ing to Pliny (*N. H.*, vi. 144) the little valley of Petra is not quite 2 miles across, and lies at the junction of two roads, from Palmyra and Gaza respectively, 600 miles from the latter. These and other ancient notices leave no doubt as to the identity of the site with the modern Wādī Músá in the mountains which form the eastern wall of the great valley between the Dead Sea and the Gulf of Akaba. Wādī Músá lies just north of the watershed between the two seas, in 30° 19' N. lat. and 35° 31' E. long.¹ Travellers coming up the Arabah usually approach the ruins of Petra from the south-west by a rough path, partly of artificial construction²; but the natural entrance is from the east down a narrow defile more than a mile long, called the Sîk ("shaft"). The Sîk is a contraction in the valley of a stream which comes down from the east, rising in a spring now known as the Fountain of Moses ('Ain Músá),³ and passing between the villages of Eljî and 'Aireh (Palmer). Both these places are ancient; the latter is the fortress Wo'aira of Yâkût,⁴ while Eljî, mentioned by Edrisi, is the "Gaia urbs juxta civitatem Petram" of the *Onomasticon*.⁵ Below these and above the ravine the characteristic rock-cut tombs and dwellings of the Nabatæans begin to appear. But to reach the city proper from these upper settlements one must traverse the whole length of the defile, which is simply a narrow waterway, in some places not more than 10 or 12 feet broad, and walled in by rich brown or red precipices rising from 60 to 120 feet (De Luynes; Stanley doubles this height) above the stream. In ancient times there was a paved path beside the channel, and remains of an arch spanning it are seen high in the air near the entrance. Towards the lower end of the gorge, a turn in the dark path and the descent of a side valley admit a sudden flood of light, and here stands the most famous ruin of Petra, the so-called Khazna, or "treasury of Pharaoh," with a rich façade of late Roman style, not built but hewn out of the rose-coloured limestone. The next turn gives room for a rock-cut theatre, and from this point the gorge begins to open out into the little plain described by Strabo, and gives perhaps the most striking view of the multiplicity of grottoes with elaborate classical façades which line the enclosing mountain-wall. The plain itself is strewn with ruins of temples and other buildings, and stairs once led up the rocky walls to higher structures, of which the most notable is now called the "convent" (Al-Deir). The grottoes are inhabited in cold weather by the Liyâthina Fellâhîn, who also hold the upper part of the valley, and are so troublesome and extortionate that no thorough exploration of the district has yet been carried out. It is not even known where the torrent-bed leads on leaving the plain of Petra. De Luynes describes the water as wholly absorbed by the sands near the theatre, but there is an unexplored gorge to the south-west which is the continuation of the valley.

The Nabatæans, as we see from Diodorus, used Petra as a place of refuge and a safe storehouse for their treasures of frankincense, myrrh, and silver before they gave up their nomadic habits. But Petra was not only safe and well

¹ The latitude and longitude are taken from De Luynes's map. Ptolemy, who, according to Olympiodorus, spent some time in Petra, and doubtless owes to this fact his excellent information about the caravan-routes in Arabia, gives the latitude, with surprising accuracy, as 30° 20'.

² Compare Diod., xix. 97, who describes the Nabatean fortress—it was not a town at the time in question (312 B.C.), for the Nabatæans were still nomads when they were attacked by Antigonus—as ascended to by a single artificial path.

³ This seems to be the fountain mentioned by Nowairi, *sp. Quatre-méros*, p. 84, which flowed with blood and was changed to water by Moses. The name Od-demâ, which gave rise to this legend, may possibly be a relic of the old name of Edom.

⁴ Perhaps also the Iram, یرام, of Gen. xxxvi. 43.

⁵ See Tuch's *Genesis*, 2d ed., p. 271, note.

watered, it lay close to the most important lines of trade. The modern pilgrim-road from Damascus to Mecca, which has taken the place of the old incense-route, passes indeed a little to the east by Ma'an. But to touch Petra involves no great detour even on this line, and in ancient times, when Gaza was the great terminus of the Arabian trade, Petra was the place where the Gaza road branched off from that to Bostra, Palmyra, and north Syria. The route from Egypt to Damascus is also commanded by Petra, and from it too there went a great route direct through the desert to the head of the Persian Gulf. Thus Petra became a centre for all the main lines of overland trade between the East and the West, and it was not till the fall of the Nabataean kingdom that PALMYRA (*q.v.*) superseded it as the chief emporium of north Arabia. Many Roman and other foreign merchants were settled here even in the time of Strabo, and he describes the caravans which passed between it and Leuce Come on the Red Sea coast as comparable to armies.

Petra¹ is a Greek name which cannot have been that used by the Semitic inhabitants, and from Josephus (*Ant.*, iv. 7, 1; 4, 7) and the *Onomastica* (ed. Lag., p. 286 *sq.*) it may be concluded that the natives called the place Rēkem (רִקֶּם), a designation probably derived from the variegated colours of the rocks about Wādī Mūsā, to which all travellers refer with admiration.² But Petra had yet another ancient name familiar from the Bible. The Biblical Sela (generally with the article הַסֵּלָה), a city of Edom (2 Kings xiv. 7; Isa. xvi. 1; also Judges i. 36, where E.V. has "the rock"; perhaps also Isa. xlii. 11), appears to be identified with Petra by the LXX., and certainly is so by the *Onomastica*. Petra, in fact, or the "rock," seems to be simply a translation of Sela, but a somewhat loose one,—for the Hebrew name, corresponding to the Arabic Sal', is properly a hollow between rocks, just such a place as Petra is. The fortress of Edom, according to Obadiah 3, lay "in the clefts of the Sela," and seemed impregnable. And that the name of Sela survived the Nabataean occupation is known from Yāqūt, who places a fortress Sal' in Wādī Mūsā (comp. Nöldeke in *Z.D.M.G.*, xxv. 259). Petra, therefore, was a city before the Nabataeans, and, occupying one of the few cultivable spots in the district, probably never wholly ceased to be inhabited. This identification disposes of another which was accepted alike by the Jewish and Christian Aramaic versions of the Old Testament, and, passing from the Aramæans to the Arabs, has given rise to the modern names Fountain and Wādī of Moses (comp. Yāqūt, iv. 879). According to these versions Rkēm, Rkām, or more precisely Rkēm of Ga'ā (that is, Eljā), is Kadesh Barnea, where flowed the waters of Strife or "well of judgment" (Gen. xiv. 7; Num. xx. 1 *sq.*, xxvii. 14), where Moses struck the rock. This view is ably supported by Greene (*The Hebrew Migration from Egypt*); others identify Kadesh with 'Ain Kādīs (Kudais) on the south border of Judæa.

Petra survived the fall of the Nabataean kingdom, and indeed most of the buildings may be dated from the 2d and 3d centuries. It appears from coins that Hadrian took it into favour and gave it his name. But Palmyra absorbed its trade with the Persian Gulf, and long before Islam the great incense-route was deserted and left Petra, like the more southern Nabataean city of Egra (Hijr), to fall into ruin. The ruins were an object of curiosity in the Middle Ages, and were visited by Sultan Bibars (Quatremère, *l.c.*). The first European to describe them was Burckhardt, and since his time they have often been visited. See the descriptions, plans, and views of Laborde and Linant, *Arabie Pétrée* (Paris, 1830-34); the Duc de Luynes, *Voyage d'exploration à la mer morte, &c.*, Paris,

PETRARCH (1304-1374). Francesco Petrarca, eminent in the history of literature both as one of the four classical Italian poets and also as the first true reviver of learning in mediæval Europe, was born at Arezzo on 20th July 1304. His father Petracco held a post of notary in the Florentine Rolls Court of the Riformagioni; but, having espoused the same cause as Dante during the quarrels of the Blacks and Whites, Petracco was expelled from Florence by that decree of 27th January 1302 which condemned the poet of the *Divine Comedy* to lifelong exile. With his wife he took refuge in the Ghibelline township of Arezzo; and it was here, on the very night when his father, in company with other members of the White party, made an unsuccessful attempt to enter Florence by force, that Francesco first saw the light. He did not remain long in his birthplace. His mother, having obtained permission to return from banishment, settled at Incisa, a little village on the Arno above Florence, in February 1305. Here Petrarch spent seven years of boyhood, acquiring that pure Tuscan idiom which afterwards he used with such consummate mastery in ode and sonnet. Here too, in 1307, his brother Gherardo was born. In 1312 Petracco set up a house for his family at Pisa; but soon afterwards, finding no scope there for the exercise of his profession as jurist, he removed them all in 1313 to Avignon. This was a step of no small importance for the future poet-scholar. Avignon at that period still belonged to Provence, and owned King Robert of Naples as sovereign. But the popes had made it their residence after the insults offered to Boniface VIII. at Anagni in 1303. Avignon was therefore the centre of that varied society which the high pontiffs of Christendom have ever gathered round them. Nowhere else could the youth of genius who was destined to impress a cosmopolitan stamp on mediæval culture and to begin the modern era have grown up under conditions more favourable to his task. At Incisa and at Pisa he had learned his mother-tongue. At Carpentras, under the direction of Conventino of Prato, he studied the humanities between the years 1315 and 1319. Avignon, at a distance from the party strife and somewhat parochial politics of the Italian commonwealths, impressed his mind with an ideal of civility raised far above provincial prejudices. What Petrarch lost in depth and intensity he gained in breadth and serenity by this exile's education. That disengagement from local circumstance which marks his patriotic theories, that conception of self-culture as an end in itself which distinguishes the humanism he inaugurated, were natural to a man who had no country, and who found the spiritual city of his studies and his aspirations in all quarters of the habitable globe.

Petrarch's real name, according to Tuscan usage, was Francesco di Petracco. But he altered this patronymic for the sake of euphony, to Petrarca, proving by this slight change his emancipation from usages which, had he dwelt at Florence, would most probably have been imposed on him. It does not appear that he was attached to either his father or his mother; and, though he loved his brother Gherardo dearly, we recognize in him that type of character for which the self-chosen ties of friendship are more enthralling than the piety of domestic affection. Petracco, who was very anxious that his eldest son should become an eminent jurist, sent him at the age of fifteen to study law at Montpellier. Like Ovid and many other poets, Petrarch felt no inclination for his father's profession. His intellect, indeed, was not incapable of understanding and admiring the majestic edifice of Roman law, but he shrank with disgust from the illiberal technicalities of practice. There is an authentic story of Petracco's flinging

¹ Arabia Petraea is not properly Stony Arabia, but the Arabia of which Petra is the centre—*ἡ κατὰ Πέτραν Ἀραβία* of Agathemerus.

² The rock-hewn city of Rākīm (Istakhri, 64; *Géogr. d'Abulf.*, Fr. tr., ii. 2, 5), which Schultens (*Ind. Geog. in Vit. Sal.*) proposes to identify with Petra, is a different place, close to 'Ammān (Mokaddas, p. 175).

the young student's books of poetry and rhetoric upon the fire, but saving Virgil and Cicero half-burned from the flames at his son's passionate entreaties. Notwithstanding Petrarch's firm determination to make himself a scholar and a man of letters rather than a lawyer, he so far submitted to his father's wishes as to remove about the year 1323 to Bologna, which was then the headquarters of juristic learning. There he stayed with his brother Gherardo until 1326, when his father died, and he returned to Avignon. Banishment and change of place had already diminished Petrarch's fortune, which was never large; and a fraudulent administration of his estate after his death left the two heirs in almost complete destitution. The most precious remnant of Petrarch's inheritance was a MS. of Cicero. There remained no course open for him but to take orders. This he did at once on his arrival in Provence; and we have good reason to believe that he advanced in due time to the rank of priest. A great Roman noble and ecclesiastic, Giacomo Colonna, afterwards bishop of Lombez, now befriended him, and Petrarch lived for some years in partial dependence on this patron.

On the 6th of April 1327 happened the most famous event of Petrarch's history. He saw Laura for the first time in the church of St Clara at Avignon. Who Laura was remains uncertain still. That she was the daughter of Audibert de Noves and the wife of Hugh de Sade rests partly on tradition and partly on documents which the abbé de Sade professed to have copied from originals in the last century. Nothing is now extant to prove that, if this lady really existed, she was the Laura of the *Canzoniere*, while there are reasons for suspecting that the abbé was either the fabricator of a romance flattering to his own family, or the dupe of some previous impostor. We may, however, reject the sceptical hypothesis that Laura was a mere figment of Petrarch's fancy; and, if we accept her personal reality, the poems of her lover demonstrate that she was a married woman with whom he enjoyed a respectful and not very intimate friendship.

Petrarch's inner life after this date is mainly occupied with the passion which he celebrated in his Italian poems, and with the friendships which his Latin epistles dimly reveal to us. Besides the bishop of Lombez he was now on terms of intimacy with another member of the great Colonna family, the Cardinal Giovanni. A German, Ludwig, whom he called Socrates, and a Roman, Lello, who received from him the classic name of Lælius, were among his best-loved associates. He probably owed his livelihood to the generosity of prelates, with whom he played the courtier or the secretary; for we do not hear of his having occupied any benefice at this period. Avignon was the chief seat of his residence up to the year 1333, when he became restless, and undertook his first long journey. On this occasion he visited Paris, Ghent, Liège, Cologne, making the acquaintance of learned men and copying the manuscripts of classical authors. On his return to Avignon he engaged in public affairs, pleaded the cause of the Scaligers in their lawsuit with the Rossi for the lordship of Parma, and addressed two poetical epistles to Pope Benedict XII. upon the restoration of the papal see to Rome. His eloquence on behalf of the tyrants of Verona was successful. It won him the friendship of their ambassador, Azzo di Correggio,—a fact which subsequently influenced his life in no small measure. At the same time his treatment of the papal question made him pose as an Italian patriot clinging to the ideal of Rome as the sovereign city of civilization. Not very long after these events Petrarch made his first journey to Rome, a journey memorable from the account which he has left us of the impression he received from its ruins.

It was some time in the year 1337 that he established

himself at Vaucluse and began that life of solitary study, heightened by communion with nature in her loneliest and wildest moods, which distinguished him in so remarkable a degree from the common herd of mediæval scholars. Here he spent his time partly among books, meditating on Roman history, and preparing himself for the Latin epic of *Africa*. In his hours of recreation he climbed the hills or traced the Sorgues from its fountain under those tall limestone cliffs, while odes and sonnets to Madonna Laura were committed from his memory to paper. We may also refer many of his most important treatises in prose, as well as a large portion of his Latin correspondence, to the leisure he enjoyed in this retreat. Some woman, unknown to us by name, made him the father of a son, Giovanni, in the year 1337; and she was probably the same who brought him a daughter, Francesca, in 1343. Both children were afterwards legitimized by papal bulls. Meanwhile his fame as a poet in the Latin and the vulgar tongues steadily increased, until, when the first draughts of the *Africa* began to circulate about the year 1339, it became manifest that no one had a better right to the laurel crown than Petrarch. A desire for glory was one of the most deeply-rooted passions of his nature, and one of the points in which he most strikingly anticipated the humanistic scholars who succeeded him. It is not, therefore, surprising to find that he exerted his influence in several quarters with the view to obtaining the honours of a public coronation. The result of his intrigues was that on a single day in 1340, the 1st of September, he received two invitations, from the university of Paris and from King Robert of Naples respectively. He chose to accept the latter, journeyed in February 1341 to Naples, was honourably entertained by the king, and, after some formal disputations on matters touching the poet's art, was sent with magnificent credentials to Rome. There, in the month of April, Petrarch assumed the poet's crown upon the Capitol from the hand of the Roman senator amid the plaudits of the people and the patricians. The oration which he delivered on this occasion was composed upon these words of Virgil:

"Sed me Parnassi deserta per ardua dulcis
Raptat amor."

The theme was well chosen; and the ceremony, though we cannot but regard it with a somewhat pitying smile, was symbolical of much. According to mediæval conceptions, Rome, though abandoned by her emperor and pope, was still the mistress of the world; and the poet, who upon that April day uttered the passion for Parnassus which drew him through steep and desert regions, was destined to revive the arts and sciences in the midst of a barren age. The ancient and the modern eras met together on the Capitol at Petrarch's coronation, and a new stadium for the human spirit, that which we are wont to style Renaissance, was opened.

With the coronation in Rome a fresh chapter in the biography of Petrarch may be said to have begun. Henceforth he ranked as a rhetorician and a poet of European celebrity, the guest of princes, and the ambassador to royal courts. During the spring months of 1341 his friend Azzo di Correggio had succeeded in freeing Parma from subjugation to the Scaligers, and was laying the foundations of his own tyranny in that city. He invited Petrarch to attend him when he made his triumphal entry at the end of May; and from this time forward for a considerable period Parma and Vaucluse were the two headquarters of the poet. The one he called his transalpine, the other his cisalpine Parnassus. The events of the next six years of his life, from May 1341 to May 1347, may be briefly recapitulated. He lost his old friend the bishop of Lombez by death and his brother Gherardo by the entrance of the latter into a Carthusian monastery. Various

small benefices were conferred upon him; and repeated offers of a papal secretaryship, which would have raised him to the highest dignities, were made and rejected. Petrarch remained true to the instinct of his own vocation, and had no intention of sacrificing his studies and his glory to ecclesiastical ambition. In January 1343 his old friend and patron Robert, king of Naples, died, and Petrarch was sent on an embassy from the papal court to his successor Joan. The notices which he has left us of Neapolitan society at this epoch are interesting, and it was now, perhaps, that he met Boccaccio for the first time. The beginning of the year 1345 was marked by an event more interesting in the scholar's eyes than any change in dynasties. This was no less than a discovery at Verona of Cicero's *Familiar Letters*. It is much to be regretted that Petrarch found the precious MS. so late in life, when the style of his own epistles had been already modelled upon that of Seneca and St Augustine. No one, not even Erasmus, would have profited more by the study of those epistolary masterpieces, or would have been better able to imitate their point and ease of diction, had he become acquainted with them at an earlier period.

In the month of May 1347 Cola di Rienzi accomplished that extraordinary revolution which for a short space revived the republic in Rome, and raised this enthusiast to titular equality with kings. Petrarch, who in politics was no less visionary than Rienzi, hailed the advent of a founder and deliverer in the self-styled tribune. Without considering the impossibility of restoring the majesty of ancient Rome, or the absurdity of dignifying the mediæval Roman rabble by the name of *Populus Romanus*, he threw himself with passion into the republican movement, and sacrificed his old friends of the Colonna family to what he judged a patriotic duty. To follow the meteoric course of Rienzi through those months of mock supremacy, exile, and imprisonment at Avignon does not concern Petrarch's biographer. It will be enough to say that the poet contented himself with writing a rhetorical exhortation to the Roman people on the occasion of the tribune's downfall, giving vent, as usual, through eloquence to emotions which men of more practical character strove to express in act.

Petrarch built himself a house at Parma in the autumn of 1347. Here he hoped to pursue the tranquil avocations of a poet honoured by men of the world and men of letters throughout Europe, and of an idealistic politician, whose effusions on the questions of the day were read with pleasure for their style. But in the course of the next two years this agreeable prospect was overclouded by a series of calamities. Laura died of the plague on the 6th April 1348. Francesco degli Albizzi, Mainardo Accursio, Roberto de' Bardi, Sennuccio del Bene, Luchino Visconti, the cardinal Giovanni Colonna, and several other friends followed to the grave in rapid succession. All of these had been intimate acquaintances and correspondents of the poet. Friendship with him was a passion; or, what is more true perhaps, he needed friends for the maintenance of his intellectual activity at the highest point of its effectiveness. Therefore he felt the loss of these men acutely. We may say with certainty that Laura's death, accompanied by that of so many distinguished associates, was the turning-point in Petrarch's inner life. He began to think of quitting the world, and pondered a plan for establishing a kind of humanistic convent, where he might dedicate himself, in the company of kindred spirits, to still severer studies and a closer communion with God. Though nothing came of this scheme, a marked change was henceforth perceptible in Petrarch's literary compositions. The poems written *In Morte di Madonna Laura* are graver and of more religious tone. The prose works touch on retrospective topics or deal with subjects of deep meditation. At the

same time his renown, continually spreading, opened to him ever fresh relations with Italian despots. The noble houses of Gonzaga at Mantua, of Carrara at Padua, of Este at Ferrara, of Malatesta at Rimini, of Visconti at Milan, vied with Azzo di Correggio in entertaining the illustrious man of letters. It was in vain that his correspondents pointed out the discrepancy between his professed zeal for Italian liberties, his recent enthusiasm for the Roman republic, and this alliance with tyrants who were destroying the freedom of the Lombard cities. Petrarch remained an incurable rhetorician; and, while he stigmatized the despots in his ode to Italy and in his epistles to the emperor, he accepted their hospitality. They, on their part, seem to have understood his temperament, and to have agreed to recognize his political theories as of no practical importance. The tendency to honour men of letters and to patronize the arts which distinguished Italian princes throughout the Renaissance period first manifested itself in the attitude assumed by Visconti and Carraresi to Petrarch.

When the jubilee of 1350 was proclaimed, Petrarch made a pilgrimage to Rome, passing and returning through Florence, where he established a firm friendship with Boccaccio. It has been well remarked that, while all his other friendships are shadowy and dim, this one alone stands out with clearness. Each of the two friends had a distinguished personality. Each played a foremost part in the revival of learning. Boccaccio carried his admiration for Petrarch to the point of worship. Petrarch repaid him with sympathy, counsel in literary studies, and moral support which helped to elevate and purify the younger poet's over-sensuous nature. It was Boccaccio who in the spring of 1351 brought to Petrarch, then resident with the Carrara family at Padua, an invitation from the seignior of Florence to accept the rectorship of their recently-founded university. This was accompanied by a diploma of restoration to his rights as citizen and restitution of his patrimony. But, flattering as was the offer, Petrarch declined it. He preferred his literary leisure at Vacluse, at Parma, in the courts of princes, to a post which would have brought him into contact with jealous priors and have reduced him to the position of the servant of a commonwealth. Accordingly, we find him journeying again in 1351 to Vacluse, again refusing the office of papal secretary, again planning visionary reforms for the Roman people, and beginning that curious fragment of an autobiography which is known as the *Epistle to Posterity*. Early in 1353 he left Avignon for the last time, and entered Lombardy by the pass of Mont Genève, making his way immediately to Milan. The archbishop Giovanni Visconti was at this period virtually despot of Milan. He induced Petrarch, who had long been a friend of the Visconti family, to establish himself at his court, where he found employment for him as ambassador and orator. The most memorable of his diplomatic missions was to Venice in the autumn of 1353. Towards the close of the long struggle between Genoa and the republic of St Mark the Genoese entreated Giovanni Visconti to mediate on their behalf with the Venetians. Petrarch was entrusted with the office; and on 8th November he delivered a studied oration before the doge Andrea Dandolo and the great council. His eloquence had no effect; but the orator entered into relations with the Venetian aristocracy which were afterwards extended and confirmed. Meanwhile, Milan continued to be his place of residence. After Giovanni's death he remained in the court of Bernabò and Galeazzo Visconti, closing his eyes to their cruelties and exactions, serving them as a diplomatist, making speeches for them on ceremonial occasions, and partaking of the splendid hospitality they offered to emperors and princes. It was in this capacity of an independent man of letters.

nighly placed and favoured at one of the most wealthy courts of Europe, that he addressed epistles to the emperor Charles IV. upon the distracted state of Italy, and entreated him to resume the old Ghibelline policy of imperial interference. Charles IV. passed through Mantua in the autumn of 1354. There Petrarch made his acquaintance, and, finding him a man unfit for any noble enterprise, declined attending him to Rome. When Charles returned to Germany, after assuming the crowns in Rome and Milan, Petrarch addressed a letter of vehement invective and reproach to the emperor who was so negligent of the duties imposed on him by his high office. This did not prevent the Visconti sending him on an embassy to Charles in 1356. Petrarch found him at Prague, and, after pleading the cause of his masters, was despatched with honour and the diploma of count palatine. His student's life at Milan was again interrupted in 1360 by a mission on which Galeazzo Visconti sent him to King John of France. The tyrants of Milan were aspiring to royal alliances; Gian Galeazzo Visconti had been married to Isabella of France; Violante Visconti, a few years later, was wedded to the English duke of Clarence. Petrarch was now commissioned to congratulate King John upon his liberation from captivity in England. This duty performed, he returned to Milan, where in 1361 he received news of the deaths of his son Giovanni and his old friend Socrates. Both had been carried off by plague.

The remaining years of Petrarch's life, important as they were for the furtherance of humanistic studies, may be briefly condensed. On 11th May 1362 he settled at Padua, from the neighbourhood of which he never moved again to any great distance. The same year saw him at Venice, making a donation of his library to the republic of St Mark. Here his friend Boccaccio introduced to him the Greek teacher Leontius Pilatus. Petrarch, who possessed a MS. of Homer and a portion of Plato, never acquired the Greek language, although he attempted to gain some little knowledge of it in his later years. Homer, he said, was dumb to him, while he was deaf to Homer; and he could only approach the *Iliad* in Boccaccio's rude Latin version. About this period he saw his daughter Francesca happily married, and undertook the education of a young scholar from Ravenna, whose sudden disappearance from his household caused him the deepest grief. This youth has been identified, but on insufficient grounds, with that Giovanni Malpaghini of Ravenna who was destined to form a most important link between Petrarch and the humanists of the next age of culture. The public affairs of Italy and Europe continued to interest him; nor was he ever idle in composing letters and orations, some of which were not without political importance, while all of them contributed to form a style that had the greatest influence over successive generations of Italian chancellors and secretaries. Gradually his oldest friends dropped off. Azzo di Correggio died in 1362, and Lælius, Simonides, Barbato, in the following year. His own death was reported in 1365; but he survived another decade. Much of this last stage of his life was occupied at Padua in a controversy with the Averroists, whom he regarded as dangerous antagonists both to sound religion and to sound culture. A curious treatise, which grew in part out of this dispute and out of a previous duel with physicians, was the book *Upon his own Ignorance and that of many others*. At last, in 1369, tired with the bustle of a town so big as Padua, he retired to Arquà, a village in the Euganean hills, where he continued his usual train of literary occupations, employing several secretaries, and studying unremittingly. All through these declining years his friendship with Boccaccio was maintained and strengthened. It rested on a solid basis of mutual affection and of common studies, the

different temperaments of the two scholars securing them against the disagreements of rivalry or jealousy. One of Petrarch's last compositions was a Latin version of Boccaccio's story of Griselda. On 18th July 1374 his people found the old poet and scholar dead among his books in the library of that little house which looks across the hills and lowlands toward the Adriatic.

When we attempt to estimate Petrarch's position in the history of modern culture, the first thing which strikes us is that he was even less eminent as an Italian poet than as the founder of Humanism, the inaugurator of the Renaissance in Italy. What he achieved for the modern world was not merely to bequeath to his Italian imitators masterpieces of lyrical art unrivalled for perfection of workmanship, but also, and far more, to open out for Europe a new sphere of mental activity. Standing within the threshold of the Middle Ages, he surveyed the kingdom of the modern spirit, and, by his own inexhaustible industry in the field of scholarship and study, he determined what we call the revival of learning. By bringing the men of his own generation into sympathetic contact with antiquity, he gave a decisive impulse to that European movement which restored freedom, self-consciousness, and the faculty of progress to the human intellect. The warm recognition which he met with in his lifetime and the extraordinary activity of his immediate successors prove indeed that the age itself was ripe for this momentous change. Yet it is none the less certain that Petrarch stamped his genius on the spirit of the time, that he was the hero of the humanistic effort. He was the first man to collect libraries, to accumulate coins, to advocate the preservation of antique monuments, and to collate MSS. Though he knew no Greek, he was the first to appreciate its vast importance; and through his influence Boccaccio laid the earliest foundations of its study. More than this, he was the first to approach the great authors of antiquity with intelligence. It was not the extent but the lucidity of his erudition, not the matter but the spirit of his scholarship, that placed him at an immeasurable distance of superiority above his predecessors. When we compare the use which even Dante made of classical knowledge in his *De Monarchia* with Petrarch's touch upon the ancients in his numerous prose works, we perceive that we have passed from the mediæval to the modern conception of literature. For him the authors of the Greek and Latin world were living men,—more real, in fact, than those with whom he corresponded; and the rhetorical epistles he addressed to Cicero, Seneca, and Varro prove that he dwelt with them on terms of sympathetic intimacy. So far-reaching were the interests controlled by him in this capacity of humanist that his achievement as an Italian lyricist seems by comparison insignificant.

Petrarch's ideal of humanism was essentially a noble one. He regarded the orator and the poet as teachers, bound to complete themselves by education, and to exhibit to the world an image of perfected personality in prose and verse of studied beauty. Self-culture and self-effectuation seemed to him the highest aims of man. Everything which contributed to the formation of a free, impassioned, liberal individuality he regarded as praiseworthy. Everything which retarded the attainment of that end was contemptible in his eyes. The authors of antiquity, the Holy Scriptures, and the fathers of the church were valued by him as one common source of intellectual enlightenment. Eminently religious, and orthodox in his convictions, he did not seek to substitute a pagan for the Christian ideal. This was left for the scholars of the 15th and 16th centuries in Italy. At the same time, the Latin orators, historians, and poets were venerated by him as depositaries of a tradition only second in importance to revelation. For.

him there was no schism between Rome and Galilee, between classical genius and sacred inspiration. Though the latter took the first rank in relation to man's eternal welfare, the former was necessary for the perfection of his intellect and the civilization of his manners. With this double ideal in view, Petrarch poured scorn upon the French physicians and the Italian Averroists for their illiberal philistinism, no less than for their materialistic impiety. True to his conception of independent intellectual activity, he abstained from a legal career, refused important ecclesiastical office, and contented himself with paltry benefices which implied no spiritual or administrative duties, because he was resolved to follow the one purpose of his life,—self-culture. Whatever in literature revealed the hearts of men was infinitely precious to him; and for this reason he professed almost a cult for St Augustine. It was to Augustine, as to a friend or a confessor, that he poured forth the secrets of his own soul in the book *De Contemptu Mundi*.

In this effort to realize his truest self Petrarch was eminently successful. Much as he effected by restoring to the world a sound conception of learning, and by rousing that genuine love and curiosity which led to the revival, he did even more by impressing on the age his own full-formed and striking personality. In all things he was original. Whether we regard him as a priest who published poem after poem in praise of an adored mistress, as a plebeian man of letters who conversed on equal terms with kings and princes, as a solitary dedicated to the love of nature, as an amateur diplomatist treating affairs of state with pompous eloquence in missives sent to popes and emperors, or again as a traveller eager for change of scene, ready to climb mountains for the enjoyment of broad prospects over spreading champaigns; in all these divers manifestations of his peculiar genius we trace some contrast with the manners of the 14th century, some emphatic anticipation of the 16th. The defects of Petrarch's character were no less striking than its qualities, and were indeed their complement and counterpart. That vivid conception of intellectual and moral self-culture which determined his ideal took the form in actual life of all-absorbing egotism. He was not content with knowing himself to be the leader of the age. He claimed autocracy, suffered no rival near his throne, brooked no contradiction, demanded unconditional submission to his will and judgment. His friends were treated by him as subordinates and vassals with exacting magnanimity. The preoccupation with himself, which makes his letters and prose treatises a mine of autobiographical information, rouses a certain contempt when we watch it degenerating into vanity, appetite for flattery, intrigues for the poet's crown, restless change from place to place in search of new admirers, desire for ceremonial pomp, and half-concealed detraction of superior genius. Petrarch was made up of contradictions. Praising solitude, playing the hermit at Vaucluse, he only loved seclusion as a contrast to the society of courts; while he penned dissertations on the futility of fame and the burden of celebrity, he was trimming his sails to catch the breeze of popular applause. No one professed a more austere morality, and few mediæval writers indulged in cruder satire on the female sex; yet he passed some years in the society of a concubine, and his living masterpiece of art is the apotheosis of chivalrous passion for a woman. These discords of an undecided nature displayed themselves in his political theories and in his philosophy of conduct. In one mood he was fain to ape the antique patriot; in another he affected the monastic saint. He was clamorous for the freedom of the Roman people; yet at one time he called upon the popes to re-establish themselves in the Eternal City; at another he besought the emperor to make it his

headquarters; at a third he hailed in Rienzi the founder of a new republic. He did not perceive that all these plans were incompatible. His relations to the Lombard nobles were equally at variance with his professed patriotism; and, while still a housemate of Visconti and Correggi, he kept on issuing invectives against the tyrants who divided Italy. It would not be difficult to multiply these antitheses in the character and the opinions of this singular man. But it is more to the purpose to remark that they were harmonized in a personality of potent and enduring force. Petrarch was essentially the first of the moderns, the ancestor of Hamlet and Faust, Rousseau and Childe Harold. That strange spirit of unrest and melancholy, of malady and isolation, which drove him from time to time into the desert, where he sought companionship with the great writers of the past, was the inner witness to an irresolvable contradiction between himself and the age in which he lived.

The point to notice in this complex personality is that Petrarch's ideal remained always literary. As philosopher, politician, historian, essayist, orator, he aimed at lucid and harmonious expression,—not, indeed, neglecting the importance of the material he undertook to treat, but approaching his task in the spirit of an artist rather than a thinker or a man of action. This accounts for his bewildering versatility, and for his apparent want of grasp on conditions of fact. Viewed in this light Petrarch anticipated the Italian Renaissance in its weakness,—that philosophical superficiality, that tendency to ornate rhetoric, that preoccupation with stylistic trifles, that want of profound conviction and stern sincerity, which stamp its minor literary products with the note of mediocrity. Had Petrarch been possessed with a passion for some commanding principle in politics, morality, or science, instead of with the thirst for self-glorification and the ideal of artistic culture, it is not wholly impossible that Italian humanism might have assumed a manlier and more conscientious tone. But this is not a question which admits of discussion; for the conditions which made Petrarch what he was were already potent in Italian society. He did but express the spirit of the period he opened; and it may also be added that his own ideal was higher and severer than that of the illustrious humanists who followed him.

As an author Petrarch must be considered from two points of view,—first as a writer of Latin verse and prose, secondly as an Italian lyricist. In the former capacity he was speedily outstripped by more fortunate scholars. His eclogues and epistles and the epic of *Africa*, on which he set such store, exhibit a comparatively limited command of Latin metre. His treatises, orations, and familiar letters, though remarkable for a prose style which is eminently characteristic of the man, are not distinguished by purity of diction. Much as he admired Cicero, it is clear that he had not freed himself from current mediæval Latinity. Seneca and Augustine had been too much used by him as models of composition. At the same time it will be conceded that he possessed a copious vocabulary, a fine ear for cadence, and the faculty of expressing every shade of thought or feeling. What he lacked was that insight into the best classical masterpieces, that command of the best classical diction, which is the product of successive generations of scholarship. To attain to this, Giovanni da Ravenna, Colluccio Salutato, Poggio, and Filelfo had to labour, before a Poliziano and a Bembo finally prepared the path for an Erasmus. Had Petrarch been born at the close of the 15th instead of at the opening of the 14th century there is no doubt that his Latinity would have been as pure, as versatile, and as pointed as that of the witty stylist of Rotterdam.

With regard to his Italian poetry Petrarch occupies a

very different position. The *Rime in Vita e Morte di Madonna Laura* cannot become obsolete, for perfect metrical form has here been married to language of the choicest and the purest. It is true that even in the *Canzoniere*, as Italians prefer to call that collection of lyrics, Petrarch is not devoid of faults belonging to his age, and affectations which have imposed themselves with disastrous effect through his authority upon the literature of Europe. He appealed in his odes and sonnets to a restricted audience already educated by the chivalrous love-poetry of Provence and by Italian imitations of that style. He was not careful to exclude the commonplaces of the school, nor anxious to finish a work of art wholly free from fashionable graces and from contemporary conceits. There is therefore a certain element of artificiality in his treatment; and this, since it is easier to copy defects than excellencies, has been perpetuated with wearisome monotony by versifiers who chose him for their model. But, after making due allowance for peculiarities, the abuse of which has brought the name of Petrarchist into contempt, we can agree with Shelley that the lyrics of the *Canzoniere* "are as spells which unseal the inmost enchanted fountains of the delight which is the grief of love." That is to say, Petrarch in this monumental series of odes and sonnets depicted all the moods of a real passion, and presented them in a style of such lucidity, with so exquisite a command of rhythmical resources, and with humanity of emotion so simple and so true, as to render his portrait of a lover's soul applicable to all who have loved and will love for ages. If space sufficed much might be written about the peculiar position held by Petrarch between the metaphysical lyrists of Tuscany and the more realistic amorists of succeeding generations. True in this respect also to his anticipation of the coming age, he was the first Italian poet of love to free himself from allegory and mysticism. Yet he was far from approaching the analysis of emotion with the directness of a Heine or De Musset. Though we believe in the reality of Laura, we derive no clear conception either of her person or her character. She is not so much a woman as woman in the abstract; and perhaps on this very account the poems written for her by her lover have been taken to the heart by countless lovers who came after him. The method of his art is so generalizing, while his feeling is so natural, that every man can see himself reflected in the singer and his mistress shadowed forth in Laura. The same criticism might be passed on Petrarch's descriptions of nature. That he felt the beauties of nature keenly is certain, and he frequently touches them with obvious appreciation. Yet he has written nothing so characteristic of Vaucluse as to be inapplicable to any solitude where there are woods and water. The *Canzoniere* is therefore one long melodious monody poured from the poet's soul, with the indefinite form of a beautiful woman seated in a lovely landscape, a perpetual object of delightful contemplation. This disengagement from local circumstance without the sacrifice of emotional sincerity is a merit in Petrarch, but it became a fault in his imitators. Lacking his intensity of passion and his admirable faculty for seizing the most evanescent shades of difference in feeling, they degenerated into colourless and lifeless insipidities made insupportable by the frigid repetition of tropes and conceits which we are fain to pardon in the master.

Petrarch did not distinguish himself by love-poetry alone in the Italian language. His odes to Giacomo Colonna, to Cola di Rienzi, and to the princes of Italy display him in another light. They exhibit the oratorical fervour, the pleader's eloquence in its most perfect lustre, which Petrarch possessed in no less measure than subjective passion. Modern literature has nothing nobler, nothing more

harmonious in the declamatory style than these three patriotic effusions. Their spirit itself is epoch-making in the history of Europe. Up to this point Italy had scarcely begun to exist. There were Florentines and Lombards, Guelfs and Ghibellines; but even Dante had scarcely conceived of Italy as a nation, independent of the empire, inclusive of her several component commonwealths. To the high conception of Italian nationality, to the belief in that spiritual unity which underlay her many discords and divisions, Petrarch attained partly through his disengagement from civic and local partisanship, partly through his large and liberal ideal of culture. It was the function of the Renaissance to bring all parts of the Italian peninsula into an intellectual harmony by means of common enthusiasm for arts and letters. But it remained for the present century to witness the political consolidation of the Italian people under a single government.

The materials for a life of Petrarch are afforded in abundance by his letters, collected and prepared for publication under his own eyes. These are divided into *Familiar Correspondence*, *Correspondence in Old Age*, *Divers Letters*, and *Letters without a Title*; to which may be added the curious autobiographical fragment entitled the *Epistle to Posterity*. Next in importance rank the epistles and eclogues in Latin verse, the Italian poems, and the rhetorical addresses to popes, emperors, Cola di Rienzi, and some great men of antiquity. For the comprehension of his character the treatise *De Contemptu Mundi*, addressed to St Augustine and styled his Secret, is invaluable. Without attempting a complete list of Petrarch's works, it may be well to illustrate the extent of his erudition and his activity as a writer by a brief enumeration of the most important. In the section belonging to moral philosophy we find *De Remediis Utriusque Fortune*, a treatise on human happiness and unhappiness; *De Vita Solitaria*, a panegyric of solitude; *De Otio Religiosorum*, a similar essay on monastic life, inspired by a visit to his brother Gherardo in his convent near Marseilles. On historical subjects the most considerable are *Rerum Memorandarum Libri*, a miscellany from a student's commonplace-book, and *De Viris illustribus*, an epitome of the biographies of Roman worthies. Three polemical works require mention: *Contra ejusdam anonymi Galli columnias Apologia*, *Contra Medicum quendam Invektivatum Libri*, and *De sui ipsius et multorum Ignorantia*,—controversial and sarcastic compositions, which grew out of Petrarch's quarrels with the physicians of Avignon and the Averroists of Padua. In this connexion it might also be well to mention the remarkable satires on the papal court, included in the *Epistolæ sine Titulo*. Five public orations have been preserved, the most weighty of which, in explanation of Petrarch's conception of literature, is the speech delivered on the Capitol upon the occasion of his coronation. Among his Latin poems *Africa*, an epic on Scipio Africanus, takes the first place. Twelve *Eclogues* and three books of *Epistles* in verse close the list. In Italian we possess the *Canzoniere*, which includes odes and sonnets written for Laura during her lifetime, those written for her after her death, and a miscellaneous section containing the three patriotic odes and three famous poetical invectives against the papal court. Besides these lyrical compositions are the semi-epical or allegorical *Trionfi*,—Triumphs of Love, Chastity, Death, Fame, Time, and Divinity, written in terza rima of smooth and limpid quality. Though these Triumphs, as a whole, are deficient in poetic inspiration, the second canto of the *Trionfo della Morte*, in which Petrarch describes a vision of his dead love Laura, is justly famous for reserved passion and pathos tempered to a tranquil harmony.

The complete bibliography of Petrarch forms a considerable volume. Such a work was attempted by Domenico Rossetti (Trieste, 1828). It will be enough here to mention the Basel edition of 1581, in folio, as the basis for all subsequent editions of his collected works. Two editions of the *Canzoniere* deserve especial notice,—that of Marsand (Padua, 1820) and that of Leopardi in Le Monnier's collection. Nor must Fracassetti's Italian version of the *Letters* (published in 5 vols. by Le Monnier) be neglected. De Sade's *Life of the poet* (Amsterdam, 1764-67) marks an epoch in the history of his numerous biographies; but this is in many important points untrustworthy, and it has been superseded by Gustav Koerting's exhaustive volume on *Petrarch's Leben und Werke* (Leipzig, 1878). Georg Voigt's *Wiederbelebung des classischen Alterthums* (Berlin, 1859) contains a well-digested estimate of Petrarch's relation to the revival of learning. Mezière's *Petrarque* (1868) is a monograph of merit. English readers may be referred to a little book on Petrarch by Henry Reeve, and to vols. II. and IV. of Symonds's *Renaissance in Italy*. (J. A. S.)

PETREL, the name applied in a general way to a group of Birds (of which more than 100 species are recognized) from the habit which some of them possess of apparently walking on the surface of the water as the apostle St Peter (of whose name the word is a diminutive form) is recorded (Matt. xiv. 29) to have done. For a long while the Petrels were ranked as a Family, under the name of *Procell-*

aviidæ,¹ and thought to be either very nearly allied to the Gulls, *Laridæ*, or intermediate between that Family and the *Steganopodes*; but this opinion has gradually given way, and it is now hard to resist the conclusion that they have to be regarded as an "Order," to which the name *Tubinares* has been applied from the tubular form of their nostrils, a feature possessed in greater or less degree by all of them, and by which each may at a glance be recognized. They have usually been subdivided into three groups or Subfamilies, (1) *Pelecanoidinæ* (or *Halodrominæ*), containing some three or four species known as Diving-Petrels, with habits very different from others of the Family, and almost peculiar to high southern latitudes from Cape Horn to New Zealand; (2) *Procellariinæ*, or Petrels proper; and (3) *Diomedeinæ*, or Albatrosses (cf. MALLEMUCK, vol. xv. p. 334). Recently, however, the anatomy of the group has been subjected to very close examination by Garrod and W. A. Forbes, the latter of whom has summed up the results obtained by himself and his predecessor in an elaborate essay, forming part ix. of the *Zoology* of the voyage of the "Challenger," which shew determinations that differ greatly from any that had been reached by prior systematists. According to these investigators, the *Tubinares* are composed of two Families, *Procellariidæ* and *Oceanitidæ*, whose distinctness had never before been suspected²—the latter consisting of four genera not very much differing in appearance from many others, while the former includes as Subfamilies the Albatrosses, *Diomedeinæ*, with three genera, *Diomedea*, *Thalassiarche*, and *Phæbetría*, and the true Petrels, *Procellariinæ*, in which last are combined forms so different externally and in habit as the Diving-Petrels, above noticed, the Storm-Petrels, *Procellaria*, the Flat-billed Petrels, *Prion*, the FULMAR (vol. ix. p. 817), the SHEARWATERS (*q.v.*), and others. Want of space forbids us here dwelling on the characters assigned to these different groups, or the means which have led to this classification of it, set forth at great length in the essay cited, where also will be found copious references to previous studies of the Petrels, among which may here be especially mentioned those of MM. Hombron and Jacquinot (*Comptes Rendus*, 1844, pp. 353-358, and *Zool. Voy. au Pol Sud*, vol. iii.), Prof. Coues (*Proc. Acad. Philadelphia*, 1864, pp. 72-91, 116-144, and 1866, pp. 25-33, 134-197), and Mr Salvin (*Orn. Miscellany*, ii. pp. 223-238, 249-257; and *Zoology*, *Voy. "Challenger,"* pt. viii. pp. 140-149).

Petrels are dispersed throughout all the seas and oceans of the world, and some species apparently never resort to land except for the purpose of nidification, though nearly all are liable at times to be driven ashore, and often very far inland, by gales of wind.³ It would also seem that during the breeding-season many of them are wholly nocturnal in their habits, passing the day in holes of the ground, or in clefts of the rocks, in which they generally nestle, the hen of each pair laying a single white egg, sparsely speckled in a few species with fine reddish dots. Of those species that frequent the North Atlantic, the common Storm-Petrel, *Procellaria pelagica*, a little bird which has to the ordinary eye rather the look of a Swift or Swallow, is the "Mother Carey's chicken" of sailors, and is widely believed to be the harbinger of bad weather; but seamen hardly discriminate between this and others nearly resembling it in appearance, such as Leach's or the

Fork-tailed Petrel, *Cymochorea leucorrhœa*, a rather larger but less common bird, and Wilson's Petrel, *Oceanites oceanicus*, the type of the Family *Oceanitidæ* mentioned above, which is more common on the American side. But it is in the Southern Ocean that Petrels most abound, both as species and as individuals. The Cape-Pigeon or Pintado Petrel, *Daption capensis*, is one that has long been well known to mariners and other wayfarers on the great waters, while those who voyage to or from Australia, whatever be the route they take, are certain to meet with many more species, some, as *Ossifraga gigantea*, as large as Albatrosses, and several of them called by sailors by a variety of choice names, generally having reference to the strong smell of musk emitted by the birds, among which that of "Stink-pot" is not the most opprobrious. None of the Petrels are endowed with any brilliant colouring—sooty-black, grey of various tints (one of which is often called "blue"), and white being the only hues their plumage exhibits; but their graceful flight, and their companionship when no other life is visible around a lonely vessel on the widest of oceans, give them an interest to beholders, though this is too often marred by the wanton destruction dealt out by brutal or thoughtless persons who thus seek to break the tediousness of a long voyage. The distribution of the several species of Petrels in the Southern Ocean has been ably treated by Prof. A. Milne-Edwards in the *Annales des Sciences Naturelles* for 1882 (ser. 6, *Zoologie*, vol. xiii. art. 4, pp. 1-22), of which essay a translation will be found in the *Mittheilungen des Ornithologischen Vereins in Wien* for 1884. (A. N.)

PETRIE, GEORGE (1790-1866), Irish antiquary, was the son of James Petrie, a native of Aberdeen, who had settled in Dublin as a portrait and miniature painter. He was born in Dublin in January 1790, and was educated to become a painter. Besides attaining considerable reputation as a landscape painter of Irish scenes, he devoted much of his artistic skill to the illustration of the antiquities of the country. Even in boyhood his love of archæology vied with his love of art and of nature. In 1828 he was appointed to conduct the antiquarian and historical section of the Ordnance Survey of Ireland, but this department of the work was not persevered in by the Government. In 1832 he became editor of the *Dublin Penny Journal*, a periodical designed to disseminate information among the masses, to which he contributed numerous articles on the history of the fine arts in Ireland. Petrie may be regarded as the first scientific investigator of Irish archæology, his contributions to which are also in themselves of prime importance. His *Essay on Round Towers*, for which in 1830 he received the prize of the Irish Academy, must still rank, whether or not his opinion be accepted that the round towers served the joint purpose of belfries and fortalices, as the standard work on the subject. A second edition was published in 1845. Among his other more important contributions to Irish archæology are his *Essay on the Military Architecture of Ireland* and his *History and Antiquities of Tara Hill*. In 1847 he received the degree of LL.D. from the university of Dublin, and in 1849 he was placed on the civil list for an annual pension of £300. He died 17th January 1866.

See the *Life and Labours in Art and Archæology of George Petrie*, by William Stokes, 1868.

PETROLEUM. The word "petroleum" (*rock-oil*: Germ., *erdöl*, *steinöl*) is used to designate the forms of bitumen that are of an oily consistence. It passes by insensible gradations into the volatile and ethereal naphthas on the one hand and the semi-fluid malthas or mineral

History.—Petroleum has been known by civilized man

¹ Most commonly but erroneously spelt *Procellariidæ*.

² It is due to Prof. Coues to state that in 1864 he had declared the genus *Oceanites*, of which he only knew the external characters, to be "the most distinct and remarkable" of the "*Procellariæ*," though he never thought of making it the type of a separate Family.

³ Thus *Estrelata hesitata*, the Capped Petrel, a species whose proper home seems to be Guadeloupe and some of the neighbouring West-Indian Islands, has occurred in the State of New York, near Boulogne, in Norfolk, and in Hungary (*Ibis*, 1884, p. 202):

from the dawn of history. Herodotus wrote of the springs of Zacynthus (Zante), and the fountains of Hit have been celebrated by the Arabs and Persians. Pliny and Dioscorides describe the oil of Agrigentum, which was used in lamps under the name of "Sicilian oil," and mention is made of petroleum springs in China in the earliest records of that ancient people. The abundance of petroleum and the fire-temple at Baku on the Caspian have been frequently described by travellers who have gone overland from Europe to India, from the time of Marco Polo to recent years. Petroleum in North America was first mentioned by a Franciscan missionary, Joseph de la Roche d'Allion, in a letter written in 1629 and published in Sagard's *Histoire du Canada* in 1636. Peter Kalm described the springs on Oil Creek in his book of travels in North America, published in London in 1772. In 1750 the French commander at Fort Duquesne described them in a letter to General Montcalm, and later, towards the close of the last century, frequent mention is made of oil-springs in correspondence relating to what is now western Pennsylvania, Ohio, West Virginia, and Kentucky. In 1765 and 1826 the British Government sent embassies to the court of Ava, in the reports of which mention is made of the petroleum springs and wells near Rangoon on the Irawadi. During the early years of the present century the occurrence of bitumen, and particularly of its liquid forms, was noticed by scientific men and travellers in various localities. In Europe, Boussingault's researches upon the petroleum of Bechelbronn (Lower Alsace) and the discovery of paraffin by Reichenbach attracted much attention. Petroleum was observed and described as early as 1814 in Washington county, Ohio, in wells at that time being bored for brine. In 1819 a well bored for brine in Wayne county, Kentucky, yielded so much black petroleum that it was abandoned. It has continued to yield small quantities until the present time. In 1829 a well drilled for brine near Burkesville, Cumberland county, Kentucky, yielded such a flow of petroleum that it was regarded as a wonderful natural phenomenon. This well is estimated to have yielded, up to 1860, 50,000 barrels of oil, the larger part of which was wasted. Of the rest a few barrels were bottled and sold as a liniment in the United States and Europe under the name of "American oil."

