an argillaceous odour, and, when sprinkled with water, throws out a light-whitish smoke. It is infusible in the fire, and, though it loses about an eighth part of its weight, its bulk is scarcely diminished. Bricks composed of this substance, either baked or unbaked, float in water; and $\frac{1}{20}$ th part of clay may be added to their composition without taking away their property of swimming. These bricks resist water, unite perfectly with lime, are subject to no alteration from heat or cold, and the baked differ from the unbaked only in the sonorous quality which they have acquired from the fire. Their strength is little inferior to that of common bricks, but much greater in proportion to their weight; for M. Fabroni found that a floating brick, measuring 7 inches in length, $4\frac{1}{2}$ in breadth, and 1 inch 8 lines in thickness, weighed only $14\frac{1}{4}$ oz., whereas a common brick weighed 5 lbs. $6\frac{3}{4}$ oz.

As an experiment, M. Fabroni constructed the powder magazine of a ship of these bricks; the vessel was set on fire, and sank without exploding the powder.

This earth has been found near Clermont, in the Auvergne. Ehrenberg has shown that it is entirely composed of microscopic siliceous shells. Bricks composed of this earth weigh only half as much as the ordinary ones.

Fire bricks are made extensively in the neighbourhood of Newcastle-on-Tyne and at Stourbridge. For the analyses of the clays of which these and others are constructed, see CLAY.

Stone Bricks.—These are manufactured at Neath, in Glamorganshire, and are very much used in the construction of copper furnaces at Swansea. They are usually known as the ‘Dinas bricks.’

The materials of which the bricks are made are brought from a quarry in the neighbourhood. They are very coarse, being subjected to a very rude crushing operation under an edge stone, and, from the size of the pieces, it is impossible to mould by hand. There are three qualities, which are mixed together with a little water, so as to give the mass coherence, and in this state it is compressed by the machine into a mould. The brick which results is treated in the ordinary way, but it resists a much greater heat than the Stourbridge clay brick, expands more by heat, and does not contract to its original dimensions. The composition of the three materials is as follows:—

	From Pendreyn	From Dinas	
Silica	94·05	100·	91·95
Alumina, with a trace of ox. iron	4·55	traces	8·05
Lime and magnesia	—	traces	traces
	98·60	100·	100·00

—*Dr. Richardson: Knapp's Technology.*

Since the introduction of the Siemens gas-furnace, and the Bessemer process for cast-steel manufacture, into countries which, unlike our own, are not well supplied with fire-resisting materials, great difficulty has been experienced in obtaining bricks of a sufficiently refractory character to withstand the extremely high temperature developed in the melting chamber, as well as the sudden and violent alternations in other parts of the furnace. In order to obviate this difficulty, Mr. Joseph Khern, a well-known Austrian metallurgist, has introduced a plan of manufacturing siliceous bricks, which he describes as being superior to any other refractory material obtained in Austria. The chief ingredient is quartz of the highest possible degree of purity, especial care being taken to reject all such samples as show any admixture of iron or copper pyrites, carbonate of lime, or even mica, or felspar. The quartz so selected is heated in quantities of from 10 to 15 tons, in a Rumford lime-kiln for 10 or 12 hours, till it attains a full red heat, when it is quenched in water; the fragments are then cleaned by a simple jigging process, and subsequently are crushed under a tilt hammer, sufficiently fine to pass through a sieve having 60 holes to the square inch. The hammer weighs $2\frac{1}{2}$ cwt., and is capable of crushing $3\frac{1}{2}$ tons of quartz in 12 hours. Two varieties of clay are used, differing slightly in plasticity; they are prepared by careful weathering, pulverisation under light stamp-heads, and grinding under edge rollers; a final sifting is performed through a sieve of 600 apertures to the inch. The purest quartz is reserved for the first quality of brick, which have to resist the greatest

heat; while the second and third class, for less exposed positions, are made chiefly of the remains of bricks which have been already used, ground and sifted afresh. The following are the mixtures employed:—

First class: 16 parts of quartz to 1 plastic clay, or 14 parts of quartz to 1 of leaner clay. Second class: 16 parts of ground bricks of the 1st class, to 1 of clay. Third class: 8 parts of ground bricks of the 2nd and 3rd classes, to 1 of clay.

The latter class are made more with a view to obtain mechanical strength than fire-resisting power.

The materials are mixed together dry, and are thoroughly incorporated by kneading with water, and treading under men's feet; about 18 cubic feet are operated upon at one time. Sufficient water must be added to allow the mixture to be worked into a ball between the fingers without crumbling. The second and third class bricks are formed in open moulds, the stuff being beaten down by a metal rammer of about 4½ lbs. weight; the first class, however, are subjected to a pressure of about 3 tons to the square inch during a period of three quarters of an hour, before they are removed from the moulds. The drying takes place in chambers, through which a current of air passes, at the ordinary temperature in summer, but artificially warmed in winter; the bricks are fit for burning in from 4 to 6 days. The kilns are rectangular chambers, each having two step-grate fireplaces in one of the shorter sides, and a flue communicating with a high chimney at the opposite end. The capacity is about 2,300 or 2,500 bricks. As soon as the kiln is filled, the charging aperture is partly closed, and a gentle fire is kept in the grates, the flue damper being shut. After 36 hours, the charging hole is entirely closed, and the draught is urged by opening the damper inch by inch at intervals, until, at the end of 65 or 70 hours, the whole of the charge has attained a strong white heat. The fires are then removed, the damper is shut down, the grates are filled with sand, and any cracks that may have formed in the kiln are carefully luted up. After standing in this way for 24 hours, the charging place is gradually opened, and in from 36 to 48 hours more, the burnt bricks may be removed.

BRICK CLAY. The familiar term for any clay used in the manufacture of bricks. A good clay for this purpose is a silicate of alumina, combined in various proportions with sand. *Brick clay* is used by geologists in contradistinction to *Boulder clay*.

BRICK EARTH. A marly earth, containing much alumina, largely employed in brick-making.

BRICK KILN. See KILN.

BRICK OIL. This is a relic of old pharmacy: it was prepared by putting red-hot roughly powdered brick into linseed oil. It is no longer used, except by old apothecaries and druggists in remote country towns.

BRICK RED COPPER ORE. See TILE ORE.

BRIDGE. See IRON BRIDGE.

BRIMSTONE. (*Soufre*, Fr.; *Schwefel*, Ger.) SULPHUR.

Our Imports of Brimstone for the years ending 1871 were as follows:—

1869		1870		1871	
Quantity	Value	Quantity	Value	Quantity	Value
Cwts.	£	Cwts.	£	Cwts.	£
1,015,329	388,723	1,065,360	386,660	937,049	303,717

BRISTLE. The stiff glossy hair of swine, which grows chiefly on the backs of those animals, both in the wild and the domesticated state. Bristles are used in the manufacture of brushes.

In 1864 our Imports of Bristles from Russia were 1,958,112 lbs., valued at 252,923*l.*; from Prussia 59,113 lbs., valued at 7,635*l.*; from Hamburg 207,274 lbs., valued at 26,772*l.*; from Belgium 34,880 lbs., valued at 4,505*l.*; from France 51,859 lbs., valued at 6,699*l.*; from other parts 34,897 lbs., valued at 4,507*l.*: total amount, 2,346,135 lbs., valued at 303,041*l.* In the same year we exported 12,395 lbs. valued at 2,264*l.* The importations for 1872 were:—From Russia, 1,800,933 lbs.; from Germany, 572,727 lbs.; from Holland, 492,921 lbs.; from Belgium, 94,842 lbs.; from France, 60,030 lbs.; and from other countries, 46,642 lbs. The total value being 517,309*l.*

BRISTOL DIAMONDS. Brilliant crystals of quartz, found in the St. Vincent Rocks, near Bristol. They are often cut and polished for ornaments.

BRITANNIA METAL. An alloy of tin with copper and antimony. In the best kinds a little nickel is used. See ALLOYS.

BRITISH GUM. See DEXTRINE.

BRITTLE SILVER-GLANCE. See SILVER ORES.

BRITTLE SILVER ORE. See SILVER ORES.

BRITTLE SULPHURET OF SILVER. See SILVER ORES.

BROAD CLOTH. A fine kind of woollen cloth, which exceeds twenty-nine inches in width. All of less width are known as *narrow cloths*.

BROAD GAUGE. Rails laid wide apart, as on the Great Western Railway and its branches, in contradistinction to the *narrow gauge*, as on all the other railways of the Kingdom. The broad gauge rails are 6 feet apart; the narrow gauge rails $4\frac{1}{2}$ feet.

BROAD LEAF. The *Terminalia latifolia*, a tree, native of Jamaica, the wood of which is used for boards, scantlings, shingles, and staves. It is sometimes mistaken for the almond tree, owing to the shape of its fruit. See TERMINALIA.

BROADSIDE. A seaman's term—the full length or side of a ship. A printer's term—a full printed page of any sized sheet.

BROCADE. A rich stout silk, formerly much worn by ladies of rank. A name commonly given to any variety of stuff upon which raised flowers are embroidered. The name is also given to a cloth of silk and gold manufactured in Eastern countries.

BROCATELLE. Linsey-woolsey is so called in France. A silk material which is used for lining carriages.

BROCATELLI MARBLE. An artificial marble made from fragments of natural marbles united by means of an artificial cement.

BROCHANTITE. An ore of copper found in this country at Roughton Gill, in Cumberland. It has also been discovered in Siberia, Nassau, and elsewhere. Its composition is sulphuric acid, 17·7; protoxide of copper, 70·3; water, 12·0.

BROCKRAM. A Cumberland miner's term for a *breccia*.

BROMA. A preparation of chocolate.

BROMACETIC ACID.—Obtained by Messrs. Perkin and Duppa. They take a mixture of crystallisable acetic acid and bromine in the proportion of equal equivalents, introduce it into a sealed tube, which is placed in an oil bath and heated to 150° C. The mixture which is nearly colourless, or of a light amber colour, is transferred to a retort, and the excess of acetic acid driven off by heating to 200° C. On cooling, a beautiful white crystalline solid is obtained, which is bromoacetic acid, together with hydrobromic acid and bibromoacetic acid. The mixed acids are heated to 130° C., carbonic acid passed until the reaction of hydrobromic acid, with nitrate of silver, is no longer evident. Carbonate of lead is then added, the whole heated to 100° C., and allowed to stand for some hours; the liquid filtered off from the crystalline deposit.

The acid thus obtained crystallises in rhombohedra, is exceedingly deliquescent, and very soluble in water or alcohol. It fuses below 100° C., and boils at 208° C. When distilled with acetate of potassium, it gives off acetic acid; when heated with metallic zinc, it yields acetate and bromide of zinc.

It attacks the epidermis powerfully, raising a blister like that produced by a burn. It forms crystallisable salts with most bases, many of which decompose rapidly.

Messrs. Perkin and Duppa have formed the salts of the alkalis and alkaline earths. The lead salt is obtained by neutralising bromoacetic acid with oxide of lead, and recrystallising in water, washing the crystalline precipitate with cold water, and recrystallising from water.

The silver salt is obtained by treating bromoacetic acid with carbonate of silver, or by adding solution of bromoacetic acid to solution of nitrate of silver. It is thrown down as a crystalline precipitate.

Bromoacetate of methyl is a colourless mobile liquid, having an aromatic odour; it boils at 144° C. The bromoacetate of ethyl boils at 159° C.; that of amyl at 207° C.

By the action of ammonia on bromoacetic acid, bromide of ammonium is formed, and glycecol, or a body isomeric with it.

Bibromoacetic Acid. Formed when bromine and acetic acid are heated in presence of light, but it is difficult to obtain in large quantities. It is a liquid boiling at 240° C., which is partially decomposed every time it is distilled, evolving hydrobromic acid. It does not solidify at 15° C. It has a very high specific gravity. The silver salt is a crystalline precipitate which is, however, decomposed, by boiling with water, into bromide of silver and a soluble acid.

BROMATES. Compounds of BROMIC ACID with alkalis, alkaline earths, and metals.

BROMIC ACID. A combination of bromine with oxygen, forming bromates.

BROMIC SILVER. See SILVER ORES.

BROMIDES. Compounds of BROMINE with alkalis and metals.

BROMIDE OF SILVER. A salt much used in photography. It is formed by adding a soluble bromide to nitrate of silver, when a white precipitate is produced. See PHOTOGRAPHY.

BROMITE. Native bromide of silver.

BRONZE. (*Bronze*, Fr. and Ger.) A compound metal consisting of copper

and tin, to which sometimes a little zinc and lead are added. There is some confusion amongst Continental writers about this alloy; they translate their bronze into the English *brass*.

See, for an example of this, 'Dictionnaire des Arts et Manufactures.' This has arisen from the carelessness of our own writers. Dr. Watson, 'Chemical Essays,' remarks: 'It has been said that Queen Elizabeth left more *brass ordnance* at her death than she found iron on her accession to the throne. This must not be understood as if gun-metal was made in her time of brass, for the term brass was sometimes used to denote copper; and sometimes a composition of iron, copper, and calamine was called brass; and we, at this day, commonly speak of *brass cannon*, though brass does not enter into the composition used for casting cannon.'

Bronze is an alloy of copper and tin.

Brass is an alloy of copper and zinc.

In many instances, we have zinc, lead, &c., entering into the composition of alloys of copper and tin. However this may be, the alloy is called a bronze, if tin and copper are the chief constituents.

This alloy is much harder than copper, and was employed by the ancients to make swords, hatchets, &c., before the method of working iron was generally understood. Most modern archeologists, following the Danish antiquaries, recognise a *bronze age*; that is to say, an epoch of civilisation when bronze was the only metal in general use for cutting instruments, and other useful or ornamental objects. This period is generally held to have been subsequent to the so-called *stone age* and anterior to that of *iron*. Some authorities, however, arguing on metallurgical rather than on archæological grounds, have called this chronology in question, and have maintained that a knowledge of iron must have preceded that of bronze. Be that as it may, it is certain that the use of bronze was general at a very early period in the history of Western civilisation.

The art of casting bronze statues may be traced to the most remote antiquity, but it was first brought to a certain degree of refinement by Theodoros and Ræcus of Samos, about 700 years before the Christian era, to whom the invention of modelling is ascribed by Pliny. The ancients were well aware that by alloying copper with tin, a more fusible metal was obtained, that the process of casting was therefore rendered easier, and that the statue was harder and more durable. It was during the reign of Alexander that bronze statuary received its greatest extension, when the celebrated artist Lysippus succeeded, by new processes of moulding and melting, in multiplying groups of statues to such a degree that Pliny called them the *mob of Alexander*. Soon afterwards enormous bronze colossuses were made, to the height of towers, of which the isle of Rhodes possessed no less than one hundred. The Roman consul Mutianus found 3,000 bronze statues at Athens, 3,000 at Rhodes, as many at Olympia and at Delphi, although a great number had been previously carried off from the last town.

From the analyses of Mr. J. A. Phillips, we learn that most of the ancient coins were bronzes, the quantity of tin relatively to the copper varying slightly. The proportions of copper and tin in many of those coins are given below, the other ingredients being omitted:—

		Copper.	Tin.
A coin of Alexander the Great,	335 B.C.	86·72	13·14
„ Philippus V.	200 B.C.	85·15	11·10
„ Athens	„	88·41	9·95
„ Ptolemy IX.	70 B.C.	84·21	15·59
„ Pompey	53 B.C.	74·11	8·56
„ the Atilia family	45 B.C.	68·72	4·77
„ Augustus and Agrippa,	30 B.C.	78·58	12·91

The arms and cutting instruments of the ancients were composed of similar bronzes, as the following proportions, also selected from Mr. J. A. Phillips' analyses, will show:—

		Tin.	Copper.
Roman sword blade, found in the	Thames	85·70	10·02
„	Ireland	91·39	8·38
Celtic	Ireland	90·23	7·50

Layard brought from Assyria a considerable variety of bronze articles, many of them objects of ornament, but many evidently intended for use. Amongst others was a bronze foot, which was constructed for the purpose of support of some kind. This was submitted to the examination of Dr. Percy. It was then found that the bronze had been cast round a support of iron. By this means the appearance of considerable lightness was attained, while great strength was insured. This discovery proves in a

very satisfactory manner, that the metallurgists of Assyria were perfectly conversant with the use of iron, and that they employed it for the purpose of imparting strength to the less tenacious metals which they employed in their art-manufactures. This bronze, as analysed in the Metallurgical Laboratory of the Museum of Practical Geology, consists of copper 88·37, tin 11·33.

Examination has shown that all the bronze weapons of the Greeks and Romans were not only of the true composition for insuring the greatest density in the alloy itself, but that these, by a process of hammering the cutting edges, were brought up to the greatest degree of hardness and tenacity.

Before 1542, 'brass ordnance' (*bronze*) was founded by foreigners. Stow says that John Owen began to found brass ordnance, and that he was the first Englishman who ever made that kind of artillery in England.

Bell founding followed. Bell-metal and other broken metal were allowed to be exported hitherto; but it being discovered that it was applied to found guns abroad, 'brass, copper, latten, bell metal, pan metal, gun metal, and shroff metal, are prohibited to be exported.'

Bronze has almost always been used for casting statues, bassi-rilievi, and works which are to be exposed to atmospheric influences. In forming such statues, the alloy should be capable of flowing readily into all the parts of the mould, however, minute; it should be hard, in order to resist accidental blows, be proof against the influence of the weather, and be of such a nature as to acquire that greenish oxidised coat upon the surface, which is so much admired in the antique bronzes, called *patina antiqua*. The chemical composition of the bronze alloy is a matter therefore of the first moment. The Brothers Keller, celebrated founders in the time of Louis XIV., whose *chefs-d'œuvre* are well known, directed their attention towards this point, to which too little importance is attached at the present day. The statue of Desaix, in the Place Dauphine, and the column in the Place Vendôme are noted specimens of most defective workmanship from mismanagement of the alloys of which they are composed. On analysing separately specimens taken from the bas-reliefs of the pedestal of this column, from the shaft, and from the capital, it was found that the first contained only 6 per cent. of tin, and 94 of copper, the second much less, and the third only 0·21. It was therefore obvious that the founder, unskilful in the melting of bronze, had gone on progressively refining his alloy, by the oxidisement of the tin, till he had exhausted the copper, and that he had then worked up the refuse scoriæ in the upper part of the column. The cannon which the Government furnished him for casting the monument consisted of:—

Copper	89·360
Tin	10·040
Lead	0·102
Silver, zinc, iron, and loss	0·498
	100·000

The moulding of the several bas-reliefs was so ill executed, that the chisellers employed to repair the faults removed no less than 70 tons of bronze, which was given them, besides 300,000 francs for their work. The statues made by the Kellers at Versailles were found, on chemical analysis, to consist of:—

	No. 1.	No. 2.	No. 3.	The mean.
Copper	91·30	91·68	91·22	91·40
Tin	1·00	2·32	1·78	1·70
Zinc	6·09	4·93	5·57	5·53
Lead	1·61	1·07	1·43	1·37
	100·000	100·000	100·000	100·000

The analysis of the bronze of the statue of Louis XV. was as follows:—

Copper	82·45	Its specific gravity was 8·482
Zinc	10·30	
Tin	4·10	
Lead	3·15	
	100·00	

The bronzes of France, according to M. L. E. Rivot, contain nearly always four metals, copper, tin, lead, and zinc. They may contain also very small and variable quantities of iron, nickel, arsenic, antimony, and sulphur.

The alloys most proper for bronze to be afterwards struck for medals is composed of from 8 to 12 parts of tin and from 88 to 92 of copper; to which if 2 or 3 parts in the hundred of zinc be added, they will make it assume a finer bronze tint. The alloy of the Kellers is famous for this effect. The metal should be subjected to three or four successive stamps of the press, and be softened between each blow by being heated and plunged into cold water.

The addition of a small proportion of phosphorus has recently been recommended to improve the quality of bronze.

The bronze of bells, or bell-metal, is composed, in 100 parts, of copper 78, tin 22. This alloy has a fine compact grain, is very fusible and sonorous. The other metals sometimes added are rather prejudicial, and merely increase the profit of the founders. Some of the English bells consist of 80 copper, 10·1 tin, 5·6 zinc, 4·3 lead; the latter metal, when in such large quantities, is apt to cause isolated drops, hurtful to the uniformity of the alloy.

The *Tam-tams and Cymbals of Bronze*.—The Chinese make use of bronze instruments forged by the hammer, which are very thin and raised up in the middle; they are called gongs, from the word *tshoung*, which signifies a bell. Klaproth has shown that they contain nothing but copper and tin, in the proportion of 78 of the former metal and 22 of the latter. Their specific gravity is 8·815. This alloy, when newly cast, is as brittle as glass; but being plunged at a cherry-red heat into cold water, and confined between two discs of iron to keep it in shape, it becomes tough and malleable. The cymbals consist of 80 parts copper and 20 tin.

Bronze vessels, naturally brittle, may be made tenacious by the same ingenious process, for which the world is indebted to M. Darcey. Bronze mortars for pounding have their lips tempered in the same way.

Cannon Metal consists of about 90 or 91 copper, and 10 or 9 of tin. From the experiments of Papacino d'Antony, made at Turin, in 1770, it appears that the most proper alloy for great guns is from 12 to 14 parts of tin to 100 of copper; but the Comte Lamartillière concluded, from his experiments made at Douay, in 1786, that never less than 8 nor more than 11 of tin should be employed in 100 parts of bronze.

Gilt Ornaments of Bronze.—This kind of bronze should be easy of fusion, and take perfectly the impression of the mould. The alloy of copper and zinc (brass) is, when fused, of a pasty consistence, does not make a sharp cast, is apt to absorb too much amalgam, is liable to crack in cooling, and is too tough or too soft for the chaser or turner; and if the quantity of zinc was increased, to make the metal harder, it would lose the yellow colour suitable to the gilder. A fourfold combination of copper, zinc, tin, and lead is preferable for making such ornamental bronze articles; and the following proportions are probably the best, as they unite closeness of grain with the other good qualities. Copper 82, zinc 18, tin 3 or 1, lead $1\frac{1}{2}$ or 3. In the alloy which contains most lead, the tenacity is diminished and the density is increased, which is preferable for pieces of small dimensions. Another alloy, which is said to require for its gilding only two-thirds of the ordinary quantity of gold, has the following composition: copper 82·247, zinc 17·481, tin 0·238, lead 0·024.

The antique bronze colour is given to figures and other objects made from these alloys by the following process:—Two drachms of sal-ammoniac, and half a drachm of salt of sorrel, (binocalate of potash,) are to be dissolved in fourteen ounce measures (English) of colourless vinegar. A hair pencil being dipped into this solution, and pressed gently between the fingers, is to be rubbed equally over the clean surface of the object slightly warmed in the sun or at a stove; and the operation is to be repeated till the wished-for shade is obtained.

The bronze founder ought to melt his metals rapidly, in order to prevent the loss of tin, zinc, and lead by their oxidisement. Reverberatory furnaces have been long used for this operation, the best being of an elliptical form. The furnaces with dome tops are employed by the bell founders, because, their alloy being more fusible, they do not require so intense a heat; but they also would find their advantage in using the most rapid mode of fusion. The surface of the melting metals should be covered with small charcoal or coke; and when the tin is added, it should be dexterously thrust to the bottom of the melted copper. Immediately after stirring the melted mass so as to incorporate its ingredients, it should be poured out into the moulds. In general, the metals most easily altered by the fire, as the tin, should be put in last. The cooling should be as quickly as possible in the moulds, to prevent the risk of the metals separating from each other in the order of their density, as they are very apt to do. The addition of a little iron—in the form of tin plate—to bronze, is reckoned to be advantageous.

One part of tin, and two parts of copper (nearly one atom of tin and four of

copper, or more exactly 100 parts of tin and 215 copper), form the ordinary speculum metal of reflecting telescopes, which is of all the alloys the whitest, the most brilliant, the hardest, and the most brittle. The alloy of 1 part of tin and 10 of copper (or nearly one atom of the former to eighteen of the latter), is the strongest of the whole series.

Ornamental objects of bronze, after being cast, are commonly laid upon red-hot coals till they take a dull red heat, and are then exposed for some time to the air. The surface is thereby freed from any greasy matter, some portion of the zinc is dissipated, and the alloy assumes more of a coppery hue, which prepares for the subsequent gilding. The black tinge which it sometimes gets from the fire may be removed by washing it with a weak acid. It may be made very clean by acting upon it with nitric acid, of specific gravity 1.324, to which a little common salt and soot have been added, the latter being of doubtful utility; after which it must be well washed in water, and dried with rags or sawdust.

For the following Table we are indebted to Mr. Robert Mallet, F.R.S., whose investigations in this direction have been most extensive, and as accurate as they are extensive:—

	Chemical Constitution	Composition by Weight per Cent.	Atomic Weight	Specific Gravity	Fracture ¹	Colour of Fracture	Ultimate Cohesion per Square Inch	Inverse Order of Ductility	Order of Malleability at 600° F.	Inverse Order of Hardness	Inverse Order of Fusibility	Commercial Titles, characteristic Properties in working, &c.	
1	Cu	100.00+	31.6	8.667	E	Tile red	24.6	1	2	10	16	Copper.

Bronze, Phosphorised. By carefully dropping phosphorus on melted bronze or copper a product rich in phosphorus is produced. This alloy is claiming much attention, and will be fully treated of under the head of PHOSPHOR BRONZE AND COPPER, which see. See also ALUMINIUM BRONZE.

Bronze Imports are now included under the heads of Brass, Bronze and Metal, Bronzed and Lacquered. Of these articles the following Imports are given in 1872:—

	Cwts.	£
From Germany	679	7,128
„ Holland	536	4,718
„ Belgium	303	2,317
„ France	4,236	44,102
„ United States of America	7,848	35,331
Other countries	3,773	16,179
Total	17,375	109,774

In the same year the *Exportation* of the same metals is given as—

To all countries 1,018 cwts. valued at 5,650l.

¹ E signifies earthy; c c, coarse crystalline; F c, fine crystalline; o, conchoidal; v, vitreous; v c, vitreous-conchoidal; T c, tabular crystalline.

² All these alloys are found occasionally in bells and specula with mixtures of Zn and Pb.

BRONZE PAINT. Bronze paint, commonly called gold paint, is made by mixing gold-coloured bronze powder with pure turpentine as a vehicle. The turpentine of commerce has at all times an acid reaction, which is detrimental to the colour of the metal powder. The turpentine used for this purpose has, therefore, to be mixed with lime to neutralise the acid before it is thus employed.

BRONZE POWDERS have been much used of late in the decorative painting of houses, &c. They are prepared of every shade, from that of bright gold to orange, dark copper, emerald green, &c. Pale gold is produced from an alloy of $13\frac{1}{4}$ of copper and $2\frac{3}{4}$ of zinc; crimson metallic lustre—from copper: ditto, paler, copper and a very little zinc; green bronze with a proportion of verdigris; another fine orange by $14\cdot4$ copper and $1\frac{3}{4}$ zinc; another ditto, $13\frac{3}{4}$ copper and $2\cdot4$ zinc: a beautiful pale gold from an alloy of the two metals in atomic proportions.

The alloy is laminated into very fine leaves with careful annealing, and these are levigated into impalpable powders along with a film of fine oil to prevent oxidisement, and to favour the levigation.

Mr. Brandeis, in his account of his articles of manufacture furnished to the New York Exhibition, says:—

‘Bronzes, or, more correctly, metallic powders resembling *gold dust*, were invented in 1648, by a monk, at Furth, in Bavaria, named Theophrastus Allis Bombergensis. He took the scraps or cuttings of the metallic leaves then known as ‘Dutch leaf,’ and ground them with honey. This roughly made bronze powder was used for ornamenting parchments, capital letters in Bibles, choral books, &c.’

At Furth bronze powders are largely made for Europe, and with little change or improvement. There are four sorts of Dutch leaf:—

Common leaf, soft, and of reddish cast, composed of 25 or 30 per cent. of zinc to 75 or 70 per cent. of copper.

French leaf contains more zinc, is harder, less ductile, and has a purer yellow colour.

Florence leaf has a larger proportion of zinc, and is of a greenish gold colour; and lastly,

White leaf, composed of tin. The more zinc these alloys contain, the harder, the more brittle, and more difficult are they to work into perfect leaves. The manner of beating is similar to the mode for producing gold leaves.

The scraps, cuttings, and fragments of these leaves are the materials for the German bronze powders. First brushed through a sieve and ground with gum water on marble slabs for six hours, the gum washed out, the powders sorted, dried, and a coating of grease given to make them appear more brilliant, and to protect them from oxidation. Varieties of colour, such as orange, &c., are produced by a film of sub-oxide upon the surface of the particles. The price of bronze powders depends upon the demand, and the supply of the waste material of the metal leaves, and prices change accordingly.

Messrs. Brandeis patent their process, and in place of being dependent upon uncertain supplies of metal of unknown composition, they take the metals at once in a state of purity (say copper by voltaic precipitation): it is alloyed with zinc, cast into ingots, rolled into ribands, cut, annealed, and rolled until the metal is thin and leaf-like; then it is taken to a steam-mill, and ground. The bronze powder is washed out and dried, then introduced into an air-tight room, with an arrangement of boxes; the air of the chamber is set in violent motion by bellows, and the powder diffused throughout; the bronze powders are deposited, the finest in the upper boxes, and the coarser powders below. When settled, *mineral* varnish is introduced; the boxes fitted with tight lids are made to revolve, and the particles are thus rapidly coated, and the highest metallic brilliancy imparted. Different shades of colour, pink, crimson, &c., are produced by submitting the powder to heat and oxidation before the rapid revolutions of the varnishing boxes.

The quantity thus produced by one firm, with three steam-engines at work, enables the finished bronze powders to be produced at a rate about equal to the price the German manufacturer has to pay for his materials—the cuttings and scraps of leaves. Hence, for the purposes of trade and art, a large exportation of bronze powders takes place from America to Europe, South America, and China.

The bronze powders are largely used in japanning, bronzing tin and iron goods, ornamental works of paper, wood, oil-cloth, leather, &c.; while sign-boards and the decoration of public buildings have effective metallic brilliant surfaces of beauty and durability. In fact, for ornamental decorations, the demand steadily increases.

In Holland and Germany the subject has been examined, with the view of ascertaining the effect of chemical composition.

De Heer E. R. König has given a Table of the analyses of the best European samples of bronze powders and leaves (*Volkshight*):—

	Copper	Zinc	Iron	Tin
	Per cent.	Per cent.	Per cent.	Per cent.
1. Light yellow	82·38	16·69	0·16	0
2. Gold yellow	84·50	15·30	0·07	0
3. Messing yellow, or brass yellow colour	90·	9·61	0·20	0
4. Copper bronze, orange colour	98·93	0·73	0·08	0
5. Copper red, high shade of purple colour	99·90	0·00	trace	0
6. Purple violet	98·22	0·5	0·30	trace
7. Light green	84·32	15·02	0·03	trace
8. Tin white or leaden grey	0·00	2·39	0·56	97·46

Vanadate of copper has recently been recommended as a new bronze. Dr. B. W. Gerland has shown that a solution of vanadate of copper in aqueous sulphurous acid deposits brilliant yellow crystals, after part of the sulphurous acid has been removed by boiling. These crystals are quite uniform in appearance, and contain cupric oxide, vanadic acid, and sulphurous acid. They change rapidly, under the influence of air, their beautiful metallic lustre quickly disappearing, and the yellow colour changing to a dark green. If, however, these crystals are removed from the mother-liquor, and treated with fresh sulphurous acid, although in the first instance formed in sulphurous acid solution, they now decompose, and two fresh kinds of crystals, the one brown the other orange yellow, are formed. Continuing to add sulphurous acid, the brown crystals are redissolved, while the orange yellow are left intact.

After filtration, washing, and drying, a residue is left of microscopic scales of a deep orange-yellow colour, possessing a most beautiful lustre. They are free from copper and sulphur, and are perfectly unalterable in the air.

The composition of this substance previously dried over vitriol is, according to analysis, as follows :—

Water (loss by heating)	8·73
Pentoxide of vanadium	91·06
Impurities	0·21
	100·00

These numbers correspond to the formula of metavanadic acid, which requires—

Water	8·97
Pentoxide of vanadium	91·03
	100·00

In some instances, Dr. Gerland obtained the same bronze or gold-like substance by treating vanadate of copper suspended in water with sulphurous acid gas; but in many others the effect of the gas was the formation of vanadic oxide in solution.

The vanadate of copper used in these experiments was prepared by precipitation from vanadate of ammonia by sulphate of copper. The mother-liquor contained both copper and vanadic acid. After evaporation the latter is found in the residue as metavanadic acid, with the same metallic appearance as that above described, and can be obtained by washing with water. The crystal, however, obtained in this manner most obstinately retains copper, sometimes to the extent of 12 per cent. Repeated treatment with sulphurous acid is the best method of purification. A sample of the bronze as thus prepared was analysed by Professor Roscoe, who found—

Water	9·12
Pentoxide of vanadium	90·88
	100·00

Samples of vanadium bronze obtained by these three different methods have the same composition, the same appearance, and the same chemical properties. Vanadium bronze is essentially distinguished from the amorphous brick-red hydrated vanadic acid by its indifference to reagents. Sulphurous acid scarcely acts on it, neither does ammonia, and even a solution of carbonate of soda only dissolves it after long-continued boiling. In the air it is perfectly permanent. It is probable that this metavanadic acid will become a favourite bronze, and be rated at even a higher value than gold bronze.

BRONZING. The process for giving to metals, plaster, wood, or any other body, a bronze-like surface. Various processes have been adopted for producing this effect.

When brass castings are to be bronzed, it is essential, in the first place, that they should be thoroughly cleansed from grease, and brightened either with the file or emery-paper, or by boiling in a strong ley and then scouring with fine sand and water. Vinegar alone is sometimes employed to produce the green bronze colour; sometimes dilute nitric acid, and often the muriate of ammonia (*sal-ammoniac*). This latter salt and vinegar are frequently combined, and often a little common table salt is added to the bronzing fluid.

Coins and medals may be bronzed with the following solution:—2 parts of verdigris and 1 part of sal-ammoniac are to be dissolved in vinegar; the solution is to be boiled, skimmed, and diluted with water till it has only a weak metallic taste, and upon further dilution lets fall no precipitate. This solution is made to boil briskly, and is poured upon the objects to be bronzed. These are well washed with clean water, and then lacquered.

To give fresh-made bronze objects an antique appearance, three quarters of an ounce of sal-ammoniac, and a drachm and a half of binoxalate of potash (salt of sorrel) are to be dissolved in a quart of vinegar, and a soft rag or brush moistened with this solution is to be rubbed over the clean bright metal till its surface becomes entirely dry by the friction. This process must be repeated several times to produce the full effect; and the object should be kept a little warm. Copper acquires very readily a brown colour by rubbing it with a solution of the common liver of sulphur, or sulphuret of potassium.

The Chinese are said to bronze their copper vessels by taking 2 ounces of verdigris, 2 ounces of cinnabar, 5 ounces of sal-ammoniac, and 5 ounces of alum, all in powder, making them into a paste with vinegar, and spreading this pretty thick like a pigment on the surfaces previously brightened. The piece is then to be held a little while over a fire, till it becomes uniformly heated. It is next cooled, washed, and dried; after which it is treated in the same way once, and again till the wished-for colour is obtained. An addition of sulphate of copper makes the colour incline more to chestnut brown, and of borax more to yellow. It is obvious that the cinnabar produces a thin coat of sulphuret of copper upon the surface of the vessel, and might probably be used with advantage by itself.

To give the appearance of antique bronze to modern articles, we should dissolve 1 part of sal-ammoniac, 3 parts of cream of tartar, and 6 parts of common salt in 12 parts of hot water, and mix with the solution 8 parts of a solution of nitrate of copper of specific gravity 1.160. This compound, when applied repeatedly in a moderately damp place to bronze, gives it in a short time a durable green coat, which becomes by degrees very beautiful. More salt gives it a yellowish tinge, less salt a bluish cast. A large addition of sal-ammoniac accelerates the operation of the mordant.

The best and most rapid bronzing liquid, which may be applied to copper, brass, iron, or to new bronze, with equal advantage, is a solution of the chloride of platinum (*nitro-muriate of platinum*), called chemical bronze; but it is expensive. With the chloride of platinum, almost any colour can be produced, according to the degree of dilution and the number of applications.

Some beautiful effects are produced upon bronze, and also upon iron castings, by treating them with dilute acids. The action here is scarcely to be described as bronzing; it is, in fact, merely developing the true colour of the metal or alloy.

With the view of rendering the action of the bronzing liquid as uniform as possible, small articles are dipped; for larger articles, the bronzing liquid is *dabbed* on plentifully with a linen rag. The dabbing process is to prevent the occurrence of streaks, which might arise if the liquid were applied in straight strokes. When properly bronzed and washed, the work is usually black-leaded, to give it a polished appearance.

Bronzing of Objects in Imitation of Metallic Bronze.—Plaster of Paris, paper, wood, and pasteboard, may be made to resemble pretty closely the appearance of articles of real bronze, modern or antique. The simplest way of giving a brilliant aspect of this kind is with a varnish made of the waste gold-leaf of the beater, ground up on a porphyry slab with honey or gum-water. A coat of drying linseed-oil should be first applied, and then the metallic powder is put on with a linen dossil. Mosaic gold ground up with six parts of bone-ashes has been used in the same way. When it is to be put on paper, it should be ground up alone with white of eggs or spirit varnish, applied with a brush, and burnished when dry. When a plate of iron is plunged into a hot solution of sulphate of copper, it throws down fine scales of copper, which being repeatedly washed with water, and ground along with six times its weight of bone-ashes, forms a tolerable bronzing.

Browning of Gun-Barrels and other Arms.—By this process the surface of several articles of iron acquire a shining brown colour. This preparation, which protects the

iron from rust, and also improves its appearance, is chiefly employed for the barrels of fowling-pieces and soldiers' rifles, to conceal the fire-arms from the game and the enemy. The finest kind of browning is the Damascus, in which dark and bright lines run through the brown ground.

This operation consists in producing a very thin uniform film of oxide or rust upon the iron, and giving a gloss to its surface by rubbing wax over it, or coating it with a shell-lac varnish.

Several means may be employed to produce this rust speedily and well. The effect may be obtained by inclosing the barrels in a space filled with the vapour of muriatic acid. Moistening their surface with diluted muriatic or nitric acid will answer the same purpose. But the most common material used for browning is the butter or chloride of antimony, which, on account of its being subservient to this purpose, has been called *browning salt*. It is mixed uniformly with olive-oil, and rubbed upon the iron slightly heated, which is afterwards exposed to the air, till the wished-for degree of browning is produced. A little aquafortis is rubbed on after the antimony, to quicken its operation. The brown barrel must be then carefully cleaned, washed with water, dried, and finally polished, either by the steel burnisher, or rubbed with white wax, or varnished with a solution of 2 ounces of shell-lac and 3 drachms of dragon's blood, in 2 quarts of spirits of wine.

The following process may also be recommended:—Make a solution with half an ounce of aquafortis, half an ounce of sweet spirits of nitre, 1 ounce of spirits of wine, 2 ounces of sulphate of copper, and 1 ounce of tincture of iron, in so much water as will fill together a quart measure. The gun-barrel to be browned must first of all be filed and polished bright, and then rubbed with unslaked lime and water to clear away all the grease. Its two ends must now be stopped with wooden rods, which may serve as handles, and the touch-hole must be filled with wax. The barrel is then to be rubbed with the solution, applied to linen rags or a sponge, till the whole surface be equally moistened; it is allowed to stand 24 hours, and is then scrubbed off with a stiff brush. The application of the liquid and the brushing may be repeated twice or oftener, till the iron acquires a brown colour. After the last brushing, the barrel must be washed with plenty of boiling water containing a little potash, then washed with clean water, dried, rubbed with polishing woods, and then coated with shell-lac varnish.

BROMIDES. Compounds of bromine with electro-positive elements.

BROMINE. (*Symb. Br.*; *Atomic weight*, 80. *Density in liquid state*, 2·97. *Density of vapour by experiment*, 5·39; *by calculation*, 5·536, on supposition of the density of hydrogen being 0·0692).—This element exists in very small quantity in sea-water, and to a larger extent in certain mineral springs, as those of Kreuznach and Kissingen. The water of the Dead Sea is comparatively rich in bromine—a sample taken from a depth of 300 mètres having yielded M. Lartet 0·7 per cent. of this element. The mother-liquors of many brine springs, especially those of Schönebeck, near Magdeburg, are rich in bromides. The element also occurs in carnallite and some of the other salts worked at Stassfurt, and in two silver ores found in the mines of Mexico and Chile, and known as *bromyrite*, or bromide of silver, and *embolite* or chloro-bromide of silver. *Megabromite* and *microbromite* are names applied to ill-defined varieties of embolite, according as they contain more or less bromine.

Bromine was discovered in 1826, by Balard, of Montpellier, in the bittern produced from the water of the Mediterranean. Bromine is a very interesting substance, and its discovery has had great influence on the progress of theoretical and applied chemistry. It is the only element, save mercury, which exists in the liquid state at ordinary temperatures. The liquid presents a deep brownish-red colour, and emits dense reddish vapours, which are extremely irritating when breathed. Its odour is sufficiently characteristic to have given the element its name (*βράμιος*, a stench). Bromine is slightly soluble in water, one part requiring 30 parts of water for its solution. The aqueous solution is of a yellowish tint when freshly made, but is readily decomposed by exposure to light. It forms a definite crystalline hydrate with five atoms of water. Bromine is much more soluble in alcohol or in ether. Exposed to a temperature of about 145° Fahr. bromine boils, and at 9·5° it freezes to a red crystalline solid.

Preparation 1. From bittern.—Chlorine gas is passed in for some time; this has the effect of combining with the metallic base of the bromide present, the bromine being, in consequence, liberated. When the bittern no longer increases in colour, the operation is suspended or chloride of bromine would be formed, and spoil the operation. The coloured fluid is placed in a large globe, with a neck having a glass stopcock below like a tap funnel, the upper aperture being closed with a stopper. Ether is then added, the stopper replaced, and the whole well agitated. After a short repose, the ether rises to the surface, retaining the bromine in solution. The stopper being

removed to permit the entrance of air, the stopcock is opened, and the aqueous fluid is permitted to run out. As soon as the highly-coloured ethereal solution arrives at the aperture in the stopcock, the latter is shut; a quantity of solution of potash is then poured, by the upper aperture, into the globe, and the stopper is replaced. The whole is now to be agitated, by which means the bromine combines with the potash, forming a mixture of bromate of potash and bromide of potassium. The stopcock is again opened, and the aqueous fluid received into an evaporating vessel, boiled to dryness, and ignited. By this means the bromate of potash is all converted into bromide of potassium. The bromine may be procured from the bromide of potassium by distillation with peroxide of manganese and sulphuric acid. In this operation one equivalent of bromide, two equivalents of sulphuric acid, and one of peroxide of manganese, yield one equivalent of sulphate of manganese, one of sulphate of potash, and one of bromine; or, in symbols, $KBr + 2SO^2 + MnO^2 = KO,SO^3 + MnO,SO^3 + Br$. ($2KBr + 2SO^3 + MnO^2 = K^2SO^4 + MnSO^4 + Br^2$). The reaction, in fact, takes place in two stages, but the ultimate result is as represented in the equation.

Preparation 2.—In some saline springs where bromine is present, accompanied by considerable quantities of salts of lime, &c., the brine may be evaporated to one-fourth, and, after repose, decanted or strained from the deposit. The mother-liquid is to have sulphuric acid added in order to precipitate most of the lime. The filtered fluid is then evaporated to dryness, redissolved in water, and filtered; by this means more sulphate of lime is got rid of. The fluid is then distilled with peroxide of manganese and hydrochloric acid.

Preparation 3.—Bromine may be obtained by Leisler's method, patented in 1866, from the mother-liquors left in the treatment of the salts called carnallite and kainite, found in the mines of Stassfurt in Prussia, and Kalucz in Hungary. When these liquors are heated with bichromate of potash and dilute hydrochloric acid, the bromine is distilled off, and may be condensed in a receiver containing pieces of iron whereby a bromide of iron is formed. Stassfurt is now one of the chief localities for the manufacture of bromine, and about 400 cwts. are produced there annually.

Bromine, like chlorine, may be employed as a disinfectant. In medicine and in photography it is used in the form of certain bromides, such as those of potassium, ammonium, and cadmium. Bromine has also been employed in the preparation of some of the aniline and anthracene colours.

With hydrogen, bromine forms *hydrobromic acid*; and with many of the metals it forms well-defined *bromides*. A *chloride of bromine* is known, as also a *bromide of nitrogen*—the latter being an explosive compound resembling chloride of nitrogen. The only well-developed oxide of bromine is *bromic acid*, BrO^2HO ($HBrO^3$).

Solutions of bromine in water may have their strength determined, even in presence of hydrochloric or hydrobromic acids, by means of a solution of turpentine in alcohol. One quarter of an equivalent of turpentine (34 parts) decolorises 80 parts or 1 equivalent of bromine.

BRONZITE. A silicate of magnesia and protoxide of iron, with a metalloid bronze-like lustre on the cleavage-planes. The species has been lately made to include certain minerals formerly referred to the species *Diallage*—such as the well-known lustrous mineral in the Cornish serpentine. A green variety of bronzite occurs with the diamonds of South Africa.

BROOM, DYERS, or *Greenweed*. The *Genista tinctoria*, a dwarf shrub from the flowers of which a bright yellow colour is obtained, which for dyeing green with woad is said to be preferred by dyers to all other yellows. See **WOAD**.

BROOMS. Sweeping brushes. These are made of cocoa-nut fibre, of date-palm leaves, of broom-corn, and in this country of birch twigs, sedge, the common heath, and of the broom.

BROOM CORN. *Sorghum dura*. Cultivated in America to make brooms, the grains being used as food for poultry. A closely allied grass, the *Holcus saccharatus*, a native of China, abounds in sugar. This grass is generally known by the name of *Sorgho*. It has been used from time immemorial by the inhabitants of China, who extract sugar from it. The Toulon Agricultural Association recommended its introduction into France, to take the place of beet-root. They state that it is richer in sugar than any known plant, except the vine. Beet-root contains from 8 to 10 per cent. of sugar; the sorgho from 16 to 20 per cent., from which about 8 per cent. of pure alcohol can be obtained. The refuse is said to be excellent food for cattle. The plant grows rapidly, and does not require irrigation.

BRORA COAL. An inferior coal lying in the Oolitic deposits of Brora, in Sutherland, Scotland. See **COAL**.

BROSSONETIA PAPYRIFERA. The Paper Mulberry. The fibrous bark is used in China and Japan for the manufacture of a kind of paper, while the Polynesian islanders use it in the preparation of their Tapa cloth.

BROWN BERRIES. A name occasionally given to the fruit of the *Rubus fruticosus*, or common bramble.

BROWN COAL is of a brownish-black colour, and presents, in some cases, the texture of wood, when it is called LIGNITE; but, in some varieties, all organic structure has disappeared, and it is then called Pitch coal, from its strong resemblance to true coal.

The beds of brown coal are usually of small extent, and are of later date than the true carboniferous strata, belonging generally to the Tertiary period.

Brown coal is worked in Saxony and in countries where there is an absence of true carboniferous deposits. It burns with an empyreumatic odour, and generally contains more pyrites than ordinary coal.

At Steierregg, in Southern Styria, brown coal occurs in the form of a basin; and has been opened out through a distance of more than two miles. The coal, from 8 to 16 feet thick, is of good quality. It contains 9 to 14 per cent. of water, and leaves from 5 to 12 per cent. of ash after combustion.

The following is an analysis of a variety from Oregon:—volatile matter, 49·5; fixed carbon, 42·9; ash, 2·7; water, 4·9=100·00.

A variety of brown coal, called the Paper-coal of Rott, near Bonn, and of Erpel on the Rhine, contains numerous remains of freshwater fishes, *Leuciscus papyraceus*; and of frogs, *Palæophrygnos grandipes*. The ashes of this coal are rich in infusorial remains.

For an account of the brown coals of this country, see LIGNITE and BOGHEAD COAL.

The following is a summary of the state of the brown coal-mines of Europe at the dates given, which are the latest returns obtainable, upon which reliance can be placed:—

HANOVER.—Government mines near Münden, on the Steinberg, and near Wallensen, in the Wanzerbruche; and private mines near Dransfeld, produced in

	Centners of 100 lbs.	Value of produce in Thalers=2s. 10½d.
1861	99,177	8,959
1862	108,314	7,526
1863	92,658	6,188

NASSAU produces *Lignit*, a bituminous wood, preserving the ligneous structure; *Pseudolignit*, in which the woody structure is more or less obliterated; *Meerkohl* (literally *sea-coal*), a miry earthy coal resembling turf; *Blätterkohl* (literally *leaf-coal*), a dark-coloured aggregate of decomposed leaves. The total produce in 1864 amounted to 1,032,000 centners (of 50 kilogrammes of 2·204 avoirdupois pounds).

ITALY.—*Lefte Gandino, in the Val Sterina, in Lombardy.* This bed extends over 500 hectares. The lignite produced is of a kind resembling peat. It is sold at 15 francs per ton. *Cadibona, near Savona, in the Gulf of Genoa*, produces about 1,000 tons annually. From *Sarzanella, near Spezia*, 25,240 to 31,300 tons of lignite are extracted yearly. At *Monte Bamboli, between Grosseto and Piombino*, the production, which may amount to 30 tons daily, does not exceed 10,000 tons in the year, as owing to the unhealthiness of the climate, the works cannot be carried on more than seven or eight months. At the *Monte Rufoli or Podemnovo* mine, the field of lignite extends over 2,000,000 square mètres. At *Monte Massi and Castel Tatti* mines, in the year ending June 30, 1865, the amount of lignite produced was about 6,000 tons.

PRUSSIA.—The annual production of brown coal from the beds in the vicinity of Stettin does not exceed 7,000 tons. The total production of brown coal in Prussia was as follows:—

	In Metrical tonnes of 20 Zollverein centners.	Statute tons
1860	3,194,640	
1862	3,815,129	
1864	4,649,527	
1867		5,587,719
1868		5,677,398
1869		6,005,062

Brandenburg.—According to the best information, there were sent to Berlin 462,298 tonnen of Bohemian and Saxon brown coal. *Kottbus.*—The quantity taken from the pits Felix and Conrad, at Borsdorf, Julius at Friedrichshain, and Franz at Klein Kölzig, was about 400,000 tonnen. *Silesia, Breslau.*—One pit in the neighbourhood of Saaran produced 21,000 tonnen, of the value of 2,000 thalers. *Halle.*—There were produced in the district of Meresburg, from the 3 government and 192 private works, the amount of 12,255,365 tonnen; in the government district of Magdeburg, 7,794,563 tonnen; in the total district of the Bergamt of Halle, 24,149,214 tonnen.

Rhine, Essen.—There were produced at the pit Nachtigall, near Höxter, 10,873 tonnen of brown coal, value 881 thalers. Of Brown coal, or Lignite, the produce in the Zollverein amounted in 1861 to 4,622,312 tonnen, of the value of 16,631,122 francs. Prussia alone produced 4,427,442 tonnen, of the value of 11,396,239 francs. The total produce in the Prussian States will be seen in the following table:—

	1862 Metrical tonnen.	1861 Metrical tonnen.
Stassfurt-Schönebeck	746,529	612,300
Weissenfels	368,455	334,800
Halle-Eisdorf	325,642	284,300
Bitterfeld	247,340	178,780
Oschersleben	160,856	176,400
Brühl-Euskirchen	137,486	123,950
Aschersleben	122,154	115,600
Frankfort-on-Oder	118,117	89,700
Merseburg-Durrenburg	105,817	85,480
Forty-eight smaller districts	1,482,733	1,193,330
Total	3,815,129	3,194,640

This shows an increase of 620,489 tonnen. Throughout the entire Zollverein, in the year 1863, the brown coal produced at 843 collieries yielded 109,189,899 cwts., valued at 5,061,241 thalers.

AUSTRIA.—The production of Brown coal in Austria, in Vienna centners of 123½ pounds avoirdupois:—

1855	16,439,306	1860	27,780,470
1856	18,760,269	1861	32,086,781
1857	19,923,406	1862	36,235,347
1858	23,223,079	1863 (Statute Tons)	1,990,861
1859	23,702,428	1864	2,090,852

SAXONY.—Here much of the brown coal is collected on or near the surface. This is much finer than that from the pits, and is made up like peat, in the shape of bricks. The bricks made at Margaret Hut amounted in 1862, to 3,000,000, equal to 15,000 cwts., and in 1863 to 2,250,000, equal to 12,000 cwts. In Upper Lusatia, and on the left bank of the Elbe, in 1863, there were only two pits which produced

Situation of Works	Total produce, including Bricks		Number of Bricks made from Refuse and Dust used for Fuel
	bush.	cwts.	
1859—Upper Lusatia	1,975,444	2,963,166	2,381,200
Left bank of Elbe	2,030,413	3,045,619	50,994,000
Total	4,005,857	6,008,785	53,375,200
1860—Upper Lusatia	2,199,560	3,299,340	1,985,600

Left bank of Elbe	3,026,615	4,663,237	57,341,000
Total	5,842,484	8,572,317	61,922,000

more than 400,000 bushels; 3 pits from 200,000 to 400,000 bushels; 4 pits from 100,000 to 200,000 bushels; 19 pits from 50,000 to 100,000 bushels; 36 pits from 20,000 to 50,000 bushels; 62 pits from 5,000 to 20,000 bushels; and 32 pits less than 5,000. Besides these, there were—1 pit belonging to the Crown, producing 424,712 bushels; 4 pits belonging to shareholders, producing 738,939 bushels; and 159 private pits, producing 4,681,833 bushels.

The Brown coal of Saxony was returned as follows in the years given:—

1859	300,439 tons
1860	320,632 "
1861	369,182 "
1862	399,740 "
1863	428,615 "

Bavaria produced in 1861 46,700 tons, from 56 Brown coal works.

" " 1862 46,739 " 49 " "

BOHEMIA.—In the year 1864, there were 306,345 tonnen of Bohemian brown coal brought into the Berlin market.

SWITZERLAND.—The coal-mines of Semsales, Bogens, and St. Martin, produce a lignite-coal of first-rate quality. From 31,300 to 37,560 quintals, or from 2,817 to 3,130 tons, are extracted yearly.

GREECE.—The mines at Koumi produce a kind of coal known as lignite. According to the accounts furnished, 5,000 drachmas per annum is the maximum which has been obtained from these mines since 1849, when the receipts amounted to 10,400 drachmas, and in 1847 to 12,000 drachmas.

BROWN DYE. Upon this subject some general views are given in the article DYEING, explanatory of the nature of this colour. The dye presents a vast variety of tints—from yellow and red to black-brown—and is produced either by mixtures of red, yellow, and blue with each other, or of yellow or red with black, or by substantive colours, such as catechu or oxide of manganese alone. We shall here notice only the principal shades, leaving their modifications to the caprice or skill of the dyer.

Brown, from mixture of other colours.

Wool and woollen cloths must be boiled with $\frac{1}{3}$ th their weight of alum and sulphatartrate of iron, afterwards washed, and rinsed through the madder bath, which dyes the portion of the stuff imbued with the alum red, and that with the salt of iron black, the tint depending upon the proportion of each and the duration of the madder bath.

A similar brown is produced by boiling every pound of the stuff with two ounces of alum and one ounce of common salt, and then dyeing it in a bath of logwood containing either sulphatartrate, acetate, or sulphate of iron; or the stuff may be boiled with alum and tartar, dyed up in a madder bath, and then run through a black bath of iron mordant and galls or sumach. Here the black tint is added to the red till the proper hue be hit. The brown may be produced also by adding some iron liquor to the madder bath, after the stuff has been dyed up in it with alum and tartar. A better brown of this kind is obtained by boiling every pound of wool with two ounces of alum, dyeing it up in cochineal, then changing the crimson thus given into brown, by turning the stuff through the bath after acetate of iron has been added to it.

Instead of cochineal, archil or cudbear, with a little galls or sumach, may be added.

A superior brown is produced upon cotton goods which have undergone the oiling process of the Turkey-red dye. Such goods must be galled, mordanted with alum, sulphate of iron, and acetate of lead (equal to $\frac{2}{3}$ ds of the alum); after washing and drying, dyed in a madder bath, and cleared with a soap boil. The tint of brown varies with the proportion of alum and sulphate of iron.

Brown may be produced by direct dyes.

The decoction of oak-bark dyes wool a fast brown colour, of different shades according to the concentration of the bath. Alum improves the colour.

The bastard marjoram (*Origanum vulgare*) dyes cotton and linen a reddish-brown with acetate of alumina, and wool of a dark brown.

The bark of the mangrove-tree (*Rhizophora mangle*) gives a red-brown colour to wool when boiled with alum and tartar, and a fast chocolate colour when sulphate of iron is added.

The pods of the East Indian *Mimosa cineraria* and the African *Mimosa nilotica*, called the *bablat*, give cotton a brown, with acetate or sulphate of copper.

The root of the water lily (*Nymphaea alba*) gives to cotton and wool beautiful shades of brown. A mordant of sulphate of iron and zinc is first given, and then the wool is turned through the decoction of the root till the wished-for shade is obtained. The cotton must be mordanted with a mixture of the acetates of iron and zinc.

Walnut (*Juglans regia*) peelings, when ripe, contain a dark brown dyestuff, which communicates a permanent colour to wool. The older the infusion or decoction of the peel, the better dye does it make. The stuff is dyed in the lukewarm bath, and needs no mordant, though it becomes brighter with alum; or this dye may be combined with the madder or fustic bath, to give varieties of shade. For dyeing silk, this bath should be hardly lukewarm, for fear of causing inequality of colour.

The peelings of horse-chestnuts may be used for the same purpose: with muriate of tin they give a bronze colour, and with acetate of lead, a reddish brown.

Catechu gives cotton a permanent brown dye, as also a bronze and mordoré, when its solution in hot water is combined with acetate or sulphate of copper, or when the stuff is previously mordanted with the acetates of copper and alumina mixed, sometimes with a little iron liquor, rinsed, dried, and dyed up, the bath being at a boiling heat.

Ferrocyanide of copper gives a yellow-brown or a bronze to cotton and silk.

The brown colour called *carmelite* by the French is produced by 1 lb. of catechu to 4 ozs. of verdigris, with 5 ozs. of muriate of ammonia. The bronze (*solitaire*) is given by passing the stuff through a solution of muriate or sulphate of manganese, with a little tartaric acid, drying, passing through a potash-ley at 4° Baumé, brightening and fixing with solution of chloride of lime.

These examples show in how many ways the browning of dyes may be modified, upon what principles they are founded, and how we have it in our power to turn the shade more or less towards red, black, yellow, blue, &c.

Under the heads of different substances employed by the dyers will be found some description of the methods employed for the purpose of extracting their colours. For some good practical receipts, Love's 'Art of Cleaning, Dyeing, Scouring, and Finishing,' may be consulted.

BROWN HEMATITE. See IRON ORES.

BROWN IRON ORE, or *Limonite*. See IRON ORES.

BROWN OCHRE. The soft and decomposed varieties of brown iron ore.

BROWN SUGAR. Strictly, the common dark Mucovado sugar; ordinarily, the common varieties of West Indian sugar. See SUGAR.

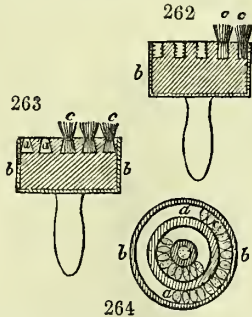

BROWSE. A metallurgical term for a variety of slag.

BRUCINE. ($C^{16}H^{26}N^2O^8$ [$C^{28}H^{50}N^4O^{14}$]; *syn.* Canimarine, Vomicine.) A very bitter and poisonous alkaloid accompanying strychnine in nux vomica and in the false angustura bark (*Brucia antidysenterica*). It is somewhat less poisonous than strychnine, and, like that base, is used in the treatment of paralysis, but in rather larger doses. Brucine is prepared by the same process as strychnine.—C. G. W.

BRUCITE. *Native hydrate of magnesia.*—So called after Dr. Bruce, of New York. This mineral accompanies other magnesia minerals in serpentine. It is broad foliated, folia several inches square being easily obtainable, and either opaque, silvery white, or translucent. Thomson gives its composition: magnesia, 66·67; protoxide of manganese, 1·57; protoxide of iron, 1·18; lime, 0·19; water, 30·39 = 100.

BRUNSWICK GREEN. An oxychloride of copper, used as a pigment. Copper filings or turnings are moistened with a solution of sal-ammoniac, and left in contact with the air. The oxychloride thus forms: it is washed off with water, and dried at a gentle heat.

BRUSHES. (*Brosses*, Fr.; *Bürsten*, Ger.) Since Mr. Mason introduced his mode of securing the hairs in brushes, it has, in all the better class of brushes, been very generally adopted. His patent dates 1830. Modified contrivances, partaking more or less of the original conditions, have been introduced in the manufacture. The principles of Mr. Mason's invention and its subsequent modifications consist in a firmer mode of fixing the knots, or small bundles, of hair into the stock or the handle of the brush. This is done by forming grooves in the stocks of the brushes for the purpose of receiving the ends of the knots of hair, instead of the holes drilled into the wood, as in brushes of the common constructions. These grooves are to be formed like a dovetail, or wider at the bottom than the top; and when the ends of the knots of hair have been dipped into cement, they are to be placed in the grooves and compressed into an oval form, by which the ends of the hair will be pressed outwards, into the recess or wider part of the dovetailed groove; or the grooves may be formed with threads or teeth on the sides, instead of

being dovetailed; and the cement and hairs, being pressed into the teeth or threads, will cause them to adhere firmly to the stock or handle of the brush.

A metal ferrule may be placed on the outside of the stock of the brush, if necessary, and secured by pins or rivets, or in any other convenient manner, which ferrule may also form one side of the outer grove.

Fig. 264 is a plan view of the stock of the round brush; *fig. 263* is a section of the same; *aa* are the dovetailed grooves which are turned out of the wood; *b* is the metal ferrule; *cc* are knots, or small bundles of hair, to form the brush. After a number of the knots of hair are prepared, the ends are to be dipped into proper cement, and then placed into the grooves, when their ends are to be squeezed by a pair of pliers, or other means, which will compress them into the oval shape, as shown in *fig. 264*, and cause the ends of the hairs to extend outward under the dovetailed part of the recess.

The knots of hair are to be successively placed in the grooves, and forced up by a tool against the last knot put in, and so on, until the grooves are filled; *fig. 262* is a brush with teeth or threads of a screw formed upon the sides of the groove; into these teeth or threads the cement and hairs will be forced by the compression, by which means they will be held firmly in the stock of the brush.

BRUSHITE. A hydrated phosphate of lime occurring in the guano of Aves Island and Sombrero in the Caribbean Sea, and named after Professor Brush, of Yale College, U.S.

BRUSH ORE or **BLACK BRUSH.** An iron ore found in the Forest of Dean.

BRUSH WHEELS. In light machinery, wheels are sometimes made to turn each other by means of bristles fixed in their circumference; these are called brush wheels. The term is sometimes applied to wheels which move by their friction only.

BRYLE, or **BRÖIL.** *A mining term.* The loose matter found in a lode near the surface of the earth; probably a corruption of **BEUEYL**.

BUCKING. *A mining term.* Bruising of the ore. A *bucking iron* is a flat iron fixed on a handle, with which the ore is crushed; and a *bucking plate* is an iron plate on which the ore is placed to be crushed.

BUCKING, or **BOWKING.** A process of boiling goods in alkaline liquids for bleaching. See **BLEACHING**.

BUCKRAM. A linen cloth of much strength, made very stiff with size.

BUCKTHORN. (*Rhamnus catharticus*.) This plant is a native of England; it grows to the height of from 15 to 20 feet; its flowers are greenish coloured, and its berries four-seeded. It is the fruit of this plant which is sold under the name of French berries. The juice of these, when in an unripe state, has the colour of saffron; when ripe and mixed with alum, it forms the sap green of the painters; and in a very ripe state, the berries afford a purple colour. The bark also yields a fine yellow dye. See **SAP GREEN**.

The alder buckthorn (*Rhamnus frangula*) grows naturally, and is very abundant in woods and thickets in some parts of Britain. The berries of this species are often substituted for those of the above; but they are easily detected, since they contain only two seeds. In a green state, they dye wool green and yellow; when ripe, bluish grey, blue, and green. The bark also dyes yellow, and, with preparation of iron, black.—*Lawson*.

Rock buckthorn (*Rhamnus saxatilis*), the berries of which are used to dye morocco leather yellow. These, in common with the narrow-leaved buckthorn berries (*R. Clusii*) and those of the yellow-berried buckthorn (*R. infectorius*), are sold as Avignon berries. The wood of the *Rhamnus erythroxylon* (which is a native of Siberia, but grows freely in this climate), in a ground state, yields the bright red colour known to dyers under the name of *red wood*.

BUCKWHEAT. (*Blé Sarrasin*, Fr.; *Buckweizen*, Ger.) The common buckwheat (*Polygonum Fagopyrum*, from *poly*, many, and *gonu*, a knee, in reference to its numerous joints) is cultivated for feeding pheasants and other game; and is now being largely used in France and in this country in distilleries.

'In France, besides being used for feeding fowls, pigs, &c., it is given to horses; and it is said that a bushel of its grains goes further than two bushels of oats, and, if mixed with four times its bulk of bran, will be full feeding for any horse for a week. Its haulm, or straw, is said to be more nourishing than that of clover, and its beautiful pink or reddish blossoms form a rich repast for bees.'—*Lawson*.

It has been stated that the leaves of the common buckwheat (*Polygonum Fagopyrum*), yield, by fermentation, Indigo-blue. On examining this plant, for the purpose of ascertaining whether this statement was correct, Schunck was unable to obtain a trace of that colouring matter; but he discovered that the plant contains a considerable

quantity of a yellow colouring matter, which may very easily be obtained from it. This colouring matter crystallises in small primrose-yellow needles. It is very little soluble in cold water, but soluble in boiling water, and still more soluble in alcohol. Muriatic and sulphuric acid change its colour to a deep orange, the colour disappearing on the addition of a large quantity of water. It dissolves easily in caustic alkalis, forming solutions of a beautiful deep yellow colour, from which it is again deposited in crystalline needles on adding an excess of acid. It is, however, decomposed when its solution in alkali is exposed for some time to the air, being thereby converted into a yellowish-brown amorphous substance, resembling gum. Its compound with oxide of lead has a bright yellow colour, similar to that of chromate of lead. The compounds with the oxides of tin are of a pale but bright yellow colour. On adding protosulphate of iron to the watery solution, the latter becomes greenish, and, on exposure to the air, acquires a dark green colour, and appears almost opaque. The watery solution imparts to printed calico, colours, some of which exhibit considerable liveliness. Silk and wool do not, however, acquire any colour when immersed in the boiling watery solution, unless they have previously been prepared with some mordant. The composition of this substance in 100 parts is as follows:—carbon 50.00, hydrogen 5.55, oxygen 44.45. Its formula is probably $C^{30}H^{20}O^{20}$ [$C^{15}H^{20}O^{10}$]. It appears to be identical with *Rutine*, the yellow colouring matter contained in the *Ruta graveolens*, or common rue, and in capers; and with *Ilixanthin*, a substance derived from the leaves of the common holly. From 1,000 parts of fresh buckwheat leaves, a little more than one part of the colouring matter may be obtained. As the seed of the plant is the only part at present employed, it might be of advantage to collect and dry the leaves, to be used as a dyeing material.—E. S.

The *Tartarian Buckwheat* (*Polygonum Tartarium*) differs from the former in having the edges of its seeds twisted. It is not considered so productive, but it is more hardy; and better adapted for growing in mountainous situations.

The *Dyer's Buckwheat*. (*Polygonum tinctorium*.) This plant was introduced to the Royal Gardens at Kew by Mr. John Blake, in 1776. Authentic information as to its properties as a dye-yielding plant was only received at a comparatively recent period, from missionaries resident in China, where it has always been cultivated for its colouring matter. In Europe, attention was first directed to its growth by M. Delille, of the Jardin du Roi at Montpellier, who in 1835 obtained seeds from the Baron Fischer, Director of the Imperial Gardens at St. Petersburg. It has since that time become sufficiently valuable to render its cultivation as a dye-drug of sufficient importance. The Japanese are said to extract blue dyes from *Polygonum Chinensis*, *P. barbatum*, and the common roadside weed, *P. aviculare*.—Lawson.

BUDDLE. See DRESSING ORES.

BUDDLING. *A mining term.* The process of separating the metalliferous ores from the earthy matters with which they are associated, by means of an inclined hutch, called a *buddle*, over which water flows. It is indeed but an arrangement for availing ourselves of the action of flowing water to separate the lighter from the heavier particles of matter. See DRESSING ORES.

BUDE LIGHT. A highly illuminating flame invented by Sir Goldsworthy Gurney, of Bude, in Cornwall. Oxygen gas is driven through the centre of an argand flame of ordinary coal-gas, by which an intense combustion is established, and hence the high illuminating power is obtained.

BUFF LEATHER. A leather prepared with some albuminous substance and oil. See LEATHER.

BUFF STICKS. Pieces of wood upon which buff leather is fastened; they are used for polishing.

BUGLE. A kind of bead used for ornamenting dresses.

BUHL. Buhl-work consists of inlaid veneers; and differs from marquetry in being confined to decorative scrollwork, frequently in metal, while the latter is more commonly used for the representation of flowers and foliage. Boule, or Buhl, was a celebrated cabinet-maker in France, who was born in 1642 and died in 1732. He was appointed 'Tapissier en titre du Roi,' and he gave his name to this peculiar process of enlaving wood with either wood or metal. See MARQUETRY, PARQUETRY.

BUHR-STONE is a cellular flinty quartz rock, constituting one of the jaspers varieties of the quartz family. It forms a celebrated grit-stone, much used in France and other parts of the Continent for grist mills. Those of La Ferté-sous-Jouarre (Seine-et-Marne) are regarded as superior to all others. In consequence of the necessity for carefully piecing these stones together, they are naturally expensive; yet the demand for buhr-stones continues great. Written also BURR and BURRH.

BUKE or BUCK MUSLIN. A clear muslin woven for tambour working, and used principally for ladies' dresses. It is often called 'book' muslin.

BULL-DOG. A name given to an iron slag. See IRON.

BULLY TREE. A species of *Mimusops* (*mimus*, a mimic, $\epsilon\psi$, appearance) which grows in Demerara and Berbice, where it is used for house frames and other purposes in building, also for the spokes of wheels. It may be obtained nearly 30 feet long, and squares about 25 inches.

BULRUSH, or *Tall Club.* (*Scirpus lacustris*; Celtic, *cirs*, rushes.) The bulrush, belonging to the natural order of *Cyperaceae*, grows naturally on alluvial soils which are occasionally covered with fresh water. A species of *Typha* (Natural Order, *Typhaceae*), is also known commonly as bulrush. It is much used by coopers for putting between the staves of barrels, and by chair-makers. Many other plants belonging to this order are employed for economical purposes, such as forming seats, ropes, mats, and fancy basket-work, also for thatching houses.

BUNCH. A miner's term for an isolated mass of ore. A lode is said to be *bunchy* when the metalliferous ore is found in irregular and sparsely distributed masses, the other portions being made up of valueless earthy minerals.

BUNCHY. In mining. A lode in which the ore occurs in isolated masses scattered through it.

BUNG. A large cork for casks. The name in Persia for hemp, the *Cannabis sativa*.

BUNNY. In mining. A pipe of ore or a mass—not a vein or lode.

BUNTING. An open-made worsted stuff, used for making flags.

BUNTKUPFERERZ. (Ger. Variegated copper ore). This term is commonly applied, even by English mineralogists, to an ore of copper, otherwise known as *Erbescite*, *Phillipsite*, *Bornite*, and *Purple Copper Ore*. By our Cornish miners it is generally known as *Horse-Flesh Ore*. See COPPER, ORES of.

BURGUNDY PITCH. Burgundy pitch, when genuine, is made by melting frankincense (*Abietis resina*) in water and straining it through a coarse cloth. The substance usually sold as Burgundy pitch is, however, common resin incorporated with water and coloured with palm-oil. In some cases American turpentine is employed. See PITCH and TAR.

BURLERS. Women are so called who are engaged in removing from woollen cloths, with tweezers, all irregular threads or hair.

BURNETT'S FLUID. A solution of chloride of zinc is commonly known as Sir William Burnett's disinfecting fluid. It is largely used as a powerful disinfectant.

BURNING HOUSE. A miner's term. In Cornwall the kiln or oven in which the tin and other ores are placed to sublime the volatile constituents, sulphur and arsenic, is so called.

BURNT LEAVINGS. See COPPER.

BURNT SUGAR. See CARMEL.

BURROW. A miner's term for a heap of rubbish.

BUSKS. The flat whalebones, or steel supports for the stays of women.

BUSSORAH GUM. See BASSORA.

BUTT. A large cask. The beer and wine butt should contain three barrels, or 108 imperial gallons. The wine butt formerly held 130 of the old wine gallons.

In the leather trade, a butt is a rounded crop, or a full hide.

BUTTER. (*Beurre*, Fr.; *Butter*, Ger.) Butter is the fatty matter of milk, usually that of the cow. Milk is composed of butter, caseine, sugar of milk, several salts, and water. The butter exists in the form of very small globules of nearly uniform size, quite transparent, and strongly refractive of light. Milk left in repose throws up the lighter particles of butter to the surface as cream. It was imagined that the butter was separated in the process of churning, in consequence of the milk becoming sour; but this is not the case, for milk rendered alkaline by bicarbonate of potash affords its butter fully more readily than acidulous milk. The best temperature for churning milk or cream is 53° F.; that of 60° is too high; and under 50° is too low. By the churning action the heat rises from 3° to 4° F. All the particles of butter are never separated by churning; many remain diffused through the butter-milk, and are easily discoverable by the microscope. These are more numerous in proportion to the bulk of the liquid; and hence it is more economical to churn cream than the whole milk which affords it. It is computed that a cow which gives 1,800 quarts (old English) of milk per annum eats in that time 8,000 lbs. of hay, and produces 140 lbs. of butter. Analysis shows that this weight of hay contains 168 lbs. of fat. The finest flavoured butter is obtained from milk churned not long after it is drawn; but the largest proportion is derived from the cream thrown up by milk after standing 24 hours in a temperature of about 50° F. The butter-milk, which contains the very fermentable substance, *caseine*, should be well separated from the butter by washing with cold water, and by beating with the hands, or preferably, without water, for the sake of fine flavour, by the action of a press.

The Tartars and French have long been in the habit of preserving butter, by

melting it with a moderate heat, whereby are coagulated the albuminous and curdy matters remaining in it, which are very putrescible. This fusion should be made by the heat of a warm bath, about 176° F., continued for some time, to effect the more complete purification of the butter. If in this settled liquefied state it be carefully decanted, strained through a tammy cloth, and slightly salted, it may be kept for a long time nearly fresh, without becoming in any degree rancid, more especially if it be put up in small jars closely covered.

In Cornwall and Western Devon, the first process in the manufacture of butter is the formation of the cream by heat. After the milk has stood for from twelve to twenty hours at rest, so that the cream globules may rise to the surface, it is exposed to a very slow heat, until it acquires a temperature of about 200° F.; care being taken that, if it exceeds this, the milk never boils. The pellicle of cream being formed, the vessel is removed from the fire, and allowed to cool; when cold, the butter is made from this cream in the usual way.

When subjected to microscopical examination, milk is found to consist of infinitely minute globular particles floating in a serous fluid. Raspail says the largest of these globules are not above 1-2500th of an inch in diameter. These globules consist essentially of butter. In the East, butter is prepared for keeping by carefully melting it over a very slow fire, and removing the scum as it rises. Thénard recommends this process, but directs that it should be carried out by the use of a water-bath. If good fresh butter is wrapped in a piece of linen and plunged into a strong brine, it will keep good, without saltiness, for a long period.

Butter is preserved by salting in Ireland, in Holland, and in the Channel Islands. In 1872 we exported 56,322 cwts., of the value of 327,431*l.*—of which 23,431 cwts. were sent to Brazil. See MILK.

BUTTERS, MINERAL. The old chemists called several of the metallic chlorides,—butters; as *butter of antimony*, *butter of tin*, *butter of bismuth*, &c.

BUTTER OF ANTIMONY. An old name for the anhydrous chloride of antimony.

BUTTER OF CACAO. See CACAO.

BUTTER, VEGETABLE. A greasy substance expressed from the kernels of the *Bassia butyracea*, a native of North India. This grease is said to make excellent soap. Shea butter is obtained from the *B. Parkii*, of West Africa, and has been used in making candles and soap. The butter-tree of Sierra Leone is the *Pentadesma butyracea* (Br.), the fruit of which yields much grease, eaten by the negroes.

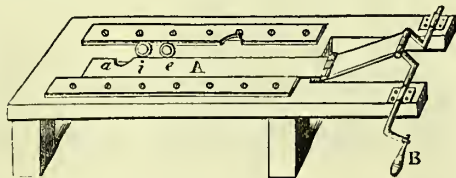

BUTTON MANUFACTURE. This art is divided into several branches, constituting so many distinct trades. Metal, horn, leather, bone, and wood, are the substances frequently employed for buttons, which are either plain, or covered with silk, mohair, thread, and other ornamental materials. The most durable and ornamental buttons are made of various metals, polished, or covered with an exceedingly thin wash, as it is termed, of silver or gold.

The buttons intended to be covered with silk, &c., are termed in general *moulds*. They are small circles, perforated in the centre, and made from those refuse chips of bone which are too small for other purposes. For the large and coarser buttons, pieces of hard wood, are sawn into thin flakes, of an equal thickness; from which, by a machine, the button moulds are cut out at two operations.

White metal and brass buttons, as well as plated buttons, are stamped by the fly-press, out of copper-plate, covered on one side with silver at the flattening mill. The copper side is placed upwards in stamping, and the dye or hole through which they are stamped is rather chamfered at its edge, to make the silver turn over the edge of the button. The backs are stamped in the same manner as the gilt buttons. The shanks are soldered on with silver solder, and heated, one by one, in the flame of a lamp, with a blow pipe urged by bellows. The edges are now filed smooth in the lathe, care being taken not to remove any of the silver which is turned over the edge.

They are next dipped in acid, to clean the backs, and boiled in cream of tartar and silver to whiten them; after which they are burnished, the backs being first brushed clean by a brush held against them as they revolve in the lathe. The mode of burnishing is the same as for gilt buttons. When the buttons are first cut they have exceed-

265

ingly sharp edges, to correct which and to produce a round, smooth, wire-like edge, they are rolled between two parallel pieces of steel, one moving horizontally

past the other, which is fixed, and both of them containing polished grooves on their corresponding faces. To the movable piece *A*, *fig.* 265, motion is given by means of the handle *B*. In both the grooved pieces, which are about eighteen inches in length, there are semicircular openings as at *a*, which, by corresponding once during each revolution of the hand, admit of the blank *e* being dropped into the grooves, after which it is carried, revolving as it proceeds, between the pieces of steel, till coming to the hole *i*, it drops through into a basket. This operation is performed with amazing celerity by a boy, who drops the blanks into the cavity with his left hand, while he turns the handle with his right: they are now ready to receive the shanks.

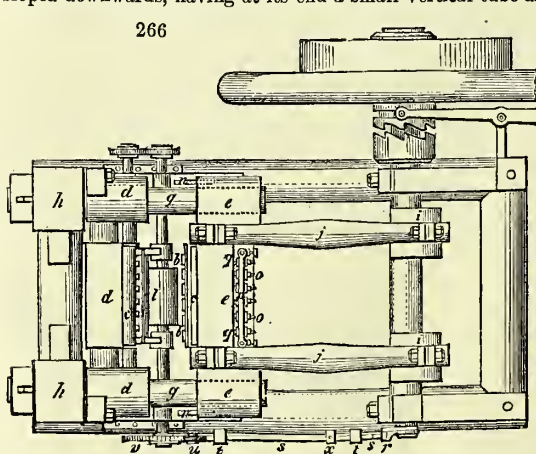

Button shanks are made by hand from brass or iron wire, bent and cut by the following means:—

The wire is lapped spirally round a piece of steel bar. The steel is turned round by screwing it into the end of the spindle of a lathe, and the wire by this means lapped close round it till it is covered. The coil of wire thus formed is slipped off, and a wire fork or staple with parallel legs put into it. It is now laid upon an anvil, and by a punch the coil of wire is struck down between the two prongs of the fork, so as to form a figure 8, a little open in the middle. The punch has an edge which marks the middle of the 8, and the coil being cut open by a pair of shears along this mark, divides each turn of the coil into two perfect button shanks or eyes.

Buttons to be gilded are stamped out from copper (having sometimes a small alloy of zinc), laminated in the flattening mill to the proper thickness. These circular pieces, called blanks, are annealed in a furnace to soften them; and the maker's name, &c. is struck on the back by a monkey, which is a machine very similar to a pile engine. This stamp also renders the face very slightly convex, that the buttons may not stick together in the gilding process. The burnishing is performed by a piece of hamatite or blood-stone, fixed into a handle, and applied to the button as it revolves by the motion of the lathe.

A great number of the buttons, thus prepared for gilding, are put into an earthen pan, with the proper quantity of gold to cover them, amalgamated with mercury in the following manner:—The gold is put into an iron ladle, and a small quantity of mercury added to it; the ladle is held over the fire, till the gold and mercury are perfectly united. This amalgam being put into the pan with the buttons, as much aquafortis, diluted with water, as will wet them all over, is thrown in, and they are stirred up with a brush, till the acid, by its affinity to the copper, carries the amalgam to every part of its surface, covering it with the appearance of silver. When this is perfected, the acid is washed away with clean water. This process by the workman is called quicking.

The old process, in gilding buttons, called the drying-off, was exceedingly pernicious to the operator, as he inhaled the vapour of the mercury, which is well known to be a virulent poison. In order to obviate this, the following plan of apparatus has been employed with success:—The vapour, as it rises from the pan of buttons heated by a charcoal fire, is conducted into an oblong iron flue or gallery, gently sloped downwards, having at its end a small vertical tube dipping into a water cistern

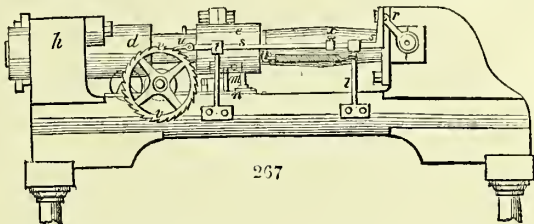

work; a portion of the description is retained, especially such parts of his machinery as appear to be still in use.

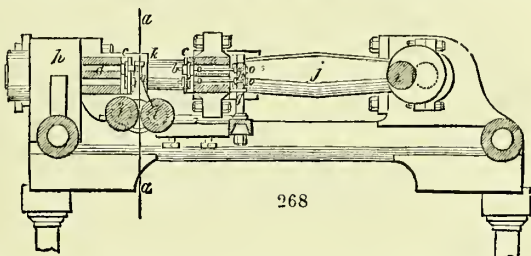

for condensing the mercury, and a large vertical pipe for promoting the draught of the products of the combustion. By act of parliament 5 grains of gold are allotted for the purpose of gilding 144 buttons, though they may be tolerable well gilt by half that quantity. In this last case, the thickness would be about the 214,000th part of an inch.

Mr. Holmes of Birmingham patented a process which was fully described in the former edition of this

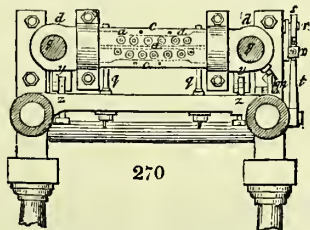

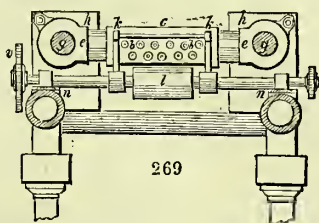

Having explained the peculiar form of his improved metallic shanks for buttons, and the tools employed in making the same, he proceeds to describe the machinery or apparatus by which he carries his invention into effect. He takes a sheet of metal, say about 30 or 40 feet long, and of the proper width and thickness, which thin sheet is to be wound upon a roller, and placed above the machine, so that it can be easily drawn down

into the machine as required for feeding the punches and dies. *Fig. 266* is a plan-view of a machine intended to work any convenient number of sets of punches and dies placed in rows. *Fig. 267* is a side view, and *fig. 268* a longitudinal section, taken through the machine between the punches and counter dies, *fig. 269* representing its appearance at the face of the punches, and *fig. 270* the opposite view of the counter dies. *a a* are the punches; *b b*, the counter dies;

each being mounted in rows in the steel plates *c c*, fixed upon two strong bars *d* and *e*, by counter-sunk screws and nuts; the punches and dies being retained in their proper position by the plates, which are screwed on to the front of the steel plates, and press against the collars of the punches and dies. The bars *d* and *e* are both

mounted on the guide-pins *g g*, fixed in the heads *h h*, of the frame, which guide-pins pass through the bosses on the ends of the bars. The bar *d* is stationary upon the guide-pins, being fixed to the heads *h h*, by nuts and screws passed through ears cast on their bosses. The bar *e* slides freely upon the guide-pins *g g*, as it is moved backwards and forwards by the crank *i i*, and connecting-rods *j j*, as the crank-shaft revolves. The sheet of thin iron to be operated upon is placed, as before stated, above the machine; its end being brought down as at *a a*, and passed between the guide-rod and clearing plate *k*, and between the pair of feeding-rollers *l l*, which, by revolving, draw down a further portion of the sheet of metal between the punches and dies, after each operation of the punches.

As the counter dies advance towards the punches, they first come in contact with the sheet of metal to be operated upon; and after having produced the pressure which cuts out the discs, the perforations of the sheet are pushed on to the ends of the punches by the counter dies; and in order that the sheet may be allowed to advance, the carriage which supports the axes of the feeding-rollers, with the guide-rod and clearing-plate, are made to slide by means of the pin *m*, which works in a slot in the sliding-piece *n*, bearing the axis of the feeding-roller *l l*, the slide *n* being kept in its place on the framework by dovetailed guides, shown in *fig. 270*.

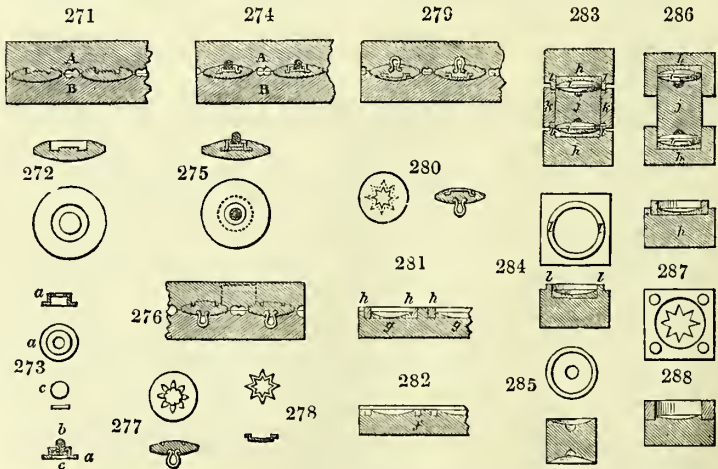

When the counter dies have advanced near to the sheet of metal, the pin *m* comes in contact with that end of the slot in the piece *n* which is next to the punches, and forces the carriage with seed-rollers and clearing-plate, and also the sheet of metal,

onwards, as the dies are advanced by the reaction of the cranks; and after they have cut out the discs, and raised the shanks, the sheet of metal will remain upon the punches; and when the bar *e* returns, the finished backs and shanks are forced out of the counter dies, by the clearing-pins and rods *o o*, which project through the bar *e*, and through the holes before mentioned in the counter dies; these clearing-pins being stationary between the bars *p p*, mounted upon the standard *g g*, on the cross bar of the frame, as shown in *figs.* 266, 268, 269. Immediately after this is done, the pins *m* come in contact with the other ends of the slots in the pieces *n*, and draw back the feeding-rollers *l l*, together with the clearing-plate *k* and the sheet of metal, away from the punches, into the position represented in the figures.

At this time the feeding of the metal into the machine is effected by a crank-pin *r*, on the end of the crank-shafts coming in contact with the bent end of the sliding-bar *s*, supported in standards *t t*; and as the crank-shaft revolves, this pin *r* forces the bar *s* forward, and causes the tooth or pall *u*, on its reverse end, to drive the ratchet-wheel *v*, one or more teeth; and as the ratchet-wheel *v* is fixed on to the end of the axle of one of the rollers *l*, it will cause that roller to revolve; and by means of the pair of spur-pinions on the other ends of the axles of the feeding rollers, they will both revolve simultaneously, and thereby draw down the sheet of metal into the machine. It will be perceived that the standards which support the clearing-plate and guide-bar are carried by the axles of the feeding rollers, and partake of their sliding motion: also that the clearing-pins *o*, are made adjustable between the bars *p*, to correspond with the counter dies. There is an adjustable sliding-stop *x* upon the bar *s*, which comes in contact with the back standard *t*, and prevents the bar *s* sliding back too far, and consequently regulates the quantity of sheet metal to be fed into the machine by the pall and ratchet-wheel, in order to suit different sizes of punches and dyes. In case the weight of the bar *e*, carrying the counter dies, should wear upon its bearings, the guide-pins *g g* have small friction rollers *y y*, shown under the bosses of this bar, which friction rollers run upon adjustable beds or planes, *z z*, by which means the guide-pins may be partially relieved from the weight of the bar *e*, and the friction consequently diminished.

BUTTONS OF HORN.—Mr. Thomas Harris obtained, in April 1841, a patent for improvements in the manufacture of horn buttons, and in their dies. His invention relates, first, to a mode of applying flexible shanks to horn buttons; secondly, to a mode of ornamenting horn buttons, by enlaving the front surface thereof; thirdly, to a mode of ornamenting what are called horn buttons, by gilding or silvering their surfaces; fourthly, to a mode of constructing dies, by applying separate boundary circles to each engraved surface of a die, by which the process of engraving, as well as the forming of accurate dies, will be facilitated; fifthly, to a mode of constructing dies, used in the manufacture of horn buttons, whereby the horn or hoof employed will not be permitted to be expressed beyond the circumference of the button.

Fig. 271 represents, in section, a pair of dies, A and B, used in producing the

improved horn buttons, according to the first improvement; the upper die A is made to produce the back surfaces of the buttons, and the recess or groove for receiving the

flexible shank. *Fig. 272* shows, in section and back view, the form of a button produced by the dies.

Buttons thus formed are now ready to receive flexible shanks; and if the buttons are to have plain smooth front surfaces, then, in fixing the flexible shanks, the same kind of under die, *B*, may be used; but if the front surface of the button is to be embossed or ornamented, then, in place of that die, a similar one, having engraved or suitably ornamented surfaces, is to be used. When fixing the shanks to buttons, the lower or face die, containing the previously formed buttons, is to be heated till a drop of water will nearly boil upon it.

The shank is applied as follows:—a metal shell or collet *a* (see *fig. 273*) is placed over the flexible shank *b*, and a plate of metal *c* is laid under the shank; these are placed in the groove or recess of the button, which had been previously heated in the lower die; the upper die *A* (*fig. 274*) is then to be placed on the lower die *B*, and the two submitted to pressure, until they become cool, when the shank will be firmly attached, as shown at *fig. 275*, and the bottom may be finished in the usual way.

The second part of the invention, which relates to a mode of ornamenting horn buttons, by enlaving the front surface thereof, is performed in a manner similar to what has been above described, for fixing flexible shanks, and consists in first forming the front face or surface of a button, in suitable dies, for providing a recess; and then, by a second-pressure in dies, to fix the ornamental surface; and, when desired, the surrounding front surface of the button may be embossed. *Fig. 276* is a longitudinal section of a pair of dies, for forming a recess in the face of a button. *Fig. 277* shows, in front view and section, a horn button produced by these dies. *Fig. 278* shows a metal ornament, to be inlaid or fixed in the front surface of the button, but it should be stated that the ornamenting surface, to be fixed in the front surface of the button, may be of pearl or other material; and the size and device varied according to taste. *Fig. 279* shows in section a pair of dies, for giving the second pressure for affixing the ornamental surface; and, if desired, the remaining front surface of the button may be ornamented, by having the lower die engraved, or otherwise suitably ornamented. *Fig. 280* shows in front view and section a button made according to this part of the invention.

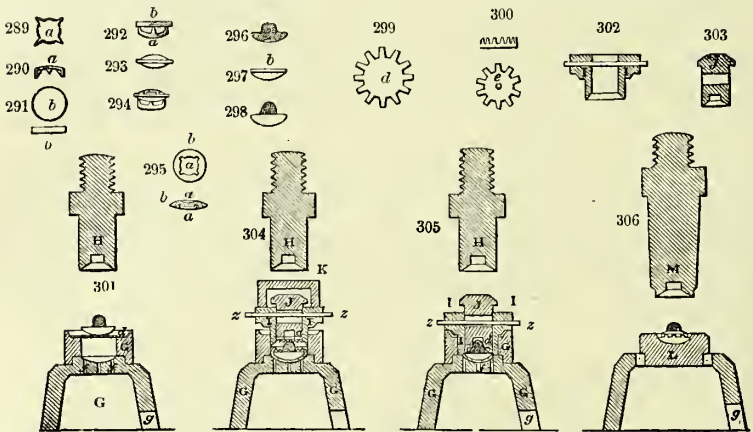

The third part of the invention relates to a mode of ornamenting horn buttons, by gilding or silvering their surfaces. This is effected by applying a suitable cementing or adhesive material with a soft brush to the button, in order that gold- or silver-leaf may be attached to its surface. The cementing or adhesive material preferred to be used is dressing varnish rendered sufficiently liquid by essence of turpentine; and when the varnish is nearly dry, gold- or silver-leaf is applied thereto, and pressed in the same manner as practised when gilding and silvering other surfaces; by thus treating horn buttons a very novel manufacture of that description of buttons may be produced.

The fourth part of this invention relates to the construction of dies used in the manufacture of horn buttons. *Fig. 281* is a section of a die, constructed according to this part of the invention; and *fig. 282* is a section showing the die without the bounding circles, which confine the patterns; *f* is the die engraved at the parts *g g*; around each of which engraved surfaces are circular grooves or recesses to receive the bounding circles *h h*, which fit accurately. By the after-insertion of these circles, the workman is not confined to move his graver within the bounding line, as that line is not present when engraving the plate; and the graver may pass beyond, and the grooves and the bounding circles may readily be made with great accuracy to each of the engraved surfaces.

The fifth part of the invention also relates to a mode of constructing dies for the manufacture of horn buttons, and consists in forming the dies so that the bounding circle shall be a sufficient depth for the counter die to slide within it, and fit accurately in order that the circumference of each button shall be smoothly and accurately formed. *Fig. 283* represents in section two dies, and one counter die, made according to this part of the invention; *fig. 284* shows one of the dies in plan and section; and *fig. 285* a plan and section of a counter die suitable for flexible shank buttons. *h h* are the dies, having the engraved surfaces *i i* on separate circular discs of metal, such as have heretofore been used; *j* is a counter die, and *k* a tube within which the counter die is held, the object of this tube being to guide the projecting edges *l l* of the dies as shown, and thus keep the dies and counter dies correct to each other. *Fig. 286* is a section of two dies *h*, and a counter die *j*; but in this case the tube *k* is dispensed with, the dies being deeper sunk, and thus guiding the counter die correctly. By the use of these dies, the edges of horn buttons will be more accurately formed, and consequently require less finishing. This description of dies may be made according to the mode described in the fourth part of this invention; that is, by forming the boundary circle separately, as will be understood by referring to *fig. 287*, which is a

side-section of a die complete, with its boundary circle formed in a similar manner to that described above. *Fig. 288* represents, in plan and section, a variation in the means of affixing a separate bounding circle to each engraved surface; and it is suitable for working without the tube. In using these dies they are to be heated but slightly, whether for buttons with metal shanks, or to receive flexible shanks, and are to be pressed as heretofore. The patentee claims, first, the mode of manufacturing horn buttons with flexible shanks, by first forming buttons by pressure and heat, and then by a second pressure in dies, to affix flexible shanks thereto, as above described. Secondly, the mode of ornamenting horn buttons, by causing suitable surfaces to be affixed in the front surfaces, by pressing the buttons with the ornaments in dies, as above described. Thirdly, the mode of ornamenting horn buttons by gilding and silvering their surfaces as described. Fourthly, the mode of constructing dies used in the manufacture of horn buttons, by applying separate bounding circles to each engraved surface, for a button; and fifthly, the mode of manufacturing horn buttons in dies, wherein the horn or hoof is prevented from being expressed at the circumference of the buttons as described.

BUTTONS, COVERED.—Mr. Joseph Parkes obtained in 1840, a patent for improvements in the manufacture of covered buttons made by dies and pressure, by the application of horn as a covering material. The process resorted to by the patentees for carrying out this invention is very similar to that pursued in manufacturing Florentine buttons; such modifications being applied as are rendered necessary for adapting such process to the peculiar nature of the material employed for covering the face of each button. *a* (*fig. 289*) shows a plan of a disc of iron plate, with four projecting points,

which is formed by suitable dies in a fly-press, as is well understood; the points are then turned down, and the disc *a* is sunk into the shape shown at *fig. 290*, and two such sunk discs are applied to the internal core of the button-board of each button: *b* (*fig. 291*) shows a plan and edge view of a circular disc of button-board suitable for forming the internal core of a button.

The dies being placed in suitable presses, as is well understood in using similar dies in manufacturing Florentine and other covered buttons, one of the sunk discs *a* is placed in the under die, with the points upwards, having a disc of button-board placed on the points, as shown at *fig. 292*; the upper die or punch is then caused to descend and press the button-board *b* into the shape shown at *fig. 293*; which, when thus formed, is to have a die *a* applied on the other side, as shown at *fig. 294*. The disc *a*, to be next fixed to the button-board, is placed in a suitable die, the disc which has already been fixed being upwards; the die or punch is now to be pressed down, which will produce the button-board, with the discs *a a*, on either side, into the shape shown at *fig. 295*; and it will be seen, that one of the discs will by the shape of the die, be sunk concave, whilst the other disc *a*, on the other side, will be formed convex or according to the figure of the face of the intended button.

The core of button-board (*fig. 295*) is now ready to be inserted into the fabric which is to become the flexible shank of the button, and which flexible shank is formed by sinking a portion of fabric in suitable dies, as is well understood when making similar shanks in Florentine or other covered buttons; and the shank being so sunk, the button-board of core (*fig. 295*) is to be placed thereon, with the concave surface

towards the protruding shank; and the edges of the fabric are then to be pressed over the core, as is well understood, which will produce the partly formed button (*fig. 296*), which is a side view, and consists of the shank containing the core, which is next inserted into the metal shell *e* (*fig. 297*), and these parts being placed in a suitable die, are pressed together, and the partly manufactured button (*fig. 298*) will be produced, consisting of the shank containing the core, covered on the front surface with the metal shell *e*, which, by the die, has its edges bent down on the fabric of the flexible shank. The button, thus far formed, is now in a condition to be covered with a thin plate of horn, which is performed in the following manner:—*d* (*fig. 299*) shows a disc of horn, cut out by suitable dies, the circumference being scalloped, in order that in folding over the mould (*fig. 298*) the horn may not be puckered. *e* (*fig. 300*) shows a collet, for affixing the covering of horn to the button, the collet being similar to that used in what is called 'Sandar's plan of making Florentine and other covered buttons.'

The method of covering the mould of the button with horn is described as follows:—*Fig. 301* represents, in section, a lower covering die, and also a proper punch for pressing the parts into the lower die; these dies being in a suitable press, as is well understood. The lower die is to be kept heated to such an extent that the workman can just bear his hand to rest, for a very short time, on the upper surface of the die; the heating is preferred to be accomplished by means of a flame of gas below the die; and it will be seen that there are holes *ff*, in the die, through which the heat of the flame may pass, and *g* is an opening to allow of atmospheric air flowing under the lower die. The disc of horn *d* is placed in the lower die *g*. The shape or mould (*fig. 298*) is then placed on the horn, and the punch or die *h*, is caused to descend, and press the parts into the die *g*; and the punch *h* is then raised, in order to allow of the introduction of the parts shown at *figs. 302* and *303*, which consist of the tube *i*, and the punch or die *j*. The lower edge of the tube *i* is made bell-mouthed, so as to cause the scalloped edges to be pressed on the back of the buttons, and the die or punch *j* is caused to force the collet to be forced through the horn in the button; and, in using these parts, the collet is placed in the tube *i*, which with its punch is inserted into the die *s*, as shown at *fig. 304*, which figure represents the die *g* and punch *h* in the condition just described, after having forced the parts into the die *g*; and this figure also shows the tube *i*, with a collet *d* and the punch or die *j* placed in the tube *i*; and all things are in a condition to receive the pressure of the punch *h*. In order to prevent the pressure coming on the punch or die *j* before the horn has been folded down by the tube *i*, the hollow block *k* is placed over the die or punch *j*; consequently when the punch *h* is caused to descend, it will force down the tube *i*, and cause it to gather the edges of the horn, and press them on the back of the mould of the button, when the punch *h* will be raised again, and the block removed, which will leave all things in the position shown at *fig. 305*; and then again, the bringing down of the punch *h* will cause the die or punch *j* to descend, and force the collet into the button, the die *j* being retained in the tube *i* by means of the pin *z*, passing through a slit formed therein, which allows of the die *j* rising and falling in the tube *i*, but prevents its coming out of that tube. The button, thus far formed, is now in a condition to be completed in the finishing dies (*fig. 306*), the lower dies being kept heated in a similar manner to the die *c*. The dies being fixed in a suitable press, the button to be finished is inserted into the die *L* (which may be ornamented or plain), with the shank upwards, and the punch or die *m* is caused to descend and press the button into shape.

When the front of the button is to be plain, the disc of horn should be polished before being used for covering; but when used to cover a button, and finished by an engraved or ornamented die, the polishing is not necessary. The button being thus made is to be finished by placing it in a lathe to be 'edged,' as is commonly practised in finishing horn buttons.

The patentee does not claim the means of making the mould or shape shown at *fig. 298*, nor the dies employed when separately considered, very similar dies having been before used in the manufacture of other covered buttons; nor does he confine himself thereto, so long as the peculiar character and essence of the invention be retained; viz., that of manufacturing covered buttons, made by dies and pressure by the application of thin sheet horn as the covering material. He claims the mode herein described of manufacturing covered buttons by the application of horn as a covering material.

PORCELAIN BUTTONS.—These buttons were first manufactured by Messrs. Minton and Co. under Prosser's patent for the compression of dry porcelain clay in moulds (the process will be fully described under the head *TESSERÆ*). Several houses have adopted the same process in this country. Mr. Bagaterasse has a large establishment at Briare, where he manufactures these buttons on a large scale, and being in competition with

Mr. Lebœuf of Breil, they are sold very cheaply. Bagaterasse has greatly improved the process by striking several hundred buttons at once, instead of doing them singly as by Prosser's original process. See TILES and TESSERÆ:

In 1872 we imported of Buttons and Studs—not of metal—to the value of 134,015*l.*; chiefly from Germany and Holland.

BUTTY. A miner who contracts to raise coal at a certain price per ton. He employs men to do his work, and they have usually an overlooker engaged by the butty, and called the 'Doggy.'

BUTYLAMINE, $C^8H^{11}N$ ($C^8H^{11}N$). A volatile organic base, homologous with methylamine. It is found in the more volatile portion of bone-oil. It may be prepared artificially by processes analogous to those employed for methylamine, amylamine, &c., substituting the butylic cyanate, urea, or iodine, for those of methyle and amyle. See AMYLAMINE.—C. G. W.

BUTYRIC ACID. A volatile fatty acid, discovered by Chevreul, who obtained it by saponifying butter with an alkali. Rancid butter owes its smell to the formation of this acid. See Watts's 'Dictionary of Chemistry.'

BUTYRIC ETHERS. Compounds formed by the direct action of butyric acid on alcohols. To the presence of small quantities of these ethers, the peculiar flavour of pine apples, melons, and some other fruits is due. Pine-apple rum owes its flavour to the presence of the butyrate of ethyl. 'A solution of butyric ether is very extensively used in perfumery, and in confectionery, under the name of pine-apple oil. It is prepared for this purpose by the following process:—Butter is saponified by a strong solution of potash-ley; the soap is dissolved in very little absolute alcohol, and to the solution is added a mixture of alcohol and sulphuric acid, until a strongly acid reaction is set up. The whole is then distilled; heat being applied as long as anything comes over with a fruity odour.' See Watts's 'Dictionary of Chemistry.'

BUKUS. The box tree. The value of the box wood sent from Spain to Paris is given as 10,000 francs a year. The box-wood tree formerly grew abundantly at Boxhill, in Surrey. In 1815 the trees were cut down and produced upwards of 10,000*l.*—*Baird.* See BOX WOOD.

BUZZING, or **BUSTLING.** Terms sometimes applied to the process of working scrap iron in the charcoal hearth (*Percy*). See IRON.

C

CABBAGE BARK. The bark of the cabbage tree of the West Indies (*Andira inermis*), formerly used in medicine as a purgative and anthelmintic. It has been supposed that this tree furnishes the partridge-wood of the cabinet-maker.

CABBAGE PALM. The young leaf-buds of this palm, the *Areca oleracca*, are boiled and eaten as a vegetable in India.

CABBLING. A term used amongst metallurgists. In Gloucestershire it is called *Scabbling*. Finery iron is smelted with charcoal, and when a soft mass of about two hundredweight is formed it is hammered out into a flat oval from two to four inches in thickness; this is allowed to cool, and is then broken up into small pieces, which is the process of cabbling or scabbling.

CABLE. (*Cable*, Fr.; *Ankertau*, Ger.) A strong rope or chain, connecting the ship with the anchor for the purpose of mooring it to the ground. The *sheet anchor* cable is the strongest, and is used at sea after the bower, which is in constant use, goes, gives way, or requires help: the *stream* cable is smaller, being used chiefly in rivers. A cable's length is 100 to 140 fathoms in the merchant service; in the Royal Navy, 4 cables are employed each of 100 fathoms, 2 cables being attached end to end. The greatest improvement in mooring vessels has been the introduction of the chain cable, which, when duly let out, affords in the weight of its long catenary curve, an elastic tension, and play to the ship under the pressure of the wind. The dead strain upon the anchor is thus greatly reduced, and the sudden pull, by which the flukes or arms are readily snapped, is in a great measure obviated. The best iron cables are chains made of links, whose sides are stayed by cross bars or stud, welded across the middle of the link. Experience has taught that the ends of these links wear out much sooner than the sides. To remedy this evil, Mr. Hawkes, iron manufacturer, obtained a patent in July 1828, for constructing these anchor chains with links considerably stouter at the ends than in the middle. With this view he forms the short rods of iron, of which the links are to be made, with swells or protuberances about one-third of their length from each of their ends, so that when these are welded to-

gether, the slenderer parts are at the sides, and the thicker at the ends of the elliptic links. Such rods as the above are formed at once by rolling, swaging, or any other means; but in practice, this plan has not been extensively carried out; the simple round iron seems best.

The first avowed proposal to substitute iron cables for cordage in the sea service is stated to have been made by Mr. Slater, surgeon of the Navy, who obtained a patent for the plan in 1808, though he does not seem to have had the means of carrying it into effect—a very general misfortune with ingenious projectors. It was Lieut. Samuel Brown, of the Royal Navy, who, in January 1808, had represented to the Naval Boards the policy of employing iron rigging and chain cable, and who, in February of that year, enrolled a patent for those articles, and in 1811 first employed chain cables in the vessel 'Penelope,' of which he was commander, for the purpose of experimental experience, this vessel of 400 tons having been fitted expressly for the trial by Captain Brown, Mr. Bruton, and other friends, at personal expense and risk, with iron rigging, chains, and cables, in place of hemp and rope.

He made a voyage in this ship from England to Martinique and Guadaloupe and home again, in the course of four months, having anchored many times in every variety of ground without any accident. He multiplied his trials, and acquired certain proofs that iron might be substituted for hemp in making cables, not only for mooring vessels, but for the standing rigging. Upon his return from the West Indies, Captain Brown strongly represented the advantages practically experienced of iron over hemp. A committee of naval officers reported upon the whole affair, and the Government ordered the 'Namur' of 74 guns, the 'Monmouth' of 64, the 'Crescent' frigate, and the 'Alonzo' sloop, to be fitted with two chain cables of 100 fathoms each, and Lieut. Brown was promoted to the rank of captain. These chains were of various forms of links; those, for instance, supplied to the 'Crescent' were composed of very short links with parallel sides.

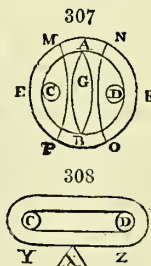

Since this period, chain cables have been universally introduced into all the ships of the Royal Navy; but the twisted links employed at first by Brown have been replaced by straight ones, stayed in the middle with a cross rod, the contrivance of Captain Brown, which was secured by patent in this country.

The twisting of the links was done in order to assimilate the chain to the form of rope, and for the purpose of making it run out with less concussion to the ship; but this in practice was found really to let the cable render out too easily, and was discontinued in practice.

Some of the cables supplied in 1811 to the ships of war were found to have defective links; their general use was suspended until the beginning of 1812, when Captain Brown invented a mode of shutting the link with a long scarf, and introduced a machine to put upon the chain any amount of strain that ought to be brought to bear, and thus ascertain defects of workmanship and material. This *proving machine* led to the introduction of stay pins in the links; about the middle of 1812, chain cables were thus brought to great perfection, and very generally introduced into the Royal Navy.

The first thing to be considered in the manufacture of iron cable is, to procure a material of the best quality, and, in using it, always to keep in view the direction of the strain, in order to oppose the maximum strength of the iron to it. The best form of the links may be deduced from the following investigation:—

Let a B (*fig. 307*) be a circular link or ring, of one-inch rod iron, the outer circumference of the ring being 15 inches and the inner 9. If equal opposite forces be applied to the two points of the link c D, pulling c towards e, and d towards f, the result will be, when the forces are sufficiently intense, that the circular form of the link will be changed into another form with two round ends and two parallel sides, as seen in *fig. 308*. The ratio of the exterior to the interior periphery, which was originally as 15 to 9, or 5 to 3, is no longer the same in *fig. 308*. Hence there will be a derangement in the relative position of the component particles, and consequently their cohesion will be progressively impaired, and eventually destroyed. In *fig. 307*, the segment MN of the outside periphery being equal to 3 inches, the corresponding inside segment will be $\frac{2}{3}$ ths of it. If this portion of the link, in consequence of the stretching force, comes to be extended into a straight line, as shown in *fig. 308*, the corresponding segments, interior and exterior, must both be reduced to an equal length. The matter contained in the 3 inches of the outside periphery must therefore be compressed, that is, condensed into $1\frac{1}{2}$ inch; or the inside periphery, which is only $1\frac{1}{2}$ inch already, must be extended to 3 inches: that is to say, the exterior condensation and the interior expansion must take place in the

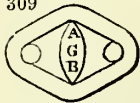

reciprocal proportion. But, in every case, it is impossible to effect this contraction of one side of the rod and extension of the other, without disruption of the link.

Let us imagine the outside periphery divided into an infinity of points, upon each of which, equal opposite forces act to straighten the curvature; they must undoubtedly occasion the rupture of the corresponding part of the internal periphery. This is not the sole injury which must result; others will occur, as we shall perceive in considering what passes in the portion of the link which surrounds *CD* (*fig. 308*), whose length is $4\frac{1}{2}$ inches outside and $2\frac{1}{10}$ th inside. The segments *MP* and *NO* (*fig. 307*), are actually reduced to semi-circumferences, which are inside no more than half an inch and outside as before. There is thus contraction in the interior with a quicker curvature or one of shorter radius than in the exterior. The derangement of the particles takes place here in an order inverse to that of the preceding case, but it no less tends to diminish the strength of that portion of the link; whence we may certainly conclude that the circular form of cable link is an extremely faulty one.

Leaving matters as we have supposed in *fig. 307*, but suppose that *G* is a rod introduced into the link, hindering its two opposite points *AB* from approximating.

309

This circumstance makes a remarkable change in the results. The link, pulled as above described, must assume the quadrilateral form shown in *fig. 309*. It offers more resistance to deformation than before; but as it may still suffer change of shape it will lose strength in so doing, and cannot therefore be recommended for the construction of cables which are to be exposed to very severe strains.

Supposing still the link to be circular, if the end of the stay comprehended a larger portion of the internal periphery, so as to leave merely the space necessary for the plan of the next link, there can be no doubt of its opposing more effectively the change of form, and thus rendering the chain stronger. But, notwithstanding, the circular portions which remain between the points of application of the strain and the stay would tend always to be straightened, and of consequence to be destroyed. Besides, though we could construct circular links of sufficient strength to bear all strains, we ought still to reject them, because they would consume more materials than links of a more suitable form, as we shall presently see.

The effect of two opposite forces applied to the links of a chain is, as we have seen, to reduce to a straight line or a straight plane every curved part which is not stayed: whence it is obvious that twisted links, such as Brown first employed, even with a stay in their middle, must of necessity be straightened out, because there is no resistance in the direction opposed to the twist. A cable formed of twisted links, for a vessel of 400 tons, stretched 30 feet, when put to the trial strain, and drew back only 10 feet. This elongation of 20 feet proceeds evidently from the straightening of the twist in each link, which can take place only by impairing the strength of the cable.

Twisted cables are not now made, and but little of twisted chain. They were made to give the familiar form of rope to the chain, to please the sailors' prejudice.

From the preceding remarks, it appears that the strongest links are such as present in their original form, straight portions between the points of tension; whence it is clear that links with parallel sides and round ends would be preferable to all others, did not a good cable require to be able to resist a lateral force, as well as one in the direction of its length.

Let us suppose that by some accident the link *fig. 308* should have its two extremities pulled towards *y* and *z*, whilst an obstacle *x*, placed right opposite to its middle, resisted the effort. The side of the link which touches *x* would be bent inwards; but if, as in *fig. 310*, there is a stay, *A G B*, the two sides would be bent at the same time; the link would notwithstanding assume a faulty shape.

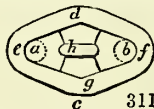

310

In thus considering the vicious forms, we are naturally directed to that which has had at one time the preference, as is shown in *fig. 311*; but this form of link and stay-pin is so faulty, as to give place now to the general use of the simple link of parallel sides (see *fig. 312*)

312

311

and with a very different stay-pin, as will be shown hereafter. This old link has a cast-iron stay with large ends; it presents in all directions a great resistance to every change of form; for let it be pulled in the direction *ab* against an obstacle *c*, it is evident that the portions *de* and *df*, which are supported by the parts *ge* and *gf*, cannot get deformed or be broken without the whole link giving way. As the matter composing *ge* and *gf* cannot be shortened, or that which composes *de* and *df* be lengthened, these four sides will remain necessarily in their relative positions, by virtue of the large-ended stay *h*, whose profile is shown in *fig. 314*. We have examined the strength of a link in every direction, except that perpendicular to its plane. *Fig. 313* represents the assemblage of three links in the

above predicament; but we ought to observe that the link *c*, placed between the links *A* *B*, could not resist the pressure or impact of the two lateral links.

Process of manufacturing Iron Cables.—The implements and operations are arranged in the following order:—

1. The cutting, by a machine, of iron bars, in equal lengths, but with opposite bevells, to allow of the requisite crossing and splicing of the ends in the act of welding.

2. A reverberatory furnace, in which a number of rods or round bars of the best possible wrought iron, and of proper dimensions, are heated to a red heat. The furnace is like those used in the sheet-iron works, but somewhat larger, and needs no particular description here.

3. The bending of each of these pieces by a machine, so as to form the links; the last operation is done rapidly while the iron is red hot.

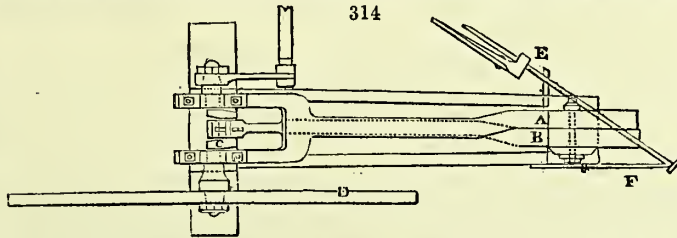

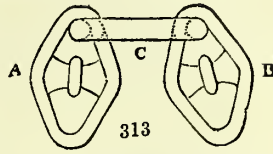

4. The welding of the links at small forge fires, fitted with tools for this express purpose, and the immediate introduction of the stay, by a top tool and hammer.

5. Proving the cables by an hydraulic press, worked by a pump, with levers to ascertain the strain applied by working the pump.

Any ordinary shears will do to cut the iron, if furnished with a gauge or stop, to regulate the length of link.

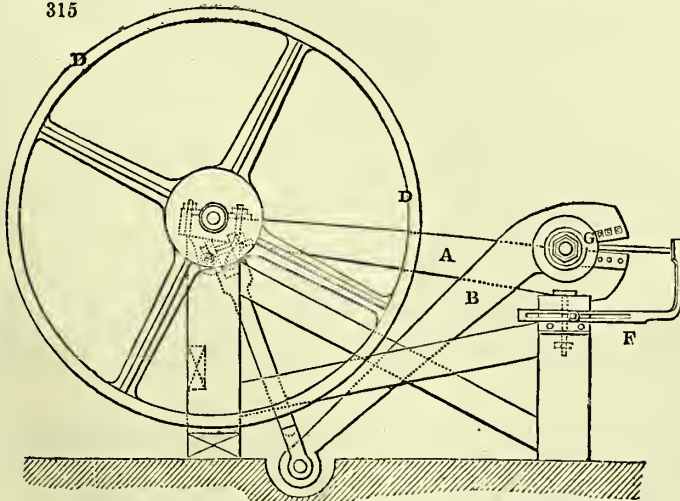

The following forms of apparatus employed by the late Mr. Brunton and others, relate more to the history of the past manufactures, than to the present practice on a large scale.

Figs. 314 and 315 are a plan and elevation of the shears with which rods are cut

into equal pieces, for a link, moved by a steam-engine, or worked by four or more labourers. These must be relieved, however, frequently by others, for each shears machine is calculated to require nearly one horse in steam-power.

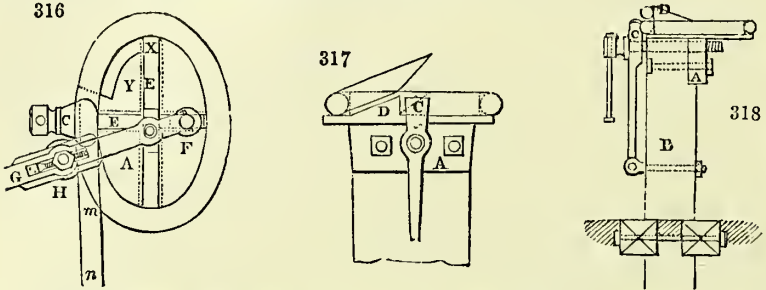

315

A and *B* are the two cast-iron limbs of the shears. The first is fixed and the second is movable by means of a crank-shaft *c*, driven by a heavy fly-wheel *D*. The cutting

jaws, *c*, are of steel pieces made fast by bolts, and may be changed at pleasure. *f* is a stop which determines the equal lengths of the pieces cut off, and can be shifted to suit different lengths: a piece of iron is shown as being cut off between the upright stop and the shears.

The following figures represent the plan and elevation of a machine for bending links into an elliptic form, superseded by the machine hereafter to be described. It is represented at the moment when a link is getting bent upon it.

A is an elliptic mandrel of cast iron; it is fixed upon the top of a wooden pillar *n*, solidly supported in the ground. *c* is the jaw of the vice, pressed by a square-headed screw against the mandrel *A*.

D, part of the mandrel comprehended between *x* and *x*, formed as an inclined plane, so as to preserve an interval equal to the diameter of the rod between the two surfaces that are to be welded together.

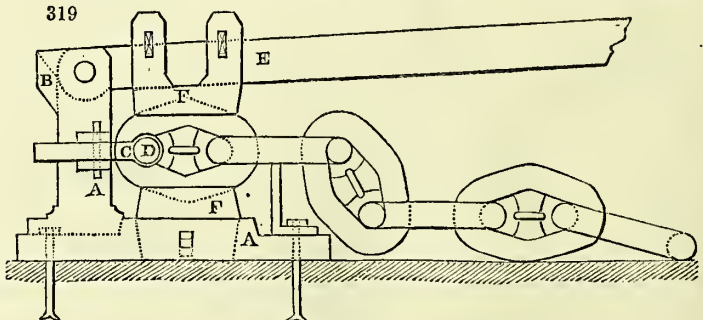

E, rectangular slots (shears) passing through the centre of the nut of the mandrel, in which each of the pins *F* may be freely slidden.

G, horizontal lever of wrought iron six feet long. It carries at *n* a pulley or friction-roller of steel, whose position may be altered according to the diameter of the links. It is obvious that as many mandrels are required as there are sizes and shapes of links.

The piece of iron intended to form a link being cut, is carried, while red hot, to the bending machine, where it is seized with the jaw of the vice *c*, by one of its ends, the slant of the cut being turned upwards; this piece of iron has now the horizontal direction *m n*; on pushing the lever *G* in the line of the arrow, the roller *H* will force *m n* to be applied successively in the elliptic groove of the mandrel; thus, finally, the two faces that are to be welded together will be placed right opposite each other.

The length of the small diameter of the ellipse ought to exceed by a little the length of the stay-piece, to allow of this being readily introduced. The difference between the points *F E* is equal to the difference of the *radii vectores* of the ellipse. Hence it will be always easy to find the excentricity of the ellipse.

Fig. 319 is a lever press for squeezing the old form of links upon their stays

after the links are welded. This machine was contrived for the purpose of superseding manual labour, but the skill and dexterity of the workmen have quite superseded this machinery; however completely this and other machines may do the work, hand labour does the work quicker and better, almost beyond comparison. The hand practice is as follows:—

The links bent are carried to the forge hearth to be welded, and to receive their

stay; two operations performed at one heating. Whenever the welding is finished, while the iron is still red hot, the link is placed upright upon the stake, *i. e.*, the shorter axis vertical and the longer axis of the link horizontal; then a workman introduces the stay with a pair of tongs or pincers; while another workman strikes down upon it. This mechanical compression first of all joins perfectly the sides of the link against the concave ends of the stay, and afterwards the retraction of the iron on cooling increases still more this compression. If each link be made with the same care, the cable must be sound throughout. It is not delivered for use, however, till it be proved by the hydraulic press, at a draw-bench made on purpose, and examined link by link, on the side of the machine, or on a bench erected for the purpose, to detect any flaw the strain may have caused.

The following Table of compared materials and strains is given as a matter of historical reference. It is believed the dates of the experiments are 1815 and 1816; since then, alterations in the make of iron, and the introduction of new fibres, as well as hemp, render this Table of value, as the materials here employed were, no doubt, good examples, and subjected to critical attention:—

Table of Iron Cables as substituted for Hemp, with the Strains applied at that Date.

Iron Cables Diameter of Iron Rod	Hemp Cables Circumference of Rope	Old Proof, by Mr. Brunton
Inches	Inches	Tons
$0\frac{7}{8}$	9	12
1	10	18
$1\frac{1}{8}$	11	26
$1\frac{1}{4}$	12	32
$1\frac{3}{8}$	13	35
$1\frac{3}{5}$	14 to 15	38
$1\frac{1}{2}$	16	44
$1\frac{5}{8}$	17	52
$1\frac{3}{4}$	18	60
$1\frac{7}{8}$	20	70
2	22 to 24	80

It would be imprudent to put hemp cables to severer strains than those indicated in the Lloyd's Table, drawn up from experiments; but the iron cables of the above sizes will support a double strain without breaking. They ought never, in common cases, however, to be exposed to a greater stress. A cable destined for ships of a certain tonnage should not be employed in those of greater burden. Thus treated, it may be always trusted to do its duty, and will last longer than the ship to which it belongs. It has often been stated, that chain cables possess double the strength of the iron of which they are made, owing to the *forms* of the links employed: this, however, is an absurd error; for, suppose the two sides of a link to be of inch-iron, yet a part of the strength must be lost in the bending of the ends, for the straining force is at right angles, at the ends, to what it is at the side, or would be exerted upon portions of straight rods; next, to make a link, the two ends have to be joined by welding, and wherever this join is made, there is every chance for less union, and no possible means of getting the fibre to be stronger than if they had never been separated; strength really must be lost by heating the iron and shaping the link.

Mr. Lenox has found in practice, that an inch bolt will bear $21\frac{1}{2}$ tons, while the inch cable will break at 34 tons, and not at the double strength, or 43 tons, of two lengths of straight iron.

One of the most valuable qualities of iron cables is their resisting lateral as well as longitudinal strains, as explained under *figs.* 311 and 313.

Vessels furnished with chain cables have been saved by them from the most imminent peril. The 'Henry,' sent out with army stores during the Peninsular war, was caught on the northern coast of Spain in a furious storm. She ran for shelter into the Bay of Biscay among the rocks, where she was exposed for three days to the hurricane. She possessed fortunately 70-fathoms chain cables, which held good all the time, but it was found afterwards to have had the links of its lower portion polished bright by attrition against the rocky bottom. A hemp cable would have been speedily worn to pieces in such a predicament.

In the contracts for the Admiralty of chain cables for the British Navy, it is stipulated that 'the iron shall have been manufactured in the best manner from pig iron smelted from ironstone only, and selected of the best quality for the purpose, and shall not have received in any process whatever, subsequent to the smelting, the admixture of either cinders or oxides produced in the manufacture of iron, and shall also have

been puddled in the best manner upon iron buttons, and at least three times sufficiently drawn out at three distinct welding heats, and at least twice properly fagotted.'

The following is a Table of the breaking proof of chain cables, and of the iron for the purpose of making them, and the proofs required by Her Majesty's Navy for chains:—

Size of Bolt	Proof of Bolt	Proof of Chain	Navy Proof of Chain
Inches	Tons cwts.	Tons cwts.	Tons
$\frac{1}{2}$	5 7	8 11	$4\frac{1}{2}$
$\frac{3}{8}$	8 7	13 4	$5\frac{1}{2}$
$\frac{1}{2}$	12 1	19 5	$10\frac{7}{8}$
$\frac{3}{4}$	16 4	26 5	$13\frac{3}{4}$
1	21 8	34 5	18
$1\frac{1}{4}$	27 2	48 15	$22\frac{3}{4}$
$1\frac{1}{2}$	33 10	53 11	$28\frac{1}{2}$
$1\frac{3}{4}$	40 10	65 0	34
$1\frac{7}{8}$	48 4	77 0	$40\frac{1}{2}$
1	56 11	90 10	$47\frac{1}{2}$
$1\frac{1}{8}$	65 12	105 0	$55\frac{1}{2}$
$1\frac{1}{4}$	75 6	120 10	$63\frac{1}{4}$
2	85 14	137 0	72
$2\frac{1}{8}$	96 15	155 0	$81\frac{1}{4}$

In these iron cables, the matter in the link is thrown very much into one plane; the link being of an oval form, and provided with a stay. As there are emergencies in which the cable must be severed, this is accomplished in those of iron by means of a bolt and sheckle (shackle), which is inserted in the Royal Navy cable at the end of every $12\frac{1}{2}$ fathoms, and at the end of every 15 fathoms in the merchant service; so that by striking out this bolt or pin, this cable is parted with more ease than a hempen one can be cut. And the iron cable can be reconnected when the ship is clear, while with the hempen cable it would be necessary to cut it with an axe, and thus permanently injure the cable. Mr. Lenox's plan for securing these bolts is now made part of the Government contracts.

We have avoided all relating to the general history and application of chain cables, but in connection with the following particulars, obtained from Brown, Lenox, and Co.'s chain works at Millwall, we must admit the important part performed by this house in the improvement of this manufacture. The following remarks refer to chain cables for the Royal Navy, messenger and mooring chains for the Trinity Corporation, and ship cables for merchant service, showing the practice in 1858.

After selecting the best iron, cutting it off into required lengths, and heating it as before described, the links for chain cables may be bended at the rate of about 60 per minute, by machinery at Lenox's works, in Wales, worked by water-power,—the welding of the links in all cases being effected by hand labour.

In the practice with the *bending machine* at Newbridge works, Pont-y-Prid, Glamorganshire, it is as follows:—When the iron is cut to the requisite length for links, from 20 to 60 pieces, according to size, are put into the furnace, and when heated, are placed separately on the bending mandrel *c* (*fig. 320*) the machine is set in motion, and one revolution forms a link, which is pinched off the mandrel by a small crowbar, and another piece of iron applied, and so on, until from 40 to 60 links are formed in a minute.

The bending machine is connected with a water-wheel, or other power, by an ordinary coupling clutch, or box, which a lever throws into and out of gear at pleasure.

There is a stub or knob of iron on the mandrel under which the point of the piece of iron to be bent is fixed: the mandrel being oval, or of the inside shape of the link, when turned, is followed by the roller above, and this, pressing upon the piece of iron, forms it to the shape of the mandrel.

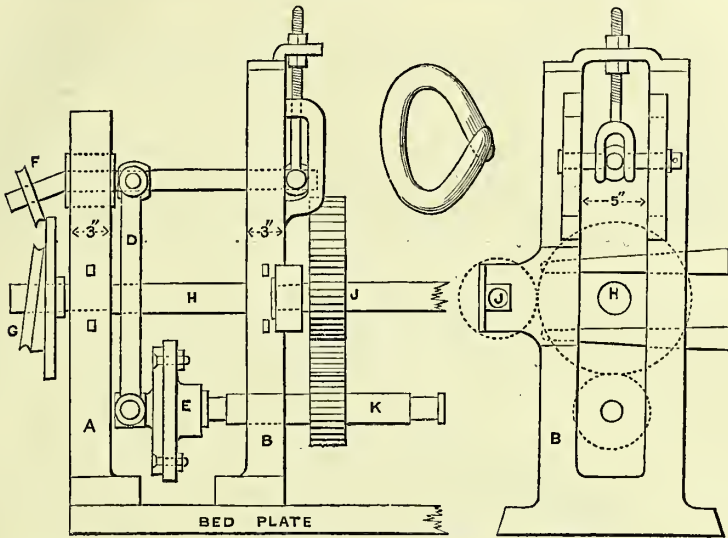

A B C (*fig. 320*) are standards, D connecting-rod, E crank for lifting, F F the roller for pressing sides of links, G mandrel, H mandrel spindle, I wheel for mandrel spindle, J pinion on main spindle, X crank spindle.

The form of the link, after being bended into shape (*fig. 320*) is shown with the two slant-cut surfaces of the ends to be welded together and hammered into form.

For short lengths of chain the bending may be effected by hand; in this case the process is simple:—A sufficient length of the best iron is cut off, and, while hot, is partially bent by the workman over an iron ring, one end of the bar resting on the ground; the bend is finished upon the anvil; one entire end of the link is thus formed.

The two slanting-cut ends are made to approach each other; heated up to a high temperature, the expert workman, by a peculiar blow, detaches the scales of oxide, and

320

instantly presses both surfaces together; two men then by repeated blows effect the welding junction, and thus the link is formed.

The shape of the link, after due consideration of the advantages of particular patterns, seems to resolve itself into the decided preference for a link of parallel sides, unchanged in form from the round of the iron employed, while the ends may be reduced, somewhat flattened, and increased in breadth. The links thus in contact have the pressure sustained by a greater breadth of surface, and compression can scarcely alter the form.

The length of a good link may be of round iron 6 diameters in length of link A A (fig. 323), and from B to B 3·7 to 4 diameters of the iron rod employed, and 1·7 to 2 diameters inside.

The stub, staple, or cross-bit is of cast iron, and is placed across; its use is to prevent the sides from collapsing by extension of the chain; in fact, to keep up a succession of joints, and prevent the chain from becoming a rigid bar of metal.

The stud or cross-piece shown at C is of cast iron, with dates and marks upon the surface. It is cast with a hollow bearing, having a curve to receive the round iron of the link; its shoulders, or feathering, enables the workman to insert it readily, and a few blows upon the yielding iron give the requisite grip; and all proper service only tends more firmly to keep it in position, very different indeed from the form fig. 312 which would positively injure the link.

In all cases this cross-piece has been of cast iron. Wrought iron was tried, but found to be too expensive. Malleable iron has been patented, but it is a question whether it can supersede common foundry iron, from the cheapness and facility of the latter.

The cables are proved and tested by regulated strains brought to bear continuously up to the *proof strain*, and then even up to the ultimate destruction of some of the links, if the final strength or opposition to resistance is required to be known. The proof of cable should be 600 lbs. for each circle of iron $\frac{1}{4}$ th of an inch in diameter.

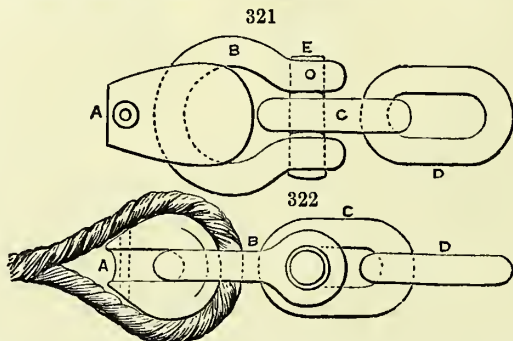

The chain is attached at one end horizontally to a hydraulic press, the other end to the enormous heat of a bent iron lever, whose power is multiplied by second and third iron levers, all working upon knife-edges, and to the last lever a scale pan is attached; 1 lb. being here placed is equivalent to a strain of 2,240 lbs. upon the bar or chain that is being tested. This machine of Brown, Lenox, and Co., Millwall, is more powerful than that used in the Royal dockyard. The proving machine, invented by Captain Brown in 1813, was a great step towards the production of confidence.

In practice, *length* after *length* is tried up to the proof required; when the tension is to be exerted to the uttermost, a few links are taken: in such experiments it is usual for one link alone to give way, and the strength of the cable itself is uninjured by testing to find its ultimate strength.

Perfection of practice is found when the link and the stay yield together; in the largest chain cables ever produced, such were the due proportions and symmetry of form affording equality of resistance, that the cross-piece split or broke at the time the link fractured and opened.

To measure these chains, or be near them when under such tension, is not without danger. The cable, on being struck, rings out with strange shrill sound, a link may suddenly snap, the chain lashes about, and the fragments fly to a great distance, penetrating the factory roof at times, and, at the moment of fracture, the link becomes very hot.

The cables are usually told-off into lengths. The Government length is $12\frac{1}{2}$ fathoms; for the merchant service the length is 15 fathoms; as explained, these lengths are united by shackles. In the merchant service cable, larger links are placed at each extremity for the anchor shackle to pass through, but in the Royal Navy cables, each length is alike provided with large links; thus, then, at any time, any end of any length may be placed to the anchor stock. See *figs. 321, 322.*

To obviate evils from the twisting of the chain cable, swivels are inserted: in the Government cables, a swivel is inserted in the middle of every other length; for the merchant service there does not appear to be any precise rule. Sometimes one, two, or more swivels may be in 100 fathoms; and in cheap chains, bought and judged by weight and figures, no swivel whatever exists in the cable.

The effect of such twisting, or torsion, is to form a link, and give powerful lateral pressure upon the link; the stud or cross-piece is forced out, and the link itself may yield at the moment that any flaw from imperfection of welding occurs.

The mooring swivel is that by which a ship can ride with two anchors down at the same time and two bridles on board the ship. The mooring swivel, being equal in strength to the two cables, is over the bow, and enables the ship to swivel round her anchors without fouling hawse; in any direction the ship can swing round this swivel or point, leaving her anchors undisturbed, whereas by two cables out, without this, she would require great care to prevent them from fouling, and even being lost. This is an essential advantage of chain over hemp.

The splicing shackle is to unite or splice a hempen cable to be used on board ship, attached to the chain cable, which lies on the ground or bottom, so that the vessel rides lightly at her anchor, while the iron chain cable preserves the hempen cable from being destroyed by the rocky bottom, and the ship has the light hemp cable rendered buoyant by the water, which lifts portions of the chain cable by the motions of the vessel; and thus, the ship is relieved from weight and the anchor from jerks.

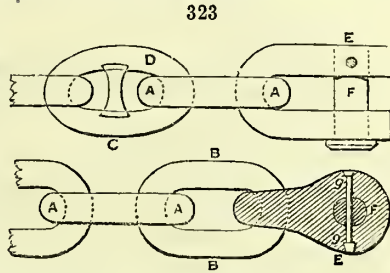

The splicing shackle, on the Hon. George Elliott's plan, is shown above (*fig. 322*). The rope is served round an iron thimble A, on the shackle B, with end links, and enlarged links without stay-pins C, D, leading to the anchor, while the hempen cable A goes to the ship.

In the Royal Navy, 4 cables are employed to moor the ship, two being end to end.

When the ships lay long on certain shores, the pin or fastening often gets loose by constant tappings and vibrations of the chain cable on the rocky or shingly bottom. Men-of-war at some stations suffered severely in this way, and the commander at Malta had reason to represent it as a very serious matter. Mr. Lenox's plan for securing the bolts and pins is now made a point of contract to be adopted in all fastenings for the Royal Navy.

Simple as it would seem to devise a plan, yet it was years before all the difficulties could be surmounted. This arrangement may be understood by reference to the

figure of a shackle with links, (*fig. 323*): at *ε* is seen the aperture at right angles to the bolt *ε*, (of oval iron) through this channel, cut through the shackle and the bolt, a tapering but not quite cylindrical steel pin, fits exactly; but does not quite proceed through the iron; it is shown at *gg*. Various plans used to be resorted to before this final preference; for the steel pins, of whatever form, got loose by repeated tapping on the rocky bottom, or the links upon each other. Mr. Lenox succeeded in cutting the cavity at *ε* of the form of a hollow cone, and to complete the fastening, a pellet or cylinder of lead that will just allow insertion at *ε* is driven, and then by repeated blows the lead is made to fill up the cavity, the superfluous quantity of lead being cut off by the hammer at *ε*. To release the bolt it is only necessary to find the small space at the small end of the steel pin, to insert a punch, and then, with a few blows, the steel pin *gg* is driven out of its conical bearing, and its flat top and cutting edges enable it to emerge again at *ε*. Being forced out, the bolt *ε* is taken out, and the chain severed if required; the aperture at *ε* can be cleared of its lead by a proper cutting-out tool, and the steel pin replaced to make all fast.

This operation can be effected on the darkest night; the sailor can sever the chain cable, and thus when one vessel is driving down upon another, more chain may be attached to the cable severed, and no harm done; while with hempen cable it might be found more than difficult, and even impossible, to cut them in time.

All the principles involved, and perfection of practice, in making chains and chain cables, have recently been deeply considered and fully verified by the firm of Brown, Lenox, and Co., Millwall, who, for the purpose of obtaining comparative results up to the greatest links required for the 'Leviathan'—now the 'Great Eastern,'—selected iron of the same identical quality and worked it into rods, links, and chains. The progression of resistance to increased strains, by increase of mass of iron, with all the influences of variation of make, flaws in the material, and other circumstances inseparable from practice, were thus matters of critical experiment.

Commencing with $\frac{1}{2}$ inch chain, and trying four links of small chains up to $2\frac{7}{8}$ ths, being the largest diameter of round iron for the greatest cable links ever hitherto made, being those for the sheet anchor of the 'Leviathan,' taking the breaking strains, and reducing all the links to the proportion borne upon a circle $\frac{1}{8}$ th of an inch in diameter, the minimum breaking force was 796.25 lbs., and the maximum 1052.3 lbs.

Sometimes the fracture was found to be dependent upon flaws, sometimes from over heating, or unequal heating, and other practical causes; but the whole series of experiments was important and interesting.

The iron *lengthens* to the intense strains employed, long before fracture. The comparison of actual extension, while under enormous force at ordinary temperatures was ascertained by the following impressive experiments:—

The 'Leviathan,' second size cable of $2\frac{5}{8}$ diameters of iron employed in the links. Three links measured $35\frac{1}{4}$ inches by strain of 10 tons (of course it requires power to extend them fairly).

	At 50 tons	.	.	.	stretched $\frac{1}{4}$ of an inch
	" 85 "	"	"	"	" $\frac{11}{10}$ "
(Proof)	" 110 "	"	"	"	" $1\frac{1}{8}$ "
	" 124 "	"	"	"	" $1\frac{7}{8}$ "
	" 140 "	"	"	"	" $2\frac{7}{16}$ "
	" 150 "	"	"	"	" $3\frac{1}{4}$ "

$\frac{1}{2}$	$2\frac{5}{8}$	1·575	9	0	21	$3\frac{1}{2}$

As the merchant marine may frequently be called upon for public service, it may be useful to know the particulars, which are promulgated from Lloyd's. A chain cable seldom breaks with the duty assigned, if proportioned to the tonnage, if the iron be sound and the workmanship good.

In 1871 and 1872 we exported of anchors, grapnels, chains, and cables as follows:—

	1871		1872	
	Tons	Value	Tons	Value
To Russia	632	£11,588	—	—
„ Sweden	314	5,131	704	£12,828

In the same years we exported of 'cordage, cables, and ropes of hemp or like material,' to nearly the same countries as above:—In 1871, 131,382 cwts., valued at 366,365*l.*; and in 1872, 139,083 cwts., valued at 403,119*l.*

It is much to be regretted that we are unable to separate the anchors from the chains and cables.

Weights of Ordinary Anchors, Sizes and Lengths of Chain Cables, and Sizes and Lengths of Hawsers and Warps, to be recommended when the Surveyors are applied to by Ship Builders and Ship Owners.

SHIP'S TONNAGE	ANCHORS								CHAINS		HAWSERS AND WARPS

¹ The stream cables may be of iron, of proportionate sizes.

See COIR, HEMP, WIRE ROPE.

CACAO (commonly, but improperly *CocOA*). The seeds of the *Theobroma Cacao* (or 'Cacao of the Gods,' as Linnæus named the tree). They are imported from the West Indies, the Caracas, from Brazil and some other parts of America. The seeds are oval, large as an olive, obtuse at each end. Simply torried and bruised they constitute the *CocOA* of the shops, but frequently this is made from the fragments of the seed-coats, which impart to the preparation an astringent property. When the carefully prepared seeds are ground into a paste, sweetened, and flavoured with vanilla or cinnamon, it constitutes *CHOCOLATE* (*chocolata*), which furnishes a nourishing beverage.

Cacao contains an active principle called *theobromine*, similar in its properties to theine and caffeine, the alkaloids in tea and coffee. A fatty or oily matter, called *butter of cacao*, is also present in the cocoa-seeds to the extent of one-half their weight.

In 1871 we imported of cocoa-seeds 17,368,302 lbs. of the value of 594,622*l.*; of the husks and shells, 10,533 cwts., valued at 11,030*l.*; and of cocoa-paste or chocolate, 78,501 lbs., valued at 7,234*l.* And in 1872 15,044,134 lbs. of cocoa, valued at 467,144*l.*; 8,725 cwts. of husks and shells, valued at 8,555*l.*; and of cocoa-paste or chocolate, 102,423 lbs. valued at 9,847*l.*

From June 1853, the duty on the seeds has been 1*d.* per lb., on the husks and shells, 2*s.* per cwt., and on the paste or chocolate, 2*d.* per lb.

Cocoa or Cacao must not be confounded with *Coca*, a narcotic plant chewed by the Indians of South America, or *Coco*, one of the *Araceæ*, the underground stems of which are used as food. See *Coca* and *Coco*.

CACHALOT. A name for the sperm whale (*Physeter macrocephalus*). This whale yields sperm-oil, spermaceti, and ambergris.

CADMIA. The *Cadmia Arabibus* of old writers was the ancient name of Calamine, the *lapis calaminaris* of the older chemists. See Watson's 'Chemical Essays.'

CADMIUM. (*Symbol*, Cd.; *Atomic weight*, 56.) A metal discovered by Stroemer about the beginning of the year 1818. It derives the name *Cadmium* from *Cadmia fossilis*—a denomination by which the common ores of zinc were formerly distinguished. It occurs chiefly in Silesia in several ores of zinc, and may be readily recognised by means of the blowpipe; for, at the first impression of the reducing or smoky part of the flame, the ores containing cadmium stain the charcoal all round them with a reddish-yellow circle of oxide of cadmium. The Silesian native oxide of zinc contains from $1\frac{1}{2}$ to 11 per cent. of cadmium. The only native compound of cadmium is the sulphide called *Greenockite*. See GREENOCKITE.

Cadmium may be extracted by dissolving the ores containing it in sulphuric acid, leaving the solution acidulous, and diluting it with water, then transmitting through it a stream of sulphuretted hydrogen, till the yellow precipitate ceases to fall. The powder, which is sulphide of cadmium, is to be dissolved in concentrated muriatic acid, the excess of which is to be expelled by evaporation; and the salt being dissolved in water, carbonate of ammonia is added in excess; cadmium separates as a carbonate, while the adhering copper or zinc is retained in solution by the ammonia. Herapath has shown that, in distilling zinc *per descensum*, the first portions of gaseous metal which are disengaged burn with a brown flame and deposit the brown oxide of cadmium. See ZINC.

Cadmium has the colour and lustre of tin, and is susceptible of a fine polish. Its fracture is fibrous; it crystallises readily in regular octahedrons: and when it suddenly solidifies, its surface gets covered with fine mossy vegetations. It is soft, easily bent, filed, and cut, soils like lead any surface rubbed with it. It is harder and more tenacious than tin, and emits a creaking sound when bent, like that metal. It is very ductile, and may be drawn out in fine wire, and hammered into thin leaves, without cracking at the edges. Its specific gravity, after being merely melted, is 8.604; and 8.6944 after it has been hammered. It is very fusible, melting at a heat much under redness; indeed, at a temperature little exceeding that of boiling mercury, it boils and distils over in drops. Its vapours have no smell. It is but slightly altered by exposure to air. When heated in the atmosphere it readily takes fire and burns with a brownish-yellow smoke, which is destitute of smell. In strong acids it dissolves with disengagement of hydrogen, and forms colourless solutions. Chromate of potash causes no precipitate in them, unless zinc or lead be present.

There are two oxides of cadmium: a suboxide Cd^2O and a protoxide CdO . The *protoxide* is a brown powder obtained by igniting the metal, or by heating its carbonate or nitrate. It is neither fusible nor volatile at a very high temperature. When in the state of a hydrate, it is white. This oxide of cadmium consists of 87.45 parts of metal and 12.55 oxygen, in 100 parts. The other, or *suboxide of cadmium*, is obtained by heating the oxalate of cadmium to about the melting point of lead. It is a green powder resembling oxide of chromium.

CADMIUM, ALLOYS OF. One hundred parts of copper at a red heat combine with eighty-two parts of cadmium. This alloy is of a yellowish-white colour. Platinum at a red heat will take up 117 parts of cadmium. This alloy is silver white, very brittle, and refractory in the fire. With mercury, cadmium forms a hard, brittle, white amalgam. These alloys have no commercial value or manufacturing interest.

Some of the alloys of cadmium are remarkable for their fusibility; thus, an alloy of 1 part cadmium, 6 parts of lead, and 7 of bismuth melts at $180^{\circ} F.$, or considerably below the temperature of boiling water. Alloys containing cadmium have been used for stopping teeth.

CADMIUM, SALTS OF. Bromide, chloride, iodide, and sulphate of cadmium have been prepared and examined, but with the exception of the use of the bromide and iodide in photography, none of these salts are of any importance in the arts. The sulphate has been applied to the eyes by surgeons to remove specks on the cornea.—See Watts's 'Dictionary of Chemistry.'

CADMIUM YELLOW or **CADMIUM SULPHIDE.** The artificial sulphide of cadmium is prepared by fusing cadmium with sulphur, by igniting cadmic oxide (protoxide of cadmium) with sulphur, or it is precipitated in yellow flakes, as a hydrate, when sulphuretted hydrogen or an alkaline hydrosulphate is brought in contact with a cadmium salt. This forms the pigment cadmium yellow, or *jaune brillant*. The sulphide occurs native as *Greenockite*. See GREENOCKITE.

CAEN STONE. A variety of Oolitic limestone, which is largely quarried at Caen in Normandy, and which has been used for a long period in Gothic churches and other buildings. See OOLITIC LIMESTONE.

CERULEUM. A blue pigment, consisting of stannate of protoxide of cobalt, mixed with stannic acid and sulphate of lime.

CÆSIUM. (*Symbol*, Cs.; *Atomic weight*, 133.) One of the new metals discovered by aid of the spectrum analysis in 1860 by Kirchoff and Bunsen. It has not been

found except in company with RUBIDUM. Its name is derived from *cæsius*, 'sky-blue,' which colour it imparts to flame, and when its radiations are decomposed by a prism, it gives two blue lines, one rather faint in the middle of the blue space of the ordinary solar spectrum, and the other brighter, situated towards the violet end.

Cæsium was first detected in the mineral water of Dürkheim, ten kilogrammes (about two pounds and a quarter) of which contained not quite two milligrammes (0·015 grain). It has since been detected in the waters of Kreuznach, and in those of Baden-Baden, Bourbonne-les-Bains, Haute-Marne; in the salines of Aussee; and in the lepidolite or lithium-mica of Zinnwald, of Rozena, and of Hebron in Maine, United States. But the most abundant source of cæsium yet discovered is a rare mineral found in Elba, and known as *Pollux*; Pisani has found as much as 32 per cent. of cæsium in this mineral.

Pure metallic cæsium has not yet been obtained; but an amalgam of cæsium can be procured by electrolysing a solution of chloride of cæsium, using mercury as the negative pole. For the salts of cæsium, see Watts's 'Dictionary of Chemistry.'

CAFFEINE. $C^8H^{10}N^2O^2$ ($C^8H^8N^2O$). A weak alkaloid discovered in coffee. It is white, crystallisable in silky needles, fusible, volatile, and soluble in water, alcohol, and ether. It is identical with *Theine* and with *Guaranin*.

According to Robiquet, the proportion of caffeine in 1,000 of coffee is as follows:—Martinique 6·4, Alexandrian 4·4, Java 4·4, Mocha 4, Cayenne 3·8, St. Domingo 3·2. It is probable that 0·64 per cent. is an ordinary proportion. According to Liebig, the proportions are per lb.: Martinique 32 gr., Alexandrian 22, Java 22, Mocha 20, Cayenne 19, St. Domingo 16. To obtain caffeine, H. J. Versman of Lubeck mixes 10 lbs. of bruised raw coffee with 2 of lime, made previously into hydrate; treats the mixture in a displacement apparatus with alcohol of 80° till the fluid which passes through no longer furnishes evidence of the presence of caffeine. The coffee is then roughly ground and brought nearly to the state of a powder, and the refuse of the once digested mixture from the displacement apparatus, dried and ground again, and mixed with hydrate of lime, is once more macerated. The grinding is more easily effected after the coffee has been subjected to the operation of alcohol, having lost its horny quality, and the caffeine is thus more certainly extracted. The bright alcoholic liquid thus obtained is then to be distilled, and the refuse in the retort to be washed with warm water to separate the oil. The fluid is now evaporated into a crystalline mass, filtered, and expressed. The impure caffeine is freed from oil by pressure between folds of blotting-paper, purified by solution in water with animal charcoal, and is thus obtained in shining white silky crystals. See THEINE and GUARANIN.

CAFFEONE. The aromatic principle of coffee is so called. It is a brown oil heavier than water, and slightly soluble in that fluid when boiling. It is prepared by distilling coffee with water, agitating the distillate with ether, and evaporating the ether. Considerably less than a grain will flavour a pint or two of water.

CAHOUN NUTS. The fruits of *Attalea funifera*, the *A. cohune* of Martius. The tree producing these nuts is a plume-like palm, a native of Honduras. The nuts grow in clusters like bunches of grapes. An oil is extracted from these nuts by expression equal to that of the cocoa-nut. See COCOA-NUT.

CAINE. The Brazilian name for the American oil-palm, *Elæis melanococca*. Of its very long leaves the Brazilians make ropes, and its expressed oil is much used by them. See ELZEIS and PALM OIL.

CAIRNGORM, or CAIRNGORUM, is the name generally applied to the more pellucid and paler coloured varieties of smoky quartz, with a tint resembling that of sherry or amber. It is so called from the district of Cairngorum, or the 'Blue Mountain,' in the south-west of Banff, where these crystals are frequently found. When of a good colour, this crystal is made into ornaments, and used for jewellery; indeed, so great a favourite is the Cairngorum with the people of Scotland, that brooches, pins, bracelets, and a variety of ornaments, are made with this stone, for use by all classes.

CAJUPUT OIL is obtained from the leaves of the tree called *Melaleuca minor*, which grows upon the mountains of Amboyna, and in other of the Molucca Islands. It is procured by distillation of the dried leaves with water, is prepared in great quantities in the island of Banda, and sent to Holland in copper flasks: hence, as it comes to us, it has a green colour.—*Ure*. M. Guibort appears to have detected copper in several samples of cajuput oil. Pereira says, 'All the samples of the oil which I have examined, though green, were quite devoid of copper;' and Mr. Brande observes, that none of the samples which he has examined have contained even a trace of copper. It is very limpid, lighter than water, of a strong smell resembling camphor, and pungent taste like cardamoms. In 1831, oil of cajuput was greatly extolled as a remedy for cholera; and to meet the sudden and large demand, various adulterations and imitations were introduced. One of these consisted of oil of rosemary, flavoured with cardamoms or oil of cardamoms, and coloured. According to

Blanchet, the composition of oil of cajuput is, carbon 77·92, hydrogen 11·69, oxygen 10·39. It is used in medicine as a stimulant. See OILS, ETHEREOUS.

CAKING COAL. A coal which fuses together when heated. All the caking coals are bituminous, and usually make good coke. See COAL.

CAL or **KAL**, sometimes **CALLEN**. A miner's term for iron ochre, especially in St. Just in Cornwall. The term is sometimes applied to Wolfram.

CALABA-TREE, *Calophyllum Calaba*, so called from the beauty of its leaves. From the roots of several species an oil is expressed, which is used for burning in lamps, and from the incised trunk a resin is obtained, which is known in commerce by the name of Tacamahaca gum. The true calaba tree is a native of the Caribbee Islands; it grows to the height of sixty feet, and its wood is much valued for staves and for cask headings.

CALABAR BEAN. See ORDEAL BEAN.

CALABAR-SKIN. The skin of the Siberian squirrel is sometimes so called. It is imported and used for making muffs and trimmings.

CALABASHES. The pericarp of the fruit of the Calabash tree, one of the *Bignoniaceæ* (*Crescentia cujete*). It is a native of the tropical regions of America, and produces a melon-like fruit, containing a slightly acid pulp, which is sometimes eaten. After the removal of the pulp, the pericarp is used for cups, bottles, baskets, &c.

CALAITÉ. See TURQVOIS.

CALAMANCO. A sort of woollen stuff of a shining appearance, chequered in the warp, so that the checks are seen only upon one side.

CALAMANDER. A wood, the produce of a species of *Diospyros*, from Ceylon. See COROMANDEL.

CALAMINE. Unfortunately, there is some confusion among mineralogists in the application of this term. It appears that the *Lapis calaminaris* of the older writers included two distinct ores of zinc—the carbonate and the hydrous silicate. In the early part of this century Smithson pointed out the differences between the two species. Brongniart soon afterwards gave the name of Calamine to the silicate, and several years later Beudant proposed the term Smithsonite for the carbonate. This usage of the names is still retained by Dana and by certain Continental writers, but English mineralogists have been accustomed to reverse this use of the terms. In this country, therefore, the carbonate of zinc is invariably distinguished as *calamine*, whilst the silicate is known as Smithsonite or Electric Calamine. See ZINC.

CALAMINE, ELECTRIC.—Hydrous silicate of zinc, known otherwise as *Smithsonite* or *Hemimorphite*. The term 'electric,' applied to this mineral, refers to its pyroelectric properties, or its power of exhibiting electric polarity when heated, the two extremities of a heated crystal assuming opposite electrical conditions.

CALAMUS (κάλαμος, a reed). A genus of plants belonging to the palm tribe. The *C. Rotang* and *C. Scipionum* are mentioned as two species which produce the Rattan canes of commerce. The Dragon's Blood of commerce is obtained from the *C. Draco*, a native of Sumatra and Borneo. See DRAGON'S BLOOD; RATTAN.

CALAMUS AROMATICUS. The *Acorus*, or sweet Flag. The drug sold under this name in our shops is the produce of the *Acorus calamus*. The plant is a native of this country, of various parts of Europe, and of India. The Indian variety furnishes a famous medicine in the Levant, while the Turks candy it and regard it as a remedy against contagion. The rushes which were formerly strewn over the floors of rooms were the leaves of this plant. It has been said that the *Acorus calamus* is sometimes employed in rectifying gin. By distillation it yields a volatile oil used in scenting snuff, and in the production of aromatic vinegar.

CHALCANTHUM. See CHALCANTHUM.

CALCAR. A name given by glass-makers to a small furnace—in which the first calcination is made of sand and potash—for the formation of a *frit*, from which glass is made.

CALCAREOUS EARTH (*Terre calcaire*, Fr.; *Kalkerde*, Ger.) commonly denotes lime, in any form; but, properly speaking, it is pure lime. This term is frequently applied to marl, and to earths containing a considerable quantity of lime.

CALCAREOUS SPAR. Crystallised native carbonate of lime, of which there are many varieties.

Carbonic acid 44·0, lime 56·0, may be regarded as the usual composition of calc spar; it often contains impurities upon which depend the colours assumed by the crystal. The carbonates of lime are extensively distributed in nature, as marbles, chalk, &c. See ICELAND SPAR, MARBLE, &c.

CALCAREOUS TUFFA. This term is applied to varieties of carbonates of lime, formed by the evaporation of water containing that mineral in solution.

It is formed in fissures and caves in limestone rocks, about the borders of lakes, and near springs, the waters of which are impregnated with lime. In the latter cases it is

frequently deposited upon shells, moss, and other plants, which it covers with a calcareous crust, producing frequently a perfect representation in stone of the substance so enveloped.—H. W. B.

CALCEDONY. See CHALCEDONY.

CALCEDONYX. See CHALCEDONYX.

CALCINATION (from *Calcine*). The operation of expelling from a substance, by heat, either water or volatile water combined with it. Thus, the process of burning lime, to expel the carbonic acid, is one of calcination. The result of exposing the carbonate of magnesia to heat, and the removal of its carbonic acid, is the production of *calcined magnesia*. The term was, by the earlier chemists, applied only when the substance exposed to heat was reduced to a *calx*, or to a friable powder, this being frequently the oxide of a metal. It is now, however, used when any body is subjected even to a process of roasting.

CALCIPHYRE. A name given by Brongniart to a compound of granular limestone with garnet or felspar, usually porphyritic.

CALCITE. Crystallised carbonate of lime. See ICELAND SPAR.

CALCIUM (*Symbol*, Ca.; *Atomic weight*, 20.) The metal contained in the oxide well known as lime. It was first obtained by Davy, in 1808, by the electrolysis of the hydrate, carbonate, chloride, or nitrate of lime. Matthiessen obtained it by heating, in a porcelain crucible, a mixture of two atoms of chloride of calcium with one of chloride of strontium, and a small quantity of chloride of ammonium, until the latter is volatilised. The current from six cells of Bunsen's battery is then sent through the mixture by a charcoal pole of as large size as possible, and a piece of iron pianoforte wire (No. 6), not more than two lines in length, which is united with the negative pole of the battery by means of a stronger line reaching close to the surface. A small crust is to be formed round the wire at the surface. To collect the small globules deposited on the wire, the latter must be taken out every two or three minutes, together with the crust. The globules are crushed in a mortar, and the flattened granules are then picked out. Calcium is a brilliant pale yellow metal, malleable and ductile. See LIME.

CALCIUM, CHLORIDE OF. Ca Cl (CaCl_2). A deliquescent salt readily obtained by dissolving chalk in hydrochloric acid. A saturated solution boils at 355°F ., and is therefore sometimes employed as a bath where such a temperature is required. The hydrated chloride, obtained by evaporation of the solution, causes great depression of temperature when dissolved in water; hence its use in certain freezing mixtures. Mercury may be frozen by means of a mixture of crystallised chloride of calcium and snow. The anhydrous salt obtained by heating the hydrate, is extremely deliquescent, and is therefore used as a desiccating agent. After exposure to sunlight, the chloride appears luminous in the dark, and was formerly called *Hombert's Phosphorus*.

CALCIUM, FLUORIDE OF. CaF (CaF_2). This salt occurs in the bones and teeth of animals, and in minute quantity in sea-water, and in the water of certain springs. It is found native as Fluor Spar.

CALCIUM, OXIDE OF. See LIME.

CALCIUM, PHOSPHIDE OF. By distilling phosphorus over lime at a low red heat, an impure phosphide of calcium is obtained. This salt, when thrown into water, evolves phosphuretted hydrogen, which is spontaneously inflammable. After the phosphide has been slaked, by exposure to a moist atmosphere, it also yields phosphuretted hydrogen when brought in contact with water, but the gas thus obtained does not ignite spontaneously.

CALCIUM, SULPHIDES OF. Several sulphides of calcium are known, but are of no importance in the arts. *Canton's Phosphorus* is an impure sulphide, obtained by calcining oyster-shells, and heating the product with one-third of its weight of flowers of sulphur, in a closed crucible.

CALC-SINTER. The incrustations of carbonate of lime upon the ground, or the pendulous conical pieces called stalactites, attached to the roofs of caverns, are so called.

CALC-SPAR. Crystallised carbonate of lime or calcite.

CALCULUS. The stony-looking morbid concretion occasionally formed in the bladders and other parts of living animals. Its examination belongs to medical chemistry.

CALEMBEG. An ornamental wood; it is often called aloes wood, and sometimes green sandal-wood, being of a greenish colour, and slightly scented.

CALEMBERRI. A name sometimes given to coromandel wood. See COROMANDEL WOOD.

CALENDER (*Calandre*, Fr.; *Kalender*, Ger.), a word derived from the Greek *κύλινδρος* 'cylinder,' is the name of a machine consisting of two or more cylinders revolving so nearly in contact with each other, that cloth passed through between

them is smoothed, and even glazed, by their powerful pressure. It is employed either to finish goods for the market, or to prepare cotton and woollen webs for the calico printer, by rendering their surfaces level, compact, and uniform. This condensation and polish, or *satinage* as the French call it, differ in degree according to the object in view, and may be arranged in three different series:—1. For goods which are to receive the first impression by the block, a very strong pressure is required, for upon the uniformity of the polish the neatness and the regularity of the printing and the correspondence of its members depend. 2. The pieces already dyed up at the madder-bath, or otherwise, and which remain to be filled in with other colours, or *grounded in*, as it is technically called, must receive a much less considerable gloss. 3. The degree of glazing given to finished goods depends upon the taste of purchasers, and the nature of the article; but it is, in general, much less than for the first course of block printing.

The calico printers of Alsace employ an improved form of calender to that usually employed in this country, which is the contrivance of M. Charles Dollfus. It is described as possessing the following advantages:—1. It passes two pieces at once, and thus does double the work of any ordinary machine. 2. It supersedes the necessity of having a workman to fold up the goods, as they emerge from the calender with the aid of a self-acting folder. 3. It receives, at pleasure, the finished pieces upon a roller, instead of laying them in folds; and, by a very simple arrangement, it hinders the hands of the workman from being caught by the rollers.

The most remarkable feature of M. Dollfus's machine is its being managed by a single workman. Six or eight pieces are coiled upon the feed roller, and they are neither pasted nor stitched together, but the ends are merely overlapped half a yard or so. The workman is careful not to enter the second piece till one third or one half of the first one has passed through on the other side, to prevent his being engrossed with two ends at a time. He must, no doubt, go sometimes to the one side and sometimes to the other of the machine to see that no folds or creases occur, and to be ready for supplying a fresh piece as the preceding one has gone through. The mechanism of the folder in the Alsace machine is truly ingenious: it performs extremely well, and saves an extra workman. The lapping-roller works by friction, and does its duty better than similar machines guided by the hand.

The numerous accidents which have happened to the hands of workmen engaged in calenders should direct the attention towards an effective contrivance for preventing such misfortunes. These various improvements in the Alsace machine may be easily adapted to the ordinary calenders of almost every construction.

The folder is a kind of cage in the shape of an inverted pyramid, shut on the four sides, and open at top and bottom: the top orifice is about five inches, the bottom one an inch and a half: the front and the back, which are about four feet broad, are made of tin plate or smooth pasteboard, and the two sides are made of strong sheet-iron, the whole being bolted together by small bars of iron. Upon the sheet-iron of the sides, iron uprights are fixed, perforated with holes, through which the whole cage is supported freely by means of studs that enter into them. One of the uprights is longer than the other, and bears a slot with a small knob, which, by means of the iron piece, joins the guide to the crank of the cylinder, and thereby communicates to the cage a see-saw movement: at the bottom extremity of the great upright there is a piece of iron in the shape of an anchor, which may be raised, or lowered, or made fast by screws.

At the ends of this anchor are friction rollers, which may be drawn out or pushed back and fixed by screws: these rollers lift alternately two levers made of wood, and fixed to a wooden shaft.

The paws are also made of wood: they serve to lay down alternately the piles of the cloth which passes upon the cage, and is folded zigzag upon the floor, or upon a board set below the cage; a motion imparted by the see-saw motion of the cage itself.

To protect the fingers of the workmen, above the small plate of the spreading-board or bar, there is another bar, which forms with the former an angle of about 75°: they come sufficiently near together for the opening at the summit of the angle to allow the cloth to pass through, but not the fingers. See *Bulletin de la Société Industrielle de Mulhausen*, No. 18.

It is not thought necessary to give a drawing of the calender usually employed in this country; a few remarks may not, however, be out of place. The iron rollers are made hollow for the purpose of admitting either a hot roller of iron, or steam, when hot calendering is required. The other cylinders used formerly to be made of wood, but it was liable to many defects. The advantage of the paper roller consists of its being devoid of any tendency to split, crack, or warp, especially when exposed to a considerable heat from the contact and pressure of the hot iron rollers. The paper, moreover, takes a vastly finer polish, and being of an elastic

nature, presses into every pore of the cloth, and smooths its surface more effectually than any wooden cylinder, however truly turned, could possibly do.

The paper cylinder is constructed as follows:—The axis of the cylinder is a strong square bar of the best wrought iron, cut to the proper length. Upon this bar a strong round plate of cast iron is first put, somewhat less in diameter than the cylinder when finished; a quantity of thick stout pasteboard is then procured, and cut into round pieces an inch larger in diameter than the iron plate. In the centre of the plates, and of every piece of the pasteboard, a square hole must be cut to receive the axis; and the circle being divided into six equal parts, a hole must also be cut at each of the divisions an inch or two within the rim. These pieces of pasteboard being successively put upon the axis, a long bolt of malleable iron, with a head at one end, and screwed at the other, is also introduced through each of the holes near the rim; and this is continued until a sufficient number of pasteboards are thus placed to form a cylinder of the length required, proper allowance being made for the compression which the pasteboard is afterwards to undergo. Another round plate is then applied, and nuts being put upon the screws, the whole are screwed tight, and a cylinder formed. This cylinder is now to be placed in a stove, exposed to a strong heat, and must be kept there for at least several days; and, as the pasteboard shrinks by exposure to the heat, the screws must be frequently tightened until the whole mass has been compressed as much as possible. When the cylinder is thus brought to a sufficient degree of density, it is removed from the stove; and, when allowed to cool, the pasteboard forms a substance almost inconceivably dense and hard. Nothing now remains but to turn the cylinder; and this is an operation of no slight labour and patience. The motion in turning must be slow, not exceeding about forty revolutions in a minute; the substance being now so hard and tough that tools of a very small size must be used to cut, or rather scrape it, until it is true. Three men are generally employed for the turning, even when the motion of the cylinder is effected by mechanical power, two being necessary to sharpen the tools for the third, who turns, as quickly as he blunts them.

Let us suppose it to be a five-rollered machine: when a person stands in front of the calender, the cloth coming from behind above the uppermost cylinder 1, passes between 1 and 2; proceeding behind 2, it again comes to the front between 2 and 3; between 3 and 4 it is once more carried behind, and lastly, brought in front between 4 and 5, where it is received and smoothly folded on a clean board, or in a box, by a person placed there for the purpose. In folding the cloth at this time, care must be taken that it may be loosely done, so that no mark may appear until it be again folded in the precise length and form into which the piece is to be made up. The folding may be done either by two persons or by one, with the aid of two sharp polished spikes placed at a proper distance, to ascertain the length of the fold, and to make the whole equal. When folded into lengths, it is again folded across upon a smooth clean table, according to the shape intended, which varies with different kinds of goods, or the particular market for which the goods are designed.

When the pieces have received the proper fold, the last operation previous to packing them is the pressing. This is commonly performed by placing a certain number of pieces, divided by thin smooth boards of wood, in a common screw press similar to those used by printers for taking out the impression left by the types in the printing-press. Besides the wooden boards, a piece of glazed pasteboard is placed above and below every piece of cloth, that the outer folds may be as smooth and glossy as possible. The operation of the common screw-press being found tedious and laborious, the hydraulic press is now had recourse to in all well mounted establishments. See **HYDRAULIC PRESS.**

For lawns and muslins of a light texture, the operation of smoothing requires a different process in some respects than close heavy fabrics. They only require to be slightly smoothed to remove any marks which they may have received at the bleaching; and, as their beauty depends rather on their transparency than their closeness, the more the cylindrical form of the yarn is preserved the better. They are therefore put through a small machine, consisting of three rollers or cylinders: and, as the power required to move this is small, the person who attends it generally drives it by a small winch; or the same effect may be produced by passing the muslins between only two or three rollers of the above calender, lightly loaded.

In the thick fabrics of cloth, including those kinds which are used for many parts of household furniture, as also those for female dress, the operation of glazing is used both to add to the original beauty of the cloth, and to render it more impervious to dust or smoke. The glazing operation is performed entirely by the friction of any smooth substance upon the cloth; and to render the gloss brighter, a small quantity of bleached wax is previously rubbed over the surface. The operation of glazing by the common plan is very laborious, but the apparatus is of the most simple kind. **A**

table is mounted with a thick stout cover of level and well-smoothed wood, forming an inclined plane; that side where the operator stands at work being the lowest. The table is generally placed near a wall, both for convenience in suspending the glazing apparatus, and for the sake of light. A long piece of wood is suspended in a groove formed between two longitudinal beams, placed parallel to the wall, and fixed to it. The groove resembles exactly the aperture between the shears of a common turning lathe. The lever, of which the groove may be supposed to be the centre or fulcrum, is faced at the bottom with a semi-cylindrical piece of finely polished flint, which gives the friction to the cloth stretched upon the table below. Above the flint are two cross handles, of which the operator lays hold, and moves them backward and forward with his hands, keeping the flint pressing slightly upon the cloth. When he has glazed a portion equal to the breadth of the flint, he moves his lever between the shears sidewise, and glazes a fresh part: thus he proceeds from one side or selvage of the cloth to the other; and when all which is upon the table is sufficiently glazed, he draws it over, and exposes a new portion to the same operation. To preserve the cloth at a proper tension, it may be wound smoothly upon a roller or beam, which being set so as to revolve upon its own axis behind the table, another roller to receive the cloth may be placed before, both being secured by a catch, acting in a ratchet wheel. Of late years, however, a great part of the labour employed in glazing cloth has been saved, as the common four or five bowl calender has been altered to fit the purpose by direct pressure.

As a matter of accommodation, the different processes of packing, cording of boxes, sheeting of trunks, and, in general, all the arrangements preparatory to shipment, and also the intimations, and surveys necessary for obtaining drawbacks, debentures, or bounties, according to the Excise laws, are generally conducted at the calender houses where goods are finished.

CALEDONITE (*from Caledonia*). A cupreous sulphato-carbonate of lead found in minute bluish-green crystals associated with other ores of lead at the Lead Hills mines in Lanarkshire. This mineral has also been found in Cumberland, at Tanné in the Hartz, at the Mine la Motte, Missouri.

CALIBRE (*Calibre, Fr.; Calibro, It.*) The bore or diameter of a gun, or the diameter of a bullet; it is measured in inches, and in smooth-bore guns is larger than the diameter of the ball.

CALICO (*from Calicut, in India*). A term for any white cotton cloth, which was first manufactured in, and introduced from, India. In this country we have shirting calicoes, unbleached calicoes, and the like. In the United States the term is restricted to cotton cloths having patterns printed upon them.

CALICO-PRINTING is the art of producing a pattern on cotton cloth, by printing in colours, or mordants, which become colours, when subsequently dyed. Calico derives its name from Calicut, a town in India, formerly celebrated for its manufactures of cotton cloth, and where calico was also extensively printed. Other fabrics than cotton are now printed by similar means, viz. linen, silk, wool, and mixtures of wool and cotton. Linen was formerly the principal fabric printed, but since modern improvements have produced cotton cloth at a comparatively cheap rate, linen fabrics are now sparingly used for printing, and then principally for handkerchiefs, linen cloth not producing such beautiful colours, in consequence of the small affinity of flax for mordants, or colouring matters. Silk printing, also, is chiefly confined to handkerchiefs, but the printing of woollen fabrics or moussoline-de-laines is an important branch of the art. The earliest mode of ornamenting cloth with designs was, no doubt, by embroidery with the needle, and this mode was almost coeval with the art of dyeing, which is of very remote antiquity. Herodotus mentions that Amasis, king of the Egyptians, sent to the Lacedæmonians a pectoral of linen, adorned with many figures of animals, woven into the cloth, and enriched with gold and a variety of colours. A similar pectoral was taken among the spoils at the battle of Issus, and presented to Alexander the Great, who wore it afterwards as part of his military attire. Cloth was, however, stained in a rude manner by ancient tribes with juices of plants. Herodotus mentions a Scythian tribe who stained their garments with figures of animals by means of the leaves of a tree bruised with water, which figures would not wash out, and lasted as long as the cloth. It is an interesting speculation as to what this dye was. The garments so stained were probably woollen, as in early times the outer garments were always woollen, and the particular dye might have been indigo in a soluble state, as produced by fermenting the leaves with water; according to Sir William Jones, the leaves of the shrub henna, when bruised in water, stain the skin or nails orange, and would doubtless do the same on woollen cloth. The first record of calico-printing as an art is that of Pliny, who describes the process followed by the Egyptians, who seemed to have attained a very considerable degree of refinement in the art. 'Robes and white veils,' says he, 'are painted in

Egypt in a wonderful way. They are first imbued, not with dyes, but with dye-absorbing drugs, by which, though they seem to be unaltered, yet, when immersed for a little while in a cauldron of the boiling dye-liquor, they are found to become painted. Yet, as there is only one colour in the cauldron, it is marvellous to see many colours imparted to the robe, in consequence of the influence of the excipient drug. Nor can the dye be washed out. A cauldron, which would of itself merely confuse the colours of cloths previously dyed, is thus made to impart several pigments from a single dye-stuff, *painting as it boils.*' The last expression, *pingitque dum coquit*, is perfectly graphic and descriptive of some processes in calico-printing.

Calico-printing is of very ancient date in India, and probably this country is the birthplace of the art, since, beyond doubt, cotton cloth originated in India, and the abundance of dye-stuffs, and the facility with which cotton receives dyes, rendered the staining it with figures a natural consequence, and there is good reason to suppose that the Egyptians learnt the art from India, since the Indians were highly civilised twenty-two centuries ago; and there was undoubtedly communication between India and Egypt before the time of Pliny. There is an account of Indian calico-printing by Father Cœurdoux, a missionary at Pondicherry, and in a manuscript account sent from thence by M. du Fay, and communicated to the Royal Academy of Sciences at Paris by the Abbé Mazeas, also from the report by M. Beaulieu, of operations performed under his inspection at Pondicherry.—*Bancroft.*

These accounts describe the mode of producing the chintz calicoes, which were celebrated in Europe before the art had been introduced and simplified there. From these accounts of the cumbrous and tedious processes adopted by the natives, we have no difficulty in understanding the necessity that arose for the intervention of European skill and science, and can readily comprehend how it is that the European printer, to say nothing of superior artistic excellence, can compete successfully in India with the proverbially low-priced labour of Hindostan. After the cloths were partially bleached, they underwent several alternate steepings in goats'-dung, beating, washing, and drying in the sun; they were then soaked in an astringent solution obtained from myrabolams, mixed with buffaloes' milk; squeezed out of this, they were dried in the sun, and, by pressure with wooden rollers, made smooth enough to have a pattern drawn on them with a pencil, applying various mordants: the general course was to paint on a mordant of iron liquor, similar in constitution to that at present used in calico-printing. This formed a black with the tannin substance previously applied. The next step was to give the blue, and for this purpose the cloth required to be freed from the astringents by maceration in goats'-dung, well washing and drying in the sun; the parts intended to be white were then protected by a coat of melted wax; the cloth was then dipped in an indigo vat: when dyed, the wax had to be thoroughly removed by boiling in water, steeping in dung, washing with a sort of impure soda, renewed steeping in dung, washing and drying in the sun; after this the cloth was treated, as before, with the astringent milk mixture, dried and smoothed. It was then ready to receive the red and chocolate mordants, the red being simply alum mixed with a little soda to render it basic, and the chocolate, this red mixed with the iron mordant; (the use of acetate of alumina not being known, the albumen of the milk and the tannin combined with and fixed the alumina on the cloth). After careful sun-drying, the cloth was well steeped and rinsed in water to remove the excess of mordants, &c., and then dyed with madder or chaya root. After this they were washed with dung and soap, exposed to the sun, and watered occasionally till the white parts were bleached. Yellow, made from alum and myrabolams was now pencilled in, and green formed by the yellow going over the blue. This process gave chintzes, the colours of which were generally very bright and lively, and most of them exceedingly durable. M. Koehlin Roder, of Mulhouse, brought home from India a rich collection of cloths in every state of preparation, which are in the cabinet of the *Société Industrielle* of that interesting emporium of calico-printing. The native implements for applying the wax and colouring bases are placed alongside of the cloths, and form a curious picture of primeval art. There is among other samples an ancient *pallampoor*, five French yards long and two and a half broad, said to be the labour of Hindoo princesses, which must have taken a lifetime to execute.

Calico-printing was not, however, in all oriental countries executed with the pencil. The shawl-printers of Cashmere use small wooden blocks for their complicated patterns. Mr. Buckingham states, that at Orfah, in Mesopotamia, the printers employ wooden blocks of 4 to 6 inches square, and use them nearly in the same manner as the block-printers in this country; and it is well known that the Chinese employed block-printing long before any species of printing was known in this country.

Calico-printing has been for several hundred years practised by the oriental methods in Asia Minor and the Levant; but it was unknown as an English art till

about the close of the seventeenth century. It is believed that the first attempts at imitating the printed calicoes of India were made in Holland, the Dutch East India Company having introduced the Indian chintzes there before their introduction into this country. It is uncertain where or when these first attempts were made; but it appears the art soon spread to Germany, for about the close of the seventeenth century Augsburg had obtained a notoriety for printed linens and cottons. The art was most probably introduced into England about 1676, by Flemish emigrants. Mr. James Thompson, of Clitheroe, one of the most eminent English calico-printers, fixed the date at 1690, and supposed that a Frenchman, a refugee, at the time of the revocation of the edict of Nantes, was the first to print calicoes in this country, and that his works were at Richmond on the Thames; but there is evidence to show that prior to this date, calicoes were printed in this country, for Sir Joshua Child, a distinguished director of the East India Company, in a pamphlet published in 1677, mentions that calicoes were then brought over from India to be printed in this country, in imitation of the Indian printed chintzes. It appears, from a petition addressed to the House of Commons by the East India Company in 1627, that Indian calicoes were at that time imported, and in 1631, in a catalogue of legal imports from India, painted calicoes are mentioned as to be allowed. In 1634, apparently, attempts were made to ornament fabrics with coloured patterns by mechanical means, for in that year Charles II. granted an exclusive patent for fourteen years, for the art or mystery of affixing wool, silk, and other materials of divers colours upon linen, silk, or cotton cloth, leather, and other substances, by means of oil, size, or other cements, to make them useful for hangings, &c., the patentee paying 10*l.* yearly to the Exchequer. Calico-printing was commenced in 1689, at Neufchâtel, by Jaques Deluze, a native of Sain-tonge, and this establishment rapidly became prosperous, and in time the parent of numerous offshoots in Germany, Portugal, and France.

Some time after the Richmond establishment, a considerable printing work was established at Bromley Hall, in Essex, and several others sprung up successively in Surrey, to supply the London shops with chintzes, their import from India having been prohibited in 1700 by Parliament. The art in its infancy had to struggle with many difficulties; an excise tax on all printed or dyed calicoes of 3*d.* per square yard was enacted in 1702, and which was increased to 6*d.* per square yard in 1714, only half these duties being laid on printed linens.

The silk and woollen weavers had all along manifested the greatest hostility to the use of printed calicoes, whether brought from the East or made at home. In the year 1680 they mobbed the India House in revenge for some large importations then made of the chintzes of Malabar. They next induced the Government, by incessant clamours, to exclude altogether the beautiful robes of Calicut from the British market. But the printed goods imported by the English and Dutch East India Companies found their way into this country, in spite of the excessive penalties annexed to smuggling, and raised a new alarm among the manufacturing population of Spital-fields. The sapient legislators of that day, intimidated as would appear, by the East London mobs, enacted in 1720 an absurd sumptuary law, prohibiting the *wearing of all printed calicoes whatsoever, either of foreign or domestic origin.* This disgraceful enactment, worthy of the meridian of Cairo or Algiers, proved not only a death-blow to rising industry in this ingenious department of the arts, but prevented the British ladies from attiring themselves in the becoming drapery of Hindostan.

The effect of this law,' says Mr. Edmund Potter, in his lecture on Calico-Printing, before the Society of Arts, as reporter on printed fabrics in the Exhibition of 1851, 'was to put an end to the printing of calicoes in England, and to confine the printers to the printing of linens. In 1736, so much of this Act was repealed as forbade the use or wear of printed goods of a mixed kind, containing cotton; and these fabrics were allowed to be printed, weighted with a duty of 6*d.* per square yard. In 1750, the entire production of Great Britain was estimated at 50,000 pieces per annum. In 1764, printers established themselves in Lancashire, tempted, doubtless, by the cheapness of fuel, and by this being the locality in which the cloth was manufactured. In 1774, the printer was released from his fetters with regard to the kind of cloth he must use, by the repeal of this law, so as to leave him the choice of his material; but he was still saddled with a duty of 3*d.* per square yard, to which a halfpenny was added in 1806. On the accession of Lord Grey's government to office it was one of their first acts to repeal this duty. Thus, after a period of about 140 years from its first introduction, the print trade was allowed to enter into competition with other kindred fabrics on a fair footing.'

France pursued for some time a similar false policy with regard to calico-printing, but she emerged sooner from the mists of manufacturing monopoly than England. Her avowed motive was to cherish the manufacture of flax, a native product, instead of that of cotton, a raw material, for which prejudice urged that money had to be

exported. Her intelligent statesmen of that day replied, that the money expended in the purchase of cotton was the product of French industry beneficially employed, and they therefore took immediate measures to put the cotton fabrics upon a footing of equality. Meanwhile the popular prejudices became irritated to such a degree, by the project of permitting the free manufacture and sale of printed cottons, that every French town possessed of a chamber of commerce made the strongest remonstrances against it. The Rouen deputies declared to the Government, 'that the intended measure would throw its inhabitants into despair, and make a desert of the surrounding country'; those of Lyons said, 'the news had spread terror through all its workshops:' Tours 'foresaw a commotion likely to convulse the body of the State:' Amiens said, 'that the new law would be the grave of the manufacturing industry of France;' and Paris declared that 'her merchants came forward to bathe the throne with their tears upon that inauspicious occasion.'

The Government persisted in carrying its truly enlightened principles into effect, and with manifest advantage to the nation, for the despair of these manufacturing towns has been replaced by the most signal prosperity.

France probably produces at the present time nearly 5,000,000 pieces of print per annum, which, considering the quality of many of them, may be considered a very important manufacture.

The great disadvantage under which the French printers labour is the higher price they pay for cotton fabrics and fuel above that paid by the English printers.

The repeal, in 1831, of the consolidated duty of 3½*d.* per square yard upon printed calicoes in Great Britain is one of the most judicious acts of modern legislation. By the improvements in calico-printing, due to the modern discoveries and inventions in chemistry and mechanics, the trade had become so vast as to yield in 1830 a revenue of 2,280,000*l.* levied upon 8,596,000 of pieces, of which, however, about three-fourths were exported, with a drawback of 1,579,000*l.* 2,281,512 pieces were consumed in that year at home. When the expenses of collection were deducted, only 350,000*l.* found their way into the Exchequer, for which pitiful sum thousands of frauds and obstructions were committed against the honest manufacturer. This reduction of duty enables the consumer to get this extensive article of clothing from 50 to 80 per cent. cheaper than before, and thus places a becoming dress within the reach of thousands of females in the humbler ranks of life. Printed goods, which in 1795 were sold for 2*s.* 3*d.* the yard, may be bought at present for 6*d.* The repeal of the tax has been no less beneficial to the fair dealers, by putting an end to the contraband trade, formerly pursued to an extent equally injurious to them and the revenue. It has, moreover, emancipated a manufacture eminently dependent upon taste, science, and dexterity from the venal curiosity of petty excisemen, by whom private improvements, of great value to the inventor, were in perpetual jeopardy of being pirated and sold to any sordid rival. The manufacturer has now become a free agent, a master of his time, his workmen and his apparatus; and can print at whatever hour he may receive an order; whereas he was formerly obliged to wait the convenience of the excise officer, whose province it was to measure and stamp the cloth before it could be packed—an operation fraught with no little annoyance and delay. Under the patronage of Parliament, it was easy for needy adventurers to buy printed calicoes, because they could raise such a sum by drawbacks upon the export of one lot as would go far to pay for another, and thus carry on a fraudulent system of credit, which sooner or later merged into a disastrous bankruptcy. Meanwhile the goods thus obtained were pushed off to some foreign markets, for which they were, possibly not suited, or where they produced, by their forced sales, a depreciation of all similar merchandise, ruinous to the man who meant to pay for his wares.

Calico-printing was first practised in Scotland in 1738, twenty-six years previous to its introduction into Lancashire. The following sketch of the early Lancashire printing is taken from Mr. Potter's pamphlet:—'The trade was established in Lancashire in 1764, by Messrs. Clayton, of Bamber Bridge, near Preston; the cloth that was printed being made with linen warp and cotton weft, and produced principally at Blackburn; this was the reason of many printers settling near Blackburn, which was for a long time the great seat of the print trade. The introduction of power-loom cloth caused the migration of a considerable print trade to Stockport, Hyde, Staleybridge, and North Derbyshire. The Claytons were followed by Mr. Robert Peel, who entered into the cotton business, and added to it the printing business. He carried on the business for some years at Brookside, near Blackburn, aided by his sons. The eldest son afterwards branched off from his father's concern, and established himself at Bury with his uncle, Mr. Haworth, and Mr. William Yates.

'During the period 1796 to 1821, the Forts, Hargreaves, and Thompsons fairly

established themselves as extensive and wealthy printers, not more by their energy and business talent than by their scientific attainments, and by the unbounded and lavish support which they gave to everything which art and science could suggest to assist them. Mr. James Thompson of Primrose, near Clitheroe, was for forty years the recognised head of the print trade. The era of his commencement in the trade was the beginning of a series of discoveries and new applications in chemical science to the purposes of calico-printing. During forty years he devoted himself and the ample funds his business placed at his disposal to the advancement of taste in connection with his trade. No sums, however large, were spared to draw into its service the talent even of Royal Academicians, and of many other eminent men high in art.' Mr. John Mercer, of the house of Fort Brothers, and a contemporary of Mr. Thompson, for a long period worked enthusiastically and rendered valuable assistance to the trade by the introduction of chemical novelties; and many styles founded by him are still popular. The house of Hargreaves Brothers and Co., during the same period, took a prominent position in the production of new and original colours and styles.

In France M. Koechlin was looked up to as the leader of the trade, and was mainly instrumental in establishing sound scientific principles in the art. 'During the progressive improvement, dating from 1831, one house may be named, of high standing, who introduced a colour superior in brilliancy, fastness, and utility for domestic wear, to any other previously known. This was the madder purple of Messrs. Thomas Hoyle and Sons, a colour which may be said to have superseded the old Navy blue print in English wear. Messrs. Hoyle and Sons maintained their well-deserved superiority for many years. The London printers, up to the repeal of the duty, still held their position for first-class goods. They made great use of the flat press printing-machine. Their plates were well engraved, and for a long time they succeeded in getting a smartness of impression, better than any at that time obtained from the cylinder. Some few of the Lancashire printers adopted the press, the better to compete with the town printer. The rapidly increasing trade in Lancashire, and with it the power of so much cheaper production, gradually undermined the London printers, and brought about a complete change in their class of work.'—The London printers now print fine shawls, handkerchiefs, waistcoatings, and a superior class of cotton prints for furniture hangings. The present annual production of printed cloth of all kinds in Great Britain may be estimated at about 20,000,000 pieces. In 1840 the quantity produced was about 16,000,000. The quantity now, probably, rather exceeds 20,000,000 of pieces; but, from the absence of any very authentic statistics, the quantity is very difficult to arrive at. The print trade, according to Mr. Bazley, consumes a weight of cotton about one-seventh the entire import into this country.

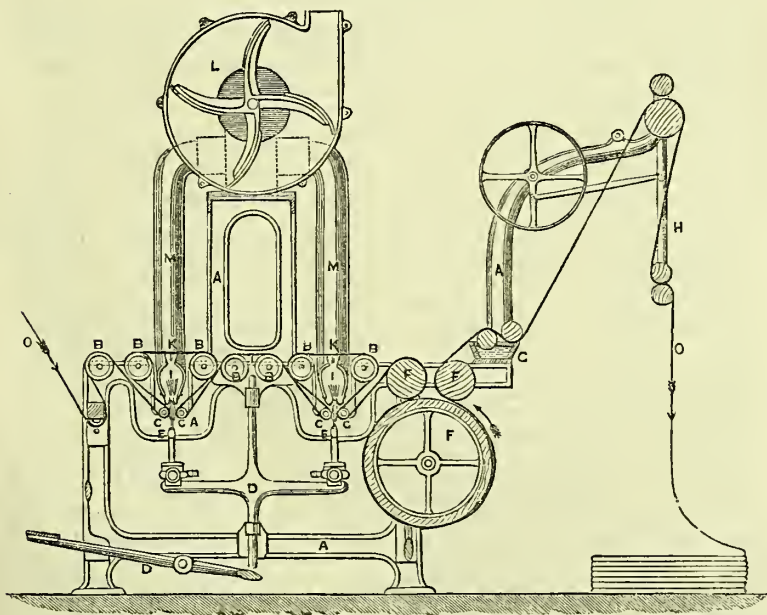

Owing to her natural advantages, England has by far the largest portion of the calico-printing trade, and especially of the export trade; and probably at the present time England produces as many printed pieces as all the rest of the world put together. The United States produces next to ourselves in quantity; France and Switzerland the next to America in *quantity*, but far superior to her in *quality*, and second only to ourselves in value of production. France is the only competitor we have to meet in the neutral markets of the world. The Zollverein, Austria, and Bohemia produce for their own markets, and by high protecting duties prevent any other supply, except of very fine French goods. Holland produces a small quantity of medium goods; Belgium also produces a few; Naples has a few small print works; Russia produces for her own market, and the number of works has rapidly increased of late—her market is almost prohibited to us; Spain produces a limited quantity of inferior goods; Portugal has a slight production; Turkey produces a few printed goods, hardly worth notice; the Sultan Abdul Medjid has tried the experiment of organising print works on the English principle, with English artisans and foremen, but the experiment was a complete failure; Egypt also has revived the art, with very inferior results. The Chinese undoubtedly practised the art of calico-printing many centuries before ourselves. Mr. Potter was able to exhibit samples of Chinese work to the Society of Arts, which he described as of very primitive taste and rude execution. 'Mulhausen, it may not be uninteresting to mention,' says Mr. Potter, 'is certainly the seat of the finest printing in the world. Calico-printing was first established there in 1746, by the firm of Koechlin and Co., and is still carried on by descendants of the original firm; and during the whole period, and not less so now, the house has had a high and justly deserved reputation for talent and taste; and to them the chemistry of the trade is most deeply indebted for many valuable processes and discoveries. Other houses of almost equal celebrity followed, and Mulhausen has justly maintained its reputation of being, for fine goods, the first calico-printing district in the world.'

The first step in calico-printing is to remove the fibrous down from the surface of

the cloth, which is done by passing the piece rapidly through a flame of gas, or over a red hot semi-circular plate. The latter method will be found described under the head of BLEACHING.

There are two methods in use of singeing with flame: one invented by Henry Gledhill, in which coke is burnt in a furnace provided with a cast-iron plate for a top, in which is left an aperture about 42 inches long and $\frac{5}{16}$ ths of an inch wide at the outside, but which is $\frac{3}{4}$ ths of an inch on the inside. The coke rests upon fire-bars in the usual manner, being fed from a close-fitting fire-door. The ash-pit, instead of being open as usual, is also provided with a closely-fitting door; a pipe from the blast fan is introduced into the side of the ash-pit. A fire being lighted, the furnace is filled with coke, and the fan being started, both the fire-door and the ash-pit door are closed and luted with clay; the flame now rises through the rectangular aperture to a height of about two feet, a hopper over the apparatus conducts the products of combustion into a chimney or flue, connected with the main chimney of the factory. The grey pieces are now passed rapidly over the flame, about 8 inches above the iron plate, being unwound from a roller, and after passing through a trough of water, being rewound on another roller. The flame is depressed by the cloth, and extends about a foot in length. The effect of this singeing is to thoroughly remove all the

324

fibrous down on one side of the cloth without weakening it or making it appear thin. In some print works this singeing machine is supplemented by the copper semi-circular hot plate (BLEACHING, *fig. 109*), which is arranged to receive the cloth on coming from the coke-gas flame. Singeing by coal-gas is a very cleanly and economical mode, but after its introduction it fell partly out of use on account of the thinning of the cloth by the gas flame being drawn through it. The gas singeing machine patented by Mather and Platt, overcomes this defect. The flame impinges against the surface of the cloth, which is thoroughly cleansed without being impoverished, and the gas is so perfectly consumed that there are no stains from imperfect combustion. There is also a considerable saving both of gas and time as compared with the old method. *Fig. 324* is a vertical section of this machine, A, framing of the machine; B, binding rollers on rails; C, rollers where the flame impinges on the cloth; these are moveable to make a wide or narrow opening for the flame, for a mild or keen singe; D, arms and levers for supporting the burners, &c. across the machine, and bringing or taking away the flame from its work; E, gas-burners and flame; F, drawing drum and pressing rollers; G, water-box and rollers for killing sparks; H, plaiter; I, tubes for taking away the dust, heat, &c., drawn through

by the exhaust fan, which also causes a perfect combustion of gas, and produces a perfectly clear flame. In the top of each tube is fitted a steel doctor or scraper, *k*, for cleaning the singed side of the cloth. *l*, exhaust fan; *m*, suction-pipe of fan; *n*, delivery pipe of fan; *o*, cloth being singed.

The bleaching requisite for printing cloths is of much superior nature to that sufficient for calico intended to be sold in the white state. It is sufficient for the latter to be white enough to please the eye: a result easily obtained by chlorine treatment after a comparatively mild alkaline boiling; but the former must be so well boiled with lime and alkali, as to remove every particle of resinous and glutinous matter previous to the chlorine steep. This, if not attended to, becomes a source of great annoyance to the printer in his subsequent operations, from the difficulty of obtaining sufficiently good whites without injuring the colours. The high pressure kiers patented by Barlow, and which are fully described in the article BLEACHING, have been found to facilitate the thorough scouring of the cloth very much at a less cost than the old kiers.

The pieces, on leaving the bleach-house drying machine are taken to the 'white room,' a large room for storing the bleached goods, where they are unstitched, folded, sorted into the different qualities in use, and distributed to the proper compartments of the room, whence they are withdrawn as wanted for printing.

Till about the year 1760, the printing of linens or calicoes was done by hand, wooden blocks being employed, on which the pattern is raised in relief. About this time a modification of the press used for printing engravings was adapted to printing with flat engraved copper plates on fabrics. This press was used to produce certain styles only, generally single colours, where delicacy of outline was required, shaded or stippled work being also introduced. The printing by blocks in several colours was the principal mode still, till in 1785 the cylinder printing-machine was invented by a Scotchman named Bell, and brought into successful use at Mossely, near Preston, by the house of Livesey, Hargreaves, and Co. The house of Oberkampf, of Jouy, in France, almost immediately adopted the invention, and have been frequently considered, in France at least, the originators of the machine; but it is now pretty certain that the honour of the invention is due to Great Britain. The introduction of the cylinder machine gradually caused the disuse of the flat press, the London printers continuing to use them long after the Lancashire printers had given them up; the first cylinder machine was used in London in 1812. Blocks are still freely used for some description of prints, such as woollen or mousseline-de-laine goods, and also for introducing colours after printing by the cylinder and dyeing, &c.—the cylinder not being capable of fitting in colours, after the piece has once left the machine. A blocking-machine, called the Perrotine, was introduced in France in 1834 by M. Perrot, and is still extensively used there, but though tried in this country, it never came into general use. It executes as much work as twenty hand printers, and for the special purposes for which it was invented is a satisfactory machine; the patterns capable of being printed by it are, however, limited in size, in consequence of the narrow width of the blocks. Surface printing, or printing from cylinders engraved in relief, was an invention preceding by a few years the engraved copper cylinder, but apparently not in general use. In 1800, a Frenchman, named Ebingar, patented somewhat the same sort of thing, and in 1805, James Burton, of the house of Peel, at Church, invented the mule machine, which worked with one or two engraved copper cylinders, and one or two wooden rollers engraved in relief. This machine is very little used now, the impression produced by it not having the precision of that from copper rollers, and improvements in engraving copper rollers having given the printer many of the advantages possessed by the surface roller. Quite lately, however, Mr. James Chadwick has patented a species of surface roller which promises to become useful. The ordinary stereotyped patterns described hereafter are adapted by screws to a brass or other metal roller, which is then fitted on the mandrel used with the ordinary engraved rollers, and a firmness and solidity thus given which was never possessed by the wooden surface roller.

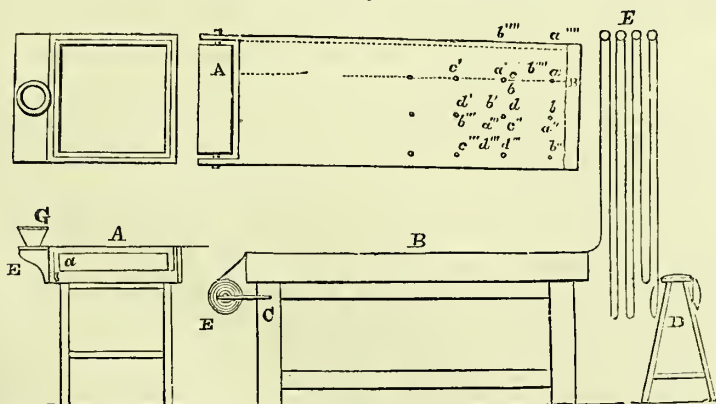

Printing by block is thus performed:—The hand blocks are made of sycamore or pear-tree wood, or of deal faced with these woods, and are from 2 to 3 inches thick, 9 or 10 inches long, and 5 broad, with a strong box handle on the back for seizing them by. The face of the block is either carved in relief into the desired design, like an ordinary wood-cut, or the figure is formed by the insertion edgewise into the wood of narrow slips of flattened copper wire. These tiny fillets, being filed level on the one edge, are cut or bent into the proper snape, and forced into the wood by the taps of a hammer at the traced lines of the configuration. Their upper surfaces are now filed flat, and polished into one horizontal plane, for the sake of equality of impression. As the slips are of equal thickness in their whole depth, from having been made by running the wire through between the steel cylinders of a flattening mill, the lines of the figure, however much they get worn by use, are always

equally broad as at first; an advantage which does not belong to wood-cutting. The interstices between the ridges thus formed are filled up with felt-stuff. Sometimes a delicate part of the design is made by the wood-cutter, and the rest by the insertion of copper slips.

The colouring matter or mordant, properly thickened, is spread with a flat brush, by a child, upon fine woollen cloth, stretched in a frame over the waxcloth head of a wooden drum or sieve, which floats inserted in a tubful of old paste, to give it elastic buoyancy. The inverted sieve drum should fit the paste-tub pretty closely. The printer presses the face of the block on the drum-head, so as to take up the requisite quantity of colour, applies it to the surface of the calico, extended upon a flat table covered with a blanket, and then strikes the back of the block with a wooden mallet, in order to transfer the impression fully to the cloth. This is a delicate operation, requiring equal dexterity and diligence. To print a piece of cloth 28 yards long and 30 inches broad, no less than 672 applications of a block, 9 inches long and 5 inches broad, are requisite for each colour; so that if there are 3 colours, no less than 2016 applications will be necessary. The blocks have pin-points fixed into their corners, by means of which they are adjusted to their positions upon the cloth, so as to join the different parts of the design with precision. Each printer has a colour-tub placed within reach of his right hand; and for every different colour he must have a separate sieve. Many manufacturers cause their blocks to be made of three layers of wood, two of them being deal, with the grain crossed to prevent warping, and the third sycamore, for engraving.

The printing shop is an oblong compartment, lighted with numerous windows at each side, and having a solid table opposite to each window. The table B (*fig. 325*) is

325

formed of a strong smooth flag, with a surface truly plane. Its length is about 6 feet, its breadth 2 feet, and its thickness 3, 4 or 5 inches. It stands on strong feet, with its top about 36 inches above the floor. At one of its ends there are two brackets c for supporting the axes of the roller E, which carries the white calico to be printed. The table is covered with blanket stretched tightly across and hooked at the side. The hanging rollers E are laid across joists fixed near the roof of the apartment above the printing shop, the ceiling and floor between them being open bar work, at least in the middle of the room. Their use is to facilitate the exposure, and, consequently, the drying of the printed pieces, and to prevent one figure being daubed by another. Should they come to be all filled, the remainder of the goods must be folded lightly upon the stool D.

The printer stretches a length of the piece upon his table A B, taking care to place the selvage towards himself, and one inch from the edge. He presents the block towards the end to determine the width of its impression, and marks this line A B, by means of his square and tracing point. The spreader or teer now besmeared the cloth with the colour, at the commencement, upon both sides of the sieve head; because, if not uniformly applied, the block will take it up unequally. The printer seizes the block in his right hand, and dips it twice in different directions upon the sieve cloth, then he transfers it to the calico in the line A B, as indicated by the four points a b c d, corresponding to the four pins in the corners of the block. Having done so, he takes another dip of the colour, and makes the points a b fall on c d, so as to have

at the second stamp *a' b'*, covering *a b*, and *c' d'*; and so on, through the rest, as denoted by the accented letters. When one table length is finished, he draws the cloth along, so as to bring a new length in its place.

The grounding in, or re-entering (*reintage*), of the other colours is the next process. The blocks used for this purpose are furnished with pin-points, so adjusted that, when they are made to coincide with the pin-points of the former block, the design will be correct; that is to say, the new colour will be applied in its due place upon the flower or other figure. The points should not be allowed to touch the white cloth, but should be made to fall upon the stem of a leaf, or some other dark spot.

Every colour is printed separately, the printer going all through the piece with one block; the rest of the colours are next separately fitted into their places by the appropriate blocks, and the piece is then ready for the subsequent operations for raising the colours. Calico intended for printing by block is always smoothed by the calender (see *CALENDER*) the object being to leave the cloth stiff, so as to facilitate the printer joining the different block impressions. When pieces that have been printed by machine are required to have other colours inserted by block, as for instance, the grounding-in of blues, yellows, greens, &c., after printing and dyeing in madder colours, the same sort of process is adopted, the pieces being dried and calendered, and then printed by blocks technically termed *grounds*; these grounds are cut from sketches or tracings, taken from the dyed piece when calendered, and, consequently, fit accurately those parts which are intended to be blocked. The grounding-in of colours, after the operations of dyeing, was formerly done by pencils, which were merely small thin pieces of wood, which were dipped in the colour, and the necessary portions of the patterns, such as leaves, &c., painted in by hand. Of course, this method soon gave way to blocks; but the use of these pencils was continued down to a comparatively recent period for certain colours, such as *pencil-blue*, which being a solution of reduced indigo, was too speedily oxidised when spread on the sieve, and required instant application of the pencil. Even this colour was eventually applied by block, by a peculiar kind of sieve.

Of late years the tedious hand labour of cutting or copping blocks has been much reduced by stereotyping; when the pattern has several repeats on the block, a casting in type-metal being made of the pattern, and as many of these as requisite arranged on a plain block, and securely nailed down. It is obvious that the matrix once made, an infinite number of castings can be easily produced; the skilled labourer is therefore reduced to a small portion of what was formerly requisite. The ordinary way of making the mould is to draw or trace on a small block of pear tree (sawn across the grain, so that the pattern is put on the end of the grain), the pattern to be typed. Slips of copper of varying thickness, but uniform width, are then driven down to a certain distance in the wood, just as in the ordinary way of copping blocks. When the pattern is thus completed, the slips are pulled out, of course leaving the pattern indented in the wood; the block is now rubbed with chalk, and a border about $\frac{1}{16}$ th of an inch deep of card nailed round the block. Melted type-metal is now run in level with the top of the card, and when cold, a tap with a hammer on the under side of the block easily detaches the type, which requires very little trimming to be ready for putting on the block; when a number of these are arranged on a block, the surface is filed and ground on a stone till perfectly level. The introduction of Burch's patent typing machine still further simplified the stereotyping process. In this beautiful invention the matrix is formed by steel punches of varying shapes, which are moved up and down by a stirrup and lever, and which are kept heated, by a gas flame ingeniously applied, to the temperature sufficient to char wood, and by moving the block about under these punches and depressing them, the pattern is burnt into the wood to a uniform depth, and the labour of cutting and bending slips of copper, &c., done away with.

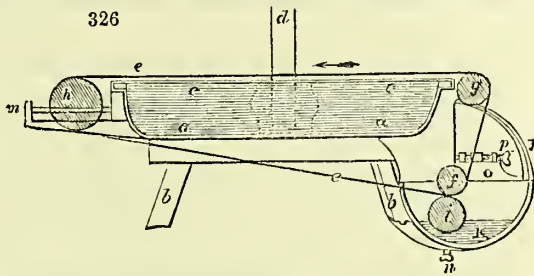

There are some interesting modifications of block-printing apparatus which may be here described. In 1834, Mr. Hudson, of the Gale Print Works, near Rochdale, patented a mechanical teerer which was to dispense with the labour of children. The contrivance consists in a travelling endless web, moved by power, which by passing progressively from the colour vat over the diaphragm, brings forward continuously an equable supply of the coloured paste for the workmen's block.

Fig. 326 represents the construction of this ingenious apparatus, shown partly in section. *a a* is a vessel of iron, supported upon wooden standards, *b b*, over the upper surface of which vessel a sheet or diaphragm, *c c*, of oiled cloth, or other suitable elastic material, is distended, and made fast at its edges by being bent over a flange, and packed or cemented, to render the joints water-tight. A vertical pipe *d* is intended to conduct water to the interior of the vessel *a*, and, by a small elevation of the column, to create such upward pressure as shall give to the diaphragm a slight bulge like the swimming tub.

An endless web, *e e*, passing over the surface of the diaphragm, is distended over

three rollers, *f g h*, the lower of which, *f*, is in contact with the colour-roller *i* in the colour-trough *k*. On the axle of the roller *i* a pulley wheel is fixed, which allows the roller to be turned by a band from any first mover; or the roller may receive rotatory motion by a winch fixed on its axle. On this said axle there is also a toothed wheel, taking into *d* another toothed wheel on the axle of the roller *f*; hence, the rotation of the colour-roller *i* in the one direction will cause the roller *f* to revolve in the

326

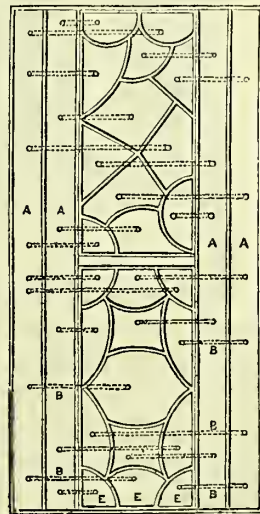

opposite, and to carry forward the endless web, *c c*, over the elastic diaphragm, the web taking with it a stratum of colour received from the roller *i*, equally distributed over its surface, and ready for the printer to dip his block into.

The axles of the rollers *f* and *g* turn in stationary bearings; but the axle of *h* is mounted in sliding nuts, which may be moved by turning the screws *m*, for the purpose of tightening the endless web. The axle of the colour-roller *i* turns in mortises, and may be raised by screws *n*, in order to bring its surface into contact with the endless web. To prevent too great a quantity of colour being taken up, the endless web passes through a long slit, or parallel aperture in the frame *o*, which acts as a scraper or doctor, and is adjustable by a screw *p*, to regulate the quantity of colour carried up. The contents of the vessel *a*, and the colour-trough *k*, may be discharged when required by a cock in the bottom of each. This contrivance did not come into general use, but is still employed at some print works in England. The Tobying sieve is a mode of applying with one block several colours at once, whereby the cost of several blocks is saved, and, what is of more consequence, the cost of labour is very much reduced, as one printer produces the same result as the combined efforts of several.

Whenever designs are composed of coloured parts, where each colour lies separate, and where the outlines of the coloured parts are not too close together, a sieve of the following construction is made use of (*fig. 327*). A block of wood is scooped out in hollow compartments *e*, which vary in size and number according to the number and extent of the shades to be printed; these compartments communicate by tubes *b* at the bottom, with reservoirs *a*, at the sides of the sieve, over the compartments is then stretched tightly a woollen sieve; the surface of this cloth is cemented with melted resin string about $\frac{1}{4}$ th of an inch thick, following the configurations of the compartments; the use of this is to prevent the colours mixing and becoming blended at the edges. Colours are now put in the reservoirs, which are kept filled up above the height of the cloth, so that a gentle pressure is exerted against the under side of the sieve. The colours are made of such a thickness as to pass through the cloth, and keep the upper surface moist, but still not too thin, or they would spread when printed. The sieve being thus prepared, the block is furnished with guides, which, working against the sides of the sieve frame, constrain the block to be always dipped in one place, and thus each part of the pattern finds itself furnished with its proper colour. Sometimes the compartments for the colours are made of metal when required to be durable, so as to serve for a large number of pieces of the same pattern.

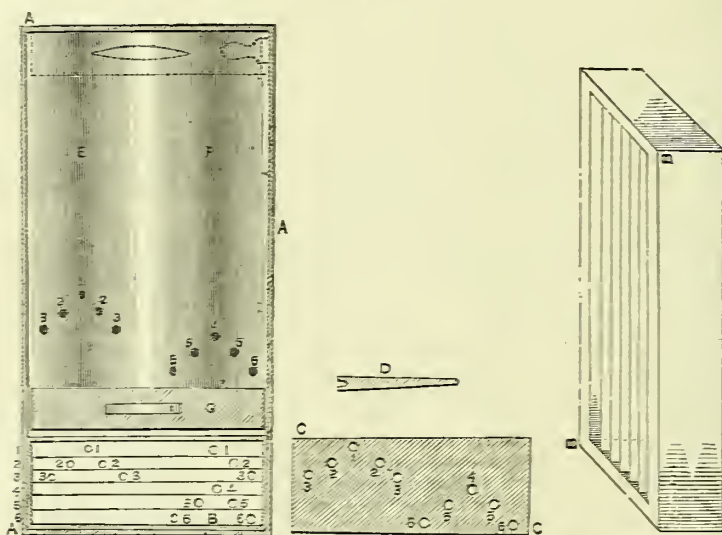

327

When colours are required to melt into one another, technically called *rainbowed* (*fondus*, Fr.), the following apparatus is used:—*A A* (*fig. 328*) is a rectangular frame of wood, about 6 inches deep, 2 feet long, and about 1 foot broad. On this frame is stretched, by means of small hooks, a woollen cloth, and the frame then laid on the elastic surface of the usual *swimming tub*, the cloth downwards and pasted or gummed

to the oilskin cover of the tub. At one end is now put the colour reservoir B B, which consists of a wooden or metal box, divided into water-tight compartments longitudinally by strips of thin metal; this box is of such a width as to fit easily into one end of the frame, and resting on a board of the same size, fixed across the frame; the depth of the box may be about 4 inches, and the width about 8 inches; but this is regulated by the number of colours to be blended or *rainbowed*. A semi-circular piece of wood, of nearly the same width as the frame, is covered with printers' blanket, and a handle formed on the top, so that the teerer can move backwards and forwards. The colour-lifter, c c, is a flat piece of wood just covering the colour-box: on the under side of this are inserted wooden pegs, as d, at certain places determined by the width of the stripe of rainbowed colour and the number of shades composing it. These pegs are of turned wood, about $\frac{1}{8}$ th of an inch thick at the small end, and about $\frac{3}{8}$ ths of an inch at the thick end, this end being also recessed so as to lift more colour; they are nearly as long as the colour-box is deep. In the figure, suppose it is desired to produce on the sieve two stripes, say z of a dark green in centre, and two shades of green at each side, and x of chocolate in centre, purple next, and drab next, at each

328

side, the colour-box is filled thus: In No. 1 compartment is put the darkest green; in No. 2, the medium green; in No. 3, the palest green; in No. 4, the chocolate; in No. 5, the purple; and in No. 6, the drab. The colour-lifter is so studded with pegs, that when put into the colour-box, the pegs 1, 2, 3, 4, 5, and 6 respectively dip into their appropriate colours. The brush, or semi-circular roller, g, is then moved up to the top, as shown in the dotted lines, the colour-lifter being then lifted up out of the colour-box is held a moment till the colour has ceased dropping from the pegs, and then lifted over, and the pegs allowed to deposit the colour on the sieve, as shown by the black spots 1, 2, 3, 4, 5, and 6. The lifter is then returned to the box, and a fresh portion of colour lifted, and deposited, as before, at a different part of the sieve, the spots of colour being of necessity all in straight lines; the brush g is then moved backwards and forwards by the teerer till the colours are sufficiently rubbed together or blended at the edges. It is necessary to observe, that the thickness of the colours must be pretty uniform, and sufficiently thin to allow them to mix at the edges. By this means one colour is made to melt insensibly into another, and a beautiful shaded effect produced on the sieve, and consequently on the piece, when printed from a block dipped on it.

The Perrotine is a machine for executing block-printing by mechanical power; and it performs as much work, it is said, as 20 expert hands. It is in use in many factories in France and Belgium, in a very satisfactory manner; but there is reason to believe that there are none of them now working in this country. Three wooden blocks, from $2\frac{1}{2}$ to 3 feet long, according to the breadth of the cloth, and from 2 to 5 inches broad, faced with pear-tree wood, engraved in relief, are mounted in a powerful

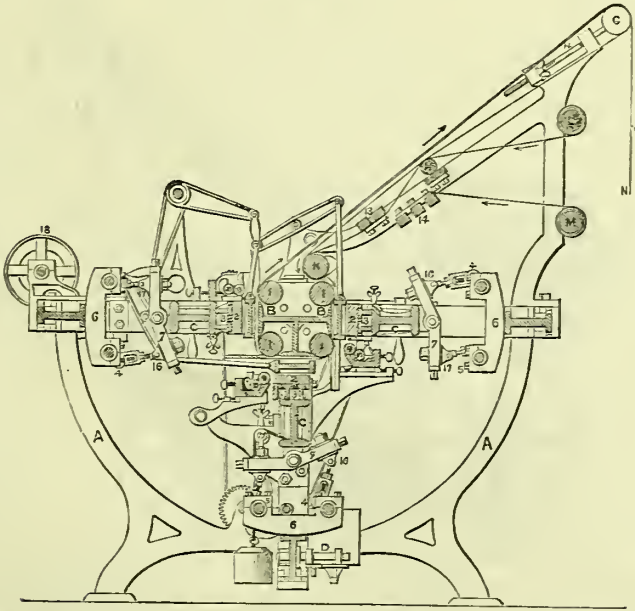

cast-iron framework, with their planes at right angles to each other, so that each of them may, in succession, be brought to bear upon the face, top, and back of a square prism of iron covered with cloth, and fitted to revolve upon an axis between the said blocks. The calico passes between the prism and the engraved blocks, and receives successive impressions from them as it is successively drawn through by a winding cylinder. The blocks are pressed against the calico through the agency of springs, which imitate the elastic pressure of the workman's hand. Each block receives a coat of coloured paste from a woollen surface, smeared after every contact with a mechanical brush. One man, with one or two children for superintending the colour-giving surfaces, can turn off about 30 pieces English per day, in three colours, which is the work of fully 20 men and 20 children in block-printing by hand. It executes some styles of work to which the cylinder machine, without the surface roller, is inadequate.

The annexed cuts are taken from the 'Traité de l'Impression des Tissus,' of M. Persoz.

Fig. 329 is a vertical section, and fig. 330 an elevation.

A cast-iron framework. В В В cast-iron tables, planed smooth, over which circulate the blanket, the backcloth, and the piece that is printed; c c c sliding pieces, to which the block holders 3, are screwed, and causing the engraved blocks, 2, to move alternately

329

against the woollen surface, from which they receive the colours and the stuff to be printed, by the action of the arms 4 and 5, the supports of which, 6, rest on the frame A. and which act, through the medium of connecting rods, on the beams, 7, keyed to the slides c. The lower of these slides, being in a vertical position, takes by its own weight a retrograde movement, regulated by a counterweight. E E E are moveable colour-sieves, keyed to connecting rods, and receiving from the power applied to the machine the kind of movement which they require. These sieves, which are flat, and covered with cloth on the surface opposite to the blocks, slide in grooves on the sides of the tables, and receive from the furnished rollers the colours which they afterwards transmit to the blocks. F F F are the colour-troughs filled with colour, and furnished each with two rollers 8 and 10, the last of which, dipping into the troughs, are charged with colour, which they communicate to the roller 8, the latter being covered with woollen cloth; and these in their turn transmit their colour to the sieves E, on which it is spread by the fixed brushes, 9. As it is important to be able to vary at pleasure the quantity of colour supplied to the sieves, and consequently to the blocks, the rollers, 10, are in connection with levers, 11, which, by means of

adjusting screws, bring them into more or less intimate contact with the rollers 8, and consequently vary the charge of colour at pleasure.

The blanket, baelcloth, and fabric are circulated as follows:—At the four angles formed by the three tables, *B*, are rollers, 1, armed on their surface with needle-points, which prevent the cloths from slipping as they pass round, and thus secure the regular movement of the stuff to be printed, a movement determined by the toothed wheels 21 (*fig. 330*) fixed at the extremities of the axes of these rollers. *G* is a roller for stretching the endless web, resting with the two ends of its axes on two cushions forming the extremities of the screws 12, by which the roller can be pushed further out when required, to give the cloth the necessary tension. *H* is another tension roller, supporting the blanket and baelcloth. *K* is a roller which serves similar purposes for the blanket, the baelcloth, and the fabric in course of being printed. *T*, the blanket, which in its course embraces the semicircumference of the roller *G*, passes over the roller *H*, and behind *K*, to circulate round the cylinders 1, and over the surfaces of the tables *B*. *L* is a cylinder from which the baelcloth is unwound, being first stretched by the roller *H*, and then smoothed by the scripping bars 13, from which it proceeds to join the blanket on arriving at the roller *K*. *M* a roller, from which the fabric to be printed is unrolled by the movement of the machine, first passing over the scripping bars 14, and joining at *K* the blanket and baelcloth, which

330

it accompanies in their course till it arrives at the roller *G*, when it separates and passes off in the direction of the line *x*, to the hanging rollers, where it is dried.

The machine is put in movement, either by a man with a winch-handle, or by power communicated by a strap which passes over the pulley 18. This pulley has several diameters, so as to give several speeds; it is loose on the driving shaft, and carries catches which lock into those of a sliding catch-box on the shaft, when the machine is to be put in movement. The movement of the machine is intermittent because the printing is intermittent; moreover, it must be so regulated that the fabric advances a distance exactly equal to the breadth of the blocks, and that it moves forward whilst the sieves are charged with colour from the rollers 8 8. This result is obtained by means of a regulator, or dividing wheel 20. The wheels 21, fixed at the extremities of the axis of the cylinders 1, and having each the same number of teeth, receive their movement from a central wheel toothed in the same manner, and placed behind the wheel 20. The last receives an alternating motion from a rack, 24, fixed in a copper piece, 25, and which rises and falls alternately, being keyed at its lower end to one of the spokes of the wheel 28. By varying the position of the point at which the end of the rack is connected with the spoke 26, the length or range of its movement is proportionally changed, and more or less of the teeth of

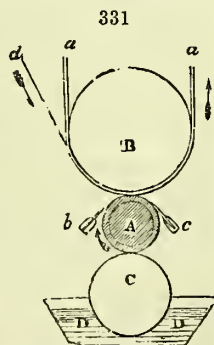

the wheel 20 are made to pass, which renders proportionally, greater or less, the advance of the cloth at each movement; and this is further regulated by a ratchet wheel placed at D. At each half turn of this last, the lever 22 raises the catch or pallet, and throws out of gear the wheels 21 during the other half turn; but as in the working of these wheels there would be inevitably a backward movement, this is prevented by a break, consisting of a pulley, mounted on the shaft of the axis of the wheel 20, and a brass wire which after making a turn and a half, or two turns, on this shaft, is stretched by the weight 23, which offers a sufficient resistance to any recoil. The slides or block-holders are put in motion by the wheels 27 and 28, gearing with the larger wheel 29. And to vary their action at pleasure, both for causing the blocks to bear more or less strongly on the sieves, so as to be more or less charged with colour, and likewise for attaining the exact pressure, which suits best for the colour to be laid on, it is sufficient to move the points of junction, 16 and 17, to a greater or less distance from the point marked 15, which constitutes the centre of oscillation of the beams that work the slides. The movement of the sieves is controlled by that of the cam 11, 30, which works them all three by putting in motion a shaft with which they are respectively keyed. The furnishing rollers receive their movement from gearing with pinions on the axes of the rollers 8 8. The general working of this complex machine remains to be described. When put into regular motion, and the three blocks have delivered their impression exactly at the same instant, three simultaneous movements then commence.

1st. The stuff advances a distance exactly equal to the breadth of the blocks, and with it the blanket and backcloth, so that the portion of the fabric which leaves the third block behind it, is fully printed; that which was under the second advances opposite the third; that which was under the first, moves along to the second; and a fresh breadth of white or imprinted fabric arrives opposite the first. 2nd. While the cloth is advancing as above stated, the sieves take the place which they occupy in the section, *fig. 329*, that is to say, the first on the right hand rises, the second moves from left to right, the third descends, and in this movement all three press slightly on the furnishing rollers 8, from which they receive the colour, which has been spread uniformly by the brushes 9. 3rd. In the meantime, the slides, or blockholders, by a forward movement, push the blocks against the sieves, to charge them with colour, and the blocks at the same time receive from the slides a gentle backward movement, during which the sieves deviate from their position; the blocks then return upon them, and are drawn back again after being applied to a new part of the colour surface. When these simultaneous movements have taken place, the action of the machine proceeding without intermission, the sieves move back from before the blocks, and these are pushed up against the latter, printing the position of the fabric that is stretched upon them. This brings the machine to that position at which the description commenced; and this succession of movements is renewed and repeated as long as the operation lasts; the printer having it always in his power to suspend the advance of the stuff whilst the working of the blocks and sieves continues, so that the colour may be re-applied to the same part of the fabric as often as may be required for a good impression.

There have been several attempts at block-printing by machinery in this country, amongst which the machines of Mr. Joseph Burch have been most successful; but from one cause or another, none of them have ever come into general use, and it is unnecessary therefore to particularise them.

The copper-plate printing of calico is almost exactly the same as that used for printing engravings on paper from flat plates, and being nearly superseded by the next machine, need not be described.

The cylinder printing-machine is one by which one or more colours are rapidly printed from engraved copper cylinders or rollers by the mere rotation of the machine, driven by the agency of steam or water. The productive powers of this printing automaton are very great, amounting for some styles to a piece of 30 yards per minute, or a mile of printed cloth per hour. *Fig. 331* will give the reader a general idea of this elegant and expeditious plan of printing. The pattern is engraved upon the surface of a hollow cylinder of copper, and the cylinder is forced by pressure upon a strong iron mandrel, which serves as its turning shaft. To facilitate the transfer of the impression from the engraving to the cotton cloth, the latter is lapped round another large cylinder, rendered elastic by rolls of woollen cloth, and the engraved cylinder presses the calico against this elastic cushion, and thereby prints it as it

revolves. Let *A* be the engraved cylinder mounted upon its mandrel, which receives rotatory motion by wheels on its end, connected with the steam or water power of the factory. *B* is a large iron drum or roller, turning in bearings of the end frames of the machine. Against that drum the engraved cylinder *A* is pressed by weights or screws; the weights acting steadily, by levers, upon its brass bearings. Round the drum *B* the endless web of felt or blanket stuff *aa*, travels in the direction of the arrow, being carried round along with the drum *B*, which again is turned by the friction of contact with the cylinder *A*. *c* represents a clothed wooden roller, partly plunged into the thickened colour of the trough *DD*. That roller is also made to bear, with a moderate force, against *A*, and thus receives, by friction, in some cases, a movement of rotation. But it is preferable to drive the roller *c* from the cylinder *A*, by means of a system of toothed wheels attached to their ends, so that the surface speed of the wooden or paste roller shall be somewhat greater than that of the printing cylinder, whereby the colour will be rubbed, as it were, into the engraved parts of the latter.

As the cylinder *A* is pressed upwards against *B*, it is obvious that the bearers of the trough and its roller must be attached to the bearings of the cylinder *A* in order to preserve its contact with the colour-roller *c*. *b* is a sharp-edged ruler of gun-metal or steel, called the *colour doctor*, screwed between two gun-metal stiffening bars; the edge of which wiper is slightly pressed at a tangent upon the engraved roller *A*. This ruler vibrates with a slow motion from side to side, or right to left, so as to exercise a delicate shaving action upon the engraved surface, as this revolves in the direction of the arrow. *c* is another similar sharp-edged ruler, called the *lint doctor*, whose office it is to remove any fibres which may have come off the calico in the act of printing, and which if left on the engraved cylinder, would be apt to occupy some of the lines, or at least to prevent the colour from filling them all. This *lint doctor* is pressed very slightly upon the cylinder *A*, and has no traverse motion.

What was stated with regard to the bearers of the colour-trough *D*, namely, that they are connected, and moved up and down together, with the bearings of the cylinder *A*, may also be said of the bearers of the two doctors.

The working of this beautiful mechanism may now be easily comprehended. The web of calico, indicated in the figure by the letter *d*, is introduced or carried in along with the blanket stuff *aa*, in the direction of the arrow, and is moved onward by the pressure of the revolving cylinder *A*, so as to receive the impression of the pattern engraved on that cylinder.

Before proceeding to describe the more complex machines which print upon cloth several colours at one operation, by the rotation of so many cylinders and rollers, it is advisable to give some insight into the modern method of engraving the copper cylinders. These were formerly engraved altogether by hand, in the same manner, and with similar tools, as the ordinary copper-plate engravings, till the happy invention of Mr. Jacob Perkins, of America, for transferring engravings from one surface to another by means of steel roller dies, was with great judgment applied by Mr. Joseph Lockett sen. to calico-printing, so long ago as the year 1808, before the first inventor came to Europe with the plan. The pattern is first reduced or increased in size to such a scale, that it will repeat evenly over the roller to be engraved; and as rollers are of varying diameters, owing to old patterns being turned off, &c., this drawing to scale has to be adopted for every roller, the exact circumference of the roller being taken and the pattern arranged in accordance with this. This pattern is next engraved in intaglio on a roller of softened steel, which is of such a size that one repeat of the pattern exactly covers its surface; generally these rollers are about 3 inches long and from $\frac{1}{2}$ an inch to 2 or 3 inches in diameter. The engraver aids his eye with a lens when employed at this delicate work. This roller is hardened by heating it to a cherry-red in an iron case containing pounded bone-ash, and then plunging it into cold water: its surface being protected from oxidisement by a chalky paste. This hardened roller is put into a press of a peculiar construction, called the clammng-machine, where by a rotatory pressure, it transfers its design to a similar roller in the soft state; and as the former was in intaglio, the latter must be in relief. This second roller being hardened, and placed in the engraving-machine, is employed to engrave by indentation upon the full sized copper cylinder the whole of its intended pattern. The first roller engraved by hand is called the *die*; the second, obtained from it by a process like that of a milling tool, is called the *mill*. By this indentation and multiplication system not only has the cost of engraving been much diminished, but designs and styles have been brought into requisition which by no other means could have been obtained. The restoration of a worn-out cylinder becomes extremely easy in this way; the mill being preserved, need merely be properly rolled over the copper surface again. The die roller is made of such a size that its circumference is exactly a fractional part of that of the mills, say one-half, one-third, one-fourth; then

in the clammng-machine the die revolving in contact with the mill repeats its surface so many times on the surface of the mill. By this means as little skilled labour as possible is used. When a pattern having more than one colour is to be engraved, the drawing is reduced to scale as before, each roller being made of the same diameter; then a tracing is made of each colour, which is engraved on a separate die and mill—a mill being required for each colour—which engraves its separate copper roller; when these rollers come to be worked in the printing-machine, each roller fits its part of the pattern into place, and the original pattern is reproduced. The annexed drawings of engraving machinery are from those made by Messrs. Gadd and Hill, of Manchester, to whose courtesy are due also the drawings of the printing-machines and their drying apparatus hereafter described. *Fig. 332* is a front view of the clammng-machine, and *fig. 333* is a side view of the same.

A A cast-iron frame-work; *B* a headstock screwed on the frame work *A*; *c* a sliding piece, capable of movement from back to front on the headstock *B*; the position being determined, it is secured by the screw shown under *c*; the roller *D* revolves in bearing attached to the sliding piece *c*; the supporting piece *E* has a motion backwards and forwards on the supporting piece *o*, which moves up or down; *e* is a small steel roller, which again supports the die roller seen in the centre of the drawing. The roller *F* is of softened steel called the mill, which revolves in bearings attached to the headstock, which has a sliding movement on the slide block *H*, which is moved from right to left by the screw *I*, worked by the lever *K*. *L* is a pinion gearing into the toothed wheel *N*, and turned by the winch-handle *M*; the shaft *P* has a sliding movement through the wheel *N*, and carries the boss *o*, which has a square aperture to receive the centre of the mill, which is squared to fit into it. *q* is a screw used to tighten and keep in the desired position the saddle pieces *E o*, which together are pushed up or down to meet the varying size of the die.

The die *d* having been hardened, is inserted in the machine resting on the auxiliary hard steel roller *e*, which again rests on the supporting piece *E*; the die being in contact with the hard steel roller *D*, the soft steel roller or mill *E* is next forcibly screwed up in contact with the die, rotatory motion being given to the roller *D* by the toothed wheels, those portions which are in intaglio in the die become in relievio on the mill. It is then ready for the machine engraver to transfer its pattern to the copper roller. *Fig. 334* is an elevation of the engraving machine. *A A* is a mandrel which carries the copper roller *B*; the mandrel is fitted in the universal joint *C*, which is secured on the shaft of the wheels *D D*, which are a double pair of wheels for the purpose of altering the speed from fast to slow, and are moved by the winch-handle or pulley. The lever *E* is fitted, works loosely on the shaft, on which is keyed the wheel *F*. By means of the screw *G*, the lever *E* can be secured to the wheel *F*.

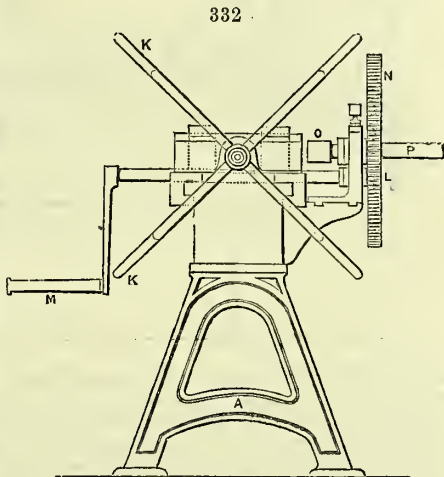

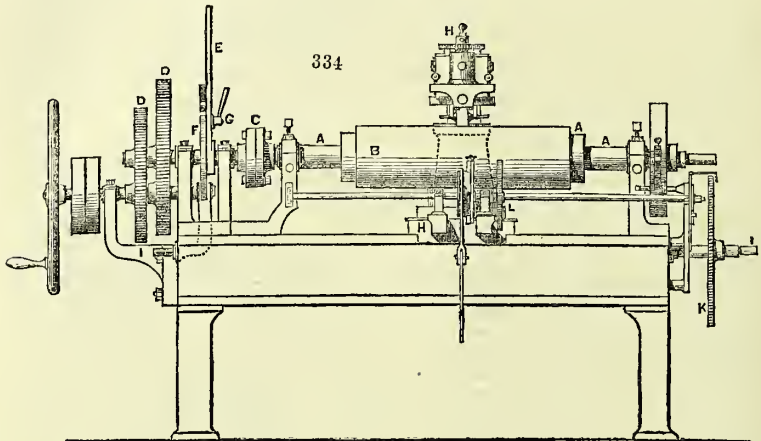

Fig. 333 is a side view of the same. It shows the mandrel (A) carrying the copper roller (B) and the universal joint (C) on the shaft of the wheels (D D). A winch-handle (M) is used to operate the wheels (D D). A lever (E) is fitted to the shaft, which is keyed with a wheel (F). A screw (G) is used to secure the lever (E) to the wheel (F).

By means of the screw *G*, the lever *E* can be secured to the wheel *F*.

By this contrivance the motion termed *rocking* is effected, that kind of motion being required when the pattern repeats at great intervals. The mill works in bearings attached to the pillar and carriage H H, which is moved from right to left by the screw I I; the mill is forcibly pressed against the copper roller by a *weighted lever*, which forces down the bearings of the mill in the pillar H; this lever cannot be shown in the figure, but is at right angles to the roller. The mill being in contact with the

copper roller, revolves with it simultaneously on the roller being moved by the wheels D D or the lever E, and consequently impresses or engraves its pattern on the copper roller; when the mill has traversed the circumference, it is then moved to its next relative position by the screw I, which moves the pillar and carriage H; the exact distance the mill moves is determined by an index on the wheel K, which is divided into segments, corresponding with the number of repeats laterally on the roller. The apparatus shown at L is used occasionally when the machine is employed for turning off an engraved pattern, which, however, is generally performed in a slide lathe, and is unnecessary further to describe here,

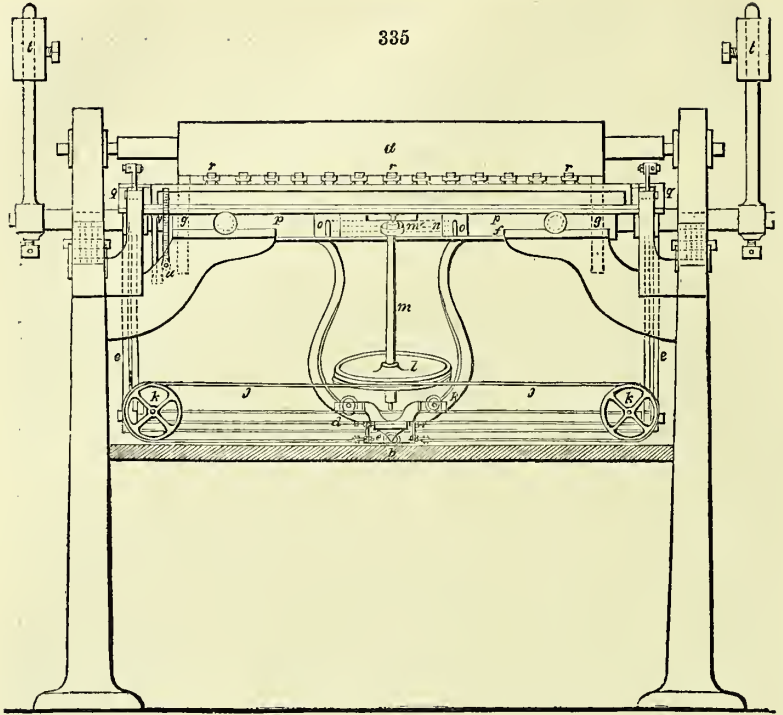

Etching by nitric acid is largely employed in engraving for calico-printing. The roller is coated all over with a thin film of bituminous varnish. Lines of any required form or quantity are then traced upon it, which lay bare the copper surface beneath. On immersion in a bath of diluted acid, those parts of the roller only which are exposed become bitten or etched to any required depth, the remaining surface of the roller being protected by the varnish. This process is employed in combination with the mill process, for engraving all 'solids,' that is, those parts of an engraving which are intended to contain masses of colour, to be transmitted to the calico in the printing-machine. For this purpose the outline of the solid to be engraved is first put on with the mill; the roller is then varnished, and a number of diagonal or angled parallel lines are traced upon it with a diamond-point. Those portions which are intended to be white on the calico, are 'stopped out,' or covered with varnish, by the operative, and the roller is ready for immersion in the bath of diluted acid. The roller is removed when the requisite depth is obtained, is well washed and the bituminous coating is removed, and after slight examination and addition by the hand engraver is ready for the printer. But the two most notable applications of etching in the trade of engravers to calico-printers have been the 'Eccentric' and 'Pentagraph' systems. The former owed its greatest development to the late Mr. Joseph Lockett, son of the founder of the eminent firm which still bears his name. It is not essential to the scope of this article, to give an elaborate description of the beautiful and ingenious machinery employed, nor would it be possible without a very elaborate set of drawings. It may suffice to record that by means of diamond-points, actuated by elaborate machinery, a most curious variety of configurations is produced on the roller. In this process the exact effect that will be produced by any given modification of the machine, cannot be determined beforehand, though an approximation can be made; but when a pattern is produced, and notes are taken of the relative position of the wheels, &c., the same pattern can at any time be reproduced. This system is applicable principally to ground-works or, as they are termed, 'covers,' which form the bases of backgrounds of many classes of design much in vogue on

account of their utility and variety. The Pentagraph system is of later development. The process is the following:—

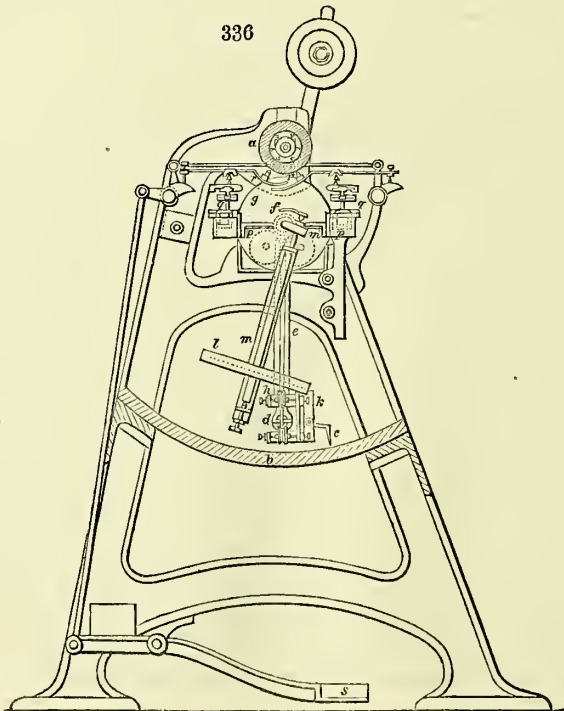

The pattern is first enlarged to several times its size: this is conveniently done by the camera. The paper pattern being put in the camera, an enlarged copy is thrown on a table in a darkened room, and is there easily traced on paper. It is then transferred to a thin zinc plate, and this plate is then engraved with a graver, the lines of the engraving being adapted for the tracing-point to work easily in. The zinc pattern, if of a 2- or more coloured pattern, is coloured for the guidance of the operative. It is then laid on the bed or table of the pentagraph machine, and a varnished roller being mounted in the machine, a number of tools, corresponding in number to the repeats laterally, and carrying diamond points, are placed in contact with the roller. The operative then carries the tracer successively into all the lines of the pattern, a lever allowing the points to touch the roller only when necessary. The pattern is thus traced by the etching points on the roller a less size than that on the zinc plate, or the same size as the paper drawing. The roller is then painted and etched with nitric acid, as before described. In 1834 Horton Deverill of Manchester patented the first application of the pentagraph principle to engraving cylindrical surfaces for calico-printing. It was the simplest form of the ordinary pentagraph, viz., a rhomboidal arrangement of levers, the relative adjustment of which, through appropriate connections, secured the transfer to the roller of the design from its enlarged copy. The time was not propitious for the adoption of this clever invention; a machine was tried by Mr. Lockett, and abandoned less on account of any inherent defect, than because of the very limited use which could be made of it in the then prevalent style of engraving. In 1848 Isaac Taylor patented the substitution for the single rhomboidal frame of Deverill's pentagraph, several such frames in a continuous series. It was proposed to secure by this means a higher power of diminution in a compact machine, and as a result, a more perfect engraving. He also multiplied the number of bars supporting the tracing or etching tools. With this machine commenced the first commercial application of the pentagraph system of engraving in England, though on a very limited scale. In 1854 William Rigby introduced and patented an improved machine, based on the American invention of William Whipple. Whipple had constructed a machine with a curved bed for the zinc plate instead of the flat tables of Deverill and Taylor. The tracing point was attached to a swinging frame, and motion was communicated to the roller, and etching tools respectively in a similar manner to that shown in Rigby's machine, *figs.* 335 and 336. In a patent dated January 1, 1857, Rigby applied two rows of etching tools to his machine, whereby the time occupied in tracing the pattern was very considerably diminished. This method was soon very extensively adopted: a reference to the annexed figures will more clearly show the main features of this machine.

In *figs.* 335 and 336, *a* represents the cylinder to be operated upon; and *b*, the bed or table for the reception of the enlarged pattern or original device; *c*, the tracer, which is made to traverse in the direction of the arc of the bed or table, and by means of its connection with the carriage *h*, the rail *d*, and the connecting arms *e e*, communicates part of a revolution to the bar or axis *f*, and thence to the cylinder through the dies *g g*, on which the cylinder rests. The cylinder being thus moved in a rotatory direction, will receive from the tools in contact with it diminished copies of the transverse lines which may have been gone over by the tracer on the enlarged pattern or device. The tracer *c* being connected with the carriage *h* which travels along the rail *d*, will, in passing over a line running longitudinally with the machine, communicate a partial revolution to the wheel *l* by means of the bands of steel *j j*, similar to watch-springs, which pass under and over the small wheels *k k*, and are passed round and secured to the large wheel *l*, which is mounted on the vertical shaft *m*, carrying at its upper end the small drum *m'*, round which passes the steel band *n*, secured at each end to the pieces *o o*. These pieces are secured by bolts or screws to the sliding frames *p*, to which the upper tool bar or bars *q*, which support the graving, drilling, or etching tools *r r r*, are fixed. Thus any motion of the large wheel *l* will be imparted to the drum *m'*, and by it through the steel band *n* to the sliding frames *p* and the tool bars *q*, and, consequently, to the tools *r*, thereby transferring to the cylinder diminished copies of any lines in a lateral direction that may be gone over by the tracer. It will be evident that the result of the simultaneous action or compounding of the two motions, by passing the tracer over any diagonal or curved line, will be the production of a diminished copy of such diagonal or curved line by each of the tools. *s* is a treadle with a vertical link and appropriate leverage, by which the tools may be brought in contact with the cylinder when required; *t t* are counterbalance weights for the connecting arms *e e*, lower rail *d*, &c.; *u* and *v* represent a worm and wheel for the purpose of giving the roller an extra partial revolution when it is required to engrave upon a different portion of the circumference of the cylinder; and to effect a

335

336

similar purpose in the longitudinal direction, the tool bar may be made to shift in its sliding frame with an adjusting screw attached to it, by means of which any degree of exactitude in the setting of the tools may be obtained.

In the machine, as shown in the accompanying drawings, the design executed on the cylinder would bear the same proportion in size to the enlarged pattern on the bed or table that the small drum *m'* bears to the large wheel *l*, and the radius of the discs *g g*, to the radius of the circular bed; but by the adoption of wheels and discs of different diameters, any desired proportion between the pattern engraved and the enlarged pattern may be adopted.

By minor improvements, an alternate reverse action is given to the tools and bars, thus adapting the machine for turnover patterns; also more than one row of points may be attached to each bar. In 1857 William Shields patented a machine in which he substituted a flat table for the curved table of Whipple and Rigby, and applied an ingenious and original method of varying the dimensions of the design on the zinc plate in transferring it to the roller. The tracing instrument communicates motion to the etching tools through the intervention of inclined planes, so that by varying the angle of these planes motion is transmitted in the required proportion; motion is communicated to the cylinder through similar apparatus. The remarkable facilities offered by this machine caused its immediate adoption by Messrs. Lockett, Leake, and Co., of Manchester, by whom it has been most extensively used in their own works, and manufactured for the trade in England and on the Continent. A reference to the annexed diagram will more clearly show the peculiarities of this machine.

Fig. 337 is a longitudinal section of the machine; fig. 338 is a plan-view. The framework of the machine is shown at *a*, provided with a table *b*, upon which is placed

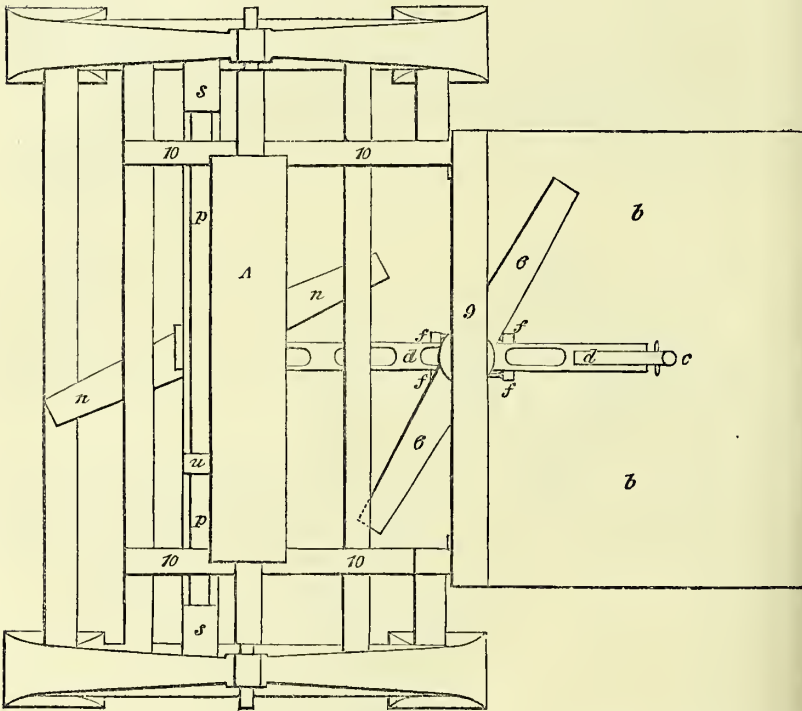

337

the design to be copied. The tracer *c* is jointed upon a rod *d*, which rod *d* passes freely through a bar *e*, and between slides *f*, mounted upon the said bar, which therefore act as guides when the rod is moved to and fro in the direction of its length. This rod *d* is attached at one end to a cross-bar *g*, carried by parallel bars *h*, which rest upon flanged rollers *i*, capable of rolling upon fixed rails *k*; as therefore the tracer *c* and bar *d* are moved longitudinally, the bar *g* and its parallel supports are caused to partake of a like motion. To the bar *h* is fixed a bracket *l*, which carries at its upper end a stud *m*, projecting into a groove formed lengthwise in a lever *n*; this lever is

attached by an arm *o* to a cross-bar *p*, and is capable of being turned upon its centre so as to occupy any angle in reference to the tracer rod *d*, being confined in any desired position by a tightening screw *q*, and thereby constituting an inclined plane for the stud *m* to act against; the cross-bar *p* rests upon flanged rollers *r*, which roll upon a fixed bar *s*, provided with a groove for the purpose of allowing the arm *o* to travel along its length. To the bar *p* are affixed the carriages *u* of the tools. The upper part of the bar *e* (through which the tracer rod passes) carries a stud *5* situate within a groove formed in a lever *6*, which lever, like that shown at *n*, is capable of being turned upon its centre to any angle, so as to constitute an inclined plane for the stud *5* to act against, and of being confined to any desired position by means of tightening screws *7*. The boss of the lever *6* carries an arm *8*, which extends upward, and is there connected with a cross-bar *9*, to which are attached parallel bars *10*, running upon flanged rollers *11*, situate upon fixed bars *12*, upon which the cylinder

338

A bears so as to communicate rotatory motion thereto. The operation of the machine is as follows:—The tracer being pushed inward or drawn outward, will cause the parallel bars *h* to move in a similar direction, thus carrying the bar *g* and stud *m* along the inclined groove in the lever *n*, by which means the bar *g* will be caused to move transversely, carrying with it the tools along the surface to be operated upon, and thus the operation in one direction is accomplished. A crosswise movement of the tracer will cause the rod *d* to move the bars *e g* transversely, and the stud *5* will be forced against the inclined plane within the lever *6*, so as to effect a longitudinal motion of the bars *10*, whereby the ribs *13* will act against a part upon the axis of the cylinder *A*, so as to cause it to revolve, and thus the motion in the other direction is obtained. By subsequent improvements the pentagraph system has been greatly extended in its application to many styles of engraving hitherto unapproachable. Conspicuous amongst them may be noted the employment of the punch and a vibratory motion imparted to the roller, by means of which circumferential lines are engraved on the roller which have equal working qualities with those obtained by the mill.

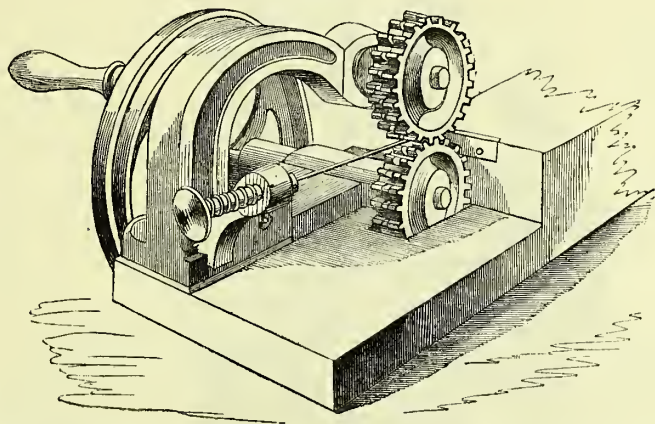

With regard to the 2- and 3-coloured machines, we must observe, that as the calico

in passing between the cylinders is stretched laterally from the central line of the web, the figures engraved upon the cylinders must be proportionately shortened, in their lateral dimensions, especially for the first and second cylinders.

Cylinder printing, although a Scotch invention, has received its wonderful development in England, and does the greatest honour to this country. The economy of labour introduced by these machines is truly marvellous; one of them, under the guidance of a man, to regulate the rollers, and the service of two boys, to supply the colour-troughs, &c., being capable of printing as many pieces as nearly 200 men and boys could do with blocks.

Pieces for printing by machine are stitched together end to end, in bundles containing from 20 to 40 pieces. This was formerly done by girls, but they are now more economically employed in tending stitching machines. Perhaps the original stitching machine employed in print-works is that shown in *fig. 339*. It is still used in dyehouses, where pieces are temporarily stitched together to enable them to undergo various dyehouse operations, and where rapid unstitching is of consequence, which is easily performed by unloosing the ends of the thread and pulling it straight out.

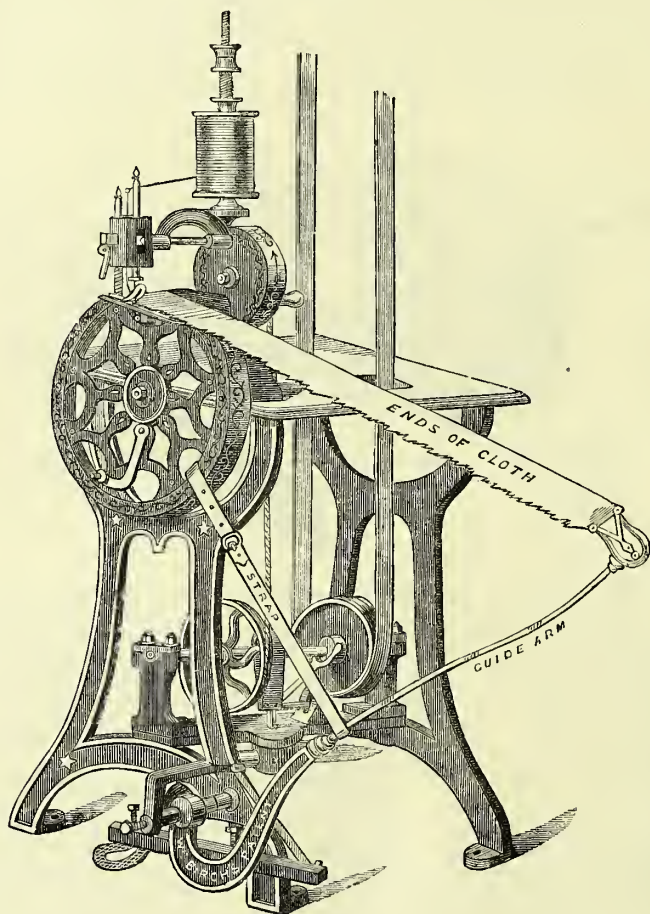

339

This machine was the invention of Charles Morey, in 1849. A pair of wheels are fitted with leaves on their peripheries, and gear into one another like cog-wheels. These wheels are mounted in suitable bearings fixed to a sole plate, and receive rotatory motion by means of a winch-handle. The centre of the teeth of both wheels is cut away, so as to form a circular groove between the two teeth which happen to be together. Opposite to this groove, and attached to the frame, there is a bracket which carries a sliding piece, with a spiral spring wrapped round it. In the end of the sliding piece, which passes through the bracket, there is a receptacle for the eye-end of a needle, the point of which rests in the groove formed by the wheel; the needle is threaded, and the fabric to be stitched placed behind the wheels, to which rotatory motion is communicated, whereby the fabric is successively folded into undulations, which, as the operation proceeds, are forced on the point of the needle; when the needle is full, and the piece at the other side of the wheels, the needle is pushed back on the spring, removed from the machine, and the thread drawn through the pieces, which are then basted or stitched together. This is a very rapid mode of stitching ends of pieces together; but where a number of pieces are stitched end to end for the purpose of being put through several operations without unstitching, a firmer description of stitching is required, and a machine of more elaborate construction is used. A machine invented in America, and hence called the American Machine, was for a long time used. In this machine the ends of the pieces were hooked round a circular table, three sets of pieces being put on at once; the needle now traversed the inside circumference, sewing the ends, which were then unhooked. This was found troublesome and not sufficiently expeditious, and afterwards a modification of the Wilcox and Gibbs sewing-machine was introduced. This is being rapidly superseded by a very beautiful machine invented by William Birch, of Manchester (*fig. 340*). It is not within the scope of this article to give a satisfactory description of the details of this machine; in general terms, we may say that it makes the common flat chain-stitch, which is easily drawn out again when required. It is simple in its working, and is so

arranged that the attendant has nothing to do but to put the ends together and hook the right-hand side of the piece ends upon the tentor hooks of the guido arm, and the left-hand side upon the hooks of the feed wheel; the machine will then start itself and guide the fabric across the machine. When the ends are sewn, the guide arm will leave the fabric, fall down, and stop the machine until another pair of piece ends is attached. This arrangement enables one person to sew as many pieces per day as two or three can on other machines. These machines sew wet or dry, thick or thin, cloth, with equal facility. They are driven by steam-power. *Fig. 341* is the same machine, placed upon a portable stand to work by the foot; the stand is

340

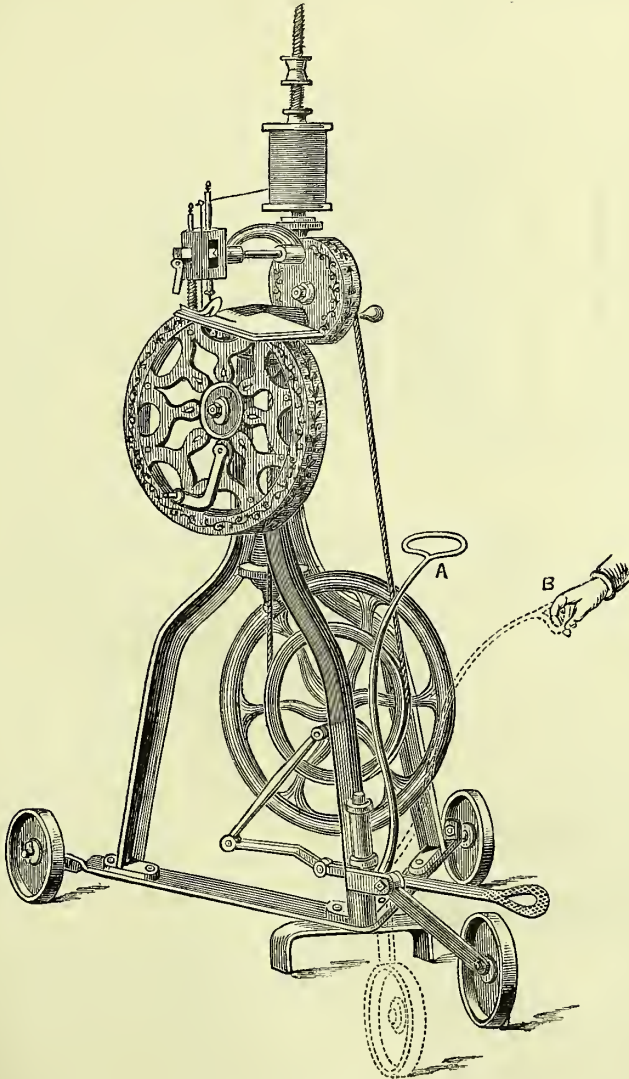

constructed that when stationary it rests upon two wheels and a leg, and when being moved about, the act of pulling the handle presses a third wheel with a swivel upon the floor, and the machine is thus easily removed from place to place. There is no guide arm to this machine, which is used chiefly in the dyehouse.

Pieces are also frequently gummed together at the ends, which is done by pasting the ends for about $1\frac{1}{2}$ inch with paste or gum, and, after laying one on the other, drying them immediately on a steam-pipe in front of the operator. This mode is advantageous for some purposes, as when the pieces come, in the subsequent operations, into hot water, they are easily detached one from the other.

By whichever of these modes the pieces are joined together, they are then wound

in rolls of about 40 pieces by a machine called a candroy, which winds them on the wooden beam which fits in at the back of the printing-machine; the cloth during the operation of winding becomes stretched laterally quite smooth, by the aid of one or two grooved stretching bars, as described in *fig. 347*, a due degree of strain being kept on the piece by its passing under and over several plain wooden bars, and to the axis of the

341

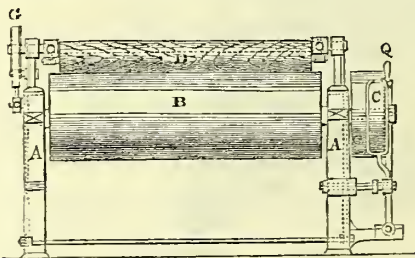

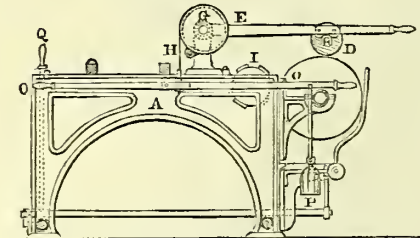

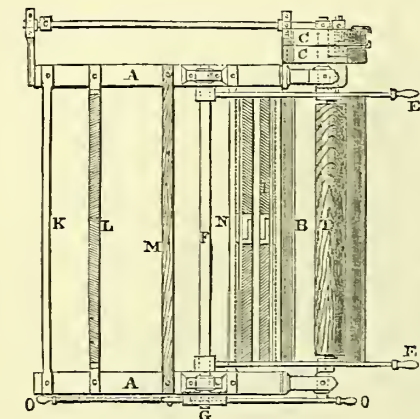

wooden beam which receives the pieces being suspended weights which keep it forcibly in contact with the wooden drum which turns it by friction. In this machine the ends of the axis of the beam pass through slots, which allow it to rise as the pieces become wound on, and the diameter consequently increases. If fewer pieces than 40 are to be printed in one pattern or colouring, it is usual to stitch a few yards of old cloth between two pieces where the change is intended to be made; by this means the

printer, on coming to the waste piece stops his machine, and fits another pattern or changes the colours without damaging good cloth.

A very good sort of candroy for this purpose is that made by Furnival, of Haslingden: plan, side and end elevation of which are annexed (*fig. 342*). *A A* are the cast-iron sides of the machine; *B*, a cast-iron roller turned by the pulleys *C C*, keyed upon the same centre; *D*, a roller or shell, upon which the cloth is wound, the roller *D* being pressed upon the roller *B* by the levers *E E*, which are keyed upon the shaft *F*, and on the end of the same shaft the brake pulley *C* is keyed; the friction of the wrought-iron strap *H* round the brake pulley holds the levers *E* tightly upon the ends

342

of the roller *D*, but allows the levers to rise as the roller *D* increases in diameter by the cloth being wound upon it; *I* is a brass spreading roller (further described where the finishing room is treated of) to stretch the cloth before the entering between the rollers *B* and *D*; *K* and *N* are wrought-iron bars; *L* and *M* are scripping bars. *O* is a lever working on a pivot; to the longer end of this lever and near the pivot is fastened one end of the iron strap *H*, and near the handle of the same end of the lever is a weight *P* depending from a chain; *Q Q* are handles for starting or stopping the machine by shifting the strap on or off the loose pulley. The cloth is passed under the iron bar *X* over the scripping bar *L*, under the scripping bar *M*, over the iron bar *N*, under the spreading roller *I*, and wound upon the shell *D*; to remove the roll of cloth when finished winding, the handle *O* with the weight is lifted, which relieves the pulley *G* from the pressure of the iron strap and allows the levers *E* to be lifted, when the shell with its load of cloth is detached.

The proper hygrometric state of calico when printing should be attended to; very dry calico does not take colours or mordant nearly so well as when containing a certain amount of hygrometric moisture. Practically this is attained by the bleached pieces being stored in the 'white room,' generally several hundred pieces in advance, and they easily absorb sufficient moisture from the air to be in a proper state for printing on.

Should, however, circumstances prevent this taking place, the pieces are conditioned by being passed through the spray of water. The machine for this purpose consists of a rectangular box, closed with a

stratum of water at the bottom; one or more revolving brushes, set at a right angle to the piece, dip slightly into the water, and being made to revolve very rapidly, a continuous fine spray is produced, and the pieces are drawn rapidly through the upper part of the machine, entering and leaving the machine through narrow apertures, a little wider than the pieces, and are wound on a batching roller. In its rapid passage through the spray the cloth becomes slightly damped. The 'white room' where the bleached calico is stored is generally placed in some cool part of the works, and sometimes built over a part of one of the reservoirs.

A shearing-machine is now generally employed to remove any knots, loose fibres, or

down from the white cloth previous to printing by machine. The shearing-machine of Mather and Platt here shown, *fig. 343*, takes up the pieces from the stitched bundle, and winds them, after shearing, in a roll ready for the printing-machine. *a* is the brush for the back of the cloth; *b*, spiral cutter; *c*, beds; *d*, brush for face

343

of cloth; *e*, main driving shaft; *f*, batching roller. The machine has fast and loose driving pullies 12 inches in diameter by $3\frac{1}{2}$ inches broad, which make 250 revolutions per minute. The cloth passes rapidly over the spiral knives, which revolve also rapidly, and give a slicing effect from side to side of the cloth. In some cases this machine is used instead of singeing before bleaching, but is generally used as a final remover of loose matters before printing.

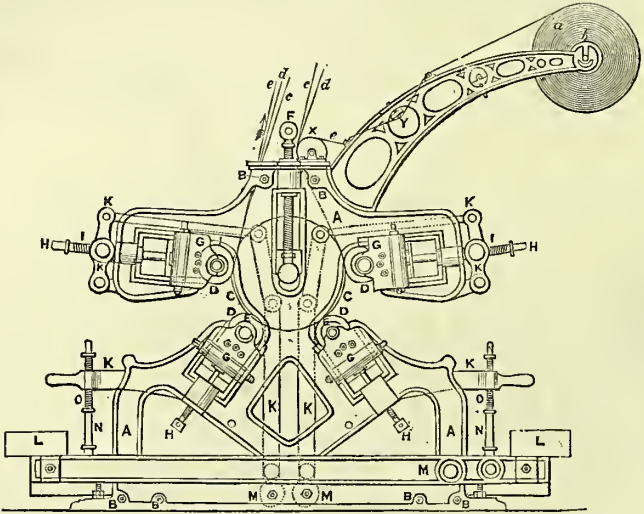

In mounting two or more cylinders in one frame, several adjustments become necessary. The first and most important is that which ensures the correspondence between the parts of the figures in the successive printing rollers, for unless those of the second and subsequent engraved cylinders be accurately inserted into their respective places, a confused pattern would be produced upon the cloth as it advances round the pressure cylinder.

Each cylinder must have a forward adjustment in the direction of rotation round its axis, so as to bring the patterns into correspondence with each other in the length of the piece; and also a lateral or traverse adjustment in the line of its axis, to effect the correspondence of the figures across the piece; and thus, by both together, each cylinder may be made to work symmetrically with its fellows.

Fig. 344 is an end-elevation of a 4-colour printing-machine, and *fig. 345* is a section of same: the same letters of reference refer to both. *A* is the cast-iron framework, bolted to a corresponding framework by the bolts *B*, with a space of from 3 to 4 feet between; *c* is the pressure cylinder, about 2 feet diameter, of iron, but hollow, and between 3 and 4 feet long, according to the sort of cloth the machine is intended to print; *D* are the copper rollers, the width of a piece of cloth; *E* are wrought-iron mandrels on which the copper roller is forced by a screw press, the mandrel being about 4 inches in diameter where the roller fits on, but with journals of smaller diameter. The roller is made with a projecting piece inside, about $\frac{1}{2}$ an inch broad and $\frac{1}{4}$ of an inch deep, extending all the width of the roller; this tab, as it is called, fits in a slot cut in the mandrel, which causes it to turn without slipping on the mandrel; the pressure cylinder or bowl *c*, rests with its gudgeons in bearings or bushes, which can be shifted up and down in slots of the side cheeks *A*; these bushes are suspended from powerful screws *F*, which turn in brass nuts made fast to the

frame A. These screws counteract the pressure upwards of the two lowest rollers, and enable the bowl to be lifted out of the way of the rollers, &c., when

344

they have to be removed. G G are sliding pieces, moving in arms of the framework, by means of screws H H. These sliding pieces carry the bearings of the mandrels; to them are also attached the colour boxes and doctors. The screws H

345

work in female screws $1'$, which form part of a system of jointed levers K . These levers are for the purpose of giving an additional pressure or nip to the rollers D , the

pressure being also elastic. There are four pairs of levers, each pair bearing upon one mandrel. It will be sufficient to describe one side only, both sides being precisely alike. The two highest rollers are pressed against the cylinder by the compound levers κ' , which have attachments to the arms of the framework at f , and to the inside of the main framework at g and m' as fulcrums, and are jointed together at h , but the bent levers h, g, i , merely fit into sockets i , of the horizontal levers $m' \kappa'$, which are weighted at the ends κ' , by moveable weights made to fit expanded parts. The two lowest rollers are pressed against the cylinder by the system of compound levers κ'' , which have attachments to the framework at k and m'' as fulcrums; the screws $n'' n''$, working in female screws $r' r'$, as in the other set of levers. For convenience of removing the rollers, colour boxes, &c., these levers are provided with a hinged piece κ , in a socket o , on the top of which work the screws $l l$, which, by means of the female screw in the lever $k \kappa'$ serve still further to regulate the pressure; the lever $\kappa'' k$ is shown as when the machine is printing, but when the rollers, &c., are to be removed, the lever is lifted by the handle, and the hinged piece κ pulled over, the lever with its burden being then lowered down; the weighting of these levers, which are partly outside the machine, is best seen in *figs. 344 and 345* where z are the weights, q are colour boxes, the sides and bottom of which are made of sheet copper, and the ends of gun-metal; in each end is a slot which receives the brass journals of the wooden furnishing rollers p , which are wrapped with a few folds of coarse calico, and, by revolving in the colour and against the engraved rollers d , supply it equally all over with the colour; the superfluous colour is next wiped off by the colour doctors t . These doctors are thin blades of steel or brass, which are mounted in doctor-shears, or plates of metal screwed together with bolts; the shears have journals which rest in bearings moveable backwards and forwards by the screws s ; the doctors are kept in close contact with the engraved roller by levers and weights, for the way of arranging which, see *fig. 346*, where A, B, C , are the levers attached to the doctor

346

shears. On the ends of these levers weights are hung, and by this means the doctors are pressed forcibly against the roller.

After printing the pattern on the piece, the roller d is cleaned from threads or dust by the lint doctors t , pressed against the roller by the screws s , *fig. 345*; any loose threads from the piece are prevented by the lint doctors from going into the colour, and

consequently under the cleaning doctors, where by preventing them from perfectly wiping the blank parts of the roller, smears on the piece would ensue. The colour boxes are mounted on wooden boards, to give them greater strength, and are tightened up against the roller by the screws *rr* and *ww*; the lower pair of colour boxes are removed from the copper roller when not in use by the handles *v*, after detaching the screws *ww*. There is a toothed wheel slipped on to each mandrel, working into a toothed wheel on the axis of the furnishing roller, which ensures the copper roller and furnishing roller always turning together. By means of an eccentric, fixed on the axis of the pressure bowl, and connected with each cleaning doctor, a regular vibratory movement is given to them, which prevents the doctor being worn down unequally. Sometimes for the highest rollers, and especially in machines of more than four colours, the cumbersome colour box is dispensed with, and a doctor inserted in a curved frame is applied to the roller instead. In this arrangement the doctor forms the bottom of the colour reservoir, and is pressed strongly against the roller; the curved frame stopped off at the sides with a piece of copper curved to fit both roller and frame, and which is padded with a piece of folded cotton cloth, forms the colour box. This doctor box takes but little room, and wastes but little colour, but is only used for the uppermost rollers. Neither of these arrangements can be shown in *fig. 345*. The roll of pieces is shown at *a*, wound on the wooden roller *b*, the axis of which rests in bearings at the end of the arms. The piece is conducted under a

347

small wooden roller, next over a square iron bar, and next against the scripping bar *y*, thence over the wooden roller *z*, round which also pass the grey piece *d*, and the woollen blanket *e*. The scripping bar is a bar of iron or brass, with curved surface, furrowed by grooves, cut right and left from the centre, as in *fig. 347*. In passing over this bar, the cloth is stretched equally from the centre, and any folds or creases removed. In order that the piece may be constantly stretched, the roller *b* is provided with a wooden pulley, round which passes a leather strap, one end of which is made fast to the framework, and to the other is attached a weight; the friction of the strap against the pulley causes a retarding action of the piece, and consequently keeps it stretched.

Fig. 348 is an elevation of a 12-colour machine, which is inserted to show the way in which all machines are driven. The large spur-wheel is keyed on the axis of the

348

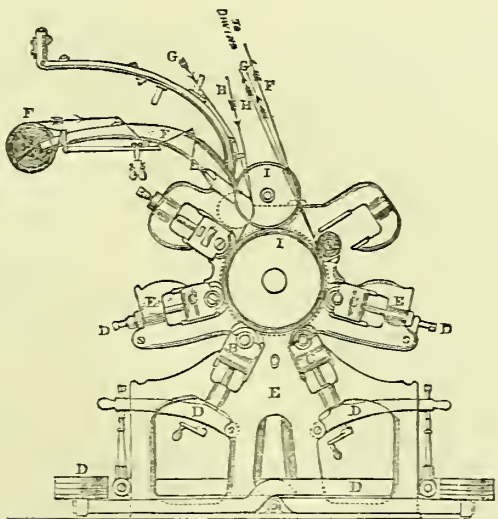

pressure bowl, and works into pinions staked on the mandrels; there is a peculiarity about these pinions, or box-wheels, as they are called, which may be observed in *fig. 348*, but is shown on an enlarged scale in *fig. 349*, which is a box-wheel detached. This wheel may be compared to the fine adjustment of a microscope, as by means of it

the rollers receive the final and delicate adjustment so as to register accurately with one another. It consists essentially of two parts: the disc *A*, carrying the cogs; and the hollow axis *B*, carrying a disc at one side, and the connecting piece and screw *C D* at the other. The part *A A*, or shell of the wheel, is about 10 inches in diameter and 3 inches broad across the cogs; one side of the shell is cut out to receive the plate shown by dotted lines. This plate is provided with the hollow axis *B*, which comes through the shell, and projects about 3 inches, the part projecting being cut through at *F F*; fastened to it also is the connecting piece *C*, in which works the screw *D*; this screw just fits in two projecting lugs *G F*, cast on the shell *A*. The screw-nut *E* forms part of the axle piece, and works in the slide *H*. When this wheel is used, it is slipped on the mandrel which carries the copper roller, and a cotter is driven through the cleft axle and through a corresponding cotter hole in the mandrel, thus firmly connecting the mandrel and wheel; the mandrel and roller being put in their place in the machine, the cogs of the mandrel wheel work into the main driving wheels, as shown in *fig. 348*. The coarse adjustment of the rollers being made when putting them in their places, the fine adjustment is made by turning the screw *D*. It is obvious that the screw *D*, by pressing against the lugs *G* of the shell *A*, which is geared into the driving wheel, will turn the mandrel and roller without moving the cogs. By this arrangement, any roller may be moved round about 2 inches at any time after being fixed in its place. All machines of more than one colour are fitted with these wheels, which indeed are indispensable.

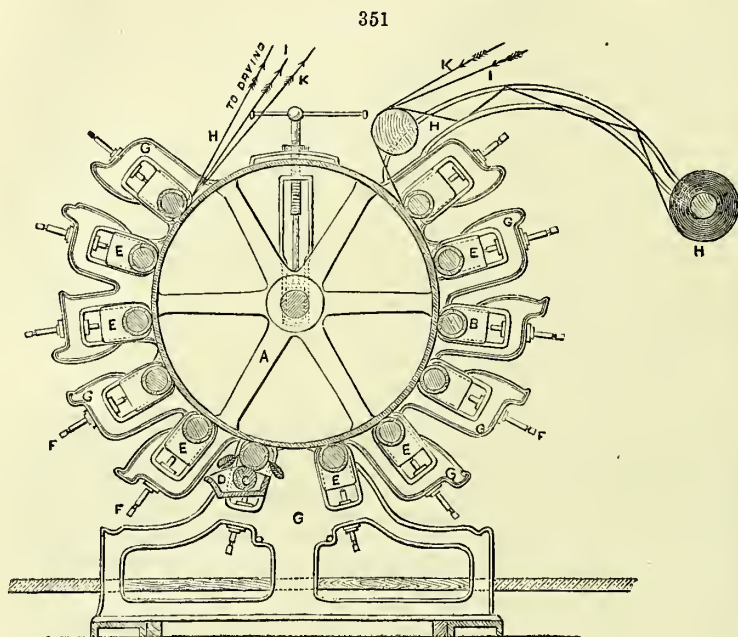

Fig. 350 represents a 6-colour printing-machine as made by Mather and Platt. *A* is the bowl or cylinder; *B*, copper printing rollers upon iron mandrels; *C*, blocks, &c.,

350

or journals for carrying the mandrels and copper rollers, the blocks being adjustable by screws for fitting the pattern; *D*, setting up screws and levers for giving the pressure of copper rollers on to the cloth being printed; *E*, framing of machine, with nips or horns cast on, in which the blocks work; *F*, white cloth to be printed running from batch through the machine, and thence to the drying apparatus; *G*, grey or intermediate cloth; *H*, blanket or back-cloth; *I*, friction-wheel for drawing traverse

motion. *Fig. 351* represents a 12-colour printing-machine of Mather and Platt; A, the bowl or cylinder; B, copper printing rollers on mandrels; C, wooden furnishing-

rollers, (one nip only shown in section); D, copper colour box, (one nip only shown in section); E, blocks or journals for carrying the mandrels and copper rollers, the blocks being adjustable by screws for fitting the pattern; F, setting-up screws for giving the pressure of copper rollers on to cloth being printed; G, framing of machine with nips or horns cast on in which the blocks work; H, the white cloth to be printed running from batch through machine and thence to drying apparatus; I, grey or intermediate cloth; K, blanket or back-cloth. The cuts here given with the exception of *fig. 348* do not show any gearing or connection with the motive power, as to show this effectually several more drawings would be required, and the arrangement will naturally suggest itself to those conversant with mechanics.

The system of turning cylinder-machines, patented by Mr. Joseph Leese, possesses several advantages. In this plan a small high-pressure oscillating engine is attached directly to the axis of the large cylinder, thereby dispensing with the heavy gearing and shafting required when machines are turned by a large stationary engine; the machine printer also has perfect command over the speed of the machine, and can fit the pattern, when it is turning very slowly, with more convenience than on the usual system. On this system also machines can be put down in any portion of the works, and are independent of the stationary engine.

This system of turning is now employed in most modern print-works, or where new machines have been put down.

Four-, five-, and six-colour machines, similar to the above, are now at work in many establishments in Lancashire, which will turn off a piece of 28 yards per minute, each of the three or four cylinders applying its peculiar part of the pattern to the cloth as it passes along, by ceaseless rotation of the unwearied wheels. At this rate, the astonishing length of one mile of many-coloured web is printed with elegant flowers and other figures in an hour. When we call to mind how much knowledge and skill are involved in this process, we may fairly consider it as the greatest achievement of chemical and mechanical science.

The printers of goods intended for hangings, which are generally of elaborate floral designs, employ machines capable of printing from 10 to 20 colours at once. These machines are necessarily of very large dimensions. *Fig. 352* is an end-view of a 20-colour machine, made by Messrs. Gadd and Hill, of Manchester for Mr. Kay, of

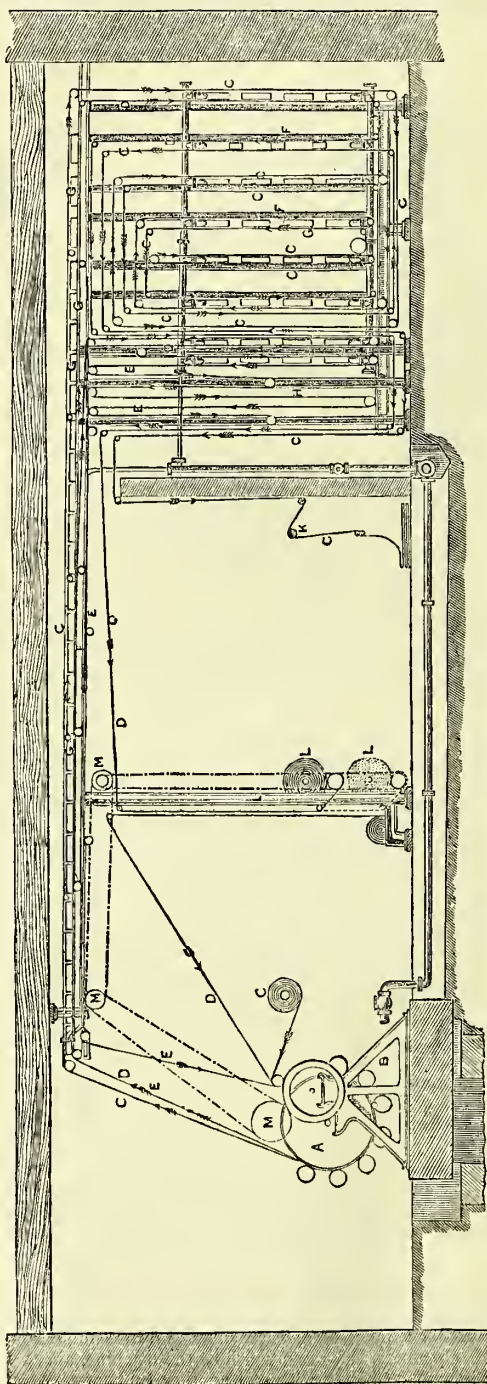

Castleton Print Works, and is employed in printing very beautiful floral patterns on woollen fabrics, in imitation of those produced by hand-labour in France.

352

The general course of printing is thus performed:—The pieces to be printed are wound on a beam, and, last of all, a few yards of common coarse cotton or calico, kept for this purpose: this is for the printer to fit the pattern on, to save good cloth. The roll of cloth being put in its place behind the machine, the printer's assistant stations himself behind to guide the cloth evenly, and pluck off any loose threads he may see. The machine printer stands in front, and, after having fitted the pattern on the cloth, attends to supplying the colour boxes with colour, and regulating any misfitting or inequality in the printing. The machine then prints rapidly. After running through 30 or 40 pieces, the printer stops the machine, removes the doctors, and files them anew to a bevelled sharp edge.

To prevent the blanket being too soon soiled, it is usual to run grey or unbleached pieces between the blanket and the white pieces. The blanket, grey, and printed pieces are dried separately. There are several ways of drying after the machine. In the early days of machine-printing, the 'hot room' behind the machine was heated by a cast-iron furnace, termed the 'pot,' which was kept red-hot or nearly so, and large cast-iron pipes formed the flue, which after traversing the hot room, delivered the smoke, &c. into a chimney. This arrangement gave way to cylinders, similar to those used in drying machines and were also employed in conjunction with the steam-chests hereinafter described for drying the printed cloth as well as the grey or intermediate cloth and the blanket, but experience having shown that many colours and mordants are injured by the sudden drying given by the cylinders, these have been pretty generally abandoned in favour of steam-chests, in drying with which, the printed cloth does not absolutely touch the heated surface, but keeps moving on in very close proximity, the cylinders where they are retained being reserved for the 'grey' and the blanket. One of the most recent arrangements only, is shown in *fig. 353*, being that of Messrs. Mather and Platt; *A*, the printing-machine with copper rollers, (an 8-colour machine here shown); *B*, place of steam-engine to drive the machine; *C*, white cloth to be printed, running from batch through machine, and thence to drying apparatus; *D*, grey or intermediate cloth; *E* blanket or back-cloth; *F*, framing of apparatus for supporting and carrying the rollers and steam-chests; *G*, hollow steam-chests or chambers, the same width as the machine, about 1 foot broad and 3 or 4 inches deep, and connected with one another by bent pipes at the end; *H*, upright with tightening trough apparatus for blanket; *I*, upright with

tightening rack apparatus for blanket; *x*, plaiting apparatus for printed cloth; *l*, upright and batching apparatus for grey cloth; *m*, driving pulleys and straps for batching and plaiting apparatus.

The doctors used in cleaning off the superfluous colour from the rollers, are generally thin blades of steel, of a thickness varying from $\frac{1}{32}$ nd of an inch to $\frac{1}{16}$ th of an inch, according to the sort of engraving on the roller; but some colours, such as those containing salts of copper, would be too corrosive on a steel doctor, and in this case doctors of a composition like brass are used. They are filed to a bevelled edge, and require to be retouched with the file after printing from 10 to 30 pieces. The cylinder or drum, in contact with which revolve the copper rollers, is wrapped round with a cloth called 'lapping,' which is generally a coarse strong woollen cloth of peculiar make, and is folded tight on the cylinder about $\frac{1}{2}$ an inch thick. The blanket is next put on and drawn tight: this blanket is a very important part of the machine; it is a thick woollen web, about 40 yards long, and requires to be made with great care, so as to be uniform in texture, thickness, and elasticity. If the blanket is uneven, it has the effect of throwing the pattern into confusion at the uneven places.

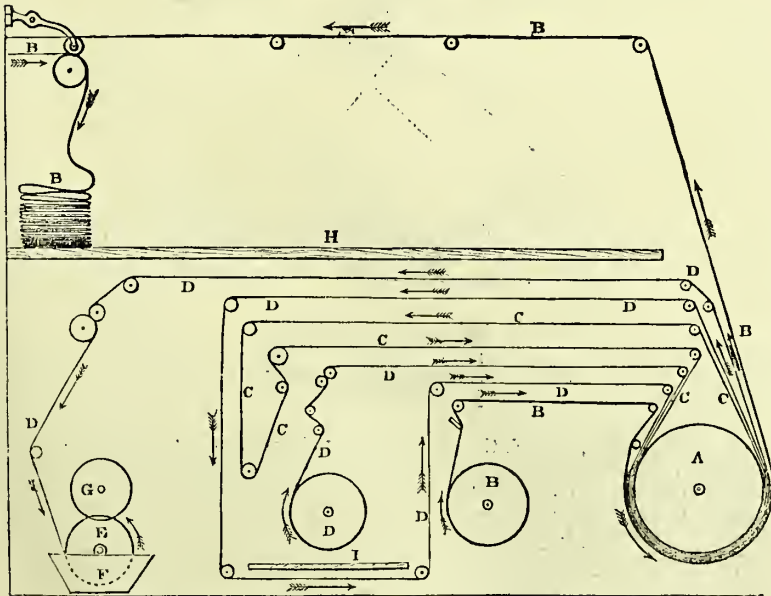

A good blanket will serve to print 10,000 pieces, being washed whenever loaded with colour, and then is suitable for covering the tables of the block printer.

In the year 1835 Messrs. Macintosh and Co. patented an India-rubber blanket, which consists of several thick cotton webs, cemented together with dissolved India-rubber. This blanket is very useful and economical for some purposes; the surface being very smooth, great delicacy of impression is obtained, and when soiled it is not necessary to remove it from the

machine, as it is easily washed by being passed through a special washing machine, which will be found described subsequently. An India-rubber blanket will print 20,000 pieces, which is twice as much as a woollen one will do, the price per yard being also lower. Several descriptions of these blankets are made by Messrs. Macintosh, some of them having a coating of vulcanised India-rubber on the face that is printed from, thereby giving a still more elastic surface. A great improvement has been recently made in these India-rubber blankets by shrinking or preparing the cotton previous to cementing, according to the patent process of Mr. John Mereer, viz. by soaking in strong alkali, and afterwards in dilute sulphuric acid; this process contracts the fibre to a certain extent, and the cloth is found to possess a great increase of strength. When made into blankets they are found to be more capable of resisting the severe strains of the printing process, and consequently many more pieces can be printed from them than from the old sort. They are made by Kay and Co. of Acerington, and others, and are now in general use. The woollen blanket, however, seems to be preferred for several styles. Several patents have been taken out for printing without blankets, but have never come into general use; but recently a mode of printing with grey or unbleached calico has come into use, which is very favourably spoken of. In this method a roll of grey cloth is so disposed behind the machine that the fabric can be conducted five times through the machine before finally going away to be wound on a beam for removal. There are, therefore, five layers of cloth under the white calico when printing, which gives a sufficiently elastic bed for printing from; and very delicate shapes can be got. Any given part of the grey cloth is five times uppermost on the pressure cylinder, and consequently one piece of grey cloth is used to print five pieces of white. Gutta-percha pressure cylinders, or 'bowls,' have been suggested by Dalton, an English printer; but though theoretically preferable to iron, they do not appear to be much used.

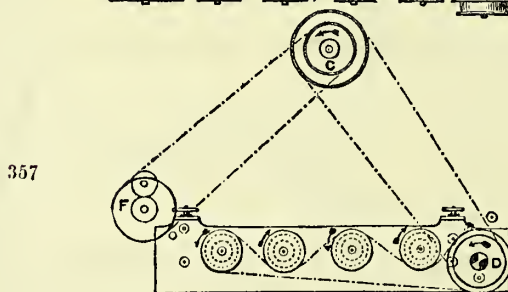

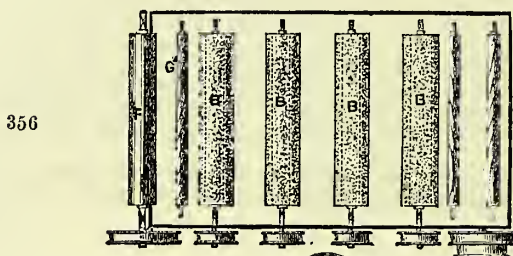

In printing with aniline black (No. 240), the grey intermediate cloth, unless removed from the machine without drying in the 'hot room,' and before this peculiar

354

black has begun to form upon the cloth, will be stained and spoiled for future printing upon, in consequence of the extraordinary fastness of this colour, which resists the ordinary bleaching operations; and this is the place to describe a very simple arrangement for wetting the grey pieces, after they have served their purpose, and thus preventing the formation of the black. The arrangement (*fig. 354*) is that in use at the Oriental Print Works at Apponaug, in the United States. A is the printing-

machine cylinder; *B*, the roll of white cloth, and cloth passing through the machine, and hot room, and being plaited down; *C*, the blanket; *D*, the roll of grey cloth, and grey cloth passing twice through the printing-machine, and then through the wetting machine; *E*, a wooden roller working in a water trough; *F*, water trough, with a stream of water kept running through it; *G*, shell upon which the grey cloth is wound after passing through the water; *H*, gallery above the machine where the printed cloth is plaited down; *I*, platform for putting up the grey rolls. Mr. Furnival of Haslingden has introduced a machine for washing India-rubber blankets: *fig. 355* is a longitudinal section, *356* a plan, *357* is a side elevation, and *358* a cross section. *A*, an iron cistern containing water, and forming the framework of the machine; *B*, circular brushes, with a pulley keyed on the end of each; these brushes are turned by a strap from the

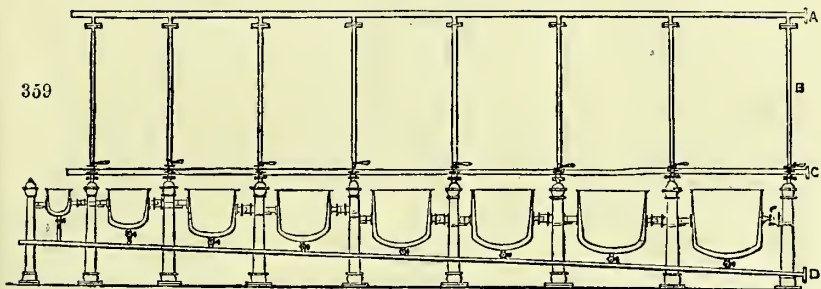

main driving-shaft *C*, through the carrier pulley *D*, by a strap as shown in the dotted line *F*, so that the brushes may revolve in opposite directions; *F* are squeezing rollers of brass or wood, also turned by a strap from the driving-shaft *C*. Clean water is supplied to the machine by being spirted upon the blanket before entering between the squeezing rollers *F*. The blanket on leaving the printing-machine charged with waste colour, enters into the machine and is passed through, as shown by the line *O*, under and over the adjustable guide-rollers *G*, and is brought into contact with the revolving brushes, and leaves the machine by the squeezing rollers *F*; it is then dried, and returns again to the printing-machine.

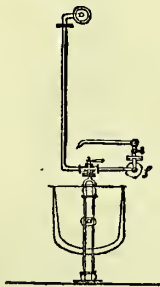

The thickening of mordants and colours is a subject of very great importance to the printer. It is obvious that a mere solution of salts or colouring matters, such as used in dyeing, cannot be used in printing a pattern; capillary attraction speedily causes such a solution to spread beyond the limits of the pattern, and nothing but confusion is the result. A proper degree of inspissation is then essential. To the capability of very thick colour being printed by engraved plates or rollers under

severe pressure is due the superior smartness of outline characteristic of goods produced by these means. Where colour can be laid on the outside of the cloth, so as to penetrate as little as possible to the other side, much brighter shades are produced. In order to obtain the most brilliant shades of colour, it is necessary that the cloth act as a sort of mirror behind the colour, which cannot be the case if the fibre is perfectly saturated with colour. Independent of this, a great economy of colouring material follows from the proper application of the colour or mordant to the face only. This is especially noticeable in madder goods, where the mordant, if printed in excess, is apt to give up a portion from the cloth in the dyebeck, thereby consuming a certain quantity of madder in pure loss.

The colour-house should be a spacious apartment on the ground floor, with the roof ventilated in such a manner that the steam produced finds a speedy exit; at one end, or down one side, is fixed a range of colour-pans, varying in size, and supplied with steam and cold water. Colour-pans are usually made to swing on pivots, whereby they are easily emptied and cleaned. A range of this sort, as manufactured by Messrs. Storey & Co., of Manchester, is represented in *fig. 359*. This range con-

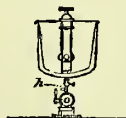

360

361

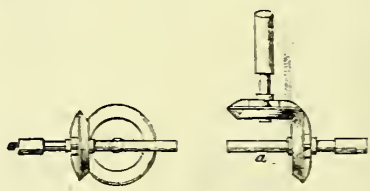

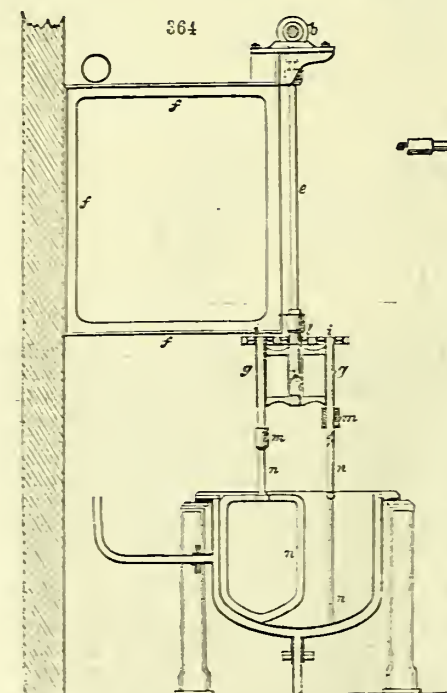

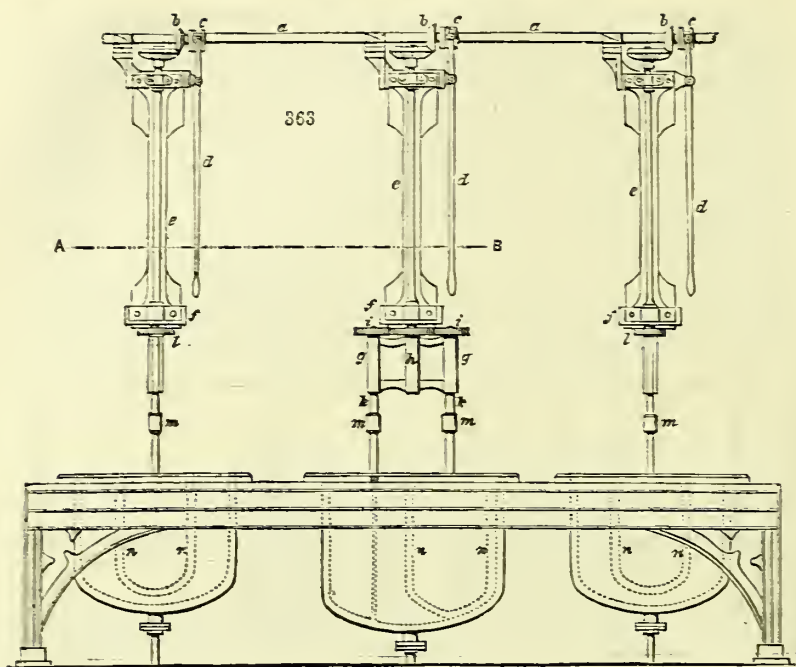

362

sists of 8 double-cased copper pans, containing from 1 to 28 gallons, riveted together at the top, wired at the edges, and made perfectly steam-tight; they are supported on cast-iron pillars, and are so arranged or fitted as to swivel or turn over when the colour is required to be emptied, by means of a brass stuffing-box attached to pan, and working in the corresponding part attached to pillar on the one side, and moving at the other on a plain brass nozzle, supported by a pedestal projecting from pillar, the nozzle having a blank end, thereby cutting off the communication of steam, which is carried to the following pan. They are also supplied with a condense-tap to carry off the waste steam and water. Each pillar in the range, except the last, is supplied with a brass tap on the top, with 3 flanges, to connect the steam and cold water pipes, as more fully explained hereafter.

A, *fig. 359*, is a copper pipe, with one blank end, and open at the other with flange for the admission of steam, which passes through the downward-bent pipe marked B, in connection with the brass tap on top of pillar, the plug of this tap being open at bottom to admit the steam down the pillar as far as the stuffing-box, marked E, through which it rushes into the casing of pans, and out by the condense-pipe D, when required. C is a copper pipe, with one blank end and open at the other, for the admission of cold water for cooling the colour after boiling, and is likewise connected with the tap on top of pillar, as shown in *fig. 360*, marked F, the water passing through

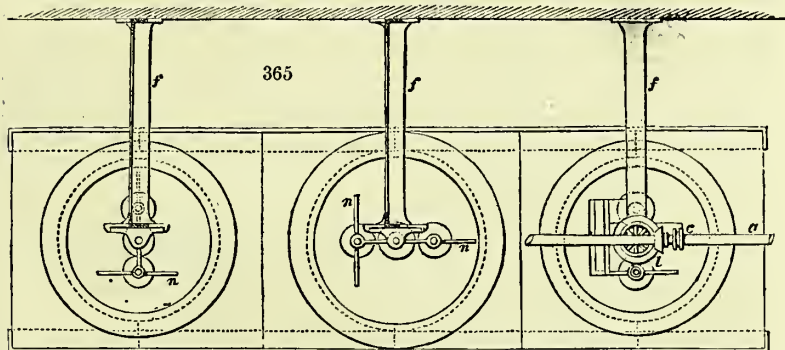

precisely in the same manner as the steam in A. *p* is the condensepipe, with one blank end and open at the other, with flange, underneath the pans, to carry off the water or steam, and is supplied with ground brass nozzles to fit the condensetap at bottom of pan, being accurately adjusted, so that in the swelling of pan it leaves its seat and returns perfectly steam-tight. *Fig. 360* represents an end-view of range, showing more fully the position and connection of steam and cold water pipes to brass tap, the cold water pipe running along back of range, the steam-pipe above, parallel with centre of pans, and the downward-bent pipe in front; and likewise the stoppage in pillar, so far as is necessary, there should be an aperture for the steam or water to

meet the brass stuffing-box. In this *fig.* is also shown the copper pipe, with elbow swivel tap, for supplying pans with cold water (one pipe to supply two pans), and

fixed on top of cold water pipe exactly opposite pillar, as further shown in *fig. 361* marked *g*. *Fig. 362* is an end-view of range, with pillar cut, in order to show the position of condense-tap at bottom of pan, and its connection with condense-pipe, and where the point of separation takes place in swivelling, by the line marked *h*. It will be seen by the foregoing that the process of boiling and cooling is rapid and certain, everything being accurately adjusted and steam-tight throughout the whole apparatus.

The colours are placed in these pans and stirred well all the time they are being boiled; good stirring is very essential to produce smooth colours. This was formerly done by hand with a flat stick, but lately the best print works have been fitted with machinery over the pans to stir mechanically. A very effective plan of this sort is represented in *figs. 363* and *364*. It is that of Messrs. Mather and Platt, of Manchester, the boilers in this drawing being not reversible, though the plan can be just as easily adapted to that description of pans. *Fig. 363* is a front elevation; *fig. 364* is a transverse section, and *fig. 365* is a sectional plan, the same letters referring to all. *a* is a horizontal shaft above the pans, fitted with a pair of mitre wheels, *bb*, for each pan. The vertical wheel *b* is not keyed on the shaft *a*, but is brought into connection with it when required by the catch box *c*, which slides on a key on the shaft, and revolves with it (see *small cuts*); the catch box is worked by a lever-handle *d*, and thus motion is given to the vertical shaft *e*. The shafts *a* and *e* are both supported by the framework *f*, fastened to the wall; the shaft *e* is terminated by the frame *ghg*, the centre of which, *h*, is a continuation of the shaft *e*; and the wings *g* are hollow to carry the shafts *k*, which are surmounted by the cog wheels *ii*, which gear into a cog

wheel *l* on the shaft *e*. The agitators *nn* are made of flat brass rod, and are curved to fit the bottom; they are connected with the shafts *kk* by a hook joint, which is steadied by the conical sliding ring *m*; the agitators thus hang from the shaft *e*, and nearly touch the bottom of the boiler. When the shaft *e* is put in motion, the agitators have two movements, one round each other, and also each on its own axis; as they are set at right angles to each other, as shown in *fig. 365*, it follows that no part of the pan can escape being stirred. When the colour is made, the piece *m* is slid up on *k*, and the agitators unhooked and taken out, the waste of colour being very trifling, in consequence of the agitators being outlines only. The saving of labour effected in a colour-house by this machinery is very great, as, after turning-on the steam, the pan may be left to itself till the colour is finished.

From the great variety of substances used in mordants and colours, of very different chemical properties, a variety of thickening substances is required. Chemical combination between the mordants or colour and the thickening substance is to be avoided as much as possible, for such combination may be regarded as so much pure loss, the fibre of the fabric not being able to decompose and assimilate them. Several circumstances may require the consistence of the thickening to be varied; such as the nature of the mordant, its density, and its acidity. A strong acid mordant cannot be easily thickened with starch; but it may be by roasted starch, vulgarly called British gum, and by gum arabic or Senegal. Some mordants which seem sufficiently inspissated with starch, liquefy in the course of a few days; and being apt to run in the printing-on make blotted work. In France, this evil is readily obviated, by adding one ounce of spirits of wine to half a gallon of colour.

The very same mordant, when inspissated to different degrees, produces different tints in the dye-copper; thus, the same mordant, thickened with starch, furnishes a darker shade than when thickened with gum. Yet there are circumstances in which

the latter is preferred, because it communicates more transparency to the dyes, and because, in spite of the washing, more or less of the starch always sticks to the mordant. Gum has the inconvenience, however, of drying too speedily, and forming a hard crust on the cloth, which does not easily allow the necessary capillary attraction to take place, and the tints obtained are thin and meagre. The substances generally employed in thickening are:—

- | | |
|---|--|
| <ol style="list-style-type: none"> 1. Wheat flour. 2. Wheat starch. 3. Torrefied wheat starch, or British gum. 4. Torrefied potato farina. 5. Gum substitutes or soluble gums. 6. Gum Senegal. 7. Gum tragacanth. 8. Salep. | <ol style="list-style-type: none"> 9. Pipe-clay or china-clay mixed with gum Senegal. 10. Sulphate of lead. 11. Molasses. 12. Dextrin. 13. Albumen of eggs. 14. Lactarine. 15. Gluten. 16. Glue. |
|---|--|

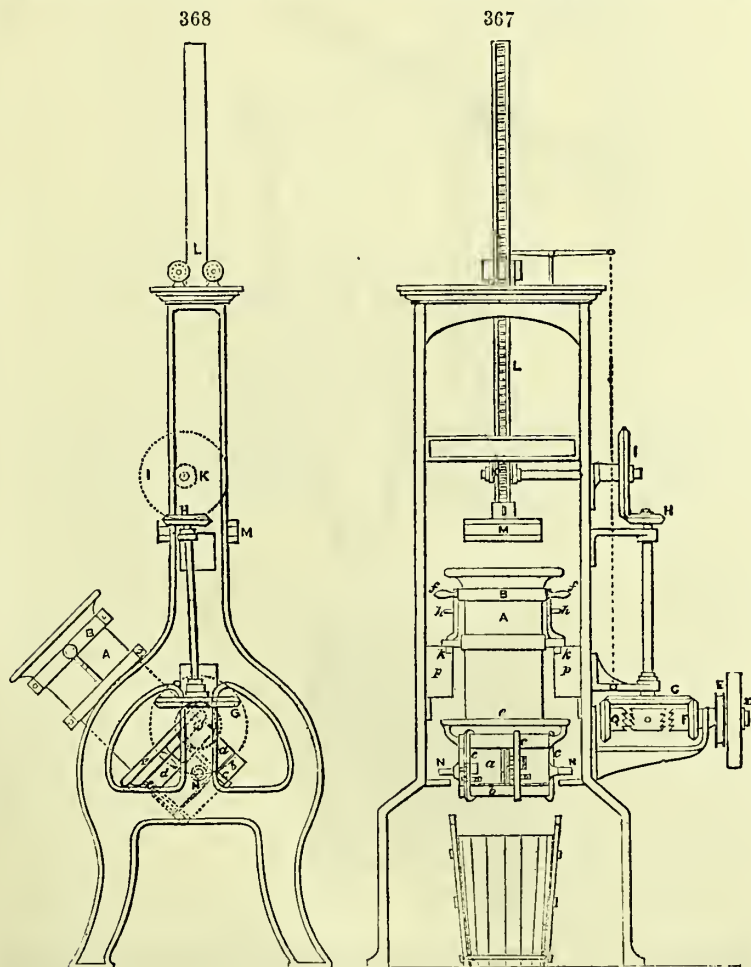

Those most used are the first seven. The rest are only adapted for special styles or colours. The artificial gums produced by roasting starch or farina are very largely in use. The action of heat on starch causes a modification in it. According to the degree of heat and its duration a greater or less modification ensues; the higher the heat, the more soluble in water the gum, but also the browner and of less thickening properties. The addition of various acids and alkalis to starch or farina before calcination causes them to become soluble at lower temperatures than without: different acids also produce different results; those most generally used are nitric, acetic, muriatic, oxalic, and recently lactic acid has been proposed by Pochin. The proportion of acid used is very small, and, though the effect is produced, the acid disappears during calcination. Small quantities of alkalis are also used for special modifications of these gum-substitutes. The making of these gums is a distinct branch of trade, and finds employment for large capital and numerous hands. In giving the receipts for the various colours, care will be taken to specify the nature and proportion of thickening to be employed for each colour; a most important matter, often neglected by English writers upon calico-printing.

It is often observed that goods printed upon the same day, and with the same mordant, exhibit inequalities in their tints. Sometimes the colour is strong and decided in one part of the piece, while it is dull and meagre in another. The latter has been printed in too dry an atmosphere. In such circumstances a neutral mordant answers best, especially if the goods be dried in a hot flue, through which humid vapours are in constant circulation.

In padding, where the whole surface of the calico is imbued with mordant, the drying apartment or flue, in which a great many pieces are exposed at once, should be so constructed as to afford a ready outlet to the aqueous and acid exhalations. The cloth ought to be introduced into it in a distended state; because the acetic acid may accumulate in the foldings, and dissolve out the earthy or metallic base of the mordant, causing white and grey spots in such parts of the printed goods. Fans may be employed with greater advantage, combined with hot flues. See VENTILATION.

The mordant and thickening, or the dye decoction and thickening, being put in one of the copper pans, is stirred by hand or machinery and boiled till perfectly smooth; the steam being then shut off, cold water is admitted to the double casing, and the colour cooled. It is then emptied out of the pan into a straining cloth, stretched over a tub, and strained to remove all gritty particles, which would be very injurious to the copper rollers. A very useful straining machine was invented a few years ago by Dollfus Mig and Co. and patented in this country. This machine is shown in *fig. 366*. It consists of a case or cylinder, in which a piston is worked, either by hand or power, to press the colour through a cloth made of cotton, linen, hair, or other suitable material at the bottom of the case or cylinder; or, instead of the said cloth, a wire gauze may be used. The bottom of the piston may be made of wood, copper, brass, gutta percha, caoutchouc, or other suitable material. The manner of working the apparatus will be clearly understood by reference to the drawings, in which *fig. 366* is a side elevation of the said machine or apparatus, and *fig. 367* a front elevation of the same. *a* represents the case or cylinder, which is strengthened at its upper part by the iron band *b*, and also at its lower part by the ring *a*. The skeleton plate *b*, which forms the bottom of the cylinder, is removable, and sustained by the four hooks *c*. To disengage the plate *b*, springs are fitted on the ring *d*, which act upon two of the hooks *c*, so as to throw them out from under the grid *b*. Upon the ring *a* the second ring *d* is laid, which supports the circular handle *e*. The upper parts of the four hooks *c* lie upon four inclined planes fitted on the ring *d*. The

modus operandi is as follows:—If the ring *d* is turned right or left, the skeleton plate *b*, on which one of the said cloths or wire gauze has previously been placed, will be brought firmly up to the extremity of the cylinder *a*; and if the said cylinder be filled with colouring matter, the piston *m*, being worked by the pulley *e*, the wheels *r*, *g*, *h*, *i*, *k*, and the rack *l*, will force it through the cloth or sieve, to be received in a vessel under it for the purpose; and by a proper arrangement of the teeth of the said rack *l*, the piston can only descend to any required point in the cylinder. To facilitate the working of the apparatus and increase its general efficiency, the cylinder is fixed on pivots at *n*, so that it may be easily inclined or brought towards the operator for the purpose of introducing the colouring matter or cleaning the vessel. To the

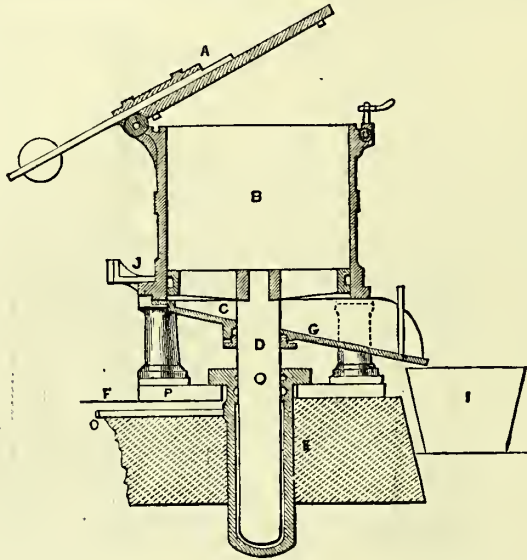

ring or band *b* are fixed the two handles *f* and the two catches *h*. The catches being raised from the notch *k* on the frame *P*, the cylinder may be pulled forward by means of the handles *f*, till the hooks, being acted upon by a spring, re-engage themselves at *k* on the lower part of the frame *P*, and *vice versa*. On the shaft *x* is placed a second wheel *q*, by which a reverse motion is obtained, and the piston *m* raised to its original position.

A straining machine patented by Samuel Ridge and Co. of Manchester has been introduced into some of the largest print works in Lancashire, and is very favourably spoken of (*figs.* 368, 369, 370, 371).

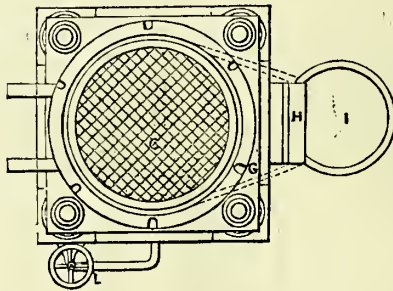

Fig. 368, sectional view of strainer; *fig.* 369, ground plan, showing sieve, paddle

and colour-tub; *fig. 370*, end elevation of pumps; *fig. 371*, side elevation of pumps; A, lid lever and balance weight; B, cylinder for holding colour; C C, piston for supporting copper sieves, for the colour to pass through; D, ram for raising piston; E, hydraulic cylinder; F, floor-line; G G, trough for conducting colour to tub; H H, paddle for stopping colour whilst changing tubs; I I, colour tubs; J, fixing for balance to rest on whilst filling with colour; K, for fastening down lid; L, valve for raising and lowering piston; M, end elevation of pumps, showing safety valve, cistern, and fly-wheel; N, side elevation, showing cisterns, pumps, fly-wheel, fast and loose pullies,

368

36

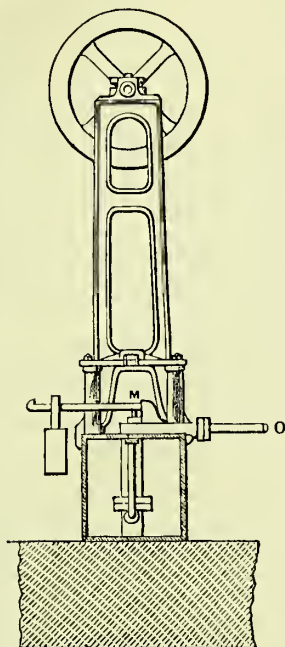

and strap guide; O O, showing the ends of pipes that require connecting together, let the distance be whatever it may between the pumps and strainer; P, foundation plate. Where two letters together are alike they refer to both sectional view and ground plan. This strainer will strain 80 gallons of thick colour in four minutes, and be washed out ready for any other sort of colour in six minutes.

Colours for printing by block are for the most part thickened in the same manner as those for machine, but are much thinner, since very thick colour cannot be applied by block. Some substances also can be used in block printing that are inapplicable to machine, such as pipe-clay and china-clay, which, however finely ground, still contain gritty particles which would speedily scratch and destroy the delicate engraving of the machine rollers.

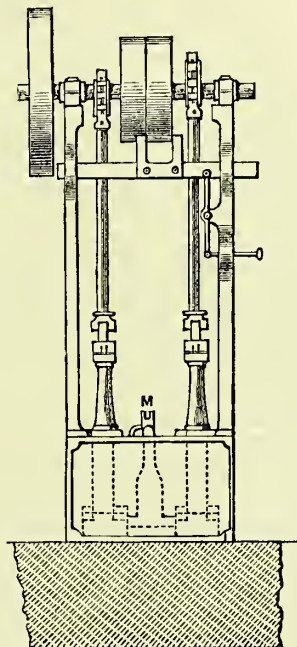

A spacious drug-room is attached to the colour-house where all the drugs used are

kept away from the steam of the colour-house. Near the colour-house should be a well appointed laboratory, where drugs can be tested and experiments made.

370

371

Formerly, all the decoctions and mordants used in print-works were made on the spot; but the trade having very much extended, the manufacture of the various mordants and decoctions of dyewood is now a separate business, and printers can be supplied with these articles at the same or in some cases a lower rate than they could be produced for on the works, the quality also being uniform and good. The printer now only makes for himself a few unimportant articles. The province of the foreman colour-maker, who is generally a well-paid and responsible servant, is to combine these primary materials so as to form the different colours required for the different styles of work; as the taste of customers varies, he is required to be able to make any given variation of shade at will, and be able to judge of the quality of the various materials submitted to him. The ordinary decoctions that are kept in stock in the colour department are:—

Logwood liquor.
Peachwood liquor.
Sapan liquor.
Quercitron-bark liquor.
Gall liquor.

Persian-berry liquor.
Cochineal liquor.
Fustic liquor.
Catechu liquor.

Ammoniacal cochineal liquor.
Extract of indigo.
Extracts of madder.

And the various mordants and solutions are:—

Red liquor, or acetate of alumina.
Iron liquor, or acetate of iron.
Buff liquor, or pyrolignite of iron.
Permuriate of iron.
Permuriate of iron.
Protomuriate of iron.

Protochloride of tin in solution.
Oxymuriate of tin in solution.
Nitrate of copper in solution.
Acetate of copper in solution.
Lime juice.
Ammonia liquor.

Acetic acid.
Pyroligneous acid.
Nitric acid.
Muriatic acid.
Sulphuric acid.
Caustic-soda liquor.
Caustic-potash liquor.
Aniline hydrochlorate.
Aniline.

Many other dry acids and salts are also kept in stock. For the constitution of the various mordants and their preparation, see MORDANTS.

It would be impossible to particularise all the styles of calico-printing. The variety is infinite; but they may be broadly classed as follows:—

I. *Madder styles*, varieties of which are—

a. The simplest form is a pattern printed in mordants on white ground, such as black and red; black, red, and purple; black and two reds, &c., chocolate being sometimes substituted for black, and brown from catechu being also introduced; these are dyed with madder, the ground remaining white.

b. Any or all of the above mordants, together with lime-juice, technically termed *acid*, printed, and a fine pattern printed all over or *covered* in purple or light chocolate, then dyed madder. In this style the red is a peculiar one, termed *resist* red; and the result when dyed is, that the acid and red have prevented the purple or chocolate fixing on those parts, the red remaining pure and the acid having formed a white, the rest of the ground being covered with the fine pattern or cover; of this style large quantities are printed in black, purple, and acid, and covered in paler purple, the cover roller being any small full pattern, and this not being required to fit to the other pattern, a great variety of effects may be produced by varying the cover: often a still weaker purple is padded or blotched in a plain shade all over the piece, and in this case the only white in the pattern is that reserved by the acid.

c. The French pink style, which is wholly various shades of reds or pinks, and is printed in one or more shades of red and *acid*, then covered or blotched in pale red, then dyed madder and subjected to a peculiar clearing with soap, whereby pink shades of very great delicacy are obtained.

All these are what are termed *fast* colours, and having, after dyeing, undergone severe soaping, cannot be altered by the usual domestic washing process.

In this category must now be classed goods, mordanted as for madder, but with weaker mordants, and dyed with alizarine artificially made from anthracene, which produces shades equal if not superior to those dyed with madder, and which do not require as much soaping or other brightening process as madder. At this date it cannot be absolutely affirmed that these colours are as fast to light and air as those of madder, but inasmuch as the alizarine of the purest sorts of the artificial product is identical with that of madder, it is almost certain that modes of dyeing, &c., will eventually be used which will give a result identical in every way with madder dyeing.

II. The samo styles are dyed with garancin instead of madder; heavier and darker colours being employed. These goods are not soaped, garancin producing bright colours at once; but the shades, though still classed as fast colours, do not possess the permanence of those dyed with madder.

III. The first style is frequently relieved by lively colours, such as green, blue, yellow, &c., blocked in after dyeing and clearing; these colours are generally what are termed steam-colours, being fixed by steaming the cloth, and afterwards washing in water only, or the printed or dyed pattern is covered with a resist paste blocked on, and various shades of drab, slate, buff, &c., printed with a small pattern all over; sometimes these colours are mordants, to be subsequently dyed with cochineal, quercitron bark, &c., or they may be colours composed of dyewood decoctions, mixed with mordants, and are fixed by passing through soda or other solutions; the result in either case being that the original pattern, generally a group of flowers, being protected by the paste which prevented the subsequent colour fixing there, stand out pure, the rest of the ground being covered by the small pattern or *cover*. White may be also reserved by the paste, and frequently these white parts are blocked with blue, yellow, green, &c., as before.

IV. *Padded styles*.—In these the cloth is first padded (as will be hereafter explained) all over with a liquid mordant, dried and printed in spots or figures with strong acid, or *discharge* as it is called, then put through the dyeing operations necessary for the shade required; the printed spots remaining white, and the rest of the piece one plain shade. The white portions are frequently relieved by steam-colours blocked in.

V. *Indigo-blue*:—a style of considerable importance. In this, a resist paste, either alone or accompanied by resist yellow, or orange mordant, is printed on white calico, which is then dipped in the indigo vat, till the shade of blue wanted is obtained. If yellow or orange is present, these colours are raised with bichromate-of-potash liquor. The peculiar colours printed in this style have the property of preventing the indigo fixing on the printed parts, and the result is dark blue ground, with white, orange, or yellow spots, steam-colours being sometimes blocked in the whites.

VI. *China-blues*:—a modification of the indigo-blue style, but in this case the pattern is produced by indigo colours, printed on white cloth: the pieces are next put through a peculiar process, fixing the indigo in the cloth, the result being blue figures on white ground. All indigo styles are fast or permanent.

VII. *Turkey red and discharge*.—On dyed Turkey-red cloth is printed an acid, or acid-solutions mixed with pigments or salt of lead; the printed pieces are passed through chloride-of-lime solution, when chlorine is eliminated by the acid colours, and discharges the red. The pigments or lead-salt being fixed in the cloth at the same time, after washing and chroming where yellow has to be obtained, the piece presents a pattern, bitten as it were in the Turkey-red ground. Black is also printed along with the other colours. A modification of this style is the well-known Bannanna style used for handkerchiefs. Turkey-red cloth is folded in a hydraulic press on a lead plate perforated with a pattern. When a sufficient number of folds are made on this plate, a precisely similar plate is put on the top, so as to register accurately with the bottom one; pressure being now applied, the cloth is squeezed tightly between the two plates, a tap being opened above the upper plate, solution of chlorine is forced through the perforations, and in its passage through the cloth, discharges the dye; the chlorine liquor is followed by water, and the operation is finished: the pieces when removed from the press being discharged, according to the pattern of the lead plates.

VIII. *Steam-colours*.—In this style colours are formed from mixtures of dyewood extracts and mordants, together with various acids and salts, and being printed on calico which has been mordanted with peroxide of tin, the pieces are exposed to steam at 212° in close vessels, which causes an intimate union of the calico with the dyewood extract and mordant, so that subsequent washing with water removes only the thickening substance, and leaves the cloth dyed according to the pattern in various colours. Woollen fabrics and de-laines are always printed in this manner, and also often silk; animal fabrics not being well adapted for mordanting and dyeing in the same manner as cotton fabrics, owing to the peculiar property of wool to absorb colouring matters, which renders the obtaining of whites, an impossibility where the wool is steeped in a dye decoction. These steam-colours are very brilliant and tolerably permanent to light, but do not withstand hot soap solution, which alters their shades.

The invention of the superb colours made from aniline, which only dates from 1856 has caused a considerable alteration in the composition of steam-colours; far more beautiful shades are now produced from aniline colours than formerly was possible from dyewood decoctions, and though not faster, in many cases not so fast to light as these, some of them will bear a slight soaping with improvement in their tone. Within the last five years the colouring matter of madder extracted in a tolerably pure form has been successfully applied as a steam-colour, various shades of red, pink, chocolate, and purple are produced from extracts of madder mixed with aluminous, ferruginous, or chromous salts of volatile acids and the colours thus composed are thickened, printed, and fixed by steaming. These colours, when properly made and fixed, are as fast to soap and light as those of madder dyed goods. Still later the alizarine artificially made from anthracene has been applied to the same purposes as extracts of madder.

IX. *Pigment-printing*.—The colours in this class are the same pigments as used by painters, such as Scheele's green, ultramarine blue, chrome yellow, &c., and being quite insoluble in water are, so to speak, cemented to the fibre. The vehicle used for fixing these, is generally albumen, which coagulates when the cloth is steamed, and imprisons both cloth and fibre with the coagulum; of course these colours, though not altered in shade by soap, are detached in part by severe treatment, such as rubbing, &c.

The last two classes melt into each other in the very beautiful steam chintz styles, where aniline black (described hereafter), madder extract or alizarine reds, pinks, and purples, pigment green, blue, or other pigment shades, and aniline violets are simultaneously printed, fixed by steaming and soaped, thus producing delicate patterns which under no circumstances could be done by madder dyeing, aided by the subsequent introduction of steam-colours. When albumen is used in sufficient quantity for the pigments and aniline violets, these colours are quite as fast as those with madder extract or alizarine, and even compare favourably with madder-dyed shades.

X. *Spirit-colours* are made in somewhat the same manner as the steam-colours, but contain larger quantities of mordant and acid, and would not bear steaming, because the calico would be too much tendered by the acid, and are therefore only dried and hung up a day or two, and then washed in water. They are the most brilliant colours, but generally fugitive, and are not much used.

XI. *Bronzes*: formerly a style in large demand, but now almost obsolete; done by padding the cloth in solution of protochloride of manganese, precipitating the oxide by means of alkali, peroxidising this by chloride of lime, and then printing on colours composed of protochloride of tin and pigments or decoctions; the protochloride of tin immediately deoxidises, bleaching the brown oxide of manganese, and, where mixed with decoctions or pigment, leaving a dyed pattern cutting through the ground.

First Style: Madders.

Madder styles being the most important, demand the most detailed descriptions. The colours used are of the class termed mordants, which, not colouring matters themselves, act by combining with both cloth and colouring matter. They are generally the acetates or pyrolignites of iron and alumina.

Red Liquor is the technical name of the pyrolignite of alumina used as mordant for red, &c. See *RED LIQUOR*.

Resist-red Liquor is a pyrolignite of alumina which contains little or no sulphates, and has the property of not being decomposed by protochloride of tin to so great an extent as the ordinary Red Liquor.

Iron Liquor is the pyrolignite of iron used as mordant for black, purple, &c. It is made by steeping iron borings, turnings, or thin pieces of scrap iron in crude pyroligneous acid (see ACETIC ACID, and PYROLIGNEOUS ACID), occasionally allowing access of air to the iron by drawing off the liquor and pouring it upon iron contained in another vat, the two vats being thus alternately full of liquor, the iron becoming oxidised by the air when uncovered is more easily dissolved. This iron liquor is not a mere solution of acetate of iron; such a salt would be of little use as a printer's mordant, being decomposed and peroxidised by the air with too great rapidity. It contains, in addition to the protoacetate of iron, the various substances found in the crude pyroligneous acid, such as pyrocatechin, pyroxanthogen, empyreumatic oil, resin, furfural, creosote, &c., which substances have a strong affinity for oxygen, and tend to prevent the acetate of iron passing into a peroxidised state. The preparation of these liquors on a large scale forms a separate business.

Fixing Liquor.—For a long time it has been customary to add to black and purple colours, or mordants, some substance which has a tendency to prevent the oxide of iron from passing to the state of peroxide. The oxide of iron necessary to produce the best results with madder is a mixture of protoxide and peroxide of iron, probably the black or magnetic oxide, though this point is not precisely determined. If the oxide should pass to the red oxide state, inferior shades are produced; and the object of the printer introducing fixing liquor into his colour is to prevent this injurious tendency.

The earliest fixing liquor used was a solution of arsenious acid; and though other fixers have from time to time been introduced, the preparations of arsenic still hold their ground. A very good fixing liquor, that has been much used in France and England, is made as follows:—

No. 1. *Purple Fixing Liquor*.— $7\frac{1}{2}$ gallons water, $1\frac{1}{2}$ gallon acetic acid, 9lbs. sal-ammoniac, 9lbs. arsenious acid; boil till the arsenic is dissolved, and let stand till quite clear.

In 1844, Mr. John Mercer patented an assistant mordant liquor for the same purpose, which was made as follows:—

No. 2. To 100 lbs. potato starch, add $37\frac{1}{2}$ gallons water, 123 gallons nitric acid, specific gravity 1.3, and 4 oz. oxide of manganese. The chemical action which takes place amongst these ingredients is allowed to proceed till the nitric acid is destroyed. To the residuum thus produced are added 50 gallons of pyroligneous acid, and the compound is the assistant mordant liquor in a fit state to add to the various mordants used in printing and dyeing. The intention in making this liquor is to carry on the decomposition of the nitric acid and starch as far as possible without forming oxalic acid, and as little as possible of carbonic acid, which is greatly aided by the catalytic action of the oxide of manganese, preventing the formation of oxalic acid. Apparently there is formed by this process saccharic acid, or an acid in a low state of oxidation, which is the active agent in preventing the peroxidisation of the iron when added to purple mordants. This liquor has been largely used, and is still preferred by some printers. Of late, various fixing liquors have been made and sold by manufacturing chemists, pyroligneous acid and arsenious acid, or arsenite of soda, forming the staple of them; some of these have chlorate of potash added, the object being the formation of arseniate of iron when the cloth is dried, whereby the acetic acid is more speedily driven off; and since arseniate of iron does not pass beyond a certain degree of oxidisation in the air, the mordant is kept in a proper state for dyeing good colours. The following is also a good purple fixing colour:—

No. 3. *Purple Fixing Liquor*.—Boil together till dissolved 2 gallons water, 25 lbs. soda crystals, $22\frac{1}{2}$ lbs. arsenious acid. When dissolved, add to 50 gallons wood acid, previously heated to 120° F.; let stand for a day or two till the tar of the acid is settled, and add 3 quarts muriatic acid.

The following madder colours are from some in practical use; and though almost every colour-maker has different receipts for his colours, they may be taken to represent the general principles on which these colours are composed.

In all these colours the thickening substance is first beaten up with a little of the liquid till quite fine and free from lumps, then the remainder of the liquid added, and the whole boiled and stirred in one of the double-cased steam-pans till quite smooth; cooled, and strained.

No. 4. *Black for Machine (Madder)*.—4 gallons iron liquor at 24° T., 4 gallons pyroigneous acid, 4 gallons water, 24 lbs. flour; boil, and add 1 pint oil.

No. 5. *Black for Garancin (Machine)*.—7½ gallons water, 3 gallons iron liquor at 24° T., 1½ gallon purple fixing liquor (No. 3), 24 lbs flour, 1 pint oil.

No. 6. *Dark red for Madder (Machine)*.—12 gallons red liquor at 18° T., 24 lbs. flour.

No. 7. *Pale reds for Madder (Machine)* are made by reducing the standard liquor, No. 8, with gum-water to the shade wanted: for instance, No. 3 pale red is 1 of No. 8 and 3 of gum-water, No. 9.

No. 8. *Standard red Liquor*.—10 gallons hot water, 40 lbs. alum, 25 lbs. white acetate of lead; rake up till dissolved, let settle, and decant the clear.

No. 9. *3 lbs.-Gum-substitute Water*.—10 gallons water, 30 lbs. gum-substitute, No. 5 in the list of thickeners.

No. 10. *Dark resist-red Madder (Machine)*.—12 gallons resist-red liquor, 18° T., 24 lbs. flour; boil, and when nearly cold add 12 lbs. of muriate-of-tin crystals.

No. 11. *Dark resist-red Machine*.—Same as No. 10, but 6 lbs. of tin crystals only.

Of these last two, No. 10 is used when it has to resist a chocolate cover, and No. 11 when it has to resist a purple cover.

No. 12. *Pale resist-red Madder (Machine)*.—Made by reducing resist-red liquor with water, and thickening it. For instance, No. 5 pale red: 12 gallons resist-red liquor at 5° T., 9 lbs. flour; boil, and add, when cool, 2 lbs. tin crystals.

No. 13. *Chocolates* are made from iron liquor and red liquor mixed, and the red liquor is a multiple of the iron; as, for instance, 3 *chocolate (madder) (machine)*:—3 gallons iron liquor at 24° T., 9 gallons red liquor at 18° T., 24 lbs. flour, 1 pint oil, No. 6 *Chocolate*:—1 gallon iron liquor at 24° T., 6 gallons red liquor at 18° T., 14 lbs. flour, ½ pint oil.

No. 14. *Strong red for Garancin (Machine)*.—10 gallons red liquor at 18° T., 2 gallons water, 24 lbs. flour.

No. 15. *Resist red for Garancin (Machine)*.—12 gallons resist-red liquor at 14° T., 24 lbs. flour; boil, cool, and add 9 lbs. tin crystals. This for resisting chocolate.

No. 16. *Resist red for Garancin (Machine)*.—12 gallons resist-red liquor at 14° T., 24 lbs. flour; boil, cool, and add 4½ lbs. tin crystals. This for resisting purple.

No. 17. *Brown Standard for Madder*.—50 gallons water, 200 lbs. catechu; boil 6 hours, then add 4½ gallons acetic acid, and add water to make up to 50 gallons; take out, and let stand 36 hours, and decant the clear; heat it to 130° F., and add 96 lbs. sal-ammoniac, dissolve, and leave to settle 48 hours; decant the clear, and thicken it with 4 lbs. gum-Senegal per gallon.

No. 18. *Brown Colour for Madder (Machine)*.—4 gallons No. 17, 1 gallon acetate of copper (No. 19), 2 quarts acetic acid, 2 quarts gum-Senegal water, 4 lbs. per gallon.

No. 19. *Acetate of Copper*.—1 gallon hot water, 4 lbs. sulphate of copper, 4 lbs. white acetate of lead; dissolve, let settle, decant the clear, and set at 16° T.

No. 20. *Brown for Madder (Machine)*.—7 gallons of No. 17, 1½ gallon of No. 19, 1½ gallon gum red (No. 21).

No. 21. *Gum red*.—3 gallons red liquor at 18° T., 12 lbs. gum-substitute; boil.

No. 22. *Brown for Garancin (Machine)*.—2 gallons of No. 18, 1 gallon 4 lbs.-gum-substitute water.

No. 23. *Brown for Garancin (Machine)*.—2 gallons No. 17, 3½ gallons 4 lbs.-gum-substitute water, 3 quarts acetic acid, 3 quarts No. 19.

No. 24. *Drab for Madder (Machine)*.—4 gallons No. 17, 1 gallon protomuriate of iron at 9° T., 3 gallons No. 19, 1 gallon 4 lbs.-gum-substitute water. For garancin, add 4 gallons gum-water instead of 1 gallon.

No. 25. *Drab for Madder (Machine)*.—5 gallons No. 24, 1 quart muriate of iron at 9° T., 5 gallons 4 lbs.-gum-substitute water, 3 quarts No. 19.

No. 26. *Madder Fawns* are made by adding to madder drab ½th, or so, of red liquor, according to the shade wanted.

No. 27. *Madder Purples*.—Iron liquor, mixed with purple fixing liquor, is diluted with gum-water according to the shade wanted. For instance, No. 4 *purple for madder (machine)*:—1 gallon of iron liquor at 24° T., 2 gallons No. 3, 4 gallons farina gum-water No. 28. No. 12. *purple*:—1 gallon iron liquor at 24° T., 2 gallons No. 3, 12 gallons No. 28.

No. 28. *Dark Farina Gum Water*.—10 gallons water, 60 lbs. dark calcined farina; boil,

No. 29. *Garancin Purples* are reduced from iron liquor to the shade wanted with the following gum:—20 lbs. light British gum, 8 gallons water, 1 gallon purple fixing liquor No 3; boil well, then take out, and let stand 3 or 4 days before using. *Colour*: 1 measure iron liquor, 8, 10, 20, 30, &c., of the above gum, according to shade wanted.

No. 30. *Padding Purples*.—Reduce to shade with the following gum:—6 $\frac{3}{4}$ gallons water, 1 gallon No. 3, 1 quart logwood liquor at 8° T., 9 lbs. flour; boil, and add 5 quarts farina gum, No. 28. For instance, *70-padding purple for machine*:—1 gallon iron liquor at 24° T., 70 gallons of the above gum.

Madder purples for some styles, such as the black, acid, and purple padded style, are thickened with 1 $\frac{1}{2}$ to 2 lbs. of flour per gallon, the object being to keep the colour on the surface of the fibre, thereby obtaining economy of dye-stuff, together with brilliancy of colour.

Colours, either red or purple, applied on the top of already printed colours are called 'covering' colours when a small pattern is applied, and 'padding' colours when a uniform shade without pattern is applied.

Block colours are made from any of the preceding receipts, by making them a little thinner; the strength of the mordants being also reduced. Colours for dyeing with extract of madder, artificial alizarine, and garancin require to be made much weaker in mordant, in consequence of the less severe treatment after dyeing which goods dyed with these substances require to bring out the full brilliancy of the colours.

No. 31. *Alkaline red Mordant*.—In a vessel capable of holding 12 gallons, put 10 lbs. alum, and dissolve with 5 gallons boiling water, then add gradually 3 quarts caustic soda at 70° T., mixed with 1 gallon cold water, fill up with cold water; let settle, decant and repeat the washing till the clear liquor is tasteless; filter to a pulp, take off, and add to it 5 pints caustic acid at 70° T.; boil down to 3 gallons, add 9 lbs. dark gum-substitute, and boil again a short time.

No. 32. *Pale red Alkaline Mordant*.—1 measure of the above colour and 2 or 3 measures of dark gum-substitute water.

No. 33. *10 Acid*.—1 gallon lime juice at 10° T., 1 lb. starch; boil.

No. 34. *20 Acid*.—1 gallon lime juice at 20° T., 1 lb. starch; boil.

No. 35. *30 Acid*.—1 gallon lime juice at 30° T., 1 lb. starch; boil.

No. 36. *Acid Discharge*.—1 gallon lime juice at 22° T., 1 lb. bisulphate of potash; filter, and thicken the clear with 1 lb. starch.

No. 37. *Acid Discharge*.—1 gallon lime juice at 28° T., 2 lbs. bisulphate of potash; filter, and thicken the clear with 5 lbs. dark British gum.

In the last two colours, the bisulphate throws down a quantity of flocculent matter, which has to be filtered out.

No. 38. *Reserve Paste*.—3 $\frac{1}{2}$ gallons lime juice at 50° T., 2 $\frac{1}{4}$ gallons caustic soda at 70° T.; beat to boil, then, in a separate vessel, beat up 56 lbs. pipeclay with 3 $\frac{3}{4}$ gallons boiling water, and add 3 $\frac{1}{4}$ gallons 6 lbs.-gum-Senegal water; add to the other solution, and boil 20 minutes.

No. 39. *Reserve Paste*.—4 gallons lime juice at 60° T., 3 gallons caustic soda at 70° T.; boil, and add 48 lbs. pipeclay beat up with 2 quarts boiling water, and 4 gallons 6 lbs.-gum-Senegal water; boil 20 minutes.

The above two pastes are used for blocking on madder work, to protect the pattern from the following covering shades, which are raised with quercitron bark, &c. &c. No. 38 is a paste used where there are only black and reds to preserve, and No. 39 is used where there is also purple.

Covering Shades.

No. 40. *5 Drab*.—1 quart iron liquor at 24° T., 5 quarts water, 2 $\frac{1}{2}$ lbs. light British gum.

No. 41. *10 Drab*.—1 quart iron liquor at 24° T., 10 quarts water, 4 $\frac{1}{2}$ lbs. light British gum.

No. 42. *5 Drab*.—1 quart iron liquor at 24° T., 1 quart red liquor at 20° T., 5 quarts water, 2 $\frac{1}{2}$ lbs. light British gum.

No. 43. *10 Drab*.—1 quart iron liquor at 24° T., 1 quart red liquor at 20° T., 10 quarts water, 5 lbs. light British gum.

No. 44. *Olive*.—2 gallons red liquor at 12° T., 1 gallon iron liquor at 14° T., 6 lbs. light British gum.

No. 45. *Olive*.—3 gallons red liquor at 18° T., 2 gallons iron liquor at 8° T., 10 lbs. light British gum.

No. 46. *Sage*.—9 quarts red liquor at 9° T., 1 quart iron liquor at 12° T., 4 lbs. light British gum.

No. 47. *Sage*.—14 quarts red liquor at 3° T., 1 pint iron liquor at 12° T., 5½ lbs. light British gum.

No. 48. *Chocolate Brown*.—6 gallons red liquor at 15° T., 1 gallon iron liquor at 24° T., 10½ lbs. light British gum, 3½ lbs. flour.

No. 49. *Slate*.—3 quarts logwood liquor at 8° T., 2 quarts iron liquor at 24° T., 1 quart red liquor at 18° T., 1 quart No. 50, 7 gallons water, 18 lbs. light British gum; boil.

No. 50. *Gall Liquor*.—28 lbs. ground galls, 2 gallons acetic acid, 12 gallons water; stir occasionally for two days, and filter.

No. 51. *Hazel*.—4 quarts brown No. 18, 2 quarts bark liquor at 10° T., 1 pint logwood liquor at 12° T., 1 quart cochineal liquor at 8° T., 16 oz. measure No. 52, 4½ quarts 6 lbs.-gum-Senegal water.

No. 52.—1 quart nitrate of iron at 80° T., 1 pint nitrate of copper at 100° T.

No. 53. *Standard for Buffs*.—10 gallons water, 40 lbs. copperas, 20 lbs. brown acetate of lead: stir till dissolved, settle, and use the clear; reduced to shade wanted with gum-Senegal water.

No. 54. *Chrome-oxide Standard*.—3 gallons water, 12 lbs. bichromate potash; dissolve with heat, put in a mug of 12 gallons capacity, add 3¼ pints oil of vitriol diluted with 6 quarts cold water, add gradually 3 lbs. sugar; when the effervescence has ceased, boil down to 3 gallons.

No. 55. *Drab*.—5 quarts gum-tragacanth water (8 oz. per gallon), 2½-quarts No. 55, ¾ pint cochineal liquor at 4° T., ¼ pint bark liquor at 8° T.

No. 56. *Fawn*.—1 gallon No. 55, 2 gallons 8 oz.-gum-tragacanth water, ½ gallon brown No. 17.

No. 57. *Slate*.—1 gallon No. 55, 1 gallon 8 oz.-gum-tragacanth water.

No. 58. *Gum-tragacanth Water*.—10 gallons water, 5 lbs. gum tragacanth in powder; stir occasionally for 3 days.

No. 59. *Fast Blue Standard*.—150 gallons water, 18 lbs. indigo in pulp, 24 lbs. copperas, 28 lbs. lime previously slaked; stir occasionally for 2 days, let settle, and draw off the clear liquor, and to every 10 gallons add 1 pint muriate-of-tin liquor at 120° T.; filter on flannel to a thick paste.

No. 60. *Fast Blue for Machine*.—1 quart No. 59, 6 oz. muriate-of-tin crystals, 3 quarts of gum-water.

No. 61. *Fast Blue Standard*.—4 lbs. indigo ground to pulp, 3 quarts caustic soda at 70° T., 3 quarts water, and granulated tin in excess; boil in an iron pot till perfectly yellow, when tried on a piece of glass.

No. 62. *Fast Blue (Block)*.—1 quart No. 61, 12 oz. muriate-of-tin crystals, 12 oz. lime juice at 60° T., 3 quarts 6 lbs.-gum-Senegal water.

No. 63. *Fast Green*.—1½ quart No. 60, 2 quarts lead gum No. 64, ½ lb. muriate-of-tin crystals.

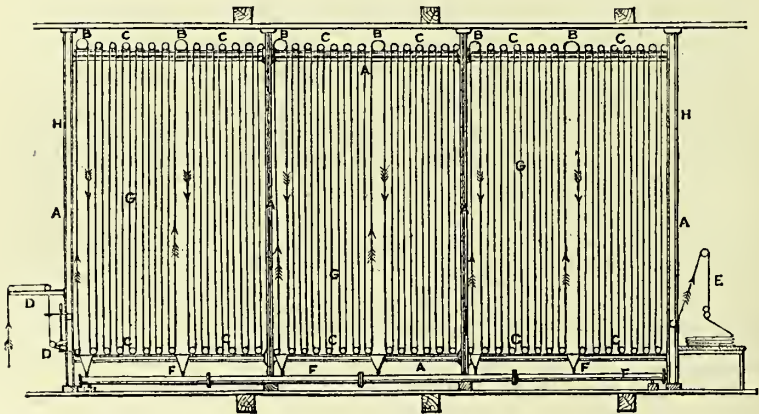

No. 64. *Lead Gum*.—1 gallon hot water, 8 lbs. white acetate lead, 4 lbs. nitrate lead; dissolve, and add 1 gallon 6 lbs.-gum-Senegal water.

The course of operation for the styles 1, 2, and 3 above, is to print in one or more of the madder colours; after dyeing, the goods are hung in the ageing room for a day or two, then brought to the dye-house. The 'ageing' room is a spacious airy chamber, with an arrangement of rails at the top of it, from which the pieces can be hung in long folds. These chambers are kept at an equable summer temperature, and in proper hygroscopic conditions, due ventilation being also provided. These 'ageing' rooms, as they are called, are in several print-works of enormous dimensions, and are generally separate buildings. Those of Messrs. Edmund Potter and Co., and Messrs. Thomas Hoyle and Co., in Lancashire, may be particularised as forming quite a feature in the works. The pieces stay in these chambers from 1 to 6 days, according to the style of work, during which time the colour which was deposited on the outside of the fibre gradually penetrates it, and becomes more firmly attached, a portion of the base being deposited, and acetic acid given off in vapours. Where colours are required to absorb a certain amount of oxygen, such as iron mordant, catechu browns, &c., they find the necessary conditions here. On the proper ageing of printed goods depends in a great measure the success of many styles; should the room be too hot, or too dry, imperfect fixation of the colour ensues, and meagre and uneven tints are obtained in the subsequent operations. In countries where in summer the atmosphere is dry, great difficulty is found in ageing properly. In America catechu browns have been known to require weeks before being of the proper shade. These are of course exceptional cases; the scientific printer knows how to combat these evils by the introduction of watery vapour, or even by erecting his ageing room over a reservoir of water, with rather open boarding for floor; many colours also may have deliquescent salts introduced. In England the process of ageing is of pretty uniform duration.

These ageing rooms have now almost lost their importance, owing to the introduc-

tion of the 'ageing machine,' which leaves the printed pieces in such a condition, that a few hours is sufficient to perform the work formerly occupying days, and hence a notable economy of space and time. In a patent of Mr. John Thom in 1849, for sulphuring mousseline-de-laines, a claim is made for using the same apparatus, or a modification of it, for passing calico printed goods through a mixture of air and aqueous vapour. Mr. Thom found that a printed piece as it came from the machine, absorbed nearly an ounce of moisture to the pound of cloth, without feeling damper; and that an exposure to a moist atmosphere for one minute and a half was sufficient to produce this result. The ageing machine introduced by Mr. Thom into the Mayfield Printworks, had a capacity of 30 cubic yards. The moisture was obtained by having a cistern of water kept heated to 180° F. in the machine. Mr. Crum was the next printer to take this idea and work it into more practical shape, by very much extending the size of the machine, and by other minor alterations. The use of this machine rapidly spread, and is now almost universal. *Fig. 372* shows the machine as arranged by Mather and Platt. It consists of a chamber about 36 feet long, 20 feet high, and 13 feet broad; generally it is partitioned off one of the disused ageing rooms. A, is the framing forming the machine and for carrying rollers, &c.; B, rollers 9 inches diameter for drawing the cloth, these are driven by gearing; C, rollers of tin plate, not driven; D, entering rollers and rails; E, plaiter for folding cloth on delivery from

372

the machine; F, steam or vapour pipes, with steam taps and funnels for spreading the vapour; G, the cloth passing through the machine. The machine is enclosed in a wooden room, the boards or walls fitting close at the ends H and G; space being left on each side for passage and for getting to the rollers, taps, &c.; one or two Daniell's hygrometers are put in different places of the machine. Two pieces, side by side, are run through at once, the temperature being 70° to 75° F., and sufficient steam being allowed to escape into the machine to cause a difference of 4° on the hygrometers. The pieces occupy about 20 minutes during their passage through the machine; on emerging from which, they are plaited down into loose bundles of several pieces, which are then drawn away and left on the floor of the room all night. The temperature and hygrometric condition of this outside room should be as near as possible those of the ageing machine. What takes place in ageing in this manner has not been fully investigated; but it is probable that as the piece leaves the printing machine, the mordant is almost altogether on the surface of the fibre in an unaltered state, that the thorough permeation of the piece by the aqueous vapour dissolved in the air, restores to the cloth the normal water removed by the drying in the hot-room, and that under the influence of this, and the slightly elevated temperature, first, a separation of mordant from the thickening substance takes place, and the solution diffused through the fibre, and secondly, that the fibre now begins to play the part of an acid of superior affinity for the base of the mordant to the volatile acetic solvent, and gradually withdraws it from the mordant, acetic acid being freely given off, evident enough to the eyes and nose on going inside the machine. The change once begun is more slowly carried on in the outside room, but still with much more rapidity than under the former conditions of ageing rooms. The chemical action of cellulose

or cotton fibre in decomposing acetates of iron and alumina, has been denied by some chemists, especially by the late Mr. Walter Crum, the eminent printer of Thornliebank, who, in a very interesting paper printed in the *Journal* of the Chemical Society for 1863, propounded the theory, that capillary action of the fibre separates the mordant from the thickening substance, which is left at the outside of the fibre, that by desiccation the acetates are decomposed, and the bases left in the interior cavities. He also attributes to the cloth an attraction of surface, whereby bases are separated from their solvents, in the same manner as that in which charcoal decomposes certain salts. He points out also, that the fibre may act as a dialyser to retain within its pores, or in the interior cavity of the cotton fibre tube, a colloid solution of alumina or iron; the crystalline portion of the mordant having passed through when the printed cloth is immersed in water (dunging operation). Mr. Crum gives some beautiful drawings of the appearance of dyed cotton fibres under the microscope, showing in many cases that a clot of mordant base has been formed in the interior cavity of cotton fibre and been subsequently dyed there. His drawings, however, for the most part show that the walls of the tubes are dyed throughout their substance; a fact not, as we think, sufficiently explained by his theory. Other microscopists who have examined dyed cotton fibre, have failed to detect imprisoned particles of colour inside the tube, but have noticed that the wall of the tube throughout its substance is dyed; which, if correct, certainly points to a chemical action of the cell wall. That cotton fibre has a separating power, even when immersed in water, may be shown by putting bleached cotton cloth overhead in a solution of oxide of lead in lime (plumbite of calcium) for half an hour or so, removing, rinsing very well in water, and passing through a solution of bichromate of potash, whence the cloth will emerge dyed a bright yellow. This reaction is noticed by Mr. Crum as an illustration of the surface attraction exercised by cotton fibre; the withdrawal of indigotine, or white indigo, from a solution of it, by cotton cloth immersed therein, being also given by Crum as an illustration of the same force; but the former, at all events, may equally serve as an illustration of the chemical power of cotton fibre to sieze and combine with bases, and this power is, we think, further illustrated by the rapidity with which acetates are decomposed under the influence of the ageing machine and torrents of acetic acid given off. There is room, apparently, for further investigation of this obscure point. That pigments such as prussian blue, chromate of lead, &c., can be precipitated and imprisoned inside the cotton tubes, is not of course, denied; but the action here seems quite different from that of ageing. Probably even in well-aged goods, a precipitation of this latter sort takes place to some extent, when the arseniate phosphate or silicate of soda of the dunging solution reacts upon mordant separated from its thickening, and remaining inside the cotton tube. Thus, it is quite conceivable that two separate actions have taken place in goods about to be dyed; viz., a chemical combination of the tube wall with the base of the mordant, and an imprisonment of an insoluble salt inside the tube, by double decomposition.

The next operation is that termed *dunging*, which is the same in principle for all varieties of madder or garancin goods: and as it is an operation the careful performance of which is of vital importance to the success of the subsequent operations, a somewhat detailed description of it will not be out of place. The process of dunging has for its object—

1. Precipitating on the fibre, by double decomposition, that portion of the mordant which has escaped decomposition in the ageing room.
2. Rendering insoluble and inert those portions of the mordant which are not in direct contact with the fibre, and which, if allowed to diffuse in water only, would fix on and stain the white or unprinted parts of the cloth.
3. Softening and removal of the thickening substances.
4. Neutralising the acids which may have been added to the mordants, or used as resists or discharges, and which otherwise would dissolve in the water and weaken the colours.
5. The formation, in the case of iron mordants, of a compound of oxide of iron, and certain organic or inorganic acids which will not become peroxidised beyond a certain point. The use of cow-dung, derived from India, has been continued down to the present time, though for several years printers have largely introduced various substitutes.

No very exact analysis has been made of cow-dung. Morin's is as follows:—

Water	70·00
Vegetable fibre	24·08
Green resin and fat acids	1·52
Undecomposed biliary matter	0·60
Peculiar extractive matter (<i>bubuline</i>)	1·60

Albumen	0.40
Biliary resin	8.80

Another analysis gives the total constituents of 100 parts of cow-dung as follows :— Water, 69.58; bitter matter, 0.74; sweet substance, 0.93; chlorophyll, 0.28; albumin, 0.63; muriate of soda, 0.08; sulphate of potash, 0.05; sulphate of lime, 0.25; carbonate of lime, 0.24; phosphate of lime, 0.46; carbonate of iron, 0.09; woody fibre, 26.39; silica, 0.14; loss, 0.14.

According to M. Kœchlin's practical knowledge on the great scale, it consists of a moist fibrous vegetable substance, which is animalised, and forms about one-tenth of its weight; 2, of albumen; 3, of animal mucus; 4, of a substance similar to bile; 5, of muriate of soda, muriate and acetate of ammonia, phosphate of lime, and other salts; 6, of benzoin or musk.

Fresh cow-dung is commonly neutral when tested by litmus-paper; but sometimes it is slightly alkaline, owing, probably, to some peculiarity in the food of the animal.

Probably the hot water in which the calico-printer diffuses the dung exerts a powerful solvent action, and in proportion as the uncombined mordant floats in the bath it is precipitated by the albumen, the animal mucus, and the ammoniacal salts; but there is reason to think that the fibrous matter in part animalised or covered with animal matter, plays here the principal part; for the great affinity of this substance for the aluminous and ferruginous salts is well known.

It would appear that the principal function of dunging is to hinder the uncombined mordant diffused in the dung-bath from attaching itself to the unmordanted portion of the cloth, as already observed; for if we merely wished to abstract the thickening stuffs, or to complete by the removal of acetic acid the combination of the mordanting base with the goods, dung would not be required, for hot water would suffice. In fact, we may observe, that in such cases the first pieces passed through the boiler are fit for dyeing; but when a certain number have been passed through, the mordant now dissolved in the water is attracted to the white portions of the cloth, while the free acid impoverishes the mordanted parts, so that they cannot afford good dyes, and the blank spaces are tarnished.

It seems to be ascertained that the mordant applied to the cloth does not combine entirely with it during the drying; that this combination is more or less perfect according to the strength of the mordants, and the circumstances of the ageing; that the operation of dunging, or passing through hot water, completes the combination of the cloth with the mordanting base now insoluble in water; that this base may still contain a very minute quantity of acetic acid or sulphate of alumina; that a long ebullition of water impoverishes the mordant but a little; and that even then the liquid does not contain any perceptible quantity of acetate or sulphate of alumina or iron.

A very able and learned memoir upon this subject, by M. Penot, Professor of Chemistry, appeared in the *Bulletin* of the Society of Mulhausen, in October 1834, and an ingenious commentary upon it, under the title of a *Report* by M. Camille Kœchlin, in March 1835.

Experience has proved that dunging, is one of the most important steps in the process of calico-printing, and that if it be not well performed the dyeing is good for nothing.

In dunging calicoes the excess of uncombined mordant is in part attracted by the soluble matters of the cow-dung, and forms an insoluble precipitate, which has no affinity for the cloth, especially in presence of the insoluble part of the dung, which strongly attracts alumina. The most important part which that insoluble matter plays, is to seize the excess of the mordants, in proportion as they are dissolved by the water of the bath, and thus to render their reaction upon the cloth impossible. It is only in the deposit, therefore, that the matters carried off from the cloth by the dung are to be found.

M. Camille Kœchlin ascribes the action of cow-dung chiefly to its albuminous constituent combining with the alumina and iron, of the acetates of these bases dissolved by the hot water of the bath. The acids consequently set free soon become evident by the test of litmus-paper, after a few pieces are passed through, and require to be got rid of either by a fresh bath or by adding chalk to the old one. The dung thus serves also to fix the bases on the cloth, when used in moderation. It exercises, likewise, a deoxidating power on the iron mordant, and restores it to a state more fit to combine with colouring matter.

The use of cow-dung is open to some objections, amongst which are its giving a certain amount of greenish colouring matter to the white mordants, and its being apt

to vary in its constituents from difference in the food of the animals, their health, &c.; the method of using substitutes for it being now well known, and better colours and whites being more easily obtained from them than with dung, this substance has almost ceased to be used in calico-printing processes. The dunging operation ought to be a definite chemical decomposition, which cannot be the case with a variable substance like dung. The substitutes for dung in use are:—

- | | | |
|--------------------------------|--|----------------------|
| 1. Phosphate of soda and lime. | | 4. Silicate of soda. |
| 2. Arseniate of soda. | | 5. Silicate of lime. |
| 3. Arsenite of soda. | | |

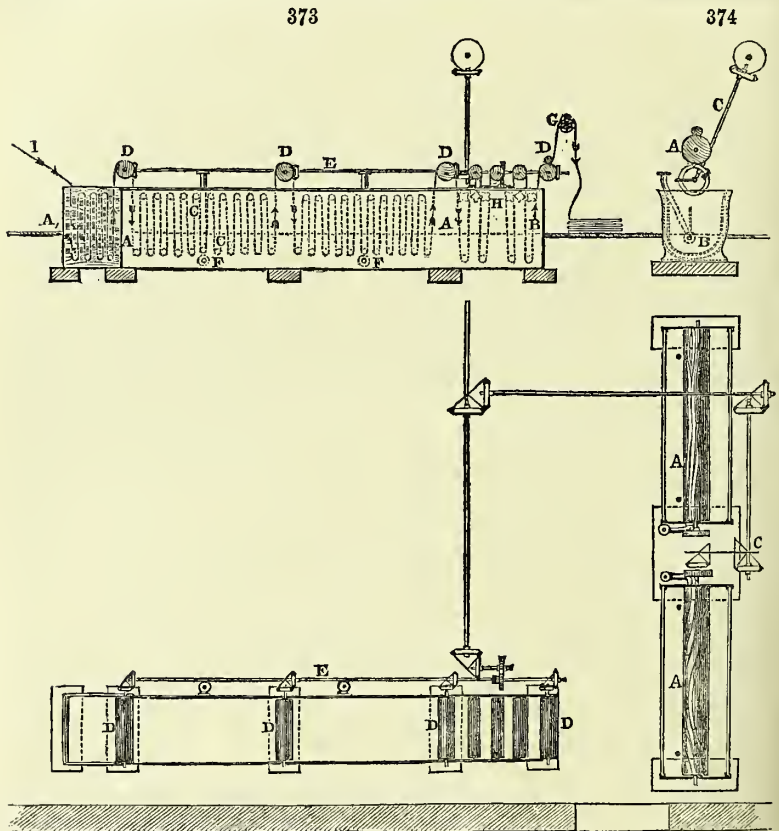

Each of these has its peculiar virtues, and the printer determines for himself which is best adapted for his styles. The first was patented by John Mercer, about 1842, and is made by calcining bones, then decomposing them with sulphuric acid, filtering out the sulphate of lime, and, to the clear superphosphate of lime, adding carbonate of soda till slightly alkaline; the resulting mixture of phosphate of soda and phosphate of lime is dried down to a powder; the use of arseniates formed part of the same patent. Arsenite of soda followed as a matter of course, though not so safe in use as phosphates and arseniates. Silicate of soda was suggested by Adolph Schlieper, of Elberfeld, and patented by Jäger in 1852. It is the ordinary soluble glass dissolved in water. It is open to the objection of being too alkaline, and requires care in the use. The silicate of lime was suggested by Higgin with a view to remove this objection. The silicate of lime is formed in the dung cistern, by mixing silicate of soda and muriate of lime, when sparingly soluble silicate of lime is formed; the quantity in solution at one time being never so much as to be dangerous, and fresh portions being dissolved as wanted. Dunging salts, or liquors, are now made by the manufacturing chemist, containing various mixtures, arseniates, phosphates, arsenites, &c., which are adapted for every variety of dunging. Great economy of time and material result from the use of these dung-substitutes. In some of the largest print-works, instead of, as with dung, running off the spent-dung cistern after passing through from 100 to 200 pieces, and having to fill again, and heat to the proper temperature, it is found possible to run pieces through the same cistern charged with substitute, at the rate of two pieces per minute half a day, and with light goods a whole day—before letting off; of course, occasionally adding some of the substitute, to make up for that saturated by the mordants. The dunging process is always performed twice: the first time in a cistern with rollers; and the second, in a beck similar to a dye-beck, washing well between. The first is called *fly-dunging*; the other, second dunging.

The manner of immersing the goods, or passing them through the dung-bath, is an important circumstance. They should be properly extended and free from folds, which is secured by a series of cylinders. The immersion should take place as fast as possible; for the moment the hot water penetrates the mordanted cloth, the acetic acid quits it, and, therefore, if the immersion was made slowly, or one ply after another, the acid, as well as the uncombined mordant, become free, would spread their influence, and would have time to dissolve the aluminous subsalts now combined with the cloth, whence inequalities and impoverishment of the colours would ensue.

The fly-dung cistern should be set with about 30 gallons of dung to 1,000 gallons of water; or, to the same quantity, 3 to 4 gallons of dung-substitute liquor; a little chalk is added, to make the cistern slightly milky. The heat varies for different styles—from 150° F. to boil. Where there is acid discharge or resist, and the colours are heavy, fly-dunging at boil is necessary, to enable the acid to cut properly through the colour; the nearer to 150° F. that the bath will give good whites at, the better will be the subsequent dyed colour. With cow-dung, an excess of it is injurious, both to white ground and mordant.

Figs. 373 and 374 are Furnival's arrangement of first and second dunging vessels. A 1 to A is a smaller cistern provided with rollers, top and bottom, in which a stronger solution of dunging liquor than that in the main vessel is sometimes put; A A is the main fly-dung vessel, divided into two compartments, made of cast-iron plates bolted together. The whole fly-dung cistern is from 20 to 30 feet long, 4½ feet wide, and 5 to 6 feet deep. The pieces enter the machine at the end 1, passes over and under the rollers c c, being drawn through by the draw-rollers d, which are placed over the divisions in the cistern; these rollers being connected and turned by the driving-shaft e; they then pass through the compartment A B, where they are spirted with water from perforated pipes fixed almost level with the top of the cistern, and beaten by the square beaters H, which are also connected with and turned by the shaft e; F are the steam-pipes for heating the liquid. The cistern A A is set with a solution of arseniate of soda, containing from 10 to 50 grains arsenic acid per gallon, according to

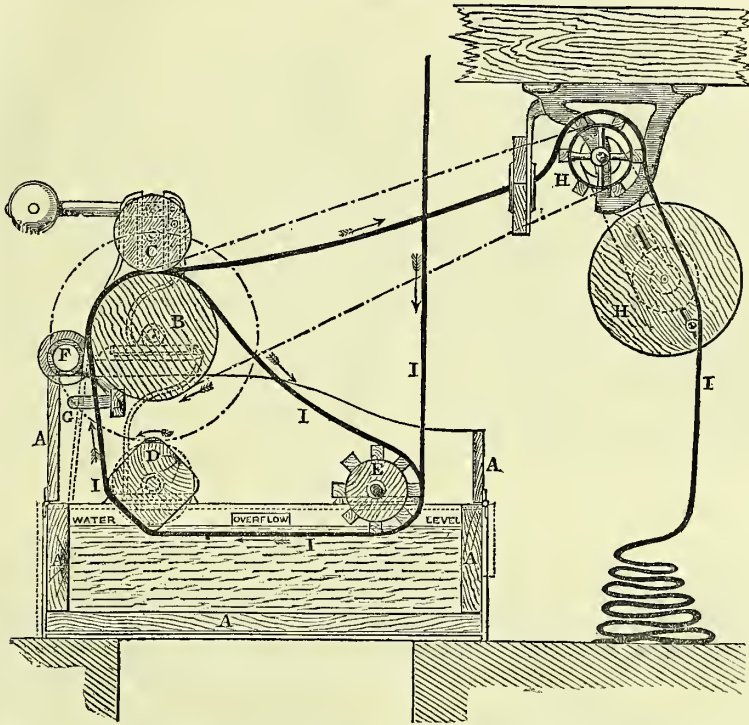

the strength and nature of the mordants to be dunged; usually a little chalk is added sufficient to make the liquid slightly milky. The first compartment is either set with the same solution, or sometimes with a more concentrated one. The temperature varies from 150° F. to boil, according to the style under treatment. On leaving the cistern they pass successively through two or more becks, very similar to dye-becks (which see farther on) where they run spirally through a solution of arseniate of soda, much weaker than that of the fly-dung cistern, generally about 8 to 12 grains arsenic acid per gallon; to which some printers add a little cow-dung or bone-size solution. The time occupied in the transit of a piece through the second dung becks is from 20 to 30 minutes, and the temperature from 150° to 170° F. *Fig. 374* shows a plan and sectional elevation of two second dung becks; the piece is brought from the

first dung cistern and entered into the end of one of the second dung becks, over the roller A, and under the steam-pipe B, being drawn through the entire length in a spiral and progressive manner; a few yards of cloth are left lying at the bottom of the cistern each time it passes over the roller A; B is the perforated steam-pipe for heating the liquid; C, the drawing shaft for giving motion to the draw-roller A. On leaving the first second dung beck, the pieces pass in a similar manner through the second, or others, if more than two; they next pass through a washing machine. *Fig. 375* is a section of the washing machine now most generally used for all purposes in print-works; A, the framing and wooden trough of the machine; B, large roller for drawing the cloth through machine; C, pressing roller above roller B; D, square beater roller, running in a contrary direction to the cloth, at about 180 revolutions per minute; E, wince roller; F, perforated water-pipe; G, peg rail; H, plaiter wince; I, cloth passing through the machine; it enters at one end, and passes spirally through to the delivery end. The advantages of this machine are, great simplicity and efficiency. The square bowl causes the cloth to rise and fall upon the surface of the water, which, being allowed

to flow off at the overflow shown, is always kept at the right level. After this rinsing, the cloth passes between the squeezing rollers at the top of the machine, previous to

375

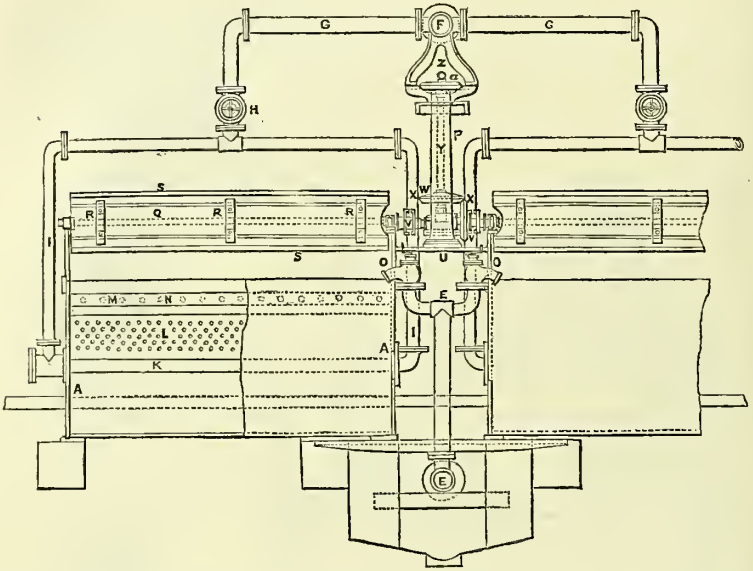

which it receives a spirt of clean water. It then passes into the trough over the lagged roller, as shown, and the operation is repeated until the cloth is sufficiently washed. This machine will wash about 90 yards of cloth per minute. Whenever a washing machine is mentioned in this article, it is to be understood that this sort of machine is meant. The drawing is of the machine as made by Mather and Platt.

Up to this point there is scarcely any difference in the operations on pieces destined for styles I *a*, *b*, &c., and II. Those intended for dyeing with madder are printed in stronger colours than those for dyeing with garancin, since the soaping process reduces the strength of colour considerably, and garancin colours undergo no severe treatment after dyeing. The general process of dyeing is thus performed:—

Fig. 376 represents a front elevation of a pair of dye-becks, with automatic winch-reel, and *fig. 377* is an end-elevation of one of them. The drawing is kindly supplied by Messrs. Mather and Platt, of Salford. *A A* is a cast-iron cistern, 8 feet long by 4 feet deep by 3 feet wide, with curved bottom; brackets *B B* are cast on the ends to support the system on the stone foundation. This beck is fixed over a channel *c*, which communicates with the system of drains which carries away the waste liquors into the river. There are two holes in the curved bottom—one at each end—which, when the beck is in use, are stopped with moveable plugs; one of these holes communicates direct with the drain and the other with a trough *D*, which communicates with a pit outside the dye-house, and where the spent madder can be run for the purpose of making into garanceux; *E* is a water-pipe, with a branch into each beck, with a screw tap attached; *F* is a main steam-pipe, which divides into branches *G*, furnished with valves at *H*; the pipes *G* subdivide in branches *I*, one of which goes down each end of the dye-beck, the perforated pipe *K*, which traverses the beck from end to end, connecting them; a perforated iron diaphragm is placed across the beck from end to end; above this is a strong rod *M*, from end to end, carrying pieces *N* projecting at right angles from it. Bolted on the ends of the dye-beck is the framework *O*, which carries the bearings of the shaft *Q* of the winch reel; keyed on the shaft are three sets of

arms κ , which terminate in forks, in which fit the spars s ; the reel is boarded between the spars, as at τ . The framework o of the two dye-becks is connected by the piece v , which carries the bearings of the short shaft ν , on which is keyed one of a pair of

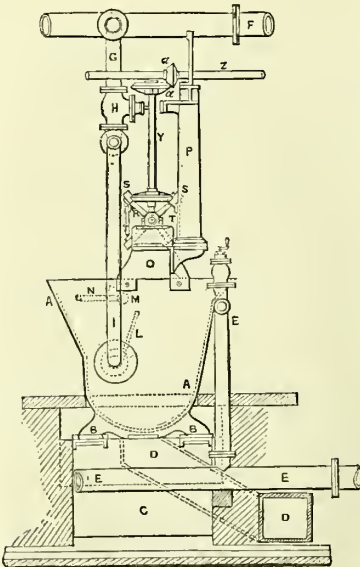

376

mitre wheels $w w$; there are sliding catch boxes $x x$, on this shaft, which revolve with it; there are corresponding catch boxes keyed on the ends of the shaft q ; the connecting piece v carries also the pillar p , which carries the bearings of the vertical shafts x , and also of the horizontal shaft z ; keyed on the shafts x and z are bevel wheel $a a$, and at the bottom of shaft x , the mitre wheel w . Permanent motion being given to the shaft $v \nu$, by this gearing, either of the reels can be put in motion or stopped by the catch boxes $x x$, worked by lever handles, in or out of the catch boxes on the ends of the reels. In working the becks, two pieces are knotted end to end, and each length passed over the reel down between two of the studs κ , under the steam-pipe k , up behind the diaphragm L , being then knotted together so as to form an endless web, the bulk of which lies on the bottom of the beck. The drawing shows a beck adapted for 15 lengths of 2 pieces each, or 30 pieces. About 200 gallons of water are put in the beck before the pieces are put in; and, after the pieces, the dye-stuff is added, the reel set in motion, and the steam gently turned on; from the steam going in at each end, the beck is uniformly heated; the heat is then gradually raised to boil, generally in about two hours, the pieces continually revolving with the reel so as to bring each portion successively into the air, agitating the dyeing materials at the same time.

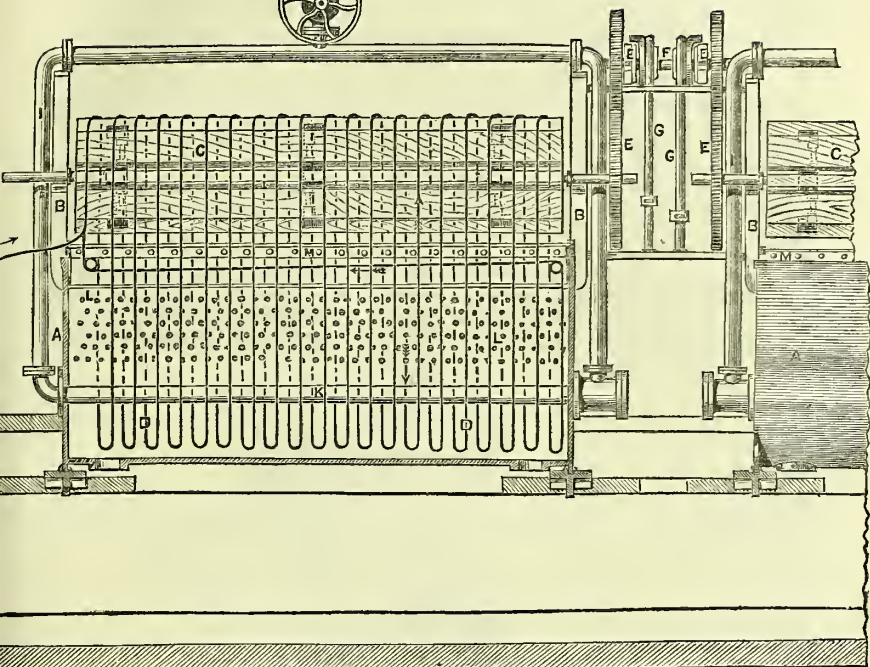

This gradual heating of the dye-beck was a method arrived at by practice, and it

377

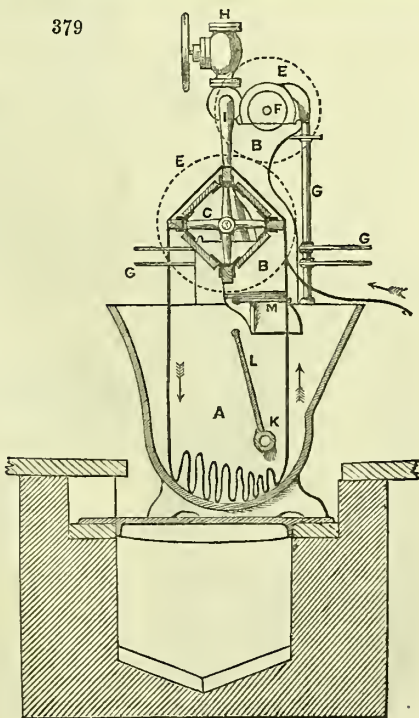

378

was only within a few years that chemical science has shown the wisdom, if not the necessity, of the system. Some dye-stuffs, and especially madder, do not contain their colouring matter ready formed in considerable quantity, but contain a colour-forming principle, which is acted on by nitrogenous ferment also present, whose activity is unlocked by the solution in water, and by the aid of which the colour-forming principle becomes decomposed into true colouring matter and some other substance. The newly-formed colouring matter is assimilated by the mordant nearly as fast as produced. As with most ferments, the temperature of boiling water destroys the ferments in dye-stuffs, and a very inferior result would in many cases be produced, were a boiling heat to be given during the first periods of dyeing. See Madder. With the colouring matters of dye-stuffs properly formed and separated from woody fibre, these precautions are generally unnecessary, as is explained when treating of madder extract and alizarine. When the dyeing is finished, the steam is shut off, the knots untied, and the pieces pulled over into a pit of water

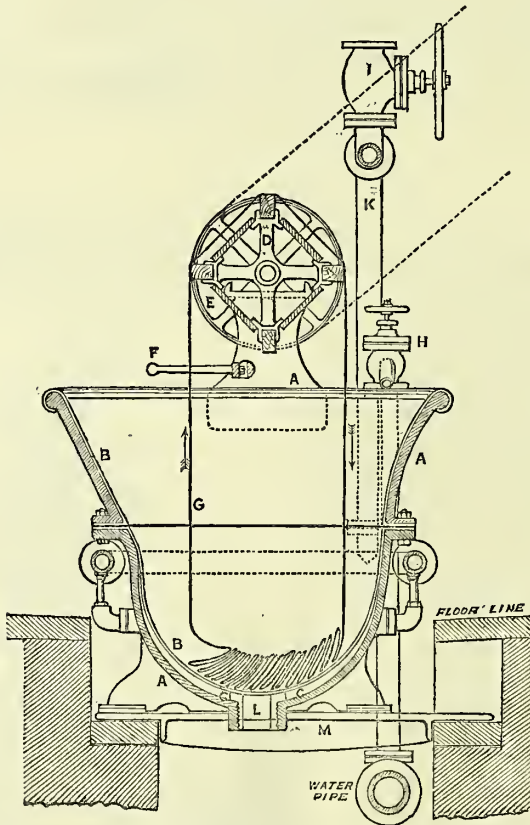

379

mounted with a winch reel, which is always placed behind every dye-beck. After wincing in this, the pieces are fastened together again, and put through the washing machine two or three times; they then are ready for the subsequent operations.

Another method of dyeing is now adopted by several printers, termed spiral-dyeing. In this process 30 to 40 pieces are left stitched together, entered into the dye-beck at one end, and caused to revolve spirally through the liquor and over the vince from end to end of the beck; the end which was entered first is now passed through a porcelain eye, brought back across the face of the beck, and knotted to the last end of the set of pieces, after passing through another eye which directs the cloth into the dye beck again. The process is now continuous, and the pieces constantly moving from end to end and back again, pass through all parts of the dye-beck, and are all subjected to the same heat. It is said that much greater uniformity of dye is obtained by this method. *Figs. 378 and 379* show the spiral or endless dye-beck of Mather and Platt. A, cast-iron dye-beck; B, fixings for carrying vince; C, winces; D, cloth being dyed; E, spur wheels, and catch boxes, &c., for driving; F, driving shaft; G, handles and tappet shafts for putting in motion or stopping the vince; H, steam-valve; I, steam-pipes; K, perforated steam-pipe passing through the beck; L, mid-feather; M, peg-rail for keeping the pieces from entangling. Messrs. Mather and

380

Platt have recently introduced a double-cased dye-beck, for which they claim the following advantages:—

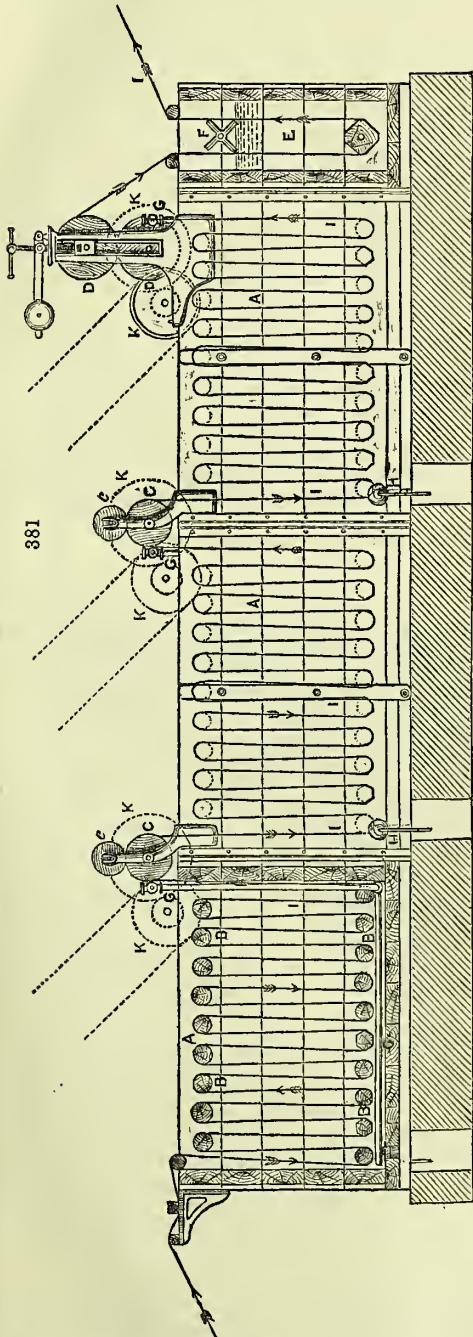

- 1st. Having neither internal steam-pipe, nor midfeather, there is no possibility of tearing or damaging the goods in the process of dyeing.
- 2nd. As no steam is admitted to the dyeing solution, its strength is maintained uniform, and, in fact, rather increased to the end of the operation.
- 3rd. Perfect freedom from stains is insured.
4. The work is more regular, and effected at less cost of material than with becks, to

which steam is admitted in the ordinary way. It is double cased in the lower part, the lining being made of copper, and the outer shell of cast-iron.

Fig. 380 shows a section of this beck. A, cast-iron outer casing of dye-beck, bolted together in two parts; B, copper lining of beck; C, steam space, in the bottom half of beck only; D, wince, making 42 revolutions per minute; E, driving pulley; F, peg rail; G, cloth being dyed; H, water-valve and pipes; I, steam-valve; K, steam-pipes, supplying the steam space at intervals along the body of beck; L, let-off plug and seating; M, silk for carrying beck.

Chintz work is dyed with from 1 lb. to 5 lbs. madder per piece of 30 yards, according to the pattern; generally, a little chalk is added, and if there is no purple in the pattern, some sumac, which is found to economise madder, but will not do where there is purple, the shade of which it deadens.

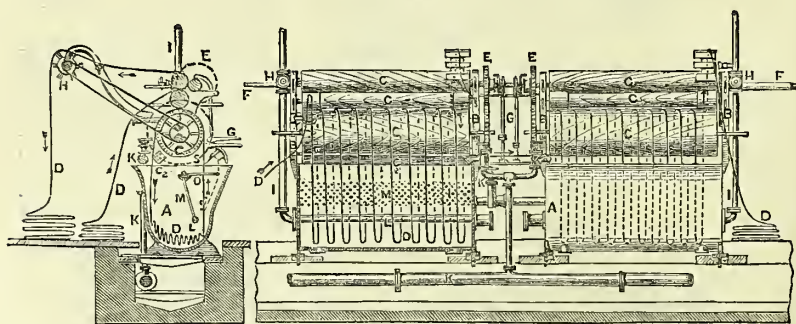

The extensive use in topical printing of madder extract, which is the colouring matter of madder in a nearly pure state, led Messrs. A. Duncan and Co., of Manchester, to experiment on dyeing pieces by running them stitched together, and extended to the full width through a series of cisterns similar to the 'fly-dung' cisterns, charged with a pure extract of madder and boiling water. The theory was that if the madder extract were kept in large excess of the requirements of the pieces, and the cisterns kept boiling, the mordants would become saturated with colouring matter in a very short time. Their experiments resulted in a patent taken out in 1871; and although it can scarcely at the present time be said that the trade is satisfied as to the economy of the process, very excellent results have been arrived at by some printers, and the process would appear one of great promise. Well-dyed pieces both of light and full shades have been obtained in from 3 to 5 minutes, being the time required for a given

point in a piece to travel from the entering end to the issuing end of the apparatus.

The cisterns are kept constantly charged with extract diluted with water, in quantity corresponding to that required by the pieces if dyed in the ordinary beck; thus, the cisterns are kept up to the original strength, which, as above stated, is excessive compared with the actual wants of the mordants. This, however, is of no consequence if the arrangement be such that the issuing pieces bring away with them only a very small percentage of the excess of dye. This is managed by squeezing them under bowls and passing them through water, which is employed to fill up the cisterns. *Fig. 381* represents a section of the 'open dye-beck' of Mather and Platt, arranged specially for this process. A, wooden cisterns; B, wooden rollers with brass centres, fixtures, &c. for immersing the cloth; C, drawing rollers, from cistern to cistern; D, strong squeezing rollers; E, washing-off cistern with beater F; G, steam-boiling pipes, &c., which do not inject steam into the liquor, but terminate in condensed water-pipes H; I, cloth passing through the machine; K, drawing pullies and spur wheels. In reference to this open dyeing process, it is obvious that unless the extract of madder used is very pure and free from fine particles of woody fibre and chemical salts, the constant addition of it, without drawing anything off, would result in time in the cisterns being loaded with impurities which would weaken and eventually stop the dyeing power of the extract, no matter in what quantity added. The extract made by Tennants and Co., of Scotland, specially for this purpose, is claimed to be of the degree of purity required. It is probable, however, that the artificial alizarine now made in perfect purity, and consequently entirely free from woody fibre and resinous colouring matters, will be found most suitable for this process, if it becomes a well-established one in calico-printing works. Much will, of course, depend on the prices of the artificial and the natural alizarine as delivered to consumers. It may be here stated that the value of the open and quick dyeing process as an economiser of material and time has been somewhat reduced by the discovery that several sets of pieces may be dyed with artificial alizarine in the ordinary dye-beck without letting-

382

off between each set, but merely adding after the withdrawal of a set (of say 30 pieces) the quantity of alizarine necessary for the next set, entering these at once in the boiling hot liquor, which becomes cooled down by the wet pieces to about 130° F., and recommencing the dyeing; the becks being brought to boil in an hour, and the pieces withdrawn. As many as 5 sets can be done in this way, and as the dyeing with artificial alizarine in an ordinary beck need not last above an hour, the economy in time of the open dyeing would appear somewhat doubtful.

Maddered goods, on issuing from the dye-beck, are far from possessing the beauty that they afterwards show, the colours are dull and heavy, and the white part stained with a reddish shade; various clearings are required, in which soap plays a principal part. Garancined goods show pretty nearly the colour they are intended to be; but as the white is also stained, a peculiar clearing is given them, which will be described further on. Madder goods are cleared with soap in a beck similar to a dye-beck. They receive generally two soapings at boil of about half-an-hour each, with from $\frac{1}{4}$ to $\frac{1}{2}$ lb. of soap per piece each time, washing between. If the white is not sufficiently good, the pieces are spread out on the grass for a day or two, and are afterwards winced in hot water to which a little solution of chloride of lime or soda is added. They are then washed and dried.

The success of the spiral system of dyeing led printers to adopt a similar system for soaping, and at the principal print-works this operation is now performed in a series of becks, generally 7 or 8. The pieces enter at one end of the first beck of the series, and after passing spirally through this, traverse successively the remainder of the

series. Clean soap liquor is kept flowing into the last beck of the series; and as each beck is connected by a pipe with the next, the soap solution is flowing all the time in a contrary direction to the pieces and leaves the first beck in a thoroughly exhausted condition; the pieces in their onward passage keep meeting with soap liquor less charged with colouring matter and impurities, until finally they pass through almost unsoiled soap solution. The passage of a given point of a piece through the series, occupies about half-an-hour. *Fig. 382* shows two of these becks in action; they are those of Mather and Platt. A, cast-iron soap-becks; B, fixings for carrying rollers; C, wooden rollers; C₂, square wooden doffing roller; D, cloth being soaped on the continuous system, any number of becks may be used for this purpose, they are generally worked in ranges of 7; 2 only here shown; E, spur wheel and catch box for driving; F, driving shaft; G, handles and tappet shafts for putting in motion or stopping the rollers; H, steam-valve; I, steam-pipes; K, water-valves and pipes; L, perforated steam-pipes passing through becks; M, midfeather; N, delivery wince on each beck, which can be used if necessary; O, peg rail.

The waste soap liquor at present allowed to run into the rivers, polluting them, and being the means of keeping in suspension for a long distance fine particles of dyo-stuffs, will probably be soon turned to advantage by the printer, for the experiments on the large scale of Mr. John Thom, of Birkaere, have conclusively shown that by a very simple and easy process, all the fatty matter with the coloured impurities dissolved in the soap can be precipitated and collected, and a patent taken out by Thom and Stenhouse in 1872 describes methods of separating useful and commercial articles from these precipitates. After soaping, the pieces are well washed in the washing machine.

Pieces of any style, after undergoing the final process, are passed through a pair of squeezing rollers, or put in the hydroextractor, when the moisture is driven out by centrifugal force; they are then dried on the cylinder drying machine. See HYDRO-EXTRACTOR.

Plate Purple is a style composed of black and one or more shades of purple only, and requires a little different treatment. Print in black No. 4, dark purple to shade No. 27 and acid, say No. 35, cover pad in pale purple No. 30, age. Fly dung at 170° F., second dung at 165° F. half an hour; wash and ground with dry Turkey madder root giving $\frac{1}{20}$ th of its weight in chalk, and 3 quarts of bone size to the beck; bring to 175° F. in two hours, and keep at 175° F. half an hour; wash well and soap 15 pieces, $\frac{7}{8}$ ths, 30 yards, half an hour at boil with 5 lbs. soap to 15 pieces; wash well and wince 5 minutes at 140° F. with 2 quarts chloride-of-lime liquor at 8° F. to 300 gallons; wince and soap again at boil half an hour with 3 lbs. soap to 15 pieces; wash and wince 5 minutes in 4 quarts chloride of lime at 8° F. and 2 lbs. carbonate-of-soda crystals to 200 gallons water at 160°; well wash and dry.

In this style, as in any where there is severe soaping, it is necessary to give a slight excess of madder in the dye, so as to ensure perfect saturation—if this is not done, the colour speedily degrades, and becomes impoverished. It may be observed here, that the style Plates are such as formerly were printed by the plate or flat press, and are generally small patterns, with padded or well covered grounds, the colours being few, and frequently only different shades of one colour.

Plate Pinks or Swiss Pinks.—A style imported from Switzerland, consisting of various shades of red and delicate pinks, produced as follows. Print in No. 6 with second or third shades as No. 7—acid No. 34 may be also printed and a very pale shade of red covered, aged two or three days, dunged at 160° F.—if dung-substitute is used, care must be taken to use one that is not caustic from free alkali: the dyeing must be done with the finest quality of French or Turkey madder. The pieces must have sufficient madder allowed to over-dye them, or dye a heavy brownish red. For a full plate pink on $\frac{7}{8}$ ths cloth, from 4 to 6 lbs. of French madder will be required. About 5 per cent. of chalk may be added to the dye where the water is soft. The heat should be raised to 150° F. in 2 hours, and kept at that heat half an hour. It is necessary to keep the heat low in dyeing French pinks, to prevent the impurities from fixing on the mordants, as only the very finest portion of the colouring matter must be fixed—after dyeing, the pieces are well washed and soaped with about half a pound of soap per piece in a beck at 140° F. for half an hour, they are then well washed and entered in a beck with cold water to which has been added sufficient oxymuriate of tin or sulphuric acid to make faintly sour, a little steam is turned on, and the heat raised to about 120° F. in half an hour; the colours which on entering the beck were full shades of red, gradually assume an orange tint, and when of a bright orange colour, the pieces are taken out and winced in water. This operation, termed *cutting*, is the one that decides the depth of tint in the finished pieces. The longer the pieces are kept in the beck and the greater the heat, the paler and more delicate the shade of pink obtained. After this treatment they are put in a beck

with soap and boiled for an hour, taken out, washed well, and put in a strong pan charged with soap and water, the lid screwed down, and boiled at a pressure of two atmospheres, either by direct fire or high-pressure steam, for two or three hours, then taken out, washed, and put in a beek with water at 160° F. charged with a little hypochlorite of soda; they stay in this about ten minutes, and are then washed and dried. In some print-works, after the high-pressure boil, the pieces are spread out on the grass for a night or two, and then cleared in hypochlorite, &c. The use of the acid here is not very clear, it probably completely purifies the colour from iron which may have been in the mordant, but it also seems to render the combination of alumina, tin, lime, colouring matter and fat-acid a definite one by removing a small quantity of the mordant. The French chemists assert, that after the final process, a definite atomic compound of lime and alumina, colouring matter, and fat-acid remains.

The quality of the soap used by printers is of great importance. It is made for them specially from palm-oil, and requires to be as neutral an oleo-stearate as possible; an alkaline soap like domestic soap would impoverish and degrade the shades.

The soaping process has a two-fold action:—

To clear the white while decomposing the compound of lime and colouring matter which forms the stain; this is done by double decomposition, forming oleo-stearate of lime, which dissolves or forms an emulsion with the excess of soap; and a compound of soda and colouring matter, which dissolves. In its action on the dyed parts, it probably first removes resinous and other impurities which are loosely held by the mordant, and secondly gives up a portion of its fat-acid to the dyed parts—the resinous acids or possibly phosphoric acid from the dyed parts, by combining with the soda, setting free fat-acid for this purpose.

In reference to the above Swiss pink style, it may be observed that various shades of pinks are required for different markets, and where as in many cases a full rich inexpensive colour is required, the method of dyeing at low heats as described above is unnecessary, and the becks are brought nearly to a boil. Where an orange-tinted shade is required the goods may be dyed with garancin of good quality or with a mixture of madder and garancin.

A few years ago Mr. Thomas Lightfoot, of Accrington, discovered that madder or garancin-dyed goods, if dried and steamed in the manner usual in fixing steam colours, became much less degraded by soap in the clearing process for Swiss pinks, and that a considerable saving of madder or garancin might thus be effected, weaker mordants and consequently less dye-stuff being employed. Mr. Lightfoot patented the use of steam as an intermediate process between the dyeing and soaping of these colours, and the process is now generally used. Mr. John Graham had in 1855 patented the use of steam for 'fixing' the colours of dyed cloth, but his patent does not mention any subsequent process, and it is doubtful in what respects his so-called fixed colours were better than the ordinary dyed goods. Some printers pass the dyed goods through an oily emulsion previously to drying before steaming, with the object of causing a combination between the base of the mordant, the colouring matter and the oily acid, and so dispense with some of the usual soaping processes. Swiss pinks are sometimes 'covered' with a pattern which harmonises with that of the pinks, in a discharge yellow made of salts of lead mixed with acid; and after 'covering,' the goods are passed through strong chloride-of-lime solution which, being decomposed by the acid, the free chloride liberated destroys the pink-dyed part under the yellow, and the insoluble lead salt left in its place is dyed or raised with bichromate of potash. A style of madder work occasionally extensively printed is the madder orange style, where the orange is a salt of lead and called 'madder orange' because it has passed through the madder process along with the proper madder colours. The cloth is padded with solution of sulphate of soda containing 4 ounces of the crystallised salt per gallon, dried and printed in madder black, and purple, or black, red and purple with orange, say of Nos. 4, 6, 27, the orange No. 64a, and cover, or cover and pad with weaker purples, an acid 33 to 35 may also be printed along with the other colours. After 'ageing,' instead of dunging, run through a cistern set with 2 lbs. crystallised sulphate of soda and $\frac{1}{4}$ ounce of crystallised phosphate of soda per gallon of water at 150° F.; wash well and dye with madder as usual; wash and clear by running through a beek set with 300 gallons water at 140° F., 2 quarts chloride of lime solution at 8° Twaddell, and 2 quarts of solution of carbonate of soda at 8° Twaddell, run through water, then through the spiral soaping becks at boil for half an hour, then run through water, next through a chloride of lime and soda cistern set as before but boiling, then through the spiral soaping becks at boil, again into chloride of lime and soda set as above but at boil; wash well and raise the lead colour to yellow by passing for half a minute through a cistern containing 300 gallons of cold water, 30 lbs. of bichromate of potash and 3 quarts of sulphuric acid; run from this into water and wash well; to change the yellow into orange run through

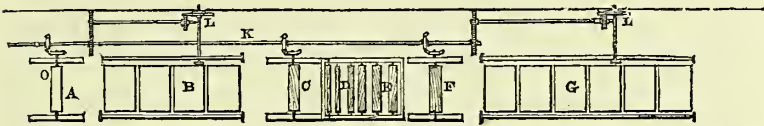

a cistern containing 300 gallons of boiling water, 5 lbs. bichromate of potash, and 5 lbs. quicklime. After the passage of every 10 pieces add 1 oz. bichromate of potash and 1 oz. quicklime dissolved in 3 gallons of water; after this orangeing, wash well and dry.

No. 64a, *Orange*.— $7\frac{1}{2}$ gallons of water; 60 lbs. white acetate of lead; $22\frac{1}{2}$ lbs. litharge; boil 20 to 30 minutes till all dissolved, let settle and thicken the clear liquor with calcined wheat starch (British gum).

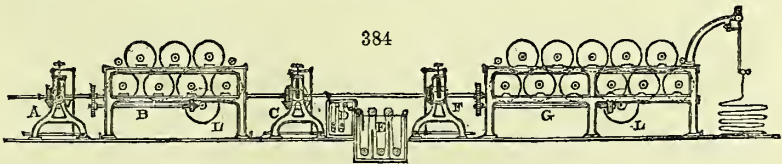

Second Style: Garancin.

Almost all the madder styles are imitated by dyeing with garancin, a concentrated preparation of madder (see Madder), which dyes fine brilliant colours at once, not requiring to be soaped to develop the shades, but not possessing the extreme solidity of madder colour. Garancin dyeing is the most economical way of using madder, since more colouring matter is obtained in this way than by using madder direct, and consequently garancin is principally used for full heavy colours, which, if dyed with madder and soaped, would be to a certain extent abraded and not stand so finely on the surface of the cloth. Chocolate grounds, black, red, and chocolate, with brown or drab, dark purple plates, black and scarlet ground, are thus dyed; in short, wherever the pattern is very full and cheapness essential, garancin is resorted to. The colours or mordants for garancin are usually about two-thirds of the strength of similar colours for madder (see the list of colours); the ageing and dunging, &c., are the same as for madder; the dyeing is performed in the same manner, using from one-fourth to one-third the quantity that would be used of madder. A little chalk is also added, where the water is soft; and the dyeing is commenced at 110° F., and carried to 185° F., or

383

384

190° F. in two hours; then got out and well washed and rinsed in water at 140° F., in a beek, for 10 minutes, then squeezed and dried. The white is always stained a little, though not to the same extent as in maddered goods, and this slight stain is removed by a process peculiar to garancin goods.

Fig. 383 is a plan, and fig. 384 an elevation of the chlothing apparatus used for clearing the white grounds of garancin-dyed goods, for which we are indebted to Mr. Furnival. A is a padding machine with two brass or one brass and one vulcanised India-rubber roller, and box to hold the solution of hypochlorite of lime; B is a drying machine with copper cylinders, for partially drying the goods after the first chlothing; C is a second padding machine similar to A; D is a steaming box, with rollers top and bottom, and perforated steam-pipe; E is a water cistern with divisions and rollers; F is a water mangle or padding machine, similar to A and C, with water only in the trough; G is a drying machine large enough to thoroughly dry the cloth; these machines are connected with and turned by the shaft K; to prevent pulling the cloth, and to adjust the speed of the machines with each other, the rollers O are made exactly the same size, and the speed of the drying machines is regulated by the friction plates L. The cloth is passed between the rollers in the first chlothing machine A, which is set with solution of hypochlorite of lime from $\frac{1}{2}^{\circ}$ to $2\frac{1}{2}^{\circ}$ Twaddell's hydrometer, according to the depth of stain on the white, over the first drying machine cylinders of B, into solution of hypochlorite of lime again in the trough of, and through the rollers of C, from this through the steaming-box D, entering the box by a narrow slit, which just admits the piece, and leaving by a similar opening, which is protected by a sort of hood which dips into the water in E, then between the rollers of the water mangle F and over the cylinders of the drying machine G. The cloth passes through the various

machines at the rate of 90 to 120 yards per minute, with the attendance of one man and two boys. By chloring in this manner the stained whites are bleached without degrading the dyed colours as would be the case if the goods were winced in a solution of the hypochlorite.

There are several varieties of garancin, each adapted to particular styles. For dark full black, chocolate, and red, with brown or drab, and where there is no purple, a garancin termed 'chocolate garancin,' made from the commonest descriptions of madder, answers very well, and this class of goods is usually dyed with chocolate garancin, assisted by small quantities of sumac, quercitron bark, and peachwood, which additions give full rich shades. Where there is purple, none of these adjuncts can be used, and the garancin requires to be made from a superior description of madder.

Within the last few years great improvements in the manufacture of purple garancin have been made. Good purple garancin contains two colouring matters, alizarine and purpurine, one or two coloured resins and pectic acid. Of the two colouring matters, alizarine only dyes a pleasing purple, purpurine giving a reddish and comparatively dull shade; the pectic acid and resins are simply injurious, though they can be to a considerable extent masked by the addition of a little chalk to the beck when dyeing. Mr. S. Pineoffs, experimenting on various ways of destroying the injurious parts of purple garancin without injuring the alizarine, discovered that sealing up the garancin in a strong tube with a little water, and exposing the tube to a high temperature for a few hours, so that the contents would be under a pressure of two atmospheres, greatly improved the garancin. Further experiments in the same direction by Dr. E. Schunck resulted in a joint patent taken out on Oct. 15, 1852, by Pineoffs and Schunck for the preparation of a substance called by them 'Commercial Alizarine.' The process consisted in first making garancin in the ordinary manner, but washing very carefully, so that no acid was left in the substance. The garancin was then filtered and pressed and packed into a strong iron cylinder, furnished with a false bottom perforated with holes, on which the pressed and broken-up cake of garancin was placed; near the bottom of the cylinder, and under the false bottom, was a small tap, for allowing the escape of condensed water, and both at the top and bottom, the vessel was provided with pipes for the admission of steam. The material having been placed on the false bottom, the man-hole lid in the upper part was closed, and high-pressure steam at about 30 lbs. to the square inch admitted and allowed to blow freely through the bottom tap for a few minutes. This was then closed, and the steam allowed to act on the material for about fourteen hours, the bottom tap being occasionally opened to blow off the condensed water. The steam was then turned off, and the contents of the cylinder removed, dried, and ground.

In this process the pectic acid is destroyed, and a large portion of the resins either destroyed or rendered insoluble in the solution of the alizarine when dyeing. It is a disputed point whether the purpurine is destroyed or converted into alizarine. A French chemist has asserted that he has changed purpurine into alizarine by heating it in a tube with water under a pressure of 4 atmospheres, but this statement has been negatived by other chemists. The garancin operated upon by Pineoffs and Schunck's patent has lost a considerable portion of its dyeing power, although it now dyes very pure shades, hence it would appear that the purpurine is really destroyed. Higgin followed soon after, patenting a mode of preparing a superior purple garancin, by boiling for several hours the ordinary purple garancin with water and small quantities of alkalies or alkaline salts. In this process the purpurine is not destroyed, but the resins and pectic acid are removed in solution in the menstruum employed. This garancin, though not dyeing purple of such extreme purity as commercial alizarine, has the advantage over this latter of dyeing black and good reds with a very good purple. Pernod, a French garancin maker, subsequently patented a method of boiling purple garancin in water in a tall wooden vat by high-pressure steam. In this process the pectic acid is changed into a soluble modification of it, and washed out with water afterwards. This preparation, as made by the firm in which Mr. Pernod is a partner, is of great purity and strength, and compares very well with the commercial alizarine, both these preparations dyeing purples almost as pure as the finest soaped madder purples.

These improved garancins stain the white grounds very little, and produce considerably faster work than the ordinary garancins; the goods may even be soaped to a considerable extent. A garancin that will bear as severe soaping as madder, or a method of so dyeing with garancin as to produce the same effect, is still a desideratum. When this can be accomplished, there will be an end of dyeing with madder, which will be considered a raw material, and be all manufactured into garancin.

Owing to the introduction of artificial alizarine there has been already a sensible falling off in the consumption of these fine purple garancins, and it appears probable

that if the artificial product can be brought in at even a little higher relative price than these dye-stuffs, the superior colours produced by it and the comparative cleanliness of its use, will drive garancins out of the market.

Garanceux.—In ordinary madder-dyeing, the madder can never be made to give up all its colouring matter; when all colouring matter soluble in water has been exhausted, there still remains about a quarter of the whole quantity combined with lime and mixed with the woody fibre.

Before the patent of Steiner in 1832 this spent madder was thrown away. He showed the printers that they were thus squandering thousands of pounds, and the collection of spent madder and its conversion into garanceux soon became universal; a second patent by Steiner in 1843 having shown a more practicable method of utilising waste madder.

The spent madder is run off into a pit outside the dye-house, where it is mixed with a small quantity of sulphuric acid, to precipitate any colouring matter in solution. It is then allowed to drain dry; removed from the pit, it is boiled in a leaden vessel, with more sulphuric acid, for several hours, then washed on a filter till free from acid, and after draining is ready for use. It dyes to about one-third the strength of ordinary chocolate garancin, and is principally used for the commoner garancin styles. Mr. John Lightfoot, of Accrington, has patented an improvement in the ordinary process of making garanceux. He recommends large vats to be provided, two or more in number, each sufficiently large to contain all the waste dyeing liquor produced in the dye-house in one day, and so arranged that the liquor runs from the dye-becks into them; at a certain point in the trough that conducts the liquor to the vats is placed a lead cistern with a valve and perforated bottom: this cistern holds a regulated quantity of concentrated sulphuric acid, and whenever a dye-beck is let off and the liquor flowing down the trough, a quantity of acid, proportionate to the quantity of madder, is allowed to run down through the perforated bottom and mix with the hot liquor; the acidulated liquor then runs into the vat, a tightly fitting cover on which keeps the liquor hot. When the day's dyeing is done, the vat is left covered up all night; next day the lid is raised, and by means of holes and pegs in the side of the vat, all the clear liquor is drained away, the vat filled anew with water, stirred up, and when settled, the clear drawn off again; this washing being repeated till all the acid is washed away, the garanceux is then run on a filter to drain for use. The advantages of this plan are, first, the saving of fuel, by economising the heat of the waste liquor, and, secondly, the production of one-fourth more colouring matter.

A beautiful modification of the garancin style was patented by Mr. John Lightfoot junior on Dec. 26, 1867. So long ago as 1846 Mr. Philippi of the firm of Mr. Bonecke and Co., of Rochdale, patented a method of producing, in addition to the ordinary black, reds, chocolate, purple and browns of madder work, several other colours such as blue, green, and yellow, all these colours being printed at once and undergoing the same operations; the blue was an indigo colour, the yellow a chromate of lead, and the green a compound of these two. The patentee never got beyond the stage of printing a few hundred pieces, for the style, though admitting of certain novelties in design, was not warmly received by the public on account of the inferiority of the blues, greens, and yellows. The style soon fell into disrepute and was almost forgotten. Lightfoot revived it, making several important improvements and Messrs. F. W. Grafton and Co. of Accrington, in whose employment he was, became the ultimate owners of, and manufacturers under the patents of Mr. Lightfoot. We give here an outline of the process, using the words of the patentee:—

‘I make a preparation of indigo, fulfilling the required conditions, by employing much less tin, whether as oxide or in the state of salt, in the process of dissolving the indigo than has hitherto been used, and also by dispensing with the addition of a salt of tin to the precipitated indigotine, whether this has been made by the aid of oxide or salt of tin, or, as is sometimes the case, by the aid of metallic tin, because I have ascertained that if the tin is in excess of a certain proportion to the indigo, oxide of tin is left in the fibre during the process of fixing the indigo colours and the mordants, and thus acting itself as a mordant becomes dyed by the dye-stuff, producing with the indigo compound colours which in the case of blue are more or less purple and dull, and in the case of green are more or less a sombre olive. This use of tin in excess has been one of the causes of the failures to which I have before alluded.

‘I prepare a paste or pulp of indigotine and tin suitable for my improved process by any of the following methods:—I take of dry indigo in a ground or powdered state one and a quarter pounds, or when indigo pulp is used, using such a quantity as to be equal to one and a quarter pounds of dry indigo, of protochloride of tin in crystals one and a quarter pounds, and of caustic soda at thirty degrees on Twaddell's hydrometer, or of caustic potash at forty degrees on Twaddell's hydrometer, one gallon. I put

these materials in a pan and raise to boil in half an hour, and then add one gallon of boiling water. I prefer now to allow the mixture to become perfectly cold, and pour it into three gallons of cold water, in which I prefer to dissolve eight ounces of sugar or one pound of treacle (though this addition is not essential) I add to this solution two and a half pints of muriatic acid at thirty-two degrees of Twaddell's hydrometer, or one pint of sulphuric acid of commerce, previously diluted with one pint of water, and allowed to stand till clear, or three quarts of acetic acid at eight degrees of Twaddell's hydrometer. The indigotine may also be precipitated by a mixture of protochloride of tin solution at one hundred and twenty degrees of Twaddell's hydrometer, with any of the acids named, using one quarter of a pint of tin solution and only half the quantities of the acids given above: this quantity of tin solution being the maximum that I can use when precipitating the indigotine for producing a fine blue and green. Of all these precipitants I prefer to use "acetic acid alone." Instead of using protochloride of tin crystals in making the indigo solution, protoxide of tin made by precipitating a solution of protosalt of tin with an alkali may be used, the precipitate being washed with water and filtered to a thick paste, or anhydrous protoxide of tin made in any convenient way may be employed, in all cases taking such a proportion of oxide as shall contain an amount of tin about equal to but not greater than that in one and a quarter pounds of crystallised protochloride. In some cases the mixture of one and a quarter pounds of indigo and one gallon of alkali may be boiled with metallic tin in powder or granulated, the quantity of the latter being such that when the boiling is finished and the indigo all dissolved there shall be metallic tin undissolved. In all these cases I precipitate the indigotine as previously described. I filter the indigotine precipitate through a deep conical filter so as leave as small a surface exposed to the air as possible; when filtered, the pulp should measure one gallon or thereabouts.

'To make a blue colour for printing I take four gallons of indigotine precipitate and fourteen pounds of gum-Senegal in powder, stirring until dissolved (other suitable thickening substances may be used), after straining, the colour is ready for printing.

'To make a green colour I take four and a quarter gallons of indigotine pulp and eighteen pounds of gum-Senegal in powder, stir till dissolved, and add eleven pounds of nitrate of lead in powder, and eleven pounds of white acetate of lead in powder, stir till dissolved and strain.

'Compound colours may be made by mixing the blue and green colours with each other or with the ordinary mordants for dyeing. With the blue and green above described and the ordinary ferruginous and aluminous mordants I print cotton and linen fabrics, and after cooling hang the pieces in a room known to printers as an ageing room for one night; I then cause them to undergo what is known as the fixing operation by passing them into a solution of silicate of soda or silicate of potash at eight degrees of Twaddell's hydrometer, or into a solution of carbonate of potash at twelve degrees of Twaddell's hydrometer, to which about one ounce of chalk in powder per gallon may be added, or into a mixture of silicate of soda or silicate of potash at eight degrees of Twaddell's hydrometer with carbonate of potash at twelve degrees of Twaddell's hydrometer. I heat the bath at ninety degrees Fahrenheit or thereabouts in a cistern fitted with rollers at the top and bottom, and the passage of the pieces may be at the rate of twenty-five yards per minute. On leaving this the pieces must be quickly winced in a pit of cold water fitted with a reel about four feet above the surface of the water. By this wincing the indigotine attached to the fibre becomes again indigo blue. If green has been printed, I next pass the pieces into a solution of bichromate of potash containing one ounce of bichromate of potash per gallon of water at one hundred degrees Fahrenheit for five minutes: the goods are then washed. If only blue has been printed along with the mordants this process may be omitted. I next subject the pieces to the operation known to calico printers as "second dunging," and which consists in making the pieces circulate in a beck containing cow-dung and water at a temperature to about one hundred and sixty degrees Fahrenheit for from fifteen to twenty minutes. They are then washed with water and dyed with madder, munjeet, flower of madder, garancin, extract of madder, cochineal, mixtures of garancin with sumac and bark, or with either of them, after which the ordinary operations of clearing the white grounds may be performed, preference being given to the chloride of lime clearing usually adopted with garancin colours.'

Another variety of garancin work is that where an orange is introduced along with black, red, and chocolate. The orange colour is made as follows:—3 gallons of pyroligneous acid at 7 T., 1 gallon of water, 7 lbs. acetate of lime, dissolve and strain; then boil with 10lbs. of flour and 3 gallons of water, cool, and add 8 lbs. of muriate of tin crystals, dissolved in 1 gallon of water. The dyeing is with 3 ozs. garancin, 1½ ozs. of sumac, 1½ oz. of bark, 1 oz. of ground Persian berries per piece of 25 $\frac{8}{9}$ yards. The bark and berries are first put in the beck with the pieces, heat up to

120° F. in half an hour, then add the garancin and sumac, and bring up to 150° F., take out, hot water, and clear as usual.

Third Style: Reserved.

Maddered or garancined goods are often left with white spots, as leaves, &c., and when dyed these spaces are filled with various bright colours, such as green, blue, yellow, &c. These colours are the ordinary steam colours described hereafter, and are fixed in the same manner.

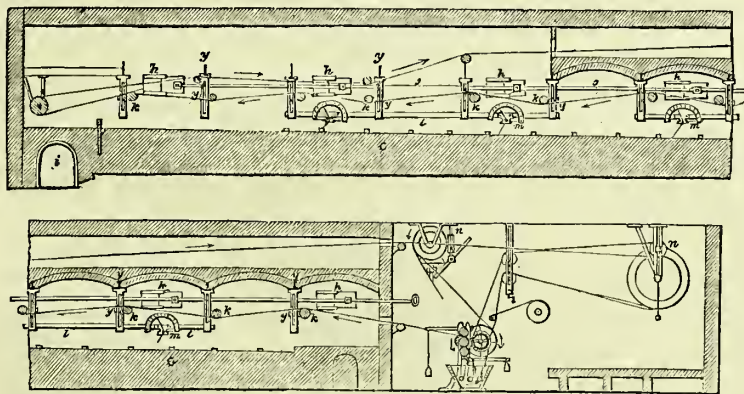

Another way of combining madder or garancin colours with steam colours is by blocking on the dyed object, generally groups of flowers, a reserve paste (No. 39), and when this is dry, covering by machine in small patterns with various shades of drab, olive, &c. (Nos. 5, 44, 46, &c.), which then are dunged and dyed with quercitron bark, cochineal, madder and bark, &c. &c. When the paste has been applied, the colours underneath, or the white spots reserved, are unaffected by the covering colour, and stand out clear surrounded by the covering colour. In the white spaces reserved are now blocked steam colours, which are raised by steam as described further on. This style admits of almost endless combinations of patterns as far as regards the 'covering,' for any small pattern roller of the 'covering' class can be printed over the reserved colours, and a great variety of shades can be produced by varying the dyeing of this 'cover.'

Fourth Style: Padded.

In this style the white cloth is mordanted all over by padding in red or iron liquor, or mixtures of them, and drying in the padded flue; then a pattern is printed on in acid, and the usual dunging and dyeing operations performed, the result being a dyed ground with a white pattern.

Fig. 385 represents a section of the padding flue used in mordanting for this style.

385

It consists of a long vaulted chamber, about 35 yards long by 5 yards, and 4 yards high, cut in two at nearly half its length, by six small arches built in an opposite direction to that of the chamber, the object of which is to preserve the principal arch from the action of the heat, and to hinder the dried pieces from being exposed, on coming to the higher part, to moisture and acids, which are disengaged in great abundance and might condense there. c c is a long furnace, the flue of which forms the bottom of the chamber; the top of the flue is covered with plates of cast iron fitting one into another, and which can be heated to near red heat by the flame of the furnace. f f is an arched passage by which the interior of this stove can be reached. h h are ventilating holes in the lateral wall which can be opened and closed at will, by means of the rod j j, which is connected with sliding doors over the apertures. k k are cast-iron supports for turned copper rollers, which are fixed to the cross pieces y y, and serve to conduct the piece. l l are bars of iron which carry the fans m m, which are covered by gratings, and make about 300 turns per minute.

In front of this hot flue is placed all the apparatus necessary for padding the pieces, and moving them through the drying chambers. This movement is caused by pullies r r driven from a prime mover.

The mordant liquor being put in the box of the padding machine, the pieces wound on a beam and placed above the machine are conducted through the box, then between the two lowest rollers above the box, from them through the liquor again, passing

next through the highest rollers, and so on into the flue, the course being easily traced by the arrows; on leaving the flue dry, they are wound on a beam, or plated down on the wooden platform behind the machine. The 3 rollers of the padding-machine are made of brass, and are wrapped with a few folds of calico; the iron journals of them work in slots, the lowest one being at the bottom of the slot working in brass bearings; a weighted lever presses the top roller in forcible contact with the others. Another method of padding, and one now becoming very generally adopted, is, to dispense with the flues as above described, and, after padding, to dry the pieces over an ordinary cylinder drying-machine, the cylinders of which are covered with woollen printing blanket.

Padded goods after printing in acid are passed through the ageing-machine, and after lying all night are dunged and dyed. A few of these shades are here given.

a. Claret and white. Pad in red liquor, at 10° T., dry, cool, and pad again in same liquor, dry, cool, and print in acid No. 37, age three nights. Fly-dung at boil, wash, second dung at 160° F., $\frac{1}{2}$ hour, wash, dry, and *singe*, wash and dye 12 pieces 7 ft. 8 in. 30 yards with 18 lbs. ground peachwood, 21 lbs. of French madder, 5 lbs. sumac, 5 lbs. prepared logwood, run the pieces in the beck cold for 20 minutes, and then bring to a boil in 1 hour and 10 minutes, boil 15 minutes, get out, rinse and wash, bran 10 minutes at boil in a beck with a few pounds of bran, rinse in a pit, and bran again at boil, wash and dry.

Prepared logwood is thus made.—Ground logwood is spread out on a floor, damped with water, and heaped up. It is then turned over once a day for a fortnight and occasionally wetted, during which time it changes from a dull red to a bright scarlet. It is then ready for use. Some change, probably oxidation, has taken place, and the wood dyes further after this process.

b. Scarlet and white.—Padded and dunged as for clarets; then 10 pieces dyed with 15 lbs. French madder, 15 lbs. Dutch crop madder, 7 lbs. peach wood, 4 lbs. sumac with 3 quarts bone size: bring to a boil in 2 $\frac{1}{4}$ hour, and boil a quarter of an hour; wash and bran, &c.

c. Scarlet and yellow.—Proceed as for scarlet and white, but dye 10 pieces with 22 $\frac{1}{2}$ lbs. Dutch crop madder; 22 $\frac{1}{2}$ pounds French madder; 7 $\frac{1}{2}$ lbs. sumac, wash, bran, and dry; then pad in red liquor at 10° T., age 2 nights, fly-dung at 130° F., wash and warm water at 120° 10 minutes, dye 10 pieces with 20 lbs. quercitron bark, heat to 120° in one hour, keep at 120° 15 minutes, wash and dry.

d. Burgundy and white.—Pad, &c., as for clarets; dye 10 pieces with 18 lbs. French madder, 18 lbs. peachwood, 1 $\frac{1}{2}$ lb. logwood, 5 lbs. sumac, 4 quarts glue. Heat to boil in 1 $\frac{3}{4}$ hour, boil $\frac{1}{4}$ of an hour, wash and bran at boil 10 minutes, wash and dry.

e. Tyrian purple and white.—Pad, &c., as for clarets; dye 10 pieces with 5 lbs. prepared logwood, 5 lbs. Dutch crop madder, and 7 lbs. peachwood 2 lbs. bran, and 3 quarts bone size. Bring to boil in 1 $\frac{3}{4}$ hours, boil $\frac{1}{4}$ of an hour, wash and bran at 150° 5 minutes with 1 lb. bran per piece; wash and dry.

f. Puce and white.—Pad, &c. as for clarets; dye 12 pieces with 3 lbs. fine ground cochineal, 1 lb. ground galls, 4 lbs. prepared logwood, 3 lbs. peachwood, heat to 170° in 1 hour, and 20 minutes, keep at 170° 10 minutes, wash, bran at 160° 10 minutes; wash and dry.

g. Amber and white.—Pad, &c. as for clarets; dye 10 pieces with 20 lbs. quercitron bark, 10 lbs. Dutch crop madder, 2 quarts bone size. Heat to 160° in 1 hour and 15 minutes, keep at 160° 15 minutes, wash, bran 10 minutes at 150°; wash and dry.

h. Peach and white.—Pad, &c. as for clarets; dye 10 pieces with 2 lbs. ground cochineal, 2 lbs. peachwood, 6 oz. logwood, heat to 140° in 1 $\frac{1}{4}$ hour, wash, bran at 140° 10 minutes; wash and dry.

i. Black and white.—Pad in red liquor at 20° T. once, print in No. 36, age 3 nights, fly-dung at boil, second dung at 140°, 20 minutes, wash, dry, and *singe*, wash and dye 10 pieces with 60 lbs. prepared logwood, 4 gallons of bone size, and 6 oz. carbonate-of-soda crystals, heat to boil in 1 hour and 10 minutes; wash well and dry.

k. Olive, drabs, &c. with white.—A great variety of shades may be obtained by varying the mordants. For drabs pad in iron liquor diluted about 10 times according to the shade wanted, and dye in bark, or bark and logwood. For olives, pad in mixtures of red liquor and iron liquor, diluted, and dye in bark, or bark and logwood. The acid used may be No. 33.

l. Bark dyeing.—Dye 10 pieces with 25 lbs. bark, and 3 quarts bone size; heat to 190° in 1 $\frac{1}{2}$ hour, and keep at 190° 10 minutes, wash and bran at 160° 10 minutes, wash and dry.

m. Bark and Logwood dyeing.—Dye 10 pieces with 20 lbs. bark, and 30 oz. prepared logwood, with 3 quarts bone size; heat as in bark dyeing.

Fifth Style: Indigo.

The indigo dye-house is always on the ground of a building, and is fitted up with a number of stone vats let into the ground. There are generally several rows of these vats, about 3 feet apart. They are about 8 feet long by 4 feet wide, and 8 to 10 feet deep. Some of them have steam-pipes inserted, which go to near the bottom, so that they can be heated when necessary. There are about 10 vats in a row.

A. *Blue and white.* The simplest form of blue styles is blue and white; dark blue ground with white figures. The cloth is printed in one of the following reserve pastes:—

No. 65. *Reserve paste for Block.*—3 lbs. sulphate of copper dissolved in 1 gallon of water, 15 lbs. pipe-clay, heat up with some of the liquor: 1 gallon of thick gum-Senegal solution, and 1 quart of nitrate of copper at 80° T.

No. 66. *Reserve paste for Machine.*—2½ lbs. sulphate of copper, 1 gallon of water, thickened with 9 lbs. flour, and 2 pounds dark British gum.

No. 67. *Reserve paste for Machine.*—5 lbs. sulphate of copper, 2 lbs. white acetate of lead, 2 gallons water, dissolve and thicken the clear with 3 lbs. flour and 2 lbs. pale British gum: when cold, add half a pint of nitrate of copper at 80° T., to every 2 gallons of colour.

No. 68. *Reserve paste for Machine.*—4 gallons boiling water, 16 lbs. of sulphate of copper, 8 lbs. white acetate of lead, let settle and pour off the clear liquor; thicken 3 gallons of this with 8 lbs. of flour, and 4 lbs. pale British gum. When boiled, add 4 lbs. sulphate of zinc, and dissolve. The foregoing are all to resist deep shades of blue. For light shades of blue dipping, any of the following:—

No. 69. *Mild paste for Block.*—25 lbs. dark British gum, 15 quarts of water, boil 10 minutes and add 7½ lbs. soft soap; stir well in, and when mixed, add 20 lbs. sulphate of zinc, stir well in, and add 10 lbs. pipe-clay beaten up into 7½ quarts of water, and 7½ gills of nitrate of copper at 80° T. Mix all well together.

No. 70. *Mild paste for Machine.*—8 lbs. dark British gum; 3¾ quarts water; boil, and add 2 lbs. soft soap, cool, and add 6 lbs. sulphate of zinc dissolved in 2 quarts of boiling water, and one quart of nitrate of copper at 80° T.

After printing in one of these reserves, hang in a rather humid atmosphere for 2 days, and then dip blue.

Indigo for use in the dye-house is ground with water to a fine pulp: a series of cast-iron mills with curved bottoms, are arranged in a line; one or two iron rollers are moved backwards and forwards on the curved bottom in each mill by an upright rod, which is furnished with a roller at the bottom, and is connected with a horizontal rod worked by an eccentric. Indigo and a certain quantity of water are left in these mills several days, till the pulp is perfectly smooth. The method of blue dipping is as follows:—

In a line of ten vats, the first one is set with lime; as—

(No. 1.) 1,000 gallons water, 250 lbs. of hydrate of lime, or lime slaked to a dry powder; when used it is well raked up.

The indigo vats vary according to the style of work; for deep blue and white, or blue and yellow, or orange, the following is a good one:—

(No. 2.) 1,000 gallons water, 50 lbs. indigo previously pulped, 140 lbs. copperas, and 170 lbs. lime; dissolve the copperas in the water, then add the indigo, stir well up, and add the lime, previously riddled, to separate small stones. Rake up every two hours for two days, and let settle clear. The clear liquor, when taken up in a glass, must have a deep yellow colour, be perfectly transparent, and be immediately covered with a pellicle of regenerated indigo when exposed to the air. Eight or nine vats are all set alike.

The pieces to be dipped are hooked backwards and forwards on a rectangular frame which just fits the vats, so that the cloth can be immersed, but still not so deep as to touch the sediment of the vats. The process is thus performed:—The lime-vat No 1 being stirred up, the frame which contains two pieces, is lowered down into it, so as to completely immerse the pieces; a gentle up-and-down movement is given by hand. The frame is allowed to stay 10 minutes in, is then lifted out and supported over the vat by rods put across. After draining here a few minutes, it is then removed and immersed in vat No. 2, or the first indigo vat. It stays here seven minutes, is lifted out, and drained as before over the vat 8 minutes, then removed to No. 3 vat, and so on till it has gone through the whole series, or till the shade of blue is considered strong enough. After the last dip the pieces are unhooked and winced in a pit of water, then winced about 10 minutes in a pit containing sulphuric acid at 6° T., washed well in the wheel, squeezed, and dried. In large dye-houses there is an arrangement for collecting all the waste indigo which is washed off the pieces, by running all the water used into a vaulted chamber under the dye-house,

where it passes from one compartment to another, gradually depositing the suspended indigo, which is periodically removed.

In heavy bodies of colour, the paste sometimes slips or the shapes become irregular; this is counteracted by using the first indigo vat raked up instead of clear. The vats are used till nearly exhausted, and then the clear liquor pumped off to be used instead of water for setting fresh vats with.

B. *Blue and Yellow, or Orange.*—Print in one of the reserve pastes, and yellow or orange colour made as follows:—

No. 71. *Chrome-yellow for Machine.*—2 gallons water, 20 lbs. sulphate of copper, 20 lbs. nitrate of lead; dissolve, and beat up with 12 lbs. flour, and 2 gallons sulphate-of-lead bottoms; boil all together.

The sulphate of lead here is the bye-product in making red mordant No. 8, and is drained to a thick paste.

No. 72. *Orange.*—Make a standard liquor by dissolving 24 lbs. white acetate of lead in 6 gallons water, and stirring 12 lbs. litharge in it till perfectly white, then let settle, and use the clear.

For the orange colour take 2 gallons of this standard liquor, instead of the gallons of water in the above yellow colour.

Follow the same routine in dipping, &c., as for blue and white. After wincing in sulphuric-acid sours, wash well, and wince 10 minutes in bichromate-of-potash solution, 2 oz. per gallon at 100° F. Wash well, and wince in dilute muriatic acid at $\frac{1}{2}$ ° T., containing 1 oz. oxalic acid per gallon, till the yellow is quite bright. The small quantity of chromic acid set free oxidises and destroys the indigo that may be attached to the yellow colour. After this souring, wash and dry.

If orange was printed instead of yellow, treat as for yellow; and after the murio-oxalic sour, wash, and raise orange in the following:—10 lbs. bichromate of potash, 300 gallons water, and 3½ lbs. of lime previously slaked to a thin paste, heat to 180° F., and wince the pieces in till the orange is full and bright; then take out and wash well, and dry.

Other varieties of blue dyeing are:—

c. Two blues.

d. Two blues and white.

e. Two blues, white, and yellow or orange.

f. Dark blue and green.

g. Two blues and yellow.

For c and e a pale shade of blue is first given to the cloth. The light blue vat is thus composed:—

No. 3. (*Light Blue Vat.*) 1,000 gallons water, 40 lbs. indigo, 70 lbs. copperas, 80 lbs. lime. For c. Dip light blue by three immersions, draining well between; unhook, wince in water, then in sulphuric sours at 2° T.; wash, squeeze, and dry; then print on a reserve paste, and proceed as for dark blue and white; when finished, the pale blue having been protected by the reserve, has remained unaltered, all the rest being dark blue.

For f. Instead of reserve paste, print on yellow No. 71, and dip dark blue, sour and raise the yellow with bichromate of potash, omit the souring after chroming, and wash and dry. The yellow falling on the pale blue, makes a green.

For d. On white cloth print an object in muriate of manganese, thickened with dark British gum, raise this as described under the head *Bronzes*, dry and block in a reserve paste No. 65, then lime and dip in the dark blue vat, letting stay in half an hour, remove, oxidise in the air, wash and sour with dilute muriatic acid to which some muriate-of-tin liquor has been added, wash and dry; where the peroxide of manganese had been is now dark blue, the ground pale blue with white object.

For e. Print as d, with yellow or orange in addition, and after the sulphuric sours, raise yellow or orange as before.

Dip light blue; print reserve paste and yellow; dip dark blue; wince; sour in sulphuric sours at 6° T.; wince in water; chrome at 140° F. 10 minutes at 2 oz. bichromate per gallon; wince, wash, and sour in the following:—7 lbs. oxalic acid, 3 lbs. strong sulphuric acid; dissolve in water to stand 8° T.; wince till the yellow is bright; then wash and dry.

A style formerly very much in vogue, but now scarcely ever used, is the neutral or lazulite style. It consists in combining mordants with reserves, and dipping blue; the colours throw off the blue, and are subsequently dyed with madder.

Neutrals are of two sorts:—

1. Where reds and chocolate, or black, with resist white are printed, and dipped light blue, the resist white being only required to resist the blue.

2. Where the white is required to cut through the black, reds or chocolate in addition to the blue,

The following are examples of lazulite colours for the first variety :—

No. 73. *Black (Machine)*.—4 quarts logwood liquor at 12° T., 1 quart gall liquor at 9° T., 1 quart red liquor at 20° T., 1 quart iron liquor at 24° T., 1 quart acetic acid, thicken with 3 lbs. flour, and 8 oz. starch : when boiled add 1 pint Gallipoli oil, and 1 pint turpentine.

No. 74. *Chocolate (Machine)*.—5 quarts red liquor at 12° T., 1 quart iron liquor at 24° T., 1½ lb. sulphate of copper, 24 oz. measure of nitrate of copper at 100° T., thicken with 2½ lbs. flour, and ½ lb. dark British gum.

No. 75. *Chocolate (Block)*.—5 quarts red liquor 12° T., 1 quart iron liquor 24° T., 2¼ lbs. sulphate of copper, 36 oz. measure nitrate of copper at 100° T., 9 lbs. pipe-clay beat up well, and add 3 quarts of gum-Senegal solution at 5 lbs. per gallon.

No. 76. *Dark resist Red (Block)*.—2 quarts red liquor 22° T., 5½ oz. white acetate of lead, 4¼ oz. sulphate of copper, dissolve, and beat up in 6¾ lbs. pipe-clay. Thicken separately 2 quarts red liquor at 12° T., with 12 oz. flour, and add when boiling hot 8 oz. of soft soap melted; mix well, add the pipe-clay mixture to this, and then 2 quarts red liquor at 2° T., thickened by dissolving gum-Senegal in it. Stir the whole well together.

No. 77. *Dark resist Red (Machine)*.—20 quarts nitrate of zinc at 36 B., 10 quarts water coloured with a little peachwood, 12½ lbs. alum, 10 lbs. acetate of lead; dissolve all together with heat, stir till cool, thicken all together with 8 lbs. flour, and 1½ lb. dark British gum.

No. 78. Any shade of pale red is made for block by substituting the red liquor in colour No. 76 by the mordant No. 8, reduced with water, according to the shade wanted.

No. 79. Any shade of pale red for machine is made by reducing the quantities of alum and acetate of lead in colour No. 77.

The white reserve for this variety of neutrals is either of the mild pastes.

No. 80. *Resist Brown*.—2 gallons water, 24 lbs. catechu, 6 lbs. sal-ammoniae, 1 gallon acetic acid; boil 15 minutes, and add 7½ gallons gum-solution, 5 quarts nitrate of copper at 100° T.

Process.—The colours after printing are aged 3 days, then dipped light blue in the following blue vat :—

(No. 4.) *Neutral vat*.—1,000 gallons water, 120 lbs. indigo, 135 lbs. copperas, 150 lbs. lime; rake up for two days, and let settle.

A frame with rollers top and bottom is lowered into this, and the pieces are run through; after leaving the vat, they are made to travel over rollers in the air for a sufficient distance to turn them blue; then into a pit of water, from that into a beck with cow-dung and water, at 160° F., where they run 15 minutes, then washed and dyed madder or garancin, &c. &c.

In the second variety of neutrals, the white is required to resist both mordants and blue, and is made thus :—

No. 81. *Neutral White for Blocks*.—7 quarts lime juice at 30° T., 1 quart water, 4½ lbs. sulphate of copper, 24 lbs. pipe-clay, 5½ quarts lime juice at 30° T., previously thickened with gum-Senegal.

No. 82. *Neutral White for Machine*.—1 gallon lime juice at 42° T., 2 lbs. sulphate of copper, 32 oz. measure nitrate of copper at 100° T., thickened with 1½ lb. starch.

The black is the ordinary madder or garancin black, Nos. 4 and 5 process.

The neutral white is first printed either by block or machine; if the latter, it cannot be in a pattern which should register accurately with the subsequent colours, as it must be dried perfectly before the other colours are printed, to avoid obtaining irregular shapes; the above reserve colours are then printed over the neutral white. Mild paste Nos. 69, 70 may also be printed along with the other colours, to reserve a white under the blue only. The subsequent process is the same as for the first variety.

After dyeing madder and garancin, and clearing with soap, &c., steam or spirit colours are generally blocked in. Parts of the yellow being made to fall over the blue form green.

Sixth Style: China Blues.

China blues, so called from the shade of blue resembling that on porcelain. In this style indigo is printed on, and made to penetrate and fix in the cloth by the subsequent process.

The colour is made thus :—

No. 83. *Standard China Blue*.—In an indigo mill are put 45 lbs. indigo, 9 gallons iron liquor at 24° T., and 18 lbs. copperas, the whole ground till quite fine; then add 7½ gallons gum-Senegal solution at 6 lbs. per gallon; grind an hour longer, take out and wash the mill with 6 quarts hot water, and add to the above.

No. 84. *China blue gum*.—Gum-Senegal solution at 3 lbs. per gallon, containing 4 oz. copperas per gallon.

Colours are made by reducing the standard blue with the gum, according to the pattern and strength required. For instance, for two blues of medium shades:—

No. 85. *Strong Blue*.—1 volume standard, 2 volumes gum.

No. 86. *Pale Blue*.—1 volume standard, 10 volumes gum.

After printing, age one night, and raise as follows:—Two vats similar to indigo vats are set. No. 1. 1,000 gallons water, 500 lbs. slaked and dry lime.—No. 2. Solution of copperas at 5° T. In each vat is lowered a frame, which is provided with rollers at top and bottom, and in addition, has a pair of bushes at each side of the frame, just above the surface of the liquor, in which are put beams, on which the pieces are wound alternately; the bearings of the beams being just above the surface of the liquor, allow the roll of pieces to be always half in and half out of the liquor. The course of proceeding is this:—A beam containing two or three pieces stitched end to end is placed on a small frame at one side of vat No. 1, and by means of a cord previously threaded through the rollers in the vat, the pieces are slowly wound through the vat and on to a beam placed in the bearings at the opposite side of the vat, by means of a winch handle fitted on this beam; when the pieces have thus passed through vat No. 1, which is kept in a milky state all the time, the beam is lifted out and transferred to one of the pair of bearings in vat No. 2; the pieces are wound through this vat in the same manner; after this vat, they are removed to No. 1 vat, and worked through; this alternate limeing and copperasing is continued till the pieces have been 4 times through each vat; then detach and wince in water; then put into sulphuric sours at 10° T., immersing completely in the liquor till the whites appear quite clear; then wash well, soap in a beck at 120° F. a quarter of an hour with $\frac{1}{4}$ lb. soap per piece; wash again and sour in sulphuric sours at 1° T. at 110° F.; wash well and dry.

The various phenomena which occur in the dipping of China blues are not difficult of explanation with the lights of modern chemistry. We have, on the one hand, indigo and sulphate of iron alternately applied to the cloth; by dipping it into the lime, the blue is deoxidised, because a film of the sulphate of iron is decomposed, and protoxide of iron comes forth to seize the oxygen of the indigo, to make it yellow-green, and soluble at the same time in lime-water. Then, it penetrates into the heart of the fibres, and, on exposure to air, absorbs oxygen, so as to become insoluble and fixed within their pores. On dipping the calico into the second vat of sulphate of iron, a layer of oxide is formed upon its whole surface, which oxide exercises an action only upon those parts that are covered with indigo, and deoxidises a portion of it; thus rendering a second dose soluble by the intervention of the second dip in the lime-bath. Hence we see that while these alternate transitions go on, the same series of deoxidisement, solution, and re-oxidisement recurs: causing a progressively increasing fixation of indigo within the fibres of the cotton.

Other indigo styles are dipped greens, blue with white discharge.

Dipped Greens.—There are 4 vats similar to indigo vats in a row, set with—

First: (No. 5.) *Light blue Vat for Greens*.—1,000 gallons water, 25 lbs. indigo, 45 lbs. copperas, 65 lbs. lime, dry slaked, 17 lbs. caustic soda, 24° T.; raked up 2 days, and settled clear.

Second: (No. 6.) *Yellow Vat for Greens*.—1,000 gallons water, 250 lbs. brown acetate of lead, 130 lbs. dry slaked lime; rake up till dissolved, and let settle clear.

Third: (No. 7.) Filled with water only.

Fourth: (No. 8.) Set with bichromate of potash at 4° T.

Each of these vats is mounted with a frame with rollers top and bottom; the pieces to be dipped are stretched end to end, and a length of cord being threaded through all the vats and fastened to a drawing roller at the end of the fourth, the pieces are drawn slowly through between the first and second; the cloth is made to travel several yards so as to ensure oxidation of the indigo before going into the lead vat; after leaving the fourth, they are detached, winced, and washed well.

For dipped greens, either white cloth is printed in patterns, as spots, &c., with mild paste, Nos. 69, 70; or a pattern previously printed in madder colours and dyed, &c. is covered up with mild paste by block; the cloth being now dipped green, the pattern or spots are reserved or untouched by the green: a very good effect is produced by dipping the Burgundy and acid No. 4, green, when the Burgundy part comes out a beautiful chocolate, and the white part green.

Acid Discharge on Blue.—A blue and white style, but which permits the most delicate pattern to be printed, which is not the case with the ordinary blue and white style. The cloth is first dipped a medium shade of blue, washed and dried, then padded in bichromate of potash at 6° T. and carefully dried in the shade, without artificial heat, and printed in the following colour:—

No. 87. *White Discharge for Blues*.—1 gallon water, thicken with 2 lbs. flour, and 2 lbs. dark British gum; when partly cooled, add 2 lbs. oxalic acid, and when quite cold, $7\frac{1}{2}$ oz. measure sulphuric acid. A few seconds after the colour is printed on the padded cloth the blue is discharged, and a dirty white left in the printed parts; after printing, the pieces are dried so as to leave them slightly damp, and immediately winced in chalk and water, then winced in sulphuric sours at 20° T., winced and well washed; the printed pattern is now a pure white, and if care has been taken not to dry the bichromate too hard, and not expose it to sunlight, the blue is bright and good.

This ingenious process was the invention of Mr. John Mercer. At the moment the block applies the preceding discharge to the bichromate dye, there is a sudden decoloration, and a production of a peculiar odour.

The pieces padded with the bichromate must be dried at a moderate temperature, and in the shade. Whenever watery solutions of chromate of potash and tartaric acid are mixed an effervescence takes place, during which the mixture possesses the power of destroying vegetable colours. This property lasts no longer than the effervescence.

In the 'Moniteur Scientifique' of Dr. Quesnoville for July 1873 are described some new processes, invented by P. Schützenberger and F. Lalande for the fixation of indigo upon cloth. The active agent for the reduction of the indigo is the hydro-sulphite of soda, discovered by the former, and which is made as follows:—'Bisulphite of soda, standing at 30° to 35° Baumé, is brought in contact in a covered vessel with twisted sheet zinc, or granulated zinc, filling up to the top of the vessel without occupying more than one-fourth of its real volume. After the lapse of about one hour, the liquid is poured into an excess of milk of lime, which precipitates the salts of zinc. The clear liquid is drawn off either by filtration and pressure, or by decantation after the addition of water. Air should be excluded as much as possible. By mixing the hydro-sulphite thus obtained with ground indigo, and the amounts of lime or soda necessary to dissolve the reduced indigo, we obtain at once a yellowish liquid containing no insoluble matter except the earthy impurities of the indigo.' One pound of indigo may be thus reduced, so as to form a solution not exceeding 4 to 6 quarts in volume. This solution is diluted with water to form a blue vat or an alkaline solution of the reduced indigo, containing a large excess of hydro-sulphite of soda, is suitably thickened and printed by a copper roller in the ordinary printing-machine. The oxidation during printing is so slight that after an hour's work, the remnant of the colour is still yellow and soluble. The entire colour is utilised, 50 to 60 per cent. less indigo being consumed with the new process than with the old. The shades obtained are more beautiful and fast, and the impression is better defined. This new indigo blue, requiring no subsequent fixing process, can be printed along with a great number of other colours, such as aniline black, madder colours either for dyeing or as extracts, catechu shades, Guignet's green and other colours fixed with albumen. Specimens of some of these colours printed along with the new blue, are given in the 'Moniteur,' and the new process would appear from these to be successful.

Seventh Style: Discharge on Turkey-Red Ground.

No. 88. *White Discharge (Machine)*.—8 lbs. light British gum, 1 gallon tartaric-acid liquor 62° T., 1 gallon acetic acid 6° T.

No. 89. *White Discharge (Block)*.—The above colour a little thinner.

No. 90. *Black for Turkey Red*.—7 gallons logwood liquor at 8° T., 1 gallon pyro-ligneous acid, 10 lbs. starch; boil and add 2 lbs. 10 oz. copperas; boil again and cool, then add $3\frac{1}{2}$ pints pernitrate of iron at 80° T., and 1 gallon of blue paste.

No. 91. *Blue Paste*.—(a) 6 lbs. copperas, 2 quarts water; dissolve: (b) 4 lbs. prussiate of potash, 1 gallon of water; dissolve. Mix a and b together, and add 1 quart standard red liquor No. 8, 1 quart nitric acid 60° T.

No. 92. *Yellow Discharge (Block)*.—1 gallon lime juice at 50° T., 4 lbs. tartaric acid, 4 lbs. nitrate of lead; dissolve, thicken with 6 lbs. pipe-clay, and 3 lbs. gum-Senegal.

No. 93. *Yellow Discharge (Machine)*.—Thicken the above with $1\frac{1}{2}$ lb. starch, instead of the pipe-clay and gum.

No. 94. *Yellow Discharge (Machine)*.—1 gallon lime juice at 40° T., $4\frac{1}{2}$ lbs. tartaric acid, 5 lbs. white acetate of lead, $1\frac{1}{2}$ lb. starch; boil and cool, then add 1 lb. 14 oz. nitric acid at 60°

No. 95. *Blue Discharge (Machine)*.—(a) 1 lb. Prussian blue, 1 lb. oxalic acid, 1 quart hot water; grind well together, and leave to react on each other 24 hours; then (b) 3 quarts of water, $1\frac{1}{4}$ lb. starch; boil, and add 2 lbs. tartaric acid, and mix a and b together.

No. 96. *Green Discharge (Machine)*.— $1\frac{1}{2}$ gallon No. 95 blue, 1 gallon No. 94 yellow.

Process:—Print in any of the above colours, and as soon as dry from the machine, put through the decolouring vat.

(No. 9.) *Decolouring Vat*.—1,000 gallons of water, 1,000 lbs. chloride of lime; rake well up, till quite smooth and free from lumps, then immerse a frame with rollers top and bottom, as in dipping greens, &c.; keep the vat stirred up so as to be milky, and run the pieces through at the rate of 1 piece of 28 yards in 3 minutes; on leaving the squeezing rollers, conduct into water and rinse, then wince 10 minutes in bichromate of potash at 4° T.; wash and wince in very dilute muriatic acid; wash well and dry.

In this style, such is the permanence of the Turkey-red dye, that it is not much altered by passing through chloride of lime, whilst in the parts printed in the discharge colours an instantaneous disengagement of chlorine takes place, which decolorises the dyed ground, and where a mineral colour or mordant formed part of the discharge, it is left in place of the red dye. This style was invented in 1811 by M. D. Kœchlin, and patented in England by Mr. James Thompson, of Primrose, who printed immense quantities of it.

The Bandanna printing, being a business of itself, is more fitly described in another place. (See BANDANNA.)

Eighth Style: Steam Colours.

The printing of steam colours may be considered as a mode of dyeing at one operation, for in most cases one or more mordants are mixed with dye-wood decoctions, and printed on the cloth, the subsequent steaming causing the mordant to combine with the colouring matter, and both with the cloth. Steam colours in some cases are made so as to produce a fair colour when printed on ordinary white calico: but much superior colours are produced by mordanting the cloth first, so as to fix peroxide of tin in the fibre; and as this is the almost universal rule, it is this sort of steam printing alone that will be described. Woollen fabrics, indeed, require a good preparation by tin, &c. before lively and substantial colours can be fixed on them by steam.

The following is the mode of preparing calicoes for steam colours:—

Pad the pieces stitched together, in a padding machine with wooden bowls, through a solution of stannate of soda at 10° T. twice over, letting them lie wet an hour between; immediately after padding the second time, run through a cistern with rollers, containing dilute sulphuric acid at 1½° to 3° T., thence into a pit of water, wince well, and run through a washing-machine. It has been observed by Mr. James Chadwick, that if the cloth, with oxide of tin newly precipitated on it, is subjected to any severe washing, it loses a considerable quantity of oxide, so that no more washing must be given at this stage than will remove the free sulphuric acid. It appears that the cloth, once dried with the oxide in it, does not part with the oxide again by severe washing. After washing, the pieces are unstitched, and put into the hydro-extractor, then dried gently over the steam cylinders, and are then ready for printing.

The following list of steam colours comprises the usual variety of shades printed on calico:—

No. 97. *Steam Black (Machine)*.—1 gallon logwood liquor at 12° T., 1 quart gall liquor at 9° T., 1 quart mordant, 2 lbs. flour, 6 oz. starch; boil ten minutes, and add ½ pint nitrate of iron.

Steam Black Mordant.—1 quart acetic acid, 1½ quart acetate of copper at 3° T., 1½ quart iron liquor at 24° T., 1 quart red liquor at 20° T.

No. 98. *Chocolate (Machine)*.—3 gallons logwood liquor at 12° T., 2 gallons Sapan liquor at 12° T., 1 gallon nitrate of alumina, ½ gallon bark liquor at 12° T., 4 gallons water, 17 lbs. starch; boil, and add 8 oz. chloride of potash, 2½ lbs. red prussiate.

No. 99. *Dark Blue (Machine)*.—7 gallons water, 14 lbs. starch, 2¾ lbs. sal-ammoniac; boil, and add whilst hot 12 lbs. yellow prussiate of potash in powder, 6 lbs. red prussiate of potash, 6 lbs. tartaric acid, and when nearly cold, 1 lb. sulphuric acid (specific gravity, 1·85), 1 lb. oxalic acid dissolved in 2 quarts hot water, and 6 gallons prussiate-of-tin pulp.

No. 100. *Dark Blue*.—8 quarts water, 4 lbs. yellow prussiate of potash, 3 lbs. pale British gum; boil, and add 1 lb. bisulphate of potash, 2 lbs. muriate of ammonia, 8 oz. alum, 4 oz. oxalic acid, 4 oz. sulphuric acid at 170° T., 4 quarts tin pulp No. 103.

No. 101. *Cinnamon*.—1 quart cochineal liquor at 8° T., 1 quart logwood liquor at 8° T., 1 quart berry liquor at 10° T., 6 oz. alum, 4 oz. cream of tartar, 8 oz. starch; boil, and whilst warm add 3 oz. muriate of-tin-crystals.

No. 102. *Orange*.—12 lbs. annatto, 1 gallon caustic soda at 70° T., 5 gallons water; boil 20 minutes, strain, and add 3 quarts red mordant No. 198, 6 lbs. alum; heat till clear, and add 4 gallons thick gum-substitute water.

No. 103. *Tin Pulp*.—To protochloride-of-tin solution add as much yellow prussiate

of potash in solution as will precipitate all the tin as ferroproussiato; this is washed by decantation, and filtered to a stiff paste.

No. 104. *Light Blue for Machine*.—1 gallon dark blue No. 99, 3 gallons 4-lb. gum-substitute water.

No. 105. *Green (Machine)*.—7 gallons Persian-berry liquor, at 12° T., 15 lbs. yellow proussiato of potash, 8 lbs. alum, 28 lbs. gum-substitute; boil, and add 2 lbs. muriate of tin crystals, 2 lbs. oxalic acid.

No. 106. *Pink (Machine)*.—4 gallons cochineal liquor at 6° T., 2 lbs. alum, 2 lbs. bi-tartrate of potash, 8 oz. oxalic acid, 4 gallons thick gum-Senegal water.

No. 107. *Purple (Machine)*.—2 gallons logwood liquor, at 12° T., 12 oz. alum, 8 oz. red proussiato of potash, 4 oz. oxalic acid, 8 gallons gum-substitute water. If for block, add 12 gallons gum-water instead of 8 gallons.

No. 108. *Dark Red (Machine)*.—8 quarts Sapan liquor at 12° T., 2 quarts bark liquor at 8° T., 2 quarts nitrate of alumina No. 109, 6½ lbs. starch, 1 lb. gum-substitute, 4 quarts water, 4 oz. chlorate of potash, 12 oz. alum.

No. 109. *Nitrate of Alumina*.—8 gallons boiling water, 24 lbs. nitrate-of-lead crystals, 24 lbs. alum, 5 lbs. carbonate-of-soda crystals; let settle, and use the clear.

No. 110. *Blue Standard*.—1 gallon water, 12 oz. alum, 4½ oz. oxalic acid, 1¾ lb. yellow proussiato of potash, 1 gallon gum-substitute water.

No. 111. *Lavender Liquor*.—2 gallons red liquor at 18° T., 6 lbs. ground logwood; let steep for 48 hours, then strain off the liquor.

No. 112. *Lavender*.—4 gallons lavender liquor No. 111, 5 gallons blue standard No. 110, from 24 to 48 gallons gum-water, according to shade wanted.

No. 113. *Drab*.—4 gallons lavender liquor, 4 gallons blue standard, 1 gallon bark liquor at 8° T., from 40 to 70 gallons gum-water, according to shade wanted.

No. 114. *Stone*.—4 gallons lavender liquor No. 111, 6 gallons blue standard No. 110, 1 gallon bark liquor at 120° T., reduced same as drab.

No. 115. *Sage Greens for Blotch Grounds*.—2 gallons yellow No. 118, 2 gallons blue standard No. 110, from 28 to 56 gallons gum-water, according to shade wanted.

No. 116. *Yellow*.—4 gallons berry liquor at 12° T., 1½ lb. alum.

No. 117. *Brown Standard*.—14 quarts bark liquor at 12° T., 3½ quarts Sapan liquor at 12° T., 1½ quart logwood liquor at 12° T., 12 quarts 8-lb. gum-substitute water, 3½ lbs. alum, 2 oz. chlorate of potash, 5 oz. red proussiato. All shades of light browns are made from this by reducing with gum-substitute water, according to shade wanted.

No. 118. *Yellow*.—4 gallons bark at 8° T., 2 quarts red liquor at 18° T., 2 quarts nitrate of alumina No. 109, 12 oz. tin crystals, 5 lbs. starch.

No. 119. *Green for Block*.—28 lbs. yellow proussiato of potash, 6 gallons hot water; in a separate vessel 10 gallons 6-lb. gum-Senegal water, 2 gallons water, 1 gallon muriate of tin at 120° T.; mix the proussiato solution with the tin and gum by pouring one into the other, and violently agitating; when quite fine and free from flocculent matter, add 12 gallons berry liquor at 10° T., then add 12 lbs. and 2½ lbs. oxalic acid dissolved in 5 gallons water, then 3 quarts acetic acid, and 2½ gills extract of indigo.

No. 120. *Brown*.—6 quarts berry liquor at 20° T., 6 quarts Brazil-wood liquor at 8° T., 3 lbs. alum, 3 quarts lavender liquor, 6 quarts 6-lb. gum-Senegal water, 24 oz. nitrate of copper at 100° T.

Printing with pigment colours, and fixing them by steaming was formerly a separate style; but owing to the introduction of aniline colours and madder extracts, goods are now printed so frequently with all these classes of colours at once, that it is useless to separate them. In printing pigments the ordinary pigments, such as used in oil painting, are mechanically attached to the cloth by a species of cementing. The first fixing vehicle used was a solution of caoutchouc in naphtha, which was mixed with the pigment so as to make colours of sufficient viscosity to print. The naphtha was then driven off by steaming, and the pigment was then cemented to the cloth by a film of caoutchouc. This method makes very fast colours, not affected by soaping and moderate friction; but, unfortunately, the naphtha volatilising during the printing process, rendered the use of it too dangerous, and after it was found that explosions of the naphtha vapour frequently took place, calico printers turned their attention to some other fixing vehicle. Animal substances, of which the white of eggs is the type, and which, soluble in water, are coagulated by heat, are now usually employed. Of these, four may be particularised:—Albumen of eggs; blood albumen, or dried serum of blood; lactarine, and gluten. The first is made by simply drying gently the white of eggs into flakes. The second is the serum of blood dried in the same manner. The third is made by separating the solid part of buttermilk, purifying it from butter and free acid, and drying it. The fourth is the residue of starch-making from wheat-flour by the simple washing process, the gluten being gently dried.

The latter two thickeners require a small quantity of alkali to bring them in solution; they then resemble albumen in their power of coagulating by heat. There are few colours of this style printed, chiefly ultramarine blue, carbon drab, and sienna-and-umber-browns; examples of these will be found further on.

The invention of aniline colours, commencing with the discovery of mauve in 1856 by W. H. Perkin, followed soon after by that of fuchsine or magenta, by Verguin, and subsequently by the production from aniline of a vast quantity of beautiful colours, has almost revolutionised steam-printing. These colours being of extraordinary purity and brilliancy, and in some cases being as fast to light as the colours above described, are now universally employed, to the almost extinction of the old dyewood, &c., colours. In conjunction with the chrome green of Guignet and the various colours obtained from extracts of madder and artificial alizarine, most exquisite prints are now produced, where the genius of the designer, being no longer checked by the exigencies of the printer who, to make reds, purples, and chocolates fast to soap was compelled to dye them with madder, and thus make a break between the printing of these and their illumination by steam colours subsequently, has now full play, and a great variety of colours being printed at one operation, and all raised or fixed together afterwards; patterns of great delicacy of execution and beauty of colouring can be produced solid and fast to soap, which it was perfectly impossible to do before the introduction of these colours. It may therefore be confidently affirmed that the introduction of madder extract has directly tended to make a marked improvement in the artistic taste applied to calico-printing. The shades of colour produced from aniline colours, madder extracts, and pigments are infinite. It will only be within the scope of this work to give a selection which will illustrate the principles upon which they are made.

No. 121. *Magenta Standard*.— $1\frac{1}{4}$ lb. magenta crystals, 4 gallons methylated spirit 2 gallons water.

No. 122. *Gum-tragacanth Water*.—1 gallon water, 10 oz. gum-tragacanth; boil 6 hours or till quite smooth, and make the bulk up to 1 gallon.

No. 123. *Egg-albumen-solution*.—1 gallon of cold water, 8 lbs. of egg-albumen; stir till dissolved, and strain.

No. 124. *Blood-albumen-solution*.—1 gallon cold water, 8 lbs. blood-albumen; stir till dissolved, and strain.

No. 125. No. 45 *Magenta Paste* (for dark magenta).—2 quarts water, 2 lbs. fine wheat flour, 1 lb. of white British gum (slightly roasted wheat starch), 45 oz. measure of No. 121; boil well, cool, and add 2 quarts of No. 123.

No. 126. No. 35 *Magenta paste* (for dark magenta).—The same as No. 125, but 35 oz. measure of No. 121.

No. 127. No. 20 *Magenta gum* (for medium shade).—2 quarts of No. 122, 2 quarts of No. 123, 20 oz. measure of No. 121.

No. 128. No. 10 *Magenta gum* (for pale shade).—The same as No. 127, but 10 oz. measure of No. 121.

No. 129. No. 4 *Magenta gum* (for padding or 'blotching').—The same as No. 127, but 4 oz. measure of No. 121.

No. 130. *Dark Mauve paste*.—2 lbs. wheat flour, 1 lb. white British gum, 1 quart of water, 100 oz. measure of strong solution of mauve crystals in spirit; boil well, cool, and add 1 quart of No. 123.

No. 131. *Medium shade Mauve paste*.— $1\frac{1}{2}$ lb. wheat flour, $\frac{3}{4}$ lb. white British gum, 1 quart of water, 60 oz. measure mauve solution as No. 130; boil well, cool, and add 1 quart of No. 123.

No. 132. No. 20 *Pale Mauve* (for dark and pale mauve).—2 quarts of No. 122, 2 quarts of No. 124, 20 oz. measure mauve solution as No. 130.

No. 133. No. 10 *Pale Mauve* (for a third shade).—2 quarts of No. 122, 2 quarts of No. 124, 10 oz. measure mauve solution as No. 130.

Mauves with glycerine, arsenious acid, and acetate-of-alumina fixing. In these colours there is no action until the goods are steamed, when arsenite of alumina is formed in an insoluble state in the cloth and the mauve remains united with this mordant.

No. 134. *Glycerine and arsenious-acid solution*.—1 gallon of glycerine, 4 lbs. arsenious acid; boil well till dissolved.

No. 135. *Acetate of alumina*.—1 gallon of water, 3 lbs. of alum, $2\frac{1}{2}$ lbs. acetate-of-soda crystals.

No. 136. *Mauve-reducing paste*.—2 gallons of water, 3 gallons of No. 135, 1 gallon of No. 122, 6 lbs. wheat starch; boil, cool, and add gradually 2 quarts of No. 134.

No. 137. *Dark Mauve*.—5 lbs. starch, 5 quarts water, 3 quarts of No. 122, 1 quart of vinegar, $\frac{1}{4}$ lb. mauve crystals; boil, cool, and add when cooling 5 quarts of No. 135, and when cold $2\frac{1}{2}$ pints No. 134.

No. 138.—For pale or medium shades, dilute No. 137 with No. 136 to the required shade.

- No. 139. *Dark Cochineal Red*.—1 gallon of cochineal liquor at 6° T., 1½ lb. starch; boil, cool, and add 3 oz. muriate-of-tin crystals, 2 oz. oxalic acid.
- No. 140. *Scarlet*.—5 lbs. starch, 3 gallons cochineal liquor at 7° T., 2 quarts Persian-berry liquor at 12° T.; boil and add ¾ lb. binxalate of potash, dissolve, and add when nearly cold ¾ lb. muriate-of-tin crystals, cool, and add 1 gallon of No. 141.
- No. 141. *Peroxide-of-Tin Pulp*.—6 gallons of water, 30 oz. measure strong ammonia liquor, 1½ quart oxychloride-of-tin solution at 120° T., mix well, wash by decantation 3 times, and filter to a stiff pulp.
- No. 142. *Drab*.—1 gallon of water, 8 oz. ultramarine, 4 oz. lamp-black, beat up fine, and add 1½ gallon of No. 124, 1½ gallon of No. 122.
- No. 143. *Carbon Drab*.—8 lbs. lamp-black, 1 gallon of acetic acid at 8° T.; mix well together, and add 1 gallon of No. 124, and 1 gallon of No. 122.
- No. 144. *Ultramarine Blue with Lactarine*.—1½ lb. lactarine, 3½ pints water; mix well, and add 2½ oz. measure liquid ammonia specific gravity 880, 5 oz. measure caustic soda at 32° T.; then having beaten up 3 lbs. ultramarine with 1½ pint water, mix with the lactarine solution.
- No. 145. *Ultramarine Blue with Gluten*.—6 lbs. ultramarine, 5 quarts water; mix, and add gradually 3½ lbs. ground gluten; let it stand a few minutes, then add 1 quart caustic soda at 16° T.; mix well, and let stand a few hours before using.
- No. 146. (No. 4.) *Ultramarine Blue with Albumen*.—4 lbs. ultramarine, 1 quart of water, 1 quart of No. 122, 2 quarts of 123.
- No. 147. (No. 3.) *Ultramarine Blue*.—As No. 146, but 3 lbs. ultramarine.
- No. 148. (No. 2.) *Ultramarine Blue*.—As No. 146, but 2 lbs. ultramarine.
- No. 149. *Guignet's Green Standard*.—13 lbs. Guignet's green in paste, 1 gallon of No. 150, grind in a mill till quite fine.
- No. 150. 3 lbs. *Albumen-Solution*.—1 gallon of water, 3 lbs. of blood-albumen, stir till dissolved.
- No. 151. (No. 2.) *Dark Green*.—2 gallons of No. 149, 1 gallon No. 150.
- No. 152. (No. 2.) *Green*.—1 gallon of No. 149, 2 gallons of No. 150.
- No. 153. (No. 14.) *Pale Green for Padding*.—1 gallon of No. 149, 10 gallons of No. 150, 4 gallons of water.
- No. 154. *Dark Brown*.—26 oz. burnt sienna in paste, 2½ quarts of No. 122, 1 pint of water, 2 quarts of No. 124.
- No. 155. *Medium Brown*.—The same as with No. 154, but 12 oz. of burnt-sienna paste.
- No. 156. *Pale Brown for Padding*.—1½ oz. burnt-sienna paste, 3 pints of water, 1 pint of No. 22, 2 quarts of No. 124.
- No. 157. *Orange*.—5 lbs. pigment orange (dichromate of lead in paste), 2 quarts of No. 122, 2 quarts of No. 124.
- No. 158. *Drab*.—20 oz. of burnt-sienna paste, 14 oz. of ultramarine, 1 quart of water, 6 quarts of No. 122, 6 quarts of No. 124.
- No. 159. *Drab for Padding*.—8 oz. of ultramarine, 8 oz. burnt-sienna paste, 16 oz. yellow ochre in paste, 7 gallons No. 124, 1 gallon of No. 122, 6 gallons of water.
- No. 160. *Black for Printing with Aniline Colours*.—5 gallons of logwood liquor at 12° T., 1 gallon of quercitron-bark liquor at 12° T., 1½ gallon of acetic acid at 8° T., 14 lbs. starch, 3 lbs. delaine gum, boil, and add 1½ lb. chlorate of potash dissolved in 5 quarts of hot water, cool, and add 4 quarts of No. 161.
- No. 161. *Nitro-acetate of Chromium*.—6 gallons of water, 12 lbs. of bichromate of potash, 16 lbs. sulphuric acid diluted with 3 quarts of water, add by degrees 2 lbs. brown sugar, and when the effervescence has ceased, and 19½ lbs. of nitrate of lead and 19½ lbs. of acetate of lead dissolved in 1 gallon of water, let settle, and use the clear liquor.
- No. 162. *Dark Red from Extract of Madder containing Acetate of Lime*.—8 lbs. extract of madder, 4 lbs. acetic acid, 1½ lb. starch, boil in a pot immersed in a water-bath, when cold add ½th of its bulk of No. 163.
- No. 163. *Acetate of Alumina*.—1 gallon of water, 4 lbs. of alum, 4 lbs. acetate of lead, stir till dissolved, let settle, and use the clear liquor.
- No. 164. *Pale Reds from the above description of Extract of Madder*.—4 lbs. of extract, 2 lbs. acetic acid, 6, 8, or 10 quarts of gum-gedda-solution at 4 lbs. per gallon, 1 pint of No. 163.
- No. 165. *Dark Red from Extract of Madder not containing Acetate of Lime*.—10 lbs. extract of madder, 2 quarts of acetic acid at 12° T., 6 quarts of starch paste at 2 lbs. per gallon, 1 pint of No. 122, 1½ quart olive oil, 1½ quart of No. 163, 1 pint of acetate-of-lime solution at 28° T.
- No. 166. *Reducing Paste for Pale Reds (Extract without Acetate of Lime)*.—7 pints of water, 1 pint of No. 122, 1 pint of acetic acid, 2 lbs. starch, boil and cool.
- No. 167. *Pale Reds from No. 165*.—1 gallon of No. 165, 4 to 6 gallons of No. 166.

No. 168. *Dark Red with artificial Alizarine.*—1 lb. of No. 169, 7 lbs. wheat starch, 2½ lbs. acetic acid at 8° T., 12 lbs artificial alizarine of 10 per cent. strength, 5 quarts of acetate-of-lime solution at 18° T., 2 gallons of water, 2 quarts olive oil, boil well, cool, and add 2½ gallons of No. 163 reduced to 11° T.

No 169. 1 gallon of water, 1 lb. gum-tragacanth, boil till dissolved, and add water to make up to 1 gallon.

No. 170. *Dark Red with artificial Alizarine.*—1 quart of 10 per cent. alizarine, 15 oz. measure acetic acid 12° T., 3½ pints of starch paste at 2 lbs. per gallon, ½ pint of acetate-of-lime-solution at 20° T., 12½ oz. measure of No. 163, ½ pint of olive oil.

No. 171. *Pale Red from artificial Alizarine.*—2¾ quarts of 10 per cent. alizarine of Meister, Lucius and Brünnig, 1½ quart of acetic acid at 12° T., 8¼ quarts of starch paste at 2 lbs. per gallon, 1 quart of acetate-of-lime solution at 20° T., 1¼ quart of No. 163, 1½ quart of olive oil.

No. 172. *Purple with artificial Alizarine.*—2 lbs. of artificial alizarine as in No. 171, 1 pint acetic acid at 8° T., 3½ quarts gum-gedda solution at 4 lbs. per gallon, ½ pint of pyrolignite of iron liquor at 10° T., 2½ oz. measure of acetate-of-lime solution at 20° T.

Madder Extract Chocolate.—M. Horace Koechlin discovered that oxide of chromium gave with madder extract a beautiful chocolate colour: an addition of solution of acetate of chromium to any soiled madder-extract red colour left after printing, converts this latter into a very good chocolate, and is a good way of utilizing dirty colour, too valuable to throw away. A good chocolate may also be made by mixing madder-extract red with the chrome black No. 160, for instance 6 of old madder-extract red and 1 of chrome black.

After printing, the pieces are hung up for some time to equalise their temperature, and are then steamed.