About the year 1847 E. W. Binney of Manchester, England, called attention to the petroleum discovered at Riddings, near Alfreton in Derbyshire, and a few years later he, together with James Young and others, commenced the manufacture of illuminating and other oils from it. The supply of crude material from this source soon became inadequate, and they then commenced distilling the Boghead mineral that had been found near Bathgate in Scotland. The success attending this enterprise soon attracted attention in the United States of America, and a number of establishments were in operation in the course of a few years, some of them being licensed under Young's patents. In 1851, when petroleum on Oil Creek was worth 75 cents a gallon in the crude state, it was tested as a crude material for the manufacture of illuminating oil by Messrs William and Luther Attwood, and Joshua Merrill, at the United States Chemical Manufacturing Company's works at Waltham, near Boston, Massachusetts, and its merits for that purpose fully established. But its scarcity at that time prevented its use in commercial quantities, and the establishments at Boston and Portland, Maine, under the charge of Messrs Merrill and William Attwood, continued to use Boghead mineral and albertite for a number of years after petroleum was produced in sufficient quantity. Petroleum was refined and offered for sale in Pittsburgh, Pennsylvania, as early as 1855, but the quantity was too small to influence even the local trade; it, however, created a small demand for the

crude oil. The well-known fact that brine-wells often produced petroleum led those who sold the "American oil" to embellish the label on the bottles with a derrick and other accompaniments of a brine-well; and the story is told that the projector of the first well drilled exclusively for petroleum was led to undertake it through reflecting upon this picture. Some oil from one of the natural springs near Titusville, Pennsylvania, was sent to Professor B. Silliman, junior, of Yale College, and he made a report upon it which has become a classic in the literature of petroleum. This report was so satisfactory that a company was organized in New Haven, and E. L. Drake was sent to drill a well upon land that was leased in the valley of Oil Creek, a short distance below the spot where the city of Titusville now stands. The region was then almost a wilderness, and many delays were experienced before he succeeded in getting his men and machinery in operation. He was at first thwarted by quicksands and water, but he finally drove an iron pipe 36 feet down to the rock. This device, said to have been original with Drake, has been of great value in artesian boring ever since he used it. After drilling 33 feet on the 28th of August 1859, the drill fell suddenly 6 inches into a crevice, and was left until the next day, when the drill-hole was found to be nearly filled with petroleum. No spot in the entire territory where petroleum has since been obtained could have been selected where the oil was to be obtained nearer the surface. The success of this enterprise led to the immediate drilling of other wells, first in the valley of Oil Creek and its tributaries, and later over the higher land between Oil Creek and the Alleghany river below Tidioute. As this territory began to be exhausted, the region of the lower Alleghany, in Butler and Clarion counties, yielded wells of great richness, and finally the Bradford field in McKean county became the centre of production. A careful comparison of the situations of some of the most productive wells led to the discovery that the areas yielding oil were not irregular in outline, but extended across the country in narrow belts, without regard to the present configuration of the surface. The areas of these belts were in general parallel, and extended in a north-east and south-west direction, 15° to 20° from the meridian. As the exhaustion of the oil-fields of Butler and Clarion counties led producers to seek a more productive locality, lines were run by compass on the supposed axis of the oil-belt over forest-covered hills for many miles, until they reached the town of Bradford, near which wells had previously been drilled without success. Deeper wells were drilled, and oil was obtained, resulting in the development since 1875 of about 68,000 acres of the most uniformly productive and extensive oil-territory yet discovered.

In the province of Ontario, Canada, principally in the vicinity of Enniskillen, a territory of limited extent but great productiveness has been under development for the last twenty years. In the region about Baku and in the valley of the Kuban, at the eastern and western extremities of the Caucasus, petroleum has been obtained for an unknown period, and is now being produced from artesian borings in large quantities. In Galicia and Roumania it is also obtained in commercial quantities. These regions with the United States furnish the petroleum of commerce. Japan, China, Burmah, and Italy have yielded petroleum in quantities sufficient to supply a local demand, but the vast quantity of the American oil and low price at which it is furnished have rendered the production in these countries unprofitable.

Geographical Distribution.—Petroleum "was found about one hundred years since in making the duke of Bridgewater's tunnel at Worsley, at Wigan and West Leigh in the Lancashire coal-fields, at Coalbrookdale and Wellington

in Shropshire and Riddings in Derbyshire, two other coal-fields; also in a peat-bog at Down Holland, near Ormskirk, in Lancashire, but never in commercial quantities. The greatest supply has not been more than fifty gallons a day, and even that soon diminished." A tar-spring was known at Coalport, in Shropshire, early in the present century. Although there are extensive deposits of solid bitumen in eastern France and Switzerland, the petroleum springs that occur at Saint Boès, Basses Pyrénées, are unimportant. In Alsace, at Lobsann and Bechelbronn, petroleum has been obtained for many years for local uses. Although reported from many localities in Germany, the only point that has promised to be of any importance is the Lüneburg heath, south of Hamburg. Petroleum is also reported near Hölle, in Dithmarschen, Schleswig-Holstein. On the eastern shores of the Adriatic—in Dalmatia and Albania—and in the Ionian Islands, petroleum springs have been mentioned by the writers of classical antiquity. In Armenia and Persia petroleum has been used for unknown centuries, and it appears to be widely distributed in the mountains that surround the tableland of Iran. In Algeria, Egypt, Kashmir, the Punjab, Assam, Java, and other East Indian islands petroleum is reported. In North America the successful development of the petroleum-fields of north-west Pennsylvania following the completion of Drake's well led in a few years to the drilling of wells in a great many localities where petroleum-springs had been observed. The following so-called "petroleum-fields" have produced oil in commercial quantities more or less valuable.

| Name. | Maximum production in | Yield in barrels to 1880. |
|--|--|---------------------------|
| Oil Creek, Venango county, Pennsylvania | 1862 | 35,517,297 |

Besides these localities petroleum has been observed over an area 1500 miles long by an unknown breadth in the valley of the Mackenzie and its tributaries, and in New Brunswick, Newfoundland, and other portions of eastern Canada. It also occurs at many different points along the Appalachian system of mountains from Point Gaspé on the St Lawrence to northern Alabama. It has been noticed in Kansas, Missouri, Wyoming, Colorado, and Texas in the United States, in southern Mexico, in the West India Islands, and in the northern states of South America. Petroleum is one of the most widely distributed substances occurring in nature, but an examination of the geographical localities in which it chiefly occurs will show them to be intimately connected with the principal mountain-chains of the world.

Geological Relations.—It has been frequently remarked that petroleum occurs in all geological formations, from the Silurian up to the Tertiary. While this is true as a general statement, it is misleading, for petroleum is not uniformly distributed through all formations, but occurs principally in two epochs of geological history; these are

the Silurian and the lower half of the Tertiary. The vast accumulations along the principal axis of occurrence in the western hemisphere are found in Silurian and Devonian rocks; the most productive axis of occurrence in the eastern hemisphere lies in the Eocene and Miocene of the Carpathians, Transylvania, and the Caucasus. In England the small quantity of petroleum that has been observed has sprung from the Coal-measures. In the valley of the Rhone and in Savoy it is in Jurassic limestones. The bitumen of the Apennines, of Dalmatia and Albania, of Roumania, Galicia, and the Caucasus, issues for the most part from rocks that are Eocene. But little is known respecting the geology of the bitumen of Asia Minor and Persia; the Punjab is also Eocene, and the little that is known of the deposits in Burmah and the East Indian Islands indicates that they are of the same age. East of the Mississippi river petroleum has been reported from localities that describe an ellipse upon the border of the Cincinnati anticlinal, which consists of an elevation of Silurian rocks extending from central Kentucky to Lake Erie, with the city of Cincinnati nearly in its centre, sloping beneath the newer formations in all directions. Starting at Great Manitoulin Island, in the northern part of Lake Huron, it is next reported at Port Huron, Michigan; Chicago, Illinois; Terre Haute, and in Crawford county, Indiana; Henderson, Cloverport, Bowling Green, and Glasgow, Kentucky; and around Nashville, and south-eastwards to Chattanooga, Tennessee, where the Silurian rocks again reach the surface. Turning north, the line extends almost unbroken through the eastern counties of Kentucky into Ohio and West Virginia, into Pennsylvania and New York, the ellipse being completed by the petroleum-fields of Canada. At Great Manitoulin Island petroleum was obtained in the Trenton limestone, at Chicago and Terre Haute in the Niagara limestone, both of which are Silurian. The Kentucky geologists regard the great Devonian black slate as the source of the oil in that State. There it is found saturating sandstones at Glasgow, and in crevices at Burkesville and other points on the Cumberland river. In the neighbourhood of Nashville, where the Lower Silurian rocks reach the surface, petroleum occurs within geodes, which are enclosed in the solid mass of the blue limestone. North-east of Nashville the present location of the oil is found to be in rocks that lie in an ascending series. Around Burkesville it is found in the Upper Silurian, immediately beneath the Devonian black slate. Farther north it lies in the Devonian and Subcarboniferous sandstones, which, in Johnson county, Kentucky, are now partly above the drainage-level of the country. The so-called "oil-break" of West Virginia and Ohio yields petroleum from sandstones that lie within the Coal-measures. Still farther to the north-east, in Pennsylvania and New York, the oil-sands are all found beneath the Coal-measures in the Upper Devonian, while in Canada they again descend to the Lower Devonian. "Petroleum exists in the Cretaceous rocks which extend along the eastern slope of the Rocky Mountains from British Columbia to Mexico, and in many of the interior valleys." The bitumen of the Pacific slope, of Mexico, the West Indies, and South America, is Miocene in California and Eocene in Trinidad and Peru. From these statements it will be seen that there is a vast area in the Mississippi valley, estimated at 200,000 square miles, beneath which petroleum has been obtained, the formations of which are nowhere more recent than the Coal-measures. Another vast area, extending from California through Mexico to Peru, and including the West India Islands, yields petroleum from Tertiary rocks; while on the eastern continent a belt of country extends from the North Sea to Java, the bitumen-bearing rocks of which are Tertiary so far as is known. At present

the bulk of petroleum produced issues from rocks older than the Carboniferous, while the formations yielding bitumen, in by far the greater number of localities, are of Eocene age. In the great "oil-region" of the United States petroleum occurs in crevices to a very limited extent. In Canada and West Virginia it occurs beneath the crowns of anticlinals, and in Pennsylvania it saturates the porous portions of formations that lie far beneath the influence of superficial erosion, like sand-bars in a flowing stream or detritus on a beach. These strata are not of any particular geological age, but run through a vast accumulation of sediments embraced in all the formations between the Lower Devonian and Upper Carboniferous. They lie conformably with the enclosing rocks, and slope gently to the south-west. The Bradford field in particular resembles a sheet of coarse-grained sandstone 100 square miles in extent, by from 20 to 80 feet in thickness, lying with its south-western edge lowest and submerged in salt water, and its north-eastern edge highest and filled with gas under an extremely high pressure. In Galicia the sandstones holding the oil are very much disturbed, while in the Caucasus the deposits of sand are erratic both in regard to position and extent, and lenticular in outline, being enclosed in a formation consisting of stiff blue clay.

Chemistry.—The first chemical research upon petroleum was conducted by Vauquelin in 1817 upon the naphtha of Amiano. Prior to the discovery of petroleum in commercial quantities, a number of European chemists had made determination of the atomic constitution of several different varieties, and it had become generally understood that the oil consisted of an equal number of atoms of carbon and hydrogen. It has since been determined that some varieties of petroleum contain nitrogen and others contain sulphur and oxygen. These last-named elements are, however, to be properly considered as components of impurities. The proximate principles of petroleum have been determined and examined chiefly by Schorlemmer in England, Pelouze and Cahours in France, and C. M. Warren and S. P. Sadtler in the United States. Many other chemists have contributed valuable assistance to the work. These researches have established the fact that Pennsylvania petroleum consists chiefly of two homologous series of isomeric compounds having the general formula C_nH_{2n+2} , at one extremity of which marsh gas is found and solid paraffin at the other (see PARAFFIN). This oil also contains a smaller proportion of the olefine series, having the formula C_nH_{2n} , with traces in the Bradford oil of the benzole series. Rangoon petroleum contains a larger proportion of both the olefine and the benzole series than Pennsylvania oil. It has been shown that Caucasian petroleum contains the additive compounds of the benzole group which have the same percentage composition as the olefines and furnish an illuminating oil containing more carbon than Pennsylvania oils of the same specific gravity. The residues from the manufacture of petroleum have been shown to contain very dense solids and liquids of high specific gravity, having a large proportion of carbon and possessed of remarkable fluorescent properties. Some petroleum are easily oxidized into asphaltum and kindred products. Colourless illuminating oils under the action of light absorb oxygen, which is converted into ozone, and they become yellow and viscid and of greatly impaired quality when the action is prolonged.

Origin.—The origin of petroleum has been a subject of speculation among scientific men during the last half century. It is a subject involved in much greater obscurity than the origin of coal, for, unlike coal, it has no organic structure; hence it can only be inferred upon circumstantial evidence that it is of organic origin; yet such evidence is so strong that few competent judges have ventured to decide

otherwise. The arguments in favour of a chemical origin have been advanced almost wholly by a school of French chemists during the last twenty years. They are based upon the results of a class of experiments first inaugurated by Berthelot, in which powerful deoxidizing agents like the alkali metals or iron at a white heat are caused to react with steam and carbonic acid. The hydrogen of the water and the carbon of the carbonic acid, having been deprived of their oxygen, unite in the nascent state to form a mixture of oily fluids closely resembling petroleum. Sufficient quantities of these oils have been prepared to prove their identity with each other and with crude petroleum. Before concluding from this circumstance that petroleum is the product of similar reactions, it is necessary to assume a condition of the earth's interior concerning which we know nothing; and, while the theoretical chemistry of the earth, based upon the nebular hypothesis, does not forbid such possibilities, there are other considerations relating to the origin of petroleum based upon the known rather than the possible that render the assumption that petroleum is of mineral origin forced and unnecessary. It is found that, when shale, coal, peat, wood, or animal matter, in fact any recent or fossil organic matter, is subjected to destructive distillation at low temperatures, there is obtained among other products an oily fluid which chemistry shows to consist chiefly of the same compounds of carbon and hydrogen as are found in Pennsylvania petroleum. There are other petroleum, however, occurring in Canada, Tennessee, and other localities somewhat different in composition, which are often found under conditions that make it extremely difficult to account for their origin upon any hypothesis that does not regard them as a product of the decomposition of animal remains. They fill the cavities of fossil corals and orthoceratites in Canada and of geodes in Tennessee, in all of which the oil appears to be hermetically sealed until the rock-mass is broken. The formation in which these oils occur consists of thickly-bedded Silurian limestones that were probably deposited in a deep sea at a somewhat high temperature, in which vast quantities of sea-animals perished and became buried. It is therefore most strictly in accordance with observed facts to assume that these oils, in whatever manner they may have been produced from the original animal remains, are indigenous to the rocks in which they are found. These indigenous oils do not occur locally in considerable quantity, although the aggregate amount scattered through any formation in which they occur can easily be shown to be large.

In those localities, notably north-western Pennsylvania and eastern Ohio, where petroleum occurs in large quantity, it occurs quite uniformly, saturating heavy beds of uncemented sandstone. This sandstone is overlaid with an impervious shell of slate, containing much silica, that holds down both the oil and gas within the sandstone under great pressure, not locally in cavities but over wide areas. The sandstone is also, so far as can be ascertained, underlaid with a vast formation of shale more than 1000 feet in thickness, containing large numbers of fossil animals and such a quantity of fossil sea-weeds that Dr J. S. Newberry has suggested that the Silurian ocean here contained a veritable sargasso sea. This shale, so filled with the remains of fucoids, has been several times submitted to destructive distillation, and has yielded as high as 50 gallons to the ton of distillate oil that was in many respects scarcely to be distinguished from crude petroleum. During the present century the French chemical geologists have held that all forms of bitumen are the product of metamorphism. Prominent among these may be mentioned Daubrée, who in his *Observations sur le Métamorphisme* has shown the strict correspondence between his laboratory experiments, in which all forms of bitumen were produced, and the opera-

tions of nature. No evidence appears to be lacking to show that those operations of nature in which heat, pressure, and steam have joined, usually denominated by physicists "metamorphism," when acting upon strata containing organic remains, are an adequate origin for petroleum as it occurs in the oil-regions of Pennsylvania and in Galicia. Petroleum occurs on the western slope of the Appalachian system from Point Gaspé on the Gulf of St Lawrence to northern Alabama, and there it is most abundant in the neighbourhood of strata in which there is the greatest accumulation of organic remains. The accumulations of sediment from which this mountain-system was constructed were deposited in a current whose course was parallel with the axis of the system, and, as has been so fully shown by Professor James Hall (*Paleontology of New York*, vol. iii., Introduction), these sediments were deposited in great thickness and of very coarse materials in the north-east, gradually thinning and increasing in fineness as they reached the Mississippi valley in the south-west. From the latest conclusions of American geologists it may be inferred that originally the eastern border of these deposits lay over a region now covered by the Atlantic Ocean. When the elevation took place that brought the metamorphic rocks of New England, New York, Pennsylvania, and Virginia to the surface, the eastern border remained submerged, while the western border was brought above the sea-level. The facts that concern petroleum are found in the comparatively undisturbed and nearly level position of this western border, in which the rocks holding the petroleum lie at present, like sand-bars in a current, and the further evidence that they afford that the metamorphic action which has altered nearly all the formations of the eastern border became extinct along a plane that descended deeper and deeper from the surface as the western slope of the system is traversed. This evidence further shows that along the western borders of the system, although the rocks and the coal that they enclose are unaltered near the surface, at the same time vast areas of the fucoidal shale and even limestones containing indigenous petroleum may have been invaded by the heat-action and their volatile contents distilled at great depths. This distillate, being forced up by heat and hydrostatic pressure, would naturally accumulate in any overlying bed of rock porous enough to receive it. In Galicia, Roumania, and Transylvania the metamorphic core of the Carpathians is flanked by beds of fucoidal shale rich in the remains of marine animals, which are intercalated with the beds of sandstone that contain the oil. This hypothesis, which regards petroleum as a distillate, includes the facts as thus far observed, is in harmony with scientific possibilities, and is reasonable, as it does not require any extraordinary assumption of either chemical or geological conditions. While the maintenance of any particular theory concerning the origin of petroleum is primarily of very little practical value, it is indirectly of value to conclude whether by some deep-seated chemical action the oil is at present being prepared in the laboratories of nature, or whether its generation has been long since completed. If a correct interpretation of the phenomena observed in relation to petroleum leads to the hypothesis that the fluid is in most instances a distillate, and especially in those localities where it is most abundant, then the conclusion is inevitable that the generation of petroleum is practically completed, and the deposits are vast natural storehouses which when once emptied are as completely removed from future production as a worked-out bed of coal.

Methods of Production.—While petroleum has been produced for an immemorial period in Persia, China, Japan, Burmah, Baku, and Galicia, and while the primitive

methods employed in each country in its production furnish interesting subjects for study, it is scarcely possible in this article to do more than indicate in a general manner how the vast quantities produced at the present time in the United States and Canada are brought to the surface, stored, and transported. In both Galicia and the Caucasus, which, with Canada and the United States, now furnish the petroleum of commerce, the ancient methods of production are being rapidly superseded by those employed in America. In the United States the development of oil-territory has acquired a habit that has become well defined, and has been repeatedly exemplified during the last twenty years. The first step is the sinking of a test or "wild-cat" well outside the limits of any proved productive territory, the progress of such well being eagerly watched not only by those who pay for it but also by many others who hope to profit by the experiment. The striking of oil in such a well is the signal for a grand rush, and a speculative floating population invades the place. After a time the speculative phase is succeeded by that of settled development. The oil-territory has become outlined. The sagacious ones have secured control of the most profitable tracts, while the floating element has moved on to a new field. Between the period of active development and absolute exhaustion comes that of decay, when the derricks are rotting and falling to wreck, and when property that has ceased to be productive has been sold at an extravagant price, and after accumulating debts has been abandoned. Finally the wave passes over and nature restores as she restores after the ruin of battle-fields. A visit to Pithole city, which in 1865 was, next to Philadelphia, the largest post-office in Pennsylvania, showed in 1881 fields of maize and timothy where some of the most famous wells had been, and of the city a score of houses tumbling to decay and not an inhabitant. It is not to be inferred, however, that any of the sections into which the oil-regions have been divided entirely cease to produce oil. There are wells now producing within sight of the spot where Drake drilled the first well; but large tracts cease to be centres of speculative investment, the old wells cease to be remunerative, and the new wells no longer hold out the possibilities of a grand lottery.

Wells are sometimes drilled by the owners of the land, but the larger part are drilled under leases. These leases are drawn with a great variety of conditions, but they usually stipulate that the lessor shall pay to the lessee a certain portion of the oil produced, the amount varying from one-tenth to one-fourth in proportion to the supposed richness of the territory. One well to five acres is considered as many as a judicious arrangement will allow, but many wells have been drilled much closer, and in some instances several wells have been drilled on one acre. The oil-sand of different localities varies as it occupies different geological horizons. The Venango oil-sand extends from Tidioute in Warren county to Herman Station in Butler county, Pennsylvania, a distance of 62 miles. It is uniformly a conglomerate of smooth white quartz pebbles, from a quarter to three-quarters of an inch in thickness. In other districts of the United States, Canada, and Galicia the oil-sand is a true sandstone of varying colour and texture. In the Caucasus the sand is fine, and resembles a quicksand, as it rises with the oil and accumulates around the wells.

When the location of a well has been determined, a derrick or "rig" is built, which consists of the derrick itself and a small house for an engine, with the necessary foundation for both. This foundation is made of heavy timbers dovetailed and keyed together. The derrick consists of a framework firmly braced in the form of a truncated pyramid, and about 70 feet high. At its base are two large reels, upon one of which the drilling cable is coiled and upon the other the sand-pump rope. At one side of the derrick a heavy post, called the Samson post, is framed into the main sill, upon the top of which rests the walking-beam, one end of it being connected with the engine of from 12 to 15 horse-power, whilst the other supports the drill. When the engine is in motion the walking-beam alternately raises and drops the drill. The boiler is made like the tubular boilers usually employed on locomotives, and is placed at a distance from the well to prevent the ignition of the gas that often accompanies the oil. The engine should be reversible, and so

placed that the driller in the derrick can easily control its motion by the use of cords and pulleys. A string of is represented in fig. 1. First we have the *a*, which is attached directly to the end of beam, into the jaws of which the cable is set-screw *b*, and the long screw of which, *c*, is ward by the driller as the rock is penetrated. of the cable is fastened to the rope-socket screwed into the sinker-bar *e*, that is, a solid about 20 feet in length which serves to give tools. The sinker-bar is screwed into the the jars. The jars, *f*, consist of two links of which are 21 inches long, with cross-heads 8 inches deep, in consequence of which the links have 13 inches of play. The lower link of the jars is screwed into another long iron bar called the auger-stem, *g*, which is in turn screwed to the bit or drill *h*. The jars are the centre of action, and the manner in which they perform their work may be best explained, perhaps, in this way. Suppose the tools to have been just run to the bottom of the well, the jars closed, and the cable slack, the men now reel up the slack until the sinker-bar rises, the "play" of the jars allowing it to come up 13 inches without lifting the auger-stem; when the links come together they slack back about 4 inches and clamp the cable into the temper-screw. If now the vertical movement of the walking-beam is 24 inches, the sinker-bar rises 4 inches, when the cross-heads of the links come together with a smart blow; then the auger-stem is picked up and lifted 20 inches. On the down-stroke the auger-stem falls 20 inches, while the links slide 4 inches carrying the sinker-bar down 24 inches. The links are never allowed to strike on the down-stroke, while the blow of the up-stroke prevents the drill from becoming wedged into any seam or crevice into which its weight might drive it. When the tools are all ready for operation, either a wooden conductor is placed perpendicularly in a sort of shaft sunk to the bed-rock, or an iron tube called a "drive-pipe" is driven upon it through the soil. In either case great care is taken to start the well perpendicularly to the derrick-floor. The tools are swung into position from the top of the derrick, and the free end of the cable is coiled around the shaft of the reel in such a manner that when the free end is tightened the tools are lifted, and when it is loose the reel-shaft revolves within the coils. By holding the cable firmly the tools rise, and as it is loosened they fall. The well is started in this manner and carried down until the string of tools can be suspended beneath the walking-beam, when a cable as long as the supposed depth of the completed

Fig. 1.—String of Tools.

well is wound upon the reel, the end carried over a pulley at the top of the derrick and then fastened into the rope-socket, the temper-screw attached, and the drilling continued to the bottom of the well. Day and night the machinery is kept in motion, one driller and one engineer and tool-dresser work from noon until midnight, and another pair work from midnight until noon. The driller, with a short lever inserted in the temper-screw, walks round and round to rotate the drill. He watches the jars, and at intervals lets down the temper-screw. When the screw is run out or the drill needs sharpening, he arranges the slack cable so that it will run freely over the pulley and proceeds to "draw out." The cable is unclamped from the temper-screw and the engine disconnected from the walking-beam and attached to the cable-reel. When all is ready the long cable is reeled up and the tools drawn out. The bit is replaced by one newly sharpened, and after the well has been sand-pumped the tools are again lowered and drilling resumed. When the drilling proceeds without accident the work is exceedingly monotonous.

From the top of the bed-rock to a point below the surface-water of the region, the well is drilled of the same diameter as the interior of the drive-pipe. This point is usually from 300 to 400 feet below the surface. At this point the drill-hole is tapered, and a pipe armed with a steel shoe is ground into the tapered hole to a water-tight joint. The inside diameter of this casing-pipe is 5½ inches, and below it the well is carried down 5½ inches in diameter to the bottom. The casing pipe excludes the fresh surface-water, and only water enough is put into the well to wash out the drillings, unless salt water is encountered. The casing-pipe becomes a permanent fixture, into which is introduced the 2-inch pipe, through which the oil flows or is pumped. This 2-inch pipe may be introduced or removed at pleasure, without disturbing the casing-pipe or drive-pipe, or letting water into the well upon the oil.

When drilling has been completed the well is torpedoed. From one to twenty-five gallons of nitro-glycerin are lowered into the well in tin cylinders and exploded, usually by percussion. The effect of firing such a large amount of this powerful explosive is not apparent at the surface, but soon a gurgling sound is heard approaching from beneath; the oil rises from the well and falls first like a fountain and then like a geyser, forming a torrent of yellow fluid, accompanied by a rattle of small stones and fragments of the canister in a shower of spray 100 feet in height.

The generation of such an enormous volume of gas in a limited area, the walls of which are already under a very high gas-pressure,

Fig. 2.—Pumping Well.

and which is held down by 2000 feet of motionless air, must be followed by an expansion into the porous rock that drives both oil and gas before it, until a point of maximum tension is reached. The resistance then becomes greatest within the rock, and, reaction following, oil and gas are driven out of the rock and out of the well until the expansive force is expended.

Figs. 2 and 3 show the general arrangement of pumping and flowing wells. After the well is torpedoes it is prepared for flowing. A section of 2-inch pipe, perforated with holes, which serves as a strainer, is lowered into the well and other sections coupled to it, until a sufficient length is introduced to reach from the bottom to a point above the oil-sand. An indiarubber packer is then attached in such a manner that within it the pipe that is above it slides in that which is below it, and the rubber is forced against the sides of the drill-hole with the weight of 1200 to 1800 feet of 2-inch pipe, thus making a gas-tight joint. The pressure of the gas within the oil-sand and below the packer forces the oil to the surface. As the flow diminishes, a pump-barrel is introduced to the bottom of the well and the oil is lifted to the surface. Gas-pumps are also used to remove the pressure of the atmosphere from the well and rock. In some of the older districts from twelve to forty wells are attached to one engine, and pumped by what is called a "sucker-rod" connexion. In West Virginia five different horizons of sandstone have yielded oil. A well was put down there in 1865 to the "first white oak sand," 255 feet in depth, and pumped at intervals for fifteen years; it was then reamed out to 8 inches in diameter, and from the bottom of the old well was carried down $4\frac{1}{2}$ inches in diameter to the third sand. A tube was inserted with a packer at the bottom of the 8-inch hole to stop off the heavy oil of the first sand. Through this oil of a specific gravity .79 (45° B.) was pumped from the third sand, and through a second tube, introduced beside the first to the bottom of the old well, oil of a specific gravity .83 (27° B.) was pumped from the first sand, both pumps being simultaneously worked by the same walking-beam. The first-sand oil was worth seven dollars a barrel, while the third-sand oil was worth only one dollar a barrel.

The average duration of the profitable production of an oil-well is estimated at five years. This period is subject to great fluctuations, as there are wells in the Cade Creek district of the Bradford field that were abandoned in two years, while wells on Triumph Hill, Venango county, where the sand is 125 feet thick, have been pumped fifteen years. The yield of some single wells has been enormous. A well in Donegal township, Butler county, Pennsylvania, produced more

than 110,000 barrels in ten years, and twelve wells, of which this was one, on the same farm produced over 750,000 barrels.

In Burmah and other Eastern countries petroleum was stored and transported in flasks and jars. In the United States it was for many years transported in barrels made tight for oil by being coated on the inside with a stiff solution of glue. Later, it was transported on the rivers in bulk barges, and on the railroads in tanks upon cars. These tanks were at first made of wood, but they have lately been made of iron. The usual form is a plain cylinder, 24 feet 6 inches long and 66 inches in diameter, having a capacity of from 4000 to 5000 gallons. These cars are also used in the Caucasus. At the present time, in all the regions producing petroleum in commercial quantities, the bulk of the crude oil is transported through pipe-lines, which consist of lines of pipe carried across the country, often for hundreds of miles, through which the oil is forced by powerful pumps under a pressure of from 1000 to 1600 lb to the square inch. Each well has a tank into which the oil flows from the well, and from which it is carried in a 2-inch pipe by gravity to a pumping station, where it is pumped into the "main line." Main lines run out of the oil-regions of Pennsylvania to Cleveland (Ohio), Pittsburgh (Pennsylvania), Buffalo (New York), and New York, Philadelphia, and Baltimore on the Atlantic coast. They are constructed of 6-inch pipe, the joints of which are screwed into couplings like sections of gas-pipe. During recent years the production of petroleum in excess of any demand for it has led to the storage of vast quantities (30,000,000 barrels in 1882) in iron tanks of enormous size. Many of these tanks are owned by private individuals, but the majority belong to the pipe-lines. There are 1375 iron tanks connected with the united pipe-lines, ranging in capacity from 1000 to 38,000 barrels, and representing a total storage capacity of 38,000,000 barrels. These tanks are frequently fired by lightning or other accidents, and when burning present a spectacle of unsurpassed grandeur.

The bulk of the trade in crude petroleum in the United States is conducted through the pipe-lines and their certificates. When oil is received into the line from a well, the amount is ascertained and passed to the credit of the well-owner on the books of the company, less 3 per cent. to cover loss in handling. This oil is held like a bank-deposit, subject to transfer on a written order. When such an order has been "accepted" by an officer of the company it becomes an "acceptance" or "certificate," and is then negotiable like a certified cheque. As the exchanges deal only in certificates of 1000 barrels they are made of that amount so far as is possible. When oil is delivered by the pipe-lines a pipage charge of 20 cents per barrel is paid and a storage fee of \$12.50 per 1000 barrels per month must be paid at least once in six months. The issuing of certificates by the pipe-lines has made speculation in oil, brokerage, and exchanges possible to an extent vastly beyond the requirements of any actual trade in the oil itself.

About 250,000,000 barrels of petroleum have been produced in the United States and Canada from 1859 to 1884. No reliable statistics are to be had of the production in other regions, but of late years the Caucasian fields have yielded about 5,000,000 barrels per annum. The total annual production for 1883 cannot be far from 35,000,000 barrels.

Technology.—The technology of petroleum is quite simple. In the crude state it enters largely into mixtures with other oils, tallow, lead, soap, graphite, &c., that are chiefly used for lubrication. Crude petroleum is also filtered through charcoal. Crude oils that are too fluid for lubrication are reduced to the required consistence by partial evaporation, both by exposure to the sun in shallow tanks and also by distillation of the more volatile portion in stills. Such oils are called "reduced oils." In the technology of petroleum by distillation a great variety of details are employed by different manufacturers, but in general they may be treated under the three heads of destructive distillation or "cracking," distillation with superheated steam, and distillation *in vacuo*. The stills used vary greatly in respect of form and capacity. Formerly stills holding 80,000 gallons were used, but recently they have been constructed of a capacity of from 40,000 to 48,000 gallons. They are ordinarily made either in the form of plain cylinders 30 feet in length and 12 feet 6 inches in diameter, and set horizontally in banks of three or more, or there may be an upright cylinder 30 feet in diameter and 9 feet in height, set vertically with numerous fire-boxes arranged around the circumference. Another form of still is an upright cylinder holding about 1000 gallons, heated from beneath and furnished with a steam-coil immersed in the body of the oil. In this coil the steam is superheated to the temperature of the oil, and is then allowed to escape into it, by which means the overheating of the oil is prevented and the distillation assisted by the mechanical action of the steam in lifting the oil-vapour out of the still. Another form of still is a vacuum still, in which a partial vacuum is maintained by a pump. The top of the still is usually constructed with a high dome, into which the vapours rise and from which they escape into the condensers. The condensers usually consist of a large number of 2-inch pipes immersed in water contained in a long trough. The distillation

Fig. 3.—Flowing Well.

commences at a very low temperature and proceeds at a constantly rising temperature, the distillate steadily increasing in specific gravity. The last portions distil at nearly a red heat, and are nearly solid at ordinary temperatures, with a specific gravity above 900°.

The oil is first allowed to settle in large tanks, when about 1 per cent. of water and sediment is removed. It is then pumped to stills into which "live" steam is introduced. Distillation commences at once and is allowed to proceed until the specific gravity of the distillate reaches '74 (60° B.). The oil in this condition is called "gas-oil," and is used to a limited extent in the manufacture of illuminating gas. The distillate is crude naphtha, and is redistilled and divided into (1) rhigolene or cymogene, having a specific gravity of '62 and boiling at 65° Fahr.; (2) gasolene, specific gravity '68 (90° to 80° B.); (3) C naphtha, specific gravity '70 (80° to 68° B.); (4) B naphtha, specific gravity '72 (68° to 64° B.); and (5) A naphtha, specific gravity '74 (64° to 60° B.). Below 60° goes to illuminating oil. The crude oil from which the naphtha has been removed is then put into a suitable still and distilled until the distillate has a specific gravity of '81 (40° B.). This distillate is crude illuminating oil. The oil remaining in the still may then be "cracked" by destructive distillation, or may be distilled for lubricating oil. If it is to be "cracked" the fires are slacked and the distillation allowed to proceed slowly, in consequence of which the vapours of the heavy oil are repeatedly condensed upon the dome of the still and made to fall back upon the hot oil beneath. The result is the production of a large volume of permanent gas, chiefly marsh gas and hydrogen, a distillate of suitable specific gravity for illuminating oil, and a heavy tarry residue, called "residuum," that remains in the still. By this method of manipulation the crude oil is converted into crude naphtha, crude illuminating oil, and residuum, while the gas is burned as a waste product. The residuum is run out of the still and sold to manufacturers of lubricating oil. If the oil is not to be cracked, the heavy oil, from which the illuminating oil and naphtha have been removed, is often distilled with superheated steam and treated for lubricating oil. If simply distilled and treated with chemicals after removal of the paraffin, the oil is called in the United States "paraffin oil." The crude paraffin oil is placed in barrels in an ice-house, and, after it has been several days at rest, paraffin crystallizes from it. The paraffin is removed by pressure, and may be purified by any of the methods described under PARAFFIN (p. 242 above). The oil from which the paraffin has been pressed may be subjected to a further distillation in a steam-coil or other suitable still, and deprived of certain oils that boil at a high temperature but have a pungent and offensive odour. When drawn off, the oil remaining in the still is found to be light-coloured and nearly tasteless and odourless. It is called "deodorized neutral heavy hydrocarbon oil," and is found to be a very valuable lubricating oil. The distillate above mentioned after treatment is called "mineral sperm," and is used as an illuminating oil on cars and steamboats, where a more volatile oil would be objectionable. Any of these distillates, from gasolene to the most dense lubricating oil, may be purified by filtration or by treatment with acids and alkalis. Filtration is usually applied to the different grades of naphtha to deprive them of disagreeable odour, for which purpose gravel and both wood and animal charcoal are used, either separately or together. Lubricating oils are often filtered through animal charcoal to deprive them of both colour and odour. The dense vacuum residues recently prepared under the name of cosmoline, vaseline, &c., are filtered through animal charcoal while hot and perfectly fluid. Oils are treated with chemicals in high cylindrical tanks of small diameter, where they are thoroughly mingled by means of air forced into the bottom of the tank under pressure. These agitators often hold 50,000 gallons. The illuminating oils are usually treated with 5 per cent. of oil of vitriol at a temperature of about 60° Fahr. The acid "sludge," consisting of the oil of vitriol combined with the impurities of the oil and forming a black tarry liquid, settles to the bottom of the tank and is drawn off. The oil is then agitated with water, then treated with a solution of caustic soda, and finally washed with water containing caustic ammonia. Hydrochloric acid is used to a limited extent, and nitric and chromic acids are used to destroy fluorescence in dense oils. Those illuminating oils especially that are prepared by cracking are thrown after treatment, and while warm, in a thin spray into a large tank. This causes a small amount of very volatile oil produced by cracking to be evaporated, and brings the oil up to test. Finally the oil is exposed under a skylight in large shallow tanks until it has become perfectly clear from settling of all impurities. The acid "sludge" is for the most part sold to manufacturers of commercial fertilizers or restored by evaporation and used over again. More than 45,000 tons of oil of vitriol were used in 1880 by the manufacturers of petroleum in the United States. The alkali sludge is thrown away. The following table shows the average percentage of commercial products obtained from crude petroleum of '79 (45° B.) from Pennsylvania, Ohio, &c.—

| | Per cent. |
|---------------------------------------|-----------|
| Gasolene | 1 to 1½ |
| "C" naphtha | 10 |
| "B" naphtha | 2½ |
| "A" naphtha | 2 to 2½ |
| | 16½ |
| Illuminating oil | 50 to 54 |
| Lubricating oil | 17½ |
| Paraffin wax = 4½ lb per barrel | 2 |
| Loss | 10 |
| | 100 |

If the oil is "cracked," the yield is—

| | |
|------------------------|-----|
| Naphthas | 10½ |
| Illuminating oil | 70 |
| Residuum | 2 |
| | 88½ |
| Loss | 11½ |
| | 100 |

Lubricating Oils.—Crude petroleum and the heavy distillates from petroleum, finished either by treatment or by filtration, have been slowly winning their way with consumers of lubricating oils for the last twenty years, and may now be said to have a recognized value. This result has been due as much to improved processes of manufacture, and consequently to improved quality of the products, as to a recognition of their merits. When properly prepared, and exempt from volatile matter and offensive odour, they are found to be possessed of great endurance, to be free from a tendency to gum, and to be incapable of spontaneous combustion. When mixed with animal and vegetable oils liable to spontaneous combustion, these oils prevent it. They are therefore now in large demand, a demand which is likely to increase as new applications are found for them and their quality is improved.

Illuminating Oils.—Oils of this class manufactured from petroleum have nearly superseded the use of other illuminating fluids throughout the world. They are largely sold in Great Britain under the name of "paraffin oils"; in the United States they are called "kerosene," and on the European continent "refined petroleum." The different qualities are known as "water white," "standard," and "prime," and are further distinguished as "low test" and "high test" oils. The characters chiefly relied on in the trade are "colour" and "test." The colour should be as light and free from opalescence as possible. Colour is, however, a matter of little importance except as it indicates unskilful manufacture of the oil. The "test" is of paramount importance, and indicates the temperature Fahr. at which the oil will give off a sufficient amount of vapour to ignite explosively when the oil is properly tested. While the methods of testing petroleum vary greatly, the apparatuses used for that purpose may be divided into three classes. The first class is designed to ascertain the tension of the vapour given off by a given sample at a certain fixed temperature; these are chiefly used in France. The others are designed to show at what temperature a given amount of oil, usually half a pint, will give off a sufficient amount of vapour to form an explosive mixture with the air above the oil. These are divided into "open testers," in which the oil is heated in an open vessel, and "closed testers," in which the oil is heated in a closed vessel. The tester invented by Sir F. A. Abel (see PARAFFIN, p. 239) has been adopted in Great Britain and her colonies, while in the United States and on the Continent a great variety are in use. The numerous accidents, many of a frightful nature, and involving great loss of property and often of human life, that have followed the use of illuminating oils which had not been properly freed from the volatile products of the petroleum, have led in most European countries and many of the American States to the enactment of stringent laws forbidding the sale or use of oils the test of which does not come within the prescribed legal limits. Very valuable researches on the flashing of oils have been made by Dr C. F. Chandler of New York, and by other American chemists. Dr Chandler showed that oils burning in lamps of ordinary construction in a room the temperature of which was below 90° Fahr. failed to reach an average temperature of 100° Fahr. In metal lamps, particularly "student lamps," the average temperature was several degrees higher than in glass lamps, a fact which shows glass lamps to be safest in this respect. Dr C. K. White of New Orleans has examined illuminating oils with respect to the amount of volatile material that, when added to good oil, will render it dangerous. He found that from 1 to 5 per cent. of the ordinary naphthas of commerce would render illuminating oil of the best quality extremely dangerous. Five per cent. of crude naphtha reduced the flashing point from 118° to 70° Fahr. These researches have all demonstrated the wisdom of English legislation on this subject, but unfortunately have not been productive of equally good results in the United States. Petroleum legislation is there in a very unsatisfactory condition. The very worthless law passed by Congress in 1867 has long been repealed, and no other has been substituted for it. A number of the States (seventeen in 1880) are without legislation in reference to this subject, while legislation in other States is based upon local influence rather than fixed principles, and ranges in its

requirements from extreme laxity to unreasonable exaction, in consequence of the lack of intelligent national Governmental action. Nearly all the nations of continental Europe have petroleum laws in the main based upon an intelligent appreciation of the subject and but little inferior to English legislation.

The Uses of Naphtha.—The lightest products obtained from petroleum are rhigolene, which is used in surgery, and cymogene, which is used as the volatile fluid in ice-machines. Gasolene is the lightest fluid obtained in considerable quantity, and is used in automatic gas-machines for the carburation of gas or air. The question of increasing the illuminating power of gas (see GAS, vol. x. p. 101), by causing it to absorb fluid hydrocarbons, was discussed as early as 1832, but it was only after petroleum furnished a cheap and suitable fluid that inventors succeeded in securing results of any value. While hundreds of machines have been patented in England, America, and continental Europe for accomplishing this purpose, it is only quite recently that an American inventor, Dr. Walter M. Jackson, has succeeded in constructing a machine that satisfactorily meets all the requirements of the problem. His metrical carburetter measures both the fluid and the gas or air in such a manner that the least amount of the hydrocarbon fluid required to produce the effect sought is furnished to the gas, and the whole is immediately absorbed. By this means a uniform carburation is secured, furnishing a gas of uniform quality, that never contains a sufficient amount of fluid to admit of condensation in any part of the apparatus. Both crude petroleum and the products of its manufacture have been used as a material for the manufacture of gas by distillation. The different qualities of naphtha are used in mixing paint, in the manufacture of oil-cloths for floors and of varnishes, as a solvent for gums and resins, in the preparation of alkaloids, in the manufacture of india-rubber, in washing wool, and in removing oils and grease from seeds and textile fabrics.

Petroleum as Fuel.—In the region of the Caucasus and on the Caspian Sea, where other fuel is scarce and dear and petroleum is plentiful and cheap, the latter is used with complete success on both steamships and locomotives. Petroleum and its products have been used with practical success in the manufacture of iron in the United States. Both illuminating oil and naphtha are now very widely used in stoves; but naphtha-stoves are extremely dangerous, and their use should be prohibited by law. In the valley of the Euphrates, near Mosul, petroleum is used as a fuel in burning lime.

Petroleum in Medicine.—Although petroleum has been used as a remedial agent for an unknown period in the countries where it is a natural product, its physiological effects have never been very fully investigated. Barbados tar, Haarlem oil, Seneca oil, and American oil, all consisting wholly or in large part of crude petroleum, were sold by apothecaries for years before petroleum was obtained by boring. They were mainly used as liniments for external application, particularly in rheumatism. The oil of the Alleghany valley early had a local reputation as an internal remedy for consumption, and it has lately been prescribed for bronchitis. The most volatile product of petroleum obtained by distillation, called rhigolene, has been used to produce local insensibility, by means of the intense cold resulting from its rapid evaporation; and the same fluid when inhaled as vapour or the gas escaping from fresh oil will produce an intoxication or insensibility resembling the effects of laughing-gas, resulting in death if its action is prolonged. The products of petroleum that have proved most valuable in medicine are the filtered paraffin residues sold under the names of cosmoline, vaseline, &c., that are now so widely used as ointments, either plain or medicated. They are of about the consistency of butter, with very little taste or odour, and will keep indefinitely without becoming rancid. These valuable properties have caused them to almost entirely supersede all other preparations containing animal or vegetable fats.

Looking towards the past, it may be said that petroleum has attained universal diffusion as a lighting agent; it is fast displacing animal and vegetable oils as a lubricator on all classes of bearings, from railroad-axes to mule-spindles, and also where other oils are liable to spontaneous combustion; it is very largely used as fuel for stoves, both for heating and cooking; it is very successfully used for steam purposes when other fuel is scarce and petroleum plentiful; it is likely to be used for the production of pure iron for special purposes; and it has become a necessity to the apothecary as petroleum ointment. Looking towards the future, what assurance have we that these varied wants, the creation of a quarter of a century, will be satisfied? While it is not probable that the deposits of petroleum in the crust of the earth are being practically increased at the present time, there is reason to believe that the supply is ample for an indefinite period. Yet the fact is worthy of serious consideration that the production of petroleum as at present conducted is everywhere wasteful in the extreme.

There are very few works that treat exclusively of petroleum. An article in the *Bull. de la Soc. Géol. de France*, xxv., gives the best résumé of the mention made by classical writers. Travellers overland to India and Persia have usually described Baku (see Kaempfer, 1712; Hanway, 1743; Foster, 1784; Kinnier, 1845). On the occurrence of petroleum in Burmah, see *Journals of the Embassies to the Court of Ava*, Symes (1795), Crawford (1826), Yule (1855); in Persia,

Carl Ritter's *Erdk. v. Asien*, 1840; in Japan, B. S. Lyman's *Reports, Geolog. Survey of Japan*, 1874-75; in Galicia, Von Hauer (1853), Fottlerle (1853, 1859, 1862), J. Noth (1873), Eruno Walter (1880), in *Jahrbuch der K.-K. Geo. Reichsanstalt*; in Roumania, Von Hauer, *Geologie Siebenbürgens*, 1863; H. Coquand, *Bul. Soc. Géol. de France*, xxiv. 505, 1867; in Canada, T. Sterry Hunt, in *Reports of Geol. Survey of Canada* of various dates, 1863-73; in Pennsylvania, J. F. Carll, *Reports*, 1., 11., and 111., with maps, *Second Geological Survey of Pennsylvania*, 1874-1880. On the chemistry of petroleum, see C. M. Warren, in *American Journal of Science and Chemical News*; Shorlemmer, in *Quar. Journal of the Chemical Society*; Pelouze and Cahours in *Ann. de Chimie et de Physique*; Berthelot in the same, all at various dates, 1863-1880. On the origin of petroleum, see Lesquereux, in *Trans. Am. Phil. Soc.*, xlii., 1866; J. S. Newberry, in *Ohio Ag. Report*, 1859; T. Sterry Hunt, in *Chem. News*, vi. 5 et sq.; Byasson, in *Revue Industrielle*, 1876; Mendeljeff, in *Bull. Soc. Chim. de Paris*, 1877. On testing petroleum, see John Attfield, in *Chem. News*, xiv. 257; F. Crace Calvert, *Chem. News*, xxi. 85; C. F. Chandler, in *American Chemist*, ii. 409; Boverton Redwood, in *English Mechanic and World of Science*, xxii. 335, 1875; F. A. Abel, in *Chem. News*, xxxv. 73. On the general subject, see T. Sterry Hunt, "History of Petroleum or Rock Oil," in *Canadian Naturalist*, [1], v. 245; *Chem. News*, vi. 5; *Report of Smithsonian Institution*, 1862; J. Lawrence Smith, in *Report to the Judges of the Centennial Exposition, Philadelphia*, 1876; S. F. Peckham, monograph on petroleum, including bibliography of petroleum and allied subjects to 1881, in *Reports of the Tenth Census of the United States*. PETROLOGY. See ROCKS.

PETRONIUS. Petronius Arbitrator, although excluded from the list of classical writers available for the purposes of education, is one who enjoyed a great reputation, especially in France, at a time when Latin authors were more read as literature than they are in the present day. A recent critic¹ of Petronius has stated, though with evident exaggeration, that no ancient writer except Aristotle has found so many interpreters. But there is perhaps none about whose history and era there has been so much controversy, nor is the controversy yet settled with absolute certainty. He hides himself so completely behind the mask of his fictitious personages that we learn nothing of his fortunes, position, or even of the century to which he belonged, directly from himself. He does not belong to any of the classes of "viri illustres" (poets, orators, historians, philosophers, grammarians, and rhetoricians) whose lives were written by Suetonius. Though he is mentioned by critics, commentators, and grammarians of a late date (such as Macrobius, Servius, and Priscian), the only hint we have of anything bearing on his personal position is contained in two lines of Sidonius Apollinaris, a writer of the latter part of the 5th century A.D., who associates him with the masters of Latin eloquence, Cicero, Livy, and Virgil, in the lines—

"Et te, Massiliensium per hortos
Sacri stipitis, Arbitrator, colonum
Hellepontiaco parem Priapo."

If these lines are to be construed as implying that Petronius lived and wrote his work at Marseilles, this inference could hardly be reconciled with the indirect evidence which leads to the identification of the author of the *Satiræ* with the C. Petronius of whom Tacitus has painted so vivid a picture in the sixteenth book of the *Annals* (ch. 18, 19). His place of residence in his later years at least was not Marseilles but Rome. There is nothing, however, in what Tacitus says incompatible with the supposition that Marseilles was his birthplace; or perhaps the allusion might be explained by the supposition—supported by a note of Servius on Virgil, *Æn.*, iii. 57—that the scene in the early part of the long novel, of which two fragmentary books have been preserved, was laid at Marseilles. The chief personages of the story, as they appear in these fragments of books xv. and xvi., are evidently strangers in the towns of the south of Italy where the adventures in which they share are supposed to take place. Their Greek-sounding names (Encolpius, Ascyltos, Giton, &c.), and their literary training also, accord with the characteristics of the old Greek colony in the 1st century A.D. The high position among Latin writers assigned by Sidonius to Petronius, and the mention of him by Macrobius in juxtaposition with Menander, when compared with the absolute silence of such writers as Quintilian,

¹ J. N. M. De Guerle, *Recherches Sceptiques sur le Satyricon*.

Juvenal, and Martial, who might have been expected to have taken some notice of him if he had flourished immediately before their own day, seem adverse to the generally received opinion that the *Satiræ* was a work of the age of Nero. Yet the silence of Quintilian may be explained by the fact that Petronius is not one of those writers who were capable of being turned to use in the education of an orator. The silence of Martial and Juvenal may be accidental. Even if it is to be explained on the ground of want of appreciation, this would prove nothing more than that a work so abnormal in form and substance was more highly prized by later generations than by the author's contemporaries.

But, if we pass from these faint traces of external evidence to that afforded by the style of the book and the state of manners described in it, we are led to the inference that there is no other age to which it can be assigned on better grounds than the age of Nero. If, again, we compare the impression we form of the character, genius, and habits of the writer with the elaborate picture which Tacitus paints of a man who, so far as he plays any part in history, is merely one of the victims of an abortive conspiracy, we find grounds of probability for identifying them with one another. Tacitus does not tell us that he was the author of any important work, and this has been urged as conclusive on the question. But Tacitus does not think it necessary in what he tells us of Germanicus or Claudius to mention their poetical and historical works. In introducing Silius Italicus as the witness of a particular occurrence he does not add that he was the author of the poem on the Punic War. He mentions that the poetical gifts and reputation of Lucan and Seneca were among the causes that excited Nero's jealousy, but he does not mention the *Pharsalia* of the one or the *Tragedies* of the other. The prominence which Tacitus gives to the portrait of Petronius points to his enjoyment of greater notoriety than was due to the part he played in history. He paints him with the keen and severe eye with which he fastens on the traits of character and the manner of life illustrative of the moral corruption of the time, but at the same time with that appreciation of intellectual power which forces him to do justice to men who in other respects were detestable. Such a work as the *Satiræ* he could, from a moral point of view, have regarded with no other feelings than those of detestation; yet he could not have refused his admiration to the unmistakable proof it affords of easy careless power, and of a spirit, if not courageous in any good sense, yet indifferent to death, and capable of meeting calamity with Epicurean irony.

The account he gives of C. Petronius is "that he spent his days in sleep, his nights in attending to his official duties or in amusement, that by his dissolute life he had become as famous as other men by a life of energy, and that he was regarded as no ordinary profligate, but as an accomplished voluptuary. His reckless freedom of speech, being regarded as frankness, procured him popularity. Yet during his provincial government, and later when he held the office of consul, he had shown vigour and capacity for affairs. Afterwards returning to his life of vicious indulgence, he became one of the chosen circle of Nero's intimates, and was looked upon as an absolute authority on questions of taste ('arbiter elegantiæ') in connexion with the science of luxurious living." This excited the jealousy of Tigellinus, and led to his condemnation. Petronius's death is then described, which was in keeping with his mode of life and character. He selected the slow process of opening his veins and having them bound up again, while in conversing with his friends he avoided the serious subjects natural at such a time, and listened to their recitation of light odes and trifling verses. He then dined luxuriously, slept for some time, and, so far from

imitating the practice of others by flattering Nero or Tigellinus in his will, he wrote, sealed, and sent to the emperor a document which professed to give, with the names of the partners of his vices, a detailed account of the scandalous life of the court.

That this portrait, drawn with such characteristic lines, and painted in such sombre colouring, is sketched from the life in Tacitus's most graphic manner is unquestionable. A fact confirmatory of its general truth is added by the elder Pliny (who calls him T. Petronius), who mentions that just before his death he destroyed a murrhine vase of great value to prevent its falling into the hands of Nero. The question arises whether there is ground for identifying the author of the fragment which we possess under the name of *Satiræ* with the person so minutely and faithfully described by Tacitus. Do the traits of this picture agree with that impression of himself which every writer of marked individuality unconsciously leaves on his work? Further, is there any reason for supposing, as some have maintained, that in this fragment we possess the actual document sent to Nero? The last question may be at once dismissed. The only fragments connected by any kind of continuity which we possess profess to be extracts of the fifteenth and sixteenth books of a work that must have extended to a great length. It would have been impossible to have composed one-tenth part even of this fragment in the time in which Petronius is said to have composed his memorial to Nero. Those who find in the representation of the vulgar, ostentatious, illiterate, but tolerably good-natured Trimalchio a satire on Nero or Tigellinus are capable of finding any meaning they desire in any literary work of a past age.¹ But at the same time it is legitimate to note that the author of the banquet of Trimalchio and of the lives of Encolpius and Giton had both the experience and the literary gifts which would enable him to describe with scathing mockery the

"Luxuriam imperii veterem noctesque Neronis,"

and that he was not one to be restrained by any prudery from describing them in their most revolting details.

On the other hand, the arguments against identifying the writer of the fragment with the original of the portrait of Tacitus, based on the silence of the historian as to his authorship, may be explained by reference to the historian's practice in regard to the authors of other literary works.² Unless these works had any bearing on the part which their authors played in history, he did not feel himself called upon to mention them; and such a work as the *Satiræ* he would have regarded as especially beneath the dignity of history, of which he had so proud a consciousness. The impression of his personality produced by the author corresponds closely with that of the Petronius of the *Annals*, not only in the evidence it affords of intimate familiarity with the vices of the age, but in the union of an immoral sensualism with a rich vein of cynical humour and an admirable taste, which we should expect to find in one who rose to favour by his social and convivial qualities, and who received the title of "elegantiae arbiter." The Epicurean maxims, such as—

"Vivamus dum licet esse bene,"

quoted by his actors, and the frequent introduction of short poems into their conversations, are in conformity with the opinions and tastes of one who in his last hours "audiebat referentes nihil de immortalitate animæ et sapientium placitis, sed levia carmina et faciles versus." Further, the name "Arbiter," by which he is mentioned in later writers, is not an ordinary Latin cognomen, but may have been bestowed on him by his contemporaries from the fact that his judgment was regarded as the criterion

¹ The supposition of M. Gaston Boissier that the individual satirized is Pallas, the freedman of Claudius, is much more probable.

of good taste, and Tacitus, in the phrase he perpetuates, may have fixed this as his designation for later writers.

The style of the work, where it does not purposely reproduce the solecisms, colloquialisms, and slang of the vulgar rich—for the most part freedmen of foreign origin—is recognized by the most competent critics as written in the purest Latin of the Silver Age. Coincidences of expression and thought with passages in the satires of Persius are not infrequent.¹ The false taste in literature and expression fostered by the false style of education is condemned by Persius and Petronius on the same grounds. When the latter speaks of the "mellitos verborum globulos" he may possibly have had Seneca in his eye. Again, there would have been no point in putting into the mouth of the old poet whom the adventurers pick up verses on the capture of Troy and the Civil War at any other era than that in which the *Troica* of Nero and the *Pharsalia* of Lucan were the fashionable poems. The pertinacity of the reciting poet, which is exposed with such quiet humour by Petronius, is a feature of the age, common to it with the age of Martial and Juvenal. But we learn from Tacitus that the luxury of the table, which appears so profuse and extravagant in the "dinner of Trimalchio," reached its highest pitch under Nero, and afterwards fell out of fashion (Tac., *Ann.*, iii. 55).

The internal evidence based on the style and character of the work thus appears to favour the opinion that the book was written in the time of Nero; nor is there any one more likely to have been its author than the C. Petronius whose manner of life and whose death are so elaborately described by Tacitus.

The work, of which there have been preserved 141 sections or chapters of a narrative, in the main consecutive, although interrupted by frequent gaps, must have been one of great originality as regards form, subject-matter, and mode of treatment. The name *Satiræ*, by which it is designated in the best MSS., indicates that it claims to be of the type of the original "satira" or "miscellany" to which Varro, in imitation of the Greek writer Menippus, had given the character of a medley of prose and verse composition. But, while in the title and form of the work it belonged to a familiar type, yet from another point of view it is to be regarded as the earliest extant specimen of an original and most important invention in Roman literature. We find in it indeed not only a medley of prose and verse composition, in which the former is much the most prominent element, but also much desultory matter, disquisitions on art and eloquence, stories and anecdotes, &c. But the novelty of form recognized in Petronius consists in the string of fictitious narrative by which these are kept together. The original Italian satira, superseded by the Latin comedy, had developed into the poetical satire of Lucilius and Horace, and into the miscellaneous prose and verse essays of Varro. In the hands of Petronius it assumed a new and most important phase in its development. The careless prodigal who gave his days to sleep and his nights to pleasure was so happily inspired in his devices for amusing himself as to introduce into Roman literature, and thereby transmit to modern times, the novel

based on the ordinary experience² of contemporary life,—the precursor of such novels of adventure and character as *Gil Blas* and *Roderick Random*. There is no evidence of the existence of a regular plot in the *Satiræ*; but we find one central figure, Encolpius, who professes to narrate his adventures, and to describe all that he saw and heard, while allowing various other personages to exhibit their peculiarities and express their opinions dramatically. From the nature of the adventures described there seems no reason why the book should not have gone on to an interminable length.

The fragment opens with the appearance of the hero, Encolpius, who seems to be an itinerant lecturer travelling with a companion named Ascyrtos and a boy Giton, in a portico of a Greek town, apparently in Campania. Encolpius delivers a lecture, full of admirable sense, on the false taste in literature, resulting from the prevailing system of education, which is replied to by a rival declaimer, Agamemno, who shifts the blame from the teachers to the parents. The central personages of the story next go through a series of questionable adventures, in the course of which they are involved in a charge of robbery. A day or two after they are present at a dinner given by a freedman of enormous wealth, Trimalchio, who had risen, as he boasted, "from a penny," and who entertained with ostentatious and grotesque extravagance a number of men of his own rank, who had not been so prosperous in life. We see actually in flesh and blood specimens of those "Cappadocian knights" to whom we have many pointed references in Martial and Juvenal. We witness their feats of gluttony; we listen to the ordinary talk of their guests about their neighbours, about the weather, about the hard times, about the public games, about the education of their children. We recognize in a fantastic and extravagant form the same kind of vulgarity and pretension which the satirist of all times delights to expose by pen or pencil in the illiterate and ostentatious millionaires of the age. Next day Encolpius separates from his companions in a fit of jealousy, and, after two or three days' sulking and brooding on his revenge, enters a picture gallery, where he meets with an old poet, who, after talking sensibly on the decay of art and the inferiority of the painters of the age to the old masters, proceeds to recite in a public portico some verses on the capture of Troy, till his audience take to stoning him. The scene is next on board ship, where Encolpius finds he has fallen into the hands of some old enemies. They are shipwrecked, and Encolpius, Giton, and the old poet get to shore in the neighbourhood of Crotona, where, with the view of attracting the attention of the inhabitants, notorious fortune-hunters, the adventurers set up as men of fortune. The fragment ends with a new set of questionable adventures, in which prominent parts are played by a beautiful enchantress named Circe, a priestess of Priapus, and a certain matron who leaves them her heirs, but attaches a condition to the inheritance which even Encolpius might have shrunk from fulfilling.³

What, then, may be said to be the purpose of the book, and what is its ethical and literary value? It can hardly be called a satire in the ordinary, and certainly not in the Roman sense of the word. There is no trace of any purpose of exposing vice with any wish to correct it. If we can suppose the author to have been animated by any other motive than the desire to amuse himself, it might be that of convincing himself that the world in general was as bad as he was himself. Juvenal and Swift are justly regarded as among the very greatest of satirists, and their estimate of human nature is perhaps nearly as unfavourable as that of Petronius; but their attitude towards human degradation is not one of complacent amusement but of indignant condemnation. They too, like Petronius, take pleasure in describing things most repugnant to all sense of delicacy with the coarsest realism, but theirs is the realism of disgust, not, like that of Petronius, a realism of sympathy. It might have been thought difficult to sink lower in the cynical tolerance of immorality than Martial occasionally has sunk. But there is all the difference in the world between Martial and Petronius. Martial does not gloat over the vices of which he writes with cynical frankness. He is perfectly aware that they are vices, and that the reproach of them is the worst that can be cast on any one. But further, Martial, with all his faults, is, in his affections, his tastes, his relations to others, essentially human, friendly, generous, true. There is perhaps not a single sentence in Petronius which implies any knowledge of or sympathy with the existence of affection, conscience, or honour, or even the most elementary goodness of heart, or of that amount of mutual confidence which is necessary to keep a band of brigands or a circle of

¹ E.g., compare Persius, ii. 9, 10—

"O si
Ebulliat patruus, præclarum funus, et O si
Sub rastro crepet argenti mihi seria dextro
Hercule"—

with *Satiræ* 88, "Alius domum promittit, si propinquum divitem extulerit, alius si thesaurum effoderit," &c. The "ebulliat patruus" may be compared with a phrase in the dinner of Trimalchio, "homo bellus tam bonus chrysanthus animam ebullit." Persius has the phrase "Dives arat Curibus quantum non milvus eberat," which is a close parallel to Petr., 37, "fundos habet qua milvi volant." Again, both Persius and Petronius use the rare word "baro," which occurs only two or three times elsewhere.

² In this respect the work of Petronius seems to have differed from the Greek romances.

³ Omnes qui in testamento meo legata habent, præter libertos meos, hac conditione percipient quæ dedi, si corpus meum in partes conciderint et astante populo comederint (141).

swindlers together. In estimating such a work, which in its spirit not less than in its form and its literary execution is essentially abnormal, it is necessary to bear in mind that it has reached us in so fragmentary and mutilated a shape that we may altogether have missed the key to it, and that it may have been intended by its author to be a sustained satire, written in a vein of reserved and powerful irony, of the type realized in our modern *Jonathan Wild* or *Barry Lyndon*. But, if this is not the explanation, we must fall back on the more obvious but still difficult solution that, in the entire divorce of intellectual power and insight from any element of right human feeling, the work is an exceptional phenomenon in literature. From an ethical and human point of view it is valuable only as a gauge of the degradation in which much of Roman society was sunk in the age when Persius wrote his satires—a work more pervaded by a spirit of moral purity than any other in Latin literature—and Christianity made its first converts in Rome.

But, as a work of original power, of humorous representation, of literary invention and art, the fragment deserves all the admiration which it has received. We recognize the "arbitrator elegantiae" in the admirable sense of the remarks scattered through it on education, on art, on poetry, and on eloquence. Though a better critic than a poet, yet he can write verse not only with good taste and simplicity, rare among the poets of that age, but with a true feeling of nature, as, for instance, in his description of a grove of plane-trees, cypresses, and pines—

"Has inter ludebat aquis errantibus anois,
Spumeus et querulo vexabat rore lapillos."

And in some of his shorter pieces he anticipates the terseness and elegance of Martial. The long fragment on the Civil War does not seem to be written so much with the view of parodying as of entering into rivalry with the poem of Lucan, but he has caught the tone and style of the author whom he censures. In the epigram extemporized by Trimalchio late on in the banquet.

"Quod non expectes, ex transverso fit—
Et supra nos Fortuna oegotia curat,
Quare da oobis vina Falerna, puer."

we have probably a more deliberate parody of the style of verses produced by the illiterate aspirants to be in the fashion of the day. We might conjecture that the chief gift to which Petronius owed his social and his literary success was that of humorous mimicry, in which the most intellectual and at the same time sensual among the Romans—as, for instance, Sulla—took a great delight. The man who could describe the dinner of Trimalchio and mimic the talk and peculiarities of the various guests with such humorous zest was just the man to keep the table in a roar during the prolonged revels in the palace of Nero. If the old "vexata questio" of the distinction between wit and humour were to be revived, the critic who could determine by analysis what is the essence of the talent of Martial on the one hand and of Petronius on the other would go very near to solving it. He would have, however, to abandon the theory that humour is more essentially humane and sympathetic than wit. Petronius is perhaps the most strictly humorous among Latin writers, and humour is in him combined with the rarer gift of conceiving and representing character. In Trimalchio and his various guests, in the old poet, in the cultivated, depraved, and moody Encolpius, in the Chrysis, Quartilla, Polyænia, &c., we recognize in living examples the play of those various appetites, passions, and tendencies which satirists deal with as abstract qualities. Another gift he possesses in a high degree, which must have availed him in society as well as in literature,—the gift of story-telling; and some of the stories which first appear in the *Satiræ*—e.g., that of the Matron of Ephesus—have enjoyed a great reputation in later times. His style, too, is that of one who must have been an excellent talker, who could talk sense when sense was wanted, who could have discussed questions of taste and literature with the most cultivated men of any time as well as amused the most dissolute society of any time in their most reckless revels. One phrase of his is often quoted by many who have never come upon it in its original context, "Horatii curiosa felicitas."

Perhaps next after a day spent in the ruins of Pompeii nothing else makes us feel so near the actual daily life of the Roman world in all its petty details in the 1st century A.D. as this fragment of Petronius. Another obvious observation that is suggested by it is that of the superiority of the novel over any other form of literature for the purpose of literally reproducing the commonplace experience of actual life in every age. Opinions may differ as to the value or interest of the literal reproduction of the customs and manners of such an age as that of Nero.

Compared with the amount of attention which was given to Petronius both by scholars and men of letters in the 17th and 18th centuries, comparatively little has been done for him in recent times. The only good critical edition of the fragments is that of Büchler. An interesting chapter is devoted to him in M. Gaston Boissier's *L'Opposition sous l'Empire*. For those who wish to read him in a modern translation, the French version by M. H. De Quérle is the one to be recommended. (W. Y. 8.)

PETROPAVLOVSK, a district town of western Siberia, in the government of Akmolinsk, is situated on the right bank of the Ishim river, 185 miles to the west of Omsk.

The old fort occupies a hill about 100 feet high, which slopes abruptly to the Ishim, while the wooden houses and the broad, unpaved, but regular streets of the town occupy partly the declivities of the hill and partly the (sometimes inundated) banks of the river. The fertile steppes to the east, west, and south of the town largely supply it with corn and cattle, and at the same time give great facilities for trade with the Kirghiz, with Turkestan, and with Bokhara. Its exports passing through the custom-house are estimated at an annual value of about £200,000, the chief items being cottons (upwards of £100,000), woollen stuffs, corn, metals, metallic wares, and spirits. The value of the cattle imports exceeds £150,000 annually, and the aggregate value of the skins, cotton goods, furs, tea, and wool imported reaches the same figure. The town has several tallow-melting houses, tanneries, and glue and soap works; and its industries are steadily increasing. The population (7850 in 1865) now exceeds 11,500.

The small fort of Petropavlovsk, consisting of an earthen palisaded wall, was founded in 1752, and was the military centre of the Ishim line of fortifications. It became at once a place of trade with the Kirghiz, and in 1771 had a population of 914 inhabitants. It received municipal institutions in 1807.

PETROPAVLOVSK is also the name of a Russian seaport in Kamchatka, on the eastern shore of the Bay of Avatcha in 53° N. lat. and 158° 44' E. long. Its beautiful harbour, one of the best on the Pacific, is but little frequented, and the town consists merely of a few huts with some 500 inhabitants. Its naval institutions were transferred to Nikolaievsk after the attack of the allies in 1854.

PETROPOLIS, a town of Brazil, in the province of Rio de Janeiro, lies at a height of 2400 feet above the sea on a beautiful and healthy plateau, surrounded by the wooded heights of the Serra da Estrella, which lie between it and the coast region. It is about 25 miles almost due north from Rio de Janeiro, and is reached by a railway (22 miles) from Maua; the last 10½ miles are on the Rigi system. Founded by the emperor of Brazil as a colony for distressed German immigrants, Petropolis has grown into an elegant and thriving town of 8000 or 10,000 inhabitants, and, besides the royal palace and park, has a number of good hotels and public buildings.

PETROVSK, a town of European Russia, in the province of Saratoff, lies on both banks of the Medveditsa, a tributary of the Don, 64 miles north-north-west of Saratoff on the Volga by the highway to Moscow. It was founded by Peter I. in 1698 to defend the district from the encroachments of the Kuban Tatars, and by the beginning of the 19th century it had become a place of 6921 inhabitants, with ten churches and a monastery (St Nicholas). In 1864 the population was 10,128, and it has since increased to upwards of 15,000.

This Petrovsk must not be confounded with (1) Petrovsk, a seaport town of from 4000 to 5000 inhabitants in northern Daghestan, which possesses one of the best roadsteads on the west coast of the Caspian; nor (2) with the crown iron-works of this name in Transbaikalia, deserving mention for its convict establishment, where the "Decembrists" were kept for several years.

PETROZAVODSK, a town of Russia, capital of the government of Olonetz, lies on the western shore of Lake Onega, 300 miles to the north-east of St Petersburg. The small river Lososinka divides it into two parts,—the town proper and the iron-works. Two cathedrals built towards the end of last century, two lycæums for boys and girls, a mining school, an ecclesiastical seminary, and several primary schools are the chief public buildings and institutions. The Government cannon-foundry can turn out annually more than 5000 tons of pig-iron, and the same weight of guns, gun-carriages, and ammunition, but its actual production is subject to great fluctuations. Within the district there are a few private iron-works as well as important saw-mills. The inhabitants engage in agriculture and fishing, and there is some trade with St Petersburg,—timber, fish, and furs being exported in exchange for corn, groceries.

and manufactured wares. The population (11,027 in 1865) was 11,970 in 1881.

Peter I., who was the first to give attention to the mineral resources of Olonetz, founded an iron-work, Petrovskii Zavod, on the Lososinka river, in 1703; the "zavod" prepared guns and arms, and within its walls a small palace and a church were built for the czar. The iron-work continued in operation for only twenty-four years; a copper-work, and subsequently a private iron-work, founded by Frenchmen, had no better success. The Government cannon-foundry was instituted in 1774; the settlement that sprang up was called Petrovsk, and received municipal institutions in 1777. Petrozavodsk became capital of the government of Olonetz in 1802.

PETTY, SIR WILLIAM (1623-1687), statistician and political economist, and author of the *Down Survey of Irish Lands*, was born on 26th May 1623. He was the son of a clothier at Romsey in Hampshire, and received his early education at the grammar-school there. About the age of fifteen he went to Caen (Normandy), taking with him a little stock of merchandise, on which he traded, and so maintained himself whilst learning French, improving himself in Latin and Greek, and studying mathematics and other sciences. On his return to England he seems to have had for a short time a place in the royal navy. He went abroad again in 1643, and remained for three years in France and the Netherlands, pursuing his studies at Utrecht, Leyden, Amsterdam, and Paris. In the last-named city he read Vesalius with the celebrated Hobbes. The philosopher was then preparing his *Tractatus Opticus*, and it is said that Petty drew the diagrams for him. In 1647 Petty obtained a patent for the invention of double writing, or, in other words, of a copying machine. In politics he espoused the side of the Parliament. His first publication was a letter to Samuel Hartlib in 1648, entitled *Advice for the Advancement of some Particular Parts of Learning*, the object of which was to recommend such a change in education as would give it a more practical character. In the same year he took up his residence at Oxford, where he was made deputy professor of anatomy, and where he gave instruction in that science and in chemistry. In 1649 he obtained the degree of doctor of physic, and was soon after elected a fellow of Brasenose College. He gained some notoriety in 1650 by restoring to life a woman who had been hanged for infanticide. In 1651 he was made professor of anatomy at Oxford, and also became professor of music at Gresham College. In 1652 he went to Ireland, having been appointed physician to the army in that country. In 1654, observing that the admeasurement and division of the lands forfeited in 1641 and granted to the soldiers had been (to use his own words) "most inefficiently and absurdly managed," he entered into a contract to execute a fresh survey, which he completed in thirteen months. By this he gained £9000, and part of the money he invested profitably in the purchase of soldiers' debentures. He thus became possessor of so large a domain in the county of Kerry that, according to Aubrey, he could behold from Mount Mangerton 50,000 acres of his own land. He set up iron-works in that neighbourhood, opened lead-mines and marble-quarries, established a pilchard-fishery, and commenced a trade in timber. In Macaulay's *History of England* there is an account of the settlement which he founded at Kenmare. Besides the office of commissioner of distribution of the lands he had surveyed, he held that of secretary to the lord lieutenant, Henry Cromwell, and was also during two years clerk of the council. In January 1658 he was elected to Richard Cromwell's parliament as member for West Looe in Cornwall. He was accused by Sir Jerome Sankey before the House of Commons of malversation and fraud in the conduct of his survey; but the matter did not come to an issue in consequence of the dissolution of the parliament, and Petty afterwards published tracts in his defence. After the Restoration he returned to England

and was favourably received and knighted by Charles II., who was "much pleased with his ingenious discourses," and who, it is said, intended to create him earl of Kilmore. He obtained from the king a new patent constituting him surveyor-general of Ireland. In 1663 he attracted much notice by the success of his invention of a double-bottomed ship, which twice made the passage between Dublin and Holyhead, but was afterwards lost in a violent storm. He was one of the first members of the Royal Society, and sat on its council. He died at London on the 16th of December 1687, and was buried in the church of his native place. His will, a curious and characteristic document, is printed in Chalmers's *Biographical Dictionary*.

Petty was a man of remarkable versatility, ingenuity, and resource. Evelyn declared he had "never known such another genius," and said of him, "If I were a prince I would make him my second councillor at least." His character does not seem to have been an elevated one, though Henry Cromwell, who knew him well, appears to have esteemed him highly.

The survey executed by Petty was, somewhat whimsically, called the "Down Survey," because the results were set down in maps; it is called by that name in Petty's will. He left in MS. a full account of the proceedings in connexion with it, which was edited by the late Major-General Sir Thomas A. Larcom for the Irish Archaeological Society in 1851. The maps, some of which were injured by a fire in 1711, are preserved in the Public Record Office, Dublin. The survey "stands to this day," says Larcom, "with the accompanying books of distribution, the legal record of the title on which half the land of Ireland is held, and for the purpose to which it was and is applied it remains sufficient." Petty's name is associated with the foundation, or, as it is safer to say, the successful prosecution of what has been somewhat too ambitiously termed "the science of political arithmetic." It is essentially the same with what is called comparative statistics. In Petty's time trustworthy numerical expressions of social facts could seldom be directly obtained, and thus large room was left for more or less probable inference from the available data. As we might have expected from his intellectual character, the expedients to which he resorts in seeking to arrive at determinations of this kind are very ingenious, but often unsatisfactory and even delusive. Whilst, however, he sometimes makes too much of the defective materials he could command, he strongly insists on accurate and continued observation as the only sure basis.

Petty was not merely a statistician, he was also a political economist, and one of no mean rank. He is one of the first in whom we find a tendency to a view of industrial phenomena which was at variance with the then dominant mercantilist ideas, and he exhibits a statesmanlike sense of the elements in which the strength of a nation really consists. Roscher names him as having, along with Locke and Dudley North, raised the English school to the highest point it attained before the time of Hume. His *Treatise of Taxes and Contributions* has been recently pronounced to be "the first great work on economic theory, which it may fairly be said to have founded." However this may be, it certainly contains a clear statement of the doctrine that price depends on the labour necessary for production. Petty is much concerned to discover a fixed unit of value, and he thinks he has found it in the necessary sustenance of a man for a day. He understands the cheapening effect of the division of labour. He states correctly the notion of "natural and true" rent as the remainder of the produce of land after payment of the cost of production; but he seems to have no idea of the "law of diminishing returns." He has much that is just on the subject of money: he sees that there may be an excess of it as well as a deficiency, and regards the prohibition of its exportation as contrary to sound policy. But he errs in attributing the fall of the rate of interest which takes place in the progress of industry to the increase in the quantity of money. He protested against the fetters imposed on the trade of Ireland, and advocated a union of that country with Great Britain. Whilst the general tendency in his day was to represent England as in a state of progressive decline—an opinion put forward particularly in the tract entitled *Britannia Lanquens*—Petty declared her resources and prospects to be not inferior to those of France.

A complete list of his works is given in the *Athenæ Oxonienses*. The most important are: the *Treatise of Taxes and Contributions* (1662, 1667, and 1685); *Political Arithmetic*, presented in MS. to Charles II., but, because it contained matter likely to be offensive to France, kept unpublished till 1691, when it was edited by Petty's son Charles; *Quantulumcunque, or a Tract concerning Money* (1682); *Observations upon the Dublin Bills of Mortality in 1651, and the State of that City* (1683); *Essay concerning the Multiplication of Mankind* (1686); *Political Anatomy of Ireland* (1691). Several papers appeared in the *Philosophical Transactions*. It is much to be regretted, as McCulloch long since remarked, that a complete and uniform edition of his writings has not been published.

PETUNIA. See HORTICULTURE, vol. xii. p. 264.

PEUTINGER, CONRAD (1465-1547), a prominent and

useful citizen of Augsburg, remembered for his services to the new learning. He was one of the first to publish Roman inscriptions (see vol. xiii. p. 124), and his name remains associated with the famous *Tabula Peutingeriana* (see MAPS, vol. xv. p. 517), which was in his hands when he died, and was found again among his MSS. in 1714. This important Roman itinerary table was first published as a whole by Scheyb (Vienna, 1753); the most elaborate edition is by Desjardins (Paris, 1869 and following years).

PEWTER¹ is a generic term for a variety of alloys, which all agree in this, that tin forms the predominating component. The finest pewter (sometimes called "tin and temper") is simply tin hardened by the addition of a trifle of copper. Ordinary pewter is tin alloyed with lead, which latter ingredient is added chiefly on account of its cheapness, and therefore often in excessive proportion. The law of France restricts the percentage of lead to 16.5, with a toleration of 1.5 per cent. of error, an alloy of this or a higher degree of richness in tin being, according to an old investigation by Vauquelin, as proof against sour wine or vinegar as pure tin is. Higher percentages of lead are dangerous, and besides spoil the appearance of the alloy. The composition of an alloy containing only these two components can be ascertained approximately by determining the specific gravity (see METALS, vol. xvi. p. 67 sq.).

Plate pewter is a hard variety much used for plates and dishes; a good quality is composed of 100 parts of tin, 8 of antimony, 2 of bismuth, and 2 of copper. Closely allied to it is the silver-white alloy called "Britannia metal," which is much used in Great Britain for the making of teapots more especially. To give an idea of its very variable composition the following two analyses may be quoted:—

| | | |
|---------------|-------|-------|
| Tin..... | 85.7 | 81.9 |
| Antimony..... | 10.4 | 16.2 |
| Copper..... | 1.0 | 0.0 |
| Zinc..... | 2.9 | 1.9 |
| | 100.0 | 100.0 |

Pewter wares are shaped chiefly in three ways. Measures and spoons are cast in moulds of brass made of two closely-fitting but detachable halves, the surface of the mould being powdered over with sandarach, or painted over with white of egg or oil, before use to prevent adhesion. Plates and dishes are made preferably by hammering. In large establishments milk-jugs and similar articles are often produced by "spinning," i.e., by pressing a flat plate of pewter against a rapidly-revolving blunt tool, and thus raising it into the desired shape. (Cf. LEAD, vol. xiv. p. 378.)

PPAFF, CHRISTIAN HEINRICH (1773-1852), chemist and physicist, younger brother of J. F. Pfaff noticed below, took his degree as doctor of medicine at Stuttgart in 1793. He travelled with a noble family as physician, and practised for a time at Heidenheim; but he afterwards became professor (extraordinary in 1797, ordinary in 1801) of medicine, physics, and chemistry at the university of Kiel. He was a most prolific author of memoirs on sanitary and medical, and especially on chemical and physical, subjects. His work in chemistry was chiefly analytical and mineralogical. In physics he was distinguished as one of the earlier experimenters with the voltaic current, and had a considerable share in the experimental investigation of its properties. He also made important researches on the carrying power of magnets, more particularly on the effect of the extent of the attracting surface. Comparatively few of his memoirs are now quoted, owing to the fact that none of his results contained any capital discovery; nevertheless he deserves to be remembered as one of the energetic workmen who aided in raising the stately pile of modern experimental science.

¹ Old Fr. *peudre*; Ital. *pettro*; comp. Eng. *spelter*.

PPAFF, JOHANN FRIEDRICH (1765-1825), German mathematician, was born on 22d December 1765 at Stuttgart. He received his early education at the Carlsschule, where Schiller, afterwards his life-long friend, was a school-companion. His mathematical capacity was early noticed; and after leaving school he pursued his studies in that department at Göttingen under Kästner, author of a *History of Mathematics*; and in 1787 he went to Berlin and studied practical astronomy under Bode. In 1788 Pfaff became professor of mathematics in Helmstädt, and so continued until that university was abolished in 1810. From that time till his death (20th April 1825) he held the chair of mathematics at Halle. Pfaff's researches bore chiefly on the theory of series, to which he applied the methods of the so-called Combinatorial School of German mathematicians, and on the solution of differential equations. His two principal works are *Disquisitiones analyticae maxime ad calculum integralem et doctrinam serierum pertinentes* (4to, vol. i., Helmstädt, 1797) and "Methodus generalis, æquationes differentiarum particularum, nec non æquationes differentiales vulgares, utrasque primi ordinis inter quocumque variables, complete integrandi" in *Abh. d. Berl. Acad.* (1814-15). The former work contains Pfaff's discussion of the equation $(a + bx^n)x^2dy/dx^2 + (c + ex^n)xdy/dx + (f + gx^n)y = X$, which generally bears his name, but which had originally been treated in a less complete manner by Euler. The latter work contains an important addition to the theory of partial differential equations as it had been left by Lagrange.

An interesting review of Pfaff's memoir was published by Gauss in the Göttingen *Gelehrte Anzeigen* for 1815 (republished in vol. iv. of his complete works). For fuller details regarding Pfaff and his work, consult Gerhardt, *Geschichte der Mathematik in Deutschland* (Munich, 1877, p. 198), and Pfaff's correspondence, edited by C. H. Pfaff.

Another brother of this family, JOHANN WILHELM ANDREAS PPAFF (1774-1835), was professor of pure and applied mathematics successively at Dorpat, Nuremberg, Würzburg, and Erlangen.

PFALZBURG, a town of German Lorraine, lies high on the west slopes of the Vosges, 25 miles to the north-west of Strasburg. In 1880 it contained 3379 (mainly Roman Catholic) inhabitants. The principality of Pfalz-burg, originally a part of Luxemburg, afterwards belonged in turn to the bishop of Metz, the bishop of Strasburg, and the duke of Lorraine, and passed into the possession of France in 1661. The town was of importance as commanding the passes of the Vosges, and was strongly fortified by Vauban in 1681. The works resisted the Germans for four months in 1870, but have since been razed.

PFEIFFER, FRANZ (1815-1868), an eminent writer on mediæval German literature and on old forms of the German language, was born at Solothurn on the 27th of February 1815. Having studied at the university of Munich, he went to Stuttgart, where in 1846 he became librarian at the royal public library. In 1857, having established his fame as one of the foremost authorities on his spécial subject, he was appointed professor of German literature and language at the university of Vienna; and in 1860 he was made a member of the Imperial Academy of Sciences. He died on the 29th of May 1868.

As an editor of mediæval literature Pfeiffer was unsurpassed among the scholars of his day, and by his work in this department he did much to foster the critical study of writers who before his time were known only to specialists. Among the many writings edited by him may be mentioned the works of the German mystics of the 14th century, the *Buch der Natur* of Conrad of Megenberg, the *Predigten* of Berthold of Ratisbon, the *Edelstein* of Ulrich Boner, the *Barlaam und Josaphat* of Rudolf of Ems, and the poems of Walther von der Vogelweide. Of his independent writings the most important are *Zur deutschen Literaturgeschichte*, *Ueber Wesen und Bildung der höfischen Sprache in mittelhochdeutscher Zeit*, *Der Dichter des Nibelungenliedes*, *Forschung und Kritik auf dem Gebiete des deutschen Alterthums*, and *Altdeutsches Gedichtsbuch*. Pfeiffer's style is clear and vigorous, and on every

subject which he discussed, he was able to throw fresh light. A biographical sketch of him by Bartsch occurs in Uhland's *Briefwechsel mit Freiherrn von Lassberg*, which Pfeiffer edited.

PFEIFFER, IDA LAURA (1797-1858), traveller, was born at Vienna, the daughter of a merchant named Reyer, 14th October 1797. Ida was the only sister of six brothers, and in her youth acquired masculine habits. Her training was Spartan, and accustomed her to the endurance of hardships and deprivations. On 1st May 1820 she married Dr Pfeiffer, a prosperous advocate of Lemberg, twenty-four years older than herself. Through over-zeal in denouncing abuses her husband incurred official persecution, and in a few years after his marriage was reduced to the greatest poverty. Ida, living mostly apart from her husband, underwent great drudgery, but, through her own exertions, managed to educate her two sons. After being relieved of this responsibility she resolved to indulge her intense longing to travel, and, with the most limited means, succeeded in making a series of journeys which, in extent, are probably unparalleled in the case of any other woman. In 1842 Madame Pfeiffer visited Egypt and Palestine, and, with considerable hesitation, published an account of her journey in three small volumes, *Reise einer Wienerin in das Heilige Land*, in 1845. In the same year she set out again, this time to Scandinavia and Iceland, describing her tour in two volumes, *Reise nach dem Skandinavischen Norden und der Insel Island* (Pesth, 1846). In 1846 she started on her first journey round the world, visiting Brazil, Chili, and other countries of South America, Tahiti, China, India, Persia, Asia Minor, and Greece, and reaching home in 1848. The results were published in three volumes at Vienna in 1850, under the title *Eine Frauenfahrt um die Welt*. For her next and most extensive journey she received the support of the Austrian Government to the small extent of £150. Starting in 1851, she went by London to South Africa, her purpose being to penetrate into the interior; but, this proving impracticable, she proceeded to the Malay Archipelago, spending eighteen months in the Sunda Islands and the Moluccas. After a visit to Australia, Madame Pfeiffer proceeded to California, Oregon, Peru, Ecuador, New Granada, the Missions Territory, and north again to the American lakes, reaching home in 1854. Her narrative, *Meine zweite Weltreise*, was published in four volumes at Vienna in 1856. In May of the same year Ida set out to explore Madagascar, where at first she was cordially received by the queen. Unfortunately, she unwittingly allowed herself to be involved in the plot of a Frenchman to overthrow the government, and, with brutal treatment, was expelled from the country. After being detained by her sufferings in Mauritius for some months, Ida returned by England to Vienna, where she died 27th October 1858. The *Reise nach Madagascar* was issued in 1861, with a biography by her son.

All Madame Pfeiffer's narratives have been translated into English as well as other languages, and have maintained a steady popularity up to the present time. Although Ida Pfeiffer can hardly be said to have broken up new ground in her travels, she certainly did much to increase our knowledge of countries about which our information was most meagre. Moreover, her scientific collections—for she was as good a collector as observer—were of considerable extent, and great value and novelty, and were regarded as important acquisitions by the Vienna museum. She was made an honorary member of the Berlin and Paris Geographical Societies, and received from the king of Prussia the gold medal of science and art. Her travels altogether covered 150,000 miles by sea and 20,000 by land. Ida Pfeiffer was short in stature, and latterly slightly bent; her manners were simple, unassuming, and womanly.

PFORZHEIM, one of the chief industrial towns in the grand-duchy of Baden, is pleasantly situated at the confluence of the Nagold, the Würm, and the Enz, on the northern margin of the Black Forest, 15 miles to the south-east of Carlsruhe. The most prominent buildings are the old palace of the margraves of Baden-Durlach and

the Schlosskirche, the latter an interesting edifice of the 12th to the 15th centuries, containing the tombs and monuments of the margraves. The staple industry is the manufacture of gold and silver ware and jewellery, which gives employment to nearly 10,000 workmen, besides which there are iron and copper works, and manufactures of chemicals, paper, leather, cloth, and other articles. A brisk trade is maintained in timber, cattle, and agricultural produce. In 1880 the population was 24,037, having almost doubled itself in twenty years. Four-fifths of the inhabitants are Protestants.

Pforzheim (Porta Hercyniæ) is of Roman origin, and has belonged to Baden for 600 years. From about 1300 down to 1565 it was the seat of the margraves of the Baden-Durlach-Ernestine line, now extinct. The town was taken by the troops of the Catholic League in 1624, and was destroyed by the French in 1689. The story of the 400 citizens of Pforzheim who sacrificed themselves for their prince after the battle of Wimpfen (1622) has been relegated by recent historical research to the domain of legend. The humanist Reuchlin was born at Pforzheim in 1455.

PHÆDRUS, the author of five books of Latin fables in verse, lived in the reigns of Augustus, Tiberius, Caligula, and Claudius. To his literary vanity we owe most of our scanty knowledge of his life. He was born on the Pierian Mountain in Macedonia, but seems to have been brought at an early age to Italy, for he mentions that he read a verse of Ennius as a boy at school. According to the heading of the chief MS. he was a slave and was freed by Augustus. He incurred the wrath of Sejanus, the powerful minister of Tiberius, but on what grounds is not known. Devoting himself to literature, he lived in poverty and died at an advanced age. The first two books of his fables were published together; the third, fourth, and fifth appeared later, each by itself. The third book is dedicated to Eutychus, a wealthy man of business and probably a freedman, to whom the poet appeals for promised help. The fourth book is dedicated to Particulon, who seems to have dabbled in literature. From the fact that Seneca, writing in 43 or 44 A.D. (*Consol. ad Polyb.*, 27), knows of no Latin writer of fables we may infer that Phædrus published his fables after that time, but the exact date is unknown. His work shows little or no originality; he simply versified (in iambic trimeters) the fables current in his day under the name of "Æsop," interspersing them with anecdotes drawn from daily life, history, and mythology. He tells his fable and draws the moral with business-like directness and simplicity; his language is classical, neat, and clear, but thoroughly prosaic, though it occasionally attains a dignity bordering on eloquence. He is fond of abstract words. From a literary point of view Phædrus is far inferior to those masters of fable-writing, Babrius and La Fontaine; he lacks the quiet picturesqueness and pathos of the former, and the exuberant vivacity and humour of the latter. Though he frequently refers to the envy and detraction which pursued him, Phædrus seems to have attracted little attention in antiquity. He is mentioned by Martial (iii. 20, 5), who imitated some of his verses, and by Avianus. Prudentius must have read him, for he imitates one of his lines (*Prud., Cath.*, vii. 115; cp. Phædrus, iv. 6, 10).

The first edition of the five books of Phædrus was published by Pithou at Troyes in 1596. But, from the gaps in the books as well as from the disproportionate shortness of some of them, it is plain that this collection is incomplete. In the beginning of the 18th century there was discovered at Parma a MS. of Perotti (1430-1480), archbishop of Siponto, containing sixty-four fables of Phædrus, of which thirty-two were new. These new fables were first published at Naples by Cassitto in 1808, and afterwards (much more correctly) by Jannelli in 1811. Both editions were superseded by the discovery of a much

better preserved MS. of Perotti in the Vatican, which was published by Angelo Mai in 1831. For some time the authenticity of these new fables was disputed, but they are now generally accepted, and with justice, as genuine fables of Phædrus. They do not form a sixth book, for we know from Avianus that Phædrus wrote five books only, but it is impossible to assign them to their original places in the five books. They are usually printed as an appendix. Even thus it is probable that we have not the whole of Phædrus.

In the Middle Ages Phædrus exercised a considerable influence through the prose versions of his fables which were current, though his own works and even his name were forgotten. Of these prose versions the oldest existing seems to be that known as the "Anonymus Nilantianus," so called because first edited by Nilant at Leyden in 1709 from a MS. of the 10th or beginning of the 11th century. It approaches the text of Phædrus so closely that it was probably made directly from it. Of the sixty-seven fables which it contains thirty are derived from lost fables of Phædrus. But the largest and most influential of the prose versions of Phædrus is that which bears the name of "Romulus." It contains eighty-three fables, is as old as the 10th century, and seems to have been based on a still earlier prose version, which, under the name of "Æsop," and addressed to one Rufus, may have been made in the Carolingian period. The preface of Romulus, in which he professes to have translated the fables from the Greek, is a mere fiction of the copyist; no such Romulus as this ever existed, although in the Middle Ages he was sometimes thought to have been a Roman emperor, and has still a place in the *Biographie Universelle* (1863). The collection of fables in the Weissenburg (now Wolfenbüttel) MS. is based on the same version (the *Æsopus ad Rufum*) as *Romulus*. These three prose versions contain in all one hundred distinct fables, of which fifty-six are derived from the existing and the remaining forty-four presumably from lost fables of Phædrus. Some modern scholars, as Burmann, Dressler, and L. Müller, have tried to restore these lost fables by versifying the prose versions.

The collection bearing the name of Romulus became in its turn the source from which, during the second half of the Middle Ages, almost all the collections of Latin fables in prose and verse were wholly or partially drawn. A version of the first three books of *Romulus* in elegiac verse enjoyed a wide popularity, even into the Renaissance. Its author (generally referred to since the edition of Nèvelet in 1610 as the Anonymous of Nèvelet) was long unknown, but Hervieux has lately shown grounds for identifying him with Walther of England, chaplain to Henry II. and afterwards archbishop of Palermo. The version dates from the latter part of the 12th century. It was especially popular in Italy, where the Italian translation of Accio Zuccho (Verona, 1479) was frequently reprinted. Another version of *Romulus* in Latin elegiacs was made by Alexander Neckam, born at St Albans in 1157, and towards the end of his life (early part of 13th century) abbot of the Augustinian monastery at Exeter. Neckam knew and copied Walther's version, but his own never had the same popularity. Amongst the collections partly derived from *Romulus* the most famous is probably that in French verse by MARIE DE FRANCE (*q. v.*). About 1200 a collection of fables in Latin prose, based partly on *Romulus*, was made by the Cistercian monk Odo of Sherrington; they have a strong mediæval and clerical tinge. In 1370 Gerard of Minden wrote a poetical version of *Romulus* in Low German.

Since the first edition of Phædrus by Pithou in 1596 the editions and translations have been very numerous; among the editions may specially be mentioned those of Burmann (1718 and 1727), Bentley (1726), Schwabe (1806), Berger de Kivrey (1830), Orelli (1832), Eyssenhardt (1867), L. Müller (1877), Hervieux, in his work *Les Fabulistes Latins depuis le siècle d'Auguste jusqu'à la fin du moyen âge*, Paris, 1884. For the mediæval versions of Phædrus and their derivatives see L. Roth, in *Philologus*, i. p. 523 *sq.*; H. Oesterley, *Romulus die Paraphrasen des Phædrus und die æsopische Fabel im Mittelalter*, 1870 (untrustworthy); E. Grosse, in *Jahrb. f. class. Philol.*, vol. cv. (1872); and especially the learned work of Hervieux, who gives the Latin texts of all the mediæval imitators (direct and indirect) of Phædrus, some of these texts being now edited for the first time. (J. O. FR.)

PHAETHON ("the shining one"), in Homer an epithet of the sun, and used by later writers as a name for the sun, is more generally known in classical mythology as a son of the Sun and the ocean nymph Clymene. He persuaded his father to let him drive the chariot of the sun across the sky, but he lost control of the horses, and driving too near the earth scorched it; mountains were set on fire, rivers and seas dried up, Libya became a desert, and the Æthiopians were blackened by the heat. To save the earth from utter destruction Zeus killed Phaethon with a thunderbolt. He fell to earth at the mouth of the Eridanus, a river of northern Europe (identified in later times with the Po), on the banks of which his weeping sisters

were transformed into poplars and their tears into amber. This part of the legend points to the mouth of the Oder or Vistula, where amber abounds. Phaethon was the subject of a drama of Euripides, of which some fragments remain. The suggestion that the legend of Phaethon is a mythical expression of vast increases of temperature produced at long intervals by changes in the relative position of the earth and the heavenly bodies was made by Plato (*Timæus*, 22 C, D).

PHALANGER. Among the anonymous additions to Charles l'Ecluse's posthumous work *Cura posterioris seu plurimarum non ante cognitarum aut descriptarum . . . animalium novæ descriptiones*, published at Leyden in 1611, occurs the following:—

"In our third expedition, under Admiral Van der Hagen, there was seen at Amboyna a rare and truly marvellous animal. The 'cousa,' as it is called by the natives, is a reddish animal, a little larger than a cat, which has under its belly a kind of pouch in which the mammae are placed, and in this the young are born, and remain there hanging firmly on until large enough to be turned out by their mother. They return, however, continually to the pouch until sufficiently developed to follow their mother and to find food for themselves. These animals live on grass, green leaves, and other vegetable food, and their flesh is eaten by the Portuguese and other native Christians, but not by the Mohammedans, who consider the cousa to be an unclean, and forbidden animal, mainly on account of its want of horns."

This early account forms the first mention of any of the numerous marsupials of the eastern hemisphere, as there can be no doubt that the animal called the cousa by the natives of Amboyna nearly 300 years ago was the Grey Cuscus (*Cuscus orientalis*), a member of the only marsupial genus occurring in any Eastern land then known to Europeans. About a hundred years afterwards the same animal was seen by the Dutch traveller Valentyn, also at Amboyna, and still later Buffon gave to a pair of cuscuses examined by him the name that heads this article, "Phalanger," on account of the peculiar structure of the second and third toes of the hind feet, which are united in a common skin up to the nails, a character now known to be present in a large proportion of the Australian marsupials. Later, Captain Cook in 1770 and 1777, Governor Phillip in 1788; and J. White in 1790 discovered various different kinds of phalangers, and now we know of not less than ten genera, with about thirty-five species, forming the sub-family *Phalangistinae* of the family *Phalangistidae*, whose general characters have already been noticed in the article MAMMALIA (vol. xv. p. 382).

Phalangers as a whole are small woolly-coated animals, with long, powerful, and often prehensile tails, large claws, and, as in the American opossums, with opposable nailless great toes. Their expression seems in the day to be dull and sleepy, but by night they appear to decidedly greater advantage. They live mostly upon fruit, leaves, and blossoms, although some few feed habitually upon insects, and all relish, when in confinement, an occasional bird or other small animal. Several of the phalangers possess flying membranes stretched between their fore and hind limbs, by the help of which they can make long and sustained leaps through the air, like the flying squirrels; but it is interesting to notice that the possession of these flying membranes does not seem to be any indication of special affinity, the characters of the skull and teeth sharply dividing the flying forms, and uniting them with other species of the non-flying groups. Their skulls (see fig. 1) are as a rule broad and flattened, with the posterior part swollen out laterally, owing to the numerous air-cells situated in the substance of the squamosals. The dental formula is very variable, especially as regards the premolars, of which some at least in each genus are reduced to mere functionless rudiments, and may even vary in number on the two sides of the jaw of the same individual. The

incisors are always $\frac{3}{1}$, the lower one very large and procivous, and the canines normally $\frac{1}{1}$, of which the inferior

FIG. 1.—Skull of Naked-eared Cuscus (*Cuscus gymnotis*). After Peters.

is always minute, and in one genus generally absent. The true molars number either $\frac{4}{4}$ or $\frac{3}{3}$.

The genera, of which not less than ten must be allowed as valid, may be arranged as follows.

- I. Molars with curved crests, $\frac{4}{4}$.
 - (A) Pm.² minute or absent; pm.¹ and pm.³ functional, the latter standing obliquely.
 - a. Canines separated from incisors; tail hairy 1. *Phalangista*.
 - b. Canines close to incisors; tail naked, scaly 2. *Cuscus*.
 - (B) Pm.² functional; pm.³ forming an even series with the molars.
 - c. Without a flying membrane; first two anterior toes opposable to rest; tail prehensile 3. *Pseudochirus*.
 - d. With a flying membrane; toes normal; tail bushy, non-prehensile 4. *Petaurista*.
- II. Molars with round or pointed cusps.
 - (C) Molars $\frac{4}{4}$. Functional premolars $\frac{2 \text{ or } 3}{0}$.
 - e. Lower premolar row interrupted; upper i.¹ directed forwards; pm.² functionless 5. *Dactylopsila*.
 - f. Lower premolar row continuous; upper i.¹ directed downwards; pm.² functional.
 - a. A flying membrane 6. *Petaurus*.
 - b. No flying membrane 7. *Gymnobelideus*.
 - (D) Molars $\frac{3}{3}$.
 - g. Functional premolars $\frac{1}{1 \text{ or } 0}$; tail round; no flying membrane 8. *Dromicia*.
 - h. Functional premolars $\frac{3}{1}$; tail distichous; no flying membrane 9. *Distoechurus*.
 - i. Functional premolars $\frac{3}{2}$; tail distichous; a flying membrane 10. *Acrobata*.

1. *Phalangista*, Cuv.

Upper incisors forming a semicircular series. Upper i.¹ scarcely larger than the others, parallel, its anterior surface flattened, point transversely truncated. Canines some way from and shorter than incisors, in front of the premaxillary-maxillary suture.^a Pm.¹ small, some way separated both from canine and pm.³; pm.² suppressed; pm.³ large, obliquely placed. Molars large, quadrangular, their summits with distinct crescentic ridges. Lower incisors large; canines very small, but persistent; pm.¹ and pm.² small, or, commonly, absent; pm.³ large and obliquely placed; molars like the upper ones.

Dental formula.^b—i. $\frac{1.2.3}{1.0.0}$ c. $\frac{1}{1}$ pm. $\frac{1.0.3}{1.2.3}$ m. $\frac{1.2.3.4}{1.2.3.4} \times 2 = 34$ to 38.

Skull low, without frontal sinuses; bullæ scarcely inflated; premaxillary long; the anterior palatine foramina almost confined to the premaxilla; mandible with no trace of an external opening into the inferior dental canal.

Feet normal; tail long and bushy, only naked for a few inches along the under-side of the tip.

Range.—The whole of Australia and Tasmania; not yet found in New Guinea.

This genus, by its somewhat elongated premaxilla, restriction

^a At the point of exit from the bone, but the roots are of course situated in the maxilla.

^b In this special dental formula, necessitated by the peculiar development of the teeth of the phalangers, the numbers are those of each individual tooth,—the larger numbers representing fully-developed functional teeth, and the smaller the minute and functionless ones. An asterisk to one of the latter shows that the tooth is sometimes or commonly absent, though it should be remarked that the presence or absence of these minute teeth is not of any systematic importance.

of the palatine foramina to the latter bones, and by the shape of its upper pm.³, shows a certain tendency towards the kangaroo (*Macropodidae*), the family to which the *Phalangistidae* are undoubtedly most nearly allied.

The true phalangers, or opossums as they are called by the Australian colonists, consist of four or five hardly separable species, of which the best known is the Vulpine Phalanger (*Ph. vulpecula*), so common in zoological gardens, where, however, it is seldom seen, owing to its nocturnal habits. It is of about the size and general build of a small fox, whence its name; its colour is grey, with a yellowish white belly, white ears, and a black tail. It is a native of the greater part of the continent of Australia, but is replaced in Tasmania by the closely allied Brown Phalanger (*Ph. fuliginosa*). Its habits are very similar to those of the Yellow-bellied Flying-Phalanger (*Petaurus australis*) described below,—except that, of course, it is unable to take the wonderful flying leaps so characteristic of that animal. Like all the other phalangers, its flesh is freely eaten both by the natives and by the lower class of settlers.

2. *Cuscus*, Lacép.

Upper incisor row angular in front. Upper i.¹ considerably longer than the others, round, pointed. Canines close against the last incisors, longer than any of the other teeth, placed apparently on the suture. Pm.¹ well developed; pm.² minute or absent; pm.³ large, rounded, its axis slightly oblique. Molars and all the lower teeth much as in *Phalangista*, but rather larger in proportion.

Dental formula.—i. $\frac{1.2.3}{1.0.0}$ c. $\frac{1}{1}$ pm. $\frac{1.2^*.3}{1.2^*.3}$ m. $\frac{1.2.3.4}{1.2.3.4} \times 2 = 34$ to 40.

Frontal region of skull in adult animals markedly convex, owing to the presence of large frontal sinuses; bullæ not inflated; premaxillary bones very short; palatine foramen entering the maxilla; no external opening into the inferior dental canal.

Feet normal; tail long, naked and scaly for its terminal two-thirds, prehensile.

Range.—From Celebes to the Solomon Islands, and southwards, through New Guinea to North Queensland.

The cuscuses are curious sleepy-looking animals, which inhabit the various islands of the East Indian archipelago as far west as Celebes, being the only marsupials found west of New Guinea. As already noted, it was a member of this genus, the Grey Cuscus (*C. orientalis*), a native of Amboyna, Timor, and the neighbouring islands, which was the first Australian marsupial known to European naturalists. There are altogether about eight species known, all of about the size of a large cat; their habits resemble those of other phalangers, except that they are said to be somewhat more carnivorous.

3. *Pseudochirus*, Ogilb.

Upper incisor row angular. First upper incisor but little longer than the others, but nevertheless the longest tooth in the jaw. Canine small, behind suture. Pm.¹ rather small; pm.² and pm.³ larger, each with two roots, neither placed at all obliquely. Molars quadrangular, with very distinct crescentic ridges; all the teeth from the incisors backwards forming a nearly continuous series. Lower pm.³ only forming part of the molar series.