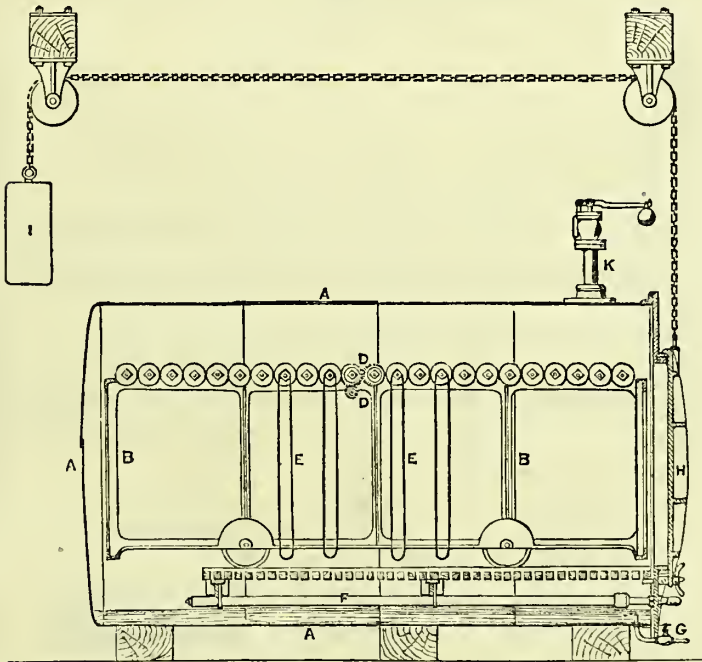

There are two methods of steaming now commonly employed—the column and the chest. The column is a hollow cylinder of copper, from 3 to 5 inches in diameter, and about 44 inches long, perforated over its whole surface with holes of about $\frac{1}{16}$ th of an inch, placed about $\frac{1}{4}$ of an inch asunder. A circular plate, about 9 inches diameter, is soldered to the lower end of the column, destined to prevent the coil of cloth from sliding down off the cylinder. The lower end of the column terminates in a pipe, mounted with a stopcock for regulating the admission of steam from the main steam boiler of the factory. In some cases, the pipe fixed to the lower surface of the disc is made tapering, and fits into a conical socket, in a strong iron or copper box, fixed to a solid pedestal; the steam-pipe enters into one side of that box, and is provided, of course, with a stopcock. The condensed water of the column falls down into that chest, and may be let off by a descending tube and a stopcock. In other forms of the column, the conical junction pipe is at its top, and fits there into an inverted socket connected with a steam chest, while the bottom has a very small tubular outlet, so that the steam may be exposed to a certain pressure in the column when it is encased with cloth.

The pieces are lapped round this column, but not in immediate contact with it; for the copper cylinder is first enveloped in a few coils of blanket stuff, then with several coils of white calico, next with the several pieces of the printed goods, stitched end-wise, and lastly, with an outward mantle of white calico. In the course of the lapping and unlapping of such a length of webs, the cylinder is laid in a horizontal frame, in which it is made to revolve. In the act of steaming, however, it is fixed upright, by one of the methods above described. The steaming lasts for 20 or 30 minutes according to the nature of the dyes; those which contain much solution of tin admit of less steaming. Whenever the steam is shut off, the goods must be immediately uncoiled, to prevent the chance of any aqueous condensation. The unrolled pieces are free from damp, and require only to be exposed for a few minutes in the air to appear perfectly dry. Were water condensed during the process, it would be apt to make the colours run.

The other method of steaming, and the one now most generally employed, is that of the chest. This is an iron chamber generally now of cylindrical shape, as being the strongest form. This cylinder is about 10 feet long and 8 feet wide, fixed horizontally. It is closed at one end, the other is provided with strong closely-fitting folding doors, or with a strong door suspended from pullies, and balanced with a heavy weight. In either case the doors are fitted with iron screws, so that they can be screwed close to the cylinder and thus rendered steam-tight. There is a second roof inside the cylinder, which receives any drops of condensed water, and carries them past the pieces at the sides. There is a perforated false bottom, underneath which is a perforated steam-pipe, laid from end to end of the chest; this pipe admits the steam, which is further diffused by the holes in the false bottom. On the false bottom is laid

a pair of rails parallel with the sides of the chest; these rails are continued outside the chest into the room, the parts next the chest for about 3 feet being hinged so as to be moved on one side when the doors are opened or shut. Upon the rails moves a rectangular frame of iron which just fits inside the chest, and stands as high as the entrance to the chest will admit, generally about 6 feet high by 4 feet wide. This frame, when drawn out into the room, is filled with pieces in the following manner:— They are first wound on an open reel, one by one, the selvages of each fold being kept as parallel as possible. The piece is then slid off the end of the reel, pulled flat, and a needle and thread passed through all the selvages of one side, and loops made, through which are passed wooden rods, which rest on the sides of the carriage, or they are wound on the reel and suspended on a thin wooden rod covered with calico, which rod is supported at the ends upon the sides of the wooden frame. Generally a grey piece is wound on the reel along with the printed piece on the face side, this is to prevent the colours marking off on the white parts. The piece being thus suspended with selvages downwards, the carriage being filled with the rods, is run into the chest,

386

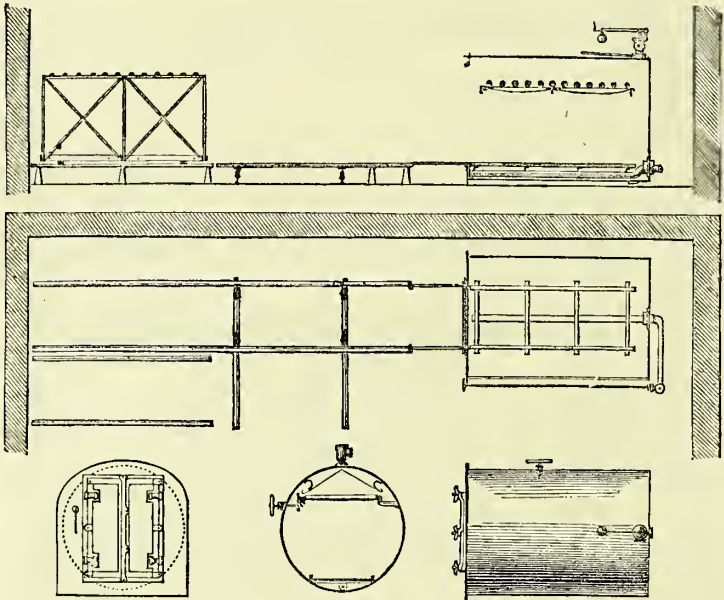

the doors firmly shut, and steam turned on, the steam escaping by a safety valve. They hang thus for 45 minutes, are taken out, unfolded, and loosely folded for washing off. They are next stitched end to end, and passed through a cistern with water, from that into a cistern containing a very weak solution of bichromate of potash; they are then put into a washing machine, hydro-extracted, starched, and dried.

Fig. 386 is a section of Mather and Platt's steaming chest: A, the body; made cylindrical of wrought-iron plates; B, carriage fitted with square wooden rollers, all geared together by spur wheels, worked by a handle passing through a stuffing box on the outside of the cylinder; C, square wooden rollers; D, handle and wheels; E, cloth hanging on the rollers; F, perforated steam-pipe; G, tap and pipe for running off condensed water; H, moveable door, arranged to be suspended by a chain, &c.; I, balance weight for door; K, safety valve. *Fig. 387*, for which we are indebted to Mr. Furnival, shows a chest fitted with folding doors, the arrangement of the interior roof, the stuffing-box and handle, and the railway arrangement for running the carriage in and out of the cylinder, and also the double line for allowing one carriage to be filled whilst another is in the steam-chest, and thus avoid loss of time in filling and emptying.

The arrangement of moveable square wooden rollers is to allow of the roll of pieces placed upon these rollers being occasionally turned part round, so that they may be uniformly steamed, which would not be the case if the same part were always resting on the wooden roller.

Colours fixed by steaming are either pigments insoluble in water, cemented to the cloth by the coagulation of the albumen or other nitrogenous vehicle with which they are mixed, or, as in the case of aniline colours, this coagulum becomes itself a mordant and at the time of coagulation and adherence to the fibre carries with it the colour in chemical union; or, as in the case of dyewood and cochineal colours, these may be described as coloured lakes temporarily held in solution by acids, and during the steaming, the cloth gradually withdraws these lakes from solution, the acid being either dissipated or so modified as to be incapable of holding the lakes dissolved. The state of the steam is an important matter. It is not the heat alone that produces the effect; for it may easily be demonstrated that heating cloth, when printed and *dried*, has no effect whatever. The steam, to be effective, must be as saturated with moisture as possible, and for this reason the steaming apparatus should never be near the boiler: it is no disadvantage for the steam to travel a considerable distance before

387

being applied. In some print-works the steam is made to pass through water in a vessel placed below the steam-chest, so that it arrives in the chest perfectly saturated with water. At the same time, the steam must not be of so low tension as to cause a deposit of moisture on the pieces, which would be very injurious, by causing the colours to run or mix. Steam-blue depends for its fixation on the decomposition of ferrocyanic acid by the high temperature and presence of vapour of water into white insoluble ferrocyanide of iron and potassium, which, by acquiring oxygen from the air or during the washing-off, becomes Prussian blue. The shade of it is much modified by the oxide of tin in the cloth and the prussiate of tin that forms part of the colour. It appears that tin substitutes iron, forming a compound ferrocyanide of tin and iron, or a ferro-stanno-cyanide of iron, which is of a deep violet-blue colour. Greens are mixtures of yellow lakes with the Prussian blue, formed by decomposition. In both these colours there is a large quantity of hydrocyanic acid disengaged during the steaming; steam being decomposed, its hydrogen going to form hydrocyanic acid.

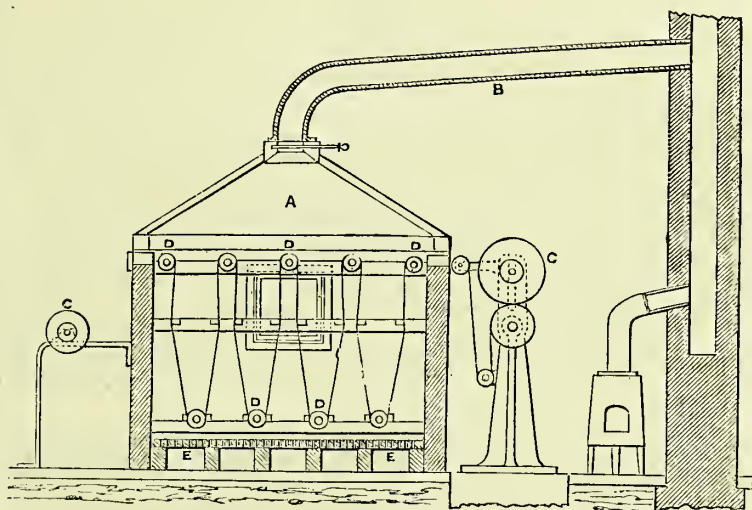

Madder-extract and alizarine colours require more care in steaming than ordinary dyewood colours. The steam-chest should be fitted with a manometer to indicate the pressure of the steam inside the chest. The steam at first should only be about 3 lbs.

pressure, and after one hour the pressure increased, until at last a pressure of about 7 lbs. is given.

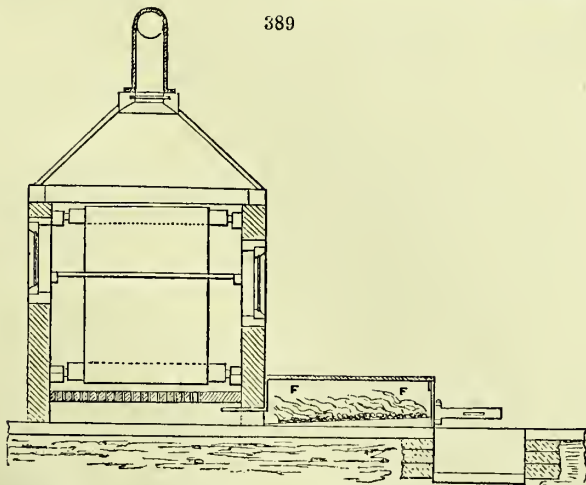

Mousseline-de-laines are treated somewhat in the same manner, the preparation of the cloth being different, and the colours are made in such a manner as to fix equally on both the wool and the cotton of the fabric. The steaming and washing-off are nearly the same as for calicoes. The following is the method in detail:—

The cloth is first well bleached and sulphured. This operation is usually performed by hanging the goods in a close stone or brick chamber. Trays of sulphur being lighted, the door is closed tight, and the pieces stay in the sulphurous gas for several hours, and are then removed and washed. An improvement on this method was patented by John Thom, and is here shown.

388

389

Thom's Sulphuring Apparatus.—Fig. 388. A is the roof, made of sheet lead, 4 lbs. to the foot. B is a lead pipe, of one inch diameter, taking off the excess of sulphurous acid to the flue, c and c are rolls of pieces, going in on one side and coming off at the other. D and D, rollers of wood, three inches in diameter, with iron centres at the ends. E and E, tiles, as in malt kilns, to let the gas pass up through to the cloth.

Fig. 389 shows the chamber: it is six feet in length by four feet in breadth, and about

five feet high. There are two windows, which are placed opposite each other. F is a cast-iron tray for burning the sulphur. It is placed on a flag, inclining towards the chamber at about one inch to a foot. It is furnished with a slide, on which to put the sulphur to be pushed in, and to admit what air may be wanted. The space for air may be from half an inch to an inch wide. It costs 18*l.* to 20*l.*

Preparation.—Pad the pieces, previously well bleached in a wooden padding machine through stannate of soda at 10° twice over, then pass through a cistern with rollers, containing dilute sulphuric acid at 3° T., wash gently, and partially dry, then pad through sulphomuriate of tin at 4° T. twice.

No 173. *Sulphomuriate of Tin.*—3 quarts muriate of tin at 120° T., 1 quart sulphuric acid at 170° T., mixed together gradually, and 4 quarts muriatic acid added; reduce to 4° T.

Run from this without washing into a large cistern with rollers, containing dilute chloride of lime at $\frac{1}{2}^{\circ}$ T., then wash, put in the hydro-extractor, and dry. When wanted for printing, pad through gum-Senegal water at 8 oz. to the gallon, and dry. After printing they are hung the same as calicoes to equalise the temperature, then hung in the steam-chest in the same manner as calicoes, and steamed 45 minutes. After steaming, they are unrolled and loosely folded for washing-off, which is done by wincing over a reel in a pit of water gently for $\frac{1}{4}$ of an hour, then transferred to a washing-machine or large automatic wince reel, and washed till no more coloured liquor comes away, then hydro-extracted, and dried over the steam cylinders. After drying, it is found advantageous to hang the pieces in a cool room, with covered shutter sides, for a day or two, so that they may imbibe a little moisture, and the colours appear richer. The wool in mousseline-de-laines is apt to be partially decomposed during steaming, and sulphuretted hydrogen liberated, which decomposes the metallic salts, such as nitrate of copper, used in some colours, and produces a very disagreeable effect, termed *silvering*. To avoid this, it is now customary to wind on the reel for steaming, at the same time as the printed piece, a grey or unbleached piece, which has been padded in a weak solution of acetate of lead, and dried. By this means the printed piece is steamed in contact with the prepared piece, and any sulphuretted hydrogen that may be disengaged is immediately absorbed by the acetate of lead.

The following are the colours used in mousseline-de-laine printing:—

No. 174. *Dark Red.*—4 gallons cochineal liquor at 10° T., 7 lbs. starch; boil, and when cooled to 180° F., add $1\frac{1}{4}$ lb. oxalic acid, and when this is dissolved, $1\frac{1}{4}$ lb. muriate-of-tin crystals.

No. 175. *Chocolate.*—6 gallons Sapan liquor at 12° T., 2 gallons logwood liquor at 12° T., 1 gallon bark liquor at 12° T., 16 lbs. starch; boil, and add $5\frac{3}{4}$ lbs. alum, 12 oz. chlorate of potash, $4\frac{1}{2}$ lbs. red prussiate of potash.

No. 176. *Yellow.*—4 gallons berry liquor at 10° T., $5\frac{1}{4}$ lbs. starch, 1 lb. pale British gum; boil, and add $1\frac{3}{4}$ lb. muriate-of-tin crystals.

No. 177. *Dark or Royal Blue.*—6 gallons water, $6\frac{1}{2}$ lbs. starch, $2\frac{1}{4}$ lbs. sal-ammoniac; boil well, and add 6 gallons tin pulp No. 103; mix well into the paste, and add 16 lbs. pounded yellow prussiate of potash, 8 lbs. red prussiate, 24 lbs. tartaric acid, and $1\frac{1}{2}$ lb. oxalic acid previously dissolved in 4 pints hot water.

No. 178. *Pale Blues* are made from the dark blue No. 177, by reducing with gum-substitute water; say 1 of dark blue and seven of gum-water for pale blue, for two blues, and 1 of dark blue and 14 of gum-water for blotch or ground blue.

No. 179. *Green.*—4 gallons berry or bark liquor at 12° T., 3 lbs. alum, 6 lbs. starch; boil, and add 6 lbs. powdered yellow prussiate of potash, 1 lb. muriate-of-tin crystals, 1 lb. oxalic acid, and $2\frac{3}{4}$ pints extract of indigo.

No. 180. *Pale Green.*—3 quarts berry liquor at 6° T., $1\frac{3}{4}$ lb. yellow prussiate of potash, $9\frac{1}{2}$ oz. alum, $\frac{3}{4}$ pint acetic acid, 16 quarts 4 lbs. gum-Senegal water, 8 oz. weight muriate-of-tin liquor at 12° T., $\frac{3}{4}$ pint extract of indigo.

No. 181. *Dark Brown.*— $2\frac{1}{2}$ quarts Sapan liquor at 8° T., 1 pint logwood liquor at 12° T., 5 quarts bark liquor at 10° T., 12 oz. alum, 1 oz. chlorate of potash, 6 lbs. gum-substitute; boil, and add 4 oz. red prussiate of potash, 2 oz. oxalic acid.

No. 182. *Pale Browns* are made from the dark brown No. 181, by reducing with gum-water, say 1 to 3 or 1 to 5.

No. 183. *Pale Red.*—1 lb. fine-ground cochineal, 1 lb. liquor ammonia, specific gravity 0.88; put in a jar with tight-fitting cover, which may be luted down; keep in a warm place for 48 hours, then mix with two gallons boiling water, and simmer in a mug down to 1 gallon, then strain off, wash the cochineal with a little water, and strain again; to the liquor made up to 1 gallon add 4 oz. alum, 4 oz. muriate-of-tin crystals, 4 oz. oxalic acid, and 1 gallon 6-lb. gum-Senegal water.

No. 184. *Scarlet.*—2 gallons cochineal liquor at 12° T., 4 lb. starch; boil, and add 4 oz. oxalic acid, 4 oz. binoxalate of potash, 8 oz. pink salts (double permuriate of tin and ammonia), and 8 oz. muriate-of-tin crystals.

No. 185. *Scarlet*.—3 gallons standard No. 186, 1 quart berry liquor at 10° T., 4½ lbs. starch; boil, and add 8 oz. binxalate of potash, 8 oz. oxalic acid, 1¼ lb. pink salts, ½ pint oxymuriate of tin at 120° T.

No. 186. *Standard*.—2 lbs. fine-ground cochineal, 6 quarts water, 1 quart red liquor at 20° T., 4 oz. nitric acid, 2 oz. oxalic acid; boil 20 minutes, and strain off.

No. 187. *Medium Blue*.—6 gallons standard blue, No. 188, 1½ quart oxymuriate of tin at 120° T., added gradually, and beaten fine, then 2¼ quarts extract of indigo.

No. 188. *Standard Blue*.—10 lbs. yellow prussiate of potash, 3 lbs. alum, 2 lbs. oxalic acid, 4 gallons water, 4 gallons 6-lb. gum-water.

No. 189. *Medium Green*.—8 quarts berry liquor at 8° T., 3 lbs. yellow prussiate of potash, 1½ lb. alum, 7 quarts 6-lb. gum-water, 1 quart water, 1 quart acetic acid, 14 oz. weight muriate-of-tin liquor, 1 pint extract of indigo.

No. 190. *Lilac*.—8 quarts lavender liquor No. 191, 6 oz. oxalic acid, 2 oz. measure extract of indigo, 8 quarts 6 lbs. gum-Senegal water.

No. 191. *Lavender Liquor*.—2 gallons red liquor, 10 lbs. ground logwood; steep 12 hours, and strain off.

No. 192. *Dove*.—6 quarts blue for doves, No. 193, 4 quarts lavender liquor No. 191, 8 quarts 6-lb. gum-Senegal water.

No. 193. *Blue for Doves*.—5 quarts water, 2 lbs. yellow prussiate of potash, 2 lbs. alum, 5 quarts 6-lb. gum-water, 1 pint extract of indigo.

No. 194. *Orange*.—3 gallons berry liquor at 10° T., 9 lbs. gum-Senegal, 3 pints red mordant No. 198, 12 oz. muriate-of-tin crystals; boil 15 minutes.

No. 195. *Drab Standard*.—6 quarts purple liquor No. 196, 1 quart bark liquor at 10° T., ½ pint red liquor at 20° T., ¼ pint extract of indigo.

Drabs are made from this by reducing with gum-water, about 1 to 3.

No. 196. *Purple Liquor*.—1 gallon lavender liquor No. 191, 3 oz. oxalic acid.

No. 197. *Silver-drab Standard*.—3 quarts gall liquor at 12° T., 2 quarts standard blue No. 188, 1 quart lavender liquor No. 191.

Colours reduced with gum-water from this, 1 to 2 or 3.

No. 198.—*Red Mordant*.—1 gallon water, 6 lbs. alum, 3 lbs. white acetate of lead; stir till dissolved, let settle and use the clear.

No. 199. *Buff Standard*.—1 quart cochineal liquor at 8° T., 3½ quarts berry liquor at 10° T., 1 quart red mordant No. 198, 20 oz. oxalic acid.

Colours reduced from this with gum-water.

No. 200. *Olive*.—1 quart lavender liquor No. 191, 2 quarts berry liquor at 10° T., 2 quarts 8-lb. gum-Senegal water.

Aniline Colours for Mousseline-de-Laines.

No. 201. *Pale Magenta*.—6 oz. measure of solution of 4 oz. magenta crystals in 4 quarts methylated spirit, 3½ quarts of gum-gedda solution at 3 lbs. per gallon, 1 pint of 6-lbs. egg-albumen solution.

No. 202. *Medium Magenta*.—Same as No. 201, but 18 fluid ounces of magenta solution.

No. 203. *Pale Violet*.—6 oz. measure of Hofmann's Violet (spirituous solution), 3½ quarts of 3-lbs. gum-gedda solution, 1 pint of 6-lb. blood-albumen solution.

No. 204. *Medium Violet*.—The same as No. 203, but 18 oz. fluid of Violet solution.

No. 205. *Strong Solution*.—28 fluid oz. of Hofmann's Violet, 3½ quarts of water, 2 lb. white British gum; boil, cool, add 1 pint of 6-lb. blood-albumen solution.

No. 206. *Strong Mauve*.—8 lbs. flour, 4 lbs. white British gum, 10 quarts water, 5 quarts Mauve Standard; boil, cool, and add 6 quarts of 6-lb. blood-albumen solution.

No. 207. *Mauve Standard*.—6 oz. Brook, Simpson, and Spiller's R Violet, 2 quarts acetic acid, 2 quarts of water.

No. 208. *Pale Mauve*.—1½ gallon of 6-lb. blood-albumen solution, 3½ gallons of gum-gedda solution, 30 fluid ounces of Mauve Standard.

No. 209. *Iodine Green*.—8 quarts of 6-lb. blood-albumen, 3 quarts of gum-gedda solution, 1½ pint of glycerine arsenical solution No. 134, 1½ pint acetic acid, 1 quart of iodine green paste.

In mousseline-de-laine printing success depends more on the bleaching and preparing of the cloth than in any other style. To Mr. John Mercer is due the merit of having effected an improvement in the preparation of woollen fabrics, the importance of which can hardly be overrated. Before his discovery of the power of prepared wool to absorb chlorine, mousseline-de-laines could only be effectively printed by block, which allows a large body of colour to be laid on, and the fibre supersaturated with it. Machine colours were meagre and dull. But mousseline-de-laines prepared with tin, and then subjected to the action of chlorine gas (as in the process given above, where the acid salt of tin remaining in the cloth disengages chlorine from the chloride

of lime), have their power of absorbing and retaining colour considerably enhanced. The exact part the chlorine plays is not well known, probably a compound similar to the chloro-protein of Mulder is formed. The effect produced is not one, as might be supposed, of oxidation; but apparently a merely heightened power of the wool to assimilate colouring matter. Wool subjected to chlorine without tin is much improved in its capacity for colour, but nothing like the same when prepared with tin also. The whole of the chlorine may be removed from the cloth by passing through an alkali, which renders it necessary to give the stannate-of-soda padding previously to the chlorinating. It may fairly be assumed that the development of mousseline-de-laine printing by cylinder to the present perfection is due in a great measure to this chlorinating process. It ought also to be stated that, with rare liberality, Mr. Mercer gave the discovery to the trade, reserving for himself no right whatever.

Ninth Style: Spirit Colours.

Topical colours of great brilliancy, but possessed of very little solidity, are made somewhat like steam colours, but with much larger proportions of 'spirits,' by which term is meant the metallic salts and acids, which, combining with the dye-stuff decoctions, give the peculiar tone and vivacity to these colours. These colours, from the large admixture of these salts, are necessarily very acid, and cannot be steamed without the destruction of the cloth. They are merely gently dried after printing, and hung in the ageing room for several hours, then rinsed in water, washed, and dried.

The following are examples of spirit colours:—

No. 210. *Black*.—1 gallon logwood liquor at 8° T., 1 gallon water, 10 oz. copperas, 3 lbs. starch; boil, and add $\frac{1}{2}$ pint pernitrate of iron at 80° T.

No. 211. *Pink*.—1 gallon Sapan liquor at 8° T., 1 gallon water, 2 lbs. common salt, $\frac{1}{2}$ lb. starch; boil, cool, and add 1 pint oxymuriate of tin at 120° T., 3 oz. measure nitrate of copper at 80° T.

No. 212. *Blue*.—1 gallon water, 1 lb. yellow prussiate of potash, 6 oz. alum, $\frac{1}{2}$ lb. starch; boil, and add $\frac{3}{4}$ pint nitrate of iron at 80° T., $\frac{1}{2}$ gill oxymuriate of tin at 120° T.

No. 213. *Brown*.—1 gallon berry liquor at 8° T., 2 lbs. light British gum; boil, and add 1 lb. muriate-of-tin crystals, 2 quarts spirit pink No. 150, 2 quarts spirit purple No. 214.

No. 214. *Purple*.—1 gallon logwood liquor at 8° T., 1 gallon water, 10 oz. copperas, 2 lbs. starch; boil, and add 1 pint protomuriate of iron at 80° T., 1 pint oxymuriate of tin at 120° T.

No. 215. *Orange*.— $\frac{1}{2}$ gallon berry liquor at 8° T., 12 lbs. light British gum; boil, add 6 lbs. muriate-of-tin crystals, 4 gallons spirit pink No. 211.

No. 216. *Chocolate*.— $2\frac{1}{2}$ gallons spirit pink No. 211, 1 gallon spirit blue No. 212.

No. 217. *Red*.—3 gallons Sapan liquor at 4° T., 1 lb. sal-ammoniac, 1 lb. verdigris, $4\frac{1}{2}$ lbs. starch; boil, cool, and add 5 lbs. pink salts, 1 lb. oxalic acid.

No. 218. *Yellow*.—1 gallon berry liquor at 10 T., $\frac{1}{2}$ lb. alum, 1 lb. starch; boil, and add 1 pint of muriate-of-tin liquor at 120 T.

No. 219. *Green*.—1 gallon spirit blue No. 212, 1 gallon spirit yellow No. 218.

No. 220. *Spirit Pink for Blocking Madder Work*.— $4\frac{1}{2}$ gallons Brazil-wood liquor at 108° T., 9 lbs. pink salts, 3 lbs. sal-ammoniac, 2 lbs. sulphate of copper, $5\frac{1}{2}$ oz. oxalic acid dissolved in 1 pint water, $4\frac{1}{2}$ gallons of 6-lb. gum-Senegal water, $1\frac{1}{8}$ quart oxymuriate of tin at 120° T.

Tenth Style: Bronzes.

The cloth is padded in solution of sulphate of manganese, the strength of which determines the shade of brown produced; for a medium shade of brown, suitable for discharge colours, the liquor may be 80° T.

After padding and drying, pad the pieces through caustic soda at 24° T., and again through caustic soda at 12° T., wince well in water, and then in solution of chloride of lime at 2° T. till perfectly brown; wash well in water, and dry.

The colours for printing on this dyed ground are so made as to discharge the brown and substitute their own colour in place of it.

No. 221. *Blue Discharge*.—(a) 6 gallons water, $3\frac{3}{4}$ lbs. yellow prussiate of potash, 10 lbs. starch, 6 lbs. light British gum; boil, and add 12 lbs. tartaric acid, 6 lbs. oxalic acid, $1\frac{1}{4}$ quart pernitrate of iron: then take (b) 5 quarts of this standard, 3 quarts muriate of tin at 120° T.

No. 222. *Discharge Yellow for Chroming*.—(a) 1 gallon water, 5 lbs. nitrate of lead, 4 lbs. light British gum; boil, and add 4 lbs. tartaric acid; then take (b) 3 quarts this standard, 1 quart muriate of tin at 120° T.

No. 223. *Discharge Green*.—2 quarts yellow standard No. 222 (a), 1 quart blue standard No. 221 (a), 1 quart muriate of tin at 120°

No. 224. *Discharge Pink*.—(a) 2 gallons Brazil-wood liquor at 12° T., 4 oz. sulphate of copper, 4 oz. sal-ammoniac, 4lbs. starch; boil, and add 8 oz. measure oxy-muriate of tin at 120° T.: then take (b) 2 quarts of this standard, 1 quart muriate of tin at 120° T.

No. 225. *White Discharge*.—2 gallons water, 8 lbs. light British gum; boil, and add 8 lbs. tartaric acid, and 1 gallon muriate of tin at 120° T.

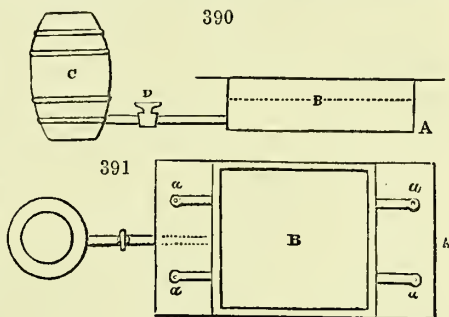

Black.—Spirit black No. 210.

After printing, hang for a few hours, and wince in a pit with water freely flowing into it; then wince in chalky water, again in water, then wince in bichromate of potash at 4° T., to raise the green and yellow; wash and dry.

The discharging agent in these colours is the protomuriate of tin, which, by its superior attraction for oxygen, robs the peroxide of manganese of a portion. The protoxide of manganese formed by this change being then soluble in the acid, and subsequently washed away, the pigment Prussian blue and chromate of lead, also the Brazil lake, are left fixed in the discharged place.

PENCIL BLUE.—Before the introduction of steam blues and the species of indigo blues termed fast blues, the only blue that could be introduced into dyed prints was a solution of deoxidised indigo, dissolved in caustic alkali: this at first was applied by the

printer with a small flat bit of wood termed a pencil; he dipped this in the blue colour, and instantly applied it to the proper parts of the pattern, thus the colour arrived at the cloth before it had time to oxidise and the indigo to become insoluble. It is evident that this process was one of extreme clumsiness, as it required skill to apply the blue just to the proper places, and an apparatus for applying the blue, still called pencil blue, was at last devised. It consists of a copper

case or box A, (fig. 390) in which is laid a frame B, filled with pretty stout canvas. The box communicates by a tube with the cistern c, mounted with a stopcock d. Fig. 391 represents the apparatus in plan: A, the box; B the canvas; with its edges a a a a, fixed by pin-points to the sides. The coloured is *teered*, or spread even, with a wooden scraper as broad as the canvas. In working with this apparatus, the colour being contained in the vessel c is drawn off into the case A, by opening the stopcock d, till it rises to the level of the canvas. The instant before the printer daubs the block upon the canvas, the *teerer*, boy or girl, runs the scraper across it to renew its surface; and the printer immediately transfers the colour to the cloth. In this kind of printing great skill is required to give even impressions. As the blue is usually applied to somewhat large designs, it is very apt to run; an inconvenience counteracted by dusting fine dry sand upon the cloth as soon as it is blocked. The goods must be washed within 24 hours after being printed.

Pencil blue, before the introduction of China blues, was printed by cylinder with a doctor-box.

No. 226. *Pencil Blue*.—10 gallons of pulp of indigo, containing 40 lbs. indigo, 40 lbs. yellow orpiment, 11½ gallons of caustic soda at 70° T., 18½ gallons of water, 4 lbs. lime; boil till quite yellow, when spread on glass; let settle and thicken the clear with 120 lbs. gum-Senegal.

Pieces printed in pencil blue are washed in water immediately after drying and sometimes soaped a little. Mr. Bennett Woodcroft, struck with the waste of indigo attending the printing of either China blue or pencil blue some few years ago invented and patented a method of printing pencil blue by the cylinder machine. His plan was to attach to an ordinary single-colour machine an India-rubber apparatus which enveloped the colour-box and piece after printing: this apparatus was filled with coal-gas; a glass plate formed part of the long bag through which the piece travelled after printing, so as to enable the printer to see the progress of his work. By this means the de-oxidised indigo was fairly applied to the cloth, and oxidation only ensued when the piece left the apparatus. The saving of indigo was said to be considerable, but the plan was not generally adopted.

Pencil blue is sometimes printed along with garancin mordants and dyed garancin. The blue withstands the dyeing and clearing. In America it is often thus printed.

SAFFLOWER DYEING.—The beautiful but fugitive colouring matter of safflower is

applied in the printing for dyeing a self-colour, generally after the goods have been printed in black and red mordant, or black alone, and dyed madder or garancin. It is commonly used for cotton velvets, the colour given to velvet appearing very brilliant from the nature of the cloth. The process is as follows:—Safflower contains two distinct colouring matters; one yellow, being soluble in water; and the other pink, insoluble in water, the latter only being valuable. The yellow matter is therefore carefully washed away. To effect this, the safflower is put into canvas bags, 4 lbs. in a bag, and these bags put into running water and occasionally trodden upon till the water runs off perfectly colourless from them. 12 of these bags are then emptied into a cask with 90 gallons of water and 10 quarts of pearlsh liquor at 24° T., stirred up for 2 hours after standing all night, drain off the liquor, add 90 gallons more water and 3 pints of pearlsh liquor; stir up well, and after standing for three hours, drain off again; this weak liquor is saved for putting on fresh safflower: about 30 gallons of the safflower solution is put in a tub mounted with a vince over it, and a mixture of vinegar and lime-juice is added to it till it is feebly acid to test-paper. The carthamic acid, a red colouring matter of safflower, is thus precipitated, and remains as an exceedingly fine powder in suspension in the liquid; 2 pieces of 30 yards of velvet are put in and winced backwards and forwards five times, then wound upon the reel and allowed to stay there half an hour, then wince five times more, wind up again and let stay half an hour; wince again five times and wind up again; run off the liquor and put in 30 gallons of fresh liquor and acid as before; repeat the process wincing three times of five ends each, and letting lie wound on the reel half an hour each time; then take out and wince in very dilute acetic acid, hydro-extract, and dry. The pieces when wound on the reel should be opened out flat or they might be uneven. Carthamic acid, being of a resinous nature, has the property of attaching itself to cloth, and dyeing it a beautiful pink like the petals of a rose; this dye is very fugitive, strong sunlight even being injurious to it. There has been no way yet discovered of making it permanent.

MUREXIDE.—The purpate of ammonia, or murexide, was discovered by Liebig and Wöhler in 1838, and in its pure state is one of the most beautiful products of chemistry. It is a crystalline substance of a beautiful metallic green, like the wings of the cantharides fly, and is produced when uric acid is dissolved in dilute nitric acid, the solution evaporated somewhat, and ammonia added; from the beautiful crimson liquid, murexide crystallises. This substance had, until a short time ago, no practical application. M. Albert Schlumberger discovered that metallic insoluble salts, possessing all the brilliancy of the original substance, could be made; and this fact was soon applied to a practical use by the French chemists, who succeeded in fixing a beautiful murexide crimson upon cotton cloth. The process was patented in this country for French interests in February 1857, and was for some time in extensive use. The process is as follows:—

Print in the colour.

No. 227. 1 gallon water, 4 lbs. nitrate of lead, 1 lb. murexide, 1½ lb. starch; boil. After printing, hang a few hours, then run through a cistern with rollers above and below, and provided with a cover, through apertures in which the pieces enter and leave. This cistern is kept supplied with ammoniacal gas; on leaving this cistern they pass into water, and from that into a cistern charged with 2 lbs. bichloride of mercury, 4 lbs. acetate of soda, ½ lb. acetic acid, 80 gallons water; run very slowly through this, wash and dry. In the first operation purpate of lead is formed on the cloth, and in the second, on changing bath, the lead is wholly or partly removed, and oxide of mercury left in its space; the resulting lake is a colour of great brilliancy and purity, so much so that few of the ordinary colours will bear to be looked at along with it. Though perfectly fast as to soap, it appears that strong sunlight is rather injurious to its permanency.

This colour is now of historical interest only, aniline magenta having entirely rendered it obsolete.

A few outline illustrations of the various madder styles will render them more clear.

1 *a*. Black, 2 reds, purple and brown on white ground. Print by machine in colours 4, 5, 6, 9, 27, (No. 12 shade) and 18; age 3 nights; fly-dung at 160° F., second dung at 150° F., wash and dye with French or Turkey madder, bringing to boil in 1½ hour, and boiling ¼ hour; wash and soap twice at 180° F., wash; chloride-of-lime bath (see No. 1 plate purples), wash and dry.

1 *b*. Black, red, white and brown figures, covered in purple. Print in colours, 4, 11, 34, and 18; when dry, cover with a fine pattern in 27, (12 shade); age 3 nights; fly dung at 170° F., second dung at 160° F.; wash, dye, and clean as 1 *a*.

1 *c*. Print in colours 6, 7 (No. 3 shade), 34; dry and cover in 7, (6 shade) and blotch (or pad with a roller engraved with a pin, which has the effect of giving a uniform shade) in 7 (10 shade); age three nights, and treat as described under the head *Swiss Pinks*.

1 *d*. Some printers prefer to mordant for Swiss pinks with alkaline mordants, con-

sidering the composition of the colours to be a guarantee against their containing iron; in such case, they print in colours 31, 32, and 35, covering in paler shades of 32 after dyeing; fly-dung with 3 cwt. cow-dung, 12 lbs. sal-ammoniac, 1,000 gallons water at 110° F.; second dung with $\frac{3}{4}$ cwt. cow-dung at 110° 15 minutes; wash and dyo as for 1 *c*. In this method of mordanting, the aluminate of soda that has escaped decomposition by the carbonic acid of the air is decomposed by the muriate of ammonia, and alumina precipitated on the cloth.

2 *a*. Black, chocolate, red, and brown on white ground. Print in colours 5, 13 (6 shade), 14, and 22; age 3 or 4 nights; fly-dung at 160° F., second dung at 160° F., and dye with chocolate garancin or garanceux (see p. 638).

2 *b*. Black, chocolate, red, and purple. Print as 2 *b*, but dye with purple garancin (see p. 638).

3 *a*. For chintz work treat as 1 *a*, then in the parts of the pattern meant for ground-in, block the colours 118 yellow, 119 green, and 110. If the pattern is such as to admit of it, all these colours may be printed at once from one block, using the tobying sieve, p. 585; the colours, however, for this method must be thickened with gum; steam, &c., as described for steam colours.

3 *b*. Black, 2 reds, blue, green, and yellow covered in drab, or other shades. Print in 4, 6, and 7; dye, &c., as 1 *a*; block in colour 38 with a block which covers all the pattern, and also those portions which are intended for the steam colours: when this paste is dry, cover by machine in any of colours 40 to 47, age 2 or 3 nights; fly-dung at 160° F., second dung at 150° F., and dye with bark, or bark and logwood or cover in colour 48, and dye madder and bark as dir: *g* (p. 642) for chocolate; or cover in colour 49 or 51, and after drying and ageing, wincing in chalky water; or in any of colours 55, 56, or 57, rinsing in carbonate of soda liquor at 5° T. when dry. After obtaining the ground shade by any of these processes and drying, ground in by block colours 118, 119, and 110, steam, wash, and dry.

3 *c*. For furniture hangings, which are generally printed in large groups of flowers, a very pretty pea-green ground is often blocked in as groundwork, which is made and fixed as follows:—

No. 228. *Pea-Green*.—(a) Standard: 6 lbs. sulphate of copper, 1 gallon water, 4 lbs. brown acetate of lead; dissolve, let settle, and use the clear.—(b) Colour, 2 measures of standard, 1 measure of 7-lb. gum-Senegal solution.

After printing, age two nights, and pass through a cistern with roller, set with caustic potash liquor at 15° T., which has 8 oz. per gallon of arsenious acid dissolved in it. The liquor should be heated to 110° F.; out of this wash and dry.

3 *d*. Instead of blocking-in steam blue and green, fast blue and green are introduced where the colours are required to be particularly permanent; colours 62 or 63 or both are blocked-in and raised as follows:—5 stone cisterns, each mounted with a hand reel, and containing about 200 gallons each, are set with carbonate-of-soda liquor, No. 1 at 7° T., No. 2 at 6° T., No. 3 at 5° T., No. 4 at 4° T., and No. 5 at 3° T.; wince 10 times backwards and forwards in each pit, beginning with No. 1, and ending with No. 5; wince in water and wash. The change that takes place here is similar to that in raising China blues. The indigo is maintained in a deoxidised state by the protoxide of tin formed, until it has fixed itself in the cloth by reoxidation in the air. Where fast green has been printed, the pieces are wincing in bichromate-of-potash liquor at 4° T. for 10 minutes, then washed and dried.

3 *e*. Black and purple and white with buff ground. Print in 4 and 27 (12 shade), age, dung, and dye, &c., as directed for plate purples (p. 635); block over the pattern and portions of the unprinted part the paste No. 39; blotch with pad roller in No. 53 (6 shade), dry and raise as follows:—Wince 14 minutes in caustic soda at 2° T. at 110° F., then wince the water till quite buff, then wince in 400 gallons water with 1 quart chloride of lime at 12° T. 10 minutes; wash and dry.

Silk-Printing.

Silk, in its capacity for receiving colours, holds a medium place between cotton and wool. From its being an animal substance, it is difficult to obtain white grounds or objects after dyeing mordanted silk, the silk itself attracting colouring matter somewhat as a mordant. Previously to printing silk, it is well scoured by boiling for 2 hours with $\frac{1}{4}$ lb. of soap to every pound of silk, then well washed and dried. For handkerchiefs, black, chocolate, and red mordants are printed, aged, and dunged off same as for cottons, and dyed with madder or garancin, soaped, washed, and dried. Purples cannot be obtained on silk by mordanting and dyeing madder, the colour produced being a mixture of red and purple. All sorts of colours can be produced on silk by steam, the whites remaining brilliant. For steam colours, silk is mordanted with tin, by steeping 4 hours in a solution of sulphomuriate of tin at 2° T., made by

dissolving 1 lb. of muriate-of-tin crystals in water, and adding 1 lb. of sulphuric acid at 170° T., and reducing to 2° T. After steeping, the silk is washed with water, and dried. The following are specimens of steam colours for silk :—

No. 229. *Black*.—2 gallons logwood liquor at 8° T., 1 quart iron liquor at 10° T., 1 lb. flour, 1 lb. light British gum ; boil, and add 6 oz. yellow prussiate of potash ; cool, and add 2 oz. sulphate of copper, 1 pint muriate of iron at 80° T., $\frac{1}{2}$ pint pernitrate of iron at 80° T.

No. 230. *Chocolate*.—2 gallons of Sapan liquor at 12° T., 5 quarts logwood liquor at 12° T., 1 quart bark liquor at 16° T., 2 lbs. alum, $1\frac{1}{2}$ lb. sal-ammoniac, 14 lbs. gum-Senegal.

No. 231. *Red*.—3 gallons of cochineal liquor at 4° T., $1\frac{1}{2}$ pint bark liquor at 12° T., 3 lbs. starch ; boil, then cool, and add 1 lb. oxalic acid, 1 lb. muriate-of-tin crystals.

No. 232. *Yellow*.—3 gallons of bark liquor at 16° T., 8 oz. alum, 3 oz. muriate-of-tin crystals, 3 oz. oxalic acid, 9 lbs. gum-Senegal.

No. 233. *Green*.—1 gallon of yellow, No. 232, $\frac{1}{2}$ pint extract of indigo, $2\frac{1}{2}$ oz. measure of muriate of tin at 120° T.

No. 234. *Blue*.—1 gallon of water, 1 lb. yellow prussiate of potash, $\frac{1}{4}$ lb. oxalic acid, $\frac{1}{2}$ lb. tartaric acid, 2 oz. sulphuric acid at 170° T., 1 gallon of 6-lb. gum-Senegal water.

Aniline colours for silk do not require any fixing substance, such as albumen, the silk itself being capable of combining with such colours. A preliminary mordanting with muriate of tin, though not essential, improves the shades, and is given as follows :—Wince the silk for one hour in muriate-of-tin solution at 1 $\frac{1}{2}$ ° T., wince in water, and dry. The following colours will show the exceedingly simple nature of these preparations :—

No. 235. *Dark Magenta*.—6 measures of 3-lb gum-Senegal solution, and 1 of Simpson's No. 2 Roseine.

No. 236. *Pale Magenta*.—5 measures of 3-lb. gum-Senegal solution, and 1 of Dark Magenta colour.

No. 237. *Blotching Magenta*.—8 measures of 3-lb. gum-Senegal solution, and 1 of No. 2 Roseine.

No. 238. *Dark Primula*.—20 measures of 3-lb. gum-Senegal solution, and one of Hofmann's Violet.

No. 239. *Pale Primula*.—4 measures of 3-lb. gum-Senegal solution, and one of Dark Primula colour.

Mauves are reduced the same way, but using Hofmann's Blue Violet Liquor.

Artificial gums will not do for silks, as they leave the silk stiff and harsh. Steam as usual for half an hour with rather a low pressure, wash and dry.

No. 240. *Aniline Black*.—This splendid and unique black was invented by the late Mr. John Lightfoot, of Accrington, in 1859, and patented in January 1863. This black, when developed on the cloth, is unaffected by light or soap. Strong acids merely turn it dark green, the black colour being restored in all its intensity by alkalis. Strong hypochlorite-of-lime solution turns the black into a chocolate or dark brown, but long washing with water restores the black, with scarcely any loss of strength. It can be printed along with steam colours and madder colours, and with lead oranges and yellows. There is no colour that can compare with it in fastness. Exposure to air containing sulphurous acid or sulphuretted hydrogen causes the black to turn dark green, but the black is immediately restored by a passage in soap solution. For the invention of this black Mr. Lightfoot received the gold medal of the Société Industrielle of Mulhouse. The original colour was the following :—One gallon of starch paste at 1 lb. starch per gallon, 4 oz. chlorate of potash, 8 oz. aniline previously mixed with 8 oz. measure of muriatic acid of commerce ; 4 oz. measure of chloride-of-copper solution at 88° T., 2 oz. of sal-ammoniac. It was soon found that from its great acidity and the action of the copper salt upon the steel 'doctors' of the printing machine, this colour was too inconvenient for general use. H. Cordillot proposed in December 1863, a black made with ferricyanide of ammonium : which salt had, however, been previously mentioned in Lightfoot's specification ; but the colour was dear, decomposed rapidly, required a high temperature for its development, and attacked the fibre of the cloth, inconveniences which caused its speedy abandonment. The discovery of Charles Lauth, of Paris, that sulphide of copper used in place of chloride of copper, whilst being nearly unacted upon by the other ingredients of the colour until the printing had been performed, underwent speedy decomposition when on the cloth, and a soluble copper salt was formed by oxidation of the sulphide by the chlorate of potash, gave the crowning impetus to this colour, and its use became universal by printers. The action of the hydrochlorate of aniline upon the steel 'doctors' still proving an inconvenience, M. Camille Kœchlin substituted tartrate of aniline for the hydrochlorate, adding chloride of ammonium, in order to decompose this tartrate when upon the cloth, and reproduce hydrochlorate of aniline, which salt is essential for the proper development of the black. The modified colour of C. Kœchlin is still largely used in

France, and the recipe for it will be found below. James Higgin patented subsequently the employment of salts of oxide of chromium, such as tungstate, arseniate, &c., mixed with an insoluble copper salt, such as arseniate or tungstate, hydrochlorate of aniline and chlorate of potash being used along with them. In this colour the chrome oxide acts as a carrier of oxygen, chromic acid being formed and instantly decomposed again by the aniline, some chloride of copper being also formed by the mutual reaction of the hydrochlorate of aniline, and the arseniate of copper further assists in the reaction. This black has been and is largely used. There is still some action of this colour upon the 'doctor,' and there is a liability of tendering the cloth when printed in heavy masses. To prevent any action upon the steel 'doctors,' Higgin patented the use of the disulphocyanide of copper, a substitute for the sulphide of copper of Lauth, it having been found that under some conditions of printing the sulphide of copper was decomposed and a soluble copper salt formed in the furnishing-box of the printing machine, and even sometimes in the colour before being put in the furnishing-box. The disulphocyanide of copper is perfectly insoluble in hydrochloric acid, and, of course, equally so in the hydrochlorate of aniline; there is no soluble copper salt formed until the colour is printed and dried. This colour has been and is still very extensively used. The most recent improvement is that patented by Lightfoot in 1871. Chlorate of soda or ammonia is used instead of chlorate of potash and a much larger proportion of aniline is used than in former colours, this being not quite neutralised by hydrochloric acid, making, as the patentee says, a basic salt of aniline; the chlorates of soda and ammonia being much more soluble than the potash salt, allows a larger quantity to be used. Sulphide of copper is the copper salt used in this black. The patentee claims that no injurious action on the 'doctor' takes place in printing this colour, and that patterns of any size and body can be printed without tendering the fibre, also that the intensity of the black is so great owing to the large quantity of aniline used, that it resists the action of a sulphureous atmosphere like that of manufacturing towns longer than other blacks. Lightfoot proved by several experiments that the only metals which develop aniline black from a mixture of hydrochlorate of aniline and chlorate of potash are vanadium, copper, uranium, and iron. Their activity is in the order in which they are here placed. The black from iron salts is not nearly so good as that from copper, and practically a good black can only be made where a copper salt is employed. The exact reactions set up in the aniline-black colour have not been yet satisfactorily explained. M. Brandt, in a paper recently read before the Société Industrielle of Mulhouse, asserts that there are two distinct blacks, one of them of a brownish shade and the other of a blue shade, and that a black of the best and most solid appearance is a mixture of the two blacks.

No. 241. *C. Kachlin's Black*.—20 lbs. of starch, 20 lbs. dark British gum, $2\frac{1}{4}$ gallons of aniline, $2\frac{1}{2}$ gallons of water, beat up well together, and add the following solution: 8 gallons of water, 11 lbs. chlorate of potash, 11 lbs. of sal-ammoniac; boil all well for $1\frac{1}{2}$ hour and cool, then add 1 gallon of sulphide-of-copper paste. When about to print, add to every gallon of the above colour 22 oz. of tartaric acid, dissolved in 1 pint of hot water, it must be added gradually, and well stirred in. This is a very disagreeable colour to make, and a quantity of the aniline is boiled off. The sulphide of copper is made as follows:—

A. 2 quarts of caustic soda solution at 70° T., 1 lb. of flour of sulphur, dissolve by constant stirring;

B. 9 gallons of water, $5\frac{1}{2}$ lbs. sulphate of copper, heat to 170° F.

Add A to B, stirring well, let settle and wash by decantation 4 times, filter to 2 quarts of paste.

No. 242. *Higgin's Disulphocyanide-of-Copper Black*.—1 gallon of water, 1 lb. wheat starch, 1 lb. dark British gum, 2 oz. of disulphocyanide paste, boil, and add 8 oz. chlorate of potash, cool, and add 1 lb. of hydrochlorate of aniline.

No. 243. *Lightfoot's Chlorate-of-Soda Black*.—1 gallon of chlorate paste, No. 244 48 oz. measure basic hydrochlorate-of-aniline solution, No. 246, 1 pint sulphide of copper

No. 244. *Chlorate Paste*.—10 gallons of water, 23 lbs. wheat starch, $5\frac{1}{2}$ lbs. sal-ammoniac 4 lbs. chlorate of potash, 2 gallons chlorate-of-soda solution, No. 245, boil and cool.

No. 245. *Chlorate-of-Soda Solution*.—1 gallon of caustic soda solution at 70° T., 13 quarts of water in which has been dissolved $7\frac{1}{4}$ lbs. tartaric acid, heat up to 170° F., and add 12 lbs. chlorate of potash, dissolve, and add a solution of $7\frac{1}{2}$ lbs. tartaric acid in $6\frac{1}{2}$ quarts of water, stir till cold, filter and press the sediment with a weighted board, then take it off and mix with $1\frac{1}{2}$ gallon of cold water, and filter and press again. Mix the filtrates, and set at 28° T.

No. 246. *Basic Hydrochlorate of Aniline*.—8 measures of aniline and 6 of muriatic acid at 34° T.

Aniline black unless basic should not be hard dried after printing, but only just enough

to prevent the colour from marking off on the white grounds. The pieces should not be passed through the ageing machine, but hung up in a slightly moist atmosphere at about 70° F., for about 24 hours; when, if the colour has assumed a dark myrtle-green shade, almost black, the goods are ready for raising. If only black has been printed, the goods are passed through milk of lime, or solution of carbonate of soda at 2 oz. per gallon, at 160° F., washed and dried; or they may have a passage afterwards in weak hot solution of bichromate of potash, which gives a browner shade of black; or they may be raised by a passage in boiling soap solution. If printed along with lead-orange (No. 64 a.), the process is as follows:—1st. Give a passage of half a minute in a liquor composed of 2½ lbs. sulphate-of-soda crystals, and 3 oz. of bichromate of potash per gallon of water at boil. 2nd. Wince in cold water. 3rd. Wince in a liquor composed of 100 gallons of boiling water, 1 gallon of bichromate of potash solution at 18° T., 24 oz. measure of caustic soda solution at 70° T. Keep the goods in until the orange is well dyed, then wince in cold water and soap at 160° F. for ¼ hour, in a soap solution containing 2 lbs. of soap to 100 gallons of water, then wash and dry.

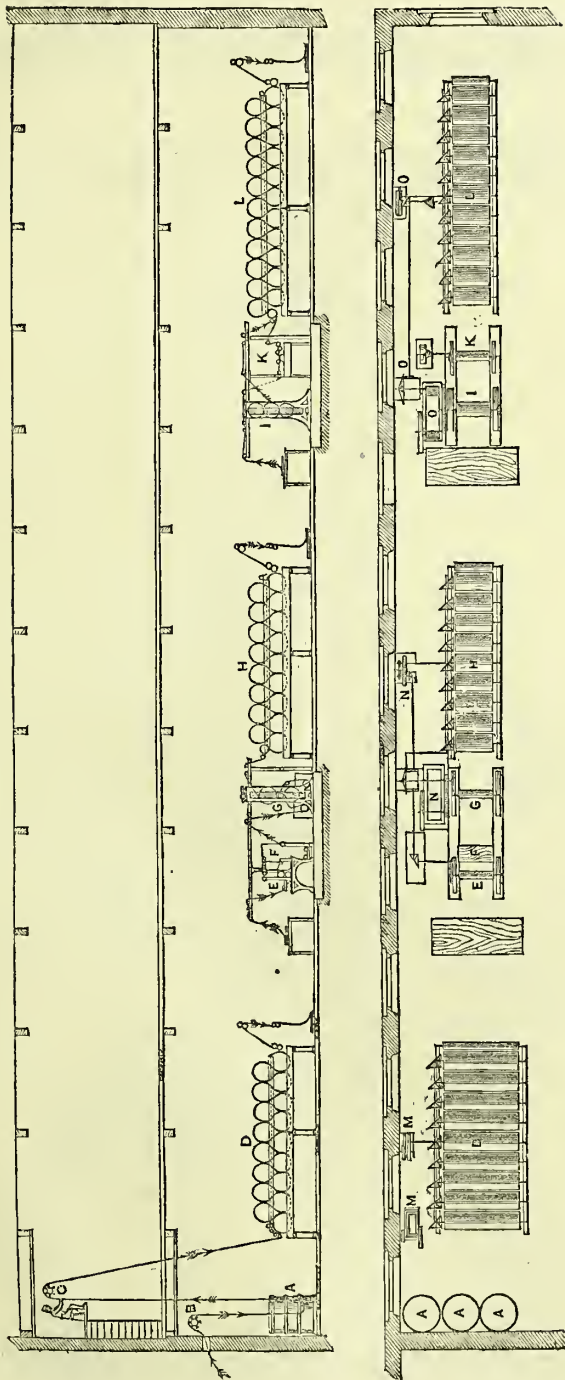

When aniline black is printed along with madder mordants, the ordinary dunging process raises the black at the same time as it prepares the mordants for dyeing.

Printed along with colours intended for steaming, a passage in ammonia vapour is given to the goods after ageing and before steaming. This is necessary in order to neutralize the acid in the black, which would tender the fibre, if not neutralised. This ammonia passage is given in a rectangular box, which is 7 feet long, 4 feet wide, and 6 feet deep; provided with rollers at the top and bottom; a lining of sheet lead for about 6 inches deep, is put in the bottom of the box; a steam-pipe is placed along the bottom of the box, lengthwise, down the centre, a smaller pipe is placed along the steam-pipe, on the top of it; this pipe is perforated with smaller holes. A lid covers the whole of the box, except a slit through which the pieces enter, and another by which they leave after passing up and down over and under the rollers. Steam being turned on the pipe, liquid ammonia is allowed to run into the small pipe from a reservoir outside, and to issue from the perforations, dropping on the steam-pipe. The pieces are now passed through, and are then ready for steaming.

The last operation in calico-printing is what is called the Finishing, which comprehends starching, drying, breadthening, calendering, measuring, and making-up. The starching is a very important operation, simple as it may appear, in consequence of the extremely varying requirements of the print buyers. A variety of starches are used, differing in the nature of the paste they give when boiled with water, some being gummy, and others firm and stiff, and at all degrees between the two. Compounded starches adapted to different styles, are made and sold by the manufacturing chemists.

Fig. 392 is an elevation and plan of a finishing room for calicoes, as arranged by Mather and Platt: A, circular boxes for receiving cloth; B, wince for drawing cloth from the squeezers in the dye-house; C, opening wince for the cloth from the boxes to the drying machine; D, drying machine; E, chloring machine; F, steaming-box; G, water-mangle; H, drying-machine; I, starching-mangle; K, Jones' patent back stiffening machine; L, drying-machine; M, engine and gearing for drying-machine; N, engine and gearing for chloring arrangement E, F, G, H; O, engine and gearing for starching arrangement I, K, L.

Several details which cannot be shown in this plan, can also be but imperfectly described in words. The opening wince C, is placed at a height of 30 to 40 feet above the cloth-box, the higher the better, the pieces arrive in the box A in the form of a rope; before any chloring or finishing can be done, this rope must be opened out, and the pieces presented to the drying-machine extended to the full breadth; this is done by a boy who sits on a platform near the wince, and the piece gradually untwisting during its passage from the box to the wince, is pulled flat out by the boy just before going over the wince C. Again the constant passage of the pieces over so many machines has pulled them lengthwise, and consequently diminished their breadth. To counteract this, and restore the pieces to something like their usual breadth, a peculiar roller, called a spreading roller, is fixed on every drying-machine. The 'spreading roller' is composed of brass or iron diagonal saw-tooth grooved plates or rails, each about 2 inches wide and ¾ths inch thick, and of length according to necessity; each of these rails has 2 small friction pulleys at one end, and 2 slide pieces in suitable places. The rails are mounted on the periphery of discs and cams supported in their centres by a fixed shaft; the discs are prepared with grooves to correspond with the 2 slides in each rail, and work on the shaft by the pull of the cloth. The cams are fixed at a variable angle, and give a throw causing a longitudinal motion of the rails, to open out the cloth whilst passing over. The cloth enters into contact with the spreader when the rails are closed and leaves it at the opposite side, when they

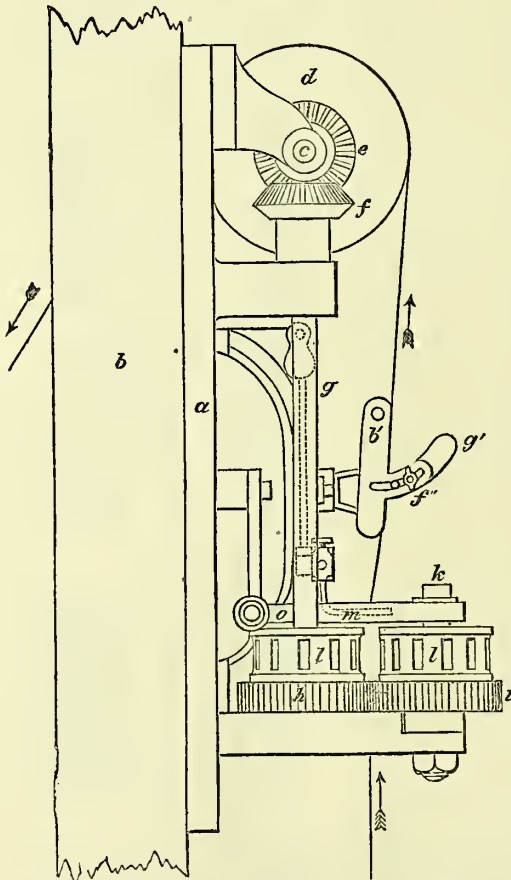

are widest apart or expanded longitudinally. Two rails compose one width as per *figs. 393 and 394*, which are shown closed and open, having been moved right and left

395

396

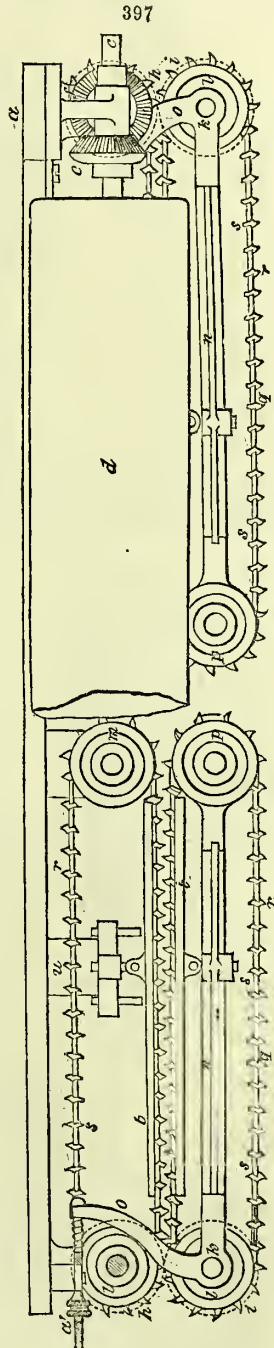

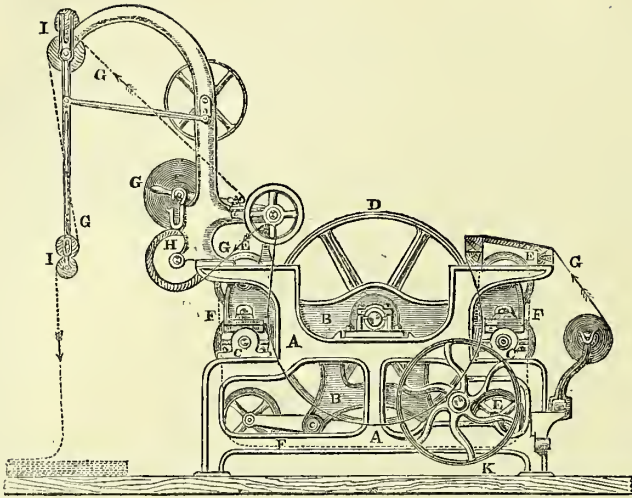

by means of the excentric motion of the cams. *Fig. 395* shows the saw teeth, diagonal grooves, of the bars. The bars move each about 1 inch outwards from the centre, and

pull out the cloth to an extent of 2 inches in the width. An opening machine, patented by William Birch of Salford in 1871, is now used by many calico-printers and bleachers. A detailed description of this machine would involve too many drawings for the size and aim of this work: a general idea alone of it can be here given. *Fig. 396* is an end elevation, and *fig. 397* a plan of part of the machine. The side frames *a* of the machine are bolted to upright beams *b*, or other framework at the upper part of the building or other required place, and the fabric to be acted upon is drawn through the machine from vats, receptacles, or other places at the lower part of the building, by its being connected to the drying, folding, or other machine to which they require to go. In bearings at the top of the frames *a* there is a shaft *c* carrying a roller *d* and bevel wheels *e*, which gear into other bevel wheels *f* on shafts *g*, to which are fixed spur-wheels *h* gearing into spur-wheels *i* on stationary studs *k*. To the spur-wheels are cast or fixed chain-wheels *l*, and on studs at the back there are chain-wheels *m*, and on cranked levers *n, o*, chain-wheels *p*, the levers working on the stationary studs *k*. On the several pairs of chain-wheels there are two pairs of endless bands *q*, having external projections *r* and internal projections *s*, the latter gearing with the chain-wheels, and between these endless bands the fabric to be acted upon is passed, and in order to obtain sufficient grip the external projections on one of each pair of bands passes between those on the other, and to prevent the bands from bulging inwards there are plates *t*, one plate at each side, being connected to the arm *n*, and the other plate at each side to a bracket *u* connected to one of the cross frames.

When the fabric has to be opened, spread, and guided, it is passed between the endless bands and the single and double corrugated bars, and over the roller *d* to the machine required, the central corrugated bar having been raised, to allow the passage of the fabric, the bolts being withdrawn from the slots for the purpose; but when the connections are complete the central bar is turned down and afterwards bolted. When the machine to which the fabric is connected is set to work, the fabric in its passage turns the roller *d*, which gives revolving motion to the gearing and horizontal travelling motions to the endless bands from the centre to the outside where they are in contact with the fabric, and these outward motions of the bands open and spread out the fabric.

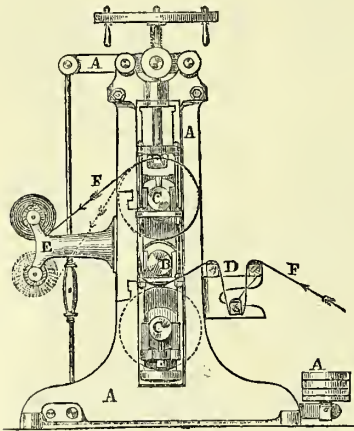

The machine has also a very ingenious self-acting arrangement for keeping the cloth from swerving to either side during its passage through; but a description of it would be too elaborate for this work. Every machine saves the labour of a boy or girl. The drying-machine will be found described in the article BLEACHING. To extend the pieces to their utmost width a machine called a breadthening machine is employed. *Fig. 398* is Mather and Platt's belt-stretching machine: *A* is the framing; *B*, moveable frame, supporting the breadthening pulleys and belts, regulated for breadthening by screws; *C*, hollow bars, on which frame *B* slides, and through which the screws for regulating work; *D*, breadthening pulleys; *E*, tightening pulleys for endless belts; *F*, endless belt, which works half round pulley *D* and pulleys *E*, and between the pulley *D* and the belt, the cloth is held

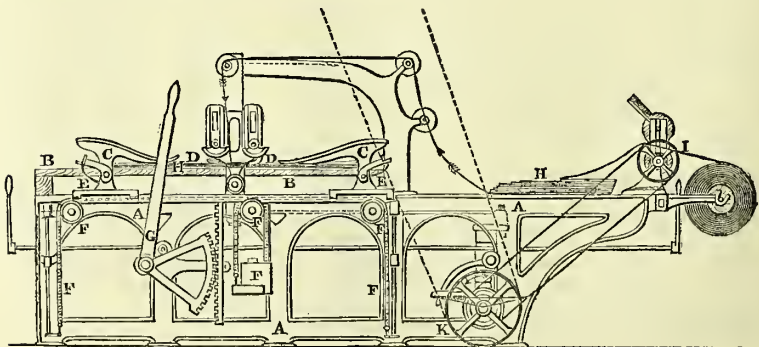

while being broadthened; g, cloth passing through the machine; h, batching apparatus; i, plaiting apparatus, the machine being prepared to either plait or batch; k, driving pullies. For some descriptions of goods, such as furniture prints, a glazing calender is employed. Fig. 399 is an elevation of Mather and Platt's calender;

399

A, the framing with levers, screws, &c.; B, metal bowl heated by steam or gas; C, paper or cotton bowls; D, entering rails, &c.; E, batching apparatus; F, cloth passing through the machine. The friction of the heated metal bowl against the cloth, pressing against the larger bowls gives a glaze to the cloth. Pieces have now to be made up in folds of uniform length, generally about a yard. This operation is done by girls hooking one selvage of a piece backwards and forwards on long steel hooks, fixed on a wooden frame, standing about 4 feet 6 inches from the ground; these hooks are moveable, so as to give various lengths of fold as required. Plaiting and

400

measuring machines have been introduced to economise labour. *Fig. 400* is Knowles and Hayward's plaiting machine, of which Mather and Platt are the sole makers. It will plait goods of any quality or material, from the heaviest drill to the finest muslin, however highly glazed, laying them in folds of uniform length, which can be varied as required: *A* is the framing of the machine; *B*, fixed table on which the cloth is plaited; *C*, cams for lifting the folding blade, to which are also attached the cards for holding cloth, rising as the thickness of the folds increases; *D*, folding knives, moving longitudinally to make the fold, and vertically as the thickness of the folds increases on the table; *E*, spring for relieving the pressure of the cards on the cloth whilst it is being passed under the cards which hold it on the return of the blade; *F*, rack motion and compensating chains and weights for cams, cards, and folding blades; *G*, levers and quadrant raising the cams, cards, &c., when taking out cloth from machine; *H*, cloth being folded; *I*, draw rollers to give equal and regular delivery of cloth to folding blades; *K*, driving-pulley, &c.

The next step is to fold these lengths into three, and pile the folded pieces in an hydraulic press, where they are pressed, and are then ready for packing and delivery.

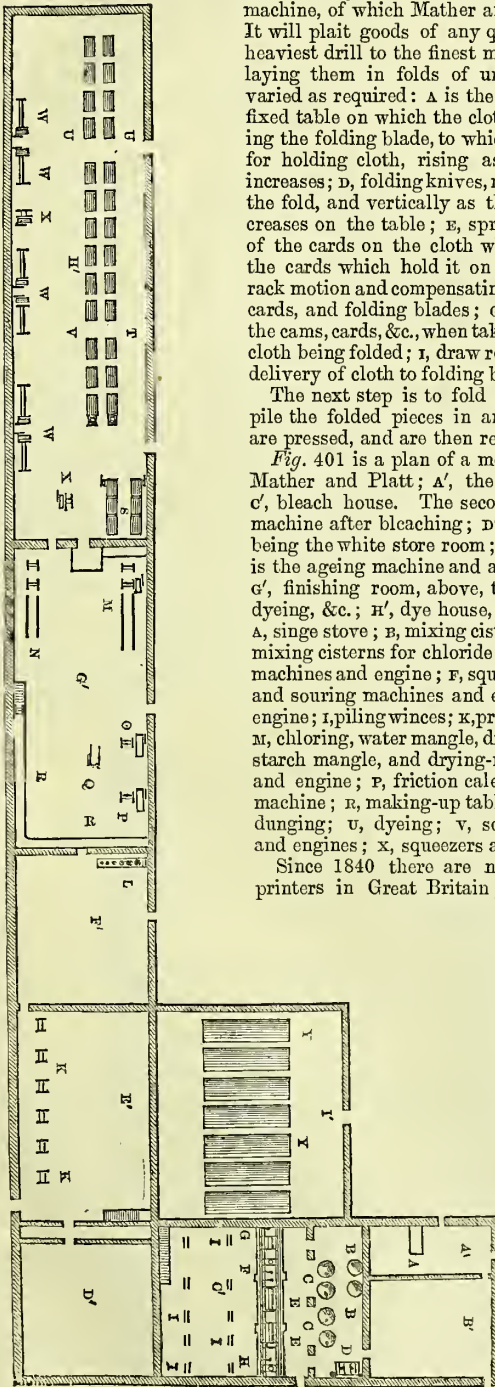

Fig. 401 is a plan of a modern print works, erected by Mather and Platt; *A'*, the singe house; *B'*, grey room; *C'*, bleach house. The second story contains the drying-machine after bleaching; *D'*, white room, the second story being the white store room; *E'*, printing room, above this is the ageing machine and ageing room; *F'*, colour house; *G'*, finishing room, above the drying-machine after the dyeing, &c.; *H'*, dye house, single story; *I'*, boiler house; *A*, singe stove; *B*, mixing cisterns for the kiers; *C*, kiers; *D*, mixing cisterns for chloride of lime and sours; *E*, washing machines and engine; *F*, squeezers and engine; *G*, chloring and souring machines and engine; *H*, white squeezer and engine; *I*, piling winces; *K*, printing machines; *L*, colour pans; *M*, chloring, water mangle, drying-machine, and engine; *N*, starch mangle, and drying-machine; *O*, finishing calender and engine; *P*, friction calender and engine; *Q*, damping machine; *R*, making-up tables; *S*, first dunging; *T*, second dunging; *U*, dyeing; *V*, soaping; *W*, washing machines and engines; *X*, squeezers and engines; *Y*, boilers.

Since 1840 there are no data as to the number of printers in Great Britain; but Mr. John Graham, in an unpublished 'History of the Lancashire Printers,' gives a table, which he was at considerable care to compile from perfectly trustworthy sources, showing that in the Lancashire district, which includes also the contiguous counties, there were, in 1846, 128 firms employ-

- 540 cylinder machines.
- 39 perrotines.
- 7187 block tables.

The producing power of the Lancashire district having thus been doubled in 6 years.

Several printing firms, both in England and Scotland, have since that period much enlarged their powers of production. There are

many who manufacture 10,000 pieces of printed cloth per week; and there are four concerns of great magnitude whose united production at the present time probably does not fall short of four millions of pieces per annum, or nearly $\frac{1}{5}$ th of the total quantity printed.

Calico, and other printing has, since the repeal of the duty, risen steadily in importance, till it is now one of the most influential manufactures of Great Britain. From a table compiled by the late Mr. Binyon, and communicated by Mr. John Graham, there were in 1840:—

	Firms	Employing	Cylinder Machines	Surface Machines	Flat Presses	Discharg- ing Presses	Block Tables
In Lancashire . . .	93		}	247
„ Scotland . . .	70	75		...	82	124	4997
„ Ireland . . .	3	13		5	1	...	308
„ America . . .	47	106		834

The following estimate of the exports of printed goods is from Mr. Potter's Lecture before the Society of Arts, as reporter for printed fabrics exhibited in the Exhibition of 1851:—

'In reference to the exports of printed goods, our information is rather obscure, owing to their being classed with dyed goods of all kinds. After considerable thought and calculation, I have ventured to estimate them for 1851, at 15,544,000 pieces, or rather more than three-fourths of our entire production. These goods are, however, many of them of the cheap and more staple class of prints, or slight goods suited to warm climates, and for markets where cheapness is the great recommendation. In value, I should be disposed to estimate our export of printed goods at 5,775,000*l*.

'In reference to the entire export of manufactured cotton goods (exclusive of yarns), it may be assumed that out of 23,447,103*l*., given as the export of 1851, about one-fourth may be placed to the account for the print trade. I have endeavoured to estimate, from the Table of Exports for 1851, the probable quantity of *low priced* prints we export, and should be disposed to class them as follows:—

	Pieces.
'Coast of Africa and the Cape	300,000
New Zealand and South Sea Islands	36,000
China, Manilla, and Singapore	550,000
British West Indies	300,000
Foreign West Indies	300,000
St. Thomas	200,000
India	1,570,000
Mauritius and Batavia	325,000
Chili and Peru	800,000
Brazil and East Coast of South America	1,000,000
Egypt	84,000
Turkey, Ionian Isles, Greece, and Malta	1,000,000
Total	6,465,000

'I find those countries which take our lowest description of goods, and where the duties are chiefly very light—our Colonies, India and China—receive from us about 6½ millions of pieces, or about 40 per cent. of our export in printed goods. A great proportion of the finer part of our exports, perhaps three-fourths, are very seriously taxed, either for protection, as in the United States, the Zollverein, and Belgium, or for revenue, as in Brazil and the other South American markets. A part, however, of these better goods find their way into consumption in Canada, Turkey, the Ionian Isles, Egypt, &c., subject to very moderate duties.'—(Potter.)

'The home-consumption,' says Mr. Potter, 'I estimate at 4,500,000; the excise returns for 1830 gave it as 2,281,512 pieces. The repeal of the duty, and the decrease in the cost of production, giving the consumer goods in much better taste and value at one-half the price, have greatly tended to this increase.' 'The immense increase of production in lower goods has not decreased the taste in the higher in this country, though it may have caused it to make less apparent progress than when the larger part

of the supply was of fine goods. We find specimens of good taste on the lowest material, printed at the lowest possible price for export, showing a taste superior to that in use for our best work twenty years ago, employing greater talent in design, greater skill in engraving—the cost of production cheap, because repaid by the quantity produced. This diffusion of art and of a better taste cannot be otherwise than beneficial, even to the higher class of productions, as preparing a taste and demand for them in countries where high price would never have given prints any admission. The improvement of the lower cannot militate against that of the higher, either in the moral, intellectual, or artistic world. The productions of the highest class of French goods of to-day, whether furniture or dresses, are superior in taste and execution to those of any former period. The productions of the first-class printers of Great Britain maintain an equal advance, and are superior in taste and execution, in every respect, to those of former years. Great competition and rapidity of production are not immediately beneficial to high finish and execution in art; but this tendency to quickness of production, rather than perfection, rectifies itself; and machinery, which perhaps at first does not give the polish that excessive labour formerly supplied, ultimately exceeds it by its cheaper and more regular application. It is remarkable how taste or novelty in that class of demand, which would strike the casual observer as the one fitted for its greatest development, is limited in quantity. The limit or commencing point, in which taste or novelty enters freely into the composition of a print, is for the supply of the working and middle classes of society. They require it quiet, modest, and useful; and any deviation, for the sake of novelty, which calls in the aid of the brighter and less permanent colour, quickly checks itself. The sober careful classes of society cling to an inoffensive taste, which will not look obsolete and extravagant after the lapse of such a time as would render a garment comparatively tasteless and unfashionable in a higher class. This trade is, to the printers, most extensive and valuable, and has its necessary and practical bearing on his taste; and hence it is in this branch of the business the English printer is most decidedly superior to his French competitors.

The returns given in the 'Annual Statement of the Trade of the United Kingdom' for our *Export of Piece Goods Printed in 1872* is as follows:—

It would appear that occasionally attempts were made, during the early days of printing, to produce work possessing a high degree of artistic excellence; and as the specimens that have been preserved to our time are very rare, it is fair to conclude that these experiments were not successful in a pecuniary point of view. In the museum of the Peel Park, at Salford, there is a curious and interesting piece of printed linen, bearing the date 1761 (at this period cloth of all cotton was prohibited), and which must have been printed from copper plates of very unusual size. Apparently, the pattern has been produced by two plates, each about 4 feet 6 inches by 3 feet. The design is printed in madder red, and is thus described by Mr. Plant, the curator of the museum. 'The printed piece of linen measures, in the full length of the design, 6 feet 10 inches by 3 feet 2 inches in breadth. The composition in the design is very bold and free—in my opinion indicating very strongly the feelings of an artist who had been educated in the Flemish school. The grouping of the trees, figures, cattle, and fowls, is probably a direct copy from an engraving or sketch by Berghem, whose paintings and engravings of such subjects are well known for their truth to nature. His works bear date 1638 to 1680. Perhaps, to fill up the design, and form a picturesque composition, the artist has borrowed from the French painters the classic ruins which form the sides of the design; it has had the effect of producing an anachronism. The upper group represents a peasant seated upon the wall of a well blowing a flute; near him stands a woman with a distaff; a group of sheep, cow, and a dog, in the foreground. The background shows a landscape, and on each side this group are ruins, columns, and trees, reflected in the stream below. On a broken bank, midway between the two groups, are two dogs chasing a stag. The lower group, although there is no defined line of separation between the groups, represents a peacock, fowls, and chickens, upon a bank and ruins; landscape and river scenery beyond. Over, a hawk carrying a chicken, the sides occupied with a ruined portico, tomb, and pedestal and vase, trees, and broken ground; and below are ducks swimming, and water-plants on the bank. At the bottom of the piece are those parts of the pattern which would print or fit on the top part of the design. On the stone-work of the well, in the upper group, is printed, 'R. JONES, 1761;' on the broken stone-work, in the centre of the lower group, is printed, 'R. I. and Co., OLD FORD, 1761.'" Old Ford is situated at Bow, where the East London Water Works now are, and where there was a print-works at the time specified. This design was no doubt printed for furniture hangings or tapestry, for which it is exceedingly well adapted, and the work being altogether a remarkable production for the period.

CALIPERS; CALIPER COMPASSES. Compasses with bowed legs, employed to measure the size of any round or conical body. In use, the two points are opened to the required width, and so much wood, metal, or stone is turned off the piece of work, that the two points exactly fit.

CALK. To drive oakum, or untwisted old tarred rope into the seams of any vessel to prevent water from entering it or to stop a leak. After calking a ship, hot tar is applied to protect the oakum driven in. *Calk* is a term used amongst miners for lime.

CALLOOE HEMP. A fibre obtained from one of the Asiatic nettles—probably the *Urtica tenacissima*, which is a native of Sumatra and Rungpore. Its fibres are exceedingly strong, and are converted into cordage. China-grass cloth, and some other fabrics are made from the fibres of the Nettle. See NETTLE.

CALLOW. The top or rubble bed of a quarry. This is obliged to be removed before the useful material is raised; it is the great source of expense in working a quarry.—(Brande). Frequently termed the 'overburthen.'

CALLYS or KALLYS. An old Cornish term, still used in the remote mining districts, and applied to hard ground—chiefly to a variety of the Killas or Clay Slate.

CALOMEL. (*Chlorure de Mercure*, Fr.; *Kalomel*, *Chlormercur*, *Versüsstes Quecksilber*, Ger.) The sub-chloride of mercury, or mercurous chlorido of modern chemists, Hg^2Cl (Hg^2Cl^2). Calomel is found native in the Palatinate, in crystals often well defined, coating the cavities of a ferruginous gangue, associated with cinnabar; also at the quicksilver mines of Idria in Carniola, at Almaden in Spain, and Horzowitz in Bohemia. The native calomel is known as *horn-quicksilver*. The manufacture of this substance upon the large scale may be performed in various ways. The cheapest, and most direct consists in mixing $1\frac{1}{2}$ part of pure quicksilver with 1 part of pure nitric acid, of specific gravity from 1.2 to 1.25; and in digesting the mixture till no more metal can be dissolved, or till the liquid has assumed a yellow colour. At the same time, a solution is made of 1 part of common salt in 32 parts of distilled water, to which a little muriatic acid is added; and when heated to nearly the boiling point, it is mixed with the mercurial solution. The two salts exchange bases, and a subchloride of mercury precipitates in a white powder; which, after being digested for some time in the acidulous supernatant liquor, is to be washed, with the greatest care, in boiling water. The circumstances which may injure the process are the following:—1. When less mercury is employed than the acid can dissolve, there is formed a nitrate of mercury which gives rise to some corrosive sublimate and causes a proportional defalcation of calomel. 2. If the liquors are perfectly neutral at the moment of mixing them, some sub-nitrate of mercury is thrown down, which cannot be removed by washing, and which gives a noxious contamination to the bland calomel. The acid prescribed in the above formula obviates this danger.

The following are the directions given by the London College for the preparation of this salt:—2 lbs. of mercury are boiled to dryness in a suitable vessel with 3 lbs. of concentrated sulphuric acid: the sulphate of mercury thus obtained is rubbed when cold, first with 2 lbs. more mercury in an earthen vessel until perfectly mixed, and then thoroughly incorporated with $1\frac{1}{2}$ lb. of chloride of sodium; the whole is then sublimed in an appropriate vessel; the sublimate is rubbed to a fine powder, and then washed with boiling distilled water, until the washings are no longer tinged by sulphuretted hydrogen. This process is absolutely necessary in order to remove every trace of corrosive sublimate which is always formed in greater or less quantity.

At Apothecaries' Hall 50 lbs. of mercury are boiled with 70 lbs. of sulphuric acid to dryness in a cast-iron vessel; 62 lbs. of the dry salt are triturated with $40\frac{1}{2}$ lbs. of mercury until the globules disappear; and 34 lbs. of common salt are then added. The mixture is submitted to heat, and from 95 lbs. to 100 lbs. of sublimed calomel are obtained. It is washed in large quantities of distilled water, after having been ground to a fine and impalpable powder.

According to the patent of Mr. Josiah Jewell, the vapour of calomel was to be transmitted into a vessel containing water, in order to condense it at once into an impalpable powder. But this process was beset with many difficulties. The vapour of the calomel was afterwards introduced into a large receiver, into which steam was simultaneously admitted; but this plan has also been found to be precarious in the execution. The best way is to sublime the calomel into a very large chamber from an iron pot, in the same way as the flowers of sulphur are formed. The great body of cool air serves to cause the precipitation of the calomel in a finely comminuted state. It is afterwards washed with water, till this is no longer coloured by sulphuretted hydrogen.

A patent was obtained in September 1841, by Anthony Todd Thomson, M.D., for an improved method of manufacturing calomel and corrosive sublimate, as follows:—This invention consists in combining chlorine in the state of gas with the vapour of mercury or quicksilver, in order to produce calomel and corrosive sublimate. The apparatus employed consists of a glass, earthenware, or other suitable vessel, mounted in brickwork, and communicating at one end with a large air-tight chamber, and at the other end by means of a bent tube, with an alembic, such as is generally used in generating chlorine gas. The alembic is charged with a mixture of common salt, bin-

oxide of manganese, and sulphuric acid, or of binoxide of manganese and muriatic acid in order to produce chlorine gas.

The mode of operating with this apparatus is as follows:—A quantity of mercury or quicksilver is placed in a glass vessel, and the temperature of the same is raised to between 350° and 660° F., by means of an open fire beneath. The chlorine gas, as it is generated, passes from the alembic through the bent tube into the glass vessel, and there combining with the vapour of the mercury, forms either corrosive sublimate or calomel, according to the quantity of chlorine gas employed.

The product is found at the bottom of the air-tight chamber, and may be removed from the same through a door, when the operation is finished.

Prof. Wöhler proposes to prepare calomel in the humid way by decomposing a solution of corrosive sublimate by sulphurous acid. The commercial salt is dissolved in water at 122° to saturation. Sulphurous acid gas, evolved by heating coarse charcoal powder with concentrated sulphuric acid, is passed into the hot solution: the separation of the calomel commences immediately. When the solution is saturated with the gas, it is digested for some time, then left to get cold, and filtered from the calomel, which is afterwards washed. The filtrate usually contains some unchangeable corrosive sublimate, which may be converted into calomel, either by heating to boiling, or by a fresh introduction of sulphurous acid and heating. Calomel obtained in this manner is a crystalline powder of dazzling whiteness, glittering in the sunlight.

The presence of corrosive sublimate in calomel is easily detected by digesting alcohol upon it, and testing the decanted alcohol with a drop of caustic potash, when the characteristic brick-coloured precipitate will fall, if any of that salt be present. To detect subnitrate of mercury in calomel, digest dilute nitric acid on it, and test the acid with potash, when a precipitate will fall in case of that contamination.

117.75 parts of calomel contain 100 of quicksilver.

Great confusion has unfortunately arisen between the formulæ of the two chlorides of mercury—calomel and corrosive sublimate.

If 100 be taken as the atomic weight of mercury, the formula of calomel is Hg^2Cl (as given above), and that of corrosive sublimate is $HgCl$. But if, as is often the case, 200 be assigned to mercury as its atomic weight, the formula of calomel becomes $HgCl$ (or rather, for theoretical reasons, Hg^2Cl^2) and that of corrosive sublimate $HgCl^2$. As fatal mistakes might occur by substituting one of these compounds for the other, the formulæ should never be used apart from the specific names.

CALORIC. A term once extensively used in physical science, and perhaps somewhat too hastily abandoned. When employed there was a very general impression that *heat* was the effect of some undeveloped cause, and to this cause the term *caloric* was applied. The modern hypothesis regarding heat as a mode of motion, the term has been dispensed with. See **HEAT**.

CALORIFERE OF WATER. In former editions, hot-water apparatus was described under this head: now see **HOT-WATER APPARATUS**.

CALORIMETER. An instrument intended to measure the quantity of heat produced by burning bodies, devised by Lavoisier and Laplace. The principle upon which these instruments depended may be easily understood. To convert a certain quantity of ice into water, a given amount of heat is necessary. Now suppose we construct a funnel-shaped vessel, and having placed in the middle of it a vessel containing boiling water, or hot mercury, or oil, or a red-hot piece of metal, it is packed round with ice, care being taken that no heat shall escape, except it is employed to thaw the ice. The water formed by the ice is collected in a vessel placed below the funnel, and the quantity collected during the cooling of the heated body will represent the heat given out and employed in liquefying the ice. For nice experiments certain exact determinations are required, for which, and the general rules to be observed, some good treatise on Physics should be consulted. See Watts's 'Dictionary of Chemistry:' article **HEAT**.

CALOTYPE (signifying *beautiful picture*). A name given by Mr. Henry Fox Talbot to a photographic process invented by him in 1840, and patented in 1841.

Mr. Talbot's description of his process is as follows:—

Take a sheet of the best writing-paper, having a smooth surface, and a close and even texture. The water-mark, if any, should be cut off, lest it injure the appearance of the picture. Dissolve 100 grains of crystallised nitrate of silver in six ounces of distilled water. Wash the paper with this solution with a soft brush on one side, and put a mark on that side, whereby to know it again. Dry the paper cautiously at a distance from the fire, or else let it dry spontaneously in a dark room. When dry, or nearly so, dip it into a solution of iodide of potassium, containing 500 grains of that salt dissolved in one pint of water, and let it stay two or three minutes in the solution.

Then dip the paper into a vessel of water, dry it lightly with blotting-paper, and finish drying it at a fire, which will not injure it even if held pretty near; or else it may be left to dry spontaneously. All this is best done in the evening by candle-light: the paper, so far prepared, is called *iodised paper*, because it has a uniform pale-yellow coating of iodide of silver. It is scarcely sensitive to light, but nevertheless it ought to be kept in a portfolio or drawer until wanted for use. It may be kept for some considerable time without undergoing change, if protected from sunshine. When the paper is required for use, take a sheet of it, and wash it with a liquid prepared in the following manner:—

Dissolve 100 grains of crystallised nitrate of silver in two ounces of distilled water; add to this solution one-sixth of its volume of strong acetic acid. Let this be called mixture A.

Make a saturated solution of crystallised gallic acid in cold distilled water. The quantity dissolved is very small. Call this solution B.

Mix together the liquids A and B in equal volumes, but only a small quantity of them at a time, because the mixture does not keep long without spoiling. This mixture Mr. Talbot calls the *gallo-nitrate of silver*. This solution must be washed over the iodised paper on the side marked, and being allowed to remain upon it for half a minute, it must be dipped into water, and then lightly dried with blotting-paper. This operation in particular requires the total exclusion of daylight; and although the paper thus prepared has been found to keep for two or three months, it is advisable to use it within a few hours, as it is often rendered useless by spontaneous change in the dark.

Paper thus prepared is exquisitely sensitive to light; an exposure of less than a second to diffused daylight being quite sufficient to set up the process of change. If a piece of this paper is partly covered, and the other portion exposed to daylight for the *briefest possible period of time*, a very decided impression will be made. This impression is latent and invisible. If, however, the paper be placed aside in the dark, it will gradually *develop itself*; or it may be brought out immediately by being washed over with the gallo-nitrate of silver, and held at a short distance from the fire, by which the exposed portions become brown, the covered parts remaining of their original colour. The pictures being thus procured, are to be fixed by washing in clean water, and lightly drying between blotting-paper, after which they are to be washed over with a solution of bromide of potassium, containing 100 grains of that salt, dissolved in eight or ten ounces of water; after a minute or two, it is again to be dipped into water, and then finally dried. The Collodion process has almost entirely superseded the Calotype. See COLLODION and PHOTOGRAPHY.

CALUMBA. See COLOMBA.

CAMBAY STONE. A variety of carnelian imported from the East Indies.

CAMBOGIA. See GAMBOGE.

CAMBRIC. (*Batiste*, Fr.; *Kammertuch*, Ger.) A sort of very fine and rather thin linen fabric, first made at Cambray. An excellent imitation of it is made in Lancashire and in Scotland, woven from fine cotton yarn, hard twisted. Linen cambric of a good quality is also now manufactured in the United Kingdom from power-spun flax; this is frequently called *Cambric muslin*.

CAMELEON MINERAL. See CHAMELEON MINERAL.

CAMEO. (*Camée*, Fr.; *Cammeo*, It.) Correctly a precious stone engraved in relief, as opposed to an *intaglio*, which is cut into the stone. The earliest cameos appear to have been cut upon the onyx, and subsequently, on the agate. The true cameo is formed upon a stone having two or more layers, differing in colour; and the art of the cameo-engraver consists in so cutting as to appropriate those differently coloured layers to distinct parts or elevations of the work.

Many of the varieties of chalcedony present in section transparent and opaque layers; and beautiful works have been cut upon such specimens of this material. The chalcedony and agate are, however, not unfrequently coloured artificially. The layers vary very much in their structure, some being absorbent and others not so. Such stones are taken, and if it is desired to have black and white layers, they are boiled in a solution of sugar or honey, and then in sulphuric acid. The sugar or honey is, in the first place, absorbed by the more porous layers, and then decomposed by the acid. Red or brownish-red layers are produced by occasioning the stone to absorb a solution of sulphate of iron, and then by exposure to heat effecting the peroxidation of the metal. This being done, layers very strongly contrasted in colour are the result; and very fine cameos have been cut upon stones so prepared. See AGATE.

In Italy and in France, the art of producing the *cammeo duro* has been to some extent revived; but the immense labour which such hard materials require renders them so expensive, that these cameos have not come into general use.

The shells of several molluscous animals are now commonly used. Many of these

shells afford the necessary variety of colour, and are soft enough to be worked with facility, yet hard enough to wear for a considerable time without injury.

The natural history of the mollusca producing the shells, and the best account of the manufacture of cameos, was given by Dr. J. E. Gray, of the British Museum, in a paper read before the Society of Arts in 1847, to which, and to his paper in the *Phil. Trans.*, we are indebted for much of the following information.

It was the custom in Holland to use the pearly nautilus as a cameo shell, and several kinds of turbines or wreath-shells, which have an opaque white external coat over an internal pearly one. These are now rarely employed. The shells now used are those of the flesh-eating univalves (*Gasteropoda ptenobranchiata zoophaga*), which are peculiar for being all formed of three layers of calcareous matter, each layer being composed of three perpendicular laminae placed side by side; the laminae comprising the central layer, being placed at right angles with one of the inner and outer ones; the inner and outer being placed longitudinally with regard to the axis of the line of the shells, while the inner laminae are placed across the axis, and concentrically with the edge of the mouth of the cone of the shell.—(Gray, *Phil. Trans.*)

This structure furnishes the cameo-cutter with the means of giving a particular surface to his work, a good workman always putting his work on the shell in such a manner, that the direction of the laminae of the central coat is longitudinal to the axis of his figure. The central layer forms the body of the bas-relief, the inner laminae being the ground, and the outer one, the third or superficial colour, which is sometimes used to give a varied appearance to the surface of the figure. The cameo-cutter, therefore, selects for his purpose those shells which have three layers of different colours, as these afford him the means of relieving his work; and secondly, those which have the three layers strongly adherent together, for if they separated, his labour would be lost.

The following are the kinds of shells now employed:—1. The bull's mouth (*Cassis rufum*), which has a red inner coat, or what is called a *sardonyx* ground. 2. The black helmet (*Cassis Madagascariensis*), which has a blackish inner coat, or what is called an *onyx* ground. 3. The horned helmet (*Cassis cornutum*), with a yellow ground. 4. The queen's conch (*Strombus gigas*), with a pink ground.

The bull's mouth and the black helmet are the best shells. The horned helmet is apt to separate from the ground, or *double*; and the last, the queen's conch, has but seldom the two colours marked with sufficient distinctness, and the finish of the ground colour flies on exposure to light.

The red colour of the bull's mouth extends only a slight distance in the mouth of the shell, becoming paler as it proceeds backwards. The dark colour extends farther in the black and yellow varieties. Hence the bull's mouth only affords a single cameo large enough to make brooches of, and several small pieces for shirt-studs. The black helmet yields on an average about five brooches, and several pieces for studs, while the queen's conch affords only one good piece.

Forty years since, very few cameos were made from any shells but the black helmet, and the number of shells then used amounted to about 300 annually, nearly all of which were sent from England, being all that were then imported. The black helmet is imported into England from Jamaica, Nassau, and New Providence. They are not found in Madagascar, though naturalists have for a long period called them *Madagascar helmets*.—(Gray).

Of the bull's mouth, half are received direct from the Island of Bourbon, to which place they are brought from Madagascar, and the other half are obtained from the Island of Ceylon, being received by the way of Calcutta; hence they are often called 'Calcutta shells.'

So rapidly has the trade in these shells increased, that Dr. Gray informs us, that in Paris 100,500 shells are used for cameos annually. These are divided as follows:—

	Price	Value		Price	Value		
Bull's mouth .	80,000	1s. 8d.	6,400l.	Horned helmet .	500	2s. 6d.	60l.
Black helmet .	8,000	5 0	1,920	Queen's conch .	12,000	1 2½	725

The manufacture of shell cameos was for some time confined to Italy; about twenty-five years since, an Italian commenced making them in Paris, and now the trade belongs to the French capital, where not less than 300 persons are engaged in the manufacture. Nearly all the cameos made in France were sent to England, and in Birmingham mounted as brooches, and exported to America and the British Colonies.

CAMERA LUCIDA. An instrument invented by Dr. Wollaston, for the purpose of enabling anyone, without a knowledge of the rules of drawing or perspective, to delineate any external object with accuracy. It consists essentially of a quadrangular glass prism.

CAMERA OBSCURA, literally *dark chamber*. An instrument invented by

Baptiste Porta. It is employed for the production of photographic pictures, and will be fully described in the article devoted to that art. See PHOTOGRAPHY.

CAMES. Slips of lead employed by glaziers in glazing church or cottage windows in the olden style. They were formerly called 'lattices,' and hence leaded windows were termed lattice windows.

CAMLET or **CAMBLER.** A light stuff, formerly much used for female apparel. It is made of long wool, hard spun, sometimes mixed in the loom with cotton or linen yarn. Several fabrics of the same kind are now introduced under other names.

CAMPEACHY WOOD (*Hematoxylon Campechianum*). Logwood brought from the bay of that name. See LOGWOOD.

CAMPHENE. The radicle of camphor; various hydrocarbons isomeric or polymeric with oil of turpentine are so called. See WATT'S 'Dictionary of Chemistry.'

CAMPHINE. Rectified oil of turpentine is sold in the shops under this name for burning in lamps. Crude oil of turpentine is redistilled with potash, and then with water, and lastly, to secure its perfect purity, with chloride of calcium. The oil thus prepared forms a limpid colourless liquid; its specific gravity is about 0.870, but it is subject to some slight variations; C^2H^4 appears fairly to represent this, and several other similar oils. It is very inflammable, burning with a bright red flame, and without a proper supply of air it evolves much dense smoke, hence peculiar lamps (*Camphine lamps*) are required. Where it has, from exposure to air, absorbed oxygen, and become *resinified*, it is unfit for purposes of illumination. Such *camphine* very rapidly clogs the wick with a dense carbon, and is liable to the thick black smoke, which is so objectionable in the camphine lamps if they are not properly attended to.

To purify old *camphine*, it must be redistilled from carbonate of potash, or some similarly active substance to deprive it of its resin. See LAMPS.

CAMPHOLE. One of the oils obtained from coal-tar. Mansfield gave this name to the oils *cumole* and *cymole*, which boil at 284° and 330° F., when collected together. The specific gravity of crude camphole ranges from 0.88 to 0.98, and the less volatile portions frequently contain naphthaline, which raises their specific gravity. This substance, either alone or mixed with pyroxylic spirit, is applicable for burning in lamps or for dissolving resins, as a substitute for oil of turpentine.

CAMPHOR, or **CAMPHIRE.** (*Camphre*, Fr.; *Kampher*, Ger.) This immediate-product of vegetation was known to the Arabs under the names of *kamphur* and *kaphur*, whence the name *camphora*. Camphor was not known to the ancients; it is first mentioned by Avicenna, and Serapion calls it *cafur*. Symeon Seth, who lived in the eleventh century, describes it. It is found in a great many plants, and is secreted, in purity, by several laurels; it occurs combined with the essential oils of many of the *Labiatae*; but it is extracted, for manufacturing purposes, only from the *Laurus camphora*, or *Camphora officinarum*, a member of the Laurel order, which abounds in China and Japan, as well as from a tree which grows in Sumatra and Borneo, called, in the country, *Kapcur barros*, from the name of the place where it is most common. This Sumatra camphor is the produce of the *Dryobalanops camphora*. The camphor exists, ready formed, in these vegetables, between the wood and the bark; but it does not exude spontaneously. On cleaving the tree which produces the Sumatra camphor masses of pure camphor are found in the trunk. Sumatra camphor is not imported into this country, as it is eagerly bought up by the Chinese, who prize it highly.

To prepare camphor the wood of the laurus is cut into small pieces, and put with plenty of water into large iron boilers, which are covered with an earthen capital or dome, lined within with rice straw. As the water boils, the camphor rises with the steam, and attaches itself as a sublimate to the stalks, under the form of granulations of a grey colour. In this state it is picked off the straw, and packed up for exportation to Europe.

Formerly Venice held the monopoly of refining camphor, but now France, England, Holland, and Germany refine it for their own markets. All the purifying processes proceed on the principle that camphor is volatile at the temperature of 400° F. The substance is mixed, as intimately as possible, with 2 per cent. of quicklime, and the mixture is introduced into a large bottle made of thin uniform glass, sunk in a sand-bath. The fire is slowly raised till the whole vessel becomes heated, and then its upper part is gradually laid bare in proportion as the sublimation goes on. Much attention and experience are required to make this operation succeed. If the temperature be raised too slowly, the neck of the bottle might be filled with camphor before the heat had acquired the proper subliming pitch; and, if too quickly, the whole contents might be exploded. If the operation be carried on languidly, and the heat of the upper part of the bottle be somewhat under the melting-point of camphor,

that is to say, a little under 350° F., the condensed vapour would be snowy, and not sufficiently compact and transparent to be saleable. Occasionally, sudden alterations of temperature cause little jets to be thrown up, out of the liquid camphor at the bottom, on the cake formed above, which soil it, and render its resublimation necessary.

If to the mixture of 100 parts of crude camphor and 2 of quicklime, 2 parts of bone-black, in fine powder, be added, the small quantity of colouring matter in the camphor will be retained at the bottom, and whiter cakes will be produced. A spiral slip of platina foil immersed in the liquid may tend to equalise its ebullition.

By exposing some volatile oils to spontaneous evaporation, at the heat of about 70° F., Proust obtained a residuum of camphor:—from oil of lavender, 25 per cent. of its weight; from oil of sage, 12½; from oil of marjoram, 10 per cent.

Refined camphor is a white translucent solid, possessing a peculiar taste and smell. It may be obtained, from the slow cooling of its alcoholic solution, in octahedral crystals. It may be scratched by the nail, is very flexible, and can be reduced into powder readily by mixing it with a few drops of alcohol and giving a few blows to the camphor. Its specific gravity varies from 0.985 to 0.996. Mixed and distilled with six times its weight of clay, it is decomposed, and yields a golden yellow aromatic oil, which has a flavour analogous to that of a mixture of thyme and rosemary; along with a small quantity of acidulous water tinged with that oil, charcoal remains in the retort. In the air, camphor takes fire on contact of an ignited body, and burns away with a bright fuliginous flame. Pieces of ignited camphor thrown into water execute peculiar rotatory movements.

Camphor is little soluble in water; one part being capable of communicating smell and taste to 1,000 of the fluid, this is the *Misture Camphoræ* of the apothecary. 100 parts of alcohol, specific gravity 0.806, dissolve 120 parts of camphor, at ordinary temperatures. It is separated in a pulverulent state by water. Ether and oils, both expressed and volatile, also dissolve it.

When distilled with 8 parts of aquafortis, camphor is converted into camphoric acid. Camphor absorbs 144 times its volume of muriatic acid gas, and is transformed into a colourless transparent liquid, which becomes solid in the air, because the acid attracts humidity, which precipitates the camphor. One part of strong acetic acid dissolves 2 parts of camphor. By Dr. Ure's analysis, camphor consists of 77.38 carbon, 11.14 hydrogen, and 11.48 oxygen.

Dumas (1) and Blanchet and Sell (2) have given the following composition:—

	(1)	(2)
Carbon	78.02	77.96
Hydrogen	10.39	10.61
Oxygen	11.59	11.43

There are two kinds of camphor imported:—

JAPAN CAMPHOR, called **DUTCH CAMPHOR**, because it is always brought by the Dutch to England. It comes by the way of Batavia, and is imported in tubs (hence it is called *tub camphor*), covered with matting, and each surrounded by a second tub, secured on the outside by hoops of twisted cane.

CHINA CAMPHOR, or **FORMOSA CAMPHOR**, is imported from Singapore and Bombay, in chests lined with lead-foil, containing about 1½ cwt.

It has been suggested to introduce the camphor trees into other countries. South Georgia and Florida are named as suitable localities. The *Laura camphora* is commonly found in all the nurseries around Paris, and sold at 5 francs for a plant 30 inches high. At full growth the tree attains an altitude of from 40 to 50 feet. The wood of the camphor tree is in favour for carpenters' work; it is light, is easily worked, durable, and not liable to be attacked by insects. It is said that in Sumatra numbers of trees are cut down before one is found to repay. Not a tenth part of the trees attacked yield either camphor or camphor oil.

The camphor is distinguished by the names of head, belly, and foot, when in bulk. The head camphor is in large white flakes; the belly camphor, small brown flakes, transparent, like resin coarsely powdered; the foot, like dark-coloured resin. A native 'Catty' may be divided into:—1. Capallo, or large head, = 2.2; 2. Capallo cachell, or small head, = 3.5; 3. Baddan, or belly, = 4.2; 4. Cakee, or foot, = 6.1; = 1 Catty, 16.

CAMPHOR, ARTIFICIAL. When hydrochloric (muriatic) acid is passed into oil of turpentine, surrounded by ice, two compounds are obtained, one solid and the other fluid. The first, solid artificial camphor $C^{20}H^{16}HCl$ ($C^{10}H^{16}HCl$), is white, transparent, lighter than water, and has a camphoraceous taste. The fluid is termed *liquid* artificial camphor, or terebene.

CAMPHOR JULEP. Water in which camphor is dissolved.

CAMPHOR, OIL OF LAUREL. When the branches of *Camphora officinarum* are distilled with water, a mixture of camphor and a liquid essential oil is obtained. This is the oil of camphor; it has a density of 0.910, and its composition is $C^{20}H^{16}O$. By exposure to oxygen gas, or to the action of nitric acid, it absorbs oxygen, and becomes solid camphor $C^{20}H^{16}O^2$ ($C^{10}H^{16}O$).

This is an esteemed article in the Eastern markets; it undergoes no preparation, and though named oil, it is rather a liquid and volatile resin. The natives of Sumatra make a transverse incision in the tree to the depth of some inches, the cut sloping downwards so as to form a cavity of the capacity of a quart; a lighted reed is placed in it for about 10 minutes, and in the space of a night the cavity is filled with this fluid. The natives consider this oil of great use as a domestic remedy for strains, swellings, and inflammations.

Dr. Royle states the trees are of large dimensions, from $2\frac{1}{2}$ to 7 feet in diameter. The same tree that produces the oil would have produced the camphor if unmolested, the oil being supposed to be the first stage of the camphor's forming, and is consequently found in younger trees.

CAMPHOR STORM GLASSES. Glasses called usually storm glasses, and sold as indicators of atmospheric changes. 'Storm glasses' are made by dissolving camphor $2\frac{1}{2}$ drachms, nitre 38 grains, sal-ammoniac 38 grains, water 9 fluid drachms, rectified spirit of wine 11 fluid drachms.

Plumose crystals form in the glass, and are said to condense and collect at the bottom of the bottle on the approach of a storm, and to rise up and diffuse themselves through the liquid on the approach of fine weather; but Dr. Parrion thinks that their weather-predicting qualities are false, and that light is the agent which, together with temperature, influences the condition.

CAM-WOOD. An African dye wood, shipped principally from Sierra Leone, in short logs. Mr. G. Loddiges, in his Botanical Cabinet, figures the plant producing it under the name of *Baphia nitida*; it is a leguminous plant, and has been introduced into, and has flowered in this country.

CANADA BALSAM. A product of the *Abies balsamea*, or balm of Gilead fir. The finest variety of this balsam is used for mounting objects for the microscope. See BALSAM.

CANADA PLATES. Tin plates, so called by having been made for the Canadian trade.

CANADA RICE. The *Zizania aquatica*, a Canadian grass.

CANADA SUGAR. A dark sugar made from the sugar maple, *Acer saccharinum*.

CANADA YELLOW ROOT. The *Hydrastis Canadensis* (*Xanthorhiza*), a shrub growing in North America, so named from the colour of its root. It is intensely bitter, hence it is used as a tonic medicine, and a good yellow dye is extracted from its roots.

CANARIUM COMMUNE. A small tree, growing in India, Ceylon, and various parts of the Eastern Archipelago. It is probably the source of the concrete resinous exudation commonly known as *Gum Elemi*. See ELEM.

CANARY WOOD. A wood is imported into this country under the name of Madeira mahogany, which appears to be this canary wood. It is the produce of the Royal Bay, *Laurus indica*, a native of the Canary Islands. It is rather a light wood, and of a yellow colour.

CANASTER. An American tobacco, so called from the peculiar rush basket in which it was imported.

CANAÜBA. The leaves of the canaüba tree of Brazil (*Copernicia cerifera*) yield a wax which appears to be the same as that produced by the Carnaüba Palm.

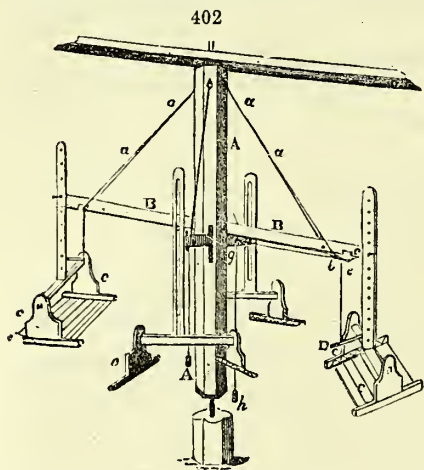

CAND or KAND. A name in some mining districts for Fluor spar.

CANDLE. (*Chandelle*, Fr.; *Kerze*, *Licht*, Ger.) Candles are either dipped or moulded. As the quality of the candle depends on the material employed in its manufacture, the first part of the tallow-chandler's process is the sorting of the tallow. Mutton suet with a proportion of ox tallow is selected for mould candles, because it gives them gloss and consistence. Coarser tallow is reserved for the dipped candles. After being sorted, it is cut into small pieces, preparatory to being melted or *rendered*; and the sooner this is done after the fat is taken from the carcase the better, because the fibrous and fleshy matters mixed with it promote its putrefaction. Tallow is too commonly melted by a naked fire applied to the bottom of the vessel, whereas it should be done either in a cold set-pan, where the flame plays only round the sides a little way above the bottom, or in a steam-cased pan. After being fused a considerable time, the membranous matters collect at the surface, constituting the *cracklings* used sometimes for feeding dogs, after the fat has been squeezed out of it by a press. The liquid tallow is strained through a sieve into another copper, where it is treated with water at a boiling temperature, in order to wash it. After a while, when the foul

water has settled to the bottom, the purified tallow is lifted out, by means of tinned iron buckets, into tubes of moderate size, where it concretes, and is ready for use.

It is a remarkable circumstance, that the wicks for the best dipped candles are still cotton rovings imported from Turkey, notwithstanding the vast extension and perfection of cotton-spinning in this country. Four or more of these Turkey skeins, according to the intended thickness of the wick, are wound off at once into bottoms or clues, and afterwards cut by a simple machine into lengths corresponding to those of the candles to be made. The operations for cutting, twisting, and spreading wicks, are performed upon a series of threads at once. The apparatus is placed in a box, in front of which the operator sits. A reel extends across the box at the hinder part, upon which the cotton threads have been previously wound: from this reel they are drawn off into proper lengths, doubled, and cut by an ingenious mechanism. By dipping the wicks into the melted tallow, rubbing them between the palms of the hands, and allowing the tallow which adheres to harden, they may be arranged with facility upon the broaches for the purpose of dipping. The dipping room is furnished with a boiler for melting the tallow, the dipping mould or cistern, and a large wheel for supporting the broaches. From the ceiling of the workshop a long balanced-shaped beam is suspended, to one end of which a wooden frame is attached for holding the broaches with the wicks arranged at proper distances. The opposite arm is loaded with a weight to counterbalance the wooden frame, and to enable the workmen to ascertain the proper size of the candles. The end of the lever which supports the frame is placed immediately above the dipping cistern; and the whole machine is so balanced that, by a gentle pressure of the hand, the wicks are let down into the melted tallow as often as may be required.

The following is a convenient apparatus for dipping candles. In the centre of the dipping-room a strong upright post *A A*, (*fig. 402*) is erected, with turning iron pivots

at its two ends. Near its middle, six mortises are cut at small distances from one another, into each of which is inserted a long bar of wood, *B B*, which moves vertically upon an iron pin, also passing through the middle of the shaft. The whole presents the appearance of a large horizontal wheel with twelve arms. A complete view of two of them only is given in the figure. From the extremity of each arm is suspended a frame, or port, as the workmen call it, containing 6 rods, on each of which are hung 18 wicks, making the whole number of wicks upon the wheel 1,296. The machine, though apparently heavy, turns round by the smallest effort of the workman; and each port, as it comes in succession over the dipping-mould, is gently pressed downwards, by which means the wicks are regularly immersed in

melted tallow. As the arms of the lever are all of the same length, and as each is loaded with nearly the same weight, it is obvious that they will all naturally assume a horizontal position. In order, however, to prevent any oscillation of the machine in turning round, the levers are kept in a horizontal position by means of small chains, *a a*, one end of which is fixed to the top of the upright shaft, and the other terminates in a small square piece of wood *b*, which exactly fills the notch *c* in the lever. As one end of the levers must be depressed at each dip, the square piece of wood is thrown out of the notch by the workman pressing down the handle *d*, which communicates with the small lever *e*, inserted into a groove in the bar *b*. In order that the square piece of wood fixed in one extremity of the chain, may recover its position upon the workman's raising the port, a small cord is attached to it, which passes over a pulley inserted in a groove near *c*, and communicates with another pulley and weight, which draws it forward to the notch. In this way the operation of dipping may be conducted by a single workman with perfect ease and regularity, and even despatch. No time is lost, and no unnecessary labour expended, in removing the ports after each dip; and, besides, the process of cooling is much accelerated by the candles being kept in constant motion through the air. The number of revolutions which

the wheel must make, in order to complete one operation, must obviously depend upon the state of the weather and the size of the candles; but it is said that, in moderately cold weather, not more than two hours are necessary for a single person to finish one wheel of candles of a common size. Upon the supposition, therefore, that six wheels are completed in one day, no less a number than 7,776 candles will be manufactured in that space of time by one workman.

The process of moulding is even less complicated in its details than that of dipping. The moulds are made of some metallic substance, usually pewter, and consist of two parts. The shaft or great body of the mould is a hollow cylinder, finely polished in the inside, and open at both extremities. The top of the mould is a small metallic cup, having a moulding within-side, and a hole to admit the wick. The two parts are soldered together, and when united, as will readily be imagined, have the shape of a moulded candle. A third piece, called the foot, is sometimes added: it is a kind of small funnel, through which the liquid tallow runs into the mould, and being screwed to the opposite extremity of the shaft, is removable at pleasure. This additional piece may certainly be useful in very mild weather; since, by removing it, the candles may be drawn more easily from the moulds; but, in general, it may be dispensed with.

Eight or twelve of these moulds, according to their size, are fixed in a frame, which bears a great resemblance to a wooden stool, the upper surface of which forms a kind of trough. The tops of the moulds point downwards, and the other extremity, which is open, is inserted into the trough or top of the stool, and made quite level with its upper surface. In order to introduce the wicks into the mould, the workman lays the frame upon its side on an adjoining table, and holding in his left hand a quantity of wicks, previously cut to the proper length, he introduces into the mould a long wire with a hooked point. As soon as the hook of the wire appears through the hole in the top of the mould, he attaches to it the looped end of the wick, and, immediately drawing back the wire, brings the wick along with it. In this manner each mould in succession is furnished with a wick. Another workman now follows, and passes a small wire through the loop of each wick. This wire is obviously intended to keep the wick stretched, and to prevent it from falling back into the mould upon the frame being placed in the proper position for filling. The frame is then handed to the person that fills the moulds, who previously arranges the small wires in such a manner that each wick may be exactly in the axis of the mould.

The moulds are filled by running tallow into each of them, or into the trough, from a cistern furnished with a cock, and which is regularly supplied with tallow of the proper temperature from an adjoining boiler. When the workman observes that the moulds are nearly half filled he turns the cock, and laying hold of that portion of the wick which hangs out of the mould, pulls it tight, and thus prevents any curling of the wick, which might injure the candles; he then opens the cock, and completes the process of filling. The frame is now set aside to cool; and when the tallow has acquired a proper consistence, which the workman easily discovers by a snapping noise emitted by the candles upon pressing his thumb against the bottom of the moulds, he first withdraws the small wires which kept the wicks tense, and then, scraping off the loose tallow from the top of the frame with a small wooden spade, he introduces a bodkin into the loop of the wick, and thus draws each candle in succession from its mould. The candles are now laid upon a table for inspection, and afterwards removed to the storehouse. Previous to storing them up, some candle-makers bleach their candles, by exposing them to the air and dews for several days. This additional labour can be necessary only when the dealer is obliged to have early sales; for if the candles are kept for some months, as they ought to be, before they are brought to market, they become sufficiently whitened by age.

Wax Candles.—Next to tallow, the substance most employed in the manufacture of candles is wax. Wax candles are made either by the hand or with a ladle. In the former case, the wax, being kept soft in hot water, is applied bit by bit to the wick, which is hung from a hook in the wall: in the latter, the wicks are hung round an iron circle, placed immediately over a large copper-tinned basin full of melted wax, which is poured upon their tops, one after another, by means of a large ladle. When the candles have by either process acquired the proper size, they are taken from the hooks, and rolled upon a table, usually of walnut-tree, with a long square instrument of box, smooth at the bottom.

Spermaceti Candles are moulded in the same manner as those composed of stearine, or stearic acid, to be described presently.

In June 1825, M. Gay-Lussac obtained a patent in England for making candles from *margaric and stearic acids*, called *stearine*, by converting tallow into the above fat acids by the following process:—Tallow consists, by Chevreul's researches, of *stearine*, a solid fat, and *oleine*, a liquid fat; the former being in truth the larger proportion. When tallow is treated with an alkaline body, such as potash, soda, or lime, it is

saponified; that is, its stearine and oleine become respectively stearic and oleic acids, and, as such, form compounds with these bases. When by the action of an acid, such as the sulphuric or muriatic, these combinations are decomposed, the fats reappear in the altered form of stearic and oleic acids; the former body being harder than tallow, and of a texture somewhat like spermaceti, the latter body being fluid like oil. 'The decomposition of the soap should be made,' says the patentee, 'in a large quantity of water, kept well stirred during the operation, and warmed by steam introduced in any convenient way. When the mixture has been allowed to stand, the acid of the tallow or fat will rise to the surface, and the water being drawn off, will carry the alkaline or saline matters with it; but, if the acids of the tallow should retain any portion of the salts, fresh water may be thrown upon it, and the whole well agitated, until the acids have become perfectly free from the alkaline matters; and when allowed to cool, the acids will be formed into a solid mass. The mass is now to be submitted to considerable pressure in such an apparatus as is employed in expressing oil from seeds; when the liquid acid will run off in the form of a substance resembling oil, leaving a solid matter, similar, in every respect, to spermaceti, which is fit for making candles.'

The wick to be used in the manufacture of the stearine candles, and which forms one of the features of this invention, is to be made of cotton yarn, twisted rather hard, and laid in the same manner as wire is sometimes coiled round the bass strings of musical instruments. For this purpose, straight rods or wires are to be procured, of suitable lengths and diameters, according to the intended size of the candles about to be made; and these wires, having been covered with cotton coiled round them, as described, are to be inserted in the candle moulds as the common wicks are; and when the candle is made, and perfectly hard, the wire is to be withdrawn, leaving a hollow cylindrical aperture entirely through the middle of the candle. The first successful application of the fat acid, or stearic candles, appears to have been made by Messrs. Motard and Nilly. They made stearine candles, which they called '*bougies de l'étoile*,' for which the 'Society of Encouragement' voted them their silver medal. See STEARINE.

Messrs. Hempbell and Blundell have given a very minute account of the process for making palm-oil, stearic and margaric acids, in their specification of their patent for this mode of manufacturing candles:—

1. Their first process is called *crystallisation*, which consists in pouring the melted palm-oil into iron pans, allowing it to cool slowly, whereby, at about 75° F., the oleine separates from the crystalline stearine and margarine.

2. The concreted oil is subjected to the action of an hydraulic press, in order to separate the oleine from the solid fats.

3. This process is called *oxidation*. To 104 lbs. of the stearine and margarine, melted in an iron pan, about 12 lbs. of slaked and sifted quicklime are added, with diligent stirring, during which the temperature is to be slowly raised to 240° F., and so maintained for about 3 hours, till a perfect chemical combination takes place. This is shown by the mass becoming thin, transparent, and assuming a glassy appearance when it cools. The fire being now withdrawn, cold water is added, very gradually at first, with brisk stirring till the whole mass falls into a state of powdery granulation, when it is passed through a wire sieve to break down any lumps that may remain.

4. *Separation of the Stearic and Margaric Acids from the lime.* For this purpose, as much muriate of lime (chloride of calcium) is taken as will, with its equivalent quantity of sulphuric acid (8 lbs. of dry muriate of lime, require 7 lbs. of the strongest sulphuric acid), produce as much muriatic acid as will dissolve the lime combined with the fat acids: and therefore that quantity of muriate of lime dissolved in water must be treated with as much sulphuric acid as will saturate its lime and throw it down in the state of sulphate of lime. Add the supernatant solution of muriatic acid in such proportion to the stearate and margarate of lime as will rather more than saturate the lime. Three pounds of muriatic acid diluted with 9 lbs. of water are stated as enough for 1 lb. of lime. The mixture is to be let alone for 3 or 4 days, in order to insure the complete separation of the lime from the fat acids; and then the mixture is heated so as to melt and cause them to separate in a stratum on the top of the liquid. The resulting muriate of lime is drawn off into another tub, and decomposed by its dose of sulphuric acid, so as to liberate its muriatic acid for a fresh operation.

5. The fat acids, being well washed by agitation with hot water, are then set to cool and crystallise, in which state they are subjected to the action of the hydraulic press, at a temperature of 75° F., whereat the margaric acid runs off from the solid stearic acid.

6. *Bleaching.* The stearic acid is taken from the press, and exposed upon water in large shallow vessels placed in the open air, where it is kept at the melting temperature from 1 to 12 hours, stirring meanwhile, in order to promote the bleaching action of the atmosphere. The margaric acid is bleached in a similar manner in separate vessels.

7. *Refining Process.* The fat is warmed again, and poured in a liquid state into an

agitating tub; where, for every 1,000 lbs. of the stearic acid, about $2\frac{1}{2}$ lbs. of common black oxide of manganese, and 40 lbs. of concentrated sulphuric acid, diluted with 200 lbs. of pure water are to be used. This solution ('mixture'), while warm from the heat evolved in diluting the acid, is placed in a suitable vessel above the agitating tub. The stearic acid being at the melting point, in the vessel below, agitation is to be given with a revolving shaft, while the mixed manganese and acid are run slowly down into it, till the whole be well mixed, which generally requires about two hours. The mass is allowed to lie in this state for 48 hours; after which it may be boiled by steam for 2 or 3 hours, when it will be sufficiently refined. The sulphuric acid, which is at the bottom, is now run off, and the stearic acid which remains is well washed with pure water. It is then put into large conical vessels of stone-ware, inclosed in a box or jacket, kept warm by steam-heat, and lined with conical bags of a suitable strong filtering paper, through which, being warm, it finds its way; and when the stearic acid has been thus filtered, it is run into blocks, when it will be found to be a beautiful stearic acid or palm-wax, and is ready to be made into candles in the usual way.

The chief solid constituent of palm-oil is margaric acid. This they direct to be melted with tallow, in the proportion of from 10 to 20 lbs. of the former to 100 lbs. of the latter. See *Newton's Journal, C. S.*, xi, 207.

Messrs. Price and Co. introduced, in 1840, on the occasion of Her Majesty's marriage (when, for the illuminations, a cheap self-snuffing candle was required), a new composite candle, which was a mixture of stearic acid and cocoa-nut stearine. Mr. George Gwynne, in 1840, patented a process for purifying the fatty acids by distillation; this was followed by a similar patent by Dubrunfant; and Mr. Wilson, of Belmont, Vauxhall, obtained in August 1842, a patent for improvements in treating fats for making candles. These advances led to many modifications in candle-manufacture.

If distilled fats are used in making composite candles, they are bleached and hardened in that operation. When palm-oil is the material, it is first saponified, then distilled, granulated by fusion and slow cooling, and cold-pressed; by which means stearic acid and a light-coloured oil are obtained, which may be mixed with the stearine of cocoa-nut oil, or other stearine. A cheaper article may be had by mixing the entire product of the above distillation with half its weight of distilled and cold-pressed stearic acid of tallow. Tallow is deprived of its oleine by pressure, accompanied by artificial cold if necessary; this being added to the other hard matter, the mixture is converted into fatty acids, and distilled, and the entire product of distillation is employed for making candles; or it may be pressed to make them harder. As distilled stearic acid is more crystalline than undistilled, 2 or 4 per cent. of wax may be added to assist the combination of the fatty acid with the stearine.

Candles consisting of alternate layers of tallow and stearine have been made by dipping their wicks alternately in these two fatty bodies in a fluid state. Mr. W. Sykes has gone to the expense of a patent on the contrivance. The wicks are impregnated with a solution of bismuth or borax.

In a lecture delivered before the Society of Arts by Mr. Wilson, and published in their Journal, he described the progress of the more recent improvements. In this he says:—'Candles, beautiful in appearance, were made by distilling the cocoa-nut acids; but, on putting them out, they gave off a choking vapour, which produced violent coughing.' This prevented those candles from being brought into the market. 'By distilling cocoa-nut lime-soap, we made beautiful candles, resembling those made from paraffine, burning perfectly; but the loss of material in the process was so great, that the subsequent improvements superseded its use. Under one part of this patent, the distillation was carried on sometimes with the air partially excluded from the apparatus by means of the vapour of water, sometimes without, the low evaporating point of the cocoa-nut acids rendering the exclusion of air a matter of much less importance than when distilling other fat acids.' At this time, in conjunction with Mr. Jones, Mr. Wilson appears to have first tried using the vapour of water to exclude the air from the apparatus during distillation. This led, in 1842, Messrs. E. Price and Co. to patent, in the names of Wilson and Jones, a process which involved the treatment of fats, previously to distillation, with sulphuric acid, or nitrous gases. M. Frémy, in his valuable paper in the '*Annales de Chimie*,' describes treating oils with half their weight of concentrated sulphuric acid, by which their melting point was greatly raised. He gave, however, particular directions that the matter under process should be kept cool. Instead of doing this, Mr. Wilson found it advantageous to expose the mixture of fat acid and fat to a high temperature, and this is still done at Price's works.—

'Our process of sulphuric acid saponification was as follows.—Six tons of the material employed—usually palm-oil, though occasionally we work cheap animal fat, vegetable oils, and butter, and Japan wax—were exposed to the combined action of $6\frac{3}{4}$ cwts. of concentrated sulphuric acid, at a temperature of 350° F. In this process

the glycerine is decomposed, large volumes of sulphurous acid are given off, and the fat is changed into a mixture of fat acids, with a very high melting point. This is washed, to free it from charred matter and adhering sulphuric acid, and is then transferred into a still, from which the air is excluded by means of steam. The steam used by us is heated in a series of pipes similar to those used in the hot-blast apparatus in the manufacture of iron, the object of heating the steam being only to save the still, and reduce to a small extent gaseous loss in distillation.' 'We still,' says the patentee, 'employ this process, and in some cases reduce the quantity of acid employed to 4 lbs., and even 3 lbs., to a cwt. of the fat.'

Vegetable tallow melts at a degree of heat somewhat above that of animal tallow, but considerably below that of vegetable wax. Mr. Wilson treats his tallow by putting 6 tons of it into an iron still capable of holding 9 tons, heats it gradually to 350° F., and then adds gradually 1,440 lbs. of sulphuric acid of 1·8 specific gravity. At the expiration of about 2 hours, the tallow is pumped into a vessel, containing water slightly acidulated with sulphuric acid; and is therein agitated by free steam passing through it for 2 hours. The materials are then left to repose for 6 hours; both these vessels, and the former, should be provided with a cover and a means of conveying the gases which may be evolved into a chimney. The vegetable tallow is next distilled in such a manner that the atmosphere is excluded. This is best effected by the use of steam highly heated, which he introduces into the still, in numerous jets below the tallow. The distilled products are received into condensers, and they may be used alone, or they may be mixed with other matters for making the best class of candles. The patentee improves paraffine by a like process. He makes candles with 2 or 3 wicks, by mixing palm-oil pressed with tallow, or the above distilled fat, for burning in candle lamps.

In 1854, Mr. Tighman obtained a patent for the exposure of fats and oils to the action of water at a high temperature, and under great pressure in order to cause the combination of the water with the elements of the neutral fats; so as to produce at the same time free fat acid and solution of glycerine. See GLYCERINE.

He proposed to effect this by pumping a mixture of fat and water, by means of a force-pump, through a coil of pipe heated to about 612° F., kept under a pressure of about 2,000 lbs. to the square inch; and he states that the vessel must be closed, so that the requisite amount of pressure may be applied to prevent the conversion of water into steam. Mr. Wilson improved upon this process, by passing steam into fat at a high temperature; and by this process hundreds of tons of palm-oil are now treated. The glycerine and fat distil over together, but no longer combined; and the former, being separated, is subjected to a redistillation, by which it is purified. This distillation is effected by transmitting through the fat contained in an iron still, steam at about 600° or 700° F., heated by passing through iron pipes laid in a fire. The steam is transmitted till the oily matter is heated to about 350°; the vapours produced being carried into a high shaft by a pipe from the cover of the iron vessel. The hot oily matter is then run into another vessel made of brick lined with lead, and sunk in the ground, for the purpose of supporting the brick-work under or against the internal pressure of the fluid. It has a wooden cover lined with lead, directly beneath which, and extending across the vessel, is a leaden pipe, 1 inch in diameter, having a small hole on each side, at every 6 inches of its length; and through this pipe is introduced a mixture of 1,000 lbs. of sulphuric acid, specific gravity 1·8, and the same weight of water. The introduction of the mixture, which falls in divided jets into the heated fat, produces violent ebullition; and by this means the acid and fat are perfectly incorporated before the action of the acid becomes apparent by any considerable discoloration of the fat. As the ebullition ceases, the fat gradually blackens; and the matter is allowed to remain for 6 hours after the violent ebullition has ceased. The offensive fumes produced are carried off by a large pipe, which rises from the top of the vessel, then descends, and afterwards rises again into a high chimney. At the downward part of this pipe a small jet of water is kept playing, to condense such parts of the vapours as are condensable. At the end of the six hours above mentioned, the operation is complete, and the product is then pumped into another close vessel and washed, by being boiled up (by means of free steam) with half its bulk of water. The water is drained off, and the washing repeated, except that in the second washing the water is acidulated with 100 lbs. of sulphuric acid. The ultimate product is allowed to settle for 24 hours; after which it is distilled in an atmosphere of steam—once, or oftener—until well purified; and the product of distillation is again washed, and after being pressed in the solid state, is applied to the manufacture of candles.

The following definitions of terms applied to candles are by Mr. Wilson:—

Belmont Sperm.—Made of hot-pressed, distilled palm-acid.

Belmont Wax.—The same material, tinged with gamboge.

Best Composite Candles.—Made of a mixture of the hard palm-acid, and stearine of cocoa-nut oil.

Composites, Nos. 1, 2, and 3, are made of palm-acids, and palm-acids and cocoa-nut stearine, the relative proportions varying according to the relative market prices of palm-oil and cocoa-nut oil at the particular time when the candles are manufactured.

Composite, No. 4.—A description of candle introduced at a price a very little above the price of tallow dip candles. They are somewhat dark in colour, but give a good light.

The highest priced candles are usually made in the ordinary mould; but at Messrs. Price and Co.'s manufactory they have a machine for moulding the ordinary stearine candles, the others of a similar nature. When one set of candles is discharged from the mould, the moulds are re-wicked for the next process of filling. These moulds are arranged, side by side, 18 in number, on a frame; and for each mould there is a reel capable of holding 60 yards of wick, enclosed in a box. The moulded candle, being still attached to the cotton wick, when it is forced out of the mould, brings the fresh wick into it. The moulded candles are, by a very ingenious contrivance, held firm in a horizontal position while a knife passes across and severs the wick. The wicks for the new set of candles are firmly secured, by forceps, to the conical caps of the moulds; these are carried into a vertical position, and slid upon a railway to a hot closet, where they become sufficiently warm to receive the fat, which, kept at the melting point by steam-pipes, is held in a cistern above the rails; from this cistern the moulds are filled by as many cocks, which are turned by one impulse. If we imagine an extensive series of these sets of moulds travelling from the machine over a railway, in regular order, and that, when the fat has become solid, these return, the candles are discharged, and the process is renewed—the machine will be tolerably well understood. Each machine holds about 200 frames of moulds, and each contains 18 bobbins, starting each with 60 yards of cotton wick.

Night-Lights.—These are short thick cylinders of fat, with a very thin wick, so proportioned one to the other that they burn any required number of hours. The moulds in which these are made are metal frames, perforated with a number of cylindrical holes, and having a moveable bottom, with a thin wire projecting from it into every mould. These are filled with melted fat, and when cold, the bottoms are forced up, and all the cylinders of fat ejected, each having a small hole through which the wick, a cotton, previously impregnated with wax, is inserted. This being done, the night-light, being pressed on a warm porcelain slab, is melted sufficiently to cement the wick. These night-lights are burned in glass cylinders, into which they fit.

Child's Night-Lights are melted fat poured into card-board boxes, which have a hole in the bottom, through which the wick and its metallic support are placed.

Dr. Ure made a set of experiments upon the relative intensities of light, and duration of different candles, the results of which are contained in the following Table:—

Number in a Pound	Duration of a Candle	Weight in Grains	Consumption per Hour in Grains	Proportion of Light	Economy of Light	Candles equal one Argand
	<i>h.</i> <i>m.</i>					
10 mould . . .	5 9	682	132	12 $\frac{1}{4}$	68	5.7
10 dipped . . .	4 36	672	150	13	65 $\frac{1}{2}$	5.25
8 mould . . .	6 31	856	132	10 $\frac{1}{2}$	59 $\frac{1}{2}$	6.6
6 ditto . . .	7 2 $\frac{1}{2}$	1160	163	14 $\frac{3}{4}$	66	5.0
4 ditto . . .	9 3.6	1707	186	20 $\frac{1}{4}$	80	3.5
Argand oil flame	512	69.4	100	

A Scotch mntchkin, or $\frac{1}{8}$ th of a gallon, of good seal oil, weighs 6010 gr., or 13 $\frac{1}{10}$ oz. avoirdupois, and lasts in a bright Argand lamp 11 hours 44 minutes. The weight of oil it consumes per hour is equal to 4 times the weight of tallow in candles 8 to the pound, and $\frac{1}{4}$ th the weight of tallow in candles 6 to the pound. But its light being equal to that of 5 of the latter candles, it appears from the above table that 2 pounds weight of oil, value 9*d.*, in an Argand, are equivalent in illuminating power to 3 pounds of tallow candles, which cost about 2 shillings. The larger the flame in the above candles the greater the economy of light.

MINERAL CANDLES. Under this general head several varieties of candles have been manufactured at the works of Price's Candle Company; and these candles manufactured by Price's Candle Company, at Belmont and Sherwood, are made according to processes patented by Dr. Warren De La Rue. The novelty of these substances

consists:—1. In the material from which they are obtained. 2. In the method by which they are elaborated. 3. In their chemical constitution.

The *raw material* is a semifluid naphtha, drawn up from wells sunk in the neighbourhood of the river Irrawaddy, in the Burmese Empire. The geological characteristics of the locality are sandstone and blue clay. In its raw condition the substance is used by the natives as a lamp-fuel, as a preservative of timber against insects, and as a medicine. Being in part volatile at common temperatures, this naphtha is imported in hermetically-closed metallic tanks, to prevent the loss of any constituent. Reichenbach, Christison, Gregory, Reece, Young, Wiesman (of Bonn), and others have obtained from peat, coal, and other organic minerals, solids and liquids bearing some physical resemblance to those procured from the Burmese naphtha; but the first-named products have, in every instance, been formed by the decomposition of the raw material. The process of De La Rue, is, from first to last, a simple separation, without chemical change.

In the commercial processes, as carried out at the Sherwood and Belmont Works, the crude naphtha is first distilled with steam at a temperature of 212° F.; about one-fourth is separated by this operation. The distillate consists of a mixture of many volatile hydro-carbons; and it is extremely difficult to separate them from each other on account of their vapours being mutually very diffusible, however different may be their boiling points. In practice, recourse is had to a second or third distillation, the products of which are classified according to their boiling points or their specific gravities, which range from 0.627 to 0.860, the lightest coming over first. It is worthy of notice, that though all these volatile liquids were distilled from the original material with steam of the temperature of boiling water, their boiling points range from 80° F. to upwards of 400° F.

These liquids are all colourless, and do not solidify at any temperature, however low, to which they have been exposed. They are useful for many purposes. All are solvents of caoutchouc. The vapour of the more volatile, Dr. Snow has found to be highly anæsthetic. Those which are of lower specific gravity are called in commerce *Sherwoodole* and *Belmontine*; these have great detergent power, readily removing oily stains from silk, without impairing even delicate colours. The distillate of the higher specific gravity is proposed to be used as lamp-fuel; it burns with a brilliant white flame; and, as it cannot be ignited without a wick, even when heated to the temperature of boiling water, it is safe for domestic use.

A small percentage of hydro-carbons, of the benzole series, comes over with the distillates in this first operation. Messrs. De La Rue and Müller have shown that it may be advantageously eliminated by nitric acid. The resulting substances, nitrobenzole, &c., are commercially valuable in perfumery, &c.

After steam of 212° F. has been used in the distillation just described, there is left a residue, amounting to about three-fourths of the original material. It is fused and purified from extraneous ingredients (which Warren De La Rue and H. Müller have found to consist partly of the colophene series) by sulphuric acid. The foreign substances are thus thrown down as a black precipitate, from which the supernatant liquor is decanted. The black precipitate, when freed from acid by copious washing, has all the characteristic properties of native asphaltum. The fluid is then transferred to a still, and, by means of a current of steam made to pass through heated iron tubes, is distilled to any required temperature. The distillates obtained by this process are classed according to their distilling points, ranging from 300° to 600° F. The distillations obtained, at 420° F. and upwards, contain a solid substance, resembling in colour and in many physical and chemical properties, the paraffine of Reichenbach; like it, it is electric, and its chemical affinity is very feeble; but there are reasons for believing that a difference exists in the atomic constitution of the two substances. The commercial name of *Belmontine* is given to one of the fluids from the Burmese pitch. Candles manufactured from the solid material (*Paraffine*) possess great illuminating power. It is stated that such a candle weighing $\frac{1}{4}$ th lb., will give as much light as a candle weighing $\frac{1}{2}$ th lb. made of spermaceti or stearic acid. Its property of fusing at a very low temperature into a transparent liquid, and not decomposing below 600° F., recommends this substance as the material of a bath for chemical purposes. As to the fluids obtained in the second distillation, already described, they all possess great lubricating properties; and, unlike the common fixed oils, not being decomposable into an acid, they do not corrode the metals, especially the alloys of copper, which are used as bearings of machinery. This aversion to chemical combination, which characterises all these substances, affords, not only a security against the brass-work of lamps being injured by the hydro-carbon burnt in them, but also renders these hydro-carbons the best detergents of common oil lamps. It is an interesting physical fact, that some of the non-volatile liquid hydro-carbons possess the fluorescent property which Stokes has found to reside in certain vegetable infusions.

An important characteristic of the Burmese naphtha is its being almost entirely destitute of the hydro-carbons belonging to the olefant-gas series. See NAPHTHA.

The OZOKERIT candles, so called, have been recently introduced by the Messrs. Field and Co. These candles are made of ozokerit, that is to say mineral paraffine, also called mineral wax, which is found in beds in sandstone near Slanik in Moldavia, in the vicinity of coal-mines, and mineral salt. It is also found in the Carpathian Mountains, and it is from this source that the English merchants get their supply. This material has a rough appearance, is of a brown, greenish, or yellow colour; it is translucent at the edges, and its fracture is resinous. It is naturally fragile, but in softening it can be kneaded like wax. If exposed to the air it turns black. Friction electrifies it negatively, and it emits an aromatic hydro-carbonaceous odour. At the low temperature of 66° C. it flows, and other substances, less fusible, necessary in the manufacture of candles can then be added. The power of the light of ozokerit candles can be deduced from the experiments of Dr. Letheby, who has shown that the light of 754 ozokerit candles equals that of 891 paraffine, or 1150 wax candles. Ozokerit candles can be coloured mauve or magenta, and then present a pleasing appearance. See PARAFFINE, and MINERAL CANDLES.

Our Exports of Candles of all sorts were as follow:—

CANELLA, or *Wild Cinnamon*. The *Canella alba*, a tree growing in the West Indies. The bark is used as an aromatic and tonic. The negroes of the West Indies employ it as a condiment.

CANE-MILL. The mill employed for crushing the sugar-cane. See SUGAR.

CANES. The produce of various species of the genus *Calamus*. The *Calamus Rotang* and *C. Scipionum* are said to produce the rattan canes of commerce, but it is

probable that several species are cut indiscriminately. The best rattans are obtained from Sumatra, Borneo, and Malacca; from these places they are exported to Europe, Bengal, and China; in the latter country the consumption of rattans is immense. The average annual importation to this country amounts to about 11,000,000. The stems of the rattan are coated with a flinty bark; they are easily split, and from them the bottoms of chairs and similar articles are manufactured. The resinous matters of the rattan is the dragon's blood of commerce.

Rattan anes are often counfounded with the bamboo. They are, however, as stated above, the produce of various species of the genus *Calamus*, whilst the bamboo is a grass belonging to the genus *Bambusa*. Rattans are cylindrical, jointed, very tough, and strong, from the size of a goosequill to that of the human wrist, and from fifty to a hundred feet in length. They are used for wicker-work, seats of chairs, walking-sticks, &c.

The bamboo is a plant of the reed kind, growing in the East Indies, and other warm climates, and sometimes attaining the height of sixty feet. Old stalks grow to five or six inches diameter, and are so hard and durable as to be used for building, and for all sorts of furniture, for water-pipes, and for poles to support palanquins. The smaller kinds are used for walking-sticks, flutes, &c. See BAMBOO.

Canes of various kinds are employed in manufactures, as the Sugar-cane, &c. The arundo (*the reed*), a genus of plants belonging to the grasses, are also largely used. They are imported from Spain and Portugal for the use of the weaver, and for the manufacture of fishing rods.

CANGICA WOOD, called also in England *Angica*. It is of a rose-wood colour; and is imported from the Brazils in trimmed logs, from eight to ten inches diameter. As a variety in cabinet work, small quantities of this wood are employed.

CANNABIC COMPOSITION. This material for architectural decoration is described by Mr. B. Albano to have a basis of hemp, amalgamated with resinous substances, carefully prepared and worked into sheets of large dimensions.

Ornaments in high relief and with great sharpness of detail are obtained by pressure of metal discs, and they are of less than half the weight of papier-maché ornaments, sufficiently thin and elastic to be adapted to wall surfaces, bearing blows of the hammer, and resisting all ordinary actions of heat and cold without change of form. Its weather qualities had been severely tried on the Continent, as for coverings of roofs, &c., remaining exposed without injury.

This composition is of Italian origin, and in Italy it has been employed for panels, frames, and centres. It is well fitted to receive bronze, paint, or varnish; the material is so hard as to allow gold to be burnished, after gilding the ornaments made of it.

CANNABIS INDICA. Indian hemp. See HEMP.

CANNABIS SATIVA. Common hemp. See HEMP.

CANNABINE. A poisonous resin extracted from hemp (*Cannabis sativa*). The narcotic properties of *chasschisch* or *bang* depend on the presence of this resin.

CANNA EDULIS. The rhizomes or tubers of this plant are supposed to yield the starch known in commerce as *Tous-les-mois*, but it is probably derived from *C. glauca* or *C. Achiras*. (Pereira; Bentley and Redwood, 1872). See *Tous-les-Mois*.

CANNEL COAL is generally considered to be a variety of bituminous coal. Its name *Canwyl*, a candle, is derived from the readiness with which it kindles and burns with flame. Cannel coal is obtained most abundantly in Lancashire, especially around Wigan, which district produces 650,000 tons per annum, while the Manchester district produces about 130,000 tons. It is found abundantly in Scotland, where it is known as gas-coal; the quantity produced in 1865 was 322,000 tons. In Flintshire a very fine cannel has been found, especially at Leeswood, near Mold; about 150,000 tons are raised, nearly all of which is used for the distillation of coal-oil. Cannel coal is also found in Derbyshire, in Warwickshire, and in Yorkshire.

Detailed Statement of the Production of Cannel Coal in Great Britain.

ENGLAND.

Tons

Staffordshire, North.—A Cannel coal of uncertain quality occurs in this district, especially between Hanley and Harecastle. It is usually termed in the locality 'pill' or 'peal,' and is sold at the pit's mouth at 10s. the ton. The quantity of this Cannel which is raised annually is about 10,000

Nottinghamshire.—The chief if not the only place in this county at which Cannel is worked is at Hucknall Torekard, near Nottingham. Nearly all that is raised is appropriated for oil-making, the quantity produced being 48,000

Derbyshire.—The places producing this variety of coal are the following:—

Renishaw, near Chesterfield.—This is not strictly a Cannel.

Swanwick Colliery.—This is a Cannel of fair average quality.

Clay Cross.—But little is worked on this estate at present.

The total production of Derbyshire is estimated at about **Tons**
 **43,000**

Yorkshire.—The mines in Yorkshire producing Cannel are:—

- | | |
|------------------------------|---------------------------|
| 1. Silkstone Fall, Barnsley. | 5. College, Birstal. |
| 2. Adwalton Moor, Leeds. | 6. Oakwell, Leeds. |
| 3. Bruntcliffe, Leeds. | 7. Ardsley Main, Ardsley. |
| 4. Gilderstone, Leeds. | |

Some of this is an inferior Cannel, known, locally, as 'drub' or 'stub,' and a considerable quantity of the true Cannel of the West Riding will not coke. The quantity raised annually from the Yorkshire district may be taken at . 185,000

Lancashire.—The collieries in the East Lancashire (Manchester) district producing Cannel coal are the following:—

- | | |
|--------------------------|------------------------------|
| 1. Bank, Little Hulton. | 5. Hulton, Bolton. |
| 2. Blackrod, Chorley. | 6. Scot Lane, Blackrod. |
| 3. Blackrod, Blackrod. | 7. Stonehill, Farnworth. |
| 4. Bridgewater, Worsley. | 8. Rigby Pit, Auderton Hall. |

The total estimated production being **120,000**
 The collieries in the West Lancashire (Wigan) district producing Cannel are:—

- | | |
|------------------------------|-----------------------------|
| 1. Haigh, Haigh and Aspull. | 3. Kirkless Hall, Kirkless. |
| 2. Aspull, Haigh and Aspull. | 4. Standish, Standish. |

(These belong to the Wigan Coal and Iron Company.)

- | | |
|----------------------------|------------------------------|
| 5. Rose Bridge, Ince. | 9. Walthew House, Pemberton. |
| 6. Douglas Bank, Wigan. | 10. Gidlow Lane, Wigan. |
| 7. Norley Hall, Pemberton. | 11. Rowenhead, St. Helen's. |
| 8. Ince Hall, Wigan. | |

The total production of these collieries was **530,000**

Cheshire.—Duckinfield, Stockport, is the only colliery in this county producing Cannel coal. The present yield being **12,000**

The Estimated Production of Cannel Coal in England.

	Tons
North Staffordshire	10,000
Nottinghamshire	48,000
Derbyshire	43,000
Yorkshire	185,000
Lancashire	650,000
Cheshire	12,000

The total annual production in England being about . 948,000

At least 50,000 tons of this, possibly much more, is reserved for the manufacture of the mineral oils.

WALES.

North Wales.—This is the only district at present producing Cannel. The collieries yielding it are:—

- | | |
|--------------------------|-------------------|
| 1. Leeswood Green, Mold. | 4. Coppa, Mold. |
| 2. Leeswood Hill, Mold. | 5. Nerquis, Mold. |
| 3. Coed Talon, Mold. | 6. Wern, Bagilt. |

From these works the quantity of Cannel coal raised was, as nearly as could be ascertained, 150,000 tons, almost the whole of which was consumed in the oil works of Flintshire, which are now much reduced in extent.

SCOTLAND.

We have reliable information as to the output of Cannel coal from this important field.

At a meeting of coal-owners held in Glasgow, the estimated quantity raised annually was as follows:—

	Tons
Lanarkshire	172,000
Linlithgowshire	28,000
East and Mid Lothian	55,000
Fifeshire	29,000
Ayrshire	38,000

Giving as the total quantity . 322,000

The stock of Cannel coal on hand when this estimate was made was stated to have been 61,500 tons, making the total quantity raised as 383,500 tons. Mr. Binney informs us that nearly 100,000 tons of this is used in making oil.

The Total Quantity of Cannel Coal produced in the United Kingdom, may be estimated as:—

	Tons
England	948,000
Wales	150,000
Scotland	322,000

1,420,000

At a low estimate 250,000 tons of this has been submitted to distillation for coal-oil;

therefore, for gas-making and other pur-

poses, the total quantity obtained will be 1,170,000

See SHALES and SHALE OIL.

This coal, when worked for ornament, is cut with a saw, and the pieces are rough-shaped with a chopper. For making a snuff-box, whether plain, screwed, or excentric turned, the *plank-way*, or the surface parallel with the seam, is most suitable; it is also proper for vases, the caps and bases of columns, &c. Cylindrical pieces, as for the shafts of columns, should be cut from either edge of the slab, as the laminae then run lengthways, and the objects are much stronger: cylindrical pieces thus prepared, say 3 inches long and $\frac{3}{8}$ ths of an inch diameter, are so strong they cannot be broken between the fingers. Similar pieces have been long since used for the construction of flutes, and in the British Museum may be seen a snuff-box of Cannel coal, said to have been turned in the reign of Charles I., and also two busts of Henry VIII. and his daughter Lady Mary carved in the same material. The plank-way surfaces turn the most freely, and with shavings much like those of wood; the edges yield small chips, and at last a fine dust, but which does not stick to the hands in the manner of common coal. Flat objects, such as inkstands, are worked with the joiners' ordinary tools and planes. The edges of Cannel coal are harder and polish better than flat surfaces.—*Holtzapffel*. See COAL and BOGHEAD COAL.

CANNON. See ARTILLERY and SHELL.

CANNON-BALL TREE. *Couroupite Guianensis*. A tree belonging to the *Lecythideæ*, a suborder of the dicotyledonous plants belonging to the natural order *Myrtaceæ*. These trees are natives of South America, and are distinguished by their very large fleshy flowers and singular fruit. The cannon-ball tree obtains its name from the peculiar large heavy woody fruit, which is as big as a thirty-six-pound shot. The shells of this fruit are used for drinking vessels.

CANTHARIDES. The blister beetle or Spanish fly, the *Cantharis vesicatoria*. Cantharides are chiefly collected in Hungary, Russia, and the south of France. They are imported from St. Petersburg in cases, each containing 160 to 170 lbs. and also from Messina in barrels or cases holding each 100 lbs. See Pereira's 'Materia Medica,' Bentley and Redwood, 1872.

CANTON'S PHOSPHORUS. Sulphate of lime being heated with charcoal in a crucible is converted into sulphide or sulphuret of calcium. If this preparation is spread over a sheet of paper, and exposed to bright sunshine, it will, when taken into a dark room, emit a phosphorescent light. This solar phosphorus was discovered by Canton, and is prepared according to his directions by calcining for an hour at a red heat a mixture of 3 parts of ground oyster-shells and 1 part of sulphur. See PHOSPHORUS and PYROPHORUS.

CANVAS. (*Canvas*, Fr.; *Kanevas*, Ger.) A coarse cloth made of hemp or flax, which is used for the sails of ships and for tents. It has been found that sails of ships made with the selvages and seams of the canvas running down parallel to their edges are very apt to bag, and become torn in the middle, from the strain to which they are subjected by the pressure of the wind. To obviate this inconvenience a mode of making sails, with the seams and selvages running diagonally, was proposed by Admiral Brooking, and a patent granted to him for the same on November 4, 1828. The invention of Messrs. Ramsay and Orr has a similar object, viz., that of giving additional strength to sails by a peculiar manner of weaving the canvas of which they are made.

The improvement consisted in weaving the canvas with diagonal threads; that is, placing the weft yarn, or shoot, in weaving, at an oblique angle to the warp yarns, instead of making the decussation of the warp, or weft threads, or yarns, at right angles to each other, as in the ordinary mode of weaving.

To accomplish this object the loom must be peculiarly constructed; its warp and work beams must stand at an oblique angle with the sides of the loom, and the batten and slay must be hung in a peculiar manner, in order to beat up the weft or shoot, in lines ranging diagonally with the warp.

Canvas painted of various patterns is used for covering halls, &c., and is generally called *floor-cloth*. A finer kind of canvas, properly prepared, is employed by artists.

CAOUTCHOUC, GUM-ELASTIC, or INDIA-RUBBER (*Caoutchouc*, Fr. ; *Kautschuk*, *Federharz*, Ger.) occurs as a milky juice in several plants, such as the *Siphonia Cakuca*, called also *Hevea Guianensis*, *Cautschuc*, *Jatropha elastica*, *Castilleja elastica*, *Cecropia pelleta*, *Ficus religiosa* and *indica*, *Urceola elastica*, &c. Dr. Lindley's account of the plants that yield the most important supplies of commercial caoutchouc, with plates of the leaves and flowers, will be found in Mr. Hancock's work on Caoutchouc. These are stated to be *Siphonia elastica*, *Hancornia speciosa*, *Ficus elastica*, and *Urceola elastica*. It is, however, extracted chiefly from the first plant, which grows in South America and Java. The tree has incisions made into it through the bark in many places, and it discharges the milky juice, which is spread upon clay moulds, and dried in the sun, or with the smoke of a fire, which blackens it. Portions of this milky juice have been occasionally sent to Europe in bottles; some few arrived with the milky emulsion, but generally they were found to be resolved into a coagulum floating in an aqueous solution. A small bottle from Cayenne or the Isle of France, in the possession of M. D'Arcet, passed some years without change, but the severe winter of 1788-9 caused it to pass to the solid state, and the bottle was broken.

Sir Joseph Banks is reported to have had a bottle of liquid unaltered, but which afterwards was decomposed. Fifty gold louis-d'ors, it is said, were offered by him at Lisbon in vain for a second supply.

Caoutchouc, Gum-Elastic, or India-Rubber, are the general names for a substance now so well known, familiar, and important, that it seems matter for surprise that the latter half of the preceding century should have passed away before it was made known to Europe by memoirs read to a learned body. For the remainder of the century, its extraordinary property of elasticity and the grotesque objects made by the Indians, caused it to be met with in the cabinets of the curious; its use was still confined to erasing marks of black-lead pencil from paper, and in this country it received the common name of lead-eater.

Europe is indebted to the observations of M. de la Condamine, who, despatched from France on a scientific mission, found the natives and residents of that part of South America which he visited constantly using syringes, bottles for non-corrosive liquids, boots, and many other articles, made of India-rubber. In 1736, he wrote to the Academy of Sciences at Paris an account of this substance; which during his ten years' residence in Para, and journeys in the country, and along the banks of the Amazon, he had constant observation of the use of by the natives.

He describes the forms of bottles and articles moulded with clay, coated with the milky juice of trees, in successive layers, and when dried in the sun, the earth broken out, and says that the Indians, with a point of hard wood, impressed ornaments upon the soft mass.

He also states that the gum-resin spread upon cloth formed a waterproof covering of great use for bagging to keep biscuits, food, and clothing dry from rain, and as a substitute for tarpaulins; and he especially notes the use of a great canvas prepared with liquid India-rubber, to cover the quadrant circle as it stood on its legs, which allowed it to be left in the rain and snow, and thus enabled them to make observations at intervals of weather, and avoid the great labour of removing the instruments to boxes and places of shelter. To obviate the adhesion of objects recently made to each other, especially if the sun is upon them, 'Spanish white, and even dust is employed:' the inconvenience is thus prevented, and the articles immediately take the brown colour which is ultimately acquired by the exposure of the white juice to the sun and air, smoke and fire, methods employed by the Indians.

M. de la Condamine found in the province of Esmeraldes this substance, called by the natives *Hhévé*; it is obtained by a single incision from the plants, and is a white liquid like milk, which hardens and blackens in the air. The Indians made flambeaux $1\frac{1}{2}$ inch thick and 2 feet long, that burnt very well without a wick for 24 hours with a brilliant flame and without any disagreeable odour. This caoutchouc was wrapped in two leaves of bananier to form the flambeaux; he used these lights habitually, on his route along the river Esmeraldes, and especially in the wood of Sylanche, where he was detained for days.

It was in 1751, that M. de la Condamine brought the subject into notice, for M. Fresneau had found and described trees in Cayenne, yielding elastic resin. Writing to his

friend, he records the localities, trees, tools, and details for obtaining the sap, and forming articles.

M. de la Condamine concludes his remarks upon the memoir of M. Fresneau with words of sufficient import, and indeed with prophetic spirit, and says, 'it will be an exclusive object of commerce for that colony which possesses this species of treasure.'

MM. Herissant and Macquer in 1761, gave their chemical observations to the Académie Royale on caoutchouc, or elastic resin of Cayenne. They refer to the softening and solution by oils and heat, 'but the caoutchouc does not again takes its solidity or elasticity.' By rectifying oil of turpentine upon lime and dissolving caoutchouc in it, they obtained a pasty mass which allowed the caoutchouc to regain its former elastic state. They point out that ether may be advantageously used, and they complain of the great expense of Dippel's animal oil as a solvent. While pointing out the surgical uses of caoutchouc, Macquer describes the necessity for carefully rectifying the ether, taking 8 or 10 pounds, and only receiving the first 2 pounds for the solution of caoutchouc. He used, instead of clay, moulds of wax, held by pincers, and plunged in the ethereal solution, and by repeated coatings, allowing the ether to evaporate, a thin covering was obtained; by the heat of boiling water the wax flowed out, and a tube of caoutchouc remained. He states that he found it difficult to get the tubes uniform. M. Grossart in 1768, published his experiments on preparing tubes of India-rubber by means of ether and boiling water: these memoirs seem to have remained without sufficient reference and study.

It has been received as an opinion in England and America, that one of the earliest notices of the useful properties of India-rubber is that given by Dr. Priestley, in a work evidently got up with great care, called, 'A Familiar Introduction to the Theory and Practice of Perspective, by Joseph Priestley, LL.D., London, 1770.' At the end of the preface is the following addition: 'Since this work was printed off, I have seen a substance excellently adapted to the purpose of wiping from paper the marks of a black-lead pencil. It must, therefore, be of singular use to those who practise drawing. It is sold by Mr. Nairne, Mathematical Instrument-maker, opposite the Royal Exchange. He sells a cubical piece of about half an inch for three shillings, and he says it will last several years.'

It will be remarked that no name for the substance is mentioned; the preface is dedicated 'to Sir Joshua Reynolds, Knt., F.R.S., Leeds, March 20th, 1770;' and we may fairly conclude that the substance was at this time a novelty in art and trade.

It seems probable, that the experiments with balloons, and the application of airtight varnishes, especially those by Messrs. Charles and Robert, called more general attention to the properties of India-rubber in Europe.

Mr. Hancock says, 'This substance came first into notice about the beginning of the last century, moulded into the shapes of bottles and animals. It was sold as high as a guinea the ounce, and used for rubbing out pencil-marks; but scarcely anything was known of its history, except that it came from America.'

The juice itself has been of late years imported. It is of a pale yellow colour, and has the consistence of cream. It becomes covered in the bottles containing it with a pellicle of concrete caoutchouc. Its specific gravity is 1.012. When it is dried it loses 55 per cent. of its weight; the residuary 45 is elastic-gum. When the juice is heated it immediately coagulates, in virtue of its albumen, and the elastic-gum rises to the surface. It mixes with water in any proportion; and when thus diluted, it coagulates with heat and alcohol as before.

Hitherto the greater part of the caoutchouc has been imported into Europe from South America, and the best from Para; but of late years a considerable quantity has been brought from Java, Penang, Singapore, Assam, and Africa. Many years ago, Mr. William Griffith published an interesting report upon the *Ficus elastica*, the caoutchouc tree of Assam, which he drew up at the request of Captain Jenkins, agent in that country to the Governor-General of India. This remarkable species of fig-tree is either solitary or in twofold or threefold groups. It is larger and more umbrageous than any of the other trees in the extensive forest where it abounds, and may be distinguished from the other trees at a distance of several miles, by the picturesque appearance produced by its dense, huge, and lofty crown. The main trunk of one was carefully measured, and was found to have a circumference of no less than 74 feet; while the girth of the main trunk along with the supports immediately round it, was 120 feet. The area covered by the expanded branches had a circumference of 610 feet. The height of the central tree was 100 feet.

It has been estimated, after an accurate survey, that there are 43,240 such noble trees within a length of 30 miles and a breadth of 8 miles of forest, near Perozepore, in the district of Chardwar, in Assam.

Lieutenant Veitch has since discovered that the *Ficus elastica* is equally abundant in the district of Naudwar. Its geographical range in Assam seems to be between

25° 10' and 27° 20' of north latitude, and between 90° 40' and 95° 30' of east longitude. It occurs on the slopes of the hills up to an elevation of probably 22,500 feet. This tree is of the Banyan tribe, famed for its pillared shade, 'whose daughters grow about the mother tree,' which has furnished the motto, *Tot rami, quot arbores*, to the Royal Asiatic Society. Species of this genus afford grateful shade, however, in the tropical regions of America as well as Asia.

Many species of other trees yield a milky tenacious juice, of which bird-lime has been frequently made; as *Artocarpus integrifolia* and *Lakoocha*, *Ficus indica* and *religiosa*, also *F. Tsiela*, *Roxburghii*, *glomerata*, and *oppositifolia*. From some of these an inferior kind of caoutchouc has been obtained.

The juice of the *Ficus elastica* of Chardwar is better when drawn from the old than from the young trees, and richer in the cold season than in the hot. It is extracted by making incisions a foot apart, across the bark down to the wood, all round the trunk, and also the large branches, up to the very top of the tree: the quantity which exudes increasing with the height of the incision. The bleeding may be safely repeated once every fortnight. The fluid, as fresh drawn, is nearly of the consistence of cream, and pure white. Somewhat more than half a *maund* (42 lbs.) is reckoned to be the average produce of each bleeding of one tree; or 20,000 trees will yield about 12,000 maunds of juice; which is composed in 10 parts, of from 4 to 6 parts of water, and, of course, from 6 to 4 parts of caoutchouc. The bleeding should be confined to the cold months, so as not to interfere with or obstruct the vigorous vegetation of the tree in the hot months.

Mr. Griffith says, that the richest juice is obtained from transverse incisions made into the wood of the larger reflex roots, which are half exposed above ground, and that it proceeds from the bark alone. Beneath the line of incisions, the natives of Assam scoop out a hole in the earth, in which they place a leaf of the *Phrynium capitatum* (Linn.), rudely folded up into the shape of a cup. He observes that the various species of *Tetranthera*, upon which the *Moonga* silkworm feeds, as also the castor-oil plant, which is the chief food of the Eria silkworm, do not afford a milky caoutchouc juice. Hence it would appear that Dr. Royle's notion of caoutchouc forming a necessary ingredient in the food of silkworms, and being 'in some way employed in giving tenacity to their silk,' seems to be unfounded. If Botany discountenances this idea, Chemistry would seem to scout it altogether; for silk contains 11·33 per cent. of nitrogen, and caoutchouc contains none at all, being simply a solid hydro-carbide, and therefore widely dissimilar in constitution to silk, which consists of oxygen 34·04, nitrogen 11·33, carbon 50·69, and hydrogen 3·94, in 100 parts.

This hydro-carbide emulsion is of common occurrence in the orders *Euphorbiaceæ* and *Urticaceæ*, which may be looked on as the main sources of caoutchouc. The American caoutchouc is said to be furnished by the *Siphonia elastica*, or the *Hevea Guianensis* of Aublet, a tree which grows in Brazil, and also in Surinam.

Dr. Royle sent models of cylinders of 1½ to 2½ inches in diameter, and 4 or 5 inches in length, to both the Asiatic and Agricultural Societies of Bengal, to serve as patterns for the natives to mould their caoutchouc by. Mr. Griffith says that this plan of forming the caoutchouc into tumblers or bottles, as recommended by the committee of the London Joint-Stock Caoutchouc Company, is, in his opinion, the worst that can possibly be offered; being tedious, laborious, causing the caoutchouc to be blackened in the drying, and not obviating the viscidty of the juice when it is exposed to the sun. He recommends, as a far better mode of treating the juice, to work it up with the hands, to blanch it in water, and then subject it to pressure. Better methods have recently occurred while experimenting upon the caoutchouc juice. This fluid, with certain precautions, chiefly exclusion from air and much warmth, may be kept in the state of a creamy emulsion for a very long time. Mr. Hancock states, some barrels treated with ammonia arrived in England in a fluid state.

However plausible these observations may appear, the practical men wanted sheet rubber to cut into threads, &c., and Mr. Hancock states he had a cylinder made of masticated rubber, of a convenient size, and sent it to Para as a pattern for the natives, and great numbers of cylinders were soon after in the market, well made, of the quality desired, and called tubes. Such cylinders are still imported (1857).

Great interest was taken by Mr. Hancock to introduce the native juice into this country; and, after great expense, he had the disappointment of finding the barrels contained coagulated India-rubber and watery fluid. Some samples, by peculiar treatment, escaped; whatever might have been expected, there seemed but little confidence in these plans, and valuable as the native juice might be at one time, yet by solvents and by working the rubber with machinery, it is far more profitable to employ this state, than to import a large quantity of watery fluid, with all the expenses of casks and cooerage, while the solid article is excellently adapted to take care of itself.

Sharp and clean casts were taken with this liquid, and as it is susceptible of being tinted with delicate colours, it might be used for beautiful ornamental purposes; when the solid rubber separates, it is white, but in small pieces or thin sheets, it is semi-transparent.

The specific gravity of caoutchouc is 0.925, and it is not permanently increased by any degree of pressure. By cold or long quiescence it becomes hard and stiff. When the milky juice has become once coherent, no means hitherto known can restore it to the emulsive state. By long boiling in water it softens, swells, and becomes more readily soluble in its peculiar menstrua; but when exposed to the air it speedily resumes its former consistence and volume. It is quite insoluble in alcohol; but in ether, deprived of alcohol by washing with water, it readily dissolves, and affords a colourless solution. When the ether is evaporated, the caoutchouc becomes again solid, but is somewhat clammy for a while. When treated with hot naphtha, distilled from native petroleum, or from coal-tar, it swells to 30 times its former bulk; and if then triturated with a pestle, and pressed through a sieve, it affords a homogeneous varnish, which being applied by a flat edge of metal or wood to cloth, prepares it for forming the patent water-proof cloth of Macintosh. Two surfaces of cloth, to which several coats of the above varnish have been applied, are, when partially dried, brought evenly in contact, and then passed between rollers, in order to condense and smoothe them together. This double cloth is afterwards suspended in a stove-room to dry, and to dispel the disagreeable odour of the naphtha.

Caoutchouc dissolves in the fixed oils, such as linseed oil, but the varnish has not the property of becoming concrete upon exposure to the air.

It has lately been asserted that caoutchouc is soluble in the oils of lavender and saffras. Roxburgh found it perfectly soluble in the oil of cajeput.

It melts at 248° F., and stands afterwards a much higher heat without undergoing any further change. When the melted caoutchouc is exposed to the air, it becomes hard on the surface in the course of a year. When kindled, it burns with a bright flame and a great deal of smoke.

Neither chlorine, sulphurous acid gas, muriatic acid gas, ammonia, nor fluosilicic acid gas, affect it, whence it forms very valuable flexible tubes for pneumatic chemistry. Cold sulphuric acid does not readily decompose it, nor does nitric acid, unless it be somewhat strong. The strongest caustic potash-lye does not dissolve it even at a boiling heat.

According to Dr. Faraday, the pure caoutchouc, obtained from the sap, had a specific gravity of 0.925, and no reduplication of it in a Bramah's press was found to effect permanent alteration.

The specific gravity of the best compact Para caoutchouc,				
taken in dilute alcohol, is	.	.	.	0.941567
The specific gravity of the best Assam is	.	.	.	0.942972
"	"	Singapore	.	0.936650
"	"	Penang	.	0.919178

Having been favoured by Mr. Sievier, formerly managing director of the Joint-Stock Caoutchouc Company, and by Mr. Beale, engineer, with two different samples of caoutchouc juice, Dr. Ure subjected each to chemical examination.

That of Mr. Sievier, is greyish brown, that of Mr. Beale is of a milky grey colour; the deviation from whiteness in each case being due to the presence of aloetic matter, which accompanies the caoutchouc in the secretion by the tree. The former juice is of the consistence of thin cream, has a specific gravity of 1.04125, and yields, by exposure upon a porcelain capsule, in a thin layer, for a few days, or by boiling for a few minutes with a little water, 20 per cent. of solid caoutchouc. The latter, though it has the consistence of pretty rich cream, has a specific gravity of only 1.0175. It yields no less than 37 per cent. of white, solid, and very elastic caoutchouc.

It is interesting to observe how readily and compactly the separate little clots or threads of caoutchouc coalesce into one spongy mass in the progress of the ebullition, particularly if the emulsive mixture be stirred; but the addition of water is necessary to prevent the coagulated caoutchouc from sticking to the sides or bottom of the vessel and becoming burnt. In order to convert the spongy mass thus formed into good caoutchouc, nothing more is requisite than to expose it to a moderate pressure between the folds of a towel. By this process the whole of the aloetic extract, and other vegetable matters, which concrete into the substance of the balls and junks of caoutchouc prepared in Assam and Java, and contaminate it, are entirely separated, and an article nearly white and inodorous is obtained. Some of the cakes of American caoutchouc when cut exhale the fœtor of rotten cheese; a smell which adheres to the threads made of it after every process of purification.

In the interior of many of the balls which come from both the Brazils and East

Indies, spots are frequently found of a viscid tarry-looking matter, which, when exposed to the air, act in some manner as a ferment, and decompose the whole mass into a soft substance, which is good for nothing. Were the plan of boiling the fresh juice along with its own bulk of water, or a little more, adopted, a much purer article would be obtained, and with incomparably less trouble and delay, than has been hitherto brought into the market.

'I find that neither of the above two samples of caoutchouc juice affords any appearance of coagulum when mixed in any proportions with alcohol of 0.825 specific gravity; and, therefore, I infer that albumen is not a necessary constituent of the juice, as Dr. Faraday inferred from his experiments published in the 21st vol. of the *Journal of the Royal Institution*.

'The odour of Mr. Sievier's sample is slightly acescent, that of Mr. Beales, which is by far the richer and purer, has no disagreeable smell whatever. The taste of the latter is at first bland and very slight, but eventually very bitter, from the aloetic impression upon the tongue. The taste of the former is bitter from the first, in consequence of the great excess of aloes which it contains. When the brown solution, which remains in the capsule after the caoutchouc has been separated in a spongy state by ebullition from 100 grains of the richer juice, is passed through a filter and evaporated, it leaves 4 grains of concrete aloes.

'Both of these emulsive juices mix readily with water, alcohol, and pyroxylic spirit, though they do not become at all clearer; they will not mix with *caoutchoucine* (the distilled spirit of caoutchouc), or with petroleum-naphtha, but remain at the bottom of these liquids as distinct as mercury does from water. Soda caustic lye does not dissolve the juice; nitric acid (double aquafortis) converts it into a red curdy magma. The filtered aloetic liquid is not affected by the nitrates of baryta and silver; it affords with oxalate of ammonia minute traces of lime.'

The best solvent is a mixture of 100 parts of bisulphide of carbon with from 6 to 8 parts of anhydrous alcohol. If the alcohol be mixed with a little water a dough is obtained, from which the caoutchouc may be drawn out into threads and spun. By Gerard's process, gutta-percha is also soluble in the above mixtures of bisulphide of carbon and alcohol.

The sulphuration of caoutchouc, a valuable invention, is due to Mr. Charles Goodyear of New York.

Caoutchouc, according to the experiments of Dr. Ure, which have been confirmed by those of Dr. Faraday, contains no oxygen, as almost all other solid vegetable products do, but is a compound of merely carbon and hydrogen, in the proportion, by these results, of 90 carbon to 10 hydrogen, being three atoms of the former to two of the latter. Dr. Faraday obtained only 87.2 per cent. of carbon. Melted caoutchouc forms a very excellent chemical lute, as it adheres very readily to glass vessels, and withstands the corrosive action of acid vapours. Caoutchouc is much used for effacing the traces of plumbago pencils, whence it derived the name of India-rubber. It has been employed very extensively for making elastic bands or braces. The caoutchouc bottles are skilfully cut into long spiral slips, which are stretched, and kept extended till nearly deprived of their elasticity, and till they form a thread of moderate fineness. This thread is put into a braid machine, and covered with a sheath of cotton, silk, linen, or worsted. The clothed caoutchouc is then laid as warp in a loom, and woven into an elegant riband. When woven, it is exposed upon a table to the action of a hot smoothing iron, which, restoring to the caoutchouc all its primitive elasticity, the riband retracts considerably in length, and the braiding corrugates equally upon the caoutchouc cores. Such bands possess a remarkable elasticity, combined with any desired degree of softness. Sometimes cloth is made of these braided strands of caoutchouc used both as warp and as weft, which is therefore elastic in all directions. When a light fabric is required, the strands of caoutchouc, either naked or braided, are alternated with common warp yarns. For this mixed fabric a patent has been obtained. The original manufacturer of these elastic webs was a major in the Austrian service who erected a factory for them at St. Denys, near Paris.

I. CAOUTCHOUC MANUFACTURES.

But before entering upon these special divisions we may advert to some of the steps that have created this new employment for capital, commerce, and skill, especially as Mr. Hancock conceives it but just to the memory of the late Mr. Macintosh, to record the circumstances which led to his invention of the 'Waterproof double textures,' that have been so long celebrated through the world by the name of 'Macintoshes.'

It will be recollected that on the introduction of coal-gas, the difficulties were very great to purify it from matters that gave a most disagreeable odour to the gas and

gas-apparatus; the nuisance of these products led to many inconveniences. Mr. Macintosh, then employed in the manufacture of cudbear, in 1819 entered into arrangements with the Glasgow Gas Works to receive the tar and ammoniacal products. After the separation of water, ammonia and pitch, the essential oil termed naphtha was produced, and it occurred to him that it might be made use of as a solvent for India-rubber, and by the quality and quantities of the volatile naphtha, he could soften and dissolve the India-rubber. After repeated experiments to obtain the mixtures of due consistency, Mr. Macintosh, in 1823, obtained a patent for waterproof processes, and established a manufactory of articles at Glasgow, and eventually, with partners, entered upon the extended scale of business at Manchester, now so well known as the firm of Charles Macintosh and Co.

The action of many solvents of India-rubber is first to soften and then to form a sort of gelatinous compound with India-rubber, requiring mechanical action to break the bulk so as to get complete solution, when the original bulk is increased twenty or thirty times to form a mass: it may be imagined that in the early trials much time was occupied, and manual labour, to break up the soft coherent mass, &c., while hand-labour, sieves, the painters' slab and muller, and other simple means were resorted to.

Macintosh, Hancock, and Goodyear, alike record the simple manipulations they first employed, and the impression produced at the last, when they compared their small personal efforts with the gigantic machinery now used to effect the same results.

Mr. T. Hancock's first patent was in April 1820: 'For an improvement in the application of a certain material to various articles of dress and other articles, that the same may be rendered elastic.' Thus, to wrists of gloves, to pockets to prevent their being picked, to waistcoats, riding-belts, boots and shoes without tying and lacing, the public had their attention directed. To get the proper turpentine to facilitate solution, and remedy defects of these small articles, and to meet the difficulties of practice and failures, Mr. Hancock gave constant zeal, and pursued the subject until, united with the firm of C. Macintosh and Co., he produced one of the most important manufactures known.

To get two clean pieces to unite together at their recently-cut surfaces, to obtain facile adhesion by the use of hot water, to cut the India-rubber by the use of a wet blade, to collect the refuse pieces, to make them up into blocks, and then cut the blocks into slices, were stages of the trade which required patience, years of time, and machinery to effect with satisfaction to the manufacturer.

To operate upon the impure rubber was a matter of absolute necessity for economic reasons: the bottles made by the natives were the purest form, but larger quantities of rubber could be cheaply obtained, full of dirt, stones, wood, leaves, and earth. To facilitate the labour of cutting or dividing, Mr. Hancock resorted to a tearing action,

403

and constructed a simple machine for the purpose. (See *fig.* 403). A shows the entrance for pieces of rubber; B, interior of fixed cylinder, with teeth; C, cylinder to revolve with teeth or knives; D, the resulting ball of rubber.

This machine had the effect of tearing the India-rubber into shreds and small fragments by the revolution of a toothed roller; the caoutchouc yielded, became hot, and ultimately a pasty mass or ball resulted; when cooled and cut it appeared homogeneous. Waste cuttings put, in the first instance, on the roller, were dragged in, and there was evidence of action of some kind taking place; the machine was stopped, the

pieces were found cohering together into a mass, this being cut showed a mottled grain, but being replaced and subjected to the revolving teeth of the rollers, it became very hot; and was found to be uniformly smooth in texture when cooled and cut open.

The first charge was about 2 ounces of rubber, and required the power of a man to work it. The next machine soon formed a soft solid, with speed and power, from all kinds of scraps of India-rubber, cuttings of bottles, lumps, shoes, &c. : a charge of 1 lb. gave a smooth uniform cylindrical lump of about 7 inches in length and 1 inch in diameter. This process, including the use of heated iron rollers, was long kept secret; it is now known as the masticating process, and the machines are called 'Masticators.' In the works at Manchester the charges are 180 lbs. to 200 lbs. of India-rubber each, and they produce, by steam-power, single blocks 6 feet long, 12 or 13 inches wide, and 7 inches thick. The Mammoth machine of Mr. Chauffée, in the United States, weighs about 30 tons, and appears to have been invented about 1837. It is a valuable machine, differing in construction from Hancock's masticators, but it answers well in many respects; it may be considered as the foundation of the American trade.

In 1820 the blocks were cut into the form of square pieces and sold by the stationers to rub out pencil-marks, and then thin sheets were introduced for a variety of purposes. A cubical block cut by a keen sharp blade kept constantly wet, gave a sheet of India-rubber; the block raised by screws and the knife guided, enabled sheets of any thickness to be cut, sometimes so even and thin, as to be semi-transparent; when warm, the small sheets could be joined edge to edge, and thus large ones produced. From the blocks, rollers of solid rubber could be made, cylinders were covered for machinery, billiard tables had evenly cut pieces adjusted, tubes and vessels for chemical use were employed, and constantly increasing trials were made of the masticated rubber.

These remarks upon the early and successful manufacturers will better enable the outline of improvements to be followed. It can readily be imagined that when capital and interest combined to meet the changing requirements of the public, the trade applications became more numerous; many of these were secured by patents, but very many were worked as secret processes.

The department of operative industry which embraces caoutchouc manufactures has, within a few years, acquired an importance equal to that of some of the older arts, and promises, ere long, to rival even the textile fabrics in the variety of its designs and applications. The manufacture of caoutchouc has, at present, these principal branches:—1. The condensation of the crude lumps or shreds of caoutchouc, as imported from South America, India, &c., into compact homogeneous blocks, and the cutting of these blocks into cakes or sheets for the stationer, surgeon, shoemaker, &c. 2. The filature of either the India-rubber bottles, or the artificial sheet caoutchouc, into tapes and threads of any requisite length and fineness, which, being clothed with silk, cotton, linen, or woollen yarns, form the basis of elastic tissues of every kind. 3. The conversion of the refuse cuttings and coarser qualities of caoutchouc into a viscid varnish, which, being applied between two surfaces of cloth, constitutes the well-known double fabrics, impervious to water and air; and by special applications to one surface, constitute the single-texture fabrics. 4. The vulcanisation of India-rubber. 5. The mechanical applications resulting from the changed India-rubber. 6. The solarisation of caoutchouc.

The caoutchouc, as imported in skinny shreds, fibrous balls, twisted concretions, cheese-like cakes, and irregular masses, is, always more or less, impure, but sometimes it is fraudulently interstratified with earthy matter. It is first cleansed by being cut into small pieces, and then washed in warm water. It is next dried on iron trays, heated with steam, while being carefully stirred about to separate any remaining dirt, and is then passed through a pair of iron rolls, under a stream of water, whereby it gets a second washing, and becomes at the same time equalised by the separate pieces being blended together. The shreds and cuttings thus laminated, if still foul or heterogeneous, are thrown back into a kind of hopper over the rolls, set one-sixteenth of an inch apart, and passed several times through between them.

In the establishment of William Warne and Co. at Tottenham, rinsing and lamination are superseded by a process of washing practised in Mr. Nickels's second operation, commonly called the *grinding*, or, as it should more properly be styled, the *kneading*. The mill employed for agglutinating or incorporating the separate fragments and shreds of caoutchouc into a homogeneous elastic ball, is a cylindrical box or drum of cast iron, 8 or 9 inches in diameter, set on its side, and traversed in the line of its horizontal axis (also 8 or 9 inches long) by a shaft of wrought iron, furnished with 3 rows of projecting bars, or kneading arms, placed at angles of 120 deg. to each other. These act by rotation against 5 chisel-shaped teeth, which stand obliquely up from the front

part of the bottom of the drum. The drum itself consists of 2 semi-cylinders; the under one of which is made fast to a strong iron framing, and the upper one is hinged to the under one behind, but bolted to it before, so as to form a cover or lid—which may be opened or laid back at pleasure—in order to examine the caoutchouc from time to time, and take it out when fully kneaded. In the centre of the lid a funnel is made fast, by which the cuttings and shreds of the India-rubber are introduced, and a stream of water is made to trickle in, for washing away the foul matter often embedded in it. The power required to turn the axis of one of these mills—as the drums or boxes are called—may be judged of from the fact, that if it be only 2 inches in diameter, it is readily twisted asunder, and that it requires to be 3 inches to withstand every strain produced by the fixed teeth holding the caoutchouc against the revolving arms. Five pounds constitute a charge of the material. Mills vary in size, and charges range from 7 to 14 lbs.

One of the most remarkable phenomena of the kneading operation, is the prodigious heat disengaged in the alternate condensation and expansion of the caoutchouc. Though the water be cold as it trickles in, it soon becomes boiling hot, and emits copious vapours. When no water is admitted, the temperature rises much higher, so that the elastic lump, though a bad conductor of heat, cannot be safely touched with the hand. As we shall presently find that caoutchouc suffers no considerable or permanent diminution of its volume by the greatest pressure which can be applied, we must ascribe the heat evolved in the kneading process to the violent intestine movements excited throughout all the particles of the elastic mass.

During the steaming much muddy water runs off through apertures in the bottom of the drum. In the course of half an hour's trituration the various pieces become agglutinated into a soft, elastic, ovoid ball, of a reddish-brown colour. This ball is now transferred into another similar iron drum, where it is exposed to the pricking and kneading action of 3 sets of chisel points, 5 in each set, that project from the revolving shaft at angles of 120 deg. to each other, and which encounter the resistance occasioned by 5 stationary chisel teeth, standing obliquely upwards from the bottom of the drum. Here the caoutchouc is kneaded dry along with a little quicklime. It soon gets very hot; discharges in steam through the punctures, the water and air which it had imbibed in the preceding washing operation; becomes in consequence more compact; and in about an hour assumes the dark brown colour of stationers' rubber. During all this time frequent explosions take place, from the expansion and sudden extrication of the imprisoned air and steam.

Instead of close boxes and tearing teeth or knives, rollers of iron are now employed (1858): their forms are corrugated, cut or indented, the pieces of India-rubber are thrown between, and by heat and pressure are cleansed and incorporated; streams of water, warm or cold, regulate these operations at will, of course with large rollers of metal exposed to air and streams of water. The temperature is now kept so low that the previous statement may appear exaggerated to those who work with more power but with less velocity in the modern arrangements. Mr. Hancock, however, says, 'the heat it acquires is very surprising; I have found in cutting a heavy charge open, and closing it upon the bulb of a thermometer, that the temperature reached 280°;' this heat was only due to motion of the machine and friction upon the rubber, as the materials and the machine were cold at the outset of the experiment.

From the second set of drums the ball is transferred into a third set, whose revolving shaft being furnished both with flat pressing bars, and parallel sharp chisels, perpendicular to it, exercises the twofold operation of pricking and kneading the mass, so as to condense the caoutchouc into a homogeneous solid. Seven of the finished balls, weighing, as above stated, 5 lbs. each, are then introduced into a much larger iron drum of similar construction, but of greater strength, whose shaft is studded all round with a formidable array of blunt chisels. Here the separate balls become perfectly incorporated into one mass, free from honeycomb cells or pores, and therefore fit for being squeezed into a rectangular or cylindrical form in a suitable cast-iron mould, by the action of a screw-press. When condensed to the utmost in this box, the lid is secured in its place by screw bolts, and the mould is set aside for several days. It is a curious fact, that Mr. Sievier tried to use this as a moulding force, by the hydraulic press, without effect, as the cake of caoutchouc after being so condensed, showed much more resiliency than after the compressing action of the screw. The cake-form generally preferred for the recomposed, ground, or milled caoutchouc, is a rectangular mass, about 18 inches long, 9 inches broad, and 5 inches thick.

This is sliced into cakes for the stationer, and into sheets for making tapes and threads of caoutchouc, by an ingenious self-acting machine, in which a straight steel blade, with its edge slanting downwards, is made to vibrate very rapidly to and fro in a horizontal plane; while the cake of caoutchouc clamped or embraced at each side between two strong iron bars, is slowly advanced against the blade by screw-work,

like that of the slide-rest of a lathe. In cutting caoutchouc by knives of every form, it is essential that either the blade or the incision be constantly moistened with water; for otherwise the tool would immediately stick fast. As the above straight vibrating knife slants obliquely downwards, the sheet which it cuts off spontaneously turns up over the blade in proportion as it is detached from the bottom mass of the cake. The thicker slices are afterwards cut by hand, with a wetted knife, into small parallel-opipeds for the stationer, the sections being guided rectangularly by saw lines in a wooden frame. Slices may be cut off to almost any desired degree of thickness, by means of an adjusting screw—a mechanism that acts against a board which supports the bottom of the cake, and raises it by an aliquot part of an inch, the cutting blade being caused to vibrate always in the same horizontal plane. These thin slices constitute what is called sheet caoutchouc, and they serve tolerably for making tubes for pneumatic apparatus, and sheaths of every kind; since, if their two edges be cut obliquely with clean scissors, they may be made to coalesce, by gentle pressure, so intimately, that the line of junction cannot be discovered either by the eye, or by inflation of a bag or tube thus formed.

The mode of recomposing the cuttings, shreds, and coarse lumps of caoutchouc into a homogeneous elastic cake, specified by Mr. Nickels, for his patent, sealed October 24, 1836, is not essentially different from that above described. The cylinders of his mill are more capacious, are open at the sides like a cage, and do not require the washing apparatus, as the caoutchouc has been cleansed by previous lamination and rinsing. He completes the kneading operation, in this open cylinder, within the space of about two hours, and afterwards squeezes the large ball so formed into the cheese-form, in a mould subjected to the action of an hydraulic press. As he succeeds perfectly in making compact cakes in this way, his caoutchouc must differ somewhat in its physical constitution from that recomposed by Mr. Sievier's process. He uses a press of the power of 70 tons; such pressure, however, must not be applied suddenly, but progressively, at intervals of two or three minutes between each stroke; and when the pressing is complete, the caoutchouc is allowed to remain under pressure till it is cold, when he thrusts it out of the mould entirely, or, placing his mould in the slide-rest mechanism, he gradually raises the caoutchouc out of it, while the vibrating knife cuts it into slices in the manner already described. The elegant machine by which these sheets are now so easily and accurately sliced, was originally contrived and constructed by Mr. Beale, engineer, Church-lane, Whitechapel.

II. FILATURE OF CAOUTCHOUC FOR MAKING ELASTIC FABRICS

The following particulars may be deemed as belonging to the history of the manufacture of threads of native rubber,—the cured, or vulcanised, or mineralised rubber having quite superseded the modes of preparing threads from native bottle caoutchouc.

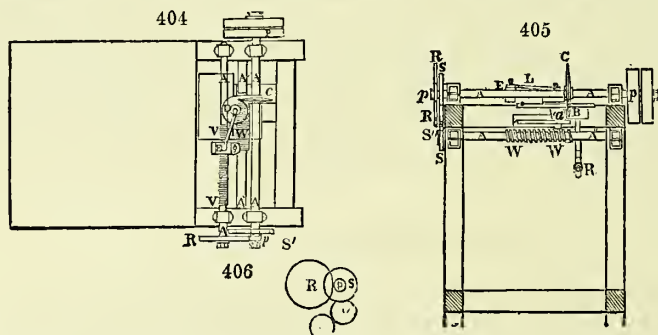

Messrs. Rattier and Guibal mounted in their factory at St. Deny's, Dr. Ure says, in the year 1826 or 1827, a machine for cutting a disc of caoutchouc into a continuous fillet spirally, from its circumference towards its centre. This flat disc was made by pressing the bottom part of a bottle of India-rubber in an iron mould. A machine on the same principle was made the subject of a patent by Mr. Joshua Proctor Westhead, of Manchester, in February 1846; and, being constructed with the well-known precision of Manchester workmanship, it has been found to act perfectly well in cutting a disc of caoutchouc, from the circumference towards the centre spirally, into one continuous length of tape. For the service of this machine, the bottom of a bottle of India-rubber of good quality being selected, is cut off and flattened by heat and pressure into nearly a round cake of uniform thickness. The cake is made fast at its centre by a screw nut and washer to the end of a horizontal shaft, which may be made to revolve with any desired velocity by means of appropriate pullies and bands, at the same time that the edge of the disc of caoutchouc is acted on by a circular knife of cast steel, made to revolve 3,000 times per minute, in a plane at right angles to that of the disc, and to advance upon its axis progressively, so as to pare off a continuous uniform tape or fillet from the circumference of the cake. During this cutting operation, the knife and caoutchouc are kept constantly moist with a slender stream of water. A succession of threads of any desired fineness is afterwards cut out of this fillet, by drawing it in a moist state through a guide slit, against the sharp edge of a revolving steel disc. This operation is dexterously performed by the hands of young girls. MM. Rattier and Guibal employed, at the above-mentioned period, a mechanism consisting of a series of circular steel knives, fixed parallel to each other at minute distances, regulated by interposed washers upon a revolving shaft; which series of knives acted against another similar series, placed upon a parallel adjoining shaft,

with the effect of cutting the tape throughout its length into eight or more threads at once. An improved modification of that apparatus is described and figured in the specification of Mr. Nickels's patent of October 1836. He employed it for cutting into threads the tapes made from the recomposed caoutchouc.

The body of the bottle of India-rubber, and in general any hollow cylinder of caoutchouc, is cut into tapes, by being first forced upon a mandril of soft wood of such dimensions as to keep it entirely distended. This mandril is then secured to the shaft of a lathe, which has one end formed into a fine-threaded screw, that works in a fixed nut, so as to traverse from right to left by its rotation. A circular disc of steel, kept moist, revolves upon a shaft parallel to the preceding, at such a distance from it as to cut through the caoutchouc, so that, by the traverse movement of the mandril shaft, the hollow cylinder is cut spirally into a continuous fillet of a breadth equal to the thickness of the side of the cylinder. Mr. Nickels has described two methods of forming hollow cylinders of recomposed caoutchouc, for the purpose of being cut into fillets by such a machine.

It is probable that the threads formed from the best India-rubber bottles, as imported from Para, are considerably stronger than those made from recomposed caoutchouc, and therefore much better adapted for making Mr. Sievier's patent elastic cordage. When, however, the kneading operation has been skilfully performed, it is found that threads of the *ground* caoutchouc, as it is incorrectly called by the workmen, answer as well for any ordinary purpose of elastic fabrics, and are, of course, greatly more economical, from the much lower price of the material.

The following *figs.* 404, 405, 406, represent the machine for cutting the spiral riband. The disc *D*, placed horizontally, turns round its vertical axis, so as to present its periphery to the edge of a knife *C*, formed like a circular blade, whose plane is

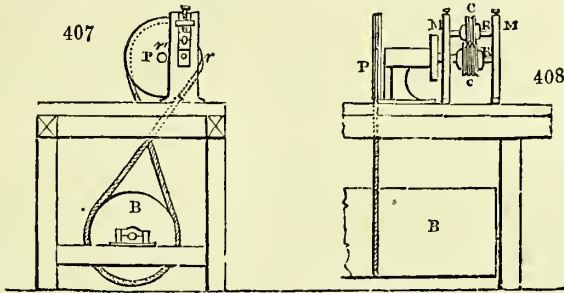

perpendicular to that of the bases of the disc. It is obvious, that if the disc alone revolved, the motionless knife could act only by pressure, and would meet with an enormous resistance. A third movement becomes necessary. In proportion as the disc is diminished by the removal of the spiral band, the centre of this disc must advance upon the knife in order that the riband may have always the same breadth. The inspection of *fig.* 406, will make the accordance of the three motions intelligible. The knife *C* is placed upon a shaft or axis *A*, which carries a pulley, round which a belt or cord runs which drives the whole machine.

The shelf *A* bears a pinion *p*, which takes into a wheel *R*, placed upon a shaft *A'*; upon which there is cut a worm or endless screw, *v v*. This worm bears a nut *E*, which advances as the screw turns, and carries with it a tie *I*, which in its turn pushes the disc *D*, carried upon a shoulder, constantly towards the knife. This shoulder is guided by two ears which slide in two grooves cut in the thickness of the table. The diameter of the pinion *p* is about one fifth of that of the wheel *R*; so that the arbour *A* turns five times less quickly than the arbour *A'*; and the fineness of the screw *v v* contributes further to slacken the movement of translation of the disc.

The rotatory movement of the disc and its shoulder, is given by an endless screw *w w*, which governs a pinion *p*, provided with ten teeth, and carried by the shaft *A*, upon which the shoulder is mounted. The arbour *A'* of this endless screw receives its motion from the first shaft *A*, by means of the wheels *s* and *s'* mounted upon these shafts and of an intermediate wheel *s''*. This wheel, of a diameter equal to that of the shaft *A'*, is intended merely to allow this shaft to recede from the shaft *A*. The diameter of the wheel of this last shaft is to that of the two others in the ratio of 10 to 8.

Second machine for subdividing the ribands. Figs. 407, 408.—The riband is engaged between the circular knives *c c*, which are mounted upon the rollers *R R*; thin brass washers keep these knives apart at a distance which may be varied, and two extreme washers mounted with screws on each roller maintain the whole system. The axes of these rollers traverse two uprights *M M*, furnished with brasses, and with adjusting screws to approximate them at pleasure. The axis of the lower roller carries a wheel

r, which takes into another smaller wheel *r'*, placed upon the same shaft as the pulley *P*, which is driven by a cord. The diameter of the wheel *r* is three times greater than the wheel *r'*. The pulley *P* is twice the size of the wheel *r'*; and its cord passes round a drum *B*, which drives the rest of the machine.

Threads of caoutchouc are readily pieced by paring the broken ends obliquely with scissors, and then pressing them together with clean fingers, taking care to admit no grease or moisture within the junction-line. These threads must be deprived of their elasticity before they can be made subservient to any torsile or textile manufacture. Each thread is *inelasticated* individually in the act of reeling, by the tenter boy or girl pressing it between the moist thumb and finger, so as to stretch it to at least eight times its natural length, while it is drawn rapidly through between them by the rotation of the power-driven wheel. This extension is accompanied with condensation of the caoutchouc, and with very considerable disengagement of heat, as pointed out in Nicholson's Journal upwards of 35 years ago, by Mr. Gough, the blind philosopher of Kendal. To stretch the thread, in the act of reeling, the sensation of heat is too painful for unseasoned fingers. The reels, after being completely filled with the thread, are laid aside for some days, more or fewer, according to the quality of the caoutchouc, the recomposed requiring a longer period than the bottle material. When thus rendered inelastic, it is wound off upon bobbins of various sizes, adapted to various sizes of braiding, or other machines, where it is to be clothed with cotton or other yarn.

In the process of making the **ELASTIC TISSUES**, the threads of caoutchouc being first of all deprived of their elasticity, are prepared for receiving a sheath upon the braiding machine. For this purpose they are stretched by hand, in the act of winding upon the reel, to 7 or 8 times their natural length, and left two or three weeks in that state of tension upon the reels. Thread thus *inelasticated* has a specific gravity of no less than 0.948732; but when it has its elasticity restored, and its length reduced to its pristine state, by rubbing between the warm palms of the hands, the specific gravity of the same piece of thread is reduced to 0.925939. This phenomenon is akin to that exhibited in the process of wire-drawing, where the iron or brass gets condensed, hard, and brittle, while it disengages much heat; which the caoutchouc thread also does in a degree intolerable to unpractised fingers.

For the solution of India-rubber, for the manufacture of elastic tissues, the following has been strongly recommended:—

The raw India-rubber is soaked in clear water, and boiled for about an hour, to remove dirt. It is then taken out of the water and cut into round slices about one centim. in thickness. It is then rolled out into layers about 2 mètres long and 0.15 mètre broad. The rubber is then dried in a warm chamber. After the drying follows the solution. About 26 kilos of rolled caoutchouc are placed in a wooden vat, lined with zinc, and treated with a mixture of 50 kilos benzol, and 70 kilos oil of turpentine. Both these liquids must be perfectly free from fatty matters, or the solution of India-rubber will be useless. The caoutchouc, before being brought into contact with the solvents, is torn up into small fragments. The mass is stirred occasionally, till it forms a thick, homogeneous liquid. To test the benzol and turpentine, small portions of each are evaporated to dryness in the water-bath. If any trace of fat remains, the sample is at once rejected.

In the manufacture of elastic fabrics, the riband looms at Holloway displayed to great advantage the mechanical genius of the patentee, Mr. Sievier. Their productive powers may be inferred from the following statement:—'5,000 yards of 1-inch braces are woven weekly in one 18-riband loom, whereby the female operative, who has nothing to do but watch its automatic movements, earns 10s. a-week: 3,000 yards of 2-inch braces are woven upon a similar loom in the same time.' But one of Mr. Sievier's most curious patent inventions is that of producing, by the shrinking of the caoutchouc threads in the foundation or warp of the stuff, the appearance of raised figures, closely resembling coach-lace, in the weft. Thus, by a simple physical operation, there is produced, at an expense of one penny, an effect which could not be effected by mechanical means for less than one shilling. This manufacture is not now carried on in that locality.

III. OF THE WATER-PROOF DOUBLE FABRICS.

In 1837, Mr. Hancock obtained a patent to produce waterproof cloth with greatly reduced quantities of dissolved caoutchouc, and in some cases without any solvent at all. The masticated rubber, rolled into sheets, was moistened on both sides with a solvent and rolled up. The following day these were submitted to rollers of different speeds, and the whole became a plastic mass. Instead of a wooden plank, as the bed of the machine, a revolving iron cylinder was used, kept hot by steam or water, and the coated cloth passed over flat iron chambers, heated the same way, to evaporate the small quantity of solvent. Masticated rubber has been spread without any solvent by these machines; but the spreading is best effected by the rubber being in some degree softened by the addition of small quantities of the solvent.

Sheets of rubber have been prepared by saturating the cloth with gum, starch, glue, &c., then rubber dough was placed on this smoothed surface; sufficient coatings of the rubber were spread to make up the desired thickness, the cloth was immersed in warm water to dissolve the gum, when the sheet of rubber came off with ease, and the plastic, or dough state, was the precursor of vulcanisation experiments and success.

The clamminess of caoutchouc is removed by Mr. Hancock in the following manner:—10 lbs. of it are rolled out into thin sheets between iron cylinders, and at the same time 20 lbs. of French-chalk (silicate of magnesia) are sifted on and incorporated with it, by means of the usual kneading apparatus. When very thin films are required (like sheets of paper), the caoutchouc, made plastic with a little naphtha, is spread upon cloth previously saturated with size, and when dry is stripped off. Mixtures of caoutchouc so softened may be made with asphalt, with pigments of various kinds, and with plumbago, sulphur, &c.

The first form of bags or pillows, or ordinary air-cushions, is well known, and was manufactured by C. Macintosh and Co. as early as 1825 and 1826; when pressure is applied they yield for the instant to the compressing body, and then become rigid, and the whole strain is borne by the inelastic material of the bag. Mr. T. Hancock once tried an ordinary pillow between boards in a hydraulic press, and he records that it bore a pressure of 7 tons before it burst. To remedy the evils of this form an ingenious arrangement was made of inserting slips of India-rubber into the fabric, so that it expanded in every direction. This yielding of the case, and division into strengthened partitions, enabled seats, beds, and other applications to be made.

The gas-bags now so commonly used appear, by Mr. Hancock's statement, to have been made for experimental purposes in the year 1826; and in May 1826, at the suggestion and for the use of Lieut. Drummond, to be employed in the Trigonometrical Survey of these islands, with the oxy-hydrogen jets of gas on balls of lime.

They were made strong and of rough materials—fustian made air-proof with thin sheet rubber. Mr. Hancock, to try whether the rubber was absolutely impervious to water, had a bag made and weighed it from time to time during 30 years; the decrease of weight is shown:—

	lb.	oz.	drch.
Oct. 21, 1826 weight 1	1	4
Oct. 25, 1827 „ 1	1	2
Oct. 2, 1835 „ 1	0	6
Nov. 1844 „ 6	14	12
Oct. 1849 „ 0	13	4
Feb. 1851 „ 0	7	8
May 1854 „ 0	3	14
In 1856 it was cut open and weighed 0	3	12

It was quite dry. Thus 12 oz. of water had evaporated or escaped in a quarter of a century, and 13 oz. 8 dr. in 30 years of observation.

He remarks that bags of such cloth made with a thin coating of rubber, soon evaporated sufficient water to cause mildew, when laid upon each other; but this slow evaporation does not interfere with their ordinary applications.

The porosity of caoutchouc would appear to explain the readiness with which it is permeated by different liquids which have no chemical action upon it. Thin sections of dry caoutchouc of the best kinds absorb from 18 to 26 per cent. of water in the course of a month, and become white from having been brown. It is, however, found that endosmose action is constantly active in India-rubber. In tubes through which gas flows there is always some escape of hydrogen deprived of much of its carbon.

To enumerate the applications of these double fabrics for cushions, life-preservers, &c., beds and boats, would be out of place here.

For single-texture fabrics, or cloth with one side only prepared, the process is the same as that described for double fabrics, only that one side only is proofed, or covered with India-rubber solution or paste; and this kind of waterproof has an advantage over the old, that the surface worn outside, being non-absorbent, imbibes no moisture and requires no drying after rain or wear. The objection to single-texture fabrics, of being liable to decomposition by the heat of the sun and from close packing, has been obviated by a discovery adopted by Messrs. Warne and Co., termed by them the Sincalor process (*sine calore*, without heat); by which the properties of the rubber are so changed that heat, grease, naphtha, and perspiration, which decompose the ordinary India-rubber waterproof, in no way affect the waterproof goods of the 'Sincalor' process. The singular changes effected by this process are especially shown by the application of a hot iron to the surface, which destroys it without the usual decompositions; the substance is burnt, but is not rendered sticky. The process is stated to be secret.

IV. VULCANISATION.

Of all the changes effected by chance, observation, or chemical experiments of late years, few cases have been so important as the change in India-rubber by the process called Vulcanisation. The union of sulphur with caoutchouc gives new properties so valuable, that it may be said the former well-known quality of elasticity is now rendered so variable that almost every range, from the most delicate tenuity to the hardness of metals, can be obtained at will by the manufacturer. These changes in the caoutchouc are produced with a degree of permanence to defy air, water, saline and acid solutions; the material is incapable of being corroded, and more permanent under harsh usage than any other set of bodies in the world. Such are the results of the processes that induce a 'change' in caoutchouc when sulphur and heat are employed; where metals and minerals are employed, 'metallised' and 'mineralised,' 'thionised,' and a number of other terms have been used.

When caoutchouc is mixed with from 2 to 10 per cent. of sulphur, and then heated to 270° and 300°, it undergoes a change, it acquires new characters, its elasticity is greatly increased, and is more equable; it is not affected nor is the substance altered by cold, no climate effects a change, heat scarcely affects it, and when it does it does not become sticky and a viscid mass; if it yields to a high temperature it is to become harder, and will ultimately yield only at the advanced temperature to char and to decompose. All the ordinary solvents are ineffectual. The oils, grease, ether, turpentine, naphtha, and other solvents scarcely alter it, and the quantity of sulphur that will effect the change is known not to exceed 1 or 2 per cent. Further, if peculiar solvents, such as alkalis, remove all apparent sulphur from it, still the change remains; indeed, the analogy of steel to iron by the changes of condition effected by some small quantities of other bodies seems to be an analogous condition. Whatever the theory, which is exceedingly obscure, still the practice, by whatever name, is to obtain this changed state and exalted elastic properties.

'Vulcanisation' was discovered in America. Mr. Goodyear relates, that having made a contract for India-rubber mail bags, they softened and decomposed in service, and while he thought a permanent article had been made, the colouring materials and the heat, united to soften and to destroy the bags; hence, by this failure, distress of all kinds arose, and the trade was at an end. During one of the calls at the place of abandoned manufacture, Mr. Goodyear tried a few simple experiments to ascertain the effect of heat upon the composition that had destroyed the mail-bags, and carelessly bringing a piece in contact with a hot stove, it charred like leather. He called the attention of his brother, as well as other individuals who were present, and who were acquainted with the manufacture of gum elastic, to the fact, as it was remarkable, and unlike any before known, since gum elastic always melted when exposed to a high degree of heat. The occurrence did not at the time appear to them

to be worthy of much notice. He soon made other trials, the India-rubber always charring and hardening.

As ordinary India-rubber is always tending to adhere, many plans had been tried to prevent this. Chalk, magnesia, and sulphur had been patented in England and America, but no one seems to have supposed any other change would be produced by heat. Mr. Goodyear proceeded to try experiments, and produced remarkable results: samples of goods were shown about and sent to Europe.

The late Mr. Brockedon, so well known for his talents and love of scientific investigations, had long pursued means to obtain a substitute for corks, and, after much ingenuity, had devised India-rubber stoppers. As soon as all mechanical difficulties were over, objections were taken to the colour of the substance. Some samples of a changed rubber came into his possession, of which it was declared they would keep flexible in the cold, and were found not to have an adhesive surface. These caused numerous experiments, as it was recognised that a change had been effected, and although Mr. Brockedon failed, yet Mr. Hancock kept on working, combining sulphur, with every effect, but that of vulcanisation, as he was ignorant of the power of heat to effect this change. He used melted sulphur, and produced proof of absorption, for the pieces of caoutchouc were made yellow throughout; by elevating the temperature he found they became changed, the lower end of slips 'nearest the fire turning black, and becoming hard and horny' (the sulphur was melted in an iron pot). By these simple observations, as they now seem, Mr. Goodyear in America and Mr. Hancock in England were induced to take out patents, and commence that series of manufacturing applications to which there seemed no limit. The first English patent was by Mr. Hancock. The general method is to incorporate sulphur with caoutchouc, and submit it to heat; if any particular form is required, the mixture is placed in moulds, and takes off any delicate design that may be upon the metal mould, and if these are submitted to higher degrees of heat, the substance and evolved gases expand, and thus a very hard, horny, or light but very strong substance is produced, called hard India-rubber, or 'vulcanite.' Mouldings, gun-stocks, combs, cabinet-work, and hundreds of forms may be obtained by these curious means. The term 'vulcanisation' was given by Mr. Brockedon to this process, which seemed by the employment of heat and sulphur to partake of the attributes of the Vulcan of mythology. For the 'change' or 'vulcanising' to get a yielding but permanently elastic substance, steam heat is usually employed in England, but in America, ovens, with various plans for producing dry heat, are generally employed.

The articles thus made being more elastic, unaffected by heat, cold, or solvents, attracted much attention, and Mr. Parkes was engaged to find out a method of producing the same effects now secured by patent: all ordinary means were used and given up, but he finally succeeded. The process of cold sulphuring of Mr. Parkes consists in plunging the sheets or tubes of caoutchouc into a mixture of 100 parts of sulphuret of carbon and 2½ parts of protochloride of sulphur, for a minute or two, and then immersing them in cold water. Thus supersulphuration is prevented in consequence of decomposing the chloride of sulphur on the surface by this immersion, while the rest of the sulphur passes into the interior by absorption. Mr. Parkes prescribes another, and perhaps a preferable process, which consists in immersing the caoutchouc in a closed vessel for 3 hours, containing a solution of polysulphuret of potassium indicating a density of 25° Beaumé, at the temperature of 248° Fahr., then washing in an alkaline solution, and lastly in pure water. A uniform impregnation is thus obtained.

In the first instance sulphur, caoutchouc, and heat were alone employed; the temperature and the time to which the mixtures are subjected to heat being determined by practical experiments. Vulcanised rubber is not only the changed substance, as produced by sulphur, but it contains metallic oxides, &c., metallic and mineral substances; and these compounds, are perhaps much better fitted for their respective uses than the pure sulphur and India-rubber. White lead, sulphide of antimony, black lead, and other substances enter into these combinations. After the early experiments with vulcanised rubber there seemed reason to believe that changes slowly took place. The rubber was found to become brittle, and bands stretched out broke immediately. To a great extent this has been remedied by the use of lead, which seems to combine with the sulphur, for changes are believed by practical men to take place with pure elastic vulcanised caoutchouc which do not occur when metallic matters are duly mixed. This is a trade statement, which may be true for some special uses. The brittleness may perhaps more fairly be admitted to be due to inexperience, and the difficulties to meet the demands of the public for a new article; but to those whom it may most concern, we have raised this question so far as to obtain the conscientious opinion of Mr. Thomas Hancock (now retired from business), who considers that by the peculiar plan of vulcanising by a bath of sulphur,

and employing high pressure steam (described in Patent of 1843), he obtains what he calls *pure vulcanising*, that is, the use of sulphur, rubber, and heat. He states 'That by this mode, the greatest amount of *extensile elasticity* is obtained, and that this quality is diminished in proportion as other matters are present in the compound.' It may, however, be useful to record some of the results of early trials made by competent authorities, with the view of testing its ultimate employments. Mr. Brockedon stated at the Institution of Civil Engineers, that he had kept vulcanised India-rubber in tranquil water for 14 years without visible change, and he summed up the then knowledge of trade production, that there was perhaps no manufacturing process of which the rationale was so little understood as that of vulcanising caoutchouc; all was conducted on the observation of facts, a given quantity of sulphur to a certain thickness of rubber, at a certain temperature; and certain results were reckoned upon with confidence, but more from practice than theory. Mr. Brockedon had placed vulcanised rubber for 10 years in damp earth, and it exhibited no change.

When articles were moulded, the metal of the mould was not a matter of indifference; if of tin, the article was usually delivered perfectly clean, but if of brass or copper, then the material adhered to it, probably from the greater affinity of the sulphur for the metal than for the caoutchouc: these surface effects may well be borne in mind, for it appears not to be an easy matter to vulcanise large masses of caoutchouc, while sheets and thin films are readily changed. The soft masses of materials are placed in moulds, strongly secured, if a high temperature is to be used, and the mass comes out with the form thus given to it, and more or less elastic; hence the surface of a mass is always likely to be advanced in the vulcanising changes.

At present a very large proportion of the articles made have the forms given to them in the plastic state, and then subjected to heat; the change is effected, and they retain their form, although rendered permanently elastic.

Mr. Brockedon and Mr. Brunel tried this substance on the Great Western Railway, in place of felt, to be used between the under sides of bearing rails and sleepers of railways. It appeared, by constant trials of nearly a year, to be quite indestructible to any action to which it had been exposed; the slips were indented by the edge of the rail, but not permanently so, and the surface was glazed, as if by friction; the slips were 6 inches wide, and weighed 8 oz. to the yard in length: the transit of the carriages was easier over that part of the line.

To test the power of endurance to heavy blows, Mr. Brockedon subjected a piece of vulcanised India-rubber, $1\frac{1}{2}$ inch thick and 2 inches in area, to one of Nasmyth's steam-hammers of 5 tons; this first rested on the rubber without effect, then was lifted 2 feet and dropped upon it without injury, then lifted 4 feet, and the vulcanised cake was torn, but its elasticity was not destroyed. Still more severe trials were made: a block of vulcanised caoutchouc was placed as between cannon balls, with the whole power of the heaviest steam-hammers employed, but the iron spheres split the block, and the elasticity of the vulcanised caoutchouc was not destroyed.

Sheets of enormous size—ship-sheets—have been made 50 yards long and 56 inches wide, others 10 feet square; these are intended to pass over a steam-vessel's side, to adapt a valve, fix a pipe, or repair, from the interior, the vessel itself, without going into dock. These stout sheets, $\frac{3}{8}$ th inch thick, are let down by ropes over a ship's side, and brought over the hole or place for repair by the pressure of the water on the elastic sheet, when the leak may be stopped and the ship pumped dry, pipes renewed, shot-holes and leaks stopped. Indeed, an early application of compounds of native rubbers and other materials was applied directly as sheathing for ships with success; but litigation among the parties caused the business to cease. Since the various plans for getting a flexible material have been successful, there seems no doubt but many unexpected applications will be made.

Messrs. Macintosh had coated some logs of wood with vulcanised India-rubber, and caused them to be towed in the wake of a vessel all the way to Demerara and back, and it was found that the coated logs were quite intact, while the uncoated timber was riddled by marine borers. The same firm stated: 'That the only effect they could trace upon long immersed vulcanised caoutchouc, was a slight change of colour, perhaps a hydrate produced by superficial absorption, but this change of colour disappeared on being dried. If they were called upon to select a situation for the substance to retain its properties for the longest period, they would select immersion in water. After years of experience in the use of hose-pipes, pipe-joints, valves for pumps and steam-engines, they had never known an injury from the contact of any kind of water.'

Mr. Goodyear sums up the advantages of vulcanised rubber under the following heads, as being either properties new or superior to those possessed by the natural caoutchouc:—

- | | |
|---|--|
| <ol style="list-style-type: none"> 1. Elasticity. 2. Pliability. 3. Durability. 4. Insolubility. 5. Unalterability by climate or artificial heat or cold. 6. Inadhesiveness. 7. Impermeability to air, gases, and liquids. | <ol style="list-style-type: none"> 8. Plasticity. 9. Facility of receiving every style of printing. 10. Facility of being ornamented by painting, bronzing, gilding, japanning, and mixing with colours. 11. Non-electric quality. 12. Odour. |
|---|--|

Mr. Burke, in describing his patented process, for the use of the golden sulphuret of antimony, says, that he avoids two principal defects of the usual article, viz. its efflorescence of sulphur with an offensive odour, and its consequent decomposition and becoming rotten. He employs crude antimony ore (the sulphuret of that metal, in fine powder), and converts it by boiling in water with soda or potash (carbonates) into the orange sulphuret of that metal (Kermes mineral) by the addition of hydrochloric acid to the fluid in slight excess. He combines this compound (after being well washed) with caoutchouc or gutta-percha, either together or separately, according to the degree of elasticity which he wishes to obtain. This mixture is afterwards subjected to a heat of from 250° to 280° F. He masticates the caoutchouc in the usual iron box, by means of the kneading fluted revolving rollers, subjecting the whole to heat. The antimonial compound is then added in quantities varying from 5 to 15 lbs., according to the strength and elasticity required in the compound. At the end of from one to two hours' trituration, the block is removed from the box, and while in a warm state it is strongly compressed in an iron mould; and after being under pressure for a day or two is subjected to a steam heat for a couple of hours. The block thus prepared may now be cut into sheets, and afterwards divided into threads, or formed into such other articles as are desired. This forms the elastic red rubber.

The chief improvements operated in caoutchouc by the process of vulcanisation are the properties of resisting and remaining unaffected by very high degrees of heat and cold, and increased compressibility and elasticity. In its natural state India-rubber becomes rigid by exposure to cold, and soft and plastic by heat, or under the action of boiling water. Articles manufactured of this substance suffer and lose the qualities which constitute their value in cold and in hot countries. A piece of India-rubber cloth, for instance, taken to Moscow in December or January, would assume all the qualities of a piece of thin sheet iron, or thick pasteboard; the same cloth would in India or Syria become uncomfortably pliable, and present a moist and greasy appearance; and, indeed, after being folded up some time, would be found to be glued together. Nothing but vulcanisation insures the equable condition of the articles in the most intense cold, and, in heat up to and above 300°, makes India-rubber fit for practical purposes. These advantages have conduced to its being very extensively used in connection with machinery of every description; and as steam power is still further employed, and as the numerous other advantages possessed by vulcanised India-rubber become known (for it is only of late that any idea of their extent has been realised) its application will be extended and its consumption proportionally increased.

The compressibility and the return to its former dimensions, when the pressure has ceased, in one word, the elasticity of the India-rubber, is increased to such a degree by vulcanisation, that comparing the improved with the original article, it may be said that the native India-rubber is almost devoid of elasticity. The high degree of elasticity which it obtains by vulcanisation is shown by the results of the following experiments, in which a block of the vulcanised India-rubber, of the kind used for the manufacture of railway carriage springs, measuring 6 inches outside disc, 1 inch inside disc, and 6 inches deep, was taken and exposed to pressure:—

A pressure of	$\frac{1}{2}$ ton	reduced it to	.	.	.	$5\frac{9}{16}$ deep.
"	1	"	"	"	"	$5\frac{13}{16}$ "
"	$1\frac{1}{2}$	"	"	"	"	$4\frac{9}{16}$ "
"	2	"	"	"	"	$4\frac{3}{16}$ "
"	$2\frac{1}{2}$	"	"	"	"	$3\frac{13}{16}$ "
"	3	"	"	"	"	$3\frac{1}{16}$ "
"	$3\frac{1}{2}$	"	"	"	"	$3\frac{1}{4}$ "
"	4	"	"	"	"	3 "

The block was left under pressure for 48 hours, and in each case returned to its original dimensions after a short period when the pressure was removed.

Among the most recent uses of India-rubber and canvas, are those of its manufacture into gas and ballast bags, the former are used for the transport of gas, and

applied to the various emergencies of gas engineering. India-rubber gas-tubing is now in general use, the great advantage over metal tubes being, the ease with which gas can be conveyed to whatever part of the building it may be required in; this, where any alterations are being effected, is a great desideratum. Ballast bags, large stout bags of India-rubber and canvas, capable of holding from 1 to 5 or 10 tons of water, are coming into use as the most convenient form of ballast, thus saving valuable space which is made available for cargo. These bags may be emptied at any time, and when flattened down and rolled up, can be conveniently stowed away. India-rubber bags for inflation have also in a few cases been made use of for buoying up vessels, but hitherto the practice has been experimental only, and such floating machines are not as yet generally in use.

The vulcanising of India-rubber on silk or woollen goods was for a long time considered impracticable, because the process of vulcanisation destroyed the fibre and texture of the two substances; but it is stated that now this process is effected in a manner which deprives neither silk nor wool of their natural qualities and strength. By this improvement, combined with Silver's patent process of annihilating the unpleasant smell which all India-rubber goods used to acquire in the process of manufacture, the advantages of that substance for clothing purposes are extended to the lightest and the warmest of our textures. Silk and India-rubber garments are made without any deterioration of the strength and durability of the stuff, while they are perfectly free from odour of any kind.

V. MECHANICAL APPLICATIONS OF CAOUTCHOUC.

Numerous important applications of caoutchouc have been made in the mechanical arts, among which we may mention, springs for railways and common road carriages, military carriages, lifting springs for mining ropes and chains, towing ropes and cables, rigging of ships, recoil of guns on ships, the tyres and naves of railway and other wheels, axles and axle bearings, windows of railway carriages, railway switches, bed of steam-hammer, couplings for locomotives and tenders, packing for steam and water joints, shields for axle boxes, sockets for water pipes, bands for driving machinery, valves for pumps, tubes for conveying acids, beer, water, and other fluids, packing for pistons, &c.

The Exhibition of 1862 presented to us an enormous display of India-rubber manufacture. The applications of caoutchouc to driving belts for machinery, to washers and buffers, were numerous, and many of them excellent.

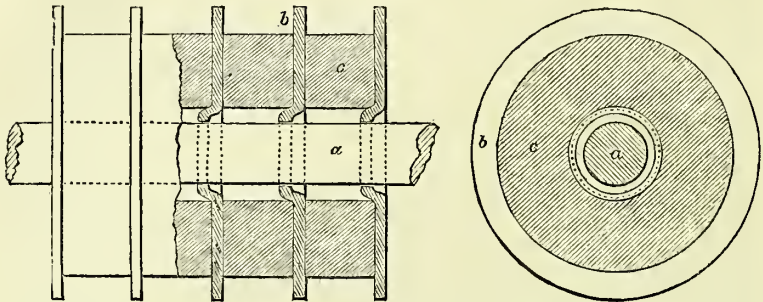

Messrs. Perreaux and Co. were exhibitors of a valve for pumps made of vulcanised caoutchouc. Its simplicity and efficiency were remarkable: the valve was simply a cylinder of India-rubber, with its two sides at the uttermost end pressed together like lips, and then vulcanised, which makes the material retain the form given to it. This valve, when in position, was open below, and closed above in the form of a wedge; the fluid easily passes upwards owing to the elasticity of the material, but the downward pressure firmly closes the lips and prevents return. Of ebonite and kamptulicon there were many examples, embracing a curious variety of articles from philosophical apparatus in the form of electrical machines, to pieces of furniture, and ornaments for ladies' wear. See EBONITE and KAMPTULICON.

Springs.—The first proposal to use caoutchouc for springs that we are aware of occurs in *Lacey's* patent, in 1825, when blocks of caoutchouc were proposed to be used, having dividing plates of iron between each series; but little seems to have been done towards any practical application at that time: later, in 1844, *Melville* proposed to use spheres of caoutchouc, enclosing air, and separated by discs of wood or metal, the whole being enclosed in iron cases, and used for buffers and bearing springs for railway carriages. In 1845 *Walker* and *Mills* proposed to use bags of caoutchouc enclosing air, and contained in cases of iron, for use as buffer springs.

The next improvement is contained in *Fuller's* patent of 1845, which consists in the use of cylindrical rings of vulcanised India-rubber, in thicknesses varying from $\frac{1}{2}$ to 3 inches, and with diameter of ring suitable to the power of spring required; between each of these cylindrical rings he places a thin iron plate, through a hole in the centre of which passes a guide rod. *Fig. 409* shows Fuller's spring in section and plan. These springs have been extensively used as buffer-, bearing-, and draw-springs for railway uses, alone and in combination with *De Bergue's* improvements: some defects have been found in practice in this form, to obviate which, the ingenuity of later inventors has been exercised; the defects alluded to are, the tendency to swell out at the central unsupported part of the ring, thus from the undue tension rendering it liable to break

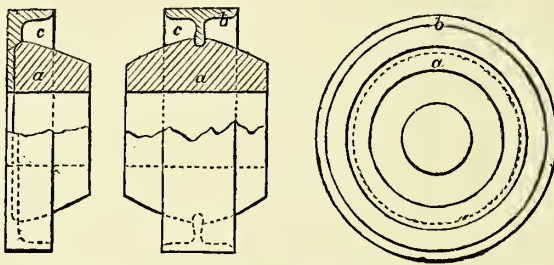

under sudden concussion, and occasioning complete disintegration of the material where not breaking.

409

To obviate these defects, *George Spencer* (in 1852 and 1853) proposed to mould the caoutchouc at once in the form it assumes under pressure, and then to place a confining ring of iron on the larger diameter. (See *fig. 410*). By this ingenious plan, the caoutchouc loses its power of stretching laterally, being held by the ring *b*, secured in a groove moulded in the cone to receive it; when the pressure is applied to the ends, the rubber is squeezed into the cuplike spaces *c*, and thus the action of the spring is limited. By this plan, rubber of a cheaper and denser kind can be used than on the old cylindrical plan, and the patentee states that many thousands of carriages and trucks are fitted with these springs which give entire satisfaction; among which, are those on the Brighton, South-Western, North London, South Wales, Vale of Neath, Bristol and Exeter, Taff Vale, Lancashire and Yorkshire, St. Helen's, Bombay and Baroda, Theiss Railways, and many others. These cones are used as buffer-, bearing- and draw-springs for railway carriages, and are made in several sizes to suit various

410

uses. To show the power that such springs are equal to, we append the result of an experiment on a No. 1 cone (for inside buffers), 3 inches in length, $3\frac{3}{4}$ inches diameter at ring, 5 inches diameter of ring.

1st Experiment, without the confining ring, weight of cone $1\frac{1}{4}$ lb.

	Inches	Giving a stroke of
Without any pressure the cone measured	3	.
With pressure—280 lbs.	$2\frac{1}{2}$	$\frac{1}{2}$ inch.
„ —448 lbs.	2	1 „
„ —672 lbs.	$1\frac{1}{2}$	$1\frac{1}{2}$ „

2nd Experiment.

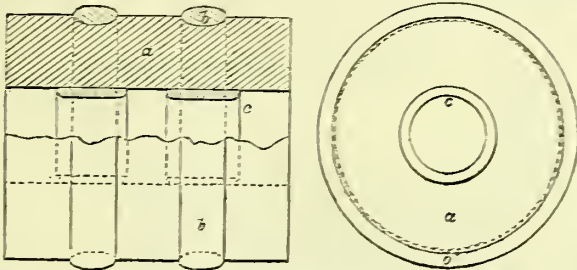

With the confining ring *b*, on the same double cone; the following were the results:—

Without any pressure the cone measured	3 inches, as before.
With—448 lbs.	$2\frac{3}{4}$ „
„ 1,680 lbs.	2 „
„ 2,912 lbs.	$1\frac{3}{4}$ „
„ 15,680 lbs.	$1\frac{1}{2}$ „

The advantages are stated to be, less first cost than steel; less weight, 6 cwt. being saved in each carriage by their use; and great durability.

Coleman's improvement consists in the use of iron rings to confine the lateral swellings of India-rubber cylinders. (See *fig. 411*). They are used as bearing-springs

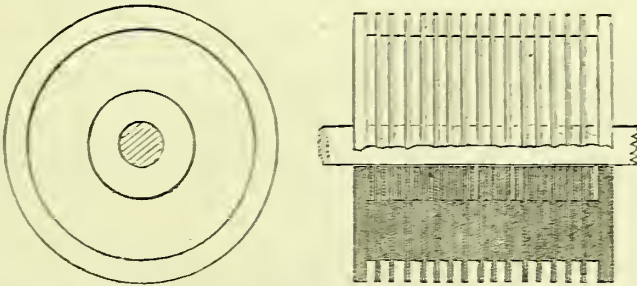

411

for engines and tenders on the North-Western Railway, by J. E. M^cConnell, Esq., who prefers them to steel, as being easy in action, durable, safe, and easy of repair; they are used also as buffer- and draw-springs.

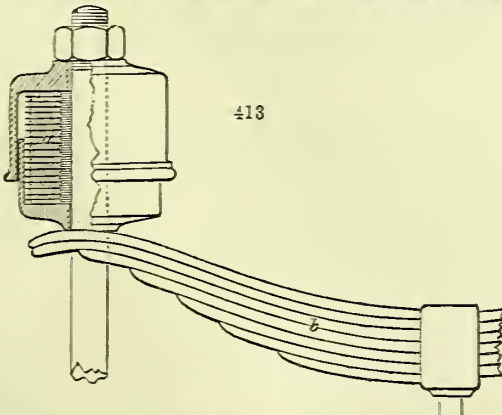

The next form of these springs is the invention of *R. Eaton* (see *fig. 412*). This spring seems to be peculiarly adapted to use where a powerful spring, acting through

412

a small space, and taking little room, is required, as for use in mining ropes and chains, &c. *Eaton's* main idea is the use of laminae of India-rubber, of a maximum thickness of $\frac{1}{4}$ an inch, with dividing plates, as in *Lacey's* and *Fuller's*, which avoids the objections stated above, by supporting the India-rubber at smaller intervals; for springs,

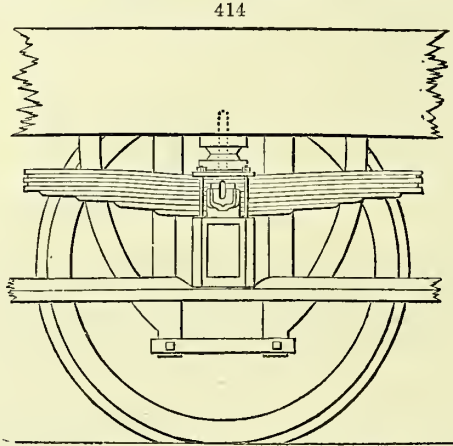

413

where great power is wanted in little compass, and to act through short distances,—as in engine bearing-springs, lifting-springs, and some kinds of draw-springs—this form proves to be well suited.

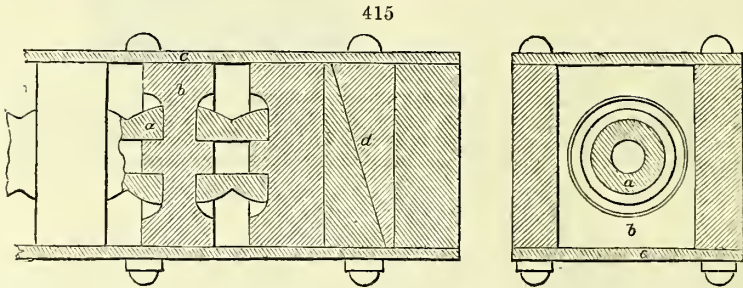

Hodge's compound spring is designed to obviate the frequent breakage of the steel springs on locomotive engines. *Fig. 413* shows one of these springs; a block of India-rubber is placed on each end of the steel spring, or is suspended under the engine frame; they are in use on several of the English railways, and are said to answer the purpose intended well.

Scott's patent (see *fig. 414*), dated May 1856, consists in the use of blocks of India-rubber, or cones, placed over the centre of the spring; they are to obviate the danger of

overloading carriages and trucks, a frequent source of danger to the springs, and are made to take the whole load in case of a spring breaking.

Bridges' Patent (*fig. 415*).—This inventor ingeniously proposes to use Spencer's cones in blocks of wood, instead of iron confining rings. A series of them are enclosed in a case formed in the side timbers of the underframe of the railway truck or carriage; the cup space is formed in the block of wood, as our figure shows, and no

guide rods are required; the principle is applied to draw- and bearing-springs. The advantages proposed by this arrangement are, the dispensing with guide rods and the taking the ultimate blow on blocks of wood, which deadens its effect; they are said to answer very well.

In 1847, *Mr. De Bergue* patented some improvements in the application of Fuller's spring to buffer-, bearing-, and drawing-springs for railway uses.

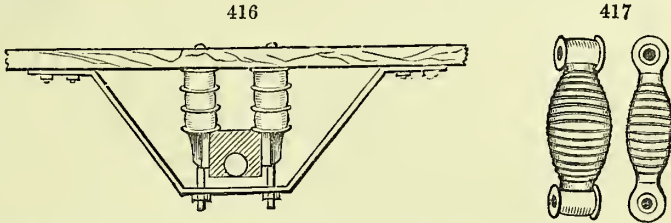

The applications for common road carriages, patented by *Mr. Fuller* of Bucklersbury in 1852 and 1855, have been extensively used, both in the form of cylindrical rings acting by compression and also of suspension springs for lighter kinds of vehicles.

Respecting these springs, *figs. 416, 417*, we have been furnished by the patentee with the following particulars:—

The form generally used for heavy purposes, such as drays, vans, waggons, &c., consists of a series of rings of cylindrical or circular form, working in a perpendicular rod or spindle, on each side the axle, with the usual separating plates or washers; the depth and diameter of the rings being regulated by the weight to be sustained and the speed required.

During the Crimean war, these springs were introduced by *Mr. Fuller* to the notice

of the Government authorities at the Royal Arsenal, Woolwich, and were in consequence adopted for all kinds of military carriages, store waggons, ammunition waggons, &c. They were also applied in the suspensory form for the medical cars and ambulance waggons for the wounded, for which purposes the use of India-rubber on the principle of extension is found to produce the easiest and most satisfactory spring hitherto discovered.

When the material is used as a suspension spring, the most advantageous form for the purpose is found to be that of round cord of the best and purest quality, prepared by solvents, and about $\frac{1}{4}$ th or $\frac{3}{8}$ ths inch diameter.

A continuous length of such cord is wound at a considerable tension over the ends of two metal sockets or rollers, in shape something resembling a cotton reel, and whilst in a state of tension, bound at each end with strong tape or other suitable binding; the number of cords composing the spring, varying from 10 to 20, 30, or 40, according to the strength required.

Another important adaptation of India-rubber by Mr. Fuller, is that of anchor springs, towing ropes, and springs for the recoil of guns and mortars.

418

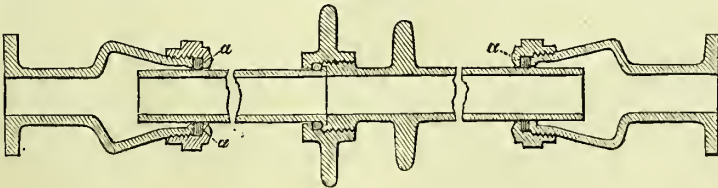

Wheel tyres.—Fig. 418 shows an important application to the tyres of wheels for railway purposes. A thin band of India-rubber is inserted between the tyre and spoke ring, by first covering it with a thin plate of iron, to protect the India-rubber while the hot tyre is put on, when the wheel is instantly thrown into water and cooled. This has been severely tested for some time, and found to answer very well; the advantage gained is the saving in the breaking and wear of the tyres.

For Windows.—Small ropes of India-rubber are inserted in grooves at each side of the window, and so stop out draught and prevent noise.

For steam-hammer beds.—A plate of India-rubber $\frac{5}{8}$ ths inch thick, is placed under the bed of the hammer; the effect is greatly to diminish the transmission of shocks to the building, and to cheapen the foundation: as an instance of useful application, we may state, that at Messrs. Ransome and May's works, at Ipswich, the working of the steam-hammer shook the building and windows to an alarming extent; but the insertion of blocks of vulcanised rubber under the anvil, almost entirely obviated these effects.

Joints between engines and tenders.—Messrs. Lund, Spencer, and Fenton, have also introduced the use of rings of this material to form a joint between the locomotive and tender (fig. 419). They are extensively used, and entirely prevent the leakage

419

common to the old ball-and-socket joints, and are much cheaper in first cost. Rings of India-rubber were proposed by Mr. Wickstead, for closing the socket joint of water pipes, and they are used in a variety of forms for that purpose.

A large trade has been established in the supply of bands of India-rubber for driving machinery; for many purposes they answer better than leather, water having no effect on them and there being little or no slip and fewer joints; they are made in widths, and belts costing 150*l.* each have been used in some cases. They are made with two or more layers of thread cloth between, and outside of which the rubber is placed.

VI. SOLARISATION OF CAOUTCHOUC.

Singular as caoutchouc is in its properties and its applications, it is probable that besides the mechanical and electrical qualities and general resistance to chemical action, it may yet be found to have other modifications peculiar and valuable. The practical men most conversant with this substance, and deeply involved with patents and successful manufactures, record their conviction of the influence of solar light, and the marked distinctions supposed to exist between the influence of solar and terrestrial heat upon this substance.

Mr. Hancock says, 'In my early progress, I found that some of the rubber I employed was very quickly decomposed when exposed to the sun: as the heat was never more than 90°, and rubber exposed to a much higher temperature was not injured by it, I suspected that light had some effect in producing this mischief. To ascertain this, I cut two square pieces from a piece of white rubber, one of these I coloured black, and exposed it to the sun's rays; in a short time, the piece which had been left white, wasted away, and the sharp angles disappeared, it seemed like the shape of a thin piece of soap after use; the blackened piece was not at all altered or affected. The lesson taught me by this experiment was of great value ever after.'

Speaking of the annoyances and failures in the early Macintosh goods by heat, grease, &c., Mr. Hancock says, 'The injurious effect of the sun's rays upon thin films of rubber we discovered and provided against before much damage accrued.'

Mr. Goodyear says, 'In anticipation of the future as relates to a mode of treatment in manufacture, which, though lightly esteemed and little thought of now, I believe will be extensively practised hereafter, I feel bound to make a strong though qualified claim to the process of Solarisation. This process consists in exposing caoutchouc when combined with sulphur, to the sun's rays.' Again, 'when exposed to the sun's rays for several hours, a change is produced which may be called natural vulcanisation, in all thin fabrics or thin sheets of caoutchouc.' 'Solarisation is an effectual and cheap process of curing India-rubber.' He further says, 'it is well established that India-rubber melted at about 200°, and in the sun's rays at 100° or less. Another effect yet more remarkable in the treatment of gum elastic, is that of the sun's rays upon it; when combined with sulphur and exposed to the sun, either in hot weather or cold, it becomes solarised, or divested of its adhesive quality; whereas, no other kind of light or heat has any similar effect, until the high degree of heat is applied to it, about 270°, which is used in vulcanising,'—*Goodyear*, p. 114, vol. i. New Haven, U.S.

Our recent *Imports* of Caoutchouc have been as follow:—

Our *Exports* of caoutchouc manufactures in the same year were valued at 854,539*l*.

In 1872 we imported 157,148 cwts., valued at 1,762,886*l*.

CAOUTCHOUCINE. A thin volatile oily liquid, obtained by the destructive distillation of caoutchouc. Mr. C. Greville Williams has shown that this liquid is composed principally of two hydrocarbons, called *caoutchin* $C^{20}H^{16}$ ($C^{10}H^{16}$), and *isoprcne* $C^{10}H^8$ (C^5H^8).

Mr. William Barnard, in the course of some experiments upon the impregnation of ropes with caoutchouc, which he conducted at the factory of Messrs. Enderby at Greenwich, discovered that when this substance was exposed to a heat of about 600° F. it resolved itself into a vapour, which, by proper refrigeratory methods, was condensable into a liquid possessing very remarkable properties, to which the name *caoutchoucine* has been given. For this invention 'of a solvent not hitherto used in the arts,' Mr. Barnard obtained a patent, in August 1833. His process for preparing it is described in his specification as follows:—'I take a mass of the said caoutchouc, or India-rubber, as imported, and having cut it into small lumps, containing about two cubic inches each (which I prefer), I throw these lumps into a cast-iron still (which I find adapted for the purpose, and a diagram of which is annexed to, and forms part of this my specification), with a worm attached (*fig. 420*): A is the still; B, the cover ground to a metallic fit, to admit of a thermometer to take the temperature; C, the fire-place; D, the ash-pit; E, the worm-tub and worm; F, the brickwork of the still; G, a roller and carriage, in connection with a crane, or other means, to raise the cover to take out the residue, and to charge the same; H, the chain.

'I then apply heat to the still in the usual manner, which heat is increased until the thermometer ranges at about 600° F., or thereabouts. And as the thermometer ranges upwards to 600° F. a dark coloured oil or liquid is distilled over, which I claim as my said invention, such liquid being a solvent of caoutchouc, and other resinous and oleaginous substances. When the thermometer reaches 600° F., or thereabouts, nothing is left in the still but dirt and charcoal.

'I have found the operation of distillation to be facilitated by the addition of a portion of this oil, either previous or subsequent to the rectification, as hereinafter mentioned, in the proportion of one-third of oil to two-thirds of caoutchouc.

'I afterwards subject the dark coloured liquid thus distilled, to the ordinary process of rectification, and thereby obtain fluids varying in specific gravity, of which the lightest hitherto has not been under 670, taking distilled water at 1,000, which fluids I also claim as my said invention.

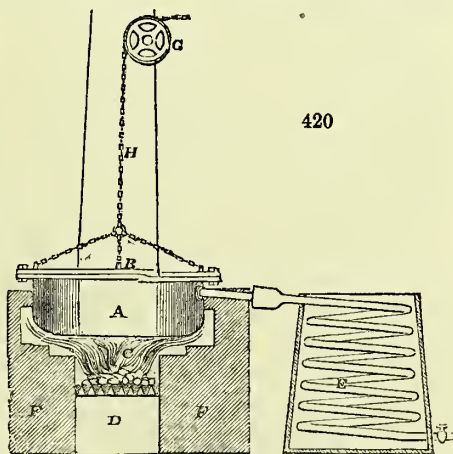

'At each rectification the colour of the liquid becomes more bright and transparent, until at the specific gravity of 0.680, or thereabouts, it is colourless and highly volatile.

'In the process of rectification (for the purpose of obtaining a larger product of the oil colourless) I put about one-third of water into the still. In each and every state the liquid is a solvent of caoutchouc, and several resinous and oleaginous substances, and also of other substances (such as copal), in combination with very strong alcohol.

'Having experienced much difficulty in removing the dirt which adheres to the bottom of the still, I throw into the still lead and tin in a state of alloy (commonly called solder), to the depth of about half an inch, and, as this becomes fused, the dirt which lies on the surface of it is more easily removed.

'Objections have been made to the smell of this liquid:—I have found such smell removed by mixing and shaking up the liquid with nitro-muriatic acid, or chlorine, in the proportion of a quarter of a pint of the acid (of the usual commercial strength) to a gallon of the liquid.'

The discovery of the chemical solvent, which forms the subject of the patent above described, has excited considerable interest in the philosophical world, not only from

its probable usefulness as a new article of commerce, but also from two very extraordinary characteristics which it is found to possess, viz., that, in a liquid state, it has less specific gravity than any other liquid then known to the chemists, being considerably lighter than sulphuric ether, and, in a state of vapour, is heavier than the most ponderous of the gases.

This material (when mixed with alcohol) is a solvent of all the resins, and particularly of copal, which it dissolves without artificial heat, at the ordinary temperature of the atmosphere; a property possessed by no other solvent known; and hence it is peculiarly useful for making varnishes in general. It also mixes readily with oils, and will be found to be a valuable and cheap menstruum for liquefying oil-paints; and without in the slightest degree affecting the most delicate colours, will, from its ready evaporation, cause the paint to dry almost instantly.

Cocoa-nut oil, at the common temperature of the atmosphere, always assumes a concrete form; but a portion of this caoutchoucine mixed with it will cause the oil to become fluid, and to retain sufficient fluidity to burn in a common lamp with extraordinary brilliancy.

Caoutchoucine is extremely volatile; and yet its vapour is so exceedingly heavy, that it may be poured, without the liquor, from one vessel into another, like water. One of the real practical objections to caoutchoucine seemed to be its easy decomposition. Messrs. Enderby and Barnard found that, if exposed to air, and especially if a small quantity of water was present, that it was speedily decomposed, changing colour to deep brown or black. Specimens, however, remain perfectly clear and without change, in bottles, after twenty years.

After caoutchouc has been subjected to destructive distillation, and the caoutchoucine or volatile oil of caoutchouc has distilled off, there remains in the retort a residual mass which, when dissolved in oil, forms a varnish impervious to moisture, and consequently much used by shipwrights.

CAPERS. The *Capparis spinosa*, the flower-buds of which constitute the capers of the shops. Their quality depends exclusively upon the age at which they are gathered, the smallest and youngest being the most delicate and the dearest; and the largest, the coarsest and cheapest. The buds are plucked before they open, and thrown into strong vinegar, slightly salted, where they are pickled. The crop of each day is added to the same vinegar tub, so that in the course of the six months during which the caper-shrub flowers, the vessel gets filled, and is sold to persons who sort the capers by means of copper sieves. This metal is attacked by the acid, wherefrom the fruit acquires a green colour, much admired by ignorant connoisseurs. About 60,000 lbs. a year are consumed in this country.

The capsules of the caper spurge, *Euphorbia Lathyris*, are sometimes pickled as a substitute for capers; but although the acid destroys some of the acrid properties, the free use of them is dangerous.—*Pereira*.

The unripe fruit of the garden Nasturtium (*Tropæolum majus*) is also pickled as a substitute for capers.

CAPILLAIRE. Originally a kind of syrup, extracted from maiden-hair. The term is now applied to a finely clarified simple syrup, which is made usually with orange-flower water.

CAPNOMORE. A substance discovered by Reichenbach in wood-tar.

CAPRYLAMINE. $C^{16}H^{19}N$ ($C^8H^{10}N$). A volatile base obtained by Squire, and also by Cahours, by acting on ammonia with iodide of capryle. It is homologous with methylamine, &c.—C. G. W.

CAPSICUM. The dried ripe fruit of *Capsicum fastigiatum*, imported from Zanzibar, known in commerce as *Guinea Pepper* and *Pod Pepper*. See **PEPPER**.

CAPSTAN. (*Cabestan*, Fr.; *Spille*, Ger.) A machine whereon the cable is wound successively in weighing the anchor of a vessel. It is a species of wheel and axle; the axle being vertical, and pierced with holes near its top for the insertion of the ends of horizontal levers, called handspikes, which represent the wheel. These are turned by the force of men moving in a circle. The power applied to the lever is to the resistance to be overcome (the weight of the anchor, for example), when the forces are *in equilibrio*, as the radius of the cylinder round which the cable is coiled is to the circumference described by the power. It is manifest that the radius of the axle must be augmented in this computation by half the diameter of the cable, which is supposed to lie always one coil thick upon it. The force of a man thus applied, has been commonly estimated as equal to the traction of 27 pounds hanging over a pulley. Friction being so variable a quantity in capstans, renders the exact calculation of its mechanical effect somewhat uncertain. A stout man, stationed near the bottom of the axle, holds fast the loose part of the cable, which has already made two or three turns; and, being aided by its friction upon the wood, he both prevents it from slipping backwards, and uncoils each turn as it is progressively made.

Mr. Hindmarsh, of Newcastle, obtained a patent, in February 1827, for a contrivance to enable a capstan or windlass to be occasionally worked with increased mechanical advantage. With this view, he placed toothed wheel-work, partly in the drum-head of the capstan, and partly in the upper part of the barrel, upon which the cable is coiled and uncoiled in successive portions.

The drum-head, and also the barrel, turn loosely upon a central spindle, independently of each other, and are connected together either by the toothed gear, or by bolts. On raising or withdrawing the connecting pinion from the toothed wheels, and then locking the drum-head and barrel together, the capstan works with a power equal only to that exerted by the men at the capstan-bars, as an ordinary capstan; but on lowering the pinion into gear with the wheel work, and withdrawing the bolts which locked the drum-head to the barrel, the power exerted by the men becomes increased in proportion to the diameter and number of teeth in the wheel and pinions.

Fig. 422 is the external appearance of this capstan. Fig. 421 a horizontal view of the toothed gear at the top of the barrel. The barrel, with the whelps *a a*, turn loosely upon a vertical spindle fixed into the deck of the vessel. The drum-head *b* also turns loosely upon the same spindle. The circular frame *cc*, in fig. 421, in which the axes of the toothed wheels *d d d* are mounted, is fixed to the central spindle. The rim *eee*, with internal teeth, is made fast to the top of the barrel, and the pinion *f*, which slides upon the spindle, is connected to the drum-head.

When it is intended to work the capstan with ordinary power, the pinion *f* is raised up into the recess of the drum-head, by means of a screw *g*, fig. 422, which throws it out of gear with the toothed wheels, and it is then locked up by a pin *z*: the bolts *h h* are now introduced, for the purpose of fastening the drum-head and barrel together, when it becomes an ordinary capstan.

But when it is required that the same number of men shall exert a greater power, the bolts *h* are withdrawn, and the pinion *f* lowered into gear with the toothed wheels. The rotation of the drum-head, then carrying the pinion round, causes it to drive the toothed wheels *d d d*; and these working into the toothed rim *eee*, attached to the barrel, cause the barrel to revolve with an increasing power.

Thus, under particular circumstances, a smaller number of men at the capstan or windlass (which is to be constructed upon the same principle) will be enabled to haul in the cable and anchor, or warp off the vessel, which is an important object to be effected.

In 1819, Captain Phillips obtained a patent for certain improvements in capstans, a part of which invention is precisely the same as this in principle, though slightly varied in its adaptation.

James Brown, ship-rigger, in his capstan, patented in 1833, instead of applying the moving power by handspikes, having fixed two rims of teeth round the top of the capstan, acts upon them by a rotatory worm, or pinions turned by a winch.

Fig. 423 is an elevation of this capstan, and fig. 424 is a horizontal top view. *a* is an upright shaft, fixed firmly to the deck, serving as an axle round which the body of the capstan revolves. A frame *c*, fixed to the top of a stationary shaft *a*, above the body of the capstan, carries the driving apparatus.

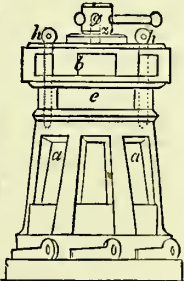

The upper part of the body of the capstan has a ring of oblique teeth *d*, formed round its edge; and above this, on the top of the capstan, is a ring of bevel teeth *e*. A horizontal shaft *f*, mounted in the top frame *c*, has a worm or endless screw, which takes into the teeth of the ring *d*; and a short axle *g*, having its bearings in the central shaft *a*, and in the frame *c*, carries a bevel pinion, which takes into the bevel teeth of the ring *e*.

The bearings of the shaft *f*, in the top frame, are in long slots, with angular returns, something like the fastening of a bayonet, which is for the purpose of enabling the shaft to be readily lifted in and out of gear with the teeth of the ring *d*; the outer bearing of the axle *g* of the bevel pinion is also supported in the frame *c*, in a similar way, in order to put it in and out of gear with the teeth of the

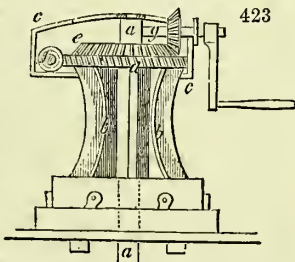

421

422

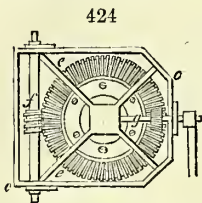

423

bevel ring *e*. A mode of shifting these is essential; because the two toothed rings, and their driving worm and pinion, give different speeds, and, of course, cannot be both in operation at the same time.

The worm of the shaft *f* being placed in gear with the teeth of the ring *g*, on applying rotatory power thereto, by means of winches attached to the ends of the shaft, the barrel or body of the capstan will be made to revolve with a slow motion, but with great power; and thus two men at the winches will do the same work as many men with capstan bars in the ordinary way.

If a quicker movement than that of the endless screw is desired, then the driving power may be applied by a winch to the axle *g* of the bevel pinion, that pinion being put into gear with the bevel ring *e*, and the endless screw withdrawn. It should, however, be here remarked, that the patentee proposes to employ two short axles *g*, placed opposite to each other, with bevel pinions acting in the bevel-toothed ring, though only one is shown in the figure to avoid confusion. He also contemplates a modification of the same contrivance, in which four short angles *g*, placed at right angles, with pinions taking into a bevel ring, may be employed, and made effective in giving rotatory motion to the barrel of a capstan by means of winches applied to the outer ends of the axle, and turned by the labour of four men.

CAPUT MORTUUM. A term employed by the alchemists to express the residuum of distillation or sublimation, the volatile portions having been driven off.

CARAJURA. A red dye stuff: see CHICA, RED.

CARAMEL. Burnt or dried sugar, used for colouring spirits and gravies. It is a black, porous, shining substance, soluble in water, to which it imparts a fine dark brown colour. The French are in the habit of dissolving the sugar, after it has been exposed for some time to a temperature sufficiently high to produce the proper colour, in lime-water: this is sold under the name of 'colouring.'

CARAPA OIL. See CRAB OIL.

CARAT. The term carat is said to be derived from the name of a bean, the produce of a species of *Erythrina*, a native of the district of Shangallas in Africa, a famous gold-dust mart. The tree is called *kuara*, a word signifying 'sun' in the language of the country, because it bears flowers and fruit of a flame-colour. As the dry seeds of this pod are always of nearly uniform weight, the savages have used them from time immemorial to weigh gold. The beans were transported into India at an ancient period, and have been long employed there for weighing diamonds. The carat of the civilized world is, however, an imaginary weight, consisting of four nominal grains, a little lighter than four grains troy (*poids de marc*). It requires 74 carat grains and $\frac{1}{16}$ th to equipoise 72 of the other. The diamond carat, though containing 4 diamond grains, is equal to only $3\frac{1}{2}$ grains Troy.

It is stated that the *karat*, a weight used in Mecca, was borrowed from the Greeks, and was equal to the 24th of a denarius or denier. The Encyclopedists thus explain the *carat*:—'The weight that expresses the fineness of gold. The whole mass of gold is divided into 24 parts, and as many 24th parts as it contains of pure gold it is called gold of so many *carats*. Thus gold of twenty-two parts of pure metal is gold of twenty-two *carats*. The carat of Great Britain is divided into four grains; among the Germans into 12 parts; and among the French into 32.' Among assayers, even in this country, the German division of the carat is becoming common.

CARAWAY SEEDS. The fruits, commonly called seeds, of the *Carum Carui*, an umbelliferous plant. They are used for flavouring cordials. The oil of Caraway is employed to correct, by its aromatic properties, the nauseating and griping qualities of some medicines.

CARBAMIC ACID. The combination of gaseous ammonia with carbonic-acid gas produces a white substance formerly called anhydrous carbonate of ammonia, but now recognised as a salt of carbamic acid. This carbamate of ammonia readily combines with water, and passes into normal carbonate of ammonia.

CARBAMIDE. A white crystalline powder obtained by the action of gaseous ammonia on phosgene gas, or oxychloride of carbon.

CARBAZOTIC ACID. See PICRIC ACID.

CARBIDES. A term synonymous with *carburets*. Thus, cast-iron being a combination of iron and carbon may be called a carbide or carburet of iron. In like manner the hydrocarbons are sometimes termed carbides of hydrogen.

CARBO-HYDRATES. Organic compounds containing carbon and the elements of water; such as starch and cellulose.

CARBO-HYDRIDE, commonly *Hydrocarbon*. A term used to denote those

bodies which consist of carbon and hydrogen only. The number of hydrocarbons now known is very great, and the list is increasing every day. They were formerly little understood, but so much has now been done that the anomalies and difficulties attending their history are rapidly disappearing. Although the number of individual bodies is very considerable, they are derived from a few great families. The principal are the following :—

Homologues of Olefant gas.	
”	Methyle.
”	Marsh gas.
”	Benzole.
”	Naphthaline.
Isomers of Turpentine.	

The other families which yield hydrocarbon derivatives are less important than the above, and will not be noticed here.

It is curious that the destructive distillation of organic matters is, of all operations, the most fruitful source of these bodies. Coal yields a great number, the nature varying with the temperature. When ordinary coals are distilled at very high temperatures, as in the production of gas, hydrocarbons belonging to the first four families are produced, and also a considerable quantity of naphthaline; but when, on the other hand, they are distilled at as low a heat as is compatible with their thorough decomposition, they yield fluid hydrocarbons, principally belonging to the first two classes, accompanied, however, by a considerable quantity of paraffine. The homologues of olefant gas have acquired extreme interest, owing to the brilliant results obtained by MM. Berthelot, and De Luca, by Cahours, and Hofmann in the study of their derivatives. The homologues of methyle have attracted considerable attention, in consequence of the successful isolation, by MM. Frankland and Kolbe, of the singular group of hydrocarbons known as the organic radicals, and which, until then, were regarded as hypothetical bodies, existing only in combination.

The hydrocarbons homologous with benzole not only exist in considerable quantity in ordinary coal naphtha, but are produced in a great variety of interesting reactions. Those contained in the following Table will show this :—

Table of the Physical Properties of the Benzole Series.

Name	Formulae	Boiling point	Specific gravity	Specific gravity of vapour	
				Experiment	Theory
Benzole . . .	$C^{12}H^6$ ($C^6 H^6$)	176	0·850	2·77	2·699
Toluole . . .	$C^{14}H^8$ ($C^7 H^8$)	230	0·870	3·26	3·183
Xylole . . .	$C^{16}H^{10}$ ($C^8 H^{10}$)	259	3·668
Cumole . . .	$C^{18}H^{12}$ ($C^9 H^{12}$)	298	...	3·96	4·150
Cymole . . .	$C^{20}H^{14}$ ($C^{10}H^{14}$)	347	0·861	4·65	4·636

Benzole has already been sufficiently described, and will not, therefore, be further alluded to. All these hydrocarbons yield a great number of derivatives when treated with various reagents. By first treating them with strong nitric acid, so as to obtain nitro-compounds, that is to say, the original substance in which an equivalent of hydrogen is replaced by hyponitric acid NO^4 (N^2O^4), strongly odorous oils are produced. When treated with sulphide of ammonium or protacetate of iron, these oils become reduced, and yield a very interesting series of volatile organic bases or alkaloids; these are aniline, toluidine, xylidine, cumidine, and cymidine. Mr. Barlow has shown that special precautions are necessary in converting cymole into nitrocymole, preparatory to the formation of the alkaloid cymidine. Cymole is acted on too violently by nitric acid to allow of the nitro-compound being formed, unless the precaution is taken of cooling the acid and hydrocarbon, by means of a freezing mixture, before allowing them to react on each other. The nitro-compound, when well formed, may be reduced in the ordinary manner. These alkalis have of late years acquired special importance in consequence of the valuable dyes that Mr. Perkins has succeeded in producing from them. See ANILINE.

Paraffine is a solid hydrocarbon of great interest; it is found both in wood and coal tar. When coal is distilled for the purpose of producing gas, the temperature is so high as to be unfavourable for its production, and consequently mere traces only are found in ordinary coal-tar. But if any kind of coal be distilled at the lowest possible temperature, not only is the resulting naphtha of much lower density than that produced in the ordinary manner, but considerable quantities of paraffine are found in the distillate. The last-mentioned substance is every day becoming more

important, in consequence of the valuable illuminating properties that have been found to belong to it. Colourless, inodorous, hard at all moderate temperatures, it forms the most elegant material for candles yet discovered. See PARAFFINE.

Modern researches have shown that the hydrocarbons generally are formed on one type—viz., hydrogen. Assuming hydrogen in the free state to be a double molecule, H_2 , the hydrocarbons are formed by the substitution of one or two equivalents of a positive or negative radical for one or two of the equivalents of hydrogen; thus methyle, the formula of which (for four volumes) is C^2H^3 or C^2H_3 , is hydrogen in which both equivalents are replaced by methyle. Olefiant gas is hydrogen in which one equivalent is replaced by the negative radical acetyle, or vinylo, and so on.

There is one large class of hydrocarbons the rational formulæ for which are not known, and which will probably remain in this condition for some time. We allude to the numerous essential oils isomeric with oil of turpentine. Many of these have almost the same boiling point and precisely the same vapour-density as their type; but in odour, fluidity, density in the liquid state, and various other minor points, are essentially different. The following Table exhibits some of their physical properties:—

Table of the Physical Properties of some Isomers of Oil of Turpentine.

Name	Formula	Boiling point	Specific gravity	Specific gravity of vapour by experiment
Oil of turpentine . . .	$\text{C}^{20}\text{H}^{16}$ ($\text{C}^{10}\text{H}^{16}$)	322	0·864	4·764
„ athamantha . . .	$\text{C}^{20}\text{H}^{16}$ ($\text{C}^{10}\text{H}^{16}$)	325·4	0·843	...
„ bergamot . . .	$\text{C}^{20}\text{H}^{16}$ ($\text{C}^{10}\text{H}^{16}$)	361·4	0·869	...
„ birch tar . . .	$\text{C}^{20}\text{H}^{16?}$ ($\text{C}^{10}\text{H}^{16?}$)	313·0	0·847	5·28
Caoutchine . . .	$\text{C}^{20}\text{H}^{16?}$ ($\text{C}^{10}\text{H}^{16?}$)	338·0	0·842	4·46
Oil of carui, or caruene . . .	$\text{C}^{20}\text{H}^{16}$ ($\text{C}^{10}\text{H}^{16}$)	343·4
„ lemon . . .	$\text{C}^{20}\text{H}^{16}$ ($\text{C}^{10}\text{H}^{16}$)	343·4	0·8514	4·87
„ copaiva . . .	$\text{C}^{20}\text{H}^{16}$ ($\text{C}^{10}\text{H}^{16}$)	473·0	0·878	...
„ cubebs . . .	$\text{C}^{20}\text{H}^{16}$ ($\text{C}^{10}\text{H}^{16}$)	490·0	0·929	...
„ elemi . . .	$\text{C}^{20}\text{H}^{16}$ ($\text{C}^{10}\text{H}^{16}$)	345·2	0·849	...
„ juniper . . .	$\text{C}^{20}\text{H}^{16}$ ($\text{C}^{10}\text{H}^{16}$)	320·0
Terebic oil accompanying oil of gaultheria . . .	$\text{C}^{20}\text{H}^{16}$ ($\text{C}^{10}\text{H}^{16}$)	320·0	...	4·92
Terebic oil in clove oil . . .	$\text{C}^{20}\text{H}^{16}$ ($\text{C}^{10}\text{H}^{16}$)	483·8	0·9016	...
„ „ pepper . . .	$\text{C}^{20}\text{H}^{16}$ ($\text{C}^{10}\text{H}^{16}$)	332·0	0·864	4·73
„ „ balsam of tolu . . .	$\text{C}^{20}\text{H}^{16}$ ($\text{C}^{10}\text{H}^{16}$)	320·0	0·837	...
„ „ oil of valerian . . .	$\text{C}^{20}\text{H}^{16}$ ($\text{C}^{10}\text{H}^{16}$)	320·0	...	4·60

An inspection of the above Table will show that while, beyond doubt, a great number of essential oils are truly isomeric with turpentine, there are some the constitution of which is by no means well established.

The above account of some of the more prominent hydrocarbons is necessarily brief and imperfect; partly because the limits of this work preclude the possibility of entering minutely into the details of their history, and partly because many of them are described at greater length in other articles, especially under *ΝΑΡΗΤΗΑ*.—C.G.W.

CARBINOL. A synonym of methyl-alcohol or wood-spirit.

CARBOLIC ACID, *Phenic Acid*, *Phenol*, *Phenylic Alcohol*, or *Hydrate of Phenyl*, $\text{C}^{12}\text{H}^6\text{O}^2$ ($\text{C}^6\text{H}^6\text{O}$).—The less volatile portion of the fluids produced by distillation of coal-tar contain considerable quantities of this substance. It may be extracted by agitation of the coal-oils (boiling between 300° and 400° F.) with an alkaline solution. The latter, separated from the undissolved portion, contains the carbolic acid in the state of carbolate of the alkali. On addition of a mineral acid, the phenol is liberated, and rises to the surface in the form of an oil. To obtain it dry, recourse must be had to digestion with chloride of calcium, followed by a new rectification. If required pure, only that portion must be received which boils at 370°. If, instead of extracting the carbolic acid from coal-products boiling between 300° and 400°, a portion be selected distilling between 400° and 428°, and the same treatment as before be adopted, the acid which passes over between 347° and 349° will consist, not of carbolic acid, but of its homologue, cresylic acid $\text{C}^{14}\text{H}^8\text{O}^2$ ($\text{C}^7\text{H}^8\text{O}$). Commercial carbolic acid is generally very impure. Some specimens do not contain

more than 50 per cent. of acids soluble in strong solution of potash. The insoluble portion contains naphthaline, fluid hydrocarbons, and small portions of chinoline and lepidine. Carbolic acid, when very pure and dry, is quite solid and colourless. The crystals often remain solid up to 95°, but a trace of water renders them fluid. Its specific gravity is 1.065. Carbolic acid, when mixed with lime and exposed to the air, yields rosolic acid. The lime acquires a rich red colour, during the formation of the acid. No means of dyeing rods permanently with this substance have yet been made known. Unfortunately, the red tint appears to require an excess of base to enable it to exist, consequently the carbonic acid of the air destroys the colour (*Dr. Angus Smith*). I find that homologues of carbolic acid exist which boil at a temperature beyond the range of the mercurial thermometer, and that all the acids above carbolic acid afford rosolic acid, or homologues of it, when treated with lime. Creosote of commerce appears to consist of a mixture of carbolic and cresylic acids. If only that portion be received which distils at the temperature given by Reichenbach as the boiling point of creosote, it will, if prepared from coal-oil, consist almost entirely of cresylic acid (*Williamson and Fairlie*). A splinter of deal wood, if dipped first in carbolic acid and then in moderately strong nitric acid, acquires a blue tint. For a comparison of the properties of Creosote and Carbolic Acid, see CREOSOTE.—C. G. W.

More than five-and-twenty years ago, Laurent extracted carbolic acid from coal-tar by fractional distillation, as described above; the products of distillation were treated with caustic potash and the alkaline solution then neutralised by an acid so as to liberate the carbolic acid. This process was modified in 1847 by Mansfield, and in 1856 by Babœuf; these chemists substituted caustic soda for the potash, and worked upon all the light oils, instead of confining themselves to a portion only, as Laurent had previously done. Still the acid obtained by these methods was very impure, and it remained for the late Dr. F. Crace-Calvert to introduce successive improvements into the manufacture until he finally obtained a pure product. In 1859 Calvert proposed to work upon the impure benzines or naphthas of commerce; these he treated with weak alkaline solutions, and thus obtained a product which was rich in carbolic acid—containing as much as 60 per cent.—and capable of yielding a great part of this acid on distillation. By further modifications of his process, he succeeded in obtaining a pure hydrate of carbolic acid (mono-hydrate of phenol) of the composition $C^{12}H^{10}O^2$ HO [2(C⁶H⁶O)H²O]. The tarry and sulphurous odours, which clung to the earlier forms of carbolic acid, and were so prejudicial to its use for many purposes, have been entirely removed in some of Calvert's later preparations. In addition to the ordinary form of the acid, Messrs. Calvert and Co. now prepare *carbolic-acid powder* and *carbolic-acid soap*.

On an industrial scale, carbolic acid, or phenol, was first produced by the late Dr. Ernest Sell, a German chemical manufacturer, distinguished for his scientific attainments and predilections. Dr. Sell introduced the use of phenol as a substitute for the ever-varying creosote. The claims to chemical individuality of the latter substance, notwithstanding numerous investigations to which it has been submitted, are by no means finally established; many chemists, in fact, considering creosote as a mixture of phenol with larger or smaller quantities of its homologues, cresol and phlorol. The manufacture of coal-tar-derived creosote was extensively carried on by Dr. Sell in his factory at Offenbach-on-the-Main; and Dr. Hofmann saw, nearly twenty years ago, at that factory, hundredweights of phenol as white and beautifully crystallised as the specimens exhibited in London in 1862.

Of late years, carbolic acid has obtained extensive application as an antiseptic and disinfectant. Its volatility gives it the advantage of being very rapidly diffused through an infected atmosphere. During the cattle-plague it was employed with great success by Mr. Crookes. Carbolic acid is also used in surgery for dressing offensive wounds, and as an application in certain forms of skin-disease. But the most interesting use of phenol is to be found in the manufacture of certain dye-stuffs from this acid and its derivatives. The following are the more important of these carbolic-acid dyes:—

YELLOW DYES: *Picric acid*, *Carbazotic acid*, or *Trinitrophenylic acid*. Though originally discovered by Welter, the composition of this body was not properly understood until Laurent examined it in 1841. It is obtained by the action of nitric acid on carbolic acid, or on phenyl-sulphate of soda. As far back as 1847, it was used for dyeing by Messrs. Guinon, of Lyons. It is employed for imparting a yellow colour to silk and wool; and also as a green dye when associated with indigo and blue colouring matters. Picrate of soda has been substituted for the pure acid, but this salt is dangerously explosive. See PICRIC ACID.

Aurin or *Yellow Coralline*. In 1861 Kolbe and Schmidt first obtained this compound by heating carbolic acid with oxalic acid and concentrated sulphuric acid. Commercial aurin is a brittle resinous substance, having the colour and lustre of cantharides, and

yielding a red powder. The colouring principle has been isolated in a pure form, and carefully studied by Messrs. Dale and Schorlemmer.¹ Aurin is used for giving a very fine orange-yellow colour to silks and albuminized cotton.

RED DYES: *Pæonin*, or *Red Coralline*. By heating aurin with aqueous ammonia to about 140° or 150° C. (284° or 302° F.), a new colouring agent is obtained, which dyes wool and silk with a redder colour than can be obtained from aurin. This beautiful scarlet dye, known as pæonin, was discovered in 1860 by M. Persoz, jun., and its manufacture has been perfected by Messrs. Grunon, Marnas, and Bonnet, of Lyons.

It is believed that coralline is very closely related to, if not identical with, the *rosolic acid* originally obtained from coal-tar by Runge, and readily prepared by the oxidation of phenol.

BROWN DYES: *Picramic acid*. This was obtained by Wöhler by acting on picric acid with proto-sulphate of iron, neutralising the product with caustic baryta, and finally removing the baryta by sulphuric acid. Picramic acid is a deep brown substance, used for dyeing silk.

Phenicenne or *Phenyl brown*. Roth discovered this substance in 1863, by acting on carboic acid with nitro-sulphuric acid. The product is an amorphous brown powder, said to be a mixture of two distinct substances—the one yellow, and the other blackish-brown. A variety of shades, from a deep red to a golden buff, may be given to wool and silk by means of picramic acid.

Soluble Garnet (Grenat soluble). This is the isopurpurate of potash, obtained by acting with cyanide of potassium on a solution of picric acid. It has been introduced as a dye-stuff by M. J. Casthelaz. As it is explosive when dry, it should be kept as a paste and moistened with glycerine.

BLUE DYE: *Azuline*, *Azurine*, *Phenol-blue* or *phenyl-blue*. By heating coralline, or rosolic acid, with aniline, and treating the product with sulphuric acid, a blue colouring-matter is obtained in the form of a reddish substance exhibiting golden tints. This is the dye known as Azuline.

GREEN DYE: *Viridine*. A green dye has been obtained by Messrs. Grunon, Marnas, and Bonnet, by acting on rosolic acid with aniline and benzoic acid.

CARBON. (*Symbol*, C; *Atomic weight*, 6). Carbon exists in a considerable variety of forms, most of which are so unlike each other, that it is not surprising the older chemists should have believed them to be compounds.

Diamond.—The purest variety of carbon is the diamond. This gem crystallises in the regular octahedron and derived forms. The diamond does not owe its hardness and brilliancy solely to its purity, for many specimens of graphite consist of carbon as free from admixture as the best diamonds. The density of graphite and of diamond, however, is very different; for while the former seldom exceeds 2.45, and is often much lower, the diamond is very constant, generally ranging between 3.51 and 3.55. Diamonds, if they are perfectly transparent, leave no residue when burnt in oxygen gas. If not clear, they yield from 0.05 to 0.20 of ash, consisting chiefly of peroxide of iron, but also containing traces of silica. The refractive power of diamonds is as high as 2.439. Sir Isaac Newton, observing that oily or inflammable bodies generally possessed the greatest refractive powers, inferred from the high index of refraction of the diamond, that it was 'an unctuous body congealed.' This idea will appear the more happy, when it is considered that the ashes of the diamond exhibit a structure resembling that of vegetable parenchyma.

In freedom from ashes, certain graphites nearly approach the diamond, some natural varieties not yielding more than 0.33 per cent. See DIAMOND.

Graphite.—This kind of carbon is found in many parts of the world, and in different degrees of purity: it is also formed artificially. Some native varieties are exceedingly soft, of a black or greyish tint, metallic lustre, and, in consequence of making a streak on paper, of various degrees of blackness, according to the mode of preparation and other circumstances, are invaluable for the manufacture of artists' pencils, and are hence called 'Black Lead.'

A very hard graphite is found lining the retorts in which coal-gas is made: it is, when cut into plates or rods, used in galvanic arrangements, either for the poles or for the inactive elements of batteries. See GRAPHITE and PLUMBAGO.

A very dense form of carbon, having high electric conductivity, and sometimes used for the negative element in Bunsen's battery, may be obtained by heating to redness an intimate mixture of finely-divided coke and coal in the proportions of two parts of the former to one of the latter; this mixture having been ignited in an iron mould, is dipped several times in treacle, and again strongly heated. A hard compact substance is thus obtained, capable of being sawn to any required shape.

¹ 'Journal of the Chemical Society,' [2] xi. 1873, p. 434.

Coke.—This variety of carbon is produced by the ignition of pit-coal. The largest quantities are produced in the manufacture of coal-gas. It of course varies greatly in quality with the coal from which it is procured. The density of coke varies not only with the quality of the coal, but also with the greater or less rapidity of the firing and the duration of the operation. See COKE.

Anthracite is a very dense natural variety of carbon, its specific gravity varying from 1.390 to 1.7. It differs considerably in quality, some kinds being almost as free from extraneous matters as graphite, while others approach nearer to the nature of coals. Thus the hydrogen in anthracite oscillates between 1.0 and 4.0 per cent. Some varieties of coal have only 4.5 to 5.0 per cent. of hydrogen, thus approximating to those anthracites which have high hydrogens. See ANTHRACITE and COAL.

Charcoal.—There are several varieties of charcoal: among them may be mentioned those from wood, bones, and the peculiar substance found between the layers of certain pit coals, and known as 'mineral charcoal.' Ordinary charcoal from wood contains many substances besides carbon, among which may be mentioned oxygen, hydrogen, traces of nitrogen, and ashes.

Bone-charcoal contains a large quantity of earthy phosphates and carbonates, besides other matters. See CHARCOAL.

For a description of the method of preparing the variety of carbon known as Lamp-Black, see LAMP-BLACK.

The description of the charcoal best adapted for pyrotechnic purposes will be found under the head GUNPOWDER.

Carbon combines with several elements, forming in general well-marked and highly important substances. Several of these compounds will be found described under the heads CARBONIC ACID, CARBON BISULPHIDE, HYDROCARBON, &c.

CARBON, BISULPHIDE OF, or CARBON BISULPHIDE (formerly *Carburet of Sulphur* or *Sulphuret of Carbon*, also called by the elder chemists the *Alcohol of Sulphur*). A limpid, volatile, colourless, highly refractive liquid, possessing a penetrating fœtid smell and an acrid burning taste. Its specific gravity is 1.27; its formula is CS².

Bisulphide of carbon may be prepared by distilling, in a porcelain retort, pyrites, the bisulphide (bisulphuret) of iron, with a fourth of its weight of well-dried charcoal, both in a state of fine powder and intimately mixed. The vapour from the retort is conducted to the bottom of a bottle filled with cold water to condense it.

The method now usually employed for preparing bisulphide of carbon consists in passing the vapour of sulphur over charcoal or coke heated to redness. In Peroucel's apparatus, a large cylindrical fire-clay retort, set vertically, is filled with pieces of coke, and strongly heated. Sulphur is then introduced through a special tubulure, and the vapour, formed by volatilisation of the sulphur, combines with the heated carbon. The vapours of bisulphide of carbon thus formed are conducted first into a receiver, where a portion condenses, and then through a worm in a condensing apparatus, where the remainder is liquefied.

The crude bisulphide of carbon thus obtained may be purified by re-distillation over either zinc or bichloride of mercury (corrosive sublimate).

The bisulphide of carbon is insoluble in water, but it is soluble in alcohol. It dissolves sulphur, phosphorus, and iodine. The solution of phosphorus in this liquid has been employed for electrotyping very delicate objects, such as grasses, flowers, feathers, &c. Any of these are dipped into the solution: by a short exposure in the air the bisulphide of carbon evaporates and leaves a film of phosphorus on the surfaces; they are then dipped into nitrate of silver, by which silver is precipitated in an exceedingly minute film, upon which, by the electrotype process, any thickness of silver, gold, or copper can be deposited. If a few drops of the bisulphide of carbon are put in a solution of the cyanide of silver, from which the metal is being deposited by the electroplating process, it covers the article quite brightly, whereas, without the bisulphide, the precipitated metal would be dull. See ELECTROTYPE.

Bisulphide of carbon is an excellent solvent of caoutchouc, and is therefore largely used in the vulcanisation of India-rubber. It also dissolves fats and oils, and is consequently employed in extracting fat from bones, shoddy, and other greasy refuse, and in dissolving oils from seeds; the last traces of olive oil may thus be obtained from the compressed pulp of the olive after having yielded the greater portion of the oil by expression. Liquid bisulphide of carbon is remarkable for its high dispersive power, and hollow glass prisms filled with the bisulphide are often used in optical researches. As the liquid has never been frozen, it has been occasionally employed in the construction of thermometers for measuring very low temperatures. Bisulphide of carbon is highly inflammable, and the vapour, if mixed with nitric oxide, burns with an intense light possessing strong actinic properties; hence this light has been employed for photographic purposes. The vapour of bisulphide of carbon is highly

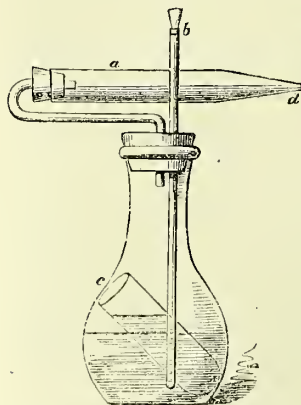

poisonous, and advantage has been taken of this character to use it as a vermin-destroyer. A small quantity of the bisulphide, enclosed in an air-tight chamber with grain infested with weevils will destroy the insects and their larvæ. It is curious that the vapour of bisulphide of carbon passed over wood undergoing destructive distillation, alters the character of the carbonaceous residue, and produces a material having high conducting powers for heat and electricity, and extremely sonorous when struck.

CARBONADO. A massive variety of diamond, found in small black pebbles in Brazil, and used for polishing hard stones.

CARBONATES. By this term is understood, in popular language, the salts formed by the union of carbonic acid with bases. In conformity with the language of modern chemistry, a carbonate may be defined as carbonic acid in which the hydrogen is replaced by a metal. Thus, carbonate of potash, according to the old definition, is a compound of carbonic acid gas (*carbonic anhydride*) with potash; whilst, according to the new definition it is merely carbonic acid (the true hydrate, not the anhydride), in which potassium takes the place of hydrogen. See SALTS.

The carbonates are among the most valuable of the salts, whether we regard their physical, geological, chemical, or technical interest. Were limestone and marble the only carbonates familiarly known, they would be sufficient to stamp this class of salts as among the most important. The carbonates of lime, potash, soda, ammonia, and lead, are articles of immense importance to the technologist, and are prepared on a vast scale for various purposes in the arts. The carbonates of iron and copper are among the most valued ores of those metals. Numerous processes of separation in analysis are founded on the various degrees of solubility in water and certain reagents of the different carbonates. By taking advantage of this fact, baryta, strontia, and lime, may be separated from magnesia and the alkalis. There are few analytical problems which have attracted more attention than the accurate determination of the carbonic acid in the carbonates. This has partly arisen from the frequency with which the potashes, soda-ashes, limestone, and other carbonates of commerce, are sent to chemists for analysis. The number of instruments contrived for the purpose is something extraordinary, especially when the simplicity and ease of the operation is considered. Among them all, there is none more convenient or easy to use than that of Parnell. 'It consists of a glass flask (*fig. 425*) of about two ounces capacity, fitted with a sound cork, through which two tubes pass, one serving to connect a chloride-of-calcium tube, *a*, while the other, *b*, will be described presently.

425

A small test-tube, *c*, is so placed in the flask, and is of such a size, that it cannot fall down, but its contents may be made to flow out by inclining the apparatus to one side. To perform the experiment, a weighed quantity of the carbonate is placed in the flask, and water added up to the level seen in the figure; the test-tube is then filled nearly to the top with concentrated sulphuric acid, and is carefully lowered into the flask; the cork with the tubes attached is then affixed, the aperture *b* being closed with a small cork. The whole apparatus is now carefully weighed; the flask is then to be inclined so as to allow some of the acid to flow out, and, when the effervescence has subsided, a little more, and so on until no more carbonic acid is evolved. The flask is now to be so inclined as to cause the whole of the acid to mingle with the aqueous fluid, and thus cause a considerable rise of temperature; this expels the carbonic acid from the liquid; but as an atmosphere of the latter gas fills the flask, it must be removed and replaced by air, as the difference in density of the two is very

considerable. For this purpose, the cork *b* is removed and air is sucked out of *d*, until it no longer tastes of carbonic acid; the flask is then allowed to become perfectly cold, and, the little cork being replaced, it is then re-weighed: the difference in the two weighings is the amount of carbonic acid in the specimen. On drawing air for some time through the apparatus, it begins slowly to acquire weight, arising from the moisture in the atmosphere being absorbed by the chloride of calcium, and although the error introduced by this means is too minute to affect ordinary experiment, it must not be neglected where, from the quantity of material in the flask being limited, or other causes, a small difference has an important bearing on the result. In this latter case another chloride-of-calcium tube is to be attached to the aperture *b*, and the air must be drawn through by means of a suction-tube applied at *d*.—C. G. W.'s *Chemical Manipulation*,

The commercial value of the carbonates of potash and soda may equally well be determined by ascertaining the quantity of dilute sulphuric acid required to neutralise them.

The following carbonates are such as find some use in the arts—or being found native, are brought under the notice of the miner:—

CARBONATE OF AMMONIA, COMMERCIAL. The sesquicarbonate of chemists, sal volatile, or volatile or smelling salts of the shops. Bicarbonate of ammonia has been found in considerable quantities, forming crystalline masses, in a bed of guano on the western coast of Patagonia.

CARBONATE OF BARYTA. This compound occurs in nature as the mineral *Witherite*, which is found in lead mines.

CARBONATE OF CALCIUM, or of LIME. Carbonate of lime is found abundantly in the mineral kingdom. Calcareous spar, arragonite, Iceland spar, limestone, chalk, and marble, are carbonates of lime. Its uses are well known. *Gay-Lussite* is a double carbonate of lime and soda.

CARBONATE OF COBALT. See COBALT.

CARBONATE OF COPPER. *Malachite* and *azurite* are the two carbonates of this metal found in nature. See COPPER.

CARBONATES OF IRON. *Spathic ore*, is the most important native form which occurs. See IRON.

CARBONATE OF LEAD. *White lead ore* or *cerussite* is found in the lead mines of Cornwall, Devonshire, Cumberland, and Scotland. The pigment *white lead* is a carbonate of lead. See LEAD.

CARBONATE OF MAGNESIA. *Magnesite* occurs native, associated with serpentine and other magnesian rocks. *Magnesia alba* of the pharmacopœists is a hydrocarbonate.

CARBONATE OF MANGANESE. This salt is found in nature in rose-coloured rhombohedra known as *manganese spar*, or *diallogite*.

CARBONATE OF NICKEL. A mineral called *emerald nickel* occurs at Texas, in Pennsylvania, and at Unst, Shetland. This is the only native carbonate of this metal.

CARBONATE OF POTASH. Vegetable alkali, salts of tartar, pearl-ashes, ashes, are several names given to this salt. See POTASH.

CARBONATE OF SILVER. See SILVER ORES.

CARBONATE OF SODA. Commonly called Soda. See SODA.

CARBONATE OF STRONTIA. Occurs native as *STRONTIANITE*: it is found at Strontian in Argyleshire—hence its name; in the Hartz and other localities.

All these and the other rarer carbonates will be described under their respective heads.

CARBONIC ACID. (*Symbol*, CO^2 ; *Atomic weight*, 22). The name commonly applied to a compound of carbon and oxygen. This gas was formerly termed *fixed air*, in consequence of its occurrence in a fixed form in chalk, marble, and other solid carbonates, from which the gas may be readily released by the action of stronger acids, conveniently by hydrochloric or muriatic acid.

In modern chemistry carbonic acid gas is usually termed *carbonic anhydride*, the name *carbonic acid* being restricted to the combination of the gas with water; indeed, the dry gas does not exhibit acid reactions. Carbonic acid gas is also known in modern nomenclature as *carbon dioxide*.

Carbonic acid is destitute of colour, has a sour smell, and an acidulous pungent taste; it imparts to moist, but not dry, litmus-paper a transient reddish tint, and weighs, per 100 cubic inches, 47·19 grains, and per cubic foot, 815·44 grains, or little more than $3\frac{3}{4}$ oz. avoirdupois. It may be condensed into the liquid state by a pressure of 40 atmospheres; and this liquid may then be solidified by its own sudden spontaneous evaporation. If air contains 4 per cent. in bulk of this gas, it is rendered unfit for respiration and combustion, animal life and burning bodies being speedily extinguished by it. See Dr. Angus Smith's 'Air and Rain.'

Carbonic acid is constantly given off by animals during respiration; and, ordinary combustion consisting mainly in the combination of carbon with oxygen, this acid is formed in enormous quantities in all our manufactories and by our ordinary fires.

Carbonic acid is, consequently, continually being poured into the air. The purity of the atmosphere is, however, maintained by the action of the vegetable world, all plants removing carbonic acid from the air, and, under the influence of light, decomposing it again into carbon, which goes to the formation of wood and other vegetable products, and oxygen, which is given out to the atmosphere.

Notwithstanding this beautiful provision of Nature, we find carbonic acid accumulating in caverns, deep wells, and long-closed cellars, rendering them dangerous. It is the 'bad air' and 'damp' of the metal miner; the 'choke damp,' 'after damp,' and 'stythe' of the coal miner. The last two terms are especially employed to express the suffocating vapour which follows an explosion of 'fire-damp.' This gas, being

much denser than common air, can be pumped out of any place containing it. Milk of lime—quicklime mixed with water—may be used with advantage to purify the air of a sunk apartment, by its affinity for, or power of absorbing this aerial acid.

In the actual condition of the atmosphere, from 4 to 6 volumes of carbonic acid exist in every 10,000 volumes of air.

This acid gives the fresh and pleasant taste to sparkling-water and to all fermented drinks. Champagne and bottled beer owe their sparkling properties to carbonic acid gas generated by fermentation after the liquid has been bottled.

Many springs are very highly charged with this acid, and form a sparkling beverage, as Seltzer water (*Selterswasser*) and the like. Large quantities of similar water are made artificially in this country, and sold under the names of Soda Water, Aërated Water, &c. See Watts's 'Dictionary of Chemistry.'

CARBONIC ANHYDRIDE. See **CARBONIC ACID.**

CARBONIC OXIDE. (*Symbol, CO; Atomic weight, 14.*) This gas is known in modern chemistry as *carbon monoxide* or *carbonous oxide*. Carbonic acid is readily deprived of half its oxygen at a red heat by charcoal and other deoxidising substances, and so reduced to carbonic oxide.

This gas is presumed to contain two volumes of carbonic vapour and one volume of oxygen condensed into two volumes, so that its combining measure is two volumes. Carbonic oxide is 14 times heavier than hydrogen. It is very fatal to animals, and when inspired in a pure state almost immediately produces coma. It has never been liquefied. It is easily kindled, and burns with a pale blue flame like that of sulphur, combining with half its volume of oxygen, and forming carbonic acid, which retains the original volume of the carbonic oxide. This combustion is often witnessed in a coke or charcoal fire. The carbonic acid produced in the lower part of the fire is converted into carbonic oxide as it passes up through the hot embers, and afterwards burns with a pale-blue flame where it meets the air.—*Graham.*

Carbonic oxide plays an important part as a reducing agent in many metallurgical operations.

CARBONIFEROUS LIMESTONE, or MOUNTAIN LIMESTONE. A sub-division of the Carboniferous System, which yields some of the finest British marbles, such as those of Derbyshire and Bristol. The same limestone in Ireland is also rich in marbles. Lead-ore is common in the Carboniferous Limestone of Derbyshire, Yorkshire and Cumberland, and red hematite in that of Ulverston and Whitehaven; whilst in the North of England and in Scotland the Carboniferous Limestone series contains interstratified beds of coal; indeed, a large part of the workable coal of East and Mid-Lothian is referable to this series.

CARBONIFEROUS SYSTEM. That geological formation which, in order of time, succeeds the OLD RED SANDSTONE, and is succeeded by the PERMIAN SYSTEM, although in the absence of that system, they may be overlaid by rocks of still later geological age. The carboniferous system comprehends:—

The Lower Limestone Shale: The Carboniferous or Mountain Limestone: Yoredale Rocks (Upper Limestone Shale): and the Coal-Measures, Lower, Middle, and Upper.

CARBON PRINTING. See **PHOTOGRAPHY.**

CARBUNCLE. A term applied to the garnet when cut with a convex face (*en cabochon*). This gem was much prized by the ancients, and in high repute during the middle ages, from its supposed mysterious power of emitting light in the dark. Benvenuto Cellini affirms, in his treatise on jewellery, that he had seen the *carbuncle glowing like a coal with its own light.*

'The garnet was, in part, the *carbunculus* of the ancients, a term probably also applied to the spinel and oriental ruby. The Alabandic carbuncles of Pliny were so called because cut and polished at Alabanda. Hence the name *Almandine* now in use. Pliny describes vessels of the capacity of a pint formed from carbuncles, 'non claros ac plerumque sordidos ac semper fulgoris horridi,' devoid of lustre and beauty of colour,—which probably were large common garnets.'—*Dana.*

CARBURETS. Compounds of carbon, now called *Carbides*.

CARBURETTED HYDROGEN. A compound of carbon and hydrogen. Marsh-gas or fire-damp is frequently called *Light Carburetted Hydrogen*. See **GAS-COAL**, and consult Watts's 'Dictionary of Chemistry.'

CARD, CARDBOARD, called also *Pasteboard*, from the circumstance that several sheets of paper are pasted together to form the board or card, which is then subjected to a very great pressure between rollers.

A patent machine for cutting cards was invented by Mr. Dickinson. It consists of a pair of rollers with circular revolving cutters, the edges of which are intended to act against each other as circular shears; and the pasteboards, in passing between these rollers, are cut by the circular shears into cards of the required dimensions. These rollers are mounted in suitable standards with proper adjustments, and are

made to revolve by a band and pulley connected to the axle of a crank, or by any convenient means. *Fig. 426* is a front view of this machine: *a a* and *b b* are the two rollers, the upper one

turning upon an extended axle, bearing in the standards, the lower one upon pivots. These rollers are formed by a series of circular blocks, between a series of circular steel cutters, which are slidden on to iron shafts, and held together upon their axle by nuts screwed up at their ends. The accurate adjustment of the cutters is of the first importance to their correct performance; it is therefore found necessary to introduce spiral springs within the blocks, in order to press the cutters up to their proper bearings. A section of one of the blocks is shown at *fig. 427*, and an end view of the same at *fig. 428*, with the spiral springs inserted.

At the outer extremity of the axle of the roller *a*, a rigger *c*, is attached, whence a band passes to a pulley *d*, on the crank-shaft *e*, to which a fly-wheel *f*, is affixed, for the purpose of rendering the action uniform. Rotatory motion being given to the crank-shaft, the upper roller is turned, the lower roller moving at the same time by the friction against the edges of the cutters.

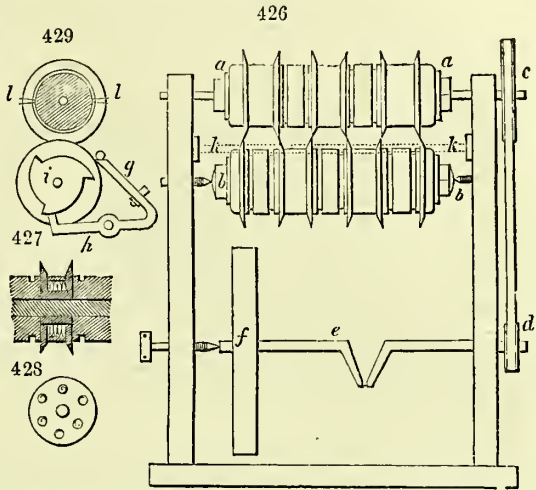

Fig. 429 is an end view of the rollers, showing the manner in which the pasteboards are guided and conducted between the cutters. In front of the machine a moveable frame *g*, is to be placed, for the purpose of receiving the pasteboards, preparatory to cutting them into cards, and a stop is screwed to this frame for the edge of the pasteboard to bear against, which stop is adjustable to suit different sizes. From the back part of this frame the arm *h*, extends, the extremity of which acts against the periphery of a ratchet wheel *i*, fixed at the end of the roller *b*, and hence, as the roller goes round, the frame is made to rise and fall upon its pivots, for the purpose of guiding the pasteboard up to the cutters; at the same time a rod *k*, hanging in arms from the sides of the standards (shown by dots in *fig. 426*), falling upon the pasteboard, confines it, while the cutters take hold, and racks, corresponding with the indentations of the rollers, are placed as at *l l*, by means of which the cards, when cut, are pushed out of the grooves.

As various widths of card will require to be cut by this machine, the patentee proposed to have several pairs of rollers ready adjusted to act together, when mounted in the standards, in preference to shifting the circular cutters, and introducing blocks of greater or less width.

The second part of the invention is a machine for pasting the papers, and pressing the sheets together to make pasteboard. This machine consists of several reels on which the paper is to be wound, along with a paste trough, and rotatory brushes.

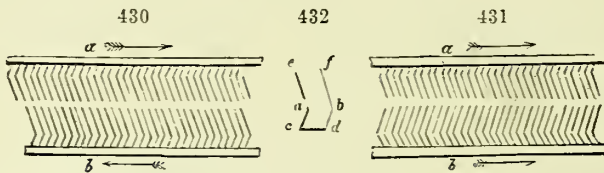

Damped paper is to be wound upon two reels, and conducted from thence over two other reels. Two fluted rollers revolving in the paste-trough supply paste to two circular brushes; by these brushes the papers are to be pasted on one side, and then pressed together by rollers to make the pasteboard; after this, the pasteboard is drawn on to a table, and it remains there until sufficiently dry to be wound upon other rollers, by which it is subjected to the necessary pressure. Cards are glazed or enamelled by the use of porcelain-clay, white lead, and subnitrate of bismuth.

CARDS (*Cardes*, Fr.; *Karden*, Ger.) are instruments which serve to disentangle the fibres of wool, cotton, or other analogous bodies, to arrange them in an orderly lap of fleece, and thereby prepare them for being spun into uniform threads. The fineness and the levelness of the yarn, as well as the beauty of the cloth into which it enters, depend as much on the regularity and perfection of the carding, as upon any subsequent operations of the factory. The quality of the carding depends more upon that of the cards than upon any attention or skill in the operative, since it is now nearly an automatic process, conducted by young women called card-tenters.

Cards are formed of a sheet or fillet of leather pierced with a multitude of small holes, in which are implanted small staples of wire with bent projecting ends called *teeth*. Thus every piece of wire is double toothed. The leather is afterwards applied to a flat or cylindrical surface of wood or metal, and the co-operation of two or more such surfaces constitute a card. The teeth of cards are made thicker or slenderer, according as the filaments to be carded are coarser or finer, stiffer or more pliant, more valuable or cheaper. It is obviously of great importance that the teeth should be all alike, equably distributed, and equally inclined over the surface of the leather, a degree of precision which is scarcely possible with handwork. To judge of the difficulty of this manipulation, we need only inspect the annexed figures, 430, 431. The wire must first be bent at right angles in *c* and *d*, *fig.* 432, then each branch must receive a second bend at *a* and *b* at a determinate obtuse angle, invariable for each system of cards. It is indispensable that the two angles *c a e* and *d b f* be mathematically equal, not only as to the twin teeth of one staple, but through the whole series: for it is easy to see that if one of the teeth be more or less sloped than its fellow, it will lay hold of more or less wool than it, and render the carding irregular. But though the perfect regularity of the teeth be important, it is not the sole condition towards making a good card. It must be always kept in view that these teeth are to be implanted by pairs in a piece of leather, and kept in by the cross part *c d*. The leather must therefore be pierced with twin holes at the distance *c d*: and pierced in such a manner that the slope of the holes, in reference to the plane of the leather, be invariably the same; for otherwise the length of the teeth would vary with this angle of inclination, and the card would be irregular.

A third condition essential towards producing perfect regularity, is that the leather ought to be of the same thickness throughout its whole surface, otherwise the teeth, though of the same length and fixed at the same angle, would be rendered unequal by the different thicknesses of the leather, and the operation of carding would be in

consequence extremely defective. *Fig.* 430 shows the card-teeth acting against each other, as indicated by the arrows in two opposite directions; in *fig.* 431 they work one way.

Of late years very complex but complete and well-acting machines have been constructed for splitting the leather or equalising it by shaving, for bending and cutting the wires, and implanting them in the leather, into holes pierced with perfect regularity. Card machines which fashion the teeth with great precision and rapidity, and pierce the leather, have been for a considerable time in use at Halifax, in Yorkshire, a town famous for the excellence of its card-cloth, as also Leeds, Glasgow, and several other places. The wires and the leather thus prepared are given out by the manufacturer to women and children, who put them together.

The simplest machine for equalising the leather which can be employed, is that of M.M. Scribe of Lille, where the leather is drawn forwards by a roller over a solid horizontal table, or bed, and passed under a nicely adjusted vertical blade, which shaves it by a scraping motion to a perfectly uniform thickness. About one-half the weight of the leather is lost in this process and in the subsequent squaring and trimming.

A machine for making cards, invented by a Mr. Ellis of the United States, for which a first patent was obtained in this country by Joseph Cheeseborough Dyer, Esq., of Manchester, in 1811, and a second and third with further improvements in 1814 and 1824, is one of the most elegant automats ever applied to productive industry. It is, however, necessarily so complicated with different mechanisms as to render its representation impracticable in such engravings as are compatible with the scope of this Dictionary. The following general description of its constituent parts must therefore suffice:—

The first thing to be done after having, as above, prepared the long sheets or fillets of leather of suitable length, breadth, and thickness, for making the cards, is to stretch the leather, and hold it firmly: which is accomplished by winding the fillet of leather upon the roller or drum, like the warp-roller of a loom, and then conducting it upwards, between guide rollers, to a receiving or work roller at the top of the machine, where the fillet is held fast by a cramp, by which means the leather is kept stretched.

Secondly, the holes are pierced in the leather to receive the wire staples or teeth of

the card, by means of a sliding fork, the points of which are presented to the face of the leather; while the fork is made to advance and recede continually, by the agency of levers worked by rotatory cams upon a revolving main shaft.

The points of the fork being thus made to penetrate into the leather, the holes for receiving the staples are pierced, at regular distances and in correct order, by shifting the leather fillet so as to bring different parts of its surface opposite to the points of the sliding fork. This is done by cams, or indented wheels and gear, which shift the guide-rollers and confining drums laterally, as they revolve and consequently move the fillet of leather at intervals a short distance, so as to present to the points of the fork or piercers at every movement, a different part of the surface of the leather.

Thirdly, the wire of which the teeth or points of the card are to be made, is supplied from a coil on the side of the machine, and is brought forward at intervals, by a pair of sliding pincers, which are slidden to and fro through the agency of levers actuated by rotatory cams upon the main shaft. The pincers having advanced a distance equal to the length of wire intended to form one staple, or two points, this length of wire is pressed upon exactly in the middle by a square piece of steel, and being there confined, a cutter is brought forward, which cuts it off from that part of the wire held in the pincers.

The length of wire thus separated and confined is now, by a movement of the machine, bent up along the sides of the square steel holder, and shaped to three edges of the square, that is, formed as a staple; and in the same way, by the continued movements of the machine, a succession of pieces of wire are cut off, and bent into staples for making the teeth of the card as long as the mechanism is kept in action.

Fourthly, the wire staple thus formed is held with its points or ends outwards, closely contiguous to the forked piercer described above, and by another movement of the mechanism the staple is protruded forward, its end entering in the two holes made previously in the leather by sliding of the fork.

While the wire staple is being thus introduced into the leather, its legs or points are to be bent, that is, formed with a knee or angle, which is the fifth object to be effected. This is done by means of a small apparatus consisting of a bar or bed, which bears up against the under side of the wire staple when it has been passed half-way into the holes in the leather, and another bar above it, which being brought down behind the staple, bends it over the resisting bar to the angle required; that is, forms the knee in each leg. A pusher now acts behind the staple, and drives it home into the leather, which completes the operation.

The leather being thus conducted, and its position shifted before the piercer progressively, a succession of the above-described operations of cutting the wire, forming the staple, passing it into the leather, and bending its legs to the angular form, produces a sheet of card of the kind usually employed for earthing or combing wool, cotton, and other fibrous materials. It may be necessary to add, that as these wire staples are required to be set in the leathers, sometimes in lines crossing the sheet, which is called ribbed, and at other times in oblique lines, called twilled, these variations are produced by the positions of the notches or steps upon the edge or periphery of the cam, or indented wheel, which shifts the guide rollers that hold the fillet or sheet of leather as already described.

CARDS, PLAYING. (*Cartes à jouer*, Fr.; *Spielkarten*, Ger.) Playing cards were probably invented in the East. In Italy cards originally bore the name of *Naibi*, and they are still, in Spain and Portugal, called *Naipes*, signifying, in the Oriental languages, *divination*. Cards were first painted by hand: the art of printing cards was discovered in Germany between 1350 and 1360. It has been stated that cards were in use in Spain in 1332: in 1387, John I., King of Castile, prohibited their use. In France, we find that card-playing was practised in 1361; and at the end of the 14th century, we find Charles VI. amusing himself with cards during his sickness. The figures on modern cards are of French origin, and are said to have been invented between 1430 and 1461.

Mr. De La Rue obtained, in February 1832, a patent for certain improvements in the manufacture of playing cards, which he distributed under three heads: first, printing the pips, and also the picture or court-cards, in oil colours by means of types or blocks; secondly, effecting the same in oil colours by means of lithography; and thirdly, gilding or silvering borders, and other parts of the characters, by the printing process, either by types, blocks, or lithography.

In the ordinary mode of manufacturing playing cards, their devices are partly produced by copperplate printing, and they are filled up with water-colours by the means called stencilling.

The patentee does not purpose any material alteration in the devices or forms upon the cards, but only to produce them with oil colours; and, to effect this, he follows precisely the same mode as that practised by calico-printers.

A set of blocks or types, properly devised, are produced for printing the different pips of hearts, diamonds, spades, and clubs, or they are drawn, as other subjects, in the usual way, upon stone. The ink, or colour, whether black or red, is to be prepared from the best French lamp-black, or the best Chinese vermilion ground in oil, and laid on the types and blocks, or on the stone, in the same way as printers' ink, and the impressions taken on thick drawing-paper, by means of a suitable press, in the ordinary manner of printing.

The picture or court-cards are to be produced by a series of impressions in different colours, fitting into each other exactly in the same way as in printing paper hangings, or silks and calicoes, observing that all the colours are to be prepared with oil.

For this purpose a series of blocks or types are to be provided for each subject, and which, when put together, will form the whole device. These blocks are to be used separately, that is, all the yellow parts of the picture, for instance are to be printed at one impression, then all the red parts, next all the flesh colour, then the blue portions, and so on, finishing with the black outlines, which complete the picture.

If the same is to be done by lithography, there must be as many stones as there are to be colours, each to print its portion only; and the impression, or part of the picture, given by one stone must be exactly fitted into by the impression given from the next stone, and so on until the whole subject is complete.

A superior kind of card is supposed to be made, with gold or silver devices in parts of the pictures, or gold or silver borders round the pips. This is to be effected by printing the lines which are to appear as gold or silver, with gilder's size, in place of ink or colour; and immediately after the impression has been given, the face of the card is to be powdered over with gold-dust, silver, or bronze, by means of a soft cotton or wool dabbler, by which the gold, silver, or bronze will be made to adhere to the picture, and the superfluous portions of the metal will wipe off by a very slight rubbing. When the prints are perfectly dry, the face of the card may be polished by means of a soft brush.

If it should be desirable to make these improved cards to resemble ivory, that may be done by preparing the face of the paper in the first instance with a composition of size and fine French white, and a drying oil, mixed together to about the consistence of cream; this is to be washed over the paper, and dried before printing, and when the cards are finished they will exactly resemble ivory.

The only thing remaining to be described, is the means by which the successive impressions of the types, blocks, or stones forming the parts of the pictures, are to be brought exactly to join each other, so as to form a perfect whole design when complete; this is by printers called registering, and is to be effected much in the usual way, by points in the tympan of the press, or by marks upon the stones.

The parts of the subject having been all accurately cut or drawn to fit, small holes are to be made with a fine awl through a quire or more of the paper at once, by placing upon the paper a gauge-plate, having marks or guide-holes, and by observing these, the same sheet laid on several times, and always made to correspond with the points or marks, the several parts of the picture must inevitably register, and produce a perfect subject.

In the year ended March 31, 1873, there were 1,043,384 packs of cards manufactured, on which the stamp duty of 3*d.* per pack was paid, producing 13,048*l.* 11*s.*

Playing cards imported at the duty fixed April 8, 1862, at 3*s.* 9*d.* per dozen packs, were as follows:—

CARDAMOM. The fruit of the *Elettaria Cardamomum*, or the true official cardamom. Cardamoms are produced naturally and by cultivation in Malabar, at Travancore, and the western part of Soonda. The Malabar cardamoms are distinguished in commerce as *shorts*, *short-longs*, and *long-longs*. The three sorts are brought from Bombay in chests, the *shorts* fetching from 3*d.* to 6*d.* per lb. more than the *longs*.

CARLE. A sort of hemp.

CARLOCK. The name given by the Russians to the isinglass obtained from the air-bladder of the sturgeon.

CARLSBAD TWINS. Large felspar crystals which are porphyritically embodied in a regularly constituted rock, as in the granite of Carlsbad in Bohemia, and the granite of some parts of Cornwall.

CARMEL. A substance used by confectioners for covering sweetmeats.

CARMINE. CARMINIC ACID. (*Carmin*, Fr.; *Karminstoff*, Ger.) The colouring matter of the cochineal insect. See COCHINEAL.

There are several methods of preparing carmine, the following being the most approved: Dr. Pereira speaks highly of this process. A decoction of the black cochineal is made in water; the residue, called *carmine grounds*, is used by paper-stainers. To the decoction is added a precipitant, usually bichloride of tin. The decoction to which the bichloride has been added is put into a shallow vessel and allowed to rest. Slowly a deposit takes place, which adheres to the sides of the vessel, and the liquid being poured off, it is dried: this precipitate is carmine. The liquid, when concentrated, is called *Liquid rouge*.

By the *Old German Process*, carmine is prepared by means of alum, without any other addition. As soon as the water boils, the powdered cochineal is thrown into it, stirred well, and then boiled for six minutes; a little ground alum is added, and the boiling is continued for three minutes more. The vessel is removed from the fire, the liquor is filtered, and left for three days in porcelain vessels, in the course of which time a red matter falls down, which must be separated and dried in the shade. This is carmine, which is sometimes previously purified by washing. The liquor, after three days more, lets fall an inferior kind of carmine; but the residuary colouring matter may also be separated by the muriate of tin.

The proportions for the above processes are 580 parts of clear river water, 16 parts of cochineal, and 1 part of alum: there is obtained from $1\frac{1}{2}$ to 2 parts of carmine.

Another *Carmine with Tartar*.—To the boiling water the cochineal is added, and after some time a little cream of tartar; in eight minutes more a little alum is added, and the boiling continued for a minute or two longer. Then take it from the fire and pour it into glass or porcelain vessels; filter, and let it repose quietly till the carmine falls down. Then decant and dry in the shade. The proportions are 8 lbs. of water, 8 oz. of cochineal, $\frac{1}{2}$ oz. of cream of tartar, and $\frac{3}{4}$ oz. of alum; and the product is an ounce of carmine.

The Process of Alxon or Langlois.—Boil two pails and a half of river water (30 pints), throw into it, a little afterwards, a pound of cochineal, add a filtered solution of six drachms of carbonate of soda and a pound of water, and let the mixture boil for half an hour: remove the copper from the fire, and let it cool, inclining it to one side. Add six drachms of pulverised alum, stir with a brush to quicken the solution of the salt, and let the whole rest 20 minutes. The liquor, which has a fine scarlet colour, is to be carefully decanted into another vessel, and there is to be put into it the whites of two eggs well beat up with half a pound of water. Stir again with a brush. The copper is replaced on the fire, the alumina becomes concrete, and carries down the colouring matter with it. The copper is to be taken from the fire, and left at rest for 25 or 30 minutes, to allow the carmine to fall down. When the supernatant liquor is drawn off, the deposit is placed upon filter-cloth stretched upon a frame to drain. When the carmine has the consistence of cream-cheese, it is taken from the filter with a silver or ivory knife, and set to dry upon plates, covered with paper to screen it from dust. A pound of cochineal gives in this way an ounce and a half of carmine.

Process of Madame Cenetie of Amsterdam, with salt of sorrel.—Into six pails of river water boiling hot, throw two pounds of the finest cochineal in powder; continue the ebullition for two hours, and then add 3 oz. of refined saltpetre, and, after a few minutes, 4 oz. of salt of sorrel. In ten minutes more take the copper from the fire, and let it settle for four hours; then draw off the liquor with a siphon into flat plates, and leave it there for three weeks. Afterwards there is formed upon the surface a pretty thick mouldiness, which is to be removed dexterously in one pellicle by a slip of whalebone. Should the film tear and fragments of it fall down, they must be removed with the utmost care. Decant the supernatant water with a siphon, the end of which may touch the bottom of the vessel, because the layer of carmine is very firm. Whatever water remains must be sucked away by a pipette. The carmine is dried in the shade and has an extraordinary lustre.

Carmine by the Salt of Tin, or the Carmine of China.—Boil the cochineal in river water, adding some Roman alum; then pass through a fine cloth to remove the cochineal, and set the liquor aside. It become brighter on keeping. After having heated this liquor, pour into it, drop by drop, solution of tin till the carmine be precipitated. The proportions are one pailful of water, 20 oz. of cochineal, and 60 grains of alum, with a solution of tin containing 4 oz. of the metal.

To make Ordinary Carmine.—Take 1 pound of cochineal in powder; 3 drachms and a half of carbonate of potash; 3 drachms of alum in powder; 3 drachms and a half of fish-glue.

The cochineal must be boiled along with the potash in a copper containing five pailfuls of water (60 pints); the ebullition being allayed with cold water. After boiling a few minutes the copper must be taken from the fire, and placed on a table at such an angle as that the liquor may be conveniently transvased. The pounded alum is then

thrown in, and the decoction is stirred: it changes colour immediately and inclines to a more brilliant tint. At the end of fifteen minutes the cochineal is deposited at the bottom, and the bath becomes as clear as if it had been filtered. It contains the colouring matter, and probably a little alum in suspension. It is then decanted into a copper of equal capacity, and placed over the fire, adding the fish-glue dissolved in a great deal of water, and passed through a searce. At the moment of ebullition, the carmine is perceived to rise up to the surface of the bath, and a coagulum is formed, like what takes place in clarifications with whites of egg. The copper must be immediately taken from the fire, and its contents be stirred with a spatula. In the course of fifteen or twenty minutes the carmine is deposited. The supernatant liquor is decanted, and the deposit must be drained upon a filter of fine canvas or linen. If the operation has been well conducted, the carmine when dry crushes readily under the fingers. What remains after the precipitation of the carmine is still much loaded with colour, and may be employed very advantageously for carminated lakes. See LAKE.

There are sold at the shops different kinds of carmine, distinguished by numbers, and possessed of a corresponding value. The difference depends upon two causes, either upon the proportion of alumina added in the precipitation, or of a certain quantity of vermilion put in to dilute the colour. In the first case the shade is paler, in the second it has not the same lustre. It is always easy to discover the proportion of the adulteration. By availing ourselves of the property of pure carmine to dissolve in water of ammonia, the whole foreign matter remains untouched, and we may estimate its amount by drying the residuum.

Carmine is, according to Pelletier and Caventou, a triple compound of the colouring substance and an animal matter contained in cochineal, combined with an acid added to effect the precipitation. The most successful investigator into the colouring matter of the cochineal has been Mr. Warren De La Rue. This chemist had the opportunity of submitting the living insect to microscopical examination. He found it to be covered with a white dust, which was likewise observed on the adjacent parts of the cactus leaves on which the animal feeds. This dust, which he considered to be the excrement of the animal, has, under the microscope, the appearance of white curved cylinders of a very uniform diameter. On removing the powder with ether, and piercing the side of the insect, a purplish-red fluid exudes, which contains red colouring matter, in minute granules assembled round a colourless nucleus. These groups seem to float in a colourless fluid, which appears to prove, that whatever may be the function of the colouring matter, it has a distinct and marked form, and does not pervade, as a mere tint, the fluid portion of the insect. To this colouring matter, Mr. De La Rue has given the name of CARMINE ACID.

It has been shown by Schützenberger that the carminic acid in carmine is combined with a nitrogenous base called *tyrosine*.

There are some remarkable peculiarities about the production of carmine. The shade and character of the colour are altered by slight, very slight, differences of the temperature at which it is prepared; and with every variation in the circumstance of illumination, a change is discovered in the colour. Sir H. Davy relates the following anecdote in illustration of this:—

‘A manufacturer of carmine, who was aware of the superiority of the French colour, went to Lyons for the purpose of improving his process, and bargained with a celebrated manufacturer in that city for the acquisition of his secret, for which he was to pay 1,000*l.* He saw all the process, and a beautiful colour was produced, but he found not the least difference in the French method and that which had been adopted by himself. He appealed to his instructor, and insisted that he must have kept something concealed. The man assured him that he had not, and invited him to inspect the process a second time. He very minutely examined the water and the materials, which were in every respect similar to his own, and then, very much surprised, he said: “I have both lost my money and my labour; for the air of England does not admit of our making good carmine.”—“Stay,” said the Frenchman, “don’t deceive yourself; what kind of weather is it now?”—“A bright sunny day,” replied the Englishman. “And such are the days,” replied the Frenchman, “upon which I make my colour: were I to attempt to manufacture it on a dark and cloudy day, my results would be the same as yours. Let me advise you to make your carmine on sunny days.” Experiments on this subject have proved that coloured precipitates which are brilliant and beautiful when they are precipitated in bright sunshine, are dull, and suffer in their general character, if precipitated in an obscure apartment, or in the dark.

To revive or brighten Carmine.—We may brighten ordinary carmine, and obtain a very fine and clear pigment, by dissolving it in water of ammonia. For this purpose we leave ammonia upon carmine in the heat of the sun, till its colour is extracted.

and the liquor has got a fine red tinge. It must be then drawn off and precipitated by acetic acid and alcohol, next washed with alcohol, and dried. Carmine dissolved in ammonia has been long employed by painters under the name of *Liquid carmine*.

Carmine is the finest red colour which the painter possesses. It is principally employed in miniature painting, water colours, and to tint artificial flowers, because it is more transparent than the other colours. This valuable pigment is often adulterated with starch. Water of ammonia enables us to detect this fraud by dissolving the pure carmine, and leaving the starchy matter, as well as most other sophisticating substances. Such debased carmine is apt to spoil with damp.

CARNALLITE. A hydrous chloride of potassium and magnesium, named after Von Carnall, of the salt-mines at Stassfurt, near Magdeburg, in Prussia. The carnallite occurs in the upper beds of these salt-deposits, known as the 'Carnallite region.' It is also found under similar conditions at Kalusz in Galicia, and is said to occur likewise at Maman in Persia. See **ABRAUM SALTS**.

Carnallite occurs massive or in coarsely-granular forms; when pure it is colourless, but in most cases it presents a reddish colour due to included six-sided plates of micaceous iron-ore (peroxide of iron). The specific gravity of the salt is 1.6. It deliquesces in the air, and dissolves freely in water. The formula of carnallite is $2\text{MgCl} + \text{KCl} + 12\text{HO}$ ($\text{MgCl}^2 + \text{KCl} + 6\text{HO}^2$). A specimen of pure carnallite would therefore contain 34.2 per cent. of chloride of magnesium, 26.8 of chloride of potassium, and 39 of water; as raised from the mine, however, it generally contains also chloride of sodium and sulphate of potash, sometimes with organic matter and microscopic crystals of anhydrite and quartz. The carnallite beds are so intermixed with the other minerals that the commercial potash-salts known as carnallite contain only 66 per cent. of carnallite, representing $17\frac{1}{2}$ per cent. of chloride of potassium. The mineral is associated with rock-salt, kieserite, sylvine, &c. It is largely employed as a source of chloride of potassium, which is obtained from it by merely treating the salt with hot water, whereby the readily-soluble chloride of magnesium is dissolved out. The salt is also used in the preparation of chlorine gas, and in the manufacture of manures.

CARNAÜBA. The name of a palm growing in Brazil, the *Corypha cerifera*. The fruit is edible. Candles are made from the wax which is obtained from the leaves by melting the coating. The wood is very strong, and used in building.

CARNELIAN, or **CORNELIAN.** (*Cornaline*, Fr.; *Karnool*, Ger.; *Cornalina*, Ital.) A reddish variety of chalcedony, generally of a clear bright tint; it is sometimes of a yellow or brown colour, and it passes into common chalcedony through greyish red. Heintz, by his analysis, shows that the colour is due to peroxide of iron. He found per cent., Peroxide of Iron 0.050; Alumina 0.081; Magnesia 0.028; Potash 0.0043; Soda 0.075; the remainder being Silica.—*Dana*.

Carnelians are the stones usually employed, when engraved, for seals. The French give to those carnelians which have the utmost transparency and purity, the name of *Cornaline d'ancienne roche*. See **AGATE**.

The late J. Forbes, Esq., long a resident in India, and with ample means of reference to the province of Guzerat, thus describes the locality of the carnelian mines:—

'Carnelians, agates, and the beautifully variegated stones improperly called Mocha Stones, form a valuable part of the trade at Cambay. The best agates and carnelians are found in peculiar strata, thirty feet under the surface of the earth, in a small tract among the Rajepiplee hills on the banks of the Nerbudda; they are not to be met with in any other part of Guzerat, and are generally cut and polished in Cambay. On being taken from their native bed, they are exposed to the *heat* of the sun for two years: the longer they remain in that situation, the brighter and deeper will be the colour of the stone. Fire is sometimes substituted for the solar ray, but with less effect, as the stones frequently crack, and seldom acquire a brilliant lustre. After having undergone this process, they are boiled for two days, and sent to manufacturers at Cambay. The agates are of different hues; those generally called carnelians are dark, white, and red, in shades from the palest yellow to the deepest scarlet.

'The variegated stones with landscapes, trees, and water beautifully delineated are found at Copper-wange, or, more properly, Cubber-punge, 'The Five Tombs,' a place sixty miles distant.'—*Oriental Memoirs*, 2nd ed. vol. i. p. 323.

'At Neemondra, a village of the Rajepiplee district, and three miles east, are some celebrated carnelian mines. The country in the immediate vicinity of the mines is but little cultivated; and on account of the jungles, and their inhabitants the tigers, no human inhabitants are found nearer than Rattumpoor, which is seven miles off. The miners have huts at this place when stones are burned.

'The carnelian mines are situated in the widest parts of the jungle, and consist of numerous shafts worked down perpendicularly about 4 feet wide, the deepest about 50 feet. Some extend at the bottom in a horizontal direction, but usually not far, the

nature of these pits being such as to prevent their being worked a second year, on account of the heavy rains causing the sides to fall in; so that new ones must be opened at the conclusion of every rainy season. The soil is gravelly, and consists chiefly of quartz-sand, reddened with iron and a little clay. The nodules weigh from a few ounces to even two or three pounds, and lie close to each other, but for the most part distinct, not being in strata, but scattered through the masses in great abundance.

'On the spot, the carnelian are mostly of a blackish-olive colour, like common dark flints, others somewhat lighter, others still lighter with a milky tinge; but it is quite uncertain what appearance they will assume after they have been burnt.

'From Neemoudra they are carried by the merchants to Cambay, where they are cut, polished, and formed into beautiful ornaments, for which that city is so justly celebrated.'—Copeland, *Bombay Researches*; Hamilton's *Description of Hindostan*, 4to. 1820.

The stones from Cambay are offered in commerce, cut and uncut, as roundish pebbles from 1 to 3 inches in diameter. The colour of red carnelian of Cambay varies from the palest flesh-colour to the deepest blood-red; the latter being most in demand for seals and trinkets. The white are scarce, but when white and uniform they are valuable; the yellow and variegated are of little estimation in the Bombay market.

The present trade in these stones cannot be correctly ascertained, as in the Board of Trade returns they are now included with precious stones 'of the inferior class, unset.' The value of the imports cannot be ascertained.

CAROB TREE. *Ceratonia Siliqua*. This tree is often called St. John's Bread, from the idea that it furnished the 'locusts' and 'wild honey' to St. John when in the wilderness. It is an evergreen tree of large size, and is the only tree that grows in Malta. It grows abundantly in Palestine. The ripe fruit has a sweetish taste, and is eaten in times of scarcity by the country people. Large quantities of the fruit are sent annually from Palestine to Alexandria, and thence to Constantinople. The Turks pulp it with liquorice root and other fruits, to make their sherbet. The bark is sometimes, on account of its astringency, employed as a substitute for oak bark in tanning hides. M. Mennons, of Paris, has patented the application of the carob beans to the production of a species of glucose or fermentable sugar adapted to a variety of manufacturing purposes.

CAROTINE. The colouring principle of the carrot (*Daucus Carota*), which is associated in the root with a colourless substance called *hydrocarotine*.

CARPET. (*Tapis*, Fr.; *Teppich*, Ger.) A thick woollen fabric of variegated colours, for covering the floors of the better sort of apartments. This luxurious manufacture took its origin in Persia and Turkey, whence the most beautiful patterns were wont to come into Europe; but they have been for some time surpassed by the workmanship of France, Great Britain, and Belgium. To form a just conception of the elegant and ingenious processes by which carpets are made, we should visit the State establishment of the Gobelins at Paris.

The warp, says Mr. Roland, being the foundation of the fabric, ought to be of fine wool, equally but firmly spun, and consists of three yarns twisted into one thread. The yarns that are to form the velvety surface of the carpet ought also to be of the best quality, but soft and downy in their texture, so that the dye may penetrate every filament. Hemp or linen yarns are likewise employed in this manufacture, as a woof, to bind the warp firmly together after each shoot of the velvety threads. Thus we see that good carpeting consists essentially of two distinct webs woven at the same time, and firmly decussated together by the woof threads. Hence the form of the pattern is the same upon the two sides of the cloth, only the colours are reversed, so that what was green upon one side becomes red or black upon the other, and *vice versâ*. The smaller the figures the more frequent the decussation of the two planes, and the firmer and more durable the fabric.

The carpet manufacture, as now generally practised, may be distributed into two systems—that of double fabrics, and that cut in imitation of velvet. Of late years the Jacquard loom has been much used in weaving carpets, the nature of which will be found fully explained under that title.

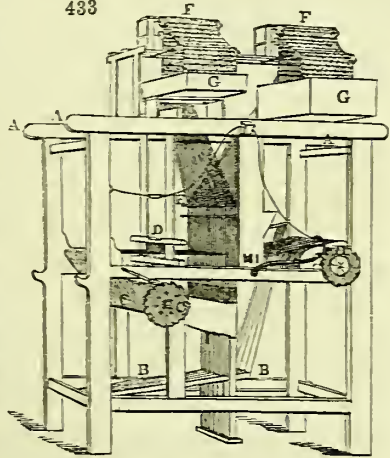

For the sake of illustration, if we suppose the double carpets to be composed of only two colours, the principle of weaving will be easily understood; for it is only necessary to raise the warp of each web alternately for the passage of the shuttle, the upper web being entirely above when the under web is being woven, or decussated, and *vice versâ*. In the Brussels carpet the worsted yarn raised to form the pile, and make the figure, is not cut; in the Wilton the pile is cut to give it a velvety aspect and softness. In the imperial Brussels carpet the figure is raised above the ground, and its pile is cut, but the ground is uncut; and in the royal Wilton the pile is both raised higher than in the common Wilton, and it is cut, whereby it has a rich cushion-like appearance. The cloth of all these superior carpets consists of woollen and

linen, or hemp; the latter being put upon a beam, and brought, of course, through heddles and a reed; but as its only purpose is to bind together the worsted fabric, it should not be visible upon the upper face of the carpet. The worsted yarn is wound upon small bobbins or pirns, with a weight affixed to each, for giving proper tension to the threads. The number varies, for one web, from 1,300 to 1,800, according as the carpet is to be 27 or 36 inches wide; and they are placed, in frames, behind the loom, filled with differently-coloured yarn, to correspond with the figure. This worsted warp is then drawn through the harness, heddles, and reed, to be associated with the linen yarn in the compound fabric.

In Kidderminster carpeting, both warp and weft appear upon the face of the cloth, whereas, in the Brussels style, only the warp is seen, its binding weft being fine hempen or linen threads. The three-ply imperial carpet, called the Scotch, is coming very much into vogue, and is reckoned by many to be little inferior in texture, look, and wear to the Brussels. Kilmarnock has acquired merited distinction by this ingenious industry. In this fabric, as well as in the two-ply Kidderminster, the weft predominates, and displays the design; but, in the French carpets, the worsted warp of the web shows the figure. Plain Venetian carpets, as used for stairs and passages, are woven in simple looms, provided merely with the common heddles and reed. The warp should be a substance of worsted yarn, so heavy as to cover in the weft completely from the view. Figured Venetian carpets are woven in the two-ply Kidderminster looms, and are provided with a mechanism to raise the pattern upon the worsted warp. The weft is an alternate shoot of worsted and linen yarn, and must be concealed.

The following figure and description will explain the construction of the three-ply imperial Scotch and two-ply Kidderminster carpet loom, which is merely a modification of the Jacquard *métier*. The Brussels carpet loom, on the contrary, is a draw-boy loom on the damask plan, and requires the weaver to have an assistant. *Fig. 433, A A A*, is the frame of the loom, consisting of four upright posts, with caps and cross-rails to bind them together. The posts are about six feet high. *c c*, the cloth-beam, is a wooden cylinder, six inches or thereabouts in diameter, of sufficient length to traverse the loom, with iron gudgeons in the two ends, which work in bushes in the side frame. On one end of this beam is a ratchet wheel, with a tooth to keep it from turning round backwards by the tension of the web. *d*, the lay, with its reed, its under and upper shell,

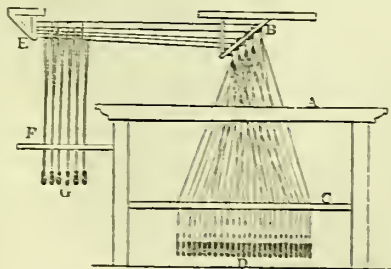

433

its two lateral rulers or swords, and rocking-tree above. There are grooves in the upper and under shell, into which the reed is fitted. *e*, the heddles, or harness, with a double neck attached to each of the tower or card mechanisms, *F F*, of the Jacquard loom. The heddles are connected and work with the treddles *B B*, by means of cords, as shown in the figure. *G G* are wooden boxes for the cards. *H*, the yarn, or warp beam.

In draw-loom of every kind, there is no sinking of any portion of the warp, as in plain cloth-weaving; but the plane of the cloth is placed low, and the threads under which the shuttle has to pass are raised, while all the rest remain stationary. The harness part of this carpet-loom is moved by an assistant boy or girl, who thus allows the weft to be properly decussated, while the weaver attends to working the front mounting or heddles. *Fig. 434, A* represents the frame of a carpet draw-loom; *B* is a box or frame of pulleys, over which the cords of the harness pass, and are then made fast to a piece of wood, seen at *e*, which the weavers call a table. From the tail of

434

From the tail of

the harness the simples descend, and to the end of each is attached a small handle *g*, called a bob. These handles being disposed in pairs, and their regularity preserved by means of a perforated board *c*, it is merely necessary to pull every handle in succession, the weaver, at the same time, working his treddles with his feet, as in any other loom. The treddles are four in number, the fabric being that of plain or alternate cloth, and two treddles allotted for each web. The harness part of the carpet draw-loom is furnished with *mails*, or metallic eyes, to save friction; two threads being drawn through each eye. The design or pattern of a carpet is drawn upon cross-rule paper, exactly in the same way as every other kind of fancy-loom work, and is transferred from the paper to the mounting by the rules for damask weaving. Suppose that a double web is so mounted that every alternate thread of the one may be raised, so as to form a sufficient shed-way for the shuttle, without depressing the other in the least: then suppose another web placed upon the former, at such a distance that it will exactly touch the convexity of those threads of the former which are raised. Then, if the threads of the latter web are sunk while the others are raised, the two would be entirely incorporated; but if this be only partially done, that is, at particular places, only those parts immediately operated upon will be affected by the action of the apparatus. If the carpet is a two-coloured pattern, as black and red, and if upon the upper surface, as extended in the loom, red flowers are to be represented upon a black ground, then all those species of design paper which are coloured may be supposed to represent the red, and those which are vacant the black. Then counting the spaces upon the paper, omit those which are vacant, and cord those which are coloured, and the effect will be produced. But as the two webs are to be raised alternately, whatever is corded for the first handle must be passed by for the second, and *vice versâ*, so that the one will form the flower, and the other the ground.

The board by which the simples are regulated appears at *f*. *d* shows the weights.

Mr. Simeox, of Kidderminster, has patented an invention for an improved manufacture of carpets, in which, by dispensing with the Jacquard loom, as well as the iron wires and tags usually employed to produce terry fabrics, such as Brussels carpets and coach-lace, he can work his machinery at greater speed and more economically. His second improvement relates to the manufacture of fabrics with cut pile, such as Wilton or Axminster carpets. He makes a ribbed fabric, greatly resembling the Brussels carpet, by a combination of woollen and linen warp and weft, arranged in such a manner that the woollen warp in the form of a ribbed surface may constitute the face of the fabric, while the linen warp forms the ground or back of the fabric. The plan he prefers, as most resembling the Brussels, consists in weaving the fabric as nearly as possible in the ordinary way, except that, instead of inserting a tag or wire to form the rib or terry, the patentee throws in a thick shoot or weft of woollen or cotton, over which the woollen warp is drawn, and forms a rib; the woollen warp being afterwards bound down with a linen shoot or weft in the ordinary way. The woollen warp employed being all of one colour, the fabric produced will be plain or unornamented, with a looped or terry pile; and upon this fabric any design may be printed from blocks.

The looms differ from the former chiefly in the employment of two separate shuttles, one for the woollen and one for the linen weft. These shuttles are both thrown by the same pickers and the same picking-sticks, and consequently the shuttle boxes must be moved up and down as may be required, in order to allow the picker to throw the proper shuttle. It will also be necessary to work the healds in a suitable manner to form the proper shreds, in order that the woollen face may be properly bound to the linen ground.

The second part of his invention relates to the production of fabrics with a cut pile, like the Axminster or Wilton rugs or carpets. The ordinary mode of making some of these fabrics is to weave the pattern in by means of a Jacquard apparatus, and pass the woollen warp over a rod or tag, which is afterwards cut by passing a suitable knife along it, thereby producing the cut pile. The patentee produces the design and surface of the fabric from the weft in place of the warp as heretofore. For this purpose the weft is made to consist of thick woollen shoots, which must be printed or stained with suitable colours, precisely as the woollen warps have been heretofore done; and the woollen shoot, when thrown in, is, by means of suitably formed hooks, pulled up and turned into loops, which, when they are properly secured to the foundation or ground of the fabric, are afterwards cut by means of knives or cutting instruments, with which the hooks are furnished, for the purpose of releasing them from the loops and producing the cut pile. The patentee observes, that cotton and other cheap materials may be employed with great advantage in the production of some of these fabrics.

Another invention of improvements in manufacturing figured fabrics, principally designed for the production of carpeting, patented by Mr. James Templeton, of

Glasgow, consists in producing the pattern either on one or both sides of the fabric, by means of printed weft; also in the use of printed party-coloured fur or weft, in the manufacture of Axminster carpets and other similar fabrics. This invention is also applicable to the production of figured chenille weft for the manufacture of chenille shawls.—Under the arrangements of the Patent Office the specifications of these patents are cheaply obtained.

CARPETS, PRINTED. Mr. Wood has taken out a patent for weaving and printing carpets, using an ordinary Brussels carpet loom. After putting in the wire, or otherwise forming the loop, he throws in the usual linen shoot, on the face, to bind it; and then, for the back shoot, he throws in a thick soft weft. Or, to make a better edge and more elastic back, he employs the ordinary two linen shoots,—one on the face, and the other in the back,—and then (or before throwing in the second linen shoot) he draws down only one-half of the lower portion of the linen warp (being one-quarter of the whole), and throws in the thick shoot which is driven up by the batten or lay, so as to cover the second linen shoot, which is then inside the fabric: from the thick shoot being bound only by each alternate yarn of the warp, it will be more elastic than if bound more closely by using every yarn; while the second linen shoot, having half the warp over it, holds down the face or first shoot; and any inequality in the taking up of the linen warp by one portion of it binding in a greater substance than the other, is remedied by drawing down the different portions in succession.

In printing Brussels and other pile carpets, the patentee first provides a table, long enough to receive the entire length or piece of the carpet to be printed: at each end of the table there is a frame of the same height or level, sufficiently long to receive the cylinder printing-machine when off the fabric; and on the surface of the table the printing blanket is laid between two rails or guides, which are fixed at exactly the same distance apart as the carpet is wide, so as to keep it in one position, and to form the guides for the printing cylinders. The carpet is fastened to one end of the table, and is then laid on the top of the same, and drawn tight at the other end by a roller, which is furnished with a ratchet wheel and click. The printing cylinders are mounted in a moveable frame, containing a corresponding number of colour cans and feeding rollers, to supply them with colour. The printing apparatus is passed over the table, and between the guide rails (the patterns on the cylinder being coloured, and bearing upon the carpet), to the frame at the other end of the table, and then back again; and this process is repeated until the fabric is sufficiently coloured. In order to insure each part of the pattern or printing surface coming again and again on the same place, toothed wheels are affixed on the axis of the printing cylinders, which gear into racks fixed on the sides of the table; so that, however frequently the printing apparatus passes over the fabric, every part of the pattern will fall on the same place. Instead of the printing apparatus being passed back again over the same table, it may, by the application of moveable frames at the end of the table, be moved sideways on to another table, and so successively. See RUGS.

CARPHOLITE. A silicate of manganese, alumina, and iron, found in the tin-mines of Schlackenwald in Bohemia.

CARPMEALS. The name of a coarse cloth which used to be manufactured in the North of England.

CARRAGEEN. *Chondrus crispus*: Irish moss. See ALGÆ.

CARRAGEENIN. The mucilaginous constituent of carrageen moss. It is called by some writers *vegetable jelly* or *vegetable mucilage*, by others *pectin*. 'It appears to me (*Pereira*) to be a peculiar modification of mucilage.'

CARRARA MARBLE. A fine-grained white marble largely quarried at Carrara in Tuscany, and valued as a statuary marble.

CARROLLITE. A sulphide of cobalt and copper. Brush regards the mineral as cobaltic pyrites in which a portion of the cobalt is replaced by copper.

CARTHAMUS, or *Safflower*. (*Carthame*, Fr.; *Färberdistel*, Ger.) *Carthamus tinctorius*, the flower of which alone is used in dyeing, is an annual plant cultivated in Spain, Egypt, and the Levant. There are two varieties of it—one which has large leaves, and the other smaller ones. It is the latter which is cultivated in Egypt, where it forms a considerable article of commerce.

Carthamus contains two colouring matters, one yellow and the other red. The first alone is soluble in water: its solution is always turbid; with reagents it exhibits the characters usually remarked in yellow colouring matters. The acids render it lighter, the alkalis deepen it, giving it more of an orange hue; both produce a small dun precipitate, in consequence of which it becomes clearer. Alum forms a precipitate of a deep yellow, in small quantity. The solution of tin and other metallic solutions cause precipitates which have nothing remarkable in them.

The yellow matter of carthamus is not employed; but in order to extract this portion, the carthamus is put into a bag, which is trodden under water, till no more

colour can be pressed out. The flowers, which were yellow, become reddish, and lose in this operation nearly one-half of their weight. In this state they are used.

For extracting the red part of earthamus, or carthamic acid, and afterwards applying it to stuff, the property which alkalis possess of dissolving it is had recourse to, and it is precipitated by an acid.

The process of dyeing consists, therefore, in extracting the colouring matter by means of an alkali, and precipitating it on the stuff by means of an acid.

This solution of carthamus is prepared with crystallised carbonate of soda, and it is precipitated by lemon-juice. It has been remarked that lemons beginning to spoil are fitter for this operation than those which are less ripe, whose juice retains much mucilage. After squeezing out the lemon-juice, it is left to settle for some days. The precipitate of carthamus is dried at a gentle heat upon plates of stone-ware; from which it is detached and very carefully ground with talc which has been reduced to a very subtle powder by means of the leaves of shave-grass (*presle*), and successively passed through sieves of increasing fineness. It is the fineness of the talc, and the greater or less proportion which it bears to the carthamus precipitate, which constitute the difference between the high- and low-priced safflower rouges.

Carthamus is used for dyeing silk, poppy, *nacarat* (a bright orange-red), cherry, rose-colour, and flesh-colour. The process differs according to the intensity of the colour, and the greater or less tendency to flame-colour that is wanted. But the carthamus-bath, whose application should be varied, is prepared as follows:—

The carthamus, from which the yellow matter has been extracted, and whose lumps have been broken down, is put into a trough. It is repeatedly sprinkled with crude pearl-ashes or soda, well powdered and sifted, at the rate of 6 lbs. for 120 lbs. of earthamus; but soda is preferred, mixing carefully as the alkali is introduced. This operation is called *amestrer*. The *amestred* earthamus is put into a small trough with a grated bottom, first lining this trough with a closely-woven web. When it is about half filled, it is placed over a large trough, and cold water is poured into the upper one till the lower one becomes full. The carthamus is then set over another trough till the water comes from it almost colourless. A little more alkali is now mixed with it, and fresh water is passed through it. These operations are repeated till the carthamus be exhausted, when it turns yellow.

After distributing the silk in hanks upon the rods, lemon-juice, brought in casks from Provence, is poured into the bath till it becomes of a fine cherry-colour; this is called turning the bath. It is well stirred, and the silk is immersed and turned round the skein-sticks in the bath, as long as it is perceived to take up the colour. For *ponceau* (poppy-colour), it is withdrawn, the liquor is run out of it upon the peg, and it is turned through a new bath, where it is treated as in the first. After this it is dried and passed through fresh baths, continuing to wash and dry it between each operation, till it has acquired the depth of colour that is desired. When it has reached the proper point, a brightening is given it by turning it round the sticks seven or eight times in a bath of hot water, to which about half a pint of lemon-juice for each pailful of water has been added.

When silk is to be dyed *ponceau*, or poppy-colour it must be previously boiled as for white; it must then receive a slight foundation of arnatto, as explained in treating of that substance. The silk should not be alumed.

The *nacarats*, and the deep cherry-colours, are given precisely like the *ponceaux*, only they receive no arnatto ground; and baths may be employed which have served for the *ponceau*, so as to complete their exhaustion. Fresh baths are not made for the latter colours, unless there be no occasion for the poppy.

With regard to the lighter cherry-reds, rose-colour of all shades, and flesh-colours, they are made with the second and last runnings of the carthamus, which are weaker. The deepest shades are passed through first.

The lightest of all these shades, which is an extremely delicate flesh-colour, requires a little soap to be put into the bath. This soap lightens the colour, and prevents it from taking too speedily, and becoming uneven. The silk is then washed, and a little brightening is given it in a bath which has served for the deeper colours.

All these baths are employed the moment they are made, or as speedily as possible, because they lose much of their colour upon keeping, by which they are even entirely destroyed at the end of a certain time. They are, moreover, used cold, to prevent the colour from being injured. It must have been remarked, in the experiments just described, that the caustic alkalis attack the extremely delicate colour of carthamus, making it pass to yellow. This is the reason why crystals of soda are preferred to the other alkaline matters.

In order to diminish the expense of the carthamus, it is the practice in preparing the deeper shades to mingle with the first and the second bath about one-fifth of the bath of archil.

Döbereiner regarded the red colouring matter of carthamus as an acid, and the yellow as a base. His carthamic acid forms, with the alkalis, colourless salts, decomposed by the tartaric and acetic acids, which precipitate the acid of a bright rose-red. Heat has a remarkable influence upon carthamus, rendering its red colour yellow and dull. Hence, the colder the water is by which it is extracted, the finer is the colour. Light destroys the colour very rapidly, and hitherto no means have been found of counteracting this effect. For this reason this brilliant colour must be dried in the shade, its dye must be given in a shady place, and the silk stuffs dyed with it must be preserved as much as possible from the light. Age is nearly as injurious as light, especially upon the dye in a damp state. The colour is very dear: a thousand parts of carthamus contain only five parts of *carthamine*.

In preparing the finest rouge, the yellow colouring matter having been separated by washing with water, the red is dissolved by the aid of alkali, and is thrown down on linen or cotton rags, by saturating the solution with vegetable acid. The colour is rinsed out of these rags, dissolved anew in alkalis, and once more precipitated by lemon-juice. The best and freshest carthamus must be selected. It is put into linen bags, which are placed in a stream of water, and kneaded till the water runs off colourless. The bags are then put into water soured with a little vinegar, kneaded till the colour is all expelled, and finally rinsed in running water.

There is a considerable consumption of safflower in the manufacture of rouge, for which there is a far greater demand than is generally supposed, this colour being employed not only as a 'toilet appendage' of the *monde*, but for theatrical use.

Rouge consists of carthamine and very fine burnt talc made into a paste with water. It is made of five regular shades, known as Nos. 6, 8, 12, 18, 24, varying in depth of colour as the numbers increase; Nos. 6 and 8 are used by fair beauties, No. 12 is medium, while Nos. 18 and 24 are for dark complexions.

Pink saucers, formerly in great request for dyeing silk stockings at home, and even now not wholly unknown to trade, consist of a shallow porcelain saucer into which a film of carthamine has been allowed to precipitate, and then is dried. The Chinese make a 'Book Rouge' in a somewhat similar way; a very strong solution of the carthamine is brushed over a cardboard, which when dry 'is fit for ladies' use.' The card is, however, no longer pink or red, but of a beautiful metallic green colour due to some special optical reason not yet explained; the pink saucers made in England exhibit in a very slight degree the same effect, which the surface of indigo also in some measure resembles.

Carthamus is the material used for dyeing ordinary red tape, and there is a curious prejudice against using other colours for this purpose, the trade objecting to any deviation from the conventional shade.

Salvétat has found it advantageous to mix the red of safflower with the pigments used in porcelain painting for purple, carmine, and violet, colours which, in consequence of the difference of their shade before and after firing, are very liable to mislead. To avoid this, he imparts to the pigment (consisting of flux, gold-purple, and chloride of silver) by means of the red of carthamus suspended in water, the same shade which he desires to obtain after firing.

The colouring matter of safflower has been examined by Salvétat, who has found much difference in carthamus of reputed good quality. The following Table gives some of his results:—

	1	2	3	4
Water	6·0	11·5	4·5	4·8
Albumen	3·8	4·0	8·0	1·7
Yellow colouring matter, <i>a</i>	27·0	30·0	30·0	26·1

CARTON PIERRE. A composition of paper mixed with whiting or glue for imitating stone or bronze. See PAPIER MACHE.

CARUTO. The fruit of the *Genipa Americana*, a native plant of British Guiana, yields the dye to which this name is given. It is of a beautiful bluish-black colour.

CARVING BY MACHINERY is an art of comparatively modern date, nearly, if not the whole of the originators and improvers of it, being men of the present day. It is true that the Medallion Lathe and many other appliances for ornamental turning and drilling can claim a much earlier origin, but these can scarcely be called carving machines, and are altogether incapable of aiding the economy of producing architectural decorations of any kind. We are not aware of any practical scheme for accomplishing this object prior to the patent of Mr. Joseph Gibbs, in 1829, which we believe was used by Mr. Nash in ornamenting some of the floors of Buckingham Palace, and on many other works of inlaying and tracery. The cutting of ornamental forms in low relief seems to have been the principal object of the inventor; and this he accomplished satisfactorily by a series of ingenious mechanical arrangements, which greatly reduced the cost, while securing unusual accuracy in this kind of work. Some modifications of machinery for copying busts, bosses, and other works in bold relief are also described in Mr. Gibbs's patents, but these were never carried into successful practice. The tracery and inlaying machine is illustrated by *fig. 435*, which is a plan of the machine. A is a shaft capable of vertical motion in its bearings, which are in the fixed framing of the machine; B, C, and D, E, are swing frames jointed together by a short vertical shaft *a*, and securely keyed to the shaft A. The point *b* is the axis of a revolving tool, which is driven

435

by the belts *c*, *d*, *e*, and the compound pulleys *f*, *g*, *h*, which increase the speed at each step; F, G, H, is the table on which the work is fixed; I, K, the work; and *k*, *l*, a templet of brass pierced with the horizontal form of the pattern to be produced in the wood; this templet is securely fixed on the top of the work, or over it, and the machine is adjusted for action.

There is a treadle, not shown in the figure, which enables the workman to lift or depress the shaft A, and the swing frames and tool attached to it; he can thus command the vertical position of the tool with his foot, and its horizontal position with his hand by the handles *m*, *n*, which turn freely on a collar of the swing frame surrounding the mandril or tool holder. The tool having been brought over one of the apertures of the templet when in rapid action, is allowed to sink to a proper depth in the wood underneath, and the smooth part of its shaft is then kept in contact with the guiding edges of the templet and passed round and over the entire surface of the figure, until a recess of the exact size and form of that opening in the templet is produced; this process is repeated for every other opening, and thus a series of recesses are formed in the oak flooring-planks which correspond with the design of the templets used. To complete the work it is requisite to cut out of some darker

or differently coloured material a number of thin pieces which will fit these recesses, and these are produced in the same way from templets which will fit the various apertures of that first used; these pieces are next glued into the recesses, and the surface when planed and polished exhibits the pattern in the various colours used. For inlaying it is important that the cutting edge of the tool should travel in the same radius as the cylindrical shaft, which is kept against the edge of the templet; but if the tool is a moulded one, a counterpart of its mouldings will be produced in the work, while the pattern, in planes parallel to that of the panel, will have the form of the apertures in the templet used. In this way, by great care in the preparation of the templets and the tools, much of the gothic tracery used in church architecture may be produced, but the process is more applicable to Bath stone than to wood when moulded tools are requisite.

Mr. Irving's patents for cutting ornamental forms in wood and stone are identical in principles of action and in all important points of construction with the arrangements previously described. In that of 1843 he particularly claims all combinations for accomplishing the purpose, 'provided the swing frame which carries the cutter, and also the table on which the article to be wrought is placed, have both the means of circular motion.' The pierced templet is the guiding power, and the work and templet are fixed on a circular iron table, which is at liberty to revolve on its axis. The swing frame which carries the cutter is single, as in Mr. Gibbs's curved moulding machine, and its radius so adjusted, that an arc drawn by the tool would pass over the centre of the circular table. The mode of operating with this machine was to keep the shaft of the tool against the guiding edge of the templet, by the joint movements of the table on its centre, and of the swing frame about its shaft; and it will be obvious that by this means any point of the table could be reached by the tool, and therefore any pattern of moulded work within its range produced, in the way already described in speaking of Mr. Gibbs's machinery. But as these modifications of the original idea are not, strictly speaking, carving machines, seeing that they only produced curved mouldings, we need not further describe them.

Perhaps the most perfect carving machine which has been made for strictly artistic works is that used by Mr. Cheverton for obtaining his admirable miniature reductions of life-sized statuary; but we can only judge of the perfection of this machine by its work, seeing that the inventor has more faith in *secrecy* than *patents*, and has not made it public.

The carving machinery which is best known, and has been most extensively used, is that invented by Mr. Jordan and patented in 1845, and was used in producing the carved decorations of the interior of the Houses of Parliament.

Its principle of action and its construction are widely different from that above described, and it is capable of copying any carved design which can be produced, so far as *that* is possible by *revolving tools*; the smoothness of surface and sharpness of finish is neither possible nor desirable, because a keen edge guided by a practised hand will not only produce a better finish, but it will accomplish this part of the work at less cost; the only object of using machinery is to lessen the cost of production, or to save time; and in approaching towards the finish of a piece of carving, there is a time when further progress of the work on the machine would be more expensive than to finish it by hand. This arises from the necessity of using smaller tools towards the finish of the work to penetrate into its sharp recesses, and the necessarily slow rate at which these cut away the material; it is consequently a matter of commercial calculation, how far it is desirable to finish on the machine, and when to deliver it into the hands of the artist, so as to secure the greatest economy. This depends in a great measure on the hardness of the material; rosewood, ebony, box, ivory, and statuary marble, should be wrought very nearly to a finish; but lime, deal, and other soft woods should only be roughly pointed.

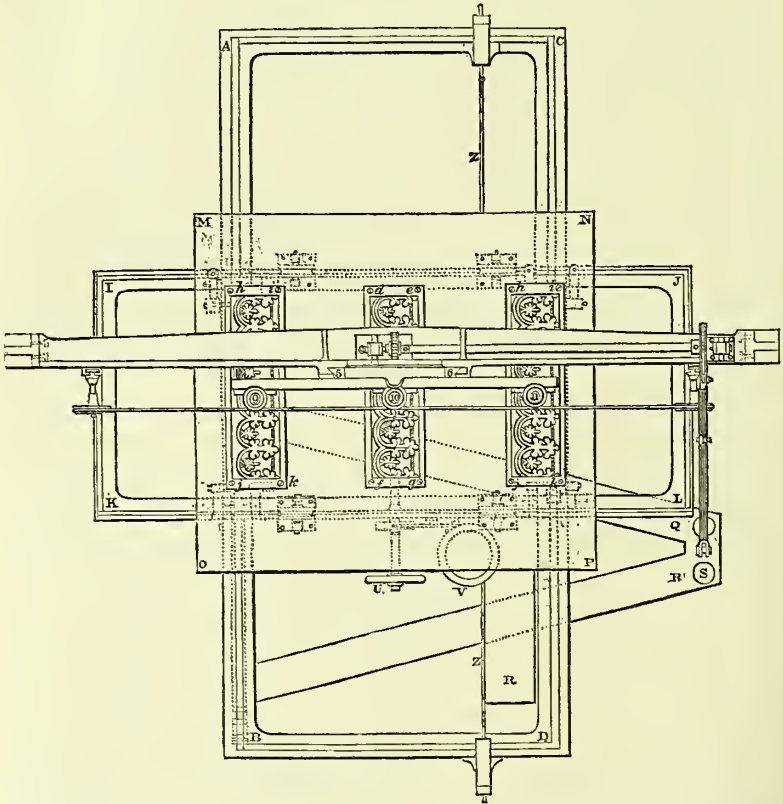

Fig. 436 is a plan of the machine, *fig. 437* a front elevation, and *fig. 438* a side elevation. The same letters indicate the same parts in all the figures. The carving machine consists of two distinct parts, each having its own peculiar motions quite independent of the other, but each capable of acting simultaneously and in unison with the other. The first, or horizontal part, is the bed plate, 'floating-table,' &c., on which the pattern and work are fixed; all the motions of this part are horizontal. The second, or vertical part, is that which carries the cutters and tracer, the only motion of which, except the revolution of the tools, is vertical.

The horizontal part consists of three castings: The bed plate A, B, C, D, which is a railway supported on piers from the floor and fixed strictly level. The carrying frame, I, J, K, L, mounted on wheels and travelling on the bed plate (the long sides of this frame are planed into (v) rails), and the 'floating-table,' M, N, O, P, which is also mounted on wheels to travel on the rails of the carrying frame. It is called the 'floating-table' because it can be moved in any horizontal direction with almost as

much facility as if it were a floating body. Primarily this table has two straight-lined motions at right angles to each other, but by combination of these it may move over any figure in a horizontal plane; and because this is accomplished without angular motion about a centre, every point in the surface of the table moves through the same figure at the same time; hence the power of producing many copies of a pattern simultaneously.

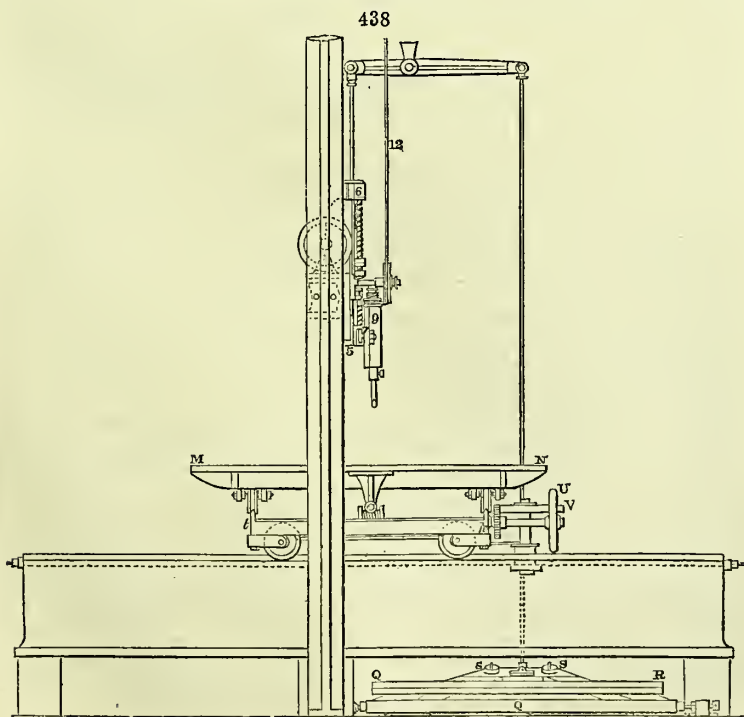

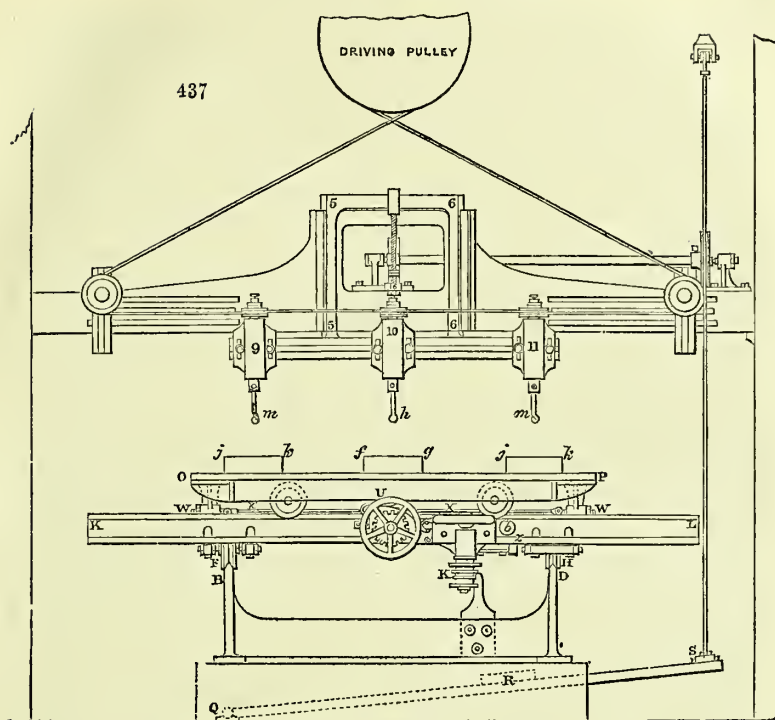

The second, or vertical part of the machine, is a cast-iron bridge supported on columns across the centre of the bed plate; on the centre of this bridge piece is a wide vertical slide, 5, 6, with a (τ) slotted bar on its lower edge; to this bar the mandril heads or tool holders, 9, 10, 11, are bolted, at such distances apart as suit the width of the work in hand, and in such numbers as it is convenient to work at one time. If the framing of the machine is massive and well fixed, six or eight narrow pieces may be carved at once; but if the width of the work is equal to half that of the table,

436

only one can be done, as in that case half the table is required for the pattern. The motion of the vertical slide is governed by the workman's foot on the treadle, r, q, s ; at s balance-weights are placed, so as to adjust the force with which the tools will descend on the work; any pressure on the foot-board r lifts the slide, and with it the tools and tracing point.

Returning to the horizontal part of the machine, d, e, f, g , is the pattern or original carving which is to be copied, and h, i, j, k , two copies in progress. The movements of the floating table are managed by the workman with the hand-wheels v, ν ; the left hand, on ν , directs the lateral motion on the frame, and the right, on v , directs the longitudinal motion on the bed plate; the left-hand movement is communicated by the cord x, x , which is fixed to brackets w, w , underneath the table, and makes one turn round a small pulley on the axis of the wheel ν . The right-hand movement is communicated by the cord z , which is fastened to each end of the bed plate, and makes one or two turns round the pulley k . When at work, the man stands inside

the frame of the bed plate, with his right foot on the board *n* and his hands on the steering wheels; on releasing the pressure of the foot the vertical slide descends by its unbalanced weight until the tracer *h* comes in contact with the pattern; the centers *m, m*, are made to revolve by steam-power at the rate of seven thousand times per minute, and are so shaped as to cut like a revolving gouge, so that they instantly cut away all the superfluous material they come in contact with; and, by the time the tracer has been brought over every part of the pattern, the pieces *h, i, j, k* will have become exact copies of it.

So far as panel carving is concerned the whole machine has been described; but it is requisite to elaborate its construction a little more for the purpose of carving on the round, and copying subjects which require the blocks to be cut into in all possible directions. Various modifications have been used, but we shall only explain that which we think best adapted to ornamental carving. It is not requisite that we should go into the various applications of this machine, to the manufacture of printing blocks, ships' blocks, gunstocks, letter cutting, tool handling, cabinet shaping, &c. &c., all of which have been shown from time to time to be within its power; nor is it requisite to describe more recent inventions founded on it, as they will more properly come under other heads.

When the machine is intended to copy any form which can be carved by hand, the floating table is differently constructed, but all other parts remain as before. In the floating table used for this purpose, there is an opening in the centre of the table, and a turning plate, which is mounted a few inches above the level of the table, to turn in bearings in standards. Underneath the turning plate, and forming a part of it, there is an arc of rather more than half a circle, having its centre in the axis on which the plate turns, and this arc is cogged on its edge to fit the threads of the tangent screw on the axis of the wheel, so that by turning this wheel, and dropping its detent into any cog, the workman can fix the plate at any angle with the horizon. There are three chucks fitted into sockets of the turn plate, and these are similarly divided on their edges by holes or cogs, into which detents fall, so as to secure them steadily in any required position.

In going through the process the workman will, of course, attack the work when it is placed in a favourable position for the tools to reach a large portion of its surface: and having completed as much as possible on that face, he would turn all the chucks through the same number of divisions; the pattern and work will still have the same relative position to each other as before, but an entirely new face of both will be presented to the tools; this will be carved in like manner, and then another similar change made, and so on until all has been completed which can be reached without changing the angular position of the turning plate. This can be done by the wheel, and when a sufficient number of these changes have been gone through, the work will be complete on every face, although the block may have required to be pierced through in fifty different directions.—T. B. J.

Notwithstanding the remarkable ingenuity displayed in the construction of this carving machine, it has not been so largely used as might have been expected. In all cases where repetitions are required its advantages are obvious, yet prejudice appears to have stood in the way of its general adoption.

CASCALHO. After the first washing of sand for gold there is a deposit left, and this, in Brazil, is called *Cascalho*. The name is also given to the alluvial soil in which Brazil diamonds are found.

CASCARILLA BARK. (Spanish, *Cascara*, bark.) The bark of *Croton eleutheria* and *C. cascarilla*, both of which shrubs grow in the West Indies. The bark possessing tonic properties is used medicinally.

CASE-HARDENING is the name of the process by which iron tools, keys, &c., have their surfaces converted into steel.

Steel when very hard is brittle, and iron alone is for many purposes, as for fine keys, far too soft. It is therefore an important desideratum to combine the hardness of a steely surface with the toughness of an iron body. These requisites are united by the process of case-hardening, which does not differ from the making of steel, except in the shorter duration of the process. The property of hardening is not possessed by pure malleable iron; but by a partial process of cementation the iron is converted externally into steel, and is subsequently hardened to that particular depth. Tools, utensils, or ornaments, intended to be polished, are first manufactured in iron, and nearly finished, after which they are put into an iron box, together with vegetable or animal charcoal in powder, and cemented for a certain time. This treatment converts the external part into a coating of steel, which is usually very thin, because the time allowed for the cementation is much shorter than when the whole mass is to be converted into steel. Immersion of the heated pieces in water hardens the surface, which is afterwards polished by the usual methods.

When the case-hardening is required to terminate at any particular part, as a shoulder, the object is left with a band or projection; the work is allowed to cool without being immersed in water; the band is turned off, and the work, when hardened in the open fire, is only effected as far as the original cemented surface remains. This ingenious method was introduced by Mr. Roberts, of Manchester, who considers the success of the case-hardening process to depend on the gentle application of the heat; and that, by proper management not to overheat the work, it may be made to penetrate three-eighths of an inch in four or five hours.—*Holtzapffel*.

The application of prussiate (ferrocyanide) of potash to this purpose is a very interesting chemical problem. The piece of iron, after being polished, is to be made brightly red-hot, and then rubbed or sprinkled over with the above salt in fine powder, upon the part intended to be hardened. The prussiate being decomposed, and apparently dissipated, the iron is to be quenched in cold water. If the process has been well managed, the surface of the metal will have become so hard as to resist the file. It has been proposed to smear over the surface of the iron with loam made into a thin paste with a strong solution of the prussiate, to dry it slowly, then expose the whole to a nearly white heat, and finally plunge the whole into cold water, when the heat has fallen to dull redness. See STEEL.

CASEIN (from *Caseus*, the Latin name for cheese). The principal part of the nitrogenised matters contained in the milk of mammiferous animals is *casein*. It forms the greatest part of cheese. It is coagulated by acids, but not by heat—in this it differs from either fibrine or albumen; it is also coagulated by rennet as in the *curding* of milk. See Watts's 'Dictionary of Chemistry.' See RENNET.

Casein is used by the calico-printer as a mordant. With lime it forms a good cement, and with borax it has been used as a substitute for glue.

CASHEW NUT. The fruit of the *Anacardium occidentale* of the West Indies. See ANACARDIUM NUT.

CASHMERE or **CACHEMERE**, a peculiar textile fabric first imported from the kingdom of Cashmere (Kashmir), and now well imitated in France and Great Britain. The material of the Cashmere shawls is the downy wool found about the roots of the hair of the Thibet goat. The Oriental Cashmere shawls are woven by processes extremely slow and consequently costly, whence their prices are very high.

Prices of Cashmere shawls of various sorts kindly given by a gentleman who has resided at Cashmere for many years:—

	£	£ s.
1. Plain pashmina, ¹ 6 ft. square	from 3	to 4 10
2. Pashmina, deeply embroidered	„ 7	„ 9 0
3. Doshala, or long and wide scarf of pashmina, with shawl-work at the edges and ends, as worn by the natives	„ 10	„ 30 0
4. Square shawl (loom-made), 6 ft. square	„ 30	„ 60 0
5. Long shawl (loom-made)	„ 50	„ 120 0

It is 4 and 5 that are the Cashmere shawls proper; the most usual article in the European market is a long shawl costing 60% or 70% in Cashmere.

Finer sorts are made occasionally (as by order of the Maharaja for presents to the Queen), whose value is as much as 300%.

The finest ever made was presented by the Maharaja to the Duke of Edinburgh at Lahore. The Duke would not receive it for himself, but for the Queen. The value of this was at least as much as 600%.

By the aid of the draw-loom, and still better of the Jacquard loom, M. Ternaux first succeeded in weaving Cashmere shawls perfectly similar to the Oriental in external aspect, which became fashionable under the name of French Cashmere. But to construct shawls altogether identical on both sides with the Eastern was a more difficult task, which was accomplished only at a later period by M. Bauson, of Paris.

The year 1819 is remarkable in the history of French husbandry for the acquisition of the Cashmere goat, imported from the East under the auspices of their government, by the indefatigable courage and zeal of M. Jaubert, who encountered every fatigue and danger to enrich his country with these valuable animals, aided by the patriotism of M. Ternaux, who first planned this importation, and furnished funds for executing it, at his own expense and responsibility. He placed a portion of the flock brought by M. Jaubert at his villa of St. Ouen, near Paris, where the climate seemed to be very favourable to them, since for several successive years after their introduction M. Ternaux was enabled to sell a great number of both male and female goats. The quantity of fine fleece or down afforded by each animal annually is from a pound and a half to two pounds.

The wool imported into Europe comes by the way of Casan, the capital of a government of the Russian empire upon the eastern bank of the Volga; it has naturally a greyish colour, but is easily bleached. Its price at Paris is about 6s. the pound

¹ *Pashmina* is a general name for the fabric made of *pashm*, or the under-wool of the shawl-goat.

avoirdupois. The waste in picking, carding, and spinning, amounts to about one-third of its weight.

The mills for spinning Cashmere wools have multiplied very much of late years in France, and the prices of the yarn have fallen by from 25 to 30 per cent., notwithstanding their improved fineness and quality.

In both modes of manufacture, the piece is mounted by 'reading-in' the warp for the different leaves of the heddles, as is commonly practised for warps in the Jacquard looms. The weaving of imitation shawls is executed, as usual, by as many shuttles as there are colours in the design, and which are thrown across the warp in the order established by the 'reader.' The greatest number of these weft yarns being introduced only at intervals into the web, when the composition of the shawl requires it, they remain floating loose at the back of the piece and are cut afterwards, without affecting in the least the quality of the texture; but there is considerable waste of stuff in the weaving, which is worked up into carpets.

The weaving of the imitation of real Cashmere shawls is different from the above. The yarns intended to form the weft are not only equal in number to that of the colour of the pattern to be imitated, but, besides this, as many little shuttles or pirns (like those used by embroiderers) are filled with these yarns as there are to be colours repeated in the breadth of the piece; which renders their number considerable when the pattern is somewhat complicated and loaded with colours. Each of these small bobbins or shuttles passes through only that portion of the flower in which the colour of its yarn is to appear, and stops at the one side and the other of the cloth exactly at its limit; it then returns upon itself after having crossed the thread of the adjoining shuttle. From this reciprocal intertexture of all the yarns of the shuttles, it results that although the weft is composed of a great many different threads, they no less constitute a continuous line in the whole breadth of the web, upon which the lay or batten acts in the ordinary way. We see, therefore, that the whole art of manufacturing this Cashmere cloth consists in avoiding the confusion of the shuttles, and in not striking up the lay till all have fulfilled their function.

In the Oriental process, all the figures in relief are made simply with a slender pirn without the shuttle used in European weaving. By the Indians the flower and its ground are made with the pirn, by means of an intertwisting, which renders them in some measure independent of the warp. In the Lyons imitation of this style, the leaves of the heddles lift the yarns of the warp, the needles embroider as in lappet weaving, and the flower is united to the warp by the weft thrown across the piece.

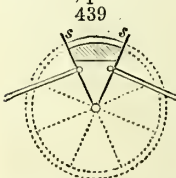

Paris manufactures the French Cashmere, properly so called, of which both the warp and the weft are the yarn of pure Cashmere down. This web represents with fidelity the figures and the shades of colour of the Indian shawl, which it copies; the deception would be complete if the reverse of the piece did not show the cut ends. The Hindoo shawl, as woven at Paris, has its warp in spun silk, which reduces its price without much impairing its beauty.

Lyons, however, has made the greatest progress in the manufacture of shawls. It excels particularly in the texture of its Thibet shawls, the weft of which is yarn spun with a mixture of wool and spun silk.

Nîmes is remarkable for the low price of its shawls, in which spun silk, Thibet down, and cotton, are all worked up together.

It appears that M. J. Girard at Sèvres, near Paris, has succeeded best in producing Cashmere shawls equal in stuff and style of work to the Oriental, and at a lower price. They have this advantage over the Indian shawls, that they are woven without seams, in a single piece, and exhibit all the variety and the raised effect of the Eastern colours. Women and children alone are employed in his factory. See INDIA SHAWLS.

CASK. (*Tonneau*, Fr.; *Fass*, Ger.) Much ingenuity has been displayed in cutting the curvilinear and bevelled edges of the staves of casks by circular saws. Sir John Robinson proposed many years back that the stave should be bent to its true curve against a curved bed, and that while thus restrained, its edges should be cut by two saws *s s*, placed in radii to the circle, the true direction of the joint as shown by the dotted circle *fig. 439*, representing the head of the cask. Mr. Samuel Brown obtained a patent in November 1825, for certain improvements in the machinery for making casks. His mechanism consists in the first place of a circular saw attached to a bench, with a sliding rest, upon which rest, each piece of wood intended to form a stave of a cask is fixed; and the rest being then slid forward in a curved direction, by the assistance of an adjustable guide, brings the piece of wood against the edge of the rotatory saw, and causes it to be cut into the curved shape required for the edge of the stave. The second feature is an apparatus with cutters attached to a standard, and traversing round with their carrier upon a centre, by means of which

the upper and lower edges of the cask are cut round and grooved, called chining, for the purpose of receiving the heads. Thirdly, an apparatus not very dissimilar to the last, by which the straight pieces of wood designed for the heads of the casks are held together, and cut to the circular figure required, and also the bevelled edges produced. And fourthly, a machine in which the cask is made to revolve upon an axis, and the cutting tool to traverse for the purpose of shaving the external part of the cask, and bringing it to a smooth surface.

The pieces of wood intended to form the staves of the cask having been cut to their required length and breadth, are placed upon the slide-rest of the first mentioned machine, and confined by cramps; and the guide, which is a flexible bar, having been previously bent to the intended curve of the stave and fixed in that form, the rest is slid forward upon the bench by the hand of the workman, which, as it advances (moving in a curved direction) brings the piece of wood against the edge of the revolving circular saw, by which it is cut to the curved shape desired.

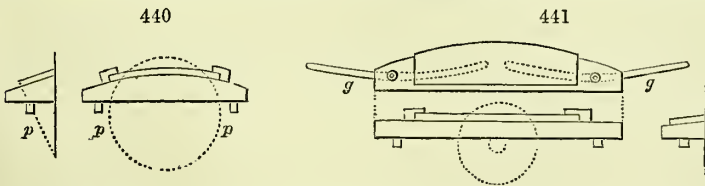

The guide is a long bar held by a series of moveable blocks fitted to the bench by screws, and is bent to any desired curve by shifting the screws; the edge of the slide-rests which hold the piece of wood about to be cut, runs against the long guide bar, and consequently is conducted in a corresponding curved course. The circular saw receives a rapid rotatory motion by means of a band of rigger from any first mover; and the piece of wood may be shifted laterally, by means of racks and pinions on the slide-rest, by the workmen turning a handle, which is occasionally necessary in order to bring the piece of wood up to, or away from, the saw.

The necessary number of staves being provided, they are then set round within a confined hoop at bottom, and brought into the form of a cask in the usual way, and braced by temporary hoops. The barrel part of the cask being thus prepared, in order to effect the chining, it is placed in a frame upon a platform, which is raised up by a treadle lever, so that the end of the barrel may meet the cutters in a sort of lathe above: the cutters are then made to traverse round within the head of the barrel, and, as they proceed, occasionally to expand, by which means the bevels and grooves are cut on the upper edge of the barrel, which is called chining. The barrel being now reversed, the same apparatus is brought to act against the other end, which becomes chined in like manner.

The pieces of wood intended to form the heads of the cask are now to be cut straight by a circular saw in a machine similar to the first described; but, in the present instance, the slide-rest is to move forward in a straight course. After their straight edges are thus produced, they are to be placed side by side, and confined, when a scribing cutter is made to traverse round, and cut the pieces collectively into the circular form desired for heading the cask.

The cask having now been made up, and headed by hand as usual, is placed between centres, or upon an axle in a machine, and turned round by a rigger or band with a shaving cutter sliding along the bar above it, which cutter, being made to advance and recede as it slides along, shaves the outer part of the cask to a smooth surface.

Mr. Smart cuts the edges of thin staves for small casks on the ordinary saw-bench, by fixing the thin wood by two staples or hooks to a curved block, the lower face of which is bevelled to give the proper chamfer to the edges, *fig.* 440. One edge having

been cut, the stave is released, changed end for end, and refixed against two pins, which determine the position for cutting the second edge, and make the staves of one common width. The curved and bevelled block is guided by two pins *p p*, which enter a straight groove in the bench parallel with the saws. This mode of bending is from various reasons found inapplicable to large staves, and these are cut, as shown in three views, *fig.* 441, whilst attached to a straight bed, the bottom of which is also bevelled to tilt the stave for chamfering the edge. To give the curve suitable to the edge, the two pins on the under side of the block run in two curved grooves *g g* in the saw-bench, which cause the staves to sweep past the saw in the arc of a very large circle, instead of in a right line, so that the ends are cut narrower than

the middle. Mr. Smart observes (*Trans. Soc. of Arts*, vol. xvii.) that in staves cut whilst straight, the edges become chamfered at the same angle throughout, which although theoretically wrong is sufficiently near for practice; the error is avoided when the staves are cut whilst bent to their true curvature.

The necessary flexibility which is required for bending the staves of casks is obtained by steaming them in suitable vessels in contact with rigid moulds. By Taylor's patent machinery for making casks, the blocks intended for the staves are cut out of white Canada oak, to the size of thirty inches by five, and smaller. They are well steamed and then sliced into pieces one-half or five-eighths of an inch thick, at the rate of 200 a minute, by a process far more rapid and economical than sawing, the instrument being a revolving iron plate, of 12 or 14 feet diameter, with two radial knives arranged somewhat like the irons of an ordinary plane or spoke-shave.

CASSAREEP or CASSIREEPE. The concentrated juice of the roots of the bitter cassava, flavoured by aromatics. It is used to flavour soups, and other dishes, and is the basis of the West-Indian dish *pepper-pot*. In French Guiana, the term *cabion* is applied to a similar condiment.—*Pereira*.

CASSAVA. (*Cassave*, Fr.; *Cassava*, Ger.) *Cassava*, or *Cassada Meal*, are names given to the starch of the root of the *Manihot utilissima*, prepared, in the following manner, in the West Indies, the tropical regions of America, and upon the African coast. The tree belongs to the natural family of the *Euphorbiaceæ*.

The roots are washed, and reduced to a pulp by means of a rasp or grater. The pulp is put into coarse strong canvas bags, and thus submitted to the action of a powerful press, by which it parts with most of its noxious juice (used by the Indians for poisoning the barbs of their arrows). As the active principle of this juice is volatile, it is easily dissipated by baking the squeezed cakes of pulp upon a plate of hot iron. Fifty pounds of the fresh juice, when distilled, afford, at first, 3 ounces of a poisonous water, possessing an intolerable offensive smell; of which 35 drops being administered to a slave convicted of the crime of poisoning, caused his death in the course of 6 minutes, amid horrible convulsions.¹

The pulp, dried in the manner above described, concretes into lumps, which become hard and friable as they cool. They are then broken into pieces, and laid out in the sun to dry. In this state they afford a wholesome nutriment, and are habitually used as such by the negroes, as also by many white people. These cakes constitute the only provisions laid in by the natives, in their voyages upon the Amazon. Boiled in water with a little beef or mutton, they form a kind of soup similar to that of rice.

The Cassava cakes sent to Europe are composed almost entirely of starch, along with a few fibres of the ligneous matter. It may be purified by diffusion through warm water, passing the milky mixture through a linen cloth, and evaporating the strained liquid over the fire, with constant agitation. The starch, dissolved by the heat, thickens as the water evaporates, but, on being stirred, it becomes granulated, and must be finally dried in a proper stove. Its specific gravity is 1.530—that of the other species of starch.

The product obtained by this treatment is known in commerce under the name of *tapioca*; and, being starch very nearly pure, is often prescribed by physicians as an aliment of easy digestion. A tolerably good imitation of it is made by heating, stirring, and drying potato-starch in a similar way.

The expressed juice of the root of manioc contains in suspension a very fine fecula, which it deposits slowly upon the bottom of the vessels. When freed by decantation from the supernatant liquor, washed several times and dried, it forms a beautiful starch, which creaks on pressure with the fingers. It is called *cipipa* in French Guiana; it is employed for many delicate articles of cookery, especially pastry, as also for hair-powder, starching linen, &c. This is imported into England from Rio Janeiro as Brazilian arrowroot.

Cassava flour, as imported, may be distinguished from arrowroot and other kinds of starch by the appearance of its particles viewed in a microscope. They are spherical, all about $\frac{1}{1000}$ th of an inch in diameter, and associated in groups; those of potato-starch are irregular ellipsoids, varying in size from $\frac{1}{300}$ th to $\frac{1}{3000}$ th of an inch; those of arrowroot have the same shape nearly, but vary in size from $\frac{1}{500}$ th to $\frac{1}{800}$ th of an inch; those of wheat are separate spheres, $\frac{1}{1000}$ th of an inch.

The empirical formula of Cassava starch is, $C^{12}H^{10}O_5$ ($C^6H^{10}O_5$), like the other starches.

Cassava has for some years been imported into France, from Martinique, as *la mous-sache* and *la cipipa*. See **TAPIOCA**.

¹ Memoir of Dr. Fermin, communicated to the Academy of Berlin, concerning experiments made at Cayenne, upon the juice of the Manioc.

CASELL YELLOW. An oxychloride of lead. It seems to be the same as *Patent Yellow* and *Turner's Yellow*. Cassell yellow may be prepared by melting together one part of sal-ammoniac with ten parts of massicot, minium, or white lead.

CASSELMANN'S GREEN. A fine green pigment, destitute of arsenic. It is a basic sulphate of copper, obtained by mixing together boiling solutions of sulphate of copper and an alkaline acetate.

CASSIA. (*Cinnamomum Cassia*.) A bark employed for flavouring. The cinnamon cassia is a native of China, and is cultivated in Java. It is imported from Singapore, Calcutta, Bombay, and Manila. This bark is imported principally for the sake of its essential oil, which it yields by distillation. One hundred pounds of good cassia bark will thus yield 12 oz. of essential oil of cassia. This oil is principally consumed in scenting what is called Brown Windsor Soap.

CASSIA BUDS. (*Flores cassiæ immature*.) The cassia buds and bark are both obtained from the same tree (*Reeves*). 'According to the latest observations which the elder Nees has made known, cassia buds are the calyces (*Fruchtkelche*) of *Cinnamomum aromaticum*, about $\frac{1}{4}$ th of their normal size. It is also said that they are collected from *Cinnamomum dulce* which is found in China.'—*Martins*, quoted by *Pereira*.

CASSIA FISTULA. The pudding pipe tree, or purging cassia. The pods of this tree are imported from Madras and Ceylon, from Barbadoes, and from Carthage and Savanilla.

CASSIE. The *Acacia Farnesiana* is grown extensively in the south of France for the sake of its fragrant flower balls: these are termed *Cassie*, and used in perfumery. The young plants are raised from seed in beds: in the third year they are planted out in fields and require for each tree about twelve square feet of land. When in maturity *Acacia Farnesiana* will yield flowers to the value of 30*l.* an acre.

CASSIS, the black currant (*Ribes nigra*, Linn.), which was formerly celebrated for its medicinal properties, with very little reason.

The only technical use to which it is now applied is in preparing the agreeable *liqueur* called *ratafia*, by the following French recipe: Stone and crush 3 pounds of black currants, adding to the magma 1 drachm of cloves, 5 drachms of cinnamon, 4 quarts of spirits of wine, at 98° Baumé, and 2½ pounds of sugar. Put the mixture into a bottle which is to be well corked; let it digest for a fortnight, shaking the bottle once daily during the first 8 days: then strain through a linen cloth, and finally pass through filtering paper.

CASSITERITE. Oxide of Tin; Stream Tin. Stream tin is the alluvial *débris* of tin veins. Cassiterite is one of the objectionable names, of which a very great number have been introduced into the science of Mineralogy. The names which are derived from districts or towns give no indication of the character of a mineral, and they indicate one locality only, for example, REDRUTHITE (*Copper glance*) is found in many other places beyond Redruth, and CASSITERITE, derived from the Cassiterides of the ancients, is used to designate a mineral which is found in all parts of the world. The confusion existing in mineralogical nomenclature is to be lamented. (See TIN ORE.)

CASSIUS, Purple powder of. A preparation used in the arts as a colour, chiefly for stained glass and porcelain. It is also employed in medicine by some French physicians, and has been prepared in the following manner:—10 parts of acid chloride of gold are dissolved in 2,000 parts of water. In another vessel, 10 parts of pure tin are dissolved in 10 parts of nitric acid mixed with 20 parts of hydrochloric acid, and this solution is diluted with 1,000 parts of distilled water. The solution of tin is added by degrees to that of the acid chloride of gold, so long as any precipitate results. This is allowed to subside; it is then washed, filtered, and dried at a very gentle heat. The tin salt above used contains both the protoxide and binoxide in certain proportions. The double compound of chloride of tin with sal-ammoniac, called the pink salt of tin, is the preferable form; as it is not altered by the atmosphere, is of definite composition, and when boiled with metallic tin it takes up just so much as will form the protochloride: 100 parts of pink salt require for this purpose 10·7 parts of metallic tin.

Professor Graham, in his 'Elements of Chemistry,' gives the following account of the Purple of Cassius, and of its preparation:—'When protochloride of tin is added to a dilute solution of gold, a purple powder falls. It is obtained of a finer tint when protochloride of tin is added to a solution of the sesquichloride of iron till the colour of the liquid takes a shade of green, and the liquid in that state added, drop by drop, to a solution of sesquichloride of gold, free from nitric acid, and very dilute. After 24 hours a brown powder is deposited, which is slightly transparent, and purple-red, by transmitted light: when dried and rubbed to powder, it is of a dull blue colour. Heated to redness it loses a little water, but no oxygen, and retains its former

appearance. If washed with ammonia, on the filter, while still moist, it dissolves, and a purple liquid passes, which rivals the hypermanganate of potash in beauty. . . . It may also be formed by fusing together 2 parts of gold, $3\frac{1}{2}$ parts of tin, and 15 parts of silver, under borax, to prevent the oxidation of the tin, and treating the alloy with nitric acid, to dissolve out the silver; a purple residue is left, containing the tin and gold that were employed.'

'Berzelius proposed the theory that the powder of Cassius may contain the true protoxide of gold combined with sesquioxide of tin, AuOSn^2O^3 , a kind of combination containing an association of three atoms of metal, which is exemplified in black oxide of iron, spinele, Franklinite, and other minerals. . . . A glance at its formula shows how readily the powder of Cassius, as thus represented, may pass into gold and binoxide of tin, $\text{AuOSn}^2\text{O}^3 = \text{Au} + 2\text{SnO}^2$.'—*Graham and Watts*.

CASTILE SOAP, or *Spanish Soap*, is prepared with olive oil and a solution of caustic soda. There are two varieties, the *white* and the *marbled*. The marbled appearance is produced in the soap, by adding, as soon as it is made and separated from the spent ley, a fresh quantity of ley, and immediately a solution of the protosulphate of iron. A precipitate of oxide of iron is at once formed, and this gives the dark coloured streaks to the soap. By exposure to the air these streaks become red, in consequence of the conversion of the black oxide of iron into the red or sesquioxide. See **SOAP**.

CAST-IRON. See **IRON**.

CAST-IRON SCOURING. Cast-iron surfaces are said to be easily scoured by adding a little of any kind of organic matter, such as glycerine, stearine, naphthaline, or creosote to dilute sulphuric acid; zinc and brass yield to the same method, with great economy of labour, time, and material.

CASTOR. A mineral occurring in Elba, associated with another species called Pollux. Castor is a silicate of alumina and lithia, closely related to, if not identical with, petalite.

CASTOR. The Beaver. See **FURS**.

CASTOR, or **CASTOREUM**. This name is given to a secretion of the Beaver (*Castor fiber*), contained in pear-shaped cellular organic sacs, placed near the genital organs of both the male and female animals. It is a substance analogous to civet and musk, of a consistence similar to that of thick honey. It has a bitter acrid taste; a powerful penetrating, fetid, and very volatile smell.

Several chemists, and in particular Bouillon, Lagrange, Laugier, and Hildebrandt have examined castor, and found it to be composed of a resin, a fatty substance, a volatile oil, an extractive matter, benzoic acid, and some salts.

The mode of preparing it is very simple. The sacs are cut off from the castors when they are killed, and are dried to prevent the skin being affected by the weather. In this state the interior substance is solid, of a dark colour, and a faint smell; it softens with heat, and becomes brittle by cold. Its fracture betrays fragments of membranes, indicating its organic structure. When chewed it adheres to the teeth somewhat like wax; it has a bitter, slightly acrid and nauseous taste.

The castor bags, as imported, are often joined in pairs by a kind of ligature. Sometimes the substance which constitutes their value is sophisticated; a portion of the castor being extracted, and replaced by lead, clay, gums, or some other foreign matters. This fraud may be easily detected, even when it exists in a small degree, by the absence of the membranous partitions in the interior of the bags, as well as by the altered smell and taste.

Castor is used to a small extent in medicine and in perfumery manufacture, the latter particularly when ambergris is scarce.

In English commerce, two varieties of American castor are made: one called the Hudson's Bay and the other the Canadian—though both are imported by the Hudson's Bay Company.

CASTORINE. A substance existing in castor. It is obtained by treating castor with hot alcohol, and filtering through a Platamour's ebullition funnel. On cooling, the alcohol deposits crystals of a fatty substance. The castorine is retained in the mother-liquor, and is procured by evaporation on the water-bath to a small bulk, and then setting aside to allow crystals to form. Castorine crystallises in needles possessing a slight odour of castoreum.—C.G.W.

CASTOR OIL. The expressed oil of the seeds of the *Palma Christi* or *Ricinus communis*, a native of the West Indies and South America; but which has been cultivated in France, Italy, and Spain.

In England the castor oil is expressed from the seeds by means of powerful hydraulic presses fixed in rooms artificially heated. It is purified by repose, decantation, and filtration, being bleached in pale-coloured Winchester quart bottles, which are exposed to light on the tops of houses.

CATALYSIS. A term introduced to denote the very peculiar phenomenon of one body establishing, by its mere presence, a like condition, in another body, to that which exists in itself. Thus a piece of meat undergoing the putrefactive fermentation, almost immediately sets up a similar action in fresh meat, or produces in a saccharine fluid that motion which is known as vinous fermentation. The action of the yeast plant,—a living organisation,—establishes an action throughout a large quantity of an infusion of malt,—*fermentation*, or that disturbance which leads to the conversion of sugar into alcohol. This catalytic power is ill understood, and we are content to hide the imperfection of our knowledge under a sounding name.

CATECHINE. *Catechuic Acid.* When *Gambir catechu* is treated with water an insoluble residue is left, which has been termed by Nees *resinous tannin*. Its composition is $C^{15}H^6O^6$ ($C^{15}H^{12}O^6$).

CATECHU. A Japanese term, from *cate* a tree, and *chu* juice. The term is applied to several astringent extracts made from the wood of several plants which grow in Bombay, Bengal, and other parts of India. The ordinary commercial catechu is prepared by boiling the chips of the interior of the trunk of the *Acacia Catechu* in water, evaporating the solution to the consistence of syrup over the fire, and then exposing it in the sun to harden. It occurs in commerce in flat rough cakes, and under two forms. The first, or the Bombay, is of uniform texture, of a dark red colour, and of specific gravity 1.39. The second is more friable and less solid. It has a chocolate colour, and is marked inside with red streaks. Its specific gravity is 1.28.

According to Sir H. Davy, the Bombay variety is richer in tannin than that from Bengal, the former containing 54.5, and the latter 41.5 in 100 parts.

Areca nuts are also found to yield catechu: and catechu is prepared from them in Ceylon, for which purpose they are cut into pieces, watered in an earthen pot with solution of nitre, and have a little of the bark of a species of *Mimosa* added to them. The liquor is then boiled with the nuts, and affords an inspissated decoction.

Good catechu is a brittle compact solid, of a dull fracture. It has no smell, but a very astringent taste. Water dissolves the whole of it, except the earthy matter, which is probably added during its preparation. Alcohol dissolves its tannin and extractive. The latter may be oxidised, and thus rendered insoluble in alcohol, by dissolving the catechu in water, exposing it for some time to a boiling heat, and evaporating to dryness.

The tannin of catechu differs from that of galls, in being soluble in alcohol, and more soluble in water. It precipitates iron of an olive colour, and gelatine in a mass which gradually becomes brown.

It has been long employed in India for tanning skins, where it is said to effect this object in five days. Sole-leather has been completely tanned by it in this country in ten days, the ox-hide having been made into a bag, with the hair outside, and kept filled with the solution of catechu. In India it has also been used to give a brown dye to cotton goods, and of late years it has been extensively introduced into the calico-print works of Europe. The salts of copper with sal-ammoniac cause it to give a *bronze colour* which is very permanent; the proto-muriate of tin, a *brownish yellow*; the per-chloride of tin, with the addition of nitrate of copper, a *deep bronze hue*; acetate of alumina alone, a *reddish brown*, and, with nitrate of copper, a *reddish-olive grey*; nitrate of iron, a *dark-brown grey*. For dyeing a golden coffee-brown, catechu has entirely superseded madder; one pound of it being equivalent to six pounds of this root.

According to Pereira, the varieties of Catechu commonly met with are:—

1. **GAMBER CATECHU** (*Catechu pallidum*) or Pale Catechu, imported under the name of *Gambir*, from Singapore and some of the neighbouring islands, where the *Uncaria Gambir* is cultivated, and an extract prepared from it. The chief use of this catechu is for tanning. In the trade it is distinguished from the black catechu and cutch by the name of *Terra Japonica*.

2. **BETEL-NUT CATECHU.** See BETEL-NUT.

3. **CUTCH.**—Catechu of the *Acacia Catechu* described above.

Bombay Catechu, named above, and examined by Davy, is obtained from the *Acacia Catechu*, and the Bengal Catechu, from the *Acacia (Mimosa) Catechu*.

NUBIAN CATECHU, another variety occasionally met with, is obtained from the fruits of gummy Acacias growing in Egypt and Nubia.

CATGUT. (*Corde à boyau*, Fr.; *Darmsaite*, Ger.) The name given to cords made of the twisted intestines of the sheep. The guts, being taken while warm out of the body of the animal, are to be cleared of feculent matter, freed from any adhering fat, and washed in a tub of water. The small ends of all the intestines are next to be tied together, and laid on the edge of the tub, while the body of them is left to steep in some water, frequently changed, during two days, in order to loosen the peritoneal

and mucous membranes. The bundle of intestines is then laid upon a sloping table which overhangs the tub, and their surface is scraped with the back of a knife, to try if the external membrane will come away freely in breadths of about half their circumference. This substance is called by the French manufacturers *filandre*, and the process *filer*. If we attempt to remove it by beginning at the large end of the intestine, we shall not succeed. This *filandre* is employed as thread to sew intestines, and to make the cords of rackets and battledores. The flayed guts are put again into fresh water, and after steeping a night, are taken out and scraped clean next day, on the wooden bench with the rounded back of a knife. This is called *curing the gut*. The large ends are now cut off, and sold to the pork-butchers. The intestines are again steeped for a night in fresh water, and the following day in an alkaline lixivium made by adding 4 ounces of potash, and as much pearlash, to a pail of water containing about 3 or 4 imperial gallons. This ley is poured in successive quantities upon the intestines, and poured off again, after 2 or 3 hours, till they are purified. They are now drawn several times through an open brass thimble, and pressed against it with the nail, in order to smooth and equalise their surface. They are lastly sorted, according to their sizes, to suit different purposes.

Whipcord is made from the above intestines, which are sewed together endwise by the *filandre*, each junction being cut aslant, so as to make it strong and smooth. The cord is put into the frame, and each end is twisted separately; for whipcord is seldom made out of two guts twisted together. When twisted, it is to be sulphured once or twice. It may also be dyed black with common ink, pink with red ink, which sulphurous acid changes to pink, and green with a green dye which the colour-dealers sell for the purpose. The guts take the dyes readily. After being well smoothed, the cord is to be dried, and coiled up for sale.

Hatters' Cord for Bowstrings.—The longest and largest intestines of sheep, after being properly treated with the potash, are to be twisted 4, 6, 8, 10, or 12 together, according to the intended size of the seams, which is usually made from 15 to 25 feet long. This cord must be free from cords and knots. When half dry, it must be exposed twice to the fumes of burning sulphur; and, after each operation, it is to be well stretched and smoothed: it should be finally dried in a state of tension.

Clockmakers' Cord.—This cord should be extremely thin, and be therefore made from very small intestines, or from intestines slit up in their length by a knife fitted for the purpose, being a kind of lancet surmounted with a ball of lead or wood. The wet gut is strained over the ball which guides the knife, and the two sections fall down into a vessel placed beneath. Each hand pulls a section. Clockmakers also make use of stronger cords made of two or more guts twisted together.

Fiddle and Harp Strings.—These require the greatest care and dexterity on the part of the workmen. The treble strings are peculiarly difficult to make, and are made at Naples, probably because the Neapolitan sheep, from their small size and leanness, afford the best raw material.

The first scraping of the guts intended for fiddle-strings must be very carefully performed; and the alkaline leys being clarified with a little alum, are added, in a progressively stronger state from day to day, during 4 or 5 days, till the guts are well bleached and swollen. They must then be passed through the thimble, and again cleansed with the lixivium; after which they are washed, spun, or twisted and sulphured during two hours. They are finally polished by friction, and dried. Sometimes they are sulphured twice or thrice before being dried, and are polished between horsehair cords.

It has been long a subject of complaint, as well as a serious inconvenience to musicians, that catgut strings cannot be made in England of the same goodness and strength as those imported from Italy. These are made of the peritoneal covering of the intestines of the sheep; and, in this country, they are manufactured—at White-chapel, and probably elsewhere,—in considerable quantity; the consumption of them for harps, as well as for the instruments of the violin family, being very great. Their chief fault is weakness; whence it is difficult to bring the smaller ones, required for the higher notes, to concert-pitch; maintaining at the same time, in their form and construction, that tenuity or smallness of diameter which is required to produce a brilliant and clear tone.

The inconvenience arising from their breaking when in use, and the expense in the case of harps, where so many are required, are such as to render it highly desirable to improve a manufacture which, to many individuals may, however, appear sufficiently contemptible.

It is well known to physiologists, that the membranes of lean animals are far more tough than those of animals which are fat or in high condition; and there is no reason to doubt that the superiority of the Italian strings arises from the state of the sheep in that country. In London, where no lean animals are slaughtered, and where, indeed,

an extravagant and useless degree of fattening, at least for the purpose of food, is given to sheep in particular, it is easy to comprehend why their membranes can never afford a material of the requisite tenacity. It is less easy to suggest an adequate remedy; but a knowledge of the general principle, should this notice meet the eyes of those interested in the subject, may at least serve the purpose of diminishing the evil and improving the manufacture, by inducing them to choose in the market the offal of such carcases as appear least overburthened with fat. It is probable that such a manufacture might be advantageously established in those parts of the country where the fashion has not, as in London, led to the use of meat so much overfed; and it is equally likely, that in the choice of sheep for this purpose, advantage would arise from using the Welsh, the Highland, or the Southdown breeds, in preference to those which, like the Lincoln, are prone to excessive accumulation of fat. It is equally probable that sheep dying of some of the diseases accompanied by emaciation, would be peculiarly adapted to this purpose.

That these suggestions are not merely speculative is proved by comparing the strength of the membranes in question, or that of the other membranous parts, in the unfattened Highland sheep, with that of those found in the London markets.

CATHARTINE. A bitter, non-azotised, purgative substance found in senna. Its formula is not known. To prepare it, an alcoholic extract of senna leaves is to be evaporated to dryness, and then treated with water as long as anything is dissolved. The aqueous solution contains the cathartine mixed with several impurities. A considerable amount of the latter may be got rid of by adding a solution of acetate of lead as long as a precipitate is formed, and then filtering through a calico bag.

CATLINITE. A clay-stone so called after Catlin the American traveller. It is carved into tobacco pipes by the North American Indians.

CAT'S EYE. A translucent quartz, presenting peculiar internal reflections. This effect is said to be owing to filaments of asbestos. When cut *en cabochon*, it is esteemed as an ornamental stone. This quartzose cat's-eye comes chiefly from Ceylon. A brown variety from South Africa, consists of fibrous quartz pseudomorphous after the mineral called crocidolite.

The *Oriental Cat's-eye* is a fibrous variety of Chrysoberyl. See CYMOPHANE.

CAT'S-EYE RESIN. See DAMMAR.

CATSUP. A name given by Dr. Kitchiner to Ketchup. See KETCHUP.

CATTEMUNDOO. A name given to an elastic gum or hydro-carbon obtained from some species of plants in India.

CAUNTER LODE. A mining term. See MINING.

CAUSTIC. Any chemical substance corrosive of the skin and flesh; as potash called common caustic,—and nitrate of silver, called lunar caustic, by surgeons.

CAVIARE. The salted roe of certain species of fish, especially the sturgeon. This product forms a considerable article of trade, being exported annually from the town of Astrakhan alone, upon the shores of the Caspian Sea, to the amount of several hundred tons. The Italians first introduced it into Eastern Europe from Constantinople, under the name of *caviale*. Russia has now monopolised this branch of commerce. It is prepared in the following manner:—

The female sturgeon is gutted; the roe is separated from the other parts, and cleaned by passing it through a very fine sieve, by rubbing it into a pulp between the hands: this is afterwards thrown into tubs, with the addition of a considerable quantity of salt; the whole is then well stirred, and set aside in a warm apartment. There is another sort of caviare,—the compressed—in which the roe, after having been cured in strong brine, is dried in the sun, then put into a cask, and subjected to strong pressure.

CAWK. The English miner's name for massive sulphate of baryta, or heavy spar.

CAYENNE PEPPER. The powdered fruit of several species of Capsicum.

CEDAR. (*Cedre*, Fr.; *Ceder*, Ger.) The cedar of Lebanon, or great cedar (*Pinus cedrus*), is a cone-bearing tree. This tree has been famous since the days of Solomon, who used it in the construction of the Temple. The wood has been obtained from Crete and Africa.

Specimens have also been procured from Morocco, showing the probability that the range of the tree not only extends over the whole group of mountains which is situate between Damascus and Tripoli, and which includes the Libanus and Mounts Amanus and Taurus of antiquity, and various others,—but that its distribution on the mountainous regions of North Africa is extensive.

Indeed, if we are to suppose that the cedar and the cedar wood mentioned by many of the ancient writers referred exclusively to the Lebanon species, we must believe that its distribution at one period extended over countries where no trace of its having existed now remains. Egypt, Crete, and Cyprus are mentioned by Pliny

and Theophrastus as native habitats of the *Cedrus*; we may thus fairly infer that the *Cedrus* of the ancients as frequently had reference to the other *Coniferae* as to the Lebanon species.

The pencil cedar is the *Juniperus Virginiana*. It is imported from America in pieces from 6 to 10 inches square. The grain of the wood is remarkably regular and soft, on which account principally it is used for the manufacture of pencils, and from its agreeable scent for the inside of small cabinets; it is also made into matches for the drawing-room.

The general use of the cedar wood dates from the highest antiquity. Pliny makes mention of cedar wood and the uses to which it was applied, and cites, as examples of its durability and imperishable nature, the timber of a temple of Apollo at Utica, in Africa, which, was nearly 2,000 years old, was found to be perfectly sound,—and the famous statue of Diana in the temple of Saguntum in Spain. Cedria, an oil or resin extracted from a cedar, was also, according to Vitruvius, used to smear over the leaves of the papyrus to prevent the attacks of worms; and Pliny states that the Egyptians applied it with other drugs in the preparation of their mummies; but whether this extract was obtained from the Lebanon cedar or from trees belonging to the genus *Cupressus* or *Juniperus*, which also afford odoriferous resins, it is now impossible to ascertain.

In regard to the cedar and cedar wood mentioned in profane history, it is difficult, from what we have already stated, to determine what has reference to the true cedar, and what belongs to other coniferous species; all that we can know for certainty is that a wood called cedar, distinguished for its incorruptible nature, was frequently used for purposes most important in the eyes of the pagan, viz., in the building and decoration of their temples, and for the statues or images of their heroes and gods.

The peculiar balsamic odour of cedar has long been held as a means to preserve articles from the attacks of insects; chips and shavings of the wood have been in this way kept in collections of linen, papers, and objects of preservation. Cabinets have been recommended, or at least the drawers and fittings, to be made of cedar. It may be useful to call attention to some facts when cedar is employed as a means of preservation.

That the odoriferous substance when diffused may affect some forms of organic life, is not disputed, but it is as probable some of the effect may be due to covering the insect with a coating of varnish, alike irritating and interfering with the texture of the surfaces of the body; but the rule cannot be general; if the creatures have a sufficient hardihood they may, and indeed do, attack the wood itself.

The following cases will show that the substances emanating from cedar may produce unexpected interference. Mr. Vulliamy states that George III. had a cabinet in the observatory at Kew with drawers of cedar wood in them; watches were placed with the intention of keeping them going. In a short time they all came to rest; the experiment, however, repeated had the same result: on examination, the oil used in different parts of the watches was found to be completely changed into a substance like gum. Mr. Farey's observations, also communicated to the Institution of Civil Engineers, still more show the extraordinary atmosphere produced in close cabinets of cedar wood, and of the effects upon delicate objects. The late Mr. Smith of Derby having shown him a small collection of minerals which have been locked up in closely-fitted drawers of cedar wood; on opening the drawers for the first time after some months, the minerals were found to be covered with a gummy matter having the strong odour of cedar, and troublesome to remove; the bright surface of the crystals appeared as if varnished in an unskilful manner. The cedar had given off a vapour that had condensed on all the minerals, and the same effect might be expected to be produced upon watches, metals, and other substances.

White cedar is a native of North America, China, and Cochin China; in the United States it occupies large tracts, denominated *cedar swamps*. The wood is soft, smooth, and of the aromatic smell, and internally of a red colour, permanent in shape, very durable, and is esteemed as a material for fences. Large quantities of shingles are made of it; it is a favourite material for wooden wares or the nicer kinds of cooper's work.

Colonel Lloyd, speaking of another species of cedar, the *Juniperus Bermudiana*, says, 'Up to this time there are great quantities of the finest cedar growing in the British island of Bermuda, and the best ships and schooners are always built of it; it is imperishable.'

The cedar known to cabinet makers as the Havannah cedar is the wood of the *Cedrela odorata* of Linnæus, and belongs to the same natural order as mahogany. All the cigar boxes from Havannah are made of this kind of cedar; it is imported from the island of Cuba, and is used for the insides of drawers and wardrobes.

New South Wales produces a cedar, *Cedrela Toona*, somewhat similar to the Havana, but more red in colour.

A similar kind is found in the East Indies; the Himalayan cedar, *Juniperus excelsa*, is harder and less odoriferous than the pencil cedar.

In the 'Sketch of the Route and Progress of Lieutenant A. Burnes and Dr. Gerard, by a recent traveller' ('Journal of Asiatic Society of Bengal,' Calcutta, vol. i., 1832), in their adventurous journey to explore the Oxus, it is stated:—

'While on the banks of the Jelum they were much struck by the immense size of the firs floating down the river. The houses in all the towns along its banks are roofed therewith.

'Immense cedar trees were seen rolled down from the hills; it was these which supplied materials for Alexander's fleet. One tree measured 13 feet in girth, which may afford some idea of their applicability.'

There is much confusion in the application of the term Cedar, several trees which are not cedars being so called.

The cedar of Lebanon is usually called *Pinus cedrus*, but sometimes *Cedrus Libanus*. The lofty *deodara*, a native of the Himalayas, with fragrant and almost imperishable wood, and often called the Indian cedar, is sometimes referred to the genus *Pinus*, and sometimes to that of *Cedrus* or *Larix*, with the specific name of *deodara*.

The wood of several coniferæ is, however, called cedar. The wood of *Juniperus Virginiana* is known as the red or pencil cedar, and that of *J. Bermudiana* is called Bermuda cedar; that of *J. Barbadosensis* forms Barbadoes cedar, while the juniper of the north of Spain and south of France and of the Levant is called *J. oxycedrus*. The white cedar of North America, a less valuable wood than the red cedar, is yielded by *Cupressus thyoides*, and the cedar wood of Japan, according to Thunberg, is a species of cypress.

The name cedar is, however, applied to a number of woods in our different colonies which are in no way related to the coniferæ; thus, the cedar of Guiana is the wood of *Icica altissima*; the white wood or white cedar of Jamaica is *Bignonia leucoxylon*; and bastard cedar is *Guazuma ulmifolia*. In New South Wales, again, the term white cedar is applied to *Melia azedarach*, and red cedar, to the *Flindersia australis*, as well as to the wood ton tree, or *Cedrela Toona*.

Cedar wood yields a very fine essential oil by distillation, in the proportion of about 15 oz. to every hundred pounds weight of wood. The perfumery-makers find a considerable use for essential oil of cedar. It is now known that all the odoriferous woods, such as sandal wood, myall wood, rose wood, yield their perfumes at the ordinary temperature. If these woods in chips be put into a glass jar for a year the interior will be coated with a heavy dew of perfume.

CEDAR GUM. A gum used for many medicinal purposes, obtained from the branches and cones of the *Widdingtonia juniperoides*.

CEDRA (*Cédrat*, Fr.) is the fruit of a species of orange, citron, or lemon, a tree which bears the same name. Its peel is very thick, and covered with an epidermis which encloses a very fragrant and highly-prized essential oil. The preserves flavoured with it are very agreeable. The citrons are cut into quarters for the dry comfits, but are put whole into the liquid ones. The liquorist-perfumer makes with the peel of the *cedra* an excellent *liqueur*; for which purpose, he plucks them before they are quite ripe; grates down the peel into a little brandy, or cuts them into slices, and infuses these in the spirits. This infusion is distilled for making perfume; but the flavour is better when the infusion itself is used. See PERFUMERY.

CEDRON. *Simaba Cedron*. A tree which grows in the hottest parts of New Granada. It yields to alcohol a crystallisable substance—*cedrin*. It has an intensely and persistently bitter taste.

CELESTINE or CELESTITE. (*Célestine*, Fr.; *Cölestin*, Ger.) Native sulphate of strontia, $\text{SrO} \cdot \text{SO}^3$ (SrSO^4). This mineral occurs in prismatic or tabular crystals belonging to the rhombic system, and often resembling those of sulphate of baryta. In other physical characters, also, the two species are likely to be confounded. Density, if carefully determined, affords a fair means of discrimination, though the difference is not very striking; the specific weight of celestine never rises above 4, whilst that of barytes is about 4.5. Blowpipe reactions offer better-marked means of distinction; celestine imparting to the flame a crimson-red colour characteristic of all strontia-compounds, whilst barytes colours the flame yellowish-green.

The name *Celestine* (from *caelestis*, 'sky-blue') has reference to the pale blue tint which the mineral frequently presents; in some cases this has been referred to the presence of a trace of phosphate of iron. It should be remembered, however, that this colour is neither a necessary characteristic nor a sufficient means of diagnosis; many of the finest specimens of celestine being colourless, whilst a blue colour, equally pronounced with that of the most typical celestine, is occasionally presented by crystals of barytes.

Celestine occurs in fine crystals, associated with sulphur and gypsum, at Girgenti in Sicily; and is also found under like circumstances at Conil in Spain. With rock-salt and gypsum, it is found at Bex in Switzerland, and at Ischl in the Salzkammergut. It occurs abundantly, also with gypsum, in the New Red marls in the neighbourhood of Bristol; it is found in nummulitic limestone (Eocene) at Mokattam, near Cairo; and in Trenton limestone (Lower Silurian), at Strontian Island and elsewhere on Lake Huron. It is recorded from the eruptive rocks of Calton Hill, Edinburgh; and from the neighbourhood of Tantellan in the East Lothians. It is found in chalk-flints at Meudon near Paris; and in the gypsum-quarries of Montmartre. Fine fibrous masses of blue celestine come from the neighbourhood of Jena.

Celestine is decomposed by ignition with charcoal into sulphide of strontium, which is converted into the nitrate by the action of nitric acid. The nitrate of strontia is employed for the production of the red light in theatrical fireworks.

CELLULAR BEAM. An application of wrought iron, in which wrought iron plates are rivetted with angle irons in the form of longitudinal cells with occasional cross struts. Fairbairn on *Cast and Wrought Iron*.

CELLULOSE. The essential part of the solid framework of plants. See Watt's 'Dictionary of Chemistry.'

CEMENTATION. A chemical process, which consists in imbedding a solid body in a pulverulent matter, and exposing both to ignition in an earthen or metallic case. In this way, iron is cemented with charcoal to form steel, and bottle glass with gypsum-powder, or with sand, to form Réaumur's porcelain.

CEMENT COPPER. The precipitate of metallic copper, formed by the action of iron on a solution of a salt of copper, is called *Cement Copper*. In like manner, the silver precipitated from a solution of a silver salt by metallic copper is known as *Cement Silver*.

CEMENTS. (*Ciments*, Fr.; *Cümente*, *Kitte*, Ger.) Substances which are capable of assuming the liquid form and of being applied between the surfaces of bodies so as to unite them firmly when solidifying. They are of very varied character.

Gum, glue, and paste are cements, the uses of which are well known.

Diamond cement is a preparation of isinglass and gum ammoniacum dissolved in alcohol (see AMMONIACUM GUM): it is employed to mend glass and china.

Sir John Robinson's cement he thus describes:—

'If it be wished to dissolve good isinglass in spirits of wine, it should first be allowed to soak for some time in cold water, when swelled it is put into the spirit, and the bottle containing it being set in a pan of cold water may be brought to the boiling point, when the isinglass will melt into a uniform jelly, without lumps or strings, which it is apt to have if not swelled in cold water previously to being put into spirits. A small addition of any essential oil diminishes its tendency to become mouldy.

'If gelatine, which has been swelled in cold water, be immersed in linseed oil and heated it dissolves, and forms a glue of remarkable tenacity, which, when once dry, perfectly resists damp, and two pieces of wood joined by it will separate anywhere else rather than at the joint. Ordinary glue may be thus dissolved, and sometimes a small quantity of red lead in powder is added.'

Shellac dissolved in alcohol, or in a solution of borax, or still better in naphtha, forms a good cement. White-of-egg alone, or mixed with finely sifted quicklime, will answer for uniting objects which are not exposed to moisture. The latter combination is very strong, and is much employed for joining pieces of spar and marble ornaments. A similar composition is used by coppersmiths to secure the edges and rivets of boilers; only bullocks' blood is the albuminous matter used instead of white-of-egg. Another cement in which an analogous substance, the curd or caseum of milk is employed, is made by boiling slices of skim-milk cheeses into a gluey consistence in a great quantity of water, and then incorporating the mixture with quicklime on a slab with a muller, or in a marble mortar. When this compound is applied warm to broken edges of stoneware, it unites them very firmly after it is cold.

A cement which gradually indurates to a stony consistence may be made by mixing 20 parts of clean river sand, 2 of litharge, and 1 of quicklime, into a thin putty with linseed oil. When this cement is applied to mend broken pieces of stone, as steps of stairs, it acquires after some time a stony hardness. A similar composition has been applied to coat over brick walls, under the name of 'Mastic.' Portland oolite powder with a little litharge and oil makes good mastic.

The iron-rust cement is made of from 50 to 100 parts of iron borings, pounded and sifted, mixed with one part of sal-ammoniac, and when it is to be applied moistened with as much water as will give it a pasty consistency. Formerly flowers of sulphur were used, and much more sal-ammoniac, in making this cement, but with

decided disadvantage, as the union is effected by the oxidisement, consequent expansion and solidification of the iron powder, and any heterogeneous matter obstructs the effect. The best proportion of sal-ammoniac is, one per cent. of the iron borings. Another composition of the same kind is made by mixing 4 parts of fine borings or filings of iron, 2 parts of potters' clay, and 1 part of pounded potsherds, and making them into a paste with salt and water. When this cement is allowed to concrete slowly on iron joints it becomes very hard.

For making architectural ornaments in relief, a moulding composition is formed of chalk, glue, and paper paste. Even statues have been made with it, the paper aiding the cohesion of the mass. Some French statuettes are so made.

Mastics of a resinous or bituminous nature which must be softened or fused by heat are the following:—

Mr. S. Varley's consists of 16 parts of whiting sifted and thoroughly dried by a red heat, adding when cold a melted mixture of 16 parts of black resin and 1 of bees'-wax, and stirring well during the cooling.

Mr. Singer's electrical and chemical apparatus cement consists of 5 lbs. of resin, 1 of bees'-wax, 1 of red ochre, and 2 tablespoonfuls of Paris-plaster, all melted together. The ochre and the plaster-of-Paris should be calcined beforehand, and added to the other ingredients in their melted state. The thinner the stratum of cement that is interposed, the stronger, generally speaking, is the junction.

Boiled linseed oil and red lead mixed together into a putty are often used by copper-smiths and engineers to secure joints. The washers of leather or cloth are smeared with this mixture in a pasty state.

The resin mastic alone is sometimes used by jewellers to cement by heat cameos of white enamel or coloured glass to a real stone, as a ground to produce the appearance of an onyx. Mastic is likewise used to cement false backs or doublets to stones to alter their hue.

Melted brimstone, either alone or mixed with resin and brick-dust, forms a tolerably good and very cheap cement.

Plumbers' cement consists of black resin 1 part, and brick-dust 2 parts, well incorporated by a melting heat.

The cement for coating the fronts of buildings consists of linseed oil, rendered dry by boiling with litharge, and mixed with porcelain clay in fine powder, to give it the consistence of stiff mortar. Pipe-clay would answer equally well if well dried, and any colour might be given with ground bricks or pottery. A little oil of turpentine to thin this cement aids its cohesion upon stone, brick, or wood. It has been applied to sheets of wire cloth, and in this state laid upon terraces, in order to make them water-tight; but it is little less expensive than lead.

The bituminous or black cement for bottle corks consists of pitch hardened by the addition of resin and brick-dust.

In certain localities where a limestone impregnated with bitumen occurs, it is dried, ground, sifted, and then mixed with about its own weight of melted pitch, either mineral, vegetable, or that of coal-tar. When this mixture is getting semifluid, it may be moulded into large slabs or tiles in wooden frames lined with sheet iron, previously smeared over with common lime-mortar, in order to prevent adhesion to the moulds, which, being in moveable pieces, are easily dismantled so as to turn out the cake of artificial bituminous stone. This cement is manufactured upon a great scale in many places, and used for making Italian terraces, covering the floors of balconies, flat roofs, water reservoirs, water conduits, &c. When laid down, the joints must be well run together with hot irons. The floor of the terrace should be previously covered with a layer of Paris-plaster, or common mortar, nearly an inch thick, with a regular slope of one inch to the yard. Such bituminous cement weighs 144 pounds the cubic foot; or a foot of square surface, one inch thick, weighs 12 pounds. Sometimes a second layer of these slabs or tiles is applied over the first, with the precaution of making the seams or joints of the upper correspond with the middle of the under ones. Occasionally a bottom bed, of coarse cloth or grey paper, is applied. The larger the slabs are made, as far as they can be conveniently transported and laid down, so much the better. For *hydraulic* cements, see **HYDRAULIC CEMENTS and MORTAR.**

An excellent cement for resisting moisture is made by incorporating thoroughly eight parts of melted glue, of the consistence used by carpenters, with four parts of linseed oil, boiled into varnish with litharge. This cement hardens in about forty-eight hours, and renders the joints of wooden cisterns and casks air- and water-tight. A compound of glue with one-fourth its weight of Venice turpentine, made as above, serves to cement glass, metal, and wood to one another. The gluten of wheat, well prepared, is also a good cement. White-of-egg with flour and water well mixed, and smeared over linen cloth, forms a ready lute for steam joints in small apparatus.

White lead ground upon a slab with linseed-oil varnish, and kept out of contact of

air, affords a cement capable of repairing fractured bodies of all kinds. It requires a few weeks to harden. When stone and iron are to be cemented together, a compound of equal parts of sulphur and pitch answers very well.

Lapidaries' cement is made of resin, tempered with bees'-wax and a little tallow, and hardened with red ochre or Spanish brown and whiting.

Opticians' cement, for fixing glasses for grinding, is made by mixing sifted wood ashes with melted pitch, the essential oil of which is absorbed by the wood ashes, and the adhesiveness of the pitch is therefore reduced. The proportions are somewhat dependent on the temperature of the weather and the qualities of the pitch; but generally about 4 lbs. of wood ashes to 14 lbs. of pitch are employed, and the cement, if too hard and brittle, is softened with hogs' lard and tallow.

Japanese cement is said to be prepared by mixing rice flour intimately with cold water, and then boiling the mixture; it is white, and dries nearly transparent. See **MORTAR**.

For Portland cement, Roman cement, Scott's cement, &c. See **HYDRAULIC CEMENTS**.

CENTAURY. *Centaurea calcitrapa*. The common star-thistle; an herb, the root and leaves of which are bitter. The term centaury is also applied to *Erythraea Centaurium* (the common centaury), one of the Gentian family. It is said to be sometimes used instead of hops.

CENTIARE. See **METRIC SYSTEM**.

CENTIGRADE SCALE. See **THERMOMETER**.

CENTIGRAMME. See **METRIC SYSTEM**.

CENTIMETRE. See **METRIC SYSTEM**.

CENTNER. The Zollverein Centner contains 110·231 English lbs. avoirdupois.

CENTRIFUGAL MACHINE. A machine in which advantage is taken of the force produced by centrifugal motion. Several of the old mills were of this description. This term has been not very correctly applied to *Barker's Mill* as it is often called; but which was fully described by *Desaguliers* (vol. ii. p. 468), in which water is made to act on a machine by its weight. Barker's mill consists of an upright pipe which communicates with two horizontal branches having holes near their ends opening in opposite directions. Desaguliers affirms the pressure to be the weight of a column, which would produce a velocity of efflux equal to the difference of the velocity of the fluid and of the machine; and hence he deduces that its performance will be the greatest possible when its retrograde velocity is one-third of the velocity acquired by falling from the surface, in which case it will raise $\frac{8}{27}$ ths of the water expended to the same height, which is double of the performance of a mill acted on by the impulse of water.

But this is a very imperfect account of the operation. When the machine (constructed exactly as we have described) moves round, the water which issues descends in the vertical trunk, and then, moving along the horizontal arms, partakes of this circular motion. This excites a centrifugal force, which is exerted against the ends of the arms by the intervention of the fluid. The whole fluid is subjected to this pressure (increasing for every section across the arm in the proportion of its distance from the axis), and every particle is pressed with the accumulated centrifugal forces of all the sections that are nearer to the axis. Every section, therefore, sustains an actual pressure proportional to the square of its distance from the axis. This increases the velocity of efflux, and this increases the velocity of revolution, and this mutual co-operation would seem to terminate in an infinite velocity of both motions. But, on the other hand, this circular motion must be given anew to every particle of water as it enters the horizontal arm. This can be done only by the motion already in the arm, and at its expense. Thus, there must be a velocity which cannot be overpassed even by an unloaded machine. But it is also plain, that by making the horizontal arm very capacious, the motion of the water from the axis to the jet may be made very slow, and much of this diminution of circular motion be prevented. 'System of Mechanical Philosophy, by John Robinson,' pp. 616, 617. Centrifugal pumps, correctly speaking, are such as have water admitted at the axis of a hollow wheel, traversed by vanes, which being made to revolve rapidly expels the water at the circumference. The pipe by which the water reaches the axis of the wheel or the reservoir which feeds it, becomes under these circumstances a suction-pipe, and if the reservoir into which the water is received from the periphery of the wheel be closed, and a pipe be carried from it upwards, the latter becomes a force pipe. Appold's Centrifugal Pump, and Gwynn's, are examples of this kind of machine in practice; they are largely employed in raising large bodies of water to a small height. Centrifugal machines were used in America in 1830; Mr. M'Carty erected one in the navy yard, New York, in 1830. M. Ch. Combes describes a centrifugal machine in a paper entitled '*Sur les Roues de Réaction*,' (*Comptes Rendus*, vol. vii. 2me. Semestre, 1838, p. 306). In this paper the theory of the centrifugal ventilator is discussed, and its obvious relations to the theory of the

centrifugal pump pointed out. In August 1838, M. Combes took out a *brevet d'invention*, entitled 'Pour un machine universelle, à force centrale, propre à déplacer les liquides et les fluides aëriiformes' (*Recherches théoriques et expérimentales sur les Roues à Réaction ou à Tuyaux*, par M. Ch. Combes, and 'Jurors' Report of Great Exhibition, 1851). Many ventilating machines for mines are constructed on this principle. (See VENTILATING MINES; also TURBINE.) Whirling machines, which are used for drying cloth, sugar, and other things, are entirely dependent on the action of centrifugal force. These machines are called hydro-extractors.

CERASIN. The name given by Dr. John to those gums which swell but do not dissolve in water; such as gum tragacanth. It is synonymous with BASSORINE.

CERATE, from *cera*, wax. An unguent, of rather a stiff consistence, made of oil, or lard, and wax, thickened occasionally with pulverulent matters.

CEREALIN. (*Ctréaline*, Fr.) A nitrogenous substance found by M. Mège Mouries in bran. See BREAD.

CEREALS. Grasses cultivated for sake of their grain, used as food-stuffs. They comprise wheat, barley, rye, oats, maize, and rice. The name is derived from the goddess Ceres.

CERESINE. A by-product obtained in purifying ozokerite for the manufacture of paraffin. By treating the crude product with sulphuric and sulphurous acids, and then with alkalis, pure ceresine is obtained in the form of a white semi-transparent opaline substance, insoluble in water, but soluble in alcohol, fusing at about 143° F., and having a specific gravity of 0.88. In Vienna, ceresine has been used as a substitute for bees'-wax in certain pharmaceutical preparations. This article is sold in round, thin plates, a few inches in diameter. It is faultlessly white, scentless, harder than wax, and translucent at the edges. The fracture resembles somewhat that of wax, but it cannot be kneaded, either in warm water or between the fingers. It is not attacked by acids, either hot or cold, and is not in the slightest degree saponified by caustic alkalis. It is volatile at high temperatures and distils over unchanged. It is closely analogous to paraffin and stearine, but is rendered more waxy in appearance by being cooled slowly. See CANDLES—OZOKERITE.

CERINE. A substance which forms from 70 to 80 per cent. of bees'-wax. It may be obtained by digesting wax for some time in spirit of wine at a boiling temperature. The *myricine* separates, while the *cerine* remains dissolved, and may be obtained from the decanted liquor by evaporation. Cerine is white, analogous to wax, fusible at 134° F., hardly acted upon by hot nitric acid, but is readily carbonised by hot sulphuric acid. When treated with caustic-alkali ley, it is converted into margaric acid and *ceraine*.

CERIUM. A peculiar metal discovered in connection with lanthanum and didymium, in *cerite*, *allanite*, *orthite*, and a few other minerals of rare occurrence, found in Sweden. Cerium has also been detected by Prof. Church in a Cornish mineral, which he found to consist of a hydrous phosphate of cerium; this mineral has been named by Mr. Greville C. Williams, *Churchite*.

Cerium, extracted from its chloride by potassium, appears as a dark red or chocolate powder, which assumes a metallic lustre by friction. It does not conduct electricity well, like other metals; it is infusible; its specific gravity is unknown. It has been applied to no use in the arts. See Watts's 'Dictionary of Chemistry.'

CEROSINE. A name applied to the wax of the sugar-cane.

CEROTIC ACID. An acid obtained by the action of boiling alcohol on bees'-wax, or by the destructive distillation of Chinese wax.

CERUSE. A name of white lead. See WHITE LEAD.

CERUSITE or **CERUSSITE.** Native carbonate of lead. See LEAD.

CEYLON CATECHU. A variety of the Bombay Catechu.

CEYLON MOSS. (*Plocaria candida*.) See ALGÆ.

CHABASITE. A hydrated silicate of alumina and lime. This zeolite is found in the fissures of some trap rocks.

CHAINWORK is a peculiar style of textile fabric, to which hosiery and tambouring belong. See HOSIERY.

CHAKKARA. A coarse sugar obtained from the cocoa-nut and other plants.

CHALCANTHITE. A name occasionally applied to the native sulphate of copper.

CHALCANTHUM. The ancient name of the native sulphate of iron.

CHALCEDONY. A hard mineral of the quartz family, often cut into seals. Under it may be grouped common chalcedony, heliotrope, chrysoprase, plasma, agate, onyx, cat's-eye, sardonyx, carnelian, and sard.

CHALCEDONYX. The name of those agates in which opaque white chalcedony alternates with the translucent grey variety.

CHALCHIHUITL. A green stone prized by the ancient Mexicans for ornamental purposes. It has been variously referred to jade, turquoise, emerald, &c.

CHALCOLITE. A name applied to *copper-uranite* or *torberite*, a hydrated phosphate of uranium and copper.

CHALCOPHYLLITE. A hydrated arsenate of copper, known also as *tamarite* and *copper-mica*, the crystals being easily separated into laminae, like mica.

CHALCOPYRITE. A mineralogical name for *copper-pyrites*. See COPPER.

CHALCOSINE. A synonym of *copper-glance*. See COPPER.

CHALCOSTIBITE. A sulphide of antimony and copper, from Wolfsberg in the Hartz.

CHALCOTRICHITE. A name applied to the hair-like forms of red oxide of copper, known commonly as *plush copper-ore*.

CHALK. (*Craie*, Fr.; *Kreide*, Ger.) An earthy carbonate of lime, white, opaque, soft, dull, or without any appearance of polish in its fracture. Its specific gravity varies from 2.4 to 2.6.

The following analysis, by Mr. W. J. Ward, shows the composition of a sample of chalk from near Gravesend (after having been dried at 212° F.): carbonate of lime, 98.52; carbonate of magnesia, 0.29; sulphate of lime, 0.14; peroxide of manganese, 0.04; phosphoric acid and organic matter, traces; ignited insoluble residue, chiefly silica, 0.65.

When purified, chalk is called *whiting* and Spanish white, in England; *Schlemmerkreide*, in Germany; *blanc de Troyes*, and *blanc de Meudon*, in France. Pure chalk should dissolve readily in dilute muriatic acid, and the solution should afford no precipitate with water of ammonia. Chalk is burnt into lime in great quantities, in which state it is used as a manure, and for making mortar and whitewash. Some of the lower beds, which are argillaceous, afford a good hydraulic cement, equal in every respect to Roman cement.

Of late years, it has become the custom to manure land with unburnt chalk spread on the surface in the proportion of about 40 loads (tons) to an acre. The effect produced by chalk applied in its crude state is similar to that resulting from the application of quicklime, but more lasting, on some lands not requiring to be renewed for several years: it also has the advantage of rendering the soil *mechanically* lighter, from the larger quantity in which it is used.

In certain districts, chalk is sometimes used as a building material.

CHALK, BLACK. An indurated clay, containing much carbon. The finer kinds are used for drawing on paper.

CHALK, FRENCH. *Steatite*, or soap stone: a soft magnesian mineral.

CHALK, RED. A clay coloured with the peroxide of iron, of which it contains about 17 per cent. Also a ferruginous carbonate of lime.

CHALLIS. About the year 1832 this article was introduced, and was certainly an elegant silk and worsted fabric. It was made on a similar principle to the Norwich crape, only thinner and softer, composed of much finer materials; and instead of a glossy surface, as in Norwich crapes, the object was to produce it without gloss, and very pliable and clothly. The best quality of challis, when finished with designs and figures (either produced in the loom or printed), commanded the attention of the higher circles, and became a favourite article of apparel at their fashionable resorts and parties for several years. The worsted yarn for the weft of this article was spun at Bradford, from numbers 52's to 64's. The making of the challis fabric soon afterwards commenced in the North, but it has given way to the ever-varying caprices of fashion.

CHALYBEATE is a name given in medicine to preparations of iron.

CHALYBITE. A synonym of carbonate of iron, or spathose iron-ore. See IRON.

CHAMELEON, MINERAL. As this compound—so long known in chemistry as a mere curiosity, on account of the surprising changes of colour which it spontaneously assumed—has of late been largely employed for whitening tallow, palm-oil, and decolouring other organic matters, it merits description in this Dictionary. It exists in two states: one of which is called by chemists the manganate of potash, and the other the permanganate; denoting that the first is a compound of manganic acid with potash, and that the second is a compound of permanganic acid with the same base. They are both prepared in nearly the same way: the former by calcining together, at a red-heat in a covered crucible, a mixture of one part of the black peroxide of manganese with three parts of the hydrate of potash (the fused potash of the apothecary). The mass is of a green colour when cold. It is to be dissolved in cold water, and the solution allowed to settle, and become clear, but by no means filtered, for fear of the decomposition to which it is very prone. When the decanted liquid is evaporated under the exhausted receiver of an air-pump, over a surface of sulphuric acid, it affords crystals of a beautiful green colour, which should be laid on a clean porous brick to drain and dry. They may be preserved in dry air, but should be

kept in a well-corked bottle. They are decomposed by water, but dissolve in weak water of potash. On diluting this, decomposition of the salt ensues, with all the chameleon changes of tint; red, blue, and violet. Sometimes a green solution of this salt becomes red on being heated, and preserves this colour even when cold, but resumes its green hue the moment it is shaken: it might, therefore, furnish the votaries of St. Januarius with an admirable means of mystifying the worshippers at his shrine. The original calcined mass, in being dissolved, always deposits a considerable quantity of a brown powder, which is a compound of the acid and peroxide of manganese combined with water. Much of the potash remains unchanged, which may be recovered.

The permanganate of potash is made by fusing with a strong heat a mixture of equal parts of peroxide of manganese and hydrate of potash, or one part of peroxide and two parts of nitre. The mass is to be dissolved in water, and if the solution be green, it should be reddened by the cautious addition of a few drops of nitric acid. The clarified liquor is to be evaporated to the point of crystallisation. Even the smallest crystals of this salt have such an intense red colour, that they appear black with a green metallic reflection. In the air they gradually assume a steel-grey hue without undergoing any essential change of nature. A very little of the salt reddens a large body of water. The least portion of any organic matter added to the solution of this salt reduces the permanganic acid to the state of peroxide, which precipitates combined with water; the liquor becoming green or colourless, according to circumstances.

A more permanent permanganic salt may be made as follows:—Melt chlorate of potash over a spirit lamp, and throw into it a few pieces of hydrate of potash, which immediately dissolve and form a limpid liquid. When peroxide of manganese in fine powder is gradually introduced into that melted mixture, it immediately dissolves, with the production of a rich green colour. After adding the manganese in excess, the whole is to be exposed to a gentle red heat, in order to decompose the residuary chlorate of potash. It is now a mixture of manganate of potash, chloride of potassium, and peroxide of manganese. It forms with water a deep green coloured solution, which, when boiled, assumes a fine red colour, in consequence of its becoming a permanganate, and it ought to be decanted off the sediment while hot. By cooling, the permanganate of potash separates in crystals possessed of great lustre; but towards the end colourless crystals of chloride of potassium are deposited. See MANGANATES.

CHAMOISITE. A hydrated silicate of alumina and protoxide of iron, occurring as a compact or oolitic iron-ore, at Chamoison, near Saint Maurice, in the Valais.

CHAMOMILE FLOWERS. The *Anthemis nobilis* of Linnaeus. The chamomile grows very abundantly in Cornwall, and some other parts of England. It is cultivated at Mitcham and in Derbyshire, for the London market. The chamomile is used medicinally, and is employed by some brewers to substitute hops in bitter beer. It would be well if no more objectionable bitter was employed.

The essential oil of chamomile is remarkable for its blue colour. In a paper read before the Chemical Society by Dr. Piesse, 'On the colouring matter of volatile oils,' this blue body was shown in an isolated state, and was named by the author *azulene*.

CHAMPAGNE. See WINES.

CHAMÑARCILLITE. An arsenio-antimonial silver-ore, occurring at Chañarcillo, in Chile.

CHAPAPOTE. A local name for Mexican asphalt.

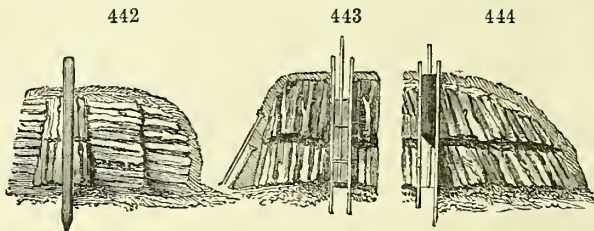

CHARBON SULFURIQUE. This name is applied to the product obtained by treating pulverised madder, either at ordinary or at higher temperatures, with a considerable quantity of rather strong sulphuric acid. MM. Persoz and Gauthier de Claubry had shown that the true colouring principles of madder are soluble without alteration in strong sulphuric acid, and it was on this observation, turned to practical account by M. Robriquet, that the preparation of his *charbon sulfurique* was based. After the action of the acid has been continued for several hours, the mass is diluted with water, the liquid filtered, and the residue well washed and dried. *Charbon sulfurique* dyes very strongly, and produces fine colours.

CHARCOAL. The fixed residuum of organic substances when they are exposed to ignition out of contact with air.

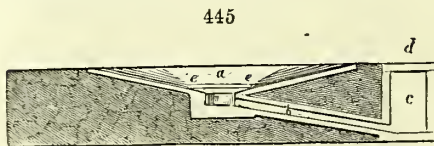

WOOD CHARCOAL.—As wood charcoal may be regarded as, especially, the representative of the practically useful charred substances, a description of it naturally precedes that of the other varieties. The earliest plan of *coaling wood*, as the manufacture of charcoal was termed, and is still called, is carried on as follows:—A piece of ground is levelled at some convenient spot in the forest, which is termed the 'hearth' or 'earth.' In the centre of this a thick pole or bundle of brushwood is placed, around which the wood is arranged, some of the pieces being laid horizontally and others set up at an inclination; or the wood may be placed

altogether at any steep angle, sloping outwards from the centre to form a flattened cone, which when complete is usually called a heap; the object, whichever way the wood is placed, is to obtain a free circulation of air under the heap, to communicate with the chimney in the centre, which is formed by then withdrawing the central pole or bundle of brushwood. The large wood should if convenient be at the bottom of the heap, and the outside packed as close as possible; the heap is then covered with small brushwood, and afterwards with turf, or the material most impervious to air which can be conveniently obtained. A fire is lighted in the centre chimney, and by leaving openings in the outside-covering at the bottom of the heap, the fire soon extends, and can be guided to any part by making temporary openings to admit the air. When the heap is sufficiently fired all the openings are closed, and lastly the chimney itself. The fire will always extend most rapidly on the side facing or towards the wind; and great care must be taken to watch and check this, by keeping the covering on that side in good order. The charcoal burner must always be careful to spread the fire as evenly as possible through the heap, and after it is coaled to stop it down carefully; he can always accelerate the process in any part of the heap if well built, by opening the outside to admit air freely: but if he finds this does not act, from any fault in setting the wood, he had better open a hole with a bar at the place required, and light a fire in the hole; this will soon communicate with the main fire in the heap. As soon as the smoke and white flame cease to escape at the vents, the whole heap must be closed from the air as carefully as possible, until the charcoal is quite cooled and is ready to draw. The fire must never burn too fast; the slower the process, if the fire is steady and regular, the better the yield of charcoal. Hard close-grained woods take a longer time to coal than soft open-grained woods, and should be placed in the heap accordingly. These technical instructions, handed down in the forests for ages as secrets from father to son amongst the 'coalliers' in every country in Europe, are the results of long practical experience, and strictly accord with the true principles on which the process is based.

To carbonise wood under a moveable covering, the plan of *Meiler*, or heaps, is employed very much in Germany. The wood is arranged either in horizontal layers, or in nearly vertical ones, with a slight slope, so as to form conical rounded heaps of different sizes. The former are called 'lying *Meiler*,' fig. 442; the latter 'standing *Meiler*,' figs. 443 and 444. Both are distributed in much the same way.

In districts where the wood can be transported into one place by means of rivers, or mountain slides, a dry flat space must be pitched upon, screened from storms and floods, which may be walled round, having a slight declivity made in the ground, towards the centre. (See fig. 445.) Into this space the tarry acid will partially fall,

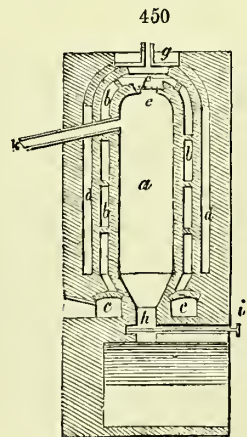

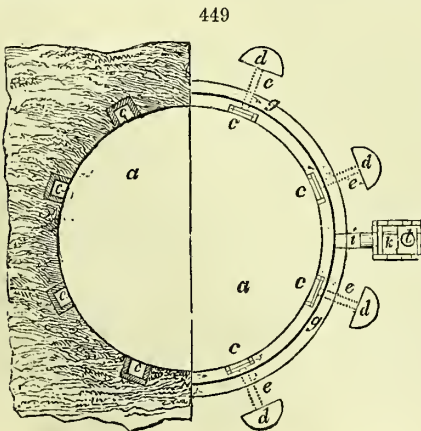

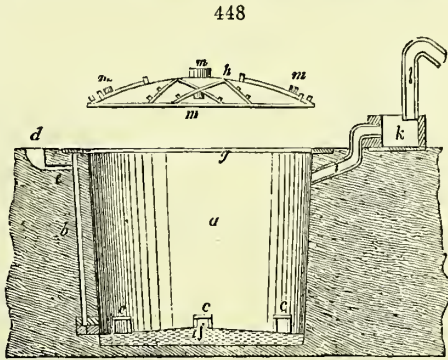

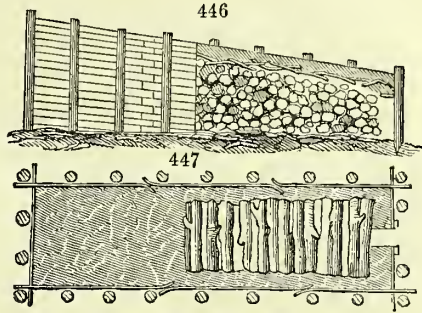

and may be conducted outwards, through a covered gutter beneath, into a covered tank. The mouth of the tank must be shut, during the coking, with an iron or stone slab, luted with clay. A square iron plate is placed over the inner orifice or the gutter to prevent it being choked with coal ashes. Fig. 445 represents a walled *Meiler* station: *a*, the station; *b*, the gutter; *c*, the tank, which is covered with the slab *d*; *e*, a slab which serves to keep the gutter clear of coals. The cover of the heaps is formed of earth, sand, ashes, or such other matter as may be most readily found in the woods. They should be kindled in the centre. From 6 days to 4 weeks may be required for charring a heap, according to its size, hard wood requiring most time; and the slower the process, the better and greater is the product, generally speaking.

Charring of wood in mounds (*Haufe* or *liegende Werke*), figs. 446 and 447, differs from that in the *Meiler*, because the wood in the *Haufe* is successively charred, and the

charcoal is raked out by little and little. The product is said to be greater in this way, and also better. Uncleft billets, 6 or 8 feet long, being laid over each other, are covered with ashes, and then carbonised. The station is sometimes horizontal, and sometimes made to slope. The length may be 24 feet, the breadth 8 feet; and the wood is laid crosswise. Piles are set perpendicularly to support a roof made of boughs and leaves covered with ashes. Pipes are occasionally laid within the upper part of the mounds, which serve to catch and carry off some of the liquid.

Fig. 448 is a vertical section, and fig. 449 a half bird's-eye view, and half cross-section at the height of the pit bottom, of Chabeausière's kiln for making wood charcoal. *a* is the oven; *b*, vertical air-pipes; *c c*, horizontal flues for admitting air to the kiln; *d d*, small pits which communicate by short horizontal pipes *e e*, with the vertical ones; *f*, the sole of the kiln, a circle of brickwork, upon which the cover or hood, *h*, reposes; *i*, a pipe which leads to the cistern *k*; *l*, the pipe destined for carrying off the gaseous matter; *m m*, holes in the iron cover or lid.

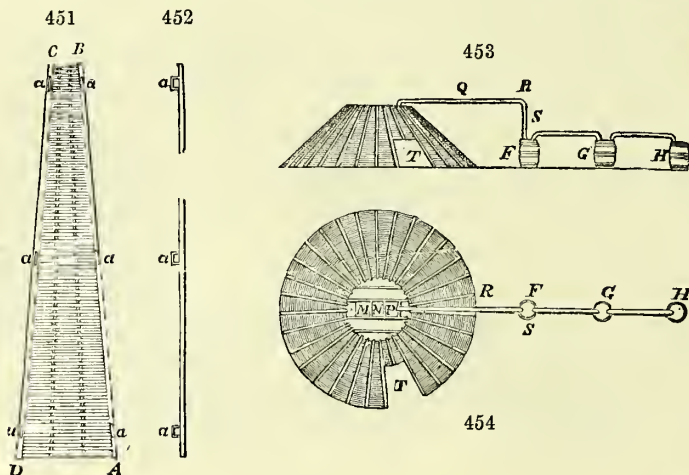

The distribution of the wood is like that in the horizontal *Meiler*, or heaps; it is kindled in the central vertical canal with burning fuel, and the lid is covered with a few inches of earth. At the beginning of the operation all the draught flues are left open, but they are progressively closed, as occasion requires. In eight kilns of this kind, 500 decasters of oak wood are carbonised, from which 15,000 hectolitres of charcoal are obtained, equal to 64,000 pounds French, being about 25 per cent., besides tar, and 3,000 veltts of wood vinegar, of from 2° to 3° Baumé.

At Crouy-upon-the-Oureq, near Meaux, there is a well-constructed kiln for making turf-charcoal. It resembles most nearly a tar-kiln. In fig. 450, *a* is the cylindrical

coking place, whose surrounding walls are heated by the flame which passes through the intermediate space *b*. The place itself is divided by partitions of fire tiles into three stages, through the apertures in which the flames of the fire *cc*, rise, and heat the exterior of the coking apartment. In order to confine the heat, there is in the enclosing walls of the outer kiln, a cylindrical hollow space *d*, where the air is kept stagnant. Through the apertures left in the upper end at *e*, the turf is introduced; they are then shut with an iron plate *f*, which is covered with ashes or sand. The fire-place opens above this aperture, and its outlet is provided with a moveable iron cover *g*, in which there is a small hole for the issue of the gases. The sole of the kiln consists of a cast-iron slab *h*, which may be raised by means of a hook, *i*, upon it. This is drawn back after the carbonisation is completed, whereby the charcoal falls from the coking space into a subjacent vault. The volatile products are carried off by the pipe *k*, and led into the condensing cistern; the gases escaping to the fire-place, where they are burned. The iron slab is protected from the corrosion of the acid vapours by a layer of coal ashes.

Charcoal obtained by the action of a rapid fire in close vessels is not so solid and so good a fuel as that which is made in the ancient way by the slow calcination of pyramidal piles covered with earth. One of the most economical ovens for making wood charcoal is that invented by M. Foucauld, which he calls a *shroud*, or *abri*. To construct one of these, 30 feet in diameter at the base, 10 feet at its summit, and from 8 to 9 feet high, he forms, with wood 2 inches square, a frame 12 feet long, 3 feet broad at one end, and 1 foot at the other. The figures 451, 452 will explain the construction.

The uprights, *AB* and *CD*, of this frame are furnished with three pairs of wooden handles *aaa*, by means of which they can be joined together, by passing through two contiguous handles a wooden fork, the frame being previously provided with props, as shown in *fig. 452*, and covered with loam mixed with grass. A flat cover of 10 feet diameter, made of planks well joined, and secured by 4 cross bars, is mounted with 2 trap doors, *mn*, *fig. 454*, for giving egress to the smoke at the commencement of the operation; a triangular hole *r*, cut out in the cover, receives the end of the conduit *QRS*, (*figs. 453* and *454*) of wood formed of three deals destined to convey the gases and condensed liquids into the casks *FGH*. Lastly, a door *t*, which may be opened and shut at pleasure, permits the operator to inspect the state of the fire. The charcoal calcined by this *abri* has been found of superior quality.

When it is wished to change the place where the *abri* is erected, and to transport it to a store of new-felled timber, the frame is taken down, after beating off the clay which covers it; the joints are then cut by a saw, as well as the ends of the fork which fixed the frames to one another. This process is economical in use, and simple and cheap in construction; since all the pieces of the apparatus are easily moved about, and may be readily mounted in the forests. For obtaining a compact charcoal, for the use of artisans, this mixed process of Foucauld is said to be preferable to either the close iron cylinder or the pile.

For making gunpowder-charcoal the lighter woods, such as the willow, dogwood, and alder answer best; and in their carbonisation care should be taken to let the

vapours freely escape, especially towards the end of the operation, for when they are re-absorbed, they greatly impair the combustibility of the charcoal.

By the common process of the forests, about 18 per cent. of the weight of the wood is obtained; by the process of Foucauld about 24 per cent. is obtained, with 20 of crude pyroligneous acid of 10° Baumé. By the process described under ACETIC ACID, 27 of charcoal, 18 of acid at 6°, are procured from 100 parts of wood, besides the tar. These quantities were the results of careful experimenting, and are greater than can be reckoned upon in ordinary hands.

Charcoal for chemical purposes may be extemporaneously prepared by calcining pieces of wood covered with sand in a crucible, till no more volatile matter exhales.

The charcoal of some woods contains silica, and is therefore used for polishing metals. Being a bad conductor of heat, charcoal is employed sometimes in powder to encase small furnaces and steam-pipes. It is not affected by water; and hence, the extremities of stakes driven into moist ground are not liable to decomposition. In like manner casks when charred inside preserve water much better than common casks, because they furnish no soluble matter for fermentation or for food to animalcules.

Lowitz discovered that wood charcoal removes offensive smells from animal and vegetable substances, and counteracts their putrefaction. He found the odour of succinic and benzoic acids, of bugs, of empyreumatic oils, of infusions of valerian, essence of wormwood, spirits distilled from bad grain, and sulphureous substances were all absorbable by freshly-calcined charcoal properly applied. A very ingenious filter has been constructed for purifying water, by passing it through strata of charcoal of different degrees of fineness.

When charcoal is burned, one-third of the heat is discharged by radiation, and two-thirds by conduction.

The following Table of the quantity of charcoal yielded by different woods was published by Mr. Mushet, as the result of experiments carefully made upon the small scale. He says, the woods before being charred were thoroughly dried, and pieces of each kind were selected as nearly alike in every respect as possible. One hundred parts of each sort were taken, and they produced as under:—

Lignum Vitæ	afforded 26·0 of charcoal of a greyish colour, resembling coke.
Mahogany	25·4 tinged with brown, spongy and porous.
Laburnum	24·5 velvet black, compact, very hard.
Chestnut	23·2 glossy black, compact, firm.
Oak	22·6 black, close, very firm.
Walnut	20·6 dull black, close, firm.
Holly	19·9 dull black, loose and bulky.
Beech	19·9 dull black, spongy, firm.
Sycamore	19·7 fine black, bulky, moderately firm.
Elm	19·5 fine black, moderately firm.
Norway Pine	19·2 shining black, bulky, very soft.
Sallow	18·4 velvet black, bulky, loose and soft.
Ash	17·9 shining black, spongy, firm.
Birch	17·4 velvet black, bulky, firm.
Scotch Pine	16·4 tinged with brown, moderately firm.

Messrs. Allen and Pepys, from 100 parts of the following woods, obtained the quantities of charcoal as under:—

Beech	15·00	Oak	17·40
Mahogany	15·75	Fir	18·17
Lignum Vitæ	17·25	Box	20·25

It is observable that the quantities obtained by Messrs. Allen and Pepys are in general less than those given by Mr. Mushet, which may be owing to Mr. Mushet not having applied sufficient heat, or operated long enough, to dissipate all the aqueous matter of the gaseous products.

To those persons who buy charcoal by weight, it is important to purchase it as soon after it is made as possible, as it quickly absorbs a considerable portion of water from the atmosphere. Different woods, however, differ in this respect. Messrs. Allen and Pepys found that by a week's exposure to the air, the charcoal of

Lignum Vitæ	gained	9·6 per cent.
Fir	13·0 "
Box	14·0 "
Beech	16·3 "
Oak	16·5 "
Mahogany	18·0 "

The following is a tabular view of the volumes of the different gases which were absorbed in the course of 24 hours, by one volume of charcoal, in the experiments of M. Théodore de Saussure, which were conducted in a way likely to produce correct results. Each portion of charcoal was heated afresh to a red heat, and allowed to cool under mercury. When taken from the mercury, it was instantly plunged into the vessel of gas:—

Ammoniacal gas . . .	90	Bicarburetted hydrogen	35·00
Muriatic acid gas . . .	85	Carbonic oxide . . .	9·42
Sulphurous acid . . .	65	Oxygen gas . . .	9·25
Sulphuretted hydrogen . . .	55	Nitrogen . . .	7·50
Nitrous oxide . . .	40	Carburetted hydrogen . . .	5·00
Carbonic acid gas . . .	35	Hydrogen gas . . .	1·75

Neumann, who made many experiments on charcoal, informs us that for the reduction of the metallic oxides, the charcoal of the heavier woods, as that of the oak and the beech, is preferable, and that, for common fuel, such charcoal gives the greatest heat, and requires the most plentiful supply of air to keep it burning; while those of the lighter woods preserve a glowing heat with a much less draught of air; and that for purposes where it is desirable to have a steady and a still fire, charcoal should be employed which has been made from wood previously divested of its bark, since it is the cortical part which crackles and flies off in sparks during combustion, which the coal or the wood itself seldom does.

For making crayons of charcoal, the willow is the best wood that can be employed, as the softness is uniform in all its parts. The durability of charcoal may be seen in several of our old churchyards, where the letters made with lampblack are still perfect, though the white lead with which the body of the stones was painted is entirely destroyed.

This property of carbon is shown, however, in a more striking manner by the writings that were found in the ruins of Herculaneum, which have retained their original blackness for two thousand years. The ancients wrote with ink made from ground charcoal.

If it be required to purify any carbonaceous matter, to render it fitter for delicate pigments, this may be done by first calcining it in a close vessel, and then lixiviating it in water slightly acidulated by nitric acid.

The incorruptibility of charcoal was well known to the ancients, and they availed themselves of this property upon all important occasions.

About sixty years ago a quantity of oak stakes were found in the bed of the Thames, in the very spot where Tacitus says that the Britons fixed a vast number of such stakes, to prevent the passage of Julius Caesar and his army. These stakes were charred to a considerable depth, had retained their form completely, and were firm at the heart.

Most of the houses in Venice stand upon piles of wood, which have all been previously charred for their preservation. In this country, estates were formerly marked out by charred stakes driven to a considerable depth into the ground. These are occasionally found, and usually the charred portions are quite perfect, although every other part has decayed.

ANIMAL CHARCOAL.—Animal charcoal especially, and other charcoal occasionally, has been much employed in the construction of filters for domestic use. The advantage of charcoal as a purifying agent—through which to pass water—has been long established. But it cannot be too generally known that the charcoal, in a few weeks loses the property upon which its value depends. When first used, it separates not only the matters mechanically suspended in water, but much of the organic matter and salts held in solution. The property appears to be entirely lost in about two months, after which time it is necessary either to renew or to restore the charcoal. See **FILTER** and **BONE BLACK**.

LIGNITE CHARCOAL.—Much of the lignite or brown coal of the Continent has been converted into charcoal, with a view to its use in metallurgical works. Mayer says that very firm charcoal is obtained by charring freshly-dug lignite without previously exposing it to the air. The complaint, however, amongst metallurgists is, that it is not generally sufficiently coherent for the furnace. The following are a few of the results of practical experiments:—

Lignite from Cologne, produced per cent. of charcoal	. . .	36·1
“ “ Iceland	“ . . .	57·5
“ “ Friesdorf	“ . . .	48·2
“ “ Stösschen	“ . . .	40·6
“ “ Paredel	“ . . .	42·0
“ “ Oberpfalz	“ . . .	46·0

PEAT CHARCOAL.—Numerous attempts have been made from time to time to utilise the peat of our bogs, and especially to bring peat charcoal into use for smelting iron, and other metallurgical processes. As far back as 1712, we are told by Carlowitz, that peat was charred in piles or stacks as wood is. Vogel informs us that in 1735, peat charcoal was made in the Hartz. Numerous experiments have been made on the Continent to produce a charcoal from peat, which should answer the requirements of metallurgy. None of these appear to have been entirely successful. Within the last few years, experiments have been made in Ireland to smelt the hæmatite iron ore of Cumberland with peat charcoal. The exact results of the experiments have not been made known, but, certain it is, they did not promise to be commercially successful, and the idea has long been abandoned. We learn from the report of Sir Robert Kane, that the relative quantities of charcoal and other substances produced from a hundred parts of peat were found to be:—

	Average	Maximum	Minimum
Charcoal	29·222	39·132	18·973
Tarry matter	2·787	4·417	1·462
Watery products	31·378	38·127	21·819
Gases	36·616	57·746	25·018

From the same report we glean the following tables, giving the determinations of carbon, &c., in different peats:—

	REGNAULT (<i>Annal. der Pharm.</i>)			MULDER (<i>Berz. Jahrb.</i>)		
	Vulcaire near Abbeville	Long near Abbeville	Champ de Fer, near Framont	Friesland compact turf	Friesland surface turf	Holland
Carbon	60·40	60·89	61·05	59·42	60·41	59·27
Hydrogen	5·90	6·21	6·45	5·87	5·57	5·41
Oxygen	33·64	32·90	32·50	34·71	34·02	35·32
Ash, in 100 parts	5·58	4·61	5·33	3·80	0·91	14·25

The following results were obtained by Sir Robert Kane, from peats from the Irish bogs; and published in the Proceedings of the Royal Irish Academy:—

	Kilbeggan in Westmeath	Kilbaha in Clare	Cappoge in Kildare
Carbon	61·04	51·13	51·05
Hydrogen	6·67	6·33	6·85
Oxygen	30·45	34·48	39·55
Ash	1·83	8·06	2·25

The determinations of charcoal and volatile matters found in peat in the following table, are: 1. from Rue, in Department of Somme; and 2. from Abbeville, by Balthier; 3. from Vauclose, by Diday; 4. from Sécherai, by Sauvage; and 5. from Kildare; 6. from Kilbeggan; 7. from Kilbaha; and 8. Cappoge, by Sir Robert Kane:—

	1	2	3	4	5	6	7	8
Charcoal	21·0	23·0	17·3	22·0	23·82	22·67	72·14	23·65
Volatile matter	72·0	72·2	65·5	39·2	73·63	75·50	72·80	70·10
Ash	7·0	4·8	17·4	8·3	2·55	1·83	8·06	6·24

Peat is usually charred by methods similar to those employed for the carbonisation of wood. Kilns, variously constructed, have been used, but the success attending the production of peat charcoal by them, has not been sufficiently great to induce us to occupy space with any description of them.

In 1849, Mr. Vignoles, C.E., patented a process for charring peat by steam, superheated to the melting point of tin or lead. Pulped peat is thrown in mass into a cylindrical drum-shaped vessel, divided, if necessary, into compartments, which is caused to revolve with great rapidity upon an axis—the velocity requisite being such as shall drive off the water or other fluid from the solid parts of the peat or turf by centrifugal force. When all the water is removed from the peat by this process, and it is in a coherent mass, it is removed and moulded into blocks. These blocks are put into large cylindrical iron vessels, into which steam, at from 45 lbs. to 60 lbs. pressure per square inch, is admitted, after a process of superheating, by traversing iron tubes heated to bright redness. This process, although strongly recommended, has never been practically adopted.

Peat charcoal, as far as heating power is concerned, ranks among the best kinds of

fuel, but it produces so much ash as to make its use very objectionable. 100 pounds of dry peat, say Messrs. Ronalds and Richardson, leave 21 lbs. of ash, and produce 47 lbs. of charcoal, therefore those 47 lbs. of peat charcoal will contain 21 lbs. or 45 per cent. of ash.

Rogers adopted in Ireland a system of drying peat and carbonising it, which was for some time carried forward with much promise of success. Green produced a draught of hot air through a drying house, by means of chimneys and fires. He then distilled the dry peat in wrought-iron cylinders, similar to those employed in making illuminating gas, the gases obtained being used as part of the fuel below. Notwithstanding all the attempts which have been made to utilise peat charcoal, there is no process now carried out on a large scale.

PLATINISED CHARCOAL.—This preparation, which appears destined to become exceedingly valuable, was introduced by Dr. Stenhouse, who thus describes the mode of preparation and some of its uses:—

‘The lighter kinds of wood charcoal, owing to the nine volumes of oxygen gas contained in their pores, possess a considerable power of oxidising the greater number of easily alterable gases and vapours. The absorbent power of charcoal, however, is comparatively much greater than its capacity for inducing chemical combination. In this respect charcoal presents a remarkable contrast to spongy platinum, which, though inferior as an absorbent for some gaseous substances—such for instance, as ammonia, of which spongy platinum absorbs only 30 volumes, while charcoal absorbs ninety—is, nevertheless, immensely more effective, both as an oxidiser, and as a promoter of chemical combination generally. As it is desirable for some purposes, while retaining the absorbent power of charcoal unimpaired, to increase its oxidating influences, it struck me that this important object might be easily effected by combining the charcoal with minutely-divided platinum. In this way, a combination is produced, to which I have given the name of platinised charcoal, which possesses the good properties of both of its constituents. In order to platinise charcoal, nothing more is necessary than to boil the charcoal, either in coarse powder or in large pieces, in a solution of bichloride of platinum, and when the charcoal has become thoroughly impregnated with the platinum, which seldom requires more than ten minutes, or a quarter of an hour, to heat it to redness in a close vessel—a capacious platinum crucible being very well adapted for this purpose. When 150 grains of charcoal were impregnated with nine grains of platinum, by the process just described, the charcoal was found to have undergone no change in its external appearance, though its properties have been very essentially altered. When a few grains of this platinised charcoal were passed up into a mixture of dry oxygen and hydrogen in the proportions to form water, over mercury, the two gases combined in the course of a few minutes, precisely in the same way as when a clay ball of spongy platinum is employed. When, however, a fragment of charcoal containing a considerably larger proportion of platinum was passed up into a similar gaseous mixture, the gases instantly combined with explosive violence, just as if platinum-black had been used. If pieces of cold platinised charcoal are held in a jet of hydrogen, they speedily become incandescent, and inflame the gas. Platinised charcoal, when slightly warmed, likewise rapidly becomes incandescent in a current of coal-gas, but the jet of gas is not inflamed, owing to the very high temperature, a white heat, which is required for this purpose.

‘In the vapour of alcohol or wood spirit, platinised charcoal becomes red hot, and continues so till the supply of vapour is exhausted. In the course of a few hours, spirits of wine, in contact with platinised charcoal and air, is converted into vinegar. I find that two per cent. of platinum is sufficient to platinise charcoal for most purposes. Charcoal containing this small amount of platinum, causes a mixture of oxygen and hydrogen to combine perfectly in about a quarter of an hour, and this is the strength of platinised charcoal that seems best adapted for charcoal disinfectant respirators. Charcoal containing one per cent. of platinum causes a mixture of oxygen and hydrogen to combine in about two hours; and charcoal containing the extremely minute quantity of $\frac{1}{4}$ per cent. platinum, produces the same effect in from 6 to 8 hours. Platinised charcoal seems likely to admit of various useful applications; one of the most obvious of these is its excellent adaptability to air-filters and respirators for disinfectant purposes. It is plain that no easily alterable organic vapours, such as effluvia or miasmata, can remain in contact, even for a few minutes, with platinised charcoal without being destroyed, their carbon being converted into carbonic acid, and their hydrogen into water.

‘Platinised charcoal also seems likely to prove a highly useful application to malignant ulcers and similar sores, on which I confidently expect, from its powerful oxidating properties, that it will act as a mild, but effective, caustic. Perhaps, however, as an application to sores, platinised asbestos, either alone, or in combination with platinised charcoal, might be found more manageable. In those diseases also

where the internal use of charcoal has been found beneficial, I should think that platinised charcoal may be advantageously substituted. In Bunsen's carbon battery also the employment of platinised charcoal may, I think, be advantageously tried.

'It is clear that the amount of platinum in the charcoal may be varied almost at pleasure, according to the strength of the platinum solution employed in its preparation, and the purposes to which the charcoal is intended to be applied. Almost any form, and even very considerable dimensions, may be given to the platinised charcoal—circumstances which greatly extend the range of its applications.'

CHARCOALS. The name by which the best tin plates are known; these are always made by charcoal fires.

CHASCHISCH, or *Hashash*. *Hadschy* is not the correct term for this narcotic drug, for *Hadschy* means a *pilgrim*; the true name is, according to pronunciation, *Chaschisch*, the Arab word for hemp (*Cannabis sativa*). By this name, all intoxicating drugs whose chief constituent is this herb are well known over the whole of the East. The mode of preparing chaschisch is the following:—

The tops and all the tender parts of the hemp plant are collected after the period of inflorescence; dried and kept for use. It must be premised that the hemp plant is in the East distinguished by its narcotic properties, although botanists are unable to detect any difference between this and the European species. The dried hemp or chaschisch, is used—

1st. Boiled in fat, butter, or oil, with a little water; the filtered product is employed in all kinds of pastry.

2nd. Powdered for smoking: 5 or 10 grains of the powder are smoked from a common pipe (*tsublik*) with ordinary tobacco (*tütüm*), or from a water-pipe (*nargiele*) with another kind of tobacco (*tombeki*). The *tombeki* is probably the leaf of a species of lobelia; it is smoked in a nargiele, and is uncommonly narcotic; so much so, that it is ordinarily steeped in water for a few hours before it is used, to weaken it, and the pipe is charged with it whilst it is yet wet.

3rd. Formed with tragacanth mucilage into pastiles, which are placed upon a pipe and smoked in similar doses. These last two preparations are termed *esrar* (*esrar* is the Arab word for *secret*); they are the most active of all the preparations of chaschisch, and the first pipe will cause cerebral congestion in beginners.

4th. Made into an electuary with dates or figs and honey. This preparation is of a dark brown, almost black colour, and tastes of dates and hemp; it is less active than the *esrar*.

5th. Lastly, another electuary is prepared of the same ingredients with the addition of spices, clove, cinnamon, pepper, amber, and musk. This preparation is used as an aphrodisiac.

Chaschisch is said not to produce stupor, but the most pleasant species of intoxication. The person under its influence feels with perfect consciousness in the best of all humours; all impressions from without produce the most grateful sensations; pleasant illusions pass before his eyes, and he feels comfortably happy; he thinks himself the happiest man on earth, and the world appears to him Paradise. From this imaginative state he passes into the every-day state, with a perfect recollection of all sensations, and of everything he has done and of every word he has spoken. The effects of a continual use of the narcotic are emaciation and nervous debility.

CHATHAM LIGHT. A flash-light used for military purposes, obtained by blowing a mixture of powdered resin and magnesium through a spirit flame.

CHAY ROOT. The root of the *Oldenlandia umbellata*, a plant grown on the Coromandel Coast in India, and valued for the red dye-stuff which it yields.

CHECK. A cloth in which coloured lines or stripes cross each other rectangularly. Blackburn in England, and Kirkcaldy in Scotland, are the principal centres of the check manufacture. See WEAVING.