Dental formula.—i. $\frac{1.2.3}{1.0.0}$ c. $\frac{1}{1}$ pm. $\frac{1.2.3}{1.2^*.3}$ m. $\frac{1.2.3.4}{1.2.3.4} \times 2 = 36$ to 40.

Skull, as in all the following genera except *Dactylopsila*; bullæ inflated; palate generally complete; a minute external opening into the inferior dental canal generally present in the position of the large vacuity characteristic of the *Macropodidae*.

Ears large; fore-feet with the first two toes together opposable to the remaining three; tail thinly-furred, prehensile.

Range.—Tasmania, Australia, and New Guinea.

There are about four species of this genus known, of which the commonest is Cook's Ring-tailed Phalanger (*Pseudochirus caudivolutus*), an animal discovered by Captain Cook during his first voyage, at Endeavour river, North Queensland.

4. *Petaurista*, Desm.

Teeth almost exactly as in *Pseudochirus*, except that the lower canine is generally absent, as well as the minute first and second premolars.

Dental formula.—i. $\frac{1.2.3}{1.0.0}$ c. $\frac{1}{1}$ pm. $\frac{1.2.3}{1.2^*.3}$ m. $\frac{1.2.3.4}{1.2.3.4} \times 2 = 34$ to 40.

Bullæ inflated, but small; palate generally incomplete from the level of the second molar; a distinct external opening into the inferior dental canal.

Sides of the body with a broad flying membrane stretching from the elbow to just below the knee; ears large and hairy; claws long and sharp; tail bushy, round, and non-prehensile.

Habitat.—New South Wales.

The only species belonging to this genus is the large black Taguan Flying Phalanger (*P. volans*), an animal very similar to certain of the large Indian flying squirrels, and which fully agrees in its habits with the Yellow-bellied Flying-Phalanger described below. In its affinities it seems to be, so to speak, a highly-specialized

Pseudochirus, in which the teeth have become somewhat further diminished and the flying membrane has been developed.

5. *Dactylopsila*, Gray.

Upper i^1 very long, directed forwards. Canine shorter than i^2 , close to it. $Pm.^2$ minute or absent; $pm.^3$ oval, in line with molars. Molars square-sided, forming a straight line, the third as long as the second. All lower premolars small and deciduous.

Dental formula.— $i. \frac{1.2.3}{1.0.0} c. \frac{1}{1} pm. \frac{1.2^*.3}{1.2^*.3} m. \frac{1.2.3.4}{1.2.3.4} \times 2 = 32$ to 40.

Palatal foramen in premaxilla; palate complete; bullæ small; no external opening into inferior dental canal.

Form normal; fourth fore-toe very much longer than the others; tail bushy, rounded.

Range.—From the Aru Islands through New Guinea to North Queensland.

Of this genus two closely-allied species are described. They are beautifully striped down the back with white and grey, and are said to be insectivorous in their habits.

6. *Petaurus*, Shaw.

Upper i^1 very long, directed downwards. Canine intermediate in length between i^1 and i^2 . $Pm.^2$ the smallest, but yet functional. Molars much rounded, as are those of all the succeeding genera; $m.^3$ much smaller than $m.^2$. Lower premolars, though small, yet permanent and forming an uninterrupted series.

Dental formula.— $i. \frac{1.2.3}{1.0.0} c. \frac{1}{1} pm. \frac{1.2.3}{1.2.3} m. \frac{1.2.3.4}{1.2.3.4} \times 2 = 40$.

Palatal foramen entering maxilla; bullæ inflated; a small external opening into the inferior dental canal.

Sides of body with a flying membrane stretching from the outside of the tip of the anterior fifth toe to the ankle; tail bushy; ears large and nearly naked.

Range.—From New Ireland to South Australia, but not Tasmania.

This genus contains about five species, the largest of which is the Yellow-bellied Flying-Phalanger (*P. australis*), whose habits are recorded by Mr Gould as follows. "This animal is common in all the brushes of New South Wales, particularly those which stretch along the coast from Port Phillip to Moreton Bay. In these vast forests trees of one kind or another are perpetually flowering, and thus offer a never-failing supply of the blossoms upon which it feeds; the flowers of the various kinds of gums, some of which are of great magnitude, are the principal favourites. Like the rest of the genus, it is nocturnal in its habits, dwelling in holes and in the apouts of the larger branches during the day, and displaying the greatest activity at night while running over the small leafy branches, frequently even to their very extremities, in search of insects and the honey of the newly-opened blossoms. Its structure being ill adapted for terrestrial habits, it seldom descends to the ground except for the purpose of passing to a tree too distant to be

chased or forced to flight it ascends to the highest branch and performs the most enormous leaps, sweeping from tree to tree with wonderful address; a slight elevation gives its body an impetus which with the expansion of its membrane enables it to pass to a considerable distance, always ascending a little at the extremity of the leap; by this ascent the animal is prevented from receiving the shock which it would otherwise sustain."

A second species, *P. sciureus*, in some ways one of the most beautiful of all mammals, has been chosen for the accompanying cut (see fig. 2).

7. *Gymnobelideus*, M'Coy.

Like *Petaurus* in every respect, but without any trace of a flying membrane.

Habitat.—Victoria.

8. *Dromicia*, Gray.

First upper incisor and canine very long. $Pm.^1$ and $pm.^2$ very minute; $pm.^3$ large. Molars rounded; their series bowed inwards. Lower canine and first two premolars very small but persistent. $pm.^3$ either large and functional or minute.

Dental formula.— $i. \frac{1.2.3}{1.0.0} c. \frac{1}{1} pm. \frac{1.2^*.3}{1.2^*.3} m. \frac{1.2.3}{1.2.3} \times 2 = 32$ to 36

Palate incomplete; bullæ very large and inflated.

No flying membrane; claws short, exceeded in length by the pads under them; toes subequal; tail thinly haired, prehensile.

Five species of *Dromicia* Phalangiers are recorded, ranging from New Guinea to Tasmania.

9. *Distochirus*, Peters.

Upper teeth much as in *Acrobata*, but $pm.^3$ reduced, shorter than molars, and crowded obliquely out of the molar series. Lower teeth also as in *Acrobata*, but $pm.^3$ is entirely suppressed.

Dental formula.— $i. \frac{1.2.3}{1.0.0} c. \frac{1}{1} pm. \frac{1.2.3}{1.2.0} m. \frac{1.2.3}{1.2.3} \times 2 = 34$.

Skull as in *Acrobata*.

No flying membrane; tail distichous; ears very short; claws well developed.

Habitat.—New Guinea only, whence a single species is known.

10. *Acrobata*, Desm.

Upper i^1 long. Canine proportionally more developed than in any other phalanger, pressed close against last incisor. Premolars all long, narrow, sharply pointed, and two-rooted. Lower $pm.^1$ minute, but always present; $pm.^2$ and $pm.^3$ functional, shaped like the upper ones.

Dental formula.— $i. \frac{1.2.3}{1.0.0} c. \frac{1}{1} pm. \frac{1.2.3}{1.2.3} m. \frac{1.2.3}{1.2.3} \times 2 = 36$.

Palate incomplete; bullæ low and small; palatal foramen nearly all in the maxillary; a well-marked external opening into the inferior dental canal; squamosals but little swollen by air-cells.

A flying membrane present, stretching from the elbow to the knee, but very narrow in its centre; tail distichous, probably slightly prehensile; toes subequal; claws small and far surpassed by the very remarkable toe-pads, which are broad and ribbed, resembling those of a gecko, and evidently have a very definite adhesive power.

Range.—South and eastern Australia.

There is only one species in this genus, the beautiful little Pigmy Flying-Phalanger, not so big as a mouse, which feeds on the honey it can abstract from flowers, and on insects. Its agility and powers of leaping are exceedingly great, and it is said by Mr Gould to make a most charming little pet. (O. T.)

PHALARIS, a Greek tyrant, who ruled Agrigentum (Acragas) in Sicily for sixteen years (probably between c. 571 and 549 B.C.). He was the son of Laodamas, and his family belonged to the Dorian island of Astypalæa, near Cnidus. As a leading man in the new city (for Agrigentum had been founded by the neighbouring city of Gela only a few years before, 582 B.C.) Phalaris was entrusted with the building of the temple of Zeus Atabyrius on the citadel, and he took advantage of his position to make himself master of the city. Under his rule Agrigentum seems to have attained a considerable pitch of external prosperity. He supplied the city with water, adorned it with fine buildings, and strengthened it with walls. His influence reached to the northern coast of the island, where the people of Himera elected him general, with absolute power, in spite of the warnings of the poet Stesichorus. Eastward on the coast he had fortified posts at Ecnomus and Phalarium, and he is said to have conquered Leontini; but that he ruled the whole of Sicily, as Suidas asserts, is unlikely. He was at last overthrown, apparently by a combination of the noble families, headed by the rich and distinguished Telemachus, and he was burned, along with his mother

FIG. 2.—Squirrel Flying-Phalanger (*Petaurus sciureus*)

attained by springing from the one it wishes to leave. The tops of the trees are traversed by this animal with as much ease as the most level ground is by such as are destined for terra firma. If

and friends, in the brazen bull. A decree was carried that no one should thereafter wear a blue dress, as blue had been the tyrant's livery.

After ages have held up Phalaris to infamy for his excessive cruelty. In his brazen bull, invented, it is said, by Perilaus of Athens, and presented by him to Phalaris, the tyrant's victims were shut up and, a fire being kindled beneath, were roasted alive, while their shrieks, conveyed through pipes in the beast's nostrils, represented the bellowing of the bull. Perilaus himself is said to have been the first victim. There is hardly room to doubt that we have here a tradition of human sacrifice in connexion with the worship of the Phœnician Baal, such as prevailed at Rhodes, where Zeus Atabyrius was no other than Baal; when misfortune threatened Rhodes the brazen bulls in his temple bellowed. The Rhodians brought this worship to Gela, which they founded conjointly with the Cretans, and from Gela it passed to Agrigentum. Human sacrifices to Baal were common, and, though in Phœnicia proper there is no proof that the victims were burned alive (see MOLOCH), the Carthaginians had a brazen image of Baal, from whose down-turned hands the children slid into a pit of fire; and the story that Minos had a brazen man who pressed people to his glowing breast points to similar rites in Crete, where the child-devouring Minotaur must certainly be connected with Baal and the favourite sacrifice to him of children. So, too, we have the fire-spitting bull of Marathon which burned Androgeus. The stories that Phalaris threw men into boiling cauldrons and vessels filled with fire, and that he devoured sucklings, all tell the same tale. From this point of view we may perhaps reconcile with history the apparently contradictory tradition which seems to have prevailed in later times, that Phalaris was a naturally humane man and a patron of philosophy and literature. This is the view of his character which we find in the declamations ascribed to Lucian, and in the letters which bear Phalaris's own name. Plutarch, too, though he takes the unfavourable view, mentions that the Sicilians gave to the severity of Phalaris the name of justice and a hatred of crime. It is recorded that he once pardoned two men who had conspired against him. Phalaris may thus have been one of those men, not unknown in history, who combine justice and even humanity with a religious fanaticism which shrinks from no horrors believed to be demanded by the cause of God.

The letters bearing the name of Phalaris (148 in number) are now chiefly remembered for the crushing exposure they received at the hands of Bentley in his controversy with the Hon. Charles Boyle, who had published an edition of them in 1695. The first edition of Bentley's *Dissertation on Phalaris* appeared in 1697, and the second edition, replying to the answer which Boyle published in 1698, came out in 1699. From the mention in the letters of towns (Phintia, Alæsa, and Tauromenium) which did not exist in the time of Phalaris, from the imitations of authors (Hærodotus, Democritus, Euripides, Callimachus) who wrote long after he was dead, from the reference to tragedies, though tragedy was not yet invented in the lifetime of Phalaris, from the dialect, which is not Dorian but Attic, nay, New or Late Attic, as well as from absurdities in the matter, and the entire absence of any reference to them by any writer before Stobæus (who lived apparently about 500 A.D.), Bentley sufficiently proved that the letters were written by a sophist or rhetorician hundreds of years after the death of Phalaris. Suidas admired the letters, which he thought genuine, and in modern times, before their exposure by Bentley, they were admired by some, e.g., by Sir William Temple, though others, as Politian and Erasmus, perceived that they were not by Phalaris.

There are editions of the epistles of Phalaris by Lennep and Valckenaer, Groningen, 1777 (re-edited, with corrections and additions, by Schæfer, Leipsic, 1823), and by E. Hercher, in *Epistolographi Græci*, Paris, 1873. The latest edition of Bentley's *Dissertation* is that with introduction and notes by W. Wagner, London, 1895.

PHARAOH (פַּרְעֹה; *Φαραώ*), which the Old Testament often uses as if it were a proper name, applicable to any king of Egypt, though sometimes such a distinguishing name as Hophra (Apries; Jer. xlv. 30) or Nechoh (Nekos) (2 Kings xxiii. 29) is added, is really an Egyptian title of the monarch (Perâa or Phuro), often found on the monuments. Apart from Hophra and Necho the Biblical Pharaohs cannot, in the present state of Hebrew and Egyptian chronology, be identified with any certainty.

PHARISEES (פְּרִישִׁים, *Φαρισαῖοι*), the Jewish party of the scribes, the opponents of the Sadducees. See ISRAEL, vol. xiii. p. 423 *sq.*, and MESSIAH.

PHARMACOPŒIA (lit. the art of the *φαρμακοποιός*, or drug-compounder) in its modern technical sense denotes a book containing directions for the identification of simples and the preparation of compound medicines, and

published by the authority of a Government or of a medical or pharmaceutical society. The name has also been applied to similar compendiums issued by private individuals. The first work of the kind published under Government authority appears to have been that of Nuremberg in 1542; a passing student named Valerius Cordus showed a collection of medical receipts, which he had selected from the writings of the most eminent medical authorities, to the physicians of the town, who urged him to print it for the benefit of the apothecaries, and obtained for his work the sanction of the senatus. An earlier work, known as the *Antidotarium Florentinum*, had been published, but only under the authority of the college of medicine of Florence. The term "pharmacopœia" first appears as a distinct title in a work published at Basel in 1561 by Dr A. Foes, but does not appear to have come into general use until the beginning of the 16th century. Before 1542 the works principally used by apothecaries were the treatises on simples by Avicenna and Serapion; the *De Synonymis* and *Quid pro Quo* of Simon Januensis; the *Liber Servitoris* of Bulchasim Ben Aberazerim, which described the preparations made from plants, animals, and minerals, and was the type of the chemical portion of modern pharmacopœias; and the *Antidotarium* of Nicolaus de Salerno, containing Galenic compounds arranged alphabetically. Of this last work there were two editions in use,—Nicolaus magnus and Nicolaus parvus; in the latter, several of the compounds described in the larger edition were omitted and the formulæ given on a smaller scale.

Until 1617 such drugs and medicines as were in common use were sold in England by the apothecaries and grocers. In that year the apothecaries obtained a separate charter, and it was enacted at the same time that no grocer should keep an apothecary's shop. The preparation of physicians' prescriptions was thus confined to the apothecaries, upon whom pressure was brought to bear, in order to make them dispense accurately, by the issue of a pharmacopœia in May 1618 by the College of Physicians, and by the power which the wardens of the apothecaries received in common with the censors of the College of Physicians of examining the shops of apothecaries within 7 miles of London and destroying all the compounds which they found unfaithfully prepared. This, which was the first authorized *London Pharmacopœia*, was selected chiefly from the works of Mezuë and Nicolaus de Salerno, with a few additions from those of other authors then in repute, but it was found to be so full of errors that the whole edition was cancelled, and a fresh one was published in the following December. At this period the compounds employed in medicine were often heterogeneous mixtures, some of which contained from 20 to 70, or more ingredients, while a large number of simples were used in consequence of the same substance being supposed to possess different qualities according to the source from which it was derived. Thus crabs' eyes, pearls, oyster-shells, and coral were supposed to have different properties. Among other disgusting ingredients entering into some of these formulæ were the excrements of human beings, dogs, mice, geese, and other animals, calculi, human skull and moss growing on it, blind puppies, earthworms, &c. Although other editions of the *London Pharmacopœia* were issued in 1621, 1632, 1639, and 1677, it was not until the edition of 1721, published under the auspices of Sir Hans Sloane, that any important alterations were made. In this issue many of the ridiculous remedies previously in use were omitted, although a good number were still retained, such as dog's excrement, earthworms, and moss from the human skull; the botanical names of herbal remedies were for the first time added to the official ones; the simple distilled waters were ordered,

of a uniform strength; sweetened spirits, cordials, and ratifas were omitted as well as several compounds no longer used in London, although still in vogue elsewhere. A great improvement was effected in the edition published in 1746, in which only those preparations were retained which had received the approval of the majority of the pharmacopœia committee; to these was added a list of those drugs only which were supposed to be the most efficacious. An attempt was made to simplify further the older formulæ by the rejection of the superfluous ingredients which had been introduced during a succession of ages, and by retention of the known active ingredients. In the edition published in 1788 the tendency to simplify was carried out to a much greater extent, and the extremely compound medicines which had formed the principal remedies of physicians for 2000 years were discarded, while a few powerful drugs which had been considered too dangerous to be included in the *Pharmacopœia* of 1765 were restored to their previous position. In 1809 the French chemical nomenclature was adopted, and in 1815 a corrected impression of the same was issued. Subsequent editions were published in 1824, 1836, and 1851.

The first *Edinburgh Pharmacopœia* was published in 1699 and the last in 1841; the first *Dublin Pharmacopœia* in 1807 and the last in 1850.

The preparations contained in these three pharmacopœias were not all uniform in strength, a source of much inconvenience and danger to the public, when powerful preparations such as dilute hydrocyanic acid were ordered in the one country and dispensed according to the national pharmacopœia in another. This inconvenience led to the insertion of a provision in the Medical Act of 1858, by which it was ordained that the General Medical Council should cause to be published under their direction a book containing a list of medicines and compounds, and such other matters and things relating thereto, as the General Council should think fit, to be called the *British Pharmacopœia*, which should for all purposes be deemed to be a substitute throughout Great Britain and Ireland for the several above-mentioned pharmacopœias. Hitherto these had been published in Latin. The first *British Pharmacopœia* was published in the English language in 1864, but gave such general dissatisfaction both to the medical profession and to chemists and druggists that the General Medical Council brought out a new and amended edition in 1867. This dissatisfaction was probably owing partly to the difficulty met with in selecting a due proportion of formulæ from each pharmacopœia so as to avoid giving offence to national susceptibilities, and partly to the fact that the majority of the compilers of the work were men not engaged in the actual practice of pharmacy, and therefore competent rather to decide upon the kind of preparations required than upon the method of their manufacture. The necessity for this element in the construction of a pharmacopœia is now fully recognized in other countries, in most of which pharmaceutical chemists are duly represented on the committee for the preparation of the legally recognized manuals.

National pharmacopœias now exist in the following countries:—Austria, Belgium, Denmark, France, Germany, Great Britain, Greece, Holland, Hungary, India, Mexico, Norway, Portugal, Russia, Spain, Sweden, and the United States of America. The Argentine Republic, Chili, and Japan have each a pharmacopœia in preparation. All the above-mentioned were issued under the authority of Government, and their instructions have the force of law in their respective countries, except those of the United States and Mexico, which were prepared by commissioners appointed by medical or pharmaceutical societies, and have no other authority, although generally accepted as the national text-books. Italy has no national pharmacopœia, the authorities used in the different states prior to the unification being still retained. Sardinia, for example, has a pharmacopœia dating from 1853; Modena, Parma, and Piacenza have one in common, published in 1839; in the States

of the Church as well as in Tuscany and Lucca an unofficial compilation is in use entitled *Orosi Farmacologia technica practica ovvero Farmacologia Italiana*: Naples has its *Ricettario Farmaceutico Napolitano* (1859); and Lombardy and Venice use the Austrian pharmacopœia. Although Switzerland has a national pharmacopœia, this does not possess Government authority, the French *Codex* being recognized in Geneva, and the canton of Ticino having a pharmacopœia of its own.

The French *Codex* has probably a more extended use than any other pharmacopœia outside the limits of its own country, being, in connexion with Dervault's *L'Officine*, the standard for druggists in a large portion of Central and South America; it is also official in Turkey. The sum-total of the drugs and preparations it contains is about 2000, or more than double the average of other modern pharmacopœias. The progress of medical knowledge during the last two hundred years has led to a gradual but very perceptible alteration in the contents of the various pharmacopœias. The original very complex formulæ have been gradually simplified until only the most active ingredients have been retained, and in many cases the active principles have to a large extent replaced the crude drugs from which they were derived. From time to time such secret remedies of druggists or physicians as have met with popular or professional approval have been represented by simpler official preparations.

International Pharmacopœia.—The increased facilities for travel during the last fifty years have brought into greater prominence the importance of an approach to uniformity in the formulæ of the more powerful remedies, such as the tinctures of aconite, opium, and nux vomica, in order to avoid danger to patients when a prescription is dispensed in a different country from that in which it was written. Attempts have been made during the last few years by international pharmaceutical and medical conferences to settle a basis on which an international pharmacopœia could be prepared, but, owing to national jealousies and the attempt to include too many preparations in such a work, it has not as yet been produced. At the fifth International Pharmaceutical Congress held in London in 1881, however, a resolution was passed to the effect that it was necessary that such a pharmacopœia should be prepared, and a commission consisting of two delegates from each of the countries represented was recommended to be appointed in order to prepare within the shortest possible time a compilation in which the strength of all potent drugs and their preparations should be equalized,—the work, when complete, to be handed over to their respective Governments or to their pharmacopœia committees. It appears probable that such a work will be presented for consideration by the commission at the forthcoming meeting of the congress at Brussels in 1885.

Several unofficial universal pharmacopœias have been published from time to time in England and in France, which serve to show the comparative strength of parallel preparations in different countries; but the results of discussions which have taken place at the international conferences above alluded to indicate that the production and acceptance of an international pharmacopœia will be a work of time, and that in such a work the numerous drugs and preparations intended to meet an unprofessional demand rather than the wants of physicians will have to be omitted. The advances that have been made in this direction are as follows. The metric or decimal mode of calculation and the centigrade scale of temperature are adopted in all pharmacopœias except those of Great Britain, of India, and in some instances of Greece. The majority omit chemical formulæ. An alphabetical arrangement is followed in all except the French, Spanish, and Greek. The great increase of medical literature and international exchange of medical journals has led to the adoption in almost every country of all the really valuable remedial agents, and the more extended use of active principles has given rise to an approximation in strength of their solutions. The difficulty of nomenclature could probably be overcome by a list of synonyms being given with each article, and that of language by the use of Latin. The greatest stumbling-blocks in the way of uniformity are the tinctures and extracts,—a class of preparations containing many very powerful drugs, but in which the same name does not always indicate the same thing; thus, extract of aconite signifies an extract of the root in the pharmacopœias of the United States, Austria, Hungary, and Russia, extract of the leaves in the Danish and Portuguese, inspissated juice of the fresh leaves in the British, Indian, Spanish, and Greek, and dry extract of the leaves with sugar of milk in the Norwegian pharmacopœias. It appears probable, however, that the growth of pharmaceutical chemistry will indicate clearly, in course of time, which of those in use form the most active and reliable preparations, while the general adoption of the metric system will lead to clearer approximation of strength than hitherto. The method adopted by the Portuguese pharmacopœia comes nearest to that uniformity which is so desirable in such preparations, as the tinctures of the fresh plants are all prepared with equal parts of the drug and alcoholic menstruum; simple tinctures in general, with unfortunately a few exceptions, with one part of the drug in five parts of alcohol of given

strength; ethereal tinctures are in the proportion of one part in ten; and the tinctures of the alkaloids and their salts contain one part of the alkaloid in ninety-nine of menstruum.

Homœopathic and eclectic practitioners as well as dentists have also their special pharmacopœias.

See Bell and Redwood, *Progress of Pharmacy* (London, 1880); Scherer, *Literatura Pharmacopœiarum* (Leipsic and Sorau, 1822); Flint, *Report on the Pharmacopœias of all Nations* (Washington, 1883); *Report of the Proceedings of the Fifth International Pharmaceutical Congress* (1881). (E. M. H.)

PHEASANT, Middle-English *Fesaunt* and *Fesaun*, German *Fasan* and anciently *Fasant*, French *Faisan*—all from the Latin *Phasianus* or *Phasiana* (sc. *avis*), the Bird brought from the banks of the river Phasis, now the Rioni, in Colchis, where it is still abundant, and introduced by the Argonauts, it is said, in what passes for history, into Europe. As a matter of fact nothing is known on this point; and, judging from the recognition of the remains of several species referred to the genus *Phasianus* both in Greece and in France,¹ it seems not impossible that the ordinary Pheasant, the *P. colchicus* of ornithologists, may have been indigenous to this quarter of the globe. If it was introduced into England, it must almost certainly have been brought hither by the Romans; for, setting aside several earlier records of doubtful authority,² Bishop Stubbs has shewn that by the regulations of King Harold in 1059 "*unus phasianus*" is prescribed as the alternative of two Partridges or other birds among the "*pitantiæ*" (rations or commons, as we might now say) of the canons of Waltham Abbey, and, as Prof. Dawkins has remarked (*Ibis*, 1869, p. 358), neither Anglo-Saxons nor Danes were likely to have introduced it into England. It seems to have been early under legal protection, for, according to Dugdale, a licence was granted in the reign of Henry I. to the abbot of Amesbury to kill hares and pheasants, and from the price at which the latter are reckoned, in various documents that have come down to us, we may conclude that they were not very abundant for some centuries, and also that they were occasionally artificially reared and fattened, as appears from Upton,³ who wrote about the middle of the 15th century, while Henry VIII. seems from his privy purse expenses to have had in his household in 1532 a French priest as a regular "*fesaunt breder*," and in the accounts of the Kytsons of Hengrave in Suffolk for 1607 mention is made of wheat to feed Pheasants, Partridges, and Quails.

Within recent years the practice of bringing up Pheasants by hand has been extensively followed, and the numbers so reared vastly exceed those that are bred at large. The eggs are collected from birds that are either running wild or kept in a mew,⁴ and are placed under domestic Hens; but, though these prove most attentive foster-mothers, much additional care on the part of their keepers is needed

¹ These are *P. archiaci* from Piskermi, *P. altus* and *P. medius* from the lacustrine beds of Sansan, and *P. desnoyersi* from Touraine, see A. Miloe-Edwards, *Ois. foss. de la France* (ii. pp. 229, 239-243).

² Among these perhaps that worthy of most attention is in Probert's translation of *The Ancient Laws of Cambria* (ed. 1823, pp. 367, 368), wherein extracts are given from Welsh triads, presumably of the age of Howel the Good, who died in 948. One of them is "There are three barking hunts: a bear, a squirrel, and a pheasant." The explanation is "A pheasant is called a barking hunt, because when the pointers come upon it, and chase it, it takes to a tree, where it is hunted by baying." The present writer has not been able to trace the manuscript containing these remarkable statements so as to find out what is the original word rendered "Pheasant" by the translator; but a reference to what is probably the same passage with the same meaning is given by Ray (*Synops. Meth. Animalium*, pp. 213, 214) on the authority of Llwyd or Lloyd, though there is no mention of it in Wotton and Clarke's *Leges Wallicæ* (1730). A charter (Kemble, *Cod. Diplom.*, iv. p. 236), professedly of Edward the Confessor, granting the wardenship of certain forests in Essex to Ralph Peperking, speaks of "*fesant ben*" and "*fesant cocke*," but is now known to be spurious.

³ In his *De studio militari* (not printed till 1654) he states (p. 195) that the Pheasant was brought from the East by "Palladius ancorista."

⁴ The writer is informed that, in 1883, 134,000 Pheasants' eggs were sold from one estate in Suffolk.

to ensure the arrival at maturity of the poults; for, being necessarily crowded in a comparatively small space, they are subject to several diseases which often carry off a large proportion, to say nothing of the risk they run by not being provided with proper food, or by meeting an early death from various predatory animals attracted by the assemblage of so many helpless victims. As they advance in age the young Pheasants readily take to a wild life, and indeed can only be kept from wandering in every direction by being plentifully supplied with food, which has to be scattered for them in the coverts in which it is desired that they should stay. Of the proportion of Pheasants artificially bred that "come to the gun" when the shooting season arrives it is impossible to form any estimate, for it would seem to vary enormously, not only irregularly according to the weather, but regularly according to the district. In the eastern counties of England, and some other favourable localities, perhaps three-fourths of those that are hatched may be satisfactorily accounted for; but in many of the western counties, though they are the objects of equally unremitting or even greater care, it would seem that more than half of the number that live to grow their feathers disappear inexplicably before the coverts are beaten. The various effects of the modern system of Pheasant-breeding and Pheasant-shooting need here be treated but briefly. It is commonly condemned as giving encouragement to poaching, and, especially under ignorant management, as substituting slaughter for sport. Undoubtedly there is much to be said on this score; but in reply to the first objection it has been urged that as a rule the poacher does not like visiting coverts that he knows to be effectively preserved, and that coverts containing a great stock of Pheasants, whose rearing has cost a considerable sum of money, are probably the most effectively preserved. As to the second objection it is to be observed that what constitutes sport is in great measure a matter of individual taste, and that the reasonable limit of a sportsman's "bag" is practically an unknown quantity. One man likes shooting a Pheasant rising at his feet or sprung by his spaniels, as it flies away from him through the trees and is still labouring to attain its full speed; another prefers shooting one that has mounted to its greatest height, and, assisted perhaps by the wind, is traversing the sky at a pace that almost passes calculation. If skill has to be considered in the definition of sport there can be no doubt as to which of these cases most requires it. In regard to cruelty—that is, the proportion of birds wounded to those killed—there seems to be little difference, for the temptation to take "long shots" is about equal in either case. The Pheasant whose wing is broken by the charge, if at a great height, is often killed outright by the fall, whereas, if nearer the ground, it will often make good its escape by running, possibly to recover, or more possibly to die after lingering in pain for a longer or shorter time. On the other hand, high-flying Pheasants, having their vital parts more exposed, are often hit in the body, but not hard enough to bring them down, though the wound they have received proves mortal, and the velocity at which they are travelling takes them beyond reach of retrieval.

Formerly Pheasants were taken in snares or nets, and by hawking; but the crossbow was also used, and the better to obtain a "sitting shot," for with that weapon men had not learnt to "shoot flying"; dogs appear to have been employed in the way indicated by the lines under an engraving by Hollar, who died in 1677:—

"The Fesant Cocke the woods doth most frequent,
Where Spaniells spring and perche him by the sent."⁵

⁵ Quoted by the writer (Broderip?) of the article "Spaniel" in the *Penny Cyclopædia*. The lines throw light on the asserted Welsh practice mentioned in a former note.

The use of firearms has put an end to the older practices, and the gun is now the only mode of taking Pheasants recognized as legitimate.

Of the many other species of the genus *Phasianus*, two only can be dwelt upon here. These are the Ring-necked Pheasant of China, *P. torquatus*, easily known by the broad white collar, whence it has its name, as well as by the pale greyish-blue of its upper wing-coverts and the light buff of its flanks, and the *P. versicolor* of Japan, often called the Green Pheasant from the beautiful tinge of that colour that in certain lights pervades almost the whole of its plumage, and, deepening into dark emerald, occupies all the breast and lower surface that in the common and Chinese birds is bay barred with glossy black scallops. Both of these species have been to a considerable extent introduced into England, and cross freely with *P. colchicus*, while the hybrids of each with the older inhabitants of the woods are not only perfectly fertile *inter se*; but cross as freely with the other hybrids, so that birds are frequently found in which the blood of the three species is mingled. The hybrids of the first cross are generally larger than either of their parents, but the superiority of size does not seem to be maintained by their descendants. White and pied varieties of the common Pheasant, as of most birds, often occur, and with a little care a race or breed of each can be perpetuated. A much rarer variety is sometimes seen; this is known as the Bohemian Pheasant, not that there is the least reason to suppose it has any right to such an epithet, for it appears, as it were, accidentally among a stock of the pure *P. colchicus*, and offers an example analogous to that of the jappanned Peafowl already noticed (PEACOCK, *supra*, p. 443), being, like that breed, capable of perpetuation by selection. To a small extent two other species of Pheasant have been introduced to the coverts of England—*P. reevesi* from China, remarkable for its very long tail, white with black bars,¹ and the Copper Pheasant, *P. semmerringi*, from Japan. The well-known Gold and Silver Pheasants, *P. pictus* and *P. nycthemerus*, each the type of a distinct section or subgenus, are both from China and have long been introduced into Europe, but are only fitted for the aviary. To the former is allied the still more beautiful *P. amherstiae* and to the latter about a dozen more species, most of them known to Indian sportsmen by the general name of "Kaleege." The comparatively plain Pucras Pheasants, *Pucrasia*, the magnificent Monauls, *Lophophorus*, and the fine Snow-Pheasants, *Crossoptilum*—of each of which genera there are several species—must, for want of space, be only mentioned here. All the species known at the time are beautifully figured from drawings by Mr Wolf in Mr Elliot's grand *Monograph of the Phasianidae* (2 vols., fol., 1870-72)—the last term being used in a somewhat general sense. With a more precise scope Mr Tegetmeier's *Pheasants: their Natural History and Practical Management* (4to, ed. 2, 1881) is to be commended as a very useful work. (A. N.)

PHENOL. See CARBOLIC ACID, vol. v. p. 85.

PHERECRATES, one of the chief poets of the Old Attic Comedy, was a contemporary of Cratinus, Crates, and Aristophanes, being older than the last and younger than the two former. At first an actor, he seems to have gained a prize for a play in 438 B.C. The only other ascertained date in his life is 420, when he produced his play *The Wild Men*. Like Crates, whom he imitated, he abandoned personal satire for more general themes. Still in some of the fragments of his plays we find him attacking Alcibiades and others. He was especially famed for his inventive imagination, and the elegance and purity

of his diction are attested by the epithet ἀττικώτατος ("most Attic") applied to him by Athenæus and the sophist Phrynichus. However, Meineke has shown from his remains that his language deviated considerably from the standard observed by the other comic poets of the day. There is genuine feeling in his address to old age (preserved by Stobæus, *Flor.*, 116, 12). He was the inventor of a new metre, which was called, after him, Pherecratean,² and frequently occurs in the choruses of Greek tragedies and in Horace.

Pherecrates is variously stated by ancient authorities to have composed eighteen and sixteen plays; Meineke reduces the list of his undoubted plays to thirteen. None of them are extant, but a considerable number of fragments have been preserved. These are given in Meineke, *Fragmenta Comicorum Græcorum*, vol. ii. (1839), and in Bothe, *Frag. Com. Gr.* (Paris, 1855).

PHERECYDES OF SYROS, one of the earliest Greek philosophers, was the son of Babys and a native of the island of Syros. The dates of his life are variously stated, but there seems to be no doubt that he lived in the 6th century B.C.; amongst his contemporaries were Thales and Anaximander. He was sometimes reckoned one of the Seven Wise Men, and a very uniform tradition represented him as the teacher of Pythagoras. Many wonderful tales were told of him, e.g., that from drinking water drawn from a well he was able to predict an earthquake three days before it took place. The accounts of his death are very discrepant, but the commonest was that he died of the *morbis pediculosus*. But, if the minute description which Hippocrates gives of the death of Pherecydes refers to the philosopher, he would seem to have died of a virulent fever, perhaps spotted typhus. He is said to have been the first Greek author who wrote in prose, but perhaps the chronicler Cadmus of Miletus preceded him. The statements of late writers, that he drew his philosophy from secret writings of the Phœnicians, and that he was a disciple of the Egyptians and Chaldeans, deserve little attention, made as they were at a time when it was the fashion to regard all wisdom as derived from the East. He was credited with having originated the doctrine of metempsychosis, while Cicero and Augustine even assert that he was the first to teach the immortality of the soul. Of his astronomical studies he left a proof in the "heliotropion," a cave at Syros which served to determine the annual turning-point of the sun, like the grotto of Posillipo at Naples.

In his book, to which Suidas gives the name of ἐπιδύμους ἢ τοῦ θεοπατρὸς ἢ θεογονία, he enunciated a system in which philosophy and mythology were blended. In the beginning, according to Pherecydes, were Zeus, Chronos (Time) or Cronus, and Chthon (Earth); Chronos begat Fire, Wind, and Water, and these three begat numerous other gods.

Another PHERECYDES of Athens, an early Greek historian, was a native of the island of Leros, and lived in the former half of the 5th century B.C. Amongst his contemporaries were Hellanicus and Herodotus. Of his works "On Leros," "On Iphigenia," "On the festivals of Dionysus" nothing remains; but numerous fragments of his great work on mythology, in ten books, have been preserved, and are collected by C. Müller in his *Fr. Hist. Gr.*, vol. i.

PHIDIAS (Φειδίας), the most famous of Greek sculptors, was born about 500 B.C., and began his artistic career, probably under the guidance of his father, Charmides of Athens, with the study of painting, an art which at that time had attained a singular largeness and dignity of style, while in sculpture these qualities were as yet being sought for with only a somewhat bold and rude result, as may be seen from the remains of it now at Olympia. To do justice to the art of sculpture in this direction there was need of a far greater mastery of technical methods, and we may suppose it to have been with this end in view that Phidias, when he had determined to

¹ The introduction of this species by Lord Tweedmouth near Guisachan in Inverness-shire is said to have been remarkably successful.

² — — | — — — — —, or, as it may be otherwise divided, — — | — — — — —.

devote himself to sculpture, became a pupil of Ageladas of Argos. It is tempting to believe that it was still under the influence of this master that he executed (between 469 and 463) the Athenian monument at Delphi commemorating the battle of Marathon; for Ageladas had sculptured at Delphi also a monumental group serving a similar purpose. In the group of Phidias was a portrait statue of Miltiades, and from this circumstance it is rightly inferred that the work had been commissioned at the time when Cimon, the son of Miltiades, was at the head of affairs in Athens. It was apparently at this same period that Phidias was employed to execute for the acropolis of Athens a statue of Athena. This statue, known in after times as "the Lemnian" and also as "the beauty," seems to have represented the goddess in the attitude of standing at rest, helmet in hand, as in a terra-cotta statuette from Cyprus in the British Museum.¹ When Pericles succeeded to the administration of affairs, and it was determined to erect new temples and other public buildings worthy of the new glory which Athens had acquired in the Persian wars, it was to Phidias that the supervision of all these works was entrusted, with an army of artists and skilled workmen under him. By 438 the Parthenon was completed, with its colossal statue of Athena in gold and ivory by Phidias himself, and with its vast extent of sculpture in marble, executed at least under his direction and reflecting in most parts his genius.² Meantime the enormous expense of these undertakings had involved Phidias in the public discontent which was growing up round Pericles (Aristoph., *Peace*, 605). The story related by Plutarch (*Pericles*, 31) is that Menon, a former assistant of Phidias, had brought a charge against him of having appropriated part of the gold and ivory allowed him for the statue of Athena, and that, being acquitted on this charge, he was next denounced for introducing portraits of himself and of Pericles on the shield of Athena, and in consequence of this charge died in prison, either a natural death or by poison. But these statements cannot be reconciled with the tradition that, after completing his Athena, he was invited to undertake at Olympia what proved to be the grandest work of his life, the colossal gold and ivory statue of Zeus in the newly-erected temple. According to this same tradition he died at Olympia, and it may be inferred that he died much honoured there from the fact that his workshop was preserved in after times as a show-place for visitors, and that his descendants obtained an hereditary right to look after the great statue of Zeus. As a means of reconciling these conflicting statements it has been supposed that the charge of appropriating the gold, had been made before he went to Olympia, and the charge of sacrilege when he had returned thence to Athens. Others again prefer to accept the story of Plutarch as it stands, and to assign the stay of Phidias in Olympia to an early period of his life—previous to 455. As to the charge of theft, it could never have reached a public trial, because every one acquainted with the management of the public treasures knew that the gold of the Athena was so sculptured that it could be removed annually and weighed by the officials of the treasuries. Pericles told the Athenians (Thuc., ii. 13) that it could be removed and utilized for the war. The other charge of having placed portraits of himself as a bald-headed old man (438) and of Pericles on the shield of Athena is incredible. Pericles with the helmet which he always wore was almost an ideal Greek in appearance. Among the Greeks fighting with the

Amazons on the shield of Athena it was probably easy to find a figure not unlike him. The same may be said of the bald-headed old man who was identified with Phidias. But there is a wide difference between idle gossip and a criminal charge. It is true that there is in the British Museum a marble fragment of what professes to be a copy of the shield, and on it there are portraits of Phidias and of Pericles; but these portraits answer so minutely to the description of Plutarch that there can hardly be a doubt of their having been produced subsequently to illustrate some current story on which that description was founded. The workmanship is several centuries later than Phidias, and it would be strange if the portraits for which he had paid with his life had been left for so long a time on the shield, or had even been allowed at any moment to be perpetuated in a copy. In answer to this objection it was fabled that the portraits had been so fixed on the shield that they could not be removed without bringing down the whole work!

To obtain something like a fair judgment of the style of Phidias it is to the sculptures of the Parthenon now in the British Museum that we must turn (see *ARCHÆOLOGY*, vol. ii. p. 356). Though executed in what was to him an inferior material, marble, it yet happened that the elevated position which these sculptures were to occupy on the temple was such as to give scope for the highest powers of composition, and so far they may be regarded as a worthy monument of his genius. Alike in the frieze, the metopes, and the remaining figures of the pediments we have the same perfect rendering of the true effects of light and shade, which above all reveals the artist who can compose his figures and his groups so as to make the spectator feel that nature would not have done otherwise had nature been a sculptor. For composition of this kind there was necessary a most complete knowledge of form in all its details, since no part was so minute as not to affect the aspect of the whole. In this respect Phidias was famed in antiquity, and the Parthenon sculptures justify that fame. He must, however, have found finer opportunities in the colossal statues of gold and ivory, where the greater difficulty of duly distributing light and shade was rewarded with greater splendour of effect. In these statues the nude parts, such as the face, hands, and feet, were of ivory, the drapery of gold; and in the statue of Zeus at Olympia the gold was enriched with enamelled colours, and the impression of the whole is described by ancient writers with unbounded praise (see vol. ii. p. 355, and A. S. Murray, *Gr. Sculpt.*, ii. p. 123). Of the Athena in the Parthenon there exist two small copies in marble found in Athens, but so rude in execution as to be of no service in conveying a notion of the style of the original. On the acropolis, and not far from the Parthenon, stood a colossal bronze statue of Athena Promachos by Phidias, the attitude and to some extent the type of which may be gathered from the small bronze found at Athens, and figured in vol. ii. p. 355. In Elis he executed a statue of Aphrodite in gold and ivory, and at Plataea a colossal Athena of wood gilt, with the face, hands, and feet of Pentelic marble. Bright but simple colours had been traditional in art before the time of Phidias. It is not supposed that he had sought to refine upon them as a colorist. What he did was to combine with their simplicity and brightness the ideal largeness and dignity of conception which he shared with the great painters of his day, and the perfection of execution which he shared with the greatest of contemporary sculptors. (A. S. M.)

¹ See A. S. Murray, *Greek Sculpt.*, ii. pl. 17; compare the Greek inscription from the base of a statue of Athena in Cyprus, which says that she was made after the Phidian model, and had laid aside her arms, Hirschfeld, *Tituli statuar.*, No. 178, or *C. I. Gr.*, No. 2073.

² See A. S. Murray, *op. cit.*, ii. p. 98 sq.

lium and Mount Elæum: the identification of the latter is uncertain.

In 659 B.C. Phigalia was taken by the Lacedæmonians, but soon after recovered its independence; it was on the whole unfortunate during the Peloponnesian War; and, in common with the other cities of Arcadia, it appears from Strabo to have fallen into utter decay under the Roman rule. The notices of it in Greek history are rare and scanty. Though its existing ruins of city-wall and forts and the description of Pausanias show it to have been a place of considerable strength and importance, yet no autonomous coins of Phigalia are known. Nothing now remains above ground of the temples of Artemis or Dionysus and the numerous statues and other works of art which still existed at the time of Pausanias's visit, about 170 A.D. A great part of the city-wall, built in fine Hellenic "isodomous" masonry, and a large square central fortress with a circular projecting tower, are the only remains now traceable,—at least without the aid of excavation. The walls, once nearly 2 miles in circuit, are strongly placed on rocks, which slope down to the little river Neda.

One very important monument of the wealth and artistic taste of the Phigalians still exists in a fairly perfect state; this is a temple dedicated to Apollo Epicurius (the Preserver), built, not at Phigalia itself, but at the village of Bassæ, 5 or 6 miles away, on one of the peaks of Mount Cotylium; it commemorates the aid rendered by Apollo in stopping the progress of a plague which in the 5th century B.C. was devastating Phigalia. This temple is mentioned by Pausanias (viii. 41) as being (next to that at Tegea) the finest in the Peloponnesus, "from the beauty of its stone and the symmetry of its proportions." It has also a special interest in having been designed by Ictinus, who, with Callicrates, was joint architect of the Parthenon at Athens. Though visited by Chandler, Dodwell, Gell, and other English travellers, the temple was neither explored nor measured till 1811-12, when Chas. Rob. Cockerell and some other archaeologists spent several months in making excavations there. After nearly fifty years' delay, Professor Cockerell published the results of these labours, as well as of his previous work at Ægina, in *Temples of Ægina and Bassæ* (1860), one of the most careful and beautifully illustrated archaeological works that has ever been produced. The labours of Professor Cockerell and his companions were richly rewarded; not only were sufficient remains of the architectural features discovered to show clearly what the whole design had been, but the internal sculptured frieze of the cella was found almost perfect. This and other fragments of its sculpture are now in the British Museum.

Fig. 1 shows the plan of the temple, which is of the Doric order, but has an internal arrangement of its cella quite unlike that of any other known temple. It stands on an elevated and partly artificial plateau, which commands a most glorious and extensive view of the oak-clad mountains of Arcadia, reaching away to the blue waters of the Messenian Gulf. Unlike other Doric temples, which usually stand east and west, this is placed north and south; but it has a side entrance on the east. It is hexastyle, with fifteen columns on its flanks; thirty-four out of the thirty-eight columns of the peristyle are still standing, with the greater part of their architrave, but the rest of the entablature and both pediments have fallen, together with the greater part of the internal columns of the cella. It will be seen from the plan that these are very strangely placed, apparently without symmetry, as regards the interior, though they are set, for what reason it is hard to say, regularly opposite the voids in the peristyle.

With the exception of one at the south end, which is Corinthian, the internal columns are of the Ionic order, and are built, not free, but engaged with the cella-wall, forming a series of recesses, which may have been designed to contain statues. Another peculiarity of this interior is that these columns reach to the top of the cella in one order, not in two ranges of columns, one over the other, as was the usual Doric fashion. These inner columns carried an Ionic entablature, of which the frieze now in the British Museum formed

a part. The pediments and external metopes of the peristyle appear to have contained no sculpture, but the metopes within the peri-

style had sculptured subjects; only a few fragments of these were, however, discovered. The position occupied by the great statue of Apollo is a difficult problem. Cockerell, with much probability, places it in the vestibule of the cella, opposite the eastern side door, so that it would be lighted up by the rays of the rising sun. The main entrance is at the northern end through the pronaos, once defended by a door in the end of the cella and a metal screen, of which traces were found on the two columns of the pronaos. There was no door between the posticum and the cella. The general proportions of the fronts resemble those of the Thesæum at Athens, except that the entablature is less massive, the columns thicker, and the diminution less,—all proportionally speaking. In plan the temple is long in proportion to its width,—measuring, on the top of the stylobate, 125 feet 7 inches by 48 feet 2 inches, while the Thesæum (built probably half a century earlier) is about 104 feet 2 inches by 45 feet 2 inches.

The material of which the temple is built is a fine grey limestone (once covered with painted stucco), except the roof-tiles, the capitals of the cella columns, the architraves, the *lacunaria* (ceilings) of the posticum and pronaos, and the sculpture, all of which are of white marble. The roof-tiles, specially noticed by Pausanias, are remarkable for their size, workmanship, and the beauty of the Parian marble of which they are made. They measure 2 feet 1 inch by 3 feet 6 inches, and are fitted together in the most careful and ingenious manner. Unlike those of the Parthenon and the temple of Ægina, the *ἀγυρὶ* or "joint-tiles" are worked out of the same piece of marble as the flat ones, at a great additional cost of labour and material, for the sake of more perfect fitting and greater security against wet.

Traces of painting on various architectural members were found by Professor Cockerell, but they were too much faded for the colours

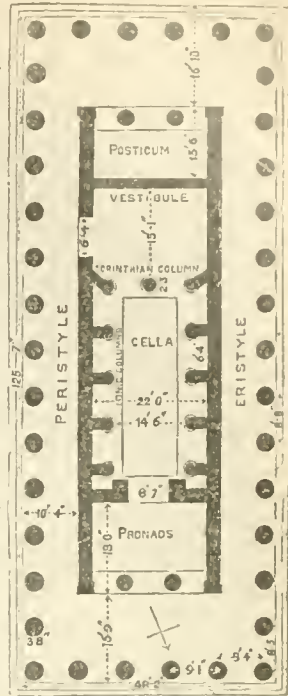

FIG. 1.—Plan of the Temple at Bassæ.

FIG. 2.—One slab of the Bassæ frieze; combat of Greeks and Amazons.

to be distinguished. The designs are the usual somewhat stiff and monotonous Greek patterns,—the fret, the honeysuckle, and the egg and dart.

The sculpture is of the greatest interest, as being an important example of the school of Phidias, designed to decorate one of the finest buildings in the Peloponnesus in the latter half of the 5th century B.C.; see *Phigalican Marbles*, Brit. Mus. Publications.

The frieze, now in the British Museum, is quite complete; it is nearly 101 feet long by 2 feet high, carved in relief on twenty-three slabs of marble $\frac{1}{2}$ to 5 inches thick (see fig. 2). The subjects are the battle of the Lapithæ and the Centaurs, and that between the Amazons and the Greeks, the two favourite subjects in Greek plastic art of the best period. They are designed with wonderful fertility of invention, and life-like realism and spirit; the composition is arranged so as to form a series of diagonal lines or *zigzags* (W), thus forming a pleasing contrast to the unbroken horizontal lines

of the cornice and architrave. The various groups are skilfully united together by some dominant line or action, so that the whole subject forms one unbroken composition.

The relief is very high, more than $3\frac{1}{2}$ inches in the most salient parts, and the whole treatment is quite opposite to that of the Parthenon frieze, which is a very superior work of art to that at Bassæ. Many of the limbs are quite detached from the ground; the drill has been largely used to emphasize certain shadows, and in many places, for want of due calculation, the sculptor has had to cut into the flat background behind the figures. From this it would appear that no finished clay-model was prepared, but that the relief was sculptured with only the help of a drawing. The point of sight, more than 20 feet below the bottom of the frieze, and the direction in which the light fell on it have evidently been carefully considered. Many parts, invisible from below, are left comparatively rough. The workmanship throughout is unequal, and the hands of several sculptors can be detected. On the whole, it must be admitted that the execution is not equal to the beauty of the design, and the whole frieze is somewhat marred by an evident desire to produce the maximum of effect with the least possible amount of labour,—very different from the almost gem-like finish of the Parthenon frieze. Even the design is inferior to the Athenian one; most of the figures are ungracefully short in their proportions, and there is a great want of refined beauty in many of the female hands and faces. It is in the fire of its varied action and its subtlety of expression that this sculpture most excels. The noble movements of the heroic Greeks form a striking contrast to the feminine weakness of the wounded Amazons, or the struggles with teeth and boofs of the brutish Centaurs; the group of Apollo and Artemis in their chariot is full of grace and dignified power. The marble in which this frieze is sculptured is somewhat coarse and crystalline; the slabs appear not to have been built into their place but fixed afterwards, with the aid of two bronze bolts driven through the face of each.

Of the metopes, which were 2 feet 8 inches square, only one exists nearly complete, with eleven fragments; the one almost perfect has a relief of a nude warrior, with floating drapery, overcoming a long-haired bearded man, who sinks vanquished at his feet. The relief of these is rather less than that of the frieze figures, and the work is nobler in character and superior in execution. The other pieces are too fragmentary to show what were their subjects.

No modern Greek village exists now on the site either of Bassæ or of Phigalia.