CHEESE. (*Fromage*, Fr.; *Käse*, Ger.) The curd of milk which has been allowed to undergo a peculiar change, by which it acquires the well-known flavour. The most celebrated English cheeses are manufactured in Cheshire, Gloucestershire, and Somersetshire. The milk of animals contains three principles, which are, by very slight changes, separated from each other. By a short repose, an oily portion rises to the surface of the milk—this consists of the cream globules, which are readily converted into butter. If any acid be added to the milk, a curd separates; this is the caseous matter, or casein, which being pressed in moulds, becomes cheese; the third portion being the serum or whey. The cheesy matter which exists in milk in a soluble state, is usually separated by means of rennet (see RENNET)—that is, it is coagulated by it, or rendered insoluble. The action of rennet upon milk is still very imperfectly understood. In order to investigate the subject, Berzelius washed and dried the stomach of a calf, and yet he found that one part of this, mixed with nearly 2,000 parts of skimmed milk, and heated to 120° F., so completely coagulated the caseous matter that no trace of it remained in solution. All acids curdle milk—muriatic (hydrochloric)

acid is said to be used for this purpose in Holland. Some vegetables readily coagulate milk, amongst others the juice of the fig-tree, and the flowers of the *Galium verum*, the yellow lady's bed-straw, or cheese rennet. The odour of the flowers of this plant is sweet, the stalks and flowers have been used in Cheshire to curdle milk, and they are said to give a peculiar flavour to that kind of cheese.

There are different kinds of cheeses according to the manner of preparing them.

Soft cheeses—as cream cheese, and Bath and Yorkshire cheese, which will not keep long, and are therefore sold as soon as made.

Hard cheeses—as Cheshire, Gloucester, Cheddar, Parmesan, and Dutch cheese.

Intermediate—we may regard the Gruyère and Stilton.

The following is the process used for cheese-making in general. The milk is first strained, then put into a large cauldron, which hangs from an iron crane over a wood fire, and heated to nearly blood-heat. It is then removed from the fire, the prepared rennet is added to it, and stirred till it is well mixed with the warm milk. The cauldron is then covered with a cloth, and left for about half an hour or an hour, till the coagulum is formed. This done, the curd is cut horizontally, with a flat wooden skimming ladle, made for that purpose, into thin slices, which are poured against the side of the cauldron, so that every portion of the curd thus rises to the surface, and is thinly sliced. The cauldron is then replaced over the fire, and the whole is well stirred with a long staff with a knob made of hard wood at the end, and small sticks placed crosswise through holes bored in it; this breaks the curd into very small pieces; the stirring is continued until the heat is raised to 135° , when the cauldron is again taken off the fire. It is then stirred for nearly an hour more with the staff, and when this is done, the curd is found in small pieces about the size of a pea, which feel elastic and rather tough. The curd is then collected in the bottom of the cauldron, and the whey floats at the top: a cloth is put under the curd, and lifted by the four corners on to an instrument, something like a small ladder which is placed across the top of the cauldron. The whey runs out through the cloth, then the curd in the cloth is put into a hoop, made of a thin piece of wood; and a board about two inches thick is placed over it; it is then put into the press. After remaining in the press about an hour, the curd is examined, and the edges which have pressed over the ring are pared off and put in the centre of the cheese. The cheese is then taken out of the hoop and turned, and a fresh cloth substituted. This is done two or three times during the day. A little finely-powdered salt is then rubbed on both sides of the cheese, and it is left in the press until the next morning; after that it is taken out and put on a shelf, where it is allowed to remain for six or eight weeks, having a little salt rubbed into it every day till it will not take any more. The weather has a great influence on the dairy. In Cheshire, cheeses are made in great perfection. In making them they are particularly careful to extract every particle of whey; to do this they press the curd very tightly in boxes with holes bored in them; they then put wooden skewers through these holes into the cheese, so that no whey can possibly remain in the curd. This process gives Cheshire cheeses the solid appearance which they possess. If there are any holes in them they are considered imperfect. In these cheeses the salt is mixed with the curd, instead of being rubbed on the outside of the cheese. This prevents fermentation, or the formation of any elastic matter. Gloucester and Somersetshire cheeses are made in just the same way as the Cheshire, except that the curd is not quite so much broken, or the skewers put through the cheese, and some portion of the cream is generally taken to make butter. Warm water is poured over the curd to wash from it any whey that may still be remaining in it, or to dissolve any of the oily part, or butter, that may have separated, before the milk had been coagulated.

Stilton cheeses require great care in making them. They are made by adding the preceding evening's cream to the morning's milk. The cream and milk must be well mixed together, and after the milk is coagulated, the curds must be strained through a sieve, only lightly pressed, and then put into a shape; when it is firm enough it is taken out, bound round with a cloth to keep it from breaking, and set on a shelf. It is sometimes powdered with flour and plunged into hot water to harden the outside. Stilton cheese is generally preferred in a mouldy state, and to hasten this, pieces of another mouldy cheese are often inserted in the new Stilton, or wine or ale poured over it. But if the cheese is rich, it does not require this, but the inside will get soft like butter, without getting mouldy.

Gruyère and *Parmesan* cheeses are made by the process first described; the only difference between them being, that a greater degree of heat is used in making Parmesan than in making Gruyère, and this renders the Parmesan cheese dry and grained, while the Gruyère is pressed and compact. A little saffron is also used to give Parmesan colour and flavour, but nothing is used for Gruyère.

Dutch cheeses are made in a very similar way to Gloucester cheeses; but instead of using rennet to curdle the milk, the Dutch use muriatic acid, or spirits of salt.

They are very careful to prevent fermentation in this cheese, and in order to effect this, the curd, after being well broken and pressed, is soaked in salt and water; salt is also rubbed on the outside of the cheeses, and it thus acquires the quality of keeping well, even in warm climates. These cheeses are generally known in Holland by the name of Edam cheeses, from the name of the place where they are made.

Another cheese much used in Holland is one made from skim milk; not having much flavour of its own, cummin seeds are mixed with the curd to supply this defect.

The *Roquefort cheese* is made in France from goats' or sheep's milk. The evening's and morning's milk are mixed, and rennet is used in the ordinary way to coagulate it. The curd is then subjected to great pressure, and when the whey is all extracted, the cheeses are laid on shelves, side by side, and frequently wiped carefully to dry them without heat. They generally wrap the cheeses in coarse cloths, to prevent them from cracking in drying. When they are quite dried, they are taken to caves dug in the rocks, where the air is always cool, and placed on shelves. They are then salted, and after about two or three days, they are rubbed with a coarse cloth, and then scraped with a knife. They are then left for fifteen days, during which time they get hard, and begin to get mouldy on the outside: the mouldiness is removed by a knife, and this process is repeated every fifteen days, for two months, and sometimes oftener. During this time the crust formed on the cheeses becomes successively white, greenish and reddish; when it is this latter colour, they are fit for use.

The *Brie cheese* is another, the quality of which is nearly as good as the last, but it is only used in the places where it is manufactured, because it will not keep. It is very simply made; the milk curdled in the usual manner is put to strain on a wicker frame. When all the whey has been extracted, the cheese is salted and put in a very cool place; the salting is repeated every two days: when salted sufficiently it is removed to a cave or placed on a bed of hay, until it softens. This cheese should be eaten when it is about the consistency of cream; it is then delicious, but if left longer, it becomes putrid.

The *Neufchâtel cheeses* are merely cream thickened by heat, and then compressed in a small mould. They are esteemed a great delicacy.

There is a small cheese much relished in Germany, made from skimmed milk. The milk is curdled by being placed near the fire; the curds are then put into a linen bag, and all the whey pressed out of them. When this has become solid, the curd is again broken in a tub, and allowed to remain in this state for several days. Putrid fermentation then begins to take place; when in this state it is taken and rolled into little balls with the hand, and flavoured with carraway seed. After a few days the inside of the ball becomes soft, and it is then esteemed a great dainty by many. Sometimes they are placed in the smoke of a chimney over a wood fire; the smoke hardens the outside, and when they are eaten, it is taken off like the rind of an apple.

The *Schabzieger*, a Swiss cheese, is made in much the same manner; the curd is worked into a paste with a large quantity of an herb, called in the country dialect *Ziegerkraut*, finely powdered. It is then pressed into a mould, and becomes very solid, and capable of being kept a long time. When eaten it is scraped and mixed with butter, and spread on bread. It possesses a very peculiar taste.

The *Jura cheese* is very much like the *Gruyère*, and is often sold for it.

There is a kind of cheese or hard curd made in Switzerland with the whey that is left after making other cheeses. The whey is heated over the fire until a thick scum arises; it is then put in a square box, all the whey runs off, and the curd, which is called *serré*, remains; this is dried, and although nearly flavourless, is much eaten by the people on the mountains, who use it instead of bread. They cut it in slices, and spread butter on it, and it forms the principal food of some of the herdsmen.

Composition of Cheese.

(Payen, *Journal Pharma.*)

	Water	Ash of the substance		Nitrogen			Fat	
		Normal	Dry	Normal	Dry	Free from ash	Normal	Dry
Cheese from Chester	30.39	4.78	6.88	5.56	8.00	8.59	25.48	36.61
„ „ Parmesan	30.31	7.09	10.18	5.48	7.87	8.76	21.68	31.12

„ „ Gruyère	32.05	4.79	7.05	5.40	7.96	8.56	28.40	41.81

If a cheese is hard and dry it is much improved by washing several times in soft water, and then laying it in a cloth moistened with wine or vinegar. This method is often practised in Switzerland, where cheeses are often kept for many years.

In England, cheeses are frequently coloured: the substance most generally used for colouring is arnotto. Sometimes the juice of the orange or carrot, and the flower of the marigold, are used for this purpose. Foreign cheeses are seldom coloured.

Cheese of certain dairies and districts is apt to undergo a remarkable decomposition, whereby valerianic acid is formed. Messrs. Iljenko and Laskowski distilled, along with water, a turbid ammoniacal liquor, which being redistilled along with some sulphuric acid, and the product neutralised by barytes, the resulting saline compound proved to be the valerianate of that base, mixed with compounds of butyric acid, caproic acid, caprylic acid, and capric acid; the cheese was from Limbourg. Valerianic acid was found by M. Balard in the cheese of Roquefort.

CHEMICAL AFFINITY. The term used to express the force, in obedience to which combinations of apparently dissimilar bodies are produced.

CHEMICAL FORMULÆ. See FORMULÆ, CHEMICAL.

CHEMICK. See BLEACHING.

CHENEVIXITE. A hydrous arsenate of peroxide of iron and protoxide of copper, from Cornwall.

CHERRY COAL. A soft non-caking coal. The coals of Staffordshire, of Derbyshire, and much of the Scotch coal appears to belong to this variety. See COAL.

CHERRY TREE. The Tunbridge turners use the wood largely, considering the wood of the black-heart cherry the best. It is a hard, close-grained wood, of a pale red-brown colour.

CHERT, a siliceous mineral nearly allied to chalcedony and flint. It generally occurs in limestone rocks, and beds of it are not uncommon in parts of the Mountain Limestone. A gradual passage from chert to limestone is not uncommon.—*Lyell*. Chert is a term often applied to hornstone, and to any impure flinty rock, including the jaspers.—*Dana*.

Chert is worked extensively out of the Carboniferous Limestone quarries of Flintshire, especially at Halkin and at Talacre. It is also produced in considerable quantities in the same formation in Derbyshire. It is used in the Potteries, for paving the mills in which flints are ground.

CHESSY COPPER or **CHESSYLITE.** The blue carbonate of copper which is found in great beauty at Chessy near Lyons. See AZURITE.

CHESTNUT. (*Castanea vesca*.) The wood of this, the sweet or Spanish chestnut, is sometimes used in house carpentry. The wood of an oak (*Quercus sessiliflora*) is often mistaken for it.

The wood of the horse chestnut (*Æsculus hippocastanum*) is one of the white woods much used by the turners of Tunbridge; it is also employed for brush backs. The white (*inner*) bark of the horse chestnut, when infused in boiling water, produces a yellow fluid, which possesses the remarkable power of *fluorescence*, that is, it *throws back* from its first surface a set of rays of high refrangibility, and of a blue colour, while the ordinary yellow rays are duly transmitted. The phenomena have been fully investigated by Professor Stokes, to whom the name is also due. See FLUORESCENCE.

CHICA is a red colouring principle made use of in America by some Indian tribes to stain their skins. It is extracted from the *Bignonia chica* by boiling its leaves in water, decanting the decoction, and allowing it to settle and cool, when a red matter falls down, which is formed into cakes and dried. It is not much used in this country. The *crajuru* or *carcuru*, which is imported from Para in Brazil is more frequently employed. The dyes are probably identical, but one is purer than the other. See CARAJURA.

CHICORY. The root of the *Chicorium intybus*; Wild Succory or Chicory. This plant is cultivated in various parts of England, growing well in a gravelly and chalky soil; also in Belgium, Holland, Germany, and France. The roots of the wild succory were formerly used medicinally; it possesses properties in many respects resembling those of the dandelion, but it is rarely employed for curative purposes in the present day.

Chicory root roasted has been employed as a substitute for coffee for more than a century. (*Constantini, Nachricht von d. Cichorianwurzel, 1771.*) It is now employed extensively as a mixture with coffee, which, although allowed, cannot be regarded other than an adulteration.

Chicory root is heated in iron cylinders, which are kept revolving as in the roasting of coffee. In this country about two pounds of lard are added to every cwt. of chicory during the roasting process: in France butter is used; by this a lustre and colour resembling that of coffee is imparted to it. When roasted the chicory is ground to powder and mixed with the coffee. Chicory has been supposed by some persons to be wholesome and nutritive, while others contend that it is neither one nor the other; however, no obvious ill effects have been observed to arise from its employment, if we except the occasional tendency to excite diarrhœa when it has

been used to excess. The analysis of chicory root by John gave 25 parts *watery bitter extractive*, 3 parts *resin*, besides *sugar*, *sal-ammoniac*, and *woody fibre*. Walfi procured *inulin* from it, but the quantity varies greatly in different roots. The following remarks on the adulteration of chicory are by Dr. Pereira:—

‘Roasted chicory is extensively adulterated. To colour it, Venetian red and, perhaps, redde are used. The former is sometimes mixed with the lard before this is introduced into the roasting machine; at other times it is added to the chicory during the process of grinding. Roasted pulse (peas, beans, and lupines), corn (rye and damaged wheat), roots (parsnips, carrots, and mangold wurzel), bark (oak-bark tan), wood dust (logwood and mahogany dust), seeds (acorns and horse-chestnuts), the marc of coffee, coffee husks (called coffee-flights), burnt sugar, baked bread, dog biscuit, and baked livers of horses and bullocks (!), are substances which are said to have been used for adulterating chicory. A mixture of roasted pulse (peas usually) and Venetian red has been used, under the name of *Hambro’ powder*, for the same purpose.

‘The following are the chief modes of examining chicory with the view to the detection of these adulterations:—

‘1st. Careful examination of the odour, flavour, and appearance to the naked eye of the suspected powder. In this way foreign substances may sometimes be detected.

‘2nd. A portion of the dried powder is to be thrown on water; the chicory rapidly imbibes the water and falls to the bottom, whereas some intermixed powders (as the marc of coffee) float.

‘3rd. The suspected powder is to be submitted to careful microscopical examination. Pulse and corn may be detected by the size, shape, and structure of the starch grains. The tissues of barks, woods, and other roots may also be frequently distinguished from those of the chicory.

‘4th. A decoction of the suspected chicory is then to be prepared, and, when cold, to be tested with solution of iodine and persulphate of iron.

‘Iodine colours a decoction of pure chicory brownish; whereas it produces a purplish, bluish, or blackish colour with decoctions of roasted pulse, roasted corn, baked bread, roasted acorns, and other substances containing starch. Persulphate or perchloride of iron does not produce much effect on a decoction of pure chicory, but it communicates a bluish or blackish tint to a decoction of oak-bark, of roasted acorns, and other substances containing tannic or gallic acids.

‘5th. By incineration, pure dried chicory yields from 4 to 5 per cent. of a grey or fawn-coloured ash. If Venetian red, or any earthy or mineral substances, be present, a larger amount of ash is obtained. Moreover, when Venetian red has been employed, the colour of the ash is more or less red.’

Our *Importations* of Chicory have been as follow:—

	Raw or Kiln-dried at 1l. 6s. 6d. per cwt. duty, imposed April 17, 1863.

CHILDRENITE. This mineral may be regarded as a hydrous phosphate of alumina and iron. The composition of a specimen analysed by Rammelsberg was: phosphoric acid, 28·9; alumina, 14; protoxide of iron, 29·3; protoxide of manganese, 9·5; water, 18·3. At Crinnis mine in Cornwall, childrenite is found on slate, and near Tavistock in Devonshire, with apatite.

CHILE SALT-PETRE. Native nitrate of soda, or cubic nitre.

CHILEITE A vanadate of copper and lead, occurring at the silver mine of Mina Granda, in Chile.

CHILLI, commonly *Chillies*. The fruit of certain species of capsicum, valued for their pungency.

CHIMNEY. (*Cheminée*, Fr.; *Schornstein*, Ger.) (The whole of this article is retained as written by Dr. Ure, his investigation on some of the points involved being

of much value.) Chimney is a modern invention for promoting the draught of fires and carrying off the smoke, introduced into England so late as the age of Elizabeth, though it seems to have been employed in Italy 100 years before. The Romans, with all their luxurious refinement, must have had their epicurean cookery placed in perpetual jeopardy from their kitchen fires, which, having no vent by a vertical tunnel in the walls, discharged their smoke and frequently their flames at their windows, to the no small alarm of their neighbours, and annoyance of even the street passengers.

Chimneys in dwelling-houses serve also the valuable purpose of promoting a salubrious circulation of air in the apartments, when not foolishly sealed with anti-ventilating stove-chests.

The first person who sought to investigate the general principles of chimney draughts, in subserviency to manufacturing establishments, was the celebrated Montgolfier. As the ascent of heated air in a conduit depends upon the diminution of its specific gravity, or, in other words, upon the increase of its volume by the heat, the ascensional force may be deduced from the difference between the density of the elastic fluid in the interior of the chimney, and of the external air; that is, between the different heights of the internal and external columns of elastic fluid supposed to be reduced to the same density. In the latter case, the velocity of the gaseous products of combustion in the interior of the chimney is equal to that of a heavy body let fall from a height equal to the difference in height of the two aerial columns.

To illustrate this position by an example, let us consider the simple case of a chimney of ventilation for carrying off foul air from a factory of any kind; and suppose that the tunnel of iron be incased throughout with steam at 212° Fahr. Suppose this tunnel to be 100 yards high, then the weight of the column of air in it will be that of a column of external air 100 yards high, assumed at 32° Fahr., inversely as its expansion by 180°; that is, as 72·727 is to 100. The column of external air at 32° being 100 yards, the internal column will be represented by 72·727; and the difference = 27·27, will be the amount of unbalanced weight or pressure, which is the effective cause of the ventilation. Calculating the velocity of current due to this difference of weight by the well-known formula for the fall of heavy bodies, that is to say, multiplying the above difference, which is 27·27, by the constant factor 19·62, and extracting the square root of the product; thus, $\sqrt{19\cdot62 \times 27\cdot27} = 23\cdot13$ will be the velocity in yards per second, which, multiplied by 3, gives 69·39 feet. The quantity of air which passes in a second is obtained of course by multiplying the area or cross section of the tunnel by this velocity. If that section is half a yard, that is = a quadrangle $2\frac{1}{4}$ feet by 2, we shall have $23\cdot13 \times 0\cdot5 = 11\cdot565$ cubic yards, = $312\frac{1}{4}$ cubic feet.

The problem becomes a little more complicated in calculating the velocity of air which has served for combustion, because it has changed its nature, a variable proportion of its oxygen gas of specific gravity 1·111 being converted into carbonic acid gas of specific gravity 1·534. The quantity of air passed through well-constructed furnaces may, in general, be regarded as double of what is rigorously necessary for combustion, and the proportion of carbonic acid generated, therefore, one half of what it would be were all the oxygen so combined. The increase of weight in such burned air of the temperature of 212°, over that of pure air equally heated, being taken into account in the preceding calculation, will give us about 19 yards or 57 feet per second for the velocity in a chimney 100 yards high incased in steam.

In comparing the numbers resulting from the trials made on chimneys of different materials and of different forms, it has been concluded that the obstruction to the draught of air is directly proportional to the length of the chimneys and to the square of the velocity, and inversely to their diameter.

With an ordinary wrought-iron pipe of from 4 inches to 5 inches diameter, attached to an ordinary stove, burning good charcoal, the difference is prodigious between the velocity calculated by the above theoretical rule and that observed by means of a stop watch, and the ascent of a puff of smoke from a little tow dipped in oil of turpentine thrust quickly into the fire. The chimney being 45 feet high, the temperature of the atmosphere 68° Fahr. the velocity per second was:

Trials	By theory	By experiment	Mean Temperature of chimney
1 . . .	26·4 feet . . .	5 feet . . .	190° Fahr.
2 . . .	29·4 " . . .	5·76 " . . .	212° "
3 . . .	34·5 " . . .	6·3 " . . .	270° "

To obtain congruity between calculation and experiment, several circumstances must be introduced into our formulæ. In the first place, the theoretical velocity must be multiplied by a factor, which is different according as the chimney is made of bricks, pottery, sheet iron, or cast iron. This factor must be multiplied by the square root of the diameter of the chimney (supposed to be round), divided by its

length, increased by four times its diameter. Thus, for pottery, its expression is $2.06 \frac{\sqrt{D}}{L+4D}$; D being the diameter, and L the length of the chimney.

A pottery chimney, 33 feet high, and 7 inches in diameter, when the excess of its mean temperature above that of the atmosphere was 205° Fahr., had a pressure of hot air equal to 11.7 feet, and a velocity of 7.2 feet per second. By calculating from the last formula, the same number very nearly is obtained. In none of the experiments did the velocity exceed 12 feet per second, when the difference of temperature was more than 410° Fahr.

Every different form of chimney would require a special set of experiments to be made for determining the proper factor to be used.

This troublesome operation may be saved by the judicious application of a delicate differential barometer, such as that invented by Dr. Wollaston; though this instrument does not seem to have been applied by its very ingenious author in measuring the draughts or ventilating powers of furnaces.

If into one leg of this differential siphon, water be put, and fine spermaceti oil into the other, we shall have two liquids, which are to each other in density as the numbers 8 and 7. If proof spirit be employed instead of water, we shall then have the relation of very nearly 20 to 19. In experiments made on furnace draughts with the instrument in each of these states, it is found that the water and oil siphon is sufficiently sensible: for the weaker draughts of common fire-places the spirits and oil will be preferable barometric fluids.

To the lateral projecting tube of the instrument, as described by Dr. Wollaston, it was found necessary to attach a stop-cock, in order to cut off the action of the chimney, while placing the siphon, to allow of its being fixed in a proper state of adjustment, with its junction-line of the oil and water at the zero of the scale. Since a slight deviation of the legs of the siphon from the perpendicular changes very considerably the line of the level, this adjustment should be made secure by fixing the horizontal pipe tightly into a round hole, bored into the chimney stalk, or drilled through the furnace door. On gently turning the stop-cock, the difference of atmospheric pressure corresponding to the chimney draught will be immediately indicated by the ascent of the junction-line of the liquids in the siphon. This modification of apparatus permits the experiment to be readily rectified by again shutting off the draught, when the air will slowly re-enter the siphon; because the projecting tube of the barometer is thrust into the stop-cock, but not hermetically joined; whereby its junction-line is allowed to return to the zero of the scale in the course of a few seconds.

Out of many experiments made with this instrument, it will be sufficient to describe a few, very carefully performed at the breweries of Messrs. Trueman, Hanbury, and Buxton, and of Sir H. Meux, Bart., and at the machine factory of Messrs. Braithwaite by Dr. Ure; in the latter of which he was assisted by Captain Eriessen. In the first trials at the breweries, the end of the stop-cock attached to the differential barometer was lapped round with hemp, and made fast into the circular peep-hole of the furnace door of a wort-copper, communicating with two upright parallel chimneys, each 18 inches square and 50 feet high. The fire was burning with fully its average intensity at the time. The adjustment of the level being perfect, the stop-cock orifice was opened, and the junction level of the oil and water rose steadily, and stood at $1\frac{1}{4}$ inch corresponding to $1\frac{3}{5} = 0.156$ of 1 inch of water, or a column of air 10.7 feet high. This difference of pressure indicates a velocity of 26 feet per second. In a second set of experiments, the extremity of the stop-cock, was inserted into a hole bored through the chimney stalk of the boiler of a Boulton and Watt steam-engine of twenty-horse power. The area of this chimney was exactly 18 inches square at the level of the bored hole, and its summit rose 50 feet above it. The fire-grate was about 10 feet below that level. On opening the stop-cock the junction-line rose $2\frac{1}{4}$ inches. This experiment was verified by repetition upon different days, with fires burning at their average intensity, and consuming fully 12 lbs. of the best coals hourly for each horse's power, or nearly one ton and a third in twelve hours. If we divide the number $2\frac{1}{4}$ by 8 the quotient 0.28 will represent the fractional part of 1 inch of water supported in the siphon by the unbalanced pressure of the atmosphere in the said chimney; which corresponds to $19\frac{1}{2}$ feet of air, and indicates a velocity in the chimney current of 35 feet per second. The consumption of fuel was much more considerable in the immense grate under the wort-copper than it was under the steam-engine boiler.

In the experiments at Messrs. Braithwaite's factory, the maximum displacement of the junction-line was 1 inch, when the differential oil and water barometer was placed in direct communication with a chimney 15 inches square, belonging to a steam boiler, and when the fire was made to burn so fiercely, that, on opening the safety-valve of the boiler, the excess of steam beyond the consumption of the engine rushed out with such violence as to fill the whole premises. The pressure of one-eighth of an inch of water denotes a velocity of draught of 23.4 feet per second.

In building chimneys, we should be careful to make their area rather too large than too small; because we can readily reduce it to any desired size by means of a sliding register plate near its bottom, or a damper plate applied to its top, adjustable by wires or chains passing over pulleys. Wide chimneys are not so liable as narrow ones to have their draught affected by strong winds. In a factory, many furnace flues are often conducted into one vertical chimney stalk, with great economy in the first erection, and increased power of draught in the several fires.

Vast improvements have been made in this country of late years in building stalks for steam boilers and chemical furnaces. Instead of constructing an expensive, lofty scaffolding of timber round the chimney, for the bricklayers to stand upon, and to place their materials, pigeon-holes, or recesses, are left at regular intervals, a few feet apart, within the chimney, for receiving the ends of stout wooden bars, which are laid across, so as to form a species of temporary ladder in the interior of the tunnel. By means of these bars, with the aid of ropes and pulleys, everything may be progressively hoisted for the building of the highest engine or other stalks. An expert bricklayer, with a handy labourer, can in this way raise, in a few weeks, a considerable chimney, 40 feet high, 5 feet 8 inches square outside, 2 feet 8 inches inside at the base, 28 inches outside, and 20 inches inside at the top. To facilitate the erection, and at the same time increase the solidity of an insulated stalk of this kind, it is built with three or more successive plinths, or recedures, as shown in *fig. 455*. It is necessary to make such chimneys thick and substantial near the base, in order that they may sustain the first violence of the fire, and prevent the sudden dissipation of the heat. When many flues are conducted into one chimney stalk, the area of the latter should be nearly equal to the sum of the areas of the former, or at least of as many of them as shall be going simultaneously. When the products of combustion from any furnace must be conducted downwards, in order to enter near the bottom of the main stalk, they will not flow off until the lowest part of the channel be heated by burning some wood shavings or straw in it, whereby the air siphon is set agoing. Immediately after kindling this transient fire at that spot, the orifice must be shut by which it was introduced; otherwise the draught of the furnace would be seriously impeded. But this precaution is seldom necessary in great factories, where a certain degree of heat is always maintained in the flues, or, at least, should be preserved, by shutting the damper plate of each separate flue whenever its own furnace ceases to act. Such chimneys are finished at top with a coping of stone-slabs, to secure their brick-work against the infiltration of rains, and they should be furnished with metallic conducting rods, to protect them from explosions of lightning.

When small domestic stoves are used, with very slow combustion, as has been proposed upon the score of a misjudged economy, there is great danger of the inmates being suffocated or asphyxied, by the regurgitation of the noxious burned air. The smoke doctors who recommend such a vicious plan, from their ignorance of chemical science, are not aware that the carbonic acid gas of coke or coal must be heated 250° F. above the atmospheric air to acquire the same low specific gravity with it. In other words, unless so rarefied by heat, that gaseous poison will descend through the orifice of the ash-pit, and be replaced by the lighter air of the apartment. Drs. Priestley and Dalton have long ago shown the co-existence of these twofold crossing currents of air, even through the substance of stoneware tubes. True economy of heat and salubrity alike require vivid combustion of the fuel, with a somewhat brisk draught inside of the chimney, and a corresponding abstraction of air from the apartment. Wholesome continuous ventilation, under the ordinary circumstances of dwelling-houses, cannot be secured in any other way.

The figures upon the following page represent one of the two chimneys erected at the Camden Town station, for the London and North-Western Railway Company. The chimneys were designed by Robert Stephenson, Esq., engineer to the company, and executed by William Cubitt, Esq., of Gray's Inn Road. In the section. *fig. 455*,

- A represents a bed of *concrete*, 6 feet thick and 24 feet square.
- B, brick footings set in cement; the lower course 19 feet square.
- c, Bramley-fall stone base, with a chain of wrought iron let into it.
- D, a portion, 15 feet high, curved to a radius of 113 feet, built entirely of Malm paviours (a peculiarly good kind of bricks).
- e, shaft built of Malm paviours in mortar.
- f, ditto, built from the inside, without exterior scaffolding.
- g, the cap, ornamented (as shown in the plan alongside) with Portland stone, the dressings being tied together with copper cramps and an iron bond.
- k, the lightning conducting rod.

Fig. 456, represents the mouldings of the top, upon an enlarged scale.

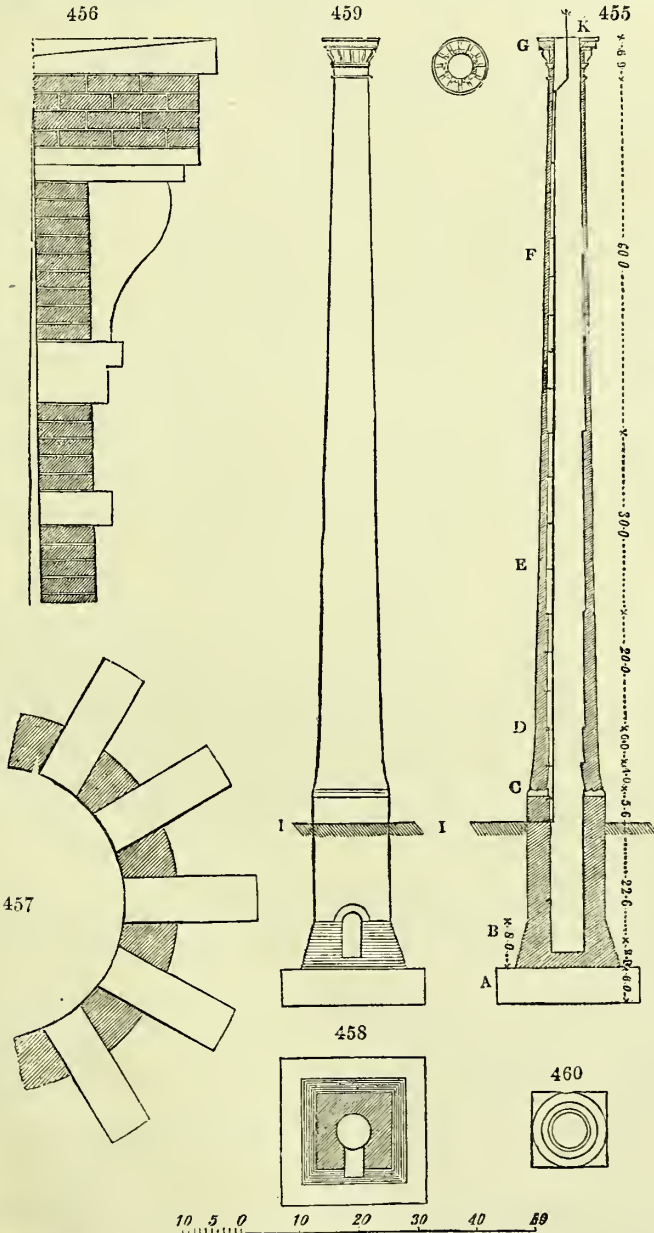

Fig. 457, a plan of the foundation, upon an enlarged scale.

Fig. 458, ditto, at the level of the entrance of the flue as seen in

Fig. 459, the elevation of the chimney.

Fig. 460, plan at the ground level i, in figs. 455 and 459.

Some modified arrangements in the mode of constructing the chimney and fire-place have been devised by Colonel Douglas Galton. These will be found fully described in the Report of the Committee 'On Waste of Coal in Combustion,' in the Report of the Royal Coal Commission.

CHINA CLAY. A fine white clay produced by the decomposition of the felspar of the granite rocks. It is found and prepared, in this country, in Cornwall and Devonshire. See CLAY.

CHINA GRASS. A fibre obtained from the stalk of the *Bahmeria* (*Urtica*) *nivca*, a plant belonging to the *Urticaceae*, or Nettle order.

CHINA INK. (*Encre de Chine*, Fr.; *Chinesischer Tusch*, Ger.) It is said that the true China ink is made from the condensed smoke or soot of burned camphor; and hence, when of the best quality, it has this odour.

Most of the China ink is made from oil lampblack, disguised as to smell with musk, or with a little camphor-black. The binding substance is gelatine, commonly made from parchment; but isinglass answers equally well. A good imitation may be made by dissolving isinglass in warm water, with the addition of a very little alkali to destroy the gelatinising power, and incorporating with that solution, by levigation on a porphyry slab, as much of the finest lampblack as to produce a mass of the proper consistence. The minute quantity of alkali serves also to saponify the oil which usually adheres to lampblack, and thereby to make a pigment miscible with water.

CHINA STONE. This is usually regarded as a semi-decomposed granite (*Pe-tun-tse*) which has nearly the same composition as the China clay (see *CLAY*). 'Indeed, the China clay can be considered as little more than this granite in a more advanced state of decomposition.'—*De la Beche*. It is evident that we have adopted the word *Pe-tun-tse* somewhat hastily as indicating this peculiar granite. The following note by M. A. Salvétat will explain its true meaning:—

'Nous ferons observer une fois pour tout que l'expression *Pe-tun-tse* désigne les tablettes ou carreaux de matière blanche dont on va parler, et que la pâte blanche s'appelle *Pe-tun*. Le mot *Tse* (vulgo *fil*) qui termine le mot *Pe-tun-tse*, sert à former des substantifs diminutifs. Ainsi *Pe-tun* signifie la matière blanche et *Tse* ajouté à *Pe-tun* indique des portions, des carreaux de pâte, des briquettes de *Pe-tun*. Il y a des carreaux de pâte de différentes couleurs: pour les distinguer, on fait précéder le mot *Tun-tse* du nom de la couleur. On dit, par exemple, *Hoang-tun-tse*, des carreaux de pâte jaune.'—*Histoire et Fabrication de la Porcelaine chinoise*, Paris, 1856.

The China stone is a kind of granite, the felspar of which is in a peculiar state, as if it had undergone a partial decomposition. It is carefully selected so as to be entirely free of schorl, and requires no other preparation for the market than to be broken into a size convenient for carriage. This granite is of a peculiar nature; it does not contain any mica, but numerous glossy scales of greenish-yellow talc. It has been stated by some authors that 'this rock (*Pegmatite* or *Graphic granite*), after exposure to the decomposing action of the weather, is the chief source' of the China stone and clay. This represents but very imperfectly—indeed, incorrectly—the conditions. The decomposition of the granite, if it be decomposition, is not brought about by the action of the weather, but by some peculiar action proceeding to a considerable depth through the whole mass. In many places, from the very surface to the depth of more than 100 feet, this condition is equally apparent; and possibly it extends to much greater depths in some places. The same stone exposed to the air does not, in any ordinary time, exhibit any signs of disintegration. No satisfactory explanation has yet been offered of the conditions which operate on the granite to produce the Kaolin and the China stone. Indeed, in the minds of many, who have carefully observed all the conditions of the China clay and of the China stone *in situ*, there has originated the idea, that they rather represent the conditions of an imperfectly-formed granite, than of such as has suffered decomposition. China stone is much used in the manufacture of the finest varieties of porcelain, and especially for the production of the most perfect glazes.

There was an agreement existing amongst the producers of China stone to send off annually only 12,000 tons; but when the demand is brisk, this has been extended to 18,000 tons, and sometimes even more. The value of the China stone at the works in Cornwall is annually about 1,800*l*. The whole that is raised is sent to the Staffordshire potteries.

CHINESE BLUE. Several compositions are sold under this name; it is sometimes a mixture of ultramarine with flake white, and sometimes a mixture of cobalt blue and white lead. See *BLUE PIGMENTS*.

CHINESE GRASS CLOTH, or *Ramcc*. A fabric woven from China grass.

CHINESE TALLOW. A white vegetable tallow covering the seeds of the *Stillingia sebifera*. It is used in making candles.

CHINESE WAX. A white waxy secretion, resembling spermaceti, found on the branches of a species of ash (*Fraxinus Chinensis*), grown in China, and probably produced by the puncture of an insect (*Coccus Pe-la*). The wax is chiefly a cerotate of ceryl. It is used in China for making candles.

CHINOIDINE. A brownish resin-like substance obtained from the mother-liquor left in the preparation of quinine.

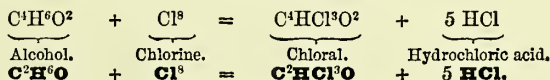

CHINOLINE. C⁹H⁷N (C⁹H⁷N).—A volatile base, found in coal naphtha, and also, accompanied by several others, in the basic fluid obtained by distilling cinchonine with potash.—C. G. W.

CHINOLINE BLUE, *Cyanine* or *Lepidine Blue*. A crystalline compound, prepared by heating chinoline oil, which consists chiefly of lepidine, with iodide of amyl, and treating the product with caustic soda. A black resinous precipitate is thus obtained, which dissolves in alcohol with production of a fine blue colour.

CHINTZ. (*Zitz*, Ger.) Probably derived from the East, the Hindoo name *cheent*, and the Persian *chinz*, signifying spotted or stained. The term is applied in this country to a fast-printed calico, in which several colours are imprinted upon a white or coloured ground, and usually glazed.

CHIOS or **CHIAN TURPENTINE**. The *Pistacia terebinthus*, growing in Syria and the Greek Archipelago, yields this turpentine. The turpentine harvest of Scio, according to Tournefort, is made from the end of July to October, by cutting crossways with a hatchet the trunks of the largest trees. The turpentine runs down on flat stones placed under the trees, where it hardens. The quantity produced from each tree does not exceed eight or ten ounces. Its consistency is that of honey; its colour greenish-yellow, with an agreeable turpentine odour. It is often called Cyprus turpentine, but is seldom seen pure in this country, other coniferous turpentines being sold for it.

CHLORAL. $C^4HCl^3O^2$ (C^2HCl^3O). This compound, discovered by Liebig in 1832, is prepared by the long-continued action of chlorine on ethyl-alcohol. A current of dry chlorine gas is passed slowly but continuously through absolute alcohol, and the final product is a yellow liquid rich in chloral. Both the gas and the alcohol should be free from moisture, as otherwise the proportion of chloral is diminished, whilst that of aldehyde and acetic acid is increased; the reaction, towards the close, should be assisted by heat. It appears that an alcoholate of chloral is first formed by the action of chlorine on alcohol; but on agitating the product with about three times its volume of strong sulphuric acid, and warming the mixture, the free chloral separates as an oily liquid floating on the acid. To purify this crude chloral it should be distilled first from oil of vitriol and then from quicklime, to remove hydrochloric acid. The production of chloral admits of being approximately represented by the following equation, but it should be remembered that the reaction is really more complicated, and that other products accompany the chloral:—

Chloral may also be obtained by other processes, such as the distillation of starch with hydrochloric acid and peroxide of manganese.

Pure chloral is a thin, oily, colourless, volatile liquid, almost tasteless, but with a peculiar pungent odour. It is soluble in water, alcohol, ether, and benzole. Its specific gravity is 1.502, and its boiling point about 200° F. (94° C.). Chloral may be regarded as acetic aldehyde, $C^4H^4O^2$ (C^2H^4O), in which three atoms of hydrogen are replaced by three of chlorine.

When chloral is long preserved in a hermetically-closed vessel it suffers a curious change, becoming converted into a solid white amorphous substance, called *insoluble chloral* or *metachloral*.

Chloral combines readily with water, forming a definite hydrate containing $C^4HCl^3O^2.2HO$ ($C^2HCl^3O.H^2O$). This is a white, solid crystalline substance, slightly volatile on exposure to the air, and incapable of being distilled without decomposition. An aqueous solution of hydrate of chloral, treated with caustic alkali, is resolved into chloroform and an alkaline formiate. When hydrate of chloral is injected under the skin it undergoes a similar decomposition, reacting with the alkali naturally present in the blood, and generating chloroform. The physiological action of the chloroform thus liberated within the system has been studied by Dr. Liebreich, of Berlin, and by Dr. W..B. Richardson. In July 1869, Liebreich took out a patent for the use of chloral, hydrate of chloral, and trichloroacetic acid for anæsthetic purposes. Since that time, the hydrate of chloral has been very largely employed as a powerful narcotic. According to Dr. Richardson, a dose of 90 grains taken internally will produce deep sleep, whilst 140 grains throw the patient into a sleep which is really dangerous. But the hydrate, like other narcotics, requires to be used with great caution. It unfortunately happens that persons who have been accustomed to take moderate doses to relieve pain and induce sleep, frequently acquire a tendency to use it habitually. This habit cannot be too strongly denounced; for, like opium-eating, it not only affects the physical organisation—leading eventually to confirmed disease—but it exercises a most baneful influence on the mental and moral constitution of the unhappy individual.

[For the physiological action of chloral and its hydrate, see Dr. Richardson's Reports presented to the British Association in 1869, 1870 and 1871].—F. W. R.

CHLORALUM. Under this name a solution of chloride of aluminium has been introduced as an antiseptic and disinfectant. It is prepared in the form of a liquid of definite strength, and as a powder. Cotton-wool containing a certain per-centage of chloralum is made for the use of the surgeon.

CHLORANILINE. $C^{12}H^6ClN$ (C^6H^3ClN). An organic base obtained by distilling chlorisatin with a concentrated solution of caustic potash. It forms with acids a series of definite well-crystallised salts.

CHLORATE OF POTASH, or CHLORATE OF POTASSIUM, formerly called oxymuriate of potash. $KO.ClO^3$ ($KClO^3$).—This important salt has become the object of a pretty extensive manufacture, in consequence of its use in the preparation of lucifer matches, as a constituent of white gunpowder and certain mixtures used in pyrotechny, and as an ingredient in some of the detonating compounds for the cartridges of needle-guns; the chlorate is also used in calico-printing and in the preparation of certain aniline colours, while the chemist frequently employs it as a convenient oxidising agent and as a source of free oxygen gas. To supply these demands, about 750 tons of the salt, valued at nearly 80,000*l.* are annually produced in this country.

Chlorate of potash was formerly prepared by transmitting an excess of chlorine gas through a solution of potash, whereby a mixture of chlorate of potash and chloride of potassium was obtained, the former salt being readily separated from the latter by its sparing solubility in water.

Having made a strong solution of purified potash, or carbonate of potash, with from 2 to 3 parts of water, a current of chlorine gas is passed through it in a Woulfe's apparatus, till it ceases to absorb any more. 'Chloride of potash' and chloride of potassium alone are formed as long as there is an excess of alkali in the solution; but afterwards in the further reaction of the materials, the chloride passes into the state of a chlorate, and, as such, precipitates from the solution. During the first half of the operation (that is, till the potash is about one half saturated with chlorine, as indicated by litmus-paper ceasing to be darkened and beginning to be blanched), only the chloride of potassium or muriate of potash falls. The process should be interrupted at this point in order to remove the salt, to wash it, to add the washings to the liquor, and then to transmit the gas freely through the solution. As the operation advances, less muriate of potash is formed, and at length nothing but the pure chlorate is separated in crystals. When, finally, the bubbles of gas pass through without being sensibly absorbed, the process is known to be completed; the liquid may then be allowed to settle, and be poured off from the crystals of chlorate of potash, which are purified from the muriate by dissolving them in three times their weight of boiling water and filtering the solution while hot. On its cooling, the chlorate will separate in pearly-crystalline plates. It may be rendered quite pure by a second crystallisation, in which state it does not affect solution of nitrate of silver.

The above potash-ley usually gets a reddish tint in the course of the process, in consequence of a little manganesic acid coming over with the chlorine, but it gradually loses this colour as the saturation becomes complete, and then the solution turns yellow. The tubes for conveying the gas should be of large diameter, if they be plunged into the saline solution, because the crystallisation which takes place in it is apt to choke them up. This inconvenience may, however, be obviated by attaching to the end of the glass tube a tube of caoutchouc terminated in a small glass funnel, or simply the neck of a caoutchouc bottle with a part of its body, whose width will not be readily closed with a saline crust. The residuary lixivium may be used in another operation, or it may be evaporated down to half its bulk and set aside to crystallise, whereby some more chlorate will be obtained, mixed indeed with muriate and carbonate, from which, however, it may be separated by a second crystallisation. In general the pure chlorate obtained does not exceed $\frac{1}{10}$ th the weight of the potash employed; because in thus treating potash with chlorine, $\frac{2}{5}$ ths of it are converted into muriate of potash and only $\frac{1}{5}$ th into chlorate, and a part of the latter adheres to the muriate, or is lost in the mother-waters of the crystallisation.

In 1821 St. Romer patented at Vienna the following method for preparing chlorate of potash by the dry way:—Ten pounds of crystallised peroxide of manganese are to be finely pulverised, mixed with 10 pounds of plumbago, and 30 pounds of common salt, and put into the leaden retort represented in *fig.* 460, p. 783. From the middle of the helmet-shaped lid of this vessel, a lead tube, 2 feet long and 2 inches wide, conducts to the receiver, which is a square earthen pan, hard glazed both within and without, of the same capacity with the retort. The end of the tube must be made fast to a frame at the height of 6 inches above the bottom of the receiver. Upon its

inner side, 4 inches apart, brackets are to be fixed for supporting a series of laths or shelves of white wood on which a number of little paper or pasteboard boxes are to be laid. In these boxes 10 pounds of the purest carbonate of potash, prepared from tartar, are to be spread. The receiver must now be covered with a lid made tight by a water lute. Twenty pounds of concentrated sulphuric acid, previously diluted with 16 pounds of water, and then cooled, are to be poured upon the mixed materials in the retort, and the lid immediately secured, with the tube adjusted in the receiver. The whole must be allowed to operate spontaneously without heat for 12 hours. At the end of this time the retort is to be surrounded with a water-bath and steadily heated during 12 hours, and then left to cool for 6 hours. The apparatus must now be opened, the cakes of chlorate of potash removed, and freed from muriate by solution and crystallisation.

Liebig proposed the following process for obtaining chlorate of potash:—

Heat chloride of lime in water till it ceases to destroy vegetable colours. In this case a mixture of chloride of calcium and chlorate of potash is obtained. This is to be dissolved in hot water, and to the solution concentrated by evaporation, chloride of potassium is to be added, and then suffered to cool. After cooling, a quantity of crystals of chlorate of potash is obtained, which are to be redissolved and crystallised again to purify them. Liebig considered that this would be a cheap process for obtaining chlorate of potash. From 12 oz. of chloride of lime, of so bad a quality that is left 65 per cent. of insoluble matter, he obtained an ounce of chlorate of potash.

The only difficulty to overcome in this process arises from the chloride of lime not being so easily decomposed by heat as is generally supposed; a solution of it may be kept boiling for an hour without losing its bleaching power. The best method is to form a thin paste with chloride of lime and water, and then to evaporate it to dryness. If it be required to prepare it by passing chlorine into cream of lime, it is advantageous to keep it very hot. The chlorate of potash which separates from the solution by crystallisation has not the form of scales which it usually possesses, but is prismatic: whether this is occasioned by some admixture has not been ascertained; but on recrystallising, it is obtained in the usual form. The solution ought not merely to be left to cool, in order to procure crystals, for the crystallisation is far from being terminated even after complete cooling; crystals continue to be deposited for 3 or 4 days.

The following modification of the process for making chlorate of potash is that of M. Vée:—A solution of chloride of lime marking 18° or 20° Baumé is to be set upon the fire in a lead or cast-iron pot, and when it begins to get hot, there is to be dissolved in it a quantity of chloride of potassium sufficient to raise the hydrometer 3° or 4° . It must then be concentrated as quickly as possible till it marks 30° or 31° , taking care that it does not boil over by the sudden extrication of oxygen. The concentrated liquor is set aside to crystallise in a cool place, when a deposit of chlorate of potash forms, mixed with chloride of potassium. The mother-waters being evaporated to the density of 36° , afford another crop of crystals, after which they may be thrown away. The salts obtained at the first crystallisation are to be redissolved, and the solution being brought to 15° or 16° is to be filtered, when it will afford upon cooling pure chlorate of potash.

The following ingenious and easy way of making this valuable chlorate was suggested by the late Professor Graham:—Mix equal atomic weights of carbonate of potash and hydrate of lime (70 of the former, if pure, and 37 of slaked lime in powder), diffuse them through cold water, and transmit chlorine gas through the mixture. The gas is absorbed with great avidity, and the production of a boiling heat. When the saturation is complete, carbonate of lime remains, and a mixture of muriate and chlorate of potash, which latter salts are to be separated, as usual, by the difference of their solubility in water.

It has been remarked on the above process, that it effects no saving of potassa, and therefore is far inferior to the one long practised in several parts of Germany, especially at Giessen, and introduced into this country a good many years ago by Dr. Wagenmann, from Berlin. The chlorine is passed into a mixture of one equivalent of chloride of potassium (76), and 6 equivalents of hydrate of lime (222), previously stirred with water to the consistence of a thin paste. Thus the calcium of the lime unites with the chlorine to form chloride of calcium, while the chloride of potassium is converted into chlorate of potash, which salt is easily separated in crystals by its sparing solubility.

Chlorate of potash may also be made by saturating with chlorine a mixture of 74 parts of chloride of potassium (muriate of potash) and 168 parts of quicklime, brought to the consistency of a thin pap by the cautious addition of water. The mass being dissolved in warm water, and evaporated and cooled, yields crystals of chlorate of potash, while a mother-water of chloride of calcium (muriate of lime) remains.

The following process has likewise been prescribed :—Mix 10 parts of good chloride of lime and water into a pap, and evaporate to dryness, whereby it is converted into a mixture of chloride of calcium and chlorate of lime devoid of bleaching power; dissolve it in water, filter, concentrate the solution by evaporation, then add to it 1 part of chloride of potassium, and cool for crystallisation. The salt which may thereby be separated from the chloride of calcium will afford 0.83 of pure chlorate of potash. By this process of Professor Liebig $\frac{1}{4}$ ths of the potash are saved, but much oxygen is wasted in the evaporation to dryness of the chloride of lime; and consequently, much chloric acid is lost towards the production of the salt. Vée mixes the chloride of lime pap, before heating it, with the chloride of potassium, boils the mixture smartly, whereby much oxygen is undoubtedly thrown off, and then sets the liquor acid to crystallise. L. Gmelin suggests that saturation of the liquor with chlorine before boiling might be advantageous. Gay-Lussac proposed to make this valuable salt by precipitating a solution of chloride of lime with carbonate (or sulphate) of potash, saturating the liquor after filtration with chlorine gas, evaporating, and crystallising.

Mr. Calvert formed a mixture of $5\frac{1}{2}$ equivalents of burnt lime for 1 equivalent of caustic potash, and passed a current of chlorine through the hot mixture. Under these conditions chloride of calcium and chlorate of potassium are produced, and the quantity of the latter is stated to be very nearly the theoretical amount.

Professor Juch's process is to pass chlorine gas into a mixture of 1 pound caustic lime and 1 pound carbonate of potash, with 8 pounds of water. The resulting chlorate of potash readily separates in the filtered liquid by crystallisation from the very soluble chloride of calcium. By this method potash is not wasted in the useless production of chloride of potassium.

The following process is now generally adopted for preparing chlorate of potash on a large scale :—An excess of chlorine gas is passed into a vessel containing milk of lime at a temperature of 120° to 140° F., the liquid being kept agitated by an iron stirred coated with lead. The reaction between the chlorine and the lime under these circumstances results in the production of chlorate of lime and chloride of calcium, with a small quantity of hypochlorite of lime; thus differing from the reaction which occurs between lime and chlorine at a lower temperature, as in the preparation of 'chloride of lime.' When the gas ceases to be absorbed by the lime, the liquid is run off into a tank lined with lead, where the suspended matter is allowed to subside, and whence the supernatant liquid is drawn off by a siphon into a leaden evaporating pan in which it is concentrated to 25° to 30° B. A hot solution of chloride of potassium is then added, by which the chlorate of lime is decomposed and chlorate of potash formed. Theoretically, every 168 parts by weight of caustic lime originally used require 74.5 parts of chloride of potassium; but practically one part of the chloride is added for every three parts of lime. The chlorate of potash and chloride of calcium are readily separated by taking advantage of the sparing solubility of the potash salt. The crude chlorate is purified by solution and re-crystallization.

Chlorate of potash, (the old oxy muriate of potash), has a cooling, somewhat unpleasant and nitrous taste; it does not bleach. At 60° F. 100 parts of water dissolve 6 parts of the salt, and at its boiling point, or 220° , 60 parts. When heated to dull ignition in a glass retort, it gives out 39.21 per cent. of its weight of oxygen, and leaves a residue of chloride of potassium. The decomposition is effected at a much lower temperature if the salt be mixed with a small quantity of binoxide of manganese, sesquioxide of iron, or black oxide of copper. Chlorate of potash is an active oxidising agent: it deflagrates upon red hot cinders like nitre: when triturated along with sulphur or phosphorus, it detonates with great violence, not without danger to the hands of the operator. Similar detonations may be produced with cinnabar or vermilion, sulphuret of potassium, volatile oils, sugar, &c; but they can be effected only by the smart blow of a heated hammer on an anvil. See LUCIFER MATCHES and PERCUSSION CAPS.

CHLORATES. Salts of chloric acid.

CHLORHYDRIC ACID. The modern name for HYDROCHLORIC ACID. The gas was discovered by Priestley in 1772; dissolved in water, it has been long known as spirits of salts. See MURIATIC ACID.

CHLORIC ACID. The acid constituent of the chlorates. This acid, which is only known in combination with one equivalent of water, is exceedingly unstable, being instantly decomposed by contact with organic matter, and undergoing gradual spontaneous decomposition in diffused daylight. It is prepared by decomposing chlorate of potash by the addition of hydro-fluosilicic acid, which forms with potash an insoluble compound.

CHLORIDES. 'The term chloride is applied to all compounds of chlorine, which may be derived from one or more atoms of hydrochloric acid, by the substitution of a metal or other radical (which may itself contain *chlorine*) for an equivalent quantity of

hydrogen.'—Watts's 'Dictionary of Chemistry.' For descriptions of the chlorides, refer to their respective metals.

The term 'chloride' is also applied in the arts to a number of bleaching compounds, such as 'chloride of lime,' the exact chemical nature of which is still obscure, though it is certain that they are not simple chlorides, or combinations of chlorine with metals. It is now generally believed, that these so-called chlorides of the alkalis and alkaline earths are either compounds or mixtures of true chlorides with hypochlorites.

CHLORIDE OF LIME. The compound so called was first employed in the liquid form as a bleaching agent in 1798; and in the following year the idea suggested itself to Mr. Charles Macintosh, at that time a partner of Messrs. Tenant and Knox, to impregnate quicklime in a dry state with chlorine, and a patent was taken out accordingly. The discovery of the bleaching property of chlorine is due to Berthollet, who announced the fact to the Academy of Sciences in 1785. In the following year, the new method of bleaching was introduced into Great Britain by Mr. Watt. In 1788, Mr. Thomas Henry of Manchester exhibited calico bleached by chlorine, without having any knowledge of the previous experiments of Watt; and in the following year a detailed method of the process was published by Berthollet. To give some idea of the rapidity with which bleaching is conducted by the improved modern processes, the writer of the article on this subject in the *Encyclopædia Britannica* quotes the following illustration:—A bleacher in Lancashire received 1,400 pieces of grey muslin on a Tuesday, which on the Thursday immediately following were returned bleached to the manufacturers at the distance of 16 miles and they were packed up and sent off that very day to a foreign market.

It is estimated that the present annual production of chloride of lime in Great Britain and Ireland amounts to 75,000 tons, of the value of three-quarters of a million sterling.

In the manufacture of chloride of lime, chlorine gas is transmitted at a proper temperature through milk of lime or over dry slaked lime, the product being thus obtained either as a liquid or as a powder. The different methods of generating the gas will be described under CHLORINE.

A great variety of apparatus has been at different times contrived for favouring the combination of chlorine with the slaked lime for the purpose of commerce. The simplest construction for subjecting lime-powder to chlorine, is a large chamber 8 or 9 feet high, built of sandstone, having the joints of the masonry secured with a cement composed of pitch, resin, and dry gypsum in equal parts. A door is fitted into it at one end, which can be made air-tight by strips of cloth and clay lute. A window on each side enables the operator to judge how the impregnation goes on by the colour of the air, and also gives light for making the arrangements within at the commencement of the process. As water lutes are incomparably superior to all others where the pneumatic pressure is small, a large valve or door on this principle might advantageously be made in the roof, and two tunnels of considerable width at the bottom of each side wall. The three covers should be simultaneously lifted off by cords passing over a pulley, without the necessity of the workman approaching the deleterious gas, when the apartment is to be opened. A great number of wooden shelves, or rather trays, 8 or 10 feet long, 2 feet broad, and 1 inch deep, are provided to receive the riddled slaked lime, containing generally about 2 atoms of lime to 3 of water. These shelves are piled one over another in the chamber, to the height of 5 or 6 feet, cross bars below each keeping them about an inch asunder, in order that the gas may have free room to circulate over the surface of the calcareous hydrate.

The alembics for generating the chlorine, which are usually nearly spherical, are in some cases made entirely of lead, in others of 2 hemispheres joined together in the middle, the upper hemisphere being lead, the under one cast-iron. The first kind of alembic is enclosed for two-thirds from its bottom in a leaden or iron case, the interval of two inches between the two being destined to receive steam from an adjoining boiler. Those which consist below of cast-iron have their bottom directly exposed to a very gentle fire; round the outer edge of the iron hemisphere a groove is cast, into which the under edge of the leaden hemisphere fits, the joint being rendered air-tight by Roman or patent cement. In this leaden dome there are four apertures, each secured by a water-lute. The first opening is about 10 or 12 inches square, and is shut with a leaden valve, with incurvated edges, that fit into the water-channel at the margin of the hole. It is destined for the admission of a workman to rectify any derangement in the apparatus of rotation, or to detach hard concretions of salt from the bottom.

The second aperture is in the centre of the top. Here a tube of lead is fixed, which descends nearly to the bottom, and down through which the vertical axis passes. To its lower end the cross bars of iron or of wood, sheathed with lead, are attached, by whose revolution the materials receive the proper agitation for mixing the dense manganese with the sulphuric acid and salt. The motion is communicated either by the

hand of a workman applied from time to time to a winch at top, or it is given by connecting the axis with wheel work, impelled by a stream of water or a steam-engine. The third opening admits the siphon-formed funnel, through which the sulphuric acid is introduced; and the fourth is the orifice of the eduction-pipe. The fourth aperture admits the eduction-pipe. This pipe is afterwards conveyed into a leaden chest or cylinder, in which all the other eduction-pipes also terminate. They are connected with it simply by water-lutes, having hydrostatic pressure of 2 or 3 inches. In this general *diversorium* the chlorine is washed from adhering muriatic acid, by passing through a little water, in which each tube is immersed, and from this the gas is let off by a pretty large leaden tube, into the combination-room. It usually enters in the top of the ceiling, whence it diffuses its heavy gas equally round.

Four days are required, at the ordinary rate of working, for making good marketable bleaching-powder. A more rapid formation would merely endanger an elevation of temperature, productive of muriate of lime, at the expense of the bleaching quality. But skilful manufacturers use here an alternating process. They pile up, first of all, the wooden trays only in alternate shelves in each column. At the end of two days the distillation is intermitted, and the chamber is laid open. After two hours the workman enters, to introduce the alternate trays covered with fresh hydrate of lime, and at the same time rakes up thoroughly the half-formed chloride in the others. The door is then secured, and the chamber, after being filled for two days more with chlorine, is again opened, to allow the first set of trays to be removed, and to be replaced by others containing fresh hydrate, as before. Thus the process is conducted in regular alternation; very superior bleaching-powder is manufactured, and the chlorine may be suffered to enter in a pretty uniform stream. But for this judicious plan, as the hydrate advances in impregnation, its faculty of absorption becoming diminished, it would be requisite to diminish proportionately the evolution of chlorine, or to allow the excess to escape, to the great loss of the proprietor, and, what is of more consequence, to the great detriment of the health of the workmen.

According to M. C. H. Mène ('Comptes Rendus,' Nov. 22, 1847), chloride of lime may be prepared almost pure, and instantaneously, by pouring upon slaked lime, water saturated with chlorine. The chlorine is absorbed the moment the liquid comes into contact with the lime, and if the supernatant water is immediately decanted, and the lime remaining at the bottom of the vessel saturated by frequent repetition of the treatment with chlorine water, *perfectly pure* chloride of lime is obtained. Labarraque finds that the absorption of chlorine by moistened hydrate of lime is greatly facilitated by mixing it with $\frac{1}{20}$ th of its weight of common salt.

Manufacturers differ much from each other in the proportion of their materials for generating chlorine. In general, 10 cwt. of salt are mixed with from 10 to 14 cwt. of manganese, to which mixture, after its introduction into the alembic, from 12 to 14 cwt. of sulphuric acid are added in successive portions. That quantity of oil of vitriol must, however, be previously diluted with water, till its specific gravity becomes about 1.6. But, indeed, this dilution is seldom actually made, for the manufacturer of bleaching-powder almost always prepares his own sulphuric acid for the purpose, and therefore carries its concentration in the leaden boilers no higher than the density of 1.65, which, from Dr. Ure's table of sulphuric acid, indicates $\frac{1}{4}$ th of its weight of water, and therefore $\frac{1}{3}$ rd more of such acid must be used.

The manufacturer generally reckons on obtaining from one ton of rock-salt, employed as above, a ton and a half of good bleaching-powder. But the following analysis of the operation will show that he ought to obtain two tons:—

When a mixture of sulphuric acid, common salt, and black oxide of manganese are the ingredients used by the manufacturer of bleaching-powder, the absolute proportions required by theory are:

1 atom chloride of sodium	58.5	29.75
1 atom binoxide of manganese	43.5	21.25
2 atoms oil of vitriol	98.0	49.00
		<hr/>		<hr/>
		200.0		100.00
and the products ought to be:				
1 atom chlorine disengaged	35.5	17.75
1 atom sulphate of soda	71.0	35.50
1 atom sulphate of manganese	75.5	37.75
2 atoms water	18.0	2.00
		<hr/>		<hr/>
		200.0		100.00

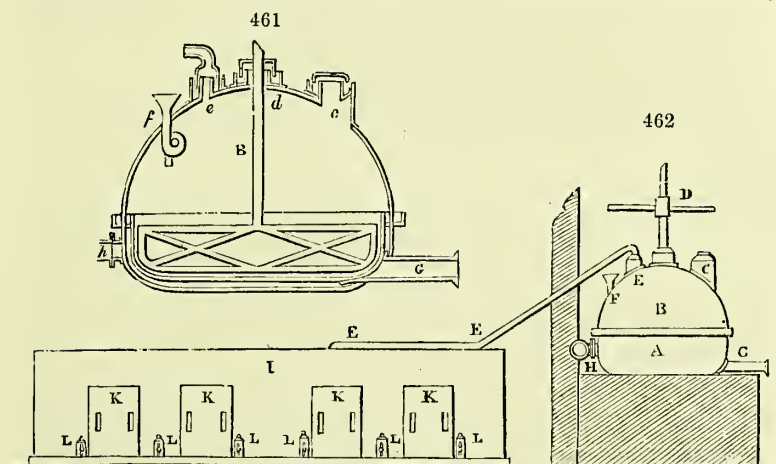

These proportions are, however, very different from those employed by the manufacturers; and they ought to be so, on account of the impurity of their oxide of man-

ganese. Moreover, the oil of vitriol has a tendency to form the acid sulphate of soda or bisulphate, instead of the normal sulphate, and this salt is only decomposed at a high temperature.

From the preceding computation, it is evident that 1 ton of salt with 1 ton of the above native oxide of manganese, properly treated, would yield 0.59 of a ton of chlorine, which would impregnate 1.41 ton of slaked lime, producing 2 tons of bleaching-powder, stronger than the average of the commercial specimens; or, allowing for a little loss, which is unavoidable, would afford 2 tons of ordinary powder, with a little more slaked lime.

Fig. 461 represents a retort of lead, well adapted to the evolution of chlorine from the mixture of salt, manganese, and sulphuric acid, or from manganese and muriatic acid.

The interior vessel is cast in lead, and it has round its bottom part a cast-iron steam case. The salt and manganese are introduced by the aperture *c*, and the sulphuric acid by the siphon-funnel *f*. The contact of these three substances is continually

renewed by the agitator or stirrer *B*, which consists of wrought or cast iron, sheathed with lead. *e* is the gas-discharge pipe. The residuums are drawn off by the bottom discharge pipe *g*. The heating case receives its steam by the pipe *h*.

The chlorine gas, is conveyed from the retort *B*, fig. 462, into the chamber *I*, by the tube *E E E*. This chamber is divided into four compartments, to receive the gas disengaged from four retorts, like the above. The bottom of it is covered with a stratum three or four inches thick of quicklime, newly slaked and sifted, which is stirred about from time to time, by the rakes *L L L L*. When the saturation is sufficient, the chloride of lime is taken out by the doors *K K K K*. The side of this apparatus allows 2 cwt. of manganese, and its equivalent quantity of salt and sulphuric acid, or of muriatic acid, to be introduced at once into the retort. *D* is the handle of the agitator.

The same form of retort will suit perfectly well to prepare chlorine for making liquid chloride of lime, which is preferred by many bleachers and calico-printers who have conveniences for preparing it themselves. The most concentrated solutions of the dry chloride of lime do not mark more than 6° B. (specific gravity 1.04), and discolour only 50 volumes of Gay-Lussac's solution of indigo, whilst the chloride made in the humid way marks from 8° to 9° B. (about 1.060), and discolours 80 volumes of the same solution.

In the chloride-of-lime apparatus, most generally used by the skilful calico-printers of Mülhausen, the mixture of muriatic acid and manganese is put into glass globes, with long necks, heated upon a sand-bath. The chlorine is conveyed by glass tubes into a cylindrical stone cistern, containing milk of lime. The furnace of the sand-baths is made of cast-iron, and has brick partitions, to give each retort its own fire. The smoke of all these fires goes off by a flue into sheet-iron pipes. The cistern is made of siliceous sandstone. Its cover is of wood, coated with a resinous cement; and it fits at its edges into grooves cut in the stone. A wheel serves to agitate the liquid continually; its paddles being kept at 2 inches distance from the sides of the cistern. The milk of lime is introduced by a funnel, and the chloride is drawn off by a discharge pipe. The lead retort and agitator used in this country seem greatly preferable to

the experimental laboratory plan described above. In all such apparatus we should avoid giving any pressure to the tubes or vessels, and should not therefore dip the extremities of the gas-pipes beneath the surface of the liquid, but rather facilitate the combination of the chlorine and the lime, by enlarging the surfaces of contact and by agitating. Intermediate vessels containing water, or the chemical cascade of M. Clement, are very useful for absorbing any muriatic acid which may be disengaged along with the chlorine, and thereby preventing the needless formation of muriate of lime in the chambers or cisterns of impregnation.

When the solution of the chloride of lime is mixed with hydrate of lime, it bears, without decomposing, a pretty high temperature, provided it be not too long continued; it may even, in certain cases, be raised to near the boiling point without suffering a marked loss of its discolouring power; but when the chloride is deprived of that excess of lime, it is decomposed in a short time, even at a heat of 110° F.

When chlorine is admitted to milk of lime, it infallibly produces some muriate of lime; but the quantity is kept at a *minimum* by constantly presenting an excess of lime to the gas with the agitator, and by keeping the temperature as low as possible. Hence the influx of gas should not be so rapid as to generate much heat. An automatic agitator, moved by steam or water power, is therefore much better than one driven by the hand of the operator, who is apt to intermit his labours.

If the liquor becomes hot at the end of the process, it should be immediately drawn off into large stone bottles and cooled. The rose colour, which sometimes supervenes, is due to a minute quantity of manganese: the strongest liquid chloride of lime that can be prepared will not discolour more than 80 times its volume of Gay-Lussac's indigo test.

In the year 1846, Mr. Pattinson patented an improved mode of manufacturing chlorine. In this process he made use of a stone vessel or generator, enclosed in a double iron vessel. The hydrochloric acid, specific gravity 1.16, is poured into the generator, and on a grating or false bottom is placed the binoxide of manganese in lumps. The temperature of the contents of the generating vessel is then raised to 180° F., by means of steam, made to circulate between the stone vessel and the iron casing. This heat is continued for about 18 hours; and then, by means of a suitable pipe passing to the bottom of the generator, steam, under a pressure of 10 lbs. to the inch, is injected into the vessel for about two minutes, and this is repeated every half hour for about six hours. In this process no mechanical agitation is required, as the steam enters with sufficient force, under the pressure above mentioned, to effect the requisite agitation of the contents, and by clearing the lumps of manganese from all adhering matters, expose a fresh surface continually to the action of the acid.

In carrying this process into practical operation, Mr. Pattinson found that the apparatus is liable to be completely deranged, and the iron vessel destroyed by the action of the hydrochloric acid, if the stone generating vessel should happen to get broken; to obviate which inconvenience, and to enable the generator to be used though in a broken condition, the inner iron vessel is perforated; and the spaces between the two iron vessels, and between the inner iron vessel and the stone generator, are filled with coal-tar, or pitch, thickened by boiling to such a consistence as to be tough, but not brittle, when cold. Steam, circulating through a coil of pipe passing between the iron vessels, serves to maintain the tar at the requisite degree of heat; and in the event of the breakage of the stone generator, the liquefied tar flows into the fissure, and prevents the escape of the hydrochloric acid into the steam vessel.

Chlorine-stills of metal or of earthenware, though used even now in many continental works, have been generally displaced in this country by vessels of sandstone. In Lancashire they are usually constructed of Yorkshire flags, cemented together by a mixture of tar and clay, while on the Tyno they are cut out of solid blocks of stone, and rendered impervious on the surface by being boiled in coal-tar.

The receivers in which the chlorine acts on the lime are usually constructed either of stone slabs or of sheet lead supported on timber framework. The receiving chambers are fitted with shelves on which the slaked lime is conveniently exposed in layers for absorption of the chlorine. In other forms of apparatus the lime is placed in a series of pots or in rotating barrels. The absorption of chlorine is accompanied by evolution of heat, but as chlorate of lime is formed at a high temperature the gas is admitted but slowly and the temperature thus maintained sufficiently low to avoid formation of the chlorate.

Several proposals have been made for utilising the waste liquors from the chlorine stills, most of which aim at reproducing oxide of manganese which may be again available for the generation of chlorine.

A method of treating the residuum was patented in 1855 by Mr. C. Tennant Dunlop.

It consists in transforming the chloride of manganese, first into carbonate and then into oxide, by the action of heat. Whatever impurity the chloride of manganese may contain—as chloride of iron, for instance—is first separated, either by calcination or by the agency of a suitable precipitant. Practical working has shown that the carbonate of manganese thus treated yields an oxide of a richness equivalent to that of 80 per cent. of peroxide. The carbonate of manganese may be obtained by precipitation from the chloride by carbonate of ammonia. The chloride of ammonium resulting from this treatment may either be employed as such, or it may be re-transformed in the usual way into carbonate for the precipitation of fresh chloride of manganese. Hydrate of lime is also used as a precipitant, the resulting hydrated oxide of manganese being subsequently converted into carbonate by the transmission through it of a stream of carbonic acid.

By another process, carbonate of manganese is obtained by passing carbonic acid through the solution of chloride of manganese which has been previously mixed with a quantity of carbonate of soda. The carbonate of soda, under the influence of carbonic acid, decomposes the chloride of manganese into carbonate, from which the oxide can be obtained. The essential feature of this invention is the production of artificial oxide of manganese, by first converting the chloride into carbonate, and afterwards this latter into oxide, by the joint agencies of heat and atmospheric air.

In a process suggested by Biuks and Gatty, the chloride of manganese in the still-liquor is heated with nitrate of soda, whereby a mixture of nitrous acid and oxygen is evolved, while a residue of chloride of sodium and oxide of manganese is obtained.

But the most valuable process which has yet been proposed for regenerating the manganese from the spent liquors is that which has been lately introduced by Mr. Walter Weldon, and is now largely employed in this country. To understand the working of this process it should be remembered that the acid liquor left in the chlorine-stills, by the action of hydrochloric acid on peroxide of manganese, consists mainly of a solution of protochloride of manganese (manganous chloride), with the sesquichlorides of iron and aluminium, chloride of calcium, and such excess of hydrochloric acid as may have been employed. This liquid is run from the generators into a well, where it is neutralised by addition of finely-divided chalk, the neutralisation being facilitated by keeping the liquid stirred up by a mechanical agitator. Not only is the free acid thus neutralised, but the chlorides of iron and aluminium are decomposed, and the oxides precipitated. The neutral liquor is then pumped up into tanks, called 'chloride of manganese settlers,' where the sulphate of lime, the oxide of iron, and the alumina held in suspension are rapidly deposited, and a clear solution of manganous chloride, of a pale pink colour, is obtained. This clear liquor is run off into a tank below called the 'oxidiser,' in which it is treated with an *excess* of milk of lime to precipitate the manganese as hydrated protoxide, which is converted into a higher oxide by the injection of air. The oxidiser is generally a cylindrical iron vessel, about 12 feet in diameter and 22 feet deep. The reactions in this vessel are best effected at a temperature of from 130° to 170° F., and if the charge of manganous liquor is not sufficiently hot, its temperature is raised by injection of steam. When sufficiently heated, the liquor is subjected to a blast of atmospheric air introduced through a large pipe reaching nearly to the bottom of the oxidiser. The milk of lime is then rapidly run in from a reservoir above, and the blowing continued until peroxidation ceases—a point usually attained when from 80 to 85 per cent. of the manganese has been converted into peroxide. The thin black sludge resulting from this action contains chloride of calcium and peroxide of manganese associated with a variable proportion of protoxide of manganese and lime. Each cubic foot of mud contains about 2 lbs. of peroxide of manganese. The product is run off from the oxidiser to the 'mud settlers,' where a thick black deposit, containing about four lbs. of the peroxide to the cubic foot, gradually subsides. This deposit, separated from the supernatant liquid, is transferred, while still moist, to the chlorine-stills, where it is treated with hydrochloric acid for production of chlorine, and the cycle of operations thus begins afresh, and may be continued indefinitely—the manganese merely playing the part of a carrier or medium of transference between the oxygen of the atmosphere and the hydrochloric acid. In an experiment continued for five hours, during which time 175,000 cubic feet of air was blown through the sludge in the oxidiser, it was found that more than 4 cwts. or 14·8 per cent. of the oxygen was absorbed, serving to reproduce 24 cwts. of peroxide of manganese. The cost of recovering the manganese by this process is said to be less than one-fourth the average cost of an equivalent amount of native manganese.

Nature of Bleaching Powder.—An elaborate series of experiments on the manufacture of chloride of lime was made in 1822 by Dr. Ure, the most important results of which are embodied in the subjoined Table:—

Prepared with Protohydrate of Lime without pneumatic pressure. The process carried on until the lime ceased to obtain chlorine.					Commercial Specimens		
	Synthesis	First Analysis	Second Analysis	Mean			
Chlorine	39.39	40.00	40.62	40.31	23	22	28
Lime	46.00	44.74	46.07	45.40	46	} 78	71
Water	14.60	15.26	13.31	14.28	31		
Chloride of Lime .	100.00	100.00	100.00	100.00	100	100	100

Mr. Graham found that hydrate of lime, dried at 212° , absorbed afterwards little or no chlorine; but that, when dried over sulphuric acid, it was in the most favourable condition for becoming chloride of lime. A dry, white, pulverulent compound is obtained by exposing the last hydrate to chlorine, which contains 41.2 to 41.4 chlorine in 100 parts, of which 39 parts are available for bleaching, the remainder going to form chloride of calcium and chlorate of lime. This appears to be the maximum absorption of chlorine by dry hydrate of lime; but the bleaching powder of commerce rarely, even when fresh prepared, contains more than 30 per cent. of chlorine, and after being kept for several months, the proportion often falls as low as 20 per cent. A compound containing one equivalent of chlorine and one equivalent of hydrate of lime, should contain 48.57 chlorine and 51.43 hydrate of lime; a compound of one equivalent of chlorine and two of hydrate of lime, should contain 32.42 chlorine and 67.58 hydrate of lime; and these are about the proportions in good commercial specimens. It would not be advisable to attempt to manufacture a more highly chlorinated product, as the stability of the compound is increased by an excess of lime. Where a stream of chlorine is transmitted through water holding hydrate of lime in suspension, the lime is entirely dissolved, and the full equivalent of chlorine is absorbed. Different views have been held by chemists respecting the constitution of bleaching powder, but it is now generally admitted that the substance consists essentially of chloride of calcium and hypochlorite of lime, with excess of slaked lime. Water poured upon bleaching powder dissolves out the bleaching combination, leaving a large residue of lime. Ten parts of water are required for one part of dry chloride. The solution emits the peculiar odour of hypochlorous acid. The reaction which occurs in the formation of 'chloride of lime' may be thus represented:—

Slaked lime and chlorine thus yield chloride of calcium, hypochlorite of lime and water. Whether the chloride and hypochlorite are united as a combination or merely mixed together, may be open to question. But good bleaching powder is not deliquescent, neither does alcohol dissolve anything from it, both which should occur if the compound contained free chloride of calcium. It is possible, however, that the two salts may exist in bleaching powder in the form of a double salt, or that the chlorine is in direct combination with the oxide. If the compound be supposed to be pure chloride of lime, the reaction is simply an absorption of chlorine; and the same should be the case with the other bleaching compounds—chloride of soda, for instance. But when carbonate of soda, saturated with chlorine (Labarraque's Liquor), is evaporated, no chlorine is evolved, and the residue still possesses bleaching properties. The true nature of bleaching powder is open, therefore, to speculation.

The bleaching action of solution of chloride of lime is very slow unless an acid be added to it. When dilute sulphuric acid in insufficient quantity is employed, no chlorine is evolved, but hypochlorous acid, which may be distilled off and condensed in a suitable receiver; but with excess of acid, chlorine only is liberated. When calicoes and other woven goods are to be bleached, they are first thoroughly cleansed by boiling successively with lime-water and a weak solution of caustic soda; they are then digested in a solution of bleaching powder, specific gravity 1.02, containing about $2\frac{1}{2}$ per cent. of chloride of lime; after which they are immersed in very dilute sulphuric acid, which, by liberating the chlorine within the fibres of the cloth, rapidly removes the colour. The goods are then washed, a second time steeped in alkali, and again passed through a weaker solution of chloride, and then through dilute acid; after which they are thoroughly washed in water. The quantity of liquor necessary for 700 lbs. of cloth is 971 gallons, containing $388\frac{1}{2}$ lbs. of chloride. When white figures are required on a coloured ground, the pattern is printed on the cloth with tartaric acid, thickened

with gum. The colour is discharged in those places where the acid was present, but elsewhere untouched. Sulphate of zinc or chloride of zinc may be employed, instead of acids, for liberating chlorine from bleaching powder.

On acting upon cotton-cloth with a concentrated solution of chloride of lime, at from 110° to 120° F., pure carbonic acid is disengaged, and the texture of the cloth is injured. Here the hydrogen of the water, and of the cotton, being seized by the chlorine, the liberated oxygen combines with the carbon to form carbonic acid. In the discharge-troughs, where printed calicoes are passed through strong solutions of chloride of lime, stalactitic crusts of carbonate of lime come to be formed in this way.

When chloride of lime is heated, it evolves oxygen gas, and sometimes chlorine, and it becomes converted into a mixture of chlorate of lime and chloride of calcium, which has no bleaching properties. Half an ounce of chloride of lime boiled in two ounces of water yields, according to Keller, 165 cubic inches of oxygen contaminated with chlorine.

The property of chlorine, to destroy offensive odours and to prevent putrefaction, gives to the chlorides of lime and soda a high value. On this important subject Pereira, has the following remarks (*Mat. Med.* vol. i.) with reference to medical police:—'If air be blown through putrid blood, and then through a solution of chloride of lime, carbonate of lime is precipitated, and the air is disinfected; but if the air be first passed through putrid blood, then through caustic potash, or milk of lime, to abstract the carbonic acid, and afterwards through the solution of chloride of lime, it retains its stinking quality. Chloride of lime may be employed to prevent the putrefaction of corpses previous to interment;—to destroy the odour of exhumed bodies during medico-legal investigations;—to destroy bad smells and prevent putrefaction in dissecting-rooms and workshops in which animal substances are employed (as cat-gut manufactories);—to destroy unpleasant odours from privies, sewers, drains, wells, docks, &c.;—to disinfect ships, hospitals, prisons, stables, &c. The various modes of applying it will readily suggest themselves. For disinfecting corpses, a sheet should be soaked in a pailful of water containing a pound of chloride, and then wrapped round the body. For destroying the smell of dissecting rooms, &c., a solution of the chloride may be applied by means of a gardening pot.' Of equal importance is this substance to the medical practitioner. The poisonous exhalations from foul sewers may be counteracted by a slight inhalation of chlorine gas, as obtained from a little chloride of lime placed in the folds of a towel wetted with acetic acid. The importance of chlorine as a disinfecting agent appears to have been fully proved during the period of the cattle plague. Both Dr. Augus Smith and Mr. Crookes, in their reports, give several very striking examples of the power of this agent in cleansing sheds and houses which had been occupied by cattle suffering under and dying from the disease. Carbolic acid, however, appears to be preferred by one of these chemists. Both these preparations may, it is clear, be used with satisfaction when required.

For estimating the amount of chlorine in bleaching powder, and thus determining the commercial value of a given sample, see CHLOROMETRY.

CHLORIDE OF POTASSIUM. See POTASSIUM.

CHLORIDES OF POTASH AND SODA. When a weak solution of caustic potash or soda is saturated with chlorine, it affords a bleaching liquor, still used by some bleachers and calico-printers for delicate processes; but the price of the alkalis has led to the disuse of these chlorides as a general means, and has occasioned an extensive employment of chloride of lime. The chloride of potash is known as *Water of Javelle*, and the chloride of soda as *Labarraque's Liquor*. They may be prepared by transmitting chlorine gas through a solution of caustic alkali or alkaline carbonate, or by decomposing chloride of lime with an alkaline sulphate or carbonate. These so-called chlorides are now generally considered to be mixtures or compounds of chlorides and hypochlorites. See CHLORIDE OF LIME.

CHLORINATION. The method of extracting gold and silver from certain ores by means of chlorine. This process is especially employed for separating gold from sulphides and arsenides which cannot be treated by the ordinary methods of amalgamation. By the aid of chlorine gas, the gold is converted into a chloride, and from a solution of this salt the metal may be precipitated as a sulphide by sulphuretted hydrogen, or reduced at once to the metallic state by means of sulphate of iron. The process enables a very small percentage of gold to be extracted with advantage from an ore; indeed, according to Mr. Allain, it is possible to extract gold from pyrites by means of chlorine, when the metal is present to the extent of only one part in 10,000 parts of roasted ore.

The chlorination-process was originally proposed by Professor Plattner, and was applied, as far back as 1851, to the extraction of gold from the arsenical pyrites of Reichenstein in Silesia—an ore containing about 200 grains of gold to the ton. In

consequence of the introduction of this process, the mines, after having been abandoned for more than five centuries, were re-opened and worked with profit. The ore is first roasted in a reverberatory furnace, and the arsenic thus becomes converted into arsenious acid, which sublimes, and is condensed in a large chamber. The residue, consisting chiefly of iron, is subjected to the action of chlorine, and the iron, with the gold which it contains, then passes into the state of chloride; the chlorides are dissolved out by water, and the gold precipitated by sulphuretted hydrogen,—the precipitation of the iron being prevented by previously acidifying the solution with hydrochloric acid. The sulphide of gold is readily decomposed by heat, yielding metallic gold on simple ignition.

Since the introduction of the chlorination-process at Reichenstein, it has been applied elsewhere with considerable success. At Schemnitz, in Hungary, the tailings left after extraction of silver by Zierrögel's method, are treated with chlorine, and the gold, though amounting to only about 0.012 per cent. of the tailings, is thus profitably separated. In California the chlorination-process was first introduced, in 1858, by Mr. Deetken; and several chlorination-establishments have since been erected in the neighbourhood of Grass Valley. The process, as conducted in California, has been described by Mr. Kustel.¹

If the ore to be chlorinated contains finely-divided gold in quartz, it needs no preparatory treatment beyond that of pulverization. But if sulphides and arsenides are to be treated, they require to be previously roasted. The concentrated ores should be roasted while damp, but pan-tailings should be first dried and then finely pulverized. The roasting is most advantageously effected in a reverberatory furnace in which the flame of the fuel is allowed to come into direct contact with the ores. A low temperature should be employed at first, and when much of the sulphur and arsenic is expelled the heat should be gradually raised until any sulphates or arsenites which are formed may be decomposed, and all the metals converted into oxides, excepting the gold, which is set free in a metallic state. The loss of gold during roasting, though stated by some to be considerable, seems really to be insignificant.

In some cases it is desirable to add common salt (chloride of sodium) to the ore during the roasting. If lead and antimony are present, no salt should be used, but if the ore be associated with minerals containing lime, magnesia, or baryta, the addition of salt is desirable. About 5 per cent., or 100 lbs. of salt to the ton of sulphides, will be found sufficient. The salt should be thoroughly incorporated with the ore, so as to favour separation of the gold. It appears that the gold first forms a tetrachloride (AuCl_4), which is converted at a higher temperature into protochloride (AuCl), and this at a red heat, is reduced to metallic gold.

The roasted ore, before being treated with chlorine, must be slightly moistened; this is effected by spreading the charge over the floor of an iron chamber, and sprinkling it with water by means of a hose; the ore being well stirred so that the wet stuff is well mixed with the dry. After being sifted, to remove lumps, the ore is transferred to the chlorination-vats. These are large circular wooden vessels, each capable of holding two or three tons of roasted ore. The inside of the vat is coated with a mixture of pitch and tar, or with some similar substance, to prevent absorption of the gold-solution by the wood. At a height of about one inch from the bottom of the vessel, is fixed a false bottom, formed of boards laid together, with spaces between, and perforated with holes for the passage of the chlorine gas. A layer of fragments of quartz, or other rock, is first spread over the false bottom, and the coarser fragments covered by finer and finer layers till a stratum of fine sand is placed on the top. The charge is laid on this prepared bed, which serves as a filter, and chlorine gas is introduced through the false bottom. The gas is generated in a leaden vessel. Sufficient chlorine for treating a charge of three tons of roasted sulphides may be obtained, according to Kustel, from the following mixture:—Pulverized manganese (peroxide) 30 lbs., common salt, 30 or 40 lbs., oil of vitriol of 66 degrees, 75 lbs., and water, 45 lbs. Having introduced the water, salt, and manganese into the generator, the vessel should be covered air tight; the acid is then gradually poured in through a funnel, and the chlorine thus produced is washed by passing through a vessel containing water to absorb any hydrochloric acid, the presence of which is prejudicial. The evolution of chlorine is assisted by heat applied under the gas-generator. When the chlorine, which passes from the wash-bottle to the chlorine-vat, has permeated through the charge, the cover of the vat is luted on. The operator should carefully avoid inhaling the chlorine, as this is a highly poisonous gas, and extremely irritating when inhaled even in small quantity.

The chlorine is allowed to act upon the ore for 12 to 18 hours; the cover is then removed from the vat, and a stream of water introduced. The solution of

¹ 'A Treatise on Concentration of all kinds of Ores, including the Chlorination Process.' By Guido Kustel. San Francisco: 1868.

chloride of gold is then conveyed through a trough lined with sheet-lead into the precipitating-vat, which is a large wooden vessel lined with lead or with asphalt. To precipitate the gold, a solution of sulphate of iron (green copperas) is employed; this is best prepared a few days before use, by pouring dilute oil of vitriol on old pieces of wrought iron. A bucket or two of this solution is poured into the precipitating-vat before the gold-solution enters, and a sufficient quantity is afterwards employed to throw down the whole of the gold. This precipitated gold gradually subsides as a dark brown powder, and the supernatant liquor when clear is drawn off. The gold is then carefully scooped out from the vat into a clear porcelain dish, and the last traces washed out by water. This finely divided gold is dried over a fire, and then melted in clay crucibles; a little borax, salt, or saltpetre being added as a flux. The use of plumbago crucibles is not advisable. The metal obtained in this way generally contains about 995-thousandths of pure gold.—F.W.R.

CHLORINE. (*Chlorine*, Fr., *Chlor*, Ger.) *Symbol*, Cl.; *Atomic weight*, 35.5.—This element was discovered by the Swedish chemist, Scheele, in 1774, and its true elementary character demonstrated by Sir H. Davy in 1810. It exists, under ordinary circumstances, as a greenish-yellow gas; but, when exposed to a pressure of 4 atmospheres, at 60° F., it condenses to a transparent liquid, which remains unfrozen even at the cold of -220° F. In the first state, its density, compared to air (reckoned 1.00), is 2.47; in the second, its density, compared to water (1.00), is 1.33. It is generally obtained either by the action of sulphuric acid on a mixture of common salt and binocide of manganese, or by the action of moderately strong hydrochloric acid on binocide of manganese alone. In the first case, the proportions are 7 parts by weight of oil of vitriol, previously diluted with 7 parts of water and 4 parts of common salt, intimately mixed with 3 parts of binocide of manganese; in the latter, which is the most convenient method, hydrochloric acid, specific gravity 1.15, is gently heated with the finely-powdered binocide, in the proportions of about three oz. of oxide to half a pint of acid. The hydrochloric acid should not be more diluted than above indicated, otherwise an explosion may occur, probably in consequence of the formation of one of the explosive oxides of chlorine. The gas must be collected either over brine or over warm water.

In the preparation of chlorine from binocide (peroxide) of manganese and hydrochloric acid, 43.5 parts by weight of manganese and 73 of acid yield 35.5 parts of free chlorine. If the peroxide of manganese be acted on by a mixture of hydrochloric and sulphuric acids, 43.5 parts of the manganese, 36.5 of hydrochloric and 49 of sulphuric acid, will produce 35.5 of chlorine gas. When the generating materials are common salt, sulphuric acid and peroxide of manganese, 58.5 parts of salt, 147 of acid, and 43.6 of manganese yield 35.5 of chlorine. In this case a bisulphate or acid sulphate of soda remains in the retort, but if the supply of acid should only be sufficient to form a neutral sulphate the complete decomposition will not be effected until a much higher temperature has been reached than was required with the larger proportion of acid. With respect to the calculations given above, it should be remarked that they refer only to theoretical reactions with pure materials, and that in practice the manufacturer will find it necessary to use *more* than the specified quantities of acid in order to allow for combination with lime, oxide of iron, and whatever other bases may be present as impurities in the raw materials.

In addition to the ordinary methods of generating chlorine already described, several others have been proposed for obtaining this element from its combinations, chiefly from hydrochloric acid. Some of these methods work with the hydrochloric acid in the state of gas. For example, the gas may be caused to act directly upon peroxide of manganese; or it may be mixed with carbonic acid gas, and the mixture transmitted through red-hot earthenware tubes; or again a mixture of hydrochloric acid and the gases evolved by heating nitrate of soda may be similarly treated. In all these cases an oxidising agent is employed to remove the hydrogen from the hydrochloric acid and thus liberate the chlorine. The simplest method of effecting this oxidation is to pass hydrochloric acid gas and atmospheric air over red-hot pumice-stone or asbestos or spongy platinum. A somewhat similar process has lately been ingeniously devised by Mr. Henry Deacon, of the Widnes Alkali Works, and has been successfully worked on a manufacturing scale. A mixture of hydrochloric acid gas and atmospheric air, heated to from 700° to 750° F., is passed over a mass of brick-work which has been soaked in a solution of sulphate of copper (blue vitriol) and dried. Under these circumstances the oxygen of the air and the hydrogen of the acid unite to form water, while the chlorine is liberated, mixed of course with the nitrogen of the atmospheric air, but this dilution of the chlorine does not prevent its employment in the manufacture of chloride of lime. The action of the copper salt in this process is rather obscure; many other salts are capable of playing a similar part, and their action is supposed to be merely catalytic, that is to say, they induce the reaction between the oxygen and

hydrogen merely by their presence or by contact, without themselves taking any direct part in the process: the chemist is familiar with many similar examples of catalytic action. For an elaborate discussion of the principles involved in Deacon's new process we may refer to the 'Journal of the Chemical Society,' Sept. 1872.

On the Industrial Manufacture of Chlorine, M. F. Lalande and M. Prud'homme have the following remarks:—

The reaction of anhydrous sulphuric acid, mixed with air or oxygen, upon heated alkaline chlorides, which has given rise to Deacon's patent for the preparation of chlorine and of sulphate of soda, has led us to generalise this process. We have chiefly experimented with silicic, boric, stannic, and phosphoric acids, and also with alumina. When any of these bodies, silica, for instance, is mixed with an alkaline chloride, or with an alkaline earth or earthy chloride, and over this mixture, while being heated to red heat, a current of dry oxygen or air is passed, chlorine is evolved, and a silicate formed of the base of the chloride employed:

At a red heat, therefore, oxygen expels chlorine, when there is simultaneously present an acid capable of uniting with the base which is formed. Chlorides heated *by themselves* in a current of oxygen (chloride of calcium, for instance) do not give off chlorine. When a current of *hydrochloric acid* gas is passed, along with oxygen, over the mixture of silica and chloride, the acid regenerates the chloride and decomposes the silicate:

In this way a *continuous* evolution of chlorine is obtained. Instead of taking the mixture of chlorine and silica, the silicate of the metal in which the chlorine is contained, or a mixture of silica and the oxide of that metal, is taken. Since analogous reactions occur with the acids above mentioned, we may state that it is general. The steam formed during the phase of reaction:

gives rise to two secondary actions:—

- (1). The chlorine decomposes the water at red heat:

- (2). The steam decomposes the chlorides at red heat:

It is probable that under these conditions an equilibrium exists between the quantities of chlorine, aqueous vapour, and hydrochloric issuing from the apparatus, or a limit of maximum between the quantity of chlorine produced and the hydrochloric acid evolved and issuing from the apparatus. This limit of maximum will be the greater according as the temperature required for the reaction be less high. Some of our experiments having been made by causing the substances operated with to be imbibed with pumice-stone, we have been induced to try whether pumice-stone alone would yield any result, that material being a complex silicate and a substance belonging to the category of those indicated by us. We have found that with pumice-stone an evolution of chlorine is obtained comparable to that obtained from the other substances, more particularly silica and lime, boric acid and lime, stannic acid and lime, alumina and chloride of sodium; since the same result is obtained with lumps of brick, it might be ascribed to the porosity of these substances; but this opinion is gainsaid by the fact, that under the same conditions pipeclay, a silicate of alumina and a very porous body, does not give rise to any appreciable reaction; it therefore appears possible that hydrochloric acid converts the surface of pumice-stone into a mixture of silica and chlorides. We have compared the production of chlorine in our experiments with that obtained by using bricks impregnated with sulphate of copper (Deacon's patent); the quantity of chlorine obtained in both cases is the same; but with bricks impregnated with sulphate of copper the reaction takes place at a lower temperature. The imperfection of our apparatus has hitherto prevented us from estimating the respective quantities of chlorine, hydrochloric acid, aqueous vapour, contained in the gases issuing from the apparatus; neither have we been able to estimate exactly the degree of temperature at which the reaction takes place.

Many other processes have been used with more or less success for the generation of chlorine. Thus, peroxide of manganese may be acted on by a mixture of hydrochloric and nitric acids, when chlorine, water, and nitrate of manganese will be obtained; this nitrate, on calcination, reproduces peroxide of manganese and some of the lower oxides of nitrogen, which, by the action of air and water, may again be oxidised to nitric acid. When a concentrated solution of chloride of magnesium (specific gravity 1.435) is mixed with peroxide of manganese, a product is obtained

which on exposure to heat yields chlorine, magnesia, and chloride of manganese. The chloride of magnesium used in this process may be obtained from carnallite, a mineral largely worked in the salt mines of Stassfurt and Kalucz. According to Longmaid's methods, chlorine is prepared by passing dry air over a mixture of common salt and iron-pyrites, roasted together; or a mixture of salt and some metallic sulphate, such as sulphate of iron. In Mac Dougal and Rawson's process any chromate or bichromate is acted on by hydrochloric acid. Shank's method is very similiar, chromate of lime being decomposed by hydrochloric acid; but the mode of reproducing the chromate is different. By Lauren's method protochloride of copper (cupric chloride), mixed with sand, is heated, and free chlorine evolved, while the residue of subchloride (cuprous chloride) is reconverted into the higher chloride by exposure to air in contact with hydrochloric acid. Mallet directs a current of air over subchloride of copper, thus forming an oxychloride, from which chlorine may be eliminated by hydrochloric acid.

Mr. Dunlop has also obtained a patent for the production of chlorine by a very elegant method, which dispenses with the use of manganese altogether. It consists in mixing common salt with nitrate of soda, and submitting the mixture to the action of sulphuric acid. Chlorine and nitrous gas are evolved, and are caused to traverse a vessel containing strong sulphuric acid, by which the nitrous gas is readily absorbed, and the chlorine passes off. A current of atmospheric air is now passed through the nitrous sulphuric acid, until the nitrous is converted into nitric acid. These mixed acids are then made to act upon common salt without any addition of nitrate of soda, and the same gaseous products are obtained as before.

A description of Mr. Weldon's process by which the refuse liquors left in the ordinary mode of preparing chlorine are utilized and the spent manganese re-oxidised, will be found under CHLORIDE OF LIME (p. 785).

Chlorine has a peculiar smell and irritates the nostrils and other air-passages most violently when inhaled. It is eminently noxious to animal life, and if breathed in its undiluted state, would prove instantly fatal. It supports the combustion of many bodies, and, indeed, several substances, such as antimony and phosphorus, spontaneously burn in chlorine without being previously kindled. The resulting combinations are called chlorides, and act most important parts in many manufacturing processes.

Water absorbs, at the ordinary temperature of the atmosphere, about $2\frac{1}{2}$ times its volume of chlorine, and acquires the colour, taste, and smell of the gas, as well as its power of destroying or bleaching vegetable colours. When this aqueous solution of chlorine is cooled down to 36° F., dark yellow crystalline plates appear in it of the hydrate of chlorine, which are composed in 100 parts of 27.7 chlorine and 72.3 water. If these crystals be heated to about 45° , they liquefy, and the gas is evolved.

Chlorine has a powerful affinity for hydrogen, not only combining with it rapidly in the gaseous state, but seizing it in many of its liquid and solid combinations: as in certain volatile hydrocarbons, which it inflames. The compound of chlorine and hydrogen gases is hydrochloric or muriatic acid gas. Bin oxide of manganese, when mixed with liquid hydrochloric acid, as in the above process, abstracts the hydrogen and eliminates the chlorine. When chlorine is passed into water, it decomposes some of it, seizes its hydrogen to form a little hydrochloric acid, and enables its oxygen to unite, either with the chlorine into chlorous acid, or with the remaining water, and to constitute oxygenated water. Hence an aqueous solution of chlorine, exposed to the sunbeam, continually evolves oxygen, and ere long becomes hydrochloric acid.

In the presence of moisture, chlorine acts powerfully upon vegetable colouring matters; water is decomposed, its hydrogen combining with the chloride to form hydrochloric acid, whilst its oxygen is liberated, and in its nascent state, or at the moment of its liberation when most active, oxidises the colouring principles, and thus bleaches them. Bleaching by means of chlorine is therefore a true process of oxidation; in some cases, however, it appears that colourless substitution-products containing chlorine are produced. The value of chlorine as a deodorizer and disinfectant consists also in its power of decomposing water, and setting free oxygen, which thus oxidises the poisonous miasmatic exhalations, and converts them into more or less innocuous products. For such purposes, chlorine is usually best employed in the form of bleaching powder, or chloride of lime; but in some cases the pure gas may be conveniently employed: it requires, however, from its poisonous nature to be used with the greatest care. In fumigating the Millbank Penitentiary, Dr. Faraday found that a mixture of 1 part of common salt and 1 part of bin oxide of manganese, when acted upon by two parts of oil of vitriol previously mixed with one part of water (all by weight), and left till cold, produce the best results. Such a mixture, at 60° , in shallow pans of red earthenware, liberated its chlorine gradually, but perfectly, for four days. The salt and manganese were well mixed, and used in charges of $3\frac{1}{2}$ pounds

of the mixture. The acids and water were mixed in a wooden tub, the water being put in first, and then about half the acid; after cooling, the other half was added. The proportions of water and acid were 9 measures of the former to 10 of the latter.—See Watts's 'Dictionary of Chemistry.'

Many of the compounds of chlorine are of great value in the arts and manufactures. Its hydrogen acid is fully described under HYDROCHLORIC ACID, while its compounds with the metals, forming important substances called chlorides, are noticed under the names of their respective metals. With oxygen, chlorine forms some unimportant anhydrides; but with oxygen and hydrogen it gives rise to a series of ox-acids, known respectively as hypochlorous, chlorous, chloric, and perchloric acids. Some of the salts of hypochlorous acid are important as constituents of the bleaching compounds popularly called 'chlorides,' as chloride of lime; and some of the salts of chlorous acid, as chlorate of potash, are also of great value in the arts. See CHLORATE OF POTASH; CHLORIDE OF LIME.

CHLORITE. A term applied to a family of minerals of a dark green colour and lamellar structure. They are hydrated silicates of alumina, magnesia, protoxide of iron, &c. The chlorite occurring in the Cornish tin-veins is known as *Peach*.

CHLOROMETRY. The name given to the process or processes by which the amount of available chlorine is estimated in substances containing it, which are employed in bleaching, or as disinfectants. The chlorides (hypochlorites) of lime, of potash, or of soda are the most important of these compounds. All these decolourising chlorides are decomposed by the action of acids, even by that of the carbonic acid of the atmosphere, chlorine being set free. The amount of chlorine capable of being thus evolved is required to be known for two reasons; to ascertain its commercial value, and to learn whether the strength of the solution employed is within the limits which enable it to be effectively and yet safely used in bleaching. A number of processes have been devised for this purpose. The method proposed by Gay-Lussac has been extensively used in manufactories; it depends upon the fact that arsenious acid in solution is oxidised by free chlorine and converted into arsenic acid with the simultaneous formation of hydrochloric acid. A solution of arsenious acid in hydrochloric acid was first prepared, of a known strength, and also a solution of the chloride of lime to be tested, by triturating a weighed quantity with water and making the mixture up to a certain bulk. A measured quantity of the arsenious acid liquor was placed in a beaker and coloured with a solution of sulphate of indigo, and the chloride of lime solution run into it from a graduated burette till the blue colour was destroyed. This process, though capable of giving accurate results when due care was taken, was liable to some objections. It was difficult to hit the exact point when the whole of the arsenious acid was converted into arsenic acid, and a little chlorine was apt to be evolved if the chloride solution was run in too quickly; moreover, it necessitated the measurement of a turbid liquid which required frequent agitation to keep the suspended matter equally diffused through it, and consequently of uniform strength throughout. To obviate these defects, the following modification of this process has been proposed by Penot. It is based upon the same reaction as Gay-Lussac's, but the change is effected in an alkaline solution, and a test-paper moistened with starch paste containing iodide of potassium is used to show when the reaction is completed. Whatever process may be employed, the mode of preparing the solution of the chloride of lime is the same. Weigh out 100 grains of the chloride to be examined, after it has been well mixed so as to obtain a fair average sample, put them into a mortar with a little water and triturate together so as to break up all lumps and produce a smooth paste, continue to rub whilst gradually adding more water, allow the heavier particles to subside, pour off the supernatant liquid into a measuring flask or cylinder capable of holding 10,000 grains, treat the residue in the mortar as before, and finally rinse the mortar out into the flask and make up the solution to exactly 10,000 grains measure and mix thoroughly.

Preparation of the Solution of Arsenite of Soda.—139·44 grains of the purest arsenious acid prepared either by crystallisation from hot dilute hydrochloric acid or by re-subliming a quantity of the arsenious acid of commerce free from sulphide, are dissolved in a flask in a few ounces of water with the addition of about 700 grains of crystallised carbonate of soda free from sulphide or hyposulphite. To facilitate the solution, the arsenious acid should be in fine powder and the mixture should be kept near the boiling point and frequently shaken. The contents of the flask with the water required to rinse it out are now transferred to a 10,000 grains measure, and when quite cold filled up to the mark and the whole then carefully mixed. The starch test may be prepared by boiling 3 parts of starch with 500 of water, and afterwards adding 1 part of iodide of potassium. The starch should be first mixed smoothly with a portion of cold water, then the remainder of the water may be added boiling, and the whole boiled for a short time. Slips of white unsized paper (filtering paper) are

dipped into the mixture and used whilst still damp, in which state they are far more sensitive than when dried as Penot proposed. To perform the operation, 1,000 grains of the solution of chloride of lime are measured out with a pipette immediately after thorough mixing, and placed in a beaker or other suitable vessel; the graduated burette having been filled up to the proper height with the arsenite-of-soda solution, its contents are gradually run into the chloride of lime till a drop of the latter taken out with a glass rod ceases to produce any colouration upon a piece of the starch test-paper above described. The operation is then completed. If the burette used contains 1,000 grains divided into 100 parts, each division corresponds to 1 per cent. of chlorine, when the solutions used are of the strength just described. The reason of this will be evident from the following considerations: one molecule of arsenious acid requires four atoms of chlorine with two atoms of water to form one molecule of arsenic acid and four molecules of hydrochloric acid. Taking the molecule of arsenious acid as 198 and the four molecules of chlorine as 132, that is 35.5×4 , a simple calculation will show that 139.436 grains of arsenious acid are equivalent to 100 grains of chlorine, and the 1,000 grains measure of the arsenious test-liquor in the burette contain one-tenth of this quantity, and are consequently equal to 10 grains of chlorine. Hence the number of divisions read off upon the burette indicates at once the percentage of chlorine in the sample examined. As it may sometimes be preferable to operate upon a larger quantity than 10 grains of chloride of lime, 2,000 grains of its solution may be taken, or it may be made of double strength; of course, in this case the number of divisions observed must be divided by two to obtain the correct result. It is as well to mention that the solution of arsenite of soda is liable to change slightly by the action of the air converting a portion into arsenate of soda, and it is recommended to keep it in small stoppered bottles entirely filled. When the store bottle is provided with the means of drawing off the solution from the bottom, a layer of petroleum oil floating upon the top of the liquid will defend it from the action of the air.

Bunsen's Method.—When free chlorine is brought in contact with an excess of solution of iodide of potassium, iodine is set free and hydrochloric acid is formed. Each atom of chlorine sets free one atom of iodine, which by means of the exceedingly delicate reaction with starch may be estimated with the greatest accuracy. 100 or 200 grains of the solution of chloride of lime prepared as before described are measured, placed in a beaker or mixing jar, and about 60 or 120 grains measure of solution of iodide of potassium containing 1 part iodide in 10 parts of water added, diluted with about 1,000 grains of water, acidulated with hydrochloric acid, and a standard solution of arsenite or hyposulphite of soda run in from a burette, till only a yellow tint remains. A little starch-paste is now added and the arsenite again added cautiously drop by drop till the blue colour just disappears. When an occasional test only is required, the method subjoined may be followed with advantage, as it obviates the necessity of preparing a standard solution.

This process is founded upon the following reaction:—One atom of chlorine, in presence of free sulphuric acid and water, converts two atoms of protosulphate of iron into one atom of persulphate of iron, with the production of one atom of hydrochloric acid:

For the experiment either pure sulphate of iron, free from peroxide, or the double sulphate of iron and ammonia, or finally a weighed quantity of thin annealed iron wire may be used, dissolved in hydrochloric or preferably in dilute sulphuric acid. Of the crystallised sulphate of iron, as 278 parts correspond to 35.5 parts of chlorine, it is easily calculated that 7.831 grains will be peroxidised by one grain of chlorine. 31.324 grains (7.831×4) of sulphate of iron are, therefore, weighed out, dissolved in water, with the addition of a few drops of sulphuric acid, and the volume made up to 2,000 grains measure. One fourth of this, or 500 grains, is taken out with a pipette, diluted with 1,500 to 2,000 grains of water, acidulated with hydrochloric acid, and the chloride-of-lime solution, made as previously described, is run into it from a 1,000-grain burette, with constant agitation, till the whole of the iron is brought into the state of peroxide. To ascertain when the reaction is finished, a dilute solution of ferricyanide of potassium is used. A drop being placed upon a white plate, a stirring rod, dipped into the mixture of the iron salt and chloride of lime, is brought into contact with it. As long as a blue colour is produced it shows that the whole of the protosalt of iron is not yet oxidised, and the addition of the chloride-of-lime solution is, therefore, cautiously continued, until, on mixing the drops, no further shade of blue is perceptible. The reading of the burette is then taken; and, as the volume used contains one grain of chlorine, the percentage of that element is easily obtained by dividing 10,000 (the number of grains of solution in which 100 grains of chloride

of lime have been dissolved) by the number of grains of solution delivered from the burette. Thus, suppose 437 grains have been used, 43·7 divisions:— as 437 : 1::10,000 : 22·89 per cent. of chlorine in the sample in question. If iron wire be taken, 6·308 grains, or, allowing 0·3 per cent. for impurities, 6·327 grains may be weighed, dissolved in dilute sulphuric acid, made up to 2,000 grains measure, and the solution thus obtained employed instead of that of the crystallized protosulphate.—W.J.W.

CHLOROFORM. When a mixture of chlorine and gaseous chloride of methyl is exposed to the sun's rays, chloroform is produced. It is prepared usually by distilling alcohol with chloride of lime. It is used to produce insensibility. See Watt's 'Dictionary of Chemistry.'

CHLOROPHANE. A name given to some of the varieties of fluor spar, which emit a phosphorescent light when heated. See FLUOR SPAR.

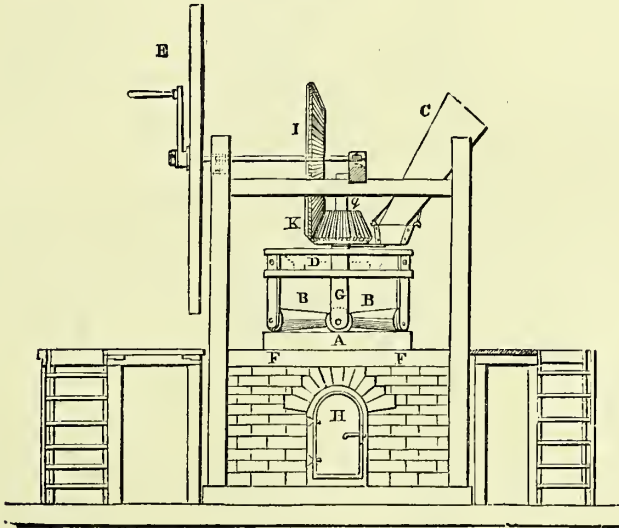

CHLOROPHYLL. The green colouring matter of leaves and other herbaceous parts of plants.

CHOCOLATE. (Eng. and Ger. ; *Chocolat*, Fr.) This is an alimentary preparation of very ancient use in Mexico, from which country it was introduced into Europe by the Spaniards in the year 1520, and by them long kept a secret from the rest of the world. Linnæus was so fond of it, that he gave the specific name, *Theobroma*, 'food of the gods,' to the cacao tree which produced it. The cacao-beans lie in a fruit somewhat like a cucumber, about 5 inches long and $3\frac{1}{2}$ thick, which contains from 20 to 30 beans, arranged in 5 regular rows with partitions between, and which are surrounded with a rose-coloured spongy substance, like that of water melons. There are fruits, however, so large as to contain from 40 to 50 beans. Those grown in the West India islands, Berbice, and Demerara, are much smaller, and have only from 6 to 15 beans; their development being less perfect than in South America. After the maturation of the fruit, when their green colour has changed to a dark yellow, they are plucked, opened, their beans cleared of the marrowly substance, and spread out to dry in the air. Like almonds, they are covered with a thin skin or husk. In the West Indies they are immediately packed up for the market when they are dried; but in the Caraccas they are subjected to a species of slight fermentation, by putting them into tubs or chests, covering them with boards or stones, and turning them over every morning, to equalise the operation. They emit a good deal of moisture, lose the natural bitterness and acrimony of their taste by this process, as well as some of their weight. Instead of wooden tubs, pits or trenches dug in the ground are sometimes had recourse to for curing the beans; an operation called *earthing* (*terrer*). They are lastly exposed to the sun and dried. The latter kind are reckoned the best, being larger, rougher, of a darker brown colour, and when roasted, throw off their husk readily, and split into several irregular fragments; they have an agreeable mild bitterish taste, without acrimony. The Guiana and West India sorts are smaller, flatter, smoother skinned, lighter coloured, more sharp and bitter to the taste. They answer best for the extraction of the butter of cacao, but afford a less aromatic and agreeable chocolate. According to Lampadius, the kernels of the West India cacao-beans contain, in 100 parts, besides water, 53·1 of fat or oil, 16·7 of an albuminous brown matter, which contains all the aroma of the bean, 10·91 of starch, 7·75 of gum or mucilage, 0·9 of lignine, and 2·01 of a reddish dye stuff, somewhat akin to the pigment of cochineal. The husks form 12 per cent. of the weight of the beans; they contain no fat, but, besides lignine, or woody fibre, which constitutes half their weight, they yield a light brown mucilaginous extract by boiling in water. The fatty matter is of the consistence of tallow, white, of a mild agreeable taste, called butter of cacao, and not apt to turn rancid by keeping. It melts only at 122° F., and should, therefore, make tolerable candles. It is soluble in boiling alcohol, but precipitates in the cold. It is obtained by exposing the beans to strong pressure in canvas bags, after they have been steamed or soaked in boiling water for some time. From 5 to 6 ounces of butter may be thus obtained from a pound of cacao. It has a reddish tinge when first expressed, but it becomes white by boiling with water.

The beans, being freed from all spoiled and mouldy portions, are to be gently roasted over a fire in an iron cylinder, with holes in its ends for allowing the vapours to escape; the apparatus being similar to a coffee-roaster. When the aroma begins to be well developed, the roasting is known to be finished; and the beans must be turned out, cooled, and freed by fanning and sifting from their husks. The kernels are then to be converted into a paste by trituration in a mortar heated to 130° F., or by the following ingenious and powerful machine. The chocolate paste has usually in France a little vanilla incorporated with it, and a considerable quantity of sugar, which varies from one-third of its weight to equal parts. For $1\frac{1}{2}$ lb. of cacao one pod of vanilla is sufficient. The roasted beans soon lose their flavour by exposure to the air.

Fig. 462 represents the chocolate mill. Upon the sole *A*, made of marble, six conical rollers *B B* are made to run by the revolution of the upright axis or shaft *g*, driven by the agency of the fly-wheel *B* and bevel wheels *I K*. The sole *A* rests upon a strong iron plate, which is heated by a small stove, introduced at the door *H*. The wooden framework *F* forms a ledge, a few inches high, round the marble slab, to confine the cocoa in the act of trituration. *C* is the hopper of the mill through which the roasted beans are introduced to the action of the rollers, passing first into the flat vessel *D*, to be thence evenly distributed. After the cacao has received the first trituration, the paste is returned upon the slab, in order to be mixed with the proper

462

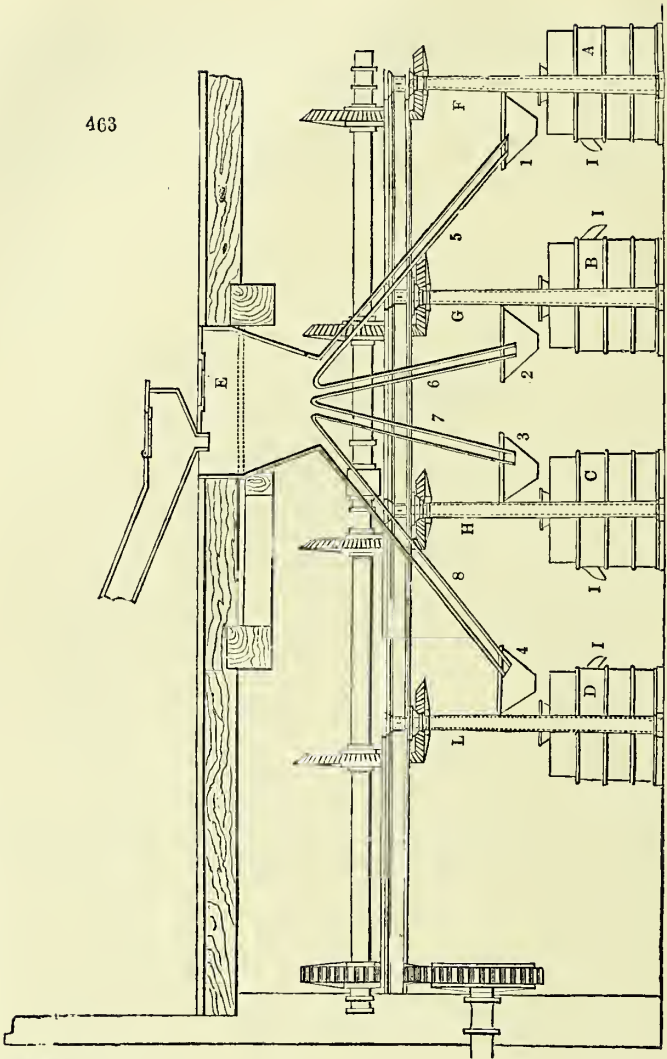

quantity of sugar and vanilla, previously sliced and ground up with a little hard sugar. When the chocolate is sufficiently worked, and while it is thin with the heat and trituration, it must be put carefully into the proper moulds. If introduced too warm, it will be apt to become damp and dull on the surface; and, if too cold, it will not take the proper form. It must be previously well kneaded with the hands to ensure the expulsion of every air bubble.

In Barcelona, chocolate mills on this construction are very common, but they are turned by a horse-gin set to work in the under story, corresponding to *H* in the above figure. The shaft *G* is, in this case, extended down through the marble slab, and is surrounded at its centre with a hoop to prevent the paste coming into contact with it. Each of these horse-mills turns out about ten pounds of fine chocolate in the hour, from a slab two feet seven inches in diameter.

Chocolate is flavoured with cinnamon and cloves in several countries, instead of the more expensive vanilla. In roasting the beans the heat should be at first very slow, to give time for the humidity to escape; a quick fire hardens the surface, and injures the process. In putting the paste into the tin plate, or other moulds, it must be well shaken down, to insure its filling up all the cavities, and giving the sharp and polished impression so much admired by connoisseurs. Chocolate is sometimes adulterated with starch; in which case it will form a mass pasty of consistence when treated with boiling water. The harder the slab upon which the beans are trituated the better; and thence porphyry is far preferable to marble. The grinding rollers of the mill should be made of iron, and kept very clean.

Fig. 463 represents the chocolate mills at the victualling-yard, Deptford, as mounted by the celebrated engineers, Messrs. Rennie. There are four double mill-stones, *A, B, C, D*, each three feet in diameter, of which the nether rests upon a bed of cast-iron, like a drum-head, kept at the temperature of about 220° by the admission of steam to the case below. Over each mill there is a feeding hopper, 1, 2, 3, 4, in communication by the pipes 5, 6, 7, 8, with the general reservoir *E*, charged upon the floor above with the cocoa through the funnel placed over it. The vertical shafts which turn these mills are marked, *F, G, H, I*; they are moved by the train of bevel-wheels

463

464

above, which are driven by an arm from the main shaft of the steam-engine. Each mill can, of course, be thrown in and out of gear at pleasure. At 1, 1, 1, 1, the discharge-spouts are shown, which pour out the semi-fluid hot chocolate into shallow cylindrical tin pans, capable of containing about nine pounds of chocolate each. These four mills are capable of converting upwards of a ton of cocoa into good chocolate in a day, on the system of double trituration.

Fig. 464 is an end view of one of the chocolate mills, with its mitre-gearing.

Our *Importations* of chocolate or cocoa paste were, in 1871 and 1872, as follows (when the duty was 2*d.* per lb., which is the duty that was settled by the Customs on June 4, 1853):—

	1871		1872

CHOKO DAMP, After Damp, Black Damp. Terms employed by miners for the atmosphere of coal-mines, after an explosion of fire-damp, which is usually air deprived of its oxygen and largely mixed with carbonic acid. Choko damp is also used to express the atmosphere of carbonic acid, which accumulates in deserted shafts, in abandoned workings, in wells, or in brewers' vats. It is removed by throwing lime-water into the space it occupies, and agitating the air.

CHROMO-LITHOGRAPHY. Printing in colours from lithographic stones. See LITHOGRAPHY.

CHROMASCOPE. An instrument for showing colours.

CHROMATES. Saline compounds of chromic acid with bases; or, chromic acid in which the hydrogen is replaced by a metal. See CHROMIUM and CHROMIC ACID.

CHROMATES OF LEAD. Some of these compounds occur native, forming the minerals known as *Crocoisite* and *Melanoehroite*. The chromates of lead are also prepared artificially, and largely used as pigments, the neutral chromate forming *Chrome Yellow*, and the basic chromate *Chrome Red*. The chrome yellow of the painter is a rich pigment of various shades, from deep orange to the palest canary yellow. It is made by adding a limpid solution of the neutral chromate of potash, to a solution equally limpid of acetate or nitrate of lead. A precipitate falls, which must be well washed and carefully dried out of the reach of any sulphuretted vapours. A lighter shade of yellow is obtained by mixing some solution of alum or sulphuric acid with the chromate before pouring it into the solution of lead; and an orange tint is to be procured by the addition of subacetate of lead in any desired proportions.

It was ascertained by MM. Riot and Delisse, that the proportion of chromic acid in chromate of lead may be much diminished without any injury to the colour, and that the same colour is produced with 25 parts of neutral chromate for 100 of chrome yellow, as when 54 parts are used. They give the following formula for the preparation of this pigment:—Acetate of lead is dissolved in water, and sulphuric acid in quantity necessary to convert the oxide of lead into sulphate is added. The clear liquid contains acetic acid and may be drawn off, and preserved for the preparation of fresh acetate of lead. The sulphate of lead is washed and treated with a hot solution of neutral chromate of potash, 25 parts being used for every 75 parts of sulphate of lead. The liquid then contains sulphate of potash which may be made available, and the precipitate consists of chromate of lead.

Chrome yellow may be prepared according to Liebig, by digesting sulphate of lead in a warm solution of chromate of potash. It may also be obtained by digesting 100 parts of freshly-precipitated chloride of lead with 47 parts of bichromate of potash. This is Anthon's process.

To prepare chrome red, Rungé directs an intimate mixture to be made of 448 lbs. of litharge, 60 lbs. of common salt, and 500 lbs. of water. As soon as the mass becomes white and swells up considerably, more water is added to prevent it from becoming too hard. After four or five days, the mass becomes a compound of chloride and hydrated oxide of lead. Without separating the mother-liquor, which contains undecomposed chloride of sodium and soda, 150 lbs. of powdered bichromate of potash are to be added, and the whole well stirred together, and finally washed.

Liebig and Wöhler contrived a process for producing a subchromate of lead of a beautiful vermilion hue. Into saltpetre, brought to fusion in a crucible at a gentle heat, pure chrome yellow is to be thrown by small portions at a time. A strong ebullition takes place at each addition, and the mass becomes black, and continues so while it is hot. The chrome yellow is to be added till little of the saltpetre remains undecomposed, care being taken not to overheat the crucible, lest the colour of the mixture should become brown. Having allowed it to settle for a few minutes, during which the dense basic salt falls to the bottom, the fluid part, consisting of chromate of potash and saltpetre, is to be poured off, and it can be employed again in preparing chrome yellow. The mass remaining in the crucible is to be washed with water, and the chrome red being separated from the other matters, it is to be dried after proper edulcoration. It is essential for the beauty of the colour, that the saline solution should not stand long over the red powder, because the colour is thus apt to become of a dull orange hue. The fine crystalline powder subsides so quickly to the bottom after every ablation, that the above precaution may be easily observed.

CHROMATES OF POTASH. Three of these salts are known, but only two of them are used in the arts, namely, the neutral chromate of potash KO.CrO_3 (K^2CrO_4), and the acid or bichromate of potash, KO.2CrO_3 ($\text{K}^2\text{Cr}_2\text{O}_7$).

The *neutral chromate* is a yellow salt, prepared by heating chrome iron-ore with a salt of potash. It contains:—

Potash	48.0
Chromic acid	52.0
	100.0

The value of a solution of chromate of potash, if it be tolerably pure, may be inferred from its specific gravity by the following table:—

At specific gravity 1.28 it contains about 50 per cent. of the salt.					
”	”	1.21	”	”	33
”	”	1.18	”	”	25
”	”	1.15	”	”	20
”	”	1.12	”	”	16
”	”	1.11	”	”	14
”	”	1.10	”	”	12

The *acid chromate* or *bichromate* (called by modern chemists the *dichromate* or *anhydrochromate of potassium*) is a red salt, which by slow cooling, may be obtained in the form of square tables, with bevelled edges, or flat, four-sided prisms. They are permanent in the air, have a metallic and bitter taste, and dissolve in about one-tenth of their weight of water at 60° F., but in one half of their weight of boiling water. The composition of bichromate of potash is: potash, 31.6; chromic acid, 68.4.

In making the red bichromate of potash from solutions of the yellow salt, nitric acid was at first chiefly used; but, in consequence of its relatively high price, sulphuric, muriatic, or acetic acid has been frequently substituted upon the large scale.

(For the preparation of both these salts refer to **CHROME IRON**.)

These salts are much employed in **CALICO PRINTING** and in **DYEING**. The bichromate of potash is also used in the photographic process known as **Carbon-printing**; a sensitive surface being obtained by bichromate of potash and gelatine. Another modern use of the bichromate is in a convenient form of galvanic cell, where it serves to oxidise the hydrogen set free by the action of an acid upon zinc.

Chromate of Potash, Adulteration of, to detect.—The chromate of potash has the power of combining with other salts up to a certain extent without any very sensible change in its form and appearance; and hence it has been sent into the market falsified by very considerable quantities of sulphate and muriate of potash, the presence of which has often escaped observation, to the great loss of the dyers who use it so extensively. The following test process has been devised by M. Zuber, of Mülhouse:—Add a large excess of tartaric acid to the chromate in question, which will decompose it, and produce in a few minutes a deep amethyst colour. The supernatant liquor will, if the chromate be pure, afford now no precipitate with the nitrates of baryta or silver; whence the absence of the sulphates and muriates may be inferred. We must, however, use dilute solutions of the chromate and acid, lest bitartrate of potash be precipitated, which will take place if less than 60 parts of water be employed. Nor must we test the liquid till the decomposition be complete, and until the colour verge rather towards the green than the yellow. Eight parts of tartaric acid should be added to one of chromate to obtain a sure and rapid result. If nitrate of potash (saltpetre) is the adulterating ingredient, it may be detected by throwing it on burning coals, when deflagration will ensue. The green colour is a certain mark of the transformation of the chromic acid partially into the chrome oxide; which is effected equally by the sulphurous acid and sulphuretted hydrogen. Here this metallic acid is deoxygenated by the tartaric, as has been long known. The tests which I should prefer are the nitrates of silver and baryta, having previously added so much nitric acid to the solution of the suspected chromate as to prevent the precipitation of the chromate of silver or baryta. The smallest adulteration by sulphates or muriates will thus be detected.

A mixture of sulphate of soda and chloride of sodium tinged with strong solution of chromium is sometimes sold for pure bichromate of potash.—H. M. N.

CHROMATYPE. A photographic process. See **PHOTOGRAPHY**.

CHROMATYPOGRAPHY. A French process for printing letter-press in colours.

CHROME ALUM. A double sulphate of sesquioxide of chromium and potash. It is obtained as a by-product in the preparation of the aniline colours, and is sometimes used in dyeing. See **ALUM**.

CHROME GREEN. This term is applied both to the green oxide (sesquioxide) of chromium, and to a green pigment prepared by mixing chrome yellow with Prussian blue.

CHROME IRON, or CHROMITE. The only ore of chromium which occurs in sufficient abundance for the purposes of art is the octahedral chrome ore, commonly called chromate of iron, though it is rather a compound of the oxides of chromium and of iron. It is formed on the type of magnetic iron-ore, being a combination of a protoxide with a sesquioxide—the protoxide metal in chrome iron-ore being chiefly iron, and the sesquioxide metal chiefly chromium; hence, the formula is $\text{FeO.Cr}_2\text{O}_3$ (FeCr_2O_4). The fracture of this mineral is imperfect conchoidal, or uneven. Hardness = 5·5; specific gravity 4·4 to 4·5; but the usual chrome ore found in the market varies from 3 to 4. It lustre is semi-metallic or resinous; colour, iron or brownish black; streak, yellowish to reddish brown. It is sometimes magnetic. Before the blowpipe it is infusible alone, but in borax it is slowly soluble, forming a beautiful emerald-green bead; fused with nitre it forms a yellow solution in water.

Chrome ore was first discovered in the Var department in France; it is also found, chiefly in serpentine, in Saxony, Silesia, Bohemia, Transylvania, the Banat, and Styria; in Norway at Røraas, in the Ural near Katherinenberg, in the United States at the Barehills near Baltimore, Chester in Massachusetts, and Hoboken in New Jersey. In Scotland it is found in the parishes of Kildrum and Towie in Aberdeenshire, in the limestone near Portsoy in Banffshire, near Ben Lawes in Perthshire, and at Buchanan in Stirlingshire. It occurs massive and in considerable quantity in serpentine-rocks at Swinans, and Haroldswick in Unst, one of the Shetlands; in Fetlar and in other of the smaller Shetland Islands.

(1) from St. Domingo, analysed by Berthier; (2) from Røraas, in Norway, analysed by Von Kobell; (3) from Baltimore, analysed by Seybert; (4) crystallised, from Baltimore, analysed by Abich; (5) analysed by Klaproth.

The chief application of this ore is to the production of Chromate of Potash, from which salt the various other preparations of this metal used in the arts are obtained.

Treatment of the Ore.—According to the old method it is reduced to a fine powder, by being ground in a mill under ponderous edge-wheels, and sifted. It is then mixed with one third or one half its weight of coarsely-bruised nitre, and exposed to a powerful heat for several hours, on a reverberatory hearth, where it is stirred about occasionally. In the large manufactories of this country, the ignition of the above mixture in pots is laid aside as too operose and expensive. The calcined matter is raked out and lixiviated with water. The bright yellow solution is then evaporated briskly and the chromate of potash falls down in the form of a granular salt, which is lifted out from time to time from the bottom with a large ladle, perforated with small holes, and thrown into a draining box. The saline powder may be formed into regular crystals of neutral *Chromate of Potash*, by solution in water and slow evaporation; or it may be converted into a more beautiful crystalline body, the *Bichromate of Potash*, by treating its concentrated solution with nitric, muriatic, sulphuric, or acetic acid, or indeed any acid exercising a stronger affinity for the second atom of the potash than the chromic acid does.

The first great improvement in this manufacture was the dispensing with nitre, and oxidising entirely by means of air admitted into the reverberatory furnace, in which the ore mixed with carbonate of potash is calcined. Stromeyer afterwards suggested the addition of lime, by which the oxidation was much quickened, and Mr. Charles Watt substituted the sulphates of potash and soda for the nitrates of those alkalis. The sulphate was first intimately mixed with the ground ore, and then the lime well incorporated with the mixture, which was heated to bright redness, for four hours with frequent stirring.

In 1847 Mr. Tilgmann obtained a patent for the use of felspar in the manufacture of certain alkaline salts, and amongst them of chromate of potash: he directs 4 parts by weight of felspar, 4 parts of lime, or an equivalent quantity of carbonate of lime, and one part of chromic ore, all in fine powder, to be intimately mixed together, and

kept at a bright red heat for from 18 to 20 hours in a reverberatory furnace, the mixture being turned over frequently, so that all parts may be exposed equally to heat and air; the temperature is not to rise high enough to cause even incipient fusion, and the charge should be kept in a porous state; when, on being examined, the charge is found to contain the proper quantity of alkaline chromate, it is withdrawn from the furnace and lixiviated with water.

In treating chromium (chromate of iron), the ore is pulverised and mixed with common salt, muriate of potash, or hydrate of lime, and exposed in a reverberatory furnace to a red or even a white heat, the mixture being stirred every ten or fifteen minutes, and steam at a very elevated temperature introduced during the operation, until the desired effect is obtained, which may be ascertained by withdrawing a portion from the furnace and testing it, as customary. The products of this operation are finally treated in the manner usual for the chromic and bichromic salts.

The mixture of chromium and common salt produces chromate of soda, the greater portion, or perhaps all of the iron contained in the chromium being absorbed by the hydrochloric acid evolved from the salt, and carried off in the form of sesquichloride of iron. From the first mixture is manufactured pure bichromate of soda, which, by the addition of hydrochloric acid, may be converted into chlorochromate; and from the last, or lime mixture, is produced a chromate of that earth, from which, by the addition of soda or potash, there may be obtained a compound salt, which, with those previously mentioned, may be advantageously employed.

M. Jacquelin first prepares chromate of lime by calcining at a bright red heat in a reverberatory furnace, for 9 or 10 hours, an intimate mixture of chalk and chrome ore. The friable and porous mass is then crushed, suspended in water, and sulphuric acid added until the liquid slightly reddens blue litmus-paper; the chromate of lime is hereby converted into bichromate; chalk is now added, until the whole of the sesquioxide of iron is precipitated, and the clear liquid, which now contains only bichromate of lime and a little sulphate, may be used for the preparation of the insoluble chromates of lead, zinc, baryta, &c., by mixing it with the acetates or chlorides of these metals. To prepare bichromate of potash, the bichromate of lime is mixed with solution of carbonate of potash, which gives rise to insoluble carbonate of lime, which is easily washed, and a solution of bichromate of potash which is concentrated and set aside to crystallise.

Mr. Booth (patent sealed Nov. 9th, 1852) mixes powdered chrome ore with one-fifth of its weight of powdered charcoal, and heats it on the hearth of a reverberatory furnace, protecting it carefully from the air. The ore is by this means decomposed, and the iron reduced to the metallic state, and is dissolved out by dilute sulphuric acid; the residue is washed and dried, and afterwards mixed with carbonate of potash and salpêtre, and heated in the same manner that the chrome ore itself is heated in the process usually employed. The solution of sulphate of iron is evaporated to crystallisation so as to produce copperas in a state adapted for commerce.

Analysis of Chrome Iron Ore.—Various methods have been proposed. The following, suggested by Mr. T. S. Hunt, gives accurate results:—The ore, finely levigated in an agate mortar, is mixed with 10 or 12 times its weight of fused bisulphate of potash, and preserved at a gentle heat for about half an hour. The fused mass is extracted with hot water, and boiled for a few minutes with excess of carbonate of soda; the precipitate is dried and fused with five times its weight of a mixture of equal parts of nitre and carbonate of soda, in a platinum or silver crucible. The mixture is kept in fusion for 10 or 15 minutes, and when cold is extracted with water. The alkaline chromate thus obtained may be precipitated by a salt of lead, or it may be supersaturated by hydrochloric acid, and boiled with alcohol, by which it is converted into chloride of chromium, from which the oxide is to be precipitated by adding ammonia in excess and boiling for a few minutes. Chrome iron ore is so difficult of decomposition, that the method of fusing it at once with nitre and an alkaline carbonate frequently fails in oxidising the whole of the chromium into chromic acid.

Mr. Calvert mixes the well-pulverised ore with three or four times its weight of a mixture made by slaking quicklime with caustic soda, and then dries and calcines the mass. He then adds one-fourth part of nitrate of soda, and calcines for two hours more, by which time he finds the whole of the chromium is converted into chromic acid. Another process, which Mr. Calvert finds to produce good results, consists in calcining the pulverised chrome ore with nitrate of baryta, adding a little caustic potash from time to time towards the end of the process.—H.M.N.

CHROME RED and CHROME YELLOW. See CHROMATES OF LEAD.

CHROME STONE. The name given to Chrome Ochre when it is so intimately mixed with the rock in which it is contained as only to be separated from it by chemical means. Such mixtures are met with at Creuzot in France, Waldenberg in Silesia, Mortenberg in Sweden, and elsewhere. See Bristow's 'Glossary of Mineralogy.'

CHROMIC ACID. There are several methods of preparing this acid; the simplest consists in decomposing bichromate of potash by oil of vitriol:—1. An excess of oil of vitriol is mixed with a warm solution of bichromate of potash; the liquid is poured off from the chromic acid, which separates in small red crystals; the crystals are drained in a funnel having its stem partly filled with coarsely-pounded glass, and are afterwards dried on a porous tile under a bell glass: 2. Mr. Warrington mixes 10 measures of a cold saturated solution of bichromate of potash with from 12 to 15 measures of oil of vitriol free from lead, and presses the red acicular crystals which separate as the liquid cools, between porous stones. If it be desired to remove the last traces of sulphuric acid, the crystals should be redissolved in water, and a solution of bichromate of baryta should be added in quantity just sufficient to throw down the whole of the sulphuric acid as sulphate of baryta; the solution may be recrystallised by evaporation *in vacuo*: 3. Meissner prepares the acid direct from chromate of baryta by digesting that salt with a quantity of dilute sulphuric acid, not sufficient for complete saturation: the solution which contains chromic acid and acid chromate of baryta is precipitated by the exact amount of sulphuric acid required, so that the solution is affected neither by sulphuric acid, nor by a salt of baryta: it is then evaporated to dryness.

Mr. Charles Watt obtains the acid by treating chromate of baryta with considerable excess of pure strong nitric acid. The chromic acid is separated from the insoluble nitrate of baryta by filtration through asbestos, and the solution is then evaporated to dryness, while nitric acid is expelled.

Chromic acid is obtained in quadrangular crystals, of a deep red colour; it has a very acid and styptic taste. It reddens powerfully litmus-paper. It is deliquescent in the air. When heated to redness, it emits oxygen and passes into the sesquioxide. When a little of it is fused along with vitreous borax, the compound assumes an emerald green colour.

As chromic acid parts with its last dose of oxygen very easily, it is capable, in certain styles of calico-printing, of becoming a valuable substitute for chlorine where this more powerful substance would not, from peculiar circumstances, be admissible. For this ingenious application, the arts are indebted to that truly scientific manufacturer, M. Daniel Kœchlin, of Mülhouse. He discovered that whenever chromate of potash has its acid set free by its being mixed with tartaric or oxalic acid, or a neutral vegetable substance (starch or sugar, for example), and a mineral acid, a very lively action is produced, with disengagement of heat, and of several gases. The result of this decomposition is the active reagent chromic acid, possessing valuable properties to the printer. Water-solutions of chromate of potash and tartaric acid being mixed, an effervescence is produced which has the power of destroying vegetable colours. But this power lasts no longer than the effervescence. The mineral acids react upon the chromate of potash only when vegetable colouring matter, gum, starch, or a vegetable acid, are present to determine the disengagement of gas. During this curious change, carbonic acid is evolved; and when it takes place in a retort, there is condensed in the receiver a colourless liquid, slightly acid, exhaling somewhat of the smell of vinegar, and containing a little empyreumatic oil. This liquid, heated with the nitrates of mercury or silver, reduces these metals. On these principles M. Kœchlin discharged indigo-blue by passing the cloth through a solution of chromate of potash, and printing nitric acid thickened with gum upon certain spots. It is probable that the employment of chromic acid would supersede the necessity of having recourse in many cases to the more corrosive chlorine.—H.M.N.

Chromic acid is now used in microscopy for hardening the preparations of soft tissues.

CHROMITE. See CHROME IRON-ORE.

CHROMIUM. (*Symbol, Cr; Atomic weight, 26.27.*) The metallic base of the oxide of chromium. It may be obtained by exposing to a very high temperature, in a crucible lined with charcoal, an intimate mixture of sesquioxide of chromium and charcoal. The spongy mass obtained is powdered in an iron mortar, and mixed with a little more sesquioxide of chromium (to oxidise as much as possible of the carbon); it is then again exposed in a porcelain crucible to a very high temperature, when a coherent metal is obtained. This metal is greyish in colour, hard and brittle, and is magnetic at low temperatures. It has received no practical applications.

CHROMIUM, OXIDE OF. There are several oxides of chromium, known to chemists, but the only one used in the arts is the sesquioxide (Cr^2O^3), known commonly as *green oxide of chromium*. This has come so extensively into use as an enamel colour for porcelain, that a fuller account of the best modes of manufacturing it must prove acceptable to many of our readers.

That oxide, in combination with water, called the hydrate, may be economically

prepared by boiling chromate of potash, dissolved in water, with half its weight of flowers of sulphur, till the resulting green precipitate ceases to increase, which may be easily ascertained by filtering a little of the mixture. The addition of some potash accelerates the operation. This consists in combining the sulphur with the oxygen of the chromic acid, so as to form sulphuric acid, which unites with the potash of the chromate into sulphate of potash, while the chrome oxide becomes a hydrate. An extra quantity of potash facilitates the deoxidation of the chromic acid by the formation of hyposulphite and sulphide of potash, both of which have a strong attraction for oxygen. For this purpose the clear lixivium of the chromate of potash is sufficiently pure, though it should hold some alumina and silica in solution, as it generally does. The hydrate may be freed from particles of sulphur by heating dilute sulphuric acid upon it, which dissolves it; after which it may be precipitated, in the state of a carbonate, by carbonate of potash, not added in excess.

By calcining a mixture of bichromate of potash and sulphur in a crucible, chromic acid is also decomposed, and a hydrated oxide may thus be obtained; the sulphur being partly converted into sulphuret of potassium, and partly into sulphuric acid (at the expense of the chromic acid), which combines with the rest of the potash into a sulphate. By careful lixiviation, these two new compounds may be washed away, and the chrome green may be freed from the remaining sulphur, by a slight heat.

Another method of preparing green oxide of chromium, is to mix intimately 45 parts of gunpowder with 240 parts of perfectly dry chromate of potash, and 35 parts of chloride of ammonium (sal-ammoniac), reduce to powder, and pass through a fine sieve; fill a conical glass or other mould with this powder, gently pressed, and invert so as to leave the powder on a porcelain slab of any kind. When set on fire at its apex with a lighted match, it will burn down to the bottom with brilliant coruscations. The black residuum, being elutriated with warm water, affords a fine bright-green oxide of chromium.

Preparation of Green Oxide of Chromium for Calico-Printing.—The following directions are given by De Kerrur. At the commencement of the process the green hydrate of the oxide of chromium is first prepared by dissolving 4 kilogrammes of bichromate of potash in 22 litres (39 pints) of boiling water. Then into a boiler or vessel containing 108 litres (24 gallons) of boiling water, 4 or 5 kilogrammes (8 or 10 lbs.) of pulverised white arsenic are thrown, and boiled for 10 minutes: a precipitate will be formed, and must be allowed to settle: the clear liquor is then run off, and immediately mixed with the solution of bichromate of potash, stirring all the time: in a short time the mixture acquires a green tint, and the hydrated oxide of chromium will be formed and precipitated. After being several times well stirred, and allowed to cool, the whole is thrown upon a filter of white wool, and the hydrate of chromium remaining on the filter is carefully washed with boiling water. It is then dried, and ready to be employed for the preparation of the chloride. In order to obtain that salt, hydrochloric acid of 22° Baumé is diluted with water, until the acid no longer gives off vapour. It is then heated, and whilst hot, as much of the hydrated oxide of chromium, prepared as above, is added as will saturate the acid and leave a slight excess of the oxide undissolved. The whole is then left to settle, and the clear liquor is decanted from the dissolved matter. In this state the solution of chloride of chromium still presents some traces of free acid, which would act injuriously upon the fibres of the cotton. To remove this, and to obtain the product in a neutral state, potash-ley (marking 36° Baumé) is poured in very gradually, until the oxide of chromium begins to be precipitated. The solution of chloride of chromium thus prepared, and which is of a dark green colour, is evaporated until it marks 46° Baumé; after cooling, oxide of chromium of the finest green colour is obtained. This preparation is sold under the name of Sea-green.

This oxide may also be prepared by decomposing, with heat, the chromate of protoxide of mercury, a salt made by adding to nitrate of protoxide of mercury (mercurous nitrate), chromate of potash, in equivalent proportions. This chromate has a fine cinnabar red, when pure; and, at a dull red heat, parts with a portion of its oxygen and its mercurial oxide. From M. Dulong's experiments it would appear that the purest chromate of mercury is not the best adapted for preparing the oxide of chrome to be used in porcelain painting. He thinks it ought to contain a little oxide of manganese and chromate of potash to afford a green colour of a fine tint, especially for pieces that are to receive a powerful heat. Pure oxide of chrome preserves its colour well enough in a muffle furnace; but, under a stronger fire, it takes a dead-leaf colour.—H.M.N.

A hydrated sesquioxide of chromium is used as a green pigment, under the name of GUIGNET'S GREEN.

CHROMIUM, BLUE OXIDE OF. The following directions have been given for the preparation of a *blue oxide* of chromium:—The concentrated alkaline solution

of chromate of potash is to be saturated with weak sulphuric acid, and then to every 8 lbs. are to be added 1 lb. of common salt, and half a pound of concentrated sulphuric acid; the liquid will now acquire a green colour. To be certain that the yellow colour is totally destroyed, a small quantity of the liquor is to have potash added to it, and filtered; if the fluid is still yellow, a fresh portion of salt and of sulphuric acid is to be added: the fluid is then to be evaporated to dryness, redissolved, and filtered; the oxide of chrome is finally to be precipitated by caustic potash. It will be of a greenish-blue colour, and being washed, must be collected upon a filter.—H.M.N.

CHRYSANILINE. See ANILINE YELLOW.

CHRYSOBERYL, or *Golden Beryl*, is composed of alumina 80.2 and glucina 19.8=100. It is of various shades of yellowish and light green, sometimes with a bluish opalescence internally. It has a vitreous lustre, and varies from translucent to transparent. Fracture, conchoidal, or uneven. Specific gravity = 3.5 to 3.8. It belongs to the trimetric system.

This stone, when transparent, furnishes a beautiful gem of a yellowish-green colour, which is cut with facets, unless it be opalescent, in which case it is cut *en cabochon*. It occurs in the Brazils and Ceylon, in rolled pebbles in the alluvial deposits of rivers; in the Ural, in mica-slate; and at Haddam, Connecticut, U.S., in granite, traversing gneiss.—H.W.B.

For varieties of Chrysoberyl, see CAT'S EYE, and CYMOPHANE.

CHRYSOCOLLA. The Greeks gave this name to Borax. It is now applied to the hydrous silicate of copper, a mineral with the composition of silica 34.3, protoxide of copper 45.2, water 20.5. It is often mixed with carbonate and oxide of copper. It is found in Chili, in the Lake Superior district, in the copper mines of South Australia, and the West Indian Islands; also in Cornwall, Saxony, and indeed in most localities where copper-mines occur. Bischof observes, that silicate of copper may be formed through the action of an alkaline, lime or magnesia silicate, on sulphate or nitrate of copper in solution. He also shows that this silicate is decomposed by carbonated waters, producing carbonate of copper. In nature the alkaline silicates are often furnished by the decomposing granite, and the sulphate of copper by the changes which constantly occur in copper pyrites.

CHRYSOLITE, or *Peridot*. The name given to the paler and more transparent crystals of olivine, the latter name being restricted to imbedded masses or grains of inferior colour and clearness. It is usually found in angular or rolled pieces, rarely crystallised. The crystals (generally, 8, 10, or 12-sided prisms), belonging to the rhombic system, are variously terminated, and often so compressed as to become almost tabular. They are generally very fragile, and therefore unfit for ornamental purposes. The chrysolite is a silicate of magnesia, with more or less protoxide of iron. An analysis of an oriental chrysolite by Stromeyer gave: silica 39.73, magnesia 50.13, protoxide of iron 9.19, alumina 0.22, protoxide of manganese 0.09, oxide of nickel 0.32 = 99.68.

As a gem, chrysolite is deficient in hardness and play of colour; but when the stones are large and of good colour, and well cut and polished, it is made into necklaces, &c., with good effect. From its softness, which is little less than that of glass, it requires to be worn with care, or it will lose its polish. The best mode of displaying the colours to the greatest advantage is to cut it in small steps. To give it the highest polish, a copper wheel is used, on which a little sulphuric acid is dropped. During the process a highly suffocating smell is given out, produced, probably, by the oxidation of the copper and the decomposition of the acid. Chrysolite is supposed to have been the topaz of the ancients. It is found near Constantinople; at Vesuvius; and the Isle of Bourbon; at Real del Monte, in Mexico; in Egypt; and at Expailly, in Auvergne.—H.W.B.

CHRYSOPRASE. An apple-green or leek-green variety of chalcedony, the colour of which is caused by the presence of nickel. It occurs at Kosemütz, in Silesia, and Belmont's lead-mine, St. Lawrence County, New York.

This stone was probably the chrysoberyl of the ancients.—H.W.B.

CHRYSOTILE. A fibrous or asbestiform variety of serpentine.

CHUNAM. A cement made of shell-lime and sea-sand, commonly used in India.

CHURCHITE. A hydrated phosphate of protoxide of cerium, found in minute crystals, forming a thin coating on quartz and clay-slate, in a Cornish tin-lode. Mr. C. Greville Williams has detected didymium in churchite.

CICKORIUM INTYBUS. See CHICORY.

CIDER. See CYDER.

CIMOLIAN EARTH. *Cimolite* (*Cimolia*, Pliny). This earth is found in the island of Argentiers, the ancient Cimolus, in Bohemia, and some parts of Russia. It has been frequently confounded with fullers' earth, because it has been used for

the same purposes—removing grease from silk or woollen fabrics. It is an aluminous silicate, consisting of silica 63, alumina 23, oxide of iron 1·25, water 12. It absorbs water rapidly, and splits into thin laminae. Powdered and mixed with water it forms a creamy mass, which absorbs oil from any fabric over which it may be spread.

CINCHONA BARK. A Parliamentary paper on the progress of India in 1872 gives information respecting the cultivation of the cinchona plant, from which quinine is obtained. It was introduced into the Hill districts of India, from South America, in 1860. The total expenditure of the experiment was 61,719*l*. The return represents a value which is simply incalculable. There are now 2,639,285 plants in the Government plantations on the Neilgherry Hills alone, without counting those of private planters in this and in other districts. The largest trees are 30½ feet high, and over 3 feet in girth round the trunk. The area covered by the plantations amounts to 950 acres, and is being largely added to every year. The bark under cultivation is much richer in quinine and the other febrifuge alkaloids than the wild bark of South America. During last year 7,295 lbs. of excellent bark were sold in the London market, while 65,688 lbs. were supplied to the local manufactory. This year 20,000 lbs. will be sent home. The alkaloid is manufactured on the spot in an exceedingly cheap form for the use of local medical stores, and hundreds of fever patients are thus annually cured. The object of providing an abundant supply of the febrifuge at a price within the means of the population at large is rapidly being realised.

From the report on the Government cinchona plantations at Ootacamund for 1870-71 we learn that the growth of the plants has been very satisfactory. The older plants of the various medicinal kinds have grown from shrubs into trees 22 feet or 23 feet high, and 18 inches to 21 inches in girth. Of the *Cinchona succirubra* the finest samples reach a height of 30 feet, with a girth of three feet. Three thousand five hundred plants of the Calisaya kind have been permanently planted out on two acres of new land. With this exception, the work of the year has been confined to filling up failures and planting along the roadside. Among the new species of plants lately introduced is the Pitayo bark, which appears to be hardy and well suited to the climate. A lanceolate variety of Calisaya introduced from Java makes but slow growth at Ootacamund. During the year 51,353 lbs. of fresh bark were supplied to Mr. Broughton, the Government Quinologist, for the manufacture of amorphous quinine. From 1,000 eight-year-old plants of *C. succirubra* as much as 2,560 lbs. have been or will be extracted during this year. This average of more than 2½ lbs. to each tree will yield, at the present rates of 2*s.* 8*d.* to 3*s.* per lb., a clear profit of at least a rupee a pound. After the tenth year an increasing profit may be yearly expected, with a steady improvement in the quality of the bark. In the cheaper kinds of bark it is unlikely that India will ever compete successfully in the home market with America, where the plant grows wild, and its culture, which is yearly spreading, costs nothing. In the finer kinds of bark, however, a successful competition is far from unlikely, if the mossaing process is steadily applied. Under this process each successive renewal of bark will become more valuable than the last, until red bark yields from 10 to 12 per cent. of crystallisable alkaloids, containing from 6 to 8 per cent. of pure quinine, while 8 or 10 per cent. of the latter may be expected from the crown barks. In that case India would defy competition, for no such bark, it appears, could be obtained from America. See PERUVIAN BARK.

CINCHONA RED. An amorphous dark reddish-brown substance, obtained from cinchona, or Peruvian bark.

CINCHONICINE. $C^{10}H^{21}N^2O^2$ ($C^{20}H^{24}N^2O$.) An alkaloid isomeric with cinchonine and cinchonidine. It is produced by the action of heat on any of the saline combinations of cinchonine.—*Pasteur*.

CINCHONIDINE. $C^{10}H^{21}N^2O^2$ ($C^{20}H^{24}N^2O$.) This alkaloid, the quinidine of Leers, is one of the isomers of cinchonine.

CINCHONINE. $C^{10}H^{21}N^2O^2$ ($C^{20}H^{24}N^2O$.) An alkaloid or organic base accompanying quinine. Some of the differences of properties on which processes for their separation may be founded are the following:—Cinchonine crystallises more readily than quinine from an alcoholic solution, in consequence of its being less soluble in that fluid. Sulphate of quinine, on the other hand, is less soluble than sulphate of cinchonine. Cinchonine is insoluble, while quinine is freely soluble in ether. See Watt's 'Dictionary of Chemistry.'

When cinchonine is distilled with a hydrated alkali it yields a product known as *chinoline oil*, containing three homologous bases—*chinoline*, *lepidine*, and *krytidine*. From this oil, a brilliant blue pigment may be obtained.

CINDER. The slags produced in the processes of iron manufacture.

CINDER BED. A bed of oyster-shells; found in the Middle Purbeck series.

CINDER FLUE. See IRON.

CINDER IRON. See IRON.

CINDER TAP. See IRON.

CINNABAR is the principal and only valuable ore of mercury which is prepared from it by sublimation.

It is a sulphide (sulphuret) of mercury, composed, when pure, of quicksilver 86·2, sulphur 13·8, in which case it is a natural vermilion, and identical with the vermilion of commerce; but it is sometimes rendered impure by an admixture of clay, bitumen, oxide of iron, &c. Cinnabar is of a cochineal-red colour, often inclining to brownish-red, and lead-grey, with an adamantine lustre, approaching to metallic in dark varieties, and to dull in friable ones. It varies from sub-transparent to opaque, has a scarlet streak, and breaks with a sub-conchoidal uneven fracture. $H = 2$ to $2\cdot5$, specific gravity = 8·99. In a matrass it entirely sublimes, and with soda yields mercury with the evolution of sulphurous fumes. When crystallised, it belongs to the rhombohedral system.

Cinnabar occurs in beds in slate-rocks. The chief European beds are at Almaden, near Cordova, in Spain, and at Idria in Carniola, where it usually occurs in a massive form, and is worked on a thick vein belonging to the carboniferous series. It also occurs abundantly in China, Japan, Huanca Vilica in South Peru, and at New Almaden in Santa Clara Co., and in other parts of California, where extensive mines of cinnabar are worked. It is also abundant in Idaho. The chief source of the mercury used in England, is Spain. Our recent imports of native Cinnabar cannot now be ascertained, as it is all entered at the Custom House under the head of 'Ores unenumerated.'

Cinnabar in the arts is used as a pigment, in the state of a fine powder, which is known by the name of vermilion. See MERCURY and VERMILION.

CINNAMON. (*Cannelle*, Fr.; *Zimmt*, Ger.) The inner bark of the *Laurus cinnamomum*, used chiefly for flavouring cordials. Cinnamon yields an exquisite essential oil by distillation which has considerable use in medicine and perfumery. It is largely used for incense, but its principal consumption is in Spain, for the fabrication of chocolate, where it is said not less than 50,000,000 lbs. are used annually, nearly the whole of which is brought from Ceylon.

Of cinnamon we imported as follows:—

	lbs.	Value
In 1870	2,215,434	£252,875
1871	1,574,946	143,520
1872	1,082,134	111,496

CINNAMON STONE. A name given to Essonite, one of the varieties of the lime garnets. Many so-called hyacinths are really nothing more than fine-coloured cinnamon stones.

CIPOLINO. An Italian marble, of white colour, with pale green markings.

CITRIC ACID. (*Acide citrique*, Fr.; *Citronensaure*, Ger.) This acid exists in the juice of fruits, especially the lemon, orange, currant, and quince. It was first procured from lemon-juice in a pure state by Scheele, who adopted the following process:—Lemon-juice was put into a large tub, and saturated with dry chalk in fine powder, noting carefully the quantity employed. The citrate of lime which precipitates being freed from the supernatant liquor is to be well washed, with repeated affusion and decantation of water. For every ten pounds of chalk employed, nine and a half pounds of sulphuric acid diluted with six times its weight of water are to be poured while warm upon the citrate of lime, and well mixed with it. At the end of twelve hours, or even sooner, the citrate will be decomposed, dilute citric acid will float above, and sulphate of lime will be found at the bottom. The acid being drawn off, the calcareous sulphate must be thrown on a canvas filter, drained, and then washed with water to abstract all the acid.

The citric acid thus obtained may be evaporated in leaden pans, over a naked fire, till it acquires the specific gravity 1·13; after which it must be transferred into another vessel, evaporated by a steam or water bath till it assumes a syrupy aspect, when a pellicle appears first in patches, and then over the whole surface. This point must be watched with great circumspection, for if it be passed, the whole acid runs a risk of being spoiled by carbonisation. The steam or hot water must be instantly withdrawn, and the concentrated acid put into a crystallising vessel in a dry, but not very cold apartment. At the end of four days the crystallisation will be complete. The crystals must be drained, re-dissolved in a small portion of water, the solution set aside to settle its impurities, then decanted, re-evaporated, and re-crystallised. A third or fourth crystallisation may be necessary to obtain a colourless acid.

If any citrate of lime be left undecomposed by the sulphuric acid, it will dissolve in the citric acid, and obstruct its crystallisation, and hence it will be safer to use the

slightest excess of sulphuric acid, than to leave any citrate undecomposed. There should not, however, be any great excess of sulphuric acid. If there be, it is easily detected by nitrate of baryta, but not by the acetate of lead as prescribed by some chemical authors; because the citrate of lead is not very soluble in the nitric acid, and might thus be confounded with the sulphate, whereas citrate of baryta is perfectly soluble in that test acid. Sometimes a little nitric acid is added with advantage to the solution of the coloured crystals, with the effect of whitening them.

Twenty gallons of good lemon-juice will afford fully ten pounds of white crystals of citric acid.

Citric acid crystallises from a cold saturated solution in prisms belonging to the rhombic system, and containing $C^{12}H^8O^{14}.2HO$ ($C^6H^8O^7.H^2O$). If, however, the crystals be deposited from a hot solution, they present different forms, and contain only one-half the normal proportion of water.

The specific gravity of the crystals of citric acid is 1.617. They are unalterable in the air. When heated, they melt in their water of crystallisation; and at a higher heat, they are decomposed. They contain 18 per cent. of water, of which one-half may be separated in a dry atmosphere, at about 100° F., when the crystals fall into a white powder. Citric acid is soluble in 0.75 parts of cold, and in 0.5 parts of boiling water.

Citric acid in crystals is composed, by Dr. Ure's analysis,—of carbon, 33.0, oxygen, 62.37, and hydrogen, 4.63; results which differ very little from those of Dr. Prout, subsequently obtained. Dr. Ure found its atomic weight to be 8.375, compared to oxygen 1,000. The composition of crystallised citric acid has been thus represented:—

	per cent. theoretical	Dumas	Prout	Ure
Carbon	35.8	36.28	34.28	33.00
Hydrogen	4.5	4.45	4.76	4.63
Oxygen	59.7	59.27	60.96	62.37

Attempts were made, both in the West Indies and Sicily, to convert the lime and lemon-juice into citrate of lime, but they seem to have failed through the difficulty of drying the citrate for shipment.

Citric acid in somewhat crude crystals is employed with much advantage in calico-printing; for many of the finer colours it cannot be replaced by any other. If adulterated with tartaric acid, the fraud may be detected by adding potash to the solution of the acid, which will cause a precipitate of cream of tartar.

The manufacture of citric acid so closely resembles that of tartaric acid, that the makers of one commonly fabricate the other. The raw material in this case is pretty generally a black fluid, like thin treacle, which comes from Sicily, and is obtained by inspissating the expressed juice of the lemon,—the rind having previously been removed from the lemon for the sake of its essential oil. This black juice is impure citric acid, and requires to be treated with chalk, as practised with respect to the first operation on tartar; by which means an insoluble citrate of lime is formed; and this after being well washed with cold water, is decomposed by sulphuric acid; and the solution, after undergoing the action of animal charcoal and proper evaporation, yields brownish crystals on cooling. These are re-dissolved, decoloured, and crystallised three or four times ere they can be sent into the market, for citric acid is more tenacious of colouring matter than most of the other vegetable acids. At Nice, and in the South of France, a portion of chloride of lime is digested upon the citrate of lime, to bleach it prior to decomposition by sulphuric acid. For this purpose, the washed citrate is exposed in shallow vessels to the action of the sun's rays covered by a weak solution of chloride of lime. In a few hours decolouration ensues; and it is moreover stated that the mucilage which hangs about the citrate of lime, and impedes the subsequent crystallisation of the acid, is in this way destroyed, and the number of re-crystallisations requisite to give a saleable aspect to the citric acid thereby diminished.

According to Perret's process, the lemon-juice is clarified with excess of magnesia, and the salt thus obtained after having been washed with cold water, in which it is insoluble, is dissolved in hot lemon-juice. The solution, on evaporation, yields a bibasic citrate of magnesia in a form convenient for exportation.

The use of a vacuum-pan for the final evaporation of a solution of citric acid has been introduced by Mr. E. A. Pontifex.

CITRATES. Combinations of citric acid with alkalis, earths and metals forming salts. See Watts's 'Dictionary of Chemistry.'

CITRON. (*Citradier*, Fr.; *Cedrato*, Ital.) The fruit of the *Citrus medica*, belonging to the family of dicotyledonous plants, the *Aurantiaceæ* or *Hesperideæ*. The rind of this fruit candied is well known as a delicate sweetmeat. The tree producing the citron is the most beautiful of the genus. A curious variety of the citron is cultivated in China, and called the fingered citron, from its lobes all separating into fingers in different shapes and sizes. The fruits of several other genera belonging to the family are greatly esteemed in the countries which produce them. See HESPERIDEÆ.

CITRONELLE OIL. An oil from the Lemon-grass (*Andropogon citratum*).

CITRUS. A genus of the family *Aurantiaceæ*, producing the orange, the lemon, &c.

CITRUS AURANTIUM. The common or sweet orange.

CITRUS BERGAMIA. The Bergamot orange.

CITRUS BIGARADEA. The bitter or Seville orange, or bigarade.

CITRUS DECUMANA. The shaddock. See SHADDOCK.

CITRUS LIMETTA. The lime. See LIME.

CITRUS LIMONIUM. The lemon. See LEMON.

CITRUS MEDICA. The citron.

CIVET. (*Civette*, Fr.; *Zibeth*, Ger.) The odour of this substance is peculiar and very characteristic, and is even more persistent than musk. It forms the base of the famous 'Jockey Club' perfume. It is the product of two small quadrupeds of the genus *Viverra* (*V. zibetha* and *V. civetta*), of which the one inhabits Africa, and the other Asia. They are reared with tenderness, especially in Abyssinia. The civet is contained in a sac situated between the anus and the parts of generation in either sex. The animal frees itself from an excess of this secretion by a contractile movement which it exercises upon the sac, when the civet issues in a vermicular form, and is carefully collected. The negroes are accustomed to increase the secretion by irritating the animal; and likewise introduce a little butter, or rather grease, by the natural slit in the bag, which mixes with the odoriferous substance, and increases its weight. It is employed only in perfumery.

According to M. Boutron-Chalard, it contains a volatile oil, to which it owes its smell, some free ammonia, resin, fat, and extractiform matter, and mucus. It affords, by calcination, an ash, in which there are some carbonate and sulphate of potash, phosphate of lime and oxide of iron.

CLACK. The valve of a pump. See PUMP.

CLAUSTHALITE. A selenide of lead which occurs in the veins of hæmatite at Clausthal and other mines in the Hartz, and at Rio Tinto in Spain.

CLAY. (*Argile*, Fr.; *Thon*, Ger.) The term clay is applied to certain hydrous silicates of alumina, derived for the most part, from the decomposition of felspathic rocks, and which are generally rendered impure by the admixture of other substances. Economically, the term is applied to any finely-divided mineral matter, which becomes plastic on being wetted, and retains its shape when moulded or pressed into any particular form. Lime, magnesia, oxide of iron, with some other colouring metallic oxides, are occasionally present in small quantities in certain natural clays: when iron is present, the clay burns red.

1. They are readily diffusible through water, and are capable of forming with it a plastic ductile mass, which may be kneaded by hand into any shape. This plasticity exists, however, in very different degrees in the different clays.

2. They congregate into a hard mass upon being dried, and assume, upon exposure to the heat of ignition, a degree of hardness sometimes so great as to give sparks by collision with hardened steel. In this state they are no longer plastic with water, even when pulverised. Tolerably pure clays, though infusible in the furnace, become readily so by the admixture of lime, iron, manganese, &c.

3. All clays, even when previously freed from moisture, shrink in the fire by virtue of the reciprocal affinity of their particles; they are very absorbent of water in their dry state, and adhere strongly to the tongue.

4. Oehrey, impure clays, emit a disagreeable earthy smell when breathed upon; the odour is indeed observable to a greater or less extent in all clays.

Brongniart distributes Clays into:—

(1.) Fire-clays (*argiles apyres*, Fr.; *Feuerfeste*, Ger.).

(2.) Fusible (*schmelzbarc*, Ger.).

(3.) Effervescent (*brausende*, Ger.), from the presence of chalk.

(4.) Oehrey (*ocreuses*, Fr.; *ochrige*, Ger.).

The following are the chief varieties of clay usually recognized:—

1. SLATE-CLAY. (*Schiefer-thon*, Ger.) Its colour is grey or greyish-yellow; massive, dull, or glimmering from admixture of particles of mica. Fracture slaty, approaching sometimes to earthy. Fragments tabular; soft, sectile, and easily

broken; sp. gr. = 2.6; adheres to the tongue, and breaks down in water. Slate-clay is ground and reduced into a paste with water for making fire-bricks; for which purpose it should be as free as possible from lime and iron.

2. **FIRE-CLAY.** In this country the geological position of the *fire-clay*, which is largely employed in the manufacture of fire-bricks, glass-house pots, &c., is immediately beneath the coal, each bed of which rests upon a stratum of greater or less thickness of a clay possessing the peculiar qualities of fire-clay, and distinguished in the mining districts, from the position it occupies with reference to the coal, by the name of *under-clay*. The Stourbridge clay is of this character. The following analysis of Stourbridge clay was made by Mr. C. Tookey in Dr. Percy's laboratory:—

Silica	65.10
Alumina	22.22
Potash	0.18
Lime	0.14
Magnesia	0.18
Protoxide of iron	1.92
Phosphoric acid	0.06
Water { combined	7.10
{ hygroscopic	2.18
Organic matter	0.58

99.66

3. **COMMON CLAY OR LOAM.**—This is an impure coarse pottery-clay, mixed with iron-ochre, and occasionally with mica. It has many of the external characters of plastic clay. It is soft to the touch, and forms, with water, a somewhat tenacious paste; but is in general less compact, more friable than the plastic clays, which are more readily diffusible in water. It does not possess the property of acquiring in water that commencement of translucency which the purer clays exhibit. Although soft to the touch, the common clay wants unctuousity, properly so called. The best example of this argillaceous substance, is afforded in the London-clay formation, which consists chiefly of bluish or blackish clay, mostly very tough. Those of its strata which effervesce with acids partake of the nature of marl. This clay is fusible at a strong heat in consequence of the iron and lime which it contains. It is employed in the manufacture of bricks, tiles, and coarse pottery ware.

4. **POTTERS' CLAY, OR PIPE-CLAY.**—This species is compact, soft, or even unctuous to the touch, and polishes with the pressure of the finger; it forms, with water, a tenacious, very ductile, and somewhat translucent paste. It is infusible in a porcelain kiln, but assumes in it a degree of hardness. Werner called it *pipe-clay*. Good plastic clay remains white, or if grey before, becomes white in the porcelain-kiln. The clay from Poole in Dorsetshire is a celebrated potters' clay, and the clay from the neighbourhood of Newton Abbot in Devonshire is a well-known pipe-clay. The following is an analysis of Poole clay, made in Dr. Percy's laboratory, by Mr. W. Weston:—

Silica	48.99
Alumina	32.11
Potash	3.31
Lime	0.43
Magnesia	0.22
Protoxide of iron	2.34
Water { combined	9.63
{ hygroscopic	2.33

99.36

Plastic Clay.—The geological position of the '*Plastic clay*,' of geologists, (the old name of the 'Woolwich and Reading beds'), is beneath the London-clay, and above the sand (Thanet sand) which covers the chalk-formation. The Plastic clay of the Paris basin is described as consisting of two beds separated by a bed of sand. The lower bed is the proper plastic clay. The plastic clay of *Abondant*, near the Forest of Dreux, analysed by Vanquelin, gave—Silica, 43.5; alumina, 33.2; lime, 0.35; iron, 1; water, 18.

This clay is employed as a fire-clay for making the bungs or *seggars*, or coarse earthenware cases, in which china-ware is fired.

The plastic clay of Dorsetshire which supplies the great Staffordshire potteries, occurs near the base of the Bagshot beds (Middle Eocene). It is grey coloured, less unctuous than that of Dreux, and consequently more friable. It becomes white in the

pottery kiln, and is infusible at that heat. It causes no effervescence with nitric acid, but falls down quickly in it, and becomes more highly coloured. Its refractoriness allows of a harder glaze being applied to the ware formed from it without risk of the heat requisite for making the glaze flow affecting the biscuit either in shape or colour. 'Most of the plastic clays of France,' says M. Brongniart, 'employed for the same ware, have the disadvantage of reddening a little in a somewhat strong heat; and hence it becomes necessary to coat them with a soft glaze, fusible by means of excess of lead at a low heat, in order to preserve the white appearance of the biscuit. Such a glaze has a dull aspect and cracks readily into innumerable fissures by alternations of hot and cold water.' Hence one reason of the vast inferiority of the French stoneware to the English. See DORSETSHIRE CLAY.

5. PORCELAIN CLAY OR KAOLIN EARTH. (*Terre à porcelaine*, Fr.; *Porzellanerde*, Ger.) Kaolin is the name given by the Chinese to the fine white clay with which they fabricate the biscuit of their porcelains. This is the purest known form of clay, its chemical composition being generally reducible to the formula $\text{Al}_2\text{O}_3 \cdot 2\text{SiO}_2 + 2\text{H}_2\text{O}$ ($\text{Al}_2\text{O}_3 \cdot 2\text{SiO}_2 + 2\text{H}_2\text{O}$), corresponding to silica, 46·3; alumina, 39·8; water, 13·9 per cent. Ordinary massive kaolin, examined under the microscope, always exhibits certain six-sided scales characteristic of the mineral species called *Kaolinite*. Kaolin and some allied substances are included by Messrs. Johnson and Blake under this species.

The term *Kaolin* appears to have been derived from the name of a mountain *Kao-ling* (Lofty ridge), from which this argillaceous earth was extracted. The kaolins possess very characteristic properties. They are friable in the hand, meagre to the touch, and difficultly form a paste with water. When freed from the coarse and evidently foreign particles interspersed through them, they are absolutely infusible in the porcelain kiln, and retain their white colour unaltered. They harden with heat like other clays, and perhaps in a greater degree; but they do not acquire an equal condensation or solidity, at least when they are perfectly pure. Most of the kaolin-clays contain some spangles of mica, which betray their origin from granite.

This origin may be regarded as one of their most distinctive features. Almost all the porcelain clays are evidently derived from the felspars contained in granite, principally in those rocks of felspar and quartz called 'graphic granite.' Hence they are to be found only in primitive mountain districts, among banks or blocks of granite, forming seams often of very considerable thickness. In the same bed quartz and mica occur, while some portions of the kaolin retain the external form of felspar.

The most valuable kaolins have been found—

In China and Japan. The specimens imported from these countries appear pretty white; but are more unctuous to the touch, and more micaceous than the porcelain clays of France.

In Saxony. The kaolin employed in the porcelain manufactories of that country has a slight yellow or flesh colour, which disappears in the kiln, proving, as Wallerius observed, that this tint is not owing to any metallic matter.

In France, at Saint-Yrieix-la-Perche, about 10 leagues from Limoges. The kaolin occurs there in a bed, or perhaps a vein, in beds of granite, or rather of that felspathic rock called *Pe-tun-tse*, which exists there abundantly. This kaolin is generally white, but sometimes a little yellowish, with hardly any mica. It is meagre to the touch, and some beds include large grains of quartz, called pebbly by the China manufacturers. This variety, when ground, affords, without the addition of any fusible ingredient, a very transparent porcelain.

Near Bayonne. A kaolin possessing the lamellated structure of felspar in many places. The rock containing it is a graphic granite in every stage of decomposition.

In England, in the counties of Devonshire and Cornwall. The kaolin or China-clay is very white, and more unctuous to the touch than those upon the continent of Europe mentioned above. Like them it is supposed to result from the decomposition of the felspars entering into the composition of granite.

Nature has, up to a certain point, provided the article which man requires for the elaboration of the most perfect production of the potters' art. The clay—China clay, as it is commonly called, or *kaolin*, as the Chinese have it—is quarried from amidst the granitic masses of Dartmoor and of Cornwall. We are not at all satisfied with any of the theories which have been put forward to account for the formation of porcelain clay. It is commonly stated to be a decomposed granite; this rock, as is well known, consisting of mica, quartz, and felspar, with sometimes schorl and hornblende. The felspar is supposed to have decomposed; and, as this forms the largest portion of the mass, the granite is disintegrated by this process. We have, therefore, the mica, quartz, and the clay, forming together a soft mass, lying but a short distance below the surface, but extending to a considerable depth. It is quite evident that this stratum is not *deposited*; had it been so, the particles constituting the mass would have arranged themselves in obedience to the law of gravity, towards which

there is not the slightest attempt. But we do not know by what process the decomposition of the solid granite could have been effected to a depth from the surface of upwards of one hundred feet, and then, as it often does, suddenly to cease. This, however, is a question into which we cannot at present enter. The largest quantity of porcelain or China-clay is manufactured in Cornwall, especially about St. Austell and St. Stephen's.

A spot being discovered where this substance abounds, the operation is commenced by removing the vegetable soil and substratum, called by the workmen the *overburden*, which varies in depth from about three to ten feet. The lowest part of the ground is thus selected, in order to secure an outlet for the water used in washing the clay. The *overburden* being removed, the clay is dug up in *stopes*: that is, in successive layers or courses, and each one being excavated to a greater extent than the one immediately below it, the *stopes* resemble a flight of irregular stairs. The depth of the *China-clay pits* is various, extending from twenty feet to fifty feet.

The clay when first raised has the appearance and consistence of mortar; it contains numerous grains of quartz, which are disseminated throughout in the same manner as in granite. In some parts the clay is stained of a rusty colour, from the presence of veins and imbedded portions of shorl and quartz; these are called by the workmen *weed*, *caple*, and *shell*, which are carefully separated. The clay is next conveyed to the floor of the washing place, and is then ready for the first operation of the process.

A heap of the clay being placed on an inclined platform, on which a little stream of water falls from the height of about six feet, the workman constantly moves it and turns it over with a *piggle* and shovel, by which means the whole is gradually carried down into an oblong trench beneath, which is also inclined, and which ends in a covered channel that leads to the *catch-pits* about to be described. In the trench the grains of quartz are deposited, but the other parts of the clay, in consequence of their greater levity, are carried away in a state of suspension.

This water is conducted into a series of pits, each of which is about eight feet long, four in breadth and in depth, and is lined on the sides and bottom with cut moorstone, laid in a waterproof cement. In these pits the porcelain earth is gradually deposited. In the first pit the grosser particles collect; and being of a mixed nature, are always rejected at the end of each day's work by an opening provided for that purpose at the bottom of the pit. When the water has filled the first pit, it overflows into the second, and in like manner into the third; and in these pits, particularly in the second, a deposit also takes place, which is often preserved, and is called by the workmen *mica*. The water, still holding in suspension the finer and purer particles of porcelain clay, next overflows into larger pits, called *ponds*, which are of the same depth as the first pits, but about three times as long and wide. Here the clay is gradually deposited, and the clear supernatant water is from time to time discharged by plug-holes on one side of the pond. This process is continued until, by successive accumulations, the ponds are filled. At this stage the clay is in the state of a thick paste, and to complete the process, it remains to be consolidated by drying. Formerly, the clay was dried by exposure to atmospheric influences only; but the demand for clay has been so large, that artificial heat is now applied to the brick tanks, so as to quicken the evaporation of the water. When sufficiently dry, the clay is cut into oblong cakes, and is ready for the market.

The following remarks on the clays and plastic strata of Great Britain are from the pen of Mr. George Maw, who has brought to bear upon the subject much geological and chemical knowledge, coupled with great experience as a practical potter.¹

'Plastic strata may be defined as beds of mechanical origin, containing alumina as an essential constituent, which have undergone little or no consolidation, or been subject to metamorphic action.

'Although common to various geological formations from the palæozoic to the most recent deposits, a very large proportion of plastic strata applicable to ceramic manufactures occurs in the recent and tertiary beds.

'Plastic strata diminish in frequency as the older deposits are approached: in the earlier palæozoic formations, the beds which were at the time of decomposition soft clays and marls, occur for the most part as shales and slates, or have undergone further metamorphism into hard porcelainites and other altered rocks unavailable for the potters' use. Indeed, the very changes which the potter effects by artificial heat have, as regards the earlier rocks, been anticipated in the laboratory of nature, pressure in combination with heat having altered their original soft and plastic condition, changing them into the hardest rocks.

'It must not, however, be supposed that all clays of economic applicability occur in a soft and plastic state, as every gradation exists between hard metamorphic rocks

¹ These remarks are taken, with slight alterations, from Mr. Maw's Appendix to the 'Catalogue of British Pottery in the Museum of Practical Geology,' 2nd edition, 1871.

and the softest clays, and many of the most valuable clays occur in a semi-indurated condition, are mined by the process of blasting, and brought to the surface in hard rock-like masses. These, by exposure to atmospheric changes and alternations of wet and drought, frost and thaw, are speedily, by the process known as *weathering*, disintegrated and reduced to the plastic condition.

'The state of *mechanical subdivision* is of no little importance in the applicability of clays to the various purposes of ceramic manufacture. Every gradation exists between an almost impalpable condition and a mixture of coarse and fine matter, the coarse residue of which sometimes forms as much as 10 or 20 per cent. of the entire weight.

'Bearing in mind that most clay-strata result from the mechanical disintegration of older rocks, it will be easily understood that their state of subdivision has been dependent for the most part on the transporting and sorting agencies of water, carrying away and separating the finer particles held longer in suspension than the coarse matter.

'The origin of some of the finer white clays must, however, be attributed to the chemical dissolution of calcareous rocks by the agency of carbonated water, the insoluble silica, alumina, magnesia, &c., associated with carbonate of lime in chalk and limestone in the finest state of subdivision, being left behind as an impalpable residuum. The writer, in a paper on 'The sources of the materials composing the white clays of the Lower Tertiaries,' published in the 'Quarterly Journal of the Geological Society' (vol. xxiii. p. 387), suggested such a derivation from the chalk, of the smooth clays of Bovey Tracey and Newton Abbot, and of similar clays from the Lower Bagshot beds of Wareham, and it seems scarcely open to question that the white clays resting on the carboniferous limestone of North Wales, Derbyshire, and Tipperary, are the remnants of the subærial dissolution of the limestone.¹

The *chemical composition* of plastic strata varies as much as their mechanical condition. They may be generally described as an association of silicate of alumina, alumina, free silica, and magnesia, with more or less water of combination. Clays and marls scarcely ever occur entirely free from iron, to which their colour is mainly due; it exists in various states of combination, further referred to below. Carbonaceous matter, especially in the tertiary and carboniferous clays, is frequently associated in a fine state of subdivision, and the alkalis are generally present in variable proportions both as silicates and carbonates.

Contraction in Burning.—This character is of so much importance in all branches of ceramic manufacture that it may be of interest to notice one or two features that the experiments exhibit.

The amount of contraction in burning, due partly to the loss of water of combination and of the carbonic acid in the carbonates, when present, and to the ignition of any carbonaceous matter contained in the clays, but more especially to the drawing together of the particles in the production of vitreous silicates, is very variable, and depends both on the chemical and mechanical composition of the clays. The presence of the alkalis and iron tends to complete vitrification, which is always accompanied by a great amount of contraction, and the production of a glass-like body with a bright conchoidal fracture. On the other hand, in clays containing much free silica or even silicate of alumina without the accompaniment of the fluxing alkalis, a small amount of contraction takes place and an open porous 'body' is the result.

The amount of contraction is not less due to the state of mechanical subdivision of the constituent particles. Clays in a coarse state of subdivision and containing a large proportion of gritty matter, especially of silicious sand, invariably contract less in burning than those of smooth and fine texture, in which the constituents are in an impalpable state of subdivision; this will be at once seen by a comparison of the amount of contraction of slabs composed of the coarse clay in its natural state with those moulded from the clays from which the coarse particles have been removed; and the larger the proportion of coarse matter in the native clay the greater is the difference between the amount of contraction of the clay in its natural and refined states. The average contraction observed in a considerable number (122) of burnt slabs composed of the native unrefined clay amounted to 6·01 per cent., and of the burnt slabs of refined clay to 7·53 per cent. of the original moulded size. This appears due to two causes: first, that a mixture of large and small particles is, to begin with, actually more dense than a mass of particles of equal size,² and therefore admits of less contraction in the drawing together of the particles in vitrification; and, secondly, that the coarser subdivision and less intimate contact seem to hinder the recombination of the constituents as vitreous silicates in the process of burning.

¹ See papers on this subject by the writer at pp. 241 and 299, vol. iv., of the 'Geological Magazine.'

² Illustrated by the fact that a bushel of shot weighs the same as a bushel of hullets, but is exceeded in weight by a bushel of mixed shot and bullets, the small shot filling the vacancies between without displacing the larger spheres.

Few clays produce a perfectly vitreous and unabsorbent body. Some burnt slabs approach to a glassy texture, while others are so highly silicious and coarse in grain as to be held together by a very slight cohesion. These are in the burnt state open and spongy, and have undergone but little contraction in the kiln. Such clays, as for example those from the North Worcestershire coalfield, of which the celebrated Stourbridge fire-bricks are made, are from their refractory character eminently suitable for the manufacture.

The great majority of clays are intermediate in character between these two extremes, and after the process of burning, form a compact but slightly porous body, subject to a moderate amount of contraction, and are available for general pottery purposes.

The Colouring Matter of Clays.—No native clay is entirely free from the presence of iron which occurs in aluminous earths in various proportions and states of combination. Those most free from iron are the white lower tertiary clays of Devon and Dorset, largely exported from Teignmouth and Poole for the manufacture of white earthenware; for this purpose the absence of iron is a matter of great importance, as it imparts to the ware a yellowish tint, to obviate which it is found necessary to cloak and neutralise the natural cream colour of the burnt clay by the admixture of very small proportions of cobalt blue.

Iron in the white and grey tertiary clays occurs principally in the form of grey carbonate of protoxide, generally in association with finely-divided carbonaceous matter, in proportions varying from a mere trace up to 4 or 5 per cent.

Iron, which is so prejudicial in clays employed for white pottery, is an essential colouring matter in those used in the manufacture of terra cotta, encaustic tiles, bricks, and all common pottery.

These may be considered separately as (a) Grey clays. (b) Yellow clays. (c) Red clays.

- (a) *Grey clays*, so largely developed as 'clunches' and fire-clays in the carbonaceous beds of the coal-measures, owe their colour, in addition to the presence of carbonaceous matter, to carbonate of protoxide of iron in a fine state of subdivision, and occasionally to the presence of finely-divided pyrites, or bisulphide of iron, which also occurs in the London clay, gault, &c.

A pale grey clay, almost white, from the base of the Ashdown Sands (Wealden), near Hastings, contains a much larger proportion of iron than its colour would seem to indicate, from its occurring in the form of the comparatively colourless basic sulphate, of which there is 1·68 per cent. present.

- (b) *Yellow clays* are coloured by hydrous sesquioxide of iron, and generally occur as surface deposits, or where red and gray clays have been subject to weathering, as on exposed surfaces or along lines of jointing. They occasionally occur interstratified with red and grey beds, but appear more generally to be the result of a kind of rusting process. Grey carbonate of iron on exposure to watery infiltrations, accompanied by atmospheric oxidation, becomes converted into the yellow hydrous sesquioxide; and bisulphide of iron, which readily decomposes under similar circumstances, becomes converted partly into sulphate of protoxide, and partly into hydrous sesquioxide, to the presence of which the yellow joint-surfaces of the London clay and gault are due.

Yellow clays have also been derived from red beds by the red anhydrous sesquioxide and the lower hydrates receiving water of combination.

- (c) *Red clays and marls*, e.g. those of the Keuper, Old Red beds, permian, coal-measures, the middle wealden, the Neocomian strata of France, the plastic clay of the London and Paris basins, and other tertiary strata, derive their colour from the presence of anhydrous sesquioxide and the lower hydrous oxides of iron which occur in variable proportions, and are generally associated with small quantities of iron in other states of combination, the colour of which the red oxide obscures. Red hæmatite may be cited as a familiar example of almost pure anhydrous sesquioxide of iron, which, when finely divided, has a strong colouring power. The red Keuper marls receive their colour from about 3 per cent. of this anhydrous sesquioxide, whilst the red clays of the *argile plastique* of Paris, and of the Neocomian beds of Beauvais, used in the manufacture of the celebrated Beauvais pottery, contain as much as 20 per cent., equivalent to 15 or 16 per cent. of metallic iron. Nearly all such red clays are variegated by lighter patches from which the oxide of iron has been abstracted; partly by a segregational process, drawing together the iron into ferruginous nodules of hydrous sesquioxide, and also from its dissolution by the acids of organic

decomposition derived from imbedded organic remains. Details of the analysis of red and other clays will be found in a paper by the writer 'On the Disposition of Iron in Variegated Strata,' Quarterly Journal of the Geological Society, vol. xxix. p. 351.

The Colouring of Burnt Clays.—The colour of burnt ferruginous clays is entirely due to the amount of iron present, irrespective of its previous state of combination, but subject to certain conditions in the general composition of the clay. The action of the kiln, with some exceptions referred to below, is uniform on nearly every state of combination in which the iron occurs; viz., to reduce it to anhydrous sesquioxide associated as silicates in a more or less intimate state of combination with the other silicates developed in the process of burning.

Yellow clays coloured with hydrous sesquioxide (*e.g.* yellow ochre), and red clays coloured with anhydrous sesquioxide, and the lower hydrates merely lose their water of combination and become bright brick reds (*e.g.* red ochre and venetian red).

Grey clays containing finely-divided pyrites or bisulphide of iron are also converted by the kiln into bright reds, the sulphur being driven off, leaving the terra cotta charged with the red anhydrous sesquioxide.

In clays charged with grey carbonates of iron the following reaction takes place: The carbonic acid (CO_2) is driven off as carbonic oxide (CO), part of its oxygen peroxidising the iron.

Grey clays containing less than 1 or $1\frac{1}{2}$ per cent. of iron change in the kiln to various shades of cream colour and buff, whilst those containing from 2 to 10 or 12 per cent. range in colour from yellowish fawn to dark reds; from 3 to 4 per cent. of iron produces in the kiln the bright red bodies used in the manufacture of red terra cotta, encaustic tiles, red building bricks, &c. There seems to be no essential difference (with the exception noticed below) in the colouring matter of the clays that burn buff and those that burn red in the kiln, the depth of colour depending merely on the amount of iron present, the buff shades regularly graduating into the deeper shades of red.

The brightest shades of red and buff are, however, produced with but a partial vitrification of the body. At a heat sufficient to insure its complete vitrification a further change of colour takes place. The bright buff shades are changed to neutral greys, and the reds to a slaty-greyish-black, which probably results from a partial reduction of the metallic colouring matter and its more intimate combination with the other vitreous silicates produced at the higher temperature. In clays containing a large proportion of carbonaceous matter the complete peroxidation and consequent colouring power of the iron seems to be arrested. In a black carbonaceous clay from Bovey Tracey, containing 13 per cent. of organic matter, the combustion of the carbon in contact with the ferruginous oxides seems wholly or partially to have reduced them to a metallic state, or lower oxide having less colouring power than the sesquioxide, and a remarkable bleaching of the burnt clay has been the result. The presence of the alkaline earths in ferruginous clays, especially of lime and magnesia, has also a singular bleaching power in the kiln, arresting the development of the bright red colour. A Permian marl, containing 6 per cent. of sesquioxide of iron and 35 per cent. of carbonate of lime, burned of a greyish buff instead of the rich red such a proportion of iron would otherwise have produced. From some experiments made by the writer, it has been ascertained that as small a proportion as 5 per cent. of caustic magnesia mixed with a red clay entirely destroys its red colour in the kiln, probably from the production of a pale-coloured double silicate of iron and the alkaline earth. A familiar example of this reaction occurs in the process of manufacturing yellow bricks in the neighbourhood of London, the colour of which is dependent on the admixture of ground chalk with brick earth, the brick earth by itself burning of a red colour.'

The composition of ordinary clay will be seen from the following analyses, by Mr. T. H. Henry:—

1. Fire-clay (Stourbridge, Brierly Hill):

Silica	51.80
Alumina	30.40
Protoxide of iron	4.14
Magnesia50
Water and organic matter	13.11

99.95

With trace of soda.

2. Three samples of Fire-clay from Wales:—No. I. inferior; the other two good; No. III. the best.

	I	II	III
Silica	50·35	56·90	54·80
Alumina	23·50	24·90	27·60
Oxide of iron	10·40	2·83	2·56
Magnesia	1·45	1·07	1·00
Soda	1·55	3·00	2·00
Water and organic matter .	11·15	11·60	11·80

3. Clay making good red bricks :—

Silica			50·40
Alumina and oxide of iron			24·00
Carbonate of lime			2·70
" magnesia			1·30
Water, &c.			21·60
			<u>100·00</u>

4. Clay inferior, on account of excess of carbonate of lime ; effervesced strongly with acids :—

Silica			33·06
Oxide of iron and alumina			11·20
Carbonate of lime			39·80
" magnesia			6·00
Water, &c.			10·00
			<u>100·06</u>

5. Black shale from coal-measures, Dudley :—

Silica			48·75
Alumina			17·95
Oxide of iron			15·70
Lime			2·32
Magnesia			1·50
Water, &c.			13·35
			<u>99·57</u>

The production of the finer kinds of clay was as follows, in the years given :—

CLAY IRON STONE. See IRON ORES.

CLAYITE. A variety of Galena. See LEAD.

CLAY-SLATE. Argillaceous Schist. See SLATE.

CLAYSTONE. An earthy felspathic rock, occurring in veins and in mountain masses. It becomes porphyritic by the intermixture of felspar crystals, and is then known as *Claystone porphyry*.

CLEAT. It is well known that most coals have a tendency to split not only along the plane of bedding, but also along two sets of divisional planes, nearly at right angles to the bedding and to one another. The coal may thus be split into rough cuboidal fragments. One of these two sets of vertical planes is much more marked than the other, and the smooth clean surface of the coal coinciding with this well-defined set of joints is known as the *cleat*, *face*, or *slyne*; whilst the other vertical surface is called the *end* or *back* of the coal. The direction of the cleat is often constant over a large area, and advantage is taken of this constancy in laying out the workings of a colliery.

CLEAVAGE. The tendency of a crystal, or crystalline substance, to split more readily in certain directions than in others. The property was originally observed in calc-spar (carbonate of lime), a mineral which crystallises in a great variety of external forms, but may always be readily cleaved along the planes of a definite rhombohedron. The natural cleavage of a mineral is frequently taken advantage of by the lapidary, in cutting hard stones; thus, a crystal of diamond, though excessively difficult to cut, can be very easily split or cleaved parallel to the faces of a regular octahedron.

By geologists, the term *cleavage* is used in a different sense. Certain rocks, such as slate, exhibit a tendency to split into very thin parallel plates, and the direction of this cleavage is often constant throughout great masses of rock. This slaty cleavage is not to be confounded with the 'lamination' of a rock, or the facility with which it divides into parallel laminae along the planes of stratification. The cleavage, though it may accidentally coincide with the bedding, usually cuts across it, at various angles, and is evidently a structure superinduced in the rock after its original deposition. Physical researches on this subject have shown that slaty cleavage may be developed by lateral compression, the direction of the planes of cleavage being at right angles to the direction in which the pressure has been applied. The ordinary clay-slates used for roofing are prepared by splitting the mass along its planes of cleavage.

CLICHY WHITE. A white lead manufactured at Clichy in France. See WHITE LEAD.

CLOTH MANUFACTURE AND DRESSING. See WOOLLEN and WOOL.
CLOUDY CHALCEDONY. Chalcedony displaying cloudy spots in a pale grey, semi-transparent base.

CLOVER. Fodder plants belonging to the genus *Trifolium*. The common red clover is *Trifolium pratense*. The white or Dutch clover *T. repens*. The shamrock is generally considered as a species of Trefoil.

CLOVE, THE. (*Clou*, Fr.; *Clavo*, Span.) The clove tree, *Carophyllus aromaticus*, is a small tree, from fifteen to thirty feet high, a native of the Moluccas. The flowers are odorous, and the bark, fruit, leaves, and roots are all more or less aromatic. The flower buds are the cloves of commerce; when prepared they have the appearance of a nail, hence their name from *clavo*, a nail. The buds as soon as they are gathered are dried in smoke over a fire, in the sun, or in a kiln. They are exported in small boxes.

The clove trade was at one time the monopoly of the Dutch. The clove tree is, however, now cultivated both in the East and West Indies, but the finest are still brought from Amboyna in the Moluccas.

CLOVE OIL. *Eugenic acid*, or *Carophyllic acid*. $C^{20}H^{12}O^4$ ($C^{10}H^{12}O^2$).—When cloves are distilled with water, a large quantity of oil passes over. It has been examined by Dumas, Ettling, Böckmann, Stenhouse, Calvi, and, more recently, by Greville Williams. Treated with solution of potash, the greater portion dissolves, leaving a small quantity of a hydrocarbon isomeric with oil of turpentine. See CARBURETTED HYDROGEN. The potash solution, on being supersaturated with a mineral acid, allows the eugenic acid to rise to the surface in the form of an oil. When freshly distilled it is colourless, and boils at 438° S. Its density at $57^{\circ}2$ F. is 1.0684. On analysis it gave:—

	Greville Williams			Calculation	
Carbon . . .	73.1	73.1	.	.	C^{20} 120 73.17
Hydrogen . . .	7.7	7.6	.	.	H^{12} 12 7.32
Oxygen . . .	19.2	19.3	.	.	O^4 32 19.51
	100.0	100.0			100.00

The density of its vapour was found to be 5.86; theory requires 5.67. The above results were confirmed by a determination of the percentage of baryta in the eugenate.—C. G. W.

CLOVES. The new bulbs produced from the subterranean axis of the hyacinth, lily, onion, and the like.

CLUTHALITE. A mineral which occurs in the amygdaloid rocks of Kilpatrick Hills. It is found in flesh-red vitreous crystals, and consists of silica, alumina, iron, and soda. It takes its name from *Clutha*, the name sometimes given to the valley of the Clyde.

COAL. (*Houille*, Fr.; *Steinkohle*, Ger.) Coal is a mineral of vegetable origin. There is abundant evidence to prove this, but there still exists considerable uncertainty as to the mode of conversion and as to the conditions under which our coalbeds were formed. This is not the place for the discussion of these questions; but it appears necessary that the hypotheses of the best authorities on the subject should be briefly given.

‘The occurrence of vegetable remains in all kinds of coal is such convincing evidence of its formation from vegetable substances, that all further proof is superfluous.’—*Gustav Bischof*.

‘There are few varieties of coal in which their vegetable origin can be detected by anatomical examination.’—*Göppert*.

‘It appears from the researches of Liebig, and other eminent chemists, that when wood and vegetable matter are buried in the earth, exposed to moisture, and partially or entirely excluded from the air, they decompose slowly, and evolve carbonic acid gas, thus parting with a portion of their original oxygen. By this means they become gradually converted into lignite or wood-coal, which contains a larger portion of hydrogen than wood does. A continuation of decomposition changes this lignite into common or bituminous coal, chiefly by the discharge of carburetted hydrogen or the gas by which we illuminate our streets and houses. According to Bischof, the inflammable gases which are always escaping from mineral coal, and are so often the cause of fatal accidents in mines, always contain carbonic acid, carburetted hydrogen, nitrogen, and olefiant gas. The disengagement of all these gradually transforms ordinary or bituminous coal into anthracite, to which the names of splint coal, glance coal, hard coal, culm, and many others have been given.’—*Lyell*.

'These drifts of plants now forming streaks of coally matter in the sandstones or shales including them, are sufficient to show that though numerous coal-beds may be the result of the growth of a peculiar vegetation in places, the roots of which required and penetrated a suitable soil beneath, it might so happen that extensive and deep accumulations of drifted plants may wholly form coal-beds under favourable circumstances.'—*De la Beche*.

True coal is so altered from its original vegetable condition as to have left scarcely any trace of its history. It is generally, however, associated with sands and clays, exhibiting numerous fragments of the ancient vegetation that obtained at the time of its formation; but these fragments are so far removed in every respect from the existing form of vegetation as to afford little clue to the condition of the Earth in this respect. In coal all trace of true woody fibre has disappeared; the water originally present, and so injurious in the less altered forms of vegetable fuel, is entirely absent, or if present at all, is so rather mechanically than chemically, while the water originally in the plant appears to have undergone decomposition, the hydrogen uniting with some part of the carbon, to form carburetted hydrogen gas, often existing in the cells, and between the plates of the coal under considerable pressure, and the oxygen being almost entirely removed. The former vegetable has now become a mineral substance, and lies in vast beds of variable thickness, and overlaying each other to the extent sometimes of more than a hundred in a single district; such beds being regularly interstratified with deposits of sand and clay, and occupying a distinct geological position, being, with only a few exceptions, confined to rocks belonging to the newer part of the Palæozoic series.

The changes undergone by vegetable matter when buried in the earth, and accumulated in large quantities, and the length of time needed to produce any marked alteration, are subjects rather more interesting, it may seem, to the chemist than to the practical man, who looks only for fuel that he may employ economically. But inasmuch as the real condition of coal varies considerably, it is desirable that the whole history of coal and lignite beds should be generally understood by any one using these substances.

Vegetable matter consists of carbon in combination with oxygen and hydrogen, as its principal constituents; nitrogen forming but a small, although an important, part in its economy. A large quantity of water is also present; and so long as the vegetable lives, there is a constant change and circulation of material particles kept up, replacing and renewing the different portions. When death takes place, there is a tendency to decomposition, or the separation of the whole into minute atoms having no further relation to each other. But this is frequently checked by various conditions, such as the presence of some substances derived from plants themselves, or the absence of sufficient oxygen gas to allow the change to take place by combining with the carbon to form carbonic acid gas, the first step in the process of destruction. These causes act constantly but partially, and thus a large quantity of vegetable matter is always in the course of decomposition, while in particular spots a large quantity is constantly being accumulated. The latter condition is seen in our climate in the gradual but steady increase of peat bogs.

That coal is derived from the vegetable kingdom no longer admits of a doubt, but the class of plants to which more especially we are to look for the origin of coal, is still a matter of much uncertainty. The idea generally entertained is that which supposes a natural basin in which vegetable matter is deposited, the layers varying in thickness, becoming covered with mud or sand.

Some microscopic observers assure us that they are enabled to detect ligneous structure in bituminous coal. Mr. Quekett has given a great number of drawings in proof of this, and he refers the coal to the *woody* matter of an extinct class of the *Conifera*. Botanists of eminence, however, assure us that there is no evidence of ligneous structure in any of the examples brought forward in proof of that hypothesis. Others maintain that such structure, though observable in the charcoal-like layers called 'mother of coal,' cannot be detected in the bituminous parts, and that by far the greater portion of the coal is composed of the *macrospores* and *microspores* of *Lepidodendra*, and other lycopodiaceous plants. The spores of these, or of allied plants, are found more or less abundantly in all true coal; indeed, in some cases they appear to make up the mass of the mineral, whilst in others they seem to have been crushed together, thus forming the brown streaks commonly seen in microscopic sections of coal.

Sir Charles Lyell, in his excellent 'Manual of Elementary Geology,' enters largely and with his usual lucid manner, into the consideration of the carboniferous plants. There can be no doubt of the existence of the remarkable flora described by him during the period when our beds of fossil fuel were forming. Referring to Sir William Logan as his authority, Sir Charles says, 'It was observed that while in the overlying

shales or "roof" of the coal, ferns and trunks of trees abound, without any *stigmariæ*, and are flattened and compressed, those singular plants of the underlay (*the stigmariæ*) very often retain their natural forms of branching freely, sending out their slender leaf-like rootlets, formerly thought to be leaves, through the mud in all directions.' This plant is singularly indicative of the class of plants from which coal has been derived.

M. Adolph Brongniart states that the number of species of carboniferous plants amounts to about 500. Lindley informs us that no less than 250 ferns have been obtained from the coal-strata. Forty species of fossil plants of the coal period have been referred to the *Lepidodendrons*. These with *Equisetaceæ*, *Calamites*, *Asterophyllites*, *Sigillaria*, of which about thirty-five species are known with their roots, *Stigmariæ*, and *Conifera* make up the remarkable flora which have been preserved to us in our coal series.

Trees and humbler plants in great variety are found in the carboniferous sandstones and shales, and in the coal itself; but it does not appear that we have any one evidence of the actual conversion of the woody fibre of these plants into coal; that is, there is no evidence of the direct conversion of wood into bituminous coal. The trees are almost invariably silicified, or converted into columns of sandstone; the carbon which constituted the original woody fibre being *substituted* by silica, or sometimes by carbonate of lime, and sometimes by iron. Sir Charles Lyell has carefully examined the phenomena, now in progress, of the great Delta of the Mississippi, and he perceives in them many facts which fully explain, to his mind, the progress of coal deposit. It cannot, however, be disguised that even while he refers the coal to the supposed submerged forests, he does not venture to explain any of those changes, which he evidently believes depend upon some peculiar conditions of climate.

Professor John Phillips, who has devoted much study to this subject, says, 'There is no necessity to enlarge upon the proofs of the origin of coal from vegetables, drawn from an examination of its chemical constitution, as compared with the vegetable products, and the composition of the ligneous parts of the plants, and from the *unanswerable identity of the carbonaceous substance*, into which a vast multitude of fossil plants have been converted. The chemical constitution of this carbonaceous product of the individual vegetables, is exactly analogous to the chemical constitution of coal; and it is quite probable that hereafter the reason of the variations to which both are subject, whether dependent on the original nature of the plant or produced by unequal exposure to decay after inhumation, or metamorphic subsequent operations, will be as apparent as that of the general argument arising from a common vegetable origin.'—*Manual of Geology*.

Mr. Jukes says, 'If therefore, we suppose wood (or vegetable matter) buried under accumulations of more or less porous rock, such as sandstone and shale, so that it might rot and decompose, and some of its elements enter into new combinations, always using up a greater quantity of oxygen and nitrogen than of carbon and hydrogen, or of oxygen and hydrogen than of carbon, we should have the exact conditions for the transformation of vegetable matter into coal.'—*The Student's Manual of Geology*.

Much stress has been laid upon the fact that we have brown coal still retaining all the unmistakable characters of wood, and the *apparent* passage of this into true coal.

Göppert states that the timber in the coal-mines of Charlottenbrunn is sometimes converted into brown coal. The same conversion was many years ago found in an old gallery of an iron-mine at Turrach in Styria. A. Schrötter explains, according to the analysis made by him, this conversion, by the separation of marsh gas and carbonic acid from the ligneous fibre of oak wood.'—*Bischof*.

The same authority says, 'This conversion of wood into coal may take place in four different ways, namely:—

1. By the separation of carbonic acid and carburetted hydrogen.
2. " " carbonic acid and water.
3. " " carburetted hydrogen and water.
4. " " carbonic acid, carburetted hydrogen and water.'

Quoting the information accumulated by Bischof for the purpose of showing the chemical changes which take place, the following analyses (see Table at top of next page) are given.

Such is, in the main, the evidence brought forward in support of the view that coal is the result of the decomposition, upon the place where it is found, of woody fibre. The following remarks by Professor Henry Rogers on the structure of the Appalachian coal exhibits some of the difficulties which surround this view:—

'Each bed is made up of innumerable very thin laminae of glossy coal, alternating

	Carbon	Hydrogen	Oxygen	Authority
Oak Wood	52.53	5.27	42.20	Gay-Lussac and Thénard.
Decayed Oak Wood	53.47	5.16	41.37	Liebig.
Fossil Wood	57.8	5.8	36.4	Regnault.
Turf	60.1	6.1	33.8	Vaux.
Lignite	72.3	5.3	22.4	Regnault.
Coal from the Maremma (Tuscany). Retinite from the brown coal mines of Walchow	76.7	5.2	18.1	Bischof.
Peat Coal	80.3	10.7	9.0	Schrötter.
Coal	80.7	4.1	15.2	Baer.
Coal	82.2	5.5	12.3	Bischof.

with equally minute plates of impure coal, containing a small admixture of finely-divided earthy matter. These subdivisions, differing in their lustre and fracture, are frequently of excessive thinness, the less brilliant leaves sometimes not exceeding the thickness of a sheet of paper. In many of the purer coal-beds these thin partings between more lustrous layers consist of little laminae of pure fibrous charcoal, in which we may discover the peculiar texture of the leaves, fronds, and even the bark of the plants which supplied a part of the vegetable matter of the bed. All these ultimate divisions of a mass of coal will be found to extend over a surprisingly large surface, when we consider their minute thickness. Pursuing any given brilliant layer, whose thickness may not exceed the fourth part of an inch, we may observe it to extend over a superficial space which is wholly incompatible with the idea that it can have been derived from the flattened trunk or limb of any arborescent plant, however compressible. When a large block of coal is thus minutely and carefully dissected it very seldom, if ever, gives the slightest evidence of having been produced from the more solid parts of trees, though it may abound in fragments of their fronds and deciduous extremities.'

It is not possible within the space which can be afforded to this article in the present work to examine further the various views which have been entertained by geologists and chemists of the formation of coal. A brief summary must now suffice:—

1. Coal is admitted upon all hands to be of vegetable origin.
2. Many refer coal to some peculiar changes which have taken place in wood; others to the formation and gradual subsidence of peat bogs (*Unger*). Fuci have also been thought by some to supply the materials for coal-beds.
3. By some the coal is thought to be formed upon the spots on which the trees grew and decayed. By others it is supposed that vast masses of vegetable matter were drifted into lakes or deltas, to be there decomposed.
4. Whether the plants grew on the soil—the *under clay*—upon which the coal is found, or were drifted to it; there must have been long periods during which nothing but vegetable matter was deposited, and then a submergence of this land, and vast accumulations of mud and sand. The number of coal-seams in some of our coal-fields and the thicknesses of the strata will be given.

Professor Henry Rogers and others suppose, that the whole period of the coal-measures was characterised by a general slow subsidence of the coasts on which we conceive that the vegetation of the coal grew; that this vertical depression was, however, interrupted by pauses and gradual upward movements of less frequency and duration, and that these nearly static conditions of the land, alternated with great paroxysmal displacements of the level, caused by the mighty pulsations of earthquakes. (See **FAULTS, HEAVES.**)

The difficulties are mainly the facts—

1. That the evidence is not clear that anything like *ligneous structure* can be detected in coal, while microspores and macrospores are sometimes found in abundance.
2. That the *woody matter* found in coal is never converted into coal, although sometimes it appears as if the bark was so changed.
3. That the coal arranges itself always in exact obedience to the underlying surface, as though a semi-fluid mass had been spread out on a previously-formed solid bed.
4. The thinning out of true coal to extreme tenuity, as mentioned by Professor Henry Rogers; numerous examples of which appear in this country.

5. The extreme difficulty connected with the subsidence of the surface of the earth to such a depth as that to which the lowest seams of coal extend.

We do not intend to answer any of these difficulties, but to leave the question open for further examination; merely remarking, in conclusion, that there can be no doubt of the vegetable origin of coal. The only question is, the conditions of

change by which bituminous coal has been produced from vegetable fibre, and that we have not completed all the links in the chain between brown coal and true coal.

The following Table shows at a glance the chemical difference between wood and brown coal on the one hand, and anthracite on the other; and serves to explain what has been said of the chemical changes by which wood is supposed to pass into bituminous and, eventually anthracite coal:—

	Locality	Authority	Carbon	Hydrogen	Oxygen	Nitrogen

Brooke and Miller divide coal into three varieties:—1. Anthracite; 2. Black coal; 3. Brown coal. The chemical differences between those being:

	1	2	3
Carbon	94·10	83·75	73·79
Hydrogen	2·39	5·66	7·46
Oxygen	1·34	8·04	13·70
Nitrogen	0·87		
Ash	1·30	2·55	4·96

Other mineralogists, as Dana, divide coal into bituminous and non-bituminous; and under these divisions they group the numerous varieties of coal which occur, as—

BITUMINOUS VARIETIES. 1. *Pitch or caking coal* (*Dana*), which burns readily with a yellow flame, and which on receiving the heat, unites into a solid mass; thus requiring poking to prevent a too complete consolidation of the mass. 2. *Cherry coal* somewhat resembles caking coal, but in burning it does not soften or cake. It burns more rapidly than caking coal, with a clear yellow flame. 3. *Splint coal* or *splent coal* is in Scotland a term for a hard laminated variety of bituminous coal, intermediate in texture, between caking and cannel coal. The name is derived from its splitting (or *splenting*) up in large flaggy or board-like laminae (*Page*). It is a coarse kind of cannel coal (*Dana*). A variety of bituminous (cannel) coal, with a slaty structure, and of a harder and tougher nature than cherry coal. Splint coal is used by Lyell as the equivalent to anthracite. 4. *Cannel coal*. A coal with a fine compact texture, a large conchoidal fracture; it receives a good polish; is sonorous when struck. It is coal more perfectly bituminised than No. 1. In Scotland this coal is called *parrot coal* from the crackling, chattering noise which it makes when first thrown into the fire.

Jet resembles cannel coal, but is blacker, and has a much more brilliant lustre.

Flint Coal. A kind of coal resembling anthracite in appearance; but containing bitumen.

Flew Coal. A coal resembling flint coal. It must be regarded as a local name for the coal found at Wedgebury in Staffordshire.

Crow Coal. A coal found near Alston, containing but a small quantity of bitumen.

Albert Coal or *Albertite*. A bituminous coal found in Nova Scotia; it has the appearance of asphaltum, and is partially soluble (about 20 per cent.), but it has not the fusibility of asphaltum.

NON-BITUMINOUS VARIETIES. *Anthracite.* A coal with a sharp-edged, shining, conchoidal fracture, not easily ignited, but when burning it gives out an intense heat, unaccompanied by smoke, and produces but little flame. Often called *stone coal*.

Culm. An impure shaly kind of coal, or anthracite shale, as the culmiferous or anthracite shales of Devon. The term is used in Parliamentary returns to signify anthracite.

Fossil Coke. An American variety, more compact than artificial coke, supposed to be produced by the action of trap rocks on anthracite.

RECENT COAL. The true coal era is a well-marked one. Geologically it lies between the Old Red Sandstone and the New Red Sandstone rocks. A newer coal is found in the lias at Richmond in Virginia, United States; and a coal belonging to the Oolites, at Brora in Sutherland, Scotland, and other places. These newer coals are very insignificant as compared with the true old coals.

BROWN COAL. This comparatively recent coal sometimes resembles bituminous coal. Other varieties have a brownish-black colour, with a coal-like lustre. It is called, when it approaches ordinary coal in hardness and appearance, *stone coal*.

Lignite. Wood in a process of change; when it still retains its woody structure, it is called *wood or board coal*; when it consists of thin layers, it is termed *paper coal*, and when soft and earthy it is known as *peat coal*.

The relative importance of mineral fuel in various countries, as indicated by the actual coal area and the real production of some of the principal coal-fields, may be understood by a reference to the subjoined Table:—

Countries	Coal Area in Square Miles	Proportion of whole Area of the Country	Annual Production according to the latest Returns
British Islands . . .	12,800	1-10	123,573,600
France	2,000	1-100	12,148,223
Belgium	520	1-22	12,544,038
Spain	4,000	1-52	500,000
Prussia	1,200	1-90	14,751,729
United States of America	220,166	3-0	21,558,329
British North America .	13,000	1-10	2,750,000
India	uncertain	...	401,279

COAL-FIELDS OF THE UNITED KINGDOM.

It will thus be seen how extremely important the coal-fields of the British Islands really are when compared with any others. This is the case, not merely in the total annual production and the proportionate extent of the deposits, but also from the great number of points at which the coal can be advantageously worked. This will be best seen by reference to the Table given at the end of the article.

The distribution of coal in the United Kingdom is of vast importance to the country. It is spread over large areas, commencing with Devonshire in the south, and extending to the northern divisions of the great Scotch coal-fields. A careful examination of all these deposits cannot but prove useful.

DEVONSHIRE. *Lignite of Bovey-Heathfield.*—Lysons, ‘Magna Britannia,’ informs us that this so-called Bovey coal was worked for use early in the last century; and Dr. Maton described those beds in 1797 as being from 4 to 16 feet in thickness, alternating with clay, and he stated that the pits were about 80 feet deep, and worked for the supply of a neighbouring pottery. A pottery was established at Ideo in 1772, and one at Bovey Tracey in 1812, both of which were supplied with fuel from those lignite beds.—*De la Beche.*

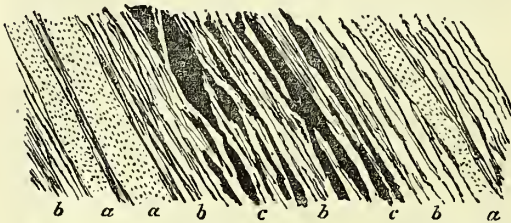

Mr. William Pengelly carefully investigated the Bovey Tracey lignites. The result of his enquiry was ‘that the Bovey lignites are the contemporaries of the ‘Hempstead Beds’ in the Isle of Wight, first discovered by the late lamented Edward Forbes in 1852, and described by him in the following year. Though their discoverer always regarded them as Upper Eocene, they have recently been grouped amongst the Lower Miocene.’ Professor Heer, of Zürich, determined forty-five species of plants from this lignite, forty-one of them being decidedly of the Lower Miocene age.

Bideford Anthracite.—The beds of anthracite stretch across the country from Barnstaple Bay, by Bideford and Averdiscot, towards Chittlehampton, a distance of about twelve miles and a half. The anthracite is mixed with the black shales of the carbonaceous deposits.

‘The anthracite is mixed with those shales in the manner represented beneath

fig. 465; *a*, sandstones; *b*, shales; *c*, culm or anthracite; so that the culm itself seems the result of irregular accumulations of vegetable matter intermingled with mud and sand. As so frequently happens with carbonaceous deposits of this kind, nodules of argillaceous iron-stone are often found in the same localities with the shales and anthracite, reminding us of the intermixture of iron ores and vegetable matters in the bogs and morasses of the present day.—*De la Beche*.

465

SOMERSETSHIRE AND GLOUCESTERSHIRE.—The Dean Forest coal-field, and the coal-measures extending further south forming the Bristol coal-field, are included in this division. The workable seams of coal in the Forest are the following:—

		ft.	in.
Dog Delf	(having a thickness of)	1	2
Smith Coal	"	2	6
Little Delf	"	1	8
Park End High Delf	"	3	7
Stakey Delf	"	2	6
Little Coal	"	1	1
Rocky Delf	"	1	9
Upper Churchway Delf	"	4	2
Lower Churchway Delf	"	2	0
Brazley Delf	"	1	9
Nag's Head, or Weaver's	"	2	9
Whittington Delf	"	2	6
Coleford High Delf	"	5	0
Upper Trenchard	"	2	0
Lower Trenchard	"	1	4

There is a small coal-field north of the Forest of Dean, which is a long narrow strip, containing two and a half square miles or 1,600 acres.—*Maclauchlan, Geological Transactions, vol. v.*

About nine miles and a half to the south of Dean Forest a considerable mass of coal-measures has been preserved from destruction, by the denuding causes which have carried off the connecting portion between it and Dean Forest, leaving at least two outlying patches on the north of Chepstow.

The Bristol coal-field occupies about fifty square miles, or 32,000 acres. The seams of coal are very thin in comparison with those which are worked in other districts. Buckland and Coneybear (‘*Geological Transactions, vol. i.*’) have well described this coal-field.

The total thickness of the whole series of strata in this Bristol coal-field has been shown by *De la Beche* to be as follows:—

Upper shales and limestones	1,800 feet, with 10 beds of coal.
Middle sandstone	1,725 feet, with 5 beds of coal.
Lower shales	1,565 feet, with 36 beds of coal.
Farewell Rock	1,200 feet.
Total	6,290 feet.

SOUTH WALES COAL-FIELD.—The total thickness of the coal-strata in this important district is very great. Logan and *De la Beche* have accumulated evidence which appears to justify the admission of 11,000, or even 12,000 feet thickness from the carboniferous limestone to the highest part of the coal series about Llanelly; in other parts of the field the series is found to be on proportions only less gigantic. The most general view which can be afforded seems thus, giving the true coal-measure about 8,000 feet:—

	Feet
Llanelly series, with several beds of coal	1,000
Penllergare series of shales, sandstones, and beds of coal, 110 beds; 26 beds of coal	3,000
Central series (Townhill sandstones of Swansea, Pennant grit of the Bristol field); 62 beds, and 16 beds of coal	3,246

	Feet
Lower shales, coals, and iron-stones (Merthyr); 266 beds, 34 beds of coal	812
Abundance of iron-stone beds and <i>Unionidae</i> occur	
Farewell-Rock and Gower shales above; the carboniferous limestone below.	

The coal on the north-eastern side of the basin is of a coking quality, excellent for the iron manufacture; on the north-western it contains little or no bitumen, being what is called stone-coal or anthracite; on the south side, from Pontypool to Caermarthen Bay, it is of a bituminous or binding quality.—*Phillips*.

SHROPSHIRE.—This district includes the small coal-field of Coalbrook Dale and that of the plain of Shrewsbury. The Coalbrook-Dale field, according to Mr. Prestwich, has some remarkable features. (*Geological Transactions*.) Perhaps there is no coal tract known, which in so small a compass, about twelve miles long, and, at most, three and a half miles wide, exhibits so many curvatures in the outcrops, crossed by so many continuous faults, some varying north by east, others east-north-east; these crossed by many of shorter length, and directed west-north-west, and in several other lines. The total thickness is supposed to be 1,000 or 1,100 feet, divided into 80 distinct strata. The coal varies in total thickness from 16 feet to 55, and in the number of its beds from 7 to 22, the increase being to the north. The 'cleat' or system of joints runs from west-north-west to east-south-east. The coal is, for the most part, of the variety called slate-coal in Scotland, and hard coal in Derbyshire. Cannel coal is rare—sulphureous coal (pyritous) very common. Petroleum abounds in the central and upper part of the field. The beds are mostly thin; the ten uppermost are too sulphureous for other uses than lime burning, and are called stinkers; twelve beds of good coal, in all 25 feet thick, the thickest being five feet, succeed, and the lowest bed of the whole formation, eight inches thick, is sulphureous.—*Phillips, Prestwich*.

STAFFORDSHIRE.—*The Coal-field of South Staffordshire*, which has been described by Mr. J. Beete Jukes, who states, its boundary would be roughly described as the space included within a boundary line drawn from Rugeley through Wolverhampton to Stourbridge; hence to the southern end of the Bromsgrove Lickey, and returning through Harborne (near Birmingham) and Great Barr back to Rugeley. This geologist classes these coal-strata in three divisions, by the well traced band of *thick coal*. The total thickness of coal near Dudley being about 57 feet, and between Bilston and Wolverhampton upwards of 70 feet. The thick coal is formed of eight, ten, or thirteen distinguishable parts, the whole seam varying in thickness from three feet to *thirty-nine feet five inches*; it is very irregular in parts, divided by sandstones, splitting with wide-shaped offshoots, and cut into 'swiles' or 'horse-backs,' which rise up from the floor. Below the thick coal, are numerous beds of sandstone-shales, coal, and ironstone, having on the average a thickness of 320 feet; and above the thick coal the thickness is 280 feet on the average.—*Records of the School of Mines*.

North Staffordshire Coal-field.—This field is comprised in the space between Congleton, Newcastle-under-Lync, and Lane End. About 32 beds of coal have been determined, rising eastward between Burslem in the centre of the field and its eastern limit near Norton Church.

DERBYSHIRE AND NOTTINGHAMSHIRE.—The Derbyshire and Nottinghamshire coals are classed as to structure in two varieties, as '*hard*' coal, in which the divisional structures are chiefly derived from the planes of stratification, crossed by one set of 'cleat' or natural joints (called 'slines,' 'backs,' &c.) so that large prismatic masses result; '*soft*' coal where the cleat fissures are numerous, and broken by cross cleat. In respect of the *quality*, some of the coal is of a 'crozling' or coking nature, easily fusible and changing its figure by 'coking'; the rest (and this is specially the case with the '*hard*' variety) makes both good furnace coal and excellent coke, which, however, is hardly melted at all, and the masses are not changed in figure by the process.—*Phillips's Manual of Geology*.

The names by which the more important beds of coal worked within this district are known, are as follow: Tupton coal, hard coal, soft coal, black shale or clod coal, low hard coal and low soft, windmill coal, Dansil coal, Ganister coal, Parkgate coal, Aston coal, Kilburn coal, furnace coal, Hazel coal, Eurcka coal, main and deep coal.

LEICESTERSHIRE AND WARWICKSHIRE.—The Leicester coal-field is best developed about Ashby-de-la-Zouch (see Mammatt on 'The coal-field of Ashby-de-la-Zouch'), where the coal is much like the hard coal of Derbyshire. Amongst the seams of coal is one variety called cannel; and another, formed by the concurrence of more than one band, from seventeen to twenty-one feet in thickness. The beds near Ashby-de-la-Zouch are as follow:—

In the Moira district—		Thickness of beds
Eureka coal	4 to 6 feet.
Stocking coal	6 to 7 „
Woodfield coal	5 „
Slate coal	3½ to 4 „
Nether main coal	14 to 15 „
Fourfoot coal	4 to 5 „
The Earl coal	4 ft. 6 in.
In the Coleorton district—		
Heath End coal	9 feet.
Lount coal	(3 beds).
Main coal	10 to 12 feet.

The *Warwickshire Coal-field* extends from a point east of Tamworth to a point east of Coventry, about twenty miles from N.W. to S.E. parallel to the Ashby coal tracts. The strata are most productive of coal near the southern extremity, where, by the coming together of two seams,—worked separately at Griff,—the five-yard seam is worked. The beds are known as the seven-feet coal and rider, slate coal, two yards, lower seam, cannel, and Ell coal.

YORKSHIRE.—Professor John Phillips gives the following mode of classification as the most natural and convenient for the Yorkshire coal:—

Magnesian limestone unconformably covers the coal seams.

Upper coals . { Shales and Badsworth coal.
Ackworth rock.
Wragby and Sharlston coals.

Red rock of Woolley, Hooton-Roberts, &c.

Middle coals . { Furnace coals Barnsley thick coal.
Intermediate coals { Rock of Horbury.
Middle coals.
Ironstone coals { Silkstone and Flockton beds.
Low Moor coals.

Flagstone rock of Woodhouse, Bradford, Elland, Peniston, &c.

Lower coals . { Shales and ganister stone.
Coals.
Shales and ganister stone.
Coals.
Shales, &c.

Millstone grit lies below the 'coal series.'

The important middle-coal series are again divided by Professor Phillips as follows:—

Iron-stone coals { Red rock of Woolley Edge.
Furnace coals of Barnsley, &c. including the eight or ten feet seam.
Rock of Horbury and Wentworth House.
Swift burning coals of Middleton, Dewsbury, &c., with bands of 'mussels.'
Bituminous coals of Silkstone and Low Moor.
Flagstone rocks beneath.

The small coal-field of Ingleton and Black Burton in Lonsdale is thrown down on the south side of the great Craven fault.

LANCASHIRE.—The coal-field of Lancashire occupies an area extending from Macclesfield to Colne, 46 miles, and from Torboch, near Liverpool, to Todmorden, about 40 miles. Excluding the millstone grit, its area is about 250 square miles.—*Heywood.*

In a line through Worsley, Bury, and Burnley to the limestone shales of Pendle Hill, we have 36 seams of coal, 10 of them not exceeding 1 foot in thickness, making in all 93 feet of coal.

The series is divisible into three parts above the millstone grit:—

Upper part, containing a bed of limestone at Ardwick, near Manchester.

Middle part, containing the greater part of the thick and valuable seams, especially cannel coal of Wigan.

Lower part, corresponding to the ganister series of Yorkshire.

CHESHIRE.—The coal-field of Cheshire is not of great importance.

NORTH WALES.—*Flintshire and Denbighshire*.—The Flintshire coal-basin extends from north to south, somewhat more than 30 miles from Llanassa to near Oswestry in Shropshire. The coal-strata dip generally eastward, and form in the northern part a trough beneath the estuary of the Dee. This coal-basin in Flintshire commences with beds of shale and sandstone. The coal is of various thickness, from $\frac{3}{4}$ to 5 yards, and consists of the common, cannel, and peacock varieties.—*Phillips and Conybeare*.

CUMBERLAND.—This coal-field extends as a narrow crescent from Whitehaven to near Hesketh Newmarket: around Whitehaven and at Workington the coal is worked extensively. At the latter place, a few years since, a very valuable colliery was destroyed by the bursting in of the sea.

There are three workable seams in the Cumberland coal-field in the neighbourhood of the three under-mentioned towns, and these are known in each place by the names given:—

Whitehaven	Workington	Maryport
Bannock band. Main band, Six-quarter coal or Low-bottom seam.	Moorbanks. Main seam. Hamilton seam.	Ten quarters. Cannel and metal seams (divided with shale from 2 feet to 5 fathoms thick).

NORTHUMBERLAND AND DURHAM.—The total thickness of the coal-measures of this district is about 1,600 feet. The number of distinct layers or beds, as usually noted by the miners, is about 600. The total thickness of the beds of coal rarely exceeds—does not on the average equal—60 feet. No bed of coal is of greater thickness, even for a short distance, than 6 or 7 feet; several are so thin as to be of no value at present; but many of these will be worked with profit. The total thickness of 'workable coal,' supposing all the beds to be found in a given tract, is not to be estimated at above 20 or 30 feet. The most part of the coal in this great district is of the coking quality, but, in this respect, there is much variation; advantage has been taken of this, in rendering available very large quantities of the dust of coal, and the small coal which formerly was burnt to waste on the pit bank. The best coke for locomotive engines is now made from the lower coals in the Auckland district of Durham, and the Shotley Bridge district of Northumberland. The best 'steam coal' is obtained from the north side of the Tyne and the Blyth district. The best 'house coal' still comes from the remains of the 'High chain' on the Tyne, and from the 'Hutton seam' on the Wear; but the collieries north of the Tees have acquired a high reputation.

As a general view of the groups of strata the following summaries may suffice:—

Upper groups of coal-measures, including chiefly thin seams of small value (8 or more) in a vast mass of sandstone in shales, with some iron-stone. At the base is a mussel band; estimated at 900 feet.

ON THE TYNE:—		ON THE WEAR AND TYNE:—		
	Ft. In.		Ft. In. Ft. In.	
Middle Group.	High main coal	6 0	Unknown.	
	Strata and thin coals	60 0	Five-quarter coal	3 9 to 6 9
	Metal coal	1 6		
	Strata and thin coals	30 0		
	Stone coal	3 0	Main coal	5 6 to 6 0
	Strata	83 0		
	Yard coal	3 0	Maudlin seam	4 6 to 6 0
	Strata	90 0		
	Bensham seam	3 0		
	Strata with several variable beds and some layers of mussels	150 0	Low main or Hutton seam	4 6 to 6 6
	Low main coal	6 0	Beaumont seam	3 0 to 6 0
	Strata	200 0	Brockwell seam	3 0 to 6 0
	Hervey's seam	3 0		
	Strata	300 0		
Brockwell Seam	3 0			
Strata above millstone grit	200 0			

—John Phillips.

The seams which are *principally* worked in this district are the high main, five-quarter main, Bensham seam, Hutton seam, Beaumont seam, low five-quarter, three-quarter seam, Brockwell, and stone coals. These seams are known by other names, each district usually adopting its own peculiar term to designate the workable seams. Thus the Bensham seam of the Tyne is known as the Maudlin seam of the Wear. The Beaumont or Harvey seam is the Townley seam of the Townley colliery and the main coal of Wylam colliery. At Hetton the high main seam of the Cramlington district separates into two, and is called the three-quarter seam at Pontop; where it unites again it is known as the Shieldrow seam. The Cramlington grey seam is the metal-coal seam and stone coal-seam of Sherriff Hill, where it is divided; while it unites at Hetton and forms the five-quarter seam of that and the Auckland district. The Cramlington yard seam becomes the main coal-seam at Hetton, Haswell, and some other localities, the Brass Thill at Pontop, and the main coal in Auckland. Again, the Cramlington five-quarter seam divides and forms the six-quarter, and the five-quarter at Sherriff Hill the Brass Thill seam at Pittington; they again unite and form the Hutton seam at Pontop colliery, and so with regard to a few others.—*Mineral Statistics.*

SCOTLAND.—‘A memoir on the Mid-Lothian and East-Lothian Coal-fields,’ by David Milne, gives the most exact account of the carboniferous system of Scotland. From this description it will be seen that the Scotch coal-field extends from the eastern unto the western shore.

There are three principal coal-basins in Scotland: 1, that of Ayrshire; 2, that of Clydesdale; and 3, that of the valley of the Forth, which runs into the second in the line of the Union Canal. If two lines be drawn, one from Saint Andrews on the north-east coast, to Kilpatrick on the Clyde, and another from Aberlady, in Haddingtonshire, to a point a few miles south of Kirkoswald in Ayrshire, they will include between them the whole space where pitcoal has been discovered and worked in Scotland.

According to Mr. Farcy there are 337 principal alternations of strata between the surface in the town of Fisherow, on the banks of the Frith of Forth (where the highest of these strata occur) and the commencement of the basaltic rocks, forming the general floor and border of this important coal-field. These strata lie internally in the form of a lengthened basin or trough, and consist of sandstone, shale, coal, limestone, ironstone, &c. Sixty-two seams of coal, counting the double seams as one; 7 limestones; 72 assemblages of stone and other strata: in all 5,000 feet in thickness.

Professor Phillips remarks of this district, ‘On the whole, allowing for waste, unattainable portions, and other circumstances, this one district may be admitted as likely to yield to the miner for actual use 2,250 millions of tons of coal.’ The coal is partly ‘splint,’ partly ‘rough,’ or ‘cherry,’ partly of the ‘cannel’ or ‘parrot’ variety. The first containing most oxygen; the last, most hydrogen and nitrogen, and the least carbon.