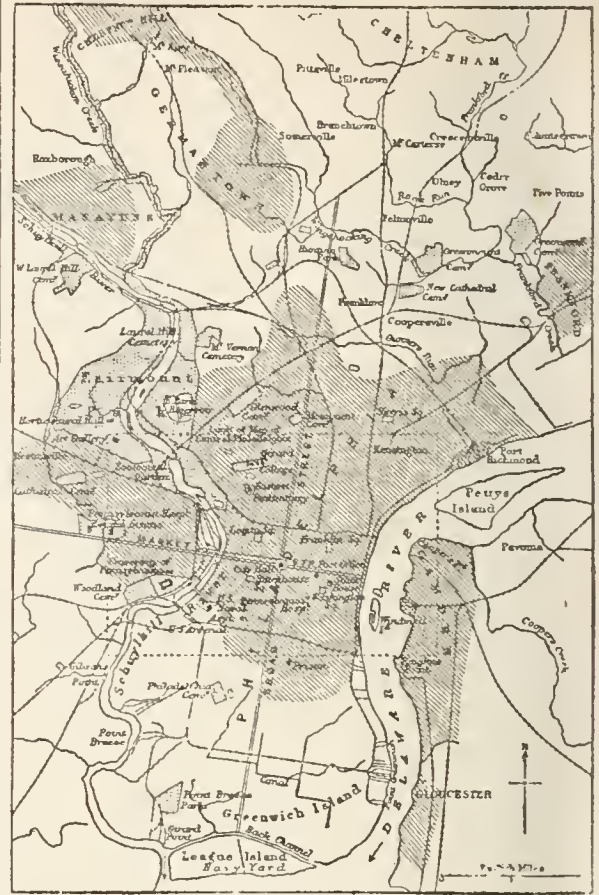

In addition to the works mentioned in the text the following may be consulted:—Leake, *Morea* (vol. i. p. 490, and ii. p. 319); Curtius, *Peloponnesos* (i. 319); Ross, *Reisen in Peloponnesos*; Stackelberg, *Der Apollo-Tempel zu Bassæ* (1826); Lenormant, *Bas-reliefs du Parthenon et de Phigalie* (1834); and Friederichs, *Geschichte der griechischen Plastik* (1868). (J. H. M.)

PHILADELPHIA, the name of several cities of antiquity, of which the two most important have been noticed under **ALA-SHEHR**, vol. i. p. 443, and **AMMONITES**, vol. i. p. 743.

PHILADELPHIA, the chief city of Pennsylvania, and the second city in the United States of America, is situated ($39^{\circ} 57' 7.5''$ N. lat., $75^{\circ} 9' 23.4''$ W. long.) on the west bank of the Delaware river, 96 miles from the Atlantic and in a direct line 125 miles north-east of Washington, D.C., and 85 miles south-west of the city of New York. Its greatest length north-north-east is 22 miles, its breadth from 5 to 10 miles, and its area 82,603 acres, or about 129 square miles (greater than that of any other city in America). The surface of the city between the rivers Delaware and Schuylkill—the latter running parallel with the Delaware and dividing the city about in half, east and west—is remarkably level. It varies, however, in elevation from $24\frac{1}{2}$ feet above the sea to 440 feet, the latter in the northern and suburban sections. The eastern and western sections of the city are connected by eight bridges. The length of river-front on the Delaware is nearly 20 miles, and the length of wharves 5 miles. On both sides of the Schuylkill, to Fairmount dam, the front is 16 miles and the length of wharves 4 miles. The mean low-water mark of the Delaware is 24 feet, and the tide rises 6 feet, while the average depth of water at the city wharves is 50 feet. The wharf-line, which varies from 14 feet to 68 feet, gives extraordinary accommodation for shipping. The Delaware is navigable at all seasons of the year for vessels of the heaviest burden, and Philadelphia affords one of the best protected harbours in the country. The

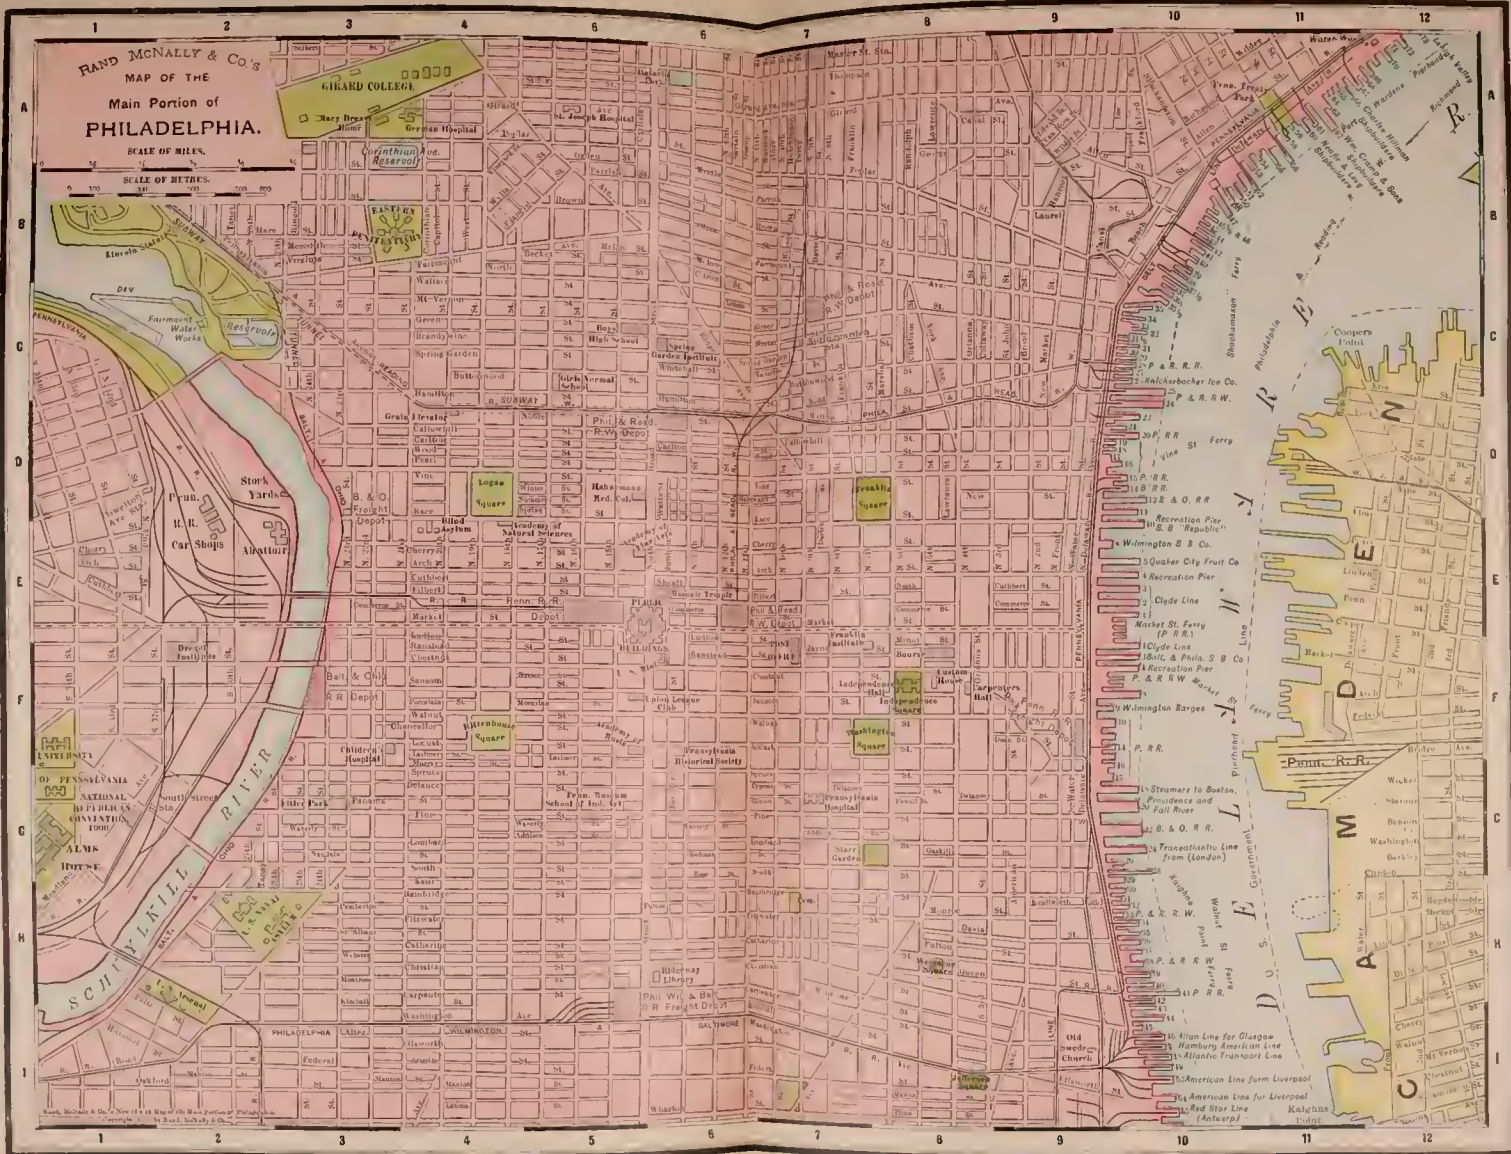

substratum of the city is a clay soil mixed with more or less sand and gravel.

The site of the present Philadelphia was originally settled by the Swedes, and so Penn found it when he came to lay

General Plan of Philadelphia.

out the city; and many of the original patentees for town lots under him were descendants of these first settlers. The original city limits were from east to west 10,922 feet 5 inches, and from north to south 5370 feet 8 inches, or more than 2 square miles. The boundaries were Vine street on the N., Cedar (now South) street on the S., the Delaware river on the E., and the Schuylkill river on the W. And this was the city of Philadelphia from its foundation until the 2d day of February 1854, when what is known as the Consolidation Act was passed by the legislature of the State, and the old limits of the city proper were extended to take in all the territory embraced within the then county of Philadelphia. This legislation abolished the districts of Southwark, Northern Liberties, Kensington, Spring Garden, Moyamensing, Penn, Richmond, West Philadelphia, and Belmont; the boroughs of Frankford, Germantown, Manayunk, White-Hall, Bridesburg, and Aramingo; and the townships of Passyunk, Blockley, Kingsessing, Roxborough, Germantown, Bristol, Oxford, Lower Dublin, Moreland, Byberry, Delaware, and Penn; and it transferred all their franchises and property to the consolidated city of Philadelphia under one municipal government. The present boundaries of the city are: on the E. the Delaware, on the N.E. Bucks county, on the N.N.W. and W. Montgomery county, and on the W. and S. Delaware county and the Delaware. The greater part is laid out in parallelograms, with streets at right angles to each other. Each main parallelogram contains about 4 acres, or is 400 feet on each

of its sides, divided by one or more small thoroughfares. Upon the city plans there are plotted 191,928 separate town lots. The main streets running north and south are numbered from First or Front to Sixty-third streets, and those running east and west were formerly named after the trees and shrubs found in the province. Thus, while the principal street in the city is named Market street, other main streets are named Chestnut, Walnut, Spruce, Pine, &c.¹ The main streets of Philadelphia are 50 feet wide, with some few exceptions: Broad or Fourteenth street is 113 feet wide, and Market street is 100 feet wide. The streets are generally paved with rubble stone, although square or Belgian blocks of granite are being extensively introduced. There are laid down on the city plans upwards of 2000 miles of streets, but at present (1884) only 1060½ miles are opened, of which 573.54 miles are paved and 44.28 macadamized. The pavements are chiefly of brick, but some of the more prominent streets have flagstone sidewalks. Market street and Chestnut street, below Eighth street, and Front street are the localities where the main wholesale business of the city is conducted. Most of the retail stores are situated in the upper part of Chestnut street and Eighth street. The principal banking institutions are in Chestnut street, between Second and Fifth streets, and in Third street between Walnut and Chestnut streets. Walnut street in the southern section of the city, and Spring Garden and Broad streets in the northern section of the city, are the chief streets for large and luxurious private residences. There is not a street of any consequence which has not a tramway along it; and the tramway system has done a great deal to increase building, until now Philadelphia is emphatically "the city of homes." There are upwards of 160,000 dwelling-houses, of which at least 110,000 are owned by the occupants. According to the returns for the census of 1880, there were 146,412 dwelling-houses in the city, which, taking the population as given by that census, 847,170, gave 5.79 persons to each house, while the number of dwellings in New York to the population gave 16.37 to each house. On the original plan of the city five squares, equidistant, were reserved for public parks. One of these, called Centre square, situated at the intersection of Broad and Market streets, has been taken for the erection of the city-hall, and the remaining four, situated at Sixth and Walnut, Sixth and Race, Eighteenth and Walnut, and Eighteenth and Race, and named respectively Washington, Franklin, Rittenhouse, and Logan, have a combined area of 29.06 acres. There are six other public squares in the city, with a total area of 18.90 acres. In addition to these public squares, Fairmount Park, with an area of 2791½ acres, including 373 acres of the water-surface of the Schuylkill river, is the most extensive public park in the United States. It lies in the north-western section of the city, and the Schuylkill river and Wissahickon creek wind through the greater portion of it.² In the park Horticultural Hall and Memorial Hall remain

¹ The geometrical laying out of the city into parallelograms made easy the adoption of the decimal system of numbering for the houses, which is readily understood and greatly helps strangers and citizens in finding their way about the streets. The houses in streets running east and west are numbered by hundreds, beginning at the Delaware and going west. Thus, from Delaware river to Front street the houses are numbered from 1 to 100; from Front street to Second street from 100 to 200; above Second street 200; above Third street 300; and so on. The even numbers are placed on the south side of the street and the odd numbers on the north side of the street. Market street is taken as a dividing line between north and south, and all the main streets stretching north and south, which lie north of Market street, are in the same way numbered running northerly, and those which lie south of Market street are numbered running southerly. The west side is given the even numbers and the east side the odd numbers.

² There are 34.27 miles of footwalk, 30.46 miles of carriage-drives, and 7.82 miles of bridle-paths within the boundaries of the park.

as mementoes of the Centennial Exhibition held there in 1876. The garden of the Zoological Society, covering 33 acres, on the outskirts of the park, was opened 1st July 1874, as the pioneer of such enterprises in the United States.³ Until within the last score of years the buildings in Philadelphia bore a singular resemblance to each other, especially the dwelling-houses. The predominant material for building was, and is, red brick, the soil affording the finest clay for brick found in the United States. The desire for uniformity in buildings, both in style and material, has happily undergone a change in recent years, although the danger now is of running to the other extreme, and thus giving the streets a decidedly bizarre appearance. There are 238¾ miles of sewers in Philadelphia, but the drainage of the city is wholly inadequate. The streets are lighted by 12,805 gas-lamps, and Chestnut street by the electric light. There are 748 miles of gas main, and the average daily consumption is 10,624,000 cubic feet.

Buildings.—The old brick Swedes Church in Swanson street in the extreme south-eastern section, dedicated on the first Sunday after Trinity 1700, is the oldest building of character now standing in the city. When it was completed it was looked upon as a great masterpiece, and nothing was then equal to it in the town. The four other colonial buildings of importance still standing are Christ (Protestant Episcopal) Church, the old State House (Independence Hall), the Pennsylvania Hospital, and Carpenter's Hall, all of them built of red brick with black glazed headers. Dr. John Kearsley, a physician, was the architect of the first-mentioned, and Andrew Hamilton, a lawyer, the architect of the second. Christ Church stands on the west side of Second street between Market and Arch streets, and its erection was begun in 1727, but it was not finished, as it now appears with tower and spire, until 1754. It was built on the site of a still older Christ Church, which was also of brick, erected in 1695. Queen Anne in 1708 presented a set of communion plate to the church, which is now used on great occasions. During his presidency Washington worshipped at this church, and his pew is still preserved, as is also that of Franklin. In 1882 the interior of the church was restored to its ancient character at an expense of about \$10,000. The nave is 75 feet long by 61 feet in width and 47 feet high; the chancel is 15 feet by 24; and the spire is 196 feet 9 inches high. The old State House or Independence Hall, on the south side of Chestnut street between Fifth and Sixth streets, was commenced in 1731, and was ready for occupancy by the Assembly towards the close of 1735. It was the scene of almost all the great civil events of the Revolutionary War. It is 100 feet in length on Chestnut street by 44 feet in depth; and prior to the centennial celebration its exterior and interior were restored as nearly as possible to their original appearance. The Pennsylvania Hospital occupies the square of ground bounded by Spruce, Pine, Eighth, and Ninth streets, and the corner-stone of the building was laid on 28th May 1755. Carpenter's Hall, where the first Congress met, stands back from Chestnut street, east of Fourth street, and was begun in January 1770. These four buildings are all very simple in their construction, but substantial and imposing, and are interesting specimens of colonial architecture. Among the notably fine buildings in Philadelphia are the old United States bank, now the United States custom-house, the Girard bank, the United States mint, and the Girard College, all of which, with the exception of the last-named, were built more than half a century ago. They are all of white marble and of the different orders of Grecian architecture, with porticos and high fluted columns. Other fine build-

³ The collection numbers 673 specimens,—mammals 251, birds 372, reptiles and batrachians 50, valued at \$46,726.

ings are the Masonic Temple, the Ridgway branch of the Philadelphia library, the Pennsylvania Academy of Fine Arts, and the Academy of Natural Sciences. There are also very many beautiful churches. The two newest buildings of magnitude are the new United States post-office, at the corner of Ninth and Chestnut streets, which is just completed (1884) at a cost of \$8,000,000, and the new municipal buildings for the city of Philadelphia at the intersection of Broad and Market streets, which are in course of construction. The post-office, which is Romanesque, is of granite, and was more than ten years in building, from October 1873 to March 1884. It has a frontage of 425 feet, a depth of 175 feet, and a height of 164 feet. The carrier delivery of the Philadelphia post-office covers the greatest territory of any city in the world, excepting London; it employs 900 men, of whom 448 are letter-carriers. The annual sales of stamps amount to \$1,600,000. About half a million of letters, &c., pass through the post-office each day. The new public buildings, as they are called, or city-hall, were begun in August 1871, and when completed will be the largest single building in America. It covers an area, including courtyards, of nearly $4\frac{1}{2}$ acres, the dimensions being 470 feet east and west and 486 feet north and south. The building will contain 520 rooms, and the topmost point of the dome, on the tower, will be 537 feet 4 inches above the courtyard, or the highest artificial construction in the world. The exterior structure is now roofed in and completed, with the exception of the tower. The total amount expended on this building to 31st December 1883 was \$9,731,488.81, and the estimated total cost is \$13,000,000. The architecture is rather rococo in character.

Population.—Previous to the census of 1830 Philadelphia was the most populous American city, but since then New York has taken the first place. In 1683 it was estimated that Philadelphia had 80 houses and 500 inhabitants. The next year the population increased 2000, and by the beginning of the last century there were 700 dwelling-houses and 4500 people. In 1800 there were 9868 dwellings and 81,009 inhabitants, and in 1820, the last census when Philadelphia stood first, she had a population of 119,325. By the census of 1880 the population of the city is placed at 847,170 (males 405,989, females 441,181), while in 1870 it was 674,022, and in 1860 565,529. About one-third of the population in 1880 were foreign born. In 1883 there were 21,237 births, of which 11,102 were males and 10,135 females. The number of emigrants landed in the year at Philadelphia was 23,473, of whom 13,899 were males and 9574 females,—a decrease of 9778 from 1882. Of these emigrants 7304 were from England, 6023 from Ireland, 5232 from Sweden and Norway, and 2991 from Germany. The mayor of Philadelphia in his annual message to councils in April 1884 places the population of the city at 1,023,000, while the Board of Health estimate it at 907,041. The death-rate of the city in 1883 was 22.13 per thousand. By the census of 1880 41 per cent. of the population were engaged in gainful occupations. In 1884 there were in Philadelphia 1294 lawyers and 1637 physicians. The city has 622 places of worship, viz., Baptist 83, Hebrew 11, Lutheran 32, Methodist 131, Moravian 5, Presbyterian 110, Protestant Episcopal 96, Quaker 15, Reformed Dutch 20, Reformed Episcopal 10, Roman Catholic 47, Swedenborgian 3, Unitarian 3, Universalist 4, and 52 among 23 other different denominations. There are 53 cemeteries and burial-grounds in the city.

Municipal Government.—By Penn's charter of 25th October 1701 Philadelphia was first created a borough city with a government of its own, separate from that of the province and county. Under this charter, with many modifications, the city was governed until the Act of the legislature of the State incorporating the city was

passed, 11th March 1789. This is the fundamental law governing the city to-day, but with such changes as have become necessary by the altered condition of affairs and the development of the entire country. The most important change was the Consolidation Act of 2d February 1854, already mentioned, whereby the old county of Philadelphia became the city of Philadelphia, the county of Philadelphia being at the same time continued as one of the counties of the State. The city is divided territorially and politically into thirty-one wards, and is governed by a mayor, elected by the people for three years, and by two bodies, called the select and common council. The upper branch is composed of one member from each ward elected for three years, who must have attained the age of twenty-five years and have been a citizen and inhabitant of the State for four years next before his election, and the last year thereof an inhabitant of the ward for which he shall be chosen. Each ward has a member of common council, elected for two years, for every 2000 taxable inhabitants; he must be twenty-one years of age and have the other qualifications required for the upper body. The mayor is the executive head of the city and the councils are the law-making power. The mayor has the right of veto upon the acts of the councils. Councils in joint meeting appoint all heads of departments not elected, establish the rate at which all taxes shall be levied that are authorized by law, and fix the salaries of all municipal officers elected by the people, as well as those they appoint. The city can make no binding contract or incur any debt unless authorized by law or ordinance and an appropriation sufficient to pay the same be previously made by councils. The sanitary care of the city is vested in a board of health composed of nine members appointed by the judges of the Courts of Common Pleas of the county, who have charge of the sanitary condition of the city and citizens. Among the duties of the board is that of keeping an accurate record of all births, marriages, and deaths. The poor of the city are under the charge of a board of twelve guardians elected by councils. These several bodies, councils, board of health, and guardians of the poor all serve without pecuniary compensation. Edward Shippen was named in the charter of 1701 as first mayor of the city. The last mayor under the English crown was Samuel Powel, elected 3d October 1775, and he was also the first mayor under the United States, being re-elected 13th April 1789. During the interim of the Revolutionary War the municipal government was suspended, and the affairs of the city were carried on by the councils of safety and other local bodies.

Police, Fire, Water.—The mayor is the nominal head of the police of the city, and all the appointments and removals are in his hands. The force consists of 1415 men, of whom 1225 are patrolmen. There are four captains and one chief of police; and the fire marshal is attached to the police department. The number of arrests made in 1883 was 45,612, and the number of commitments to the county prison 23,245.

The fire department is governed by a board of fire commissioners elected by councils, and consists of a chief engineer, six assistant engineers, and four hundred men. They are divided into twenty-nine steam-engine companies and five hook and ladder companies, with the addition of hose and hose-carriage to each. In 1883 there were 804 fires.

The largest portion of Philadelphia is supplied with water from the Schuylkill, and it was in great part for the preservation of the purity of this water-supply that Fairmount Park was created. The park has not, however, served its purpose in this respect, and the water supplied to the city is most impure. The supply also is hardly adequate to the demand, and many other sources have been suggested. The capacity of the present waterworks allows a daily average pumpage of 90,000,000 gallons, and the seven reservoirs have a total capacity of 191,224,560 gallons. The total number of gallons of water pumped in 1883 was 25,182,775,641, or a daily average of about 69,000,000. There are 784 miles of pipe under ground to supply at least 170,000 buildings, of which 151,096 are (January 1884) dwelling-houses. The dwellings are charged for water according to the number and character of appliances in use, irrespective of the amount of water used or the number of the occupants of the house. The streets have a number of fountains, erected by the Philadelphia Fountain Society, for the use of horses, dogs, and men; and there are also 5752 hydrants for the use of the fire department; but these are wholly insufficient to protect the city.

Finances.—On 1st January 1884 the funded debt of the city of Philadelphia was \$66,365,591.24, and the floating debt \$689,355.36, or a total indebtedness of \$67,054,946.60. The city assets at the same period were \$28,096,394.75, so that the excess over assets was \$38,958,551.85. This is a reduction of the city's debt from its highest point, 1st January 1880, when it amounted to \$72,264,595.76. The assessed valuation of real estate in the city of Philadelphia, 1st January 1884, was \$583,613,683, and the annual tax for the year amounted to \$10,383,381.84. In 1883 the receipts from all sources for municipal purposes were \$13,632,842.38. The various trust funds of the city are under the control of a board of directors of city trusts, composed of twelve prominent citizens appointed by the judges of the Courts of Common Pleas. The board has charge of the

Girard Fund; the Wills Hospital Fund, for the relief of indigent blind and lame; the Franklin Fund, for aiding young married artificers; and sundry funds for furnishing the poor with fuel and other purposes,—amounting in the aggregate, on 31st December 1883, to \$11,606,320.92.

There are thirty-two national banks in Philadelphia with an aggregate capital of \$17,578,000, and for the week ending 30th June 1884 their loans and discounts were \$73,525,885, deposits \$64,436,411, and circulation \$3,416,013. Their surplus on 31st December 1883 was \$8,712,303. In addition to the national banks there are six banks chartered by the State with an aggregate capital of \$714,600; eight trust and safe deposit companies, where deposits are received and a *quasi* banking business done, with a total capital of \$8,625,000, and a surplus on 31st December 1883 of \$4,589,732; and three saving funds without any capital, but where all the depositors are interested in the profits, with total deposits on 31st December 1883 of \$25,503,200.98. Philadelphia has fourteen joint-stock fire insurance companies, with a capital of \$3,950,000; five joint-stock fire and marine companies, with a capital of \$4,860,000; six mutual fire insurance companies; and six life insurance companies. In addition to these there are a real estate title insurance company and a plate-glass insurance company, their objects being expressed in their titles.

Commerce.—Until within the last sixty years Philadelphia was the commercial emporium of the United States, but since that time her commerce has been gradually declining, until now she ranks fifth in the order of ports, being preceded by New York, Boston, San Francisco, and New Orleans. At the same time her manufactures have been steadily increasing, until she has become the great manufacturing centre of the country. On 30th June 1884 there were registered as belonging to the port of Philadelphia 854 vessels, having a tonnage of 197,491 tons, 295 being steamers. For the year ending 31st December 1883 724 coast-wise vessels having a tonnage of 418,625 tons entered, and 1213 with a tonnage of 576,719 tons cleared. During the same period there entered 1066 foreign vessels with a tonnage of 813,706 tons, and 942 cleared with a tonnage of 732,333 tons. For the six months ending 30th June 1884 there entered 290 American vessels with a tonnage of 134,807 tons, and 199 cleared with a tonnage of 191,908 tons. In the same period 285 foreign vessels entered with a tonnage of 263,577 tons, and 246 cleared with a tonnage of 238,929 tons. Statistics of the exports and imports of the city have been kept since 1821; and they show that the greatest exports in any one year were in 1876, the centennial year, when they amounted to \$50,539,450. The greatest imports (\$38,933,832) were in 1880. For 1883 the exports were \$38,662,434 and the imports \$32,811,045. For the six months ending 30th June 1884 the exports were \$17,605,271, and the imports \$18,245,733. The total receipts for duties at this port for the year 1883 were \$11,834,014.55, and for the six months ending 30th June 1884 \$6,917,376.71. Lines of steamers run to Liverpool, Glasgow, New York, Boston, Baltimore, Savannah, Charleston, and other ports. Philadelphia is also the centre of the three great internal carrying lines of the State, the Pennsylvania Railroad, the Lehigh Valley Railroad, and the Reading Railroad. The last two are principally coal-roads from the great anthracite coal-fields of Pennsylvania, while the first, with its numerous branches, is the main artery from the west for the transportation of its agricultural products. The gross receipts for 1883 of the Pennsylvania Railroad, from all lines connecting directly with Philadelphia, were \$57,512,766.36. The total tonnage moved over these same lines was 57,379,115 tons, and the number of passengers for the same period was 36,584,435, and the pieces of baggage 1,774,192. The tonnage of the other two roads is proportionately large.

Industries.—The largest single classes of manufactures are the iron and steel and the textile industries. The first-named, which includes all forms of machinery and of iron and steel articles, employed in 1883 31,917 persons in 712 establishments, producing articles valued at \$58,603,781. The manufactures of wool, cotton, silk, &c., employed 60,897 persons in 1018 establishments, producing textile fabrics to the value of \$102,087,128; and these figures are rather below than above the actual facts. In the carpet manufacture alone, for which there are 216 establishments, there are 35,000,000 yards of carpet made annually. The census for 1880 gave Philadelphia 8567 manufacturing establishments, with a capital of \$187,143,857, employing 185,527 hands and producing articles valued at \$324,342,935 per annum. The seven classes producing over \$10,000,000 a year were—sugar-refineries (11), \$24,224,929; factories of woollen goods (89), \$21,349,810; men's clothing manufactories (426), \$18,506,748; cotton-mills (145), \$14,268,696; carpet manufactories (170), \$14,263,510; foundry and machine shops (226), \$13,455,288; drugs and chemicals manufactories (54), \$11,804,793. Since then, however, Philadelphia has made great strides, and the close of 1882 showed 12,063 manufacturing establishments, employing 147,137 men, 67,050 women, and 25,296 children under sixteen years of age, or a total of 242,483, and yielding products of the value of \$451,226,309. The large and important industry of brick-making, for which there are 63 yards,

produces annually about 350,000,000 bricks, of a market value of at least \$3,500,000. The fine "pressed brick" of Philadelphia is used in all parts of the country, and of late years moulded bricks of various designs and of any size have been extensively and successfully made.

Charities.—There are not less than 300 charities proper in Philadelphia, leaving out institutions of learning which come within the legal definition of the word. A few of them are municipal, but the majority are wholly private in their origin and conduct. Among the former may be classed the Blockley Almshouse for the care of the indigent poor of the city, and the house of correction, employment, and reformation at Holmesburg. This last is a mixed institution, being a workhouse both for criminals and paupers, and in 1883 there were received into it 7290 men, women, and children. On 31st December 1883 there were 1236 inmates, of whom 197 were females. The city bath-houses are another important municipal charity. There are twenty-two hospitals in Philadelphia, the most important being the Pennsylvania Hospital, projected in 1751 by Benjamin Franklin and Dr Thomas Bond. It is governed principally by the Quakers, and is supported wholly by voluntary contributions. It has a capacity for 230 patients, and recent accident cases are always admitted. The insane department of this hospital is located on Haverford road, and was opened in 1841, since which time to January 1884 there have been 8852 patients. In addition to this hospital for the insane there is an insane department attached to the City Hospital at the Almshouse, and a Friends' Asylum for the Insane at Frankford. Other important charities are the Philadelphia Dispensary, Home for Consumptives, Home for Incurables, Preston Retreat (lying-in charity), Orphans' Society, Philadelphia Working Home for Blind Men, Sheltering Arms for Infants, the Sick Diet Kitchen, and the House of Refuge for Juvenile Delinquents. This last receives children committed by the court of Oyer and Terminer upon conviction of a criminal offence, also vagrant, incorrigible, or vicious children committed by magistrates on complaint of the parent or any other person that the parent or guardian is incapable or unwilling to control them.

Education.—Penn in his frame of government provided that a committee of manners, education, and art should be appointed, so that all "wicked and scandalous living may be prevented, and that youth may be trained up in virtue, and useful arts and knowledge." The first school in Philadelphia of which we have knowledge was opened the year following the foundation of the colony. At a meeting of the provincial council held in Philadelphia "ye 26th of 10th month 1683" the governor and council, "having taken into serious consideration the great necessity there is of a schoolmaster for the instruction—and sober instruction—of youth in the town of Philadelphia, sent for Enoch Flower, an inhabitant of the said town, who for twenty years past hath been exercised in that care and employment in England," and engaged him to instruct the youth of the city. In the year 1689 the first public school in Pennsylvania was established at Philadelphia under the care of the celebrated George Keith. It was incorporated by the provincial council 12th February 1698, and was entitled "The Overseers of the Public Schools founded in Philadelphia at the request, costs, and charges of the people of God called Quakers," and in 1711 received a charter from Penn. This school, although supported by the Quakers, was open to all, and for more than sixty years continued to be the only public place for instruction in the province. It thrived and was held in high estimation, and its legitimate successor is still in operation in Philadelphia, where it maintains its ancient reputation. In 1749 Franklin published his *Proposals Relative to the Education of Youth in Pennsylvania*, which resulted the next year in the establishment of the academy and charitable school, which became a college in 1755, and in 1779 was incorporated as the university of Pennsylvania. The university at present occupies a site in Woodland avenue, in what was formerly West Philadelphia, and gives instruction in ten departments (Arts, Music, Medicine, Law, Dentistry, Philosophy, Auxiliary of Medicine, Veterinary Medicine, Towne Scientific School, and Wharton School of Finance and Economy). The faculty consists of 132 professors, lecturers, and instructors in the various departments, and for the college year 1883-84 there were 1000 students.

The public school system of Pennsylvania was not really firmly fixed until 1813, when by an Act of the legislature Philadelphia was made the first school district of Pennsylvania with a distinct educational system from that of the State in general. This district is governed by a board of public education composed of 31 members, one from each ward of the city, who are appointed, one-third each year for three years, by the judges of the Courts of Common Pleas of the county. They have the financial control and general supervision of schools, the selection of the books to be used, the oversight of the teachers, and the building of the schoolhouses. In addition to this board there are the directors of the public schools, twelve from each ward, who have the local supervision of the schools in their respective sections. They are elected by the people, one-third each year for three years. The schools are divided into primary, secondary, and grammar schools, in addition to which

there is a central high school, a finishing school for boys, and a normal school which is a finishing school for girls, and where they can also be qualified to become teachers. There are 465 public schools in Philadelphia and 236 school-buildings of a value of \$4,186,200. In 1883 the city appropriated \$1,637,651.04 to education. During the same period 105,424 children attended the public schools, at an average cost per pupil of \$15.35, and 82 male and 2086 female teachers are employed in their instruction. Another noted educational institution in Philadelphia is Girard College for orphans, endowed by Stephen Girard in 1831 for the benefit of poor white male orphan children. By the will a preference is given first to orphans born in Philadelphia, second to those born in Pennsylvania, third to those born in New York city, and fourth to those born in New Orleans. To be qualified for admission the orphans must be between six and ten years of age; and a child without a father, while the mother is living, is held to be an orphan entitled to admission. The buildings cost \$1,933,821.78, and were formally opened in January 1848. The total value of the estate applicable to the purposes of the college was on 31st December 1883 \$10,138,268.10, and the gross receipts of income for the year 1883 were \$976,961.06. During the same period there were 1105 boys inmates of the college. At Philadelphia are also the Pennsylvania Institution for the Instruction of the Deaf and Dumb; the Pennsylvania Institution for the Instruction of the Blind; the Pennsylvania Academy of the Fine Arts, founded in 1805, and the first art school in America; the School of Design for Women; the Pennsylvania Museum and School of Industrial Art; and the Jefferson Medical College.

Libraries.—Philadelphia was for many years not only the first city commercially in the country, but it was also the seat of letters. When the poet Moore visited America in 1804 he wrote to his mother, of Philadelphia, "it is the only place in America that can boast of a literary society." Unfortunately it has much degenerated in this respect in eighty years, and to-day but little attention is paid by its people to letters and literature. To Franklin, again, its first library is due. It grew out of the Junto, and in 1731 the Library Company of Philadelphia was established. In 1769 it absorbed the Union Library Company, which had been formed some few years before; and in 1792 the Loganian Library, a valuable collection of classical and other works provided for under the will of James Logan, a friend of Penn, was transferred to the Philadelphia library. It subsequently acquired, by bequest, the libraries of the Rev. Samuel Preston of London and of William Mackenzie of Philadelphia. Among the rarities in the latter was a copy of Caxton's *Golden Legend*, 1486. In 1869 it was made the beneficiary, under the will of Dr James Rush, of an estate valued at over a million dollars. It has two library buildings and possesses about 145,000 volumes, as well as valuable manuscripts and broadsides. The Mercantile Library Association is the popular circulating library of the city, and contains 149,000 volumes. Other libraries are the Athenæum, Apprentices' Library, Library of the Law Association, and Friends' Library.

Learned Societies.—The American Philosophical Society is the oldest organized body for the pursuit of philosophical investigation in its broadest sense in America. It was founded also by Franklin, 25th May 1743, and incorporated 15th March 1780, with its founder as president. It began the publication of its transactions in 1773, and the 22d volume has been recently issued. The publication of the proceedings of this society was commenced in 1838, and still continues. Its library contains about 23,000 volumes, and the society also possesses valuable manuscript correspondence of Franklin. The Academy of Natural Sciences was organized in 1812, and its ornithological collection, which contains over 25,000 specimens, is claimed to be the finest in the world. It has a fine library of works on the natural sciences, and publishes a journal and its proceedings. The Franklin Institute for the promotion of the mechanic arts started in 1824. It has a valuable library of over 20,000 volumes devoted to mechanics and kindred subjects, and has ever since its organization published a monthly journal. The Historical Society of Pennsylvania was founded in 1824, and is devoted to the preservation of material relating to the history of the State. Its collections are of great historical value, and its library contains more than 20,000 volumes. The Numismatic and Antiquarian Society of Philadelphia, founded in 1858, was the first organization on the American continent to engage in the pursuit of numismatic science. It has a fine collection of coins and a good library. Another notable body is the College of Physicians and Surgeons, with a medical library of 23,000 volumes and a fine museum of prepared specimens.

Newspapers.—The *American Weekly Mercury* was the first newspaper published in Philadelphia and the third in the colonies. It was started on 22d December 1719 by Andrew Bradford, a son of William Bradford, the first printer in the middle colonies, and this paper was the first newspaper in the same section. On 21st September 1784 the first daily newspaper in the United States was issued at Philadelphia. It was the *American Daily Advertiser*, subsequently published as *Poulson's Daily Advertiser*, and later

merged into the *North American and United States Gazette*, which is thus by succession the oldest daily newspaper in the United States. There are at present (July 1884) twenty daily newspapers published in Philadelphia, eight of them being afternoon papers, with an average circulation of 375,000, and seventy-seven weekly newspapers, chiefly religious and Sunday secular papers.

Social Life.—Among Philadelphia's claims to priority she has in her midst one of the oldest purely social clubs in existence,—the Colony or State in Schuylkill, which was formed in 1732. The other purely social clubs in the city are the Philadelphia Club, Social Art Club, and University Club. The Union League (Republican) and Commonwealth (Democratic) are mixed social and political clubs. There are some organizations of a mixed social and charitable character, such as the St George Society (1772), the St David Society (1729), the St Andrew's Society (1749), and the Sons of St Patrick or Hibernian Society (1771). The First Troop of Philadelphia City Cavalry, formed in 1774, is a military organization of high social standing. There are also a gentlemen's driving park or racecourse and innumerable cricket and boat clubs. There is an opera-house capable of accommodating 3500 persons, and five first-class theatres, but Philadelphia as a community seems not to be a theatre-going people.

History.—Down to the War of Independence the history of Philadelphia is virtually that of PENNSYLVANIA (*q.v.*). The patent granted to William Penn (see PENN, p. 495) for the territory embraced within the present Commonwealth of Pennsylvania was signed by Charles II. on the 24th of March 1681, and in the autumn of that year Penn appointed three commissioners to proceed to the new province and lay out a great city. This seems to have been his chief thought in settling the province, and his instructions to his commissioners were to select a site on the Delaware where "it is most navigable, high, dry, and healthy; that is where most ships can best ride, of deepest draught of water, if possible to load or unload at the bank or key side without boating or lightering of it." These commissioners were William Crispin, Nathaniel Allen, John Bezar, and William Heage. Crispin, who was a kinsman of the proprietor, died on the voyage out, and the remaining commissioners arrived toward the close of the year. They had been preceded by Penn's cousin, Captain William Markham, as deputy-governor, and were soon followed by the surveyor-general of the province, Thomas Holme, who, as may be understood from his office, was one of the most important men in the early history of the city and State. The site of the city was speedily determined upon, and Holme proceeded to lay it out according to the modified instructions of Penn, and his *Portraiture of the City of Philadelphia in the Province of Pennsylvania in America* was published and sold by Andrew Sowle in Shoreditch, London, in 1683. This plan shows the old part of the city as it is to-day, covering between 1200 and 1300 acres. Unfortunately no date can be fixed, even approximately, for the founding of the city; nor is the date known of Penn's first visit to the capital of his province. He landed at Newcastle on the Delaware on 27th October 1682, and two days later came up as far as Upland, now Chester, 13 miles south of Philadelphia. He doubtless did not remain long so near his pet scheme without viewing it, but when he did first come to Philadelphia is now unknown.¹

The seat of government was fixed in Philadelphia by the meeting of the governor and council on the 10th of March 1683, and the General Assembly met two days later. For 117 years the city continued to be the capital of Pennsylvania and was the most important town, commercially, politically, and socially, in the colonies during nearly the whole of this period. In October 1685 the first printing press established in the middle colonies was set up here by William Bradford; the earliest specimen of his work which has survived to our day is his *Kalendarium Pennsylvaniense or America's Messenger, being an Almanack for the year of Grace 1686*. The printing press was followed in 1690 by a paper-mill, erected by William Rittenhouse, a Mennonite preacher, on the Wissahickon creek, a locality which has ever since remained a favourite for the manufacture of paper. The one man, next to William Penn, whose influence was most deeply impressed upon Philadelphia as upon the affairs of the colony, was Benjamin Franklin, whose power was felt almost on his first landing in October 1723, when in his eighteenth year, and its impress is seen to-day. Four years after he settled here he formed a club for mutual improvement, which he called the "Junto," out of which subsequently grew the American Philosophical Society for the promotion of useful knowledge and the Library Company of Philadelphia. He also originated the present university of Pennsylvania; organized the first fire-engine company in the city, and was instrumental in founding the Pennsylvania Hospital. In March 1753

¹ In Philadelphia for many years stood a famous elm tree, known as the treaty tree, and when it was blown down in 1810 a stone was placed to mark the spot. Tradition had it that under this tree Penn, on his first coming to Philadelphia, held a treaty of amity and friendship with the Indians,—a treaty, not sworn to and never broken. The light of investigation has dispelled this tradition and relegated it to the category of mythology, along with the stories of William Tell and Captain Smith and Pocahontas.

the first Arctic expedition ever sent out from America sailed from Philadelphia. The vessel, called the "Argo," was commanded by Captain Swaine, but her voyage accomplished nothing of importance. In 1770 the first factory for the manufacture of fine porcelain in the colonies was established at Philadelphia by a Swiss and an Englishman, but the difficulty of obtaining competent workmen forced its abandonment two years later. During the war of the revolution Philadelphia was the virtual capital of the colonies and the scene of all the prominent civil events of those stirring times. The first Congress met at Carpenter's Hall on 4th September 1774; on 24th May 1775 Congress reconvened in the old State house and here continued its sittings, except when the city was threatened by the enemy and in his possession. On 2d July 1776 the "resolutions respecting independence" were passed, and on the 4th July 1776 Philadelphia was the scene of the adoption of the Declaration of Independence; and the old State house became ever afterwards Independence Hall. On 9th July 1778 "the articles of confederation and perpetual union between the independent States of America" were here adopted and signed, and in the same place the convention to frame a constitution for the United States of America met on 14th May 1787, with Washington as presiding officer, and continued its sessions until 17th September, when the work was finished and the fundamental law of the land given to the world. The affairs of state were thus placed on a firm foundation, while the affairs of the church had received the attention of the people the previous year. In June 1786 the clerical and lay delegates from the Protestant Episcopal churches in the United States met in Philadelphia and formally organized "the Protestant Episcopal Church in North America." The Congress of the United States had held its opening session in New York, but in December 1790 it reassembled at Philadelphia; and for ten years the seat of government was at Philadelphia, until it was permanently removed to the District of Columbia. Here Washington delivered his farewell address to the people of the United States, and here he retired from public life. As in Philadelphia the first bank in the colonies had been opened—the bank of North America in 1781—so in Philadelphia the first mint for the coinage of the money of the United States was established in 1792. Both of these institutions are still in full operation. In April 1816 Congress incorporated the bank of the United States, which was the second banking institution of that name chartered by the Government, and fixed it at Philadelphia. The affairs of this institution form a very important chapter in the history of the city, as indeed in the history of the whole country. It had an unsettled existence, until the final blow came from President Jackson, towards the close of his first term of office, in 1833. Being opposed to the continuance of the bank, he withdrew the public deposits, amounting to about \$8,000,000, the result of which was widespread ruin and business depression, not only in Philadelphia but elsewhere.

The two events of greatest note which have taken place in the city in recent years have been the centennial celebration of the independence of the colonies in 1876, and the bi-centennial celebration of the landing of William Penn in 1882. The centennial celebration was of the greatest moment, owing to the Exposition of the Industries of All Nations, which was open from 10th May to 10th November; the total admissions reached the number of 9,310,966 persons. (C. H. H.)

PHILÆ. See EGYPT, vol. vii. p. 783 sq.

PHILEMON, the oldest poet of the New Attic Comedy, was the son of Damon, and was born at Soli in Cilicia, or, according to others, at Syracuse; but early in life he settled at Athens. Since he died in 262 B.C. at an age variously stated at from 96 to 101 years, he must have been born somewhere about 360. He was thus older than his contemporary and great rival Menander, whom he frequently vanquished in poetical contests, and whom he long survived. Posterity, however, reversed the judgment of their contemporaries and assigned the palm to Menander. Philemon's first play was put on the stage about 330, while Menander did not exhibit until 321. It appears that, once being worsted in a poetical competition, Philemon went into exile. He certainly made a journey to the East, but whether on the occasion of his exile or in compliance with the invitation of Ptolemy, king of Egypt, we cannot say. On this journey, being driven by a storm to the coast of Cyrene, he was treated with cool contempt by Magas, king of Cyrene, whom he had satirized. From the various legends told about his death he would seem to have died in the full enjoyment and use of his poetical powers. Of the ninety-seven plays which he is said to have composed none are extant; the titles of fifty-three

have been preserved, but some of these may have been the work of his son, the younger Philemon, who is said to have composed fifty-four comedies. *The Merchant* and *The Treasure* of Philemon were the originals respectively of the *Mercator* and *Trinummus* of Plautus. The New Attic Comedy, of which Philemon was in a sense the founder, dealt mainly with subjects drawn from private life, which were worked up in elaborate plots and treated in a prosaic style, to the exclusion, on the whole, of the political tendency, stinging personal satire, and warm poetical colouring, which had marked the Old Attic Comedy. These characteristics of the New Comedy had already appeared, though in a less degree, in the Middle and even in the Old Attic Comedy; so that to Philemon belongs the credit, not of inventing, but of developing a style which had occasionally been employed before. In its absence of poetical idealism and restriction to the prosaic realism of daily life the New Comedy stands to the Old somewhat as the comedies of Molière or Sheridan stand to those of Shakespeare. Its repertoire was limited to a few stock characters—the imprudent lover, the designing fair, the stingy father, the greedy parasite, the blustering swashbuckler—and its plots rang the changes on the well-worn theme of thwarted but faithful love, rescued from its difficulties by the discovery of a long-lost relative and ending in marriage. In the many fragments of Philemon preserved by Stobæus, Athenæus, and other writers there is much wit and good sense.

The fragments have been collected and edited by Meineke, *Menandri et Philemonis Reliquiæ*, Berlin, 1823; and again in his *Fragmenta Comicorum Græcorum*, vol. iv., Berlin, 1841. They are also appended to the Didot edition of Aristophanes (Paris, 1839).

PHILEMON, EPISTLE TO. This, which is the shortest of the extant epistles of St Paul, stands to the other books of the New Testament in a relation similar to that of the book of Ruth to the other books of the Old Testament. It is an idyl of domestic life. Onesimus, the slave of one of Paul's converts in Asia Minor, had run away from his master, probably, as was often the case with runaways, after stealing some of his money. He had come to Paul, more probably at Rome than, as some have thought, at Cæsarea, and Paul had converted him. Paul sends him back to his master, begging that he may be kindly treated as being now a brother Christian, and formally undertaking to repay what he owed. The epistle is addressed not only to Philemon but to Apphia, who was probably his wife, to Archippus (possibly the head of the community at Colossæ or Laodicea, Col. iv. 17), and to the community which either, like some of the Roman *collegia*, consisted of Philemon's household or held its meetings in his house. It has sometimes been regarded as an appendix to the epistle to the Colossians on the grounds (1) that Onesimus was sent with both letters (Col. iv. 9; Philem. 10-12), (2) that in both letters salutations are sent to Archippus (Col. iv. 17; Philem. 2), and (3) that the same persons are mentioned in both letters as being with Paul at the time of writing (Col. i. 1, iv. 7-14; Philem. 1, 23, 24). This apparent connexion with the epistle to the Colossians is the basis of the chief arguments which have been used against its genuineness. Baur (*Paul*, E. T., vol. ii. p. 84) thinks that this "attractive, graceful, and friendly letter" is merely a practical commentary, in the form of a fiction, on the general conception of the relations of masters to Christian slaves which is set forth in Col. iv. 1. But this view has few supporters. The genuineness of the epistle is almost universally admitted. The best modern works upon it are Bishop Lightfoot's *Colossians and Philemon* (3d ed., London, 1879) and Holtzmann's essay, "Der Brief an Philemon," in the *Zeitschr. f. wissenschaftl. Theol.* 1873, p. 428.

PHILETAS, a distinguished poet and critic of the Alexandrian school, was the son of Telephus and a native of the island of Cos. He lived in the reigns of Philip, Alexander the Great, and Ptolemy I. of Egypt, the last of whom appointed him tutor to his son Ptolemy Philadelphus. His life thus fell in the latter part of the 4th and early part of the 3rd century B.C. He was a contemporary of Menander, a friend of the poet Hermesianax of Cos, and lived into the time of Aratus. Amongst his pupils were Theocritus and Zenodotus. He was sickly and so thin that he was said to carry lead in his shoes to keep himself from being blown away. The story runs that he died from the excessive assiduity with which he sought the answer to the sophistical problem called "The Liar."¹ A bronze statue of him was erected in Cos.

The fame of Philetas rested chiefly on his elegiac verses, in which, however, he was esteemed inferior to the younger poet Callimachus. He is frequently mentioned by the Latin elegiac poets Propertius and Ovid. From Hermesianax and Ovid we gather that his verses were amatory and celebrated the praises of the fair Bittis or Battis, but her name does not occur in the existing fragments, which are of a melancholy rather than an amatory tone. In one of his poems (*Demeter*) he depicted the grief of Demeter for the loss of Proserpine; in another (*Hermes*) the love of Polymele for Ulysses. The latter poem appears from the fragments to have been composed in hexameter verse. Further, he wrote epigrams and poems called *ἱατρικά*. There is no evidence that he wrote bucolic poems, for the passage in Moschus formerly quoted to prove this is an interpolation of Musæus. Some iambic verses are attributed to him, probably by a mistake arising from a common confusion between names beginning with *Phil*. Besides his poems, Philetas was the author of a vocabulary explaining the meanings of rare and obscure words, including words peculiar to certain dialects. He also wrote notes on Homer. The work on Naxos (*Ναξικά*), sometimes attributed to him, was perhaps rather by Philteas. The fragments of Philetas have been edited by Kayser, Göttingen, 1793, and by Bach, Halle, 1829.

PHILIDOR, FRANÇOIS ANDRÉ DANICAN (1726-1795). See CHESS, vol. v. p. 601.

PHILIP, one of the twelve apostles, mentioned fifth in all the lists (Matt. x. 3; Mark iii. 18; Luke vi. 14; Acts i. 13), is a mere name in the Synoptists, but a figure of some prominence in the Fourth Gospel. There he is said to have been "of Bethsaida, the city of Andrew and Peter," and to have received his call to follow Jesus at Bethany, having previously been, it would seem, a disciple of the Baptist (John i. 43, 44). Philip was at that time the means of bringing Nathanael to Jesus (John i. 45), and at a later date he, along with Andrew, carried the request of the inquiring Greeks to the Master (John xii. 22). Philip and Andrew alone are mentioned by name in connexion with the feeding of the five thousand (John vi. 5, 7), and Philip is also one of the few interlocutors in John xiv. After the resurrection he was present at the election of Matthias as successor to Judas, but he does not again appear in the New Testament history; it is, however, implied that he still continued in Jerusalem after the outbreak of the first persecution.

According to Polycrates, bishop of Ephesus, in his controversial letter written to Victor of Rome towards the end of the 2d century (ap. Euseb., *H. E.*, iii. 31, v. 24), the graves of Philip, "one of the twelve," and of his two aged virgin daughters were in [the Phrygian] Hierapolis; a third daughter, "who had lived in the Holy Ghost," was buried at Ephesus. Proclus, one of the interlocutors in the "Dialogue of Caius," a writing of somewhat later date than the letter of Polycrates, mentions (ap. Euseb., *H. E.*, iii. 31) "four prophetesses, the daughters of Philip at Hierapolis in Asia, whose tomb and that of their father are to be seen there." But Eusebius himself proceeds expressly to identify this Philip with the Philip mentioned in the Acts of the Apostles as living in Caesarea; and in another place he alludes to Philip "the apostle" as having preached the gospel to the Ethiopian eunuch (*H. E.*, ii. 1). Clement of Alexandria also (*Strom.*, iii. 6 [52]) incidentally speaks of "Philip the apostle" as having begotten children and as having given daughters in marriage. In another place (*Strom.*, iv. 9 [73]) Clement quotes, with concurrence, a passage from the Gnostic

¹ The problem was this: If a man says he is telling a lie, does he speak truly or falsely?