IRELAND.—The coal-measures of Ireland, if we include in this term the millstone grit, occupy large tracts of land in that country, and are upon the whole analogous, in general mineral characters and organic contents, to those of England. The same absence of limestone, the same kind of successions of sandstones and shales is remarked in them. Anthracite or stone-coal like that of South Wales is found in the Leinster and Munster districts; bituminous coal occurs in Connaught and Ulster. In Ulster the principal collieries are at Coal Island and Dungannon. The Munster coal district is stated by Mr. Griffith to be of greater extent than any English coal-field, but it is much less productive. At Ballycastle the coal is found in connection with basalt.—*Phillips.*

Mr. Hull’s remark, in the ‘Coal-fields of Great Britain,’ ‘that Ireland was once covered over two-thirds of its extent by coal-fields,’ is a proposition which we may confidently affirm on geological grounds; but the misfortunes of the sister isle began long before the landing of Strongbow, for old father Neptune had swept the coal and coal-strata clean into his lap, and left little but a bare floor of limestone behind. In plain words, if we examine a geological map of Ireland, we shall find that the carboniferous limestone overspreads its greater part; and as we always find in England that this formation is ultimately surmounted by coal-measures, so we may infer that was the same order of succession here, before the sea, which more than once overwhelmed the country after the carboniferous epoch remorselessly swept away the more valuable portion of this system of rocks.

The following remarks on the coal-fields of Ireland are translated, by Mr. W. H. Baily, from a description of them by Dr. H. B. Geinitz:—

‘Although the carboniferous limestone extends over the greater part of Ireland, and we may assume that the coal-bearing strata of the carboniferous formation may also, at one time, have exhibited a considerable extension in that country, there is, however, very little of it remaining, in consequence of the subsequent denudation observable there. In the south of Ireland the carboniferous limestone is accompanied by a series of black shales or grey sandstone, and arenaceous or sandy shales, which contain thin beds of anthracite coal in the upper strata. Professor J. Beete Jukes, who is at the head of the Geological Survey of Ireland (since deceased), distinguishes in this district (Castlecomer, Queen’s County) the following groups of the carboniferous formation, from the lower to the upper:—1. Carboniferous limestone, 3,000 feet thick. 2. Black shale, with occasional thin beds of sandstone, about 8,000 feet thick. In these occur the fossil shells, *Aviculpecten papyraceus*, *Posidonomya Becheri*, *Goniatites sphericus*, *Orthoceras Steinhaucri*, and other marine animals, indicative of a lower horizon. 3. Greenish-grey sandy shale, and black shale (flagstone series) characterised by vermicular impressions or markings, which have been referred to worm-tracks, as well as crustacean and molluscan tracks, 500 feet thick. 4. Black shales and grey sandstone, with thin beds of coal, 1,800 feet thick; making a total maximum thickness of coal-measure strata above the carboniferous limestone of 3,100 feet.

‘An extensive working is carried on in the Castlecomer coal-field, which lies on the borders of Kilkenny and Queen’s Counties. Accurate sections referring to this field, for which we are indebted to Professor Jukes, exhibit in this district five beds of coal, of which, however, the upper only are observable, and that over a very limited area, in consequence of denudation (probably from sea action upon what was once the coastline). The richer deposits of coal in the lower beds are found north-east of Castlecomer, where, at the Garrow Colliery, at the time of my visit, a coal-bearing seam, 3 ft. 10 ins. thick, was working, which yielded excellent anthracite coal, the normal Kilkenny coal of Werner. The circumstances just described are perfectly analogous to those in the neighbouring Geneva Colliery. Opinions still vary as to whether this Garrow bed is the second or third from the bottom. At all events, it is the most important in the district. In the small Leinster coal-field, somewhat further to the north-east, in the direction from Castlecomer to Athy, a seam is also worked from 18 to 20 inches thick only. The numerous remains of plants collected in this coal-district, compared with those of other coal-basins, show that the anthracite coal does not belong to the zone (horizon) of the culm, or our first zone, but rather to the commencement of the second, or *Stigillaria* zone. Marine shells occur over the Garrow seam, among which the characteristic and widely-distributed coal-measure fossils before mentioned, *Aviculpecten papyraceus* and *Posidonomya Becheri* are most frequent. Numerous well-preserved bivalve shells occur, *Anthracosia*, *Myalina*, &c., locally called “beams” by the miners, together with some remarkable crustacea of the genus *Belinurus*, from the black shales of Bilboa Colliery, situated about six miles S. W. of Carlow, the coal of which is believed to correspond with the second seam of the Castlecomer district. At this colliery, also, the well-known fossil plants *Alethopteris lonchitidis* and *Sagenaria elegans*, were easily recognisable, two forms, which, in the productive coal-formation of England especially, have the widest distribution. In the north of Ireland, where coal-bearing beds occur, in the counties of Leitrim, Fermanagh, as well as at Dungannon, in Tyrone, and Ballycastle, in Antrim, they rest upon a thick sandstone formation, apparently representing the millstone grit which separates them from the carboniferous limestone group. Sir Richard Griffiths, Bart., in his geological map of Ireland, divides the latter into an upper and lower limestone, between which the “calp” is deposited, consisting of shales and sandstones, and often more than 1,000 feet thick. It is remarkable that while in the whole of the south of Ireland the typical anthracite or Kilkenny coal predominates, in the north the prevailing deposits are bituminous, or good gas-coal. According to the investigations of Sir R. Griffiths, the coal-field of Dungannon, in Tyrone, is divided into two districts, which are distinguished as the Coal Island district and the Annaghone district. The first is six miles long, with a mean breadth of about two miles; the latter is only one mile long and half a mile broad. In this important coal-field there are eight beds of coal, of variable thickness, from 2 ft. 2 in. to 1 ft. 9 in. viz., the Annagher coal. Under these there are also two or three other seams known. These coals are, for the most part, of good quality. The occurrence of the productive coal-formation at Ballycastle, on the northern coast of Ireland, in the county of Antrim, is very interesting, where it extends, from Fair Head, in a westerly and southerly direction, to a distance of about four miles, with a mean breadth of one mile and a half. It contains, at Murlough Bay, six coal seams, from one to eight feet thick, of which four yield good gas-coal, while the two deepest are anthracite. The first four occur between two columnar isolated basaltic masses, while the two lower anthracite seams are almost in direct contact with the lower

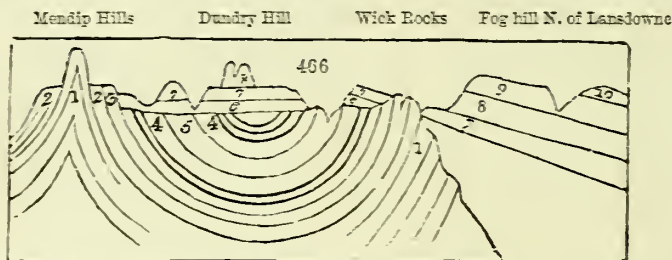

basaltic mass, which is about 70 feet thick. These coal-bearing beds appear to rest directly on the mica-schist.

As an additional characteristic of the Irish coal-fields, there follows a summary of the fossil plants which we had the opportunity of examining. I do not think that we should be justified, from a consideration of these plants, to refer the coal-bearing beds of Ireland to an older zone than to the lower, generally poor, *étage* of the Westphalian coal-formation, which represents very well the relations of their deposition. They indicate here, as there also, the commencement of the *Sigillaria* zone, whose later and richer beds were, in Ireland, destroyed, and of which only a very small area may still be preserved in some northern localities, as at Dungannon.'

The following general statement of the geological conditions of the coal-measures of these islands is continued from the pen of the late Dr. Ure:—

The great Carboniferous Formations of these islands may be subdivided into three orders of rocks: 1. the coal-measures, including their manifold alternations of coal-beds, sandstones, and shales; 2. the millstone grit and shale towards the bottom of the coal-measures; 3. the carboniferous limestone, which, projecting to considerable heights above the outcrop of the coal and grit, acquires the title of mountain limestone; resting on the Old Red Sandstone, which may be regarded as the connecting link with the transition and primary rock basin in which the coal system lies.

The coal series usually, but not invariably, consists of a regular alternation of mineral strata deposited in a great concavity or basin, the sides and bottom of which are composed of transition rocks. This arrangement will be clearly understood by inspecting *fig. 466*, which represents a section of the coal-field south of Malmesbury.

No. 1. or the Old Red Sandstone, may therefore be regarded as the characteristic lining of the coal-basins; but this sandstone rests on transition limestone, and this limestone on highly-inclined beds of slaty micaceous sandstone which, on the one hand, alternates with, and passes into a coarse breccia, having grains as large as peas; on the other, into a soft argillaceous slate. The micaceous sandstone stands bare on the north-eastern border of the Forest of Dean, near the southern extremity of the chain of transition limestone which extends from Stoke Edith, near Hereford, to Flaxley on the Severn. It is traversed by a defile, through which the road from Gloucester to Ross winds. The abruptness of this pass gives it a wild and mountainous character, and affords the best opportunity of examining the varieties of the rock.

The limestone consists in its *lower beds* of fine-grained, tender, extremely argillaceous slate, known in the district by the name of *water-stone*, in consequence of the wet soil that is found wherever it appears at the surface. Calcareous matter is interspersed in it but sparingly. Its *upper beds* consist of shale alternating with extensive beds of stratified limestone. The lowest of the calcareous strata are thin, and alternate with shale. On these repose thicker strata of more compact limestone, often of a dull blue colour. The beds are often dolomitic, which is indicated by straw-yellow colour, or dark pink colour, and by the sandy or glimmering aspect of the rock.

The *Old Red Sandstone*, whose limits are so restricted in other parts of England, here occupies an extensive area. The space which it covers, its great thickness, its high inclination, the abrupt character of the surface over which it prevails, and the consequent display of its strata in many natural sections, present, in this district, advantages for studying the formation, which are not to be met with elsewhere in South Britain. In the neighbourhood of Mitchel Dean, the total thickness of this formation, interposed conformably between the transition and mountain limestone, is from 600 to 800 fathoms.

The *mountain or carboniferous limestone* is distinguished from transition limestone

rather by its position than by any very wide difference in its general character or organic remains. According to the measurements of Mr. Mushet, the total thickness of the mountain limestone in the Gloucestershire coal-field is about 120 fathoms. The zone of limestone belonging to this coal-basin is from a furlong to a mile in breadth on the surface of the ground, according as the dip of the strata is more or less rapid. The angle of dip on the northern and western border is often no more than 10° , but on the eastern it frequently amounts to 80° .

The aggregate thickness of the coal-measures amounts to about 500 fathoms. 1. The lowest beds, which repose on the mountain limestone, are about 40 fathoms thick, and consist here, as in the Bristol coal-basin, of a red siliceous grit, alternating with conglomerate, used for millstones; and with clay, occasionally used for ochre. 2. These beds are succeeded by a series about 120 fathoms thick, in which a grey gritstone predominates, alternating in the lower part with shale, and containing 6 seams of coal. The grits are of a fissile character, and are quarried extensively for flag-stone, ashlers, and fire-stone. 3. A bed of grit, 25 fathoms thick, quarried for hearth-stone, separates the preceding series from the following, or the 4th, which is about 115 fathoms thick, and consists of from 12 to 14 seams of coal alternating with shale. 5. To this succeeds a straw-coloured sandstone, nearly 100 fathoms thick, forming a high ridge in the interior of the basin. It contains several thin seams of coal, from 6 to 16 inches in thickness. 6. On this reposes a series of about 12 fathoms thick, consisting of 3 seams of coal alternating with shale. 7. This is covered with alternate beds of grit and shale, whose aggregate thickness is about 100 fathoms, occupying a tract in the centre of the basin about 4 miles long and 2 miles broad. The sandstone No. 5 is probably the equivalent of the Pennant in the preceding figure. The floor, or pavement, immediately under the coal-beds is, almost without exception, a greyish-slate clay, which, when made into bricks, strongly resists the fire. This fire-clay varies in thickness from a fraction of an inch to several fathoms. Clay-ironstone is often disseminated through the shale.

The above description holds generally correct for the great coal-fields of south-western England, where we have *coal-measures*, *millstone grit*, and *mountain limestone* in regular order, the latter being at the base of the system. As we proceed northward to Yorkshire and Northumberland, however, the limestone begins to alternate with the true coal-measures, the two deposits forming together a series of strata about 1,000 feet in thickness. To this mixed formation succeeds the great mass of genuine mountain limestone. In Fifeshire, in Scotland, we observe a still great departure from the type of the south of England, or a more complete intercalation of dense masses of marine limestone, with sandstone and shales containing coal.

At Brora, in Sutherlandshire, we have a coal-formation belonging to the lower divisions of the Oolite period; and in the north-east of Yorkshire, we have a similar formation.

The Brora coal-field, to which of late much attention has been directed, is a remarkable example of a coal-basin among the deeper secondary strata, but above the New Red Sandstone formation. The Rev. Dr. Buckland and Sir C. Lyell, after visiting it in 1824, had expressed an opinion that the strata there were wholly unconnected with the proper coal-formation below the New Red Sandstone, and were in fact the equivalent of the oolitic series; an opinion fully confirmed by the subsequent researches of Sir R. Murchison. ('*Geol. Trans.*' for 1827, p. 293.) The Brora coal-field forms a part of those secondary deposits which range along the south-east coast of Sutherlandshire, occupying a narrow tract of about 20 miles in length and 3 in its greatest breadth.

One stratum of the Brora coal-pit is a coal-shale, composed of a reed-like striated plant of the natural order *Equisetaceæ*, which seems to have contributed largely towards the formation of that variety of coal. From this coal-shale the next transition upwards is into a purer bituminous substance approaching to *jet*, which constitutes the great bed of coal. This is from 3 feet 3 inches to 3 feet 8 inches thick, and is divided nearly in the middle by a thin layer of impure indurated shale charged with pyrites, which, if not carefully excluded from the mass, sometimes occasions spontaneous combustion upon exposure to the atmosphere; and so much indeed is that mineral disseminated throughout the district, that the shales might be generally termed 'pyritiferous.' Inattention on the part of the workmen, in 1817, in leaving a large quantity of this pyritous matter to accumulate in the pit, occasioned a spontaneous combustion, which was extinguished only by excluding the air; indeed, the coal-pit was closed in and remained unworked for four years. The fires broke out again in the pit in 1827.

The purer part of the Brora coal resembles common pitcoal; but its powder has the red ferruginous tinge of pulverised lignites. It may be considered one of the last links between lignite and true coal, approaching very nearly in character to *jet*,

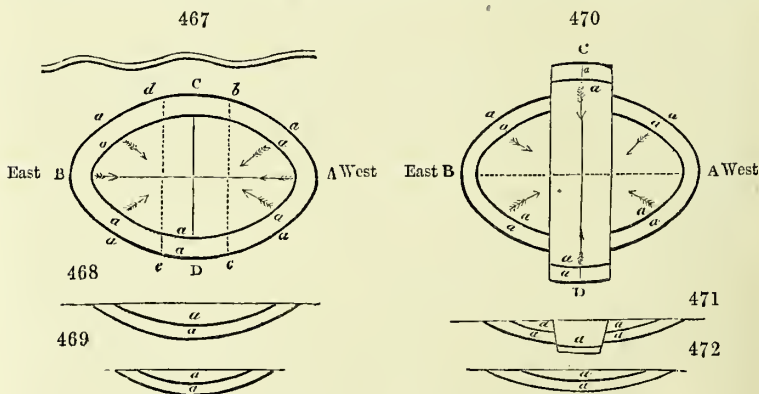

though less tenacious than that mineral; and, when burnt, exhaling but slightly the vegetable odour so peculiar to all imperfectly-bituminised substances. The fossil remains of shells and plants prove the Brora coal to be analogous to that of the eastern moorlands of Yorkshire, although the extraordinary thickness of the former, compared with any similar deposit of the latter (which never exceeds from 12 to 17 inches), might have formerly led to the belief that it was a detached and anomalous deposit of true coal, rather than a lignite of any of the formations *above* the New Red Sandstone: such misconception might more easily arise in the infancy of geology, when the strata were not identified by their fossil organic remains.

The beds of coal at Brora have been recently (1873) opened up more thoroughly for the Duke of Sutherland, with a view to supplying the district with fuel. The latest report, August 1873, says:—‘The output of coal at the Duke of Sutherland’s colliery at Brora is as yet small, but it is very satisfactory as regards quality and in the promise of quantity. In the seam which is at present being worked there is a narrow band about three inches thick, which is somewhat sulphurous; but this can easily be chipped off and detached. From various causes, it is at present inconvenient to supply the public with coals at the pit mouth, and due notice will be given when the workings are in such a condition as to admit of the public being freely supplied. A few weeks ago a 6-ton truck of Brora coal was sent south to Inverness; and coal has also been supplied from the mine to the inhabitants of Laing and the eastern districts of Sutherlandshire at about 1*l.* and in some cases rather less, per ton. This is only about half the price paid for coal from the south. The Duke of Sutherland’s lime-kilns at Laing are now almost constantly supplied from the Brora mine. When the new seam is opened up and worked, it is expected that the supply will be both regular and plentiful.’ This expectation does not appear to have been realised (1874).

For description of the oolitic coals of Scotland, see Mr. J. Judd’s paper on ‘The Secondary Rocks of Scotland,’ in ‘Quart. Journ. Geol. Soc.’, Lond. xxix. 1873, p. 97.

On the coast of Yorkshire the strata of a similar formation appear in the following descending order, from Filey Bay to Whitby:—1. Coral-rag. 2. Calcareous grit. 3. Shale, with fossils of the Oxford clay. 4. Kelloway rock (swelling out into an important arenaceous formation). 5. Cornbrash. 6. Coaly grit of Smith. 7. Pierstone (according to Mr. Smith, the equivalent of the great oolite). 8. Sandstone and shale, with *peculiar plants and various seams of coal*. 9. A bed with fossils of the inferior oolite. 10. Marl-stone? 11. Alum-shale or lias. All the above strata are identified by abundant organic remains.

The most complete and simplest form of a coal-field is the entire basin-shape, which we find in some instances without a dislocation. An example of this is to be seen at Blairengone, in the county of Perth, immediately adjoining the western boundary of Clackmannanshire, as represented in *fig.* 467, where the outer elliptical

line, marked A, B, C, D, represents the crop, outburst, or basset edge of the lower coal, and the inner elliptical line represents the crop or basset edge of the superior coal. *Fig.* 468 is the longitudinal section of the line A B; and *fig.* 469, the transverse section of the line C D. All the accompanying coal-strata partake of the same form and parallelism. These basins are generally elliptical, sometimes nearly circular, but are often very eccentric, being much greater in length than in breadth; and frequently one side of the basin on the short diameter has a much greater dip than the other, which circumstance throws the trough or lower part of the basin concavity much nearer to the one side than to the other. From this view of one entire basin, it

is evident that the dip of the coal-strata belonging to it runs in opposite directions, on the opposite sides, and that all the strata regularly erop out, and meet the alluvial cover in every point of the circumferential space, like the edges of a nest of common basins. The waving line marks the river Devon.

It is from this basin shape that all the other coal-fields are formed, which are segments of a basin produced by slips, dikes, or dislocations of the strata. If the coal (*fig. 467*) were dislocated by two slips *b c* and *d e*, the slip *b c* throwing the strata *down* to the east, and the slip *d e* throwing them as much *up* in the same direction, the outeroeps of the coals would be found in the form represented in *fig. 470*, of which *fig. 471* is the section in the line *A B*, and *fig. 472* the section in the line *c d*.

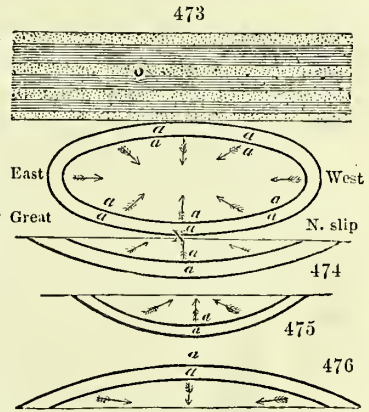

The absolute shape of the coal-fields in Great Britain has been ascertained with surprising precision. To whatever depth a coal-mine is drained of its water, from that depth it is worked, up to the rise of the water-level line, and each miner continues to advance his room or working-plaee, till his seam of coal meets the alluvial cover of the outerop, or is cut off by a dislocation of the strata. In this way the miner travels in succession over every point of his field, and can portray its basin-shape most minutely.

Fig. 473 represents a horizontal plan of the Clackmannanshire coal-field, as if the strata at the outerop all around were denuded of the alluvial cover. Only two of the

concentric beds, or of their edges *a, a*, are represented, to avoid perplexity. It is to be remembered, however, that all the series of attendant strata lie parallel to the above line. This plan shows the Oehill mountains, with the north coal-fields, of an oblong elliptical shape, the side of the basin next the mountains being precipitous, as if upheaved by the eruptive trap-rocks; while the south, the east, and the west edges of the basin shelve out at a great distance from the lower part of the concavity or *trough*, as miners call it. Thus the alternate beds of coal, shale, and sandstone, all nearly concentric in the north coal-field, dip inwards from all sides towards the central area of the *trough*. The middle coal-field of this district, however, which is formed by the great north slip, is merely the segment of an elliptical basin, where the strata dip in every direction

to the middle or the axis marked with the letter *x*; being the deepest part of the segment. The south coal-field, formed by the great south slip, is likewise the segment of another elliptical basin, similar in all respects to the middle coal-field. Beyond the outerop of the coals and subordinate strata of the south coal-fields, the counter dip of the strata takes place, producing the mantle-shaped form; whence the coal-strata in the Dunmore field, in Stirlingshire, lie in a direction contrary to those of the south coal-field of Clackmannanshire. *o*, are the Oehill mountains.

Fig. 477 is a very interesting section of the main coal-basin of Clackmannanshire, as given by Mr. Bald in the Wernerian Society's Memoirs, vol. iii. Here we see it broken into three subordinate coal-fields, formed by two great faults or dislocations of

477

the strata; but independently of these fractures across the whole series, the strata continue quite regular in their respective alternations, and preserve nearly unchanged their angle of inclination to the horizon. The section shows the south coal-field dipping northerly, till it is cut across by the great south slip *x*, which dislocates the coal and the parallel strata to the enormous extent of 1,230 feet, by which all the coals have been thrown up, not simply to the day, but are not found again till we advance nearly a mile northward, on the line of the dip, where the identical seams of coal, shale, &c., are observed once more with their regular inclination. These coals

of the middle area dip regularly northward till interrupted by the great north slip *y*, which dislocates the strata, and throws them up 700 feet; that is to say, a line prolonged in the direction of any one well-known seam, will run 700 feet above the line of the same seam as it emerges after the middle slip. Immediately adjoining the north slip, the coals and coal-field resume their course, and dip regularly northward, running through a longer range than either of the other two members of the basin, till they arrive at the valley of the Devon, at the foot of the Ochill mountains, where they form a concave curvature, or trough *a*, and thence rise rapidly in an almost vertical direction at *b*. Here the coals, with all their associated strata, assume conformity and parallelism with the face of the syenitic-greenstone strata of the Ochill mountains *c*, being raised to the high angle of 73 degrees with the horizon. The coal-seams thus upheaved, are called *edge-metals* by the miners.

In this remarkable coal-field, which has been accurately explored by pitting and boring to the depth of 703 feet, there are no fewer than 142 beds, or distinct strata of coal, shale, and sandstone, &c., variously alternating, an idea of which may be had by inspecting *fig. 478*. Among these are 24 beds of coal, which would constitute an aggregate thickness of 59 feet 4 inches: the thinnest seam of coal being 2 inches and the thickest 9 feet. The strata of this section contain numerous varieties of sandstone, slate-clay, bituminous shale, indurated clay, or fire-clay, and clay ironstone. Neither trap-rock nor limestone is found in connection with the workable coals; but an immense bed of greenstone, named Abbey Craig, occurs in the western boundary of Clackmannanshire, under which lie regular strata of slate-clay, sandstone, thin beds of limestone, and large spheroidal masses of clay ironstone, with a mixture of lime.

478

‘With regard to slips in coal-fields,’ says Mr. Bald, ‘we find that there is a general law connected with them as to the position of the dislocated strata, which is this:—When a slip is met with in the course of working the mines—if when looking to it, the vertical line of the slip or fissure, it forms an acute angle with the line of the pavement upon which the observer stands, we are certain that the strata are dislocated downwards upon the other side of the fissure. On the contrary, if the angle formed by the two lines above mentioned is obtuse, we are certain that the strata are dislocated or thrown upwards upon the other side of the fissure. When the angle is 90°, or a right angle, it is altogether uncertain whether the dislocation throws up or down on the opposite side of the slip. When dikes intercept the strata, they generally only separate the strata the width of the dike, without any dislocation, either up or down; so that if a coal is intercepted by a dike, it is found again by running a mine directly forward, corresponding to the angle or inclination of the coal with the horizon.’—*Wernerian Society's Memoirs*, vol. iii. p. 133.

479

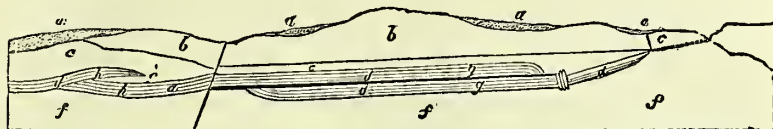

in *fig. 479* is taken, these 5 coals seem to have been overlapped or made to slide over each other by violence. This structure is represented in *fig. 480*, which is a section of the Quarrelton coal in the Johnstone field, showing the overlapped coal and the double coal, with the thick bed of greenstone, overlying the coal-field.

Fig. 481 is intended to represent an extensive district of country, containing a great coal-basin, divided into numerous subordinate coal-fields by dislocations. The lines marked *b* are slips, or faults; the broad lines marked *c* denote dikes: the former dislocate the strata, and change their level, while dikes disjoin the strata with a wall, but do not in general affect their elevation. The two parallel lines marked *a*, represent two seams of coal, variously heaved up and down by the faults; whereas the dikes are seen to pass through the strata without altering their relative position. In this manner partial coal-fields are distributed over a wide area of country in every direction.

Fig. 482 is an instance of a convex coal-field exhibited in Staffordshire, at the Castle-hill, close to the town of Dudley. 1, 1, are limestone strata; 2, 2, are coal.

Through this hill canals have been cut, for working the immense beds of carboniferous limestone. These occur in the lower series of the strata of the coal-field, and therefore at a distance of many miles from the Castle-hill, beyond the outcrop of all the workable

coals in the proper basin-shaped part of the field; but by this apparently inverted basin-form, these limestone beds are elevated far above the level of the general surface of the country, and consequently above the level of all the coals. We must regard this seeming inversion as resulting from the approximation of two coal-basins, separated by the baset edges of their mountain limestone repository.

Fig. 483 is a vertical section of the Dudley coal-basin, the upper coal-bed of which has the astonishing thickness of 30 feet; and this mass extends 7 miles in length, and 4 in breadth. Coal-seams 5 or 6 feet thick are called *thin* in that district.

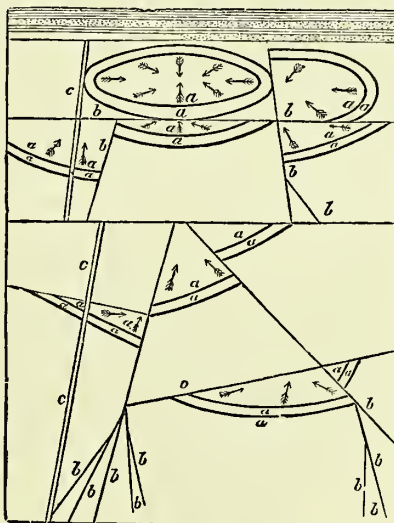

For a satisfactory description of the coal-field of South Staffordshire, the reader is referred to a memoir, 'On the Geology of the South Staffordshire Coal-field,' by J. Beete Jukes, published in the 'Records of the School of Mines.'

It is not possible in the present work to enter into any further description of the coal-fields of this country. In the selections which have been made, striking types have been chosen, which are sufficiently characteristic to serve the purposes of general illustration. There are many variations from the conditions which have been described, but these are due to disturbances which have taken place either since the formation of the coal, or during the period of the actual deposition of the coal.

The probability of finding coal in the South of England has, of late, been invested with especial interest; and we are from time to time startled with the announcement that coal has been discovered.

Not long since a paragraph appeared announcing a remarkable discovery of coal in the Isle of Wight. The late gales had denuded the shore of Whitecliff Bay of its usual mass of sand and shingle, laying bare 'a seam of coal' extending from the front of the cliff down to low-watermark, and how far beyond could not, of course, be said. The seam was alleged to be from six to seven feet wide, and it had been dug out by the fishermen and others to a depth of six feet without any signs of exhaustion, the seam rather widening as it deepened. The coal was described as resembling the ordinary kind, and burning well. The existence of coal in the Isle of Wight was a fact by no means unknown, though it has been in a great measure overlooked. During

481

482

483

a visit made to the island in 1860 Professor Ramsay and Mr. H. W. Bristow observed certain beds of a coal on the west side of the island, in Alum Bay.

These coal-seams at Alum Bay are found in the Bracklesham beds of the Middle Bagshot series, appertaining therefore to the Middle Eocene Tertiaries. The formation reappears at the opposite extremity of the Isle of Wight, namely, at Whitecliff Bay near Undercliff, the spot already mentioned. But the existence of the coal-seams at the latter spot was not detected by the Geological Survey until very lately, when the seams in question were observed by Mr. Penning, in company with a miner from the Forest of Dean, named Richard Gibbs. The seams were apparently of greater width than those at Alum Bay, although a thickness of seven feet could not be made out unless it were by adding several contiguous seams together. The discovery was communicated to Mr. Bristow, who thus describes them:—

‘The strata comprised between the well-known glasshouse sands at the base of Headon Hill and the pipe-clay-bearing sands and clays overlying the London Clay, and grouped together by Mr. Joshua Trimmer as the Middle Bagshot series, were subdivided by him into Barton Clay and Bracklesham Beds.

‘The latter are represented in Alum Bay by clays and marls in the lower part, and by white, yellow, and crimson sands above. The lower beds are remarkable for the quantity of vegetable matter contained in them, not, however, in the shape of leaves, as is the case in some of the Lower Bagshot Beds, but in the form of lignite, constituting solid beds from fifteen inches to two feet three inches thick. Four of these beds, when fully displaced, constitute conspicuous objects in the cliff, where they project out of the softer strata, and on the shore, from their black and coal-like appearance.

‘These beds of coal were recently more than usually well displayed in consequence of the prevalence of long-continued wet weather having worn away the soft intervening strata in which they are imbedded. On examining them during a brief visit made to the Island, in company with Professor Ramsay, during the autumn of 1860, it appeared evident that the beds in question occur more in the manner of ordinary coal than of mere lignite. Like true coal, each bed was based upon a stratum of clay, containing, apparently, the rootlets of plants, as in the underclay of the true coal-measures. The underclays, which occur beneath each bed of coal of carboniferous date, having been the soil which supported the vegetation which, by certain chemical changes, became subsequently mineralised and converted into coal, it is reasonable to infer from the presence of similar underclays beneath the coal in the Bracklesham Beds at Alum Bay, that the plants out of which it was formed grew on the spot, and were not drifted from elsewhere and deposited afterwards in the places where they are now found, as was undoubtedly the case with regard to the vegetable remains contained in the pipe-clay beds of the Lower Bagshot series.’

The following section of the Bracklesham beds in Alum Bay, as given by Mr. Bristow, in his ‘Memoir on the Geology of the Isle of Wight,’ will show the true position occupied by those lignite beds in the series (in ascending order):—

Dark chocolate-coloured marls and carbonaceous clay, with much	ft.	in.
<i>Lignite and Gypsum</i>	39	6
	ft.	in.
Clays and marls	15	3
<i>Lignite band</i>	1	6
Clays and marls	3	3
<i>Lignite band</i>	1	3
Clays and marls	6	0
<i>Lignite band</i>	2	3
Clays and marls	4	3
<i>Lignite band</i>	9 in. to	1 0
Clays and marls	5	0
	39	6
Whitish marl clay	25	0
Sands (principally white), light tawny yellow in the upper part; the lower three feet crimson	45	0
Conglomerate of rounded flint pebbles cemented by oxide of iron 1 ft. to	1	6
Total	111	0

The pebbles are of various sizes, the largest a foot in diameter.

The Lignite of Bovey already referred to, may be regarded as of a similar character to this of the Isle of Wight, notwithstanding the differences which have been pointed out, and the coal of Brora is not very dissimilar in its general character.

The coal of the Wealden strata is generally termed ‘lignite,’ though some approaches very closely to the character of a true coal. Whether we call it lignite or

coal, it appears to belong to the lowest stratum of the Hastings sands, known as the Ashburnham beds, which have never yet been fully explored. They rarely crop out to the surface, and would be less known than they are were it not that they are occasionally laid bare by water-courses, and are at times exposed at the base of cliffs when the sea makes deeper inroads than usual. It was this same kind of coal which gave so great a zest, at the beginning of the present century, to the costly speculation at Bexhill, near Hastings. In a boring near the seashore 'smut coal,' three feet thick, is reported to have been found at the depth of 30 yards; 'strong coal,' two feet thick, at a depth of rather more than 50 yards; and sulphureous coal of bad quality, more than four feet thick, at a further depth. Being very near the sea the salt water percolated into the boring, and although a powerful steam-engine was employed, the exploration at that spot had to be abandoned. Another attempt was made further inland, on Bexhill Down; but coal does not seem to have been found in this second effort, and after a large outlay—ruinous to the principal adventurer—the attempt was abandoned. The Bexhill coal, there is reason to believe, belonged to an upthrow of the Ashburnham beds.

The question of the existence of coal in our Southern Counties was carefully examined by the Royal Coal Commission. Several witnesses, more especially Mr. Godwin Austen and Mr. Prestwich, were examined, and the reports of their evidence are full of interest.

The following is the general purport of the report made to the Royal Coal Commission by Mr. Prestwich on the probabilities of finding coal in the South of England.

'About two centuries ago the Belgian coal-field was found to extend, beneath the newer formation on the frontiers, into France as far as Valenciennes. An uninterrupted chalk district extended northward, and the coal-measures were supposed to be lost. But at a later period valuable coal was found to exist at Anjin. This led to further search, and the coal-measures have been gradually followed in a western direction under the chalk to within thirty miles of Calais. Looking at these facts, and reasoning on theoretical considerations connected with the formation of coal in the west of Europe, Mr. Godwin Austen concluded that coal-measures might possibly extend beneath the south-eastern part of England. He showed that the coal-measures which thin out under the chalk near Theronanne probably set in again near Calais, and are prolonged in the line of the Thames Valley, parallel with the North Downs, and continuing thence under the Valley of the Kennet extend to the Bath and Bristol coal area. He showed, upon theoretical grounds, that the coal-measures of a large portion of England, France, and Belgium were once continuous, and that the present coal-fields were merely fragments of the great original deposit preserved in hollows. These views are supported by many eminent geologists who gave evidence before the Commission; but they have been controverted by Sir Roderick Murchison, who contends that in consequence of the extension of Silurian and Cambrian rocks beneath the secondary strata of the south-east of England, and of the great amount of denudation which the carboniferous rocks had undergone over the area of the South of England previous to the deposition of the secondary formations, little coal could be expected to remain under the Cretaceous rocks. Upon a general review of the whole subject, Mr. Prestwich adopts, with slight variations, the views of Mr. Godwin Austen, and is led to the conclusion that there is the highest probability of a large area of productive coal-measures existing under the Secondary rocks of the South of England. He shows that the thickness of these overlying rocks is not likely to exceed 1,000 to 1,200 feet, and considers that there is reason to infer that the underground coal-basins may have a length of 150 miles, with a breadth of two to eight miles,—limits within which are confined the rich and valuable coal-measures of Belgium.'

Mr. Prestwich shows that there are grounds for believing in the existence of coal on the south side of the Mendips, and under adjacent parts of the Bristol Channel, but at a depth of not less than 1,500 to 2,000 feet, and mentions also a small new coal basin in the Severn valley, near New Passage.

As the existence of coal under the unexplored area of the South of England is still a question of theory, an attempt is now (1873) being made to settle this important question.

The boring now going on in the parish of Netherfield, near Battle, is designed to accomplish something more than a mere exploration of the Wealden strata. In this case there is the hope of finding the Primary rocks, an expectation which was deemed chimerical by the early school of geologists, but which is now viewed in a very different light. Experience has shown that all the strata which probably intervene between one formation and another do not invariably occur. Several members of the series may be absent, and we may experience a kind of plunge from upper secondary rocks into those of the primary order. This is the probability which encourages the sub-Wealden explorers. The Ashburnham beds have been 'pierced,' and it appears that the boring tool is in some lower stratum. This may be so; but the geology of this Netherfield boring is not very clear, the depth of the boring is now above 300

feet. A bed of gypsum has been found, which is altogether about thirty feet in thickness, sometimes in thick masses, at other times nodular and irregular. This is an important addition to the Purbeck series of Sussex. Nearer the surface, limestone has been found, said to be available both for burning and building purposes. It is desirable to know whether the Palæozoic rocks are really as near the surface in the south-east of England as some geologists have supposed. The sub-Wealden explorers do not now profess to be actually in search of coal, but, without doubt, they would be glad if their enterprise should lead the way to a discovery of this kind.

From the Report of the Royal Coal Commission the following Table is taken : showing, according to their careful computation, the—

QUANTITIES OF COAL IN KNOWN COAL-FIELDS.

'Adopting 4,000 feet as the limit of practicable depth in working, and accepting the estimate of each Commissioner for the waste and loss incident to working the coal in the district assigned to him, we now present the following estimate of the quantities of available coal contained in the several districts which together comprise the coal-fields above enumerated:—

Summary of Results of Reports as to Quantities of Coal worked and unworked in certain districts.

Commissioner and Number on his Report	No.	Name of Coal-field	Amount of Coal in Statute Tons to depths not exceeding 4,000 ft., and after the necessary deductions	Amount of Coal in Statute Tons in depth exceeding 4,000 ft., and after the necessary deductions	Totals of Coal in Statute Tons in each Coal-field after the necessary deductions

NOTE.—It was an instruction to the Commissioners to whom the districts were assigned to exclude from their returns all beds of coal of less than 1 foot in thickness.

From the same Report the following remarks on the duration of coal in these islands is abstracted:—

‘The Commissioners, before proceeding to investigate the question of the duration of this quantity, based upon increasing consumption, think it useful to state the relation which 146,480,000,000 of tons bear to our present consumption, estimated at 115,000,000 per annum, in order that the vast magnitude of our stores of coal may be better appreciated. Thus we find that 146,480,000,000 of tons will support our present production for 1,273 years; the same quantity would support an annual production of 146,000,000 for 1,000 years; of 175,000,000 for 837 years; and of 230,000,000, being double our present production, for 636 years.

‘The question of the duration of the total available quantity turns, therefore, chiefly upon the statistics of consumption contained in the Report of Committee E (which was the sole labour of the Editor of this Dictionary), from which the following facts are collected:—

‘In the year 1660, the coal produce of the United Kingdom appears to have been only about 2,250,000 tons, and 40 years later the increase was only 364,000 tons. Fifty years after this, or in 1750, the quantity raised in the kingdom had increased to nearly 5,000,000 tons. In 1800, the quantity exceeded 10,000,000 tons.

‘About this period the system of canal navigation was rapidly extending, and the result was that coals were gradually finding their way into new districts, by which means the consumption of coal was greatly increased. In 1816, the production reached 16,000,000 tons according to one statement, and 27,000,000 as given with considerable probability by another.

‘Advancing to a later period, when coal statistics were more carefully collected, it appears that in 1854 the production of coal was 64,500,000 tons.

‘From that period up to, and including, 1869, the progressive increase was exhibited in a Table which has been completed up to the present time.

‘From the following Table (p. 838) it will be seen that the total quantity of coal raised in this country had reached upwards of 123,000,000 in 1872.

‘In attempting to form an opinion as to what the future consumption of coal is likely to be, it is necessary to consider the question which was referred to Committee B; namely, “Whether there is reason to believe that coal is wasted by carelessness or neglect of proper appliances for its economical consumption?” The conclusion arrived at by this Committee was, that “for some time past in our manufactures there have been constant and persevering efforts to economise coal, by the application of improved appliances for its consumption.” The Committee had reason to believe that “in some branches of manufacture, the limits of a beneficial economy appeared to have been nearly reached, and that in other cases a gradual effort would continue to be made for saving fuel.” It may be assumed, therefore, that the progress of economy in using coal is not likely to operate in future with greater effect in keeping down the increase of consumption than it has hitherto done.

‘The present consumption of coal for domestic use is generally estimated at one ton per head of the whole population, and may be assumed to absorb nearly one third of the entire production. It is probable that this rate per head will continue pretty constant; because, although more economical methods of using coal in dwellings may probably be introduced, yet the increasing wealth of the nation will cause coal to be more liberally used for domestic purposes. The future increase of consumption under this head may, therefore, be expected to coincide with the increase of the population.

‘As regards the future exportation of coal, although a very large increase has taken place within the period embraced by the preceding Table, yet there is reason to doubt whether much further increase will take place in this direction. Upon this point Committee E have reported that the probable development of the enormous coal-fields of North America, and those of India, China, Japan, and other countries, and the more effective working of the known coal-fields of Europe, will probably prevent any considerable increase in the future exportation of British coal.

‘The large increase which, in recent years, has taken place in the consumption of coal, has an intimate connection with the introduction and extension of the railway system, but for several years past the progress of railways has not been exceptionally great, and yet the consumption of coal has continued to increase with unabated rapidity.’

‘Professor Jevons, in a work “On the Coal Question,” which first appeared in 1865, and which was in a great measure founded upon a previous work by Mr. Hull on the Coal-fields of Great Britain, estimated that the rate of growth at that period in the aggregate annual consumption of coal amounted to about three and a half per cent. per annum, reckoning each annual percentage on the previous year’s consumption. He contended that coal, being the source of power, and required for every great

¹ Previously to 1867 no reliable return of the coal sent to Ireland can be obtained; therefore, for the years before that date two million tons have been taken as the estimated quantity.

² This is the quantity given in their evidence by the colliery inspectors. The Mining Record Office has not been able to complete its computation.

³ Estimated.

extension of industry, the consumption of it would keep pace with the progress of population and industry.

‘He further showed that a continuance of the same progress in population and productive industry would lead to an annual consumption of no less than 2,607,000,000 tons of coal at the end of a century. Upon this assumed rate of increase, the whole quantity of coal which we have reported as available in this country would be exhausted in 110 years.

‘But although Mr. Jevons’s theory has, up to this time, nearly accorded with observation, yet the results involved in the supposition that the annual percentage of increase in the consumption of coal will continue unabated for a very lengthened period are so prodigious that very few persons will be found to accept his theory without considerable qualifications.

‘It had been suggested by Mr. Price Williams, who gave great attention to questions of this kind, that Mr. Jevons’s conclusions at all events require modification to meet the fact, that although the population of this kingdom has long been and still is rapidly increasing, yet the *rate* of its annual growth is *diminishing*.

‘From the year 1811 to 1821, the increase was 16 per cent., while in the last decade, from 1861 to 1871, it was $11\frac{3}{4}$ per cent.

Mr. Price Williams constructed a Table, of which the following is an abstract, showing how the *Average Diminution* of the *Decennial Rate of Increase* of the *Population* is obtained:—

Year	Population of Great Britain	Rate of Increase per 10 years	Diminution of Rate per cent.
1811	12,338,573	15·977	
1821	14,309,989	15·008	— 6·065
1831	16,457,596	13·549	— 9·721
1841	18,687,537	12·249	— 9·595
1851	20,976,532	11·197	— 8·588
1861	23,325,305	11·736	+ 4·814
1871	26,062,721	...	—33·969 + 4·814
			5) —29·155
Average diminution of rate for 10 years . . .			— 5·831

Computing, from this and another Table constructed by Mr. Price Williams, the Commissioners arrived at the following conclusions:—

The total available coal in the United Kingdom was estimated at 146,480,000,000 of tons. Then, according to the views entertained, the annual consumption of coal at the end of a hundred years would be 274,000,000 of tons. A further conclusion was that, the now estimated quantity of coal available for use would upon this view represent a consumption of 360 years.

It will of course be observed that, assuming the rate of increased consumption as above, there would be a nearly corresponding increase in the products of manufacturing industry, and the figures representing such an increase would raise questions as difficult and problematical as those raised by the assumption of a population of 131,000,000 360 years hence.

The Commission then give a calculation founded upon arithmetical instead of geometrical increase in the rate of consumption of coal, that is to say:—they discard the principle of an increase in the nature of a per-centage on the previous quantity, and simply add a constant quantity equal to the average annual increase of the last fourteen years, which may be taken at 3,000,000 of tons.

Upon this basis we arrive at the following results, namely, at the end of a hundred years the consumption would be 415,000,000 of tons per annum, and the now estimated quantity of coal available for use would represent a consumption of 276 years.

There was yet another view considered. It was that the population of the whole country and the consumption of coal per head remained constant or merely oscillated without advancing. Then our available coal would represent a consumption of upwards of 1,273 years at the rate of 115,000,000 of tons per annum.

The Commissioners proceed to advert to the large amount of coal excluded from our previous estimates on the ground of excessive depth. The quantity of coal lying

beneath the Permian and other newer strata at depths exceeding 4,000 feet is computed at upwards of 41,144,000,000, as appears by the following Table:—

Estimate of Quantities of Coal at Depths over 4,000 feet beneath the Permian, New Red, and other Strata.

Districts	Square Miles	From 4,000 to 6,000 feet	From 6,000 to 10,000 feet	Total in tons
		tons	tons	tons
Between Cannock Chase, Coalbrook Dale, and the North Staffordshire Coal-field, under the New Red Marl, &c., of Eccleshall, Stafford, Breewood, and High Olley	112	3,346,022,400	..	3,346,022,400
Southern borders of the North Staffordshire Coal-field	75	2,240,640,000	..	2,240,640,000
Plains of Cheshire, between the Denbighshire and North Staffordshire Coal-fields	340	11,850,496,000	11,850,496,000	23,700,992,000
Southern borders of the Lancashire Coal-field, and the country around Manchester and Stockport	208	6,904,490,667	3,452,245,333	10,356,736,000
The Wirrell, Mersey, and country to the north	108?	1,500,000,000	..	1,500,000,000
Total	843	29,341,649,067	15,302,741,333	41,144,300,400

Of this quantity it will be seen that more than 29,000,000,000 of tons are assumed to lie at depths of between 4,000 and 6,000 feet, at which latter depth the temperature of the earth, it is supposed, would be 150° F. The remainder, amounting to more than 15,000,000,000 of tons, is assumed to lie at depths varying between 6,000 and 10,000 feet, at which maximum depth the temperature of the earth, according to the prevailing views, would be 215° F., or three degrees above the temperature of boiling water at the sea level. To these quantities are to be added 7,320,000,000 of tons returned as being at greater depths than 4,000 feet within the area of the known coal-fields. Of this quantity probably 5,922,000,000 of tons lie between the limits of 4,000 and 6,000 feet in depth, and the remaining 1,397,000,000 of tons between 6,000 and 10,000 feet.

With these additions the total quantity of coal lying at depths exceeding 4,000 feet will be a little more than 48,465,000,000 of tons.

It is entirely a matter of conjecture whether any or what portion of this coal can ever be worked; but if we were to suppose the whole to become available, we should have to make the following corrections in the number of years' duration given above as the result of the different modes of viewing the question:—

1st. The 360 years would be altered to 433 years.

2nd. The 276 years based on an increasing consumption in arithmetical ratio would be altered to 324 years.

3rd. The 1,273 years computed on the supposition of non-increasing consumption would be altered to 1,695 years.

Whatever view may be taken of the question of duration of coal, the results will be subject to contingencies, which cannot in any degree be foreseen. On the one hand, the rate of consumption may be thrown back to any extent by adverse causes affecting our national prosperity; and on the other hand, new discoveries and developments in new directions may arise to produce a contrary effect upon the consumption of coal. Every hypothesis must be speculative, but it is certain that if the present rate of increase in the consumption of coal be indefinitely continued, even in an approximate degree, the progress towards the exhaustion of our coal will be very rapid.

The numbers given in the preceding Table (p. 838) are sufficiently consistent with each other to represent the changes which have taken place over a period of years.

We find the following differences in the number of the collieries in 1858 and 1868:—

	1858	1868
England	2,090	2,268
Wales	360	364
Scotland	417	433
Ireland	40	40
Total	2,907	3,105

The increase being 198 collieries in the ten years. In 1872 the number of collieries returned were 3,001.

With the view of showing at a glance the condition of our coal trade, the produc-

” ” ” 1869 ” .			14,639,684

Or we have an increase in ten years, that is, from 1859 to 1869, of 35,447,792 tons.

The quantity of coal produced in the years 1854 to 1869, both inclusive, amounts to 1,343,793,705 tons, which added to the quantity estimated as having been produced before 1859, namely, 2,850,000,000 tons, shows that up to the end of last year, (1872) we shall have drawn from our original stores of fuel not less than 4,300,000,000 of tons of coal.

FOREIGN COAL-FIELDS.

We have not yet arrived at the period when we could pronounce with any approach to certainty on the actual number of coal-basins in the world; the total number must, however, amount to at least from 250 to 300 principal coal-fields, and many of these are subdivided by the disturbed position of the strata into subordinate basins.

The basins or coal areas may be, however, grouped into a comparatively small number of districts, and even many of these are little known and not at all measured. The greater number occur in Western Europe and Eastern North America, while Central and Southern Africa, South America, and a large part of Asia, are almost without any trace of true carboniferous rocks.

The principal coal-fields of Europe, are those of Belgium, France, Spain (in the Asturias), Germany (on the Rhur and the Saar), Bohemia, Silesia, and Russia (on the Donetz).

BELGIUM.—The Belgian coal-field is the most important, and occupies two districts: that of Liège and that of Hainault, the former containing 100,000 and the latter 200,000 acres. In each the number of coal-seams is very considerable, but the beds are thin and so much disturbed as to require special modes of working. The quality of coal is very various, including one peculiar kind, the Flenu coal, unlike any found in Great Britain, except at Swansea. It burns rapidly with much flame and smoke, not giving out an intense heat, and having a somewhat disagreeable smell. There are nearly fifty seams of this coal in the Mons district. No iron has been found with the coal of Belgium.

Belgium is traversed, in a direction from nearly west-south-west to east-north-east, by a large zone of bituminous coal-formation. The entire region is generally described under two principal divisions:—

1. The western or Hainault division, comprising
 - a. The two basins known as Levant and Couchant of Mons. That of Charleroi.
 - b. The basin of Namur.
2. The eastern or Liège division.

The Quantities of Coal of different Qualities raised in Belgium¹ from 1859 to 1866.

¹ The Coal of Belgium is divided commercially into the following qualities:—*Maigre*, Lean Coal; *Sèche*, Dry Coal; and *Grasse*, Fat Coal. These kinds are again divided into *Gros*, picked large coal; *Tout Venant*, the remainder after the selection of the *Gros*, equivalent to 'through and through' coal; *Gaillette*, smaller than the *Gros*, but not less than six inches square; *Menu*, coal which passes through a sieve with 1½-inch meshes; *Gailletterie*, the coal which remains after the separation of the *Gaillette* and *Menu*.

NETHERLANDS.—There is only one coal-mine in Holland. It is situated in the province of Limburg.

FRANCE.—The most important coal-fields of France are those of the basin of Loire and those of St.-Etienne, which are the best known and largest, comprising about 50,000 acres. In this basin are eighteen beds of bituminous coal, and in the immediate neighbourhood several smaller basins containing anthracite. Other valuable localities are in Alsace, several in Burgundy worked by very deep pits, and of considerable extent; some in Auvergne with coal of various qualities; some in Languedoc and Provence with good coal; others at Aveyron; others at Limosin; and some in Normandy. Besides these, there are several others of smaller dimensions and less extent, whose resources have not yet been developed. The total area of coal in France has not been ascertained, but is probably not less than 2,000 square miles. The annual production in 1865, exceeded 11,000,000 tons. But the coal of France is of an inferior description; and, therefore, when good and strong coals are required, the supply is obtained from the English coal-fields. The mineral combustibles of France were estimated in 1864 by the Government engineers as follow:—

	Tons
Anthracites	800,000
Hard coal—short flame	1,400,000
Forging coal	600,000
Bituminous coal—long flame	4,000,000
Soft coal—long flame	3,000,000
Lignites	200,000
Total	10,000,000

The Rate of Increase in the Production of Coal from the French Coal-fields has been as follows, to the end of 1867:—

Years	Increase		Decrease		Another Return gives
	Tons	Tons	Tons	Tons	Tons
1847	5,065,109	...	1,047,234	...	5,061,183

¹ From Mons, Charleroi, Namur, Liège, &c.

² From Saarbrück and St.-Imbert, Prussia, and Rhenish Bavaria.

³ This Table has been compiled from the 'Statistique de l'Industrie Minérale,' which is issued in France about every five years by the Minister of Agriculture, Commerce, and Public Works, but has not appeared since 1867, and then the returns were to the end of 1864 only.

The metrical quintal of the original tables is taken at 220 lbs. avoirdupois, and the English ton at 2,240 lbs.

SPAIN.—Spain contains a large quantity of coal, both bituminous and anthracite. The richest beds are in Asturias, and the measures are so broken and altered as to be worked by almost vertical shafts through the beds themselves. In one place upwards of 11 distinct seams have been worked, the thickest of which is only 14 feet. The exact area is not known, but it has been estimated by a French engineer that about 12,000,000 of tons might be readily extracted from one property, without touching the portion existing at great depths. In several parts of the province the coal is now worked, and the measures seem to resemble those of the coal districts generally. The whole coal area is said to be the largest in Europe, presenting upwards of 100 workable seams, varying from 3 to 12 feet in thickness.

The Asturias Mining Company are working many mines in this region, and they are said to produce 400,000 tons annually, or to be capable of doing so. In Catalonia and in the Basque Provinces of Biscay there are found anthracite and bituminous coals.

In the Balearic Islands also coal exists.

PORTUGAL.—Beds of lignite and some anthracite are known to exist, but the production of either is small.

ITALY.—The principal coal-mines of Italy are in Savoy and near Genoa. In the Apennines some coal is found, and in the valley of the Po are large deposits of good lignite; and a small quantity of good coal is worked in Sardinia.

SWITZERLAND.—Coal has only been found in the cantons of Berne, Fribourg, and the Valais. Beds of anthracite coal are developed in the Central and Western Alps.

GERMANY.—The Germanic Union—the Zollverein—embraces the following principal coal-beds:—

- German States { Saxony.
Bavaria.
Duchy of Hesse.
- Prussian States { The Ruhr, in Westphalia.
Silesia.
Saarbrück, and provinces of the Bas Rhin.

The true coal of Prussian Silesia stretches for a distance of seventeen leagues. The most recent information we have been able to obtain as to its production would appear to give above 850,000 English tons. The coal-fields of Westphalia were described by Sedgwick and Murchison in 1840. The productive coal-beds are on the right bank of the Rhine, and possess many features in common with the English coal-fields. Bituminous coal, and lignite or brown coal occur extensively in some districts. The coal-basin of Saarbrück, a Rhenish province belonging to Prussia, has thus been described by Humboldt, chiefly from a communication received from M. Von Dechen:—

'The depth of the coal-measures at Mont St.-Gilles, Liège, I have estimated at 3,650 feet below the surface, and 3,250 feet below the sea level. The coal-basin at Mons lies fully 1,750 feet deeper. These depressions, however, are trifling when compared with that of the coal-strata of the Saar rivers (Saarbrück). After repeated trials, I have found that the lowest strata known in the county of Duttweiler, near Bettingen, north-eastward from Saarlouis, dip 19,406 feet, and 20,656 under the level of the sea.'

The coal of the *valley of the Glane* is bituminous, and of good quality; it is procurable at a depth of 112 feet, and the seam is about two feet in thickness: about 50,000 tons annually are produced from this valley. Coal is found in Würtemberg, but not much worked. In Saxony are extensive mines of bituminous coal; at Schonfeld, near Zwickau, the coal alternates with porphyry. Near Dresden a bituminous coal is also worked, and the coke manufactured from it is used in the metallurgical works at Freiberg.

Electoral Hesse produces little beyond lignite. In Hesse Cassel some bituminous coal is worked, but to a very inconsiderable extent. Real stone coal is only as yet produced in the county of Schaumburg. It is rich in beds of brown coal.

In the *Thuringerwald* or Thuringian forest some coal is produced.

The following is a list of the coal-basins of Germany and Austria, and their situations:—

The coal-pits of the most importance are in the Rhenish provinces and Westphalia, in the western parts of Prussia, as well as in the province of Silesia. Among the coal-basins there are three of importance: these are the basins of Upper Silesia, of the Ruhr, and the Saar. Two other basins, near Waldenburg, in Lower Silesia, and near Aix-la-Chapelle, in the Rhenish province, are less considerable. The basins of Wellin and Löbejun in the province of Saxony, and of Ibbenbüren in the northern part of Westphalia, are of less extent. There is also some coal mining, but inconsiderable, near Minden, on the Weser (in Weald clay), and near Löwenburg in Silesia.

The brown coal of most importance is found in the eastern part of the country; that is, in the provinces of Saxony and Brandenburg. There this lignite is exceedingly useful, as coals are excessively dear, owing to the cost of transporting them so great a distance.

The coal-pits of the river Ruhr extend over ten miles in length on the Lower Rhine. This country supplies almost half of the coal produce, and it sends supplies to Alsatia and Switzerland, to Bavaria and Thuringia, to Berlin and the seaports of the Hanseatic Towns, as well as to Holland.

The following, from an article on 'Westphalia and the Ruhr Basin,' by Mr. T. E. Cliffe Leslie, contains most valuable information :—¹

'Twenty years ago the Ruhr Basin was nowhere in the industrial race; now it produces nearly half as much coal as the great northern coal-field of England. Twenty years ago it had only just completed a single line of railway; now the basin is a network of branches, connecting not only the towns, but the principal manufactories and collieries with the three main lines which traverse it. The following figures show the rate at which the production of coal has advanced :—

Date	English tons ²	Date	English tons ²
1851	1,771,454	1860	4,276,254
1852	1,921,962	1861	4,964,621
1853	2,146,275	1862	5,701,201
1854	2,670,099	1863	6,300,981
1855	3,252,323	1864	8,146,433
1856	3,510,502	1865	9,276,685
1857	3,635,256	1866	9,329,503
1858	3,898,502	1867	10,526,015
1859	3,793,356		

'The immense increase of production shown in these figures is mainly attributable to the introduction of railways and the low charge for the carriage of coal. Down to 1851 the Ruhr and the Rhine were the only means of transport in districts beyond the immediate neighbourhood of the collieries, and the greater part of the coal was of an inferior kind, raised where it came to the surface by small collieries along the Ruhr. In 1851 the Cologne-Minden Railway came into use for the transport of coal, and led not only to deep-pit-sinking, and the discovery of seams of superior coal in other parts of the basin, but also to the establishment of ironworks and other manufactures, affording a local market for the coal. To this local market, down to 1859, it was in a great measure confined. In that year the charge for railway carriage of coal for long distances was reduced to one *pfennig* per *centner* (a fifth of a farthing per 100 lbs.) per German mile,³ and the above figures show the subsequent increase of production. The railways and coal-mines render each other reciprocal service; the carriage of Westphalian coal is now one of the most important branches of traffic on several of the chief Prussian lines, and the low rates at which it is carried enable it to find a distant market. The projected reduction of the rate for the transport of iron ore to the same tariff as that for coal, when carried into effect, will greatly augment the market for coal as well as for manufacture of iron. Until the last few years the Ruhr Basin excelled only in the manufacture of steel; but its iron manufactures are now of the highest quality.'

The Westphalian coal-field is stated to be at least 400 square miles in extent. The number of workable seams are from 60 to 80, and the average thickness of coal is about 200 feet. The coal is of good quality, as the analysis of Essen coal shows :—

Carbon 88·08, hydrogen 5·00, nitrogen 1·39, oxygen 3·12, sulphur 1·06, ashes 1·35 = 100.

Mr. Consul-General J. A. Crowe, in his 'Report on the Trade of the Rhenish Provinces and Westphalia,' gives the following :—

The coal-fields of the Ruhr extend over a surface of 115 square miles, and are supposed to contain 40,000,000,000 tons of fuel. They are comprised chiefly in the Government districts of Duisburg, Essen, Bochum, Dortmund, and Hamm. The rapid increase of their production may be seen by a glance at the following Table :—

	British Tons
1855	3,252,223
1856	3,510,501
1857	3,635,256
1858	3,898,502

¹ Fortnightly Review, No. XXVII. March 1, 1869.

² The Prussian *Tonne* is a measure of capacity, and varies therefore in weight as applied to different articles—coal and iron, for example. The quantity of coal in a *Tonne* is about one-fifth of an English ton. In some of the reports in English blue-books the *Tonne* is translated 'ton,' which may mislead readers.

³ The German mile is about 4½ English miles.

Mr. Lowther in his Report remarks, 'The western parts of Prussia are so richly furnished with mineral fuels, particularly coals, that they do not depend for their supply on foreign countries, but rather give up a great part of their coal produce to the latter. The eastern provinces of the state have to look to the import of foreign coal, partly from Westphalia, partly from foreign countries.

'This is particularly the case with countries on the Baltic, which receive by sea coal cheaper from British harbours than from distant inland mining districts. The provinces of Saxony and Brandenburg, particularly when near the watercourses of the Elbe, receive important quantities of British coal and Bavarian brown coal, as well as great imports of coal by railway from the pits of Zwickau and Chemnitz in the neighbouring kingdom of Saxony; these pits are daily improving in extent and value.'

The coal production of Silesia was in 1871 much greater than anybody expected. It reached a height never previously attained, viz., 32,723,824 tonnen (about 5½ to an English ton), which is 4,403,767 tonnen, or 16,154,479 cwts. more than last year.

The importation of coal into Berlin amounted to—

1870.	2,697,043 tonnen	Silesian coal.	1871.	3,228,391 tonnen.
1870.	600,000	„ English coal.	1871.	1,160,919 „

This is an increase in one year of 531,348 tonnen Silesian coal, and 560,240 tonnen English coal, while during the five preceding years the importation amounted to—

Years	Silesian Coal	English Coal	English Coke
1869 . . . tonnen	1,965,927	689,952	77,386
1868 . . . tonnen	2,002,807	706,406	111,608

Increase	15,194,479

The quantity of coal raised in Prussia in 1872 was as follows :—

	Mines	People employed	Quantity Cwt.=50 kil	Value Thalers
Coal	428	140,544	590,473,512	85,118,828
Brown Coal	532	17,447	148,992,730	7,957,125

POLAND.—There are several coal-mines in Poland. The crown coal-mines produce about 1,000,000 sacks of $3\frac{1}{2}$ bushels. The coal-mines of the western district produce 8,000,000 lbs. per annum.

HUNGARY and other countries in the east of Europe contain true coal-measures of the carboniferous period; but the resources of these districts are not at present developed. The coal worked at Fünfkirchen, in Hungary, is of Liassic age. On the banks of the Donetz, in Russia, coal is worked to some extent, and is of excellent quality.

AUSTRIA.—Coal occurs in Styria, Carinthia, Dalmatia, the Tyrol, Moravia, Lombardy, and Venice; but 700,000 tons appears to be the maximum annual produce of the empire. The basin of Vienna, in Lower Austria, produces several varieties of coal, which belong to the brown coal of the Tertiary period.

The following Table gives the geographical position of coal now worked (1872), and the estimated production:—

Province	District	Principal mines	Coal	Brown Coal

The following statement of the productions and of the consumption of coal in Austria has recently been issued upon authority:—

Years	Coal produced	Coal consumed
	Tons	Tons
1848 to 1851	7,973,648	8,087,567
1852 ,, 1855	14,121,326	14,239,041
1856 ,, 1859	22,114,874	22,182,280
1860 ,, 1863	33,390,964	33,288,233
1864 ,, 1867	41,466,292	40,253,099
1868 ,, 1871	60,018,071	65,945,386

A considerable quantity of that reported as coal is lignite or brown coal, of which there are very large deposits in Austria.

SWEDEN.—Anthracite is found in small quantities at Dannemora; and bituminous coal, probably of Liassic or of oolitic age, is worked at Helsingborg, at the entrance of the Baltic.

DENMARK.—The island of Bornholm and some other islands belonging to Denmark produce coal, but it would appear to belong to the brown coal variety.

RUSSIA.—The Donetz coal-field is the most important. In that extensive district many good seams, according to Sir R. I. Murchison, of both bituminous and anthracitic coal exist.

TURKEY.—Coal is found bordering on the Carpathian mountains, in Servia, Roumelia, and Bulgaria.

The coal of Heraclea, on the south coast of the Black Sea, in Anatolia, has been, since the Crimean war, exciting much attention.

SMYRNA.—Moderately good coal is found at Nazli near Olidin. There are other coal-mines of very inferior quality.

GREECE.—There is no coal, properly so called, known to exist in Greece, but lignite has been found in several places.

NORTH AMERICA.—The coal area of the United States of America,¹ is thus described by Professor C. H. Hitchcock, Hanover, N.H., U.S.A.

There are eight distinct areas of the Coal-measures in the United States. They are—(1.) The New England Basin. (2.) The Pennsylvania Anthracite. (3.) The Appalachian Basin. (4.) The Michigan Basin. (5.) The Illinois Basin. (6.) The Missouri Basin. (7.) The Texas Basin. (8.) Areas of unknown extent, probably inconsiderable, in the Rocky Mountain Region.

1. *The New England Basin.*—This is in Massachusetts and Rhode Island estimated to cover 750 square miles. The coal is a plumbaginous anthracite, used to advantage in some smelting furnaces. Perhaps eleven beds exist, best seen in Portsmouth, R.I. Their maximum thickness is 23 ft. The coal-measures are about 2,500 ft. thick.²

2. *The Pennsylvania Anthracite.*—This is the most important coal district in the United States. Including the Broad Top semi-anthracite, of 24 square miles, the five separate basins amount to 434 square miles. The measures are from 2,000 ft. to 3,000 ft. thick. The number of distinct beds varies from two to twenty-five, according to the depth of the basin. The maximum thickness at Pottsville is 207 ft., while the average cannot be far from 70 ft.³

3. *The Appalachian Basin.*—This occupies an area of 63,475 square miles, extending from Pennsylvania to Alabama, all of bituminous coal.

In Pennsylvania the area amounts to 12,222 square miles, with an average thickness of 40 ft. of coal. The aggregate thickness of the measures varies from 825 ft. to 2,535 ft.³

In Maryland the area is 550 square miles, in three separate basins. The strata are 1,500 ft. thick. There are thirty-two beds of coal, one of 14 ft., three of 6 ft. each, and the others from 1 ft. to 5 ft.⁴

In West Virginia (with a little in Virginia) the coal area occupies 16,000 square miles. On the Kanawha River the strata are 1,250 ft. thick, with twenty-four beds of coal, of which eleven have an aggregate thickness of 51 ft. The coals are best developed along this river.⁵

In Ohio Dr. J. S. Newberry mentions that the area is greater than 10,000 square miles, with a thickness of 1,500 ft. of sediment, and ten workable beds of coal.

In Eastern Kentucky the area is stated to be 10,000 square miles.⁵

In Tennessee the area of the measures is 5,100 square miles. A characteristic section gives a thickness of 578 ft. There are seven beds of coal, with a total thickness of 14 ft. The beds vary locally in their dimensions, more than has been reported elsewhere; perhaps more carefully explored.⁶ The conviction is increasing among American geologists that coal-beds are not evenly persistent on large areas, and constantly vary in thickness.

In Georgia the area cannot be more than 170 square miles.

In Alabama, a hasty measurement of a map furnished in manuscript by Professor Safford indicates an area of 9,000 square miles. The general character of the measures must be like those of Tennessee.

4. *The Michigan Basin.*—The area is about 6,700 square miles, with 123 ft. thickness of measures, and 11 ft. (maximum) of coal. In the centre the coal is thickest, thinning out to a mere line around the edges.⁷

⁶ 'Geology of Michigan,' 1861, by A. Winchell.

⁷ 'Final Report on the Geology of Illinois,' by A. H. Worthen.

5. *The Illinois Basin.*—This occupies an area of 51,700 square miles, including Illinois, Indiana, and Western Kentucky.

In Illinois the measures occupy an area of 41,500 square miles, are from 600 ft. to 2,500 ft. thick, and contain ten beds of coal, with an aggregate thickness of 35 ft.¹

In Indiana the measures occupy an area of 6,500 square miles, are 650 ft. thick, and contain thirteen beds of coal, with an aggregate thickness of 31 ft.¹

In Western Kentucky¹ the measures are 612 ft. thick, including the Millstone grit. They contain eleven beds of coal.

6. *The Missouri Basin.*—This is the largest of all the areas, comprising more than 100,000 square miles. It is also reached by several navigable rivers. It extends from Iowa to Texas. It is separated from the Texas field only by cretaceous beds, which probably overlie coal-beds continuous from one basin to the other.

In Iowa,² Professor White's late map shows an area of about 25,000 square miles of coal-measures. He has divided the group into three divisions, each about 200 ft. The two lower ones contain the workable coal, which amounts to 8 ft. in the second, and only 20 in. in the upper division. As the lower divisions everywhere pass under the higher, the whole area may be regarded as productive.

Nebraska contains 3,600 square miles of the Upper Coal-Measures, according to map in 'Final Report upon the Geology of Nebraska,' by F. V. Hayden.

In Missouri (private communication) Professor G. C. Swallow estimates the coal area at 27,000 square miles, and in Kansas at 17,000 square miles. The measures are 2,000 ft. thick, carrying twenty coal-beds, from a few inches to 6 ft. thick.

In Arkansas, Dr. D. D. Owen³ describes two coal-beds, the thickest 5 ft. thick, and very valuable. The area is stated to be 12,000 square miles. The coal, however, underlies the conglomerate, and does not belong to the true coal-measures.

Scarcely anything is known of the coal in Indian territory. From the map, the area must be as great as that of Arkansas. I am assured by the officers of the Missouri, Kansas, and Texas Railway that they find good beds of coal all through the territory near their line of travel.

7. *The Texas Basin.*—This is barely separable from the preceding. Dr. B. F. Shumard⁴ estimated the coal area at 5,000 square miles. A. B. Roessler⁵ estimates the same at 6,000 square miles. Beds of good coal are reported at Fort Bilknope, 4 ft. in thickness.

8. Mr. G. K. Gilbert,⁶ of the expedition under the immediate direction of Lieut. George M. Wheeler, reports coal near Camp Apache, in Arizona. Carboniferous strata are known in many places in the mountainous territories, and valuable discoveries of coal may be looked for among them at no distant day.

The total coal area as thus described amounts to 230,659 square miles. No notice is to be taken of any coals which do not belong to the Carboniferous system. There are many others of commercial importance, as the Triassic of Virginia, the Cretaceous of the territories west of the Missouri River, an immense amount in California, Alaska, &c.

These facts will afford data for those who are interested in estimating the amount of coal in different countries by the number of cubic miles or tons. The statements are too brief to permit any notice of the best or of the inferior coal.

The anthracite coal-fields of Pennsylvania are divided into three great districts, viz.: 1st, Southern or Schuylkill district, embracing the Lehigh and Lykens valley coal; 2nd, the Middle district, embracing the Beaver Meadow, Shamokin and Trevorton coal; the 3rd, Northern or Wyoming and Lackawanna, embracing the Scranton, Pittston and Lackawanna coals.

Produce of these districts from 1858 to 1863.

Years	Schuylkill District	Middle District	Wyoming District	Total
	tons	tons	tons	tons
1858	3,212,879	909,000	2,186,094	6,524,838
1859	3,598,531	1,050,659	2,731,236	7,517,516
1860	3,815,822	1,091,032	2,856,896	8,059,017
1861	3,114,254	994,705	2,918,458	7,487,672
1862	3,549,844	396,227	3,130,887	7,640,905
1863	4,151,882	609,548	3,760,374	9,420,135

⁶ Official Report.

Total produce of Pennsylvania in 1864 :—

	Tons
Anthracite districts	9,876,174
Broad top and semi-anthracite	422,992
Bituminous districts	2,399,246
Total	12,698,412

Coal product of the Loyal United States, year ending June 1864, from the returns made to the Internal Review Department :—

	Tons		Tons
Rhode Island	3,656	Indiana	146,787
Pennsylvania	12,698,412	Illinois	925,293
Maryland	787,269	Michigan	16,296
District Columbia	742	Minnesota	50,204
Western Virginia	398,815	Kansas	236
Kentucky	91,036	California	44,938
Missouri	66,187	Washington Territory	7,754
Ohio	1,324,685	Total	16,472,410

The following summary of the condition of the American coal trade in 1871 is of interest :—

The quantity of anthracite coal sent to market during the year 1871 is returned officially at 14,965,501 tons, and the quantity consumed in the coal regions is estimated at 2,720,000 tons. The quantity of bituminous coal sent towards the seaboard, including 443,955 tons imported, is returned officially at 4,894,914 tons, and the quantity of bituminous mined and consumed in the United States, but not at present returned in the official tables, is estimated unofficially at 11,500,000 tons. The aggregate production of the year thus comes out at 34,081,415 tons, of which all but 269,751 tons exported, was retained as the supply of the Republic for the year. At this rate the average coal production of each American amounted last year to about 17 cwts. per head, while in 1869 the average coal production of each inhabitant of the United Kingdom was as nearly as possible 3½ tons per head. It is clear from this comparison, that, great as the coal wealth of the United States is supposed to be, American coal-mining is still in its infancy; while the corresponding branch of industry has been carried on in Great Britain to an extraordinary development. The openings for human effort are so numerous in the United States, that no very large amount of the population can be induced to apply themselves to mining industry—at any rate at present; and hence the average coal extraction of the United States per head of the population is only about one-fourth of the corresponding extraction in Great Britain. Far-seeing and thoughtful minds may come to the conclusion that, after all, there is no very great ground for national complacency, at the results brought out by the comparison, since it may be argued that we are rapidly working up our coal supplies, while the Americans are husbanding theirs. It should, perhaps, be remarked that we have accepted the American statistics as to the American coal trade as they have come upon our hands. At the same time it cannot be denied that they are characterised by great vagueness, one-third of the whole total of 34,081,415 tons being derived from unofficial estimates.

Although the returns are fairly open to the imputation of vagueness, and uncertainty as a whole, they are tolerably conclusive and satisfactory, however, as respects the anthracite coal production of the United States. The total of 14,965,501 tons already given as representing this production in 1871, compares with 15,274,029 tons, the production of 1870; so that the extraction fell off in 1871 to the extent of 308,528 tons—a result attributable, we presume, to the prolonged and troublesome strikes which prevailed last year in the Pennsylvania coal regions. The two totals of 14,965,501 tons and 15,274,029 tons include the semi-anthracite production of the Lykens Valley in each year, and they were made up as follow :—

	1870 tons	1871 tons
Schuylkill, Columbia, &c.	3,720,403	5,124,780
Northumberland	486,174	628,866
Wyoming	7,554,909	6,481,171
Lehigh	2,990,878	2,249,356
Lykens Valley (semi-anthracite)	521,665	481,328
Total	15,274,029	14,965,501

It will be observed that there was a considerable increase in the production of the Schuylkill region last year, while the extraction fell off in the Wyoming and Lehigh regions: the general result being a decline of 308,528 tons in the last year, as compared with 1870. During the ten years ending with 1871, inclusive, the production of anthracite coal in the Schuylkill, the Wyoming and the Lehigh regions appears to have been as follows:—

Year	Schuylkill	Wyoming	Lehigh
1862	2,890,598	3,145,770	1,351,054
1863	3,443,265	3,759,610	1,984,713
1864	3,642,218	3,960,836	2,054,669
1865	3,735,802	3,256,658	1,822,535
1866	4,633,487	3,736,616	2,128,867
1867	4,334,820	5,328,322	2,062,446
1868	4,414,356	5,990,813	2,507,582
1869	4,748,960	6,068,395	1,929,583
1870	3,720,403	7,554,909	2,990,878
1871	5,124,780	6,481,171	2,249,356

The aggregate extraction of each year will, however, illustrate more conclusively the progress which has been made. The figures come out as follow:—

Years	Tons	Years	Tons
1862	7,387,422	1867	11,725,588
1863	9,187,588	1868	12,912,751
1864	9,657,723	1869	12,746,938
1865	8,814,995	1870	14,266,190
1866	10,498,970	1871	13,855,307

It will be observed that the production very nearly doubled itself during ten years. It would, probably, have completely doubled itself but for the strike troubles of last year. In this current 1872 it is expected that the ground lost last year will be more than recovered; and that the progress realised will be considerable, as the aspect of the labour market has become more settled. Provision has also been made for an arbitration and conciliation tribunal to adjust any difficulties which may present themselves.

BRITISH AMERICA contains coal in the provinces of New Brunswick and Nova Scotia. The former presents three coal-fields, occupying in all, no less than 8,000 square miles; the latter exhibits several very distinct localities where coal abounds. The New Brunswick coal-measures include not only shales and sandstones, as is usual with such deposits, but bands of lignite impregnated with various copper ores, and coated by green carbonate of copper. The coal is generally in thin seams lying horizontally. It is chiefly or entirely bituminous.

NOVA SCOTIA possesses three coal regions, of which the Northern presents a total thickness of no less than 14,570 feet of measures, having 70 seams whose aggregate magnitude is only 44 feet, the thickest beds being less than four feet. The Pictou or central district has a thickness of 7,590 feet of strata, but the coal is far more abundant, one seam measuring nearly 30 feet; and part of the coal being of excellent quality and adapted for steam purposes. The southern area is of less importance. Besides the Nova Scotia coal-fields, there are three others at Cape Breton, yielding different kinds of coal, of which one, the Sydney coal, is admirably adapted for domestic purposes. There are here 14 seams about 3 feet thick, one being 11, and one 9 feet.

The areas of these coal-fields are respectively:—

Nova Scotia	Square miles
Cape Breton, Sydney District	2,500
„ Boularderie	250
„ South coal-field	104
„	180
Prince Edward's Island	5,000
Newfoundland	

The production of coal in Nova Scotia in the year 1865 to 1870 was as given in the following Table:—

Places	1866, Year ending September 30		1868, Year ending September 30		1869, Year ending September 30	
	Round	Slack	Round	Slack	Round	Slack
	tons	tons	tons	tons	tons	tons

Victoria	271
Total	504,756	63,520	616,329	69,584

BRITISH COLUMBIA.—The following is the report of Mr. Hilary Bauerman in 1860 :
Two seams of coal, averaging six to eight feet each in thickness, occur and are extensively worked for the supply of steamers plying between Victoria and Frazer's River.

The coal is a soft black lignite, of a dull earthy fracture, interspersed with small lenticular bands of a bright crystalline coal, and resembles some of the duller varieties of coal produced in the South Derbyshire and other central coal-fields in England.

In some places it exhibits the peculiar jointed structure, causing it to split into long prisms, observable in the brown coal of Bohemia.

For economic purposes these beds are very valuable. The coal burns very freely, and yields a light pulverulent ash, giving a very small amount of slag and clinker.

NEWFOUNDLAND COAL-FIELD.—This field is estimated at about 5,000 square miles. According to Mr. Jukes, formerly Director of the Geological Survey in Ireland, the entire western side of the island, along a space of 356 miles in breadth, is occupied by secondary and carboniferous rocks. The coal on the south-western point of the island has been traced at intervals along a space of 150 to 200 miles to the north-east.

GREENLAND.—Captain Scoresby discovered a regular coal-formation here. At Hasen Island, lignite or brown coal has been found, and also at Disco Island on the western coast.

ARCTIC OCEAN.—At Ryam Martin's Island coal-formations exist, and at Melville Island several varieties of coal have been discovered, much of it being of an anthracitic or of a semi-anthracitic character. We learn that at Prince Regent's Inlet indications of coal have been observed.

RUSSIAN AMERICA.—Beyond the Icy Cape and at Point Barrow coal was observed on the beach; and it has been found by digging but a few feet below the surface at Point Franklin.

OREGON TERRITORY.—Coal has been discovered and worked in Wallamette valley, nearly 100 miles above Oregon City; and anthracite has been observed by Sir George Simpson about 30 miles up one of the tributaries of the Columbia river.

UNITED STATES OF COLOMBIA.—Immense deposits of cannel coal have been discovered in the Province Rio Hacha.

CALIFORNIA.—Colonel Fremont states that a coal-formation exists in Upper California, north lat. 41½°, and west long. 107½°:—'The position of this coal-formation is in the centre of the Rocky Mountain chain, and its elevation is 820 feet above the

level of the sea. In some of the coal-seams the coal did not appear to be perfectly mineralised, and in others it was compact and remarkably lustrous.—*Fremont's Report, 1843.*

In 1847 a coal-mine was discovered near San Luis Obispo, North lat. 35°. There are three coal-mines within 300 miles of Monterey.

MEXICO.—On Salado river coal is worked by an American company. A coal-formation 50 miles in breadth crosses the Rio Grande from Texas into Mexico at Laredo; and on the Mexican shore, within 200 yards of the Rio Grande, a remarkably fine vein of coal 8 feet thick occurs.

TEXAS.—Coal is known to exist in Texas, though the country has not been geologically examined. The 'Trinity Coal and Mining Company' was incorporated by the Texan Congress in 1840, who worked both anthracite and a semi-bituminous coal. Kennedy in his work 'Texas, its Geography, &c.,' says 'Coal, both anthracite and bituminous, abounds from the Trinity River to the Rio Grande.'

SOUTH AMERICA.—In the Republic of New Granada, especially at Santa Fé de Bogotá, coal occurs: also in the island of Santa Clara, and brown coal in the province of Panama.

VENEZUELA is said to contain coal, but whether brown or bituminous does not appear certain.

PERU appears to possess some coal, but a fossil charcoal of considerable value is more abundant.

CHILE.—The coal of this district has been examined by many American engineers, and by Captains Fitzroy and Beechy and Mr. Darwin. In 1844 upwards of 20 coal-mines were open in the neighbourhood of Concepcion. At Tuleahnano a new seam of 4½ feet was proved. The coal is described by W. R. Johnson as, 'in external appearance nearly related to many of the richest bituminous coals of America and Europe;' and Mr. Wheelwright, in his report on the mines and coal of Chili, says, 'in fact, the whole southern country is nothing but a mine of coal.'

BRAZIL does not possess much coal of value.

The following communications from John Miers, Esq., F.R.S. and from N. Plant, Esq., give all that is known respecting the two coal-fields of Brazil:—

'The coal-mine for which the Visconde de Barbacena obtained a privilege is in the province of Sta. Catherina, where extensive deposits are found in a district near the junction of two small rivers flowing from the Serragerul de Sta. Catherina, and which unite to form the Rio Tuberao, which runs eastward for about 70 miles, when it enters the Lake of Laguna, in lat. 28° 23' S. The lake or bay is sufficiently deep and capacious, and is available for sea-going vessels with a draft of 11 feet, which is the depth of water over the bar in its mouth. The Rio Tuberao is navigable by vessels of that capacity as far as Piedade, which is 27 miles from the point of its entrance into the bay; but above that distance the river is only navigable by smaller craft for a few miles; so that Piedade will be the shipping port for the coal, which will have to be conveyed by a tramway from the mine, 45 miles long, along a course nearly due east and west, upon a gentle gradient. At that distance no less than 20 different sites have been seen on both sides of the Tuberao where the coal deposits crop out, the river running over several beds. This district is situated in a beautiful and well-wooded country, about 880 English feet above the level of the sea, and upon the northern flanks of the Morro de Sta. Martha or de Congouhas, a spur of the main serra that extends for a long distance parallel with the coast. This spur runs eastward, and terminates at a point 4 leagues south of Laguna. This coal-formation is evidently of considerable extent, for similar deposits are found on the southern flanks of the same spur, near the sources of the Rio Araranguá, which runs eastward, and falls into the ocean in lat. 28° 48' S., and which is navigable for a distance of 20 miles to Tresportes, where it is broad and deep. The Visconde de Barbacena's mining ground is on the Rio Bonito, an affluent of the Tuberao, where the coal shows itself wherever the surface of the hills has become denuded by gullies formed by springs, presenting cliffs, 40 feet high. Here the coal-deposits are visible to a depth of from 10 to 14 feet, and these are covered by a roofing of hard sandstone 20 feet deep. Immediately below the upper bed is another layer of coal 6 inches deep; then a stratum of greyish schist with fossil vegetable remains, succeeded by a bed of good solid coal 8 feet thick; then a layer of black schist, and another bed of coal 1 foot thick. How much deeper these beds may be is unknown, as the ground has not been bored; but it is probable that deep beds of more valuable coal exist. There is, however, a sufficient store above ground to admit of extensive workings without the necessity of sinking shafts, or of the ordinary expense of raising the coal to the surface by means of steam machinery. The existence of a thick sandstone roofing, containing vegetable impressions, offers good promise as regards this coal-formation. The samples exhibited in the Paris Exhibition brought from this mine were much broken by long carriage, but they showed a tolerably bright coal,

of a very laminated structure, with indications of pyrites scarcely visible; but it is not unlikely that seams yet undiscovered may elicit a coal of a still better quality.

'The second sample of Brazilian coal exhibited in Paris was scarcely equal in quality to the former, and seemingly was more slaty and more charged with pyrites. This was brought from a mine in the province of Rio Grande do Sul, which has been scantily worked for several years, but hitherto with little encouragement. It is situated on the Arroyo dos Ratos, a small stream that runs into the Rio Jacuahy, about half a league distant from Saõ Jeronymo, which is near 16 leagues to the westward of Porto Alegre, the capital of the province, and which has an excellent water conveyance between it and the seaport town of Rio Grande; but with all the advantages of easy transport, the coal has not been able to obtain a good reputation among the owners of the numerous steam vessels that are constantly plying between the places above mentioned, for which traffic English coal, notwithstanding its high price, is also preferred.

'There is another extensive deposit of coal in the same province, and which is said to be a coal of very good quality; but its distance, too far inland, and the want of water conveyance, are said to be great obstacles against the probable success of any attempt to work it in the present state of the country. Mr. N. Plant thus describes them:—

'The only localities on the eastern coast of South America, between the river Amazon and the river Plate, where the existence of coal has actually been determined are the two southern Brazilian provinces of Saõ Pedro do Rio Grande do Sul and Santa Catherina, and the neighbouring Republic of Banda Oriental, or Uruguay.

Lignite, brown coal, and bituminous schists, to which the name of "carvão de pedra," stone coal, has been applied in Brazil occur in thin beds along the coast and in the interior; but it is only in the two extreme southern provinces and the adjoining Republic of Uruguay that beds of bituminous coal containing palæozoic fossils have yet been discovered. Nor should I think it likely from the observations I have made during many years in nearly every province of the Brazilian Empire and the Republics of the River Plate, that coal of so early an age as even the lower oolitic rocks will ever be found in Brazil north of the province of Sta. Catherina, unless it be in the adjoining one of Paraná.

'In the province of Saõ Pedro do Rio Grande do Sul, three distinct coal-basins have been discovered, and the extent and thickness of the beds of coal to some degree determined. The district in which these coal-deposits are found is contained within the limits of latitude 30° and 32° and long. 51° and 54°. The basins are separated from each other by rolling hills of granite, syenite, and mica schist.

'The largest of these coal-basins is perhaps that occupying the valleys of the rivers Jaguarao and Candiota, between lat. 31° and 32° and longitude 53° and 54°, called the Candiota coal-field. A detailed report of this appeared in the "Reports from Her Majesty's Secretary of Embassy and Legation respecting Coal, 1867." Along a line ranging from N.E. to S.W. the upper coal-beds of this deposit can be seen at intervals for about 50 miles, where the superincumbent sandstone has been denuded, or the strata worn through by streamlets, and the same may be observed from N.W. to S.E. for about 30 miles.

'The falling away of one side of a hill some years ago on the banks of the River Candiota, near the basset-edge of the basin, laid bare five beds of coal, varying in thickness from 9 feet to 25 feet, giving 65 feet as the total thickness of coal exposed. The coal from the lower beds, which are also the thickest, is highly bituminous; but that from the upper is shaly and poor.

'The second basin lies in the valley of the Sta. Sepé, one of the tributaries of the River Jacuahy, in about lat. 30° 20' and long. 53° 30'. Two beds appear here, one of 7 feet and the other of 14 feet, which have been traced over an area of some 15 miles, and along the margins of other neighbouring streams. The coal in this deposit underlies sandstone, like that of Candiota.

'The third basin is near Saõ Jeronymo, a town on the banks of the River Jacuahy, in about lat. 30° and long. 51° 30'. This is the only coal-field being worked at the present moment on the eastern side of the Andes, on the South American continent. Although the beds of coal in this deposit are of less thickness than those of Candiota and Sta. Sepé, the nearness of the basin to the port of embarkation at the town of Saõ Jeronymo, which is only eight miles distant from the coal, renders the cost of land carriage very trifling, compared to what it would be from the other two fields, to a navigable river.

'Two shafts have been sunk in this basin to a bed of coal 6 feet thick, and a horse-way made into it, along which the coal is drawn to the surface. Borings have been made in different parts, by which it has been ascertained that the whole basin spreads over an area of about 20 miles, and that other beds of coal exist under the 6-foot seam.

'Owing to the want of miners and machinery to work this mine on a large scale, the average amount of coal being taken out at present does not exceed 200 tons per month, which is barely sufficient to supply the steamers navigating the River Jacuahy. This river falls into the Lago dos Patos, which has its outlet in the Atlantic Ocean at the scapout of Rio Grande do Sul. The coal is said to be as good for steam purposes as Newcastle coal, with the exception of leaving more ash.

'The coal-beds in the Republic of Banda Oriental are situated on the head waters of the river Negro, between lat. 31° and 32° , long. 54° and 55° , where they can be traced for several miles along the margins of the river and some of its tributaries; the beds vary in thickness from 3 to 6 feet.

'The coal-deposits actually determined and surveyed in the province of Sta. Catherina are at Boa Vista and at the river Tubarao, at "Passa-dous," between lat. 28° and 29° , long. 49° and 50° . Here beds of coal of considerable thickness can be seen along the margin of the river, and appear to extend over an area of several leagues, though the limits of the deposits have not yet been ascertained. The fossil plants found in this coal are of the same character as those found in the ironstone shales interstratifying the coal-beds on the River Candiota in the province of Rio Grande do Sul.

'Beds of bituminous schist extend over considerable areas at Missão da Corda, on the river Mearim, and in the valley of the river Itapicurú in the province of Maranhão, and, associated with lignite, it is found along the margin of the river Camaragibé in the province of Alagoas, also at the mouth of the river Camamú in Bahia, and in various parts of the province of Pernambuco. From experiments I have had made in England, these schists yielded from 15 to 20 per cent. of crude oil, though some specimens I saw in Pernambuco were so rich in oil as to readily ignite when applied to the flame of a candle.

'Lignite and brown coal are found in thin isolated beds in many places along the coast of Brazil, and in the provinces of Minas Geraes, Goyaz, and in the valleys of the Ribeira de Iguape and Tietê in São Paulo.'

THE WEST INDIAN ISLANDS.—Cuba, in the vicinity of Havannah, produces a kind of asphaltum much resembling coal, the analysis of which gives, carbon 34.97, volatile matter 63.00, ashes 2.03. At New Havannah a similar combustible is found; but it contains 71.84 of carbon. True coal does not appear to have been found in Jamaica. Sir H. de la Beche ('Trans. Geological Society of London'), describes three or four thin seams of coal imbedded in shale near the north-eastern extremity of the island.

BARBADOES.—Bitumen is found plentifully: and, on Grove Plantation estate, a good coal is stated to have been found.

TRINIDAD.—The pitch lake of this island is well known. Near it, and it is believed, extending under it, a true coal of superior quality is worked.

INDIA.—From the 'Memoirs of the Geological Survey of India,' we extract the following authentic information as to the coal resources of India:—

Coal Resources of India.

1. *Rajmahal Hills.*—In this district coal-deposits occur in many places. In the basin of the Brahmini, four or five seams are known, varying in thickness from 3 to 12 feet. In the valley of the Bansloi stream further north, several valuable beds of coal also occur, and in the Goomani Valley, and towards the north-western end of the range near Rorah. While the East Indian Railway was being constructed, many of these beds were worked; but since the opening of the line, very little has been done. This railway should have opened a trade from this coal-field to Calcutta.

2. *Raneegunge.*—This coal-field is at a distance of 120 to 160 miles N.W. of Calcutta; its greatest length being nearly E. and W. about 30 miles, and the greatest breadth nearly N. and S. about 18 miles. The area of coal-bearing rocks is about 500 square miles.

The coal of this field is a non-coking bituminous coal, composed of distinct laminæ of a bright jetty coal, and of a dull more earthy rock. The average amount of ash is some 14 or 15 per cent., varying from 8 to 25 per cent. The western end of the coal-field produces coking coal at Sanktoria.

The Raneegunge coal-field has the advantage of two branches of the Indian Railway, which traverse its richer portion. Professor Oldham has estimated that 14,000,000,000 tons are fairly obtainable from this coal-field.

3. *Kurhurbali.*—Situated north of the river Barakur, about 80 miles south of the Luckieseraï station of the East Indian Railway. Its greatest length is $6\frac{1}{2}$ miles; its breadth nowhere being more than $2\frac{3}{4}$ miles. There are several beds of good coal from 8 to 14 feet thick. The coal of Kurhurbali is of better quality than most of the

Indian coal, and is used for locomotives by the East Indian Railway Company, who have purchased the greater part of the field. After carefully excluding one-fourth for loss, waste, &c., it is estimated that 168,000,000 tons of coal remain in this field.

4. *Jherria*.—This coal-field extends along the valley of the Damudah river. Its greatest length is 21 miles, in an E. and W. direction; its maximum breadth is about 9 miles N. and S. Total area 200 square miles. It is roughly calculated that this field would yield 465,000,000 tons.

5. *Bokaro*.—This coal-field is but a mile west of the Jherria coal-field. It extends along the valley of the Damudah, forming a long narrow band of coal-bearing rocks of more than 40 miles from E. to W.; its breadth N. and S. never exceeding $7\frac{1}{2}$ miles. It is a poor coal, used only for brick and lime burning; but much has been raised and carted to Hazareebagh, and even to Gya. It is estimated that 1,500,000,000 tons of coal are in this field.

6. *Ramgurh*.—This small field occupies a triangular space. Near Ramgurh the breadth in a N. and S. direction is only a few hundred yards. It extends eastward about 12 miles, and at the eastern end expands to a breadth of 6 miles. Available coal 2,000,000 or 3,000,000 tons.

7. *Hoharo and Karunpoora*.—The field is of large extent, covering a surface of at least 450 square miles. The South Karunpoora field is thought to occupy 120 square miles. These fields are poor in coal, and what does occur is of inferior quality.

8. *Eetcoora*.—Near Eetcoora, to the N.W. of Hazareebagh, coal occurs of poor quality, but usable for brick and lime burning.

9. *Palamow*.—The principal fields of coal occur along the valley of the Damudah and its tributaries. The actual limits of the field have not been determined, but the district is poor in coal, and if worked it will be only to supply local demand.

10. *Singrowlie*.—Not far to the west of the village of Singhpur the colliery of Kotah has for years been known, and a fair amount of good coal has been produced. Coal exists in eight or nine localities, spreading over an area of about 40 miles in length from E. to W., and 20 in breadth from N. to S. No details can be obtained.

11. *Upper Sone*.—The prospects of any large amount of coal being available from this district are not good. Some thin seams, apparently unworkable, were noted by the Geological Survey in the Mahanuddy Valley, near the district of Bijragoogurh.

12. *Hutsoo or Chotteesgurh*.—Coal occurs in the Hutsoo near Koorba; in the Beeja Kurra, 25 miles N.W. of Koorba; and in the Labeled, a few miles further in the same direction. It is said to extend 200 yards along the bed of the former, and about a mile in the latter. Coal was also found in the Chornai stream, a tributary of the Hutsoo.

13. *Talcher*.—There is but little coal in this field, and that little poor in quality. The total area of the coal-bearing rocks in the field is not more than 10 square miles. 'These coal-fields, in conjunction with the reported coal-fields near Chanda, on the Wurda, and also the reported coal-fields in the vicinity of Sumbhulpur, will in a very few years become of far higher value than they are now.' *Oldham*.

This opinion appears to be founded on the probability of the formation of a line of railway from Calcutta to Bombay. The Nerbudda Coal and Iron Company have their works near Mopani, which are connected by a branch, fourteen miles in length, with the main line of the Great Indian Peninsular Railway. The coal does not appear to be of a high quality, but still it is of considerable local importance. Many small thin seams exist in several localities within Tawa Valley of the Nerbudda district, but they are unimportant.

14. *Pench River*.—Coal occurs at Sirgori village. One seam was more than 4 feet thick, and another seam 2 feet thick. (2.) Chenda or Digawani.—A seam with more than 12 feet of coal. (3.) Hurrye.—A seam; thickness unknown. (4.) Rawunwarra.—One seam with 5 feet 4 inches of coal. A second with more than three feet of coal. (5.) Parassia.—Above five feet of coal. (6.) Bhundaria.—Seam of 15 feet 2 inches, with more than 7 feet of good coal. (7.) Pootaria.—More than 5 feet of good coal. (8.) Burkoi.—About 6 feet of good coal. (9.) Gogri.—Six feet seam, with 5 feet of coal.

This coal-field is nearly 100 miles from Nagpoor; and this distance prevents any profitable working. Coal has only been raised from one seam, that at Burkoi. Since 1860 one colliery has been held on lease; but little has been done.

15. *Chanda*.—The existence of coal has been proved by boring, in the Wurdah Valley, and on the opposite side of the river. One or two sinkings have been commenced.

16. *Kota*.—Near Kota, on the Godavery, coal has been more than once reported.

17. *Cutch*.—The coal occurring at Cutch affords no hopes of proving valuable.

18. *Scinde*.—There is coal; but 'as a source of fuel it was utterly worthless.'

19. *Salt Range*.—The Salt Range may, therefore, in my opinion be rejected from

all calculation 'of the available supplies of good coal in India, excepting for immediately local demands, and for such common purposes as this inferior coal may suit.'

20. *Murree, &c.*—Patches of coal and lignite only.

21. *Darjeeling*.—Coal-bearing rocks near Punkabaree, at the foot of the Darjeeling Hills, and nests of coal and lignite.

22. *Assam*.—At Terap a minimum thickness of 5 feet of clean bright coal was seen. At Namchik, a tributary of the Deehing, within 200 feet in length, 3 thick beds of good sound coal were seen; one of them 8 feet in thickness. At Jaipur a seam of 17 feet occurs, of which 10 feet is a good coal. Several other seams exist; but from the inaccessible nature of the country it is not possible to obtain an approximate idea of the amount of fuel available. 'It can, however, be unhesitatingly asserted that this amount is very large and most valuable.'

23. *Khasi Hills*.—Good coal occurs, especially well adapted for making gas. Professor Oldham estimates the available coal of the Khasi Hills at 3,000,000 tons. 'It is not improbable that double this quantity will prove to be near the true amount.'

24. Coal-measures exist in the *Garo Hills*; but the Geological Survey failed to find any coal. At (25) *Cachar* small pockets of coal occur. Similar samples occur at (26) *Chittagong*. In the island of (27) *Cheduba* a lignite is met with.

28. *Burmah*.—In British Burmah no workable coal is known to occur. In Upper Burmah some irregular beds of inferior coal were examined by Dr. Oldham. 'They hold out no prospect of supplying anything more than a very local and limited demand, and even this with inferior fuel.'

29. *Tenasserim*.—'Beds of coal near Mergui, in the Tenasserim Provinces, were examined by Prof. Oldham in 1854. They hold out little prospect of affording a large supply, while the coal is of inferior quality.'

Coal Districts of India, with their Areas and estimated Coal Contents.

Places	Coal area in Square Miles	Estimated quantities of coal remaining
		Tons
1. Rajmahal Hills
2. Raneegunge	400	14,000,000,000
3. Kurhurbali	10	168,000,000
4. Jherria	200	465,000,000
5. Bokaro	100	1,500,000,000

Estimated total quantity of coal in the } areas estimated above }	1,320	16,142,000,000

According to the Report by Dr. Oldham, the Assam coal-field must be regarded as the most important amongst those of which the coal areas cannot be satisfactorily ascertained. The inaccessible nature of the country renders it impossible to obtain an approximation to the value of its coal-formations; and from its situation, supposing some local industry leads eventually to the development of its native resources, the coal of Assam can never come into competition with the fuel of other countries.

The Production of Coal in India from 1858 to 1866.

Compiled from Dr. Oldham's Report.

Name of Coal-field.	No. of Col- lieries	No. of Pits or Quarries	1858	1859	1860	1861	1862	1865	1864	1865	1866

Coal raised in India. The original returns are given in Bengal maunds = 40 seers each = 2,057 lbs. These have been brought into the English statute tons :—

Years	All India	Produce of Bengal	Production of other parts than Bengal
	Tons	Tons	Tons
1858	238,241
1859	374,379	368,960	5,419
1860	374,998	373,633	2,365
1861	289,120	288,336	784
1862	320,142	319,660	482
1863	354,203	352,036	2,167
1864	335,783	334,533	1,250
1865	327,517	326,312	1,205
1866	401,279	399,630	1,649

The above figures show that within the last nine years but little progress has been made in the development of the coal-fields of India. The coal-fields of Bengal are the only ones which have been worked in anything approaching to a systematic plan, and even in these there appears to have been a want of any well regulated method. There can be no doubt that, if there should spring up a large demand for native coal, there would speedily be an increased production of it. Still, since 1861, we have given us by Dr. Oldham, from the East Indian Railway's Deputy Agent, a return of the coal used on that line, which is as follows :—

	Tons	Tons
1861 . . .	36,711, leaving of coal raised in Bengal	251,625 for other uses.
1862 . . .	45,544	274,116
1863 . . .	68,063	283,973
1864 . . .	99,868	254,665
1865 . . .	104,739	221,573
1866 . . .	183,133	211,497

From this we see that as the locomotives of the railway have been burning more Indian coal, the increased supply from the Bengal collieries has not kept pace with

the demand, and in each year since 1863 there has been a steady decline in the quantity of native coal left to meet the requirements of the country.

Dr. Oldham tells us, 'That during the last eight years there has been an aggregate consumption of coal supplied for Bengal alone and the port of Calcutta, of more than 3,000,000 tons, of which about eight-ninths were raised in India, and about one-ninth imported; that there has on the whole been but little increase in the demand for coal during that period.'

Coal of India.

Years	Coal raised in all India	Coal raised in Bengal	Coal imported into Calcutta	Total consumption for Bengal
	Maunds	Maunds	Maunds	Maunds
1858	61,62,319	61,62,928		
1859	99,61,928	99,61,928	12,29,160	1,11,91,088
1860	1,00,88,113	1,00,88,113	4,96,585	1,05,84,698
1861	78,06,252	77,85,085	12,85,203	90,70,288
1862	86,43,843	86,30,843	6,76,687	93,07,530
1863	95,12,174	95,04,975	10,36,408	1,05,41,382

1867	1,18,61,031	1,18,47,178	11,46,734	1,29,93,912
1868	1,35,62,274	1,34,65,829 ¹	19,28,591	1,53,94,420

¹ The produce of Assam is included in this.

In Oude no coal is known to occur. In the Punjab no coal is known to occur, if we except as above, in the North-western Provinces, the patches of lignite which have been found in several localities along the base of the outer Himalaya, as well as in the Salt Range.

In Scinde the only coal raised was that of Synah Valley, as given above, but the irregularity and the small extent of this deposit has caused it to be abandoned. It was, in fact, an irregular patch of *lignite*.

In Bombay no coal is known to occur. In Hyderabad none. In Nagpore a small coal-field is known near to Muret, on the border of the Nerbudda District, which may, in fact, be considered a continuation (although actually separated) of the Nerbudda deposits. The coal is not now economised.

In Madras no coal is known. Coal has been more than once stated to occur on the Godavery, or some of its feeders, and even very recently; but as yet nothing but black shales, which will not support combustion, and which are, in all probability, of a totally different age from the coal-bearing rocks of India, have been met with.

Mr. Theo. W. H. Hughes in the Records of the Geological Survey of India, gives the following estimate of the area of the Indian coal-fields. He adds to it a general statement of other coal areas, which is retained, as it furnishes much information:—

Places	Area in square miles over which coal rocks may be presumed to extend	Remarks
India . . .	35,000	<i>This mileage is made up as follows:</i> Godávari area (including its affluents) 11,000 Son 8,000 Sirgújáh and Gangpúr area 4,500 Assam 3,000 Narbadá area (including its affluents) 3,500 Damúdá 2,000 Rájmahál area 300 Unsurveyed and uncomputed areas 2,700
United States . . .	500,000	Square miles 35,000 The productive area of coal is much less. Professor Hitchcock estimates the area of the true carboniferous system at 230,659 square miles.

Places	Area in square miles over which coal rocks may be presumed to extend	Remarks
China . . .	400,000	This estimate is not thoroughly reliable, but it is certain that there is an enormous coal-bearing area in China.
Australia . . .	240,000	In New South Wales the coal area is said to be 120,000 square miles. In Queensland the same area is supposed to exist.
British America.	18,000	
Great Britain . . .	12,000	Mr. Hull gives 5,431 square miles as being stored with coal to the depth of 4,000 feet.
Spain . . .	8,000	This estimate is vague; some authorities give 4,000 square miles, others 2,000.
Japan . . .	6,000	
Germany . . .	3,000	By Germany is meant all the German-speaking provinces, except those under Austrian rule.
France . . .	2,400	
Austria . . .	2,000	Some of the Austrian brown coals approach the Indian seams in thickness.
Belgium . . .	520	
Trinidad . . .	318	
Borneo	The coal of Labuan is reported to be of good quality, and very fair coal occurs in the Sarawak country.
Brazil	There are large coal-fields in this splendid country.
Cape Colonies	There is coal in this as in so many other dependencies of the English Crown.
Denmark	Only a small quantity of coal is raised in the island of Bornholm.
Falkland Islands	These islands contain coal.
Greece	Lignites have been worked at Koumi.
New Granada	The coal of this country is said to be cretaceous.
New Zealand	The calculated amount of coal in New Zealand is 4,000,000,000 tons.
Persia	A large area of coal is said to occur.
Portugal	A small coal-field exists near the mouth of the Douro.
Zambesi	This coal was brought to light by Livingstone.
Zanzibar	Some coal, said to be Zanzibar coal, was analysed by Mr. Tween, of the Geological Survey, and gave carbon 42·4, volatile matter 30·41, moisture 4 per cent., ash 27·2 = 100.

NEW SOUTH WALES.—Running down the rivers Bremer and Brisbane to the town of Brisbane, numerous outcrops of coal may be seen in the banks. Several works are situated about half way between Ipswich and Brisbane. This coal is of much importance to the steam navigation of Moreton Bay. In the parish of Maggil several collieries are established. 'The coal varies from five to six feet in thickness, dipping south forty degrees east, angle from seven to eight degrees, although not worked to its whole thickness, excepting where they wanted head room for the "horse way." The main coal separates from the top coal at about four feet; the two feet of the top coal is good, but mixed with a small quantity of earth.'—*Stuchbury.*

The following Table (p. 866) will show the number and condition of the collieries of New South Wales. The *Newcastle district* produces a good bituminous coal, useful for steam and household purposes, and also splint and cannel. The *Southern district* yields a semi-bituminous variety of good quality; and from the American creek in that district an abundance of petroleum is obtained. The *Western district* gives a superior splint coal, and oil shales in abundance.

List of Collieries and Kerosene and Shale Mines in New South Wales, with the Number of Persons employed, and Quantity of Mineral raised, in 1869.

Mines	Proprietors	Tons of Coal raised	Tons of Oil-coal and Shale raised	No. of people employed	Remarks
1. Borehole . . .	Australia Agricultural Company.	168,108	..	376

In 1872 there were 20 collieries raising coal, and 3 raising petroleum oil, cannel oil, and shale.

	Tons	Value
In the Newcastle District 7 collieries	producing 858,716	£73,561
Anvil Creek, Stony and Four Mile Creek District 4 collieries	24,032	4,449
Murrurundi District 1 colliery	300	600
Illawarra District 5 collieries	123,681	48,780
Lithgow Valley District 3 collieries	5,221	1,656
New South Wales Shale Oil Co.	8,000	24,000
Total Coal and Oil Shale	1,019,950	153,046

QUEENSLAND in 1863 exported 4,228 tons. The produce of the collieries being in 1861, 14,212 tons; in 1862, 24,067 tons; and in 1863, 2,400 tons.

Mr. R. Daintree, in his 'Notes on the Geology of the Colony of Queensland,' has the following remarks on the coal of that colony:—

'Up to the present time, within all the area occupied by Carbonaceous Mesozoic Strata, only the Maryborough beds have yielded fossil remains other than plants. On the tributaries of the Condamine, Brisbane, and Mary rivers, where numerous coal-seams are known to exist, several of which have been and are worked, the plant remains are of the same character.' Mr. Daintree then gives a list of the fossils from the Tivoli coal-mine, and then proceeds:—

'The Burrum coal-seams, worked for some time on a branch of the Mary river, lie below the Maryborough Cyprina-Sandstones. . . . Bars of coal are a marked feature in these Mesozoic lacustrine beds. . . . The appearance of these lacustrine coal-measures differs in a very marked manner from their supposed marine representatives to the westward. Coarse grits and thick-bedded sandstones form the majority of the strata, though shales, sandstones, and limestones are interstratified throughout the system.

'Whilst the affinities of the southern coal-field of Queensland are Mesozoic, a northern field of even larger extent has a distinct fauna more resembling the Palæozoic carboniferous of Europe. . . . The Dawson, Comet, McKenzie, and Bowen rivers drain this Carboniferous area, and numerous outcrops of coal have been observed on these streams. No commercial use, however, has yet been made of any of them, as the coal-measures, generally, are too far inland to be made available until the railway-system of the country is extended in that direction.'

NEW ZEALAND.—The hydrous coal-measures (lignite) lie on the eastern slopes of the axial rocks in both of the islands of New Zealand. This coal is of a brown colour, but hard and glossy, and frequently contains a quantity of fossil resin, which greatly facilitates its combustion. It is in the locality a valuable fuel, and is largely used both for domestic purposes and for raising steam. It is also applied to the manufacture of bricks and pottery, and for other economic purposes. The best known deposits of this coal in the North Island are those mined at Drury, twenty miles to the south of the city of Auckland. Seams of this coal, varying from 6 to 15 feet in thickness, occur at intervals over a large area of country. In the South Island the total quantity of this coal has been estimated at 100,000,000 tons. Two mines have been opened on this field. The Clutha mine is on the sea-coast, about three miles from the mouth of Clutha river. The other mine is in the vicinity of Tokomairo. The seam is 9 feet thick, and worked by a level in the side of a hill.

In 1864 the quantity of coal produced from the mines in this district was about 4,000 tons.

Anhydrous coal.—The most important development of the coal-seams of this class is on the west coast of the South Island. At Preservation Inlet, in the province of Otago, and at various points on the coast, the same formation occurs, but without any valuable seams of coal, as far as we yet know, until the Grey river is reached.

At Grey river the coal extends over an area which Dr. Haast has estimated at 15 miles in length by 6 in width. 'At present (1866) the output of the coal is from 250 to 300 tons per week, and is taken down the river in canoes and in 16-ton barges, and delivered alongside the vessels at 40s. per ton. It has been used to a large extent on board the steam-vessels that frequent the coast, and gives great satisfaction. A small quantity of this coal is also reported to have been tried in the Dunedin gas-works, and to have yielded a large quantity of illuminating gas.'

In the immediate neighbourhood of the Buller river the existence of workable coal-seams is considered certain over an area of at least 15 square miles. Reckoning none of the seams having a less thickness than five feet, there is a total of 38 feet of pure coal, and the quantity available in this one locality has been estimated at 200,000,000 tons. The following summary of the anhydrous coal is given in the report by Mr. Stafford to Lord Carnarvon:—

Locality	Quality of Coal	Thickness of Seam	Worked by
1. Grey River . . .	Superior	25 feet	Level free
2. Buller River . . .	Do.	38 "	Do.
3. West Wanganui . . .	Medium	8 "	Uncertain
4. Pakawan . . .	Do.	Uncertain	Do.
5. Aorere . . .	Superior	Do.	Level free
6. Batten River . . .	Medium	Do.	Do.
7. Wangapeka . . .	Do.	Do.	Do.
8. Wangarei . . .	Inferior	6 feet	Do.
9. Kawa-kawa . . .	Superior	13 "	Shaft

JAPAN.—The following are the only available notes on the coal-fields of Japan:—

Iwanai. Tomazi.—A bed of coal from four to six feet in thickness, consisting of very good *bituminous coal*, in places very pure, in others intermixed with slate, which is easily separated from it. The coal-mines lie two miles inland from a village called *Kaianoma*, some seven miles across the bay. Four seams of coal have been discovered: 2 are from 4 feet to 6 feet thick, 1 is about 1 foot thick, 1 not yet examined.

Seventy-nine pounds of coal burnt in the galley fire of Her Majesty's ship 'Salamis,'

under the superintendence of the chief engineer, yielded 17·27 per cent. of ash, 1·5 per cent. of clinker, an average volume of smoke, and a strong durable flame. The probable cost of the coal delivered would be four dollars the ton on the spot; freight to Hakodate would be three dollars the ton, and to Yokohama or Nagasaki six dollars the ton.

Coal-field near the Port of Hiogo.—Sir Harry S. Parkes communicates (1867) to the Foreign Office particulars of 'another coal-field in the immediate vicinity of the port of Hiogo,' from Mr. Frederick W. Sutton, Chief Engineer of H.M.S. 'Serpent.'

The coal is of tertiary formation, and it crops out in a number of places on the sides of a low range of hills, about six miles to the westward of Hiogo. These beds have been occasionally worked by the natives. In February 1867, 30 men were employed, and up to May they had obtained more than 170 tons of coal. Mr. Sutton says, 'the best coal brought out in my presence was quite equal to *Takasima* (Nagasaki) coal. It is not of exactly the same description, but more of an anthracite kind.'

There is no evidence of the value of this coal, and evidently the statement of the coal being of the tertiary age and of 'anthracite kind' wants consistency.

At a meeting of the Geological Society of London, April 14, 1869, a paper was read 'On the Coal-mines at Kaianoma, in the island of Yezo,' by F. O. Adams, Esq., Hon. Secretary of Legation in Japan: communicated by the Secretary of State for Foreign Affairs.

The writer states that the works at Kaianoma have made considerable progress since they were reported upon by Mr. Mitford last year. There are four seams of coal, each about seven feet thick, from 50 to 100 feet apart. A tunnel has been driven through one of the seams for a distance of between 150 and 250 feet, and at an elevation of 430 feet above the sea. From this the coal obtained is carried down to the shore on the backs of men, mules, and ponies. The writer adds, that there is abundance of coal 'of the cannel description.'

At the end of 1870, according to the 'Nagasaki Gazette,' the coal from Takasima, which has long been known to be a good coal, was ordered to be used by all steamers in the Japanese waters. The export of coal from Nagasaki has not increased of late, but this is referable to the want of ships to take it away. 1,174 tons have been shipped for, and several vessels were engaged in taking coal to China.

The Netherlands Trading Company are using the utmost energy in their efforts to develop this coal. These mines are managed by an English mining engineer, Mr. Frederick Potter. A large quantity of machinery, tools, &c. have been sent out from England, and a large steamer has been purchased for the entire use of the collieries.

The following information has recently (1874) been received from the colliery of Takasima:—'Our coal fossils here are oolitic. We have none of the coal-measure flora, but great stumps of trees, which the Japanese call "*matzi*," the name for Scotch fir, and which are no doubt coniferous woods. These hard stumps of trees give us great trouble in our working, it being impossible to cut through them with the pick. Only the islands are coal-measures, the main land being clay-slate with syenite ridges; and above the clay-slate, greenstone of the same age probably as the slate. We are now (December 1873) getting 350 tons a day, but are very short of men.'

BORNEO.—In the province of Labuan, on the north-west coast, there is abundance of coal of good quality. The seam is generally 9 feet in thickness. The coal found here burns fast, and emits a bright flame; it soon acquires a red heat, and continues in that state until it smoulders into a white ash, like that of wood; there is not much smoke from it. For several years past the coal-mines of Moara have ceased to be worked.

CHINA.—There appears to be much good coal in China. It is procured from a mine on the river Yang-tse-kiang, about 400 miles from its mouth; of the other coal-producing districts we know little.

Consul Braune in his report to Sir F. Bruce, says, writing from Tamsuy, January 21, 1864: 'It is to the coal-mines of Kelung that we must look to the future prosperity of this place as a port of trade; a depôt has been already established there by a large firm to supply their own steamer, running on the coast.'

In 1863 there were exported from the port of Tamsuy, in British vessels, 10,801 piculs of 133 lbs. avoirdupois; in foreign vessels, 1,259,152 cotties of 1 $\frac{3}{4}$ lb. avoirdupois; also from the port of Tien-tsin, 180 tons, value 1,800 taels, of 6s. 4 $\frac{1}{2}$ d. each.

Mr. Consul Mongan's report for 1864 on the trade of Tien-tsin, says: 'I allude to coal, extensive mines of which exist in the mountains to the north and west of Peking. It costs about 16s. per ton at the pit's mouth, and more than double this amount per ton is paid for transport to the coast; but the mines are worked in the rudest way, and the little coal which finds its way from the western range of Tien-tsin is conveyed on mules and camels from the mountains to Tang-chow on the Peiho,

and thence down the river in boats to this port. From the mines in the northern range, there is water communication of an indifferent kind to Tien-tsin, but the quality of their coal is much inferior to that which comes from the western mountains.

At the meeting of the British Association at Bradford (1873) Baron von Richthofen read a paper 'On the Distribution of Coal in China.' The Baron has devoted several years to the investigation of the geology, products, and resources of the interior provinces of China, and has traversed the whole country, with the exception of the south-western portions. He stated, as the result of his researches, that China exhibits the great peculiarity of containing no geological formation later than the Triassic; all the great secondary deposits, from the lias to the chalk, and all the Tertiary series being absent. It, has, therefore, been dry land throughout the whole period of these later formations; and to this peculiarity are owing the stupendous results of sub-aërial denudation which it furnishes; among which are the deep narrow gorges which its rivers have eroded nearly up to their sources, the rarity of cataracts and rapids, and the removal of rocks overlying the great coal-beds. The coal strata belonged to various geological epochs, from the Silurian upwards; but by far the greater portion belonged to the same formation as the coal of Europe and North America, viz., the Carboniferous. The coal-beds were deposited around mountains of metamorphic and primary rocks which then constituted the land, and have lain horizontally, with little disturbance, ever since that remote epoch. The deep ravines worn by the rivers cut through these coal-bearing strata, and lay them bare on the precipitous sides; so that the coal is easily accessible on the banks of the great streams. The author proceeded to describe the extent of the coal in each province, beginning with Southern Manchuria and terminating with Honan. In Manchuria the coal is confined to valleys in the hilly parts, and is not readily accessible to foreign commerce; it is accompanied, however, by an abundance of rich iron ore, which at some future date may be worked with immense advantage to the country. Coal exists further west all along the Great Wall; and there are beds 95 feet thick near Peking, in which city it is the fuel in universal use; but it is an error to suppose, as some have done, that the high hills round Peking consist of coal-measures; coal is found only in limited valleys at a great elevation. The coal of Shantung, although not situated near good harbours, is the most accessible of all Chinese coal from the sea. It exists also in the other maritime provinces, but in districts offering much fewer facilities. The greatest of all the coal districts is in the west and north-west; at the southern foot of the great mountain range (the eastern continuation of the Kuen-Lun), which here stretches across Western China. In Sze-chuen coal occupies an area of 100,000 square miles. At the centre of this vast basin the coal is bad and inaccessible, but round its borders it is of excellent quality, and near means of communication by water, although too distant from the sea to be available to foreigners. The whole surface of Northern China is covered by rich yellow earth, or *loess*, to a depth often of 1,000 and 2,000 feet, which overlies all the coal-fields. The great plain of China is bordered on the west by a vast limestone wall, 2,000 to 3,000 feet high, on the top of which extends a plateau of coal in a state of excellent preservation, owing to its capping of hard limestone which has resisted denudation. There are here 30,000 square miles of coal-bearing ground of the very best quality, in which the coal-beds lie perfectly horizontal, 30 feet thick, for a length of 200 miles. They extend westward into Shensi and Kansu, and are reported by all travellers to continue beyond the frontier of China far into Mongolia. Coal costs here, at the pit-mouth, 7*d.* per ton, and the wages of miners are 6*d.* per day. The Baron believed that the readiest way of getting at this vast coal-field from Europe was by a railway from Ili and Kulja, in Russian territory, to the north-western corner of Kansu.

SOUTH AFRICAN COAL-FIELD.—For the following account we are indebted to the Geographical Report on the Stormberg coal-field, made by Mr. E. J. Dunn, to the Governor of Cape Town:—

'In proceeding northward from Port Elizabeth to Dassykliip on Bushman's River the beds crossed appear to be of secondary age (Sunday River Beds) covered by tertiary and post-tertiary deposits, comprising calcareous beds, beds of red clay, and beds of clay conglomerate. At Dassykliip hard sandstone and quartz rock crop out. This series is passed at a distance of six miles north of Graham's Town. Between Katberg and Winchelsea beds of shale occur, and extensive dykes of dolerite traverse the country: most of the surrounding hills have a capping of igneous rock. These series of beds continuo as far as the Stormberg Mountains and from the base of that range 4,900 feet above the sea level. Above this, and forming the coal-measures, are the sandstones, shales, &c. of which the Stormberg Range consists. The coal-measures are composed of beds of sandstone, usually very thick, brown, grey, or white, in colour, frequently showing no traces of lamination through many feet in thickness.

'Sheets and dykes of igneous rock are of frequent occurrence over the whole area

occupied by the coal-measures. The general dip of the coal-measures is slightly to the north-east, but modified by the action of intrusive rocks.'

From the localities opened, the Government Reporter is enabled to give the description of the condition of the coal-field from which the following abstract has been made. At Vice's workings a shaft is sunk to a depth of 70 feet. It cuts the coal at 41 feet. The seam consists of alternate layers of coal and shale to a thickness of 3 feet 7 inches. Of coal there are 25 inches. The lower seam 13 inches thick is of poor quality. The middle one 9 inches thick is much superior, while the top 3½ inches is very inferior.

The coal is firm and hard, breaking out in good-sized blocks that do not readily break up in transport. It is laminated, splitting into thin layers; the faces of the layers are of a dull, earthy black colour, while the edges are lustrous. When burnt a good heat is given out, and the fire burns for a long time. The cinder is, however, very considerable, and retains the form of the fuel when first ignited. It does not fall into an ash. When burnt in a steam-engine or where a strong heat is induced, the result forms a pasty cinder.

Hattingh's workings are about one mile to the south-east of Vice's shaft, situate on the same seam. Of coal there are 24½ inches, with 3 partings of shale (15 inches) between the 4 layers. The third seam from the bottom, 6½ inches thick, is the best in quality.

At Kapok Kraal, about seven miles to the south-east of Burghersdorp there are 28 inches of coal in 4 seams, distributed through about 16 feet of shale, on the opposite side of the valley close to a neck where a trial has been made by means of a small shaft, there are two seams, one 16 inches, then 2 feet of shale and 9 inches of coal. Buckley's drive is opposite and about 300 feet above the hotel at the base of Bushman's Hoek. The outcrop of coal and shale is of very inferior quality, and about 3½ feet thick. About nine miles eastward from Dordrecht a seam of coal occurs 8 inches thick at November's Kraal, Tambookie Location. All the appearances are favourable to the presence of coal in this neighbourhood and throughout the district. Besides the above localities, the seam worked by Vice and Hattingh can be traced for miles along the hill sides. Numerous other outcrops are known, but they are not opened out.

Mr. Dunn says:—'There can be little doubt that more extensive deposits, and probably superior quality of coal, will be found further north and north-eastward (in Basutoland and Kafirland Proper, extending towards Natal).

For the Heating Power of British coal, see FUEL. For Coal Mining, see MINING.

COAL BRASS. This name is given to the iron pyrites (*bisulphide of iron*), found in the coal-measures, and which are employed in Yorkshire, and on the Tyne in the manufacture of copperas—the protosulphate of iron—and also in the alkali works, for the sulphur they contain. See SULPHUR ORES.

The iron ores called Brass, occurring in the coal-measures of South Wales, were particularly described by E. Chambers Nicholson and David S. Price, Ph. D., F.C.S., at the meeting of the British Association at Glasgow. Their remarks and analyses were as follow:—

'There are three kinds of ores to which the name brass is applied; they are considered to be an inferior class of ore, and are even rejected by some iron-masters. One is compact, heavy, and black, from the admixture of coaly matter, and exhibits, when broken, a coarsely pisiform fracture. A second is compact and crystalline, not unlike the darkest-coloured mountain limestone of South Wales in appearance. The third is similar in structure to the first-named variety; the granules, consisting of iron pyrites, are mixed with coaly matter, and cemented together by a mineral substance, similar in composition to the foregoing ores. It is from the yellow colour of this variety that the name brass has been assigned to the ores by the miners.

'The ores have respectively the following composition:—

	I	II	III
Carbonate of iron	68·71	59·73	17·74
Carbonate of manganese	0·42	0·37	
Carbonate of lime	9·36	11·80	14·19
Carbonate of magnesia	11·80	15·15	12·06
Iron pyrites	0·22	trace	49·72
Phosphoric acid	0·17	0·23	
Coaly matter	8·87	9·80	6·10
Clay	2·70	
	99·55	100·18	99·81

'It is unnecessary to allude to the third variety as an iron-making material; its colour admits of its being at all times separated from the others. The pyrites which it contains, we may remark, is bisulphuret of iron.

'It is to the ores I. and II. that we would direct attention. The reason of their having hitherto been comparatively disregarded may be attributed either to their having been mistaken for the so-called brass of coal, or to their being difficult to work in the blast-furnace in the ordinary manner, through the belief that they were similar in constitution to the argillaceous ores of the district. It will be seen from the above analyses that they are varieties of spathic iron ore, in which the manganese has been replaced by other bases. If treated judiciously, they would smelt with facility and afford an iron equal to that produced from the argillaceous ores. From the large amount of lime and magnesia which they contain, their employment must be advantageous in an economic point of view.

'An interesting feature in these ores is their fusibility during calcination on the large scale. When this process is conducted in heaps, the centre portions are invariably melted. This, considering the almost entire absence of silica, is apparently an unexpected result. The fused mass is entirely magnetic and crystalline. Treated with acids, it dissolves with great evolution of heat.

The following is its composition:—

Protoxide of iron	38.28
Sesquioxide of iron	32.50
Protoxide of manganese	0.38
Lime	12.84
Magnesia	13.87
Phosphoric acid	0.17
Sulphur	0.23
Silicic acid	1.20
Alumina	0.51
	99.98

'From the above analysis, it is probable that the fusibility of the compound is owing to the magnetic oxide of iron acting the part of an acid. When thoroughly calcined and unfused, the ores retain their original form; and if exposed to the air for any length of time crumble to powder from the absorption of water by the alkaline earths.'

COAL CUTTING MACHINES. See BORING and MACHINES FOR COAL CUTTING.

COAL GAS. See GAS.

COBALT. (*Symbol*, Co; *Atomic weight*, 29.5.) Little is known of the properties of this substance in the metallic state, as it has not hitherto been employed as such in the arts, and has only been obtained in a state of purity in small quantities by delicate operations in the laboratory. Like the allied metals, nickel, iron, manganese, and chromium, it may be obtained in a dark coloured pulverulent state by heating its oxide to redness, in a current of hydrogen, or in a compact button, by effecting the reduction with carbon at the highest temperature obtainable in an air furnace. Prepared in the last-mentioned way it is a brilliant white, or slightly reddish metal, less fusible than nickel or iron, but more so than chromium. It is decidedly magnetic, coming next in the scale to iron. If carbon be present in excess, a portion combines with the reduced metal, forming a compound analogous to cast-iron. It may be obtained melted, in a perfectly pure state, by heating oxalate of cobalt in a closely-covered crucible, to a strong white heat, when the oxide of cobalt is reduced by the carbon of the oxalic acid, thus: $\text{CoO.C}^2\text{O}^3 = \text{Co} + 2\text{CO}^2$. According to the older observers, it is very brittle, but Deville states that pure cobalt is extremely tenacious, even to a higher degree than iron. The specific gravity is 8.5. It forms a brittle alloy with iron. Quite recently metallic cobalt has been prepared on a commercial scale in Germany, and is said to be used as such in certain new alloys.

ORES OF COBALT.—The number of minerals containing cobalt is but small, and they are restricted to a very few localities. The following are the most important species:—

1. *Smaltine, Tin-white Cobalt, Speiss Cobalt* (Co, Fe, Ni) As. (**Co, Fe, Ni**) **As**². This is of a steel or lead-grey colour, and metallic lustre, crystallising in the cubical system. The hardness is about that of felspar. Sp. gr. 6.5 to 7.2. According as one or other of the three bases prevails, three simple types of composition may be deduced, as follow:—

- I. CoAs (**CoAs**²) = Cobalt, 28.2; Arsenic, 71.8 per cent. *Speiss cobalt, Cubical.*
- II. NiAs (**NiAs**²) = Nickel 28.3; " 71.7 " " $\left\{ \begin{array}{l} \textit{Chloanthite} \\ \textit{Rammelsbergite}, \end{array} \right.$ Prismatic.
- III. FeAs (**FeAs**²) = Iron, 27.2; " 72.8 " " $\left\{ \begin{array}{l} \textit{Löllingite} \\ \textit{ } \end{array} \right.$ "

The varieties I. and II. occur in considerable quantities at Schneeberg, in Saxony, associated with silver, copper, and other pyritic ores, quartz and hornstone replacing sulphate of baryta, fluor, and spathic carbonates; also at Riechelsdorf, in Hesse; in Bohemia, Sweden, and in a few localities in the United States. They have also been found in Cornwall; among other places, at Wheal Sparnon, and Saint Austell Consols. The nearest natural mineral in approach to type No. I. contains about 23 per cent. of cobalt; as a rule, however, the nickeliferous varieties are the more common. The predominance of one or other metal may be determined by exposing the specimens to damp air, when a green crust of arsenate of nickel forms on the varieties in which nickel is most abundant, while a pink incrustation is produced on those richest in cobalt. Type No. III. is the mineral known as arsenical pyrites, which, in reality, often contains a little cobalt, and is treated as a cobalt ore.

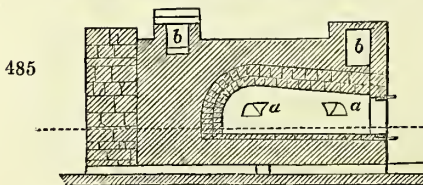

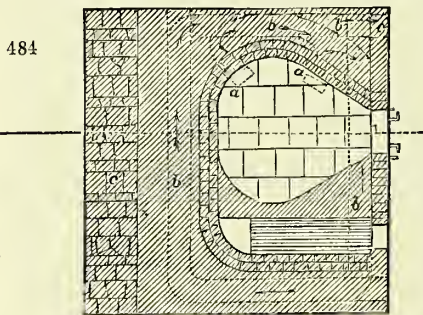

2. *Cobaltine*, *Grey Cobalt*, *Bright White Cobalt*, or *Cobalt Glance* ($\text{CoS}^2 + \text{CoAs}$) ($\text{CoS}^2 + \text{CoAs}^2$) differs from Speiss cobalt chiefly by having part of the arsenic replaced by sulphur. It crystallises in the cubical system in forms similar to those of iron pyrites, is of a white colour, with a slightly bronze-red tinge, and a brilliant metallic lustre. Its hardness is less than that of felspar, and specific gravity about 6. The typical composition is: cobalt, 35.5 per cent.; arsenic, 45.2 per cent.; sulphur, 19.3 per cent. The purest natural varieties contain about 33 per cent. of cobalt; these occur in Sweden. At Siegen, in Rhenish Prussia, a variety is found containing only 8 or 9 per cent. of iron, forming three quarters of the whole amount of bases present. Unlike the preceding species, it does not contain nickel.

3. *Linnaëite* or *Cobalt Pyrites*.—This, although crystallising in the cubical system, is analogous in composition to copper pyrites, being represented by the formula $\text{CoS} + \text{Co}^2\text{S}^3$ ($\text{CoS} + \text{Co}^2\text{S}^3$), with 58 per cent. cobalt and 42 per cent. sulphur: part of the base in either term may be replaced by copper, nickel, or iron. It is the richest of all cobalt ores, some varieties containing as much as 53½ per cent. of that substance. It is, however, rare, being found to a small extent only in the Siegen district, and in Sweden.

Among the products of the alteration of the above minerals, are—4. *Cobalt Bloom*, of the composition $3\text{CoO}.\text{AsO}^5 + 8\text{HO}$ ($\text{Co}^2\text{As}^2\text{O}^9 + 8\text{H}^2\text{O}$) with 37½ per cent. of oxide of cobalt: and 5. *Earthy Cobalt Ore*, a variety of the substance known as Wad or Bog Manganese, which at times contains as much as 15 or 20 per cent. of the same oxide, together with the oxides of iron, manganese, and copper. 6. *Cobaltic Bismuth Ore*, is a finely crystalline mixture of Speiss cobalt and bismuth-glance, found occasionally in the Schneeberg district, containing 10 per cent. cobalt and 4 per cent. bismuth. The ores of cobalt, as they come into the hands of the smelter, are, as a rule, so much mixed up with those of nickel, that they are worked for both metals.

See NICKEL.

The use of cobalt in the arts is mainly confined to the production of glasses coloured blue by oxide of cobalt, which, when finely pulverised and levigated, are used as pigments under the name of *smalts*. Oxide of cobalt, in a pure state, is also prepared, to a certain extent, for the use of porcelain manufacturers. The first point to be considered, therefore, is the production of the oxide, and next the fusion with a sufficient quantity of siliceous matter. Earthy cobalt ore may be used in the fusion process, without any further preparation; but those that contain sulphur and arsenic must be subjected to a preliminary calcination. Fig. 484 is a horizontal, and fig. 485 a vertical section of the roasting furnace employed for this purpose in the Saxon smalt works. The fire-grate is placed on one side of the hearth, which

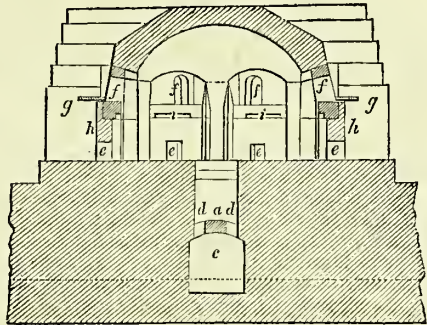

is of irregular form, being about six feet in breadth at the further end of the furnace, diminishing to 27 inches at the working door. Wood is the fuel employed. The arsenical vapours given off during roasting, pass out through the openings, *a*, *a*, by a

system of flues, *b, b*, in the direction shown by the arrows, into a chamber where they are deposited, and may be subsequently used in the manufacture of arsenical products. The charge is from 3 to 5 cwts.; the degree to which the roasting is carried varies with the composition of the ores. When many foreign metals are present, they must not be roasted 'dead' or 'sweet,' but sufficient arsenic or sulphur must be left to form with the less oxidisable metals, more especially copper and nickel, a speiss or regulus which separates from the blue glass produced in the fusion process, and subsides to the bottom of the melting pot. The oxides of those metals that are more easily oxidisable than cobalt, such as iron and bismuth, may be partially removed by an addition of metallic arsenic in the fusion, whereby the latter oxide is reduced and passes into the speiss with the production of arsenious acid, which tends to heighten the colours produced. Earthy cobalt ores containing much iron, require an addition of arsenious acid, in order to convert the protoxide of iron, which has a strong colouring power, into peroxide, which is of less consequence. In some works, the roasting is performed in muffle furnaces, the hearth being heated from below, so that the ore does not come into contact with the flame. Ores containing bismuth are subjected to the process of liquation previously to roasting.

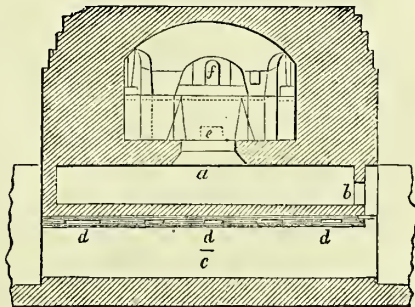

When the ores are very impure, or when it is wished to produce very deep blue colours, they are subjected to the process of concentration. Common ores, and those that are rich in copper, are first slightly roasted, and then fused in crucibles in the small furnace described below, with broken glass fragments, charcoal dust, and carbonate of potash. When the mixture is in a state of complete fusion, the slag is partly removed at intervals, and fresh quantities of ore are added, until a sufficient quantity of speiss is produced. In this process, the oxides of iron and copper in the ore form an easily fusible slag with the glass, while the cobalt is reduced by the charcoal to the metallic state, and unites with the arsenic to form a speiss. If the roasting is carried too far, or if there is an insufficiency of arsenic or of reducing matters in the mixture, a certain amount of oxide of cobalt will be taken up by the slag. The concentrated speiss produced is then pulverised and roasted 'sweet,' leaving a nearly pure basic arsenate of oxide of cobalt.

The small furnace, *figs*, 486 and 487, is similar in construction to that used for melting flint glass. The fire-place, in which wood is burnt, is a long narrow rectangular chamber, with a vaulted floor perforated by draught holes, *d, d*; *c*, the lower chamber, is the ash-pit; the flame passes through the hole, *a*, into the melting chamber above, which is a low domed structure, containing six melting pots; *f, f, f*, are the working doors,—they are faced with cast-iron frames in the ordinary way. The waste flame, after heating the pots, passes through the small flues, *i, i*, into a system of chambers, where it is employed in the accessory operations of calcining quartz, or drying wood for fuel. *h, h*, are arches through which the pots are inserted or removed,—they are built up when the furnace is at work. At *e, e, e*, are small holes, corresponding with similar ones in the pots, for removing the speiss formed during the fusion. The charge consists of roasted ore, with from 1 to 16 times its weight of quartz previously calcined and reduced to a fine powder, and carbonate of potash to the extent of about $\frac{3}{4}$ ths or $\frac{2}{3}$ ths of the amount of the quartz. Each pot contains about 3 cwts.; the fusion takes place at a low temperature, the glass

486

487

being frequently stirred with an iron rod in order to render it perfectly homogeneous; when this point is attained, the stirring is discontinued, and the speiss is allowed to settle. In 6 or 8 hours, the glass is sufficiently fluid, and it is then ladled out with iron ladles, and thrown into water. After the contents of two pots have been removed, the working doors are closed, and the fire is urged for some time, in order to bring the contents of the remaining pots which have somewhat cooled down to a proper degree of fluidity.

Grinding the smalts.—The blue glass, rendered brittle by sudden cooling, is stamped or crushed, sifted, and ground wet, under hard stones. The finely-divided glass from the mill is then passed through a system of washing-vats; the first three give a coarse sand which is usually returned to the mill for further grinding, the finer slime is allowed only a few minutes to deposit in No. 4, about a quarter of an hour in No. 5, then it filters more slowly through No. 6, and finally into a slime-pit, where the whole of the suspended matter is deposited. The darkest coloured smalts, known as *King's blue* or *azure*, are found in vats Nos. 4 and 5. No. 6 gives the lighter coloured *tub smalts*. The pale blue powder from the slime-pit is mostly returned to the melting furnace.

	SiO ₂	Al ₂ O ₃	FeO.	CoO.	KO and NaO.	
I. Norwegian high coloured	70.9	0.4	0.3	6.5	21.4	} with some car- bonate of lime.
II. German pale coloured	72.1	1.8	1.4	2.0	20.0	

Smalt is therefore a kind of glass coloured by oxide of cobalt. One part of oxide of cobalt communicates a distinctly bluish tinge to 240 parts of glass; with more than 18 per cent. the glass becomes black. In practice a potash-glass is always employed, and hence smalt may be regarded as a double silicate of potash, and protoxide of cobalt. Soda cannot be substituted for the potash, as it produces an inferior colour, and the same remark applies to some other oxides. The following are the principal facts observed with regard to the influence of the oxides of other metals on the colour of smalts. *Baryta* heightens the tone, giving an indigo tinge; *soda*, *lime*, and *magnesia*, have a decidedly lowering effect, and produce a reddish shade; *alumina* has no effect on the purity of the colour, but lowers its intensity; *iron* produces a blackish-green dull tinge, which is very prejudicial to the higher coloured varieties; *manganese* communicates a violet shade, as does also *nickel*, but in a much higher degree. *Copper*, *zinc*, *bismuth*, and *antimony*, all give a dull dirty shade, especially to the higher colours. *Oxide of lead* has no effect on the colour, but as it increases the specific gravity of the glass, and causes the ground smalts to subside too rapidly in the washing vats, producing an incomplete separation, its presence in the mixture is not desirable.

In commerce, smalts are classified both according to their contents in cobalt, and the size of the grain, the following being the chief marks:—

F.C. Fine colour.	F.C.B. Fine Bohemian colour.	F.E. Fine Eschel.
M.C. Middling colour.	M.C.B. Middling Bohemian colour.	M.E. Middling Eschel.
O.C. Ordinary colour.	O.C.B. Ordinary Bohemian colour.	O.E. Ordinary Eschel.

In the above scheme, the words *fine*, *middling*, and *ordinary*, indicate the relative quantities in cobalt, while *colour*, *Bohemian colour*, and *Eschel*, express the *state* of division. The two former are composed of angular fragments, while the latter are the finest-rounded grains deposited in the lowest washing vats and the slime-pits. Smalts that are darker in colour than F. are indicated by multiples of that letter, the highest being FFFFC; while, on the other hand, those that are lower than O are distinguished by exponents following the second letter, thus OC², OC⁴ contain respectively only $\frac{1}{2}$ and $\frac{1}{4}$ as much cobalt as O.C.

Zaffre, or *Safflor*, is the name given to a mixture of roasted ore and quartz, similar, in fact, to that employed in smalt-making, but without potash. It is used either for pottery purposes, or for bringing up the colour in smalts made from low-classed ores.

Formerly smalts were used to a great extent in colouring paper, but at present artificial ultramarine is almost exclusively used for this purpose (see ULTRAMARINE).

For an account of the method of assaying cobalt ores, see NICKEL.

The imports of cobalt can no longer be given; the Custom-house authorities now returning the cobalt ores as 'Ores unenumerated.'

COBALT BLOOM. Hydrous arsenate of Cobalt commonly occurring as a peach-blossom coloured incrustation on arsenical ores of cobalt. It is also found in crimson or peach-red crystals, and is known mineralogically as *Erythrine*. When abundant it is used in the preparation of cobalt colours. See COBALT.

COBALT BLUE, or *Thenard's Blue*, is prepared by precipitating a solution of sulphate or nitrate of cobalt by phosphate of potash, and adding to the resulting

gelatinous deposit from three to four times its volume of freshly-deposited alumina, obtained by the addition of carbonate of soda to a solution of common alum. This mixture, after being well dried, calcined, and ground, affords a blue pigment.

COBALT BRONZE. A violet-coloured substance, with strong metallic lustre. It consists of phosphate of protoxide of cobalt, and phosphate of ammonia.

COBALT, EARTHY. A protoxide of cobalt with oxide of manganese, from Saalfeld, in Thuringia.

COBALT GLANCE. A synonym for cobaltine. See COBALT.

COBALT GREEN, or *Rinnann's Green*. This pigment is a compound of oxide of cobalt and oxide of zinc. It is prepared by mixing a solution of sulphate of zinc with a salt of protoxide of cobalt, and precipitating with carbonate of soda; the precipitate is then washed, dried, and heated.

COBALT SPEISS. A substance obtained in the preparation of smalts, and consisting chiefly of arsenide of nickel, derived from the nickel associated with the cobalt ore. The speiss is used in the manufacture of nickel.

COBALT ULTRAMARINE. Thénard's Blue. See COBALT BLUE.

COBALT YELLOW. An orange-yellow pigment precipitated from an acidified solution of nitrate of protoxide of cobalt by means of nitrate of potash.

COCA. The leaves of *Erythroxylon coca*; mixed with burnt lime they are chewed by the natives in parts of South America. See ERYTHROXYLON COCA.

COCCOLOBUS. (*κόκκος*, a berry; *λοβός*, a pod.) The *Coccolobus uniferus*, or seaside grape, is a tree about twenty feet in height, with leaves of a glossy green colour—the nerves being a deep red. The fruit is in bunches, and is eaten in the West Indies. The wood yields a red colouring matter, which is used for a dye; and the wood itself, which is hard, is employed in cabinet work. A decoction of this plant is evaporated to form a substance known as Jamaica Kino.

COCCULUS INDICUS, or Indian berry, is the fruit of the *Anamirta paniculata*, a large tree, which grows upon the coasts of Malabar, Ceylon, &c., and belongs to the *Menispermaceæ* or Moon-seed order. The fruit is blackish, and of the size of a large pea. It owes its narcotic and poisonous qualities to the vegeto-alkaline chemical principle called *picrotoxia*, of which it contains about one-fiftieth part of its weight. It is sometimes thrown into waters to intoxicate or kill fishes; and it is said to have been employed to increase the inebriating qualities of ale or beer. Its use for this purpose is prohibited by Act of Parliament, under a penalty of 200*l.* upon the brewer, and 500*l.* upon the seller of the drug.

However, Dr. Pereira states, 'I am not acquainted with any official returns of the quantity annually brought over. From a druggist's private books I find that in 1834 above 2,500 bags entered—and this probably is much below the quantity imported. The greater part is consumed for illegal practices—principally for adulterating beer and ale.' Morrice, in his treatise on brewing, directs that in the manufacture of porter, three pounds of *Cocculus indicus* should be added to every ten quarters of malt. 'It gives,' says he, 'an inebriating quality, which passes for strength of liquor;' and he adds, 'that it prevents the second fermentation in bottled beer, and consequently the bursting of the bottles in warm climates.'

The Editor of this work had a fluid extract, the name of which was unknown to the Custom-house officers, submitted to him some years since. This was an extract of this deleterious drug, of which a very large quantity was then in the London docks.

The powder of the berries mixed with lard is used to destroy pediculi: hence the Germans call those grains *Läusekörner*, or *lousegrains*.

COCHINEAL. (*Cochenille*, Fr.; *Kochénille*, Ger.) Cochineal was first taken for a seed, but was proved by Læwenhoeck to be an insect, the female of that species of shield-louse, or *coccus*, discovered in Mexico so long ago as 1518. It is brought to us from Mexico, where the animal lives upon the *Cactus opuntia* or *Nopal*. Two sorts of cochineal are gathered: the wild from the woods, called by the Spanish name *Grana silvestra*; and the cultivated, or the *Grana fina*, termed also *Mestegue*, from the name of a Mexican province. The first is smaller, and covered with a cottony down, which increases its bulk with a matter useless in dyeing; it yields, therefore, in equal weight, much less colour, and is of inferior price to that of the fine cochineal. But these disadvantages are compensated in some measure to the growers by its being reared more easily and less expensively; partly by the effect of its down, which enables it better to resist rains and storms.

The wild cochineal, when it is bred upon the field nopal, loses in part the tenacity and quality of its cotton, and acquires a size double of what it has on the wild opuntias. It may, therefore, be hoped that it will be improved by persevering care in the rearing of it, when it will approach more and more to fine cochineal.

The fine cochineal, when well dried and well preserved, should have a grey colour

bordering on purple. The grey is owing to the powder which naturally covers the insects, of which a little adheres, and to a waxy fat. The purple shade arises from the colour extracted by the water in which they were killed. The grain is wrinkled with parallel furrows across its back, which are intersected in the middle by a longitudinal one: hence, when viewed by a magnifier, or even a sharp naked eye, especially after being swollen by soaking for a short time in water, it is easily distinguished from the factitious, smooth, glistening, black grains, of no value, called East India cochineal, with which it is often shamefully adulterated by certain London merchants. The genuine cochineal has the shape of an egg, bisected through its long axis, or of a tortoise, being rounded like a shield upon the back, flat upon the belly, and without wings.

These female insects are gathered off the leaves of the nopal plant after it has ripened its fruit, a few only being left for brood: they are killed either by a momentary immersion in boiling water, by drying upon heated plates or in ovens: the last become of an ash-grey colour, constituting the *silver cochineal*, or *jaspeada*; the second are blackish, called *negra*, and are most esteemed, being probably driest: the first are reddish brown, and reckoned inferior to the other two. The dry cochineal being sifted, the dust, with the imperfect insects and fragments which pass through, are sold under the name of *Granillo*. Cochineal keeps for a long time in a dry place. Hellot says that he has tried some 130 years old, which produces the same effect as new cochineal.

We are indebted to MM. Pelletier and Caventou for a chemical investigation of cochineal, in which its colouring matter was skilfully eliminated.

Purified sulphuric ether acquired by digestion with it a golden-yellow colour, amounting, according to Dr. John, to one-tenth of the weight of the insect. This infusion left, on evaporation, a fatty wax of the same colour.

Cochineal, exhausted by ether, was treated with alcohol at 40° B. After 30 infusions in the digester of M. Chevreul, the cochineal continued to retain colour although the alcohol had ceased to have any effect on it. The first alcoholic liquors were of a red verging on yellow. On cooling, they let fall a granular matter. By spontaneous evaporation, this matter, of a fine red colour, separated, assuming more of the crystalline appearance. These species of crystals dissolved entirely in water, which they tinged of yellowish red.

This matter has a very brilliant purple-red colour; it adheres strongly to the sides of the vessels; it has a granular and somewhat crystalline aspect, very different, however, to those compound crystals alluded to above; it is not altered by the air, nor does it sensibly attract moisture. Exposed to the action of heat, it melts at about 50° (122° F.). At a higher temperature it swells up, and is decomposed with the production of carburetted hydrogen, much oil, and a small quantity of water, very slightly acidulous. No trace of ammonia was found in these products.

The colouring principle of cochineal is very soluble in water. By evaporation, the liquid assumes the appearance of syrup, but never yields crystals. It requires of this matter a proportion almost imponderable to give a perceptible tinge of bright purplish red to a large body of water. Alcohol dissolves this colouring substance, but, as we have already stated, the more highly it is rectified, the less of it does it dissolve. Sulphuric ether does not dissolve the colouring principle of cochineal; but weak acids do, possibly owing to their water of dilution. No acid precipitates it in its pure state. This colouring principle, however, appears to be precipitable by all the acids when it is accompanied by the animal matter of the cochineal.

The affinity of alumina for the colouring matter is very remarkable. When that earth, newly precipitated, is put into a watery solution of the colouring principle, this is immediately seized by the alumina. The water becomes colourless, and a fine red lake is obtained, if we operate at the temperature of the atmosphere; but if the liquor has been hot, the colour passes to crimson, and the shade becomes more and more violet, according to the elevation of the temperature, and the continuance of the ebullition.

The salts of tin exercise upon the colouring matter of cochineal a remarkable action. The proto-chloride of tin forms a very abundant violet precipitate in the liquid. This precipitate verges on crimson, if the salt contains an excess of acid. The bi-chloride of tin produces no precipitate, but changes the colour to scarlet-red. If gelatinous alumina be now added, we obtain a fine red precipitate, which does not pass to crimson by boiling.

To this colouring principle the name *carminic acid* has been given. It forms the basis of the beautiful pigment called carmine. A very complete examination of the colouring matter of the cochineal insect has been made by Dr. Warren De La Rue. See **CARMINE**.

The carmines found in the shops of Paris have been analysed, and all yielded the same

products. They were decomposed by the action of heat, with the diffusion at first of a very strong smell of burning animal matter, and then of sulphur. A white powder remained, amounting to about one-tenth of the matter employed, and which was found to be alumina. Other quantities of carmine were treated with a solution of caustic potash which completely dissolved them, with the exception of a fine red powder, not acted on by potash and concentrated acid, and which was recognised to be red sulphuret of mercury or vermilion. This matter, evidently foreign to the carmine, appears to have been added, in order to increase its weight.

The preceding observations and experiments seem calculated to throw some light on the art of dyeing scarlet and crimson. The former is effected by employing a cochineal bath, to which there have been added, in determinate proportions, acidulous tartrate of potash and nitro-muriatic deutoxide of tin. The effect of these two salts is now well known. The former, in consequence of its excess of acid, tends to redden the colour, and to precipitate it along with the animal matter; the latter acts in the same manner, at first by its excess of acid, then by the oxide of tin which falls down also with the carmine and animal matter and is fixed on the wool, with which it has of itself a strong tendency to combine. MM. Pelletier and Caventou remark, that 'to obtain a beautiful shade, the muriate of tin ought to be entirely at the maximum of oxidisement; and it is in reality in this state that it must exist in the solution of tin prepared according to the proportions prescribed in M. Berthollet's treatise on dyeing.'

We hence see why, in dyeing scarlet, the employment of alum is carefully avoided, as this salt tends to convert the shade to a crimson. The presence of an alkali would seem less to be feared. The alkali would occasion, no doubt, a crimson-coloured bath; but it would be easy in this case to restore the colour, by using a large quantity of tartar. We should, therefore, procure the advantage of having a bath better charged with colouring matter and animal substance. It is for experience on the large scale to determine this point. As to the earthy salts, they must be carefully avoided.

To obtain crimson, it is sufficient, as we know, to add alum to the cochineal bath, or to boil the scarlet cloth in alum water. It is also proper to diminish the dose of the salt of tin, since it is found to counteract the action of the alum.

The alkalis ought to be rejected as a means of changing scarlet to crimson. In fact, crimsons by this process cannot be permanent colours, as they pass into red by the action of acids.

According to M. Von Grotthuss, carmine may be deprived of its golden shade by ammonia, and subsequent treatment with acetic acid and alcohol. Since this fact was made known, M. Herschel, colour-maker at Halle, has prepared a most beautiful carmine.

The officers of Her Majesty's Customs detected some time since a system of adulterating cochineal, which had been practised for many years upon a prodigious scale by a mercantile house in London. Dr. Ure stated that he had analysed about 100 samples of such cochineal, from which it appears that the genuine article is moistened with gum-water, agitated in a box or leather bag, first, with sulphate of baryta in fine powder, afterwards with bone or ivory black, to give it the appearance of *negra* cochineal, and then dried. By this means about 12 per cent. of worthless heavy spar is sold at the price of cochineal, to the enrichment of the sophisticators, and the disgrace and injury of British trade and manufactures.

The specific gravity of genuine cochineal is 1.25; that of the cochineal loaded with the barytic sulphate, 1.35. This was taken in oil of turpentine, and reduced to water as unity, because the waxy fat of the insects prevents the intimate contact of the latter liquid with them, and the ready expulsion of air from their wrinkled surface. They are not all acted upon by the oil, but are rapidly altered by water, especially when they have been gummed and barytified.

Humboldt states that so long ago as the year 1736, there was imported into Europe from South America, cochineal to the value of 15 millions of francs. Its high price had for a long time induced dyers to look out for cheaper substitutes in dyeing red; and since science has introduced so many improvements in tinctorial processes, both madder and lac have been made to supersede cochineal to a very great extent.

In order to ascertain the value of cochineal for dyeing we must have recourse to comparative experiments. We are indebted to MM. Robiquet and Anthon for two methods of determining the quality of cochineals, according to the quantity of carmine they contain. The process of M. Robiquet consists in decolourising equal volumes of decoction in different cochineals by chlorine. By using a graduated tube, the quality of the cochineal is judged of by the quantity of chlorine employed for decolourising the decoction. The process of M. Anthon is founded on the property which the hydrate of alumina possesses of precipitating the carmine from the decoction so as to

decolourise it entirely. The first process, which is very good in the hands of a skilful chemist, does not appear to us to be a convenient method for the consumer; in the first place, it is difficult to procure perfectly identical solutions; in the next place, it is impossible to keep them a long time without alteration. We know that chlorine dissolved in water reacts, even in diffused light, on this liquid; decomposes it, appropriates its elements, and gives rise to some compounds which possess an action quite different from that of the chlorine solution in its primitive state. The second process seems to us to be preferable, as the proof liquor may be kept a long while without alteration. A graduated tube is also used; each division represents one hundredth of the colouring matter. Thus the quantity of proof liquor added exactly represents the quantity in hundredths of colouring matter contained in the decoction of cochineal which has been submitted to examination. The following remarks from a practical dyer are valuable:—

‘The colouring matter of cochineal being soluble in water, I have used this solvent for exhausting the different kinds which I have submitted to examination in the colourimeter. I operated in the following manner: I took a grain of each of the cochineals to be tried, dried at 120 Fahr.; I submitted them five consecutive times to the action of 200 grains of distilled water at water-bath heat, each time for an hour; for every 200 grains of distilled water I added two drops of a concentrated solution of acid sulphate of alumina and of potash. This addition is necessary to obtain the decoctions of the different cochineals exactly of the same tint, in order to be able to compare the intensity of the tints in the colourimeter.¹

‘In order to estimate a cochineal in the colourimeter, two solutions, obtained as described above, are taken; some of these solutions are introduced into the colourimetric tubes as far as zero of the scale, which is equivalent to 100 parts of the superior scale; these tubes are placed in the box, and the tint of the liquids enclosed is compared by looking at the two tubes through the eye-hole; the box being placed so that the light falls exactly on the extremity where the tubes are. If a difference of tint is observed between the two liquors, water is added to the darkest (which is always that of the cochineal taken as type) until the tubes appear of the same tint.²

‘The number of parts of liquor which are contained in the tube to which water has been added is then read off; this number, compared with the volume of the liquor contained in the other tube, a volume which has not been changed, and is equal to 100, indicates the relation between the colouring power and the relative quality of the two cochineals. And if, for example, 60 parts of water must be added to the liquor of good cochineal, to bring it to the same tint as the other, the relation of volume of the liquids contained in the tubes will be in the case as 160 is to 100, and the relative quality of the cochineals will be represented by the same relation, since the quality of the samples tried is in proportion to their colouring power.’—*Napier*.

The exports from Guatemala consist principally of cochineal, the staple and almost the only article of exportation for a number of years past. It is chiefly produced in Old Guatemala, nine leagues distant from Guatemala, and also in Amatellan about six leagues distant. The rearing of this insect is subject to so many accidents and contingencies that it is excessively precarious, and, above all, the weather has a great effect upon it. Taking all this into consideration it is surprising that attention has not been directed to the cultivation and production of other articles suited to the climate and soil of Guatemala, and less liable to destruction by unseasonable rains and atmospheric changes than cochineal. It is reasonably to be feared that, if a longer time be suffered to pass, the cochineal of this country cannot compete with that of Teneriffe, and other parts of the world, where it is now cultivated.

Our Imports of cochineal have been as follow:—

In 1870 we imported	47,790 cwt.	valued at	£581,956.
1871	54,542	“	706,713.
1872	38,160	“	494,541.

COCK-METAL. An inferior metal; a mixture of copper and lead used for making cocks. See ALLOY.

COCO. A species of *Aracea*, to which the genus *Arum* gives the name. The rhizomes or underground stems of the *cocos* (*Colocasea*) are sometimes substituted for potatoes and yams; they abound in starchy matter.

¹ Care must be taken not to add to the water, which serves to extract the colouring matter from the different cochineals, more than the requisite quantity of acid sulphate of alumina and solution of potash, because a stronger dose would precipitate a part of the colouring matter in the state of lake.

² For diluting the liquors the same water must always be used which has served to extract the colouring matter of the cochineals under examination, otherwise the darkest decoction would pass into violet, as water was added to it, to bring back the tint to the same degree of intensity as that of the decoction to which it is compared.

COCOA. A well-known preparation from the seeds of the *Theobroma cacao*. It is stated to be made from the fragments of the seed-coats mixed with portions of the kernels. See CACAO.

COCOA-NUTS. (*Noix de Coco*, Fr.; *Cocosnuss*, Ger.) The cocoa-nut tree (*Cocos nucifera*) is a native of tropical climates. It is one of the most important and valuable of the palms.

COCOA-NUT OIL. Cocoa-nut oil is obtained by two processes: one is by pressure, the other by boiling the bruised nut and skimming off the oil as it forms on the surface.

It is a white solid, having a peculiar odour. It fuses a little above 70° F.; becomes readily rancid, and dissolves easily in alcohol. It consists of a solid fat called *cocin* or *cocinine* (a combination of glycerine and cocinic, or coco-stearic acid), and of a liquid fat or oleine. Cocoa-nut oil is used in the manufacture of soap and candles.

Mr. Soames obtained a patent in September, 1829, for making stearine and elaine by the following process:—

He takes the substance called cocoa-nut oil, in the state of lard, in which it is imported into this country, and submits it to a strong hydraulic pressure, having made it up in small packages, 3 or 4 inches wide, 2 feet long, and 1 or 1½ inch thick. These packages are formed by first wrapping up the said substance in a strong linen cloth, of close texture, and then in an outward wrapper of strong sail-cloth. The packages are to be placed side by side, in single rows, between the plates of the press, allowing a small space between the packages for the escape of the elaine.

The temperature at which the pressure is begun, should be from about 50° to 55°, or in summer as nearly at this pitch as can be obtained, and the packages of the said substance intended for pressure should be exposed for several hours previously to about the same temperature. When the packages will no longer yield their oil or elaine freely at this temperature, it is to be gradually raised; but it must at no time exceed 65°, and the lower the temperature at which the separation can be effected, the better will be the quality of the oil expressed.

When the packages are sufficiently pressed, that is, when they will give out no more oil, or yield it only in drops at long intervals, the residuum is then to be taken out and cleansed and purified, which is done by melting it in a well-tinned copper vessel, which is fixed in an outer vessel, having a vacant space between, closed at the top, into which steam is admitted, and the heat is kept up moderately for a sufficient time to allow the impurities to subside; but if a still higher degree of purity is required, it is necessary to pass it through filters of thick flannel lined with blotting paper.

Having been thus cleansed or purified, it is fit for the manufacture of candles, which are made by the ordinary process used in making mould tallow candles. Having thus disposed of the stearine, or what is called the first product, he proceeds with the elaine or oil expressed from it, and which he calls the second product, as follows: that is to say, he purifies it by an admixture, according to the degree of its apparent foulness, of from 1 to 2 per cent. by weight of the sulphuric acid of commerce, of about 1.80 specific gravity, diluted with six times its weight of water. The whole is then to be violently agitated by mechanical means, and he prefers for this purpose the use of a vessel constructed on the principle of a common barrel churn. When sufficiently agitated, it will have a dirty whitish appearance, and is then to be drawn off into another vessel, in which it is to be allowed to settle, and any scum that rises is to be carefully taken off. In a day or two the impurities will be deposited at the bottom of the oil, which will then become clear, or nearly so, and it is to be filtered through a thick woollen cloth, after which it will be fit for burning in ordinary lamps and for other uses.

The process of separating the elaine from the stearine, by pressure, in manner aforesaid, had never before been applied to the substance called cocoa-nut oil, and consequently no product had heretofore been obtained thereby from that substance fit for being manufactured into candles in the ordinary way, or for being refined by any of the usual modes, so as to burn in ordinary lamps, both which objects are attained by the method of preparing or manufacturing the said substance.

Candles well made from the above material are a very superior article. The light produced is more brilliant than from the same sized candle made of tallow; the flame is perfectly colourless, and the wick remains free from cinder, or any degree of foulness during combustion. See CANDLES; ELAINE; STEARINE.

COD. The *Morrhua vulgaris*, a fish belonging to the family of *Gadide*.

It is calculated that the take in Scotland of cod and ling amounts to about 4,000,000 individuals annually, of which upwards of 1,000,000 are from the Shetland Islands.

COD-LIVER OIL. The oil obtained from the livers of several varieties of the

Gadidæ family; especially from the torsk, *Brosimus brosmæ*. It is administered medicinally: it acts mainly as a nutritive body, and the old idea that its medicinal value depended on the iodine it contained is now proved to be false, since it holds no iodine in composition. Since the demand for cod-liver oil has been large, it has been extensively adulterated with other fish-oils.

CODEINE. $C^{36}H^{21}NO^6 + 2HO (C^{18}H^{21}NO^3 + HO^2)$. An alkaloid obtained from opium, where it occurs associated with morphine and several other bases. Codeine was discovered by Robiquet, and has been studied by Dr. Anderson and other chemists. The substitution-compounds formed from codeine by the action of hydrochloric acid were investigated by Drs. Matthiessen and Wright, and those produced by the action of hydrobromic acid have recently been studied by Dr. Wright alone.

CODILLA OF FLAX. The coarsest parts of the fibre sorted out by itself. See **FLAX**.

CELESTIN. Native sulphate of strontia. See **CELESTINE**.

COFFEE. (*Café*, Fr.; *Kaffee*, Ger.) The coffee is the seed of the *Coffea Arabica*, a tree of the order *Rubiaceæ*, and belongs to the *Pentandria monogynia* of Linnæus. There are several species of the genus, but the only one cultivated is the *Coffea Arabica*, a native of Upper Ethiopia and Arabia Felix. It rises to the height of 15 or 20 feet; its trunk sends forth opposite branches in pairs above and at right angles to each other; the leaves resemble those of the common laurel, although not so dry and thick. From the angle of the leaf-stalks small groups of white flowers issue, which are like those of the Spanish jasmine. These flowers fade very soon, and are replaced by a kind of fruit not unlike a cherry, which contains a yellow glairy fluid, enveloping two small seeds or berries convex upon one side, flat and furrowed upon the other in the direction of the long axis. These seeds are of a horny or cartilaginous nature; they are glued together, each being surrounded with a peculiar coriaceous membrane. They constitute the coffee of commerce.

It was not till towards the end of the 15th century that the coffee-tree began to be cultivated in Arabia. Historians usually ascribe the discovery of the use of coffee as a beverage to the superior of a monastery there, who, desirous of preventing the monks from sleeping at their nocturnal services, made them drink the infusion of coffee upon the report of shepherds, who pretended that their flocks were more lively after browsing on the fruit of that plant. The use of coffee was soon rapidly spread, but it encountered much opposition on the part of the Turkish government, and became the occasion of public assemblies. Under the reign of Amurath III. the mufti procured a law to shut all the coffee-houses, and this act of suppression was renewed under the minority of Mahomet IV. It was not till 1554, under Solymán the Great, that the drinking of coffee was accredited in Constantinople; and a century elapsed before it was known in London and Paris. Solymán Aga introduced its use into the latter city in 1669, and in 1672 an Armenian established the first *café* at the fair of Saint-Germain.

When coffee became somewhat of a necessary of life from the influence of habit among the people, all the European Powers who had colonies between the tropics projected to form plantations of coffee-trees in them. The Dutch were the first who transported the coffee plant from Mocha to Batavia, and from Batavia to Amsterdam. In 1714 the magistrates of that city sent a root to Louis XIV., which he caused to be planted in the Jardin du Roi. This became the parent stock of all the French coffee plantations in the Martinique.

The most extensive culture of coffee is still in Arabia Felix, and principally in the kingdom of Yemen, towards the cantons of Aden and Mocha. Although these countries are very hot in the plains, they possess mountains where the air is mild. The coffee is generally grown half-way up on their slopes. When cultivated on the lower ground it is always surrounded by large trees, which shelter it from the torrid sun, and prevent its fruit from withering before their maturity. The harvest is gathered at three periods: the most considerable occurs in May, when the reapers begin by spreading cloths under the trees, then shaking the branches strongly, so as to make the fruit drop, which they collect, and expose upon mats to dry. They then pass over the dried berries a very heavy roller, to break the envelopes, which are afterwards winnowed away with a fan. The interior bean is again dried before being laid up in store.

In Demerara, Berbice, and some of our West India islands, where much good coffee is now raised, a different mode of treating the pulpy fruit and curing the beans is adopted. When the cherry-looking berry has assumed a deep-red colour, it is gathered, and immediately subjected to the operations of a mill composed of two wooden rollers, furnished with iron plates, which revolve near a third fixed roller called the *chops*. The berries are fed into a hopper above the rollers, and falling down between them and the chops, they are stripped of their outer skins and pulp,

while the twin beans are separated from each other. These beans then fall upon a sieve, which allows the skin and the pulp to pass through, while the hard beans accumulate and are progressively slid over the edge into baskets. They are next steeped for a night in water, thoroughly washed in the morning, and afterwards dried in the sun. They are now ready for the peeling mill, a wooden edge-wheel turned vertically by a horse yoked to the extremity of its horizontal axis. In travelling over the coffee, it bursts and detaches the coriaceous or parchment-like skin which surrounds each hemispherical bean. It is then freed from the membranes by a winnowing machine, in which four pieces of tin made fast to an axle are caused to revolve with great velocity. Corn fanners would answer better than this rude instrument of negro invention. The coffee is finally spread upon mats or tables, picked clean and packed up for shipment.

The most highly-esteemed coffee is that of Mocha. It has a smaller and a rounder bean; a more agreeable taste and smell than any other. Its colour is yellow. Next to it in European reputation is the Martinique and Bourbon coffee; its colour is greenish, and it preserves almost always a silver grey pellicle, which comes off in the roasting.

The Bourbon coffee approaches nearest to the Mocha, from which it originally sprung. The Saint Domingo coffee has its two extremities pointed, and is much less esteemed than the preceding.

The coffee-tree flourishes in hilly districts where its root can be kept dry, while its leaves are refreshed with frequent showers. Rocky ground, with rich decomposed mould in the fissures, agrees best with it. Though it would grow, as we have said, to the height of 15 or 20 feet, yet it is usually kept down by pruning to that of 5 feet for increasing the production of the fruit, as well as for the convenience of cropping. It begins to yield fruit the third year, but is not in full bearing till the fifth, does not thrive beyond the twenty-fifth, and is useless in general at the thirtieth. In the coffee husbandry the plants should be placed 8 feet apart, as the trees throw out extensive horizontal branches, and in holes 10 or 12 feet deep to secure a constant supply of moisture.

Coffee has been analysed by a great many chemists, with considerable diversity of results. The best analysis perhaps is that of Schröder. He found that the raw beans distilled with water in a retort communicated to it their flavour and rendered it turbid, whence they seem to contain some volatile oil. On reboiling the beans, filtering, and evaporating the liquor to a syrup, adding a little alcohol till no more matter was precipitated, and then evaporating to dryness, he obtained 17.58 per cent. of a yellowish-brown transparent extract, which constitutes the characteristic part of coffee, though it is not in that state the pure proximate principle, called *caffeine*. Its more remarkable reaction is its producing, with both the protoxide and the peroxide salts of iron, a fine grass-green colour, while a dark green precipitate falls, which re-dissolves when an acid is poured into the liquor. It produces on the solution of the salts of copper scarcely any effect, till an alkali be added, when a very beautiful green colour is produced which may be employed in painting. Coffee beans contain also a resin, and a fatty substance somewhat like suet. According to Robiquet, ether extracts from coffee beans nearly 10 per cent. of resin and fat, but he probably exaggerates the amount. The peculiar substance *caffeine* contained in the above extract is crystallisable. It is remarkable in regard to composition, that after urea and the uric acid, it is among organic products the richest in nitrogen. It was dissolved and described in 1820 by Rungé. It does not possess alkaline properties. Pfaff obtained only 90 grains of *caffeine* from six pounds of coffee beans. There is also an acid in raw coffee to which the name of *caffaic acid* has been given. When distilled to dryness and decomposed, it has the smell of roasted coffee. See **CAFFEINE**.

Coffee undergoes important changes in the process of roasting. When it is roasted to a yellowish brown it loses, according to Cadet, 12½ per cent. of its weight, and is in this state difficult to grind. When roasted to a chestnut brown it loses 18 per cent.; and when it becomes entirely black, though not all carbonised, it has lost 23 per cent. Schröder has analysed roasted coffee comparatively with raw coffee, and he found in the first 12½ per cent. of an extract of coffee soluble in water and alcohol, which possesses nearly the properties of the extract of the raw coffee, although it has a deeper brown colour, and softens more readily in the air. He found also 10.4 of a blackish brown gum; 5.7 of an oxygenated extract, or rather *apothème* soluble in alcohol, insoluble in water; 2 of a fatty substance and resin; 69 of burnt vegetable fibre, insoluble. On distilling roasted coffee with water, Schröder obtained a product which contained the aromatic principle of coffee; it reddened litmus paper, and exhaled a strong and agreeable odour of roasted coffee. If we roast coffee in a retort, the first portions of the aromatic principle of coffee condense into a yellow liquid in the receiver; and these may be added to the coffee roasted in the common way, from which this matter has been expelled and dissipated in the air.

Chenevix affirmed that by the roasting of coffee a certain quantity of tannin possessing the property of precipitating gelatine is generated. Cadet made the same observation, and found moreover, that the tannin was most abundant in the lightly roasted coffee, and that there was nearly none of it in coffee highly roasted. Passé and Schröder, on the contrary, state that solution of gelatine does not precipitate either the decoction of roasted coffee or the alcoholic extract of this coffee. Rungé likewise asserts that he could obtain no precipitate with gelatine; but he says that albumen precipitates from the decoction of roasted coffee the same kind of tannin as is precipitated from raw coffee by the acetate of lead, and set free from the lead by sulphuretted hydrogen. With these results Dr. Ure's experiments agreed. Gelatine certainly does not disturb clear infusion of roasted coffee, but the salts of iron blacken it.

Schröder endeavoured to roast separately the different principles of coffee, but none of them exhaled the aromatic odour of roasted coffee, except the horny fibrous matter. He therefore concluded that this substance contributes mainly to the characteristic taste of roasted coffee, which cannot be imitated by any other vegetable matter, and which, as we have seen, should be ascribed chiefly to the altered caffeic acid. According to Garot, we may extract the caffeine without alteration from roasted coffee by precipitating its decoction by subacetate of lead, treating the washed precipitate with sulphuretted hydrogen, and evaporating the liquid product to dryness.

To roast coffee rightly we should keep in view the proper objects of this process, which are to develop its aroma, and destroy its toughness, so that it may be readily ground to powder. Too much heat destroys those principles which we should wish to preserve, and substitutes new ones which have nothing in common with the first, but add a disagreeable empyreumatic taste and smell. If, on the other hand, the rawness or greenness is not removed by an adequate heat, it masks the flavour of the bean, and injures the beverage made with it. When well roasted in the sheet-iron cylinder set to revolve over a fire, it should have a uniform chocolate colour, a point readily hit by experienced roasters, who now manage the business for the principal coffee dealers both of London and Paris. The development of the proper aroma is a criterion by which coffee roasters frequently regulate their operations. When it loses more than 20 per cent. of its weight, coffee is sure to be injured. It should never be ground till immediately before infusion, since the fine essential oil rapidly escapes from the finely-divided coffee.

Liebig's views of the process of nutrition have given fresh interest to every analysis of articles of food. A watery infusion of coffee is used in almost every country as a beverage, and yet it is uncertain whether it is an article of nutrition or merely a condiment. A minute examination of the raw seed, or coffee bean as it is called, must precede the determination of that disputed point. Caffeine is the principle best known, being most easily separated from the other substances, resisting most powerfully chemical reagents, and by assuming a crystalline state is discoverable in very small quantities.

Roasted coffee affords a much richer infusion to hot water containing a minute quantity of carbonate of soda, and improves the quality of the coffee on the stomach, by neutralising the caffeic acids.

Coffee, as sold in the shops in its roasted and ground state, is often adulterated with a variety of substances, but chiefly with chicory. See CHICORY.

If tannin exists in roasted coffee, as maintained long ago by Chenevix, and generally admitted since, it must be very different from the tannin present in tea, catechu, kino, oak-bark, willow-bark, and other astringent vegetables; for it is not, like them, precipitated by either gelatine, albumen, or sulphate of quinine. With regard to the action upon the animal economy of coffee, tea, and cocoa, which contain one common chemical principle called caffeine or theine, Liebig advanced some ingenious views, and, in particular, endeavoured to show that, to persons of sedentary habits in the present refined state of society they afford eminently useful beverages, which contribute to the formation of the characteristic principle of *bile*. This important secreted fluid, deemed by Liebig to be subservient to the function of respiration, requires for its formation much azotised matter, and *that* in a state of combination analogous to what exists in caffeine. The quantity of this principle in tea and coffee being only from 2 to 5 per cent., might lead one to suppose that it could have little effect upon the system even of regular drinkers of these infusions; but if the bile contains only one-tenth of solid matter, called choleic acid, which contains less than 4 per cent. of azote, then it may be shown that 3 grains of caffeine would impart to 500 grains of bile the azote which occurs in that crystalline precipitate of bile called *taurine*, which is thrown down from it by mineral acids.

One atom of caffeine, 9 atoms of oxygen, and 9 of water, being added together, produce the composition of 2 atoms of taurine. Now this is a very simple combi-

nation for the living organism to effect; one already paralleled in the generation of hippuric acid in urine, by the introduction of benzoic acid into the stomach: a physiological discovery which promised to lead to a more successful treatment of some of the most formidable diseases of man, particularly gout and gravel.

COFFEE ROASTING AND GRINDING.

The gratefulness of the beverage afforded by this seed depends upon many circumstances, which are seldom all combined. It may be ruined in the roasting; for if some berries be under and some over done, the whole when ground will yield an unpalatable infusion. The due point to which the torrefaction should be carried may be determined partly by the colour and partly by the loss of weight, which points, however, are different for each sort of coffee. But perfect equality of ustulation is difficult of attainment with the ordinary cylindrical machines. Messrs. Law, of London and Edinburgh, had long been dissatisfied with the partial manner in which the cylinder performed its duty, as it generally left some part of its contents black, some dark brown, and others paler; results which greatly injure the flavour of the beverage made with the coffee. Mr. William Law overcame these difficulties by his invention of the globular roaster, actuated by a compound motion like that of our earth. This roaster, with its double rotatory motion, is heated not over an open fire, but in an atmosphere of hot air, through a cast-metal casing. The globe is so mounted as to revolve horizontally, and also from time to time vertically, whereby the included beans are tossed about and intermingled in all directions, and inequality of torrefaction is scarcely possible. The position of the globe in *fig.* 488 shows it as turned up by a powerful leverage out of the cast-iron heater, preparatory to its being emptied and re-charged.

Messrs. Dakin and Co. have patented, and have now for some years used, another kind of apparatus, which consists mainly of steam-chests upon the upper surface of which the coffee is roasted. The advantages of this arrangement appear to be that the coffee berries are spread over the heated surface in a thin layer, and thus every berry is equally exposed to the regulated action of the steam heat. The whole being exposed to view, it can be seen when the roasting has been carried to its proper point.

Our *Imports* of coffee have been as follow:—

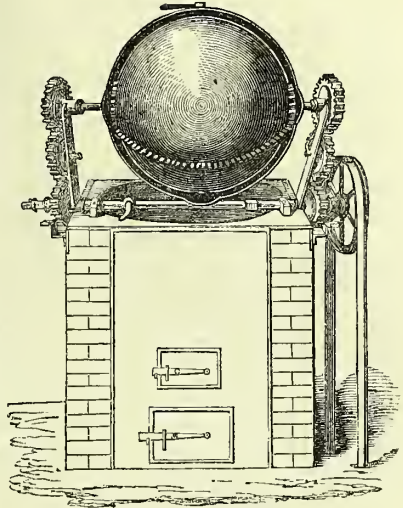

Places	1870	1871	1872
	lbs.	lbs.	lbs.
From Ceylon	97,964,922	91,035,678	77,644,766
„ other British Possessions	29,814,865	42,108,606	38,160,854
„ Brazil	14,057,893	22,940,928	17,820,211
„ Central America	14,070,079	19,540,529	14,934,128
„ other Countries	23,994,105	16,976,391	18,513,908
Total	179,901,864	192,606,132	167,073,867
Retained for Home consumption	30,629,710	31,010,645	31,661,311
Total value	£4,942,769	£5,407,110	£5,294,704

COGNAC. The finest kind of French brandy, distilled from wine—so called from the town of Cognac, in the department of Charente. See BRANDY.

COIR. The outer coating of the cocoa-nut, often weighing one or two pounds, when stripped off longitudinally, furnishes the fibres called by the native name of *Coir*, and used for small cables and rigging.

In England these fibres are used in matting and for coarse brush work. In Price

488

and Co.'s works they are advantageously employed, placed between iron trays and on the surface of the cocoa-nut and other concrete oils and fats, and subjected to great pressure; the liquid oil flows out, leaving solid fats behind. From the abundance, cheapness, and durability of this substance it is likely to come into more general use, and it has even been seriously proposed as a material for constructing ocean telegraphs, from its lightness and power of resisting sea-water. The qualities of coir for many purposes have been established for ages in the East Indies. Dr. Gilchrist thus describes the properties of coir ropes:—'They are particularly elastic and buoyant, floating on the surface of the sea; therefore when, owing to the strength of the current, a boat misses a ship, it is usual to veer out a quantity of coir, having previously fastened an oar, or small cask, &c., to its end. Thus the boat may be easily enabled to haul up to the ship's stern. Were a coir hawser,' he adds, 'kept on board every ship in the British marine, how many lives would probably be saved!'

It is stated that fresh water rots coir in a very short time, corroding it in a surprising degree, whereas salt water absolutely strengthens it, seeming to increase the elasticity. Coir is therefore unfit for running rigging, especially for vessels subject to low latitudes, it being easily snapped in frosty weather.

Nothing can equal the ease with which a ship rides at anchor, when her cables are of coir. As the surges approach the bows, the vessel gradually recedes in consequence of the cables yielding to their force; but as soon as they have passed, it contracts again, drawing the vessel gradually back to her first position: the lightness of the material adds to this effect, for the cable would float if the anchor did not keep it down. At the present time the forces exerted upon cables and the angles assumed under different circumstances, in paying out submarine telegraphic cables, have been the subject of practical attention and theoretical investigation. Some of the greatest authorities have assumed that the forces exerted, between the bottom of the sea and the ship's stern, had reference only to forms or waves of the cables, representing some curve between the vertical and horizontal line, but always concave to the water surface. For a curve to exist, in the opposite direction, was named only as a condition, without evidence of any practical kind to show that it really existed, or called for any attention to investigate it. So long since, however, as 1825, Dr. Gilchrist, among others, had described this very opposite curve of the coir; viz., of being, when in action as a cable, curved with a concave surface toward the bottom of the sea; a fact well known to the experienced sailors of England, as well as to the natives who employ these coir cables so extensively on the East Indian coast.

'A hempen cable always makes a curve *downwards*, between the vessel and the anchor, but a coir cable makes the curve *upwards*. Therefore, if a right line were drawn from the hawse-hole to the ring of the anchor, it would be something like the axis of a parabolic spindle, of which the cables would form, or nearly so, the two elliptic segments.'

In the employment of materials for ocean telegraphs, especially for deep-sea purposes, the use of iron and the proposal for using coir and other light substances, have caused the telegraphic means to be spoken of as 'heavy' or 'light' cables. Dr. Allan, of Edinburgh, proposed the abundant use of coir to make a *light cable*, say, half the weight of the lightest hitherto made, the Atlantic cable. He states that a deep sea cable may be compounded to weigh not more than 10 cwt. per mile: while the cheapness, durability in salt water, lightness, and abundant supply, will give it advantages over gutta percha and other substances used to form the bulk of the lightest cables hitherto employed.

When cocoa-nuts are sawed into two equal parts across the grain of the coir coating, they form excellent table brushes, causing wood planks to assume a very high polish by friction. If the shell should be left, the edges should be perfectly smooth, and then they will not scratch. It is a good mode to strip off the coir, and, after soaking it in water, to beat it with a heavy wooden mallet until the pieces become pliant, when they should be firmly bound together with an iron ring; the ends being levelled, the implement is fit for use; a little bees'-wax, rubbed occasionally upon them, adds greatly to the lustre of the furniture; of course the polish is mainly due to strength and rapid action producing the friction upon the wood, and other articles of furniture.

In India, the coarse bark of the nuts is extensively used to cleanse houses, and in washing the decks of vessels. Coarse stuff, matting, and bagging, are made of the fibres, as well as ropes, sails, and cables.

The general preparation is simple:—The fibrous husks or coats which envelope the cocoa-nuts, after being for some time soaked in water, become soft; they are then beaten, to separate other substances with which they are mixed, which fall away like saw-dust, the strings or fibres being left; this is spun into long yarns, woven into sail-cloth, and twisted into cables, even for large vessels. Cordage thus made is con-

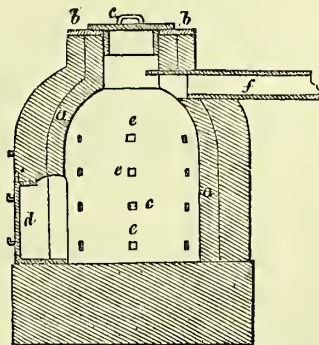

sidered preferable, in many respects, to that brought from Europe, especially the advantage of floating in water.

COKE. (Eng. and Fr.; *Coaks*, Ger.) It is necessary to distinguish between what is called gas-coke and oven-coke. The word 'coke' applies, properly, to the latter alone; for in a manufacturing sense, the former is merely cinder. The production of good coke requires a combination of qualities in coal not very frequently met with; and hence first-rate coking coals can be procured only from certain districts. The essential requisites are, first, the presence of very little earthy or incombustible ash; and, secondly, the more or less infusibility of that ash. The presence of any of the salts of lime is above all objectionable; after which may be classed silica and alumina; for the whole of these have a strong tendency to produce a vitrification, or slag, upon the bars of the furnace in which the coke is burnt; and in this way the bars are speedily corroded or burnt out; whilst the resulting clinker impedes or destroys the draught, by fusing over the interstices of the bars or air passages. Iron pyrites is a common obstacle to the coke-maker; but it is found in practice, that a protracted application of heat in the oven dissipates the whole of the sulphur from the iron, with the production of bisulphuret of carbon and metallic carburet of iron, the latter of which alone remains in the coke, and, unless silica be present, has no great disposition to vitrify after oxidation. Where the iron pyrites exists in large quantities it is separated by the coal-washing machines, some of which will be described in a general article.—See WASHING MACHINES. One object, therefore, gained by the oven-coke manufacturer over the gas-maker is the expulsion of the sulphuret of carbon, and consequent purification of the residuary coke. Another, and a still more important consequence of a long sustained and high heat is, the condensation and contraction of the coke into a smaller volume, which, therefore, permits the introduction of a much greater weight into the same space; an advantage of vast importance in blast furnaces, and above all, in locomotive engines, as the repeated introduction of fresh charges of coal fuel is thus prevented. Part of this condensation is due to the weight of the superincumbent mass of coal thrown into the coke oven, by which (when the coal first begins to cake or fuse together) the particles are forced towards each other, and the cavernous character of cinder got rid of: but the chief contraction arises, as we have said, from the natural quality of carbon, which, like alumina, goes on contracting, the longer and higher the heat to which it is exposed. Hence, good coke cannot be made in a short time, and that used in locomotive engines is commonly from 48 to 96, or even 120 hours in the process of manufacture.

The prospects of improvement in coke-making point rather to alterations in the oven than in the process. Formerly it was not thought possible to utilise the heat evolved by the gaseous constituents of the coal; but now, as an example of the incorrectness of this idea, it may be stated that at the Felling Chemical Works, 200 tons of salt per week are made by the waste heat alone, and it is also employed in partially heating the blast for one of the furnaces. There appears no valid reason why sets of coke-ovens might not be so arranged as mutually to compensate for each other, and produce upon one particular flue a constant and uniform effect. Contrivances of this kind have been projected; but hitherto, we may suppose, without uniform success, as many of our large coke-makers still continue the old mode of working.

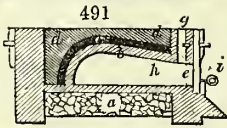

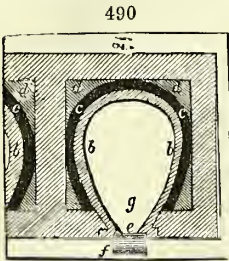

The following figure, 489, represents a *Shachtofen*, or pit-kiln, for coking coals in Germany, *a* is the lining (*chemise*), made of fire-bricks; the enclosing walls are built of the same material; *b, b*, is a cast-iron ring covered with a cast-iron plate *c*. The floor of the kiln is massive. The coals are introduced, and the coke taken out, through a hole in the side *d*; during the process it is bricked up, and closed with an iron door. In the surrounding walls are four horizontal rows or flues *e, e, e, e*, which are usually iron pipes; the lowest row is upon a level with the floor of the kiln; and the others are each respectively one foot and a half higher than the preceding. Near the top of the shaft there is an iron pipe *f*, of from 8 to 10 inches in diameter, which allows the incoercible vapours generated in the coking to escape into the condenser, which consists either of wood or brick chambers. For kindling the coal, a layer of wood is first placed on the bottom of the kiln.

489

The coking of small coal is performed upon vaulted hearths, somewhat like bakers'

ovens, but with still flatter roofs. Of such kilns, several are placed alongside one another, each being an ellipse deviating little from a circle, so that the mouth may project but a small space. The dimensions are such, that from 10 to 12 cubic feet of coal culm may be spread in a layer 6 inches deep upon the sole of the furnace. The top of the flat arch of fire brick should be covered with a stratum of loam and sand.

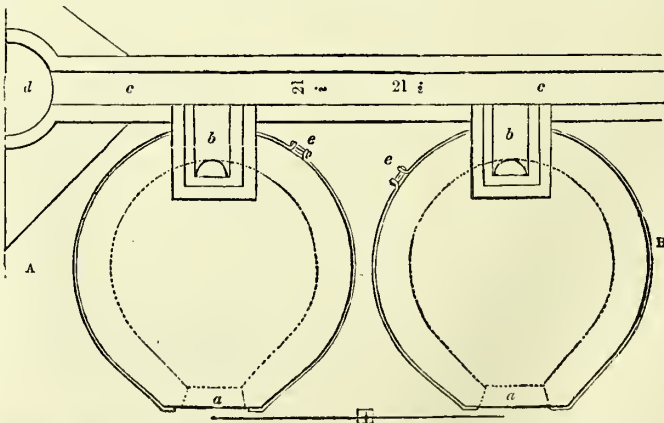

Figs. 490 and 491 represent such a kiln as is mounted at Zabrze, in Upper Silesia, for coking small coal. Fig. 490 is the ground plan; fig. 491 the vertical section in the line of the long axis of fig. 490. a is the sand-bed of the hearth, under the brick sole; b is the roof of large fire-bricks; c, the covering of loam; d, the top surface of sand; e the orifice in the front wall, for admission of the culm, and removal of the coke over the sloping stone f. The flame and vapours pass off above the orifice, through the chimney marked g, or through the aperture h, into a lateral chimney. i is a bar of iron laid across the front of the door, as a fulcrum to work the iron rake upon. A layer of coals is first kindled upon the hearth, and when this is in brisk ignition, it is covered with the culm in successive sprinklings. When the coal is sufficiently coked, it is raked out and quenched with water.

Fig. 492 represents a simple coking Meiler or mound, constructed in a circular form round a central chimney of loose bricks, towards which small horizontal flues are laid among the lumps of coals. The sides and top are covered with culm or slack, and the heap is kindled from certain openings towards the circumference. Fig. 493 represents an oblong Meiler, sometimes made 100 or 150 feet in length, and from 10 to

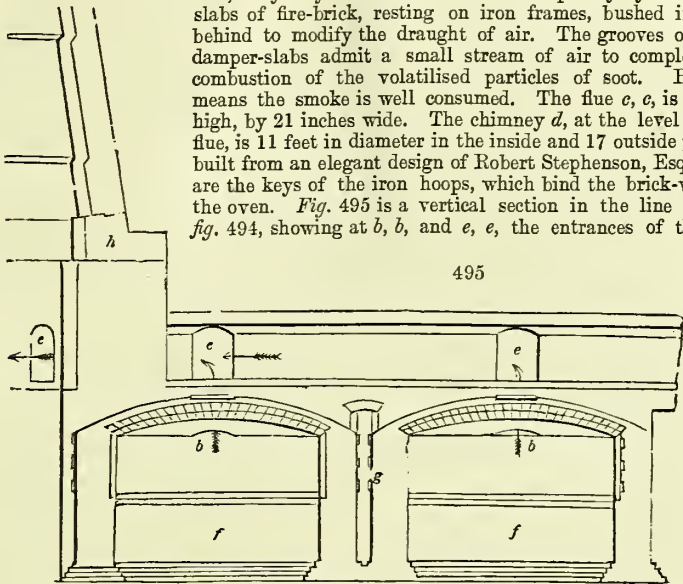

12 in breadth. The section in the middle of the figure shows how the lumps are piled up; the wooden stakes are lifted out when the heap is finished, in order to introduce kindlings at various points; and the rest of the Meiler is then covered with slack and clay, to protect it from the rains. A jet of smoke and flame is seen issuing from its left end.

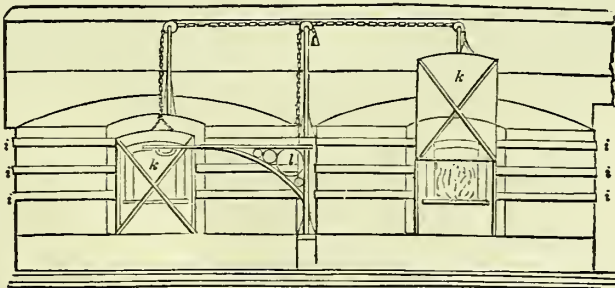

An excellent range of furnaces for making a superior article of coke, for the service of locomotive engines of the London and Birmingham Railway Company, has been

erected at the Camden Town station, consisting of 18 ovens in two lines, the whole discharging their products of combustion into a horizontal flue, which terminates in a chimney-stack 115 feet high. *Fig. 494* is a ground plan of the elliptical ovens, each being 12 feet by 11 internally, and having 3 feet thickness of walls. *a, a* is the mouth, $3\frac{1}{2}$ feet wide outside, and about $2\frac{3}{4}$ feet within. *b, b* are the entrances into the flue; they may be shut more or less completely by horizontal slabs of fire-brick, resting on iron frames, bushed in from behind to modify the draught of air. The grooves of these damper-slabs admit a small stream of air to complete the combustion of the volatilised particles of soot. By this means the smoke is well consumed. The flue *c, c*, is $2\frac{1}{2}$ feet high, by 21 inches wide. The chimney *d*, at the level of the flue, is 11 feet in diameter in the inside and 17 outside; being built from an elegant design of Robert Stephenson, Esq. *e, e* are the keys of the iron hoops, which bind the brick-work of the oven. *Fig. 495* is a vertical section in the line A, B, of *fig. 494*, showing at *b, b*, and *e, e*, the entrances of the dif-

ferent ovens into the horizontal flue; the direction of the draught being indicated by the arrows. *f, f*, is a bed of concrete, upon which the whole furnace range is built, the level of the ground being in the middle of that bed. *g* is a stanchion on which the crane is mounted; *h* is a section of the chimney wall, with part of the interior to the left of the strong line. *Fig. 496* is a front elevation of two of these elegant coke ovens; in which the bracing hoops *i, i, i*, are shown; *k, k* are the cast-iron doors, strengthened outside with diagonal ridges; each door being $5\frac{1}{4}$ feet high, by 4 feet wide, and lined internally with fire-bricks. They are raised and lowered by means of chains and counterweights, moved by the crane *l*.

496

Each alternate oven is charged, between 8 and 10 o'clock every morning, with $3\frac{1}{2}$ tons of good coals. A wisp of straw is thrown in on the top of the heap, which takes fire by the radiation from the dome (which is in a state of dull ignition from the preceding operation), and inflames the smoke then rising from the surface, by the reaction of the hot sides and bottom upon the body of the fuel. In this way the smoke is consumed at the very commencement of the process, when it would otherwise be more abundant. The coking process is in no respect a species of distillation,

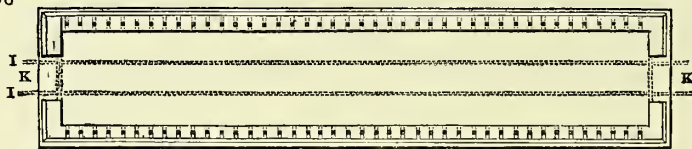

but a complete combustion of the volatile principles of the coal. The mass of coals is first kindled at the surface, where it is supplied with abundance of atmospheric oxygen; because the doors of the ovens in front, and the throat-vents behind, are then left open. The consequence is, that no smoke is discharged from the top of the chimney, at this, the most sooty period of the process, than is produced by an ordinary kitchen fire. In these circumstances, the coal gas, or other gas, supposed to be generated in the slightly heated mass beneath, cannot escape combustion in passing up through the bright open flame of the oven. As the coking of the coal advances more slowly and regularly from the top of the heap to the bottom, only one layer is affected at a time, and in succession downwards, while the surface is always covered with a stratum of red-hot cinders, ready to consume every particle of carburetted or sulphuretted hydrogen gases which may escape from below. The greatest mass, when calcined in this downward order, cannot emit into the atmosphere any more of the above-mentioned gases than the smallest heap.

The coke being perfectly freed from all fuliginous and volatile matters by a calcination of upwards of 40 hours, is cooled down to a moderate ignition by sliding-in the dampers, and sliding-up the doors, which had been partially closed during the latter part of the process. It is now observed to form prismatic concretions, somewhat like a columnar mass of basalt. These are loosened by iron bars, lifted out upon shovels furnished with long iron shanks, which are poised upon swing chains with

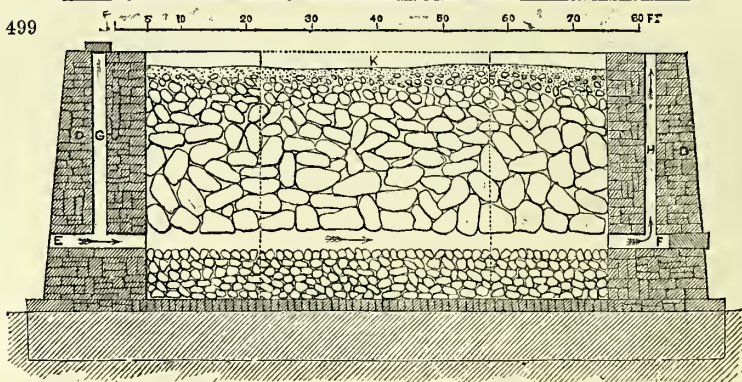

497

498

499

hooked ends, and the lumps are thrown upon the pavement, to be extinguished by sprinkling water upon them from the rose of a watering can; or, they might be transferred into a large chest of sheet-iron set on wheels, and then covered up. Good coals, thus treated, yield 80 per cent. of an excellent compact glistening coke, weighing about 14 cwts. per chaldron.

The loss of weight in coking in the ordinary ovens is usually reckoned at 25 per cent.; and coal, which thus loses one-fourth in weight, gains one-fourth in bulk.

Labourers who have been long employed at rightly-constructed coke ovens seem to enjoy remarkably good health.

Mr. Ebenezer Rogers, of Abercarn, in Monmouthshire, introduced a method of coking, which he thus described:—

'A short time ago a plan was mentioned to the writer as having been used in Westphalia, by which wood was charred in small kilns: as the form of kiln described was quite new to him, it led him to some reflection as to the principles on which it acted, which were found to be so simple and effective, that he determined to apply

them on a large scale for coking coal. The result has been that in the course of a few months the original idea has been so satisfactorily matured and developed, that instead of coking 6 tons of coal in an oven costing 80*l.* 150 tons of coal are now being coked at once in a kiln costing less than the former single oven.

'Figs. 497 and 498 are a side elevation and plan of one of the new coking kilns to a small scale; *fig.* 499 is an enlarged transverse section.

'D D are the walls of the kiln, which are provided with horizontal flues, E, F, which open into the side or bottom of the mass of coal. Connected with each of these flues are the vertical chimneys G, H. The dotted lines I I, *fig.* 498, represent a moveable railway, by which the coal may be brought into the kiln and the coke removed from it. In filling the kiln with coal, care is taken to preserve transverse passages or flues for the air and gases between the corresponding flues E F in the opposite walls. This is effected by building or constructing the passages at the time with the larger pieces of coal, or else by means of channels or flues permanently formed in the bed of the kiln. When the coal is of different sizes, it is also advantageous to let the size of the pieces diminish towards the top of the mass. The surface of the coal when filled in is covered with small coal, ashes, and other suitable material.

'When the kiln is filled the openings K at the ends are built up with bricks, as shown dotted; the kiln is not covered by an arch, but left entirely open at the top. The apertures of the flues F and the chimneys G are then closed, as shown in *fig.* 499, and the coal is ignited through the flues E; the air then enters the flues E, and passes through the coal, and then ascends the chimneys H, as shown by the arrows. When the current of air has proceeded in this direction for some hours, the flues E and chimneys H are closed, and F and G are opened, which reverses the direction of the current of air through the mass. This alteration of the current is repeated as often as may be required. At the same time air descends through the upper surface of the mass of coal. When the mass is well ignited, which takes place in from 24 to 36 hours, the external apertures of the flues E and F are closed, and the chimneys G and H opened: the air now enters through the upper surface of the coal only, and descends through the mass of the coal, the products of combustion passing up the chimneys.

'The coking gradually ascends from the bottom of the mass to the top, and can be easily regulated or equalised by opening or closing wholly or partially the apertures of the flues or chimneys. The top surface of the coal being kept cool by the descending current of air, the workman is enabled to walk over it during the operation; he inserts from time to time at different parts of the surface an iron bar, which is easily pushed down until it reaches the mass of coke, by which its further descent is prevented. In this way the workman gauges the depth at which the coking process is taking place, and if he finds it to have progressed higher at one part than at another, he closes the chimneys communicating with that part, and thus retards the progress there. This gauging of the surface is carried on without difficulty until the coking process has arrived close to the top. The gases and tarry vapours produced by the distillation or combustion descend through the interstices of the incandescent mass below, and there deposit a portion of the carbon contained in them, the residual gases passing up the chimneys. The coke at the lower part of the kiln is effectually protected from the action of the air, by being surrounded and enveloped in the gases and vapours which descend through it, and are non-supporters of combustion.

'When the mass of coal has been coked up to the top, which takes place in about seven days, it is quenched with water, the walls closing the end openings, K, are taken down, and the coke is removed. When a portion has been removed, a moveable railway is laid in the kiln, so as to facilitate the removal of the remainder of the coke.

'The flues E and F may enter at the bottom of the kiln, or at the sides above the bottom, as in *fig.* 499; in the latter case the space below, up to the level of the bottom of the flues, may be filled with small coal, which becomes coked by the radiated heat from the incandescent mass above. The transverse passages through the mass are then constructed upon this bed of small coal with the larger lumps of coal, as before mentioned. The flues and chimneys need not necessarily be horizontal and vertical; and instead of connecting a separate chimney with each transverse flue, flues may be constructed longitudinally in the walls of the kiln, so as to connect two or more of the transverse flues, which are then regulated by dampers, conveying the gaseous products from them into chimneys of any convenient height; the arrangement first described, however, and shown in the drawings is preferred. The gaseous products may be collected, and tar and ammonia and other chemical compounds manufactured from them by the usual modes. The coking or charring of peat and wood may be effected in a similar manner to that already described with regard to coal.

'The new kilns have proved entirely successful; they are already in use at some of

the largest iron-works in the kingdom, and are being erected at a number of other works. The great saving in first cost of oven, economy in working and maintenance, increased yield, and improved quality of coke, will probably soon cause this mode of coking to supersede the others now in use. The kilns are most advantageously made about 14 feet in width, and 90 feet in length, and 7 feet 6 inches in height; this size of kiln contains about 150 tons of coal.'

From the long experience of this gentleman we are induced to quote yet further from his memoir:—

'The process of coking converts the coal into a porous mass; but this is done during the melting of the coal, at which moment the gases in liberating themselves form very minute bubbles; but the practical result is the same as in wood-coal, allowing a large surface of carbon in a small space to be acted upon by the blast. As a general rule, coke made rapidly has larger pores and is lighter than coke made slowly; it accordingly bears less blast, and crumbles too easily in the furnace.

'The process of coking in the ordinary ovens may be thus explained:—When the oven is filled with a proper charge, the coal is fired at the surface by the radiated heat from the roof; enough air is admitted to consume the gases given off by the coal, and thus a high temperature is maintained in the roof of the oven. The coal is by this means melted; and those portions of it which, under the influence of a high temperature, can of themselves form gaseous compounds, are now given off, forming at the moment of their liberation small bubbles or cells; the coke now left is quite safe from waste, unless a further supply of air is allowed to have access to it. At this stage of the process, the coke assumes a pentagonal or five-sided shape and columnar structure. When the coke is left exposed to heat for some time after it is formed, it becomes harder and works better, from being less liable to crush in the furnace and decrepitate on exposure to the blast.

'It has been often remarked as a strange fact, that the hotter the oven, the better the yield of coke; hence all the arrangements of flues to keep up the temperature of the ovens. This fact is, however, the result of laws well known to chemists. When the coal is melted as above mentioned, the hydrogen in the coal takes up two atoms of carbon for each two atoms of hydrogen, forming bicarburetted hydrogen gas (C^2H^2); this at once escapes, but it has to pass upwards through the red-hot coke above, which is at a higher temperature than the melted coal below. Now when bicarburetted hydrogen gas is exposed to a bright red heat it is decomposed, forming carburetted hydrogen gas (CH^2), and depositing one atom, or one half of its carbon, in a solid form. Consequently in the process of coking, if the oven is in good working order, and the coke hot enough, the liberated carbon is detained in its passage upwards, and either absorbed by the coke, or crystallised *per se* upon it. This is simply illustrated by passing ordinary illuminating gas through a tube heated to a bright red heat; the tube will soon become coated internally, and ultimately filled with a carbonaceous deposit produced by the decomposition of the bicarburetted hydrogen contained in the gas.

'It is found that some coal which is too dry or not sufficiently bituminous to coke when put into the oven by itself in lumps, will coke perfectly if crushed small and well wetted with water and charged in this state. This fact, if followed out, would lead to an examination of the chemical nature of the effect produced by the water, and would point the way to further improvements.'

Charred Coal, as it is called, must be regarded as a species of coke. It has been largely employed in lieu of charcoal in the manufacture of tin plates. This preparation was also a discovery of Mr. Ebenezer Rogers, who thus described its manufacture:—

The preparation of the 'charred coal' is simple. The coal is first reduced very small, and washed by any of the ordinary means; it is then spread over the bottom of a reverberatory furnace to a depth of about four inches; the bottom of the furnace is first raised to a red heat. When the small coal is thrown over the bottom, a great volume of gases is given off, and much ebullition takes place; this ends in the production of a light spongy mass, which is turned over in the furnace and drawn in one hour and a half. To completely clear off the sulphur, water is now freely sprinkled over the mass until all smell of the sulphuretted hydrogen produced ceases. Charred coal has been hitherto produced on the floor of a coke oven, whilst red hot after drawing the charge of coke. See TIN-PLATE MANUFACTURE.

A process has for some time been gaining ground in France known as the '*Système Appolt*,' from its being introduced by two brothers of that name. The coking furnaces employed are vertical, and they are in compartments. The authors published a description of their process and a statement of its results, '*Carbonisation de la Houille Système Appolt, décrit par les Auteurs, MM. Appolt Frères*:' Paris, 1858; to which we must refer our readers.

M. Coppée has a coke oven which has been largely used in Belgium, and it has

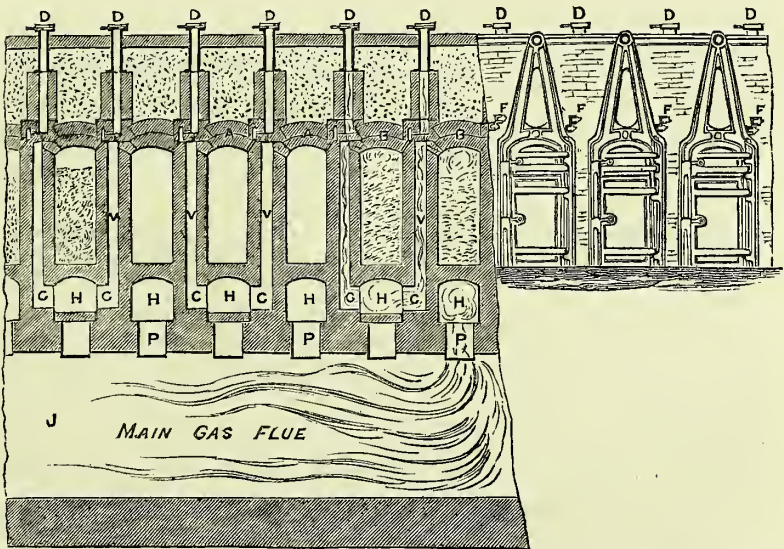

been introduced at the Thorncliffe collieries. The following objects are aimed at in the construction of the Coppée ovens :—

1. The retention (as coke) of as large a proportion of the carbon contained in the coal as possible.
2. The utilisation of the heat of the gases given off, by the use of flues arranged to maintain a high temperature, and applied in such contiguity to the oven itself as to hasten, by imparting an intense heat to the inside of the oven, the expulsion of the gases.
3. As a secondary, but consequent consideration, the application of the heat retained by the gases when they leave the stack of ovens, to the production of steam.

The Coppée ovens have each the form of a parallelogram, the usual dimensions being: length, 29 feet 6 inches; breadth, 18 inches; height, 4 feet. These are charged with coals every 24 hours. When built to be drawn every 48 hours, the ovens have the same length, but are built 5 feet 7 inches high and 24 inches broad. The thickness of brickwork between the ovens is 13·2 inches.

The coals, whether washed or otherwise, are crushed or disintegrated before being placed in the oven to the consistency of very coarse meal. At each end of the oven are two metal doors moving on hinges, and fixed securely in metal frames, the lower being 3 feet, and the upper 1 foot in height. Between each two ovens are about 28

500

vertical channels, *v v* (fig. 500), which, leading from one side of each oven, convey the gases down to the horizontal flues, *h h*, one of which runs under each oven. The ovens are arranged in groups of two. The gases from each two ovens, *A A* or *B B*, take their course down vertical channels to the horizontal flue under one of the ovens, entering such flue by the apertures *c c*. The combined gases, after passing along this flue to the end of the oven, return by the flue under the other oven, and enter, at the point *p*, into a large channel running at right angles to the ovens, *J*. They pass from this channel, either directly into a chimney, or are carried under one or several boilers.

At the commencement of the burning the admittance of air is regulated by three small channels, by means of each of which air can be conveyed to the top, either of the oven, or of the vertical flues. One of these air-passages is in the centre of the oven, and is worked by the doors, *D D*, and the others are fixed at each end of the oven, at the side of the doorway, as shown by *F F*, a very simple arrangement of sliding doors allowing the air to be applied or shut off, with great facility and promptness.

The coke is removed from the ovens by means of a ram, propelled by a cogged driving-wheel, which is worked by a small portable engine.

When the coke is ready to be taken from the oven, the engine and ram are placed opposite to the end of the oven, and three wagons of coal are placed over the three openings at the top. The coke is then pushed out by the ram, this operation occupying about two minutes. A jet of water is at once applied to the coke whilst it is being spread out on the floor. At the same time the lower doors are closed, and the coal dropped into the oven, the apertures through which the coal passes being immediately covered up by sliding doors. The coal is levelled in the ovens by means of rakes passed through the opening of the upper doors. The upper doors are then closed. The time occupied from the moment the doors are opened to their being sealed up again is eight minutes. These ovens have been found, by a large number of experiments to yield only 2 per cent. short of the actual quantity of fixed carbon contained in the coal used.

The workings of the ovens at Thorncliffe, Chapeltown, gave the following comparative results:—

	Per cent. of coke for washed coal	Per cent. of coke for unwashed coal
Common Oven	45	54
Coppée Oven	59	68

The high per-centage of carbon yielded by the Coppée oven is probably chiefly due :
 1st. To the delicate manner in which the admittance of air to the ovens can be regulated. The temperature of the common oven is comparatively low when the combustion of the coal commences, and some time is occupied before the coal is in a state of combustion. During this time a considerable quantity of air is allowed to enter the oven, and carbonic acid is formed. This naturally takes up a large proportion of the carbon in the coal, which is thus removed almost before the coking process begins. When, however, the temperature of the oven in being refilled is very high, as in the Coppée system, it is not unlikely that the free carbon, being thrown off quickly, will unite with the air and form the oxide, taking up no more carbon than if, by the introduction of a larger quantity of air, carbonic acid were formed.

2nd. To the very small space allowed in the oven for the movement of the burning gases.

3rd. To the care with which leakages are provided against.

The quickness with which coke is manufactured by the Coppée system is doubtless due to the rapid combustion caused by the action of the constantly-maintained high temperature of the side, top, and bottom of the ovens, up the enclosed thin upright layer of coal.

Such is a sufficient general description of this new method of coking coal. For further particulars as to the cost of erection, working expenses, utilisation of gases, and other matters, the reader is referred to a paper read by Mr. Emerson Bainbridge before the North of England Institute of Mining and Mechanical Engineers, and published in their 'Transactions' 1873, p. 81.

Messrs. Breckon and Dixon have patented a coke-oven in which the heat of the ignited products of combustion is utilised by circulating through flues beneath the floor of the ovens. It is said that by thus heating the floor, the process of coking is greatly facilitated.

In the so-called *anchor-ovens* the entire charge of coke may be drawn out in one mass, by means of an iron instrument termed an *anchor*, thus saving a considerable amount of labour.

COKES. A name given to tin plates which have been prepared with coke.

COLCOTHAR OF VITRIOL (*Rouge d'Angleterre*, Fr.; *Roths Eisenoxyd*, Ger.), the antiquated name of oxide of iron. It is the brownish-red peroxide of iron, produced by calcining sulphate of iron at a strong heat, levigating the resulting mass, and elutriating it into an impalpable powder. A better way of making it, so as to complete the separation of the acid, is to mix 100 parts of the green sulphate of iron with 42 of common salt, to calcine the mixture, wash away the resulting sulphate of soda, and levigate the residuum. The best sort of polishing powder, called *jewellers' rouge*, or plate-powder, is the precipitated oxide of iron prepared by adding solution of soda to solution of copperas, washing, drying, and calcining the powder in shallow vessels with a gentle heat, till it assumes a deep brown-red colour.

COLD BLAST. See IRON and HOT BLAST.

COLLIDINE. A volatile base discovered by Anderson in bone oil, and subsequently found in shale naphtha.

COLLODION. M. Malgaigne communicated to the French Medical Journals some remarks on the preparation of gun-cotton for surgical purposes. Several French chemists, at the suggestion of M. Malgaigne, attempted to make an ethereal solution of this compound by pursuing the process recommended by Mr. Maynard in the American

Journal of Medical Science, but they failed in procuring the cotton in a state in which it could be dissolved in ether. It appears that these experimentalists had employed a mixture of nitric and sulphuric acids; but M. Miallie ascertained, after many trials, that the collodion in a state fitted for solution was much more easily procured by using a mixture of nitrate of potash and sulphuric acid.

For the information of our readers, we give here a description of M. Miallie's process for its preparation. It appears from the results obtained from this chemist, that cotton in its most explosive form is not the best fitted for making the ethereal solution:—

	Parts by weight
Finely-powdered nitrate of potash	40
Concentrated sulphuric acid	60
Carded cotton	2

Mix the nitrate with the sulphuric acid in a porcelain vessel, then add the cotton, and agitate the mass for three minutes by the aid of two glass rods. Wash the cotton, without first pressing it, in a large quantity of water, and when all acidity is removed (indicated by litmus paper), press it firmly in a cloth. Pull it out into a loose mass, and dry it in a stove at a moderate heat.

The compound thus obtained is not pure fulminating cotton; it always retains a small quantity of sulphuric acid, is less inflammable than gun-cotton, and it leaves a carbonaceous residue after explosion. It has, however, in a remarkable degree the property of solubility in ether, especially when mixed with a little alcohol, and it forms therewith a very adhesive solution, to which the name of collodion has been applied.

Preparation of Collodion.—Prepared cotton, 8 parts; rectified sulphuric ether, 125 parts; rectified alcohol, 8 parts: all by weight.

Put the cotton with the ether into a well-stopped bottle, and shake the mixture for some minutes. Then add the alcohol by degrees, and continue to shake until the whole of the liquid acquires a syrupy consistency. It may be then passed through a cloth, the residue strongly pressed, and the liquid kept in a well-secured bottle.

Collodion thus prepared possesses remarkable adhesive properties. A piece of linen or cotton cloth covered with it, and made to adhere by evaporation to the palm of the hand, will support a weight of twenty or thirty pounds. Its adhesive power is so great that the cloth will commonly be torn before it gives way. The collodion cannot be regarded as a perfect solution of the cotton. It contains suspended and floating in it a quantity of vegetable fibre, which has escaped the solvent action of the ether. The liquid portion may be separated from these fibres by a filter, but it is doubtful whether this is an advantage. In the evaporation of the liquid these undissolved fibres, by felting with each other, appear to give a greater degree of tenacity and resistance to the dried mass.

Small balloons for holding gas are also made of collodion by pouring it into a glass globe, and turning it about, so that every part is covered with the fluid. As the ether evaporates, a thin film is left on the surface of the glass. To remove this, a glass tube is inserted into the neck of the flask, so that the collodion film may adhere; the air is sucked out, and the collapsed film is easily withdrawn.

For the application of collodion to photography, see PHOTOGRAPHY.

COLOCYNTH. *Citrullus Colocynthis.* The Coloquintida, bitter cucumber or bitter apple, a drastic medicine.

COLOGNE EARTH. A brown pigment, prepared from lignite or brown coal.

COLOGNE YELLOW. This pigment consists of a mixture of chromate and sulphate of lead with sulphate of lime. It is prepared by precipitating a mixture of nitrate of lead and nitrate of lime, with sulphate of soda and chromate of potash.

COLOMBA. *Cocculus palmatus.* A climbing shrub, a native of the intertropical regions of the earth. It is now cultivated in the Mauritius and the Isle of Bourbon. The root is of a large, fleshy, deep yellow colour, and divided into many irregular forks. These are cut off, sliced, strung on cords, and hung to dry in the shade.

COLOPHONY. Black resin, the solid residuum of the distillation of turpentine when all the oil has been worked off.

COLORINE. An alcoholic extract of garancine, when evaporated, is known in commerce as *colorine*. It contains the colouring principles of madder (alizarine and purpurine), together with fatty matter and other components of the garancine, which are capable of extraction by alcohol.

COLOUR. In Physics, a property of light, producing peculiar impressions through the eye. Every surface, differing in its mechanical structure or chemical character, acts differently towards the light falling on it, and according to the amount of absorption, or reflection, or refraction, so is the colour of the ray. *White* is an entire reflection, and *black* a total absorption of all the rays, and consequently are not colours. The following Table is by Mr. William Linton:—

A Table of Oil Painters' Colours, with notices of their Chemical and Artistical Properties.

	Colours	Chemical Designation and Preparation	Artistical Properties and Durability	Additional Colours,—with Remarks
WHITES.	<i>Flake White.</i>	Carbonate of Lead, with an excess of Oxide. Plates of lead, exposed to the action of vinegar-steam in beds of fermenting tan.	The best White extant for Oil or Resin vehicles when pure, which is generally ascertained by its exceeding whiteness and opacity. Its usual adulterations are Sulphate of Barytes, Chalk, Pipe-clay, &c., all of which are partially transparent, and consequently appear darker in unctuous or resinous vehicles. It has no injurious action upon Vegetable and other colours, as some have conjectured. It is perfectly soluble in diluted Nitric or Acetic Acid when free from Pipe-clay or Sulphate of Barytes. It is blackened by the foul gases common to most domestic atmospheres, and is more secure in a rapidly drying and protective vehicle.	There are other Whites of Lead, varying in body and brilliancy, and equally obnoxious to the action of mephitic vapours; as <i>Krems, Roman, and Venetian Whites, and Sulphate of Lead.</i> The Whites of <i>Bismuth, Pearl, and Antimony</i> are injured by light as well as by mephitic vapours. Those of <i>Zinc, Tin, and Barytes</i> , although they are comparatively secure against the foul gases, are too feeble in body to be satisfactory in unctuous or resinous vehicles. <i>Pattinson's Oxichloride of Lead</i> , a denser preparation, forms an admirable substratum for works in which a powerful impasto is desired.
	<i>Strontian Yellow.</i>	Chromate of Strontia. A Solution of Chloride of Strontium added to one of Chromate of Potash.	Of a pale Canary Colour. Resists the action of the foul gases and light, and is perfectly durable.	There are other Mineral Yellows, but they are all more or less objectionable. The <i>Chromates of Lead</i> , like all preparations of that metal, are blackened by the foul gases. The united oxides of Lead and Antimony furnish <i>Naples Yellow</i> , a colour readily affected by Sulphuretted Hydrogen and other foul gases, as well as by light, and by a moist steel spatula. <i>Turpith Mineral</i> or Subsulphate of Mercury is rapidly blackened by light, and by the foul airs. <i>Orpiment, or King's Yellow</i> (Arsenic and Sulphur), is equally destructible; also <i>Patent Yellow</i> (Lead and Salt heated violently).
	<i>Cadmium Yellow.</i>	Sulphide of Cadmium. A combination of Cadmium and Sulphur.	A rich and brilliant Orange. Resists the action of the foul gases, light, &c. and is perfectly durable. A good substitute, like Strontian Yellow, for <i>Naples, Chrome, and other changeable Mineral Yellows.</i>	The Zinc Yellows, of which many have been published, are too deficient in body for oil. Chromate of Cadmium and Oxide of Uranium are feeble in body and seriously injured by mephitic airs, and Chromate of Mercury and Oxide of Cerium are destroyed by them. <i>Madder Yellow</i> , like <i>Madder Red</i> , is dissipated by light. Chromate of Barytes (<i>Lemon Yellow</i>) is too feeble in body in Oil. <i>Massicot</i> blackens with foul air; so do <i>Chrome Yellow, and Chrome Orange, and Jaune Mineral</i> , being preparations of lead. Besides the European Ochres, may be noticed a great variety, of almost every conceivable tint, of <i>Red, Orange Yellow, and Purple</i> ,—from Hindostan, Canada, and Trinidad, which were in the Great Exhibition of 1851. They are perfectly durable.
YELLOWS.	<i>Yellow, Oxford, Roman, Stone, Brown, Sienna, with Orange, Puce, Purple, and other Indian and American Ochres.</i>	Native Earths, consisting of Silica and Alumina, coloured by Oxide of Iron.	All permanent Colours, whether Native, Artificial, or Burnt. The Oxides of Iron are among the most staple colours of the palette. When properly washed and prepared for oil painting, they are incapable of injuring other colours, and may be said to constitute the soundest materials with which the cho-	

	Colours	Chemical Designation and Preparation	Artistical Properties and Durability	Additional Colours,—with Remarks
YELLOWS.	<i>Jaune de Mars.</i>	A Chemical Preparation with similar properties.	mistry of Nature has furnished the painter for the imitation of her works.	Palladium Yellow is better avoided, so is Golden Sulphuret of Antimony. Chromate of Tin darkens in oil, and Platinum Yellow is worthless. Gamboge (vegetable) bleaches in the light. Brown-pink, and others of the same class are also evanescent in their layers. The Vegetable Yellows are not to be depended upon. They soon disappear when applied in delicate tints or thin glazings, especially if subjected to the action of the solar rays.
REDS.	<i>Light Red.</i>	Yellow Ochre, Burnt.	Sound, usful, and durable colours.	There are other Mineral Reds which are durable, but they are of inferior quality, and are not needed. <i>Native Cinnabar</i> is inferior in every respect to Vermilion. <i>Venetian Red</i> is an inferior representative of Indian Red, and <i>Colcothar</i> a still coarser one. <i>Red Lead</i> blackens in oil; and <i>Iodide of Mercury</i> has no claim to durability. <i>Red Precipitate</i> is worthless. <i>Phosphate of Cobalt</i> (a Pink Silicate) wants body, and darkens in oil, <i>Mineral Lake</i> (Tin and Chromium) is too feeble in body. <i>Lilac</i> and <i>Crimson Silicates</i> , from Gold, have not body enough for oil painting. Among Vegetable Reds, the <i>Madders</i> have the best reputation for standing. All vegetable colours, however, should be looked upon with suspicion when used in thin glazings.
	<i>Indian Red.</i>	A Native Iron Oxide.		
	<i>Vermilion.</i>	Bisulphide of Mercury. Mercury and Sulphur combined.	A beautiful colour, and of an excellent body. Quite permanent, and not affected by acids or caustic alkalis. Vaporised by a red heat, if pure.	
	<i>Madder Lakes.</i>	Vegetable dyes on earthy bases.	Rich and beautiful colours.	
	<i>Palladium Red.</i>	Ammonio-perchloride of Palladium.	A rich, deep, and beautiful colour.	
BLUES.	<i>Ultramarine, Native.</i>	A compound of Silicate of Alumina and Silicate of Soda, with Sulphide of Sodium: the colour is owing to the reaction of the latter on the two former constituents. The Native is prepared from Lapis lazuli.	A brilliant purplish-blue. None of the mephitic gases or light do it any injury. Acids will remove its colour. It is perfectly durable for the painter. The artificial preparation by Zuber, of Alsace (in the Great Exhibition of 1851), is of a less purple hue, and better fitted for the aerial tints of landscape.	There are other Mineral Blues, but they are better avoided. The Silicate of Cobalt and Potassa makes Cobalt Blue; and the Oxide of Cobalt and Potassa makes Smalt: both feeble pigments. Verditer and all the Copper Blues turn Green, and darken in oil. A Blue Frit, a Silicate of Copper (Alexandrian Blue), brought by Mr. Layard from Nineveh, which has retained its colour for probably 4000 years, turned black when mixed with oil. The permanence of Vitreous (called Silica) colours, when levigated for pigments, is a delusion. They are subject to all the changes and affinities of the substances which compose them. Prussian Blue is liable to change, Indigo fades in the light.
	<i>Ultramarine, Artificial.</i>			
GREENS.	<i>Chromium Green.</i>	Sesquioxide of Chromium. When Chromate of Mercury (the Orange precipitate on mixing Nitrate of Mercury and Chromate of Potash) is strongly ignited, Oxide of Chromium remains in a powder.	An opaque light Green, of a full body, and permanent in all respects. It is the colouring matter of emeralds.	There are other Mineral Greens. Those from the Artificial Ultramarine process, though durable, are wanting in body and richness. The Phosphates, Carbonates (Malachite), Disulphates, and Acetates of Copper, with Mineral, Verditer, and Verdigris Greens, are blackened by foul gases, and deoxidised or darkened by oil. Nickel Green also darkens and blackens in oil. Scheele's Green (Vert Mëtis), Arsenate of Cop-

	Colours	Chemical Designation and Preparation	Artificial Properties and Durability	Additional Colours,—with Remarks
GREENS.	<i>Terre Verte.</i>	Silicate of Protoxide of Iron, with Water, Potassa, and Magnesia. A Native Mineral.	A delicate neutral Green. Quite permanent. Like Ultramarine, its colour is destroyed by acids.	per, darkens in oil and foul air. Zinc or Cobalt Green (Rinmann's Green) is permanent, but inferior in body and colour to the Green of Chromium.
	<i>Vandyke, Cap-pah, Rubens, Cassel, and Cologne Browns.</i>	Decomposed Vegetable, with Bituminous Matter.	The best when deep, rich, and transparent.	There are other Browns, but many of them are less durable. Madder Brown, like all the other Madders, is liable to fade. Ivory and Bone Browns are not so permanent as the blacks of those substances. Catechu Brown, rich and transparent, is subject to fly when laid on thinly. Manganese Brown is semi-opaque, but a good drier. Prussian Brown (Ferrocyanide of Copper) is affected by foul gas, and destroyed by alkalis. Calcined Prussian Blue is a fine Brown, but troublesome to prepare. The peaty Browns, probably from their vegetable colouring matter, have a slight tendency to become paler when used very thinly, and exposed to strong light.
BROWNS.	<i>Terre Verte Brown.</i>	<i>Terre Verte. Burnt.</i>	A quiet beautiful colour.	
	<i>Umber.</i>	An Iron Ore with Manganese.	An useful colour both Raw and Burnt.	
	<i>Mummy.</i>	White Pitch and Myrrh, combined with Animal Matter.	Rich transparent Brown.	
	<i>Asphaltum.</i>	Bitumen. A Mineral Pitch or Resin found floating on the Dead Sea; also after the distillation of Natural Naphtha.	Asphaltum is liable to crack, except when in an unctuous or waxy vehicle.	
BLACKS.	<i>Ivory Black.</i>	Burnt Ivory.	Of a Brownish-black tint, quite permanent.	There are other permanent Blacks, as Bone-black (Burnt Bones), Lamp-black (pure Carbon), the Soot of Burnt Resin, and Turpentine. Manganese-black, a native product, and a good drier (Peroxide of Manganese). There are also Black Ochres, native earths, but they are not required.
	<i>Blue-black.</i>	Burnt Vine Twigs, &c. Common Blacks mixed with insecure Blues are sometimes substituted by empirics. The Blue-black of the ancients was made with the lees of wine.	Of a Bluish-black tint, perfectly durable.	

COLOURING MATTERS. The colour of any object, either natural or artificial, owes its origin to the effect produced on it by the rays of light. This effect is either due to the mass or substance of the body itself, as may be seen in the colours of metals and many shells, or it arises from the presence of some foreign substance or substances not absolutely essential to it, and which may in many cases be separated and removed from it. It is in speaking of these foreign substances which are often found colouring natural objects, or which are employed in the arts for the purpose of imparting colours to various materials, that we generally make use of the term COLOURING MATTER. By chemists, however, the term is only applied to organic bodies, and not to mineral substances, such as oxide of iron, cinnabar, ultramarine, &c., which, though they are employed as pigments in the arts, differ very widely in their properties from one another and from colouring matters in the narrower sense of the word. Colouring matters may be defined to be substances produced in animal or vegetable organisms, or easily formed there by processes occurring in nature (such as oxidation or fermentation), and which are either themselves coloured or give coloured compounds with bases or with animal or vegetable fibre. According to this definition, bodies like carbazotic acid and murexide, which are formed by complicated processes such as never occur in nature, are excluded, though they resemble true colouring matters in many of their properties, such as that of giving intensely-coloured compound bases. Whether, however, even after accepting the above definition, colouring matters can be considered as constituting a natural class of organic bodies, such as the fats, resins, &c., must still remain doubtful, though modern research tends to prove that these substances are related to one another by other properties besides the accidental one of colour, and will probably be found eventually to belong in reality to one natural class.

Colouring matters occur in all the organs of plants, in the root, wood, bark, leaves, flowers and fruit; in the skin, hair, feathers, blood, and various secretions of animals; in insects, for example, in various species of coccus; and in mollusca, such as the murex. Indeed there are very few plants or animals whose organs do not produce some kind of colouring matter. It is remarkable, however, that the colours which are most frequently presented to our view, such as those of the leaves and flowers of plants and the blood of animals, are produced by colouring matters with which we are but very little acquainted, the colouring matters used in the arts, and which have been examined with most care, being derived chiefly from less conspicuous organs, such as the roots and stems of plants. In almost all cases the preparation of colouring matters in a state of purity presents great difficulties, so that it may even be said that very few are known in that state.

Some colouring matters bear a great resemblance to the so-called extractive matters, others to resins. Hence they have been divided into *extractive* and *resinous* colouring matters. These resemblances are, however, of no great importance. The principal colouring matters possess such peculiar properties that they must be considered as bodies altogether *sui generis*.

As regards their most prominent physical characteristic, colouring matters are divided into three principal classes: viz., the red, yellow, and blue, the last class comprising the smallest number. Only one true green colouring matter occurs in nature, viz., chlorophyll, the substance to which the green colour of leaves is owing.¹ Black and brown colouring matters are also uncommon, the black and brown colours obtained in the arts from animals or vegetables being (with the exception of sepia and a few others) compounds of colouring matters with bases. The colours of natural objects are often due to the presence of more than one colouring matter. This may easily be seen in the petals of some flowers. If, for instance, the petals of the orange-coloured variety of the *Tropæolum majus* be treated with boiling water, a colouring matter is extracted which imparts to the water a purple colour. The petals now appear yellow, and if they be treated with boiling spirits of wine, a yellow colouring matter is extracted, and they then become white. When the purple colouring matter is absent the flowers are yellow; when, on the contrary, it is present in greater abundance, they assume different shades of brown. Precisely the same phenomena are observed in treating the petals of the brown *Calceolaria* successively with boiling water and spirits of wine. In many cases colouring matters exhibit, when in an uncombined state, an entirely different colour from what they do when they enter into a state of combination. The colouring matter of litmus, for instance, is, when uncombined, red, but its compounds with alkalis are blue. The alkaline compounds of alizarine are of a rich violet colour, while the substance itself is reddish-yellow. Many yellow colouring matters become brown by the action of alkali, and the blue colouring matters of flowers generally turn green when exposed to the same influence. The classification of colouring matters, according to colour, is therefore purely artificial. The terms red, yellow, and blue colouring matter, merely signify that the substance itself possesses one of these colours, or that most of its compounds are respectively red, yellow, or blue. In almost all cases, even when the colour is not entirely changed by combination with other bodies, its intensity is much increased thereby, substances of a pale yellow colour becoming of a deep yellow, and so on.