Heracleon, in which it is expressly said that Matthew, Philip, Thomas, and others died without "confession of the voice," or, in other words, were not, properly speaking, confessors or martyrs. A later stage of the tradition regarding Philip appears in various late apocryphal writings which have been edited by Tischendorf in his *Acta Apostolorum Apocrypha*, and in his *Apocalypses Apocryphæ*. According to the *Acta Philippi*, this apostle, along with Bartholomew and Mariamne, the sister of the latter, came to Ophioryma or Hierapolis, where the success of their preaching, and more particularly the conversion and miraculous healing of Nicanora, the wife of the governor, provoked bitter hostility. Philip was crucified head downwards, and invoked curses on his persecutors. His imprecations were heard, but the Lord Jesus immediately afterwards appeared to him and rebuked him for his want of meekness, further announcing his approaching death, and that on account of his sin he would be kept back forty days from the gates of paradise. The *Acta Philippi in Hellade* (i.e., "in the city of Athens, called Hellas") are still more fantastical. An apocryphal book, under the title *Actus Philippi*, is condemned in the canon of Gelasius. Since the 6th century Philip has been commemorated in the West, along with St James the Less, on 1st May, their relics being deposited in the same church in Rome; in the Eastern Church Philip's day is 14th November, and that of James the Less 23d October.

PHILIP, "the evangelist," is first mentioned in the Acts (vi. 5) as one of "the seven" who were chosen to attend to certain temporal affairs of the church in Jerusalem in consequence of the murmurings of the Hellenists against the Hebrews. After the martyrdom of Stephen he went to Samaria, where he preached with much success, Simon Magus being one of his converts. He afterwards instructed and baptized the Ethiopian eunuch on the road between Jerusalem and Gaza; next he was "caught away" by the Spirit and "found at Azotus" (Ashdod), whence "passing through he preached in all the cities till he came to Caesarea" (Acts viii.). Here some years afterwards, according to Acts xxi. 8, 9, he entertained Paul and his companion on their way to Jerusalem; at that time "he had four daughters which did prophesy." At a very early period he came to be confounded with the subject of the preceding notice (*q.v.*); the confusion was all the more easy because, while he undoubtedly could in a certain well-understood sense of the word be called an "apostle," writers naturally refrained from applying to him the more ambiguous designation of "evangelist." "Philip the deacon" is commemorated on 6th June.

PHILIP, tetrarch of Ituræa. See HEROD PHILIP, vol. xi. p. 755.

PHILIP, the name of five kings of Macedon. The greatest of these was PHILIP II. (382-336 B.C.), the first founder of the MACEDONIAN EMPIRE (*q.v.*). After the death of Alexander the Great, Arrhidæus, a bastard of Philip II., reigned as PHILIP III., till he was put to death by Olympias in 317. PHILIP IV., son of Cassander, reigned only for a few months in 296. PHILIP V., the last but one of the kings of Macedon and son of Demetrius II., was born in 237, and came to the throne on the death of his uncle, Antigonus Doson, in 220. In the course of the next three years he acquired a brilliant reputation by his exploits against the Ætolians and their allies in the Peloponnesus in the Social War; but after this, though his whole career was marked by military and even political ability, the bad sides of his character became predominant, and he appeared more and more as a perfidious, morose, and cruel tyrant, thus alienating the affections of the Greeks and ultimately even of his own subjects. His life was full of ambitious schemes, but he made the cardinal error of siding with Carthage against Rome. His character made it easy for the Romans to raise against him a powerful coalition of his neighbours, but Philip held his ground with vigour till the armies of the republic themselves appeared on the field. How he was finally driven out of Greece has been related under FLAMINIVS. After 196 Philip for some time accepted his reverses and sought the friendship of Rome, helping the republic against Antiochus;

but his ambition and the jealousy of the senate gradually led to fresh complications, and a new war was imminent when Philip died in 179, mainly of remorse for the death of his younger son Demetrius, the favourite of Rome, whom he had executed on an accusation forged by his elder son and heir Perseus.

PHILIP I. (1052-1108), king of France, was the son of Henry I. and Anne of Russia, and was born in 1052. He was associated with his father on the throne in 1059, the consecration taking place at Rheims (23d May), and he succeeded to the undivided sovereignty in the following year (4th August 1060), first under the regency of his mother, and afterwards, from 1062 to 1067, under that of Baldwin V., count of Flanders. In 1072 he married Bertha, daughter of Robert the Frisian, at whose hands he had sustained a shameful defeat at Cassel in the preceding year. His jealousy of William the Conqueror led him into an act of overt hostility in 1075, when his troops raised the siege of Dol, and a state of war, interrupted by inconsiderable intervals, continued thenceforward to subsist until the death of William. Philip afterwards supported, but ineffectually, the pretensions of Robert of Normandy against William Rufus. In 1092 he brought himself into collision with the church by shutting up his wife Bertha with her three children in the castle of Montreuil, and espousing Bertrada of Montfort, whom he had induced to leave her husband, Fulk of Anjou. The marriage was indeed sanctioned after Bertha's death by a subservient council at Rheims in 1094, but led to the king's excommunication by the council of Autun in the same year—a censure which was renewed by Pope Urban II. at Clermont in 1095. Having dismissed Bertrada early in 1097, he was forthwith absolved, but on a repetition of the offence three years afterwards the sentence was renewed, at Poitiers, and only removed by Paschal II. after Philip had once more submitted himself to the church. In 1100 he made his son Louis (afterwards Louis VI.) joint king, and his death took place at Melun on 29th July 1108. See FRANCE, vol. ix. pp. 537-539.

PHILIP II. (1165-1223), surnamed "Augustus," king of France, was the son of Louis VII., and was born in August 1165. When fifteen years old he was crowned joint king at Rheims on 1st November 1179. In the following year he was again crowned along with his newly-wedded wife, Margaret of Hainault, at St Denis (29th May 1180); the death of his father took place a few months afterwards. For an account of Philip II.'s character and of the leading events of his reign the reader is referred to FRANCE, vol. ix. pp. 540-542. He died at Mantes on 14th July 1223.

PHILIP III. (1245-1285), surnamed "the Rash," king of France, was born in 1245 and succeeded his father Louis IX. on 25th August 1270, at Tunis, where, after continuing the siege for some time, he made a truce of ten years and embarked for France in the following November. He was twice married, first to Isabella of Aragon in 1258, and subsequently to Mary of Brabant. He died at Perpignan on 5th October 1285. See FRANCE, vol. ix. p. 544.

PHILIP IV. (1268-1314), surnamed "the Fair," son of the preceding, was born at Fontainebleau in 1268, was married to Joanna, queen of Navarre, in 1284, accompanied his father into Aragon in 1285, and was proclaimed king of France at Perpignan on 6th October of that year. See FRANCE, vol. ix. pp. 544-545. He died at Fontainebleau on 29th November 1314.

PHILIP V. (1293-1322), surnamed "the Tall," second son of the preceding, succeeded his elder brother, Louis X., in January 1317, and was succeeded by his younger brother Charles IV. in January 1322.

PHILIP VI. (1293-1350) was the eldest son of Charles, count of Valois, the younger brother of Philip IV., and

was born in 1293. He succeeded his cousin Charles IV. in 1328, and died at Nogent-le-Roi near Chartres on 22d August 1350. See FRANCE, vol. ix. pp. 545-546.

PHILIP I. (1478-1506), of Castile and Aragon, surnamed "the Handsome," was the son of the emperor Maximilian I. and Mary, the only child of Charles the Bold, last prince of the house of Burgundy, and was born at Bruges on 22d July 1478. He succeeded his mother in 1482, Maximilian being recognized as governor and guardian during the minority by all the provinces, except Flanders, the burghers of which took possession of Philip, and carried on the government in his name. This arrangement subsisted until 1489, when a long struggle resulted in the triumph of Maximilian, who henceforth had the guardianship uncontrolled. In 1494 Philip received the homage of the various states of the Netherlands, and in 1496 he was married to Joanna (Juana la Loca), second daughter of Ferdinand and Isabella of Castile and Aragon. On the early death of the other children of these sovereigns the succession vested in Joanna, and Philip as her husband proceeded to Spain, where he was recognized as heir-presumptive by the cortes of Toledo and Saragossa (representing Castile and Aragon respectively) in 1502. He returned, however, to Flanders before the close of the year, and was still absent when, on the death of Isabella in November 1504, Ferdinand caused Joanna and Philip to be proclaimed sovereigns of Castile, but at the same time assumed the regency to himself. It was only with difficulty that Ferdinand was induced to retire to Aragon and so make way for the new king in June 1506. Philip died three months afterwards (25th September 1506) at Burgos. His children by Joanna were Charles V., emperor, and king of Spain; Ferdinand I., emperor; Isabella, queen of Denmark; Leonora, queen of Portugal and afterwards of France; Mary, queen of Hungary and governor of the Netherlands; and Catharine, queen of Portugal.

PHILIP II. (1527-1598), king of Spain, was the son of the emperor Charles V. and Isabella of Portugal, and was born at Valladolid on 21st May 1527. He was brought up in Castile under the care of his mother, who died when he was twelve years old. As Philip grew up, his father, though he rarely saw his son, watched carefully over his education and strove to fit him for political life. In 1543 Philip married Mary of Portugal, who died in 1545, soon after the birth of a son, Don Carlos. In 1548 Charles V. summoned Philip to Brussels, that he might gain some experience of the peoples whom he would be called upon to rule. He was not, however, popular with his future subjects. He had already formed his character upon the model of Spanish haughtiness. He was cold, reserved, punctilious about decorum, and wanting in geniality. The Italians did not care for him; the Flemings disliked him; the Germans hated him. His appearance and manner did not further his father's plan of securing his election to the empire. The scheme failed, and Philip's presence was in no way helpful. In 1551 he returned to the more congenial task of governing Spain.

The death of Edward VI. of England opened out to Charles V. new prospects for his son. Queen Mary regarded the emperor as her only friend, and submitted herself entirely to his guidance. She received with joy a proposal for her marriage with Philip. The English opposition broke down with the failure of Wyatt's rebellion, and in 1554 Philip came to England to claim his bride. Charles V. resigned to him Naples and Sicily that he might not come as a needy prince. Philip was well supplied with Spanish gold, and was charged by his father to spare no pains in conciliating the English. He tried his best; but his cold, ungenial manner was a hopeless obstacle to his success. Mary was devotedly attached to her hus-

band, who exercised a moderating influence over the queen's zeal for the re-establishment of Catholicism. Charles V. wished to secure England as an ally, and subordinated religious to political considerations. Philip was not naturally fitted for conciliatory action, and was not happy in England. He found that his wife was destined to be childless and that he had no prospect of succeeding to the English crown. At the end of 1555 he joyfully obeyed his father's summons to go to Brussels. Charles V., worn out by the fatigue of a long reign, resolved to abdicate in favour of his son, and this he did on 16th January 1556.

Philip II. was now king of Spain, Naples, and Sicily, duke of Milan, lord of Franche Comté and the Netherlands, ruler of Tunis and the Barbary coast, the Canaries and Cape de Verd Islands, the Philippines and Spice Islands, large colonies in the West Indies, and the vast territories of Mexico and Peru. These great dominions had fallen into his father's hands and were united only by their dependence on their ruler. It was Philip's task to give them an organic unity and combine them into a system. First he had to face a threatening league against his power. Pope Paul IV., a Neapolitan, was imbued with hatred of the Spanish rule, and formed an alliance with Henry II. of France. Philip sent the duke of Alva, who speedily reduced the intractable pope. But Philip was too good a Catholic to press his victory. He was content to leave the pope powerless, and Alva on his knees asked pardon for bearing arms against the church. The war against France was pursued with equal success and greater results. Philip's army, led by Philibert of Savoy, entered Picardy and besieged St Quentin. The French were defeated in an attempt to relieve the city, and St Quentin was stormed. The French retaliated by seizing Calais from England, and thence advanced into Flanders, where they were again defeated in the bloody battle of Gravelines. Both Philip II. and Henry II. were destitute of resources and wished for peace; but Philip II. was the better diplomatist. The treaty of Cateau Cambrésis in 1559 restored to him all that France had won by its long warfare against Charles V. in Italy and the Netherlands.

Thus Philip began his reign with glory, and Europe saw that Charles V. had no unworthy successor. Yet Philip was not anxious for military glory. His finances were embarrassed and he felt the need of a period of peace. For the purpose of maintaining his political supremacy he proposed to continue his English alliance by marrying Elizabeth when she succeeded Mary on the English throne. Elizabeth did not at once reject the proposal; but she gradually entered upon a religious policy which made marriage with Philip impossible. The Spanish king rapidly changed his plans and cemented his alliance with France by a union (24th June 1559) with Isabella, daughter of Henry II. He made arrangements for the government of the Netherlands, and at the end of 1559 returned to Spain, where he remained for the rest of his life.

The policy of Philip was steadily directed towards welding his dominions together in dependence on himself and extending his influence over Europe. The power of Charles V. had had no definite centre. The emperor had recognized the claims of his separate dominions upon him, and had striven to be neither German, Spanish, Flemish, nor Italian. Philip identified himself entirely with Spain. Castile was to be the seat of his monarchy, and that monarchy was to be absolute. He was devoted to Catholicism, and during his reign superseded the pope as the head of the Catholic party in Europe.* But the interests of Catholicism were in his mind identified with his own personal interests, and under the cover of zeal for the church he pursued the aggrandizement of Spain. In Spain itself his care for the maintenance of the Catholic

faith accorded with the temper of the people. The long continuance of war against the Moors had identified orthodoxy with purity of race, and heresy was regarded as a taint in the blood. The rigour of the Inquisition preserved the national honour; the auto-da-fé was a means of ridding the land of dangerous elements. This uncompromising spirit of Spain in religious matters its king wished to extend to the rest of his dominions.

Philip had none of his father's personal activity. Though his mind was always engaged in the business of the state, he did not care for the excitement of personal conflict. He was no warrior, and never took the field. He felt himself best qualified to direct his policy from afar. He was resolved to make the fullest use of others, yet to keep the guidance of affairs in his own hands. He increased the number of councils for the management of the business of the different provinces of his realm, and in these councils natives of the various provinces had seats. But the general direction of affairs was in the hands of a privy council, entirely composed of Spaniards. At first this council consisted chiefly of the members of Philip's household, the men whom he had known in early days. Foremost amongst them were the duke of Alva and Ruy Gomez de Silva, prince of Eboli. Alva was a general, Gomez a courtier, and the two men were in permanent opposition. This exactly suited Philip's views. He was never present in person at the sittings of the council. All questions on which he wished for its opinion were reduced to writing and laid before it. Its recommendations were similarly submitted to the king in writing. There was no initiative except by his pleasure, no decision which was not due to his personal approval. He gained all the advantages of opposing views amongst his ministers without identifying himself with any. No minister could become a necessity to him, and he could withdraw his favour at will. Philip's regents and ministers in the several provinces had large authority, but were never allowed to forget their dependence on the central power. Every land was submissive except the Netherlands, where the nobles resented their exclusion from the government, and saw with alarm the steady advance of Philip's system. A new ecclesiastical organization increased the number of bishops, who were all dependent on the king, and diminished the revenues of the monasteries, which furnished provisions for the younger members of the noble families. The introduction of the Spanish Inquisition threatened to destroy entirely the political importance of the nobles. In the general discontent the Protestant feeling of the towns made common cause with the national jealousy of the nobles. A strong opposition was formed, and in 1566 the Netherlands were in revolt. For a time Philip wavered between a policy of conciliation and a policy of repression. At last he listened to the advice of the duke of Alva, and sent him to reduce the rebels. Alva treated the revolted provinces with merciless severity; he crushed, but he could not subdue. The Netherlands were still unpacified, while Alva's cruelty destroyed their commerce. Their wealth had been the chief source of revenue to Charles V.; Philip II. no longer found it flow into his coffers. For seven years Alva resolutely tried his policy of repression; but the spirit of the Netherlands remained unbroken, and round their slumbering revolt all the enemies of the Spanish monarchy began to gather. Alva was recalled and fell into disgrace. A more pacific successor, Don Luis de Requesens, was sent to try a more conciliatory policy.

In domestic life, meanwhile, Philip was unhappy. His son Don Carlos developed an ungovernable temper, and did not hesitate to condemn his father's caution as unworthy of the traditions of his house. He wished to distinguish himself and was on the point of quitting

Spain when his father, as a measure of precaution, had him imprisoned. In prison Don Carlos yielded to sullen despair, and gave way to excesses, which Philip did not try to check. In consequence of this unwholesome life Don Carlos died in 1568, and it was a bitter blow to the haughty king to inform foreign princes of the facts. It would seem that Philip was glad to be rid of one whom he could not manage; he did not hasten the death of Don Carlos, but he took no steps to prevent it. A few months later died Queen Isabella, leaving Philip without a male heir. In 1570 he married his fourth wife, Anne of Austria, his niece, who died in 1580. Only one of her sons survived to manhood, and he succeeded his father as Philip III.

Meanwhile the hopes of Spain were fixed on Philip's half-brother, Don John of Austria, who first showed his military skill by putting down a serious revolt of the Moriscos in the Alpuxarras, and was then sent to command the Spanish fleet in the joint expedition of the Mediterranean powers against the Turk. He commanded at the decisive battle of Lepanto in 1571, which stemmed the tide of Turkish conquest. Brave and ambitious, Don John longed for a kingdom, and offered to undertake the conquest of the African coast. But Philip did not wish his brother to gain too much military glory. He sent him in 1576 to succeed Requesens in the Netherlands. Don John was full of great schemes,—to pacify the Netherlands, invade England, release Mary Queen of Scots, and become her husband. But the Spanish treasury was exhausted. Philip would send no more supplies, and left Don John to temporize with the Netherlands, a task for which he was entirely unfit. Overwhelmed with disappointment and the sense of failure, Don John died in 1578, leaving the work which he could not accomplish to be undertaken by the patient genius of Alexander Farnese.

Don John had had the art of impressing his great schemes on those around him. He sent his secretary, Escovedo, to urge his wishes on Philip, whose jealous mind was filled with suspicion. Escovedo awakened the personal dislike of Antonio Perez, and was murdered by that minister's instrumentality (see PEREZ). The fall of the old parties in the council brought forward new men and inaugurated a new policy. Cardinal Granvella, Juan Idiaquez, and Christoval de Moura became the king's chief advisers. They were men who depended solely on his favour, and were not connected with the old nobility of Castile. Hitherto Philip's policy had been in the main pacific. He had aimed at the internal consolidation of the monarchy, and had striven by every means to overcome the revolt of the Netherlands. But the resolute temper of the Netherlands was encouraged by hopes of foreign help. England, France, and even Austria in turn displayed their jealousy of Philip's power by helping to keep alive the insurrection. Round the revolt of the Netherlands centred the chief questions of European politics. Philip at length determined to make the subjection of the rebellious provinces part of a great scheme to extend the power of Spain over Europe. In the second period of his reign he came forward as the disturber of European peace, determined to reduce western Christendom to religious unity under his own rule. He interfered in the internal politics of every country and seized on every opportunity for pursuing his own schemes. His first step in the career of aggrandizement was taken in 1580 by the reduction of Portugal, when he claimed the vacant crown by right of his mother. The duke of Alva overran the country before any other power had time to interfere. The last of the great Spanish nobles, who had already felt the weight of the king's displeasure, was still a willing instrument in extending the royal despotism. Philip succeeded in impressing on Spain an unreasoning loyalty, which took

the place of its old chivalrous patriotism. In the Netherlands he put William of Orange under the ban, and the assassination of William was the first sign of the fanatical bitterness which Philip was ready to encourage and to use. In France he resolved to check the power of the court and obtain an influence over French affairs. The strongly Catholic party resented the favour shown by Henry III. to the Huguenots, and was anxious about the succession to the crown. Headed by the Guises, they formed a league with Philip in January 1585, which plunged France into long and bitter warfare. The rapid advance of the League in France and the successes of Alexander Farnese in the Netherlands awakened the alarm of England. Troops were sent to the Netherlands, and the English privateers redoubled their attacks upon the treasure-ships of the Indies in the Spanish Main. Resolved to remove all hindrances from his path, Philip undertook the reduction of England. He trusted to the strength of the Spanish navy, the military skill of Alexander Farnese, and the discontent of the English Catholics. In 1588 the French king had become a mere instrument of the League, and Philip sent against England the "Invincible Armada." Its failure involved the failure of all his schemes, though this fact was not at first obvious. Philip bore his loss with resignation. "I sent my ships," he said, "against men, not against the billows. I thank God that I can place another fleet upon the sea." But he was never able to renew his attack upon England. The murder of Henry III. of France raised the question of the succession to the French crown, and Philip's protectorate over the titular Charles X. was admitted. On the death of Charles the Catholic party were willing to recognize Philip's daughter Isabella as their queen. But the resolute bearing of Henry of Navarre kindled anew the national feeling, and the discussions about Isabella's future husband brought political questions into the foreground and weakened the cohesion of the League. The death of Alexander Farnese in 1592 deprived Philip of the great general who alone could hold in check Henry of Navarre, and Henry's change of religion and absolution by the pope in 1593 did much to remove the religious difficulty to his recognition by all parties in France. Philip's schemes for a general European ascendancy entirely failed. He could not even recover the Netherlands for the Spanish monarchy. The northern provinces, banded together as the United Netherlands, made good their independence. The southern provinces returned to their obedience, but were ceded by Philip to his daughter Isabella and her husband Albert of Austria. The English cruisers became more and more dangerous in the Spanish Main, and in 1596 the English fleet sacked Cadiz. Philip II.'s reign ended in general failure. His resources were exhausted, and in 1597 he repudiated his debts. His economic policy was disastrous. He checked commerce by unwise taxes, trusted unduly to the wealth of the Indies, and encouraged the indolent haughtiness of the Castilians. He raised Spain to a high position, but left it with a ruinous system of government, which could only end in financial decay. Yet he was resolute and persevering to the end. He bore with constancy a painful and lingering illness, and his last words were, "I die like a good Catholic, in faith and obedience to the Holy Roman Church." But he knew that he left a feeble successor. His jealous temper showed itself in the narrow education and secluded life which he prescribed for his son, and thereby intensified the boy's natural timidity. "God has not been pleased," he sadly said at the last, "to grant me a successor capable of ruling any great realm." He died at the Escorial in September 1598.

Philip II.'s character is impressed on the great archi-

tektural monument of his reign, the Escorial, built in the solitude of the Guadarrama hills. The mighty mass of buildings contained a monastery, a burying-place for the royal house, and a palace for the king. It was built in consequence of a vow made at the battle of St Quentin. The battle was fought on St Lawrence's day 1557, and this fact was commemorated by arranging the building in the form of a gridiron. The cloister of the monastery supplied the bars, and the royal palace projected like the handle. Philip loved solitude. It harmonized with his habits of quiet industry. He governed his dominions by means of despatches, as a merchant seated in his office transacts commercial business in different quarters of the globe. All that could be done by patient industry, without political insight, Philip II. did. His strength lay in his steady persistency. During his reign he was the foremost figure in European history, but the only work which he accomplished was the formation of the Spanish character into the definite shape in which it influenced European culture.

PHILIP III. (1578-1621), king of Spain, son of Philip II. by his fourth wife, Anne of Austria, was born at Madrid on 14th April 1578, succeeded his father on 13th September 1598, married Margaret of Austria on 18th April 1599, and died at Madrid on 31st March 1621. In personal character he was weak and indolent, and his time was mostly spent at the Escorial in hunting and other pursuits of a private country gentleman, while the conduct of public affairs was left almost entirely in the hands of the duke of Lerma, who held the office of first minister from the king's accession until October 1618. See SPAIN.

PHILIP IV. (1605-1665), king of Spain, son of Philip III., was born at Valladolid on 8th April 1605, was married to Isabella of France on 25th November 1615, succeeded his father on 31st March 1621, and died on 17th September 1665. From 1621 to 1643 the well-known duke of Olivares held the reins of real power in the Peninsula; he was afterwards succeeded by the duke of Carpio. See SPAIN.

PHILIP V. (1683-1746), king of Spain, was the second son of the French dauphin, Louis, by his wife Maria Anna of Bavaria, and was born at Versailles on 19th December 1683. In 1700 Philip, at that time duke of Anjou, was called by the testament of the childless Charles II. to the throne of Spain. Quitting Versailles to take possession of his inheritance on 4th December, he arrived at the Buen-Retiro palace in Madrid on 18th February of the following year. At their parting his grandfather, Louis XIV., who a few months previously had concluded with England and Holland a treaty for the partition of the Spanish dominions, exhorted him to be a good Spaniard, but never to forget that he had been born a Frenchman; it was on the same occasion that he uttered the famous *mot*, "Mon fils, il n'y a plus de Pyrénées." Philip's recognition as king by the other European powers did not take place until the war of the Spanish succession was brought to an end by the treaty of Utrecht in 1713. In 1702 he married Maria Louisa, daughter of Victor Amadeus, duke of Savoy; shortly after her death in February 1714, which he felt deeply, he married Elizabeth Farnese (December), a step to which he was advised by the then

all-powerful princesse des Ursins. The disgrace of the princess immediately followed, and her place in the royal counsels was taken by ALBERONI (*q.v.*), who remained in power till December 1719. In 1724 Philip, under the influence of a profound melancholy which had seized him, resigned the crown by royal decree, dated 14th January 1724, in favour of his eldest son, Louis, who, however, died after a short reign of only seven months. Philip died on 9th July 1746 and was succeeded by his son, Ferdinand VI. See SPAIN.

PHILIP. For the dukes of Burgundy of this name, surnamed respectively "the Bold" (1342-1404) and "the Good" (1396-1467), see BURGUNDY, vol. iv. p. 536, and FRANCE, vol. ix. p. 548. For Archduke Philip, "the Handsome," see PHILIP I. of Castile and Aragon (p. 743).

PHILIP OF SWABIA (*c.* 1170-1208), rival of the emperor OTHO IV. (*q.v.*), younger son of the emperor Frederick I., was born about 1170. He was originally intended for the church, and, after being provost of Aix-la-Chapelle, was chosen bishop of Würzburg in 1191; but in 1195 his elder brother brought about his marriage with a Byzantine princess, Irene, on which occasion he was named duke of Tuscany and Spoleto. In the following year he received also the duchy of Swabia. On the death of his elder brother he was elected king by a large body of princes and prelates at Mühlhausen (March 1198); this, however, was not acquiesced in by those opposed to the continuance of the imperial crown in the house of Hohenstaufen, whose choice fell on Otho. The coronation of the latter at Aix-la-Chapelle in July was soon followed by that of his rival at Mainz, and a civil war ensued, which, carried on with varying fortunes for ten years, was only brought to an end by the murder of Philip by Otho of Wittelsbach at Bamberg on 21st June 1208.

PHILIPPI, a city of ancient Macedonia, on a steep hill near the river Gangites (now the Angista), overlooking an extensive plain and at no great distance from the coast of the Ægean, on the highway between Neapolis (Kavalla) and Thessalonica. Originally called Crenides, or "Fountains," it took the name by which it has become famous from Philip of Macedon, who made himself master of the neighbouring gold-mines of the Hill of Dionysus, and fortified the city as one of his frontier-towns. Octavius and Antony having in 42 B.C. gained a great victory over Brutus and Cassius in the plain of Philippi, the place received a Roman colony, *Colonia Julia Philippensis*, which was probably increased after the battle of Actium (*Col. Aug. Julia Phil.*). The inhabitants received the *Jus Italicum*, and Philippi was one of the cities specially designated as "first cities" (*πρώτη . . . πόλις*, Acts xvi. 12; see Marquardt, *Röm. Staatsverwaltung*, vol. i. p. 187). It was the scene of a striking incident in the life of St Paul, and it was to his converts here that he addressed the epistle noticed below. The site of the city, now altogether uninhabited, is marked by a number of ruins—the substructions of an amphitheatre, parts of a great temple of Claudius, &c.—which have furnished a variety of interesting inscriptions. At a little distance to the east is a huge stone monument, known to the Turks as Dikelitash and to the Greeks as the Manger of Bucephalus.

See Clarke's *Travels*, iii.; Hackett, in *Bible Union Quarterly*, 1860; Heuzey, *Mission arch. en Macédoine*, and C. I. L., iii. 1.

PHILIPPIANS, EPISTLE TO THE. This is one of the most characteristic of the letters of St Paul. It was addressed to the community at Philippi (see above), the first important European city which St Paul had visited, where he had formed a community with the apparently new organization of "bishops" and "deacons," and with which he had relations of especial intimacy. The immediate occasion of his writing the letter was his receipt of money

which the Philippians had sent by Epaphroditus to supply St Paul's personal wants. They were probably wealthier than some of the other communities which he had founded, and consequently he had not the reluctance which he felt elsewhere to receive money from them; the money so sent was no doubt part of the offerings of the community which constituted the Christian sacrifice (iv. 18),—a fund which was administered by the officers of administration, i.e., the bishops and deacons. It was consequently to those officers that he specially addressed his acknowledgment of it.

He begins by a warm recognition of their steadfastness in the faith and of their sympathy with him (i. 3-7), and, as he is certain that their steadfastness will continue, so he prays that their love may abound more and more in enlightened well-doing (i. 9-11). He proceeds to tell them about himself and about other preachers of the gospel at Rome: as for himself, he is full of hope because his imprisonment has tended to make the gospel known, and has emboldened others to "speak the word of God without fear"; as for other preachers (probably the Jewish Christians who denied his apostleship and disparaged his special teaching), though some of them preach insincerely and controversially, yet, whatever be their motive, "Christ is proclaimed," and therein he finds cause of rejoicing (i. 12-18). His position is critical, for he may be condemned to death; but, whether he lives or dies, Christ will be glorified through him, so that he cannot tell which he would prefer; for himself it would be far better "to depart and to be with Christ," but for the Philippians it is better that he should "abide in the flesh" (i. 19-24). Hence he feels confident that he will live, and that he will see the Philippians again; and hence also he exhorts them not to be discouraged by persecutions, and to be at unity among themselves (i. 25, ii. 2). The reason for this second exhortation is uncertain: it may be that the differences of race at Philippi, the mingling of Romans and Greeks, of Europeans and Asiatics, had led to the factious assertion by each race of its own superiority, or it may be, though less probably, that there as elsewhere the feud raged between Gentile and Jewish Christians. And, since faction comes of self-assertion, he urges as its antidote the cultivation of "lowliness of mind," which he enforces by the great example of Jesus Christ, who, so far from asserting the divinity which belonged to Him, emptied Himself of it and took the form of a bond-servant; to this St Paul adds a strong appeal on his own account, that his work among them may not seem to have been in vain (ii. 3-18). He then, with an expression of regret that some of his fellow-workers are no longer with him, announces that he hopes to send Timothy to them as soon as he knows the issue of his coming trial; and he is hopeful that he may be able to go himself; however that may be, he sends back their own messenger, Epaphroditus, who after coming to Rome had almost sacrificed his life in the energy of his work (ii. 19-30). Then follows an abrupt transition to another subject, which has sometimes been thought to mark the commencement of a new letter. He suddenly begins to warn the Philippians in strong terms against false teachers, either Judaizing Christians, or, more probably, Jews, who were preaching the necessity of circumcision (Holsten thinks that there is a reference to the murder of James the Just); he maintains that, although he was himself a "Hebrew of Hebrews," and therefore possessed whatever "confidence in the flesh" such a one might claim, yet he counted it all as "loss" in order that he might gain "the righteousness which is of God by faith"; and borrowing a metaphor from the Greek games he regards this as a prize which has to be won by a continuous effort (iii. 2-16). He urges the Philippians to follow him in this struggle towards moral perfection, in contrast

either to the Christians who had lapsed into Epicureanism or, as some think, to the antinomian Jews (iii. 17, iv. 1). He then gives some personal messages to Enodia and Syntyche (whom Schwegler considers to be personifications of the Jewish and heathen Christian parties respectively), and to Synzygus (or, if the word be not a proper name, an anonymous "yoke-fellow" who has been variously supposed to be Paul's wife, Clement of Rome, St Peter, Lydia the purple-seller, or Epaphroditus), and mentions "Clement," about whom it has been much discussed, but to little purpose, whether he was a Philippian or a Roman, and, if the latter, whether he was the same person who figures in early legends as bishop of Rome, or whether, as Baur thinks, the name is really that of the Flavius Clemens who was condemned under Domitian for "atheism." The personal messages are followed by general exhortations to joyfulness, forbearance, trustfulness, and steadfastness in Christian virtue; and then comes that which was probably the special occasion of writing, an acknowledgment of the money which they had sent to him (iv. 4-20).

It is the more probable opinion that the epistle was written from Rome, and not from Caesarea; whether it was written in the earlier or the later period of his stay, there is a question which has been much discussed, but which the scantiness of the evidence respecting that stay, does not allow of being satisfactorily answered; most writers (De Wette, Wieseler, Wiesinger, Meyer) place it in the later period, others (Bleek, Ewald, Beyschlag, Lightfoot) in the earlier; the latter view is more probable on account of the general agreement of this epistle with the epistle to the Romans. It throws an interesting light on St Paul's external relations. He was a prisoner, probably in charge of the prefect of the praetorian guard, and consequently with opportunities of making the gospel known among the soldiers; and the mention of Caesar's household, though no doubt that term covered a large number of scattered individuals, makes it possible that he was lodged near the imperial palace on the Palatine.

The genuineness of the epistle was attacked by Baur on three grounds, which he himself states to be (1) the appearance of gnostic ideas in ii. 6-11, (2) the want of anything distinctively Pauline, (3) the questionableness of some of the historical data.¹ The attack has been renewed by one section of his followers; but it is generally admitted even by critics who reject the epistles to the Ephesians and Colossians² that the attack upon this epistle has failed. The supposed gnosticism of ii. 5-11 is not proved; the supposed identification of Clement (iv. 3) with Flavius Clemens, the cousin of Domitian, is merely an arbitrary guess; and the list of expressions which are not found in other epistles of St Paul is not greater than may reasonably be expected from the differences in the subject-matter.³

The doctrinal importance of the epistle is considerable, for it contains a passage which, if it could be certainly understood, would be at once the key and the summary of St Paul's Christology. In 2 Corinthians viii. 9 he had

¹ Paul, E. T., vol. ii. p. 45; *Theol. Jahrb.*, 1849, 501, which is partly reprinted as an addendum in Paul, E. T., vol. ii. p. 64.

² E.g., Hilgenfeld, *Einleitung*, p. 333; Renan, *St Paul*, p. 6; Pfleiderer, *Paulinism*, E. T., vol. i. p. 29.

³ Baur was followed in this attack by Schwegler (*Das nachapost. Zeitalter*, vol. ii. p. 133) and Volkmar (in the *Theol. Jahrb.*, 1856, p. 309); and he was answered by Lünemann (*Pauli ad Philipp. Epist. . . . defendit*, Göttingen, 1847), Bruckner (*Epist. ad Philipp. . . vindicata*, Leipzig, 1848), Hilgenfeld (in the *Zeitschr. f. wissenschaftl. Theol.*, 1871, p. 309). A new attack was made by Hinsch in the same *Zeitschrift*, 1873, p. 59 (criticized by Hilgenfeld, *ibid.*, p. 178), and by Holsten in the *Jahrb. f. prot. Theol.* (1875, p. 425; 1876, p. 58), which has been met by the important treatise of P. W. Schmidt, *Neutestamentliche Hyperkritik*, Berlin, 1880.

said of Christ that "though He was rich yet for your sakes He became poor"; in Philippians ii. 5-7 this is expanded into the explicit declaration that "being in the form of God He counted it not a prize (!) to be equal with God, but emptied Himself, taking the form of a servant, being made in the likeness of men." Each phrase of the passage is of great significance, but it is also of great uncertainty of meaning: the main points of uncertainty are (1) whether the subject of the sentence is the incarnate or the pre-incarnate Christ; (2) what is implied by the phrase "in the form of God," and what is its relation to the phrase "to be equal with God," some thinking that it implies an identity, others an inferiority of status; (3) what is meant by the word here rendered "prize" (*ἀπραγμόν*), some thinking that this is the right rendering, and that the meaning is "He did not tenaciously cling to His divinity but surrendered it," others thinking that it should be rendered "an act of robbery," and that the meaning is "He did not think it a usurpation to assert His divinity"; (4) what is meant by "emptied Himself," whether He only divested Himself of the outward semblance of divinity, or whether He reduced Himself to the bare consciousness of personality in becoming incarnate; this last question, that of the nature of the *kenosis*, has bearings of especial importance on the general doctrine of the Person of Christ.

Discussions of these questions from various points of view will be found not only in commentaries on the passage (e.g., Lightfoot) and works on New Testament theology (e.g., Weiss), but more particularly in Baur, *Paul*, E. T., vol. ii. p. 45 (who thinks that the conceptions are gnostic and un-Pauline); Ernesti, in *Studien u. Kritiken*, 1848, p. 889, and 1851, p. 602 (who thinks that *ἀπραγμόν* refers by way of contrast to the first Adam, who tried to seize what was not his own); Hilgenfeld, in the *Zeitschr. f. wissenschaftl. Theol.*, 1871, p. 192, and *ibid.*, 1873, p. 178; Grimm, *ibid.*, 1873, p. 33; Hinsch, *ibid.*, 1873, p. 59; R. Schmidt, *Paulinische Christologie*, 1870, p. 163 (whose explanation deserves especial consideration); Pfeiderer, *Paulinism*, E. T., vol. i. p. 146; and more recently Weiffenbach, *Zur Auslegung der Stelle Phil.*, ii. 5-11, Karlsruhe, 1884. For the question as to the nature of the *kenosis*, see Gess, *Die Lehre von der Person Christi*, Basel, 1856, pp. 81, 294.

The best modern editions of the epistle are those of B. Weiss, *Der Philipperbrief ausgelegt*, Leipzig, 1859, and Lightfoot, *The Epistle to the Philippians*, 3d ed., London, 1873. (E. HA.)

PHILIPPICUS, or PHILEPICUS, emperor of Constantinople from December 711 to June 713, was the son of the patrician Nicephorus, and became distinguished as a soldier under Justinian II. His proper name was Bardanes. Relying on the support of the Monothelete party, he made some pretensions to the throne on the outbreak of the first great rebellion against Justinian; these led to his relegation to Cephalaria by Tiberius Absimar, and subsequently to his banishment, by order of Justinian, to Cherson. Here Bardanes, taking the name of Philippicus, successfully incited the inhabitants to revolt against a prince who had made them the objects of one of his most vindictive expeditions, and on the assassination of Justinian in Asia Minor he at once assumed the purple. Among his first acts were the deposition of Cyrus, the orthodox patriarch of Constantinople, in favour of John, a member of his own sect, and the summoning of a "conciliabulum" of Eastern bishops which abolished the canons of the sixth general council, and restored to the diptychs the names of Sergius and Honorius. Meanwhile Terbelis, king of the Bulgarians, attacked Constantinople, burning some of its suburbs and carrying off many prisoners and much booty, while shortly afterwards the Saracens made similar inroads from the Asiatic side. The short reign of Philippicus was brought to a close through a conspiracy headed by two of his generals, who caused him to be blinded in the hippodrome in June 713. Of the remainder of his life nothing is known. He was succeeded by his secretary, Artemius, known as Anastasius II.

PHILIPPINE ISLANDS (Span. *Islas Filipinas*), or PHILIPPINES, an archipelago in the south-east of Asia, extending from 4° 40' to 20° N. lat., and from 116° 40' to 126° 30' E. long. On the west and north-west it is separated by the China Sea from China and the Indo-Chinese peninsula; towards the east lies the Pacific; on the north a number of smaller islands stretch out towards Formosa; and on the south, while a double connexion with Borneo is formed by the lines of the Palawan and Balabac and the Sulu Islands, the basin of the Celebes Sea, with a central depth of from 1000 to 2600 fathoms, extends, for a distance of 300 miles, between its southernmost island (Mindanao) and Celebes. As the number of the Philippines is believed to exceed 1400, and the larger islands are in several cases only beginning to be properly explored, it is impossible to give a definitive statement of their aggregate land-area. A measurement on Domann's map (1882) resulted in 114,356 square miles. Nor is it in regard to the area alone that our knowledge is defective. Though for three centuries the greater part of the territory has been nominally in Spanish possession, the interior of some of the larger islands has never been surveyed; several of the native tribes, especially in Mindanao, are altogether independent; the geology of Luzon, the best known of all the archipelago, is to a large extent matter of conjecture; and the visit of a passing botanist or naturalist is enough to add facts of primary importance to the register of flora and fauna. While none of the summits, with the exception perhaps of Apo¹ in Mindanao, exceeds 9000 feet—the loftiest probably being Halcón in Mindoro (8865 feet), Malindang in Mindanao (8685 feet), Mayon in Luzon (8275 feet), and Malaspina in Negros (8190 feet)—all the islands may be described in general as mountainous and hilly. The principal ranges have a tendency to run north and south, with a certain amount of deflexion east or west, as the case may be, so that the orographic diagram of the archipelago as a whole would have a certain similarity to a fan with northern Luzon as its centre of radiation. The geologist finds his task in the Philippines exceptionally difficult, owing to so much of the surface being covered with a dense vegetation, which often obliges him to be contented with no better indication than the pebbles of the alluvium. Nowhere, almost, are there cuttings or excavations to open up the records of the rocks. It seems certain, from the frequency not only of large tracts of coral reef along the coasts but of raised beaches at a considerable distance and elevation inland, containing shells similar to those of the adjacent seas, that much of the archipelago has been heaved from below the sea-level within comparatively recent times. As the neck of land between the Bay of Sogod and the Bay of Ragay or Guinayangan and that between this latter bay and the Bay of San Miguel consist of alluvium, tuffs, and marls, with modern shells, it appears probable that the southern parts of Luzon were at no very distant date separate islands. According to Drasche, southern and central Luzon comprises (1) a group of chloritic slates and gneiss; (2) diabases and gabbros; (3) Eocene limestones; (4) volcanic minerals and tuffs; (5) recent formations with marine fossils—tuffs, limestones, clays, and marine and fluvial alluviums. In his travels through the more northern parts of the island the same geologist verified the existence of (1) diorite, gneiss, protogenic and chloritic slates; (2) an extensive system of stratified conglomerates and sandstones; (3) modern volcanic rocks (quartzose trachyte, amphiboliferous and sanidine

¹ According to the Spanish hydrographic maps, the height of this mountain is 8813 feet; but the barometer of Rajal and Montano's expedition (which ascended to the top in 1880) indicated 10,270 feet, and that used by Schadenberg and Koeh in 1882 no less than 10,827 (see *Bull. Soc. de Géogr.*, Paris, 1881, p. 566).

trachyte, amphiboliferous andesite and dolerite); (4) tuffs and tuffaceous sandstones, with banks of limestone and marl; (5) banks of coral and breccia of coraliferous limestone, and recent volcanic products. The late origin of the coraliferous limestone is shown by the corals belonging to genera still existing in the Indian Ocean—*Galaxea*, *Favia*, *Meandrina*, *Porites*, and *Astracopora*—and being specifically similar, though not identical. A remarkable feature is the stratification of the limestone.

Volcanic forces, as has been already implied, have had a great share in shaping the archipelago, and a large number of the mountains bear the stamp of their former activity. But those that still have the credit of being working volcanoes are comparatively few.

Monte Cagua (3910 feet), discovered by Clandio Montero on the north-eastern promontory of Luzon, appears to discharge smoke continually, and the Babuyan group (to the north of Luzon) contains several orifices belonging to the same centre of eruption,—a regular volcano in Babuyan Claro, a solfatara in the Didica rocks, and a volcanic island thrown up in 1856. Of greater importance are the three burning mountains of southern Luzon—Taal, Albay, and Bulusan. Taal lies 45 miles almost due south of Manila. Being only 850 feet high, it is remarkable as one of the lowest volcanoes in the world. The present craters are situated in a small triangular island in the middle of Lake Bombon or Bongbong. A tradition exists (and has been accepted without question by many writers) that this lake, covering an area of 100 square miles, and having in the south and east a depth of 109 fathoms, was formed in 1700 on occasion of a terrible eruption, which undermined the whole mass of a gigantic mountain, 8000 or 9000 feet high; and, whether (for this is extremely doubtful) the event took place within historic times or not, the vast deposits of porous tuff in all the surrounding country appear to show that such a volcano must have existed. The water in the lake is now sweet, but tradition again asserts that it was at one time salt, possibly through direct communication with the sea. As it is exposed to strong evaporation and discharges into the sea by the Pansipit without being recruited by any considerable affluent, it is probably fed by subterranean sources. To the east of Lake Bombon stands the extinct volcano of Maquiling, at whose foot are the hot springs of Los Baños; and about 15 miles farther east is Majajai (7020 feet), of which the last eruption was in 1730. Away in the south-east of Luzon there is quite a series of high volcanic cones,—Isarog, Friga, Mazaraga, and Albay or Mayon. The last, one of the most active volcanoes in the archipelago, is extremely regular in form, rising gradually from a base about 50 miles in circuit. The first partial ascent was made by Esteban Solis in 1592, and the first complete ascent by Paton and Stewart, two young Scotchmen, in 1858. A terrible eruption on 1st February 1814 partially destroyed Camalig, Budiao, Albay, Guinobatan, and Daraga, and proved fatal to 12,000 persons, the matter thrown out forming vast deposits deep enough in some places near the mountain to bury the loftiest trees. A similar fate befell the same district during the eruptions that occurred between 20th July and 24th October 1867. On 31st October 1876 one of the terrible storms for which the Philippines are notorious burst on the mountain; the floods, pouring down the sides of Mayon and sweeping along with them the loose volcanic débris, brought destruction on Manilao, Camalig, Guinobatan, Ligao, Oas, Polangin, Libon, and other places, filling up the roads, breaking down the bridges, and completely ruining upwards of 6000 houses. During 1881 and 1882 the eruptive forces were again exceedingly active. Still farther to the south, in the very extremity of Luzon, stands the volcano of Bulusan, which, after being for a long time apparently extinct, began again to smoke in 1852. According to Jagor (*Reisen*, p. 66), it repeats in striking fashion the forms of Vesuvius, having two peaks,—in the west a bell-shaped dome, the eruption cone, and in the east a high ridge similar to Monte Somma, probably the remains of a great circular crater. As in Vesuvius, the present crater is in the centre of the extinct one. In the island of Negros, 150 miles south-south-west of Bulusan, there is the volcano of Malaspina or Canlaon (8190 feet); the island of Fuego probably takes its name from its volcanic phenomenon; and about 90 miles farther to the south-east a new volcano burst out in 1876 in the island of Camiguin (not to be confounded, as it sometimes is, with Camiguin off the north coast of Luzon), near the village of Catarman. In the great island of Mindanao we have the three volcanoes of Macaturing¹ (Sugut, Polloc, or Cottabató), inland from Ilana Bay, and Apo and Sangail (Sarangani or Butulan), both in the central cordillera and the latter almost at its southern terminus. Though the last great eruption of Cottabató was in 1856, it is still active at intervals, and in 1871 the town of the same name was

partially destroyed by earthquakes. Apo, according to Schadenberg and Koch, has three summits, in the midst of which lies the great crater, now extinct and filled with water. Considerable energy is still displayed by the solfataras and boiling springs lower down.

It is difficult to say how these various volcanoes are related to each other; José Centeno suggests with considerable probability that they form two lines of activity, an eastern comprising Isarog, Albay, Bulusan, Camiguin, Apo, and Butulan, and a western Buguias (extinct), Arayat (extinct), Taal, Canlaon, Macaturing. Three only of the larger islands, it will be observed, contain actual centres of eruption, and some of the larger volcanoes appear to be in the later stages of their activity,—Albay generally discharging an incoherent form of lava, whilst Taal and others discharge nothing but ashes. Other phenomena usually associated with volcanic activity are common enough throughout the archipelago: there is a great deposit of sulphur in the middle of the island of Leyte; inflammable gas bursts out in the south of Panay; and there are hot springs at Buguias, at Los Baños or Maynit, already mentioned, at Pagsanjan, at San Luis or Maynit in Batangas, in the Taysan Mountains, at Tibi or Tivi, &c. At Los Baños there was a regular bathing establishment erected by the Franciscans in 1671; but it was burned down in 1727, and, though rebuilt by public subscription in 1880, may be said to be in a chronic state of decay. The Tibi springs, described in detail by Jagor (*Reisen*, pp. 114, 115), are remarkable for beautiful cones produced by the deposit of siliceous material. The water in some cases is hot enough to cook food. They are situated on the east coast of Luzon on Lagonoy Bay.

Earthquakes.—Earthquakes are sufficiently frequent and violent in the Philippines to affect the style adopted in the erection of buildings; in 1874, for instance, they were very numerous throughout the archipelago, and in Manila and the adjacent provinces shocks were felt daily for several weeks. The most violent earthquakes on record in the Philippines occurred in July 1880, when the destruction of property was immense, both in the capital and in other important towns of central Luzon.

Minerals.—Though hitherto little advantage has been taken of its existence, there appears to be in several of the islands a fair amount of mineral wealth. Two coal-fields are known to exist, one beginning in Caransan in the south of Luzon, and probably extending southwards across the Strait of San Bernardino to Catbalongan in Samar, and another occupying the western slopes of Cebu and the eastern slopes of Negros, and thus probably passing under the Strait of Tañon. In the first basin there is a bed from 10 to 20 feet thick cropping out at Gato, which has given good results as a fuel for steamboats; in the second Centeno reports at least five beds of varying thickness and quality. The first discovery of the mineral was made in Cebu in 1827. Hitherto little success has attended the schemes of exploitation. Iron-ore of excellent purity occurs in various parts of Luzon, in Laguna, Bulacan, Pampanga, Camarines Norte, and notably in the Camachin Mountains between the Bulaon and the Garlan; but, with the exception of a few small foundries in Bulacan province, there are no iron-works in the country. In this department there was actually more activity a century ago. Copper-mines are worked at Mancayan, Suyuc, Bumucum, and Agbaq in the province of Lepanto, by the Cantabro-Philippine Company, founded in 1862; and the heathen natives of that region (perhaps having learned the art from Chinese or Japanese strangers) appear to have long been accustomed to manufacture copper utensils for their own use and for sale in the Christian settlements. The ore at Mancayan contains upwards of 16 per cent. of copper, 24 of sulphur, 5 of antimony, and 5 of arsenic. For a short time after 1847 copper-mines were worked

¹ It was supposed till quite recently that there were two mountains in this district,—one being Macaturing, the other Sugut, Polloc, or Cottabató.

at Assit in the island of Masbate; and it is known that copper ores exist in the provinces of Tayabas and Camarines Sur (Luzon), Antique (Panay), and the island of Capul. Gold is very generally distributed throughout the archipelago, but mostly in insignificant quantities. From the deposits in Camarines Norte (in Paracale, Mambulao, Labo), where it occurs in placers and in quartz and other rocks, about 30 oz. per month are obtained. Much more important are the gold-washings of Misamis and Surigao in Mindanao, the former of which yield about 150 oz. per month. Neither the mercury nor lead veins discovered at different times have proved of economic value.¹

Climate.—As the north part of Luzon is as far from the south of the Sulu Islands as the north of England from the south of Italy, and as the archipelago is divided by the line of the ecliptic, the climate of one region differs considerably from that of another, though the general characteristics are everywhere tropical. The northern islands lie in the region of the typhoons. Three seasons are usually recognized,—a cold, a hot, and a wet. The first extends from November to February or March; the winds are northerly, and, though there is no need for fire, woollen garments can be worn with comfort in the mornings; the sky is for the most part clear and the atmosphere bracing; and Europeans look forward to this period as the most enjoyable of the year. The hot season lasts from March to June, and the heat becomes very oppressive before the beginning of the southerly monsoon. Thunderstorms, often of terrific violence, are of frequent occurrence in May and June. The wet season is usually ushered in by the heavy rains locally known as “collas.” During July, August, September, and October the rain comes down in torrents and large tracts of the lower country are flooded. According to the observations of the Jesuits at Manila during the eight years 1870 to 1877 the total rainfall (distributed over 113 days) amounted to 66·6 inches.

| | | Cold. | Hot. | Wet. |
|--------|-----------------------|--------|--------|--------|
| Manila | Mean temperature..... | 72°·32 | 87°·26 | 84°·56 |
| | Rainfallinches | 8·65 | 10·47 | 36·01 |
| Cebu | Mean temperature..... | 75°·02 | 86°·23 | 75°·86 |
| | Rainfallinches | 12·54 | 9·29 | 26·90 |
| Davao | Mean temperature..... | 86°·90 | 83°·70 | 87°·11 |
| | Rainfallinches | 16·53 | 39·27 | 32·15 |
| Sulu | Mean temperature..... | 81°·98 | 82°·97 | 83°·03 |
| | Rainfallinches | 15·74 | 33·85 | 35·43 |

Fauna.—The mammals of the Philippines are strikingly few, especially when contrasted with those of such an island as Java; but their number may yet be slightly increased, and nine-tenths of them are peculiar species. Since *Cynopithecus niger* was struck out of the list, the only monkey known to science is *Macacus cynomolgus* (chongo of the Tagals), found in all the islands; but there are also pure white monkeys (not albinos) in Mindanao, and specimens are occasionally sold at Manila. The lemuroids are represented by the strange little *Tarsius spectrum*, the insectivora proper by *Galeopithecus philippensis* and a “tupaia,” or squirrel-shrew. Of carnivora there are three species, two civets and a wild cat, as well as the ordinary domestic animal. The rodents comprise only a few squirrels, *Sciurus philippensis*, &c., a porcupine, and two or three rats. Of cats there are between twenty and thirty species. The wild boar is regularly hunted in all the islands; the natives throughout the archipelago keep large numbers of black

pigs; and the Babuyanes group take their name from *babuy*, “a pig.” Of deer there are three species, *Cervus mariannus*, *C. philippensis*, and *C. Alfreidi*; and a chevrotain or mouse-deer (*Tragulus*) is found, more especially in Bataan. Tapa, or sun-dried deer’s flesh, is a favourite food with the natives. The statement that the horse has become wild in the interior of several islands is founded on a mistake. The ordinary domestic variety, probably of Spanish, Chinese, and Japanese origin, is “generally small, but well-shaped and hardy, the largest and best breeds coming from Batangas, Albay, and Camarines, the smallest and probably the hardest from Ilocos” (D. M. Forbes). For all kinds of field work the buffalo (“carabao”) is employed; ordinary cattle and goats are common enough, and some of the former are of great excellence. As there is a Tagalog name for it, it has been supposed that the elephant was at one time to be met with in the Philippines; and in the Sulu Islands, at least, it is said to have existed in the 17th century.