Colouring matters consist, like most other organic substances, either of carbon, hydrogen, and oxygen, or of those elements in addition to nitrogen. The exact relative proportion of these constituents, however, is known in very few cases, and in still fewer instances have the chemical formulæ of the compounds been established with any approach to certainty. This proceeds on the one hand from the small quantities of these substances usually present in the organs of plants and animals, and the difficulty of obtaining sufficient quantities for examination in a state of purity, and on the other hand from the circumstance of their possessing a very complex chemical constitution and high atomic weight.

Only a small number of colouring matters are capable of assuming a crystalline form; the greater number, especially the so-called resinous ones, being perfectly amorphous. Among those which have been obtained in a crystalline form, may be mentioned alizarine, indigo-blue, quercitrine, morine, luteoline, chrysophan, and rutine. It is probable, however, that when improved methods have been discovered of preparing colouring matters, and of separating them from the impurities with which they are so often associated, many which are now supposed to be amorphous will be found to be capable of crystallising.

Very little is known concerning the action of light on colouring matters and their

¹ Another green colouring matter, derived from different species of *Rhamnus*, has been described under the name of 'Chinese Green.' It is stated to be a peculiar substance, not as might be supposed, a mixture of a blue and a yellow colouring matter.

compounds. It is well known that these bodies when exposed to the rays of the sun, especially when deposited in thin layers on or in fabrics made of animal or vegetable materials, lose much of the intensity of their colour, and sometimes even disappear entirely, that is, they are converted into colourless bodies. But whether this process depends on a physical action induced by the light, or whether, as is more probable, it consists in promoting the decomposing action of oxygen and moisture on them, is uncertain. The most stable colouring matters, such as indigo-blue and alizarine in its compounds, are not insensible to the action of light. Others, such as carthamine from safflower, disappear rapidly when exposed to its influence. Colours produced by a mixture of two colouring matters are often found to resist the action of light better than those obtained from one alone. In one case, viz., that of Tyrian purple, the action of light seems to be absolutely essential to the formation of the colouring matter. The leaves of plants also remain colourless if the plants are grown in darkness, though in this case the formation of the green colouring matter is probably not due to the direct chemical action of the light.

The action of heat on colouring matters varies very much according to the nature of the latter and the method of applying the heat. A moderate degree of heat often changes the hue of a colouring matter and its compounds, the original colour being restored on cooling, an effect which is probably due to physical causes. Sometimes this effect is, without doubt, owing to the loss of water. Alizarine, for instance, crystallised from alcohol, when heated to 212° F. loses its water of crystallisation, its colour changing at the same time from reddish-yellow to red. At a still higher temperature most colouring matters are entirely decomposed, the products of decomposition being those usually afforded by organic matters, such as water, carbonic acid, carburetted hydrogen, empyreumatic oils, and, if the substance contains nitrogen, ammonia, or organic bases such as aniline. A few colouring matters, as for example alizarine, rubiacine, indigo-blue, and indigo-red, if carefully heated, may be volatilised without change, and yield beautiful crystallised sublimes, though a portion of the substance is sometimes decomposed, giving carbon and empyreumatic products.

Colouring matters, like most other organic substances, undergo decomposition with more or less facility when exposed to the action of oxygen; and the process may, indeed be more easily traced, in their case, as it is always accompanied by a change of hue. Its effects may be daily observed in the colours of natural objects belonging to the organic world. Flowers, in many cases, lose a portion of their colour before fading. The leaves of plants, before they fall, lose their green colour and become red or yellow. The colour of venous blood changes, when exposed to the air, from dark red to light red. When exposed to the action of oxygen, blue and red colouring matters generally become yellow or brown; but the process seldom ends here: it continues until the colour is quite destroyed; that is, until the substance is converted into a colourless compound. This may be easily seen when a fabric, dyed of some fugitive colour, is exposed to the air. The intensity of the colour diminishes, in the first instance; it then changes in hue, and, finally, disappears entirely. Indeed, the whole process of bleaching in the air depends on the concurrent action of oxygen, light, and moisture. The precise nature of the chemical changes which colouring matters undergo during this process of oxidation is unknown. No doubt, it consists, generally speaking, in the removal of a portion of their carbon and hydrogen, in the shape of carbonic acid and water, and the conversion of the chief mass of the substance into a more stable compound, capable of resisting the further action of oxygen. But this statement conveys very little information to the chemist, who, in order to ascertain the nature of a process of decomposition, requires to know exactly all its products, and to compare their composition with that of the substances from which they are derived. The indeterminate and uninteresting nature of the bodies into which most colouring matters are converted by oxidation has probably deterred chemists from their examination. The action of oxygen on colouring matters varies according to their nature and the manner in which the oxygen is applied, and it is the degree of resistance which they are capable of opposing to its action that chiefly determines the stability of the colours produced by their means in the arts. Indigo-blue shows no tendency to be decomposed by gaseous oxygen at ordinary temperatures; it is only when the latter is presented in a concentrated form, as in nitric or chromic acid, or in a nascent state, as in a solution of ferridecyanide of potassium containing caustic potash, that it undergoes decomposition. When, however, indigo-blue enters into combination with sulphuric acid, it is decomposed by means of oxygen with as much facility as some of the least stable of this class of bodies. Some colouring matters are capable of resisting the action of oxygen even in its most concentrated form. Of this kind are rubianine and rubiacine, which, when treated with boiling nitric acid, merely dissolve in the liquid and crystallise out again, when the latter is allowed to cool. The action of atmospheric oxygen on colouring matters is generally promoted by alkalis, and retarded in the presence of

acids. A watery solution of hematine, when mixed with an excess of caustic alkali, becomes of a beautiful purple; but the colour when exposed to the air, almost immediately turns brown, the hematine being then completely changed. It is almost needless to observe, that the bodies into which colouring matters are converted by oxidation are incapable, under any circumstances, of returning to their original state.

The action of reducing agents, that is of bodies having a great affinity for oxygen, on some colouring matters, is very peculiar. If indigo-blue, suspended in water, be placed in contact with protoxide of iron, protoxide of tin, or an alkaline sulphuret, sulphite, or phosphite, or grape sugar, or, in short, any easily oxidisable body, an excess of some alkali or alkaline earth being present at the same time, it dissolves, forming a pale yellow solution without a trace of blue. This solution contains, in combination with the alkali or alkaline earth, a perfectly white substance, to which the name of *reduced indigo* has been applied. When an excess of acid is added to the solution, it is precipitated in white flocks. By exposure to the air, either by itself or in a state of solution, reduced indigo rapidly attracts oxygen, and is reconverted into indigo-blue. Hence the surface of the solution, if left to stand in uncovered vessels, becomes covered with a blue film of regenerated indigo-blue. It was for a long time supposed that reduced indigo was simply deoxidised indigo-blue, and that the process consisted merely in the indigo-blue parting with a portion of its oxygen, which was taken up again on exposure to the air. It has, however, been discovered that in every case water is decomposed during the process of reduction which indigo-blue undergoes, the oxygen of the water combining with the reducing agent, and the hydrogen uniting with the indigo-blue, water being again formed when reduced indigo comes in contact with oxygen. Reduced indigo is therefore not a body containing less oxygen than indigo-blue, but is a compound of the latter with hydrogen. There are several red colouring matters which possess the same property, that of being converted into colourless compounds by the simultaneous action of reducing agents and alkalis, and of returning to their original state when exposed to the action of oxygen. There can be little doubt that the process consists, in all cases, in the colouring matter combining with hydrogen and parting with it again when the hyduret comes in contact with oxygen.

The action of chlorine on colouring matters is very similar to that of oxygen, though, in general, chlorine acts more energetically. The first effect produced by chlorine, whether it be applied as free chlorine, or in a state of combination with an alkali, or alkaline earth as an hypochlorite, usually consists in a change of colour. Blue and red colouring matters generally become yellow. By the continued action of chlorine all trace of colour disappears, and the final result is the formation of a perfectly white substance, which is usually more easily soluble in water and other menstrua than that from which it was formed. Since it is most commonly by means of chlorine or its compounds that colouring matters are destroyed or got rid of in the arts, as in bleaching fabrics and discharging colours, the process of decomposition which they undergo by means of chlorine has attracted a good deal of attention, and the nature of the chemical changes, which take place in the course of it, has often been made a subject of dispute, though the matter is one possessing more of a theoretical than a practical interest. It is a well-known fact that many organic bodies are decomposed when they are brought into contact, in a dry state, with dry chlorine gas. The decomposition consists in the elimination of a portion of the hydrogen of the substance and its substitution by chlorine. When water is present at the same time, the decomposition is, however, not so simple. It is well known that chlorine decomposes water, combining with the hydrogen of the latter and setting its oxygen at liberty, and it has been asserted, that in the bleaching of colouring matters by means of chlorine when moisture is usually present, this always takes place in the first instance, and that it is in fact the oxygen which effects their destruction, not the chlorine. This appears, indeed, to be the case occasionally. Rubian, for instance, the body from which alizarine is derived, gives, when decomposed with chloride of lime, phthalic acid, a beautifully-crystallised substance, containing no chlorine, which is also produced by the action of nitric acid on rubian, and is, therefore, truly a product of oxidation. In many cases, however, it is certain that the chlorine itself also enters into the composition of the new bodies produced by its action on colouring matters. When, for instance, the chlorine acts on indigo-blue, chlorisatine is formed, which is indigo-blue, in which one atom of hydrogen is replaced by one of chlorine, plus two atoms of oxygen, the latter being derived from the decomposition of water.

The behaviour of colouring matters towards water and other solvents is very various. Some colouring matters, such as those of logwood and brazilwood, are very easily soluble in water. Others, such as the colouring matters of madder and quercitron bark, are only sparingly soluble in water. Many, especially the so-called resinous ones, are insoluble in water, but more or less soluble in alcohol and ether, or alkaline liquids. A

few, such as indigo-blue, are almost insoluble in all menstrua, and can only be made to dissolve by converting them, by means of reducing agents, into other bodies soluble in alkalis. Those which are soluble in water, are, generally speaking, of the greatest importance in the arts, since they admit of more ready application, when they possess this property.

The behaviour of colouring matters towards acids is often very characteristic. Most colouring matters are completely decomposed by nitric, chloric, manganic, and chromic acids, in consequence of the large proportion of oxygen which these acids contain. With many colouring matters the decomposition takes place even at the ordinary temperature: with others, it only commences when the acid is warmed, especially if the latter be applied in a state of considerable dilution. Concentrated sulphuric acid also destroys most colouring matters, especially if the acid be heated. It seems to act by depriving them of the elements of water, and thereby converting them into substances containing more carbon than before, as may be inferred from the dark, almost black, colour which they acquire. At the same time the acid generally loses a portion of its oxygen, since sulphurous acid is almost always evolved on heating. Some colouring matters, such as alizarine, are not decomposed by concentrated sulphuric acid even when the latter is raised to the boiling point; they merely dissolve, forming solutions of various colours, from which they are precipitated unchanged, on the addition of water, when they are insoluble or not easily soluble in the latter. Others, again, like indigo-blue, dissolve in concentrated or fuming sulphuric acid, without being decomposed, and at the same time enter into combination with the acid, forming true double acids, which are easily soluble in water and combine as such with bases. Many colouring matters undergo a change of colour when exposed to the action of acids, the original colour being restored by the addition of an excess of alkali, and this property is made use of for the detection of acids and alkalis. The colour of an infusion of litmus, for instance, is changed by acids from blue to red, and the blue colour is restored by alkalis. An infusion of the petals of the purple dahlia or of the violet becomes red on the addition of acids, and this red colour changes again to purple or blue with alkalis, an excess of alkali making it green. The yellow colour of rutine becomes deeper with strong acids. In most cases, this alteration of colour depends on a very simple chemical change. Litmus, for example, in the state in which it occurs in commerce, consists of a red colouring matter in combination with ammonia, the compound being blue. By the addition of an acid, the ammonia is removed, and the uncombined red colouring matter makes its appearance. Ammonia and most alkalis remove the excess of acid, and, by combining with the red colouring matter, restore the blue colour. When a colouring matter, like alizarine, is only sparingly soluble in water, its solubility is generally diminished in the presence of a strong acid. Hence, by adding acid to the watery solution, a portion of the colouring matter is usually precipitated. It is very seldom that colouring matters are really found to enter into combination with acids. Indeed, only one, viz. berberine, is capable of acting the part of a true base, and forming definite compounds with acids. Some acids, such as sulphurous and hydrosulphuric acids, do certainly seem to combine with some colouring matters and form with them compounds, in which the colour is completely disguised, and apparently destroyed. If a red rose be suspended in an atmosphere of sulphurous acid it becomes white, but the red colour may be restored by neutralising the acid with some alkali. On this property of sulphurous acid depends the process of bleaching woollen fabrics by means of burning sulphur. In this case the colouring matter is not destroyed, but only disguised by its combination with the acid.

Most colouring matters are capable of combining with bases. Indeed, their affinity for the latter is generally so marked that they may be considered as belonging to the class of weak acids. Like all other weak acids, they form, with bases, compounds of a very indefinite composition, so much so, that the same compound, prepared on two different occasions, is often found to be differently constituted. Hence the great difficulty experienced by chemists in determining the atomic weight of colouring matters. There are very few of the latter for which several formulæ, all equally probable, may not be given, if the compounds with bases be employed for their determination. The compounds of colouring matters with bases hardly ever crystallise. Those with alkalis are mostly soluble in water and amorphous; those with the alkaline earths, lime, and baryta, are sometimes soluble, sometimes insoluble; those with the earths and metallic oxides are almost always insoluble in water. The compounds with alkalis are obtained by dissolving the colouring matter in water to which a little alkali is added, and evaporating to dryness: an operation which must be carefully conducted if the colouring matter is one easily affected by oxygen. The insoluble compounds, with earths and metallic oxides, are obtained either by double decomposition of a soluble compound with a soluble salt of the respective base, or by adding to a solution of the colouring matter, in water or any other menstruum, a salt of the base containing some

weak acid, such as acetic acid. It is remarkable that of all bases none show so much affinity for colouring matters as alumina, peroxide of iron, and peroxide of tin, bodies which occupy an intermediate position between acids and bases. If a solution of any colouring matter be agitated with a sufficient quantity of the hydrates of any of these bases, the solution becomes decolourised, the whole of the colouring matter combining with the base and forming a coloured compound. It is accordingly these bases that are chiefly employed in dyeing, for the purpose of fixing colouring matters on particular portions of the fabric to be dyed. When used for this purpose they are called *mordants*. Their compounds with colouring matters are denominated *lakes*, and are employed as pigments by painters. The colours of the compounds usually differ, either in kind or degree, from those of the colouring matters themselves. Red colouring matters often form blue compounds, yellow ones sometimes give red or purple compounds. The compounds with peroxide of iron are usually distinguished by the intensity of their colour. When a colouring matter gives with alumina and oxide of tin red compounds, its compound with peroxide of iron is usually purple or black; and when the former are yellow, the latter is commonly olive or brown. Almost all the compounds of colouring matters with bases are decomposed by strong acids, such as sulphuric, muriatic, nitric, oxalic, and tartaric acids, and even acetic acid is not without effect on some of these compounds. The compounds with earths and metallic oxides are also decomposed, sometimes by alkalis. A solution of soap is sufficient to produce this effect in many cases, and dyes are therefore often tested by means of a solution of soap in order to ascertain the degree of permanence which they possess.

No property is so characteristic of colouring matters, as a class, as their behaviour towards bodies of a porous nature, such as charcoal. If a watery solution of a colouring matter be agitated with charcoal, animal charcoal being best adapted for the purpose, the colouring matter is generally entirely removed from the solution and absorbed by the charcoal. The combination which takes place under these circumstances is probably not due to any chemical affinity, but is rather an effect of the so-called attraction of surface, which we often see exerted by bodies of a porous nature, such as charcoal and spongy platinum, and which enable the latter to absorb such large quantities of gases of various kinds. That the compound is indeed more of a physical than a chemical nature seems to be proved by the circumstances that sometimes the colouring matter is separated from its combination with the charcoal by means of boiling alcohol, an agent which can hardly be supposed to exert a stronger chemical affinity than water. It is this property of colouring matters which is made use of by chemists to decolourise solutions, and by sugar manufacturers to purify their sugar. The attraction manifested by colouring matters for animal or vegetable fibre is probably also a phenomenon of the same nature, caused by the porous condition of the latter, and the powerful affinity of the so-called mordants for colouring matters, may, perhaps, be in part accounted for by their state of mechanical division being different from that of other bases. Colouring matters, however, vary much from one another in their behaviour towards animal or vegetable fibre. Some, such as indigo-blue, and the colouring matters of safflower and turmeric, are capable of combining directly with the latter, and imparting to them colours of great intensity. Others are only slightly attracted by them and consequently impart only feeble tints; they therefore require, when they are employed in the arts for the purpose of dyeing, the interposition of an earthy or metallic base. To the first class Bancroft applied the term *substantive* colouring matters, to the second that of *adjective* colouring matters.

One of the most interesting questions connected with the history of colouring matters is that in regard to the original state in which these substances exist in the animal and vegetable organisms from which they are derived. It has been known for a long time that many dye-stuffs, such as indigo and archil, do not exist ready formed in the plants from which they are obtained, and that a long and often difficult process of preparation is required in order to eliminate them. The plants which yield indigo exhibit, while they are growing, no trace of blue colour. The colouring matter only makes its appearance after the juice of the plant has undergone a process of fermentation. The lichens employed in the preparation of archil and litmus are colourless, or at most light brown, but by steeping them in liquids containing ammonia and lime a colouring matter of an intense red is gradually generated, which remains dissolved in the alkaline liquid. Other phenomena of a similar nature might be mentioned, as for instance the formation of the so-called Tyrian purple from the juice of a shell-fish, and new ones are from time to time being discovered. In order to explain these phenomena various hypotheses have been resorted to. It was supposed, for instance, that the *indigofera* contained white or reduced indigo, and hence were devoid of colour, and that the process of preparing indigo-blue consisted simply in oxidising the white indigo, which was for this reason denominated *indigogene*, by some chemists. The same

assumption was made in regard to other colouring matters, all of which were supposed to exist originally in a deoxidised and colourless state. In regard to indigo, however, the hypothesis is disproved at once by the fact that reduced indigo is only soluble in alkaline liquids, and that the juice of the indigo-bearing plants is always acid. In regard to the other colouring matters it seems also to be quite untenable. The first person to throw some light on this obscure department of organic chemistry was Robiquet. This distinguished chemist succeeded in obtaining from lichens in their colourless state a beautifully crystallised, colourless substance, soluble in water, having a sweet taste, and consisting of carbon, hydrogen, and oxygen. This substance he denominated *orcine*. By the combined action of ammonia and oxygen, he found it to be converted into a red colouring matter, containing nitrogen, and insoluble in water, which was in fact identical with the colouring matter of archil. This beautiful discovery furnished chemists with a simple explanation for the curious phenomena observed in the formation of this and other colouring matters, and it was soon followed by others. Heeren and Kane obtained from various lichens other colourless substances of similar properties, and it was shown by Schunck that oricine is not even the first link in the chain, but is itself formed from another body, *lecanorine*, which, by the action of alkalis, yields oricine and carbonic acid, just as sugar by fermentation gives alcohol and carbonic acid. In like manner it was discovered by Erdmann that the colouring matter of logwood is formed by the simultaneous action of oxygen and alkalis from a crystallised colourless substance, *hæmatoxyline*, which is the original substance existing in the wood of the tree; and is like the others, not itself strictly speaking, a colouring matter, but a substance which gives rise to the formation of one.

There is, however, another class of phenomena connected with the formation of colouring matters, entirely different from that just referred to. It was discovered by Robiquet that if madder be treated for some time with sulphuric acid, and the acid be afterwards completely removed, the madder is found to have acquired a much greater tinctorial power than before. This fact was explained by some chemists by supposing that the sulphuric acid had combined with or destroyed some substance or substances, contained in the madder which had previously hindered the colouring matter from exerting its full power in dyeing, such as lime, sugar, woody fibre, &c. By others it was suspected that an actual formation of colouring matter took place during the process, and this suspicion has been verified by recent researches. Schunck succeeded in preparing from madder a substance resembling gum, very soluble in water, amorphous, and having a very bitter taste, like madder itself, and to which he gave the name of *rubian*. This substance, though not colourless, is incapable of combining with mordants, like most colouring matters. When, however, it is acted on by strong acids, such as sulphuric or muriatic acid, it is completely decomposed, and gives rise to a number of products, the most important of which is *alizarine*, one of the colouring matters of madder itself. Among the other products are a yellow crystallised colouring matter, *rubianine*, two amorphous red colouring matters resembling resins, *rubiretine* and *verantine*, and lastly, grape-sugar. When subjected to fermentation, the same products are formed, with the exception of rubianine, which is replaced by a yellow colouring matter of similar properties. This process of decomposition evidently belongs to that numerous class called by some chemists 'catalytic,' in which the decomposing agent does not act, as far as we know, in virtue of its chemical affinities. It is evident, then, that when madder is acted on by sulphuric acid an actual formation of colouring matter takes place, and it is even probable that the whole of the colouring matter found in madder in its usual state was originally formed from rubian, by a process of slow fermentation, the portion of the latter still remaining undecomposed being that which is acted on when acids are applied to madder. From the *Isatis tinctoria* or common woad plant, Schunck, in like manner, extracted an amorphous substance, easily soluble in water, called by him *indiean*, and which, by the action of strong acids, is decomposed into indigo-blue, indigo-red, sugar, and other products, among which are also several resinous colouring matters. Looking at them from this point of view, colouring matters may be divided into two classes, viz., first, such as are formed from other substances, not themselves colouring matters, by the action of oxygen and alkalis; and, secondly, such as are formed from other substances by means either of ferments or strong acids, without the intervention of oxygen. To the first class belong the colouring matters of archil, litmus, and logwood; they yield comparatively fugitive dyes, and are usually decomposed by allowing the very process to which they owe their formation to continue. To the second class belong indigo-blue, indigo-red, and alizarine, bodies which show a remarkable degree of stability for organic compounds. More extended research will probably show that many other colouring matters are formed either in one manner or the other, which will probably afford us the means of arriving at a rational mode of classifying these bodies, and of distinguishing them as a class from others.—E. S.

COLT'S-FOOT. See TESSILAGO.

COLUMBIUM or *Niobium*. A peculiar metal originally extracted from a rare mineral brought from Haddam in Connecticut, and known as *Columbite*. This is a columbate and tantalate of iron and manganese. Columbium also occurs, with tantalum, in several rare Swedish minerals. The metal received its name from Columbia (America). See **NIObium**.

COLUMNAR COAL. A name given to **ANTHRACITE**.

COLZA is a variety of cabbage,—the *Brassica oleracea*,—whose seeds afford by pressure an oil much employed in France and Belgium for burning in lamps, and for many other purposes. This plant requires a rich but light soil; it does not succeed upon either sandy or clay lands. The ground for it must be deeply ploughed and well dunged. It should be sown in July, and be afterwards replanted in a richly manured field. In October it is to be planted out in beds, 15 or 18 inches apart. Colza may also be sowed in furrows 8 or 10 inches asunder.

Land which has been just cropped for wheat is that usually destined to colza; it may be fresh dunged with advantage. The harvest takes place in July, with a sickle, a little before the seeds are completely ripe, lest they should drop off. As the seed is productive of oil, however, only in proportion to its ripeness, the cut plants are allowed to complete their maturation, by laying them in heaps under airy sheds, or placing them in a stack, and thatching it with straw.

The cabbage stalks are thrashed with flails; the seeds are winnowed, sifted, and spread out in the air to dry; then packed away in sacks, in order to be subjected to the oil mill at the beginning of winter. The oil-cake is a very agreeable food to cattle; it serves to fatten them, and is reckoned to defray the cost of the mill.

When proper manure was not applied, it was reported that colza impoverished the soil very much, as do indeed, all the plants cultivated for the sake of their oleaginous seeds. The same soil must not, therefore, be come back upon again for six years, if fine crops be desired. The double ploughing which it requires effectually cleans the ground.

The colza or wild cabbage itself is a plant of sufficient interest to call special attention to its properties. Besides yielding an oil which gives a brilliant light for the lamps of lighthouses, its seed has other properties that should induce the plant to be in favour with agriculturists, emigrants, and colonists. The recent accounts, according to Du Bow, state 'it to be admirably adapted for cattle as food; that the seeds after the oil is expressed yield a cake highly prized for fattening cattle, and as manure.' 'There is a spring variety which will succeed in almost any part of the United States, and will ultimately become an article of great importance.'

The real history of this valuable plant seems to be this:—The Abbé de Commerell, in a letter to Dr. Lettsom, dated from Paris at the Abbey of St. Victor, 1789, calls especial attention to the colza which he had cultivated for some time in the neighbourhood of Paris, 'and last year under the inspection of the Royal Society of Agriculture. The severe winter just experienced, which had destroyed great abundance of turnips and cold, had not done the least injury to my plants, which is a proof of resisting the severest cold.' The following description of the plant may lead to its adoption as sources of oil and food. To induce this we may refer to the original communication, now of course sufficiently rare: it is entitled: '*Mémoire sur la Culture, l'usage et les avantages du Choux à faucher, par M. l'Abbé de Commerell, à Paris*,' 1789. He states he found the plant in Germany, where it was only used for seed; that there are three distinct varieties, known by the colours of the 'nerves' of the leaves: violet, yellow, and green. He gives preference to the violet, 'il est plus abondant, plus sapide, et résiste mieux à l'impression du froid et à la rigueur des hivers.' He adds, that he presents to the Royal Society (Agric. de Paris) the plants which had resisted the cold of the preceding winter, 'the most rigorous of which mention is made in our annals.'

Again Commerell says: 'This plant is a kind of wild cabbage, that may be cut four or six times in the year it is sown; each cut is as plentiful as trefoil or lucerne; we leave it afterwards for the winter. About the month of February it shoots up, and the leaves of it may be cut; but in the month of April it begins to grow up, send off stalks, and bears its seed, which may be gathered in June. The first year this wild cabbage does not send stalks; its leaves appear to rise out of the ground, and thus it may be cut like grass; it may also be dried for hay. Its leaves extend to 10, 12, and 15 inches in length and 6 to 8 broad, which have not the bitter and herbaceous taste of other cabbages. It is a pulse very agreeable for man during the whole year, and a fodder equally as good as plentiful for all kinds of cattle. The milk of cows does not acquire a bad taste, nor do the cows get tired of it.

'This plant bears more and larger sized seed than turnips or cole, and the oil which I have extracted from it cold is very superior as food for man to that from poppy or cole, and is equal to the common oil of olives, in the opinion of good judges. I give the name of the *moving cabbage* to this plant. If you will make a trial of it,' he adds to Dr. Lettsom, 'you will have every reason to be satisfied, for this cabbage yields one

third more oil than turnips in proportion to the equal quantity of ground, and we may sow it in spring or in autumn.

When Commerell wrote the trials were limited for want of seed; but it now appears to be well worthy the attention of agriculturists, as a plant whose rapid growth and general favour, may remedy the scarcity of other crops more in use. The production of the oil alone forms a considerable article of the trade of France, Belgium, England, and America.

To mining districts, to manufacturers, and others in remote localities, the valuable properties of this plant and seed, as sources of oil, food, and manure, are commended. Even six crops a year are said to have been taken. Thus the bitterness of famine by the failure of other crops might be mitigated; and as the oils of seeds are now confusedly mixed together in commercial transactions, we have thought the usefulness of this plant should be more generally known by references to those qualities recorded on its original cultivation.

Colza oil is now extensively used for burning in lamps and for lubricating machinery. The Carcel, Moderator, and other lamps are contrived to give a continuous supply of oil to the wick, and by a rapid draught of air brilliant combustion of the oil is maintained without smoke.

In the lighthouses of France and England it has been employed with satisfaction, so as to replace the use of sperm-oil; the preference has been given on the grounds of greater brilliancy, a steadier flame, the wick being less charred, and the advantage of economy in price.

The Corporation of the Trinity House and the late Mr. Hume took great interest in the question of the relative merits of colza, rape, and seed oils, as compared with sperm-oil, and in 1845 referred the investigation of the power and qualities of the light from this description of oil, to Professor Faraday. He reported 'that he was much struck with the steadiness of the flame, burning 12 or 14 hours without being touched;' 'taking above 100 experiments, the light came out as one and a half for the seed-oil to one of the sperm; the quantity of oil being used in the same proportion;' and he concludes by stating his 'confidence in the results.'

The advantages then were, less trouble, for the lamps with sperm had to be re-trimmed, and the same lamp with seed-oil gave more light, and the cost then was as 3s. 9d. per gallon seed-oil, against 6s. 4d. imperial gallon of sperm.

Those interested should consult returns, ordered by the House of Commons,—
'LIGHTHOUSES: on the motion of Mr. Hume, "On the substitution of Rape-seed oil for Sperm-oil, and the saving accruing therefrom." 17th Feb. 1855; No. 75; 18th March, 1857, 196 and 196 L'

In the Supplementary Returns laid before the House of Commons by the Commissioners of the Northern Lights, there is the following report of Alan Stevenson, Esq., their engineer:—

'In the last annual report on the state of the lighthouses, I directed the attention of the Board to the propriety of making trial, at several stations, of the patent culzà or rape-seed oil, as prepared by Messrs. Briggs and Garford, of Bishopsgate Street. These trials have now been made during the months of January and February, at three catoptric and three dioptric lights, and the results have from time to time been made known to me by the light-keepers, according to instructions issued to them, as occasion seemed to require. The substantial agreement of all the reports as to the qualities of the oil renders it needless to enter into any details as to the slight varying circumstances of each case; and I have therefore great satisfaction in briefly stating, as follows, the very favourable conclusion at which I have arrived:—

- '1. The culzà oil possesses the advantage of remaining fluid at temperatures which thicken the spermaceti oil.
- '2. The culzà oil burns both in the Fresnel lamp and the single argand burner, with a thick wick, during seventeen hours, without requiring any coaling of the wick, or any adjustment of the damper; and the flame seems to be more steady and free from flickering than that from spermaceti oil.
- '3. There seems (most probably owing to the greater steadiness of the flame) to be less breakage of glass chimneys with the culzà than with the spermaceti oil.'

The above firm, who from thirty years' experience in the trade, were enabled to induce the Trinity Corporation to give this oil a fair and extended trial, state that 'for manufacturing purposes it is equally useful; it is admitted by practical men to be the best known oil for machinery; equal to Gallipoli; and technically it possesses more "body," though perfectly free from gummy matter.'

While sperm, Gallipoli, nut, or lard oils are rendered useless by the slightest exposure to frost, the colza oil will, with ordinary care, retain its fluidity: this has been acknowledged as a very important quality to railway and steam-boat companies.

It should be here stated that the terms rape-oils, seed-oils, colza or culzà, are all

now blended together, and, however much this may be regretted, yet it does not seem easy to keep distinctness in the general usages of oil, for the Customs returns class all under one head.—Rape Oil.

A number of British and colonial seed-bearing plants appear to be now employed for the sake of their oils, although on account of the mucilaginous matter contained in many of the oils, they are far inferior to the colza which they are employed to adulterate.—T. J. P.

Of the importance of the trade some estimate may be formed by the following entry.—The *Importations* of seed-oils were as follow:—

	Tons	
In 1870	13,429	valued at £594,933
1871	10,461	„ 406,426
1872	19,931	„ 788,419

COMB. The name of an instrument which is employed to disentangle, and lay parallel and smooth the hairs of man, horses, and other animals. They are made of thin plates, either plane or curved, of wood, horn, tortoise-shell, ivory, bone, or metal, cut upon one or both sides or edges with a series of somewhat long teeth, not far apart.

Two saws mounted on the same spindle are used in cutting the teeth of combs, which may be considered as a species of grooving process; one saw is in this case larger in diameter than the other, and cuts one tooth to its full depth, whilst the smaller saw, separated by a washer as thick as the required teeth, cuts the succeeding tooth part of the way down.

A few years back Messrs. Pow and Lyne invented an ingenious machine for sawing boxwood or ivory combs. The plate of ivory or boxwood is fixed in a clamp suspended on two pivots parallel with the saw spindle, which has only one saw. By the revolution of the handle a cam first depresses the ivory on the revolving saw, cuts one notch, and quickly raises it again; the handle, in completing its circuit, shifts the slide that carries the suspended clamp to the right, by means of a screw and ratchet movement. The teeth are cut with great exactness, and as quickly as the handle can be turned; they vary from about thirty to eighty teeth in one inch, and such is the delicacy of some of the saws, that even 100 teeth may be cut in one inch of ivory. The saw runs through a cleft in a small piece of ivory, fixed vertically or radially to the saw, to act as the ordinary stops, and prevent its flexure or displacement sideways. Two combs are usually laid one over the other and cut at once; occasionally the machine has two saws, and cuts four combs at once.

In the manufacture of tortoise-shell combs, very much ingenuity is displayed in soldering the back of a large comb to that piece which is formed into teeth. The two parts are filed to correspond; they are surrounded by pieces of linen, and inserted between metal moulds, connected at their extremities by metal screws and nuts; the interval between the halves of the moulds being occasionally curved to the sweep required in the comb; sometimes also the outer faces of the mould are curved to the particular form of those combs in which the back is curled round, so as to form an angle with the teeth. Thus arranged it is placed in boiling water. The joints when properly made cannot be detected, either by the want of transparency or polish. Much skill is employed in turning to economical account the flexibility of tortoise-shell in its heated state: for example, the teeth of the larger descriptions of comb are *parted*, or cut one out of the other with a thin frame saw; then the shell, equal in size to two combs with their teeth interlaced, is bent like an arch in the direction of the length of the teeth. The shell is then flattened, the points are separated with a narrow chisel or pricker, and the two combs are finished whilst flat, with coarse single cut files, and triangular scrapers; and lastly, they are warmed, and bent on the knee over a wooden mould by means of a strap passed round the foot, in the manner a shoemaker fixes a shoe last. Smaller combs of horn and tortoise-shell are parted whilst flat, by an ingenious machine with two chisel-formed cutters, placed obliquely, so that every cut produces one tooth, the repetition of which completes the formation of the comb.

Mr. Rogers's comb-cutting machine is described in the 'Transactions of the Society of Arts,' vol. xlix., part 2, page 150. It has been since remodelled and improved by Mr. Kelly. This is an example of slender chisel-like punches. The punch or chisel is in two parts, slightly inclined and curved at the ends to agree in form with the outline of one tooth of the comb, the cutter is attached to the end of a jointed arm, moved up and down by a crank, so as to penetrate almost through the material, and the uncut portion is so very thin that it splits through at each stroke and leaves the two combs detached.

The comb-makers' double saw is called a 'stadda,' and has two blades contrived so as to give with great facility and exactness the intervals between the teeth of combs,

from the coarsest to those having from forty to forty-five teeth to the inch. The *gag-saw* or *gag-vid* is used to make the teeth square and of one depth. The saw is frequently made with a loose back, like that of ordinary *back-saws*, but much wider, so that for teeth $\frac{1}{2}$, $\frac{3}{8}$, $\frac{3}{4}$ inch long, it may shield all the blade except $\frac{1}{2}$, $\frac{5}{8}$, $\frac{3}{4}$ inch of its width respectively, and the saw is applied until the back prevents its further progress. Sometimes the blade has teeth on both edges, and is fixed between two parallel slips of steel connected beyond the ends of the saw blade by two small thumb-screws. After the teeth of combs are cut they are smoothed and polished with files, and by rubbing them with pumice-stone and tripoli.—*Holtzapffel*.

COMBINING NUMBERS AND CHEMICAL COMBINATION.—

Constancy of composition is one of the most essential characters of chemical compounds; by which is meant that any particular body, under whatever circumstances it may have been produced, consists invariably of the same elements in identically the same proportion; the converse of this is not, however, necessarily true, that the same elements in the same proportion always produce the same body. See ISOMERISM.

But not only is there a fixity in the proportion of the constituents of a compound; but also, if any one of the elements be taken, it is found to unite with the other elements in a proportion which is either invariable, or changes only by some very simple multiple.

The numbers expressing the combining proportions of the elements are only relative. In England it is usual to take hydrogen as the starting-point, and to call that number the *combining number* of any other element which expresses the proportion in which it unites with one part by weight of hydrogen: and these numbers are now likewise adopted on the Continent, although in France the combining numbers are sometimes referred to oxygen, which is taken as 100. It is obvious that, whichever system is used, the numbers have the same value relatively to each other.

These combining numbers would have but little value if they expressed nothing more than the proportion in which the elements combine with that body arbitrarily fixed as the standard; but they also represent the *proportions in which they unite among themselves, in the event of union taking place*. Thus, not only do 8 parts of oxygen unite with one of hydrogen, but also 8 parts of oxygen unite with 39 of potassium, 23 of sodium, 100 of mercury, 108 of silver, &c. It is in virtue of this law that the combining proportions of many of the elements have been ascertained. Some of them do not combine with hydrogen at all, and in such cases the quantity which unites with 8 parts of oxygen, or 16 of sulphur, &c., has to be ascertained. See ATOMIC WEIGHTS; EQUIVALENTS.—H.M.W.

COMBUSTIBLE. (Eng. and Fr.; *Brennstoff*, Ger.) Any substance which, exposed in the air to a certain temperature, consumes with the emission of heat and light. All such combustibles as are cheap enough for common use go under the name of *Fuel*. Every combustible requires a peculiar pitch of temperature to be kindled, called its *accendible point*. Thus phosphorus, sulphur, hydrogen, carburetted hydrogen, carbon, each takes fire at successively higher heats. See FLAME; FUEL.

COMBUSTION. (Eng. and Fr.; *Verbrennung*, Ger.) The phenomena of the development of light and heat from any body, as from charcoal combining with the oxygen of the air, from phosphorus combining with iodine, and from some of the metals combining with chlorine. Combustion may be exerted with very various degrees of energy. We have a low combustion often established in masses of vegetable matter; as in haystacks, or in heaps of damp sawdust. In these cases, the changes going on are the same in character, only varying in degree, as those presented by an ordinary fire, or by a burning taper—oxygen is combining with carbon to form carbonic acid. The heat thus produced (the process has been termed by Liebig *Eremacausis*), increasing in force, gives rise eventually to visible combustion.

Cases of spontaneous combustion are by no means uncommon. Some years since, the editor investigated the conditions under which H. M. ships the 'Imogen' and 'Talavera' were burnt in Devonport Dockyard, and he was enabled to trace the fire to a large bin, in which there had been allowed to accumulate a mass of oiled oakum, pieces of old flannel covered with anti-attrition, sawdust, shavings, and the sweepings of the painters', wheelwrights', and some other shops.

The subject of combustion belongs to Watts's 'Dictionary of Chemistry,' where it is fully treated. See SPONTANEOUS COMBUSTION.

CONCRETE. The name given by architects to a compact mass of pebbles, sand, and lime, cemented together in order to form the foundation of buildings. Sempie says that the best proportions are 80 parts of pebbles, each about 7 or 8 ozs. in weight, 40 parts sharp river sand, and 10 of lime; the last is to be mixed with water to a thinnish consistence, and grouted in. It has been found that Thames ballast, as taken from the bed of the river, consists of nearly 2 parts of pebbles to 1 of

sand, and therefore answers exceedingly well for making concrete, with from one-seventh to one-eighth part of lime. The best mode of making concrete, according to Mr. Godwin, is to mix lime, previously ground, with the ballast in a dry state; sufficient water is now thrown over it to effect a perfect mixture; after which it should be turned over at least twice with shovels, or oftener; then put into barrows, and wheeled away for use instantly. It is generally found advisable to employ two sets of men to perform this operation, with three sets in each set, and they repeating the process, turn over the concrete to the barrow-men. After being put into the barrows, it should be at once wheeled up planks so raised as to give it a fall of some yards, and thrown into the foundation, by which means the particles are driven closer together, and greater solidity is given to the whole mass. Soon after being thrown in, the mixture is observed usually to be in commotion, and much heat is evolved, with a copious emission of vapour. The barrow-load of concrete in the fall spreading over the ground will form generally a stratum of from 7 to 9 inches thick, which should be allowed to set before throwing in a second.

Another method of making concrete, is first to cover the foundation with a certain quantity of water, and then to throw in the dry mixture of ballast and lime. It is next turned and levelled with shovels; after which more water is pumped in and the operation is repeated. The former method is undoubtedly preferable. In some cases it has been found necessary to mix the ingredients in a pug-mill, as in mixing clay, &c., for bricks. For the preparation of a concrete foundation, as the hardening should be rapid, no more water should be used than is absolutely necessary to effect a perfect mixture of the ingredients. Hot water accelerates the induration. There is about one-fifth contraction in volume in the concrete, in reference to the bulk of its ingredients. To form a cubical yard of concrete, about 30 ft. cube of ballast and 3½ ft. cube of ground lime must be employed, with a sufficient quantity of water.

Several other methods have been adopted by builders and engineers: these, however, involve the same principles and general condition; a detail of them is, therefore, unnecessary in this work. The reader desiring information is referred to works especially devoted to engineering and building. See **HYDRAULIC LIME**.

CONDY'S DISINFECTING SOLUTION. A solution of an alkaline manganate, or permanganate. See **MANGANATES** and **DISINFECTANTS**.

CONFECTIONERY. See **SWEETMEATS**.

CONGELATION. (Eng. and Fr.; *Gefrierung*, Ger.) The act of freezing liquids. The processes employed are chiefly chemical, but some are mechanical. These will have further attention under the heads **FREEZING MIXTURES**, **ICE**, and **ICE MANUFACTURE**.

CONICHALCITE. An arsenate and phosphate of copper found in Andalusia.

CONIFERÆ. The natural order of cone-bearing plants, including some of the most important trees, such as all kinds of fir, cedar, juniper, pine, cypress, &c.

CONIINE. C¹⁶H¹⁵N (C⁸H¹⁵N). A volatile base found in hemlock (*Conium maculatum*). It is supposed to be the cause of the poisonous properties of that plant.

CONIMA. A fragrant resin used for making pastiles. It is extracted from the *Hyawa*, or incense tree, which grows in British Guiana.

CONIUM. *Conium maculatum*. Spotted Hemlock. The celebrated Athenian state poison by which Socrates and Phocion died.

COORONGITE. Under this name a peculiar substance has recently been imported from South Australia. It resembles caoutchouc in many of its physical properties, and has been called by some authorities mineral caoutchouc or Elaterite; it seems, however, to be essentially different from that substance, and is probably a product of vegetable origin. It is found in thin layers spread over the surface of the ground in a sandy plain in the district known as the Coorong, in South Australia.

Coorongite is a dark brown elastic substance, which exhibits under the microscope a cellular structure interwoven with fibres. It does not vulcanize with sulphur. By destructive distillation it evolves gaseous products; and oils and acetic acid may be obtained by condensation. According to an examination in the Colony, by Mr. G. Francis, it is capable of being resolved into two substances: (1) a soft, semi-fluid balsam, of an olive-green colour, insoluble in water, mineral acids, absolute alcohol, and wood-naphtha, but soluble in ether, chloroform, benzole, turpentine, and essential oils; (2) a tough, pulverulent, elastic substance, combustible, but insoluble in any of the above-named menstrua. The specific gravity of Coorongite is 0.98 or 0.99. An analysis by Dr. Bernays yielded:

Volatile matter	97.190
Fixed carbon	1.005
Ash	1.790

The amount of moisture was only 0·4682 per cent.; but separating this from the volatile matter, the complete analysis may be thus represented:

Carbon	64·7300
Hydrogen	11·6300
Moisture	0·4682
Ash	1·7900
Fixed carbon	1·0050
Oxygen, and other substances unestimated	20·3768

100·0000

COOLERS, WATER. Vessels of porous unglazed earthenware, in which a liquid can be kept cool by constantly exuding through the substance of the ware and evaporating from the outer surface of the vessel. Such coolers, of great use in hot climates, are often known by their Spanish name *Alcarrazas*.

COOLING FLUIDS. See REFRIGERATORY.

COPAIBA, BALSAM OF. This oleo-resin is imported from Peru, and is the produce of several species of *Copaifera*.

COPAL. A resin which exudes spontaneously from two trees, the *Rhus copallinum*, and the *Eleocarpus copaliferus*, the first of which grows in America, and the second in the East Indies. A third species is said to grow on the banks of some rivers in, and near the coasts of, Guinea.

Much information has been received of late years from various sources concerning this somewhat ill-understood product. It is now known that there are three different kinds of copal in commerce, but little is known of their distinguishing characteristics. We have East Indian and West Indian copal, and, under the latter name, two very different substances. The East Indian, called also African, is more colourless, soft, and transparent, than the others; it forms a fine surface, and when heated emits an agreeable odour. It furnishes the finest varnish; fresh essence of turpentine dissolves it completely, but not old. Essence digested upon sulphur will dissolve double its own weight, without letting any fall. Fresh-rectified oil of rosemary will dissolve it in any proportion, but if the oil is thickened by age it serves only to swell the copal.

When cautiously melted, it may be then dissolved in good essence of turpentine in any proportion, producing a fine varnish of little colour.

A good varnish may be made by dissolving 1 part of copal, 1 of essence of rosemary, with from 2 to 3 of pure alcohol. This varnish should be applied hot, and when cold, becomes very hard and durable.

The West Indian species, or American, comes to us not in lumps of a globular form, but in small flat fragments, which are hard, rough, and without taste or smell. It is usually yellow, and never colourless like the other. Insects are very rarely found in it. It comes from the Antilles, Mexico, and North America. It will not dissolve in essence of rosemary.

The third kind of copal, known also as West Indian, was formerly sold as a product of the East Indies. It is found in fragments of a concavo-convex form, the outer covering of which appears to have been removed. It contains many insects. When rubbed it emits an aromatic odour. It gives out much ethereous and empyreumatic oil when melted. It forms a soft varnish, which dries slowly.

Fusel-oil, or amyl spirit, has been lately used as a solvent of the hard copal; but it does not dry into a very solid varnish.

It is now believed that the East Indian copal is the produce of *Hymenæa Courbaril*, and perhaps also of *H. verrucosa*. It is probable that the Brazilian copal is yielded by several species of the same genus, and by *Trachylobium martianum*. The African copals are supposed to be the produce of certain species of *Hymenæa* and of the *Guibourtia copallifera*.

COPEY. The wood of the *Clusia rosea* used for dyeing.

COPPER. (*Symbol*, Cu.; *Atomic weight*, 31·7.) One of the metals most anciently known. It was named from the island of Cyprus, where it was extensively mined and smelted by the Greeks. It has a reddish-brown colour inclining to yellow; a faint but nauseous and disagreeable taste; and when rubbed between the fingers imparts a smell somewhat analogous to its taste. Its specific gravity is from 8·8 to 8·9. It is much more malleable than it is ductile; so that far finer leaves may be obtained from it than wire. It is said to melt at 1,996° F., and at a higher temperature it evaporates in fumes which tinge flame of a bluish green. By exposure to heat with access of air, it is rapidly converted into black scales of protoxide. In tenacity it yields to iron; but considerably surpasses gold, silver, and platinum, in this respect.

Pure copper may be obtained in the solid state either by the reduction of the pure oxide by a stream of hydrogen gas passed over it in an ignited tube, or by the electrolytic process. See ELECTRO-METALLURGY.

ORES OF COPPER.—Copper ores do not possess any one general physical character by which they may be recognised; but they are readily distinguished by chemical reagents. Ammonia digested upon any of the cupreous ores in a pulverised state, after they have been calcined either alone or with nitre, assumes an intense blue colour, indicative of copper. Few copper ores are to be met with which do not betray the presence of this metal by more or less of a greenish film.

The following are the principal minerals which contain copper:—

Native or Virgin Copper (*Cuivre natif*, Fr.; *Gediegen Kupfer*, Ger.) This metal commonly occurs in dendritic and arborescent masses, or is indistinctly crystallised in complex and distorted forms of the cubic system. It is a frequent associate of the ordinary ores of copper, and appears to have been formed in most cases by reduction from some of these ores. Native copper is found not only in copper-bearing veins, but in the fissures and cavities of certain trappean rocks, in deposits in serpentine, and occasionally in sandstones and conglomerate. The native metal is not uncommon in some of the Cornish copper-mines, and is found abundantly in certain copper-bearing deposits in Siberia, Chili, Bolivia, and South Australia. But the most important occurrence of native copper yet recorded is that at Keewenaw Point, Lake Superior, where certain amygdaloidal trap-rocks hold large quantities of copper, in association with calcite and zeolitic minerals. The native copper of Lake Superior also occurs as the cementing materials of a conglomerate, and in a finely-divided form disseminated through sandstone. Some of this copper is remarkable for containing silver, which appears in distinct masses sharply separated from the copper in which it is embedded, the two metals not having formed an alloy. Masses of native copper have been found at Lake Superior, weighing upwards of 400 tons.

Copper Glance, Vitreous Copper Ore, Chalcocite, Redruthite, or Disulphide of Copper, (*Cuivre vitreux*, Fr.; *Kupferglanz*, Ger.) This mineral, which forms a most valuable ore, occurs both crystallised and massive. Some of the composite crystals from St. Just, in Cornwall, are known, from their form, as *nail-head copper ore*. The fracture of copper-glance is conchoidal; surface sometimes dull; colour, iron-black or lead-grey, often bluish, iridescent, or reddish from a mixture of oxide. It is easily melted even by the heat of a candle; but is more difficult of reduction than protoxide. This ore yields to the knife, assuming a metallic lustre when cut. Its density varies from 4·8 to 5·34. Copper-glance is a disulphide (cuprous sulphide), containing when pure Cu_2S , corresponding to 79·8 per cent. of copper and 20·2 of sulphur; but as found in nature it generally contains more or less iron. This is, therefore, one of the richest ores, and forms very important veins. It is to be found in all considerable copper districts; in Siberia, Saxony, Sweden, and especially Cornwall, where the finest crystals occur.

Copper Pyrites, Chalcopyrite, Towanite, or Yellow Copper Ore, (*Cuivre pyriteux*, Fr.; *Kupferkies*, Ger.) This is the common ore of copper in Cornwall and many other copper-mining districts. It resembles in its metallic yellow hue bisulphide of iron (iron pyrites); but the latter is paler, harder, and strikes fire easily with steel. Copper pyrites sometimes presents the most lively rainbow colours, and is then known, from this iridescence, as *Peacock ore*. Its specific gravity is 4·3.

Copper pyrites is a double sulphide of copper and iron, containing theoretically 34·5 per cent. of copper, 30·5 of iron, and 35 of sulphur, corresponding to the formula $\text{Cu}_2\text{S}, \text{Fe}^2\text{S}^3$, or, as sometimes expressed, CuS, FeS . Copper pyrites occurs in vast masses and extended veins, in primitive and transition districts; and is commonly accompanied with grey copper, iron pyrites, sparry iron, galena, and zinc blende.

Bornite, Erubescite, Phillipsite, Purple Copper Ore, Variegated Ore, or Horse-flesh Ore, (*Cuivre panaché*, Fr.; *Buntkupfererz*, Ger.) A double sulphide of copper and iron. A Cornish specimen, analysed by Plattner, yielded—copper, 56·76; iron, 14·84; sulphur, 28·24. The composition of the crystallised mineral appears to be reducible to the formula $3\text{Cu}_2\text{S}, \text{Fe}^2\text{S}^3$. The ore usually occurs massive, presenting a colour between copper-red and pinchbeck-brown, but often obscured by a purple tarnish. Its specific gravity varies from 4·4 to 5·5. Horse-flesh ore is abundant in some of the copper-mines of Chili and Canada. It is also found in Cornwall and in Ireland. It occurs with serpentine at Monte Catini in Tuscany, and forms thin seams in the copper-slates of Mansfeld in Prussia.

Fahl Ore, Tetrahedrite, or Grey Copper Ore, (*Fahlerz*, Ger.) An ore of variable composition, generally containing between 30 and 40 per cent. of copper. It is essentially an antimonio-sulphide or arsenio-sulphide of copper, but the copper may be partially replaced by iron, zinc, silver, or mercury. Fahlerz is a steel-grey mineral, with a metallic lustre, and frequently assumes well-defined tetrahedral forms. The

ore is generally valued for the silver which it contains rather than for its copper. It is very difficult to convert into pure copper by smelting, on account of the presence of antimony and arsenic. See FAHLERZ.

Tennantite. An arsenio-sulphide of copper and iron, closely allied to Fahlerz. It was formerly obtained crystallised in rhombic dodecahedra, from Wheal Jewell, in Gwennap, and from some other Cornish mines. This species is rare.

Cuprite, Red Oxide of Copper, Ruby Copper Ore, or Sub-oxide of Copper, (Cuiivre oxidulé, Fr.; Rotkupfererz, Ger.). This mineral frequently occurs in fine octahedral and cubic crystals, associated with other ores in the shallow workings of copper-mines. Its colour is a deep red, sometimes very bright, especially when bruised. It is friable, difficult of fusion at the blowpipe, reducible on burning charcoal, soluble with effervescence in nitric acid, forming a green liquid, and also soluble in ammonia. Cuprite is a sub-oxide of copper (cuprous oxide), Cu_2O , containing, when pure, copper 88.8, and oxygen 11.2. The impure compact varieties, associated with much iron ochre, have been called *tile-ore*, whilst certain delicate capillary varieties are known as *plush copper ore* or *chalcotrichite*.

Melaconite, or Black Oxide of Copper, (Cuiivre oxidé, Fr.; Kupferschwärze, Ger.). The native protoxide of copper (cupric oxide), CuO , generally occurs as a black earthy or pulverulent incrustation on other copper ores, from which it has been produced by decomposition.

Malachite or Green Carbonate of Copper. This mineral is found in most deposits of copper ore, especially in the upper parts where atmospheric influences have been active. It is a hydrous carbonate of copper, corresponding, when pure, with the formula, $2\text{CuO} \cdot \text{CO}_2 + \text{HO}$ ($2\text{CuCO}_3 + \text{H}_2\text{O}$): this requires 71.9 per cent. of protoxide of copper, 19.9 of carbonic acid, and 8.2 of water. Malachite is found earthy, compact, stalactitic, or mammillated. The finest examples, sometimes polished as ornamental stones, come from Siberia, and from Burra Burra in South Australia.

Azurite, Chessylite, Blue Malachite, or Blue Carbonate of Copper. A hydrous carbonate of copper containing in its purest forms $2(\text{CuO} \cdot \text{CO}_2) + \text{CuO} \cdot \text{HO}$ ($2\text{CuCO}_3 + \text{CuH}_2\text{O}^2$); which corresponds to protoxide of copper 69.2, carbonic acid 25.6, and water 5.2. Azurite thus differs from malachite in chemical composition and in colour; it is also more prone to crystallise, and magnificent specimens were formerly obtained from the copper-mines of Chessy, near Lyons.

Chrysocolla. This mineral, which is a hydrous silicate of copper of variable composition, somewhat resembles carbonate of copper, and commonly occurs as a green, bluish-green, or turquoise-blue incrustation on other copper ores. A black resinous variety, impure by the presence of much iron, is generally known as *pitch copper ore*.

Diopside or Emerald Copper. A beautiful but rare silicate of copper occurring in emerald-green crystals, composed of $\text{CuO} \cdot \text{SiO}_2 + \text{HO}$ ($\text{CuSiO}_3 + \text{H}_2\text{O}$). It is found in the Kirghese Steppes and in Chili, but cannot be called an ore of copper.

Atacamite. An oxychloride of copper containing $\text{CuCl} + 3(\text{CuO} \cdot \text{HO})$ or $\text{CuCl}^2 + 3\text{CuH}_2\text{O}^2$. This corresponds to copper 15, chlorine 16, protoxide of copper 56, and water 12. It occurs in fine rhombic crystals of a greenish black colour, and is worked as an ore at the Wallaroo and other copper-mines on Yorke Peninsula, South Australia. It is also found in the form of a green sand in the Desert of Atacama.

Phosphates of Copper. Several copper-bearing minerals containing phosphoric acid, with or without its isomorph arsenic acid, are known to the mineralogist, but none of them occur in sufficient abundance to be used as ores. *Libethenite* is a hydrous phosphate, occurring in rhombic crystals at Libethen in Hungary; and *Eklite* is a similar mineral from Ehl in Nassau.

Arsenates of Copper. A large number of these compounds are known, but are only of mineralogical interest. Among these are the species named olivenite, euchroite, tagilite, tyrolite, liroconite, cornwallite, and chalcophyllite or copper-mica.

Chalcantlite, Cyanosite, Blue Vitriol, or Sulphate of Copper. A mineral similar to the artificial salt of the laboratory. The blue water which flows from certain copper-mines is a solution of this salt. The copper is easily procured in the metallic state by plunging into it pieces of iron.

It should be remarked that many of the minerals noticed above are not available as ores of copper. Dr. Scherer, of Freiberg, has arranged the principal ores of copper as follow:—

	Copper in 100
1. Copper Glance, Cu_2S	79.7
2. Copper pyrites, $\text{Cu}_2\text{S}, \text{Fe}^2\text{S}^3$	34.8
3. Buntkupfererz, $3\text{Cu}_2\text{S}, \text{Fe}^2\text{S}^3$	55.7
4. Fahlerz, $4(\text{Cu}_2\text{S}, \text{FeS}, \text{ZnS}, \text{AgS}) (\text{SbS}^3, \text{AsS}^3)$	14—41

	Copper in 100
5. Red oxide of copper, Cu_2O	88.5
6. Malachite, $2\text{CuO}, \text{CO}_2 + \text{HO}$	57.4
7. Azurite, $2(\text{CuO}, \text{CO}_2) + \text{CuO}, \text{HO}$	55.3

We shall here give a brief account of the copper slates of Mansfeld, in Prussia, and of the copper veins of Cornwall.

Copper-slate (Kupferschiefer) of Mansfeld, in Prussian Saxony. The *Kupferschiefer* is a dark coloured bituminous schist, impregnated with copper ore, occurring with singular persistence over a large area on the south-east of the Hartz. Its geological position is in the Permian formation, below the *Zechstein*, or Magnesian limestone, and above the red sandstones and conglomerates known as the *Rotkottliegende*; indeed, the latter name ('red dead strata') has reference to the fact that the ores in the overlying schist die away on approaching these beds. The actual floor of the cupreous schist is formed by a thin bed of white sandstone, known as the *Weissliegende*, the upper part of which is slightly cupriferaous, and is smelted under the name of *Sanderz*. Upon this sandstone rest the true copper-bearing schists, forming three or four thin beds, with an aggregate thickness rarely exceeding two feet, and sometimes not attaining more than half this thickness. The schists are highly fossiliferous, and are especially rich in remains of ganoid fish belonging to the genera *Palæoniscus* and *Platysomus*. Towards their upper part, the schists become calcareous, and are sometimes known as the *Noberge*. The beds of cupreous schists, or copper-slate, are thrown into a synclinal form, and are chiefly worked near their base; the intrusion of masses of melaphyre has divided the deposit into three separate areas: those of Eisleben, Sangerhausen, and Frankenhausen. The schist is richest in the neighbourhood of faults, and the thinner beds are said to hold more copper than the thicker deposits. Only a few inches—not generally more than five—are worth working. The ore is disseminated in the form of copper pyrites, copper-glance, and purple-ore. The schist contains from 1.8 to 3.7 per cent. of copper, and this copper always contains traces of silver, 1 cwt. of copper holding from 0.53 to 0.58 lb. of silver. Although the German copper-slate is thus a very poor ore, yet by an admirable organisation of the mines and smelting-works both the copper and silver are profitably extracted, and a large population entirely supported by this industry. The copper-mines of Mansfeld have been worked since the close of the twelfth century; Martin Luther's father was a miner in this district. The metallurgical treatment of the copper-slate will be described below.

Cornish Copper Veins.—The deposits of copper in Cornwall occur as veins in granite, or in the schistose rocks which surround and cover it; and hence, the Cornish miners work mostly in the granite and clay-slate; the former of which, when metalliferous, is usually in a coarse and often a disintegrated state; this they call *growan*, the latter *killas*.

Copper veins are abundant in killas and more rare in granite; but most numerous near the line of junction of the two rocks. The different kinds of copper veins in Cornwall may be classed as follow:—

1. Copper veins, generally running east and west.
2. Second system of copper veins, or *contra lodes*.
3. Crossing veins; *cross-courses*.
4. Clay veins, called *Cross-Flookans* or *Slides*.

The width of these veins does not often exceed 6 feet, though occasional enlargements to the extent of 12 or more feet sometimes take place. Their length is unknown, but one explored in the United Mines has been traced over an extent of seven miles. The gangue of these veins is generally quartz, either pure, or mixed with green particles analogous to chlorite. They contain iron pyrites, blende, sulphide, and several other compounds of copper, such as the carbonate, phosphate, arsenate, chloride, &c. The most part of the copper lodes are accompanied by small argillaceous veins, called by the miners *flookans of the lode*. These are often found on both sides of the vein, so as to form checks or *walls*.

When two veins intersect each other, the direction of the one thrown out becomes an object of interest to the miner. In Saxony it is regarded as a general fact, that the rejected portion is always on the side of the *obtuse angle*; this also holds generally in Cornwall, and the more obtuse the angle of incidence, the more considerable the heave. The great copper vein of Carharack, in the parish of Gwennap, is an instructive example of intersection. The width of this vein is 8 feet; it runs nearly from east to west, and dips towards the north at an inclination of 2 feet in a fathom. Its upper part is in the killas, its lower in granite. This vein has suffered two intersections: the first results from encountering the vein called *Steven's flookan*, which runs from north-east to south-west, throwing it out several fathoms. The second has been caused by another vein, almost at right angles to the first, and which has heaved it 20 fathoms

to the right. The throw of the vein occurs, therefore, in one case to the right, and in the other to the left; but in both instances, it is to the side of the obtuse angle. This disposition is very singular; for one portion of the vein appears to have ascended, while another has sunk. See *FAULTS*.

The copper-mines of the isle of Anglesea, those of North Wales, of Westmoreland, the adjacent parts of Lancashire and Cumberland, of the south-west of Scotland, of the Isle of Man, and of the south-east of Ireland, also occur in primitive or transition rocks. The ores lie sometimes in masses, but more frequently in veins. The mine of Ecton, in Staffordshire, and that of Cross-gill-burn, near Alston-moor, in Cumberland, occur in carboniferous or mountain limestone.

The copper ores extracted both from the granitic and schistose localities, as well as from the calcareous, are uniformly copper pyrites more or less mixed with mundic; the red oxide, carbonate, arsenate, phosphate, and chloride of copper, are very rare in these districts.

The working of copper-mines in the isle of Anglesea may be traced to a very remote era. It appears that the Romans were acquainted with the Amlwch mine near Holyhead. Mr. Thomas F. Evans has been so fortunate as to obtain and preserve three copper cakes found at Bryndu, Amlwch, which are evidently of Roman origin. The copper-mines in Parys Mountain were not worked with activity until the year 1779. In 1784 these mines produced 3,000 tons of copper annually. This deposit lies in a greenish clay slate, passing into talc slate; a rock associated with serpentine and euphotide. The veins of copper are from one to two yards thick; and converge towards a point where their union forms a considerable mass of ore. On this the mine was first commenced by an open excavation, which is now upwards of 300 feet deep, and appears from above like a vast funnel. Galleries are formed at different levels upon the flanks of the excavation to follow the several smaller veins, which run in all directions, and diverge from a common centre like so many radii. The ore receives in these galleries a kind of sorting, and is raised by means of hand windlasses to the summit of a hill, where it is cleaned by breaking and jigging.

The water is so scanty in this mine that it is pumped up by a small steam-engine. A great proportion of it is charged with sulphate of copper. It is conveyed into reservoirs containing pieces of old iron; the sulphate is thus decomposed and metallic copper obtained by cementation. The Anglesea ore is poor, yielding only from 2 to 3 per cent. of copper; a portion of its sulphur is collected in roasting the ore.

The copper-mines of these islands, now so important, were so little worked until a recent period that in 1799 we are told in a Report on the Cornish mines, 'it was not until the beginning of the last century that copper was discovered in Britain.' This is not correct, for in 1250 a copper-mine was worked near Keswick, in Cumberland. Edward III. granted an indenture to John Ballanter and Walter Bolbolter, for working all 'mines of gold, silver, and copper;' but that the quantity found was very small is proved from the fact that Acts of Parliament were passed in the reigns of Henry VIII. and Edward VI. to prevent the exportation of brass and copper, 'lest there should not be metal enough left in the kingdom, fit for making guns and other engines of war, and for household utensils:' and in 1665 the calamine works were encouraged by the Government, as 'the continuing these works in England will occasion plenty of rough copper to be brought in.'

At the end of the seventeenth century, some 'gentlemen from Bristol made it their business to inspect the Cornish mines, and bought the copper ore for 2*l.* 10*s.* per ton, and scarce ever more than 4*l.* a ton.'

In 1700, one Mr. John Costor introduced an hydraulic engine into Cornwall, by which he succeeded in draining the mines, and 'he taught the people of Cornwall also a better way of assaying and dressing the ore.'

The value and importance of copper-mines since that period regularly increased, until within the last few years. There has been of late a steady decline in the produce of our copper-mines, and a falling off in the per-centage of metal in the ore.

Mechanical Preparation of the Copper Ores in Cornwall.—The ore receives a first sorting, the object of which is to separate all the pieces larger than a walnut; after which the whole is sorted into lots, according to their relative richness. The fragments of poor ore are sometimes pounded in stamps, so that the metallic portions may be separated by washing.

The rich ore is broken into small bits, either with a flat beater, or by means of a crushing-mill. The ore to be broken by the *bucking iron* is placed upon plates of cast iron; each about 16 inches square and 1½ inch thick. These plates are set towards the edge of a small mound about a yard high, constructed with dry stones rammed with earth. The upper surface of this mound is a little inclined from behind forwards. The work is performed by women, each furnished with a bucking-iron: the ore is placed in front of them beyond the plates; they break it, and strew

it at their feet, whence it is removed and disposed of as may be subsequently required.

The crushing-mill has of late years been brought to a great degree of perfection, and is almost universally made use of for pulverising certain descriptions of ore. For an account of this apparatus, see GRINDING AND CRUSHING APPARATUS.

Stamping-mills are less frequently employed than crushers for the reduction of copper ores. At the Devon Great Consols Mines, the concentration of the crushed copper ores is effected in the following manner:—From the crushing-mill the stuff is carried by a stream of water into a series of revolving separating sieves, where it is divided into fragments of $\frac{1}{20}$ th inch, $\frac{1}{12}$ th inch, and $\frac{1}{10}$ th inch diameter, besides the coarser particles which escape at the lower end of the sieves. The slimes flow over a small water-wheel called a *separator*, in the buckets of which the coarser portions settle, and are from thence washed out by means of jets of water into a round buddle, whilst the finer particles are retained in suspension, and are carried off into a series of slime-pits, where they are allowed to settle.

The *work* produced by the round buddle is of three sorts; that nearest the circumference is the least charged with iron pyrites, or any other heavy material, but still contains a certain portion of ore; this is again buddled, when a portion of its *tail* is thrown away, and after submitting the remainder to a buddling operation, and separating the *waste*, it is jigged in a fine sieve, and rendered merchantable.

The other portions of the first buddle are rebuddled, and after separating the waste, the ore matters are introduced into sizing cisterns, from which the finer particles are made to flow over into a buddle, from whence a considerable portion goes directly to market. That which requires further manipulation is again buddled until thoroughly cleansed. The coarser portions of the stuff introduced into the sizing cisterns pass downward with a current of water into the *tye*, and after repeated projections against the stream, the ore matter is separated, leaving a residue of mundie in a nearly pure state.

The stuff falling from the lower extremities of the separating sieves is received into bins and subsequently cleansed; each of the three sizes is jigged, and in proportion as the worthless matters are separated, they are scraped off and removed. Those portions of the stuff that require further treatment are taken from the sieves, washed down from behind the hutches, and treated by tyes, until all the valuable portions have been extracted.

In this way vein-stuff that originally contained but $1\frac{1}{2}$ per cent. of copper is so concentrated as to afford a metallic yield of 10 per cent., whilst by means of sizing-sieves, dressing-wheels, jigging-machines, and round-buddles, &c., from 40 to 50 tons of stuff are elaborated per day of 9 hours, at a cost of 12s. per ton of dressed ore.

Captain Richards, the agent of these mines, has also introduced considerable improvements in the slime-dressing department. The proper sizing of slime is as necessary as in the case of rougher work, and in order to effect this, he has arranged a slime-pit, which answers this purpose exceedingly well. This pit has the form of an inverted cone, and receives the slimes from the slime-separator, in an equally-divided stream. The surface of this apparatus being perfectly level, and the water passing through it at a very slow rate, all the valuable matters are deposited at the bottom. If slime be valuable in the mass, it can evidently be more economically treated by a direct subdivision into fine and coarser work; since a stream of water, acting on a mixture of this kind, will necessarily carry off an undue proportion of the former in freeing the latter from the waste with which it is contaminated.

The ordinary slime-pit is of a rectangular form, with vertical sides, and flat bottom. The water enters it at one of the ends by a narrow channel, and leaves it at the other. A strong central current is thus produced through the pit, which not only carries with it a portion of valuable slime, but also produces eddies and creates currents towards the edges of the pit, and thus retains matters which should have been rejected. The slime-pits at Devon Consols are connected with sets of Brunton's machines, which are thus kept regularly supplied by means of a launder from the apex of the inverted cone, through which the flow is regulated by means of a plug-valve and screw.

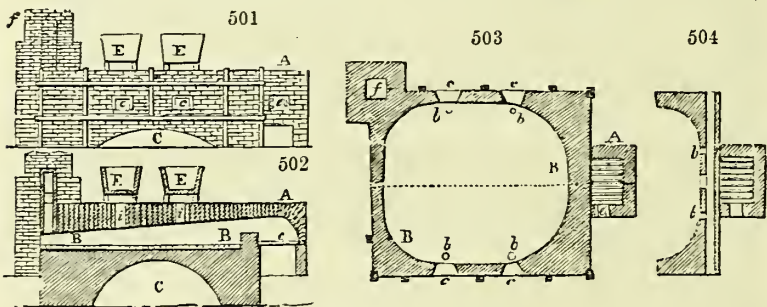

A waggon cistern is placed under each frame for receiving the work, which is removed when necessary, and placed in a packing-kieve. This is packed by machinery, set in motion by a small water-wheel. The waste resulting from this operation is either entirely rejected, or partially reworked on Brunton's machines, whilst the ore matters contained in the kieve are removed by a waggon to the ore-house where they are discharged.

Cornwall being destitute of coal, the whole of the copper ore which it produces is sent for smelting to South Wales.

Welsh Copper-Smelting: Furnaces.—The furnaces employed are of the reverberatory

construction; they vary in their dimensions and in the number of their openings according to the operations for which they are intended. There are five of them:—1. The calcining furnace, or calciner; 2. The melting furnace; 3. The roasting furnace, or roaster; 4. The refining furnace; 5. The heating or igniting furnace.

1. *The Calcining Furnace* rests upon a vault, *c*, into which the ore is raked down after being calcined; it is built with bricks, and bound by iron bars, as shown in the elevation, *fig. 501*. The hearth, *B B*, *figs. 502* and *503*, is placed upon a level with the lower horizontal binding bar, and has nearly the form of an ellipse, truncated at the two extremities of its greater axis. It is horizontal, bedded with fire-bricks set on edge, so that it may be removed and repaired without disturbing the arch upon which it reposes. Holes, not visible in the figure, are left in the sole before each door *e e*, through which the roasted ore is let fall into the subjacent vault. The dimensions of the hearth *B B*, vary from 17 to 19 feet in length, and from 14 to 16 in breadth. The fire-place *A*, *fig. 503*, is from $4\frac{1}{2}$ to 5 feet long and 3 feet wide. The bridge or low wall *b*, *fig. 504*, which separates the fire-place from the hearth, is 2 feet thick, and in Messrs. Vivians' smelting-works is hollow, as shown in the figure, and communicates at its two ends with the atmosphere, in order to conduct a supply of fresh air to the hearth of the furnace. This judicious contrivance will be described in explaining the *roasting* operation. The arched roof of the furnace slopes down from the bridge to the beginning of the chimney *f*, *figs. 501*, *503*, its height above the hearth being at the first point about 26 inches, and from 8 to 12 at the second.

Such calcining furnaces have five doors, *cccc*, *fig. 503*, and one for the fire-place, as shown at the right hand in *fig. 501*; four are for working the ore upon the reverberatory hearth. These openings are 12 inches square, and are bound with iron frames. The chimney is about 22 feet high, and is placed at one angle of the hearth, as at *f*, *fig. 503*, being joined by an inclined flue to the furnace.

For charging it with ore, two hoppers *E E*, are usually placed above the upper part of the vault, in a line with the doors; they are formed of four plates of iron, supported in an iron frame. Beneath each is an orifice for letting the ore down into the hearth.

These furnaces serve for calcining the ore and *matts*: for the latter purpose, indeed, furnaces of two stories are sometimes employed, as represented in *fig. 507*. The dimensions of each floor in this case are a little less than the preceding. Two doors, *cc*, *fig. 501*, correspond to each hearth, and the workmen, while employed at the upper story, stand upon a raised moveable platform.

2. *Melting Furnace*, *figs. 505* and *506*.—The form of the hearth is, in this case, also elliptical, but the dimensions are smaller than in the calcining furnace. The length does not exceed 11 or $11\frac{1}{2}$ feet, and the breadth varies from 7 to 8. The fire-place is, however, larger in proportion, its length being from $3\frac{1}{2}$ to 4 feet, and its breadth from 3 to $3\frac{1}{2}$; this size being requisite to produce the high temperature of the furnace. It has fewer openings, there being commonly three; one to the fire-place at *D*, a second one, *o*, in the side, kept generally shut, and used only when incrustations need to be scraped off the hearth, or when the furnace is to be entered for repairs; and the third or working door, *e*, placed on the front of the furnace beneath the chimney. Through it, the scoriae are raked out, and the melted matters stirred and puddled, &c.

The hearth is bedded with infusible sand, and slopes slightly towards the side door, to facilitate the discharge of the metal. Above this door is a hole in the wall of the chimney (*fig. 506*) for letting the metal escape. An iron gutter, *o*, leads it into a pit, *K*, bottomed with an iron receiving-pot, which may be lifted out by a crane. The pit, *M*, is filled with water, and the metal becomes granulated as it falls into the receiver. These melting furnaces are surmounted by a hopper *L*, as shown *fig. 505*.

Melting furnaces are sometimes also used for calcination. Some of those near Swansea serve this double purpose; they are composed of 3 floors (*fig. 507*). The floor A, is destined for melting the calcined ore; the other two, B, c, serve for calcination. The heat being less powerful upon the upper sole c, the ore gets dried upon it, and begins to be calcined: a process completed on the next floor. Square holes, *d*, left in the hearths B and c, put them in communication with each other, and with the lower one A; these perforations are shut during the operation by a sheet of iron, removable at pleasure.

The hearths B and c, are made of bricks; these are horizontal at the top and slightly vaulted beneath; they are two bricks thick, and their dimensions larger than those of the inferior hearth, as they extend above the fire-place. On the floors destined for calcination the furnace has two doors on one of its sides: on the lower story there are also two; but they are differently placed. The first, being in the front of the furnace, serves for drawing off the scoria, for working the metal, &c.; and the second, upon the side, admits the workmen to make necessary repairs. Below this door is placed the discharge or tap-hole, which communicates by a cast-iron gutter with a pit filled with water. The dimensions of this furnace in length and breadth are nearly the same as those of the melting furnace above described; the total height is nearly 12 feet. It is charged by means of either one or two hoppers.

3. *Roasting Furnace.*—The furnaces employed for this purpose are in general similar to the calciners; but in the smelting-works of Messrs. Vivian, the furnaces above alluded to present a peculiar construction; this is for the purpose of introducing a continuous current of air upon the metal, in order to facilitate its oxidation. This process was originally invented by Mr. Sheffield, who disposed of his patent right to Messrs. Vivian.

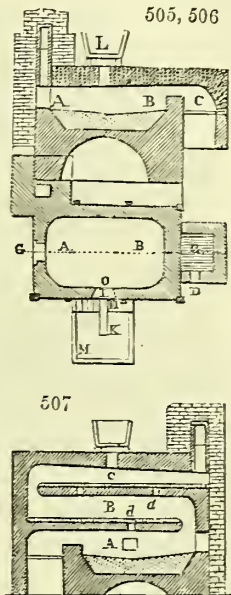

The air is admitted by a channel through the middle of the fire-bridge, which extends all its length; it communicates with the atmosphere at its two extremities, whilst square holes, left at right angles to this channel, conduct the air into the furnace. This very simple construction produces a powerful effect in the roasting. It not only promotes the oxidation of the metals, but burns the smoke, and assists in the vaporisation of the sulphur; while by keeping the bridge cool it preserves it from wasting, and secures uniformity of temperature to the hearth.

4. *Refining Furnace.*—In this, as in the melting furnace, the side slopes towards the front door instead of the side doors, because in the refining furnace the copper collects in a cavity formed in the hearth near the front door, from which it is lifted out by ladles; whereas, in the melting furnaces, the metal is run out by a tap-hole in the side. The sole is laid with sand; but the roof is higher than in the melting furnace, being from 32 to 36 inches in height. If the top arch were too much depressed, there might be produced upon the surface of the metal a layer of oxide very prejudicial to the quality of the copper. In that case, when the metal is run out, its surface solidifies and cracks, while the melted copper beneath breaks through and spreads irregularly over the cake. This accident, called the *rising of the copper*, prevents it from being laminated, and requires it to be exposed to a fresh refining process, when lead must be added to remove the oxide of copper. This is the only occasion upon which the addition of lead is proper in refining copper. When the metal to be refined is mixed with others, particularly with tin, as in extracting copper from old bells, then very wide furnaces must be employed, to expose the metallic bath on a great surface, and in a thin stratum, to the oxidising action of the air.

The door, on the side of the refining furnace, is very large, and shuts with a framed brick door, balanced by a counter-weight.

5. *Heating Furnaces,* being destined to heat the pigs or bars of copper to be laminated, as well as the copper sheets themselves, are made much longer in proportion to their breadth. Their hearth is horizontal, the vault not much depressed; they have only one door, placed upon the side, but which extends nearly the whole length of the furnace; this door may be raised by means of a counter-weight, in the same way as in the furnaces for the fabrication of sheet-iron and brass.

Series of Operations to which the Ore is subjected.—The ores which are smelted in the Swansea works are chiefly copper pyrites, more or less mingled with *gangue* (vein-stone).

This pyrites is composed of nearly equal proportions of sulphide of copper and sulphide of iron. Richer ores, consisting of oxides and carbonates of copper, &c., are also worked in.

The earthy matters which accompany the pyrites are usually siliceous, though in some mines the mineral is mixed with either clay or fluor-spar. Along with these substances, tin ore and arsenical pyrites occasionally occur with the copper; and though these two minerals are not chemically combined, yet they cannot be entirely separated by mechanical preparation. The constituent parts of the ore prepared for smelting are, therefore, copper, iron, and sulphur, with earthy matters, and, in some cases, tin and arsenic. The different ores are mixed in such proportions that the average metallic contents may amount to 8 per cent. The smelting process consists in alternate roastings and fusions.

In the roasting operation the volatile substances are mostly disengaged in the gaseous state, while the metals that possess a strong affinity for oxygen become oxidised. In the fusion the earthy substances combine with these oxides, and form glassy scoriæ or slags, which float upon the surface of the melted metal.

The calcinations and fusions take place in the following order:—

1. Calcination of the ore.
2. Fusion of the calcined ore.
3. Calcination of coarse-metal.
4. Melting the calcined coarse-metal.
5. Calcination of fine-metal (second matt).
6. Melting calcined fine-metal.
7. Roasting coarse-copper.

In some smelting-works, this roasting is repeated four times; in which case a calcination and a melting are omitted. In other works, however, a saving is made without increasing the number of roastings.

8. Refining or toughening the copper.

Besides these operations which constitute the treatment of copper properly speaking, two others are sometimes performed, in which only the scoriæ are smelted. These may be designated by the letters *a* and *b*: *a* is the re-melting of a portion of the scoriæ of the second process, which contain some metallic granulations; *b* is a particular melting of the scoriæ of the fourth operation. This fusion is intended to concentrate the particles of copper in the scoriæ, and is not practised in all smelting-works.

First Operation: Calcination of the ore.—The different ores on arriving from Cornwall and other localities where they are mined, are discharged in continuous cargoes at the smelting works, in such a way, that by taking out a portion from several heaps at a time, a tolerably uniform mixture is obtained; which is very essential, since the ores, being different in quality and contents, act as fluxes for each other. The mixed ore is transported to the works in wooden measures each holding a hundred-weight. The workmen entrusted with the calcination convey the ore into the hoppers of the calcining furnace, whence it falls into the hearth; other workmen spread it uniformly on the surface with iron rakes. The charge of a furnace is from 3 tons to 3½ tons. Fire is applied and gradually increased, till towards the end of the operation, the temperature is as high as the ore can support without melting or agglutinating. To prevent this running together, and to aid the extrication of the sulphur, the surfaces are renewed, by stirring up the ore at the end of every hour. The calcination is usually completed at the end of 12 hours, when the ore is raked into the arch under the sole of the furnace, and when cold enough to be moved, is taken out of the arch, and conveyed to the calcined heap.

The ore in this process scarcely changes weight, having gained by oxidation nearly as much as it has lost in sulphur and arsenic; and if the roasting has been rightly managed, the ore is in a black powder, owing to the oxides present.

The utilisation of the sulphurous vapours evolved during calcination is explained, p. 928.

Second Operation: Fusion of the calcined ore.—The calcined ore is likewise given to the smelters in measures containing a hundred-weight. They throw it into hoppers, and, after it has fallen on the hearth, spread it uniformly. They then let down the door, and lute it tightly. In this fusion there are added about 2 cwt. of scoriæ ('*metal slag*') proceeding from the melting of the calcined matt, to be afterwards described. The object of this addition is not only to extract the copper that these scoriæ may contain, but also to increase the fusibility of the mixture. Sometimes, when the composition of the ore requires it, lime, sand, or fluor-spar is added, more particularly the latter.

The furnace being charged, fire is applied, and the sole care of the founder is to keep up the heat so as to have a perfect fusion; the workman then opens the door, and stirs about the liquid mass to complete the separation of the 'metal' (regulus, or matt) from the scoriæ, as well as to hinder the melted matter from sticking to the sole. The furnace being ready, that is, the fusion being perfect, the founder takes out the scoriæ by the front door, by means of a rake. When the mass is thus freed from the scoriæ, a second charge of calcined ore is introduced to increase the metallic bath; which second fusion is executed like the first. New charges of roasted ore are put

in till the matt collected on the hearth rises to a level with the door-way, which happens commonly after the third charge. The tap-hole is now opened, and the matt flows out into a pit filled with water, where it is granulated and collects in the pan placed at the bottom. The granulated matt is next conveyed into the matt warehouse. The oxidation with which the grains get covered by the action of water does not allow the proper shade of the matt or coarse-metal to be distinguished; but in the bits which stick in the gutter it is seen to be of a steel-grey colour. Its fracture is compact, and its lustre metallic. The scoriæ, known as *ore-furnace slag*, often contain metallic grains; they are broken and picked with care. All the portions which include metallic particles are re-melted in an accessory process.

In this operation the copper is concentrated by the separation of a great part of the matters with which it was combined. The granulated matt produced contains in general 33 per cent. of copper; it is therefore four times richer than the ore; and its mass is consequently diminished in that proportion. Its constituents are principally copper, iron, and sulphur. It is termed *coarse-metal*.

The most important point in the fusion just described, is to make a fusible mixture of the earths and oxides, so that the matt of copper may, on account of its greater specific gravity, sink below and separate exactly from the slag. This is attained by means of metallic oxides contained in the scoriæ of the fourth operation, of which 2 cwt. were added to the charge. These consist almost entirely of oxide of iron. When the ores are very difficult to melt, about half a hundred-weight of fluor-spar is added; but this must be done with precaution, for fear of too much increasing the scoriæ.

The work proceeds day and night. Five charges are commonly put through in the course of 24 hours; but when all circumstances are favourable, that is to say, when the ore is fusible, when the fuel is of the first quality, and the furnace in good condition, even six charges a day have been despatched.

The charge is a ton and a half of calcined ore, so that a smelting furnace nearly corresponds to a calcining furnace; the latter turning out 7 tons of calcined ore in 24 hours. The workmen are paid by the ton.

Third Operation: Calcination of coarse-metal.—The object of this operation is principally to oxidise the iron, which is more easily accomplished than in the first calcining, because the metal is now disengaged from the earthy substances, which screened it from the action of the air.

This calcination is executed in the furnace already represented in *figs. 505, 506, 507*, page 915, exactly in the same way as the ore was calcined. The metal must be perpetually stirred, to expose all its surfaces to the action of the hot air, and to hinder clotting together. The operation lasts 24 hours; during the first six, the fire should be very moderate, and gradually increased to the end of the calcination. The charge is, like that of the first, $3\frac{1}{2}$ tons.

Fourth Operation: Melting the calcined coarse-metal.—In the fusion of this first calcined matt, some scoriæ of the latter operations must be added, which are very rich in oxide of copper, and some crusts from the hearth, which are likewise impregnated with it. Addition may also be made of richer crude ores, such as oxides and carbonates. The proportion of these substances varies according to the quality of the calcined matt.

In this second fusion, the oxide of copper contained in the scoriæ is reduced by the affinity of the sulphur, one portion of which passes to the state of sulphurous acid, while the other forms a subsulphide with the free copper. The matt commonly contains a sufficient quantity of sulphur to reduce the oxide of copper completely; but if not, which may happen if the calcination of the matt has been pushed too far, a small quantity of uncalcined matt must be introduced, which, by furnishing sulphur, diminishes the richness of the scoriæ, and facilitates the fusion.

The scoriæ are taken out by the front door by means of a rake. They have a great specific gravity; are brilliant with a metallic lustre, very crystalline, and present, in the cavities, crystals like those of pyroxene; they break easily into very sharp-edged fragments, and contain no granulated metal in the interior; but it sometimes occurs, on account of the small thickness of the stratum of scoriæ, that these carry off with them, when withdrawn, some metallic particles.

These scoriæ, as we have already stated (under *Fusion of the roasted Ore*), are in general melted with it. In some cases, however, a special melting is assigned to them.

The matt obtained in this second fusion is either run out into water like the first, or moulded into pigs (ingots), according to the mode of treatment which it is to undergo. This matt, termed by the smelters *fine-metal* when it is granulated, and *blue-metal* when it is in pigs, is of a light grey colour, compact, and bluish at the surface, and contains about 60 per cent. of copper.

(*b.*) *Particular Fusion of the Scoriæ of the fourth Operation.*—In re-melting these scoriæ, the object is to procure the copper which they contain. To effect this fusion,

the scoriæ are mixed with pulverised coal, or other carbonaceous matters. The copper and several other metals are deoxidised, and furnish a white and brittle alloy. The scoriæ resulting from this melting are in part employed in the first melting, and in part thrown away. They are crystalline, and often present crystals in the cavities, which appear to be those of bisilicate of iron. They have a metallic lustre, and break into very sharp-edged fragments. The white metal is melted again, and then added to the product of the second fusion.

Fifth Operation: Calcination of the second Matt, or fine-metal.—This is executed in precisely the same way as that of the first matt. It lasts 24 hours; and the charge is usually 3 tons.

Sixth Operation: Melting of the calcined fine-metal.—This fusion is conducted like that of the first matt. The black, or coarse copper, which it produces, contains from 70 to 80 per cent. of pure metal; it is run into ingots, in order to undergo the operation of roasting.

The scoriæ are rich in copper; they are added to the fusion of the calcined coarse-metal of the fourth operation.

In many smelting-houses, the fifth and sixth operations have of late years been omitted. The second matt is run into pigs, under the name of *blue-metal*, to be immediately exposed to roasting.

The disposition of the canal *c c*, *fig. 501*, which introduces a continuous current of air to the hearth of the furnace, accelerates and facilitates the calcination of the matt; an advantage which has simplified the treatment, by diminishing the number of calcinations.

Seventh Operation: Roasting the coarse-copper, the product of the sixth Operation.—The chief object of this operation is oxidation; it is performed either in an ordinary roasting furnace, or in one similar to *fig. 507*, which admits a constant current of air. The pigs of metal derived from the preceding melting are exposed, on the hearth of the furnace, to the action of the air, which oxidises the iron and other foreign metals with which the copper is still contaminated. The duration of the roasting varies from 12 to 24 hours, according to the degree of purity of the crude copper. The temperature should be graduated in order that the oxidation may be complete, and that the volatile substances which the copper still retains may escape in the gaseous form. The fusion must take place only towards the end of the operation.

The charge varies from a ton and a quarter to a ton and a half. The metal obtained is run out into moulds of sand. It is covered with black blisters, like cementation steel; whence it has got the name of *blistered copper*. In the interior of these pigs the copper presents a porous texture, occasioned by the ebullition produced by the escape of gases during the moulding. The copper being now almost entirely freed from sulphur, iron, and the other substances with which it was combined, is in a fit state to be refined. This operation affords scoriæ, which are very heavy, and contain a great deal of oxide of copper, and sometimes even metallic copper. They are known as *roaster-slag*.

These scoriæ, as well as those of the third melting and the refining, are added to the second fusion, as we have already stated, in describing the fourth operation.

In some works, the roasting is several times repeated upon the *blue-metal*, in order to bring it to a state fit for refining.

Eighth Operation: Refining or Toughening.—The pigs of copper intended for refining are placed on the sole of the refining furnace through the door in the side. A slight heat is first given, to finish the roasting or oxidation, in case this operation has not already been pushed sufficiently far. The fire is to be increased by slow degrees, so that, by the end of six hours, the copper may begin to flow. When all the metal is melted, and the heat is very considerable, the workman lifts the door in the front, and withdraws with a rake the few scoriæ which may cover the copper-bath. These are red, lamellated, very heavy, and closely resemble protoxide of copper.

The refiner then takes an assay with a small ladle, and when it cools, breaks it in a vice, to ascertain the state of the copper. From the appearance of the assay, the aspect of the bath, the state of the fire, &c., he judges if he may proceed to the toughening, and what quantity of wooden spars and wood-charcoal he must add to render the metal malleable, or, in the language of the smelters, bring it to the proper pitch. When the operation of refining begins, the copper is dry or brittle, and of a deep red colour approaching to purple. Its grain is coarse, open, and somewhat crystalline.

To execute the refining, the surface of the metal is covered with wood-charcoal, and stirred with a spar or rod of birch or other wood. The gases which escape from the wood occasion a brisk effervescence. More wood-charcoal is from time to time added, so that the surface of the metal may be always covered with it, and the stirring is continued until the operation of refining is finished; a circumstance indicated

by assays taken in succession. The grain of the copper becomes finer by degrees, and its colour gradually brightens. When the grain is extremely fine, or *close*, when the trial-pieces, half cut through and then broken, present a silky fracture, and the copper is of a fine light red, the refiner considers the operation to be completed; but he verifies still further the purity of the copper, by trying its malleability. For this purpose, he takes out a sample in a small ladle, and pours it into a mould. When the copper is solidified, but still red-hot, he forges it. If it is soft under the hammer, and does not crack on the edges, the refiner is satisfied with its ductility, and pronounces it to be in its proper state. He then orders the workmen to mould it: they lift the copper out of the furnace in large iron ladles lined with clay, and pour it into moulds of a size suitable to the demands of commerce. The ordinary dimensions of the ingots or pigs are 12 inches broad, 18 long, and from 2 to 2½ thick.

The period of the refining process is 20 hours. In the first six, the metal heats and suffers a kind of roasting; at the end of this time it melts. It takes four hours to reach the point at which the refining, properly speaking, begins; and this last part of the process lasts about four hours. Finally, six hours are required to arrange the moulds, cast the ingots, and allow the furnace to cool.

The charge of copper in the refining process depends upon the dimensions of the furnace. In different works the charge varies from 3 to 5 tons.

When the copper offers difficulties in refining, a few pounds of lead are added to it. This metal, by the facility with which it scorifies, acts as a purifier, aiding the oxidation of the iron and other metals that may be present. The lead ought to be added immediately after removing the door to skim the surface. The copper should be constantly stirred to expose the greatest possible surface to the action of the air, and to produce the complete oxidation of the lead; since the smallest quantity of this metal in copper causes a difficulty in the lamination; *i. e.*, the scale of oxide does not come clean from the surface of the sheets.

The operation of refining copper is delicate, and requires, upon the part of the workmen, great skill and attention to give the metal its proper ductility. Its surface ought to be entirely covered with wood-charcoal; without this precaution, the refining of the metal would *go back*, as the workmen say, during the long interval which elapses in moulding; whenever this accident happens, it must be stirred anew with the wooden pole.

Too long employment of the pole causes the copper to become more brittle than it was prior to the commencement of the refining; that is, when it was *dry*. Its colour is now of a very brilliant yellowish red, and its fracture fibrous. When this occurs, the refining, as the workmen say, has *gone too far*, and the refiner removes the charcoal from the top of the melted metal; he opens the side door, to expose the copper to the action of the air, and it then resumes its malleable condition.

The theory of refining may be thus explained:—We may conclude that the copper in the *dry state* before refining, is combined with a small portion of oxygen, or, in other words, that a small portion of sub-oxide of copper is diffused through the mass, combined with it; and that this proportion of oxygen is expelled by the deoxidising action of the wood and charcoal, whereby the metal becomes malleable. 2. That when the refining process is carried too far, the copper gets combined with a little carbon. Thus copper, like iron, is brittle when combined with oxygen or carbon; and becomes malleable only when freed entirely from these substances.

It is remarkable, that copper, in the *dry state*, has a strong action upon iron; and that the tools employed in stirring the liquid metal become glistening, like those used in a farrier's forge. The iron of the tools consumes more rapidly at this time than when the copper has acquired its malleable state. The metal requires also, when *dry*, more time to become solid, or cool, than when it is refined; a circumstance depending, probably, upon the difference in fusibility of the copper in the two states, and which seems to indicate the presence of oxygen.

When the proper refining point has been passed, another very remarkable circumstance has been observed; namely, that the surface of the copper oxidises less easily, and that it is uncommonly brilliant, reflecting clearly the bricks of the furnace vault. This fact is favourable to the idea suggested above, that the metal is in that case combined with a small quantity of carbon; which absorbs the oxygen of the air, and thus protects the metal from its action.

Copper is brought into the market in different forms, according to the purposes which it is to serve. That which is to be employed in the manufacture of brass is granulated. In this condition it presents more surface to the action of zinc, and combines with it more readily. To produce this granulation, the metal is poured into a large ladle, pierced with holes and placed above a cistern filled with water, which must be hot or cold, according to the form of the grains required. When it is hot round grains are obtained analogous to lead shot; and the copper in this state is called

bean shot. When the melted copper falls into cold water perpetually renewed, the granulations are irregular, thin, and ramified; constituting *feathered shot.* The *bean shot* is the form employed in brass making.

Copper is also made into small ingots, about six ounces in weight. These are intended for exportation to the East Indies, and are known in commerce by the name of *Japan copper.* Whenever these little pieces are solidified, they are thrown, while hot, into cold water. This immersion slightly oxidises the surface of the copper, and gives it a fine red colour.

Lastly, copper is often reduced into sheets, for the sheathing of ships, and many other purposes.

The cylinders for rolling copper into sheets are usually 3 feet long and 15 inches in diameter. They are uniform. The upper roller may be approached to the under one by a screw, so that the cylinders are brought closer in proportion as the sheet is made thinner.

The ingots of copper are laid upon the sole of a reverberatory furnace to be heated; they are placed alongside each other, and are formed into piles in a cross-like arrangement, so that the hot air may pass freely round them all. The door of the furnace is shut, and the workman looks in through a peep-hole from time to time, to see if they have taken the requisite temperature; namely, a dull red. The copper is now passed between the cylinders; but although this metal is very malleable, the ingots cannot be reduced to sheets without being several times heated; because the copper cools, and acquires, by compression, a texture which stops the further progress of lamination. See ANNEALING.

These successive heatings are given in the furnace above indicated; though, when the sheets are to have a very great size, furnaces somewhat different are had recourse to. They are from 12 to 15 feet long and 5 feet wide. See BRASS.

The copper, by successive heating and lamination, gets covered with a coating of oxide, which is removed by steeping the sheets for a few days in a pit filled with urine; they are then put upon the sole of the heating furnace. Ammonia is formed, which acts on the copper oxide, and lays bare the metallic surface. The sheets are next rubbed with a piece of wood, then plunged, while still hot, into water, to make the oxide scale off; and are lastly passed cold through the rolling press to smooth them. They are now cut square, and packed up for home sale or exportation.

The following estimate was given by MM. Dufrénoy and Elie de Beaumont of the expense of manufacturing a ton of copper at the time of their visit to South Wales in 1822:—

	£.	s.	d.
12½ tons of ore, yielding 8½ per cent. of copper	55	0	0
20 tons of coals	8	0	0
Workmen's wages, rent, repairs, &c.	13	0	0
	£76	0	0

The exhalations from the copper smelting-works are exceedingly detrimental to both vegetable and animal life. They consist of sulphurous acid, sulphuric acid, arsenical and arsenious acids, various acid and other vapours, with solid particles mechanically swept away into the air. See p. 928.

The following figures represent certain modifications of the copper calcining and smelting copper furnaces of Swansea.

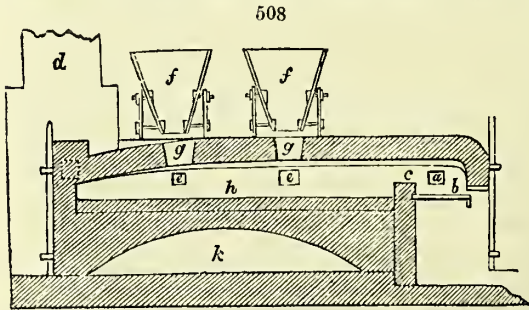

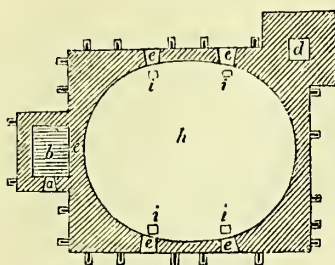

Fig. 508 is the section of the roasting furnace lengthwise; *fig. 509*, the ground plan; in which *a* is the fire-door; *b*, the grate; *c*, the fire-

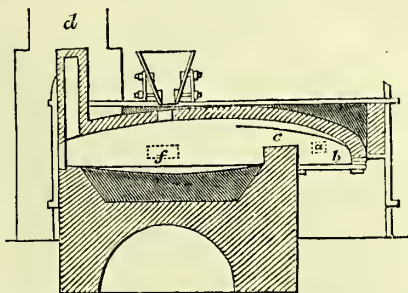

bridge; *d*, the chimney; *e e*, apertures on each side of the long sides of the furnace, through which the ore is spread, and turned over; *f f*, iron hoppers; *g g*, openings in the vaulted roof; *h* the hearth-sole; *i i*, holes in this; *k*, a vaulted space under the hearth. The hearth has a suitable oval shape, and is covered with a flat arch. Its length is 16 feet, breadth 13½ feet, mean height 2 feet.

Fig. 510 is a longitudinal section of the melting furnace; fig. 511 the ground plan, in which *a* is the fire-door; *b*, the grate; *c*, the fire-bridge; *d*, the chimney; *e*, the

509

510

side openings; *f*, the working door; *g*, the raking-out hole; *h*, iron spouts, which conduct the melted metal into pits filled with water.

The melting furnace is altogether smaller, but its firing hearth is considerably larger than in the roasting furnace. The long axis of the oval hearth is 14 feet; its short axis 10 feet; its mean height 2 feet.

Napier's Process for smelting Copper Ores.—As the copper ores of this country often contain small portions of other metals, such as tin, antimony, arsenic, &c. which are found to deteriorate the copper, Mr. Napier's process had in view to remove these metals, and at the same time to shorten the operations of the smelting process.

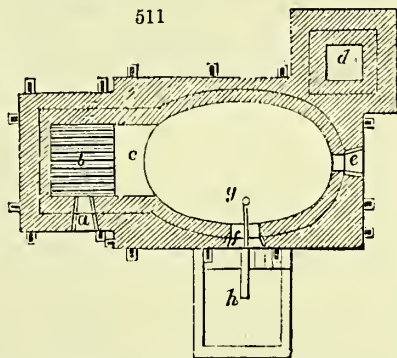

The first two operations, that of calcining and fusing the ore, are the same as the ordinary processes; but the product of this last fusion—viz., the *coarse-metal*—is again fused with a little sulphate of soda and coal mixed; and whenever this becomes solid, after tapping the furnace, it is thrown into a pit of water, where it immediately falls into an impalpable powder; the water boils, and then contains caustic soda and sulphide of sodium, dissolving from the powder those metals that deteriorate the copper; the ley is let off, and the powder washed by allowing water to run through it. The powder is then put into a calcining furnace, and calcined until all sulphur is driven off, which is easily effected from the finely-divided state of the mass. This calcined powder is now removed to a fusing furnace, and mixed with ores containing no sulphur, such as carbonates and oxides, and a little ground coal, and the whole fused; the result of this fusion is metallic copper and sharp-slag—that is, a scoria containing much protosilicate of iron, which is used as a flux in the first fusion of the calcined ore, so that any small trace of copper which the slag may contain is thus recovered.

The copper got from this fusion is refined in the ordinary way, and is very pure.

This process, which was patented in 1846, and carried on for some few years at Loughor, near Swansea, has been found in practice to be incapable of completely separating antimony, arsenic, and tin from copper, and has in consequence been abandoned.

When the copper ores contain tin to the extent of from $\frac{1}{2}$ per cent. to 2 per cent., which many of them are found to do, Mr. Napier proposed to extract this tin, and make it valuable by a process which has also been the subject of a patent. The ore is first ground and calcined, till the amount of sulphur is a little under one-fourth of the copper present; the ore is then fused with a little coal. The result of this fusion, besides the scoria, is a regulus composed of sulphur, copper, and iron, and under this is a coarse alloy of copper, tin, and iron. This alloy is ground fine, and calcined to oxidise the metals, which are then fused in an iron pot with caustic soda, which combines with the tin and leaves the copper. The oxide of copper is now fused with the regulus. The stannate of soda is dissolved in water, and the tin precipitated by

511

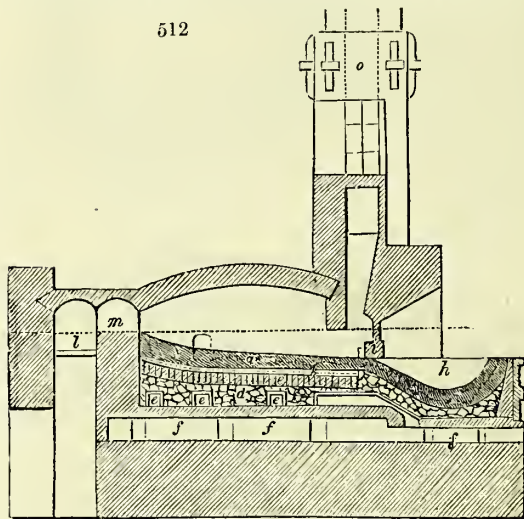

slaked lime, the precipitate is dried and fused with carbonaceous matters and a little sand, and metallic tin obtained; the caustic soda-solution is evaporated to dryness and used over again. This process was proposed for the treatment of very poor copper ores that are mixed with tin, or poor tin ores mixed with copper, but does not appear to have been practically applied.

Process formerly employed at Chessy.—The principal ore smelted at Chessy was the azure copper, or blue carbonate, which was discovered by accident in 1812. Red copper ore, also, came into operation there after 1825. The average metallic contents of the richest azure ore was from 33 to 36 per cent.; of the poorer, from 20 to 24. The red ore contained from 40 to 67 parts in 100. The ore was sorted to an average of 27 per cent. of metal, to which 20 per cent. of limestone was added; whence the cinder will amount to 50 per cent. of the ore. A few per cents. of red copper slag, with some quicklime and *Gahrslag*, was added to each charge, which consisted of 200 pounds of the above mixture, and 150 pounds of coke. When the furnace (*fourneau à manche*, see the Scotch smelting hearth, under LEAD) was in good action, from 10 to 14 such charges could be worked in 12 hours. When the crucible was full of metal at the end of this period, during which the cinder had been frequently raked off, the blast was stopped; the *matt* floating over and the metal being sprinkled with water and taken off, left the black copper to be treated in a similar way, and converted into *rosettes*. The refining of this black copper was performed in a kind of reverberatory furnace.

The cinders produced in this reduction process were either vitreous and light blue, which were most abundant; cellular, black, imperfectly fused from excess of lime; or, lastly, red, dense, blistered, from defect of lime, from too much heat, and the passage of oxide of copper into the cinders. They consisted of silicate of alumina, of lime, and of protoxide of iron; the red contained some silicate of copper.

512

The copper-refining furnace at Chessy was of the kind called *Spliss-ofen* (split-hearth) by the Germans. *Fig. 512* is a section lengthwise on the dotted line *A B* of *fig. 513*, which is the ground plan.

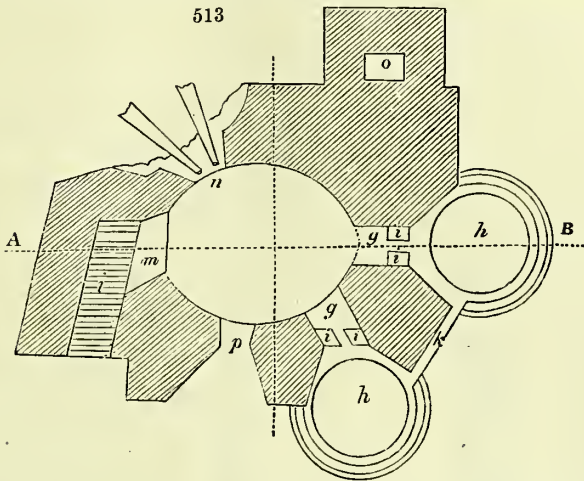

The foundation-walls were made of gneiss; the arch, the fire-bridge, and the chimney, of fire-bricks. The hearth *a* was formed of a dense mixture of coal-dust, upon a bottom of well-beat clay *b*, which reposed upon a bed of brick-work *c*. Beneath this there was a slag bottom *d*; *e* is the upper, and *f* the under discharge-hole. The hearth was egg-shaped; the longer axis being 8 feet,

the shorter $6\frac{1}{2}$ feet; in the middle it was 10 inches deep, and furnished with the outlets *g g*, which lead to each of the *split-hearths*, *h h*, *fig. 513*. These outlets were contracted with fire-bricks *i i*, till the proper period of the discharge. The two hearths were placed in communication by a canal *k*; they were each $3\frac{1}{2}$ feet in diameter, 16 inches deep; floored with well-beat coal-ashes, and received about 27 cwts. for a charge.

l is the grate; *m*, the fire-bridge; *n*, the boshes in which the *tuyères* lie; *o*, the chimney; *p*, the working door, through which the slags may be drawn off. Above this was a small chimney, to carry off the flame and smoke whenever the door was opened.

The smelting *post* or charge to be purified at once, consisted of 60 cwts. of black copper, to which a little granular copper and copper of cementation were added; the consumption of pit-coal amounted to 36 cwts. As soon as the copper was melted, the bellows were set a-going, and the surface of the metal soon became covered with a moderately thick layer of cinder, which was drawn off. This was the first *skimming* or *décrassage*. By-and-by, a second layer of cinder formed, which was in like manner removed; and this *skimming* was repeated, to allow the blast to act upon fresh

metallic surfaces. After 4 or 5 hours, no more slag appeared, and then the fire was increased. The melted mass now began to boil or work (*travailler*), and continued so to do for about $\frac{3}{4}$ of an hour, or an hour, after which the motion ceased, though the fire was kept up. The *Gahrproof* was now taken; but the metal was seldom fine in less than

$\frac{3}{4}$ of an hour after the boil was over. Whenever the metal was run off by the tap-hole into the two basins, *h h*, called *split-hearths*, a reddish vapour or mist arose from its surface, composed of an infinite number of minute globules, which revolved with astonishing velocity upon their axes, constituting what the Germans called *Sprätzen* (crackling) of the copper. They were composed of a nucleus of copper covered with a film of oxide, and were used as sand for strewing upon manuscript. The copper was separated by sprinkling water upon the surface of the melted metal, in the state of *rosettes*, which were immediately immersed in a stream of water. This refining process lasted about 16 or 17 hours; the skimmings weighed about 50 cwts.; the refuse was from 15 to 17 per cent.; the loss from 2 to 3 per cent. The *Gahrslag* amounted to 11 cwts.

Smelting of the Mansfeld Copper-Schist, (Kupferschiefer).—The cupreous ore is first roasted in large heaps of 2,000 cwts., interstratified with brush-wood, and with some schists rich in bituminous matter mixed with the others. These heaps are 3 ells high, and go on burning 15 weeks in fair and 20 in rainy weather. The bituminous matter is decomposed; the sulphur is dissipated chiefly in the form of sulphurous acid; the metal gets partially oxidised, particularly the iron, which is a very desirable circumstance for the production of a good smelting slag. The calcined ore is diminished $\frac{1}{10}$ th in bulk and $\frac{1}{5}$ th in weight; becoming of a friable texture and a dirty yellow colour. The smelting furnaces are cupolas (*Schachtöfen*), 14 to 18 feet high; the fuel is partly coal and partly coke from the Berlin gas-works and from Silesia. The blast is now given by a cylinder, but formerly with the old barbarous *Blasebälgen*, or wooden bellows of the household form. The smelting was formerly conducted as follows:—

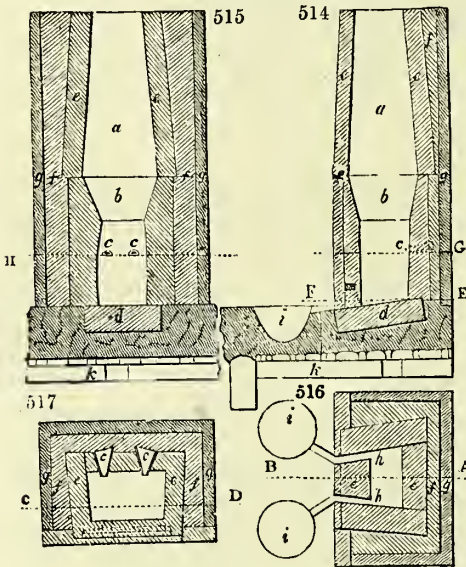

The copper-slate is sorted, according to its composition, into slate of lime, clay, iron, &c.; by a mixture of which the smelting is facilitated. For example, 1 post or charge may consist of 20 cwts. of the ferruginous slate, 14 of the calcareous, 6 of the argillaceous, with 3 of fluor-spar, 3 of rich copper slags, and other refuse matters. The nozzle at the *tuyère* is lengthened 6 or 8 inches, to place the melting heat near the centre of the furnace. In 15 hours 1 *Fuder* of 48 cwts. of the above mixture may be smelted, whereby 4 to 5 cwts. of *matt* (*Kupferstein*) and a large body of slags are obtained. The *matt* contains from 30 to 40 per cent. of copper, and from 2 to 4 *Loths* (1 to 2 oz.) of silver. The slags contain at times $\frac{1}{10}$ th their weight of copper.

The *matt* is composed of the sulphides of copper, iron, silver, zinc, along with some arsenical cobalt and nickel. The slaty slag is raked off the surface of the melted *matt* from time to time. The former is either, after being roasted six successive times, smelted into black copper, or it is subjected to the following concentration process:— It is broken to pieces, roasted by brushwood and coals three several times in brick-walled kilns, containing 60 cwts., and turned over after each calcination; a process of 4 weeks' duration. The thrice-roasted mass, called *Spurröst*, being melted in the

cupola, *fig. 514*, with ore-cinder, yields the *Spurstein*, or concentrated *mat.* From 30 to 40 cwts. of *Spurrost* are smelted in 24 hours; and from 48 to 60 per cent. of *Spurstein* are obtained, the slag from the slate-smelting being employed as a flux. The *Spurstein* contains from 50 to 60 per cent. of copper, combined with the sulphides of copper, of iron, and silver.

The *Spurstein* is now mixed with *Dünnstein* (a sulphide of copper and iron produced in the original smelting), roasted 6 successive times, in quantities of 60 cwts., with brushwood and charcoal; a process which requires from 7 to 8 weeks. The product of this six-fold calcination is the *Gahrrost* of the Germans; it has a colour like red copper ore, varying from blue grey to cochineal-red, with a granular fracture; and may be immediately reduced into metallic copper, which process is called *Kupfermachen*. But before smelting the mass, it is lixiviated with water, to extract from it the soluble sulphate, which is concentrated in leaden pans and crystallised.

The lixiviated *Gahrrost* mixed with from $\frac{1}{4}$ th to $\frac{1}{5}$ th of the lixiviated *Dünnsteinrost* and $\frac{1}{6}$ th to $\frac{1}{10}$ th of the copper-slate slag are smelted with charcoal or coke fuel in the course of 24 hours, in a mass of 60 or 80 cwts. The product is black copper, to the amount of about $\frac{1}{4}$ th the weight, and $\frac{1}{6}$ th of *Dünnstein* or *thin matt.* This black copper contains in the cwt. from 12 to 20 *Loths* (6 to 10 oz.) of silver. The *Dünnstein* consists of from 60 to 70 per cent. of copper combined with sulphur, sulphide of iron, and arsenic; and when thrice roasted, yields a portion of metal. The black copper lies undermost in the crucible of the furnace; above it is the *Dünnstein*, covered with the strong slag, or copper cinder, resulting from the slate-smelting. The slags being raked off, and the crucible sufficiently full, the eye or nozzle hole is shut, the *Dünnstein* removed by cooling the surface and breaking the crust, which is about a $\frac{1}{4}$ to $\frac{1}{2}$ inch thick. The same method is adopted for taking out the black copper in successive layers. For the desilvering of this, and similar black coppers, see *SILVER*.

the heat is slowly conducted; *h h*, the two holes through one or other of which alternately the product of the smelting process is run off into the fore-hearth. Beneath the hearth sole there is a solid body of loam; and the fore-hearth is formed with a mixture of coal-dust and clay; *k* is the discharge outlet for moisture. *Fig. 516* is a horizontal section of the furnace through the hole or eye, on the dotted line *EF* of *fig. 514*; *fig. 517*, a horizontal section of the shaft of the furnace through the *form* along the dotted line *GH* of *figs. 514* and *515*. The height of the shaft, from the line *EF* to the top, is 14 feet; from *E* to *c*, 25 inches; from *c* to the line below *b*, 2 feet; from that line to the line opposite *gg*, 2 feet. The width at the line *gg* is 3 feet 3 inches, and at *c*, 26 inches. The basins, *i i*, *fig. 516*, are each 3 feet in diameter and 20 inches deep.

During the last twenty years few processes have undergone more extensive modifications than that used for the extraction of copper and silver from the copper-schists of Mansfeld; and it is therefore necessary to present a short account of the series of operations at present employed.

The cupola furnace now used differs greatly, both in construction and dimensions, from that formerly employed in the district; being in almost all respects, excepting size, similar to the closed blast-furnaces used in this country for the manufacture of cast iron. This furnace is circular, and 30 feet in height by about 7 feet in diameter

at the top, which is the widest part; the interior dimension decreasing gradually towards the hearth, where the width is 6 feet.

The blast is supplied by six water-tuyers placed radially, or nearly so, at a height of from 4 to 5 feet above the hearth. On one side is a dam plate over which slag flows continuously whilst on the opposite side is a tapping hole through which the matt is drawn off from time to time.

The top of the furnace is closed by a cup-and-cone, and the waste-gases are conveyed to the stoves employed for heating the blast, the temperature of which is raised to 370° F.

The reverberatory furnace employed in the calcination processes is in all essential respects similar to that used in Wales for the roasting of the various matts produced in the English method of smelting.

The following is an outline of the routine generally employed:—

1. Roasting the schists in the open air, in large heaps, in order to drive off water, bitumen, and other volatile matters and at the same time to induce such a state of division between the particles of the ore as shall be most suitable to subsequent melting operations.

2. The first melting in a cupola-furnace, the object being the separation of silica and earthy matters in the form of slag and the concentration of the copper in a matt containing 36 per cent. of that metal, together with some silver.

3. The matt formed in the last operation is roasted in the open air in rectangular ‘stalls,’ the object being the elimination of a portion of the sulphur and the oxidation of some of the iron.

4. The roasted matt or coarse-metal is concentrated in a reverberatory furnace in order to fit it for the next process for extracting the silver by Ziervogel’s method. During the roasting, lead, arsenic, and zinc are to some extent eliminated and a regulus produced which is rich in copper and silver; at the conclusion of the operation this is granulated by being run into a vat of water.

5. For the extraction of the silver, the granulated matt is ground to a fine powder, and roasted in a reverberatory furnace at such a temperature that as much as possible of the copper shall be converted into oxide, whilst the silver remains in the form of sulphate; this is washed from the roasted material by means of hot water and the silver subsequently precipitated from solution by metallic copper.

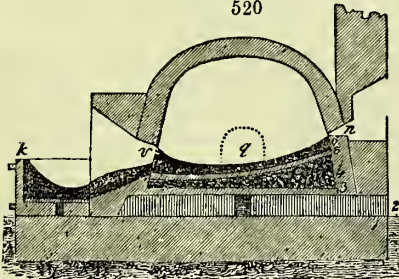

6. Fusion for blister-copper. The residue from the lixiviation vats is made into balls with about 8 per cent. of clay, which serves the double purpose of supplying materials for slag and at the same time forming the powder into lumps and preventing its clogging the furnace.

The fusion is conducted in a cupola-furnace and fluid products flow continuously from it into a basin, and arrange themselves according to their specific gravities; namely,

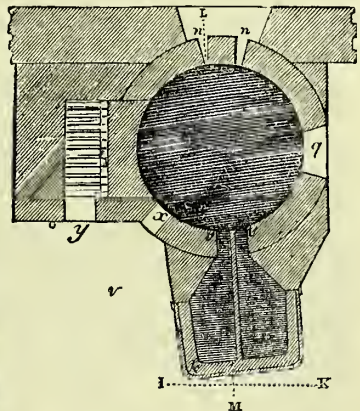

518

520

519

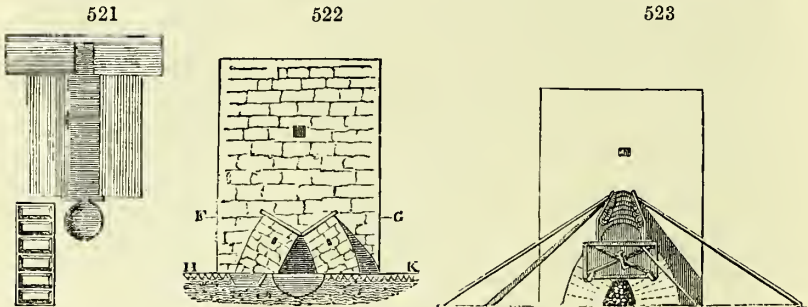

first, metal; second, a thin layer of rich matt; and thirdly, slag. The latter is broken and sorted, and any containing copper is, together with the matt, worked over in one of the earlier operations.

7. Refining the blister-copper. This is effected either in the German hearth by the action of glowing charcoal and a highly-inclined blast, and the fine-copper obtained in the form of rosettes; or the Welsh reverberatory furnace is employed, and the copper cast into ingots. For extraction of silver from the Mansfield copper regulus, see SILVER.

Figs. 518, 519, 520, represent the reverberatory furnace generally employed in the Harz, in the district of Mansfeld, Saxony, Hungary, &c., for the treatment of black copper, and for refining rosette copper upon the great scale. An analogous furnace is used at Andreasberg for the liquefaction or purification of the matts, and for workable lead when it is much loaded with arsenic.

Fig. 518 presents the elevation of the furnace parallel to the line $1\ x$, of the plan fig. 519, which plan is taken at the level of the tuyère n of fig. 520; fig. 520 is a vertical section in the line $1\ m$, fig. 519. k represents one of two basins of reception, brasqued with clay and charcoal; $n\ n$, two tuyères through which enters the blast of two pairs of bellows; g , door by which the matter to be melted is laid upon the sole of the furnace; v, v , two points where the sole is perforated, when necessary to run off the melted matter into either of the basins k ; x , door through which the slags or cinders floating upon the surface of the melted metal are raked out; y , door of the fire-place. The fuel is laid upon a grate above an ash-pit, and below the arch of a reverberatory, which is contiguous to the dome or cap of the furnace properly so called. In the section, fig. 520, the following parts may be noted: 1, 2, 3, mason-work of the foundation; 4, vapour-channels or conduits, for the escape of the humidity; 5, bed of clay; 6, brasque, composed of clay and charcoal, which forms the concavity of the hearth.

Figs. 521, 522, 523, show the furnace formerly employed for liquation in one of

the principal smelting works of the Harz. Fig. 523 exhibits the working area charged with the liquation cakes and charcoal, supported by sheets of wrought-iron; Fig. 521 is the plan, in the line $F\ G$, of fig. 522.

A liquation cake is composed of—

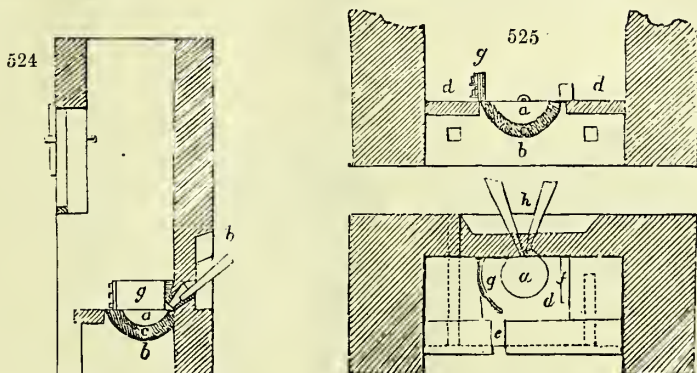

Black copper holding at least 5 or 6 *Loths* ($2\frac{1}{2}$ or 3 oz.) of silver per cwt., and weighing 90 to 96 lbs. Lead obtained from litharge, 2 cwts. Litharge, $\frac{1}{2}$ cwt.

From 30 to 32 cakes are successively worked in one operation, which lasts about 4 hours; the furnace is brought into action as usual, with the aid of slags; then a little litharge is added; when the lead begins to flow, the copper is introduced, and when the copper flows, lead is added, so that the mixture of the metals may be effected in the best possible way.

From 8 to 16 of these cakes (*pains*) are usually placed in the liquation furnace, figs. 521, 522, 523. The operation lasts 3 or 4 hours, in which time about $1\frac{1}{2}$ quintal of charcoal is consumed. The cakes are covered with burning charcoal supported, as before stated, by the iron plates. The workable lead obtained flows off towards the basin in front of the furnace; whence it is laded out into moulds set alongside. (See fig. 518). If the lead thus obtained be not sufficiently rich in silver to be worth cupellation, it is employed to form new liquation cakes. When it contains from 5 to 6 *Loths* of silver per cwt., it is submitted to cupellation in the said smelting works. See SILVER.

The refining of the eliquated copper (called *Darränge*) from which the silver has been sweated out by means of lead, can be performed only in small hearths. The following is the representation of such a furnace, called in German *Kupfergahrheerd*. Fig. 524 is the section lengthwise; fig. 525 is the section across; and fig. 526 is the ground plan: in these figures a is the hearth-hollow; b , a massive wall; c , the mass out of which the hearth is formed; d , cast-iron plates covering the hearth;

e, opening for running off the liquid slag; *f*, a small wall; *g*, iron curb for keeping the coals together.

The hearth being heated with a bed of charcoal, $\frac{3}{4}$ cwt. of *Darrlinge* are laid over it, and covered with more fuel: whenever this charge is melted, another layer of the coal and *Darrlinge* is introduced, and thus in succession till the hearth becomes full or contains from $2\frac{1}{4}$ to $2\frac{1}{2}$ cwts. In Neustadt $7\frac{1}{2}$ cwts. of *Darrlinge* have been refined in one furnace, from which 5 cwts. of *Gahrkupfer* have been obtained. The blast oxidises the foreign metals, namely, the lead, nickel, cobalt, and iron, with a little copper, forming the *Gahrslag*; which is, at first, rich in lead oxide and poor in copper oxide; but at the end, this is reversed. The slag, at first blackish, assumes progressively a copper-red tint. This slag flows off spontaneously along the channel *e*, from the surface of the hearth. The *Gahre* is tested by means of a proof-rod of iron, called *Gahreisen*, thrust through the tuyère into the melted copper, then drawn out and plunged in cold water. As soon as the *Gahrspan* (scale of copper) appears brownish-red on the outside, and copper-red within, so thin that it seems like a net-work, and possessing sufficient tenacity to admit of its being bent backwards and forwards several times without breaking, the refining is finished. The blast is then stopped; the coals covering the surface, as also the cinders, must be raked off the copper, after being left to cool. The surface is now further cooled by sprinkling water upon it, and the thick cake of congealed metal (*rondelle*) is lifted off with tongs, a process called *Schleissen* (slicing), or *Scheibenreissen* (shaving), which is continued till the last convex cake at the bottom of the furnace, styled the *kingspiece*, is withdrawn. These *rondelles* are immediately immersed in cold water, to prevent the oxidation of the copper: whereupon the metal becomes of a cochineal-red colour, and gets covered with a thin film of red oxide. Its under surface is studded over with points and hooks, the result of tearing the congealed disc from the liquid metal. Such cases are called *rosette* copper. When the metal is pure and free from oxide, these cakes may be obtained very thin, $\frac{1}{24}$ th of an inch, for example. The refining of $2\frac{1}{2}$ cwts. of *Darrlinge* takes $\frac{3}{4}$ of an hour, and yields $1\frac{1}{2}$ cwt. of *Gahr* copper in 36 rosettes, as also some *Gahrslag*. *Gahr*-copper generally contains from $1\frac{1}{2}$ to $2\frac{1}{2}$ per cent. of lead, along with a little nickel silver, iron, and aluminium. Most of the Mansfield copper is now refined in a reverberatory furnace, and sold as *Raffinadkupfer*, and not as *Gahrkupfer*.

Utilisation of the Copper Smoke.—The application of the sulphur disengaged in the calcination or roasting of copper ores to the production of liquid sulphuric acid, has long been an important object of copper-smelters. In the case of a small proportion of copper ores, containing a comparatively large proportion of sulphur, and in the state of hard lumps, free from earthy matter, this is effected in the ordinary 'pyrites burner' of the sulphuric acid works. But copper ores, for the most part, are small, poor in sulphur, with much earthy matter; and are therefore calcined in reverberatory furnaces with fire-grates. The gases from these calciners do not consist of more than 0.5 vol. of sulphurous acid in 100 vols., and are moreover largely mixed with the products of combustion from the fire-place: they were therefore unfit for the vitriol chamber, and were allowed to escape.

An important invention, by which this loss is avoided, is the calcining furnace of M. Gerstenhöfer; in which the ore, in a finely-divided state, is allowed to fall on a number of fire-brick bars or bearers, placed in rows, at different elevations. The ore, which is supplied in a continuous stream at the top, meets in its descent with a current of air in the reverse direction. The furnace being moderately heated on starting,

the ore ignites, and afterwards maintains its own combustion, without the aid of fuel, for any length of time; while the ascending current of air becomes charged with sulphurous acid of sufficient strength and purity to be conveyed to the vitriol chambers.

The annexed figures represent perpendicular transverse sections of M. Gerstenhöfer's furnace.

Gerstenhöfer's Furnace for calcining
Copper Ores.

Fig. 527 is a cross-section parallel with the front; *fig. 528* represents a section from front to back. The length of the earthen bars is about two feet six inches: twenty rows occupy about twelve feet in height; *a* is an iron box or hopper for containing a supply of ground ore, having at bottom two or more cast-iron grooved rollers, which are worked without interruption, at a speed adapted to supply ore equal to a discharge of about 10 cwts. of sulphur per twenty-four hours. As the ore sometimes has a tendency to form a cake on the bars, it is necessary to scrape these occasionally, by means of an iron rod, with curved end, which is introduced through plug-holes in cast-iron boxes, shown in *fig. 528*. The calcined ore collects in the cavity *b* at the bottom, and is raked out when convenient. The necessary amount of air is admitted partly at the back through the flue *c*, regulated by means of a screw-valve, and partly through the plug-holes in front. After passing upwards through the calciner, the air, now charged with sulphurous acid to the extent of 6 or 8 per cent. in volume, passes over the bridge, and through the flue *e* in the direction of the arrows, *fig. 528*. Provision is made at the bottom of these flues for collecting and removing particles of roasted ore carried over by the current; *f* is a brick-built chamber for a similar purpose, from the back of which the gas passes through the flue *g* to the vitriol chambers. The latter are supplied with nitric acid in the usual way; either from a nitrate-pot or oven worked independently, or with liquid nitric acid allowed to percolate a tower and mix with the gas from the calciners before entering the leaden chambers.

The Gerstenhöfer calciner is applicable to all varieties of sulphuretted copper ores, although varying in proportion of sulphur from 16 to 40 per cent.; it is also adapted to the 'coarse-metal' or regulus obtained as the result of the first reducing operation.

The calcination is conducted with ease, so that no more sulphur remains in the ore than is necessary for the smelting processes.

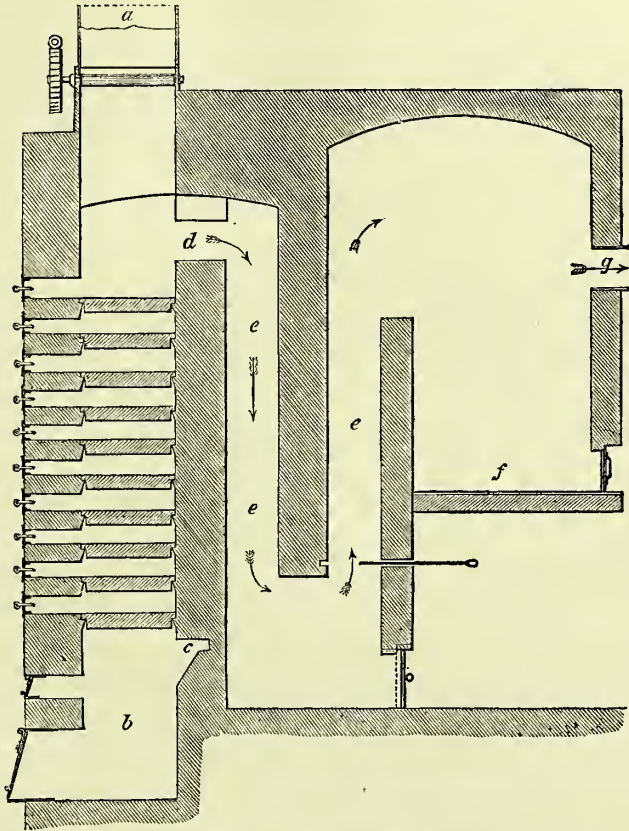

As the superiority of this calciner over every other, having a similar object, has been proved, in the Government copper smelting establishments of Freiberg and Mansfeld, and in this country, in the works of Messrs. Vivian and Sons, near Swansea (who are the proprietors of the English patent), it is expected that their general introduction into copper works will be the means of greatly reducing the smoke arising therefrom and turning it to profitable account. This was written in 1867. Although still used advantageously, its use has not, in 1874, been extended.

Mr. Peter Spence, of Manchester, has also a calciner which has been four years in operation, and has calcined 20,000 tons of copper ore. Mr. Spence, in his patent of the 3rd July 1861, thus describes his arrangements:—

'The essential feature of invention consists in submitting such ores to the action of a roasting heat as they are passed from one end of a furnace to the other, during which transference a current of air is caused to travel over them in an opposite direction; to accomplish this, a furnace of considerable length, having several doors for the purpose of introducing apparatus by which the transference may be effected, is used. It will be obvious that by this arrangement the ores may be submitted to heat in a thin stratum, that the amount of roasting may be modified by a quicker or slower

transference, and that the heat communicated may be greater towards the termination of the operation than at the commencement thereof.

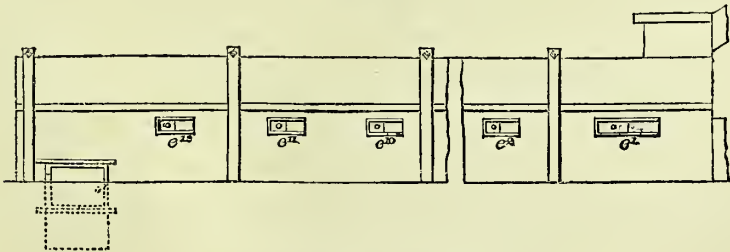

528

Gerstenhöfer's Furnace for calcining Copper Ores.

This invention will be fully understood by the accompanying drawings of apparatus. *Fig. 529* is a side view of the furnace, and *fig. 530* a longitudinal section, in both of which the two ends only are shown, the whole being of considerable length. One

529

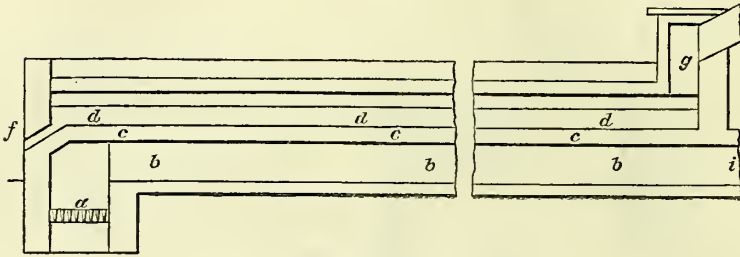

Spence's Furnace for calcining Copper Ores.

now in operation is fifty feet long, with twelve doors for the transference of the ores ; but these dimensions may be varied, and are only mentioned for the purpose of

explaining that the furnace should be of considerable length. *Fig. 531* represents a cross-section; and in describing the apparatus in the first instance we suppose that the manufacture of sulphuric acid is the object in view.

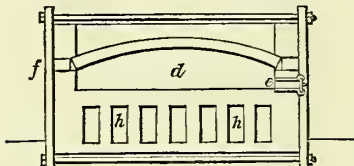

530

Spence's Furnace for Calcining Copper Ores.

At *a* are the fire-bars of the furnace, and at *b* the fire-chamber, formed by channels, as seen in *fig. 531*, extending under a partition *c*, of fire brick, which partition forms the bottom of another and distinct chamber *d*,

531

Spence's Furnace for calcining Copper Ores.

furnished at one or both sides with a number of doors *e*¹, *e*², &c. At *f* is an aperture formed through the brickwork, and constituting a communication from the external atmosphere to the chamber *d*. The ores from which sulphuric acid is to be obtained are passed through the door *e*¹ into the chamber *d* in sufficient quantity to lie about two or three inches in thickness upon the bed *e*, and to extend, say, halfway towards the door *e*². This batch having been submitted to heat, passing from the fire-chamber *b* for the required time, is pushed forward by any convenient instrument, so as to be brought opposite the door *e*², and another batch is introduced through the door *e*¹; then the first charge is removed from *e*² to *e*³, and the second from *e*¹ to *e*², and so on until the first-deposited batch shall have arrived at the other end of the furnace at *e*¹², and it is then pushed through the aperture *f* into any receptacle placed to receive it. During this transference of the material, it has gradually become heated, and a current of air entering at *f* has been passing over it, and the operation has caused the sulphur to be driven off from the ore and conveyed through the channel *g* to the ordinary sulphuric acid apparatus. The end of the fire-chamber *d* leads to a flue at *i*. The degree of roasting to be effected, and so as to secure the best results, can be ascertained only by experience; but working with a furnace fifty feet long and with twelve doors, the first charge is allowed to remain for one hour, then transferred to the second position, and a fresh charge put into the first, and so on, waiting an hour between each charge.

An advantage arising from this invention is its capability of being applied to the manufacture of sulphuric acid from any description of ores. It is well known to those engaged in the extraction of copper from ores that the sulphur thereof is frequently wasted from the impracticability of roasting certain mixed ores so as to render them into a fit condition for reduction, and also for the manufacture of sulphuric acid; but by this improved method, ores of any description, large or small, may be roasted so as to produce sulphuric acid with economical results. In calcining the mixed copper ores preparatory to smelting, as practised at the Swansea and other copper works, and with the view of economising the manufacture of sulphuric acid, the process of calcination by this method is effected with equal advantage as by the modes now practised, as the heat is made to act on a large body of ore without an exhaustive, but with an accumulative effect, so that the heat which has calcined or driven off nearly the last portion of sulphur from the ore which lies at the exit of the furnace then passes on, heating every successive charge, and gaining strength from the combustion of the sulphur until it comes into contact with the cold charge, which it rapidly heats to ignition, partly from the under heat of the bed derived from the fire, which, after leaving the furnace, is passed to a chimney, and partly from all the hot gases passing over it on their way out of the furnace to the vitriol chamber, into which they are conveyed after being mixed with nitrous gases, as is well known.

As another advantage arising from the use of this invention, it is found in the practical carrying out thereof, that the production of a given amount of sulphuric acid is effected by the expenditure of far less nitre than is commonly used, a certain amount of sulphuric acid being formed in the chamber of the furnace and passing forward in a state of vapour. Thus far we have spoken of this invention as applicable to the manufacture of sulphuric acid, but it is also applicable to roasting ores of copper preparatory to reduction. In this application the operation is precisely that above described, and will not, therefore, need a repetition of description, it being of course understood that if the ores have been previously used for the manufacture of sulphuric acid, and contain, therefore, but a small amount of sulphur, the vapours from the chamber *d* may pass into the atmosphere instead of into the vitriol chamber, if desired.

On the 14th June 1864, Mr. Peter Spence and Mr. J. B. Spence effected another patent for 'calcining and smelting copper ores.' This will be fully understood by the following description:—

'Our invention consists in applying the heat used in smelting copper ores to the purpose of calcining such materials, and in transferring the calcined ores direct to the smelting furnace. To accomplish these objects, we place the two furnaces in connection with each other, and cause a suitable flue to convey the heat used in smelting to the material to be calcined; and when this operation is complete, and the smelted ore is removed, we rake the calcined ore direct on to the bed of the smelting furnace. The calcining furnace we at present prefer to use is of that construction for which Letters Patent were granted to Peter Spence, bearing date July 3rd, 1861, No. 1695.'

In addition to these processes, it may be stated that a company has been established at Oldbury, in Staffordshire, for working the process known as 'Henderson's salt process.' We have been favoured with the following description:—

'The works are erected for the purpose of extracting the copper, and utilising the residue from the Spanish pyrites, imported mostly by the alkali makers, and the sulphur extracted by them for the purpose of making sulphuric acid. We then calcine the ore with salt in such a way as to decompose every trace of copper, and peroxidise the whole of the iron that is not already oxidised during the burning out of the sulphur. We then put the calcined ore into vats or tanks; and as the chloride of copper is readily soluble, that metal is washed out perfectly clean with hot water, and the residue of peroxide of iron is sold at the iron works in the immediate neighbourhood. This is used in the puddling furnaces, and answers well for *two purposes*: first, to keep the pig iron from cutting the bottom of the furnaces, and, secondly, to improve the quality of the wrought iron produced. We sell of this residue about 600 tons per month. The copper is precipitated from the solution by scrap iron, the precipitate run down and refined; and the whole of the copper is sold as B. S. ingot. We produce 15 to 18 tons of copper per month.' See PYRITES.

Spanish Process of refining Copper.—The refining of copper is well executed at Seville, in Spain; and therefore some account of the mode of operating is required.

The first object is to expel in a reverberatory furnace all the volatile substances, such as sulphur, arsenic, antimony, &c., which may be associated with the copper; and the second, to oxidise and convert into scoriæ the fixed substances, such as iron, lead, &c., with the least possible expense and waste. The minute quantities of gold and silver which resist oxidation cannot be in any way injurious to the copper. The hearth is usually made of refractory sand and clay with ground charcoal, each mixed in equal volumes, and worked up into a doughy consistence with water. This composition is beat firmly into the furnace bottom. But a quartzose hearth, such as a bed of fire-sandstone, is found to answer better, and to be far more durable.

Before kindling the furnace, its inner surface is smeared with a mixture of fire-clay and water.

The cast pigs, or blocks of crude copper, are piled upon the hearth, each successive layer crossing at right angles that which is beneath it, in order that the flame may have access to play upon the surface of the hearth, and to heat it to a proper pitch for making the metal flow.

The weight of the charge should be proportional to the capacity of the furnace, and such that the level of the metallic bath may be about an inch above the nozzle of the bellows; for, were it higher, it would obstruct its operation, and, if too low, the stream of air would strike but imperfectly the surface of the metal, and fail to effect, or would at least retard, the refining process, by leaving the oxidation and volatilisation of the foreign metals incomplete.

As the scoriæ form upon the surface, they are drawn off with an iron rabble fixed to the end of a wooden rod.

Soon after the copper is melted, charcoal is kindled in three iron basins lined with

loam, placed alongside the furnace, to prepare them for receiving their charge of copper, which is to be converted in them, into *rosettes*.

The bellows are not long in action before the bath assumes a boiling appearance; some drops rise up to the roof, others escape by the door, and fall in a shower of minute spherical globules. This phenomenon proves that the process is going on well; and, when it ceases, the operation is nearly completed. A small proof of copper, of the form of a watch-case and therefore called *montre*, is taken out from time to time upon the round end of a polished iron rod, previously heated. This rod is dipped 2 or 3 inches into the bath, then withdrawn and immersed in cold water. The copper cap is detached from the iron rod by a few blows of a hammer, and judgment is formed, from its thickness, colour, and polish, as to the degree of purity which the copper has acquired. These *watches* need not be drawn till the small rain, above spoken of, has ceased to fall. At the end of about 11 hours of firing, the numerous small holes observable in the first *watch* samples begin to disappear; the outer surface passes from a bright red to a darker hue, the inner one becomes of a more uniform colour, and always less and less marked with yellowish spots. It has acquired the greatest pitch of purity that the process can bestow when the *watches* become of a dark crimson colour.

Care must be taken to stop this refining process at the proper time; for, by unduly prolonging it, a small quantity of cuprous oxide would be formed, which, finding nothing to reduce it, would render the whole body of the copper hard, brittle, and incapable of lamination.

The *tuyère* being closed, the basins must be emptied of their burning charcoal, and the melted copper allowed to flow into them through the tap-hole, which is then stopped with loam. Whenever the surface is covered with a solid crust, it is sprinkled with water; and as soon as the crust is about $1\frac{1}{2}$ inch thick it is raised upon hooks above the basin, to drain off any drops, and then carried from the furnace. If these cakes, or *rosettes*, be suddenly cooled by plunging them immediately into water, they assume a fine red colour, from the formation of a film of oxide.

Each refining operation produces, in about 12 hours, $1\frac{7}{10}$ ths ton of copper, with the consumption of about $\frac{4}{5}$ ths of a ton of dry wood.

Care should be taken that the copper cake, or *rosette*, be perfectly solidified before plunging it into water, otherwise a very dangerous explosion might ensue. On the other hand, the cake should not be allowed to cool too long, lest it get oxidised upon the surface, and lose those fine red, purple, and yellow shades, due to a film of the suboxide, which many dealers admire.

When antimony or oxide of copper are combined with copper, they occasion the appearance of micaceous scales in the fractured faces. Such metal is hard, brittle, yellowish within, and can be neither laminated nor wire-drawn. These defects are not owing to arsenic, as was formerly imagined; but, most probably, to antimony in the lead, which is sometimes used in refining copper. They are more easily prevented than remedied.

According to Mr. Frèrejean, proprietor of the great copper works of Vienne, in Dauphiny, too low a temperature, or too much charcoal, gives to the metal a cubical structure, or that of divergent rays; in either of which states it wants tenacity. Too high a temperature, or too rapid a supply of oxygen, gives it a brick-red colour, a radiated crystallisation without lustre, or a very fine grain of indeterminate form; the last structure being unsuitable for copper that is to be worked under the hammer or in the rolling-mill. The form which indicates most tenacity is radiated with minute fibres glistening in mass. Melted copper will sometimes pass successively through these three states in the space of ten minutes.

Fig. 532 represents a *roasting mound* of copper pyrites in the Lower Harz, near

532

Goslar, where a portion of the sulphur is collected. It is a vertical section of a truncated quadrangular pyramid. A layer of wooden billets is arranged at the base of the pyramid in the line *a a*.

c, a wooden chimney, which stands in the centre of the mound, with a small pile of charcoal at its bottom; *b b* are large lumps of ore surrounded by smaller pieces; *f f*, are rubbish and earth to form a covering. A current of air is admitted under the billets by an opening in the middle of each of the four sides of the base, *a a*, so that two principal currents of air cross under the vertical axis, *c*, of the truncated pyramid, as indicated in the figure.

The fire is applied, through the chimney, *c*, to the charcoal at its bottom; the pile, *b b*, is kindled, and the sulphurous ores are raised to such a high temperature as to expel the sulphur in the state of vapour.

In the Lower Harz a roasting mound continues burning during four months. Some days after it is kindled the sulphur begins to exhale, and is condensed by the air at the upper surface of the pyramid. When this seems impregnated with it, small basins are excavated, in which some liquid sulphur collects; it is removed from time to time with iron ladles, and thrown into water, where it solidifies. It is then refined and cast into roll brimstone.

A similar roasting mound contains, in the Lower Harz, from 100 to 110 tons of ore and 730 cubic feet of wood. It yields in four months about one ton and a half of sulphur from copper pyrites. Lead ore is treated in the same way, but it furnishes less sulphur.

There are usually from 4 to 5 roasting heaps in action at once for each smelting works of the Lower Harz. After the first roasting two heaps are united to form a third, which is calcined anew, under a shed; the ores are then stirred up and roasted for the third time, whence a crude mixture is procured for the smelting-house.

The most favourable seasons for roasting in the open air are spring and autumn; the best weather is a light wind accompanied with gentle rain. When the wind or rain obstruct the operation, this inconvenience is remedied by planks distributed round the upper surface of the truncated pyramid over the sulphur basins.

WET METHODS OF EXTRACTING COPPER.

The Process of extracting Copper from Ores, at the Mines in the Rio Tinto District, Province of Huelva, Spain, by what is termed 'Artificial Cementation.'—This method, which was first applied here by Don Felipe Prieto, a mine proprietor of Seville, in the year 1845, is the only one employed in the present day in the copper-mines of that district.

The operation begins with the calcination of the ores, previously reduced to small pieces; piles or heaps of these ores (sometimes in the form of cones) are made on beds of stubble fire-wood of about a yard thick; each pile is made up with from 400 to 500 tons of mineral, and allowed to burn for six months; the smoke destroying all vegetation within its reach.

The ores, after being thus burnt or calcined, are thrown into wooden troughs let into the ground, about 6 yards long, 4 wide, and 1½ deep, called 'dissolvers.' In each of these troughs, or cisterns, are placed about twelve tons of calcined ore, and the trough is then filled with water; which water is, after remaining in contact with the ores for forty-eight hours, drained off into a similar trough placed at a lower level, and called a 'depositor.' The ores remaining in the dissolver are covered by a second quantity of water, left on, this time, for three days; and the process repeated four times successively, the water being always drained off into the same depositor.

From the depositors the water flows on to another set of troughs called 'pilones,' into which is placed a quantity of pig iron, broken into pieces of about the size of bricks, and piled loosely together so that the vitriol in the water may better act on its whole surface. Each of these troughs (*pilones*) will hold from 12 to 18 tons of pig iron (wrought iron answers the purpose as well, but it is much more expensive); and, as experience has demonstrated that a slow continuous movement in the water hastens the process, a man is employed for the purpose of agitating it, until all the copper suspended in the vitriol-water is deposited, which, in summer, is effected in about 2 days, and in from 3 to 5 days in winter. After the water has been renewed four or five times, and the agitation process repeated, the scales of copper deposited on the iron, as well as that in the form of coarse grains of sand found in the bottom of the trough, are collected together, washed, and melted, when it is found to produce from 65 to 70 per cent. of pure copper.

From the remains of the first washings of the above copper-scales, &c., another quality is obtained, worth about 50 per cent. for copper, which is mixed with the after-washings, yielding about 10 per cent. of copper, and passed on to the smelting furnace.

The method is very defective. Minerals containing 5 per cent. of copper, treated by this system of reduction, will scarcely give a produce of 2 per cent. of that metal.

It is, however, the only method that has hitherto been profitably employed in the Rio Tinto district.

The produce of some of the mines of this district is under 1 per cent. About 2,500 tons of the richest of the ores produced by the mines in the Rio Tinto district, are shipped from Huelva, a port near Seville, for England; and the result has been that a very large industry has been created. See PYRITES.

The Process of extracting Copper from the Water that drains out of the Mine, at Rio Tinto, called the 'System of Natural Cementation' (Precipitation).—The mine worked by the Spanish Government at Rio Tinto is formed in a mass of iron pyrites containing copper; and its immense labyrinth of excavations is known to extend over a length of 500 yards and a width of 100 yards (and probably to a much greater extent); the earliest of which workings must date back to very remote times; for in the different excavations are still to be found the impressions of hands, evidently guided by the science of the ancients, middle ages, and of more modern times.

The sixth, or lowest level in the mine, where all the operations of the present day are carried on, is 80 yards deep (from the top of the hill in which the lode is found), and it is from this level that the mine is (naturally) drained by an adit. From the roof, at the extreme end of a gallery at this level, flows, from an unknown source, a stream of water rich in copper, which, together with the drainage from other points of the mine, is directed through a channel to the adit 'San Roque,' that empties its waters at the foot of the hill, where the copper is extracted.

An able engineer has thus explained the phenomena of 'natural cementation':—"The natural ventilation through the open excavations of this mine, combined with the humidity of the ground, produces a natural decomposition of the materials composing the lode or vein, and thereby forming sulphates of iron and copper, which the water is continually dissolving and carrying off, thus forming the substance of this "natural cementation."

This said adit 'San Roque,' which empties its waters on the south side of the hill, has placed in it two wooden launders, or channels, about 12 inches wide and 15 inches deep, and (in the year 1853) 400 yards long; in the bottom of these launders are placed pieces of pig iron, and to this iron adhere the particles of copper which the slowly-flowing water contained in solution. In ten days the iron becomes coated with copper, so pure as to be worth 80 per cent. for fine-copper, and so strongly formed in scales as to resist to a certain extent the action of a file, and give a strong metallic sound on being struck with a hammer. At the expiration of ten days, or earlier, the scales of copper so formed on the iron are removed, that the surface of the iron may be again exposed to the action of the mineral water; and the process repeated to the entire extinction of the iron. The copper thus obtained passes at once to the refining furnace.

Since 1853 it has been discovered that the water escaping from the launders in the adit, 400 yards long, still contained copper, and they have been lengthened to nearly 1,000 yards with good effect.

The production of copper by cementation is carried on not only at Rio Tinto, but also at the Tharsis Mines in Spain, and at San Domingos in Portugal.

Linz Copper Process.—At Linz on the Rhine, and some other localities in Germany, the poorer sulphides of copper, containing from 2 to 5 per cent. of that metal, are treated by the following process:—

The ores coming directly from the mine, and without any preliminary dressing, are first roasted in a double-soled furnace, and then taken to a series of tanks sunk in the ground, and lined with basalt. These tanks are also provided with a double bottom, likewise formed of basalt, so arranged as to make a sort of permeable diaphragm, and on this is placed the roasted ore, taking care that the coarser fragments are charged first, whilst the finer particles are laid upon them.

The cavity thus formed between the bottom of the tank and the diaphragm, or false bottom, is connected, by means of proper flues, with a series of oblong retorts, through each of which a current of air is made to pass from a ventilator, or a pair of large bellows, set in motion by steam or water power.

In order to use this apparatus, a quantity of ore is roasted in the reverberatory furnace, and subsequently placed in the tanks, taking care that the first layer shall be in a coarser state of division than those which succeed it.

The retorts—which are formed of fire tiles, and are about 6 inches in height by 1 foot in width and 6 feet in length—are now brought to a red heat, charged with blende, and the blast applied.

The sulphurous acid thus formed is forced by the draught through the fines, where it becomes mixed with nitrous fumes, obtained from a mixture of nitrate of soda and sulphuric acid, and ultimately passes into the chambers beneath the diaphragms on which are laid the roasted ores, which must be previously damped by the addition of a

little water, of which a small quantity is also placed in the bottoms of the tanks. The sulphuric acid thus generated attacks the oxide of copper formed during the preliminary roasting, giving rise to the production of sulphate of copper, which percolates through the basaltic diaphragm into the reservoir beneath.

The liquors which thus accumulate are from time to time distributed over the surface of the ore, and the operation repeated until the greater portion of the copper has been extracted, when, by shifting the damper, the gases are conducted into another tank similarly arranged. The liquors from the first basin are now pumped into the second, and the operation continued until the ores which it contains have ceased to be acted on by the acid. When sufficiently saturated, the liquors are drawn off into convenient troughs, and the copper precipitated by means of scrap iron. The sulphate of iron thus formed is subsequently crystallised out, and packed into casks for sale.

On removing the attacked ores from the tank, the finer or upper portions are thrown away as entirely exhausted, nearly the whole of the copper having been removed from them, whilst the coarser fragments are crushed and re-roasted, and finally form the upper stratum in a subsequent operation.

It has been found that, by operating in this way, ores yielding only 1 per cent. of copper may be treated with considerable advantage, since the sulphate of iron produced, and the increased value of the roasted blende, are alone sufficient to cover the expenses of the operation.

By this process, 3 cwts. of coal are said to be required to roast one ton of ore, whilst the same quantity of blende is roasted by an expenditure of 4 cwts. of fuel.

Treatment of Copper Ores by Hydrochloric Acid.—At a short distance from the village of Twiste, in the Waldeck, several considerable bands of sandstone, more or less impregnated with green carbonate of copper, have been long known to exist. Although varying considerably in its produce, this ore, on the average, yields 2 per cent. of copper, and was formerly raised and smelted in large quantities; but this method of treatment not having apparently produced satisfactory results, the operations were ultimately abandoned.

The insoluble nature of the granular quartzitic gangue with which the copper is associated, suggested, some years since, to Mr. Rhodius, of the Linz Metallurgic Works, the possibility of treating these ores by means of hydrochloric acid, and a large establishment for this purpose was ultimately the result. The following is a description of this process, as witnessed by Mr. J. A. Phillips, in 1856:—

These works consist of a crushing mill, for the reduction of the cupreous sandstone to a small size, 16 dissolving tubs, and a considerable number of tanks and reservoirs for the reception of the copper-liquors and the precipitation of the metal by means of scrap-iron. Each of the 16 dissolving tubs is 13 feet in diameter, and 4 feet in depth, and furnished with alrge wooden revolving agitator, set in motion by a run of overhead shafting in connection with a powerful water-wheel. This arrangement admits of the daily treatment of 20 tons of ore, and the consequent production of from 7 to 8 cwts. of copper. Each operation is completed in 24 hours, the liquor being removed from the tanks to the precipitating trough by the aid of wooden pumps. The ore is *stoped* and brought into the works at 4s. per ton.

The acid employed at Twiste is obtained from the alkali works in the neighbourhood of Frankfort, contains 16 per cent. of real acid, and costs, delivered at the works, 2s. per 100 lbs. Each ton of sandstone treated requires 400 lbs. of acid, which is diluted with water down to 10 per cent. before being added to the ore. Every ton of copper precipitated requires $1\frac{1}{4}$ ton of scrap iron, at 4l. 5s. per ton.

These works yielded in 1857, 120 tons of metallic copper, and afforded a net profit of nearly 50 per cent. The residues from the washing vats, run off after the operation, contained but $\frac{1}{10}$ th per cent. of copper.

The works at Twiste were ultimately abandoned on account of a falling off in the yield of the ores.

Humid Process of extracting Copper from Burnt Cupreous Pyrites.—Very large quantities of cupreous pyrites, amounting in the aggregate to about 400,000 tons per annum, are imported into this country from Spain and Portugal. The sulphur is utilised in the manufacture of sulphuric acid, and from the burnt residue the large quantity of 1,200 tons of copper is annually extracted.

The burnt pyrites contains on the average $2\frac{1}{2}$ to 3 per cent. of sulphur, and 3 to $3\frac{1}{2}$ per cent. of copper. The extraction of the latter is effected as follows:—The ore is ground between rolls or under edge runners, and a sufficient quantity of unburnt sulphur added to it to raise the per-centage of sulphur to an amount slightly in excess of the copper, at the same time a sufficient quantity of salt, to convert the copper into chloride, is introduced. This mixture passes through a sieve of about 36 holes to the square inch, and is then ready for roasting, which is commonly effected in reverbera-

tory furnaces having flues beneath the bed through which the flame passes before coming into contact with the ore. The furnaces are sometimes supplied with independent fireplaces, but more frequently a series of them is worked by gas generated in Siemens's producers. A form of furnace is also employed, in some cases, in which the ore is placed in a sort of muffle, between which and the outer walls of the furnaces the flames are allowed to play; in this arrangement the flame and products of combustion do not come into contact with the ore.

The mixture is charged into the furnaces through hoppers in the arch, and spread evenly over the bed to a depth of 4 to 5 inches, a charge usually consisting of about 3 tons; this is stirred and rabbled from time to time in order to expose fresh surfaces to oxidation, the temperature not being allowed to exceed a dull redness. Hydrochloric acid is evolved during the roasting, and is conveyed to a condenser, from which a weak acid solution is obtained, which is subsequently employed in the lixiviation of the roasted ore.

After the expiration of about 6 to 6½ hours the whole of the copper in the ore should have been converted into a soluble chloride: a sample is taken from each furnace and washed two or three times with hot water and a little dilute hydrochloric acid, the residue is then treated with nitric acid, and the solution obtained rendered alkaline by the addition of ammonia; should more than a trace of blue colour be discernible in the solution, the sulphide of copper in the mixture has not been decomposed, and the roasting must be prolonged until a satisfactory test can be obtained. The charge is then drawn out on to the floor of the furnace-house and allowed to cool considerably, after which it is transferred in iron tram-waggons to wooden lixiviating vats capable of holding about 16 tons, and provided with false bottoms, over which a layer of cinders is spread to serve as a filter.

The hot roasted ore is then treated with hot water, and finally with a little hydrochloric acid; the stronger solutions are ready for precipitation by means of metallic iron, whilst the weaker are run into a reservoir, whence they are pumped back and serve as washing-water to a fresh lot of furnace ore, and so in turn become strong solutions.

In many works the silver present in these solutions is, previously to the precipitation of the copper, extracted by Claudet's process, which consists in mixing with them a quantity of a soluble iodide, usually that of potassium, sufficient to combine with the silver present, which amounts to from 3 to 4 grains per gallon. The insoluble iodide of silver is allowed to subside, and the copper solution drawn off from it into the precipitating vats.

When a considerable quantity of iodide of silver has been collected, it is well washed to free it from copper, and whilst suspended in water, metallic zinc in thin fragments is added, and the whole kept boiling by a jet of steam. The iodide of silver is thus decomposed, and metallic silver and solution of iodide of zinc produced; the latter serves to precipitate a fresh quantity of silver, whilst the former after being dried is ready for the smelter.

The copper present in the strong solutions is precipitated in large wooden vats, by immersing in them scrap wrought iron; if the solution be kept boiling by a steam jet, the precipitation is completed in about 12 hours. The spent liquid, which is valueless, is drawn off by a siphon from the precipitated copper, and the latter freed from iron by washing through perforated plates. After being allowed to drain, the precipitate is dried on a bed of fire-tiles heated by flues passing beneath, and is then ready for smelting; it contains, on the average, 70 to 75 per cent. of fine-metal.

The material from which the copper has been washed should contain about $\frac{1}{10}$ th per cent. of that metal, and when good pyrites have been used, consists almost entirely of sesquioxide of iron: it is largely employed under the name of 'Purple ore' or 'Blue Billy' for the fettling of puddling furnaces. See PYRITES.

Alderley Edge in Cheshire.—The hydrochloric acid process is, at the present time, carried on to a considerable extent at Alderley Edge in Cheshire, where the ore is in many respects similar to that at Twiste, with the exception that in the last-mentioned locality, mechanical agitation is dispensed with, and the acid is pumped from beneath the false bottom of one tank to the top of the next, in order that the whole solvent power of the acid may be utilised. The hydrochloric acid process was originally introduced at Alderley Edge by Mr. W. Henderson, who protected his method by a provisional Specification, dated September 30, 1857. Another specification was filed by Mr. Henderson in 1859, which included the extraction of copper from pyrites by converting the copper into chloride by calcination with common salt—a process similar to that originally suggested by Mr. Longmaid, and now extensively applied to the treatment of burnt pyrites. The sandstone of the curious elevation above the plain of Cheshire, known as Alderley Edge, is impregnated with copper existing in the state of blue and green carbonates. The beds containing this copper lie at a short distance below the surface, and are therefore easily worked.

The quantities of ore raised and copper obtained are given as follow in the 'Mineral Statistics' for the last few years:—

Years	Ore	Fine Copper	
		Tons	Cwts.
1865	14,904	207	9
1866	15,040	189	10
1867	15,152	182	7
1868	15,016	165	4
1869	13,240	260	0
1870	6,836	135	0
1871	8,608	172	0
1872	6,258	130	0

Mona and Pary's Mines, Anglesea.—The waters draining from the enormous heaps accumulated from the old and remarkable workings of these mines are collected in large ponds and precipitated by iron. In 1872, the Mona Mine produced 2,400 tons of copper ore, but there was no precipitate; but Pary's Mine produced 155 tons of precipitate and 2,813 tons of copper ore.

Wicklow Mines.—Similar precipitating processes were carried on in these mines. The process is thus described by Mr. W. W. Smyth, in his 'Mines of Wicklow and Wexford':—

From a letter of the Rev. William Henry, D.D., inserted in the 'Philosophical Transactions' for 1752, we learn that the existence of copper in solution in the water flowing from Ballymurtagh has only lately been discovered by accident, but had given rise to extensive apparatus where 500 tons of iron were at the same time employed to effect the precipitation of the costlier metal. The mode of operating was very rude; pits were dug, 10 feet long, 4 feet wide, and 8 feet deep, floored with flags and lined with stone, and the iron bars were laid on rough wooden beams fixed across from wall to wall. Dr. Henry's statement of the everlasting efficiency of the water, shows that, by him at least, the rationale of its action was little understood. 'Chains of these pits are continued along the stream, as far as the directors please, for the water never abates of its quality, if it were conveyed from pit to pit through a thousand.'

By this mode a ton of the precipitant obtained from the pits yielded 16 cwts. of the finest copper. Dr. Rutty states, that in seven years previous to 1765 the Cronbane water had yielded 17,260*l.*, from precipitate-copper; the precipitate affording above half of pure metal.

Towards the close of last century, copper was obtained by the same means at Cronbane and Tigroney. According to the 'Journal des Mines,' vol. iii., it was usual to add to the strength of the solution, by placing in the water a quantity of poor pyritous ore which has undergone a process of roasting. The form of the pits is not described, but the ratio of pure copper to the precipitated powder was only 0.328.

The quantity of precipitate or cementation-copper exported to England was, in 1788, 11½ tons; in 1789, 37 tons; in 1790, 59¾ tons.

During Mr. Weaver's management, the water was run into tanks in which the muddy particles were allowed to subside, and then passed into pits filled with plate and scrap iron; the quantity precipitated during that series of years was 442½ tons, which sold on an average at 27*l.* 8*s.* 9*d.* per ton, being in aggregate value 12,126*l.*; whilst the consumption of iron was rather less than one ton to the ton of the precipitate.

At the present date the water is economised at all the Ovoca Mines, but by a somewhat different method it is led through a series of narrow troughs or launders, inclined at angles of 10° or 12°, and interrupted at intervals by a deep chest or 'hutch.' At Tigroney the precipitate is swept down with brooms every night and morning into the hutches, the contents of which are afterwards mixed, and realise 50 to 60 per cent. of copper. The expenses of obtaining it are about 3*l.* per ton for attendance, sifting, &c. At Connarie people are kept sweeping down the launders throughout the day, by which means the precipitate, although more rapidly collected, is more impure, yielding but 43 to 54 per cent. of copper.

M. Bischoff junr. has patented a process for obtaining copper by precipitation which certainly effects the separation of the copper with great readiness, and, as he assures us, with great economy. His process differs from any other in the circumstance of his obtaining the iron in a peculiar condition. He takes the ordinary iron pyrites (*Mundic*), and reduces this to a state of coarse powder. This is then mixed with coke and exposed to heat in close furnaces. The sulphur is volatilised, and the incan-

descent coke absorbing all the oxygen, the iron is prevented from oxidising, and it remains in a metallic state combined with some carbon. When this process is completed, the powder is drawn off into close vessels and kept until required for use, carefully guarded from the air. If this preparation is thrown into a solution of sulphate of copper, there is a violent action, and the copper in a metallic state is at once thrown down. In practice, M. Bischoff prefers spreading out this preparation in thin layers, and passing the copper water through it. The process has been in use at some of the works on the banks of the Dee, and, as we understand, considerable success has attended its use. The only difficulty appears to be in preserving the finely-divided metallic iron from oxidation, which is essentially necessary to the success of the process.

Mr. S. Higgs junr. has greatly accelerated the process of precipitation by forcing steam through the solution of copper in which pieces of iron have been placed. This process has been successfully applied by him at Huel Margery copper-mine, St. Ives, Cornwall.

ALLOYS OF COPPER.—Copper forms the basis of a greater number of important alloys than any other metal. With zinc it forms brass in all its varieties. See BRASS.

Bronze and bell-metal are alloys of copper and tin. This compound is prepared in crucibles when only small quantities are required; but in reverberatory hearths, when statues, bells, or cannons are to be cast. The metals must be protected as much as possible during their combination from contact of air by a layer of pounded charcoal, otherwise two evils would result; waste of the copper by combustion, and a rapid oxidation of the tin, so as to change the proportions and alter the properties of the alloy. The fused materials ought to be well mixed by stirring, to give uniformity to the compound. See BELL-METAL; BRONZE.

By an analysis of M. Berthier, the bells of the *pendules*, or ornamental clocks, made in Paris, are found to be composed of copper 72.00, tin 26.56, iron 1.44 per cent.

An alloy of 100 of copper and 14 of tin is said by M. Dussausy to furnish tools, which, hardened and sharpened in the manner of the ancients, afford an edge nearly equal to that of steel (?).

Cymbals, gongs, and the *tam-tams* of the Chinese are made of an alloy of 100 of copper with about 25 of tin. To give this compound the sonorous property in the highest degree, it must be subjected to sudden refrigeration. M. D'Arcet, to whom this discovery is due, recommends to ignite the piece after it is cast, and to plunge it immediately into cold water. The sudden cooling gives the particles of the alloy such a disposition that, with a regulated pressure by skilful hammering, they may be made to slide over each other, and remain permanently in their new position. When by this means the instrument has received its intended form, it is to be heated and allowed to cool slowly in the air. The particles now take a different arrangement from what they would have done by sudden refrigeration; for, instead of being ductile, they possess such an elasticity, that, on being displaced by a slight compression, they return to their primary position after a series of extremely rapid vibrations; whence a very powerful sound is emitted. Bronze, bell-metal, and probably all other alloys of tin with copper, present the same peculiarities.

Some valuable researches on alloys of copper and tin have recently been made by M. Alfred Riche (*Annales de Chimie et de Physique*, xxx. [4], 1873, p. 351). It has been asserted that the Chinese work their bronze at a red heat, but M. Riche has succeeded in making tam-tams by manipulating his bronze at much lower temperatures.

The bronze-founder should study to obtain a rapid fusion, in order to avoid the causes of waste indicated above. Reverberatory furnaces have been long adopted for this operation; and among these, the elliptical are the best. The furnaces with spheroidal domes are used by the bell-founders, because, their alloy being more fusible, a more moderate heat is required; however, as the rapidity of the process is always a matter of consequence, they also would find advantage in employing the elliptical hearths. Coal is now universally preferred for fuel.

The process of coating copper with tin exemplifies the strong affinity between the two metals. The copper surface to be tinned is first cleaned with a smooth sandstone; it is then heated and rubbed over with a little sal-ammoniac, till it be perfectly clean and bright; the tin, along with some pounded resin, is now placed on the copper, which is made so hot as to melt the tin, and allow of its being spread over the surface with a dossil or pad of tow. The layer thus fixed on the copper is exceedingly thin. Bayen found that a copper pan, 9 inches in diameter and $3\frac{1}{2}$ inches deep, being weighed immediately before and after tinning, became only 21 grains heavier. Now as the area tinned, including the bottom, amounted to 155 square inches, 1 grain of tin had been spread over nearly $7\frac{1}{2}$ square inches; or only 20 grains over every sq. foot.

Copper and Arsenic form a white-coloured alloy, sometimes used for the scales of

thermometers and barometers, for dials, candlesticks, &c. To form this compound, successive layers of copper shavings and white arsenic are put into an earthen crucible; which is then covered with sea-salt, closed with a lid, and gradually heated to redness. If 2 parts of arsenic have been used with 5 of copper, the resulting compound commonly contains one-tenth of its weight of metallic arsenic. It is white, slightly ductile, denser, and more fusible than copper, and without action on oxygen at ordinary temperatures; but, at higher heats, it is decomposed with the exhalation of arsenious acid. The white copper of the Chinese consists of 40.4 copper; 31.6 nickel; 25.4 zinc; and 2.6 iron. This alloy is nearly silver white; it is very sonorous, well polished, malleable at common temperatures, and even at a cherry red, but very brittle at a red-white heat. When heated with contact of air, it oxidises, burning with a white flame. Its specific gravity is 8.432. When worked with great care, it may be reduced to thin leaves and wires as small as a needle. See GERMAN SILVER.

Tutenag, formerly confounded with white copper, is a different composition from the above. Keir says it is composed of copper, zinc, and iron; and Dick describes it as a short metal, of a greyish colour, and scarcely sonorous. The Chinese export it, in large quantities, to India.

M. Pérouze states that an alloy of equal parts of copper and nickel is greatly preferable to an alloy which contains also zinc. Even 2 of copper and 1 of nickel form a valuable alloy. See PYRITES (IRON).

COPPER, STATISTICS OF.—During a term of about 30 years, the copper-mines have sold their ores at the public sales. The following Table, from 'Records of Mining and Metallurgy,' by Messrs. Phillips and Darlington, represents the progress of copper mining from 1726 to 1855:—

Copper Ore raised and sold in Cornwall and Devon in Decennial Periods for 126 Years, from 1725 to 1855.

COPPER ASSAYING.—The substances which are submitted to assay for copper are various ores of copper, slags, and other metallurgical products, commercial varieties of copper and its alloys. The assays are made by the *dry* and *wet* methods.

Dry Assay. 1. *English or Cornish method.*—This process is very extensively employed in England; all the copper ores being bought and sold by this method. The mode of working by this method varies somewhat as to the manipulation, nature, and proportion of fluxes, form of apparatus, and other minute details; but it may be regarded as consisting essentially of the four following processes:—

1. *Fusion for regulus*, or sulphide of copper and iron.
2. *Roasting or Calcination of the regulus* into oxides of copper and iron.

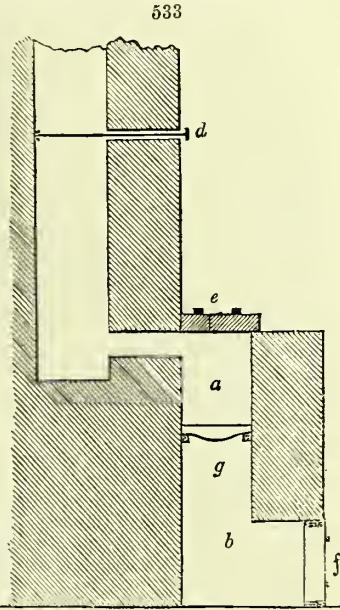

3. *Reduction or Fusion for coarse-copper*; the oxide of copper being reduced to metal, and the oxide of iron retained in the slag.

4. *Refining of the coarse-copper.*

All the ores of copper, even rich carbonates, are submitted to the whole of the above processes by some assayers; part of the processes are dispensed with by others, and the rich oxidised ores fused direct for coarse-copper, regulus and calcination.

Furnace and Implements. A *wind-furnace* or *air-furnace*—*Fig. 533* represents a vertical section of a furnace suitable for assaying copper ores: *a*, the fire-place, lined with fire-brick, 9 inches square by 12 inches deep; *b*, the ash-pit; *c*, flue or stack; *d*, damper, *e*, fire-brick covers of two sizes, each clamped with a piece of flat bar-iron; *f*, register or iron ash-pit door, provided with a revolving disc of sheet-iron, about 5½ inches diameter, having a semicircular opening; *g*, the fire-bars of cast- or wrought-iron. The draught is regulated by means of the damper, the register, or by partly removing the fire-brick cover. The fuel used is coke.

Cornish Crucibles of three sizes, (see *ASSAY*). *Copper scoop*, *fig. 535*, 12 inches in length, 4 inches in width at the widest part, and 1¼ inch at the mouth, provided with a handle about 7½ inches in length, for projecting the fluxes into the crucible. *Iron mould*, *fig. 534*, having two hemispherical cavities, each 1⅝ inch in width and ¾ths of an inch in depth. *Calcining rod*, *fig. 537*, 28 inches in length, inclusive of the blade 4 inches in length. *Crucible tongs*, *fig. 536*, represents those used for general assay purposes, those employed by copper assayers are of a different shape and larger dimensions. *Flux spoon or ladle*, *sieves*, *pestle and mortar*, *anvil*, *hammer*, *chisel*, *forceps*. *Balance*; it should carry 500 grains, and turn with from 1/20th to 1/50th of a grain. *Weights*; grain weights are convenient, but special weights are used by copper assayers: the heaviest is

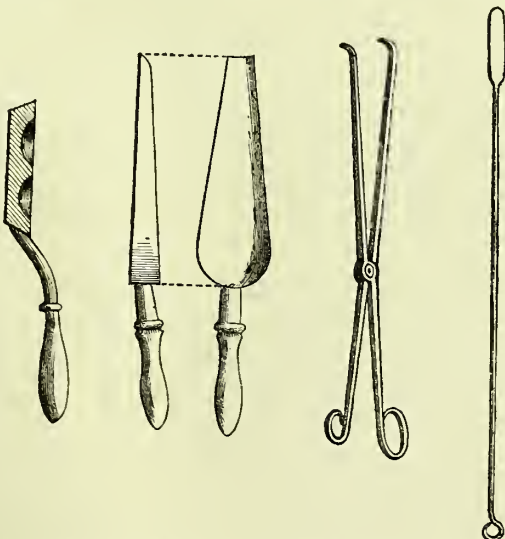

534

535

536

537

marked 100, and weighs 400 grains, the unit being subdivided into ½, ¼, ⅛, and 1/16.

Fluxes. Those employed are, *borax* calcined; *glass*, green or white, free from oxide

of lead; *tartar* or *argol*; *lime*, dry; *fluor-spar*, free from copper or lead; *nitre*; *charcoal-powder*; *carbonate of soda*, dried; *salt*; *sulphur*; *iron pyrites*, free from copper, or *sulphide of iron*. *Refining flux*; the product obtained by deflagrating a mixture of from 2 to 2½ parts by measure of tartar, 3 of nitre, and 1 of salt.—(See Assay). The fluxes are usually measured, but the better plan is to weigh them, especially until experience is gained.

For purposes of assay by this method, the ores, &c. may be conveniently divided into: 1. Ores containing over 30 per cent. of copper: *a*, oxides, carbonates, silicates, &c., which require fusion for coarse-copper and refining; *b*, various sulphides comparatively pure or containing arsenic or antimony, which require calcining 'sweet,' fusion for coarse-copper and refining; 2. ores containing less than about 30 per cent. of copper, which require the *fusion for regulus*; *a*, yellow copper ores, with or without iron pyrites, blende, galena, &c., which require partial calcination or *warming*, or the addition of nitre, or both, *to remove the excess of sulphur*; *b*, grey copper ores, poor oxides, carbonates, silicates, and poor antimonial and arsenical copper ores, which have been roasted sweet, which require *the addition of sulphur* or of *sulphur and iron* or iron pyrites to yield a proper regulus; *c*, purple copper ore, mixed oxides and sulphides, which yield a proper regulus by direct fusion.

To assist in forming an opinion as to the character of the ore, nature of the associated vein-stuff, and approximate per-centage of copper, a portion of the sample may be vanned or washed, calcined, or tested by the mouth blowpipe, or by a preliminary fusion for regulus. This will enable the assayer to determine beforehand how the ore is to be treated.

For the formation of a proper regulus, containing about 50 per cent. of copper, the following data may serve as a guide:—

100 grains of copper pyrites will require about 75 grains of nitre to yield a good regulus.

100 grains of iron pyrites will require about 180 grains of nitre to oxide it, and cause it to pass into the slag.

100 grains of grey copper ore or disulphide of copper will require about 60 grains of sulphide of iron, about 82 grains of iron pyrites, or about 55 grains of hæmatite and excess of sulphur to yield a proper regulus.

The quantity of ore operated on will vary from 100 to 400 grains according to amount of copper present.

Process: Fusion for regulus.—The largest size Cornish crucible is employed. The *raw* or calcined ore is mixed with the appropriate fluxes; about from 150 to 200 grains each of lime, glass, borax, and fluor-spar, will form a suitable mixture for many ores. The nitre, or iron pyrites or sulphur, is added according to circumstances. The crucible and its contents are submitted to a high temperature for about 15 minutes, and when tranquil the fused products are poured out into the iron mould, *fig. 534*. When the slag has set, the whole is dipped into water, removed, and when cold the regulus afterwards carefully detached from the slag. A good regulus is reddish-brown in colour, very tender, and easily reduced to powder; it should contain about 50 per cent. of copper, but may vary from 40 to 60 per cent. If the regulus is too *coarse* it resembles iron pyrites or copper pyrites in appearance, and contains too much iron and sulphur, and the ore requires more calcining, or the addition of more nitre during fusion. If the regulus is too *fine*, it is black in colour, hard, and the external surface is very smooth and bright: it indicates that the ore requires more sulphur or iron pyrites, or a substitute for them in the fusion. The slag should be uniform in colour, but it may be white, green, or black, according to the nature of the ore. It should be free from all trace of red colour, which would indicate the presence of copper. The slag should be examined for any shots of regulus.

Roasting or calcination.—The smallest or intermediate-sized crucible is used according to the weight of the ore or regulus. A dull fire is required to commence with. The finely-powdered substance is transferred to the crucible; this is placed on the top of the fuel, mouth frontwards, and in an inclined position to facilitate oxidation. The substance is constantly stirred with the calcining rod, *fig. 537*, especially at the first part of the operation, and the heat is afterwards increased to a bright red. The calcination should be completed in about 30 minutes. If any sign of clotting or softening of the particles occur, the crucible must be removed, and, if necessary, the product repowdered, mixed with some anthracite-powder or coke-dust, and recalined. Calcinations may also be made in scorifiers or roasting dishes in a *uffle* furnace.

Fusion for coarse-copper.—This is effected in the crucible used for calcination. The calcined ore or regulus is mixed with about from 50 to 150 grains of carbonate of soda, from 50 to 150 grains of tartar, and from 20 to 30 grains of borax, and exposed to a high temperature for about 15 minutes. The temperature should be sufficient to reduce the oxide of copper and melt the metal, and leave the oxide of iron in the slag. The

products are poured out into the ingot mould, quenched in water, and when cold the slag detached from the button of coarse or impure copper. The character of this will vary according to the impurities present. If any regulus is attached to the upper surface it indicates that the previous calcination has been imperfect, and the assay of the ore must be repeated. The slag should be black, and free from all trace of red colour. If the fusion has been properly made, the slag will not require to be *cleaned* or to be re-fused with reducing agents; although it is customary for some assayers to clean all such slags. When raw or calcined ores are fused for coarse-copper the addition of more carbonate of soda and borax are generally necessary. A little lime or oxide of iron may also be added with ores comparatively free from vein-stuff, to keep the slag free from oxide of copper: nitre and tartar are also used for reduction, instead of the carbonate of soda and tartar.

Refining.—This may be conducted in the crucible which has been used for the previous process. If a new one is employed a little borax should be previously fused in it. A *hot* fire is necessary. The crucible is fixed in the fuel so that the process can be easily observed through the space of the fire-brick covers, and when hot the copper button is thrown in. When the surface of the metal appears bright and clean about from 100 to 150 grains of the refining flux are quickly projected from the *copper scoop*, *fig. 535*, upon it, and the furnace closed. After the lapse of about 2 minutes the crucible is removed and the contents poured out into the mould. The *button* should be flat and have a pit or depression on the upper surface. The fracture is generally dull, granular, and of a red colour, or finely fibrous or silky, and of a salmon-red colour. The *slag* varies somewhat in colour; it should be grey, flesh-colour, pink, or pale red. It is powdered, re-fused with tartar or other reducing agents for about 10 minutes, the product poured out, and carefully examined for any shots of metal it may contain. With some assayers it is customary to submit impure copper buttons to one or more *washings* previous to refining. In *washing*, the metal and refining fluxes are projected together into the crucible and the product poured out when fused.

The following is another Method of conducting the Cornish Process.—A portion of the pounded and sifted ore is first burnt on a shovel, and examined as to its supposed richness and the amount of sulphur, arsenic, and other impurities it may contain. A little practice in this operation will enable the operator to judge with considerable accuracy of the quantity of nitre necessary in order to obtain a good regulus.

Fusion for regulus.—Two hundred grains of the mixed ore are now weighed out and carefully mixed with a flux consisting of nitre, borax, lime, and fluor-spar, and the fusion for matt or regulus is begun. The quantity of nitre used will of course vary with the amount of sulphur and arsenic present; but the other ingredients are commonly employed in the following proportions:—Borax, 5 dwts.; lime, $1\frac{1}{2}$ ladleful; fluor-spar, 1 ladleful.¹ After being placed in the crucible, the whole is generally covered by a thin stratum of common salt. After remaining in the fire for about a quarter of an hour, the fusion will be found complete, and the contents of the pot may be poured into a suitable iron mould. The button of regulus is now examined, in order to determine whether a suitable proportion of nitre has been used. If the right quantity has been employed, the button, when broken, should present a granular fracture, and yield from '8 to 10 for 20' of copper, *i.e.* from 40 to 50 per cent. However rank a sample may be, it should never be mixed with above 9 or $9\frac{1}{2}$ dwts. of nitre; and if the amount of sulphur be small, 3 dwts. are often sufficient. The grey sulphides, the red and black oxides, and carbonates, have sulphur added to them for the purpose of obtaining a regulus. Highly-sulphurised samples, requiring above $9\frac{1}{2}$ dwts. of nitre, are sometimes treated in a different way. In this case the ores are first carefully roasted, and afterwards fused with about 5 dwts. of nitre, 9 dwts. of tartar, and 3 dwts. of borax.

Roasting.—The roasting of the regulus thus obtained is performed in a smaller crucible than that used in the fusion for matt. During the first quarter of an hour, a very low temperature is sufficient. The heat is then increased to full redness, and the assay allowed to remain on the fire for a further period of about 20 minutes. During the first 15 minutes it should be kept constantly stirred with a slender iron rod; but afterwards, an occasional stirring will be found sufficient. When nearly the whole of the sulphur and arsenic has been expelled, the temperature must be raised nearly to whiteness during a few minutes, and the assay then withdrawn and allowed to cool.

Fusion for coarse-copper.—The fusion for copper is effected in the same crucible in which the roasting has been carried on. The quantity of flux to be used for this purpose varies in accordance with the weight of the button of regulus obtained. A mixture of 2 dwts. of nitre, $7\frac{1}{2}$ dwts. of tartar, and $1\frac{1}{2}$ dwt. of borax, is sufficient for

¹ The ladle used for this purpose is three-quarters of an inch in diameter and half-an-inch in depth.

the reduction of a calcined regulus that, previous to roasting, weighed from 45 to 50 grains. In the case of a button weighing from 90 to 100 grains, $3\frac{1}{2}$ dwts. of nitre, 9 dwts. of tartar, and 2 dwts. of borax, should be employed. These quantities are, however, seldom weighed, since a little practice renders it easy to guess, with a sufficient degree of accuracy, the necessary amounts.

Refining.—The prill of copper thus obtained is seldom fine, and consequently requires purification. A crucible is heated to redness in the furnace, the metallic button is taken from the mould and thrown into it, and some refining flux and salt are placed in a scoop for immediate use.¹ In a few minutes the fusion of the prill is effected. The crucible is now taken from the fire by a pair of tongs, the contents of the scoop introduced, and a gentle agitation given to it; an appearance similar to the brightening of silver on the cupel now takes place, and the crucible is returned to the fire for about four minutes. The crucible is now removed, and its contents rapidly poured into a mould. The button thus obtained will consist of refined copper, and present a slight depression on its upper surface. The slags from the reducing and refining operations are subsequently fused with a couple of spoonfuls of crude tartar, and the prill thus obtained weighed with the larger button.

2. *German Method.*—This method is used in Germany and other parts of Europe, for the estimation of copper in ores and other substances. It consists essentially of the following processes:—1. Roasting or calcination; 2. Reduction or fusion for black copper; 3. Refining.

Furnace, &c.—A *muffle furnace* is employed. The form and dimensions of a muffle furnace vary somewhat; the construction depending on the nature of the fuel employed and other circumstances. If bituminous coal is used, the muffle is heated by the flame of the fuel, and the fire-grate is placed at some distance below. When anthracite coal or charcoal is employed the muffle is surrounded with hot fuel. *Scorifiers or roasting dishes*; flat shallow vessels made of fire-clay about $2\frac{1}{2}$ inches diameter and 1 inch deep inside measure. *Crucibles*; thin oval shaped vessels of fire-clay, provided with a flat foot about $4\frac{1}{2}$ inches high and $1\frac{3}{4}$ inch internal diameter at the widest part. *Tongs, scoop, pestle and mortar*, and other implements are required. For a description of a muffle furnace, see SILVER.

Weights.—Special assay weights are used in Germany. 1. Assay centner=100 assay pounds; 1 assay pound=100 assay part pounds. The assay centner weighs 3·75 grammes, or about 58 grains. 50 grains of the substance may be taken to operate on when grain weights are used.

Fluxes, &c.—*Black flux*, the product obtained by deflagrating 1 part of nitre and $2\frac{1}{2}$ of tartar, or a mixture of alkaline carbonate and charcoal, or substitute for them *borax, glass, salt, graphite, charcoal-powder, lead, arsenic, antimony, iron pyrites*. For the purpose of assay by this method the ores and other substances may be divided into: 1. Oxidized ores, &c. which require reduction and refining; 2. Sulphurous ores, &c. which require calcination, reduction, and refining; 3. Ores, &c. poor in copper, which require fusion with iron pyrites to obtain a regulus: the regulus is afterwards treated according to 2; 4. Varieties of impure copper, which require refining with lead.

Process: Roasting.—50 grains of the ore mixed with about $\frac{1}{4}$ of its weight of graphite powder or other substitute and spread over the bottom of a scorifier or roasting dish previously coated inside with red oxide of iron. The scorifier is now placed in a muffle at a low red heat, and the calcination continued until the graphite ceases to glow and the odour of sulphurous and other gases is no longer perceptible. This is then removed, and the product powdered, remixed with about 5 per cent. or more of charcoal-powder, and recalcined. This operation is repeated a third time if necessary. The calcination is completed in about 30 minutes. Carbonate of ammonia is sometimes added to complete the calcination.

Fusion for Black Copper.—The powdered calcined product is transferred to the oval-shaped crucible, and covered with about twice its weight of black flux, and borax or glass or both added as required. The whole is covered with a layer of salt, and over this is placed a piece of charcoal about $\frac{1}{2}$ an inch square; a cover is then inserted. Lead, arsenic, or antimony or their oxides are also added when necessary as collecting agents to alloy with the copper and render it more fusible. The fusion is conducted in a muffle; the temperature is gradually increased from a red heat and the operation completed in from 30 to 40 minutes. The crucible is removed, and when cold, broken open. The button of copper should be perfectly fused and free from regulus. The slag should be well fused, glassy, and free from a red colour.

Refining.—This is conducted in a muffle upon a flat shallow piece of broken crucible about from 1 to $1\frac{1}{2}$ inch square. This is placed between hot charcoal, as, a high tem-

¹ The refining flux consists of two parts of nitre and one of white tartar fused together, and subsequently pounded.

perature is required. The button is then wrapped in paper with about an equal weight of borax, and placed upon the hot clay vessel. When the button is melted, the door of the muffle is partly opened to allow the air to enter, and the operations continued until the copper brightens, appears of a green colour, and finally becomes solid. The clay vessel is then removed from the muffle, and cooled by dipping it slowly in water. The slag is then detached from the button, which should have the characteristic properties of fine copper. The refining is also conducted on a cupel. Two cupels are treated in a muffle, and upon one is placed the button of black copper with an equal weight or more of lead, and upon the other the same weight of pure copper and lead. When melted, air is admitted by partly removing the muffle-door, and the process continued until the copper brightens. The buttons are then covered with charcoal-powder, removed, and cooled in water, and weighed. The loss upon the pure copper is added on to the assay button, and the result calculated.

Wet Assay: 1. By Cyanide of Potassium.—This is the best adapted and most direct method for estimating copper in copper ores by means of standard solutions. It was first proposed by Mr. H. Parkes. The process depends on the following reaction: when a solution of cyanide of potassium is added to a blue ammoniacal solution of copper it becomes colourless by the formation of a double cyanide of ammonia and copper. By ascertaining by direct experiment the amount of cyanide of potassium required to discharge the colour in an ammoniacal solution containing a given weight of copper, it is easy by a comparative experiment to determine the amount of copper in a given weight of ore. The standard solution of *cyanide of potassium* required, is prepared by dissolving about from 2,000 to 2,500 grains of cyanide of potassium (*gold cyanide*) in 4 pints (35,000 grains) of water. One thousand grains of this solution should be equal to about 10 grains of copper. The solution is standardised as follows:—A piece of clean, electrotype copper, of from 4 to 7 grains, is accurately weighed, dissolved in a small quantity of dilute nitric acid in a small flask, boiled to expel nitrous fumes, and diluted with water to about half a pint. Ammonia is added in excess, when it will become blue. A burette (for a description of this instrument, see ALKALIMETRY) is filled to the top line with the solution of cyanide of potassium, and run in very slowly to the cold blue solution of copper until it becomes nearly colourless, or of a faint lilac tint. The number of divisions which are read off will be equal to the amount of copper operated on. The experiment is repeated on a second or third piece of copper, and the mean result taken as standard. The decolorisation will require from $\frac{1}{2}$ to $\frac{3}{4}$ of an hour, according to the amount of copper present. A piece of white paper should be placed under and behind the flask, to aid in observing the tint of the solution during decolorisation. As the standard solution undergoes slow decomposition, it will require correction about once a week.

Process.—From 10 to 50 grains of the ore are placed in a small flask or beaker glass, and moistened with strong sulphuric acid; nitric acid is then added from time to time, and the whole digested at a gentle heat until nitrous acid fumes cease to be given off. Water is cautiously added, and the solution reheated, to dissolve the basic sulphates of copper and iron. When the ore is completely decomposed, the whole is transferred into a pint flask and diluted to about $\frac{1}{2}$ a pint; ammonia is added in excess, and when the solution is cold, the standard solution is gradually run in until there remains only a faint lilac tint. The number of divisions used are read off, and the per-centage of copper calculated. Example:—1,000 grains of the burette are equal to 10 grains of copper, and 20 grains of the copper ore require 500 grains of solution; therefore,

$$1,000 : 500 :: 10 : 5 \text{ and} \\ 5 \times 5 = 25 \text{ per cent. of copper.}$$

When peroxide of iron is present it should not be filtered off during the assay, as it would retain copper. The copper thus retained passes into solution during decolorisation. The alteration in the tint of the peroxide of iron will also afford a rough indication of the completion of the assay. The addition of sulphuric acid is only required for the decomposition when sulphides are present in the ore. The presence of silver, zinc, nickel, and cobalt, interfere with the estimation of copper by this method. Silver is easily removed by adding hydrochloric acid or chloride of sodium, and filtering before adding the ammonia. When zinc, nickel, and cobalt are present, the copper is separated with the usual precautions by means of sulphuretted hydrogen, hyposulphite of soda, or metallic iron, and the precipitates afterwards redissolved in acids, and the solution assayed as before described.

2. Precipitation Method.—This is one of the oldest wet methods of estimating copper, and when the requisite care is taken the results are accurate. It is also useful when burettes are not available. In some localities, and particularly in South America and the United States of America, the assay of copper ores is performed by this pro-

cess. The whole of the ores belonging to the different classes may be estimated in this way.

A weighed quantity of the pulverised ore is introduced into a long-necked flask of hard German glass. Nitric acid is now added, and the flask exposed to the heat of a sand-bath. A little hydrochloric acid is subsequently introduced, and the attack continued until the residue, if any remains, appears to be free from all metallic stains. The contents of the flask are transferred to a porcelain evaporating dish, and evaporated to dryness, taking care, by means of frequent stirring, to prevent the mass from spitting. The whole must now be removed from the sand-bath and allowed to cool, a little hydrochloric acid subsequently added, and afterwards, some distilled water. The contents of the basin must then be made to boil, and, whilst still hot, filtered into a beaker. A piece of bright wrought iron, about two inches in length, three-quarters of an inch in width, and a quarter of an inch in thickness, is now introduced, and the liquor gently heated on the sand-bath until the whole of the copper has been thrown down. The liquor is now removed by means of a glass siphon, and the metallic copper freed from all adhering chlorides, by means of repeated washings with hot water, and then dried in a water-bath, and weighed.

In case the mineral operated on should contain tin or antimony, very minute traces only of these metals will be found with the precipitated copper. When lead is present, it is best to add a few drops of sulphuric acid during the process of the attack; by this means the lead will be precipitated as sulphate of lead, and be removed by filtration.

Assay of Commercial Varieties of Copper, Brass, Bronze, &c.

By Hyposulphite of Soda. This is a very accurate method of estimating copper: it was first made known by Mr. E. O. Brown. The reagents required are, 1. *A standard solution of hyposulphite of soda.* This is made by dissolving 1,300 grains of the crystals in 4 pints of water; the solution is standardised by means of weighed pieces of electrotype copper by the process afterwards described, and the mean result taken as standard. 2. *Iodide of potassium.* The crystals should be free from iodate. About six times the weight of the copper present is required for each assay. 3. *Solution of Starch.* Prepared by boiling from 1 to 2 grains of starch in about half a pint of water. When cold the clear solution is decanted off for use. The estimation of the copper by this method depends on the following reactions. When iodide of potassium is added to acetate of protoxide of copper, subiodide of copper is formed, and free iodine is set free, which dissolves in the excess of iodide of potassium. By means of a standard solution of hyposulphite of soda, the free iodine is converted into iodide of sodium with the formation of tetrathionate of soda. The solution of starch serves to indicate the completion of the reaction, by the bleaching of the blue iodide of starch at first formed. The reactions may be expressed by the following equations:—

Process.—From 8 to 10 grains of the copper or alloy are dissolved in dilute nitric acid, and the nitrous acid expelled. The solution diluted with water, and carbonate of soda added until carbonate of protoxide of copper remains precipitated. Acetic acid is added in excess, and afterwards about 60 grains or less of iodide of potassium. The solution of hyposulphite of soda is now run in from a burette, until the solution acquires a yellow colour. A little of the starch-solution is now added, and the addition of the hyposulphite of soda cautiously continued until the solution becomes colourless. The number of divisions on the burette are read off, and the amount of copper calculated therefrom. Example:—If 1,000 grains of the standard solution are equal to 10 grains of copper, and 10 grains of the alloy require 600 grains of the same solution, then

$$1,000 : 600 :: 10 : 6 \text{ and}$$

$$6 \times 10 = 60 \text{ per cent. of copper.}$$

When lead is present, a little sulphuric acid should be added during the solution of the metal in nitric acid, to convert it into insoluble sulphate of protoxide of lead. To render it applicable to copper ores, after the solution of the ore and dilution, the copper must first be separated by means of sulphuretted hydrogen, hyposulphite of soda, or by iron or zinc, and the precipitate redissolved in nitric acid, taking care to expel all trace of nitrous acid before proceeding with the assay.

Assay of Slags and other Substances containing Small Quantities of Copper.

Coloration Test.—This method depends on the fact that the intensity of the blue colour of an ammoniacal solution of copper is proportionate to the quantity of metal present. There are two plans which may be followed:—a. A standard coloration

test solution is prepared by dissolving a known weight of copper (0·5 or 1 grain) in dilute nitric acid, adding excess of ammonia and diluting to 10,000 grains. This solution is kept in a well-stoppered, long, glass graduated vessel. The ammoniacal solution of copper obtained by the decomposition of a given weight of the substance is transferred to a graduated measure of the same shape and capacity, and water added until the tint corresponds to that of the standard coloration test. The percentage of copper is calculated as follows:—10,000 grains of the standard coloration test contain 0·5 grain of copper; the solution of 100 grains of the substance required dilution to 8,000 grains—

10,000 : 8,000 :: 0·5 : 0·4 per cent. of copper.

b. A series of standard coloration test solutions of copper are prepared and kept in a number of colourless *square* or *round* glass bottles. The bottles should be of the same shape and capacity. If the series comprise ten bottles, the first bottle may contain $\frac{1}{10}$ th of a grain of copper, the second $\frac{2}{10}$ ths, and so on to the last of 1 grain. From 50 to 100 grains of the powdered slag or other substance are treated with nitric or with nitro-hydrochloric acid, until decomposition is effected. In some cases previous fusion with carbonate of soda may be found necessary. The solution is diluted with water, excess of ammonia added, and filtered, or the precipitate allowed to settle and the solution decanted. If necessary, the precipitate obtained by ammonia is redissolved in acid, and reprecipitated by ammonia; and if the filtrate has a blue tint it must be added to that previously obtained. The whole of the solution is then diluted with water until there is the *same volume* of solution as in one of the test bottles. The colour is then compared with the coloration test bottles, and the one it corresponds to represents the amount of copper present in the quantity of substance operated on. From this datum the per-centage of copper is calculated. If nickel or cobalt be present the copper must first be separated by means of sulphuretted hydrogen or otherwise, and the precipitate redissolved in acid.

COPPER ORES. See COPPER.

COPPER, OXIDES OF. Two oxides are known: the red or suboxide (cuprous oxide) Cu_2O , and the black or protoxide (cupric oxide), CuO . Both occur native, and are valuable ores. The suboxide may be prepared artificially by adding grape-sugar to a solution of the blue sulphate of copper, treating the product with an excess of caustic potash, and then boiling the solution. The suboxide communicates a fine ruby-red colour to glass; this oxide is soluble to some extent in metallic copper, the metal becoming thereby 'dry' or brittle. Protoxide of copper may be prepared by calcining copper, or by igniting the nitrate or the sulphate. It communicates a green colour to glass. The protoxide is employed in organic analysis for yielding oxygen during combustions.

COPPER PYRITES. See COPPER.

COPPER, SALTS OF. **COPPER, ACETATE OF.** A basic acetate of copper (cupric acetate) is largely used as a pigment under the name of *Verdigris*. The neutral acetate is also prepared commercially, and termed *Distilled Verdigris*. It appears that the well-known pigment, *Schweinfurth* or *Emerald Green*, is a combination of acetate and arsenite of copper. See VERDIGRIS; SCHWEINFURTH GREEN.

COPPER, ARSENITE OF. The fine green pigment called *Scheele's Green* is an arsenite, and *Schweinfurth Green* is an aceto-arsenite of copper. See SCHEEL'S GREEN; SCHWEINFURTH GREEN.

COPPER, CARBONATES OF. Two of these occur native, forming the minerals known as *Malachite* and *Azurite*. An artificial basic carbonate is prepared as a pigment under the names of *Brunswick* and *mineral-green*. See AZURITE; COPPER; MALACHITE; VERDITER.

COPPER, CHLORIDES OF. Two chlorides are known; the subchloride (cuprous chloride) Cu_2Cl (Cu^2Cl^2), and the protochloride (cupric chloride) CuCl (CuCl^2). The latter is readily obtained by dissolving either oxide or carbonate of copper in hydrochloric acid; it is a deliquescent salt soluble in alcohol, the alcoholic solution burning with a fine green flame. The subchloride may be reduced from the protochloride by boiling its solution with sugar. A solution of the subchloride in hydrochloric acid is used in gas-analysis for the absorption of carbonic oxide. There are also several oxychlorides of copper; one of these occurs native, forming an ore known as *Atacamite*. See COPPER.

COPPER, NITRATE OF. This salt is prepared by dissolving copper in moderately strong nitric acid, and evaporating to crystallisation. Its formula when anhydrous is CuO, NO^5 (Cu_2NO^3). This salt is used to produce a fine green in fireworks.

COPPER, SULPHATE OF, called in commerce *Blue Vitriol*, *Blue Stone*, or *Blue Copperas*.—This salt is frequently prepared by roasting copper pyrites with free access of air, but sulphate of iron is formed at the same time, and the two salts are not readily separated. It is also obtained by heating old copper with sulphur, by which a

subsulphide of copper is produced; this is converted into sulphate, by roasting in contact with air. Large quantities of sulphate of copper are obtained in the process of silver refining, and as a by-product in Ziervogel's method of silver-extraction. Crystallised sulphate of copper contains $\text{CuO} \cdot \text{SO}^3 + 5\text{H}_2\text{O}$ ($\text{CuSO}^4 + 5\text{H}^2\text{O}$). It is largely employed in calico-printing, and as a source of other salts of copper. The salt is also used in certain forms of constant batteries, as Daniell's.

Several basic sulphates are known, some of which occur native. *Casselman's green* is an artificial basic sulphate. See COPPER; PYRITES; SILVER.

COPPER, SULPHIDES OF. At least two distinct sulphides of copper may be prepared. Copper and sulphur when melted together combine with vivid incandescence, and produce the subsulphide or disulphide (cuprous sulphide), Cu_2S . This compound also occurs native as *copper glance*; and is produced as a regulus in the ordinary process of copper-smelting, when it is called by the smelter *fine metal*. The higher sulphide (cupric sulphide), CuS , is found native as *Covellite*, and may be artificially prepared, as a hydrate, by precipitating a salt of copper with sulphuretted hydrogen. The sulphides are decomposed when heated with free access of air; at high temperatures sulphurous acid is evolved, and oxide of copper formed, whilst at low temperatures a sulphate of copper is produced.

COPPERAS. A common name for green vitriol or sulphate of protoxide of iron (ferrous sulphate). Iron pyrites is also sometimes called copperas. See PYRITES.

COPROLITES. (*κόπρος, dung; λίθος, stone*). A term properly restricted to fossilized fecal matter. True coprolites usually present the form of ovoid nodules, resembling kidney potatoes, marked on the surface with corrugations, and exhibiting internally a spiral structure due to the form of the intestinal canal through which they have passed. Some of these coprolites were formerly described, from their shape, as fir-cones; but their true origin was clearly pointed out many years ago by Dr. Buckland. They often contain scales, teeth, and bones, of fish, which represent the undigested portions of food voided in the excrements; and they are occasionally found in such connection with the skeletons of fossil saurians as to show their original position in the intestines. The coprolites of reptiles and fish are found in many of our Secondary and Tertiary rocks, and are especially abundant in the Lias. These true coprolites consist mainly of phosphate and carbonate of lime. The analyses below by Mr. Thornton J. Herapath represent the composition of a coprolite from the lias strata of Lyme Regis. It was rather large, being above 9 oz. in weight, was of a greyish colour, and when broken exhibited some traces of a crystalline structure. It furnished a greyish-white powder. Many scales of different extinct fishes, and other organic remains, were to be perceived on the external surface; the greater proportion of them appeared to belong to a species of fish which is known by the name of *Pholidophorus limbatus*. Its specific gravity was about 2.644 or 2.700, and the composition per cent. was as follows:—

	I	II	Mean
Water driven off at from 300° to 350° F.	2.560	2.668	2.6140
Water and organic matters expelled at a red heat	3.680	3.456	3.5680
Chloride of sodium, with some sulphate of soda	traces	traces	traces
Carbonate of lime	23.640	23.708	23.6740
do. of magnesia	none	none	none
Sulphate of lime	1.740	1.801	1.7705
Phosphate of do. (tribasic)	60.726	60.813	60.7695 = PO^5 28.047
do. magnesia	a little	a little	a little
Perphosphate of iron	3.980	4.135	4.0575 = PO^5 1.992
Phosphate of alumina	a little	a little	a little
Peroxide of iron	2.094	1.894	1.9940
Alumina	none	none	none
Silicic acid, with fluoride of calcium and loss	1.580	1.525	1.5525
	100.000	100.000	100.0000 = PO^5 29.969*

* In the first of these analyses, the phosphoric acid was estimated by M. Schulze's method, as perphosphate of iron; in the second, as phosphate of lead.

From the high per-centage of phosphate of lime recorded in these analyses, it must be evident that coprolites are of great value to the agriculturist as fertilising agents. Indeed, large quantities of so-called 'coprolites' are thus employed. It should, however, be distinctly understood that the term has been considerably extended in its meaning, and is now applied to all phosphatic nodules used in the formation of artificial manures, whatever may have been their origin. These nodules, or pseudo-coprolites, are especially abundant in the Red Crag of Suffolk. This Crag is a marine deposit of Pliocene (Upper Tertiary) age, rich in shells and other organic remains; and at the base of the Crag there is a bed of rolled bones, teeth, and various animal exuviae, derived from the London Clay, and associated with rolled pebbles rich in phosphate of lime. These pebbles or nodules were first described by the late Prof. Henslow as true coprolites, but it is certain, from their physical characters, that they have not a coprolitic origin. Nevertheless, these pseudo-coprolites are equally rich in phosphate of lime, as will be seen by the following analyses of two samples from the coast of Suffolk by Mr. Herapath:—¹

	I	II
Water with a little organic matter	4·00	3·560
Salts soluble in water (chloride of sodium and sulphate of soda)	traces	traces
Carbonate of lime	10·280	8·959
" magnesia	a trace	a trace
Sulphate of lime	distinct traces	0·611
Phosphate of lime (3CaO,PO ⁵)	70·920 = PO ⁵ 32·765	69·099 = PO ⁵ 31·924
" magnesia	traces only	traces
Perphosphate of iron (2Fe ² O ³ ,3PO ⁵)	6·850 = PO ⁵ 3·244	8·616 = PO ⁵ 4·081
Phosphate of alumina (2Al ² O ³ ,3PO ⁵)	1·550 = PO ⁵ 0·870	2·026 = PO ⁵ 1·158
Oxide of manganese	traces	traces
Fluoride of calcium	0·608	0·804
Silicic acid, coloured red by a little undecomposed silicate of iron	5·792	6·309
	100·000 = PO ⁵ 36·889	100·000 = PO ⁵ 37·16

Phosphatic nodules, passing under the name of coprolites, are found at the junction of the Lower Greensand and Gault, at the junction of the Gault and Upper Greensand, and at the base of the Chalk.

In an excellent paper 'On the Phosphoric Strata of the Chalk Formations,' published in the first number of Vol. IX. of the 'Journal of the Royal Agricultural Society of England,' Mr. Way observes, that he has found the coprolites from Farnham in Surrey to contain from 52 to 54 per cent. of bone-earth phosphate; and that Dr. Gilbert had informed him, that in several analyses which he had made of samples taken from several tons of the ground coprolites, he had found the proportion of phosphate of lime to vary between 55 and 57 per cent. Mr. Nesbit ('Quart. Journ. of Chem. Soc.' III. p. 235) found from 22·30 to 28·74 per cent. of phosphoric acid, which is equivalent to from 48·31 to 59·07 of tribasic phosphate, in those from the tertiary deposits of this county.

Phosphatic nodules, or coprolites, are obtained from the base of the Gault at Folkestone, and from the base of the Chalk at Cambridge. 'The Cambridgeshire phosphatic nodules,' says the Rev. O. Fisher, 'are extracted by washing from a stratum (seldom exceeding a foot in thickness) lying at the base of the Lower Chalk, and resting immediately, without any passage-bed, upon the Gault. There is, however, a gradual passage upwards from the nodule-bed into the Lower Chalk or clunch. The average yield is about 300 tons per acre; and the nodules are worth about 50s. a ton. The diggers usually pay about 140*l.* an acre for the privilege of digging, and return the land at the end of two years properly levelled and re-soiled. They follow the nodules to a depth of about 20 feet; but it scarcely pays to extract them from that depth.—'Quart. Journ. Geolog. Soc.' Feb. 1873.

The following analyses of Cambridge coprolites are published by Dr. Voelcker in the Journ. of the Roy. Agric. Soc. for 1860:—

¹ Journal Roy. Agric. Soc. Eng. 1851.

	I	II
Moisture and organic matter	4.63	4.01
Lime	43.21	45.39
Magnesia	1.12	0.48
Oxide of iron	2.46	1.87
Alumina	1.36	2.57
Phosphoric acid	25.29	26.75
Carbonic acid	6.66	5.13
Sulphuric acid	0.76	1.06
Chloride of sodium	0.09	traces
Potash	0.32	0.84
Soda	0.50	0.73
Insoluble siliceous matter	8.64	6.22
Fluorine and loss	4.96	4.95
	100.00	100.00

In the first analysis the proportion of tribasic phosphate of lime (bone-earth) reaches 54.89, and in the second analysis 57.12 per cent.

Mineral deposits rich in phosphate of lime occur in the Bala Limestone at Cwmgwymnen, about 16 miles from Oswestry; but they do not appear to be of coprolitic origin. They have been worked for agricultural purposes, and were described by Dr. A. Voelcker before the British Association in 1865.

Attention has recently been called to a remarkable phosphatic deposit in South Carolina, which is now extensively worked. This deposit occurs in beds of post-pliocene age, but is largely composed of nodules of altered marl derived from an Eocene rock known as the great Carolinian Marl Bed. These nodular fragments from the mother-rock are rich in organic remains, and are associated with bones and teeth of land animals of more recent age. For a description of the deposit, see 'The Phosphate Rocks of South Carolina,' by Francis S. Holmes, A.M. Charleston, 1870. See APATITE; MANURE.

COPYING. A new and important quality of writing-inks was introduced by the indefatigable James Watt, in 1780, who in that year took out a patent for copying letters and other written documents by pressure. The *modus operandi* was to have mixed with the ink some saccharine or gummy matter, which should prevent its entire absorption into the paper, and thus render the writing capable of having a copy taken from it when pressed against a damp sheet of common tissue paper. But although this process was very imperfect, the writing generally being much besmeared by the damping, and the copies, in many cases, only capable of being read with great difficulty, it was not for seventy-seven years after the invention of Watt that any improvements in such inks were attempted. The firm of Underwood and Burt patented a method of taking copies by the action of a chemically-prepared paper, in a chemical ink, by which, not only are far superior copies taken, and the original not at all damaged, but many copies may be taken at one time from a single document. Printed matter may be also copied at the same time, on the same beautiful principle. We give the specification of Mr. Underwood:—

'But while the means employed for producing the desired effects may be varied, I prefer the following for general use:—I damp the paper, parchment, or other material which I desire to copy upon, with a solution of 200 grains of the yellow or neutral chromate of potash dissolved in 1 gallon of distilled water, and either use it immediately, or dry it and subsequently damp it with water as it is required for use. I then prepare the material which I use for producing the characters or marks, and which may be called copying ink, by simply dissolving (in a water-bath) pure extract of logwood in distilled water; or, for printing, I use a varnish or other similar material soluble in water, and dust, or throw over it powdered extract of logwood. If I desire to take twenty copies from an original, I use about six pounds of the pure extract of logwood to a gallon of distilled water; but a larger number of copies may be taken by dusting or throwing over the original, before the ink has thoroughly dried, a powder composed of five parts of powdered extract of logwood, one part of powdered gum arabic, and one part of powdered tragacanth. When I desire to print from an original, in producing which I have used ink prepared as before described, I proceed by damping six sheets of paper, prepared as before described, and having taken off all superfluous moisture with good blotting paper, I place the original upon the upper sheet and press the whole for about half a minute in a copying press; I then remove the original, and in its place put six other sheets of the prepared paper in a damp state, and subject

the whole to pressure for about a quarter of an hour. I then take five other prepared sheets in a damp state, and having laid the original upon them, press them together for about two minutes, then replace the original by three other prepared and damped sheets, and press the whole together for about a quarter of an hour. The extract of logwood so acts upon the neutral chromate of potash that I thus obtain twenty good clear fac-similes of the original matter or design.

They have also produced an Indian ink on the same principle, which, when used in the preparation of architectural plans, maps, &c., will give one or more clear copies of even the finest lines. The only point to be observed in the taking of such copies, is that as they are taken to a scale, they must be kept pressed in close contact with the original, till they are perfectly dry, because if not, they will shrink in drying, and the scale will be spoilt.

The most complete information on this subject, and that of inks generally, is to be found in a memoir published in the 'Journal of the Society of Arts' by Mr. J. Underwood.

COQUILLA NUTS. These nuts are produced in the Brazils by the *Attalea funifera*. They are suitable for a great variety of small ornamental works, and are manufactured into the knobs of umbrellas and parasols. The same palm which yields coquilla nuts also furnishes the Piassaba fibre, or monkey-grass.

CORAH. An Indian pattern silk handkerchief.

CORAL (*Corail*, Fr.; *Koralle*, Ger.) is a calcareous substance, formed a species of marine polype, which constructs in concert immense ramified habitations, consisting of an assemblage of small cells, each the abode of an animal. The coral is, therefore, a real polypary, which resembles a tree stripped of its leaves. It has no roots, but a foot not unlike a hemispherical skull-cap, which applies closely to every point of the surface upon which it stands, and is therefore difficult to detach. It merely serves as a basis or support to the coral, but contributes in no manner to its growth, like the root of an ordinary tree, for detached pieces have often been found at the bottom of the sea in a state of increase and reproduction. From the above base a stem, usually single, proceeds, which seldom surpasses an inch in diameter, and from it a small number of branches ramify in very irregular directions, which are studded over with cells, each containing a polype. These polypes when they extend their arms, feelers, or tentacula, resemble flowers, whence, as well as from the form of the coral, they were formerly classed among vegetable productions. They are now termed zoophytes by many writers upon Natural History.

The polype which yields the ordinary red coral of commerce is known to naturalists as the *Corallium rubrum*, and is placed in the family of the *Gorgonidae*, or Sea-shrubs, a group of the order *Alcyonaria*. This red coral, therefore, occupies a different systematic position from that of the common corals which, by the accumulation of their solid parts, form the rocky masses known as coral islands, and which are referred to the order *Zoantharia*. As much misconception prevails with respect to the true nature of the *corallium* or hard parts, in these two kinds of polype, it may be useful to point out their essential difference. In the common corals, the solid calcareous structure is formed *within* the body of the polype, whilst in the red coral it is secreted by the *outer* surface of the organism, notwithstanding its position as a branched axis supporting the soft parts of the body. Both types of coral belong to the *Actinozoa*: a class of the great division of the Animal Kingdom termed the *Calenterata*. It is the red coral which is described in this article.

The finest red coral is found in the Mediterranean. It is fished for on the coasts of Provence, and constitutes a considerable branch of the trade at Marseilles. The coral is attached to the submarine rocks, as a tree is by the roots; but the branches, instead of growing upwards, shoot downwards towards the bottom of the sea: a conformation favourable to breaking them off and bringing them up. For this kind of fishing, eight men, who are excellent divers, equip a felucca or small boat called commonly a coralline. They carry with them a large wooden cross, with strong, equal, and long arms, each bearing a stout bag-net. They attach a strong rope to the middle of the cross, and let it down horizontally into the sea, having loaded its centre with a weight sufficient to sink it. The diver follows the cross, pushes one arm of it after another into the hollows of the rocks, so as to entangle the coral in the nets; then his comrades in the boat pull up the cross and its accompaniments.

Coral fishing is nearly as dangerous as pearl fishing, on account of the number of sharks which frequent the seas where it is carried on. One would think the diving-bell in its now very practicable state might be employed with great advantage for both purposes.

Coral is mostly of a fine red colour, but occasionally it is flesh-coloured, yellow, or white. The red is preferred for making necklaces, crosses, and other female ornaments. It is worked up like precious stones. See LAPIDARY.

Coral beads have ever been fashionable ornaments. Dr. Gilchrist states:—'Coral

beads are in high estimation throughout Hindostan for necklaces and bracelets for women. These beads are manufactured from the red coral fished up in various parts of Asia; they are very costly, especially when they run to any size; and they are generally sold by their weight of silver.

Coral beads were always favourite articles for ornament even in this country; and in the 'Illustrations of Manners and Expences of Antient Times in England,' by Nichols, 1798, we find the following entries from 'the churchwardens' accompts of St. Mary's Hill, London,' containing 'the inventory of John Port, layt the king's servant, as after followeth:—

'Item of other old gear found in the house:—	£.	s.	d.
'Item one oz. and $\frac{1}{3}$ of corall	0	2	6
'Jewels for her body.			
'Item, a pair of coral beads, gaudyed with gaudys of silver and gilt, 10 oz. at 3s. 4d.		1	13 4'

(John Port died in 1524.)

CORALLINE. A scarlet dye, prepared by heating a mixture of carbolic, oxalic and sulphuric acids. See CARBOLIC ACID.

CORDAGE. (*Cordage*, Fr.; *Tauwerk*, Ger.) Cordage may be, and is, made of a great variety of materials. In Europe, however, it is mostly formed of hemp, although now much cordage is made of coir. See COIR.

Professor Robinson proposed the following rule for determining the strength of cordage:—Square the circumference of a rope in inches; one fifth of the product will be the number of tons' weight which it will bear: this is, however, uncertain.

CORDOVAN. A leather made at Cordova in Spain from goat-skin. Leather made from horse-hide is called cordovan in this country.

CORDUROY. A kind of ribbed cloth. See FUSTIAN.

CORF or CORVE. A basket for carrying coals; a frame of wood to load coals on; a sledge to transport minerals on.

CORIANDER SEED. The fruit of the *Coriandum sativum*, used as a seasoning, and also for the preparation of an essential oil.

CORK (*Liège*, Fr.; *Kork*, Ger.) is the bark of the *Quercus suber*, Linn., a species of oak-tree which grows abundantly in the southern provinces of France, Italy, and Spain. The bark is taken off by making coronal incisions above and below the portions to be removed; vertical incisions are then made from one of these circles to another whereby the bark may be easily detached. It is steeped in water to soften it, in order to be flattened by pressure under heavy stones, and is then dried at a fire, which blackens its surface. The corks are bound up in bales and sent into the market.

There are two sorts of cork, the white and the black; the former grows in France and the latter in Spain. The cakes of the white are usually more beautiful, more smooth, lighter, freer from knots and cracks, of a finer grey, and of a yellowish-grey colour on both sides, and cut more smoothly than the black. When this cork is burnt in close vessels it forms the pigment called *Spanish black*.

Cork is employed to fabricate not only bottle corks, but small architectural and geognostic models, which are very convenient from their lightness and solidity.

The cork-cutters divide the boards of cork first into narrow fillets, which they afterwards subdivide into short parallelepipeds, and then round these into the proper conical or cylindrical shape. The bench before which they work is a square table, where four workmen are seated, one at every side, the table being furnished with a ledge to prevent the corks from falling over. The cork-cutter's knife has a broad blade, very thin, and fine edged. It is whetted from time to time upon a fine-grained dry whetstone. The workman ought not to draw his knife-edge over the cork, for he would thus make misses, and might cut himself, but rather the cork over the knife-edge. He should seize the knife with his left hand, rest the back of it upon the edge of the table, into one of the notches, made to prevent it from slipping, and merely turn its edge sometimes upright and sometimes to one side. Then holding the squared piece of cork by its two ends, between his finger and his thumb, he presents it in the direction of its length to the edge; the cork is now smoothly cut into a rounded form by being dexterously turned in the hand. He next cuts off the two ends, when the cork is finished and thrown into the proper basket alongside, to be afterwards sorted by women or boys.

Of late years much thicker kinds of cork boards have been imported from Catalonia, from which longer and better corks may be made. In the art of cork-cutting the French surpass the English, as any one may convince himself by comparing the corks of their champagne bottles with those made in this country.

Cork, on account of its buoyancy in water, is extensively employed for making

floats to fishermen's nets, and in the construction of life-boats. Its impermeability to water has led to its employment for inner soles to shoes.

When cork is rasped into powder, and subjected to chemical solvents, such as alcohol, &c., it leaves 70 per cent. of an insoluble substance, called *suberine*. When it is treated with nitric acid, it yields the following remarkable products:—White fibrous matter 0·18, resin 14·72, oxalic acid 16·00, suberic acid (peculiar acid of cork) 14·2, in 100 parts.

A patent was obtained some years ago for machine cork-cutting. The cutting of the cork into slips is effected by fixing it upon the sliding bed of an engine, and bringing it, by a progressive motion, under the action of a circular knife, by which it is cut into slips of equal widths. The nature or construction of a machine to be used for this purpose may be easily conceived, as it possesses no new mechanical feature, except in its application to cutting cork. The motion communicated to the knife by hand, steam, horse, or other power, moves at the same time the bed also which carries the cork to be cut.

The second part of the invention, viz., that for separating the cork into square pieces, after it has been cut into slips as above, is effected by a moving bed as before, upon which the slips are to be placed and submitted to the action of a cutting lever, which may be regulated to chop the cork into pieces of any given length.

The third part of the invention, viz., that for rounding or finishing the corks, consists of an engine to which is attached a circular knife that turns vertically, and a carriage or frame upon its side that revolves on its axle horizontally.

The carriage or frame contains several pairs of clamps intended respectively to hold a piece of the square cut cork by pressing it at the ends, and carrying it lengthways perpendicularly. The wood of the *Anona palustris*, growing in the West Indies, is so soft that corks are made of it. It is hence called **CORK-WOOD**.

CORNEO. An ore of quicksilver found in Spain, is so called locally.

COROMANDEL WOOD. The wood of the *Diospyros hirsuta*.

COROZO, COROSSO. *Vegetable Ivory.*—The commercial names for the fruit of the *Phytalephas macrocarpa*, a species of Brazilian palm. It is called the Tagua Nut in South America. It grows on the borders of the river Magdalena in great abundance, and the nuts are largely imported. The natives of the districts where the tree grows have been in the habit from time immemorial of using this vegetable ivory for making buttons, heads of walking-sticks, &c. It is used largely in this country in the place of ivory, but it does not keep its colour well. See **IVORY, VEGETABLE**.

CORROSIVE SUBLIMATE, *Chloride, or Protochloride, of Mercury, (Deutochlorure de mercure, Fr.; Aetzendes Quecksilber Sublimat, Ger.),* is made by subliming a mixture of 2½ parts of sulphate of oxide of mercury, and 1 part of sea-salt, in a stone-ware cucurbit. The sublimate rises in vapour, and encrusts the globular glass capital with a white mass of small prismatic needles. Its specific gravity is 6·225. Its taste is acrid, styptico-metallic, and exceedingly unpleasant. It is soluble in 16 parts of water, at the ordinary temperature, and in less than three times its weight. It dissolves in 2½ times its weight of cold alcohol. It is a very deadly poison. Raw white-of-egg swallowed in profusion is the best antidote. A solution of corrosive sublimate has been long employed for preserving soft anatomical preparations. By this means the corpse of Colonel Morland was embalmed, in order to be brought from the seat of war to Paris. His features remained unaltered, only his skin was brown, and his body was so hard as to sound like a piece of wood when struck with a hammer.

In the work upon the dry rot, published by Mr. Knowles, Secretary of the Committee of Inspectors of the Navy, in 1821, corrosive sublimate is enumerated among the chemical substances which have been prescribed for preventing the dry rot in timber; and it is well known that Sir H. Davy had, several years before that date, used and recommended to the Admiralty and Navy Board corrosive sublimate as an anti-dry rot application. It has been since extensively employed by a joint-stock company for the same purpose, under the title of Kyan's Patent.

The preservative liquid known as *Goadby's Solution*, which is employed for preserving wood and anatomical preparations, is composed as follows:—Bay salt 4 oz., alum 2 oz., corrosive sublimate 2 grains, water 2 pints.

CORRUGATED IRON. See **IRON**.

CORUNDUM. This mineral species contains sapphire, corundum stone, and emery. It consists of alumina, more or less coloured by metallic oxides.

The perfectly white crystals of sapphire are pure alumina.

There are two varieties of the perfect corundum: the sapphire so called, and the oriental ruby; of which the latter has a rather less specific gravity, being 3·9 against 3·97. Their form is a slightly acute rhombohedron, which possesses double refraction, and is inferior in hardness only to the diamond. The sapphire occurs also in 6-sided prisms. See **EMERY; RUBY; SAPPHIRE**.

	Blue Sapphire, China		Corundum, Bengal	Emery, Naxos
Alumina . . .	98.5	84.0	89.5	68.53
Lime . . .	0.5	.0	0.0	0.86
Silica . . .	0.0	.5	5.5	3.10
Oxide of iron . . .	1.0	7.5	1.25	24.10
Water	4.72
	100.0 Klappr.	98.0 Chen.	98.2 Tennant.	101.31 J.L.Smith.

Corundum, or *Corone*, is the Indian name for the mineral called also Adamantine spar. The Chinese specimens have a grey colour, but the variety from India is whiter. The extreme hardness of this substance, scratching everything except diamond, renders it remarkably valuable to lapidaries and seal-cutters. It is but little softer than the ruby, sapphire, or oriental topaz. It is far superior to emery for grinding, and is used throughout India and China for polishing stones, &c. Large deposits of crystalline corundum have recently been discovered in North Carolina, U.S., and have been worked commercially, especially at Corundum Hill, in Macon Co. The corundum occurs in veins running through serpentine, and is associated with ripidolite, jeffersite, &c.

COSTEANING, a mining term, from the old Cornish *Cothas stean*, fallen or dropped tin. It signifies the practice of sinking pits in search of lodes across the line of direction which the tin lodes usually traverse in Cornwall.

COTTON is a vegetable fibre covering the entire surface of the seeds of species of *Gossypium*—plants which belong to the natural order *Malvaceae*. Cotton is unlike any other textile fibre used in commerce in the fact that it is a hair formed of a single cell. In the vegetable world there is an almost endless series of cell-forms, marked by the two extremes of a perfectly spherical cell, and of a cell so attenuated as to be nearly cylindrical. The latter form is characteristic of cotton. In its early stage, the cotton hair consists of a hollow tube, a transverse section of which would present an elliptical outline; but in the course of growth, partly from the pressure of contiguous hairs, and partly from a loss of moisture, the cylinder collapses and becomes tape-like in form. The collapse is not uniform, however; all down the centre of the hair the sides are parallel, but at each edge a ridge is formed by the folding of the cell-walls. The hair thns comes to have the form of an ordinary railway rail, and its transverse section presents the general appearance of a dumb-bell. The two rounded edges of the hair have, however, a tendency to twist upon themselves, and give to it a certain curly roughness. It is this characteristic of cotton which makes it especially valuable for spinning purposes; the corrugations of the surface helping to bind the fibres together, and to give strength and elasticity to the thread.

Many other vegetable hairs have been tried as substitutes for cotton, such as the 'cotton grass,' (*Eriophorum*) often seen upon bogs and moors, but they have all failed, because they are not formed of a single hair, but of a linear series of hairs united by their extremities. In all such cases the points of union of the several cells form knots in the fibre which render the hairs liable to entanglement and severance when acted upon by machinery. Other substitutes for cotton, which have resembled it in being uni-cellular, have nevertheless failed from being too short.

The fibre of cotton is the longest uni-cellular hair known in the vegetable kingdom, and its length varies with the species, or according to the locality in which it is grown. It is this variability in the length of the fibre—in commercial language its 'staple'—which is the most important factor in determining the price; the longer the staple the more it is worth. The description of cotton which has the longest staple is known as Sea Island, the average length being 1.61 inch; Egyptian stands next, with a fibre of 1.41 inch; then Peruvian, 1.30 inch; Brazilian, 1.17 inch; New Orleans, 1.02 inch; and finally Indigenous East Indian, 0.89 inch of average length.

Comparatively little attention has yet been directed (and that only within recent years), to the improvement of the essential qualities of cotton fibre. And it may be asserted that a wide field lies yet before the cultivator for the adoption of such methods of irrigation, manuring, hybridisation, and general treatment as will lead to future developments of these qualities, and to an enlarged production of the plant. The enormous changes which modern agriculturists have brought about by the treatment, on scientific principles, of cereals and root crops are probably not more marvellous than those which another generation may see, with due care and method, in the culture of cotton. Cultivators have got to discover, from careful analysis, what materials they can add to the soil to increase the strength, length, whiteness, and lustre of the hair;

what modifications they can make in the management of the plant for the purpose of making its growth possible in districts hitherto found unsuitable. There was a time when not even the cherry—much less the grape—would scarcely ripen upon the Rhine, a district which the fostering care of man has at length transformed into a fertile wine-producing region. Much progress is also possible in the way of hybridisation and careful selection of seed, by bringing into existence fresh varieties, which shall perpetuate the best characteristics of their progenitors. The practice of hybridisation is a department of cotton-culture which has not met with the attention it deserves. The experiments in this direction of Major Trevor Clarke, whose persevering efforts to improve the native Indian varieties are well known, have shown the great value of this class of research.

The number of species of *Gossypium* producing the cotton of commerce has been very variously estimated; but Parlatore, the writer of one of the most recent monographs upon this genus (*Le Specie dei Cotoni*, Firenze, 1866), describes and figures seven good species. So great, however, is the multitude of forms at present in cultivation, that authorities are by no means agreed as to which of these forms are to be reckoned as specific. But the opinion of competent botanists is gaining ground that all these forms have descended from the three following species:—*Gossypium arboreum*, the true cotton of the Indian peninsula, and of the island of Celebes; *G. barbadense*, the Barbadoes or Bourbon cotton, from which has probably originated the celebrated Sea Island cotton; and *G. herbaceum*, or the common cotton of the East Indies, China, and the Malay Archipelago.

COTTON DYEING. See DYEING.

COTTON FACTORY, or COTTON MILL. These terms are employed indiscriminately for the purpose of describing any building or set of buildings, in which the processes of spinning or of weaving cotton by the aid of machinery are carried on. Establishments of this kind are often of great magnitude, giving employment to large numbers of work-people, and producing many varieties of fabric. But whether it be large or small, whether its productions be of one kind or of many kinds, a cotton factory needs to be arranged in a certain order, and its successive processes must be suitably organised. The hands and heads of those who labour must be specially trained and habituated to their several parts, and the whole operation conducted with the greatest attainable regularity, and with the least possible interruption at the successive stages of the work. In this manner is secured that harmonious co-operation which is scarcely less essential to economy of manufacture than is the use of steam or water power.

The successive operations carried on in the manufacture of cotton will be more fully described elsewhere; meanwhile the following synthetic view may furnish the reader with a general notion of their nature and their order:—

1. The *mixing* and opening up or loosening the cotton wool, as imported in the bales, so as to separate at once the coarser and heavier impurities as well as those of a lighter and finer kind.

2. The *willowing*, *scratching*, or *blowing*, an operation which removes the seeds and dirt, and prepares the material in the form of a continuous lap or rolled sheet for the next process.

3. The *carding*, which is intended to disentangle every tuft or knot, to remove every remaining impurity which might have eluded the previous operation, and finally to prepare for arranging the fibres in parallel lines, by laying the cotton first in a fleecy web, and then in a riband form.

4. The *doubling* and *drawing* out of the card-ends or ribands, in order to complete the parallelism of the filaments, and to equalise their quality and texture.

5. The *slubbing* operation, whereby the *drawings* made in the preceding process are greatly attenuated, with no more twist than is indispensable to preserve the uniform continuity of the spongy cords.

6. The *intermediate slubbing*, another doubling and further attenuation, which is however, omitted in the spinning of coarse yarns.

7. The *roving*, which is simply a repetition of the doubling and drawing accomplished in the *intermediate* process, but leaving the cotton in a still more attenuated condition ready for the next process.