The birds of the Philippines proper show the isolated character of the group by the absence of a large number of ordinary Malayan forms, and at the same time there is a considerable proportion of genera from Australia, India, and China. Viscount Walden (*Trans. Zool. Soc.*, vol. ix., 1877) found the known species numbered 219, and R. B. Sharpe, by the assistance of Professor Steere’s collections, brought the total up to 287 species, of which 151 were peculiar to the Philippines. To these must be added several species hitherto only found in the Sulu Islands. Palawan has a strong Bornean element. It is enough here to mention a number of peculiar woodpeckers, beautiful little parakeets (*Loriculus*), a number of pigeons (including at least one peculiar genus, *Phapitreron*), cockatoos, mound-builders, and a peculiar hornbill, *Penelopides*, known from its note as “calao” to the natives, who frequently tame it. The principal game bird is the jungle-fowl (*Gallus bankiva*).²

Alligators abound in some of the lakes and rivers; and turtles, tortoises, and various kinds of lizards are familiar enough forms; one of the last, the “chacon,” is believed by the natives to be a defence against earthquakes. The beauty and variety of the butterflies and the destructiveness of the termites are obtrusive features of the insect life; the land-shells are peculiar, numerous, and remarkable for delicacy of form and colour. Some of the molluscs attain gigantic dimensions; the “taclebo” shell sometimes weighs 200 lb. and is used for baptismal fonts. One of the most valuable kinds of fish is the “dalag” (*Ophiocephalus vagus*), and one of the most peculiar the *Hemiramphus vivipara*.

Flora.—The flora of the Philippines is essentially Malayan, intermixed with a Chinese element, but with sufficient individuality to constitute a sub-region. According to Llanos’s edition of Manuel Blanco’s *Flora de Filipinas*,³ 4479 species are known belonging to 1223 genera and 155 orders. Among the dicotyledons the orders most abundantly represented are: *Leguminosæ* (77 genera), *Rubiaceæ* and *Compositæ* (each 41), *Euphorbiaceæ* (32), *Urticaceæ* (25), *Acanthaceæ* (28), *Apocynaceæ* (22), *Asclepiadaceæ* (20), *Sapindaceæ* (20); and among the monocotyledons *Orchidaceæ* (80), *Palmæ* (28), *Araceæ* (27), *Graminaceæ* (72). Of ferns there are 50 genera. The forests contain more than 200 kinds of wood thought worthy of trial in the arsenal at Manila. Among them may be mentioned the teak-like molave (*Vitex altissima* and *geniculata*); the dongon (*Sterculia cymbiformis*); the ipel (*Eperua decandra*), greatly prized for its hardness; the lauan or lawaan (*Dipterocarpus thurifer*), a light stringy wood, often used by the Malays for their canoes; the bolongta (*Diospyros pilosanthera*), employed for fine kinds of furniture.

¹ The best résumé of geological facts in regard to the Philippines is J. Roth, “Ueber die geologische Beschaffenheit der Philippinen,” published as an appendix to Jagor’s *Reisen*, but, like the other appendices, left out in the untrustworthy English translation. Drasche gives a good deal of fresh material in *Fragmente zu einer Geologie der Insel Luzon*, reproduced in *Boletín de la Comisión del Mapa Geológico de España*, vol. viii., 1881. Perrey has collected information about the Philippine earthquakes in *Mém. de l’Acad. de Dijon*, 1860, &c.

² See Wallace, *Geogr. Distr. of Animals, and Island Life*.

³ First ed., Manila, 1837; second ed., 1845; Llanos’s ed., 4 vols., 1877-80 (summary in vol. ii.).

Products.—Mangoes, plantains, mangosteen, jack-fruit, medlars, and in general most of the Malayan fruits are to be met with; the lanzon occurs in the north, and the durian in the south, more especially in the Sulu Islands. Rice is the staple food of the natives, but, though it is extensively cultivated, the supply is not always equal to the demand. Sweet potatoes (camote), a kind of yam (psalawan), the ground-nut, and gourds are pretty generally grown, as well as occasionally peas, potatoes, and in the higher regions even wheat. The plants which are of primary commercial importance are tobacco, Manila-hemp, sugar-cane, coffee, and cocoa.

Tobacco was made a Government monopoly by Captain General José Basco y Vargas in 1781, and remained so till 1st July 1882. Though it was free to any one to grow the plant to any extent he pleased, the Government was the only purchaser, fixed its own price, and, paying its debts according to its own convenience, was sometimes three or four years in arrear. Besides, certain districts were bound to furnish a certain quantity of the leaf, and the peasant was thus often forced under severe penalties to devote himself to the tobacco crop when he would have obtained better results from something else. The best tobacco comes from the provinces of Isabela and Cagayan, and it is there that the cultivation is most systematically carried on; but the plant is also grown in other provinces of Luzon (Union, Ilocos, Lepanto, &c.) as well as in the Visayas Islands. The average production in the ten years 1872-81 was 214,400 quintals (each 101.43 English lb), of which 114,400 were from Isabela and Cagayan. About 25,000 quintals were sent to Spain as tribute, and another portion was sold by public auction for foreign export. For tobacco of the first class from Cagayan and Isabela the Government paid in recent years between 13 and 14 dollars per quintal, for the second class between 10 and 11, for the third between 7 and 8, and for the fourth between 6 and 7. About 280 million cigars were manufactured annually in six factories employing 20,000 hands, 95 millions for foreign export and the rest for home consumption. Of the foreign cigars 50 millions went to Singapore, Java, the Moluccas, and India, 30 millions to China and Japan, 4 millions to Australia, and 11 millions to Europe. Hitherto tobacco-planting has been carried on (with few exceptions) only by people of small means; but since the abolition of the monopoly several companies have been started, and the whole condition of the industry will probably soon be greatly modified. Abacá or MANILA-HEMP (*G. v.*) is best grown in the south-east of Luzon, in Samar, Leyte, and Bohol. Its cultivation requires little trouble, and the plantations, usually small, are each the property of a native family. Hand-labour and a few simple machines of native construction are all that is required in the preparation of the fibre. The abacá districts are generally very poor. Coffee was introduced, probably from Brazil, in the latter part of the 18th century, but the first plantation on a large scale was formed only in 1826. The cultivation is now pretty extensive. Philippine coffee appears in the European markets as Manila or Zamboanga coffee. The former, which comes from Batangas, Cavite, and Laguna to the amount of 70,000 piculs (a Spanish picul=140 lb) per annum, is a small but well-flavoured berry; the latter, principally grown in Mindanao and Sulu, which send a good deal of their produce direct to Singapore, is in less repute, because, while the berry is larger, less care is bestowed on the gathering and sorting. France was at one time the only great purchaser of Philippine coffee, but about two-thirds of the crop now finds its way to Spain, England, the Netherlands, and Austria. In general far too little care is given to the plantations. Sugar is extensively cultivated, and the export has increased from 1,399,431 piculs in 1871 to 3,382,664 in 1881. About a third of the whole is produced by Pampanga; and Cavite, Laguna, Pangasinan, Bulacan, and Bataan also contribute. About 1,200,000 piculs are exported from Iloilo, which collects from Panay and Negros, &c. The finest is probably that from Capiz in Panay, where, as in this southern district generally, the violet-coloured cane is grown. Most of the larger plantations (some exceeding 1000 acres) are monastic property, and are leased out to Chinese half-breeds, who are said to succeed better than Europeans. The smaller are cultivated by the proprietors with the assistance of their families and relatives, and less frequently of bond or hired labourers. A tendency has shown itself since 1870 to erect larger estates, and to import better machinery; but it will be some time before the Philippine sugar-crop is generally treated according to scientific methods. The finest Manila quality is sent to Spain, and the secondary qualities to England; for the Iloilo sugars the United States are the principal destination.

Trade.—Before the conquest there was considerable commercial intercourse between the Philippines and China and Japan, but this, which would naturally have developed enormously if the Spanish trade between Manila and America (Navidad and Acapulco) had been left free, was interrupted, and at times almost completely stopped, by a series of absurd restrictions, devised in the supposed interest of the trade between Spain and America. For a long period only a single galleon, under Government supervision, was allowed to proceed yearly from Manila to Acapulco, the value of the cargo each way being bound not to exceed a certain sum. Direct trade

with Europe *via* the Cape was commenced in 1764; but, as if the exclusion of all except Spanish ships was not sufficient, a practical monopoly of this field of enterprise was in 1785 bestowed on the Royal Company of the Philippines. With the close of the 18th century a certain amount of liberty began to be conceded to foreign vessels; the first English commercial house was established at Manila in 1809; and in 1834 the monopoly of the Royal Company expired. Manila remained the only port for foreign trade till 1842, when Cebu was also opened; Zamboanga (Mindanao), Iloilo (Panay), Sual (Luzon), Legazpi or Albay (Luzon), and Tacloban (Leyte) are now in the same category, but only Manila, Iloilo, and Cebu have proved of real importance, as they are the only ports where foreign-bound vessels have hitherto loaded. The following table shows how rapidly the trade of the country has recently developed.

| | Entered. | | Cleared. | | Spanish. | | British. | |
|------|----------|---------|----------|---------|----------|---------|----------|---------|
| | Vessels. | Tons. | Vessels. | Tons. | Vessels. | Tons. | Vessels. | Tons. |
| 1875 | 841 | 235,418 | 315 | 222,613 | 232 | 87,593 | 245 | 186,983 |
| 1876 | 311 | 216,785 | 311 | 224,442 | 194 | 80,001 | 241 | 186,631 |
| 1877 | 356 | 251,417 | 351 | 249,649 | 268 | 104,344 | 220 | 187,585 |
| 1878 | 445 | 303,420 | 446 | 305,168 | 369 | 173,401 | 314 | 234,848 |
| 1879 | 458 | 317,069 | 479 | 325,695 | 395 | 231,432 | 318 | 212,695 |
| 1880 | 542 | 449,937 | 524 | 459,145 | 454 | 391,312 | 328 | 201,966 |

The American trade increased in this period from 101 vessels (129,439 tons) to 164 (202,653). The value of the imports rose from \$11,987,162 to \$25,493,319 and of the exports from \$14,837,796 to \$23,450,285. In 1883 333 vessels (270,000 tons) entered at Manila alone, the Spanish numbering 110 (93,000 tons) and the British 132 (92,000 tons); the exports in the same year were valued at \$29,996,000.

The manufactures of the Philippines consist of a variety of textile fabrics (piña fibres, silk, cotton), some of great excellence and beauty, hats, mats, baskets, ropes, furniture, coarse pottery, carriages, and musical instruments.

Islands and Provinces.—The *Batanes* and *Babuyan*, the most northerly of the Philippines, have an area of only 280 square miles, with 8700 inhabitants, who pay no tribute. The rearing of horses is the principal occupation. The chief settlement is San José de Ibana in the island of Batan. Camiguin, the southernmost of the Babuyanes, is about 30 miles from the coast of Luzon.

Luzon or Luçon, with an area of 40,885 square miles, is the largest island in the whole archipelago, and as the seat of the Government at Manila it is the most important. The northern trunk, so to speak, extends north and south for 340 miles. From the mountains known as Caraballos of Balar or Nueva Ecija two ranges bifurcate and stretch northward—the Sierra Oriental, skirting the eastern coast till it ends at Cape Engaño, and the Sierra Occidental, keeping all the way at a distance of 25 or 30 miles from the western. Between these ranges lies the basin of the Rio Grande de Cagayan, which with its numerous affluents (Bangang, Nayan, Mayat, Pongul, Ibulao, &c., from the east; Calao, Cabagan, Pinaanauaung, and Tulay from the west) forms the largest river-system in the whole archipelago. On the western slopes of the Sierra Occidental rise two other large rivers—the Abra, which reaches the sea at Vigan or Villa Fernandina, and the Agno, which after a winding course falls into the Gulf of Lingayan. To the south-west of the mountains extends a comparatively flat region, which continues southwards to the Bay of Manila and forms one of the richest agricultural districts in the island. It is watered by the lower part of the Agno and its lower tributaries, and the Rio Grande de Pampanga with its affluents, which ultimately discharges into Manila Bay, and thus forms a convenient water-way for conveying produce to the capital. There are also in these lowlands a number of extensive lagoons, such as that of Candava. To the west of the flat region the country rises into the considerable Cordillera de Zambales, which contains a number of peaks 5000 or 6000 feet high, and terminates northwards in a great peninsula forming the Gulf of Lingayan and southwards in a similar promontory (Sierra de Mariveles) which helps to form the Bay of Manila. To the east and south of this bay the general configuration is again hilly and even mountainous; but the large area of 350 square miles is occupied by the Laguna de Bay, connected with Manila by the Pasig, on which small steamers ply. The depth of this basin, though the southern side is bordered by a semicircular range of extinct volcanoes 6000 or 7000 feet high, seldom exceeds 4 fathoms. Two long capes project from the northern side, the western one being continued by the island of Talim. From the south-east corner of the trunk of Luzon there extends for 180 miles a very irregular peninsula formed by a series of cordilleras running in a north-westerly and south-easterly direction. The following are the provinces and districts into which Luzon is divided, with their chief towns: *Manila* (258,274 inhabitants in 1877), *Manila*; *Bulacan* (252,149), *Bulacan*; *Pampanga* (226,309), *Bacolor*; *Principe* (4158),

1 The figures of the censuses may be trusted for the provinces of Luzon, &c., but often give no idea of the actual native population of the remoter districts.

Baler; *Dataan* (49,999), *Balanga*; *Zambales* (94,551), *Iba*; *Pangasinan* (293,291) *Lingayen*; *Union* (113,370), *S. Fernando*; *Ilocos Sur* (201,049), *Vigan*; *Ilocos Norte* (156,715), *Laoag*; *Abra* (42,647), *Bangued*; *Cagayan* (72,697), *Tuguegarao*; *Isabela* (38,616), *Tumauini*; *Nueva Vizcaya* (16,107), *Bayombong*; *Nueva Ecija* (123,771), *San Isidro*; *Laguna* (132,504), *Santa Cruz*; *Cavite* (132,064), *Cavite*; *Batangas* (275,075), *Batangas*; *Tayabas* (53,668), *Tayabas*; *Camarines Norte* (30,661), *Daet*; *Camarines Sur* (156,400), *Nueva Caceres*; *Albay* (257,533), *Albay*.

To the south-east of Luzon lie the Visayas—Samar, Leyte, Bohol, Cebu, Negros, and Panay, with various smaller islands.

Samar (area, 4367 square miles) is separated from the Albay peninsula by the Strait of San Bernardino, 10 miles across. From north-west to south-east it is 120 miles long; its greatest breadth is 60 miles. The provincial capital is Catbalogan on the west coast, on a bay difficult of access. The island is watered by a number of considerable streams—the Catubig, Loquilecum or Ulut, Suribao, &c. At Nipa-Nipa on the south-west coast there is a remarkable series of rock-caves in which the people were wont to deposit their dead in coffins.¹ The narrow but extremely beautiful Strait of S. Juanico separates Samar from the island of Leyte. The lesser islands of Buat, Parasan, &c., are included in the province of Samar (178,890 inhabitants). *Leyte* (2716 square miles) is 100 miles long and 30 miles wide. The chief town and port, Tacloban, lies at the eastern entrance of the Strait of S. Juanico. Sulphur for the Manila powder-factory is obtained from the solfatara at Monte Manacagan. According to Jager, the east coast is rising and the west is suffering from the encroachments of the sea at Ormoc to the extent of fifty yards in six years. South-west of Leyte is *Bohol* (area, 1496 square miles); the chief town is Tagbilaran, at the south-west corner. The province (226,546 inhabitants) comprises Siquijor and other islands. The important island of *Cebu* (2413 square miles; provincial population, 403,405) is 135 miles long from north to south, but only 30 miles broad at the most. The chief town, Cebu, is the capital of the Visayas group and is next to Iloilo in the matter of commerce. It is only along the coast that cultivation is easy, and none of the villages lie far inland. Parallel with Cebu and separated from it by a strait 15 miles wide, is *Negros* (4670 square miles; population, 204,669), with large sugar plantations, but only one large town, Jimamaylan, and no good ports. Bacolod is the administrative centre. North-west of Negros lies *Panay* (4633 square miles), which is divided into the three provinces of Antique (124,103), Iloilo (410,430), and Capiz (243,244), in accordance with its physical conformation. Iloilo is the chief town and the seat of the see of Jaro. Off the south-east coast of Panay lies the island of Guimaras (215 square miles).

In a line with the peninsula of Tayabas (Luzon) and the island of Leyte is *Burias* (190 square miles), which forms a province by itself (128 inhabitants), and *Masbate* (1211 square miles) and *Ticao* (121 square miles), which, comparatively sterile and thinly peopled (17,170), are united together. West of these islands is a considerable cluster, *I. de Tablas* (327 square miles), *Sibuyan* (159 square miles), *Romblon*, &c., constituting the province of *Romblon* (28,154). *Mindoro* (3934 square miles), one of the largest of the Philippines, lies only 10 miles south of Luzon, but its interior, peopled by about 30,000 Mangianes, a race of doubtful affinity, is practically unexplored, and its eighteen "Spanish" villages are scattered along the coast at great distances from each other and with no proper means of communication. The principal settlement is Calapan, on the north-east coast. *Marinduque* (348 square miles), included in the province of Mindoro (58,125), is a flourishing island with 48,000 inhabitants exporting various staples. South-west of Mindoro are the *Calamianes* (17,041 inhabitants), a great cluster of very small islands, the two largest being *Busuanga* (416 square miles) and *Calamian*; and beyond these extends for 230 miles in a south-westerly direction the island *Palawan* or *Paragua* (4576 square miles), which nowhere exceeds a width of 30 miles and sometimes narrows to 10. It is little visited, and apart from Puerto Princesa, the chief town (578 inhabitants), there are few Spanish posts. The *Sulu* or *Joló Archipelago* (948 square miles; about 100,000 inhabitants), annexed by Spain in 1878, consists of about 150 islands divided into the Balanguingui, Sulu, Tapul, Kucapoussan, Tawi-Tawi, Tagbabas, and Pangutarang groups. Many of the smaller islands are uninhabited, but the larger are occupied by an industrious Mohammedan population. They formerly constituted, along with a portion of northern Borneo, an independent state with an hereditary sultan and a regular nobility of great political influence. The highest hill in the principal island, Buat Timantangis, or Hill of Tears, is so called because it is the last point visible to the natives as they sail away from their native land. Sulu, the present capital, lies on the north coast of the island of Sulu.³

The whole chain of the Sulus is practically a continuation of the south-western promontory of Mindanao or Maguindanao (37,256 square miles), the second largest island of the archipelago, containing the Spanish provinces of Surigao (56,246), Cottabato (1282). Since about 1876 much light has been thrown on this interesting island⁴ by the Jesuit missionaries. It is remarkably mountainous, and appears to be divided by the Rangaya or Sugut Cordillera, which runs north-west and south-east, and is continued throughout the great western peninsula of Zamboanga, and, at the other extremity, bends south to form the peninsula of Butulan. Between the Rangaya range and that of the Tiruray lies the valley of the Rio Grande, a river navigable as far as Matingcahuan (70 or 80 miles) and connected with two great lakes, Lingauasan and Buluan, which during the rainy season merge, or nearly merge, into one. On the north side of the Rangaya range and connected with the sea by the river Iligan is the great crater-lake of Lanao, which with its little group of secondary crater-lakes probably gave rise to the name of the island, Maguindanao, "Land of Lakes." Towards the east and sloping northwards extend the valleys of the Cagayan, the Tagoloan, and the Agusan. This last is the largest river in the whole island. Rising in the Kinabunan Mountains in the south-east, it pursues a very sinuous course for more than 200 miles and falls into Butuan Bay; in the lower regions it is navigable for craft of considerable burden. Mindanao is throughout well peopled, much of it being occupied by independent Mohammedan sultanates.

Administration, &c.—The Philippines are subject to a governor-general with supreme powers, assisted by (1) a "junta of authorities" instituted in 1850, and consisting of the archbishop, the commander of the forces, the admiral, the president of the supreme court, &c.; (2) a central junta of agriculture, industry, and commerce (dating from 1866); and (3) a council of administration. In the provinces and districts the chief power is in the hands of alcaldes mayores and civico-military governors. The chief magistrate of a commune is known as the *gobernadorcillo* or *capitan*; the native who is responsible for the collection of the tribute of a certain group of families is the *cabeza de barangay*. Every Indian between the ages of 16 and 60 subject to Spain has to pay tribute to the amount of \$1.17—descendants of the first Christians of Cebu, new converts, *gobernadorcillos*, &c., being exempted. Chinese are subject to special taxes; and by a law of 1883 Europeans and Spanish half-castes are required to pay a poll-tax of \$2.50.

Ecclesiastically the Philippines comprise the archbishopric of Manila and the suffragan bishoprics of Nueva-Caceres, Nueva-Segovia, Cebu, and Santa Isabel de Jaro, which were all constituted by the bull of Clement VIII., 14th August 1595, with the exception of the last, whose separation from Cebu dates only from the bull of Pius IX., 27th May 1865. The Agustinos Calzados were established in the Philippines in the year 1565, the first prelate being Andres Urdaneta, and they have convents in Manila, Cebu, and Guadalupe. The Franciscans date from 1577, and have convents at Manila and San Francisco del Monte; the Dominicans (1587) at Manila and San Juan del Monte; the Recollects or Strict Franciscans (1606) at Manila, Cavite, and Cebu. The Jesuits, restored in 1852, maintain the missions of Mindanao and Sulu; and they have charge in Manila of the municipal atheneum, the normal school for primary teachers, and an excellent meteorological observatory. There are also sisters of charity, and nuns of the royal monastery of Santa Clara, founded in 1621.

Education.—A good deal has been done for the diffusion of primary education among the natives (every pueblo is bound to have a school), but the standard is not a high one. The press is under strict civil and ecclesiastical control, and all discussion of Spanish or general European politics is forbidden. Several daily papers, however, are published at Manila, *El Diario de Manila* dating from 1848.

Population.—As far as is known, the original inhabitants of the Philippines were the Aetas or Negritos,⁵ so called from their dark complexion. They still exist sporadically, though in limited numbers (perhaps 25,000), throughout most of the archipelago, the Batanes, Babuyanes, Samar, Leyte, Bohol, and Sulu excepted. Their headquarters are the northern part of Nueva Ecija, the provinces of Principe, Isabela, and Cagayan. To their presence in Isla de Negros the island owed its name. They are dwarfish (4 feet 8 inches being the average stature of the full-grown man), thin and spindle-legged, have a head like a Negro's, with flattish nose, full lips, and thick frizzled black hair, and possess an extraordinary prehensile power in their toes. They tattoo themselves, and wear very little clothing. Cigars they often smoke with the burning end between the teeth—a practice occasionally observed among the civilized Indians. They have no fixed abodes. Honey, game, fish, wild fruits, palm-cabbages, and roots of arums, &c., constitute their food; they sell wax to Christians and Chinese in exchange for betel and tobacco. The dog is their only domestic animal.

¹ For the antiquities discovered there, see *Z. für Ethnol.*, Berlin, 1869.

³ See the elaborate accounts of Koner in *Z. der Ges. für Ethn.*, Berlin, 1867, pp. 105, 142, and of Garin in *Bol. de la Soc. Geo. de Madrid*, 1881, as well as the old report of Dalrymple in *Oriental Repository*.

⁴ See Montano in *Bull. Soc. de Géogr.*, Paris, 1882, and Blumentritt's monograph and map in *Zeitsch. der Ges. für Ethn.*, Berlin, 1884.

⁵ In Mindanao they appear as *Mamauas*.

The Negritos¹ seem to have been driven into the more inaccessible parts by successive invasions of those Malay tribes who in very different stages of civilization and with considerable variety of physical appearance now form the parti-coloured but fairly homogeneous population of the islands.

First among these rank the Tagals. They are by preference inhabitants of the lowlands, and generally fix their pile-built dwellings near water. In Manila, Cavite, Batangas, Bulacan, Morong, Infanta, Tayabas, and Bataan they form the bulk of the population, and they also appear in Zambales, Principe, Isabela, Nueva Ecija, Mindoro, Marinduque, Polillo, &c. Their language (Tagalog) especially has made extensive encroachments on the other Philippine tongues since the conquest. The Tagal is physically well developed, has a round head, high cheek bones, flattish nose, low brow, thickish lips, and large dark eyes. The lines from the nose to the mouth are usually strongly marked. The power of smell is of extraordinary acuteness. A pair of trousers and a shirt worn outside constitute the dress of the men; that of the women differs by the substitution of the saya or gown for the trousers. Agriculture, and especially the cultivation of rice, is the Tagal's staple means of living; they are also great fishers and keep swine, cattle, and vast numbers of ducks and fowls. Externally they are mostly Roman Catholics; but abundant traces of their old superstitions may still be observed. Cock-fighting and theatrical entertainments are in great favour with the Tagals; they have quite a passion for playing on musical instruments, and learn to execute European pieces with great success. Before the arrival of the Spaniards they had an alphabet of their own (see Stanley's translation of Morga), and they still possess a body of lyrical poetry and native melodies. On the death of an adult a feast is sometimes held among the better families, but the funeral itself is conducted after the ordinary Roman Catholic fashion.

The Visayas inhabit all the islands to the south of Luzon, Masbate, Burias, Ticao, and Mindoro, and to the north of Borneo, Sulu, and Mindanao. In the 15th and 16th centuries they were called "Pintados" (i.e., painted people) by the Spaniards. Though they had attained a considerable degree of civilization before the conquest, they readily accepted Christianity and assisted in the subjugation of the Tagals. The mountains in the interior of some of the Visaya Islands are occupied by savage Visayas, generally styled Ilufoles, Montesinos, or Cimarrones. The Calamianes, who inhabit the islands of that name, and the Caragus, who inhabit the east coast of Mindanao from Cape Surigao to Cape St Augustin, are usually classed with the Visayas.

The Igorrotes or Igototes proper (for the name is by many writers very loosely applied to all the pagan mountain tribes of Luzon) inhabit the districts of Bangued, Lepanto, Tiagan, Bontoc. From their cranial characteristics they seem to be distinct from the Tagals and other "Malay" tribes, and they are said to show traces of Chinese and even Japanese intermixture. Dirty and savage-like in person, they are none the less industrious agriculturists—laying out their fields on artificial terraces on the mountain sides, and constructing irrigation canals with remarkable skill; and they also excel as miners and workers in metal. In the matter of sexual morality they form a striking contrast to the licentious Malays; they are monogamists, allow no divorce, and inflict severe punishment for infidelity. Though an attempt to subdue the Igorrotes was made as early as 1660, it was not till 1829 that Spanish supremacy was acknowledged.

For details in regard to the other tribes of the Philippines—the Ilocanos, Pampangos, Pangasinanes, Ibanags or Cagayans, Tinguians (Itanegas or Tinguies), Apayaos, Catalanganes, Vicolis, &c.—the reader is referred to Professor Ferd. Blumentritt's monograph, *Versuch einer Ethnographie der Philippinen*, Gotha, 1882. No fewer than thirty languages are officially recognized. In 1865 it was estimated that Visaya was spoken by upwards of 2,000,000 persons, Tagalog by 1,300,000, Cebuano by 386,000, &c.

Chinese immigrants, in spite of massacres and administrative restrictions, form a powerful element in the Philippines; in Manila alone they numbered 30,000 in 1880, and there is hardly a pueblo of any size in which one or more of them is not to be found. The petty trade and banking are nearly all in their hands. Chinese mestizos or half-breeds (Mestizos de Sanglay, or Mestizos Chinos) are numerous enough to form separate communities; in 1867 they were said to be 211,000 strong. The European element has never been numerically important—some 8000 or 9000 at the most; but there has grown up a considerable body of European mestizos. Traces of Indian sepoys are still seen in the neighbourhood of Manila, where sepoy regiments were quartered for about eighteen months after the conquest of Manila by the English. Owing partly to Philip II.'s prohibition of slavery the Negro is conspicuous by his absence.

There are no accurate statistics of the whole population of the Philippines; and even the number of the Spanish subjects was up till 1877 only estimated according to the number of those who paid tribute. Diaz Arenas in 1833 stated the total at 3,153,290, the

ecclesiastical census of 1876 at 6,173,632, and the civil census of 1877 at 5,561,232; Moya y Jimenez, founding on certain calculations by Del Pan, and admitting an annual increase of 2 per cent., brings the number up to 10,426,000 in 1882.

² *History*.—The Philippine, or, as he called them, the St Lazarus Islands were discovered by Magellan on 12th March 1521, the first place at which he touched being Jomonjol, now Malhou, an islet in the Strait of Surigao between Samar and Dinagat. By 27th April he had lost his life on the island of Mactan off the coast of Cebu. The surrender of the Moluccas by Charles V. in 1529 tended to lessen the interest of the Spaniards in the Islas de Poniente, as they generally called their new discovery, and the Portuguese were too busy in the southern parts of the Indian Archipelago to trouble about the Islas de Oriente, as they preferred to call them. Villalobos, who sailed from Navidad in Mexico with five ships and 370 men in February 1543, accomplished little (though it was he who suggested the present name of the archipelago by calling Samar Filipina); but in 1565 Legazpi founded the Spanish settlement of San Miguel at the town of Cebu, which afterwards became the Villa de Santisimo Nombre de Jesus, and in 1571 determined in large measure the future lines of conquest by fixing the capital at Manila. It is in a letter of Legazpi's in 1567 that the name Islas Filipinas appears for the first time. The subjugation of the islands, thanks to the exertions of the Roman Catholic missionaries and to the large powers which were placed in their hands by Philip, was effected, not of course without fighting and bloodshed, but without those appalling massacres and depopulations which characterized the conquest of South America. Contests with frontier rebellious tribes, attacks by pirates and reprisals on the part of the Spaniards, combine with volcanic eruptions, earthquakes, and tornadoes to break the comparative monotony of the subsequent history. Manila was captured by the English under Draper and Cornish in 1762, and ransomed for £1,000,000; but it was restored in 1764.

Professor Blumentritt published a *Bibliographie der Philippinen* in 1882; minor lists of authorities will be found in *Versuch einer Ethnographie*, in Moya y Jimenez, &c. It is enough to mention Morga, *Sucesos de las Islas Filipinas*, Mexico, 1609 (English translation by Henry E. J. Stanley, Hakluyt Soc., 1868); Chirino, *Relacion de las I. F.*, Rome, 1604; Combez, *Hist. de los Islas de Mindanao, Jolo, &c.*, Madrid, 1667; Agustin, *Conquistas de las I. F.*, Madrid, 1698; Juan de la Concepcion, *Hist. general de Philipinos*, Sampaloc, 1788; Zuñiga, *Hist. de Philipinas*, Sampaloc, 1803 (English partial translation by John Mavor, 1814); Comyn, *Estado de las I. F. en 1810*, Madrid, 1820 (new edition, 1877); Mas, *Informe sobre el Estado de las I. F. en 1842*, Madrid, 1843; Mallat, *Les Philippines*, Paris, 1846; Díez Arenas, *Memorias hist. y estad.*, Manila, 1850; Buzeta and Bravo, *Diccionario estad.*, &c., de las I. F., Madrid, 1850; La Girondière, *Vingt ans aux Philippines*, 1853; Semper, *Die Philippinen u. ihre Bewohner*, Würzburg, 1869; Ferrando, *Hist. de los P. P. Dominicanos en las I. F. en 1882*, Madrid, 1883. (H. A. W.)

PHILIPPOLIS, FILIPPOPEL, and (Turkish) FELIBE, a city of Thracia, previous to 1878 the chief town of a sanjak in the Turkish vilayet of Adrianople, and now the capital of the independent province of Eastern Roumelia and the chief town of one of the six departments, lies 112 miles west-north-west of Adrianople by rail and thus 309 miles from Constantinople, mainly on the right bank of the Maritza (the ancient Hebrus). The railway runs farther up the river to Sarambey and Simcina, but has no direct connexion with the other railway systems of Europe. Highways, however, from Bulgaria, Servia, and Macedonia meet at Philippopolis, which, besides being the centre of an extensive trade, carries on considerable manufactures of silk, cotton, and leather. The city is built partly on a striking group of granite eminences (whence the old Roman name, Trimontium) and partly on the low grounds along the river, which in the outskirts are occupied by rice-fields. On the left side of the river and connected with the city by a long bridge is the suburb of Karshiaka. The population, estimated at 24,000 to 28,000, consists of Bulgarians, and, in smaller proportions, of Greeks, Turks, Armenians, Jews, and Gipsies. A Greek archbishop has his see in the city, and among the public buildings are a number of Greek churches and a Greek lyceum (1868).

Eumolpia, a Thracian town, was captured by Philip of Macedon and made one of his frontier posts; and, though the soldiers seem to have given it the title of "Poneropolis," or City of Hardships, and it was not long afterwards recovered by the Thracians, the name of Philip's City has stuck to it ever since. Under the Romans Philippopolis or Trimontium became the capital of Thracia; and, even after its destruction by the Goths, when 100,000 persons are said to have been slain, it continued to be a flourishing city till it was again laid in ruins by Joannes Romaioctonus, the Bulgarian king. It passed under Turkish rule in 1360; in 1818 it was

destroyed by an earthquake; and in 1846 it suffered from a severe conflagration. During the war of 1877-78 the city was occupied by the Russians.

PHILIPPSBURG, a small town of the grand-duchy of Baden, situated on a sluggish arm of the Rhine, 15 miles to the north of Carlsruhe, was formerly an important fortress of the German empire, and played a somewhat conspicuous part in the wars of the 17th century. It originally belonged to the ecclesiastical principality of Spires, and was named Udenheim, but in 1618 it was fortified and re-christened by Bishop Philip von Sötern. At the peace of Westphalia (1648) the French remained in military possession of Philippsburg, but in 1679 it was restored to Germany, and though again captured by the French in 1688 it was once more restored in 1697. In 1734 the dilapidated fortress fell an easy prey to the French under Marshal Berwick, who, however, lost his life beneath its walls, and in 1800 the works were razed. The town was assigned to Baden in 1803. The population in 1880 was 2549.

PHILIPS, AMBROSE (1671-1749), English man of letters, was born of a good Leicester family in 1671. While at St John's College, Cambridge, he gave evidence of literary taste and skill, in verses forming part of a memorial tribute from the university on the death of Queen Mary. Going to London on the completion of his studies, Philips speedily became "one of the wits at Button's," and thereby a friend of Steele and Addison. He began to write for Tonson, working at such heterogeneous subjects as translated "Persian Tales" and a summary of Hackett's *Life of Archbishop Williams*. The first product really characteristic of the author, after his settlement in London, is the series of *Pastorals* which opened the sixth volume of Tonson's *Miscellanies* (1709). Pope's *Pastorals*, curiously enough, closed the same volume, and the emphatic preference expressed in the *Guardian*, in 1713, for Philips's pastoral style over all other successors to Spenser gave rise to Pope's trenchant ironical paper in No. 40 of the same periodical. The breach between these two wits speedily widened, and Philips was at length concerned in the great quarrel between Pope and Addison. He had come to be a man of some note both for literary work and political activity. The *Spectator* had loaded with praises the drama of *The Distress'd Mother*, which Philips adapted from Racine's *Andromaque* and brought upon the stage in 1712, and he was thus a recognized member of Addison's following. There is some doubt as to the particular part he played in the notorious contest of the two chiefs, but, whether he threatened to beat Pope or not (with the rod which he is said to have hung up at Button's for that purpose), there is ample evidence to show that both Pope and his friends had a bitter feeling towards him. Not only is he honoured with two separate lines in the *Dunciad*, but he figures for illustrative purposes in *Martinus Scriblerus*, and he receives considerable attention in the letters of both Pope and Swift. The latter found occasion for special allusion to Philips during Philips's stay in Ireland, whither he had gone as secretary to Archbishop Boulter. He had done good work in the *Freethinker* (1711) along with Boulter, whose services to the Government in that paper gained him preferment from his position as clergyman in Southwark, first to the bishopric of Bristol and then to the primacy of Ireland. Up to this time Philips had shown disinterested zeal in the Hanoverian cause, though he had received no greater reward than the positions of justice of peace and commissioner of the lottery (1717). He had also written some of his best epistles, while in 1722 he published two more dramatic works—*The Briton* and *Humphry, Duke of Gloucester*—neither of which has had the fortune, like their predecessor, to be immortalized by

romantic criticism. It was, no doubt, a grateful change for Philips to go to Ireland under the patronage of Archbishop Boulter, and to represent, through the same influence, the county of Armagh in the Irish Parliament, while his sense of his own political worth must have been flattered when he became secretary to the lord chancellor in 1726, and in 1733 judge of the prerogative court. After the archbishop's death he by and by returned to London, and dedicated a collected edition of his works to the duke of Newcastle. He died in 1749.

While it can hardly be said that Philips's *Pastorals* show poetic quality of a high order, they must be commended—and perhaps the third in particular—for ease and fluency and rhetorical vigour. In these features they are not surpassed by the pastorals in *The Shepherd's Week*, which Gay wrote, at Pope's instigation, as a burlesque on Philips's work; but the grasp of rustic simplicity and the exquisite play of fancy possessed by Gay are manifest advantages in his performance. The six epistles evince dexterous management of the heroic couplet, an energetic directness of purpose, and (particularly the "winter piece" addressed to the earl of Dorset) a noticeable appreciation of natural beauty. Similar felicitous diction and sympathetic observation, together with a determined bias towards weakness of sentiment, are characteristic of the poet's odes, some of which—addressed to children—gave occasion for various shafts from both Swift and Pope, as well as for the nickname of "Nabby-Pamby," coined by Henry Carey as a descriptive epithet for Philips. The epigrams, and the translations from Pindar, Anacreon, and Sappho, need merely be named as completing the list of the author's works.

See Johnson's *Lives of the Poets*; Spence's *Anecdotes*; the *Spectator*; the *Works* (especially the correspondence) of Pope and Swift; Stephen's *Pope* and Courthope's *Addison*, in *English Men of Letters*.

PHILIPS, JOHN (1676-1708), English man of letters, son of Dr Stephen Philips, archdeacon of Salop, was born at Bampton in Oxfordshire in 1676. After receiving private education at home, he went to Winchester School, and in due course became a student of Christ Church, Oxford. At school he showed special aptitude for exact scholarship, and at the university, under Dean Aldrich, he became one of the most remarkable men of his time. He was an ardent and successful student of the ancient classics, and took special pleasure in making himself thoroughly familiar with Virgil. At the same time he was diligent in his scientific pursuits preparatory to the medical profession he intended to follow, and, although the botany and other branches he made himself familiar with were never actually turned to account in the business of life, his acquired knowledge gave him material for literary purposes. But, over and above these studies, Philips was a careful and critical reader of the English poets that fell in with his tastes, and devoted much time to Chaucer, Spenser, and Milton. When he began to write, the influence of the two former told to some extent on his diction, and he was so enamoured of the strenuous movement and the resonant harmonies of Milton's blank verse that he adapted the form of all his original English writings to that supreme model. Were it for nothing else, John Philips will be remembered as the first to have a genuine literary appreciation of Milton. He was well known in his college for scholarship, taste, and literary resource long before publishing any of his writings, but the appearance of *The Splendid Shilling*, about the year 1703, at once brought him under the favourable notice of critics and readers of poetry. The *Tatler* (No. 250) hailed the poet as the writer of "the best burlesque poem in the British language," nor will the modern reader care to detract much from this verdict, even granting that the model and the imitation, mutually constituting a great revelation to the literary dictators of the period, would cause them considerable surprise. Philips in this poem showed the dexterous ease that comes of long study and perfect familiarity, combined with fertility of resource and humorous ingenuity of application. One important result of the work was the interested notice of the earl of Oxford and Lord Bolingbroke. The poet went to London, and

was asked to celebrate the victory of Blenheim, which he did in his favourite manner, but without conspicuous success. The *Blenheim*, published in 1705, lacks, of course, the element of burlesque, and it is difficult to resist the impression that the poet must have felt himself restrained and hampered by the stern necessity of being seriously sublime. A year later (1706) Philips published, in two books, his didactic poem entitled *Cyder*, which is his most ambitious work and is written in imitation of Virgil's *Georgics*. While there is no denying the poet's admirable familiarity with his original, or his skilful employment of the Miltonic blank verse, or the sustained energy and grace of some of the episodes in the second part, or even his intimate knowledge of the minute details connected with the management of fruit, it cannot be said that the work is a notable contribution to English poetry. It is streaked with genius, but, like the Latin *Ode to St John* (and, for that matter, the author's other works as well), it is little more than the expression of a poetical scholar feeling his way outwards into life. Philips never got beyond the enjoyment of his pipe and his study, both of which figure prominently in all his poems. He was meditating a still further work on the Last Day, when he was cut off by consumption, in 1708, at the early age of thirty-two. His friend Edmund Smith, himself a distinguished scholar and poet, wrote an elegy on the occasion, which Johnson says "justice must place among the best elegies which our language can show." Philips was buried at Hereford, and a monument to his memory, with an inscription from the pen of Atterbury, was erected between those of Chaucer and Drayton in Westminster Abbey.

See Johnson's *Lives of the Poets*, including Smith's *Prefatory Discourse*; Sewall's *Life of Mr John Philips*; the *Tatler*, &c.

PHILIPPUS, M. JULIUS, Roman emperor from 244 to 249 A.D., often called "Philip the Arab," was a native of Bostra or the Trachonitis, who, exchanging the predatory life of the Arabs who hung on the desert borders of the empire for Roman military service, rose to be praetorian prefect in the Persian campaign of Gordian III., and, inspiring the soldiers to mutiny and to slay the young emperor, was raised by them to the purple (244). Of his reign little is known except that he celebrated the secular games with great pomp in 248. A rebellion broke out among the legions of Moesia, and Decius, who was sent to quell it, was forced by the troops to put himself at their head. Philip was defeated near Verona and perished in or after the battle, leaving a very evil reputation. Eusebius knows a current opinion that Philip was a Christian; Jerome and later writers state this as a fact. But at best his Christianity must have been merely nominal and had no effect on his life or reign. With Philip perished his son and colleague, then a boy of twelve, who is known as Philippus II.

PHILISTINES (פְּלִשְׁתִּים), the name of a people which, in the latter part of the age of the Judges and up to the time of David, disputed the sovereignty of Canaan with the Israelites (see ISRAEL, vol. xiii. p. 402 *sq.*). The Philistine country (פְּלִשְׁתִּים, *Palästina*; the authorized version still uses the word in this its original sense as equivalent to Philistia) embraced the rich lowlands on the Mediterranean coast (the Shephelah) from somewhere near Joppa to the Egyptian desert south of Gaza, and was divided between five chief cities, Ashdod or Azotus (*q.v.*), Gaza (*q.v.*), and Askalon (Ashkelon; ASCALON, *q.v.*) on or near the coast, and GATH (*q.v.*) and EKRON (*q.v.*) inland. The five cities, of all of which except Gath the sites are known,¹ formed a confederation under five "lords" (Serānim).²

Ashdod was probably the foremost city of the confederation in the time of Philistine supremacy; for it heads the list in 1 Sam. vi. 17, and it was to the temple of Dagon in Ashdod that the ark was brought after the battle of Aphek or Ebenezer (1 Sam. v. 1). Hebrew tradition recognizes the Philistines as immigrants into Canaan within historical times, like the Israelites and the Aramæans (Amos ix. 7), but unlike the Canaanites. They came, according to Amos, from Caphtor (comp. Jer. xlvii. 4), and Deut. ii. 23 relates that the Caphtorim from Caphtor displaced an earlier race, the 'Avvim, who were not city-dwellers like the Canaanites, but lived in scattered villages. The very name of Philistines probably comes from a Semitic root meaning "to wander"; the Septuagint calls them Ἀλλόφυλοι, "aliens." The date of their immigration cannot be determined with certainty.³ We are scarcely entitled to take Gen. xxi. xxvi., as proving that the inhabitants of Gerar in patriarchal times were identical with the later Philistines, and the other references in the Pentateuch and Joshua are equally inconclusive. The first real sign of the presence of the Philistines is when the Danites, who in the time of Deborah were seated on the sea-coast (Judges v. 17), were compelled—obviously by the pressure of a new enemy—to seek another home far north at the base of Mount Hermon (Judges xviii.). This marks the commencement of the period of Philistine aggression, when the foreigners penetrated into the heart of the Israelite country, broke up the old hegemony of Ephraim at the battle of Ebenezer, and again at the battle of Mount Gilboa destroyed the first attempt at a kingdom of all Israel. The highest power of the Philistines was after the death of Saul, when David, who still held Ziklag, and so was still the vassal of Gath, reigned in Hebron, and the house of Saul was driven across the Jordan. But these successes were mainly due to want of union and discipline in Israel, and when David had united the tribes under a new sceptre the Philistines were soon humbled. After the division of the kingdom the house of Ephraim appears to have laid claim to the suzerainty over Philistia, for we twice read of a siege of the border fortress of Gibeon by the northern Israelites (1 Kings xv. 27, xvi. 15); but the Philistines, though now put on the defensive, were able to maintain their independence. Philistia was never part of the land of Israel (2 Kings i. 3, viii. 2; Amos vi. 2), and its relations with the Hebrews were embittered by the slave trade, for which the merchants of Gaza carried on forays among the Israelite villages (Amos i. 6). On the other hand, the trading relations between Gaza and Edom (Amos, *ut sup.*) probably imply that in the 8th century Judah, which lay between the two, was open to Philistine commerce (comp. Isa. ii. 6); Judah under Uzziah had reopened the Red Sea trade, of which the Philistine ports were the natural outlet.⁴ Soon, however, all the Palestinian states fell under the great empire of Assyria, and Tiglath-Pileser, in 734 B.C., subdued the Philistines as far as Gaza. But the spirit of the race was not easily broken; they were constantly engaged in intrigues with Egypt, and had a share in every conspiracy and revolt against the great king. Of two of these revolts, first against Sargon in 711, and afterwards against Sennacherib on Sargon's death (705), a memorial is preserved in Isa. xx., xiv. 29 *sq.* In the latter revolt Hezekiah of Judah was also engaged; it was to him that

³ For some Egyptian evidence, see PHENICIA.

⁴ The Chronicler, who represents the relations of Judah and Philistia as generally unfriendly, makes Uzziah subdue the latter country as well as Edom, assuming perhaps that he was the fulfiller of the prophecy in Amos i., in which, however, it is the Assyrians who are really pointed to as the ministers of divine justice. The old history has no trace of pretensions of Judah to sovereignty in Philistia till the time of Hezekiah. Comp. Wellhausen, *Prolegomena*, p. 212.

¹ Their modern names are Azdūd, Ghazzn, 'Askalān, 'Akir.

² The word *seren*, pl. *serānim*, means an axle, and seems to be applied metaphorically like the Arabic *kobā*.

Padi, kinglet of Ekron and a partisan of Assyria, was delivered for custody by the rebels. In 701 Sennacherib marched westward and reduced the rebel cities of Ascalon and Ekron; kinglets faithful to his cause were established in both places, and the territories of these Philistine princes and of those of Gaza and Ashdod were enlarged at the cost of Judah. The Philistine war of Hezekiah spoken of in 2 Kings xviii. 8 was probably undertaken to regain the lost territory after the disaster of Sennacherib's army. Under Esarhaddon and Assurbanipal the inscriptions still speak of the cities of Philistia as governed by kinglets tributary to Assyria; and, as the power of Nineveh declined and the monarchs of Egypt began to form plans of aggrandizement in Syria, the Philistine fortresses were the first that opposed their advance. According to Herodotus (ii. 157) Psammetichus besieged Ashdod for twenty-nine years, from which we may at least conclude that the Shephelah was the scene of a protracted conflict between the two great powers. The prophecy of Zephaniah ii. 4 *sq.* has by some been held to point to these events; but most recent writers prefer to connect it with the invasion of the Scythians, who in the reign of Psammetichus ravaged the Phœnician coast and plundered the famous temple of Aphrodite Urania (Astarte) at Ascalon (Herod., i. 105). The next king of Egypt, Necho, also made war in the Philistine country and smote Gaza (Jer. xlvii.), an event recorded also by Herodotus, who gives to Gaza (Ghazzat, Assyrian Khaziti) the name of Cadytis (Herod., ii. 159, comp. iii. 5).¹ Amidst all these calamities Philistia, like the other countries of Syria in the Assyrio-Babylonian period, must have lost great part of its old individuality. The Philistine towns continued to be important, and Gaza in particular became a great seat of international commerce—Herodotus estimates Cadytis as being almost as large as Sardis—but we can hardly speak further of a Philistine people. After the captivity Nehemiah speaks not of Philistines but of Ashdodites (iv. 7), speaking an "Ashdodite" dialect (xiii. 24), just as Strabo regards the Jews, the Idumeans, the Gazans, and the Ashdodites as four cognate peoples having the common characteristic of combining agriculture with commerce. In southern Philistia at least the population was modified by Arabian immigration. In the time of Cambyses the Arabs touched the sea immediately south of Gaza (Herod., iii. 5), and this perhaps had something to do with the fact that Gaza was the only Syrian city that resisted Cyrus, just as the Persian and Arab garrison of Gaza offered to Alexander the only resistance that he found on his march from Tyre to Egypt.

We have still to consider the much-vexed question of the origin of the Philistines. That they were a Semitic or at least a thoroughly Semitized people can now hardly be made matter of dispute. The short list of proper names derived from the Bible has been considerably enlarged from the Assyrian monuments, and suffices to prove that before as after the captivity their language was only dialectically different from that of the Israelites. The religion too was Semitic, and of that older type when the gods were not yet reduced to mere astral powers, but had individual types and special relations to certain animals. Thus Ekron had its local "Fly-Baal" (Baal-Zebub, 2 Kings i. 2 *sq.*), the fame of whose oracle in the 9th century B.C. extended as far as Samaria. The more famous Dagon, who had temples at Ashdod (1 Sam. v.; 1 Mac. x. 83) and Gaza (Judges xvi. 21 *sq.*), seems to have been more than a mere local deity; there was a place called Beth-Dagon in Judæa (Josh. xv. 41) and another on the borders of Asher (Josh. xix. 27). The name Dagon seems to come from דג, "fish," and

that his idol was half-man half-fish is pretty clear from 1 Sam. v. 4, where, however, the text is hardly sound, and we ought probably to read, omitting one of two consecutive nouns, "only his fish-part was left to him."

There are two other views about Dagon. (1) Philo Byblius (Müller, *Fr. Hist. Græc.*, iii. 567 *sq.*) makes Dagon the inventor of corn and the plough, whence he was called Ζεύς Ἀπόρρος. This implies an etymology of a very improbable kind from the Hebrew and Phœnician דג, "corn." But it is probable that, at least in later times, Dagon had in place of, or in addition to, his old character that of the god who presided over agriculture; for in the last days of paganism, as we learn from Marcus Diaconus in the *Life of Porphyry of Gaza* (§ 19), the great god of Gaza, now known as Marna (out Lord), was regarded as the god of rains and invoked against famine. That Marna was lineally descended from Dagon is probable in every way, and it is therefore interesting to note that he gave oracles, that he had a circular temple, where he was sometimes worshipped by human sacrifices, that there were wells in the sacred circuit, and that there was also a place of adoration to him situated, in old Semitic fashion, outside the town. Certain "marmora" in the temple, which might not be approached, especially by women, may perhaps be connected with the threshold which the priests of Dagon would not touch with their feet (1 Sam. v. 5; Zeph. i. 9). (2) Schrader (*K. A. T.*, 2d ed., p. 181 *sq.*) identifies Dagon with the Assyrian god Dakan, and believes that the word is Accadian. We are here in a region of pure conjecture; the attributes of Dakan are unknown, save only that Berosus speaks of an Assyrian merman-god Ἰδακων.