8. The *spinning* process, which completes the extension and twisting of the yarn. This is accomplished either with the throstle or the mule. By means of the former machine the thread is spun with a larger proportion of turns or twists, and is thus made tough and strong for purposes requiring yarn that will not readily break—as in the warps of stout fabrics. By means of the latter, yarns of less strength are produced, such as the warps of lighter fabrics, and wefts of all kinds. The latter process, being the less costly of the two, is preferred in cases where its results are otherwise suitable to the particular end in view.

9. The yarn thus completed is now converted into the special fabric for which it has been prepared—by one or other of the following processes:—

a. Weaving for which, however, certain preparatory operations are needed. The warps must be formed, first, by *winding* the yarn on large bobbins, one continuous thread on each. From a given number of bobbins the requisite number of threads are then laid side by side upon beams. These again are passed through the *sizing* machine, which adds strength and elasticity to the threads of the warp, enabling them more successfully to resist the necessary strain of wearing. The weft needs no preparation after leaving the mule, but is placed at once in the form of a 'cop' into the shuttle.

b. Doubling.—In this process two or more threads are twisted together; the doubled yarn being then either converted into warps for woven goods of special strength, such as double warp calicoes, fustians, velveteens, and cotton velvets; or is carried forward through one or other of the following operations.

c. Reeling and Binding.—Here the yarn is wound into reels or skeins and packed in bundles for the purpose of exportation, or for dyeing or bleaching, or for the manufacture of hosiery.

d. Singeing and Polishing.—By the first of these processes the thread passes through jets of gas flame, and thus loses its superfluous fibres; by the latter, having first been dyed, it acquires a high degree of glossiness, and is then used for admixture with silk in the mixed goods which of late years have become popular, under the designation of Japanese silks, &c.

There are few instances in which the whole of these operations are carried on in the same factory. To a large extent even the two main divisions—spinning and weaving—are the work of separate firms and establishments. Usually, however, these two are combined. In order the better to illustrate these main features of the factory system, we now proceed to describe a concrete example—that of a cotton mill at Stockport, containing 61,400 throstle and mule spindles, and 1,320 looms.

The mill consists of a main body with two lateral wings, projecting forwards, the latter being appropriated to store-rooms, a counting-house, rooms for winding the yarn on bobbins, and other miscellaneous purposes. The building has six floors, besides the attic story. The ground-plan comprehends a plot of ground 280 feet long by 200 broad, exclusive of the boiler sheds.

The right-hand end, *A* (*fig. 538*) of the principal building, is separated from the main body by a strong wall, and serves in the three lower stories for accommodating two ninety-horse steam-engines, which are supplied with steam from a range of boilers contained in a low shed exterior to the mill.

The three upper stories over the steam-engine gallery are used for unpacking, sorting, picking, cleaning, willowing, and lapping the cotton wool. Here are the willow, the blowing, and the lap machines, in a descending order, so that the lap machine occupies the lowest of the three floors, being thus most judiciously placed on the same level with the preparation room of the building. On the fourth main floor of the factory there are, in the first place, a line of carding engines arranged near and parallel to the windows, as shown at *B B*, in the ground plan (*fig. 538*), and, in the second place, two rows of drawing frames, and two of bobbin and fly frames, in alternate lines, parallel to each other, as indicated by *D, C, D, C*, for the drawing frames, and *E, E, E, E*, for the bobbin and fly frames in the ground plan. The latter machines are close to the centre of the apartment.

The two stories next *under* the preparation room are occupied with throstle frames, distributed as shown at *F F*, in the ground plan. They stand in pairs alongside of each other, whereby two may be tended by one person. These principal rooms are 280 feet long and nearly 50 feet wide. The two stories, *over* the preparation room, viz., the fifth and sixth floors from the ground, are appropriated to the mule jennies, which are placed in pairs fronting each other, so that each pair may be worked by one man. Their mode of distribution is shown at *G G*, in the ground plan. The last single mule is seen standing against the end wall, with its head-stock projecting in the middle.

The ground floor of the main building, as well as the extensive shed abutting behind it, marked by *X, H, H*, in the plan, is devoted to the power looms, the mode of placing which is plainly seen at *H, H, H*.

The attic story accommodates the winding frames, and warping mills, and the warp sizing machines, subservient to power weaving.

Some extra mules (self-actors), are placed in the wings.

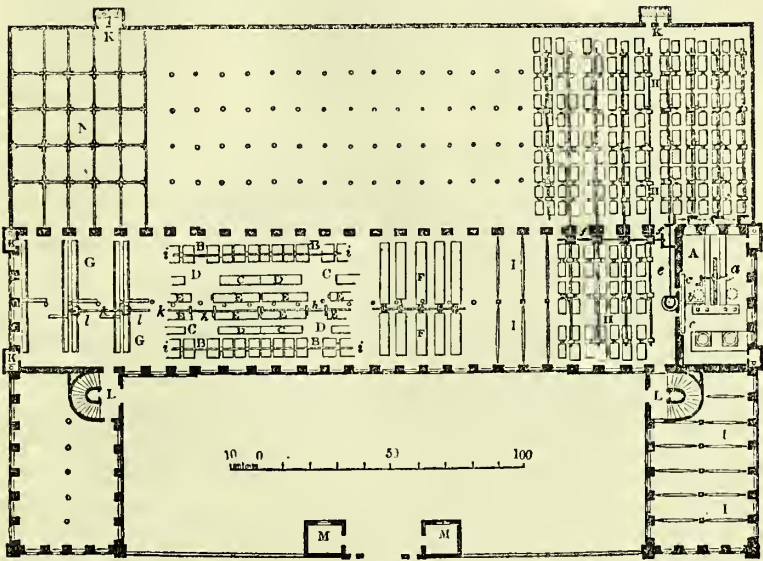

We shall briefly sum up the references in the ground plan as follows:—

A, the ground apartment for the steam-engines.

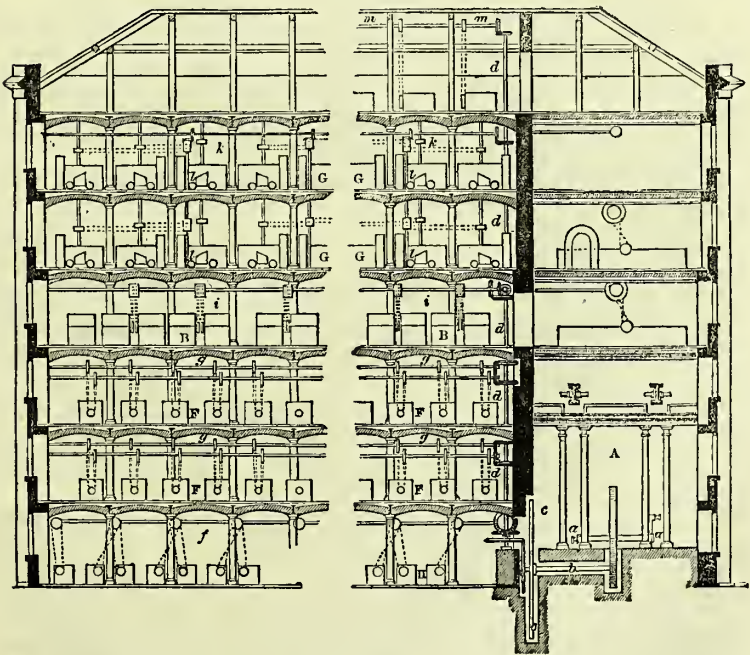

B, the distribution of the carding engines, the moving shaft or axis running in a straight line through them, with its pulleys, for receiving the driving bands,

c c, the drawing frames.
 d d, the jack, or coarse bobbin and fly frames.

538

539

e e, the fine roving, or bobbin and fly frames.
 F, the arrangement of the throstle frames, standing in pairs athwart the gallery, in the 2nd and 3rd flats.

G. the mules are here represented by their roller beams, and the outlines of their head-stocks, as placed in the 5th and 6th stories.

H. the looms, with their driving pulleys projecting from the ends of their main axes. Sometimes the looms are placed in parallel straight lines, with the rigger pulleys of the one alternately projected more than the other, to permit the free play of the driving-belts; sometimes the looms are placed, as generally in this engraving, alternately to the right and left, by a small space, when the pulleys may all project equally. The former plan is the one adopted in Mr. Orrell's mill.

I. represents the cast-iron girders which support the floors of this fire-proof building.

K. K. are closets placed in each floor, in the recesses of a kind of pilasters built against the outside of the edifice. These hollow shafts are joined at top by horizontal pipes, which all terminate in a chest connected with the suction axes of a fan, whereby a constant draught of air circulates up the shafts, ventilates the apartments, and prevents the reflux of offensive effluvia from the water-closets, however careless the work-people may be. The closets towards the one end of the building are destined for the men; towards the other for the women.

L. L. are the staircases, of a horse-shoe form, the interior space or shaft in the middle being used for the teagle or hoist. In the posterior part of the shaft a niche or groove is left for the counter-weight to slide in, out of the way of the ascending and descending platform.

M. M. are the two porters' lodges, connected to the corner of each wing by a handsome iron balustrade. They are joined by an iron gate.

It will be observed that the back loom-shed has only one story, as shown in section (fig. 540). In the ground plan of the shed, N represents the roofing, of wood-work. The rafters of the floors rest at their ends upon an iron plate, or shoe with edges (as it is called), for the girders to bear upon.

The power for driving the machinery is conveyed from the engine-rooms by shafting in the usual manner. To the horizontal ramifications from the upright shaft any desired velocity of rotation may be given by duly proportioning the diameters of the bevelled wheels of communication between them; thus, if the wheel on the end of the horizontal shaft have one-half or one-third the diameter of the other, it will give it a double or a triple speed.

In the lowest floor, the second bevel wheel above the stone block drives the horizontal shaft *e*, seen in the ground plan; and thereby the horizontal shaft *f*, at right angles to the former, which runs throughout the length of the building, as the other did through its breadth, backwards. The shaft *f* lies alongside of the back window wall, near the ceiling; and from it the transverse slender shafts proceed to the right and left in the main building, and to the shed behind it, each of them serving to drive two lines of looms. These slender or branch shafts are mounted with pulleys, each of which drives four looms by four separate bands.

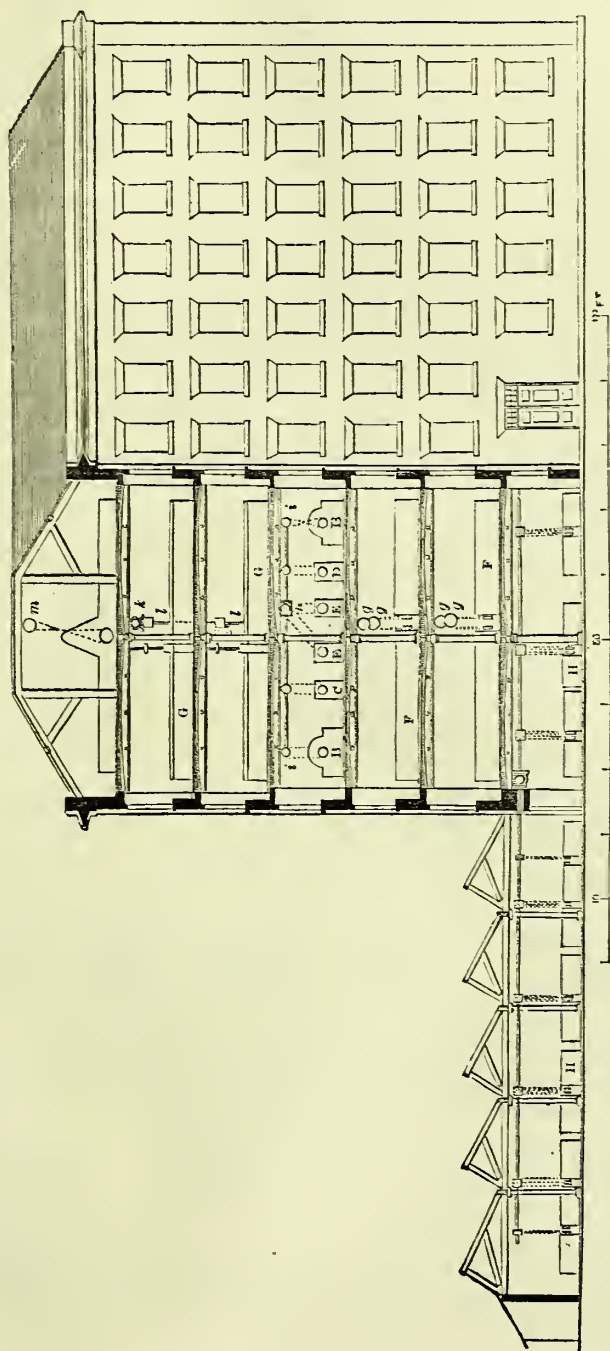

In the second and third floors, where the throistles are placed, the shaft *d* is seen in the section to drive the following shafts:—

Upon the main upright shaft *d* (fig. 540), there are in each of these stories two horizontal bevel wheels, with their faces fronting each other (shown plainly over *d d*), by which are moved two smaller vertical bevel wheels, on whose respective axes are two parallel shafts, one over each other, *g g*, which traverse the whole length of the building. These two shafts move therefore with equal velocities, and in opposite directions. They run along the middle space of each apartment; and wherever they pass the rectangular line of two throistle frames (as shown at *F* in the ground plan) they are each provided with a pulley; while the steam pulleys on the axes of two contiguous throistles in one line are placed as far apart as the two diameters of the said shaft-pulleys. An endless strap goes from the pulley of the uppermost horizontal shaft round the steam or driving-pulley of one throistle frame; then up over the pulley *g*, the second or lower shaft, *g*; next up over the steam pulley of a second throistle; and, lastly, up to the pulley of the top shaft, *g*. See *g g* in the throistle floors of the cross section.

In the preparation room, three horizontal shafts are led pretty close to the ceiling through the whole length of the building. The middle one, *k* (see the plan, fig. 538) is driven immediately by bevel wheels from the main upright shaft *d* (fig. 539). The two side ones *l*, *l*, which run near the window walls, are driven by two horizontal shafts, which lead to these side shafts. The latter are mounted with pulleys, in correspondence with the steam pulleys of the two lines of carding engines, as seen between the cards in the plan. The middle shaft *k*, drives the two lines of bobbin and fly frames, *x*, *x*, *x*, *x* (see cross section), and short shafts *i*, *h*, seen in the cross section of this floor, moved from the middle shaft *k*, turning the gallows fixed to the

ceiling, over the drawing and jack frames, give motion to the latter two sets of machines. See c d in the cross section.

540

To drive the mules in the uppermost story, a horizontal shaft *k* (see longitudinal and cross sections, as well as ground plan) runs through the middle line of the building, and receives motion from bevel wheels placed on the main upright shaft, *a*, immediately beneath the ceiling of the uppermost story. From that horizontal shaft, *k*, at every second mule, a slender upright shaft, *l*, passing through both stories, is driven (see both sections). Upon these upright branch shafts are pulleys in each story, one of which serves for two mules, standing back to back against each other. To the single mules at the ends of the rooms, the motions are given by still slenderer upright shafts, which stand upon the head stocks, and drive them by wheel-work, the steps (top bearings) of the shafts being fixed to brackets in the ceiling.

In the attic, a horizontal shaft *m m*, runs lengthwise near the middle of the roof, and is driven by wheel-work from the top upright shaft. This shaft, *m*, gives motion to the warping mills and dressing machines.

In Great Britain and throughout the greater part of the European continent the motive power used in cotton factories is derived almost entirely from steam; but in the United States and in Switzerland the large amount of available river fall is so great that water-power is extensively employed in the manufacture of cotton: the proportion in the United States being 2·1 horse-power of water to 1 horse-power of steam, and in Switzerland 3·4 of water to 1 of steam. A further peculiarity in the construction of American cotton mills is that the motion is communicated from the steam-engine or turbine or water-wheel, as the case may be, not through the medium of wheels and shafting as shown in our illustrations, but by means of huge leather belts and drums or pulleys. This plan, originating, no doubt, in the formerly very high price of iron in the United States, is stated to be more effective and economical than the European method already described.

The latest complete return of the number and extent of the cotton factories of the United Kingdom was presented to Parliament in 1871. From this return we give the following particulars :—

Cotton Factories in Great Britain and Ireland.

Number of cotton factories	2,483
„ carding engines	65,960
„ combing machines	1,906
„ spinning spindles	34,695,221
„ doubling spindles	3,523,537
„ power looms	440,676
„ power loom weavers	165,341
Amount of steam-power (horse-power)	300,480
„ water-power	8,390
Total number of persons employed	449,087

The growth during recent years of the cotton manufacture in the United Kingdom may be pretty accurately gauged by the comparison of a few particulars from the last four Parliamentary returns, those of 1856, 1861, 1868, and 1871. Thus :—

Number of	1856	1861	1868	1871
Spinning spindles	28,010,217	30,387,467	32,000,014	34,695,221
Power looms	298,847	399,992	379,329	440,676
Persons employed	379,213	451,569	401,064	449,087

In the United States the progress of the cotton manufacture has been since 1860 relatively much more rapid than in this country. From the Census returns of 1860 and 1870, the only complete and official statistics bearing upon this subject, we take the annexed figures :—

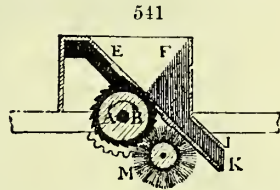

Cotton Factories in the United States.

	1860	1870
Number of spindles	5,235,727	7,132,415
„ power looms	126,313	157,310
„ persons employed	122,028	135,369

The following estimate, based upon official returns or upon a comparison of the best accessible information, of the number of cotton spinning spindles and the weight of cotton consumed in each of the manufacturing countries in Europe and America will furnish an approximately correct idea of the relative importance of the cotton industry in each at the present time (1874) :—

	Spindles	Cotton consumed, lbs.
Great Britain and Ireland	35,500,000	1,264,000,000
United States	8,000,000	476,000,000
France	5,200,000	197,000,000
Germany	5,100,000	228,000,000
Switzerland	2,500,000	56,000,000
Russia	2,000,000	120,000,000
Austria	1,600,000	106,000,000
Spain	1,400,000	67,000,000
Belgium	650,000	27,000,000
Italy	500,000	24,000,000
Sweden, Norway, and Denmark	300,000	18,000,000
Holland	250,000	9,000,000
Total	63,000,000	2,592,000,000

COTTON-GIN. The great mass of seeds with which the woolly fibres of cotton are accompanied, and to which they adhere most tenaciously, must of necessity be removed before the cotton can be turned to any useful purpose. This operation, called ginning, is always performed as near as possible to the place of growth. Formerly the object was effected by the rudest handicraft methods, such as are indeed still followed in some parts of India. These methods were, however, very slow and costly. It was, therefore, an important step forward in the history of cotton culture when Eli Whitney, an American, in the year 1793, made known his invention of the saw-gin. The working of this machine will be readily understood on reference to *fig. 541*, where *AB* is a sectional view of a roller, about 9 inches in diameter, revolving in the direction of the arrow. Throughout the length of the roller a series of circular saws, at intervals of about an inch and a half, projects beyond the wooden portion of it. Above the cylinder, a hopper *E F* contains the seed cotton, which falls upon a grating, so placed as to allow the teeth of the saws when revolving to lay hold of the fibres of cotton and pull them through the grating. The seeds being thus left behind roll down the slope of the grating, and are discharged at the spout *IK*. The brush *M* revolves against the teeth of the saws for the purpose of clearing them of the adherent fibres.

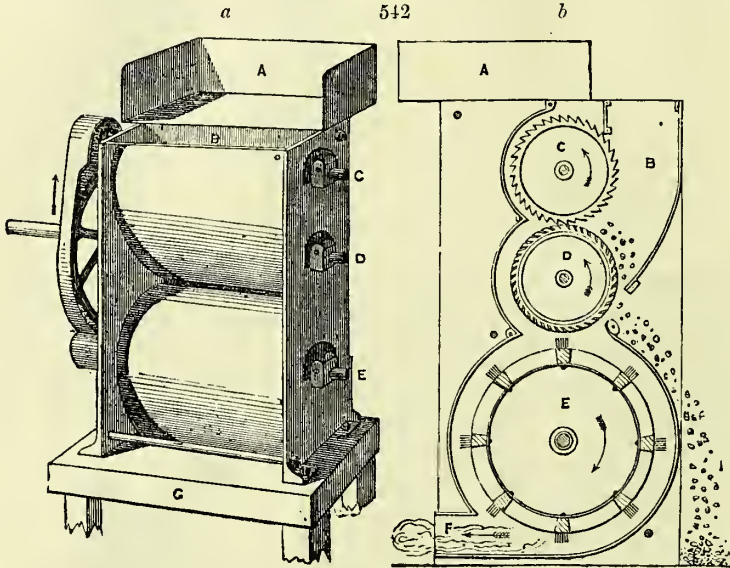

The saw-gin has in several respects been modified since its invention, with the effect of considerably increasing the out-turn, but the principle remains essentially the same as we have described. The quality of its work, however, leaves room for improvement. The rough teeth of the saws do not use the fibre gently enough, but cut and ‘nep’ or knot it, especially when the machine is allowed to get out of order or is carelessly employed. Quite recently, an American inventor has hit upon an expedient which is said to go far towards remedying these defects. This modification consists in substituting, for the circular saws, rows of pointed smooth steel wire teeth, which, whilst effectual for the purpose of drawing away the cotton from the seeds, present no rough corners or surfaces to the passing fibre.

Calvert’s toothed roller gin, illustrated by *fig. 542*, may be considered as a modification of the saw-gin. *a* is a perspective and *b* a sectional view. *A* is a box to hold the seed cotton, *B* is the hopper, and *D* is the toothed roller which draws away the cotton, whilst the disengagement of the seeds is aided by the fluted roller *C*.

The Macarthy gin differs from the saw-gin mainly in substituting for the saws a roller, covered longitudinally, at intervals, with strips of leather set on spirally. A blunted knife, working alternately up and down at right angles to the axis of the roller and along its entire length, serves to strike off the adherent seeds at the point where the fibre is being drawn through. This machine is not capable of doing as much work as the saw-gin; but, on the other hand, it delivers the cotton in very good condition, and is on this account preferred for the longer stapled and more valuable varieties. Successful efforts have been made to remove the objection to the Macarthy gin on the ground of its comparatively small out-turn, but the inability of the native labourers in most cotton-producing countries to work and keep in order any but the simplest mechanical combinations has hitherto prevented the extensive adoption of the improved machines.

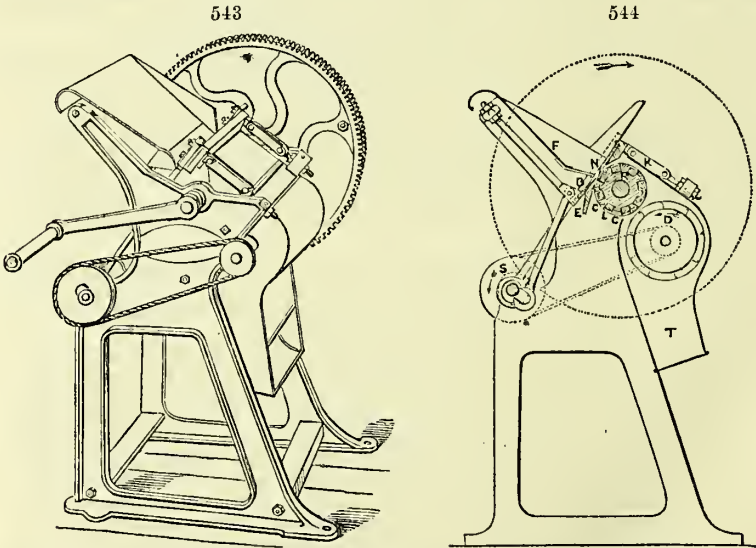

Another variety of cotton-gin is known as the Lock Jaw or Cowper’s Gin. This machine is intermittent in its action. It nips the fibre firmly, whilst an instrument pushes off the seed; then it releases its hold, allowing the clean fibre to pass away. A fresh quantity is then brought in, held in like manner, and so detached from

the seed. There is no sliding and rubbing action, as in the Macarthy Gin ; or sawing of the fibre, as in the saw-gin. The closing of the nipping blade upon the fibre is so

like the action of a jaw, that the resemblance has given to this machine its best known name.

Fig. 543 shows a perspective view, and fig. 544 a section, of it : *n* is the nipping

blade, *n* the roller on which are arranged the strips of leather, *l*. These come into action one after the other, in order to form one side of the pair of jaws to act with the nipping blade ; fine combs, *c*, are also attached to the roller between the strips of leather (when short-stapled cotton is being combed). *s* is a shaft, with cranks, to move the beater, *b*, and excentrics to move the nipping blade, *n*, which latter is confined by links, *k*, causing it to move in a curved elliptical path. *f* is a bar to fill up the

space between the roller and beater, and *p* is a doffer to take the clean cotton off the roller. At the time when the nipping blade *N* approaches the roller *R*, it is moving in the same direction, and at the same surface speed; and as it approaches it nips upon the fibre, or locks it fast between its edge and the strip of leather on the roller; the beater *B* then comes up quickly, and pushes off the seed a short distance, thus separating the fibre when it is held close up to the seed, and obtaining it, necessarily, of its full natural length.

It will be inferred from the description of this invention that it answers one of the essentials of a good cotton-gin in that it inflicts little damage upon the fibre. There is, however, in this case as in others the practical difficulty that those who have to use the machine have too little skill and intelligence to use it profitably. A further obstacle to the adoption of the best inventions when they happen, as is usually the case, to be somewhat complex, is the great distance of the cotton-fields from engineering establishments, and the consequent impossibility of promptly executing the needful repairs.

Enough has been adduced to show that the operation of cotton-ginning, simple as it may appear to be, occupies a prominent place in the chain of processes by which this natural product is at last made useful for the service of mankind. It is also evident that the various means at present within reach for effecting the separation of the fibre from the seed are all more or less objectionable. The great losses arising from bad ginning can scarcely be appreciated by those who are not practically acquainted with the various qualities as they come to market. We may observe, however, that the Report of the Commissioners appointed to examine and value the samples of cotton exhibited at the International Exhibition of 1862 estimated the average loss from this source at 2·67*d.* per lb.

COTTON GUN. See GUN COTTON.

COTTON-SEED. The practical utility of cotton-seed for any other purpose than the limited one of reproduction or for manure has until quite recently been almost unknown. In the United States it was occasionally used for fodder, and cattle were very fond of it. It was found, however, that unless given in very small quantities and only occasionally, the shorter fibres still left on the seed after the ginning process proved very unwholesome. Means have been found, however, for removing this difficulty, and the cotton-seed is now taking high rank, amongst agricultural products, as the source of no less than three valuable commodities, viz.: Oil, cattle-food, and paper material. The method of treatment as practised in the United States is as follows:—first, *Re-ginning*, by a special apparatus which entirely clears off the short fibres from the seed, making them available for paper manufacture; secondly, *Decoricating*, by which the external husk is removed, and this again, after decomposition, is utilised as manure; thirdly, the kernel is subjected to the process of *Crushing*. The products of this last operation are a valuable oil and a cattle-food cake, both of which have now taken their place as important articles of commerce. After re-ginning, the seed consists on an average of one half husk and one half kernel. The kernel yields when crushed about one third crude oil and two thirds cake.

Some idea of the wide field opened up by this new branch of manufacture may be formed from a rough statement of the quantity of seed available for its purposes. Taking the American cotton crop at 4,000,000 bales or 800,000 tons annually, the production of seed, on an average of estimates, may be put down at three times as much by weight, or 2,400,000 tons. Allowing one half this quantity for waste and resowing, there remain 1,200,000 tons of the American crop for manufacturing purposes. The available yield of the crop of India, Egypt, Brazil, and other countries can scarcely be less than two thirds of this amount. We thus arrive at an estimate of 2,000,000 tons as the annual supply of cotton-seed capable of being turned to valuable uses, most of which is now being wasted. The quantity of cotton-seed imported into the United Kingdom almost entirely for manufacturing purposes was in 1871, 174,392 tons, valued at 1,526,652*l.*; in 1872, 167,936 tons, valued at 1,404,724*l.*; and during 1873, 207,755 tons, valued at 1,608,975*l.*

COTTON-SPINNING. The many varieties of cotton with which the tropical world abounds, and the widely-differing purposes for which each, according to its peculiar fitness, is destined, have led to considerable divergence in the methods of manufacture. The treatment suitable for the shorter and rougher stapled cottons, or for their conversion into bagging, candle-wick, or the coarser kinds of clothing, is obviously very far removed from the processes proper to the finest New Orleans, whose clear and silky fibres fit it for the manufacture of velvets and cambrics. Still further removed is the treatment necessary in spinning Sea Island, which is used in the production of the most delicate muslins and laees. To describe with minuteness every part of the many kinds of operations comprised within these extremes lies obviously beyond the scope of this article. There are, nevertheless, certain well-marked stages

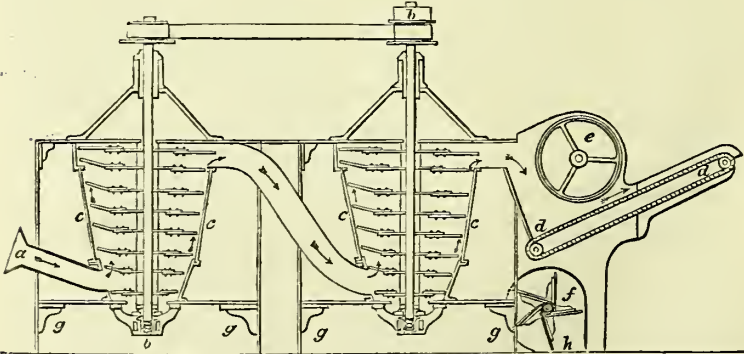

or processes common to all kinds of cotton-spinning. These we shall follow in due order, pointing out by the way such modifications of treatment as the chief varieties of raw material and of finished product require.

The long distances traversed by the cotton in its passage from the field to the factory require that every available expedient be adopted to abridge the cost of transmission. A great part of the cost consists in the charge for sea freight, which is reckoned according to bulk and not according to weight. Hence nearly all kinds of cotton, and especially East Indian descriptions, are compressed by means either of a screw or a hydraulic press into an exceedingly small space. The effect of this process is to cause the fibres to be almost welded together in solid masses; and when the bales are opened the cotton is seen to lie in hard layers, very unlike the fleecy and cloud-like condition in which it leaves the gin. The first purpose, therefore, to which the use of machinery is directed in cotton-spinning is the loosening or *opening* of the fibres. With this process is necessarily associated the cleansing of the cotton, the separation from it of as much as possible of the sand and other impurities with which it is often too freely associated, as well as of the seeds, which in a whole or a broken condition have escaped through the gin, and adhere very tenaciously to the fibres. The various kinds of machines in use for these purposes are known as *Willows*, *Openers*, or *Scutchers*.

Before proceeding to describe this class of machinery, however, it is desirable to say something with reference to the *mixing* of cotton. Under the head of *CORROU* we have alluded to the most distinctive characteristics of the principal varieties. But there are many minuter differences in every description, differences of length, strength, colour, texture, and general working qualities, with which only the practical cotton-spinner is acquainted. This is a section of technical knowledge which nothing but experience can give; and it is a mark of skill to be able so to combine or to set off these qualities against each other as to turn them to the best account. Hence the selection and the proper admixture of various growths and descriptions of cotton is no small part of the work of the spinner. Moreover, it is found in practice that even in the same 'grade,' or quality, there is considerable variation between one bale and another, and not unfrequently even in the same bale. The period of the harvest-time at which the cotton is picked, the kind of weather at the time, the part of the plant on which it is grown, and other circumstances, contribute to diversify greatly the produce of the same plantation. And however carefully it may be classified, important differences will remain. But there is reason to believe that care of this kind is not common. The best method of overcoming these last-named differences is to mix together as large a number of bales and to blend them as intimately as possible by spreading out the contents of each bale on a large stack in parallel layers, in such manner as that when it is raked down from top to bottom a small portion of each bale will come away. By this means the irregularities in the subsequent processes and in the thickness, strength, and evenness of the yarn, will be minimised.

The freeing of cotton from its grosser impurities is not an easy undertaking, and during the American Civil War when coarse, dirty, and badly-gained growths were forced into consumption, much difficulty was experienced for want of effective cleaning machinery. During this period the Cotton Opener of Messrs. Crighton and Co. was

545

introduced, and extensively adopted for the special purpose just named. This machine is illustrated in vertical section by *fig. 545*. The cotton is fed down the

open pipe *a*, to the bottom of the vertical beater *b*. This beater revolves rapidly, its arms striking the cotton against the grids *c c*, by which it is surrounded, and separating the dirt and leaf from the cotton. These fall into the dirt grid *g*, below, whilst the draught from the fan, aided by the shape of the beater, causes the cotton gradually to ascend, till it arrives at the discharge pipe, whence it descends to the bottom of the next beater, and is again similarly operated upon. The cotton, after passing the second beater, is discharged through a pipe to a cage *e*, and creeper *d*, and without any pressure leaves the machine in an open, well cleaned, fleecy state.

Various other forms of Opener are in use. All, however, rest upon the application either of centrifugal force, or of toothed rollers or cylinders for the loosening of the cotton, and upon the pneumatic force derived from the fan for the purpose of drawing away dust and other impurities. One recent improvement, however, we may mention (that of Messrs. Lord, of Todmorden) which is not so much a separate machine as a new method of feeding the opener. It consists in passing the cotton through a long horizontal tube, the lower portion of which is grated. The cotton is forced through the tube by pneumatic pressure, created by the revolution of a fan in the ordinary way. The distance traversed by the cotton serves to loosen it to a considerable extent, and to disengage much of the dirt from it, whilst at the same time there is no violent tearing or strain upon the fibre.

Perhaps the most common description of Opener in use is known as the Scutcher, a name which is associated with a particular form of construction easily recognised in *fig. 546*. The cotton is placed upon the travelling creeper marked *a*, which is made

546

of a number of narrow slips, or laths, of wood, screwed to three endless bands of leather, the pivots of which are marked *b* and *c*. Motion is given to the roller *e*, by a wheel on the end of the feed roller, thus causing the creeper to advance, carrying with it the cotton to the feeding rollers *d*; these revolving slowly pass the cotton to the second smaller pair of fluted rollers, which serve it to the beater. The top feeding rollers are weighted by levers and weights *e e*, and hold the cotton sufficiently tight for the beater to act upon it. The beater is placed inside the machine at *f*, and extends quite across its breadth, its shaft or axis being shown with the pulley upon it at *g*. The form of the beater varies, but we give the following as an example — On a shaft are placed four or five spiders, each having three or four arms (*fig. 547*); to the ends of these arms are attached steel blades, which pass along the whole length of the beater; two of the arms being shorter than the others, allow the blades attached to them to contain a double row of spikes in each, the points of the spikes being at the same distance from the axis as the other two blades. As the beater revolves about 800 turns per minute, the blades and spikes strike the cotton with considerable force as it is passed from the feeding rollers, and thus loosen and disengage it from much of its impurity. Immediately under the feed rollers and beater are placed a number of wedge-shaped bars, which form a semicircular grid, through the narrow openings of which the dirt and seeds fall to the floor, their removal being effected through the doors in the framing. To prevent the cotton passing with the dirt through the grid, a current of air, to draw the cotton from the beater to the cage, is produced by an exhaust fan (its axis being shown at *h*, *fig. 546*)

receiving its motion from a pulley on the beater shaft. The projection *i* on the framing forms a pipe, through which the fan draws the air from the beater, passing on its way through a large revolving cage or cylinder, the periphery of which is formed of sheets of perforated metal, or wire gauze. Its axis is shown at *k*.

From the cage the cotton is delivered by a second travelling creeper, and falls into a receptacle, from which it is taken and passed through the second Scutching or Lap machine, to which we shall refer presently.

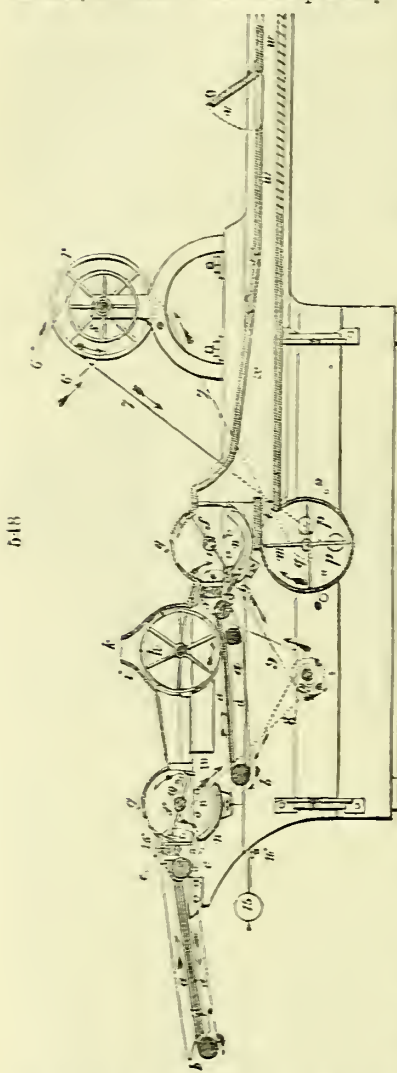

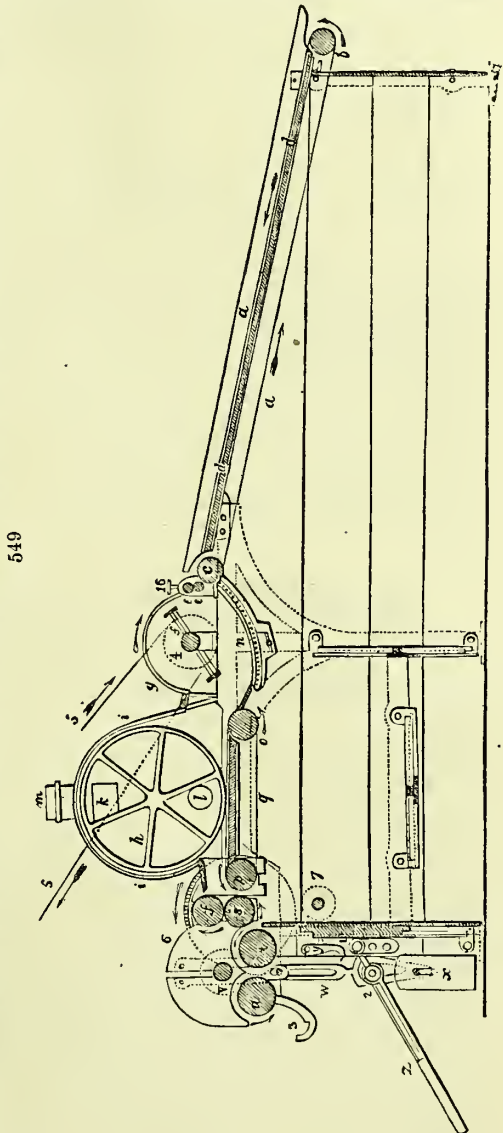

Fig. 548 exhibits a longitudinal section of another kind of Opener, or first Scutching machine. The machine is about 18 or 19 feet long, and three feet across within the case. The whole frame is made of cast iron, forming a close box, which has merely openings for introducing the raw cotton wool, for taking out the cleansed wool, and removing the dust as it collects at the bottom. These doors are shut during the operation of the machine, but may be opened at pleasure to allow the interior to be inspected and repaired. The introduction of the cotton is effected by means of an endless cloth or a wooden lath creeper similar to the one in *fig. 543*, which moves in the direction of the arrows *a a*, at the left end of the figure, by passing round the continually revolving rollers *b* and *c*. It is then delivered to the feed rollers *e*. The double-armed beater *f e* turns in the direction of the arrow, and strikes the cotton violently as it enters, so as to throw down any heavy particles upon the iron grating or grid at *n*, while the light cotton filaments are wafted onwards with the wind, in the direction of arrow *a'* along the second travelling apron. *k* is a cylindrical cage made of wire gauze or perforated zinc, from which the air is exhausted by means of a fan formerly placed at some distance from the machine, and communicating with it through a pipe fixed at the opening *k*. Now, however, the fan is placed below the machine, and communicates with the cylindrical cage, as described in *fig. 546*. The cage *k*, by its rotation, presses down the half-cleaned cotton upon the cloth *a'*, which carries it forward to the second beater *f'*, by the second set of feed rollers *e'*. The second beater throws down the heavy dust upon the second grid *n'*, through which it falls upon the bottom of the case. The cotton is wafted by the second beater into the space *z w u*, provided with a fine grid bottom. In *fig. 548* an additional ventilator is introduced beneath at *m o*, to aid the action of the scutchers in blowing the cotton onwards into the oblong trough *a*. The outlet of that fan is at *t*; and it draws in the air at its axis *q*. *u* and *v* are two doors or lids for removing the cleaned cotton wool. This last fan is suppressed in many scutchers, as the scutching arms supply a sufficient stream of air. The dotted lines show how the motion is transmitted from the first mover at *g*, to the various parts of the machine. *6' 6'* represent the bands leading to the main shafting of the mill.

The second Scutching or Lap machine differs from the first Scutching machine only in two respects. The cotton as it passes out of the machine is coiled in a continuous broad sheet

or coil upon a roller. This coil, called a *lap*, it is necessary to make as even in thickness as possible, hence a further distinction of the second scutcher consists in its being provided with the means of approximately securing the desired evenness. Formerly this was accomplished by making the feed-cloth or apron into equidistant spaces and spreading equally a given weight of cleaned cloth upon each space. This plan is still followed in many factories. It has, however, been largely displaced, on account of the costliness of the manual labour involved, by a mechanical contrivance invented by Messrs. Lord, of Todmorden, and known as Lord's regulator. This apparatus is connected with the feed rollers, and is made to increase or diminish their speed inversely as the thickness of cotton passing between them, thus approximately securing a uniform rate of delivery to the beater. This invention has been further improved by Messrs. Lord, who have added what is known as the 'Piano Motion' the purpose of which is to obtain greater delicacy in the action of the regulator, and to counteract the minuter variations in the thickness of the cotton as it enters the machine. In the improved regulator, the trough or plate under the roller, or rollers, which supply cotton to the beater, instead of being in one piece as heretofore, is divided into any convenient number of parts, each part being acted upon by a weight or spring, their object being to press the fibres between the trough, or plate, and the feed roller, so as to prevent them being drawn forward unevenly by the beater, and to prevent 'snatching.' The variations in the quantity of cotton fed to the machine produce corresponding variations in the distance between the divided trough or plate and the feed roller, and thus increase or diminish the quantity of cotton supplied to the machine.

In cases where Lord's regulator is applied the opener must be made to lap the cotton, instead of delivering it into a loose mass. Three or four laps are then made to unfold together upon the feeding lattice or apron of the scutcher, with the object of making the inevitable unevennesses of the first lap machine correct each other as far as possible, and thus aid the work of the regulator.

A section of a Lap machine is shown in *fig. 549*, where we see the feed-cloth, the scutching beater, the cylindrical cage, and the rollers for coiling up the lap. The lever shown below is for removing the pressure weight from the axis of the lap rollers, when

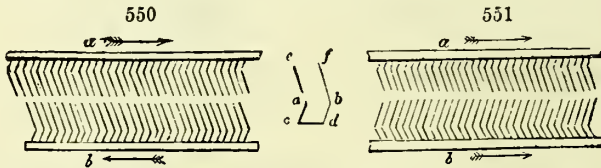

a full lap is to be removed, and replaced by an empty one. *m*, at the top, is the commencement of the pipe which leads to the suction fan, or ventilator.

It is to be observed that different kinds of cotton require different kinds of treatment in the opening and scutching operations. Some scutchers have only one beater, others two or even three. Sometimes the opener has two beaters, so that altogether the cotton is made to pass through as many as five beaters. As a rule, however, it is well to beat or tear it as little as is possible, having in view the main purpose of this operation, viz. to loosen and to cleanse it from the more palpable impurities. For not only does the staple suffer from repeated strain, but the longer stapled cottons are liable occasionally to get knotted or 'nepped,' and thus to introduce almost irreparable mischief into the subsequent operations.

The operations of opening and scutching are exposed to frequent risks of fire. Pieces of stone, of flint, of metal, and even boxes of lucifer matches are not unfrequently found in cotton. Whenever these pass into the machines and are struck by the beaters, there is imminent danger of fire. Hence the rooms in which these operations are carried on are almost invariably fireproof, and are built quite separate from the rest of the factory, communicating with it only by a covered fireproof gangway.

The cotton thus opened and to a certain extent cleaned is yet, however, in a very unfit state for being spun into yarn. The fibres, on examination, will be found mingled in a confused mass, and whether straight, or curled, or folded, lying in every possible direction. Moreover, it will be seen that there are amongst the longer fibres many so short as to be unfit for combination with them, some also will be knotted, or 'neppy,' and added to these imperfections many 'moats,' small pieces broken off the pod or the seed of the cotton, besides other forms of finer impurity. For the purpose of separating the useful fibres from the foreign accompaniments and laying them in parallel order, we have the operation of *Carding*. The essential part of this operation may be described as the mutual action of two opposite surfaces, which are studded thick with oblique-angled hooks. The wires of which these hooks are made must be very hard drawn in order to render them stiff and elastic. The middle part of the figures shows one of the staples or double teeth, the structure of which has been partly explained under *CARD*. Suppose *a*, *fig. 550*, to be a piece of a card fillet, and *b* to be

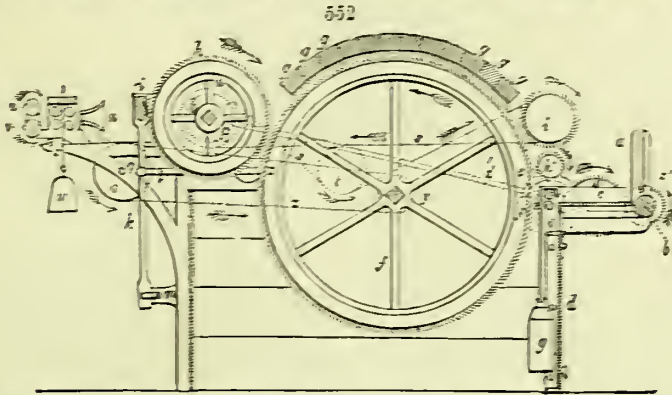

another piece, each being made fast with pins to a board; the teeth of these two cards are set in opposite directions, but are very near together, and parallel. Now suppose a flock or tuft of cotton placed between two such bristling surfaces. Let *a* be moved in the direction of its arrow, and let *b* be moved in the opposite direction, or even let it remain at rest. The filaments of cotton will be laid hold of by each set of teeth, when their surfaces are thus drawn over each other; the teeth of *a* will pull them in a forward direction, while those of *b* will tend to retain them, or to pull them backwards. The loops or doublings will, by both movements, be opened or drawn out, so that the tangled fibres will be converted into rows of parallel filaments, lying alongside or before each other. Each tooth will secure to itself one or more of them, and by the friction of its sides as well as the hooks of its points, will draw them to their utmost elongation. Though one stroke of the opposite cards be inadequate to produce this equable arrangement, yet many repeated strokes must infallibly accomplish the end in view, of laying the fibres parallel.

Let us suppose this end effected, and that all the fibres have been transferred to the card *a*, a transverse stroke of *b* will draw over to it a certain number of them, and indeed at each stroke there will be a new partition between the two cards, with increased parallelism, but still each card will retain a great deal of the cotton. To make one card strip another, the teeth of one of them must be placed in a reverse position, as shown in *fig. 551*. If *a* be now drawn in the direction of its arrow along the face of *b*, it will inevitably comb out all, or almost all, the filaments from it, since the hooks of *b* have, in this position, no power of retaining them. Even the doubled fibres or loops will slip over the sloping point of *b*, in obedience to the traction of *a*. By considering these two relative positions of the cards, which take place in hand cards simply by reversing one of them, any person will be able to understand the play of a cylinder card against its flat top, or against another cylinder card, the respective teeth

being in what we may call the teasing position of *fig. 550*; and also the play of a cylinder card against the doffer cylinder, in what may be called the stripping position of *fig. 551*.

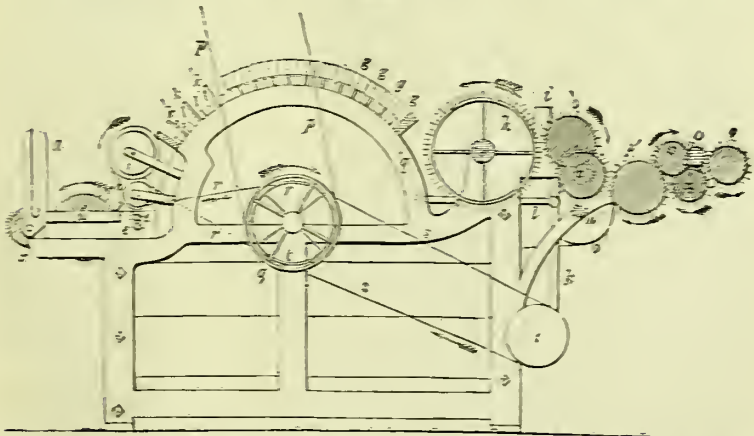

Cylinder cards, so essential to the continuity and despatch of cotton-factory labour, were the ingenious invention of Lewis Paul, of Northampton, but were greatly improved and brought into nearly their present operative state by Sir Richard Arkwright. A carding engine consists of one or more cylinders, covered with card-leather (sometimes card-cloth), and a set of plain surfaces similarly covered, made to work against each other, but so that their points do not come into absolute contact. Some cards consist entirely of cylinders, the central main cylinder being surrounded by a series of smaller ones called rollers. These are generally used for preparing the coarser stapled cotton.

Fig. 552 may be taken as a typical illustration of the carding engine. *a* is one

of the two upright slots, which are fixed at each side of the engine for receiving the iron gudgeons of the wooden rollers round which the fleece of the lapping machine is rolled. The circumference of this coil rests upon a roller *b*, which is made to turn slowly in such a direction as to aid the unfolding of the lap by the fluted cylinders *c*. The lap proceeds along the table seen beneath the letter *c*, in its progress to the fluted rollers; *g* is a weight which hangs upon the axis of the upper roller, and causes it to press upon the under one; *f* is the main card cylinder; *g g g*, the arch formed by the flat top cards; *h*, the small card cylinder for stripping off the cotton, and therefore called the doffer; *i*, the doffer-knife or comb for stripping the fleecy web from the doffer; *k l m*, the lever mechanism for moving these parts. At *d* there is a door giving

553

access to the interior of the engine, for the purpose of removing whatever dirt, &c. may happen to fall into it. In *fig. 553* we see the manner of fixing the flat tops *g g*

over the cylinder; and to make the matter clearer, three of the tops are removed. Upon the arched cast-iron side of the frame, a row of strong iron pins k is made fast in the middle line; and each top piece has, at each of its ends, a hole, which fits down upon two such opposite pins. ll are screws whose heads serve as supports to the tops, by coming into contact with the bottom of the holes, which are not of course bored through the woods of the tops. By turning the heads of these screws a little the one way or the other, the pins may be lengthened or shortened in any degree, so as to set the tops very truly in adjustment with the cylinder teeth revolving beneath them. h' is the small runner or urchin, and i' the large runner; both of which are spirally covered from end to end with narrow card fillets, in the same manner as the doffer. The main cylinder is, on the contrary, covered with card-cloth, in strips laid on parallel to its axis, with interjacent parallel smooth leather borders. The teeth of these several cards are set as represented in the figure, and their cylinders revolve as the arrows indicate. The runners as well as the doffer cylinder may be set nearer to or further from the cylinder f ; but the screws intended for this adjustment are omitted in the drawings, to avoid confusion of the lines.

The card-end or fleece taken off the doffer h by the crank and comb mechanism ikm passes through the tin-plate or brass funnel n , *fig. 552*, whereby it is hemmed in and contracted into a riband, which is then passed through between a pair of drawing rollers o . It is next received by the rollers $u v$, which carry it off with equal velocity, and let it fall into the tin cans placed below, when it is not to be re-carded, or conduct it over a friction pulley, to be wound along with many other card-ends upon a lap roller or large bobbin. In the latter case it is then conveyed to the 'finisher' carding engine.

The two pairs of rollers at o effect the extension of the card-end, and reduce its size. The under rollers are made of iron and fluted; the upper ones are also made of iron, but they are covered with a coat of leather, nicely glued on over a coat of flannel, which two coats render them both smooth and elastic. Two weights, w , press the upper cylinder steadily down upon the under ones. Between the first and second pair there is a certain interval, which should be proportioned to the length of the cotton staple. The second, or that furthest from the funnel, revolves with greater velocity than the first, and therefore turns out a greater length of riband than it receives from its fellow; the consequence is, a corresponding extension of the riband in the interval between the two pairs of rollers.

The motions of the several parts of the engine are effected in the following way:—The band, $p p$, *fig. 553*, which comes down from the pulley upon the main shaft near the ceiling of the work-room, drives, by means of the pulley q , the cylinder f , *fig. 552*. From another pulley, r , on the axis of the cylinder, the axis of t is driven by the band s working round the pulley t on its end. This shaft drives the crank and lever mechanism of the stripper knife i . A third pulley of the same side as r is fixed just within the frame to the other end of the cylinder, and from it a crossed or close band r' goes to a pulley upon the small runner h' , to give this its rapid rotation. Upon the opposite end of the engine in *fig. 552*, these wheels and pulleys are marked with dotted lines. Here we may observe, first, a pulley y upon the cylinder, and a pulley a' , which receives motion from it by means of the band z . The axis of a' , carries in front a pinion m' , which sets in motion the wheel n' . The latter imparts motion, by means of a pinion and intermediate wheel o' , to the wheel h on the doffer, and consequently to that cylinder on the one hand; and it turns, by the carrier wheel p' , a wheel x , whose axis is marked also with x in *fig. 553*, upon the other hand. The axis x' , *fig. 552*, carries, towards the middle of the engine, a very broad wheel, which is represented by a small dotted circle. The toothed wheel v of the smooth roller v' , *fig. 552*, and the two toothed wheels $o o$, *fig. 553*, of the under rollers $o o$, *fig. 552*, work into that broad wheel. The wheel of the second or delivery fluted roller is seen to be smaller than that of the first, by which means the difference of their velocities is obtained. The large runner i is driven from the main cylinder pulley, by means of the band s' , and the pulley u' , *fig. 552*. The said band is crossed twice, and is kept in tension by the pulley z' , round which it passes. The motion of the fluted rollers e , which feed in the cotton fleece, is accomplished by means of a bevel wheel b' on the end of the doffer, which works in a similar wheel c' on the oblique axis d' (dotted lines across the drum) of the pinion e' upon the lower end of the same axis which turns the wheel f' , upon the under feed roller.

Each of the feed rollers, *fig. 553*, bears a pinion ee at one end, so that the upper roller turns round with the under one. The roller b , *fig. 552*, is set in motion by means of its wheel x' ; which is driven by a wheel v' on the other end of the under feed roller, through the intervention of the large carrier-wheel w' . The original or first motion of b must be as quick as that of the fluted feed rollers e , in order that the former may uncoil as much lap as the latter can pass on.

The annexed Table exhibits the relative velocities of the different cylinders and rollers of the carding engine, which, however, are not invariable, but may be modified

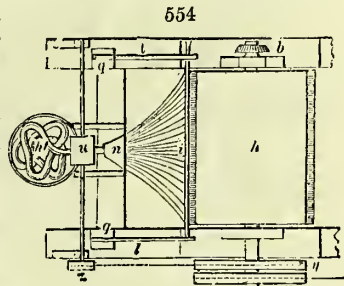

Names of the Parts	Diameter in inches	Circumference in inches	Revolutions in one minute	Velocity
Main cylinder <i>f</i>	35	109·9	130·	142·87
Doffer <i>h</i>	14	43·96	4·38	192·5
Runner or urchin <i>i'</i>	6·25	19·62	5·	98·1
Ditto <i>h'</i>	3·5	11·	470·	5170·
Fluted feed roller <i>e</i>	1·167	3·664	0·696	2·55
First drawing roller <i>o</i>	1·	3·14	68·71	215·75
Second ditto	1·167	3·664	114·52	419·6
Smooth delivery roller <i>v</i>	2·5	7·85	54·66	429·08

according to circumstances, by changing the pinions *e'*, *fig. 552*, and *w'* according to the quality or length of the cotton staple.

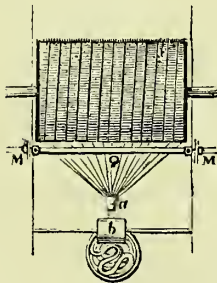

Fig. 554 is a plan of the card and the fleece, where *h* is the cylinder, *n* is the funnel, *u* the pressing rollers, and *h'* the card-ends in the can.

Figs. 555, 556 may be studied in order to facilitate the comprehension of these complex machines. *Fig. 555* is a plan: *F* is the main cylinder; *M M* is the doffer knife or comb; *G*, the carded fleece hemmed in by the funnel *a*, pressed between the rollers *b*, and then falling in narrow fillets into its can. *Fig. 556*, *K L* are the feed rollers; *A B*, the main cylinder; *C D*, the tops; *E F*, the doffer card; *M N*, the doffer knife; *d, b, c*, the card-end passing between compressing rollers into the can *a*.

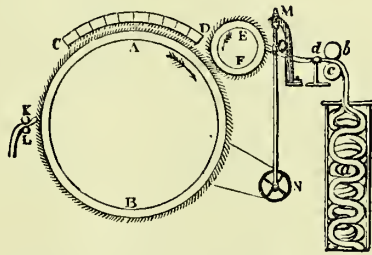

Fig. 557 is a carding-engine without top-flats, being entirely covered with rollers and clearers. This kind of engine is very well suited to the preparation for the lower

555

556

and lower medium 'counts' of yarn. For finer descriptions, the use of 'flats' or 'tops' is almost universal.

The same *fig. (557)* will serve to illustrate one of the most modern forms of carding engine, if the reader will suppose two additional rollers placed under the licker-in; all three rollers being of the same size, clothed alike and revolving in the same direction, in close proximity to each other and to the main cylinder. This engine known as the Patent Automatic Carding Engine, is made by the patentees, Messrs. W. Higgins & Sons, and Messrs. Hetherington & Sons. Its action is as follows:—The cotton is delivered by the feed rollers to the licker-in as usual; but before it reaches the main cylinder it is brought into contact with and is carded by the intermediate roller, which allows only the carded portions of cotton to pass through to the cylinder, the larger masses being taken hold of by the intermediate roller, and carried forward until they are brought into contact with the bottom roller, which still further cards and separates the fibres of cotton, allowing an additional portion to be delivered to the cylinder, the remainder being taken on by the bottom roller and likewise deposited on the cylinder. Thus, instead of the cotton being delivered in flaky

masses upon the cylinder by the licker-in, as in the ordinary mode, it is first well opened and carded, separated from dirt and seeds at the most convenient point, and then distributed lightly and evenly over the main cylinder at three separate points.

Fig. 557 also exhibits a view of a 'coiler' immediately in front of the carding

557

engine. By means of this ingenious contrivance the sliver or riband of cotton instead of coming directly out of the rollers and falling into the can, is made to pass through the upper portion of the coiler, which folds itself with a circular coil into the can placed upon the flat disc-stand at the foot of the coiler. The disc, and with it the can, is made to revolve very slowly in a contrary direction to that of the coiler, and thus every part of the can is equally filled, and the appearance of the sliver when taken out of the can is that of a series of neat and closely-packed spiral convolutions.

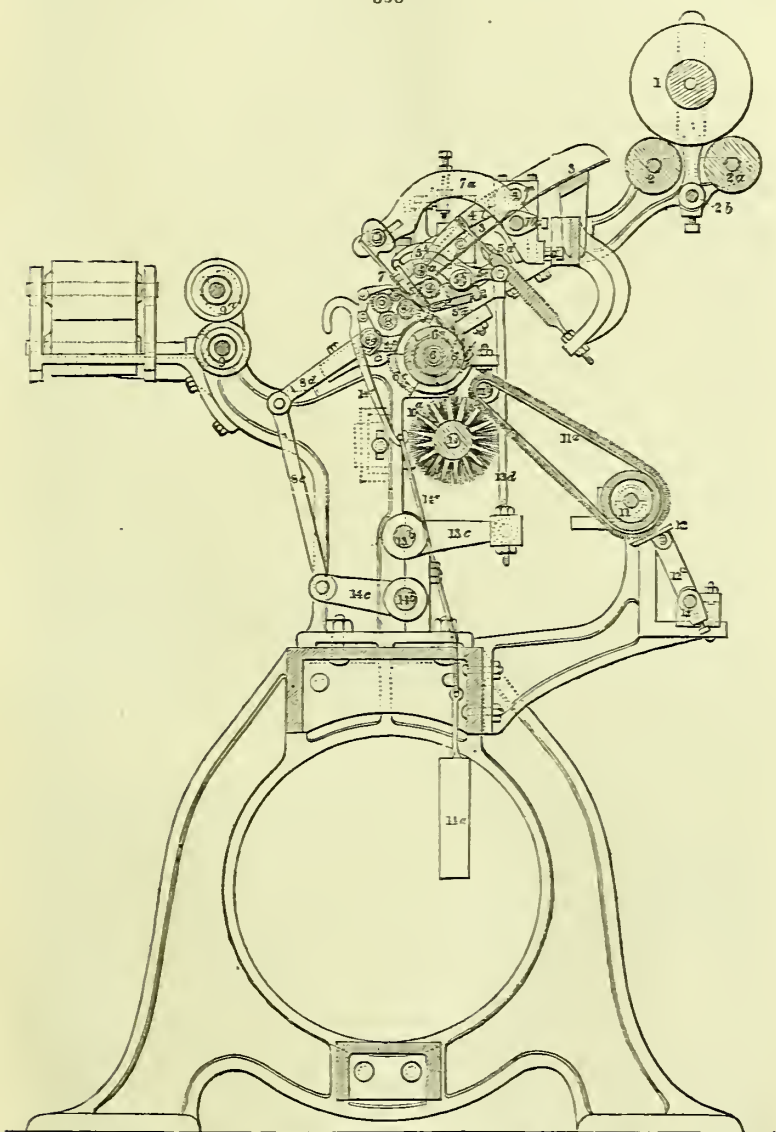

In some districts where the yarns spun are of medium 'counts' or thickness 'double carding engines' are used, engines in which there is a second cylinder fed directly by the doffer of the first. These machines turn out a large quantity of work, and in the preparation of coarse cottons are efficient and economical.

The efforts to improve the carding engine have of late years been directed rather to cleaning and maintaining the efficiency of the engine than to any changes in its method of working. The delicate points of the wires both on the cylinder doffer rollers and flats of the machine need to be kept constantly sharp. Frequent 'grinding' is therefore necessary. This is accomplished by friction against prepared surfaces of emery. Formerly manual labour was necessary to effect this purpose as regards the cards on the cylinders. Now, however, it is accomplished entirely by mechanical means. The most recent improvement of this kind is the grinding roller of Mr. Horsfall, which is made to traverse the width of the cylinder in contact with the wires whilst they are revolving rapidly in a backward direction. It is obvious that the impurities remaining after scutching must tend to clog up the wires of the carding engine. And, as a matter of fact, some parts of the cards need to be cleansed many times in a day. Especially is this the case with flats. This operation called 'stripping' was until late years a very laborious one; now, however, the labour is much lighter, in consequence of the various contrivances for machine stripping. The most important inventions of this kind are the self-stripping flats of Mr. Evan Leigh, of Mr. Buchanan, and Mr. Wellman. Of the last two there are many modifications, and indeed the mechanical stripping of carding engines is still in a state of progress.

It has already been stated that in preparing the longer stapled cottons for the spinning of fine yarns, a single carding operation is not sufficient. After passing through the first or 'breaker card,' the cotton is put through the 'finisher.' Even the

finisher card, however, has now been superseded where it has been desired to spin the best fine yarns, by the *Combing Machine*. This important invention, the discovery of M. Heilmann, an Alsatian, though patented in England in 1846, was first brought into general notice at the London Exhibition of 1851. The patent right so far as it related to the preparation of cotton was purchased by a company of five Manchester spinners for 30,000*l.*, and for a time these firms enjoyed the exclusive use of the

558

machine. Several improvements have been effected in M. Heilmann's invention by Messrs. John Hetherington & Sons of Manchester. The great advantages derived from the use of the combing machine consist in its power entirely to remove the moats and dirt from the cotton, and to separate with far greater precision than is possible with the carding engine the long from the short fibres. The spinning of the finest yarns for the manufacture of muslins, laces, and sewing cotton has thus been

wonderfully improved. The construction and operation of the combing machine will be readily understood upon a study of the accompanying illustration of a cross-section of the machine (*fig. 558*).

1 is the lap of cotton resting upon the two wooden rollers 2, 2*a*. When motion is given to these rollers, they cause the lap to unwind and deliver the sheet of cotton down the inclined conductor 3, and between the fluted steel feeding roller 4, and the leather-covered pressure roller 4*a*; to these rollers an intermittent motion is given by means of a star wheel; they make $\frac{1}{10}$ th of a revolution to one revolution of the cylinder 6, this motion being effected during the time the cushion plate 5*a* is forward, and the nipping plate 5 is lifted from it. The cushion plate 5*a* is hung upon the centre 5*b*, and the nipping plate upon the shaft 5*c*, and this shaft receives motion from a cam at the end of the machine through the lever 5*e*, the connecting rod 13*d*, lever 13*c*, and shaft 13*b*,—the parts being so arranged that the cushion plate 5*a* is pressed backward by the nipping plate 5, but as soon as the pressure is removed it is drawn forward by a spring until it arrives at the strap. Besides this movement, the nipping plate is caused to move on its own axis, which enables it to quit contact with the cushion, while the cotton is being fed in between them.

The cushion 5*a* is represented as thrown back by the nipping plate 5, and while in this position the cotton is held between them, until the combs on the cylinder pass between the fibres of cotton which protrude, and remove from them all impurities and the fibres which are too short to be held by the nipper. The combing cylinder 6*a* is attached to the shaft, or axis 6, by which it is made to revolve. The periphery of this cylinder is divided into four unequal parts, by the combs 6*b* on one side, and the fluted segment 6*c* on the other side; the spaces between them being plain to allow time for the nipper and leather detaching roller 8*a* to change their positions.

The combs on the cylinder are made with teeth at various distances, the coarser ones taking the lead, and finer teeth following, the last combs having more than 80 teeth in a lineal inch. All impurity or waste mixed with the fibres held by the nipper is carried away by these combs, which at every revolution are cleaned by the cylindrical brush 10*a*, stripping the waste from them, and depositing upon the travelling creeper 11*a*, formed of wired cloth, which carries it down until the doffing knife, or steel blade 12 removes it in the usual manner; it then drops into a waste box, and is afterwards used for inferior purposes.

As soon as the combs have all passed the fibres held by the nipper, the cushion plate 5*a* is drawn forward, the nipper plate 5 is lifted from it, and the fibres are released. The fluted segment 6*c* on the cylinder is at the same time passing immediately under the cushion plate 5*a*, the ends of the combed fibres lying upon it, and as the leather detaching roller 8*a* has been lowered into contact with the fluted segment, they are then drawn forward; but as it is necessary to prevent any fibres passing that have not been properly cleaned or combed, the top comb 7 is placed between the nipper and the roller and as this comb falls and penetrates the fibre, just in front of the part uncombed by the cylindrical combs it prevents any waste from being drawn forward with the combed cotton.

The leather detaching roller 8*a*, in addition to its occasional contact with the fluted segment 6*c*, is always in contact with the fluted steel detaching roller 8, and participates in its movements. These rollers are stationary while the cylinder combs are cleaning the fibres projecting from the nipper, but as soon as that operation is completed they are put into motion, and make part of a revolution backward, taking back with them the fibres previously combed, but taken out of the way to allow the cylinder combs to pass, in order for the next fibres coming forward to be joined or pieced to them, so as to form a continuous sliver or riband. As soon as the backward movement is completed, the leather-detaching roller 8*a* is made to approach the cylinder by the lever 8*f*, which receives motion from a cam at the end of the machine, through the lever 8*d*, connecting rod 8*c*, lever 14*c*, and shaft 14*b*. Before, however, it comes in contact with the fluted segment 6*c*, the movement of the fluted roller is reversed, and it is caused to turn forward, producing a corresponding movement of the detaching roller 8*a*, the speed being so arranged that, before they are allowed to touch each other, the peripheries of the fluted segment 6*c* and the roller 8*a* travel with an equal velocity. At this stage, the ends of the fibres cleaned by the cylinder combs and projecting from the nipper are resting upon the fluted segment; and the roller 8*a*, in coming in contact with it, presses upon those fibres, and immediately draws them forward; the front ends are then lifted by the leather roller and placed on the top of those fibres previously cleaned, and brought back to receive them. The pressure of the rollers 8 and 8*a* completes the piecing of the fibres; the motion of the rollers being continued until the hindermost ends of the fibres are drawn through the top comb, and a length of cotton is delivered to the callender rollers,—sufficient slaeck being left between to allow for the next backward movement. The roller 8*a* is then

raised from the fluted segment and ceases to revolve. From the caller roller, the combed cotton passes along the front plate or conductor, where it joins the slivers from the other five heads of the machine, and with them passes through the drawing head, and is then deposited in a can ready to be removed to the drawing frame.

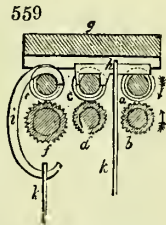

Such is a minute analysis of the movements of this complicated piece of mechanism. Perhaps a clearer and more complete view of its operation may be gathered from a summary statement.

The lap of cotton having been placed on a pair of revolving lap rollers, the fleece, or sheet of cotton, is conducted down an inclined guide to a fluted steel feeding roller, which places the cotton between the open jaws of an iron nipper. The nipper is then closed and made to approach the comb cylinder, where it holds the fibres in such a position that the combs of the revolving cylinder pass between and remove from the fibres all impurities and short or broken cotton, which are afterwards worked up into yarns of a coarser quality. As soon as the combs have all passed through the first portion of the fleece under treatment, the nipper recedes from the cylinder, and when it has reached the proper distance, opens its jaws, and allows the partially combed fibres to be drawn out of the fleece, by means of a leather-covered roller. The drawing out of these fibres brings their uncombed ends, which were before held in the nipper, under the teeth of a fine top comb, thus completing the combing of each separate fibre. Previous to the movement for drawing out fresh fibres from the uncombed fleece, the detaching roller has made a partial revolution backwards, and taken with it the combed cotton previously delivered, in order to piece to it the fibres just combed. The machine is so arranged that the forward movement of the detaching roller brings out the cotton in a continuous sliver to the front of the machine.

Both the detailed and the summary statement just presented describe only one 'head' or section of the machine. There are, however, working simultaneously side by side and identical in construction, six heads on one machine. Each of these delivers a continuous sliver of combed cotton, and the whole six slivers are finally combined into one, which is then ready for the next operation, viz., Drawing.

When the cotton leaves the carding engine (or in the case of very fine yarn the combing machine) it ought to be quite clean, having regard to the particular degree of purity and brightness required in the kind of yarn it is proposed to spin. If the dirt and other impurities have not been sufficiently got rid of at this stage, there is no hope of their being extracted afterwards. What remains now to be done before the actual spinning can take place is simply to equalise the sliver and complete the straightening of the fibres. To a great extent this last operation has been already accomplished by the carding engine; but a slight examination of the fleece as it comes from the doffer of the engine will show that the parallelism of the fibres is as yet in a very imperfect state. This double object of equalising the sliver and making the fibres quite parallel and straight, is effected by means of the *Drawing Frame*. The former end is reached by frequent combination of the sliver, by *doubling* as it is termed—whilst the latter is accomplished by drawing out or attenuating the combined slivers. The drawing operation, or *draught*, is indeed repeated in all the subsequent processes also, and it will therefore be convenient to describe it once for all.

Let *a* and *b*, *fig. 559*, represent the section of two rollers lying over each other, which touch with a regulated pressure, and turn in contact upon their axes in the direction shown by the arrows. These rollers will lay hold of the fleecy riband presented to them at the point of contact, draw it through between them, and deliver it quite unchanged. The length of the piece passed through in a given time will be equal to the circumference of one of the rollers multiplied by the number of its entire revolutions in the same time. Now if the speed and circumference of the three sets of rollers shown in the figure be the same, that is to say, if their surfaces travel at the same rate, the riband will be delivered from the last pair of rollers of exactly the same thickness or 'counts' as at its entrance at the first pair. But if the surface speed of *c* and *d* be greater than that of *a* and *b*, then the former pair will deliver a greater length of riband than the latter receives and transmits to it. The consequence can be nothing else in these circumstances than a regulated drawing or elongation of the riband in the interval betwixt *a*, *b*, and *c*, *d*, and a tendency of the filaments as they glide over each other, to assume a straight parallel direction. In like manner the drawing may be repeated by giving the rollers *e*, *f*, a greater surface speed than that of the rollers *c* and *d*. This increase of velocity may be produced, either by enlarging the diameter, or by increasing the number of turns in the same time, or finally by both methods conjoined. In general the rollers are so adjusted,

that the chief elongation takes place between the second and third pairs, while that between the first and second is but slight and preparatory. It is obvious, besides, that the speed of the middle pair of rollers can have no influence upon the amount of the extension, provided the speed of the first and third pairs remains unchanged. The rollers *a, b,* and *c, d,* maintain towards each other continually the same position, but they may be removed with their frame-work, more or less, from the third pair, *e, f,* according as the length of the cotton staple may require. The distance between the points of contact of *a, b,* and *c, d,* is, once for all, so calculated, that it shall exceed the length of the cotton filaments, in order that these filaments may not be torn asunder, by the second pair pulling them while the first holds them fast. Between *d* and *f,* where the greatest extension takes place, the distance must be as small as it can be without risk of tearing. If the distance between *d* and *f* be very great, a riband passing through will be found to be much less evenly drawn than when the two sets of rollers are set so close to each other as to act upon the shortest possible length of riband at once.

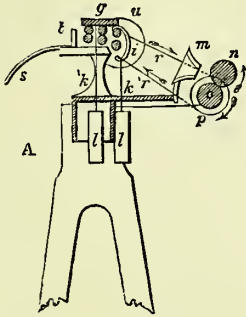

The under rollers *b, d, f,* are made of iron, and to enable them to lay firmer hold of the filaments their surfaces are fluted with triangular channels parallel to their axes. The upper rollers, *a, c, e,* are also made of iron, but they are smooth, and covered with a double coating, which gives them a certain degree of softness and elasticity. A coat of flannel is first applied by sewing or glueing the ends, and then a coat of leather in the same way. The junction edges of the leather are cut slanting, so that when joined by the glue, the surface of the roller may be smoothly cylindrical. The top rollers are sometimes called the *pressers,* because they press by means of weights upon the under ones. These weights are suspended to the slight rods *k' k;* of which the former operates on the roller *e* alone, the latter on the two rollers *a* and *c* together. For this purpose the former is hung to a c-shaped curve *i,* whose upper hook embraces the roller, not the curved portion of it used in the drawing operation and called the boss, but the central portion between the bosses, which is turned smooth for the purpose. The latter is suspended upon a brass saddle *h,* which rests upon *a* and *c.* A bar of hard wood, *g,* called a *clearer,* whose under surface is covered with flannel, rests, with merely its own weight, upon the top rollers, and strips off all the loose hanging filaments, which gather upon the roller when at work. Similar bars with the same view are made to bear up under the fluted rollers *b, d, f,* and press against them by a weight acting through a cord passing over a pulley. Instead of the upper clearers, light wooden rollers covered with flannel are occasionally applied.

Were the drawing of a riband continued till all its fibres acquired the desired degree of parallelism, it would be apt, from excessive attenuation, to tear across, and thereby to defeat the purpose of the spinner. The difficulty is got rid of in a very simple way, namely, by laying several ribands together at every repetition of the process, and incorporating them by the pressure of the rollers. The practice is called *doubling.* It is an exact imitation of what takes place when we draw a tuft of cotton wool between our fingers and thumb in order to ascertain the length of the staple, and replace the drawn filaments over each other, and thus draw them forth again and again, till they are all parallel and of nearly equal length. The doubling has another advantage, that of causing the inequalities of thickness in the ribands to disappear, by applying their thicker to their thinner portions, and thereby producing uniformity of substance.

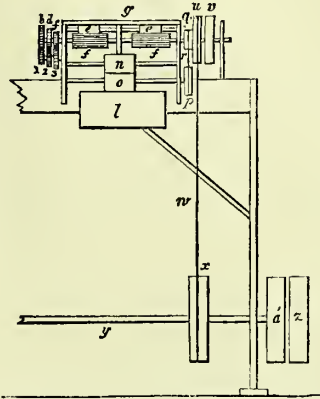

The *drawing frame,* as shown in section in *figs. 559, 561,* and in a back view in *fig. 560,* will require, after the above details, little further explanation. *l l* are the weights which press down the top rollers upon the under ones, by means of the rods *k k'* and hook *i.* Each fluted roller, is, as shown at *f, fig. 561,* provided in the middle of its length with a thinner smooth part called the *neck,* whereby it is really divided into two fluted portions, represented by *e e* in the figure. Upon this middle neck in the pressure rollers, the hook *i,* and the saddle *h* immediately bear, as shown in the former *fig. 559.* The card-ends or slivers to the number probably of six, are introduced to the drawing frame either from cans, placed at *e e, fig. 561,* and *a, fig. 560,* or from lap-bobbins; and, after passing through it, the ribands or slivers are received either into similar cans as *g,* or upon other lap-bobbins upon the other side. These appendages may be readily conceived, and are therefore not exhibited in all the drawings. Three of the slivers being laid together, are again introduced to the one fluted portion *a b, fig. 559,* and three other slivers to the other portion. The sloping curved tin or brass plate *s, fig. 560,* with its guide pins *t,* serves to conduct the slivers to the rollers. When the two threefold slivers have passed through between the three pairs of rollers, they are gathered together behind the last roller pair *e f, fig. 559,* and issue from the conical funnel *m, fig. 560,* into a single riband, which is immediately carried off with equable velocity by two smooth cast-iron rollers, *n o, figs. 560 and 561,* and either dropped into a can or wound upon a large bobbin,

Four fluted drawing portions are usually mounted in one drawing frame, which are set a-going or at rest together.

560

561

A drawing frame usually consists of three heads or portions, each similar to the other. The cotton passes once through each head, and in order to save the labour of carrying the cans from one side to another of the frame, the centre head is set in a direction contrary to the other two. By this alternate arrangement, the work goes on without interruption.

The *fast pulley* *u*, *fig. 561*, by which the whole machine is driven, derives its motion from the main shaft of the mill by means of the band *w*. The similar pulley *z*, which sits loose upon the axis, and turns independently of it, is called the *loose pulley*. When the operative desires to stop the machine, he transfers the band from the fast to the loose pulley by means of a lever bearing a fork at its end, which embraces the band. This arrangement of fast and loose pulley is common to all machines used in cotton manufacture. Upon *y*, four pulleys such as *x* are fixed, each of which sets in motion a drawing head, by means of a band like *w* going round the pulleys *x* and *u*. The toothed wheel-work, by which the motions are communicated from the backmost fluted roller to the middle and front ones, is seen in *fig. 561*.

The more frequently the drawing process is repeated, the more perfectly will its object be accomplished. The fineness of the appearance of the sliver after the last draught depends upon the number of doublings conjointly with the original fineness and number of drawings. By changing the wheels which drive the back roller, for others with a different number of teeth, the speed of the roller may be increased or

562

diminished, and thus the fineness of the sliver may be modified in any desired degree ; for, when the subsequent processes of the mill remain the same, the finer the drawings.

the finer will be the yarn. For spinning coarse numbers or low counts, for example, six card-ends are usually transmitted through the first drawing head, and converted into one riband. Six such ribands again form one in the second draught; six of these again go together into the third sliver; and this sliver passes five-fold through the last draught. By this combination 1,080 of the original card-ends are united in the finished drawn sliver = $6 \times 6 \times 6 \times 5$. The fineness of the sliver is, however, in consequence of these doublings, not increased but rather diminished. For, by the drawing, the card-end has been made 625 times longer, and so much smaller; by the doubling alone it would have become 1,080 times thicker; therefore the original thickness is to the present as 1, to the fraction $\frac{1}{1080}$; that is, supposing 1,072 feet of the riband delivered by the card to weigh one pound, 625 feet, the sliver of the last drawing, will also weigh a pound.

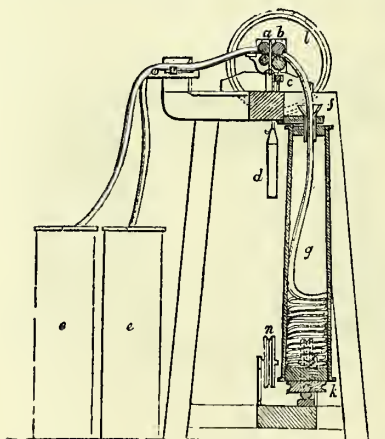

The rearmost or last drawing roller has a circumference of nearly 4 inches, and makes about 150 revolutions per minute; hence each of these drawing heads may turn off 35,000 feet of sliver in 12 hours.

Fig. 562 is a complete view of a drawing frame as manufactured by Hetherington and Sons, having the usual modern contrivances for increasing the quality and the amount of work done, viz., a stop motion behind the frame to stop the frame when a sliver breaks; a roller plate to prevent roller laps. The coiler motion, by means of which the sliver is placed in the can in circles overlapping each other on the principle described in fig. 563, the can roving frame; 4 rows of draught rollers instead of 3; and lastly, an apparatus for lifting all the roller weights from off the rollers at any time when the frame may be stopped.

A further improvement is now added to drawing frames, viz., a front stopping motion. The object of the back stopping motion is to prevent inequalities arising in the sliver from the occasional breakage of one of the slivers which are being combined together. The front one has a different purpose. It is obvious that whenever the rollers which carry forward the sliver from the front drawing rollers to the can fail to take up the cotton as fast as it is delivered, there arises an accumulation, which, from the great speed at which the sliver passes through the machine, rapidly increases. All this accumulation was formerly so far wasted that it was necessarily sent back into the mixing room to be worked over again. By the use of a front stopping motion the drawing frame is now stopped instantly, and all accumulation of this kind prevented.

Hitherto the riband or sliver has received no twist, but the fibres have lain in a linear, parallel manner, holding together in a loose mass. But in the further preparatory processes, some reduction of the thickness of the riband is necessary, so that it may gradually approach the thickness finally required in the yarn. The natural cohesion of the fibres when placed side by side will not now be sufficient to carry the sliver forward. At the next stage, therefore, a slight convolution or twist is given to it simply for this purpose. This operation takes place in the *Slubbing Frame*. The twisting should go no further than to fulfil the purpose of giving cohesion, otherwise

563

it would place an obstacle in the way of the future attenuation into level thread. The combination of drawing and twisting is what mainly characterises the spinning processes, and with this fifth operation therefore, commences the formation of yarn. As, however, a sudden extension to the wished-for fineness is not practicable, the draught is thrice repeated.

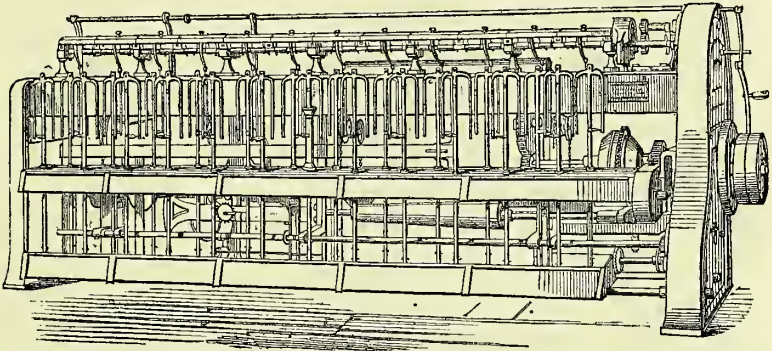

Fig. 563 is a section of the can, or lantern slubbing frame, the ingenious invention of Arkwright, which, until within the last 50 years, was the principal machine for communicating the incipient torsion to the spongy cord furnished by the drawing frame. It differs from that frame in nothing but the twisting mechanism; and consists of two pairs of drawing rollers, *a* and *b*, between which the sliver is extended in the usual way; at *e* there are brushes for cleaning the rollers; and *d* is the weight which presses the upper set upon the lower. The wiping covers

(not shown here) rest upon *a b*. The surface speed of the posterior or second pair of rollers is 3, 4, or 5 times greater than that of the front or receiving pair, ac-

ording to the desired degree of attenuation. Two drawn slivers were generally united into one by this machine, as is shown in the figure, where they are seen coming from the two cans *ee*, to be brought together by the pressure rollers, before they reach the drawing rollers *ab*. The sliver as it escapes from these rollers, is conducted into the revolving conical lantern *g*, through the funnel *f* at its top. This lantern-can receives its motion by means of a cord passing over a pulley *k*, placed a little way above the step on which it turns. The motion is steadied by the collet of the funnel *f*, being embraced by a brass busk. Such a machine generally contained four drawing heads, each mounted with two lanterns; in whose side there was a door for taking out the conical coil of roving. The motion imparted to the back roller by the band pulley or rigger *n*, was conveyed to the front one by toothed wheel-work.

The can slubbing frame has long been superseded by the *Bobbin and Fly frame*, a kind of machine which, with some modifications, is still used not only for the *Slubbing* process, but also for the two following preparatory ones, viz, *Intermediate* and *Roving*. *Figs. 564* and *565* exhibit a perspective and a sectional view of this frame. It is to be

564

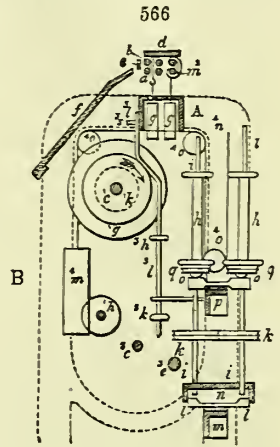

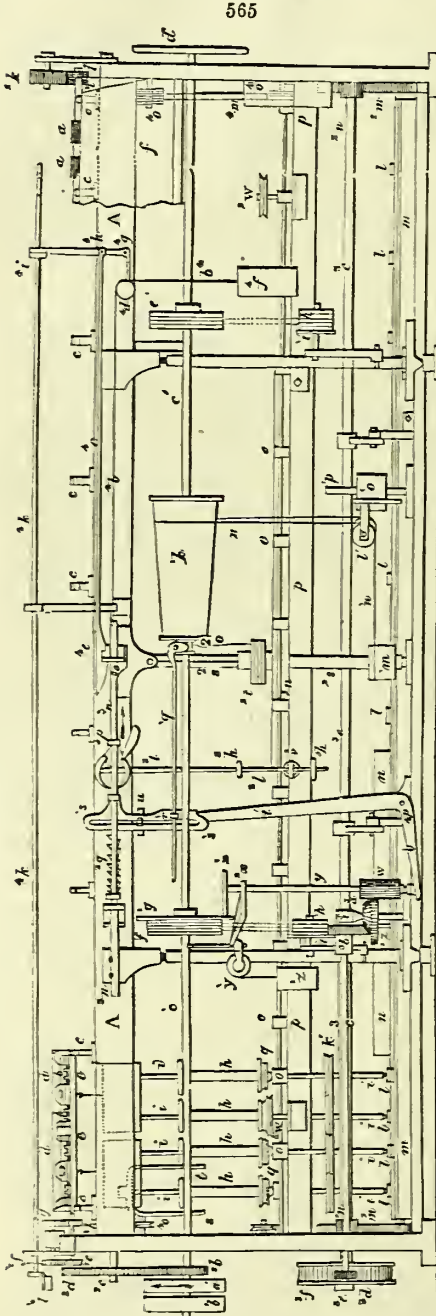

observed, however, that these illustrations, though serving well enough to explain the general construction and operation of the Bobbin and Fly frame, do not show the recent improvements, which will be described further on.

Fig. 565 exhibits a back view of this machine; and *fig. 566* a section of some of the parts not very visible in the former figure. The cotton is introduced between the drawing rollers. The cans, filled with slivers from the drawing frame, are placed in the situation marked at the back of the machine *b*, *fig. 565*, in rows parallel with the length of the machine. The sliver of each can is conducted upwards along the surface of a sloping board *f*, and through an iron staple or guide *e*, between the usual triple pair of drawing rollers, the first of which is indicated by *ab*. In *fig. 565*, for the purpose of simplifying the figure, the greater part of these rollers and their subordinate parts are omitted. After the slivers have been sufficiently extended and attenuated between the rollers, they proceed forwards, towards the spindles *iii*, where they receive the twist, and are wound upon the bobbins *h*. The machine delineated contains thirty spindles, but many bobbin and fly frames contain double or even four times that number. Only a few of the spindles are shown in *fig. 565*.

The drawing rollers in this machine do not differ essentially from those described under the section devoted to the drawing frame. This part of the machine, called the *roller beam*, is a cast-iron bench, upon which the bearers *c*, are mounted for carrying the rollers. The fluted portions of the rollers *aaa*, *fig. 567*, alternate with smooth 'necks' *zzz*. The whole length of roller is subdivided into sections. The coupling of these roller sections or subdivisions into one cylinder is secured by the square holes *x*, and square pins *y*, *fig. 567*, which fit into the holes of the adjoining subdivision. The top or pressure rollers *b*, are two-fold over the whole set; and the weighted saddle presses upon the neck *w*, which connects every pair, as was already explained under *fig. 560*.

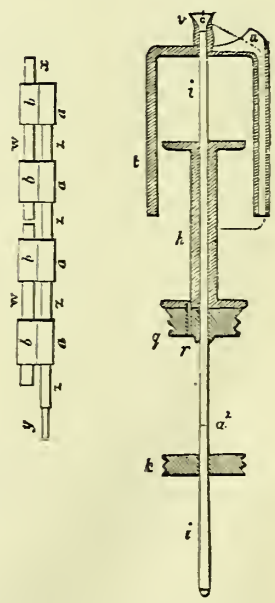

The structure and operation of the spindles *i* may be best understood by examining the section *fig. 568*. They are made of steel, are cylindrical from the top down to *a*², but from this part down to the steel tipped rounded points they are conical. The wooden bobbin *h*, slides upon the cylindrical part, which must move freely upon it, as will be presently explained. The upper end of the spindle bears a fork *s i*, which, though revolving with it, may be taken off at pleasure when the machine is standing still.

This fork or flyer, has a funnel-shaped hole at *v*. One arm of the fork is a tube *s, u*, open at top and bottom; the leg *t*, is added merely as a counterpoise to the other.

567

568

In *fig. 566*, for the sake of clearness, the forks or flyers of the two spindles here represented are left out; and in *fig. 565* only one is portrayed for the same reason. If

we suppose the spindles and bobbins (both of which have independent motions) to revolve simultaneously and in the same direction, their operation will be as follows: The sliver properly drawn by the fluted rollers, enters the opening of the funnel, proceeds thence downwards through the hole in the arm of the fork, runs along its tube u , s , and then winds round the bobbin. This path is marked in *fig. 568* by a dotted line.

The revolution of the spindles in the above circumstances twists the sliver into a soft cord; and the flyer s , t , or particularly its tubular arm s , lays this cord upon the bobbin. Were the speed of the bobbins equal to that of the spindles, did the bobbin and spindle make the same number of turns in the same time, the process would be limited to mere twisting. But the bobbin makes in a given time a somewhat greater number of revolutions than the spindle, and thus the cord is wound upon it. Suppose the bobbin to make 40 revolutions, while the spindles make only 30; 30 of these revolutions of the bobbin will be inoperative towards the winding-on, because the flyers follow at that rate, so that the cord or twisted sliver will only be coiled 10 times round the bobbin, and the result as to the winding-on will be the same as if the spindle had stood still, and the bobbin had made $40 - 30 = 10$ turns. The 30 turns of the spindles serve, therefore, merely the purpose of communicating twist.

Simple as the winding-on process may seem, a little reflection will show that there are complications involved in it which do not at first sight appear. It must be observed, in the first place, that as the cord is wound on the bobbin, the diameter of the latter increases with every succeeding layer of cord put upon it, and the length taken up by each turn becomes continually greater. It is, therefore, necessary so to reduce the number of revolutions of the bobbin as that they may not stretch nor break the cord by taking it up faster than it is delivered from the fluted rollers. A second point to be noticed is, that in order to secure a proper distribution of the cord upon the bobbin, and the regular increase of its diameter, two of its successive convolutions should not be applied over each other, but that they should be laid close side by side. This object is attained by the slowly ascending and descending motion of the bobbin upon the spindle. This up-and-down motion must become progressively slower, since it increases the diameter of the bobbin at each range by a quantity equal to the diameter of the sliver. What has now been stated generally will become more intelligible by an example.

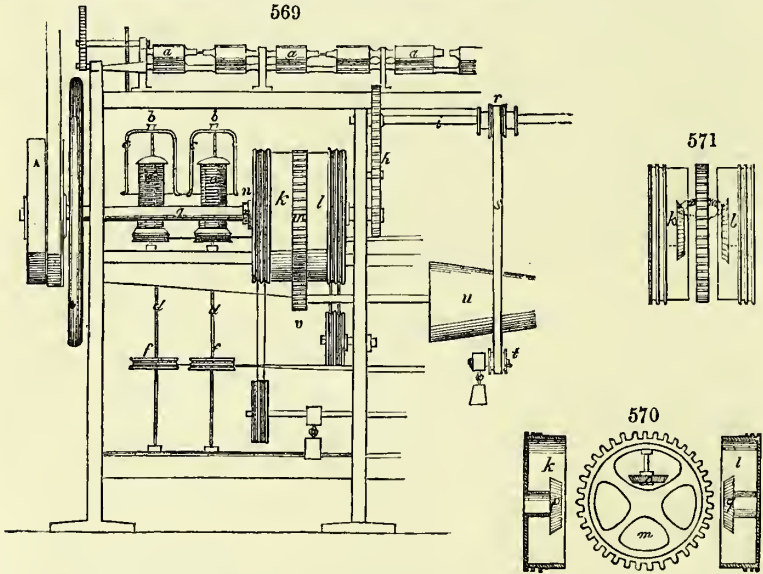

Let it be assumed that the drawing rollers deliver, in 10 seconds, 45 inches of roving, and that this length receives 30 twists. The spindles must, in consequence, make 30 revolutions in 10 seconds, and the bobbins must turn with such speed, that they wind up the 45 inches in 10 seconds. The diameter of the bobbin barrels being $1\frac{1}{2}$ inch, their circumference of course $4\frac{1}{2}$ inches, they must make 10 revolutions more in the same time than the spindles. The effective speed of the bobbins will be thus $30 + 10 = 40$ turns in 10 seconds. Should the bobbins increase to 3 inches diameter, by the winding-on of the sliver, they will take up 9 inches at each turn, and consequently 45 inches in 5 turns. Their speed should therefore be reduced to $30 + 5 = 35$ turns in 10 seconds. In general, the excess in number of revolutions which the bobbins must make over the spindles is inversely as the diameter of the bobbins. The speed of the bobbins must remain uniform during the period of one ascent or descent upon their spindle, and must diminish at the instant of changing the direction of the up-and-down motion; because a fresh range of convolutions then begins with a greater diameter.

The motions of the drawing rollers, the spindles, and bobbins are produced in the following manner:—A shaft c , *figs. 565* and *566*, extending the whole length of the machine, and mounted with a fly-wheel d , is set in motion by a band from the running pulley upon the shaft of the mill, which actuates the pulley a' . b is the loose pulley upon which the band is shifted when the machine is set at rest. Within the pulley a' , but on the outside of the frame, the shaft c' carries a toothed wheel b^2 , which by means of the intermediate wheel c^2 turns the wheel d^2 upon the prolonged shaft of the backmost fluted roller (m^2 , *fig. 566*). This wheel, d^2 , may be changed for one with a greater or less number of teeth when the cotton is to receive more or less twist; for as the spindles revolve with uniform velocity, they communicate the more torsion the less length of sliver is delivered by the rollers in a given time. Upon the same shaft with d^2 , a pinion, e^2 , is fixed, which works in a wheel, f^2 . Within the frame another changeable toothed wheel, or 'change pinion' g^2 , is made fast to the shaft of f^2 . This pinion regulates the drawing, and thereby the fineness or *number* of the roving. It works in a wheel, h^2 , upon the end of the backmost fluted roller a , *fig. 566*. The other extremity of the same roller, or, properly speaking, line of holder and the pulley is sufficient to distend the endless band n' , which runs from the cone k' , through under the pulley l' , and round the small drum m' on the shaft s^2 . A pulley or whorl t^2 with four grooves, is made fast by means of a tube to this shaft, and slides along it backwards and forwards, without ever ceasing to follow its revolutions. The shaft pos-

esses for this purpose a long fork, and the interior of the tube a corresponding tongue or catch. There is besides upon the tube beneath the pulley, at u^2 , a groove that goes round it, in which the staple or forked end of an arm like v^2 , *fig. 565*, made fast to the copping beam p , catches. By the up-and-down movement of that beam, the pulley t^2 takes along with it the arm that embraces the tube, which therefore rises and falls equally with the bobbins h' , and their pulleys or whorls q . This is requisite, since the bobbins are made to revolve by the pulleys t^2 by means of two endless cords or bands.

Such was the bobbin and fly frame prior to the improvements introduced by Mr. H. Houldsworth in the 'equation box' mechanism and the 'spring fingers.' By means of the former the differential movement of the bobbins already referred to was accomplished with much greater precision and neatness than previously. The object of the latter was, by laying the soft cord or sliver upon the bobbin with a certain degree of pressure, to put an increased weight of cotton upon it, and thus to save some portion of the time and labour lost in the then frequent operations of 'doffing' or removing the full bobbins and placing empty ones in their places.

Fig. 569 represents a portion of a fly frame with Mr. Houldsworth's invention.

$a a a$ are the front drawing rollers, turning upon bearings in the top of the machine, and worked by a train of toothed wheels, in the way that drawing rollers are usually actuated. From the drawing rollers, the filaments of cotton are brought down to $b b$, and passed through the arms of the flyers $e c$, mounted on the tops of the spindles $d d$, which spindles also carry the loose bobbins $e e$. According to the former mode of constructing such machines, the spindles were turned by cords or bands passing from a rotatory drum round their respective pulleys or whorls f , and the loose bobbins e , turned with them by the friction of their slight contact to the spindle, as before said; in the improved machine, however, the movements of the spindles and the bobbins are independent and distinct from each other, being actuated from different sources.

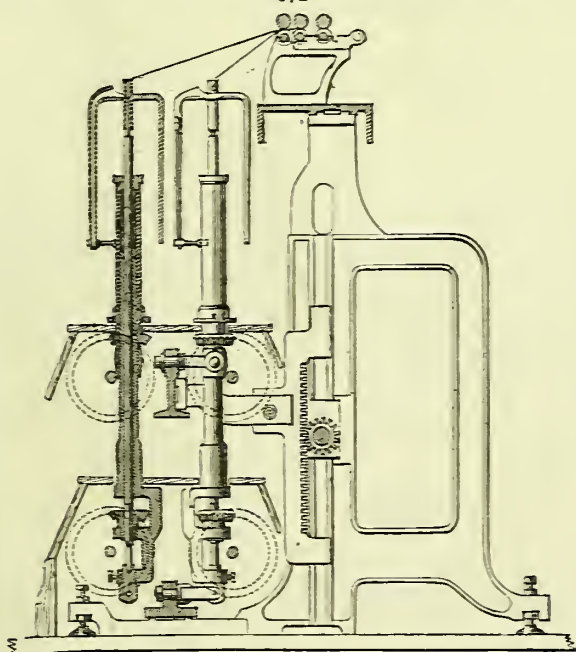

The main shaft g , turned by a band and rigger A as usual, communicates motion by a train of wheels h , through the shaft i , to the drawing rollers at the reverse end of the machine, and causes them to deliver the filaments to be twisted. Upon the main shaft g , is mounted a cylindrical hollow box or drum pulley, whence one cord passes to drive the whorls and spindles f and d , and another to drive the bobbins e . This cylindrical box pulley is made in two parts, k and l , and slipped upon the axle with a toothed wheel m , intervening between them. The box and wheel are shown detached in *fig. 570*, and partly in section at *fig. 571*. That portion of the box with its pulley marked l , is fixed to the shaft g ; but the other part of the box and its pulley k , and the toothed wheel m , slide loosely round upon the shaft g , and when brought in contact and confined by a fixed collar n , as in the machine shown at *fig. 569*, they constitute two distinct pulleys, one being intended to actuate the spindles, and the

other the bobbins. In the web of the wheel *m*, a small bevel pinion *o*, is mounted upon an axle standing at right angles to the shaft *g*, which pinion is intended to take into the two bevel pinions *p* and *q*, respectively fixed upon bosses, embracing the shaft in the interior of the boxes *k* and *l*. Now it being remembered that the pinion *q*, and its box *l*, are fixed to the shaft *g*, and turn with it, if the loose wheel *m* be independently turned upon the shaft with a different velocity, its pinion *o*, taking into *q*, will be made to revolve upon its axle, and to drive the pinion *p* and pulley box *k*, in the same direction as the wheel *m*; and this rotatory movement of the box *k* and wheel *m*, may be faster or slower than the shaft *g*, and box *l*, according to the velocity with which the wheel *m* is turned.

The main shaft *g*, being turned by the band and rigger *a*, as above said, the train of wheels *h*, connected with it, drives the shaft *i*, which at its reverse end has a pinion (not seen in the figures) that actuates the whole series of drawing rollers *a*. Upon the shaft *i* there is a sliding pulley *r*, carrying a band *s*, which passes down to a tension pulley *t*, and is kept distended by a weight. This band *s*, in its descent, comes in contact with the surface on the cone *u*, and causes the cone to revolve by the friction of the band running against it. The pulley *r* is progressively slidden along the shaft *i*, by means of a rack and weight not shown, but well understood as common in this kind of machines, and which movement of the pulley is for the purpose of progressively shifting the band *s* from the smaller to the larger diameter of the cone, in order that the speed of its rotation may gradually diminish as the bobbins fill by the winding-on of the yarns.

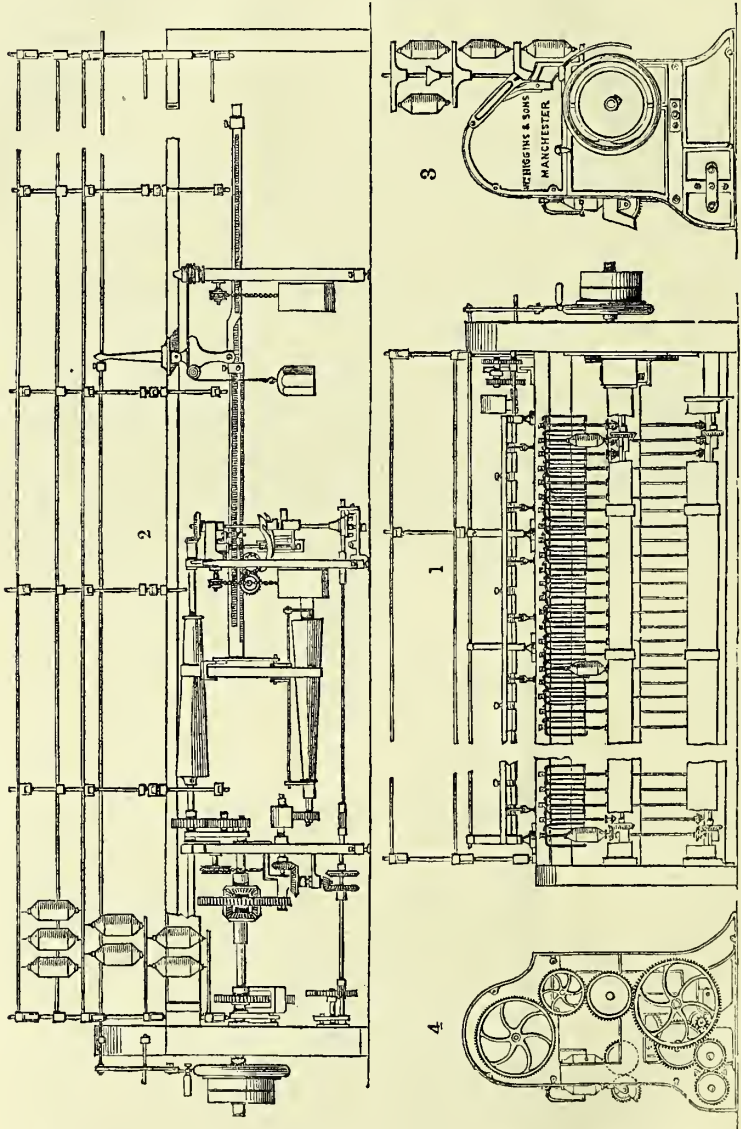

At the end of the axle of the cone *u* a small pinion *v* is fixed, which takes into the teeth of the loose wheel *m*, and as the cone turns, drives the wheel *m* round upon the shaft *g*, with a speed dependent always upon the rapidity of the rotation of the cone. Now the box pulley *l*, being fixed to the main shaft *g*, turns with one uniform speed, and by cords passing from it over guides to the whorls *f*, drives all the spindles and flyers, which twist the yarns with one continued uniform velocity; but the box pulley *k*, being loose upon the shaft, and actuated by the bevel pinions within, as described, is made to revolve by the rotation of the wheel *m*, independent of the shaft, and with a different speed from the pulley box *l*; cords passing from this pulley box *k*, over guides to small pulleys under the bobbins, communicate the motion, whatever it may be, of the pulley box *k*, to the bobbins, and cause them to turn, and to take up or

572

wind the yarn with a speed derived from this source, independent of, and different from, the speed of the spindle and flyer which twist the yarn.

It will now be perceived, that these parts being all adjusted to accommodate the taking up movements to the twisting or spinning of any particular quality of yarn intended to be produced, any variations between the velocities of the spinning and taking up, which another quality of yarn may require, can easily be effected by merely changing the pinion *v* for one with a different number of teeth, which will cause the

wheel *m*, and the pulley box *k*, to drive the bobbins faster or slower, as would be required in winding-on fine or coarse yarn, the speed of the twisting or spinning being the same.

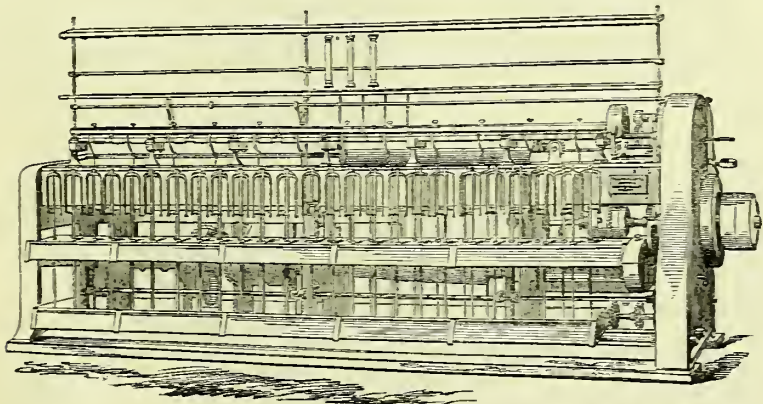

The bobbin and fly frame as thus detailed is now no longer constructed; but it seemed desirable, if not necessary, to describe with some minuteness a machine which

has formed the basis of the more modern *slubbing*, *intermediate*, and *roving* frames. These three operations, which follow each other in the order named, come next after that of drawing. They have one common object, to gradually attenuate the sliver until it is at last sufficiently reduced in thickness to be advantageously spun into yarn. But the intermediate and roving processes have one other purpose, analogous to that fulfilled by the drawing frame, viz. to secure uniformity of thickness throughout by the operation of doubling. Thus two *slubbings* are united together, and are drawn out into one *intermediate slubbing*, and two *intermediate slubbings* into one *roving*.

The *slubbing* frame usually consists of from 40 to 80 spindles. Its main features will be easily comprehended after the preceding descriptions, by a glance at *fig. 572*, which presents the principal details seen in a transverse section. The sliver is brought from the drawing frame in deep cylindrical cans and placed behind the slubbing frame (on the right hand of the figure), after being drawn through the rollers in the manner already pointed out. It will be observed, however, that instead of bobbins, as in the old bobbin and fly frame, simple wooden tubes are now used. By means of the presser attached to one end of each flyer the slubbing, as the cotton sliver is now called, is built up in a solid hard mass upon the tube, not in a cylindrical form, as in the case of the bobbin, but with the ends tapering conically as shown in *fig. 573*.

The construction of the *intermediate* and *roving* frames is identical in plan, and so far as the principal working parts are concerned it is similar to that of the *slubbing* frame. In *fig. 573*, No. 1 illustrates a front sectional view of an intermediate frame, No. 2 a back view, and Nos. 3 and 4 the two ends. Here we see in the back, and in one of the end views, the spools of cotton produced by the slubbing frame, and hence called *slubbings*, placed in the 'creel' behind the frame. The 'ends' of these slubbings are now 'drawn' or attenuated in pairs through the rollers, after the fashion previously described, and are once more slightly twisted and wound upon smaller tubes than before. These when full are transferred to the creel of the *roving* frame, and there receive treatment precisely similar to that of the intermediate frame. The 'roving', as the cord is called, after passing through the roving frame is, however, much more attenuated than the 'intermediate,' and is now ready for the final spinning process—except in mills where very fine yarns are spun. In these cases, a second or fine roving or 'jack' frame is used for the purpose of again doubling and equalising the cord and further reducing its thickness. The intermediate frame usually contains from 80 to 120 spindles, and the roving frame from 120 to 200 spindles. In *fig. 574* the front view of a roving frame is given with greater completeness than is presented in *fig. 573*.

574

The earlier processes of the cotton spinning industry which we have thus traced are usually comprehended under the technical term, the 'preparation;' and it will readily be understood from even the cursory view we have endeavoured to present, that the quality of the yarn when spun will greatly depend upon the manner in which these processes are conducted. So widely is this truth recognised amongst practical spinners, that it has become almost an axiom that a bad roving can never make a good yarn. Since the 'cotton famine' which arose out of the American civil war of 1861-65, much progress has been made in the practical management of the preparatory processes. The scarcity and high price of raw cotton during the period in question, the necessity of resorting to new and inferior descriptions, their varying

characteristics, and the difficulty of adapting them to the kind of production for which American cotton had proved eminently suitable, laid upon persons engaged in cotton-spinning, at that time, a task which required much ingenuity and patience. The result has been, however, to improve greatly the technical methods used in the art, and especially as we have stated, in the details of the preparation. This end has not been reached by any fundamental alteration, but rather by a number of minor improvements, which are the result of a closer study and a better knowledge of the working qualities of the fibre in its many varieties than had previously been thought necessary, and the consequence has been a more careful and successful treatment in every part of the chain of operations under consideration.

The great object to be kept in view throughout the 'preparation' is to produce a roving as free from impurity as possible, and as uniform in weight and texture as it can be made, consistently with due economy. For the former end, the efficiency and right management of the scutching and carding machinery are requisite; for the latter a due adjustment of the draughts and doublings, regard being always had towards the fineness and quality of the yarn required.

Without attempting anything in the way of a history of cotton-spinning, it may be well to refer briefly to some of the principal stages through which this, one of the

575

earliest of the industrial occupations of civilised life, has at length reached its present advanced position. Except the spindle and distaff, the use of which was purely handicraft, the earliest contrivance for the production of yarn was the spinning wheel of ancient India (*fig. 575*), an instrument very like the common 'wheel,' which, until the dawn of this mechanical age extinguished it, was the familiar companion of every English spinster.

The first successful effort to improve upon this primitive piece of mechanism was that of James Hargreaves, who about the year 1764 invented his 'spinning jenny,' which differed little from the spinning wheel, except in enabling one person to spin simultaneously upon several spindles, instead of one.

Fig. 576 represents the original *jenny* of Hargreaves, which contained from 16 to 40 spindles. The soft cords of rovings wound in double conical cops upon skewers

576

were placed in the inclined frame at *c*; the spindles for first twisting and then winding on the spun yarn were set upright in steps and bushes at *A*, being furnished near their lower ends with whorls, and endless cords, which were driven by passing round the long-revolving drum of tin-plate, *E*. *D* is the clasp or clove, having a handle for lifting its upper jaw a little way, in order to allow a few inches of the soft roving to be introduced. The compound clove *D* being now pushed forward upon its friction wheels to *A*, was next gradually drawn backward, while the spindles were made to revolve with proper speed by the right hand of the operative turning the flywheel *B*. Whenever one *stretch* was thereby spun, the clove frame was slid home towards *A*;

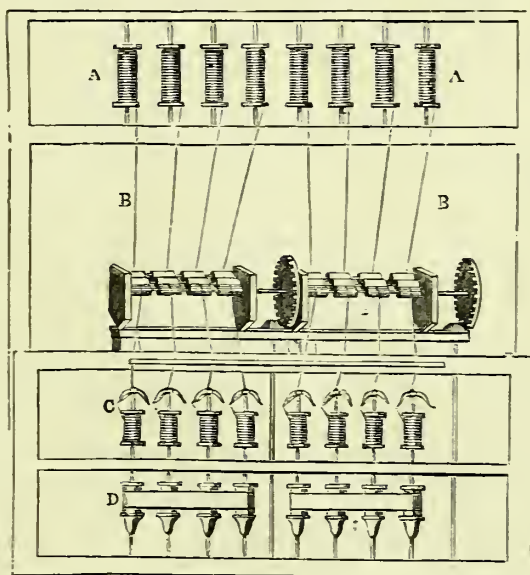

the spindles being simultaneously whirled slowly to take up the yarn, which was laid on in a conical cop by the due depression of the faller wire at *A*, with the spinner's left hand.

It will be observed that no attempt was made in Hargreaves' machine to 'draw' the cotton through rollers, which is the chief distinction between ancient and modern spinning. The discovery of this principle really preceded that of Hargreaves, and was the work of Lewis Paul of Birmingham, who, in the year 1738, took out a patent for 'spinning wool and cotton by rollers.' The patentee appears to have received important aid in the working out of the idea from John Wyatt, also of Birmingham, if indeed, the original conception be not attributable to him. It does not appear, however, that the invention attributed to Paul was ever adopted upon any large or useful scale.

We come now to the spinning machine of Arkwright, the invention of which was almost contemporaneous with that of Hargreaves' jenny.

Fig. 577 is a diagram of Arkwright's original *water-frame* spinning machine, called afterwards the *water-twist frame*. The rovings mounted upon bobbins in the creel *A A*,

577

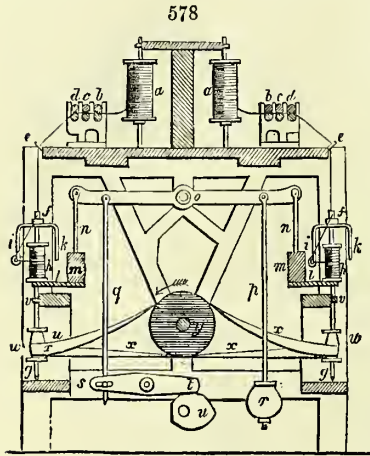

have their ends led through between the three sets of twin rollers below *B B*, thence down through the eyelet-hooks upon the end of the flyers of the spindles *c*, and finally attached to their bobbins. The spindles being driven by the band *D D* upon their lower part, continuously twist and wind the finished yarn upon the bobbins; constituting the first unremitting automatic machine for spinning which the world ever saw.

The water-twist frame, so called by its inventor because it was first driven by water, is now superseded by the *throstle* frame, of which the name has no assignable origin. *Fig. 578* exhibits a vertical section of this machine, which has upon each side of its frame, a row of spindles with all their subsidiary parts. The bobbins filled with rovings from the bobbin and fly, or the tube frame, are set up in the creel *a a*, in two ranges. *b, c, d*, are the three pairs of drawing rollers through which the yarn is attenuated to the proper degree of fineness, upon the principles already explained. At its escape from the front rollers, every thread runs through a guide eyelet *e* of wire, which gives it the vertical direction down towards the spindles *f, g*. The spindles, which perform at once and uninterruptedly the twisting and winding-on of the thread delivered by *g* in steps, pass at *v* through a brass bush or collar which keeps them upright, and revolve very rapidly upon their axes. The bobbins *h*, destined to take up the yarn as it is spun, are placed loosely upon the spindles, and rest, independently of the rotation of the spindles, upon the copping-beam *l*, but with the intervention of a strip of woollen cloth, the use of which in acting as a 'drag' upon the motion of the

bobbin will be understood by-and-bye. Upon the top of the spindles, a wire fork, called a fly or flyer, *i, k*, is made fast by

a left-hand screw, and has one of its forks turned round at the end into a little ring. The branch of the flyer at *f* is tubular, to allow the thread to pass through, and to escape by a little hole at its side, in order to reach the eyelet at the end of that fork. From this eyelet *i*, it proceeds directly to the bobbin. By the revolution of the portion of thread between the front roller *d*, and the nozzle *f*, is effected. The winding-on takes place in the following way:—Since the bobbin has no other connection with the spindle than that of the thread, it would but for it remain entirely motionless, relatively to the spindle. But the bobbin is pulled after it by the thread, so that it must follow the rotation of the spindle and fly. When we consider that the thread is pinched by the front roller *d*, and is thereby kept fully upon the stretch, we perceive that the rotation of the bobbin must be the result. Suppose now the tension to be suspended for an instant, while

the rollers *d* deliver, for example, one inch of yarn. The weight of the bobbin, and its friction upon the coping beam *l*, will, under this circumstance, cause the bobbin to hang back in a state of rest, till the inch of yarn be wound on by the whirling of the fly *i*, and the former tension be restored. The delivery of the yarn by the drawing rollers, however, does not take place, inch after inch, by starts, but at a certain continuous rate; whence results a continuous retardation or loitering, so to speak, of the bobbins behind the spindles, just to such an extent as to secure the winding of the yarn upon the bobbin as fast as it is spun.

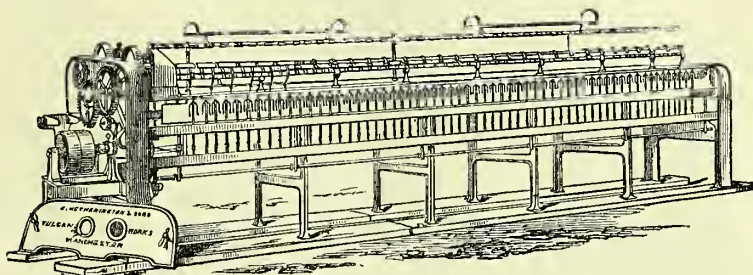

This process in spinning is essentially the same as what occurs in the fine bobbin and fly frame, but is here simplified, as the retardation regulates itself according to the diameter of the bobbin by the drag of the thread. In the fly frame the employment of this tension is impossible, because the roving has too little cohesion to bear the strain; and hence it is necessary to give the bobbins that independent movement of rotation which so complicates this machine.

The up-and-down motion of the bobbins along the spindles, which is required for the equal distribution of the yarn, and must have the same range as the length of the bobbin barrels, is performed by the following mechanism:—Every coping rail *l*, is made fast to a bar *m*, and this, which slides in a vertical groove or slot at the end of the frame, is connected by a rod *n*, with an equal-armed, moveable lever *o*. The rod *p* carries a weight *r*, suspended from this lever; another rod *q*, connects the great lever *o*, with a smaller one *s, t*, upon which a heart-shaped disc or pulley *u*, works from below at *t*. By the rotation of the disc *u*, the arm *t*, being pressed constantly down upon it by the reaction, the weight *r* must alternately rise and fall; and thus the coping rail *l* must obviously move with the bobbins *h* up and down; the bobbins upon one side of the frame rising, as those upon the other sink. Strictly considered, this coping motion should become slower as the winding-on proceeds, as in the fly-roving frame; but, on account of the smallness of the finished thread, this construction, which would render the machine complicated, is without inconvenience neglected, with the result merely that the coils of the yarn are successively more sparsely laid on, as the diameter of the bobbin increases. The movement of the whole machine proceeds from the shaft of a horizontal drum, which drives the spindles by means of the endless bands *x x*. Each spindle is mounted with a small pulley or wharf *w*, at its lower part, and a particular band, which goes round that wharf or whorl, and the drum *y*. The bands are not drawn tense, but hang down in a somewhat slanting direction, being kept distended only by their own weight. Thus every spindle, when its thread breaks, can readily be stopped alone, by applying a slight pressure with the hand or knee, the band meanwhile gliding loosely round the whorl. A more complete view of the throstle frame is presented by *fig. 579*.

Several modifications of the throstle have been attempted, but very few of any importance have stood the test of experience, at least, in England. The Danforth throstle, invented in 1829, had for its main object to increase the speed of the spindles, and so to enlarge the productive capacity of the machine. It failed, however, amongst

other reasons, for the very sufficient ones that it required much more power than the ordinary throstle, and that it could not be stopped without causing 'snarls' or twisted tangles in the yarn. The Montgomery throstle, introduced in 1832, was more successful. In this machine the spindle does not revolve, but is stationary, the flyer revolving

579

round it and winding the yarn upon the bobbins in the usual manner. It is said to produce good yarn, and although it has been discarded in this country, it still holds its ground in the United States. Perhaps the most remarkable, as well as one of the most recent improvements in the throstle frame is that of Bernhardt's 'doffing-motion.' The labour of 'doffing' or taking off the bobbins when filled with yarn, as well as the substituting of empty ones in their places, is usually accomplished by boys, who, notwithstanding the agility with which they perform the operation, necessarily keep the machine for a considerable time standing still. This loss of time, as well as the labour of the 'doffers,' is abolished by Bernhardt's invention. For a full description of this ingenious contrivance, we refer the reader to Mr. Evan Leigh's 'Science of Modern Cotton Spinning' (Manchester, 1873). The same work contains also a very full account of the ring throstle spinning frame, which in its various forms has taken deep root in the United States, and is beginning to find appreciation even in English mills, where there was formerly a strong prejudice against it.

It may be as well here to explain what is meant by the 'counts' or 'numbers of yarn. It is obvious that in all the textile industries some plan of indicating the varying thickness of the yarns is absolutely necessary. At present the methods employed are different in various countries, and, even in the same country, the systems used in the principal textiles are not identical, cotton, linen, silk, and jute having as a rule each a separate system. But all these methods are found to rest at bottom in one of two principles: First, the adoption of a fixed length as a standard, the counts being expressed by the weight of this fixed length in any given example. This plan is rarely followed, except in the case of silk, in which therefore the higher the counts the coarser is the thread. The other principle is founded upon a fixed unit of weight, and determines the counts by the length required to reach that weight. On this plan the numbering of all other kinds of yarns proceeds in nearly every country. In cotton yarns the English system has the pound (Avoirdupois) for the unit of weight and the 'hank' of 840 yards for the unit of length, and the counts is determined by the number of hanks which in any given case is needed to make up one pound in weight. The French system adopts the half kilogramme (equal to 1 lb. 1½ oz.) as the unit of weight and the hank of 1,000 mètres (1,093 yards 22 inches) as the unit of length. The English system is exclusively used in this country, in America, in India, and in a portion of the Continent. The French system prevails in France, in Alsace, and in some portions of Germany, Austria, and Italy. An effort, originating at the Vienna Exhibition of 1873, has been made to secure a uniform method in the numbering of yarns. No definite agreement has yet been arrived at, but in France, and in Alsace there is a strong desire that the French or 'metric' system should be generally adopted. The method of practically testing the counts of yarn is this:—A short length of the sample to be tested is wound upon a carefully-adjusted measuring apparatus called a 'wrap-reel,' and then weighed by means of small delicately balanced scales. The fineness is then easily determined by calculation or by reference to a previously-compiled table of equivalents.

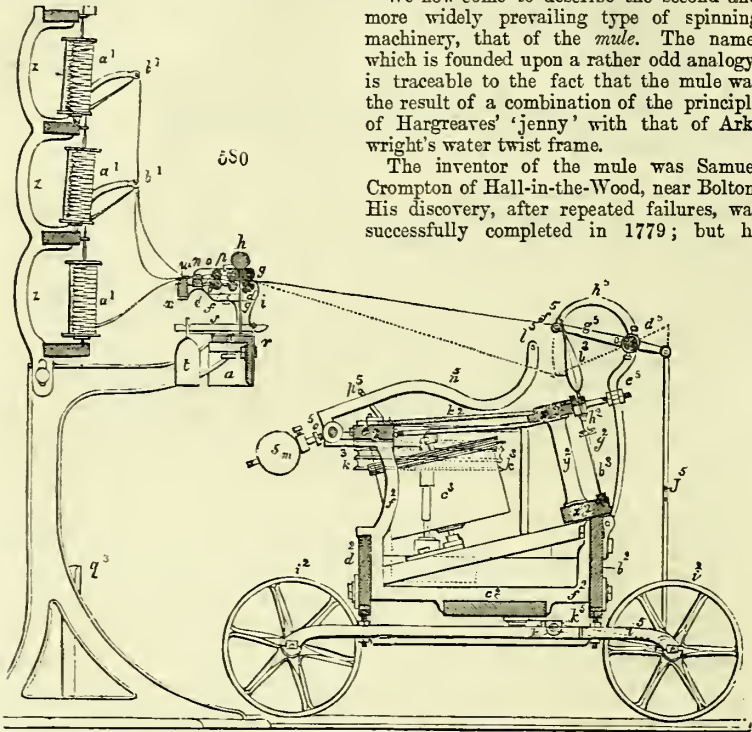

Yarn spun upon the *throstle* frame needs to be made very strong in order that it may resist the strain produced by the 'drag' of the bobbin whilst being spun. On this account the throstle can seldom be employed with advantage in spinning the finer and more delicate yarns. As a matter of fact, it is scarcely ever used in the produc-

tion of counts finer than No. 36's. Moreover, it is necessary that throstle yarn, for the reason just stated, should be highly twisted, should receive a comparatively large number of turns or twists per inch, and hence its principal characteristic is its hard, wiry and closely compact appearance. On this account it is especially suitable for the manufacture of goods which cannot be woven without much strain upon the warp, or which when finished need to be very durable.

Besides the special characteristics of throstle yarn to which we have alluded, and which greatly limit its applicability, one other must be noticed, viz. the smallness of the rate of production. This, it is obvious, increases the cost of spinning, and the throstle is therefore rarely employed, except where yarn is required possessing the characteristics already indicated.

We now come to describe the second and more widely prevailing type of spinning machinery, that of the *mule*. The name, which is founded upon a rather odd analogy, is traceable to the fact that the mule was the result of a combination of the principle of Hargreaves' 'jenny' with that of Arkwright's water twist frame.

The inventor of the mule was Samuel Crompton of Hall-in-the-Wood, near Bolton. His discovery, after repeated failures, was successfully completed in 1779; but he

reaped only a slender pecuniary reward from it, not being able to keep his secret long, nor to pay the cost of securing a patent-right in it. The beneficial results of Crompton's labours upon the economy of manufactures have, however, placed his name in the front rank of inventors. He received a parliamentary grant of 5,000*l.* a sum which, when compared with what he might have obtained under the protection of a patent, was insignificant. A statue to his memory was erected in Bolton in the year 1857, thirty years after his death.

It will have been already observed that the spinning operation, as carried on by means of the throstle is continuous, that is to say, the motion of the rollers, the spindles, and the bobbin goes on simultaneously, and the cotton is drawn, twisted and wound upon the bobbin without intermission during the whole of the time that the machine is at work. In the mule, on the contrary, the action is intermittent or rather alternate. A given length is first drawn and spun, then the motion of the rollers ceases, the spindles stop spinning, and proceed to wind up the length that has been spun. Spinning is then resumed and the alternate movements are repeated *ad libitum*. The details of this process will be readily understood on reference to *fig. 580*, which is a transverse section of the mule, and in which its principal parts are shown. The machine consists of two main sections: a fixed one, corresponding in some measure to the water frame or throstle, and a moveable one, corresponding to the jenny. The first contains in a suitable frame the drawing roller-beam and the chief moving

machinery; the second is called the carriage, in which the remainder of the moving mechanism and the spindles are mounted.

The frame of the fixed part consists of two upright sides, and two or more intermediate parallel bearings, upon which the horizontal roller beam a , the basis of the drawing rollers is supported. b, c, d are the three ranges of fluted iron rollers; e, f, g , are the upper iron rollers covered with leather; h , the wooden wiper-rollers, covered with flannel, which being occasionally rubbed with chalk, imparts some of it to the pressure rollers beneath, so as to prevent the cotton filaments adhering to them.

The skewers upon which the bobbins containing the rovings from the roving frame are set up are seen at a^1, a^1, a^1 , arranged in three rows in the creel z . The soft threads unwound from these bobbins, in their way to the drawing rollers, pass first through eyelets in the ends of the wire arms b^1 , then through the rings or eyes of the guide bar w , and enter between the back pair of rollers. The number of these bobbins is equal to the number of spindles in the mule, and twice as great as the number of fluted portions of the rollers; for two threads are assigned to each portion.

The carriage consists of two cast-iron side pieces, and several cast-iron intermediate similar pieces, such as f^2 , which altogether are made fast to the planks b^2, c^2, d^2 . The top is covered in with the plank k^2 . The carriage runs by means of its cast-iron grooved wheels, upon the cast-iron railway l , which is fixed level on the floor.

The spindles stand upon the carriage in a frame, which consists of two slant rails x^2, x^2 , connected by two slender rods y^2 , and which frame may be set more or less obliquely. The lower rail carries the brass steps for the points of the spindles b^2 ; upon the upper rail brass slips are fixed pierced with holes through which the tops of the spindles play. The spindles are as usual made of steel, perfectly straight, turned truly round, and are all arranged in one plane. To each of them a small wooden or cast-iron whorl g^2 is made fast. They are distributed into groups of 24, and the whorls are arranged at such different heights, that only two of them in each group are upon a level with each other. A small brass head h^2 , which every spindle has beneath the upper slant rail of the frame x^2 , prevents their sitting down into the step during their rotation, or sliding off their cop of yarn.

c^3 are drums, mounted in the carriage in a plane at right angles to the plane in which the spindles are placed. At top they have a double groove for a cord to run in, and the motion which they receive from the great fly wheel, or rim of the mule (not visible in this view) they impart to the spindles. Such a drum is assigned to every 24 spindles; and therefore a mule of 480 spindles contains 20 drums. In the middle of the carriage is seen the horizontal pulley k^3 , furnished with three grooves, which stands in a line with the drums c^3 .

The motion is given to the drums c^3 , upon the right hand half of the carriage by a single endless band or cord which proceeds from the middle groove of the pulley k^3 . The rotation of the spindles is produced by a slender cord, of which there are 12 upon each drum c^3 ; because every such cord goes round the drum, and also every two wharves which stand at the same level upon the spindles. It is obvious that the drums, and consequently the spindles, must continue to revolve as long as the main rim of the mule is turned, whether the carriage be at rest or in motion upon its railway.

If we suppose the carriage to be run in to its standing point, or to be pushed home to the spot from which it starts in spinning, its back plant d^2 will strike the post q^3 upon the fixed frame, and the points of the spindles will be close in front of the roller beam. The rollers now begin to turn and to deliver threads, which receive immediately a portion of their twist from the spindles; the carriage retires from the roller beam with somewhat greater speed than the surface speed of the front rollers, whereby the threads receive a certain degree of stretching, which affects most their thicker and less twisted portions and thereby contributes greatly to the levelness of the yarn. When the carriage has run out to the end of its course, or has completed a stretch, the fluted rollers suddenly cease to revolve (and sometimes even earlier, when a second stretch is to be made), but the spindles continue to whirl till the fully extended threads have received the proper second or after twist. Then the carriage must be put up, or run back towards the rollers, and the threads must be wound upon the spindles. This is the order of movements which belong to the mule. It has been shown how the rotation of the spindles is produced.

For winding-on the yarn the carriage has a peculiar apparatus, which we shall now describe. In front of it, through the whole extent to the right hand as well as the left, a slender iron rod, d^3 , runs horizontally along, in a line somewhat higher than the middle of the coping portion of the spindles, and is supported by several props, such as e^3 . Upon each end of the two rods, d^3 , there is an arm, g^3 ; and betwixt these arms an iron wire, called the coping wire, f^3 , is stretched, parallel with the rod d^3 . For the support of this wire, there are several slender bent arms h^3 extended from the

rod d^5 at several points betwixt the straight arms g^5 . The rod d^5 has, besides, a wooden handle at the place opposite to where the spinner stands, by which it can be readily grasped. This movement is applied at the left division of the machine, and it is communicated to the right by an apparatus which resembles a crane's bill. The two arms, g^5 , in the middle of the machine, project over the rods d^5 , and are connected by hinges with two vertical rods j^5 , which hang together downwards in like manner with two arms k^5 , proceeding from a horizontal axis l^5 .

By means of that apparatus the yarn is wound upon the spindles in the following manner:—As long as the stretching and twisting go on, the threads form an obtuse angle with the spindles, and thereby slide continually over their smooth rounded tips during their revolution, without the possibility of coiling upon them. When, however, the spinning process is completed, the spinner seizes the carriage with his left hand and pushes it back towards the roller beam, while with his right hand he turns round the handle of the rim or fly wheel, and consequently the spindles. At the same time, by means of the handle upon the rod d^5 , he moves the copping-wire f^5 , so that it presses down all the threads at once, and places them in a direction nearly perpendicular to the spindles; as shown by the dotted line y^5 . That this movement of the copping wire, however, may take place without injury to the yarn, it is necessary to turn the rim beforehand a little in the opposite direction, so that the threads may get uncoiled from the upper parts of the spindles, and become slack; an operation called in technical language the *backing-off*. The range upon which the threads should be wound, in order to form a conical cop upon the spindle, is hit by depressing the copping wire to various angles, nicely graduated by an experienced eye. This faller wire alone is not, however, sufficient for the purpose of winding-on a seemly cop, as there are always some loose threads which it cannot reach without breaking others.

Another wire called the *counter-faller*, l^5 , must be applied under the threads. It may be raised to an elevation limited by the angular piece p^5 ; and is counterpoised by a very light weight m^5 , applied through the bent lever n^5 , which turns upon the fulcrum o^5 . This wire, which applies but a gentle pressure, gives tension to all the threads, and brings them regularly into the height and range of the faller f^5 . This wire, must be raised once more, whenever the carriage approaches the roller beam. At this instant a new stretch commences; the rollers begin again to revolve, and the carriage resumes its former course. These motions are performed by the automatic machinery.

There is a little excentric pulley mechanism for moving the guide beam to and fro with the soft yarns, as they enter between the back rollers. On the right hand end of the back roller shaft, a worm screw is formed which works into the oblique teeth of a pinion attached to the end of the guide beam, in which there is a series of holes for the passage of the threads, two threads being assigned to each fluted roller. In the flat disc of the pinion, an excentric pin stands up which takes into the jointed lever upon the end of the guide beam, and as it revolves, pushes that beam alternately to the left and the right by a space equal to its excentricity. This motion is exceedingly slow, since for each revolution of the back roller, the pinion advances only by one tooth out of the 33, which are cut in its circumference.

After counting the number of teeth in the different wheels and pinions of the mule, or measuring their relative diameters, it is easy to compute the extension and twist of the yarns; and when the last fineness is given to ascertain their marketable value. Let the ratio of speed between the three drawing rollers be $1 : 1\frac{3}{22} : 7\frac{1}{2}$; and the diameter of the back and middle roller three quarters of an inch: that of the front roller one inch; in which case the drawing is thereby increased $1\frac{1}{3}$ time, and $7\frac{1}{2} \times 1\frac{1}{3} = 10$. If the rovings in the creel bobbins have been No. 4, the yarn, after passing through the rollers, will be No. 40. By altering the change pinion (not visible in this view) the fineness may be changed within certain limits, by altering the relative speed of the rollers. For one revolution of the great rim or fly wheel of the mule, the front roller makes about 6-tenths of a turn, and delivers therefore 22·6 lines or 12ths of an inch of yarn, which, in consequence of the tenfold draught through the rollers, corresponds to 2·26 lines of roving fed in at the back rollers. The spindles or their whorls make about 66 revolutions for one turn of the rim. The pulleys or grooved wheels on which the carriage runs, perform 0·107 part of a turn while the rim makes one revolution, and move the carriage 24·1 lines upon its rails, the wheels being six inches in diameter.

The 22·6 lines of soft yarn delivered by the front rollers will be stretched $1\frac{1}{3}$ line by the carriage advancing 24·1 lines in the same time. Let the length of the railway, or of each stretch be 5 feet, the carriage will complete its course after 30 revolutions of the rim wheel, and the 5-foot length of yarn (of which $56\frac{1}{2}$ inches issue from the drawing rollers, and $3\frac{1}{2}$ inches proceed from the stretching) is, by the simultaneous whirling of the spindles, twisted 1,980 times, being at the rate of 33 twists for every inch. The second twist, which the threads receive after the carriage has come to

repose, is regulated according to the quality of the cotton wool, and the purpose for which the yarn is spun. For warp yarn of No. 40 or 50, for example, 6 or 8 turns of the rim wheel, that is, from 396 to 528 whirls of the spindles for the whole stretch, therefore from 7 to 9 twists per inch, will be sufficient. The finished yarn thus receives from 40 to 42 twists per inch.

One spinner attends to two mules, which face each other, so that he need merely turn round in the spot where he stands, to find himself in the proper position for the other mule. For this reason the rim wheel and handle, by which he operates, are not placed in the middle of the length of the machine, but about two-fifths of the spindles are to the right hand and three-fifths to the left; the rim wheel being towards his right hand. The carriage of the one mule is in the act of going out and spinning, while that of the other is finishing its twist, and being put up by the spinner.

The quantity of yarn manufactured by a mule in a given time, depends directly upon the number of the spindles, and upon the time taken to complete every stretch of the carriage. Many circumstances have an indirect influence upon that quantity, and particularly the degree of skill possessed by the spinner. The better the machine, the steadier and softer all its parts revolve, the better and more abundant is its production. When the toothed wheels do not work truly into their pinions, when the spindles shake in their bushes, or are not accurately made, many threads break, and the work is much injured and retarded. The better the staple of the cotton wool, and the more careful has been its preparation in the carding, drawing, and roving processes, the more easy and excellent the spinning will become: warmth, dryness, cold, and moisture have great influence on the ductility, so to speak, of cotton. A temperature of 65° F., with an atmosphere not too arid, is found most suitable to the operations of a spinning-mill. The finer the yarn, the slower is the spinning. For numbers from 20 to 36, from 2 to 3 stretches of warp may be made in a minute, and nearly 3 stretches of weft; for numbers above 50 up to 100, about 2 stretches; and for numbers from 100 to 150 one stretch in the minute. Still finer yarns are spun more slowly, which is not wonderful, since in the fine spinning-mills of England, the mules usually contain upwards of 500 spindles each, in order that one operative may manage a great number of them, and thereby earn such high wages as shall fully remunerate his assiduity and skill.

In spinning fine numbers, the second speed is given before the carriage is run out to the end of its railway; during which course of about 6 inches, it is made to move very slowly. This is called the second stretch, and is of use in making the yarn level by drawing down the thicker parts of it, which take on the twist less readily than the thinner, and therefore remain soft and more extensible. The stretch may therefore be divided into three stages. The carriage first moves steadily out for about 4 feet, while the drawing rollers and spindles are in full play; now the rollers stop, but the spindles go on whirling with accelerated speed, and the carriage advances slowly, about 6 inches more; then it also comes to rest, while the spindles continue to revolve for a little longer, to give the final degree of twist. The acceleration of the spindles in the second and third stages, which has no other object but to save time, is effected by the mechanism called the *counter*, which shifts the driving band, at the proper time, upon the loose pulley, and, moreover, a second band, which had, till now, lain upon its loose pulley, upon a small driving pulley of the rim shaft. At length, both bands are shifted upon their loose pulleys, and the mule comes to a state of quiescence.

In the machine as thus described the winding-in motion is performed by means of the necessary mechanism, by manual labour. This method is, however, now used only in the spinning of the very finest yarns, and the winding-on is performed by an automatic arrangement which gave to the machines to which it was first applied the name of *self-acting mules*. Mules of this kind were first constructed, we believe, by Messrs. Eaton, formerly of Manchester, who mounted ten or twelve of them in that town, four at Wilm, in Derbyshire, and a few in France. From their great complexity and small productiveness, the whole were soon relinquished, except those at Wilm. M. de Jong obtained two patents for self-acting mules, and put twelve of them in operation in a mill at Warrington, of which he was part proprietor; but with an unsuccessful result.

The first approximation to a successful accomplishment of the objects in view, was an invention of a self-acting mule, by Mr. Roberts, of Manchester: one of the principal points of which was the mode of governing the winding-on of the yarn into the form of a cop; the entire novelty and great ingenuity of which invention were universally admitted, and proved the main step to the final accomplishment of what had so long been a desideratum. For this invention a patent was obtained in 1825. In 1830, Mr. Roberts obtained a patent for other improvements; and by a combination of both his inventions, he produced a self-acting mule, which is generally admitted to have

exceeded the most sanguine expectations, and which has been extensively adopted. The advantages gained by Mr. Roberts's improvements are the saving of a spinner's wages to each pair of mules, piecers only being required, as one overlooker is sufficient to manage six or eight pairs of mules; and the production of a greater quantity of yarn, in the ratio from 15 to 20 per cent. The yarn possesses a more uniform degree of twist, and is not liable to be strained during the spinning, or in winding-on, to form the cop; consequently fewer threads are broken in these processes, and the yarn, from having fewer piecings, is more regular.

The cops are made firmer, of better shape, and with undeviating uniformity; and, from being more regularly and firmly wound, contain from one-third to one-half more yarn than cops of equal bulk wound by hand; they are consequently less liable to injury in packing or in carriage, and the expense of packages and freight (when charged by measurement) is considerably reduced. From the cops being more regularly and firmly wound, combined with their superior formation, the yarn intended for warps less frequently breaks in winding or reeling, consequently there is a considerable saving of waste in those processes.

Several improvements have been made in the construction of self-acting mules since the date of Roberts's patent, but none of them have marked so decided a step forward. The more prominent of these may be briefly noticed.

In 1834 Mr. James Smith obtained a patent for a method of dispensing with the 'backing-off motion' of Roberts. Instead of reversing the movement of the spindles, in order to clear the spindle point and arrange the thread conveniently for the winding-on process, he elevated the counter-faller and thus, whilst the spindle was stationary, 'stripped off' the spiral coil of thread from the spindle in an upward direction. This method is still in use; but as it subjects the thread to considerable strain, it is generally used only for the coarser and stouter yarns. More recently patents have been taken out for improvements in mules, by Mr. Potter, of Manchester. Messrs. Higgins and Whitworth of Salford, Mr. Montgomery of Johnstone, Messrs. Craig and Sharp of Glasgow, and many others.

Mr. Roberts's self-acting mule, which was practically the first introduced, and with several modifications in its construction, is still the mule which is most extensively used and approved in the cotton trade. Some of the more prominent of these modifications have been effected by Messrs. Parr, Curtis, and Madeley of Manchester. Of these the following summary gives the principal features, viz. the substitution of a catch-box with an eccentric box, in lieu of a cam shaft, to produce the required changes; an improved arrangement of the faller motion, which causes the fallers to act more easily upon the yarn, and not producing a recoil in them when the 'backing-off' takes place, thus preventing 'snarls' and injury to the yarn; in applying a spiral spring for the purpose of bringing the backing-off cones into contact, by which the operation of 'backing-off' can be performed with the greatest precision. The backing-off movement is also made to stop itself, and to cause the change to be made which affects the putting-up of the carriage, which it does in less time than if an independent motion was employed. They have also an arrangement for driving the back, or drawing-out shaft by gearing in such a manner that in the event of an obstruction coming in the way of the carriage going out, the motion ceases and prevents the mule being injured.

By means of a friction motion, the object of which is to take the carriage in to the rollers, the carriage will at once stop in the event of any obstruction presenting itself. For the want of an arrangement of this nature, lives have been lost and limbs injured, when careless boys have been cleaning the carriage whilst in motion, and have been caught between it and the roller beam, and thus killed or injured.

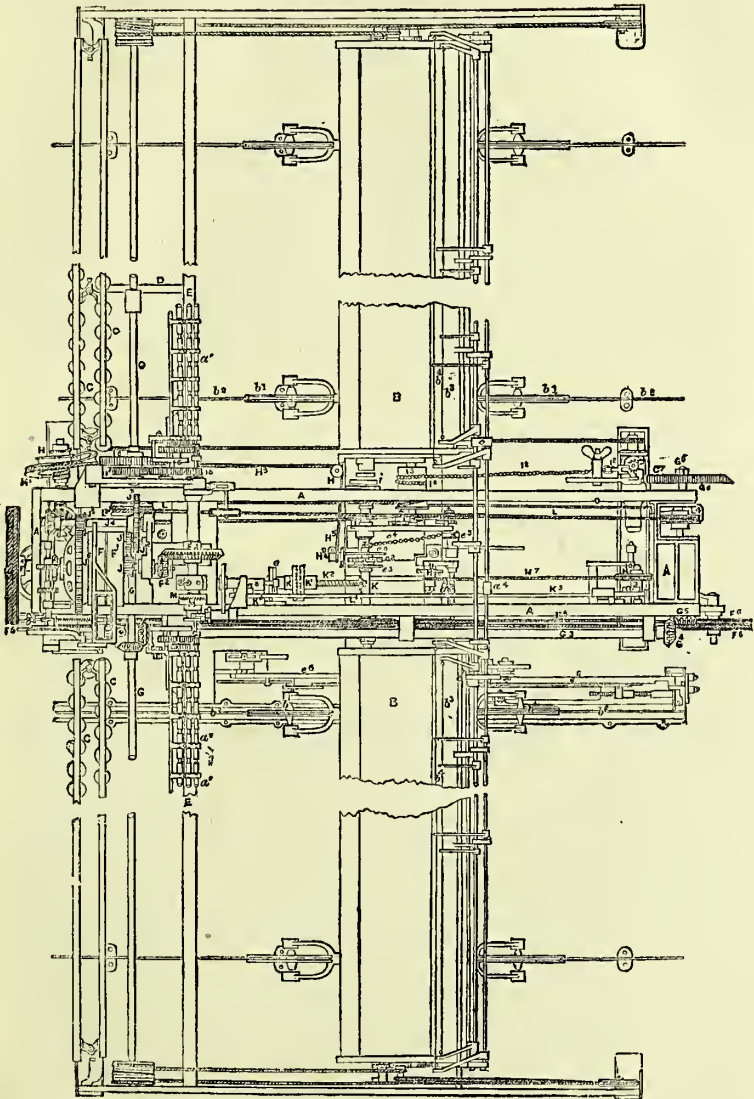

Another improvement consists in connecting the drawing-out shaft and the quadrant pinion shaft by gearing, instead of by hands, thereby producing a more perfect winding-on, as the quadrant is moved the same distance at each stretch of the carriage. They have also made a different arrangement of the headstock—or self-acting portion of the mule—causing its height to be much reduced, which makes it more steady, offers less obstruction to the light, enables the spinner to see all the spindles from any part of the mule, and allows a larger driving strap, or belt, to be used, which in low rooms is of considerable importance. The result of these various improvements is the production of one of the most perfect spinning machines now in the trade.

For spinning very coarse numbers, say 6's, they have patented an arrangement, by which the rotation of the spindles can be stopped, and the operation of backing-off performed, during the going-out of the carriage, thus effecting a considerable saving of time.

The following is a description of one of these mules:—

Fig. 581 is a plan view; *fig. 582* a transverse section; and *fig. 583* an end view, of so much of a mule as is requisite for its illustration here.

581

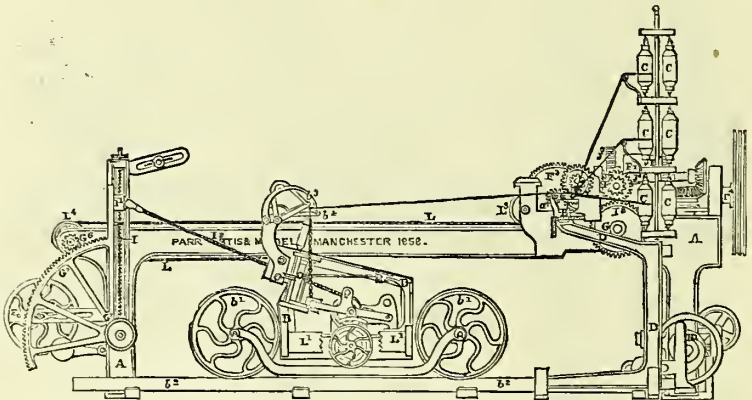

582

As there are many parts which are common to all mules, most of which have been previously described in the notice of the hand mule, we shall therefore only notice the more prominent portions of the self-acting part of the mule. Among such parts are, the framing of the headstock *A*; the carriage *B*; the rovings *c*; the supports *D*, of the roller beam *E*; the fluted rollers *a*; the top rollers *a'*; the spindles *b*; the carriage wheels *b'*; the slips, or rails, *b''*, on which they move; the faller wire *b'''*; the counter-faller wire *b''''*. The following are the parts chiefly connected with the self-acting portion of the mule:—The fast pulley *F*, the loose pulley *F'*, the bevels *F''* and *F'''*, which give motion to the fluted rollers; the back, or drawing-out shaft *G*; wheels *G'* and *G''*, by which, through the shaft *G'''* and wheels *G''''* and *G'''''*, motion is communicated to the pinion *G''''''* on the shaft *G'''''''*, and thence to the quadrant *G''''''''*. The scroll shaft *H*, the scrolls *H'* and *H''*, the catch-box *H'''*, for giving motion through the bevel wheels *H''''* and *H'''''* to the scroll shaft. Drawing-in cord *H''''''*. Screw in radial arm *I*, nut on same *I'*, winding-on chain *I''*, winding-on band *I'''*, drawing-out cord *I''''*. Pinion *J'* on front roller shaft, to give motion through the wheels *J''*, *J'''*, and *J''''*, to drawing-out shaft *G*. Pinion *J''''''*, and wheels *J'''''''*, *J''''''''*, and *J'''''''''* for giving motion to shaft *J''''''''*; pinion *J''''''''''*, giving motion to backing-off wheel *J'''''''''''*. On the change shaft *K* is keyed a pinion which gears with the wheel *J''''''''''*, and receives motion therefrom.

583

One half of the catch-box *K'* is fast to one end of a long hollow shaft on which are two cams, one of which is used to put the front drawing roller catch-work *M* into and out of contact, the other is used for the purpose of traversing the driving strap on or off the fast-pulley *F* as required. The other half of the catch-box *K'* is placed on the shaft *K*, a key fast on which passes through the boss of the catch-box, and causes it to be carried round by the shaft as it rotates. Though carried round with the shaft, it is at liberty to move lengthwise, so as to allow it to be put into and out of contact with the other half when required. The spiral spring *K''* is also placed on the shaft *K*, and continually bears against the end of the catch-box next to it, and endeavours to put it in contact with the other, which it does when permitted and the changes are required. The change lever *K'''* moves on a stud which passes through its boss *a''*: near which end of this lever are the adjustable pieces *a*. When the machine is put in motion, supposing the carriage to be coming out, the driving strap is for the most part on the fast pulley *F* when motion is given through the bevel wheels *F''* and *F'''* to the drawing rollers *a*, which will then draw the rovings *c* off the bobbins, and deliver the slivers so drawn at the front of the rollers, and the same being fast to the spindles; as the carriage is drawn out the slivers are taken out also, and as the spindles at this time are turned round at a quick rate (say 6,000 revolutions per minute), they give twist to the slivers, and convert them into yarn or twisted threads. Motion is communicated to the spindles from the rim pulley *F''''*, through the rim band *F'''''*, which passes from the rim pulley to a grooved pulley on the tin roller shaft, round which it passes and thence round the grooved pulley *F''''''* back to the rim pulley, thus forming an endless band. It will be seen that the rim band pulley and the other pulleys, over or round which the rim band passes, are formed with double grooves, and the band being passed round each, it forms a double band, which is found of great advantage, as it will work with a slacker band than if only one groove was used; there is, consequently, less strain on the band, and it is longer. A string or cord passes round the tin roller to a wharve on each spindle,

round which it passes, and thence back to the tin roller, and thus, when the tin roller receives motion from the rim band, it gives motion to the spindles. The carriage is caused to move outwards by means of the cord L , one end of which is attached to a ratchet pulley fixed on the carriage cross, or square L^1 , and is then passed over the spiral grooved pulley L^2 fast on the drawing out shaft G , and passes thence under the guide pulley L^3 round the pulley L^4 to another ratchet pulley, also on the carriage square where the other end is then fastened. The cord receives motion from the pulley L^2 , round which it passes and communicates the motion it receives to the carriage, the carriage-wheels b^1 moving freely on the slips b^2 .

When the carriage has completed its outward run, the bowl a^4 on the counter faller shaft comes against the piece a^2 , depresses it and the end of the lever κ^3 to which it is attached, and raises the other end, and with it the slide c , on which are two inclines. A round pin (not seen) passes through the boss of the catch-box next to the slide, and bears against the sliding half of the catch-box, and holds it out of contact.

When the slide c is raised, the part of the incline which bore against the pin and kept the catch-box from being in contact is withdrawn, on which the spring puts them in contact, and motion is given to the hollow shaft, and the cams thereon; one of which causes the catch-box x to be taken out of contact when motion ceases to be given to the drawing rollers and to the going-out of the carriage; and the other causes the driving strap to be traversed off from the fast pulley on to the loose one, when motion ceases to be given to the rim pulley and thence to the spindles. The inclines on the slide are so formed that, by the time the shaft has made half a revolution, they act on the pin and cause it to put the catch-box out of contact. The next operation is the backing-off or uncoiling the threads coiled on the spindle above the cop, which is effected by causing the backing-off cones attached to the wheel j^6 to be put into contact with one formed in the interior of the fast pulley F , when a reverse motion will be given to the rim pulley and thence to the tin roller and the spindles.

The backing-off cones are put into contact by means of a spiral spring, which, when the strap fork is moved to traverse the strap on to the loose pulley, it is allowed to do. Simultaneously with the backing-off the putting-down of the faller wire takes place, which is effected through the reverse motion of the tin roller shaft, which causes the catch c^1 to take into a tooth of the ratchet wheel c^2 , when they will move together, and with them the plate c^3 , to a stud in which one end of the chain c^4 is fastened, the other end of which is attached to the outer end of the finger c^5 , fast on the faller shaft. When this chain is drawn forward by the plate, it draws down the end of the figure c^5 to which it is attached, and thereby partially turns the faller shaft and depresses the faller wire b^3 , and, at the same time, raises the lever c^5 , the lower part of which bears against a bowl attached to a lever which rests on the builder rail c^6 . As soon as the lever c^5 is raised sufficiently high to allow the lower end to pass over, instead of bearing against the bowl, it is drawn forward by a spiral spring, which causes the backing-off cones to be taken out of contact, when the backing-off ceases, and the operations of running the carriage in and winding the yarn on to the spindles must take place. When the cones are taken out of contact the lower end of the lever κ is withdrawn from being over the top of the lever κ^1 , leaving that lever at liberty to turn, and the catch-box κ^6 thereupon drops into gear, and motion is communicated to the scrolls κ^1 and κ^2 , and to the cords κ^3 and κ^4 . The cord κ^3 is at one end attached to the scroll κ^1 , and passes thence, round the pulley κ^6 , to the ratchet pulley κ^9 fixed to the back of the carriage square. The cord κ^4 is at one end attached to the scroll κ^2 , and passes thence round the pulley κ^{10} to the ratchet pulley κ^{11} fixed to the front of the carriage square. It will thus be seen that the carriage is held in one direction by one band, and in another by the other band, and that it can only be moved in either direction by the one scroll giving off as much cord as the other winds on. When the catch-box κ^6 drops in gear, the scroll κ^1 winds the cord κ^3 on and draws the carriage in. It will thus be seen that the carriage is drawn out by means of the back or drawing-out shaft G , and is drawn in by the scroll κ^1 . The winding-on of the thread in the form of a cop is effected by means of Mr. Roberts's ingenious application of the quadrant or radial arm G^7 , screw I and winding-on chain r^2 and r^3 . The chain r^2 is at one end attached to the nut r^1 and at the other to the band r^3 . During the coming out of the carriage the drawing-out shaft through the means of the wheels G^1 , G^2 , G^4 , and G^3 , shafts G^3 and G^5 , and pinion G^6 , moves the quadrant which, by the time the carriage is quite out, will have been moved outwards a little past the

with it the spur pinion. A catch on a stud fixed in the side of the pinion, at that time taking into a tooth of the ratchet wheel *i* fast on the tin roller shaft, the motion of the spur pinion is communicated to the tin roller shaft, and thence to the spindles, causing the thread or yarn spun during the coming-out of the carriage to be wound on the spindles, in the form of the cop, while the carriage goes in. At the commencement of the formation of a set of cops, when the yarn is being wound on the bare spindles, the spindles require to have a greater number of turns given to them than they do when the cop bottom is formed; to produce this variation the following means are employed. At the commencement of each set, the screw in the radial arm is turned so as to turn the nut *r*¹ to the bottom of the screw, where it is near to the shaft on which the quadrant moves; consequently, little or no motion is given to the chain, and the carriage, as it goes in, causes the chain to be drawn off the band. As the formation of the cop bottom proceeds, the screw is turned and the nut is raised; by which means a less quantity of chain is drawn off the barrel; the chain, at the point of attachment, gradually following the carriage as it goes in.

During the going-in of the carriage the quadrant is drawn down or made to follow the carriage by the chain pulling it, the speed at which it is allowed to descend is regulated by the motion of the carriage; the quadrant, during the going-in of the carriage, through the pinion *g*⁶, shafts *g*³ and *g*⁸, and wheels, *g*¹, *g*², *g*⁴, and *g*⁵ driving the drawing-out shaft.

When the carriage has completed its inward run, the bowl *A*⁴ comes in contact with the piece *A*⁶, and depresses it and the end of the lever *k*³ to which it is attached, and also the slide *c*, which then allows the catch-box *k*¹ to be put in contact, and causes the cam shaft to make another half revolution. During this half revolution of the cam shaft, the cams cause the catch-box *x* to be put in contact, and the driving strap to be traversed on to the fast pulley, and, by the latter movement, the catch-box *h*⁶ is taken out of gear and the winding-in motion of the scrolls ceases, and the carriage will again commence its outward run, and with it the spinning of the thread.

Other improvements have been effected by Messrs. Dolsen and Barlow, and by Messrs. P. and J. Mc Gregor, of Manchester. The latter firm have combined some of the advantages of Robert's and Smith's mule. The chief alterations made by Messrs. Mc Gregor are: first, the regulation of the amount of 'twist' given to the yarn from the tin roller or drum shaft of the carriage; and second, the completion of the automatic action of Robert's mule, which left to the spinner the duty of occasionally regulating the coping apparatus so that as the cop was gradually built upward upon the spindle, its speed might be slightly increased to meet the lessening diameter due to its slightly spiral form. Neglect of this duty on the part of the spinner was followed by a defect in the building of the upper part of the cop, which was rendered soft. The necessity of this attention has been abolished by the improvement in question.

The mule is used for the production of both 'twist' or warp, and weft. The twist cop is usually of a larger size than the weft cop. The latter undergoes no further operation until it is placed in the shuttle of the loom, except when intended for bleaching or dyeing, or for export to distant markets. In the latter case it is wound into skeins, and it may then with advantage be spun in cops of larger size. But when taken directly to the loom, its bulk is necessarily limited by the fact, that the 'shuttle space' in weaving is very narrow, and the weight of the shuttle with its contained cop cannot with profit be indefinitely increased, because of the force absorbed in its transmission across the web.

Of the diverse purposes to which yarn is applied after the spinning process is completed, some account will be found under the head of COTTON FACTORY.

COTTON TRADE. It is impossible to call to mind the fact, that nearly the whole of the human race is clothed entirely, or in part, with cotton fabric, without realising in some measure the important place amongst the activities of mankind which is filled by the growth, manufacture, and distribution of this material. This is the ground which is covered by the term 'Cotton Trade,' when used in its widest sense. And it is obvious that the chain of operations included in the term is much enlarged by the manifold diversity of the fabrics produced, as well as by the great distances which lie between the countries where the raw material is grown, the region of its manufacture, and the world-wide fields of consumption to which it is at last distributed. Cotton is exclusively a tropical or semi-tropical product. Its conversion into clothing by means of machinery is an industry belonging, as yet, almost exclusively to temperate zones. In seeking to present a general view of the nature and extent of the Cotton Trade it will be necessary therefore to indicate the relative importance of the sources from which the raw material is supplied, as well as of the countries where it is manufactured, and the proportions in which it is distributed to the regions of consumption. A considerable quantity of cotton is still spun by purely handicraft methods, especially in China and in India. But of this we do not here take

any account. The manufacture of cotton in India by means of machinery has also of late years reached important dimensions. With this exception, there is no part of the world where cotton is converted into clothing by mechanical means, on any scale worth notice, except in Europe and in the United States. Under the head of *COTTON FACTORY* we have indicated the relative importance of the various manufacturing countries as shown in the estimated number of spinning spindles possessed by each. Now, the supply of raw material consumed in the manufacture is drawn from many fields; and the order in which these stand may be readily inferred from the following table, which shows the average annual quantities contributed by each source of supply for the use of the factories of Europe and the United States, during the three years 1871-73. The statistics referring to the production of Central Asia, which is entirely consumed in Russia, refer to the year 1867, none of a later date being accessible.

Quantities and Sources of Supply of the Cotton consumed in Europe and the United States.

	Average of the three years 1871-73.
United States	1,632,500,000 lbs.
East India	503,600,000 „
Egypt, Asia Minor and Greece	231,200,000 „
Brazil	119,400,000 „
West Indies and Peru	47,700,000 „
Central Asia	43,200,000 „
Total	<u>2,577,600,000 „</u>

This enormous aggregate which, reckoning 300 working days in the year, is equal to 8,592,000 lbs., or upwards of 3,835 tons per day, was distributed to the manufacturing countries in the following proportions:—

Great Britain and Ireland	1,216,000,000 lbs
The United States	508,100,000 „
Russia and Sweden	221,100,000 „
France	193,100,000 „
Germany	166,500,000 „
Holland	86,000,000 „
Spain	60,000,000 „
Austria	57,100,000 „
Belgium	42,200,000 „
Italy	27,500,000 „
Total	<u>2,577,600,000 „</u>

It thus appears that of all the raw cotton consumed in the manufacturing countries of Europe and America very nearly one half is used in the United Kingdom.

With regard to the distribution of the manufactured product, it is to be observed that most of the countries named in the preceding table retain for home consumption nearly all that they produce, and are also, in varying degrees, dependent for their supply of clothing upon the manufactures of other countries. The only ones which, besides supplying the wants of their own home market, have any considerable surplus for exportation, are Great Britain, France, Switzerland, Holland and Germany. Prior to 1862 the United States also exported a large proportion of their cotton manufactures. But, owing mainly to the high degree of protection with which the legislature surrounded American manufactures during and since the civil war, the exports of cotton goods from the United States have greatly declined. The well-known effects of a protective system in increasing the cost of production have not prevented a very rapid growth of the home consumption of native manufactures in the United States, thanks to their growing wealth, to their increasing population, and to the large exclusion of foreign productions by heavy import duties. But this increase in the cost of production has effectually weakened the power of American manufacturers to compete successfully with their foreign rivals in neutral markets abroad. The exports of cotton goods from France, Switzerland, and Germany go principally to South America and Africa, those of Holland to the Dutch East Indies and China. But by far the largest proportion of the population of the non-manufacturing countries derive their supplies of machine-made cotton goods from the United Kingdom. Of the proportions

we find the consumption of British cotton manufactures in Russia increased from $\frac{3}{4}d.$ per head in 1851 to $1\frac{1}{2}d.$ in 1861, and $1\frac{5}{8}d.$ in 1871. In Sweden and Norway the consumption increased from $4\frac{5}{8}d.$ in 1851 to over $13\frac{1}{2}d.$ in 1871. Germany advanced from $2s. 9\frac{1}{2}d.$ to $5s. 2\frac{1}{4}d.$ per head. Belgium stood at rather less than $11\frac{1}{4}d.$ per head in 1851, and about the same in 1861, but in 1871 the figures rose to $2s. 5\frac{3}{4}d.$, owing in a great measure to the diversion of trade occasioned by the war. In 1851 France did not use more English cotton manufactures than was equal to about $1d.$ per head of her entire population; in 1861 the figures rose to $4\frac{1}{2}d.$, but in 1871, thanks to the Commercial Treaty, the consumption reached $1s. 2d.$ per head. Spain, including Gibraltar, consumed $7\frac{1}{4}d.$ per capita in 1851, $9\frac{5}{8}d.$ in 1861, and $13\frac{3}{8}d.$ in 1871. Portugal took $3s. 7\frac{3}{8}d.$ per head in 1851, $4s. 9\frac{1}{2}d.$ in 1861, but only $4s. 2\frac{1}{4}d.$ in 1871. In Italy the consumption increased from about $1s. 8d.$ per head in 1851 to $2s. 3d.$ in 1861, but fell to $1s. 10d.$ in 1871. Turkey in Europe took $2s. 2\frac{3}{8}d.$ per head in 1851, and $4s. 3\frac{1}{4}d.$ in 1871; Turkey in Asia figures for about $5d.$ in 1851, but $20\frac{3}{4}d.$ in 1871, owing to extended commerce with the interior. The trade with China is still very small per capita, but the increase during the past 20 years has been from $1d.$ per head to nearly $4d.$ With India the increase has been from $7\frac{1}{2}d.$ to $16\frac{3}{4}d.$ Japan took nothing in 1851, but in 1871 her consumption reached more than $7d.$ per head. It is with these Eastern countries that the greatest expansion of trade is to be expected in the future. The whole of Africa consumed about $2\frac{3}{4}d.$ per head in 1851, and $7d.$ in 1871. Turning to America, there is an apparent decrease in the consumption of Canada, the figures being $5s. 8\frac{3}{8}d.$ in 1851, but only $4s. 10\frac{3}{8}d.$ in 1871, but part of the increased shipments to the United States passed through Canada; and it is this transit trade that partly accounts for the United States' figures rising from $1s. 8\frac{3}{8}d.$ per head in 1851, to $2s. 8\frac{3}{8}d.$ in 1871. The West Indies do not show much increase; in some instances there is a decrease. Mexico advanced from $7\frac{5}{8}d.$ per head in 1851 to $16\frac{7}{8}d.$ in 1871. In South America the consumption of Brazil only rose from $5s. 9d.$ to $6s. 2\frac{1}{4}d.$ per head, but Paraguay, &c., increased from $1s. 5\frac{1}{4}d.$ to $6s. 10\frac{7}{8}d.$ Chili, Peru, &c., remained almost stationary. Part of these discrepancies, however, are owing to the changes which have occurred in the course of trade. Taking the whole of South America the figures show an average consumption of $4s. 5\frac{1}{8}d.$ per head in 1851, and $5s. 9d.$ in 1871. A recapitulation of the figures for the world is as follows:—

Consumption of Cotton Products per Head.

Districts	1851		1861		1871	
	s.	d.	s.	d.	s.	d.
Europe	0	$11\frac{3}{8}$	0	$14\frac{3}{8}$	0	$30\frac{3}{8}$
Asia	0	$3\frac{1}{4}$	0	$5\frac{1}{4}$	0	$8\frac{1}{2}$
Africa	0	$2\frac{3}{4}$	0	$5\frac{1}{2}$	0	7
America	2	$11\frac{1}{2}$	2	$9\frac{1}{2}$	4	$0\frac{1}{8}$
The World	0	$6\frac{7}{8}$	0	$9\frac{3}{4}$	0	$13\frac{7}{8}$

Respecting the business results of the year 1872, Messrs. Ellison and Co. say that 'from every point of view regarding the interests of the cotton trade the past year has formed quite a contrast to its immediate predecessor. 1871 was a year of unexampled prosperity to everyone in the industry, whether as importers, exporters, or consumers; but 1872 has been a year of constant anxiety, disappointment, and general unprofitableness.' The table given on the last page of Messrs. Ellison and Co.'s report shows how unprofitable the business of the year was to consumers:—'The balance left for wages, other expenses, interest of capital, and profits was $54,216,000l.$ or $12\frac{1}{2}d.$ per lb. on the cotton consumed, against $61,147,000l.$ or $13\frac{3}{4}d.$, in 1871. This loss of $1\frac{1}{4}d.$ per lb. (nearly $7,000,000l.$), was entirely borne by the millowners, for there was no reduction in the rate of wages. Moreover, there was an important additional item of expense in the shape of a serious advance in the price of coal. Altogether the year has been the most unsatisfactory one since 1869, during which some scores of failures occurred in the manufacturing districts, but the profits realised in 1871 saved Lancashire from bankruptcy during the past 12 months.'

'Importers of the raw material,' say Messrs. Ellison and Co., 'have also had a harassing time of it. They made some money in the early part of the year, but they have lost since, and the net result has been the reverse of gratifying. To importers of East-Indian cotton the year has been one of unmixed disappointment, owing to the tenacity with which consumers, notwithstanding the high range of prices, have clung to American and long-stapled cotton. The explanation is, first, that the demand has been chiefly for the better grades and finer numbers of yarn; secondly, that the "hands" have persistently refused to work Surats; and thirdly, that the quality of the East-Indian crop was exceptionally poor.

COTTON TRADE

1001

'The total direct import of cotton into Europe in 1872, amounted to 5,488,000 bales, of which 3,880,000 bales were received into British and 1,608,000 bales into Continental ports. Of the 3,880,000 bales received into Great Britain 743,000 were re-exported to the Continent, making the total supply to foreign Europe 2,351,000 bales, and leaving 3,137,000 bales for British consumption. The stocks at the close of the year showed an increase of 70,000 bales as compared with those of twelve months previously, so that the deliveries were 5,418,000 bales, of which 3,215,100 bales were to English, and 2,203,000 to Continental spinners. The average weekly deliveries were: to English spinners, 61,820 bales, against 62,820 in 1871; and to Continental spinners, 42,365, against 45,270 bales. We believe, however, that the stocks at the mills are fully 50,000 bales in Great Britain and 100,000 on the Continent less than they were at the close of 1871, so that the actual consumption has been at the rate of 62,800 bales per week in Great Britain, against 59,900 in 1871, and 44,500, against 43,560 bales.'

Messrs. Ellison and Co. estimate the number of cotton spindles in Europe at 39,500,000 in Great Britain, and 18,580,000 on the Continent. In the United States there are about 8,350,000. The deliveries of each description of cotton in each of the past two years were as follow:—

	Deliveries 1,000's of Bales		Average	Total
	1871	1872		
				lbs.
American	3,004	2,142	2,573	1,126,974,000
Brazilian	628	1,043	835	133,600,000
Egyptian, &c. . . .	435	507	471	219,015,000
West Indian	245	233	239	50,190,000
East Indian	1,257	1,493	1,375	493,625,000
Total	5,569	5,418	5,493	2,023,404,000

For a full consumption a supply of 2,064,000,000 lbs. is requisite, or about 40,000,000 lbs. more than the average deliveries of the past two years. Messrs. Ellison and Co. estimated the supply in 1873 as compared with the actual imports in 1872 and 1871 as follows:—

	1871	1872	Weight of Import, 1873		Total
	Bales	Bales	Bales	Average	lbs.
American	3,114,000	2,036,000	2,466,000	439	1,082,574,000
Brazilian	680,000	1,006,000	760,000	160	121,600,000
Mediterranean	445,000	513,000	560,000	480	268,800,000
West Indian	240,000	237,000	240,000	210	50,400,000
East Indian	1,538,000	1,696,000	1,550,000	360	558,400,000
Total	6,017,000	5,488,000	5,576,000	273	2,081,774,000

On these figures Messrs. Ellison and Co. remark that, allowing for no increase in spindles during the past twelve months, the above supply shows an excess of only 17,774,000 lbs., or 47,600 bales of 373 lbs. over the requirements of consumers, and, bearing in mind the fact that the year commences with a stock in all Europe 80,000 bales less than at the close of 1871 (that is 150,000 bales less than in the hands of spinners, but 70,000 more in the ports), there does not appear to be very much room for an expansion of spindle power during the ensuing twelve months. With a prospective supply very little, if at all, greater than the present consuming power of Europe, and only about 2 $\frac{7}{8}$ per cent. greater than the actual average deliveries of the past two years, prices on the average, for the year round will not, perhaps, greatly vary from the mean of 1871-72, say 9 $\frac{1}{2}$ d. for Middling Uplands, and 7 $\frac{3}{4}$ d. for fair Dhollerah. Any important average advance upon these rates would lead to economy and reduced consumption, as in 1872. Any material decline would stimulate demand,

The preceding remarks, when read in connection with the Tables of Imports and Exports given, cannot but be of high value in any considerations of the state of our cotton manufactures.

COURT PLASTER. Silk or some similar fabric covered on one side with isinglass in spirits of wine, with some Benzoin or gum Benjamin.

COW-DUNG is employed in the processes of dunging in Calico-printing.

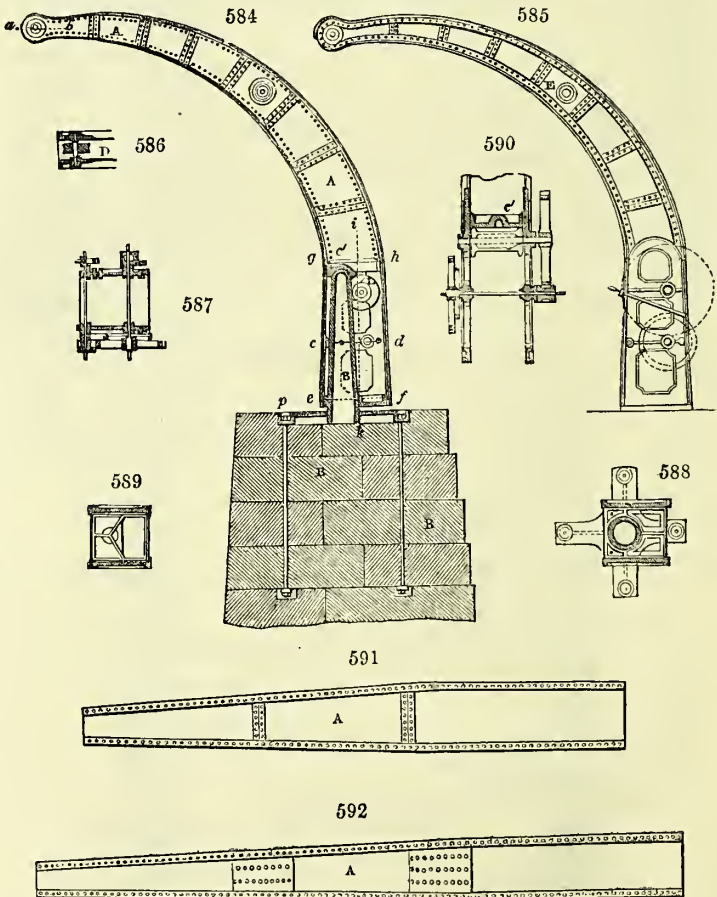

COW-DUNG SUBSTITUTE. The sulphate, carbonate, and phosphate of lime and soda. See CALICO-PRINTING.

COWDIE PINE. *Cowrie* or *Kaurie Pine*. The *Dammara australis*, a native of New Zealand, producing timber which is much valued for making masts and long spars of great strength. This pine also yields the gum-resin known as *Cowrie gum*, used in the preparation of certain varnishes.

CRANBERRY. The red acid fruit of the *Oxycoccus palustris*. The *O. macrocarpus* is the American variety. The fruit is preserved in water, and largely used.

CRANES, Tubular. Among the many applications of the hollow-girder system, this is one of the most ingenious.

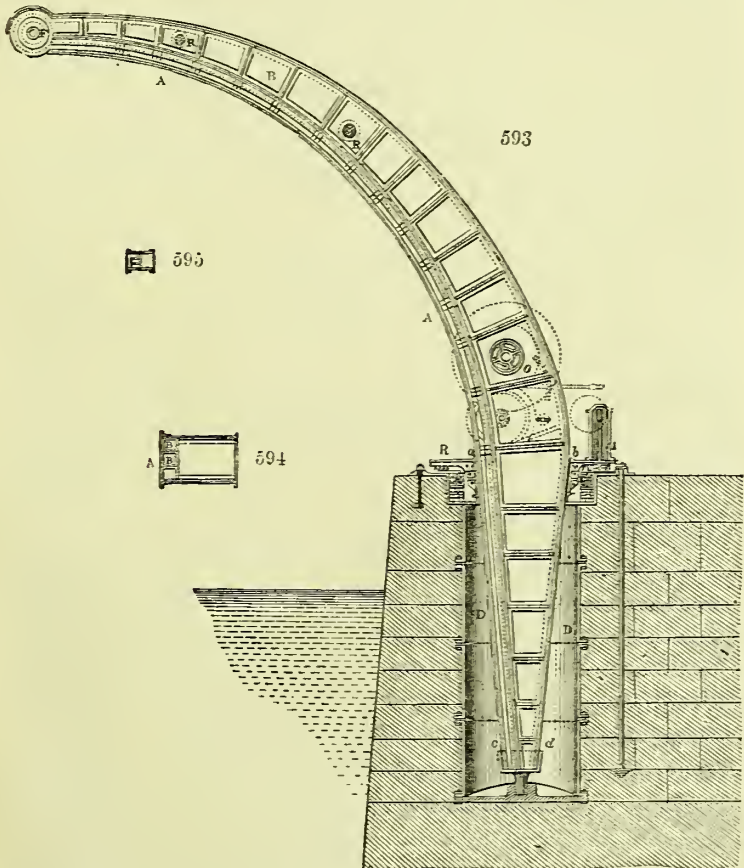

Fig. 584 is a vertical section of a crane, constructed according to a recent invention, and calculated for lifting or hoisting weights up to about 8 tons. *Fig. 585*, is an elevation of the same; *figs. 586, 587, 588, and 589*, are cross-sections, on the lines *a b, c d, e f, g h*; and *fig. 590*, a transverse vertical section on the line *i k*. $\Delta \Delta$ is the jib, which in its general outline, is of a crane-neck form, but rectangular in its cross-section, as particularly shown in *figs. 587, 588, and 589*. The four sides are formed of metal plates, firmly riveted together. Along the edges the connection of the

plates is effected by means of pieces of angle iron. The connection of the plates at the cross-joints on the convex or upper side of the jib are made by the riveting on of a plate, which covers or overlaps the ends of the two plates to be joined; the rivets at

this part are disposed as represented in *fig. 592* (a plan of the top plates), and known as 'chain riveting'; *B B* is the pillar, which is firmly secured by a base plate *p*, to a stone foundation *B*; and fits at top into a cup-shaped bearing *c'*, which is so firmly secured to the side plates of the jib, at or near to the point where the curvature commences, and on which bearing the jib is free to revolve. *Fig. 590* is a transverse vertical section of the lower part of the jib, showing the manner of fitting the bearings for the chain-barrel (which is placed in the interior), and the spindles and shafts of the wheel gearing, by which the power is applied there to *D*, the chain-pulley, which is inserted in an aperture formed in the top of the jib. The chain passing over this pulley enters the interior of the crane and is continued down to the chain-barrel. *E* is a pulley or roller, which is interposed about half-way between the chain-pulley and the chain-barrel, for the purpose of preventing the chain rubbing against the plates. *Fig. 591* is a plan of the lower plates.

Fig. 593 is a vertical section of another crane constructed upon the same principle as that just described, but calculated for lifting much greater weights (say 20 tons); it differs in having the lower or concave side *A A*, of the jib strengthened by means of three additional plates *B B B*, whereby the interior is divided into one large and three

smaller cells, as shown in *figs. 594* and *595*, which are cross-sections upon the lines *a b*.

and serve as anti-friction rollers for the upper bearing of the jib. The lowermost of the rings *F F*, rests upon a set of rollers *G G*, which are fitted into the top of the casting *D*, so that as the jib is turned round, the rings *F F*, and the anti-friction rollers which they carry, have perfect freedom to move along with it; *H* is a platform, upon which the persons working the machine may stand, and which supports the column *I*, within which there is mounted a spindle *K*, the lower end of which has keyed to it a pinion *L*, which gears into a circular rack *M M*, bolted to the top of the cylindrical casing *D*. *N* is a worm-wheel keyed to the top of the spindle *K*, into which an endless screw worked by a hand-wheel, is geared, so that, by turning the hand-wheel, the jib of the crane is made to move round in any required direction. *O* is the chain-barrel; *P* the chain-wheel; *R R* pulleys or rollers which support the chain, and prevent its rubbing against the plates of the jib.

In the cranes and hoisting machines described, the chain barrels are inclosed within the jib, and the spindles of the wheel-gearing are also inside; and this is the disposition of these parts preferred; but it will be obvious that they may be also placed outside of the jib, in a manner similarly to that generally followed in the construction of ordinary cranes.

CRAPE. (*Crêpe*, Fr.; *Krepp*, Ger.) A transparent textile fabric, somewhat like gauze, made of raw silk, ginned, and twisted at the mill. It is woven with any crossing or twel (When dyed black, it is worn by ladies as a mourning dress, Crapes are crisped (*crêpes*) or smooth; the former being double, are used in close mourning; the latter is less deep. The silk destined for the first is spun harder than for the second; since the degree of twist, particularly for the warp, determines the degree of crisping which it assumes after being taken from the loom. It is for this purpose steeped in clear water, and rubbed with prepared wax. Crapes are all woven and dyed with the silk in the raw state. They are finished with a stiffening of gum-water. White crape is appropriated to young unmarried females, and to virgins on taking the veil in nunneries.

Crape is a Bolognese invention, but has been long manufactured with superior excellence at Lyons in France, and Norwich in England. There is now a large manufactory of it at Yarmonth, by power-loom machinery.

There is another kind of stuff, called *crêpon*, made either of fine wool, or of wool and silk, of which the warp is twisted much harder than the weft. The *crêpons* of Naples consist altogether of silk. *Ærophanes*, *erape-lesse*, and *gauze* are either white or coloured crapes.

CRAYONS. (Eng. and Fr.; *Pastellstifte*, Ger.) Slender, soft, and somewhat friable cylinders, variously coloured for delineating figures upon paper, usually called chalk drawings. Red, green, brown, and other coloured crayons, are made with fine pipe or china clay paste, intimately mixed with earthy or metallic pigments, or in general with body or surface colour, then moulded and dried. See DRAWING CHALKS.

CREAM OF TARTAR. The BITARTRATE OF POTASH.

CREATINE or *Kreatine*, $C^8H^8N^3O^4 + 2HO$ ($C^8H^7N^3O^2 + H^2O$). A base existing in the juice of flesh and in urine along with creatinine. It was discovered by Chevreul, but chiefly investigated by Liebig.

CREATININE or *Kreatinine*, $C^8H^7N^3O^2$ ($C^8H^7N^3O$).^{*} A base produced from creatine by the loss of two atoms of water.

CREEP. In working a colliery on the pillar-and-stall principle it occasionally happens that the pillars are forced into the floor by the weight of the superincumbent strata, and the pavement is gradually heaved up until it may finally settle against the roof; this rise of the floor is called a *creep*. See MINING FOR COAL.

CREOSOTE or *Kreosote*. One of the many singular bodies discovered by Reichenbach in wood-tar. It derives its name from *χρῆμα*, flesh, and *σώζω*, I preserve, in allusion to its remarkable antiseptic properties. A great deal of confusion exists in the published accounts of wood creosote, owing to the variable nature of the results obtained by the chemists who have examined it. This confusion is not found with that from coal, which undoubtedly contains two homologous bodies, $C^{12}H^6O^2$ (C^8H^6O) and $C^{14}H^8O^2$ (C^8H^8O); the first being carbolic, and the second cresylic acid. The composition of carbolic acid has long been known, owing to the researches of Laurent: cresylic acid was afterwards discovered by Williamson and Fairlie. Commercial coal creosote sometimes consists almost entirely of cresylic acid. Coal oils, of very high boiling point, contain acids apparently homologues of carbolic acid, higher up in the series than even cresylic acid, and yet perfectly soluble in potash.—(*Greville Williams*.) There is little doubt that wood creosote consists essentially of the same substances as that from coal. The great difference in the odour arises chiefly from the fact of the product from coal retaining with obstinacy traces of naphthaline, parvoline, and chinoline,

all of which are extremely odorous. No creosote found in commerce is ever perfectly homogeneous, nor, in fact, is it necessary that it should be so. If perfectly soluble in potash and acetic acid of the density 1.070, and if it does not become coloured by exposure to the air, it may be considered pure enough for all medicinal purposes. The oils from wood- and coal-tar may be made to yield creosote by the following process. The oils are to be rectified until the more volatile portions (which are lighter than water) have passed over. As soon as the product running from the still sinks in water the receiver is to be changed, and the oils may be received until the temperature required to send over the oil is as high as 480° F. The oil so obtained is to be dissolved in caustic soda, all insoluble in it being rejected. The alkaline solution, after being mechanically separated, as far as possible, from the insoluble oil, is to be boiled for a very short time. Two advantages are gained by this operation: any volatile bases become expelled, and a substance which has a tendency to become brown on keeping, is destroyed. Sometimes the oil on treatment with potash yields a quantity of a crystalline paste. This is naphtbaline, and should be removed by filtration through coarse calico or canvas. The alkaline liquid is then to be supersaturated with dilute sulphuric acid, on which the creosote separates and rises in the form of an oil to the surface. This creosote is already free from the greater number of impurities, and, if rectified, may be used for many purposes. To obtain a purer article the operations commencing with solution in caustic soda are to be repeated. If the alkaline solution on boiling again becomes coloured, the purification must be gone through a third time. It is essential not to boil the alkaline solution long, or a serious loss of creosote would take place. According to Reichenbach the boiling point of creosote is 397°. Carboic acid boils between 369° and 370°. Cresylic acid boils at 397°. From this it would appear that Reichenbach's creosote consisted of cresylic acid. The specific gravity of creosote according to Reichenbach is 1.037 at 68°, that of carboic acid is 1.065 at 64°. Carboic acid and its homologues, when mixed with quicklime and exposed to the air, yield a beautiful red colour, owing to the formation of rosolic acid. See DISINFECTANTS.

CRESOL. $C^{14}H^8O^2$ (C^7H^4O). A compound found with carboic acid in coal-tar, creosote, and the tar of pine-wood.

CRESYLIC ACID. $C^{14}H^8O^2$ (C^7H^4O). A homologue of carboic acid. See CREOSOTE; DISINFECTANTS.

CRITH. ($\kappa\rho\iota\theta\eta$, a barleycorn). A unit of weight, introduced into modern chemistry by Dr. Hofmann. A crith is the weight of a litre of hydrogen at 0°C. and 760 mm. bar. pressure; this amounts to 0.089636 gramme. The use of the crith is convenient in calculating the weights of given volumes of different gases on the metric system.

CROCIDOLITE. A fibrous asbestiform mineral occurring in the Griqua Country, South Africa. White, brown, red, and blue varieties are known; and some of these, when cut *en cabochon*, resemble coloured cat's-eye, and are used in jewellery. The true crocidolite is a hydrous silicate of protoxide of iron, magnesia, and soda; but much of the so-called crocidolite from South Africa has been proved to be pseudo-morphous fibrous quartz coloured with oxide of iron and other foreign matter.

CROCOISITE. Native chromate of lead, $PbO.CrO^3$ ($PbCrO^4$) occurring in small hyacinth-red crystals in some of the Siberian mines, in Hungary, in Brazil, and in the Philippine Islands. It was in this mineral that the metal chromium was discovered in 1794, by Vauquelin. The name of the species is sometimes written, *Crocoite*.

CROCUS. The commercial name for a polishing powder made with oxide of iron. The older chemists gave this name to many of the metallic compounds, which had something of the nature of rust of iron. *Crocus Martis*, sesquioxide of iron; *Crocus Metallorum*, liver of antimony, glass of antimony, oxysulphide of antimony; *Crocus Veneris*, oxide of copper.

CROCUS. A genus of plants belonging to the natural order of *Iridaceae*. The *Crocus sativus* is the species from which the saffron of commerce is produced. The stigmata of the flowers are of a deep orange colour, and these, when dried in the loose state, form *hay saffron*; when compressed it forms the *cake saffron*. Saffron is cultivated in Cambridgeshire; it is also imported from Sicily, France, and Spain; but

CROTTLER. A name given to certain lichens in Scotland which are used for dyeing woollen stuffs brown.

CROWBERRY. The berries of *Empetrum nigrum*, eaten in the north of Europe, and used in Greenland in the preparation of a fermented beverage.

CROWN GLASS. See GLASS.

CRUCIBLES (*Cruisets*, Fr.; *Schmelztiegel*, Ger.) are small conical vessels, narrower at the bottom than the mouth, for reducing ores in assaying by the dry way, for fusing mixtures of earthy and other substances, for melting metals, and compounding metallic alloys. They ought to be refractory in the strongest heats, not readily acted upon by the substances ignited in them, not porous to liquids, and capable of bearing considerable alternations of temperature without cracking; on which account they should not be made too thick. See ASSAY; MELTING POTS.

CRUSHING AND GRINDING MACHINERY. See GRINDING AND CRUSHING MACHINERY, under DRESSING OF ORES.

CRYOLITE. (*Kryolith*, *Eisstein*, Ger.) This mineral derives its name from *κρύος*, ice,—from the circumstance of its being fusible in the flame of a candle. It is a double fluoride of aluminium and sodium, represented by the formula $AlF_3 + 3NaF$ ($AlF_3 \cdot 6NaF$), which corresponds to aluminium 13.00; sodium 32.8; fluorine 54.2 per cent. The mineral usually occurs in cleavable masses of snow-white colour, having a specific gravity of about 3. Cryolite is found only at Evigtok, in Arksutford in West Greenland, where it forms a large deposit in gneiss, associated with galena, pyrites, and spathic iron ore. It is now obtained in large quantities, and is used in the preparation of sulphate of alumina and alum; it has also been used in Germany in the manufacture of soda and soap, and of late has found a new application in America for the production of cryolite glass. The mineral is also employed in the manufacture of aluminium, and was at one time the chief source of the metal. See ALUMINIUM.

CRYOLITE GLASS. At Pittsburg in Pennsylvania an opaque milk-white glass resembling porcelain is made with cryolite. This glass may be obtained by melting together the following ingredients: silica, 67.19; cryolite, 23.84; and oxide of zinc, 8.97 per cent.

CRYPTIDINE, $C^8H^{11}N$ ($C^8H^{11}N$). A volatile base homologous with chinoline, found by Greville Williams in the less volatile portion of coal-tar.

CRYSTAL. A crystal is a body which has assumed a certain geometric form. It is produced by nature, and may be obtained by art.

The ancients believed quartz to be water converted into a solid by intense cold, and hence they called that mineral *crystal* from *κρυσταλλος*, ice. This belief still lingers, many persons thinking that *rock crystal* is, in fact, congealed water. The term *crystal* is now applied to all solid bodies which assume certain regular forms. A crystal is any solid bounded by plane surfaces symmetrically arranged. Each mineral has its own mode of crystallisation, by which it may be distinguished, and also its own peculiarity of internal structure.

We may have a mineral in a considerable variety of external forms, as *pyrites*, in cubes, octahedrons, dodecahedrons, &c.; but these are all related to a single type—the cube. Thus *galena*, whatever external form it may assume, has an internal cubical structure. *Fluor-spar*, usually occurring in cubical forms, may be cleaved into a regular octahedron. A little reflection will enable the student to see that nature in her simple arrangements maintains an unvarying internal type, upon which she builds up her varying and beautiful geometric forms. There are certain imaginary lines which are called the axes of the crystal: these may be

Rectangular and equal, as in the cube.

Rectangular and one unequal, as in the right square prism.

Rectangular and three unequal, as in the right rectangular prism.

The three axes unequal, vertical inclined to one of the lateral, at right angles to the other, two lateral at right angles with one another, as in the oblique rhombic prism.

The three axes unequal and all the intersections oblique, as in the doubly oblique prism.

Three equal lateral axes intersecting at angles of 60° and a vertical axis of varying length at right angles with the lateral, as in the hexagonal prism.

Upon these simple arrangements of the axial lines all the crystalline forms depend, the particles of matter arranging themselves around these axes according to some law of polarity which has not yet been developed. For an outline of Crystallography, see Watts's 'Dictionary of Chemistry.'

CRYSTAL. A name given to flint glass. See FLINT GLASS.

CUBE ORE. (*Würfelerz*, Ger.) A common name for *Pharmacoisiderite*: a hydrous arsenate of sesquioxide of iron, occurring in some of the Cornish copper-mines, and in Saxony, in the form of small cubes, generally of a green colour.

CUBIC NITRE. Native nitrate of soda, or Chili saltpetre. The name is supposed to refer to the form of the crystals, which, however, are rhombohedra and not cubes. The mineral is used in the preparation of nitric acid and of nitre.

CUBBEAR. This colouring matter was first made an article of trade by Dr. Cuthbert Gordon, from whom it derived its name; and was originally manufactured on a great scale by Mr. G. Mackintosh, at Glasgow, nearly 80 years ago.

It is prepared in the same manner as archil, from the same species of lichen; only, towards the end of the process, the substance is dried in the air, and is then ground to a very fine powder. See ARCHIL; LITMUS.

CULLET. Broken refuse glass.

CULM, a term applied to anthracite or coal-stone in some districts. It is still used in Parliamentary returns. See ANTHRACITE.

CUMIDINE, $C^{13}H^{12}N$ ($C^9H^{13}N$). An alkali homologous with aniline, formed by Nicholson by the action of reducing agents on nitrocumole. Its density is 0.9526, and its boiling point 437° .

CUMIN SEED. The fruit of the *Cuminum Cuminum*. This plant is much cultivated in Sicily and Malta for the sake of the seeds. These have a warm aromatic taste, and a strong and rather agreeable smell. The Dutch sometimes flavour their cheese with cumin seed. In Germany they are put into bread; and in this country they are employed to flavour curries.

CUMOLE, or *Cumène*, Hydruret of Cumenyle. $C^{15}H^{12}$ (C^9H^{12}). A hydrocarbon found in coal naphtha; it is also produced by the destructive distillation of cuminic acid with caustic baryta. See NAPHTHA, COAL, and CARBURETTED HYDROGEN.

CUPEL. A shallow cup made of bone-ashes. See ASSAY.

CUPELLATION. See ASSAYING and SILVER REFINING.

CUPREOUS MANGANESE. See MANGANESE.

CURACOA. A Dutch liqueur flavoured with Seville orange peel, cinnamon, and mace. See LIQUEURS.

CURCUMA ANGUSTIFOLIA. *The narrow-leaved Turmeric.* (East Indian Arrow Root.) This plant is found in the forests, extending from the banks of the Lona to Nagpore. At Bhagulpore the root is dug up and rubbed on a stone bed or in a mortar, and afterwards rubbed in water with the hand and strained through a cloth; the fecula having subsided, the water is poured off, and the *tikor* (fecula) dried for use. The East Indian arrow-root is a fine white powder, readily distinguishable, both to the eye and the touch, from West Indian arrow-root. To the eye it somewhat resembles a finely-powdered salt (as bicarbonate of soda or Rochelle salt). When pinched or pressed by the fingers, it wants the firmness so characteristic of West Indian arrow-root, and it does not crepitate to the same extent when rubbed between the fingers.—*Pereira*.

At Travancore this starch forms a large portion of the diet of the inhabitants.

CURLING STONE. A stone used in Scotland in playing the national game of *curling*, which is practised upon the ice during the winter. The stone is made of some hard primary rock. That of Ailsa Craig, in the Firth of Clyde, is very celebrated. Ailsa Craig consists of a single rock of greyish compact felspar, with small grains of quartz, and very minute particles of hornblende.—*Bristow*.

CURRANT. The fruit of the *Ribes rubrum* and *R. nigrum*. The name currant is derived from the similarity of the fruit to that of the Corinth raisins, or small grape of Zante, which are commonly called *corinths* or *currants*.

CURRHUS. A resin obtained from the hemp-plant (*Cannabis sativa*) grown in India.

CURRY. A seasoning originally prepared in the East Indies. The following are excellent receipts for curry:—

Coriander seeds powdered	3 ounces
Black pepper	„	5 „
Cayenne pepper	„	1 „
Fenegrice seeds	„	3 „
Cumin seeds	„	3 „
Turmeric root	„	6 „

To be thoroughly well mixed together.

CURRYING OF LEATHER (*Corroyer*, Fr.; *Zurichten*, Ger.) is the art of dressing skins after they are tanned, in order to render them fit for the purpose of the shoe-maker, coach-maker, harness-maker, &c. See LEATHER, CURRYING OF.

CUSCUS ROOT. A grass which yields a fragrant essential oil, called *Vilever*.

CUSPARIA BARK. The bark of a South American tree, the *Galipea Cusparia*, much esteemed for its medicinal properties.

CUTCH or *Kutch*. The catechu of the *Acacia Catechu*. See ACACIA CATECHU.

CUTLERY. (*Coutellerie*, Fr.; *Messerschmiedwaare*, Ger.) Three kinds of steel are made use of in the manufacture of different articles of cutlery, viz., common steel, shear steel, and cast steel. Shear steel is exceedingly plastic and tough. All the edge tools which require great tenacity without great hardness are made of it, such as table knives, seythes, plane-irons, &c.

Cast steel is formed by melting blistered steel in covered crucibles, with bottle glass, and pouring it into cast-iron moulds, so as to form it into ingots: these ingots are then taken to the tilt, and drawn into rods of suitable dimensions. No other than cast steel can assume a very fine polish, and hence all the finer articles of cutlery are made of it, such as the best scissors, penknives, razors, &c.

Formerly cast steel could be worked only at a very low heat; it can now be made so as to be welded to iron with the greatest ease. Its use is consequently extended to making very superior kinds of chisels, plane-irons, table knives, &c.

Forging of table knives.—Two men are generally employed in the forging of table knives; one called the foreman or maker, and the other the striker.

The steel called common steel is employed in making the very common articles; but for the greatest part of table knives which require a surface free from flaws, shear steel and cast steel are generally preferred. That part of the knife termed the blade is first rudely formed and cut off. It is next welded to a rod of iron about $\frac{1}{2}$ inch square, in such a manner as to leave as little of the iron part of the blade exposed as possible. A sufficient quantity of the iron now attached to the blade is taken off from the rod to form the bolster or shoulder, and the tang.

In order to make the bolster of a given size, and to give it at the same time shape and neatness, it is introduced into a die, and a swage placed over it; the swage has a few smart blows given it by the striker. This die and swage are, by the workmen, called prints.

After the tangs and bolster are finished, the blade is heated a second time, and the foreman gives it its proper anvil finish: this operation is termed smithing. The blade is now heated red hot, and plunged perpendicularly into cold water. By this means it becomes hardened. It requires to be tempered regularly down to a blue colour: in which state it is ready for the grinder.

Mr. Brownill's method of securing the handles upon table knives and forks, is, by lengthening the tangs, so as to pass them completely through the handle, the ends of which are to be tinned after the ordinary mode of tinning iron; and, when passed through the handle, the end of the tang is to be spread by beating, or a small hole drilled through it, and a pin passed to hold it upon the handle. After this, caps of metal, either copper plated, or silver, are to be soldered on the projecting end of the tang, and while the solder is in a fluid state, the cap is to be pressed upon the end of the handle and held there until the solder is fixed, when the whole is to be cooled by being immersed in cold water.

Mr. Thomason's patent improvements consist in the adaptation of steel edges to the blades of gold and silver knives. These steel edges are to be attached to the other metal, of whatever quality it may be, of which the knife, &c., is made, by means of solder, in the ordinary mode of effecting that process. After the edge of steel is thus attached to the gold, silver, &c., it is to be ground, polished, and tempered by immersion in cold water, or oil, after being heated. This process being finished, the other parts of the knife are then wrought and ornamented by the engraver or chaser, as usual.

A patent was obtained in 1827, by Mr. Smith of Sheffield, for rolling out knives at one operation.

In the ordinary mode of making knives, a sheet of steel being provided, the blades are cut out of the sheet, and the backs, shoulders, and tangs, of wrought iron, are attached to the steel blades, by welding at the forge. The knife is then ground to the proper shape, and the blade polished and hardened.

Instead of this welding process, the patentee proposes to make the knives entirely of steel, and to form them by rolling in a heated state between massive rollers; the shoulders or bolsters; and the tangs for the handles being produced by suitable recesses in the peripheries of the rollers, just as railway rails are formed. When the knife is to be made with what is called a scale tang, that is, a broad flat tang, to which the handle is to be attached in two pieces, riveted on the sides of the tang, the

rollers are then only to have recesses cut in them, in a direction parallel to the axis for forming the bolster.

The plate of steel having been heated, is to be pressed between the two rollers, by which the blades and the parts for the scale tangs will be pressed out flat and thin, and those parts which pass between the grooves or recess will be left thick or protuberant, forming the bolster for the shoulder of the blade. But if the tangs are to be round in order to be fixed into single handles, then it will be necessary also to form transverse grooves in the rollers, that is, at right angles to those which give shape to the bolsters, the transverse grooves corresponding in length to the length of the intended tang. When the plates of steel have been thus rolled, forming three or more knives in a breadth, the several knives are to be cut out by the ordinary mode of what is called slitting, and the blades and shoulders ground, hardened, and polished in the usual way.

Forks are generally a distinct branch of manufacture from that of knives, and are purchased of the fork makers by the manufacturers of table knives, in a state fit for receiving the handles.

The rods of steel from which the forks are made, are about $\frac{3}{4}$ ths of an inch square. The tang and shank of the fork are first roughly formed. The fork is then cut off, leaving at one end about 1 inch of the square part of the steel. This part is afterwards drawn out flat to about the length of the prongs. The shank and tang are now heated, and a proper form given to them by means of a die and swage. The prongs are afterwards formed at one blow by means of the stamp; this machine is very similar to that used in driving piles, but it is worked by one man. It consists of a large anvil fixed in a block of stone nearly on a level with the ground. To this anvil are attached two rods of iron of considerable thickness, fixed 12 inches asunder, perpendicularly to the anvil, and diagonally to each other. These are fastened to the ceiling. The hammer or stamp, about 100 lbs. in weight, having a groove upon either side corresponding to the angles of the upright rods, is made to slide freely through its limited range, being conducted by its two iron supporters. A rope is attached to the hammer, which goes over a pulley on the floor of the room above, and comes down to the person who works the stamp; two corresponding dies are attached, one to the hammer, and the other to the anvil. That part of the fork intended to form the prongs, is heated to a pretty white heat and placed in the lower die, and the hammer containing the other die is made to fall upon it from a height of about 7 or 8 feet. This forms the prongs and the middle part of the fork, leaving a very thin substance of steel between each prong, which is afterwards cut out with an appropriate instrument called a fly-press. The forks are now annealed by surrounding a large mass of them with hot coals, so that the whole shall become red hot. The fire is suffered gradually to die out, and the forks to cool without being disturbed. This process is intended to soften, and by that means to prepare them for filing. The inside of the prongs are then filed, after which they are bent into their proper form and hardened. When hardened, which is effected by heating them red-hot and plunging them into cold water, they are tempered by exposing them to the degree of heat at which grease inflames.

Penknives are generally forged by a single hand, with the hammer and the anvil simply.

The hammer in this trade is generally light, not exceeding $3\frac{1}{2}$ lbs. The breadth of the face, or the striking part, is about one inch; if broader, it would not be convenient for striking so small an object. The principal anvil is about 5 inches, and 10 upon the face, and is provided with a groove into which a smaller anvil is wedged. The smaller anvil is about 2 inches square upon the face. The blade of the knife is first drawn out at the end of the rod of steel, and as much more is cut off along with it as is thought necessary to form the joint. The blade is then taken in a pair of tongs, and heated a second time to finish the joint part, and at the same time to form a temporary tang for the purpose of driving into a small haft used by the grinder. Another heat is taken to give the blade a proper finish. The small recess called the nail-hole, used in opening the knife, is made while it is still hot by means of a chisel, which is round on one side and flat upon the other.

Penknives are hardened by heating the blade red hot, and dipping them into water

They are generally made of cast steel. The rods, as they come from the tilt, are about $\frac{1}{2}$ inch broad, and of a thickness sufficient for the back of a razor.

There is nothing peculiar in the tools made use of in forging razors; the anvil is a little rounded at the sides, which affords the opportunity of making the edge thinner, and saves an immense labour to the grinder.

Razors are hardened and tempered in a similar manner to penknives. They are, however, left harder, being only let down to yellow or brown colour.

The forging of scissors is wholly performed by the hammer, and all the sizes are made by a single hand. The anvil of the scissor-maker weighs about $1\frac{1}{2}$ cwt.; it measures, on the face, about 4 by 11 inches. It is provided with two gates or grooves for the reception of various little indented tools termed by the workmen bosses: one of these bosses is employed to give proper figure to the shank of the scissors; another for forming that part which has to make the joint; and a third is made use of for giving a proper figure to the upper side of the blade. There is also another anvil placed on the same block, containing two or three tools called beak-irons, each consisting of an upright stem about 6 inches high, at the top of which a horizontal beak projects; one of these beaks is conical, and is used for extending the bow of the scissors; the other is a segment of a cylinder with the round side upwards, containing a recess for giving a proper shape and smoothness to the inside of the bow.

The shank of the scissors is first formed by means of one of the bosses, above described, leaving as much steel at the end as will form the blade. A hole is then punched about $\frac{1}{4}$ inch in width, a little above the shank. The blade is drawn out and finished, and the scissors separated from the rod a little above the hole. It is heated a third time, and the small hole above mentioned is extended upon the beak-irons so as to form the bow. This finishes the forging of scissors. They are promiscuously made in this way, without any other guide than the eye, having no regard to their being in pairs. They are next annealed for the purpose of filling such parts of them as cannot be ground, and afterwards paired.

The very large scissors are made partly of iron, the blades being of steel.

After the forging, the bow and joints, and such shanks as cannot be ground, are filed. The rivet hole is then bored, through which they are to be screwed or riveted together. This common kind of scissors is only hardened up to the joint. They are tempered down to a purple or blue colour. In this state they are taken to the grinder.

Grinding and polishing of cutlery.—The various processes which come under this denomination are performed by machinery, moving in general by the power of the steam-engine or water-wheel.

Grinding wheels or grinding mills are divided into a number of separate rooms; each room contains six places called troughs; each trough consists of a convenience for running a grindstone and a polisher at the same time, which is generally occupied by a man and a boy.

The business of the grinder is generally divided into three stages, viz., grinding, glazing, and polishing.

The grinding is performed upon stones of various qualities and sizes, depending on the articles to be ground. Those exposing much flat surface, such as saws, fenders, &c., require stones of great diameter, while raisors, whose surface is concave, require to be ground upon stones of very small dimensions. Those articles which require a certain temper, which is the case with most cutting instruments, are mostly ground on a wet stone; for which purpose the stone hangs within the iron trough, filled with water to such a height that its surface may just touch the face of the stone.

Glazing is a process following that of grinding: it consists in giving that degree of lustre and smoothness to an article which can be effected by means of emery of various degrees of fineness. The tool on which the glazing is performed, is termed a glazer. It consists of a circular piece of wood, formed of a number of pieces in such a manner that its edge or face may always present the endway of the wood. Were it made otherwise, the contraction of the parts would destroy its circular figure. It is fixed upon an iron axis similar to that of the stone. Some glazers are covered on the face with leather, others with metal, consisting of an alloy of lead and tin; the latter are termed caps. In others, the wooden surface above is made use of. Some of the leather-faced glazers, such as are used for forks, table knives, edge tools, and all the coarser polished articles, are first coated with a solution of glue, and then covered with emery. The surfaces of the others are prepared for use by first turning the face very true, then filling it with small notches by means of a sharp-ended hammer, and lastly filling up the interstices with a compound of tallow and emery.

The pulley of the glazier is so much less than that of the stone, that its velocity is more than double, having in general a surface speed of 1,500 feet in a second.

The process of polishing consists in giving the most perfect polish to the different

articles. Nothing is subjected to this operation but what is made of cast steel, and has been previously hardened and tempered.

The polisher consists of a circular piece of wood covered with buff leather, the surface of which is covered from time to time, while in use, with the crocus of iron, called also colcothar of vitriol.

The polisher requires to run at a speed much short of that of the stone, or the glazer. Whatever may be its diameter, the surface must not move at a rate exceeding 70 or 80 feet in a second.

CUTTLE FISH. Mollusca belonging to the class *Cephalopoda*. The internal calcareous shell of one species (*Sepia officinalis*) is used as pounce. See *SEPIA*.

CYANANILINE. A crystalline body formed by the action of cyanogen upon aniline. See *CYANOGEN*.

CYANATES. The combinations of the various bases with cyanic acid, C^2HNO^2 (**CHNO**). The cyanate of potash, C^2NKO^2 (**CNKO**), is employed for the preparation of artificial urea. There are two modes of preparing cyanate of potash, both of which yield a good product: the first is that of Clemm, the second of Liebig. (1.) 8 parts of ferrocyanide of potassium and 3 parts of carbonate of potash are intimately mixed and fused, care being taken not to urge the heat too much. The fluid mass is allowed to fall somewhat in temperature, but not to such an extent as to solidify; 15 parts of red lead are then added by small portions. The crucible is now to be reheated with stirring, then removed, and the contents poured on to a clean iron plate. (2.) The cyanide of potassium of commerce (prepared by the method described in the article under that head) is to be melted in an iron crucible or ladle, and $3\frac{1}{4}$ parts of dry litharge in fine powder are to be added with constant stirring. When the lead has all collected at the bottom, the whole is poured on to an iron plate. The mass obtained by either of the above processes is to be reduced to powder, and boiled with repeated quantities of alcohol, until no more cyanate is extracted. This may be known when the alcohol filtered from the residue no longer yields crystals of cyanate in cooling.—C. G. W.

CYANHYDRIC ACID. See *HYDROCYANIC ACID*.

CYANIDES. The combinations of cyanogen with metals or other bodies. It is remarked in the article *HYDROCYANIC ACID* that cyanogen, C^2N (**CN**) is a compound salt-radical, analogous to the halogens chlorine, iodine, and bromine. Like the latter, it unites with metals without the intervention of oxygen, and with hydrogen to form a hydracid corresponding to the hydrochloric, hydriodic, and hydrobromic acids. The cyanides are both an important and interesting class of salts. The most important is the cyanide of potassium. The latter is formed under a great variety of circumstances, especially where carbonate of potash is heated in contact with carbonaceous matters. The nitrogen to form the cyanide in the greater number of instances is principally, and in a few entirely, derived from the atmosphere. Many chemists have experimented on this subject, and their results are by no means in harmony; but thus much is certain, that success or failure depends solely upon the circumstances under which the experiments are conducted. It has been shown that, when carbonate of potash mixed with charcoal prepared from sugar (see *CARBON*) is exposed to a very high temperature in a current of nitrogen gas, the potash in the carbonate is, at times, absolutely converted into cyanide, not a trace of carbonic acid remaining. Experiments of this class, when made with animal charcoal or coal, are less conclusive because those matters contain nitrogen. But even then the amount of cyanogen found is out of proportion to the quantity of nitrogen in the coal or other carbonaceous matters. In fact, it would seem that the presence of a certain quantity of nitrogen in the coal, &c., exercises a predisposing tendency on the nitrogen of the air so as to induce its combination with carbon with greater facility than would be the case if pure carbon were employed. Cyanide of potassium has been found on more than one occasion oozing from apertures in iron-smelting furnaces. In fact, it has been produced in such abundance at one furnace in Styria as to be sent into the market for sale to electro-platers.

Cyanide of potassium is largely prepared for the use of electro-platers and gilders. The proportions of the materials used are those of Liebig, who first made known the process. The modes of manipulation, however, differ in the details in all laboratories. The following method can be recommended from the experience of the author of this article as giving a white and good product. It can, moreover, be worked on a very

ment to enable the pot to be arrested at any desired height. The pot being heated to redness, the mixture is to be thrown in by small portions until the vessel is half full; the heat being allowed to rise gradually until the whole flows pretty quietly. During the fusion the contents are to be stirred with a clean iron rod to promote the aggregation of the spongy sediment. As soon as the rod, on being dipped into the fused mass and removed, brings with it a pure white porcelain-like product, the operation may be regarded as terminated, and the pot is to be raised from the fire by means of the crane and sling in a slightly inclined position. One of the operators now holds a large clean iron ladle under the edge of the pot, while another elevates the latter with the aid of tongs, so that the ladle becomes filled. The contents of the first ladle are then poured off into another held by the assistant who tilted the pot. The latter then pours the contents of his ladle into a large, shallow, and brilliantly clean brass basin standing in another containing a little water so as to cool the fused cyanide rapidly. Extreme care must be taken to prevent even the smallest drop of water from finding its way into the brass vessel, because on the hot cyanide coming in contact with it an explosion would occur, scattering it in every direction to the great danger of the persons in the vicinity. The two ladles are to be kept very hot, by being held over the fire until wanted, in order to prevent the cyanide from chilling until it is poured into the brass basin. The latter should be about 18 inches in diameter and $1\frac{1}{2}$ deep. It should be quite flat-bottomed. The object of so many pourings off is to prevent any of the sediment from finding its way into the product, and thus causing black specks in it. The pot, on being emptied as far as convenient, is to have the sediment removed and a fresh charge inserted. As soon as the coke of cyanide is cool, it is to be broken up into moderate-sized pieces and placed in dry and well closed jars.

The cyanide of potassium possesses great points of interest for the technical and theoretical chemist. It is the salt from which an immense number of compounds of importance may be obtained. Very large quantities are made for the purpose of preparing the auro- and argento-cyanides of potassium for the electro-platers and gilders.

Auro-cyanide of potassium is capable of being formed in several ways. The following are convenient processes. The selection of a mode of preparing it will depend upon the circumstances under which the operation is situated. 1. By the battery. This process is perhaps the most generally convenient and economical for the electro-gilder. A bath is prepared by dissolving the best commercial cyanide of potassium in good filtered or distilled water. The best salt is that sold under the name of 'gold cyanide.' A Daniell's battery of moderate size being charged, two plates of gold are attached to wires and connected with it. The larger, which is to be dissolved, is attached to the positive, and the smaller, which need be but the size of a flattened wire, to the negative pole. The action of the battery is kept up until the desired amount is dissolved. It is easy to remove the plate used, dry and weigh it at intervals so as to know the proper time to stop the operation. 2. Peroxide of gold (prepared with magnesia) is to be dissolved in a solution of cyanide of potassium.

Argento-cyanide of potassium. This solution is easily prepared for the electro-plater by the following process. Metallic silver is dissolved in nitric acid and the solution evaporated to dryness. The residue is dissolved in distilled water and filtered. To the solution cyanide of potassium, dissolved in distilled water, is added as long as precipitation takes place, but no longer. The precipitate is filtered off on calico strainers, and well washed with distilled water. It is then to be dissolved in solution of cyanide of potassium and diluted to the desired strength. The solution is frequently dark coloured at first, but it becomes colourless in a few hours, and should then be filtered from a small black precipitate which will be obtained. Many operators neglect the filtration and washing of the precipitated cyanide of silver, and merely continue the addition of the solution of cyanide of potassium to the nitrate of silver until the precipitate at first formed is re-dissolved. The first method is however to be preferred. Some, instead of precipitating with cyanide of potassium, do so with solution of common salt, and then, after washing off the precipitated chloride of silver, dissolve it in cyanide of potassium. Argento-cyanide of potassium can also be prepared with the battery by the process mentioned under auro-cyanide of potassium; this method is so convenient where the proper apparatus is at hand, that few professional electro-platers would use any other method.

CYANIDES FERRO. See FERROCYANIDES.

CYANIDE OF POTASSIUM. See CYANIDES.

CYANINE. A name given to *Chinoline Blue*. See CHINOLINE BLUE.

CYANITE. *Kyanite* or *Disthene*. A native silicate of alumina, occurring generally in flattened prisms of a blue colour. Transparent, finely-coloured specimens have occasionally been cut and polished as gem-stones, and bear some rescm-

blance to sapphires; the hardness, however, is considerably less. It is notable that the hardness of cyanite varies in different faces of the same crystal—the old name *Disthene* (*δίσ*, twice; *σθένος*, strength), having reference to this unequal resistance which the crystal offers in two different directions.

CYANOGEN. C^2N (**CN**). A compound salt-radical, analogous in its character to chlorine and the other halogens. It was the first body discovered possessing the characters of a compound radical, and the investigations made upon it and its derivations have thrown more light upon the constitution and proper mode of classifying organic substances than any other researches whatever. In consequence of its acting in all its compounds as if it were a simple body or element, chemists generally have acquired the habit of designating it by the symbol Cy. Like the haloids, it combines with hydrogen to form an acid, and with metals, without the necessity for the presence of oxygen. For a few illustrations of its analogies with chlorine, &c., see HYDROCYANIC ACID. In the article CYANIDES several of the conditions under which it is formed have also been pointed out. The modern French chemists of the school of Gerhardt very justly regard cyanogen in the light of a double molecule, thus Cy Cy, or C^2N^2 . The reason of this is because most of the phenomena of organic chemistry are more easily explained by the use of four-volume formulæ than any others. This latter mode of condensation has been shown by M. Wurtz, in his admirable work on the compound radicals, to undoubtedly exist in the case of radicals belonging to the strict hydrogen type, not as ethyle and its homologues; and numerous theoretical and experimental results are in favour of the supposition that all radicals in the free state are binary groups.

If we assume the truth of the above hypothesis, we shall regard cyanogen in the free state as a cyanide of cyanogen, analogous to hydrocyanic acid, which is a cyanide of hydrogen.

Cyanogen may very conveniently be prepared by heating cyanide of mercury in a retort of hard glass. A considerable quantity of the gas is given off, but a portion remains behind in the state of *paracyanogen*. The latter substance is a black matter, the constitution of which is by no means understood. It has, however, the same composition in the hundred parts as cyanogen itself, and is therefore isomeric with it.

Cyanogen is a colourless combustible gas, with a sharp odour. Its density is 1·81. theory requires for two volumes 1·80. If cooled to a temperature of between -13° and -22° F., it liquefies into a transparent, colourless, and very mobile fluid, having a specific gravity of 0·866. A little below 22° the fluid congeals to a mass resembling ice. The flame of cyanogen is of a pale purple or peach-blossom colour.

Some of the properties of cyanogen are very remarkable, and quite distinct from those of the true halogens. For instance, it combines directly with aniline to produce a body having basic properties. The latter is called *Cyaniline* or *Cyananiline*, and is formed by the coalescence of two molecules of cyanogen with two of aniline, the resulting formula being consequently $C^{23}H^{14}N^4$ ($C^{14}H^{14}N^4$). There are a variety of singular compounds produced by the action of cyanogen and its halogen compounds upon aniline; they have been studied with remarkable skill by Hofmann.—C.G.W.

CYANOSE or *Cyanosite*. Native sulphate of copper.

CYANURIC ACID. When cyanate of ammonia is heated it passes into urea; and urea by further heating may be converted into ammonia and cyanuric acid. This acid may also be prepared by the action of sulphuric acid on melam. Cyanuric acid contains $C^3H^3N^3O^3$ ($C^3H^3N^3O^3$), and at a very high temperature may be resolved into three molecules of cyanic acid.

CYDER (*Cidre*, Fr.; *Apfelwein*, Ger.): the vinous fermented juice of the apple. The ancients were acquainted with cyder and perry, as we learn from the following passage of Pliny the naturalist: 'Wine is made from the Syrian pod, from pears and apples of every kind.' (Book xiv. chap. 19.) The term cyder or *cidre* in French, at first written *sidre*, is derived from the Latin word *sicera*, which denoted all other fermented liquors, except grape-wine. Cyder seems to have been brought into Normandy by the Moors of Biscay, who had preserved the use of it after coming into that country from Africa. It was afterwards spread through some other provinces of France, whence it was introduced into England, Germany, and Russia. It is supposed that the first growths of Normandy afford still the best specimens of cyder. Devonshire and Herefordshire are the counties of England most famous for this beverage.

Strong and somewhat elevated ground, rather dry, and not exposed to the air of the sea, or to high winds, are the best situations for the growth of the cyder apple. The

membrane constitutes not more than two per cent. of the whole. After the apples are gathered, they are left in the barn-loft for fifteen days or upwards to mellow; some of them in this case, however, become soft and brown. This degree of maturation diminishes their mucilage, and develops alcohol and carbonic acid; in consequence of which the cyder suffers no injury. There is always, however, a little loss; and if this ripening goes a little further it is very apt to do harm, notwithstanding the vulgar prejudice of the country people to the contrary. Too much care, indeed, cannot be taken to separate the sound from the spoiled apples; for the latter merely furnish an acid leaven, giving a disagreeable taste to the juice, and hinder the cyder from fining, by leaving in it a certain portion of the parenchyma, which the gelatinous matter or the fermentation has diffused through it. Unripe apples should be separated from the ripe also, for they possess too little saccharum to be properly susceptible of the vinous fermentation.

Where cyder-making is scientifically practised, it is prepared by crushing the apples in a mill with revolving edge-stones, turned in a circular stone cistern by one or two horses. When the fruit is half mashed, about one fifth of its weight of river water is added.

In some places a mill composed of two cast-iron fluted cylinders placed parallel to each other under the bottom of a hopper, is employed for crushing the apples. One of the cylinders is turned by a winch, and communicates its motion in the opposite direction by means of the flutings working into each other. Each portion of the fruit must be passed thrice through this rude mill in order to be sufficiently mashed; and the same quantity of water must be added as in the edge-stone mill.

After the apples are crushed they are usually put into a large tub or tun for 12 or 24 hours. This steeping aids the separation of the juice, because the fermentative motion which takes place in the mass breaks down the cellular membranes; but there is always a loss of alcohol carried off by the carbonic acid disengaged, while the skins and seeds develop a disagreeable taste in the liquid. The vatting might be suppressed if the apples were so comminuted as to give out their juice more readily.

After the vatting, the mashed fruit is carried to the press and put upon a square wicker frame or into a hair bag, sometimes between layers of straw, and exposed stratum above stratum to strong pressure till what is called a cheese or cake is formed. The mass is to be allowed to drain for some time before applying pressure, which ought to be very gradually increased. The juice which exudes with the least pressure affords the best cyder; that which flows towards the end acquires a disagreeable taste from the seeds and the skins. The must is put into casks with large bungholes, where it soon begins to exhibit a tumultuous fermentation. The cask must be completely filled, in order that all the light bodies suspended in the liquid when floated to the top by the carbonic acid may flow over with the froth; this means of clearing cyder is particularly necessary with the weak kinds, because it cannot be expected that these matters in suspension will fall to the bottom of the casks after the motion has ceased. In almost every circumstance besides, when no saccharine matter has been added to the must, that kind of yeast which rises to the top must be separated, lest by precipitation it may excite an acid fermentation in the cyder. The casks are raised upon gauntrees or stillions, in order to place flat tubs below them to receive the liquor which flows over with the froth. At the end of 2 or 3 days for weak cyders, which are to be drunk somewhat sweet, of 6 or 10 days or more for stronger cyders, with variations for the state of the weather, the fermentation will be sufficiently advanced, and the cyder may be racked off into other casks. Spirit puncheons preserve cyder better than any other, but in all cases the casks should be well seasoned and washed. Sometimes a sulphur match is burned in them before introducing the cyder, a precaution to be generally recommended, as it suspends the activity of the fermentation, and prevents the formation of vinegar.

The cyder procured by the first expression is called cyder without water. The cake remaining in the press is taken out, divided into small pieces, and mashed anew, adding about half the weight of water, when the whole is carried back to the press, and treated as above described. The liquor thus obtained furnishes a weaker cyder which will not keep, and therefore must be drunk soon.

The cake is once more mashed up with water, and squeezed, when it yields a liquor which may be used instead of water for moistening fresh ground apples.

The processes above described, although they have been long practised, and have therefore the stamp of ancestral wisdom, are extremely defective. Were the apples ground with a proper rotatory rasp which would tear all their cells asunder, and the mash put through the hydraulic press in bags between hurdles of wicker-work, the juice would be obtained in a state of perfection fit to make a cyder superior to many wines. An experimental process of this kind has been actually executed in France upon a considerable scale, with the best results. The juice had the fine flavour of the

apple, was fermented by itself without any previous fermentation in the mash, and afforded an excellent strong cyder, which kept well.

When the must of the apples is weak or sour, good cyder cannot be made from it without the addition of some saccharine matter. The syrup into which potato farina is convertible by *diastase* (saccharine ferment, see STARCH and SUGAR), would answer well for enriching poor apple juice.

The value of apples to produce this beverage of good quality is proportionate to the specific gravity of their juice. M. Couverchel has given the following table, illustrative of that proposition: water being 1000:—

Juice of the green renette, queen apple (<i>reinette verte</i>)	has a spec. grav.	1094
„ English renette	„ „	1080
„ Red renette	„ „	1072
„ Musk renette	„ „	1069
„ <i>Fouillet rayé</i>	„ „	1064
„ Orange apple	„ „	1063
„ Renette of Caux	„ „	1060

Cyder apples may be distributed into three classes: the sweet, the bitter, and the sour. The second are the best; they afford a denser juice, richer in sugar, which clarifies well, and when fermented keeps a long time; the juice of sweet apples is difficult to clarify; but that of the sour ones makes bad cyder. Late apples are in general to be preferred. With regard to the proper soil for raising apple-trees, the reader may consult with advantage an able essay upon 'The Cultivation of Orchards and the Making of Cyder and Perry,' by Frederick Falkner, Esq., in the fourth volume of the 'Royal Agricultural Journal.' He adverts judiciously to the necessity of the presence of alkaline and earthy bases in the soils of all deciduous trees, and especially of such as produce acid fruits.

CYMENE. $C^{20}H^{14}$ ($C^{10}H^{11}$). A hydrocarbon obtained from the essential oil of cumin (*Cuminum cyminum*), and from other sources. Thus it may be prepared by the action of either chloride of zinc or pentachloride of phosphorus on camphor or on myristic acid. The varieties of cymene have been lately studied by Dr. Wright (*Journ. Chem. Soc.*, July 1873, p. 686).

CYMOLE. $C^{21}H^{14}$ ($C^{21}H^{28}$). *Syn.* Camphogen. A hydrocarbon found in oil of cumin and in coal naphtha. See CARBURETTED HYDROGEN.

CYMOPHANE. A variety of Chrysoberyl, which exhibits a peculiar milky or opalescent appearance. When cut *en cabochon*, it shows a white floating band of light, and is much prized as a ring stone. See CHRYSOBERYL.

CYPRINE. A pale blue mineral coloured by copper, now considered to be a variety of idocrase. It occurs at Tellemark in Norway.

CYSTINE. An alkaloïd obtained from the laburnum (*Cytisus laburnum*).

ENCYCLOPÆDIAS AND DICTIONARIES.

CATES AND WOODWARD'S ENCYCLOPÆDIA OF CHRONOLOGY, HISTORICAL AND BIOGRAPHICAL: Comprising the DATES of all the Great Events of History, including Treaties, Alliances, Wars, Battles, &c.; Incidents in the lives of Eminent Men, and their Works, Scientific and Geographical Discoveries, Mechanical Inventions, and Social, Domestic, and Economical Improvements. Medium 8vo. pp. 1,496 (double columns, brevier), price 42s. cloth.

BRANDE'S DICTIONARY OF SCIENCE, LITERATURE, AND ART; Comprising the Definitions and Derivations of the Scientific Terms in general use, together with the History and Description of the Scientific Principles of nearly every Branch of Human Knowledge. Fourth Edition, reconstructed by the late Author and the Rev. G. W. COX, M.A. assisted by Contributors of eminent Scientific and Literary Acquirements. In Three Volumes, medium 8vo. price 63s.

KEITH JOHNSTON'S GENERAL DICTIONARY OF GEOGRAPHY Descriptive, Physical, Statistical, and Historical. Forming a Complete Gazetteer of the World. New Edition, revised and corrected to the Present Date by the Author's Son, KEITH JOHNSTON, F.R.G.S. In One Volume, medium 8vo.
[In the Spring.]

M'CULLOCH'S DICTIONARY OF COMMERCE AND COMMERCIAL NAVIGATION. New Edition, revised and corrected throughout; with Supplements containing Notices or Abstracts of the New Tariffs for the United States and Spain, and of our New Bankruptcy, Naturalisation, and Neutrality Laws. Edited by HUGH G. RED. With Eleven MAPS and Thirty CHARTS. In One Volume, medium 8vo. price 63s.

URE'S DICTIONARY OF ARTS, MANUFACTURES, AND MINES. Seventh Edition, rewritten and enlarged by ROBERT HUNT, F.R.S. Keeper of Mining Records; assisted by numerous Contributors eminent in Science and familiar with Manufactures. With about 2,600 Engravings on Wood. In Three Volumes, medium 8vo. price £5. 5s.

GWILT'S ENCYCLOPÆDIA OF ARCHITECTURE. Illustrated with more than 1,100 Engravings on Wood, revised, with Alterations and considerable Additions, by WYATT PAPWORTH, Fellow of the Royal Institute of British Architects. Additionally Illustrated with nearly 400 Engravings on Wood by O. Jewitt; and more than 100 other Woodcuts. In One Volume, medium 8vo. price 52s. 6d.

CATES'S NEW DICTIONARY OF GENERAL BIOGRAPHY; Containing Concise Memoirs and Notices of the most Eminent Persons of all Countries, from the Earliest Ages to the Present Time. With a Classified and Chronological Index of the Principal Names. In One Volume, medium 8vo. price 21s.

COPLAND'S DICTIONARY OF PRACTICAL MEDICINE, Abridged from the larger work by the Author, assisted by J. C. COPLAND, M.R.C.S. and throughout brought down to the present state of Medical Science. In One Volume, medium 8vo. price 36s.

A DICTIONARY OF CHEMISTRY AND THE ALLIED BRANCHES OF OTHER SCIENCES, founded on that of the late Dr. Ure. By HENRY WATTS, B.A. F.R.S. F.C.S. assisted by Eminent Scientific and Practical Chemists. In SIX VOLUMES, medium 8vo. price £8. 14s. 6d.

MAUNDER'S POPULAR TREASURIES.

CONTAINING UNIVERSALLY REQUIRED INFORMATION, IN A PORTABLE
SHAPE, AND CONVENIENTLY ARRANGED.

THE TREASURY OF GEOGRAPHY:

Physical, Historical, Descriptive, and Political. Comprising an Account of every Country in the World. Completed by W. HUGHES, F.R.G.S. Revised and Corrected throughout; with 7 Maps and 16 Plates. Price 6s. cloth lettered; or 10s. calf.

THE BIOGRAPHICAL TREASURY:

An Alphabetical Dictionary of the Lives of all Eminent Men. Reconstructed and partly Rewritten, with about 1,000 Additional Memoirs and Notices, by W. L. R. CARES. Price 6s. cloth lettered; or 10s. calf.

THE TREASURY OF NATURAL HISTORY:

Or, Popular Dictionary of Beasts, Birds, Fishes, Reptiles, Insects, and Creeping Things. Revised and supplemented by E. W. H. HOLDSWORTH, F.L.S. F.Z.S. With above 900 Woodcuts. Price 6s. cloth lettered; or 10s. calf.

THE HISTORICAL TREASURY:

Comprising a General Introductory Outline of Universal History, Ancient and Modern, and a Series of Separate Histories of every Nation. Carefully Revised and brought down to the Present Date, by the Rev. G. W. COX, M.A. Price 6s. cloth lettered; or 10s. calf.

THE SCIENTIFIC AND LITERARY TREASURY:

Or, Popular Cyclopædia of Science, Literature, and Art. Revised and in great part Rewritten, with upwards of 1,000 New Articles, by JAMES YATE JOHNSON, Corr. M.Z.S. Price 6s. cloth lettered; or 10s. calf.

THE TREASURY OF KNOWLEDGE AND LIBRARY OF REFERENCE:

A Copious Popular Encyclopædia of General Knowledge. Revised Edition, Corrected and Enlarged. Price 6s. cloth lettered; or 10s. calf.

THE TREASURY OF BIBLE KNOWLEDGE:

Or, Dictionary of the Books, Persons, Places, Events, and other Matters of which mention is made in Holy Scripture. By the Rev. JOHN AYRE, M.A. With about 300 Woodcuts, 15 Plates, and 5 Maps. Price 6s. cloth lettered; or 10s. calf.

THE TREASURY OF BOTANY:

Or, Popular Dictionary of Trees, Shrubs, Plants, Flowers, and all Vegetable Growths, with which is incorporated a Glossary of Botanical Terms. Edited by J. LINDLEY, F.R.S. and T. MOORE, F.L.S. With 300 Woodcuts and 20 Steel Plates. In Two PARTS, price 12s. cloth lettered; or 20s. calf.

London, LONGMANS & CO.