To the male god Dagon answers in the Bible the female deity Ashtoreth, whose temple spoken of in 1 Sam. xxxi. 10 is probably the ancient temple at Ascalon, which Herodotus regarded as the oldest seat of the worship of Aphrodite Urania. This Ashtoreth is the Derketo of Diodorus (ii. 4) and Lucian (*De Dea Syr.*, 14), the Atargatis of Xanthus (*Fr. Hist. Græc.*, i. 155), whose sacred enclosure and pool were near Ascalon, and whose image had a human head, but was continued in the form of a fish.² The association of Ashtoreth with sacred pools and fish was common in Syria, and the sacred doves of Ascalon mentioned by Philo (ed. Mangey, ii. 646) belong to the same worship.³ Of the details of Philistine religion in the Biblical period we know almost nothing.⁴ Their gods were carried into battle (2 Sam. v. 21), a usage found among other Semites; their skill in divination is alluded to in Isa. ii. 6, and we have already seen that oracles were a feature in their shrines. The whole record shows a religion characteristically Semitic in type; and it is also noteworthy that at the earliest date when the Philistines appear in history the great sanctuaries are all on the coast with deities of a marine type. This raises a presumption that the Philistines came from over the sea, and that Caphtor, their original home, was an island or maritime country.⁵ In point of fact the Philistines must have entered their later seats either by sea or from the desert between Canaan and Egypt. In the latter case they come from Egypt, for a city-building people, which supplanted a race of villagers, cannot have been a tribe of Arabs. And so the theories about the origin of the Philistines reduce themselves to two, one class of writers holding that Caphtor must be sought across the Mediterranean, another placing it in the

² The name Atargatis is a later compound, of which the first half is the Aramaic form of Ashtar ('Attar), and the second is אֲתַר.

³ The Aphrodite of Gaza in Marcus, *Vit. Porphy.*, § 59, is rather Aphrodite Pandemos. She gave oracles by dreams in matters relating to marriage.

⁴ Schrader thinks that traces of Jehovah (Iahveh) worship among the Philistines are to be found in the Philistine names Padi, Mtinti, Sidkâ, &c., on the Assyrian inscriptions (see also Friedrich Delitzsch, *Wo lag das Paradies?* p. 162 *sq.*). It is probable enough that Sidkâ at least is a shortened form of a name in which the second element was that of a god; but such Phœnician names as Kalbâ (side by side with Kalbêlim), Hanno, Abdâ or Bodo, &c., show that the shortening does not in the least imply that the divine name was Iahveh.

⁵ The expression "isle" (or coastland, Hebrew יָבֵשׁ) of Caphtor in Jer. xlvii. is generally cited as conclusive to this effect; but in the context it is by no means clear that it means anything more than the coastland of Philistia.

¹ The reference to Necho and Gaza is not in the Septuagint of Jer. xlvii. 1, and it would be more natural to think of Chaldea as the enemy from the north whom Jeremiah describes.

Delta. Ancient tradition gives no help; for it takes Caphtor to be Cappadocia, led, it would seem, merely by a superficial similarity of the names. Of the two main theories the former is that which has recently found most support, and it has a definite point of attachment in the fact that the Philistines, or a part of them, are also called in the Bible Cherethites (1 Sam. xxx. 14; Ezek. xxv. 16; Zeph. ii. 5), while David's Philistine guards are in like manner called the Cherethites and Pelethites (2 Sam. viii. 18, xv. 18, &c.). Cherethites (Krētim) can hardly be anything but Cretans, as the LXX. actually renders it in Ezekiel and Zephaniah, and Caphtor would thus be the island of Crete, —an identification which seems to satisfy the conditions of a reasonable hypothesis. For, though the points of contact between Crete or Cretan religion and the Philistine coast which have been sought in Greek and Latin writers (chiefly in Steph. Byzant., s.v. "Gaza") are very shadowy, there is no doubt that Crete had an early connexion with Phœnicia and received many Semitic inhabitants and a Semitic civilization before the Greeks gradually asserted themselves in the Ægean and forced back the tide of Semitic influence (for details, see the article PHœNICIA). These facts give a reasonable explanation of the settlement on the Philistine coast within historical times of a maritime people, cognate to the Phœnicians in so many points and yet having certain distinct characters, such as would naturally be produced in a place like Crete by the grafting of a Semitic stock and culture on ruder races not Semitic (the Eteocretans).¹ The opposite view, which places Caphtor in the Delta, rests on more complicated but less satisfactory arguments. There were certainly many Semites in the Delta of Egypt, and so long as the history of the Hyksos (who were no doubt Semites) remains in its present obscurity it is always possible to suppose that their expulsion from Egypt explains the settlement of the Philistines in Canaan. But it is very questionable if the dates will fit; the name Caphtor is connected with the Delta by no historical testimony, but only by elaborate hypotheses, as that Caphtor may mean in Egyptian Great Phœnicia, and that this again may have been a name for the Egyptian coast, where there was a large Semitic population;² and the characteristic Philistine peculiarity of uncircumcision, intelligible enough on the Cretan theory, is scarcely conceivable in a race which had been long settled in Egypt. The mainstay of the Egyptian hypothesis is found in Gen. x. 13, 14,—verses which belong to the older part of the chapter (see NOAH), and reckon in the very obscure list of descendants of Mizraim or Egypt "Casluhim (whence came forth Philistim) and Caphtorim." This account places Caphtorim in some relation to Egypt, but not necessarily in a very close relation, for the Ludim, who are also made descendants of Egypt, are scarcely different from Lud or Lydia, which appears at ver. 22, in the later part of the chapter, in another connexion. But further, if the text as it stands is sound, it gives a new account of the origin of the Philistines, which can be reconciled with the other Biblical evidence only by making Casluhim a halting-place of the Philistines on their way from Caphtor to Canaan. Accordingly the advocates of the Egyptian theory propose to identify Casluhim with the arid district of Mount Casius on the coast of the Egyptian desert. But this is false etymology. Mount Casius is named from the temple of Jupiter Casius, that is, the well-known Semitic

God כסלום,³ whose name as written in Semitic letters has no possible affinity to Casluhim. And in truth the statement that the Philistines came from Casluhim, presented without a hint as to their connexion with Caphtorim, which is mentioned immediately afterwards, lies under strong suspicion of being a gloss, originally set on the margin by a copyist who meant it to refer to Caphtorim.⁴ In this case the original author will have meant Caphtorim to denote, or at least include, the Philistines (who, as they are not Canaanites, and had close relations with Egypt in historical times, fall readily enough under the Egyptian group), and tells us nothing about the origin of the race.

Literature.—Hitzig, *Urgeschichte . . . der Philistæer*, 1845, where the now untenable hypothesis of a Pelagic origin of the Philistines is maintained; Ewald, *Gesch. des V. Israel*, i. 348 sq.; and in general the books on Hebrew history and commentaries on Gen. x. and on Amos. A useful monograph is Stark's *Gaza und die philistäische Küste*, Jena, 1852. For the Assyrian evidence see especially Schrader, *Keilinschriften und Altes Testament*, 2d ed., Giessen, 1883. (W. R. S.)

PHILLIP, JOHN (1817-1867), subject and portrait painter, was born at Aberdeen, Scotland, on 19th April 1817. His father, an old soldier, was in humble circumstances, and the son became an errand-boy to a tinsmith of the place, and was then apprenticed to a painter and glazier. Meanwhile he was employing in the pursuit of art all the time he could spare from his daily duties, and, having received some technical instruction from a local artist named William Mercer, he began, at the age of about fifteen, to paint portraits. In 1834 he was enabled to make a very brief visit to London, where he studied with delighted interest in the Royal Academy Exhibition and the National Gallery. At this time, or shortly afterwards, he became assistant to James Forbes, an Aberdeen portrait-painter, under whose tuition he made considerable progress. Previously, however, he had gained a valuable patron. Having been sent to repair a window in the house of Major P. L. Gordon, his interest in the works of art which hung on the walls attracted the attention of their owner. He brought the young artist under the notice of Lord Panmure, who bought several of his productions, and in 1836 sent the lad to London, promising to bear the cost of his art-education. At first Phillip was placed under T. M. Joy, but he soon entered the schools of the Royal Academy, where he worked diligently, but with no exceptional promise or success, for two years. In 1839 he figured for the first time in the Royal Academy Exhibition with a portrait and a landscape, and in the following year he was represented by a more ambitious figure-picture of Tasso in Disguise relating his Persecutions to his Sister. For the next ten years he supported himself mainly by portraiture and by painting subjects of national incident, such as Presbyterian Catechizing, Baptism in Scotland, and the Spawife. His productions of this period, as well as his earlier subject-pictures, are reminiscent of the practice and methods of Wilkie and the Scottish genre-painters of his time, often possessing considerable grace of form, executed in a thin delicate style of painting, inclining to brownish tones of colour, and with the more powerful pigments introduced cautiously and with reserve. The Letter-writer of Seville, shown in the Royal Academy of 1854, marks a distinct change of both style and subject. Three years previously the artist's health had shown signs of delicacy, and his medical advisers had recommended a residence in a warmer climate. Spain was selected, and a fresh potency came to his art as well as to his physical frame. He was brought face to face for the first time with the brilliant sunshine and the splendid colour of the South, and it was in coping

¹ In 2 Sam. xx. 23, Ktīb, and 2 Kings xi. 4, 19, the foreign mercenaries are called not Krētim but Kārī, perhaps Carians. The Carian seamen and pirates had also a strong Semitic strain, and were at bottom the same race with the Eteocretans.

² So Ebers, *Ägypten und die Bücher-Mosis*, where the theory is supported by a very long and complex argument. Another etymology in support of the theory is given by Dietrich in *Merx's Archiv*, i. 313 sq.

³ See De Vogüé, *Syrie Centrale : Inscr. Sem.*, p. 103 sq.

⁴ So Olshausen, and Budde, *Biblische Urgeschichte*, p. 331, note. A mere transposition (so Ewald, Tuch, &c.) is much less probable.

with these that he first manifested his artistic individuality and finally displayed his full powers. In the Letter-writer, commissioned by the Queen at the suggestion of Sir Edwin Landseer, who had been greatly impressed by some of Phillip's Spanish sketches, we see the change of method in its initial stages rather than in its complete triumph. The artist is struggling with new difficulties in the portrayal of unwonted splendours of colour and light, the draperies are somewhat crude and textureless, and the picture may justly be charged with a want of complete harmony and of a due sense of the finer gradations of nature. In 1857 Phillip was elected an associate of the Royal Academy, and in 1859 a full member. In 1855 and in 1860 other two visits to Spain were made, and in each case the painter returned with fresh materials to be embodied with increasing power and subtlety in the long series of works with which his name is exclusively associated in the popular mind, and which has won for him the title of "Spanish Phillip." His highest point of execution is probably reached in the *La Gloria* of 1864 and a smaller single-figure painting of the same period entitled *El Cigarillo*. These Spanish subjects were varied in 1860 by a rendering of the Marriage of the Princess Royal with the Crown Prince of Germany, executed by command of the Queen, and in 1863 by a picture of the House of Commons, subjects presenting extreme artistic difficulties, but treated with much skill and dexterity. During his last visit to Spain Phillip occupied himself in a careful study of the art of Velazquez, and the copies which he made after that artist fetched large prices after his death, examples having been secured by the Royal and the Royal Scottish Academies. The year before his death he visited Italy and devoted much attention to the works of Titian. The results of this study of the old masters are visible in such of Phillip's works as *La Loteria Nacional*, left uncompleted at his death. This and several other of his later works exhibit symptoms of a fresh change of method, and show signs that his art was again about to take a fresh departure. During this period he resided much in the Highlands, and seemed to be returning to his first love for Scottish subjects, painting several national scenes, and planning others that were never completed. His health had been always delicate, and his strength had been taxed by severe domestic affliction and by the very exceptional rapidity and quantity of his artistic production. In the end of 1866 his excessive application to work for the next year's exhibition induced an attack of bilious fever, which was succeeded by paralysis, and the genial and talented artist expired at London on 27th February 1867 at the age of fifty.

In execution Phillip was singularly direct, forcible, and rapid. He was a noble colourist, a painter in the first and simplest sense of the word, concerning himself mainly with the visible and sensuous beauties of his subjects, their purely artistic problems of colour, tone, lighting, and texture. His art dealt with the appearances of things, a sufficiently legitimate sphere for the painter, and was seldom permeated with any very deep human or dramatic interest. His works were collected in the International Exhibition of 1873, and many of them have been excellently reproduced by the engravings of T. Oldham Barlow. In addition to the paintings which we have already specified the following are among the more important:—*Life among the Gipsies of Seville* (1853), *El Paseo* (1855), *Collection of the Offertory in a Scotch Kirk* (1855), *a Gipsy Water-carrier in Seville* (1855), *the Prayer of Faith shall save the Sick* (1856), *the Dying Contrabandist* (1856), *the Prison Window* (1857), *a Huff* (1859), *Early Career of Murillo* (1865), *a Chat round the Braserio* (1866).

PHILLIPS, JOHN (1800-1874), one of the foremost of the early geologists of England, was born 25th December 1800 at Marden in Wiltshire. His father belonged to an old Welsh family, but settled in England as an officer of excise and married the sister of William Smith, the "Father of English Geology." Both parents dying when

he was a child, Phillips passed into the care of his uncle. Before his tenth year he had attended four schools, until he entered the old school at Holt Spa, Wiltshire, where he remained for five years, gaining among other acquisitions that taste for classical learning which remained one of his distinguishing traits to the end. From school he went to the house of the Rev. B. Richardson, an accomplished naturalist, in whose charge he remained a year, and from whom he obtained not only much knowledge but the strong bent towards the study of nature which thenceforth became the master-pursuit of his life. His uncle, "Stratz Smith," at that time lived in London, where he exercised the profession of a civil and mining engineer, though a very large part of his time and earnings was given to the preparation of those maps of England and the English counties on which his fame now rests. In his zeal for geological pursuits Smith often neglected his proper professional work, until, as his nephew said, "he had thrown into the gulf of the Strata all his patrimony and all his little gains." Eventually he gave up his London house and wandered about the country, as the requirements of his maps led him. From the time that young Phillips joined his uncle in London he remained constantly with him, sharing in every piece of professional work, in the preparation of every book and map, and in every tour for fresh geological information. A youth so trained could not fail to become a geologist. In the spring of 1824 Smith went to York to deliver a course of lectures on geology, and his nephew accompanied him. This was the starting-point in Phillips's career. His extensive knowledge of natural science and especially of fossils was now turned to account. He accepted engagements in the principal Yorkshire towns to arrange their museums and give courses of lectures on the collections contained therein. York became his residence, where he obtained the situation of keeper of the Yorkshire Museum and secretary of the Yorkshire Philosophical Society. From that centre he extended his operations to other towns beyond the county; and in 1831 he included University College, London, in the sphere of his activity. In that year the British Association for the Advancement of Science was founded at York, and Phillips was one of the active minds who organized its machinery. He became the assistant general secretary, a post of great labour and proportionate usefulness, which he held for upwards of thirty years. In 1834 he accepted the professorship of geology at King's College, London, but retained his post at York, coming up to London every year to give a course of lectures there. This arrangement lasted for six years, until, in 1840, he resigned his charge of the York Museum and was appointed one of the staff of the Geological Survey of Great Britain under De la Beche. In this connexion he spent some time in studying the Palæozoic fossils of Devon, Cornwall, and west Somerset, of which he published descriptions and illustrations. Thereafter he made a detailed survey of the region of the Malvern Hills, of which he prepared the elaborate account that appears in vol. ii. of the *Memoirs* of the Survey. His direct connexion with the National Survey was but of short duration, for in 1844 he accepted the professorship of geology in the university of Dublin. Nine years later, on the death of Strickland, who had acted as substitute for Dr Buckland in the readership of geology in the university of Oxford, Phillips succeeded to the post of deputy, and eventually, at the dean's death, became himself reader, a post singularly congenial to him, and which he held up to the time of his own death, which was almost tragic in its suddenness. He dined at All Souls' College on 23d April 1874, but in retiring slipped and fell headlong down a flight of stairs. Paralysis at once ensued, and he expired on the afternoon

of the next day. In 1864 he had been elected president of the British Association.

Phillips was distinguished among his contemporaries for the sweetness and bright cheerfulness of his nature. He had great fluency as a speaker, and always spoke in so pleasant and interesting a manner as to make him a welcome and indeed indispensable interlocutor at the annual gatherings of the British Association. His social gifts were not less conspicuous than his attainments in science. But he was not a mere geologist. His sympathies went actively forth into the whole domain of science, and he himself contributed largely to astronomical literature as well as to meteorology.

From the time when he wrote his first paper in 1826 "On the Direction of the Diluvial Currents in Yorkshire" down to the last days of his life Phillips continued a constant contributor to the literature of his science. The pages of the *Journal of the Geological Society*, the *Geological Magazine*, and other publications of the day are full of valuable essays by him. He was also the author of numerous separate works, some of which had an extensive sale and were of great benefit in extending a sound knowledge of geology. Among these may be specially mentioned: *Illustrations of the Geology of Yorkshire* (1835); *A Treatise on Geology* (1837-39); *Memoirs of William Smith, the Father of English Geology* (1844); *The Rivers, Mountains, and Sea-Coast of Yorkshire* (1853); *Manual of Geology, Practical and Theoretical* (1855); *Life on the Earth: its Origin and Succession* (1860); *Vesuvius* (1869); *Geology of Oxford and the Thames Valley* (1871). To these should be added his monographs in the *Memoirs of the Geological Survey* and the publications of the Palæontographical Society, and his geological sections and maps.

PHILLIPS, SAMUEL (1815-1854), an industrious and successful *littérateur*, was the son of a Jewish tradesman in Regent Street, London, and was born in 1815. A somewhat precocious talent for mimicry and recitation had disposed his parents to train him for the stage; but they were afterwards induced, through the advice of the duke of Sussex, to send the lad to University College, London. After remaining a year at that institution Phillips proceeded to the university of Göttingen. Having renounced the Jewish faith, he returned shortly afterwards to England and entered Sidney Sussex College, Cambridge, with the design of taking orders. His father's death, however, altered his plans; and, after an unsuccessful attempt, in conjunction with his brother, to carry on his father's business, he in 1841 took to literature as a profession. His first work, the novel of *Caleb Stutely*, appeared originally in the pages of *Blackwood's Magazine*, and he subsequently contributed other anonymous tales to that and to other periodicals. In 1845 he began, through the interest of Lord Stanley, to write political leaders for the *Morning Herald*; and about the same time he obtained an appointment as literary critic on the staff of the *Times*. In the following year he purchased the *John Bull* newspaper, which he edited for only a year; for, finding his strength, which was slowly wasting under the influence of confirmed consumption, quite unequal to such laborious work, he was constrained to abandon the undertaking. From that period till his death Phillips worked cheerfully and courageously as literary critic for the *Times*, and also wrote an occasional review for the *Literary Gazette*. Two anonymous volumes of *Essays from the Times* were published by him in 1852 and 1854. They are written in a light, dashing, picturesque style, sometimes eloquent, frequently bitter, and with a tolerable show of fairness. Phillips took an active part in the formation of the Crystal Palace Company. He was appointed their literary director; he wrote their *Guide to the Crystal Palace and Park*, and the *Portrait Gallery of the Crystal Palace*. In 1852 the university of Göttingen conferred upon him the honorary degree of LL.D. He died at Brighton on the 14th of October 1854.

PHILLIPS, THOMAS (1770-1845), portrait and subject painter, was born at Dudley in Warwickshire on 18th October 1770. Having acquired the art of glass-painting at Birmingham, he visited London in 1790 with an intro-

duction to Benjamin West, who found him employment on the windows in St George's chapel at Windsor. In 1792 Phillips painted a view of Windsor Castle, and ere the two succeeding years had passed he exhibited the Death of Talbot, Earl of Shrewsbury, at the Battle of Castillon, Ruth and Naomi, Elijah restoring the Widow's Son, Cupid disarmed by Euphrosyne, and other pictures of that class. From the year 1796, however, he seems to have mainly confined himself to portrait-painting; and it was in this walk that he was destined to acquire his reputation as an artist. It was not long before he became the chosen painter of men of genius and talent, notwithstanding the rivalry of Hoppner, Owen, Jackson, and Lawrence; and he has left behind him portraits of nearly all the illustrious characters of his day. His works of this kind are distinguished by simplicity, careful and finished handling, and truth of portraiture, but in colour they are commonly cold and feeble. In 1804 he was elected associate and four years later member of the Royal Academy. In 1824 Phillips succeeded Fuseli as professor of painting to the Royal Academy, an office which he held till 1832. During this period he delivered ten *Lectures on the History and Principles of Painting*, which were published in 1833. He likewise wrote a large number of the articles on the fine arts in Rees's *Cyclopædia*. He died on the 20th of April 1845.

PHILLIPS, WILLIAM (1775-1828), an able mineralogist and geologist, who did much to foster in Britain the study of the sciences to which he was devoted, was born in May 1775. His *Outline of Mineralogy and Geology* was published in 1815 and passed through several editions. His *Introduction to the Knowledge of Mineralogy*, published in 1816, was for upwards of forty years one of the standard text-books in that science. Successive editions of it were brought out under different editors after his death. It was specially distinguished by its elaborate crystallographic details, based upon measurements with Wollaston's reflecting goniometer. But it is chiefly the services rendered by Phillips to the science of geology, then in its infancy, that entitle his name to grateful recollection. In addition to the first work above-named, he published in 1818 a most useful digest of English geology, under the title of *A Selection of Facts, from the best Authorities, arranged so as to form an Outline of the Geology of England and Wales*. This little volume contained a geological map of the country, based on that of W. Smith and some horizontal sections. Its importance in geological literature is to be found mainly in the fact that it formed the foundation of the larger work undertaken by Phillips in conjunction with W. Conybeare, of which only the first part was published, entitled *Outlines of the Geology of England and Wales; and comparative Views of the Structure of Foreign Countries* (1822). This volume made an era in geology. As a model of careful original observation, of judicious compilation, of succinct description, and of luminous arrangement it has been of the utmost service in the development of geology in Britain. Phillips was a member of the Society of Friends. He was a Fellow of the Royal, Geological, and other learned societies. He died in 1828.

PHILO, often called PHILO JUDÆUS, Jewish philosopher, appears to have spent his whole life at Alexandria, where he was probably born c. 20-10 B.C. His brother Alexander was alabarch or arabarch (that is, probably, chief farmer of taxes on the Arabic side of the Nile), from which it may be concluded that the family was influential and wealthy (Jos., *Ant.*, xviii. 8, 1). Jerome's statement (*De Vir. Ill.*, 11) that he was of priestly race is confirmed by no older authority. The only event of his life which can be exactly dated belongs to 40 A.D., when Philo, then a man of advanced years, went from Alexandria to Rome,

at the head of a Jewish embassy, to persuade the emperor Caius to abstain from claiming divine honour of the Jews. Of this embassy Philo has left a full and vivid account (*De Legatione ad Caium*). Various fathers and theologians of the church state that in the time of Claudius he met St Peter in Rome;¹ but this legend has no historic value, and probably arose because the book *De vita contemplativa*, falsely ascribed to Philo, in which Eusebius already recognized a glorification of Christian monasticism, seemed to indicate a disposition towards Christianity.

Though we know so little of Philo's own life, his numerous extant writings give the fullest information as to his views of the universe and of life, and his religious and scientific aims, and so enable us adequately to estimate his position and importance in the history of thought. He is quite the most important representative of Hellenistic Judaism, and his writings give us the clearest view of what this development of Judaism was and aimed at. Since the time of Alexander many Jews had been led to settle beyond Palestine either with commercial objects or attracted by the privileges conferred by the diadochi on the inhabitants of the cities they founded. In the great towns of Syria, Asia Minor, and Egypt there were Jewish communities many thousands strong, but the Jews were most numerous in Alexandria, where from its first foundation they formed a considerable part of the population. The development of Judaism in the diaspora differed in important points from that in Palestine, where, since the successful opposition of the Maccabee age to the Hellenization which Antiochus Epiphanes had sought to carry through by force, the attitude of the nation to Greek culture had been essentially negative. In the diaspora, on the other hand, the Jews had been deeply influenced by the Greeks; they soon more or less forgot their Semitic mother-tongue, and with the language of Hellas they appropriated much of Hellenic culture. They were deeply impressed by that irresistible force which was blending all races and nations into one great cosmopolitan unity, and so the Jews too on their dispersion became in speech and nationality Greeks, or rather "Hellenists." Now the distinguishing character of Hellenism is not the absolute disappearance of the Oriental civilizations before that of Greece, but the combination of the two with a preponderance of the Greek element. So it was with the Jews, but in their case the old religion had much more persistence than in other Hellenistic circles, though in other respects they too yielded to the superior force of Greek civilization. This we must hold to have been the case not only in Alexandria but throughout the diaspora from the commencement of the Hellenistic period down to the later Roman empire. It was only after ancient civilization gave way before the barbarian immigrations and the rising force of Christianity that rabbinism became supreme even among the Jews of the diaspora. This Hellenistico-Judaic phase of culture is sometimes called "Alexandrian," and the expression is justifiable if it only means that in Alexandria it attained its highest development and flourished most. For here the Jews began to busy themselves with Greek literature even under their clement rulers, the first Ptolemies, and here the law and other Scriptures were first translated into Greek; here the process of fusion began earliest and proceeded with greatest rapidity; here, therefore, also the Jews first engaged in a scientific study of Greek philosophy and transplanted that philosophy to the soil of Judaism. We read of a Jewish philosopher Aristobolus in the time of Ptolemy VI. Philometor, in the middle of the 2d century B.C., of whose philosophical commentary on the Pentateuch fragments

have been preserved by Clement of Alexandria and Eusebius. So far as we can judge from these, his aim was to put upon the sacred text a sense which should appeal even to Greek readers, and in particular to get rid of all anthropomorphic utterances about God. Eusebius regards him as a Peripatetic. We may suppose that this philosophical line of thought had its representatives in Alexandria between the times of Aristobolus and Philo, but we are not acquainted with the names of any such. Philo certainly, to judge by his historical influence, was the greatest of all these Jewish philosophers, and in his case we can follow in detail the methods by which Greek culture was harmonized with Jewish faith. On one side he is quite a Greek, on the other quite a Jew. His language is formed on the best classical models, especially Plato. He knows and often cites the great Greek poets, particularly Homer and the tragedians, but his chief studies had been in Greek philosophy, and he speaks of Heraclitus, Plato, the Stoics, and the Pythagoreans in terms of the highest veneration. He had appropriated their doctrines so completely that he must himself be reckoned among the Greek philosophers; his system was eclectic, but the borrowed elements are combined into a new unity with so much originality that at the same time he may fairly be regarded as representing a philosophy of his own, which has for its characteristic feature the constant prominence of a fundamental religious idea. Philo's closest affinities are with Plato, the later Pythagoreans, and the Stoics.² Yet with all this Philo remained a Jew, and a great part of his writings is expressly directed to recommend Judaism to the respect and, if possible, the acceptance of the Greeks. He was not a stranger to the specifically Jewish culture that prevailed in Palestine; in Hebrew he was not proficient, but the numerous etymologies he gives show that he had made some study of that language.³ His method of exegesis is in point of form identical with that of the Palestinian scribes, and in point of matter coincidences are not absolutely rare.⁴ But above all his whole works prove on every page that he felt himself to be thoroughly a Jew, and desired to be nothing else. Jewish "philosophy" is to him the true and highest wisdom; the knowledge of God and of things divine and human which is contained in the Mosaic Scriptures is to him the deepest and the purest.

If now we ask wherein Philo's Judaism consisted, we must answer that it lies mainly in the formal claim that the Jewish people, in virtue of the divine revelation given to Moses, possesses the true knowledge in things religious. Thoroughly Jewish is his recognition that the Mosaic Scriptures of the Pentateuch are of absolute divine authority, and that everything they contain is valuable and significant because divinely revealed. The other Jewish Scriptures are also recognized as prophetic, *i.e.*, as the writings of inspired men, but he does not place them on the same line with the law, and he quotes them so seldom that we cannot determine the compass of his canon. The decisive and normative authority is to him the "holy laws" of Moses, and this not only in the sense that everything they contain is true but that all truth is contained in them. Everything that is right and good in the

² The fathers of the church have specially noticed his Platonism and Pythagoreanism; an old proverb even says, with some exaggeration, *ἡ Πλάτων φιλονίζει ἡ Φίλων πλατωνίζει* (Jerome, Photius, and Suidas, *ut supra*). Clement of Alexandria directly calls him a Pythagorean. Eusebius (*H. E.*, ii. 4, 3) observes both tendencies. Recent writers, especially Zeller, lay weight also on his Stoic affinities, and with justice, for the elements which he borrows from Stoicism are as numerous and important as those derived from the other two schools.

³ See the list of these in Vallarsi's edition of Jerome (iii. 731-734), and compare Siegfried. "Philonische Studien," in *Merx's Archiv*, ii. 143-163 (1872).

⁴ See Siegfried, *Philo*, pp. 142-159.

¹ Enseb., *H. E.*, ii. 17, 1; Jer., *ut supra*; Phot., *Bibl. Cod.* 105; Suid., s.v. "Φίλων."

doctrines of the Greek philosophers had already been quite as well, or even better, taught by Moses. Thus, since Philo had been deeply influenced by the teachings of Greek philosophy, he actually finds in the Pentateuch everything which he had learned from the Greeks. From these premises he assumes as requiring no proof that the Greek philosophers must in some way have drawn from Moses,—a view indeed which is already expressed by Aristobulus. To carry out these presuppositions called for an exegetical method which seems very strange to us, that, namely, of the allegorical interpretation of Scripture. The allegorical method had been practised before Philo's date in the rabbinical schools of Palestine, and he himself expressly refers to its use by his predecessors, nor does he feel that any further justification is requisite. With its aid he discovers indications of the profoundest doctrines of philosophy in the simplest stories of the Pentateuch.¹

This merely formal principle of the absolute authority of Moses is really the one point in which Philo still holds to genuinely Jewish conceptions. In the whole substance of his philosophy the Jewish point of view is more or less completely modified—sometimes almost extinguished—by what he has learned from the Greeks. Comparatively speaking, he is most truly a Jew in his conception of God. The doctrine of monotheism, the stress laid on the absolute majesty and sovereignty of God above the world, the principle that He is to be worshipped without images, are all points in which Philo justly feels his superiority as a Jew over popular heathenism. But only over popular heathenism, for the Greek philosophers had long since arrived at least at a theoretical monotheism, and their influence on Philo is nowhere more strongly seen than in the detailed development of his doctrine of God. The specifically Jewish (*i.e.*, particularistic) conception of the election of Israel, the obligation of the Mosaic law, the future glory of the chosen nation, have almost disappeared; he is really a cosmopolitan and praises the Mosaic law just because he deems it cosmopolitan. The true sage who follows the law of Moses is the citizen not of a particular state but of the world. A certain attachment which Philo still manifests to the particularistic conceptions of his race is meant only "in majorem Judæorum gloriam." The Jewish people has received a certain preference from God, but only because it has the most virtuous ancestry and is itself distinguished for virtue. The Mosaic law is binding, but only because it is the most righteous, humane, and rational of laws, and even its outward ceremonies always disclose rational ideas and aims. And lastly, outward prosperity is promised to the pious, even on earth, but the promise belongs to all who turn from idols to the true God. Thus, in the whole substance of his view of the universe, Philo occupies the standpoint of Greek philosophy rather than of national Judaism, and his philosophy of the world and of life can be completely set forth without any reference to conceptions specifically Jewish.

His doctrine of God starts from the idea that God is Being absolutely bare of quality. All quality in finite beings has limitation, and no limitation can be predicated of God, who is eternal, unchangeable, simple substance, free, self-sufficient, better than the good and the beautiful. To predicate any quality (*ποιότης*) of God would be to reduce Him to the sphere of finite existence. Of Him we can say only *that* He is, not *what* He is, and such purely negative predications as to His being appear to Philo, as to the later Pythagoreans and the Neo-Platonists, the only way of securing His absolute elevation above the world. At bottom, no doubt, the meaning of these negations is that God is the most perfect being; and so, con-

versely, we are told that God contains all perfection, that He fills and encompasses all things with His being.

A consistent application of Philo's abstract conception of God would exclude the possibility of any active relation of God to the world, and therefore of religion, for a Being absolutely without quality and movement cannot be conceived as actively concerned with the multiplicity of individual things. And so in fact Philo does teach that the absolute perfection, purity, and loftiness of God would be violated by direct contact with imperfect, impure, and finite things. But the possibility of a connexion between God and the world is reached through a distinction which forms the most important point in his theology and cosmology; the proper being of God is distinguished from the infinite multiplicity of divine Ideas or Forces: God himself is without quality, but He disposes of an infinite variety of divine Forces, through whose mediation an active relation of God to the world is brought about. In the details of his teaching as to these mediating entities Philo is guided partly by Plato and partly by the Stoics, but at the same time he makes use of the concrete religious conceptions of heathenism and Judaism. Following Plato, he first calls them Ideas or ideal patterns of all things; they are thoughts of God, yet possess a real existence, and were produced before the creation of the sensible world, of which they are the types. But, in distinction from Plato, Philo's ideas are at the same time efficient causes or Forces (*δυνάμεις*), which bring unformed matter into order conformably to the patterns within themselves, and are in fact the media of all God's activity in the world. This modification of the Platonic Ideas is due to Stoic influence, which appears also when Philo gives to the *ἰδέαι* or *δυνάμεις* the name of *λόγοι*, *i.e.*, operative ideas,—parts, as it were, of the operative Reason. For, when Philo calls his mediating entities *λόγοι*, the sense designed is analogous to that of the Stoics when they call God the Logos, *i.e.*, the Reason which operates in the world. But at the same time Philo maintains that the divine Forces are identical with the "demons" of the Greeks, and the "angels" of the Jews, *i.e.*, servants and messengers of God by means of which He communicates with the finite world. All this shows how uncertain was Philo's conception of the nature of these mediating Forces. On the one hand, they are nothing else than Ideas of individual things conceived in the mind of God, and as such ought to have no other reality than that of immanent existence in God, and so Philo says expressly that the totality of Ideas, the *κόσμος νοητός*, is simply the Reason of God as Creator (*Οκοῦ λόγος ἡδὲ κοσμοποιῶντος*). Yet, on the other hand, they are represented as hypostases distinct from God, individual entities existing independently and apart from Him. This vacillation, however, as Zeller and other recent writers have justly remarked, is necessarily involved in Philo's premises, for, on the one hand, it is God who works in the world through His Ideas, and therefore they must be identical with God; but, on the other hand, God is not to come into direct contact with the world, and therefore the Forces through which He works must be distinct from Him. The same inevitable amphiboly dominates in what is taught as to the supreme Idea or Logos. Philo regards all individual Ideas as comprehended in one highest and most general Idea or Force—the unity of the individual Ideas—which he calls the Logos or Reason of God, and which is again regarded as operative Reason. The Logos, therefore, is the highest mediator between God and the world, the firstborn son of God, the archangel who is the vehicle of all revelation, and the high priest who stands before God on behalf of the world. Through him the world was created, and so he is identified with the creative Word of God in Genesis (the Greek *λόγος* meaning both "reason"

¹ For details, see Gfrörer, *Philo*, I. 63 sq.; Zeller, *Phil. der Gr.*, 3d ed., vol. iii., pt. ii. 346-352; Siegfried, *Philo*, 160 sq.

and "word"). Here again, we see, the philosopher is unable to escape from the difficulty that the Logos is at once the immanent Reason of God, and yet also an hypostasis standing between God and the world. The whole doctrine of this mediatorial hypostasis is a strange intertwining of very dissimilar threads; on one side the way was prepared for it by the older Jewish distinction between the Wisdom of God and God Himself, of which we find the beginnings even in the Old Testament (Job xxviii. 12 sq.; Prov. viii. ix.), and the fuller development in the books of Ecclesiasticus and Wisdom, the latter of which comes very near to Philo's ideas if we substitute for the term "wisdom" that of (divine) "Reason." In Greek philosophy, again, Philo, as we have seen, chiefly follows the Platonic doctrines of Ideas and the Soul of the World, and the Stoic doctrine of God as the λόγος or Reason operative in the world. In its Stoic form the latter doctrine was pantheistic, but Philo could adapt it to his purpose simply by drawing a sharper distinction between the Logos and the world.

Like his doctrine of God, Philo's doctrine of the world and creation rests on the presupposition of an absolute metaphysical contrast between God and the world. The world can be ascribed to God only in so far as it is a cosmos or orderly world; its material substratum is not even indirectly referable to God. Matter (ὕλη, or, as the Stoics said, οὐσία) is a second principle, but in itself an empty one, its essence being a mere negation of all true being. It is a lifeless, unmoved, shapeless mass, out of which God formed the actual world by means of the Logos and divine Forces. Strictly speaking, the world is only formed, not created, since matter did not originate with God.

Philo's doctrine of man is also strictly dualistic, and is mainly derived from Plato. Man is a twofold being, with a higher and a lower origin. Of the pure souls which fill airy space, those nearest the earth are attracted by the sensible and descend into sensible bodies; these souls are the Godward side of man. But on his other side man is a creature of sense, and so has in him a fountain of sin and all evil. The body, therefore, is a prison, a coffin, or a grave for the soul which seeks to rise again to God. From this anthropology the principles of Philo's ethics are derived, its highest maxim necessarily being deliverance from the world of sense and the mortification of all the impulses of sense. In carrying out this thought, as in many other details of his ethical teaching, Philo closely follows the Stoics. But he is separated from Stoical ethics by his strong religious interests, which carry him to very different views of the means and aim of ethical development. The Stoics cast man upon his own resources; Philo points him to the assistance of God, without whom man, a captive to sense, could never raise himself to walk in the ways of true wisdom and virtue. And as moral effort can bear fruit only with God's help, so too God Himself is the goal of that effort. Even in this life the truly wise and virtuous is lifted above his sensible existence, and enjoys in ecstasy the vision of God, his own consciousness sinking and disappearing in the divine light. Beyond this ecstasy there lies but one further step, viz., entire liberation from the body of sense and the return of the soul to its original condition; it came from God and must rise to Him again. But natural death brings this consummation only to those who, while they lived on earth, kept themselves free from attachment to the things of sense; all others must at death pass into another body; transmigration of souls is in fact the necessary consequence of Philo's premises, though he seldom speaks of it expressly.

Philo's literary labours have a twofold object, being directed either to expound the true sense of the Mosaic law, i.e., the philosophy which we have just described, to his Jewish brethren, or to convince

heathen readers of the excellence, the supreme purity and truth, of the Jewish religion whose holy records contain the deepest and most perfect philosophy, the best and most humane legislation. Thus as a literary figure Philo, in conformity with his education and views of life, stands between the Greeks and the Jews, seeking to gain the Jews for Hellenism and the Greeks for Judaism, yet always taking it for granted that his standpoint really is Jewish, and just on that account truly philosophical and cosmopolitan.

The titles of the numerous extant writings of Philo present at first sight a most confusing multiplicity. More than three-fourths of them, however, are really mere sections of a small number of larger works. Three such great works on the Pentateuch can be distinguished.

(I.) The smallest of these is the *Ζητήματα καὶ λύσεις* (*Questions et solutions*), a short exposition of Genesis and Exodus, in the form of question and answer. The work is cited under this title by Eusebius (*H. E.*, ii. 18, 1, 5; *Præp. Ev.*, vii. 13), and by later writers, but the Greek text is now almost wholly lost, and only about one-half preserved in an Armenian translation. Genesis seems to have occupied six books.¹ Eusebius tells us that Exodus filled five books. In the Armenian translation, first published by the learned Mechitarist Ancher in 1826, are preserved four books on Genesis and two on Exodus, but with lacunæ. A Latin fragment, about half of the fourth book on Genesis (*Phil. Jud. CII. quæstl. . . super Gen.*), was first printed at Paris in 1520. Of the Greek we have numerous but short fragments in various Florilegia.² The interpretations in this work are partly literal and partly allegorical.

(II.) Philo's most important work is the *Νόμων ἱερῶν ἀλληγορίαι* (Euseb., *H. E.*, ii. 18, 1; Phot., *Bibl.*, Cod. 103), a vast and copious allegorical commentary on Genesis, dealing with chaps. ii.-iv., verse by verse, and with select passages in the later chapters. The readers in view are mainly Jews, for the form is modelled on the rabbinic Midrash. The main idea is that the characters which appear in Genesis are properly allegories of states of the soul (*τρόποι τῆς ψυχῆς*). All persons and actions being interpreted in this sense, the work as a whole is a very extensive body of psychology and ethics. It begins with Gen. ii. 1, for the *De mundi origine*, which treats of the creation according to Gen. i., ii., does not belong to this series of allegorical commentaries, but deals with the actual history of creation, and that under a quite different literary form. With this exception, however, the *Νόμων ἱερῶν ἀλληγορίαι* includes all the treatises in the first volume of Mangey's edition, viz.:—

Νόμων ἱερῶν ἀλληγορίαι πρῶται τῶν μετὰ τὴν ἑξαήμερον (*Legum allegoriarum*, lib. i., M. i. 43-65), on Gen. ii. 1-17. (2) *Νόμ. ἱερ. ἀλλ. δεύτεραι* (*Leg. all.*, lib. ii., M. i. 66-89), on Gen. ii. 18-iii. 1. (3) *Νόμ. ἱερ. ἀλλ. τρίται* (*Leg. all.*, lib. iii., M. i. 87-137), on Gen. iii. 5-19. The commentaries on Gen. iii. 16-24, 20-23 are lost. (4) *Περὶ τῶν χειρῶν καὶ τῆς φλογίνης βομφάρας καὶ τοῦ κτισθέντος πρώτου ἐξ ἀνθρώπου Κάιν* (*De cherubim et flammeo gladio*, M. i. 138-162), on Gen. iii. 24 and iv. 1. (5) *Περὶ ὧν ἱερουργοῦσαν Ἀβελ τε καὶ Κάιν* (*De sacrificiis Abelis et Caini*, M. i. 163-190), on Gen. iv. 2-4. The commentaries on Gen. iv. 5-7 are lost. (6) *Περὶ τοῦ τὸ χεῖρον τῷ κρείττονι φιλεῖν ἐπιτίθεσθαι* (*Quod deterius potiori insidari solet*, M. i. 191-225), on Gen. iv. 8-15. (7) *Περὶ τῶν τοῦ δοκασίου Κάιν ἐγγόνων καὶ ὡς μετὰ τὴν γένεσιν* (*De posteritate Caini*, &c., M. i. 226-261), on Gen. iv. 16-25. This book, which is wanting in editions prior to Mangey's, is incorrectly given by him, but much more correctly by Tischendorf, *Philonem*, p. 84-143. None of the preceding is mentioned by its special title by Euseb., *H. E.*, ii. 18, while he cites all that follow by their titles. The reason must be that all up to this point, and no farther, are included by him in the *Νόμων ἱερῶν ἀλληγορίαι*; agreeing with this we find that these and these only are cited under that general title in the Florilegia, especially the so-called *Johannes Monachus tractatus* (see Mangey's notes before each book). We may therefore conclude with confidence that Philo published the continuous commentaries on Gen. ii.-iv. under the title *Allegories of the Sacred Laws*, and the following commentaries on select passages under special titles, though the identity of literary character entitles us to regard the latter as part of the same great literary plan with the former. (8) *Περὶ γιγάντων* (*De gigantibus*, M. i. 262-272), on Gen. vi. 1-4. (9) *Ὁ ἀπρεπὸν τὸ θεῖον* (*Quod Deus sit immutabilis*, M. i. 272-299), on Gen. vi. 4-12. (10) *Περὶ γεωργίας* (*De agricultura*, M. i. 300-328), on Gen. ix. 20a. (11) *Περὶ φυτοργίας* *Νῶε τὸ δεύτερον* (*De plantatione Noe*, M. i. 329-356), on Gen. ix. 20b. (12) *Περὶ μεθης* (*De ebrietate*, M. i. 357-391), on Gen. ix. 21; the introduction shows that this book was preceded by another which put together the views of the philosophers about drunkenness. (13) *Περὶ τοῦ ἐξένηψε Νῶε* (*De sobrietate*, M. i. 392-403), on Gen. ix. 24. (14) *Περὶ συγχύσεως διαλέκτων* (*De confusione linguarum*, M. i. 404-435), on Gen. xi. 1-9. (15) *Περὶ ἀποικίας* (*De migratione Abrahami*, M. i. 436-472), on Gen. xii. 1-6. (16) *Περὶ τοῦ τίς ὁ τῶν θεῶν πραγμάτων κληρονόμος* (*Quis rerum divinarum heres sit*, M. i. 473-518), on Gen. xv. 1-18. (17) *Περὶ τῆς ἐλς τὰ προταδεύματα συνόδου* (*De congressu quaerendæ eruditionis causa*, M. i. 519-545), on Gen. xvi. 1-6. (18) *Περὶ φυγάδων* (*De profugis*, M. i. 546-577), on Gen. xvi. 6-14. (19) *Περὶ τῶν μετονομαζομένων καὶ ὧν ἕνεκα μετονομάζονται* (*De mutatione nominum*, M. i. 578-619), on Gen. xvii. 1-22; in this work Philo mentions that he had

² See *Opp.*, ed. Mangey, ii. 648-680; Mai, *op. cit.*, vol. vii. pt. i. 96 sq.; Euseb., *Præp. Ev.*, vii. 13. A fragment on the cherubim. Exod. xxv. 18, has been published by Mai, *Class. Auct.*, iv. 430 sq. by Grossmann (1856), and by Tischendorf (p. 144 sq.).

written two books, now wholly lost, *Περὶ διαθηκῶν* (M. i. 586). (20) *Περὶ τοῦ θεοτέκτονος εἶναι τοὺς ὄνελους* (*De somniis*, lib. i., M. i. 620-658), the two dreams of Jacob, Gen. xxviii. and xxxi. (21) Book ii. of the same (M. i. 659-690), on the dreams of Joseph, the chief butler, the chief baker, and Pharaoh, Gen. xxxvii. and xl., xli. Eusebius makes Philo the author of five books on dreams; three, therefore, are lost.

(III.) A work of a very different kind is the group of writings which we may call "An Exposition of the Mosaic law for Gentiles," which, in spite of their very various contents, present on nearer examination indubitable marks of close connexion. In them Philo seeks to give an orderly view of the chief points of the Mosaic legislation in the Pentateuch, and to recommend it as valuable to Gentile readers. The method of exposition is somewhat more popular than in the allegorical commentaries, for, though that method of interpretation is not wholly excluded, the main object is to give such a view of the legislation as Philo accepted as historical. This work has three main divisions: (a) an Account of the Creation (*κοσμοποιία*), which Moses put first, to show that his legislation was conformed to the will of nature, and that therefore those who followed it were true cosmopolitans; (b) the Biographies of the Virtuous,—being, so to speak, the living unwritten laws which, unlike written laws, present the general types of moral conduct; (c) Legislation Proper, in two subdivisions—(a) the ten principal chapters of the law, (β) the special laws belonging to each of these ten. An appendix adds a view of such laws as do not fall under the rubrics of the decalogue, arranged under the headings of certain cardinal virtues.

The treatises which belong to this work are the following. (1) *Περὶ τῆς Μωϋσέως κοσμοποιίας* (*De mundi opificio*, M. i. 1-42). This work does not fall within the number of the allegorical commentaries. On the other hand, the introduction to the treatise *De Abrahamo* makes clear its immediate connexion with the *De mundi opificio*. The position of the *De mundi opificio* at the head of the allegorical commentaries, which is at present usual in the editions, seems indeed to go back to a very early date, for even Eusebius cites a passage from it with the formula *ἀπὸ τοῦ πρώτου τῶν ἐν τῶν νόμων* (*Præp. Ev.*, viii. 12 fin., ed. Gaisford). The group of the *Βίαι σοφῶν* is headed by (2) *Βίαι σοφῶν τοῦ κατὰ διδασκαλίαν τελειωθέντος ἢ περὶ νόμων ἀγράφων* [4], *ὅ ἐστι περὶ Ἀβραάμ* (*De Abrahamo*, M. ii. 1-40). Abraham is here set forth as the type of *διδασκαλική ἀρετή*, i.e., of virtue as a thing learned. This biography of Abraham was followed by that of Isaac as a type of *φυσική ἀρετή*, i.e., of innate or natural virtue, which in turn was succeeded by that of Jacob as representing *ἀσκητική ἀρετή*, i.e., virtue acquired by practice; but both these are now lost. Hence in the editions the next treatise is (3) *Βίαι πολιτικῶν ὁπερ ἐστὶ περὶ Ἰωσήφ* (*De Josepho*, M. ii. 41-79), where Joseph is taken as the pattern of the wise man in his civil relations. The Biographies of the Virtuous are followed by (4) *Περὶ τῶν δέκα λογίων ἢ κεφάλαια νόμων εἰσι* (*De decalogo*, M. ii. 180-209) and (5) *Περὶ τῶν ἀναφερομένων ἐν εἰδὲ νόμων ἐν τῇ συντηρούντῃ κεφάλαια τῶν δέκα λόγων* (*De specialibus legibus*; the unabridged title is given by Eusebius, *H. E.*, ii. 18, 5). Here under the rubrics of the ten commandments a systematic review of the special laws of the Mosaic economy is given; for example, under the first and second commandments (divine worship) a survey is taken of the entire legislation relating to priesthood and sacrifice; under the fourth (i.e., the Sabbath law, according to Philo's reckoning) there is a survey of all the laws about feasts; under the sixth (adultery) an account of matrimonial law; and so on. According to Eusebius the work embraced four books, which seem to have reached its entire, but in the editions have been perversely broken up into a considerable number of separate tractates. (a) The first book (on the first and second commandments) includes the following: *De circumcissione* (M. ii. 210-212); *De monarchia*, lib. i. (ii. 213-222); *De monarchia*, lib. ii. (ii. 222-232); *De præmiis sacerdotum* (ii. 232-237); *De victimis* (ii. 237-250); *De sacrificiis*, or *De victimis offerentibus* (ii. 251-264); *De mercede meretricis non accipienda in sacrum* (ii. 264-266). (b) The second book (on the third, fourth, and fifth commandments, i.e., on perjury, Sabbath observance, and filial piety) is incomplete in Mangey (ii. 270-295), the section *De septenario* (on the Sabbath and feasts in general) being imperfect, and that *De colendis parentibus* being entirely wanting. Mai to a large extent made good the defect (*De cophint festo et de colendis parentibus*, Milan, 1816), but Tischendorf was the first to edit the full text (*Philologia*, pp. 1-83). (c) The third book dori was the first to edit the full text (*Philologia*, pp. 1-83). (c) The third book relates to the sixth and seventh commandments (adultery and murder, M. ii. 299-334). (d) To the fourth book (relating to the last three commandments) belongs all that is found in Mangey, ii. 335-374, that is to say, not merely the tractates *De iudicio* (ii. 344-348) and *De concupiscentia* (ii. 348-359), but also those *De iudicio* (ii. 358-361) and *De creatione principum* (ii. 361-374). The last-named is, properly speaking, only a portion of the *De iustitia*, which, however, certainly belongs to the fourth book, of which the superscription expressly bears that it treats also *περὶ δικαιοσύνης*. With this tractate begins the appendix to the work *De specialibus legibus*, into which, under the rubric of certain cardinal virtues, such Mosaic laws are brought together as could not be dealt with under any of the decalogic rubrics. The continuation of this appendix forms a book by itself. (6) *Περὶ τριῶν ἀρετῶν ἥτοι περὶ ἀνδρείας καὶ φιλανθρωπίας καὶ μετῆρας* (*De fortitudine*, M. ii. 375-393; *De caritate*, ii. 393-405; *De penitentia*, ii. 405-407). Finally, in less intimate connexion with this entire work is another treatise still to be mentioned, (7) *Περὶ ὁδῶν καὶ ἐπιτιμῶν* (*De præmiis et poenis*, M. ii. 408-428) and *Περὶ ὁδῶν* (*De exhortationibus*, M. ii. 429-457), two parts which constitute a single whole and deal with the promises and threatenings of the law.

(IV.) Besides the above-named three great works on the Pentateuch, Philo was the author of a number of isolated writings, of which the following have reached us either in their entirety or in fragments. (1) *Περὶ βίαις Νωθέως* (*Vita Mosis*, lib. i.-iii., M. ii. 80-179). It is usual to group this, as being biographical in its character, with the *Βίαι σοφῶν*, and thus to incorporate it immediately after the *De Josepho* with the large work on the Mosaic legislation. But, as has been seen, the *Βίαι σοφῶν* are intended to represent the general types of morality, while Moses is by no means so dealt with but as a unique individual. All that can be said is

that the literary character of the *Vita Mosis* is the same as that of the larger work. As in the latter the Mosaic legislation, so in the former the activity of the legislator himself, is delineated for the benefit of Gentile readers. (2) *Περὶ τοῦ πάντα σπουδαῖον εἶναι ἐλεύθερον* (*Quod omnis probus liber*, M. ii. 445-470). In the introduction to this treatise reference is made to an earlier book which had for its theme the converse proposition. The complete work was still extant in the time of Eusebius (*H. E.*, ii. 18, 6): *Περὶ τοῦ δοῦλον εἶναι πάντα φαῦλον, ὃ ἐξῆς ἐστὶν ὁ περὶ τοῦ πάντα σπουδαῖον ἐλεύθερον εἶναι*. The genuineness of the writing now possessed by us is not undisputed; but see Lucius, *Der Essenismus* (1881), pp. 13-23. (3) *Εἰς Φλάκκον* (*Adversus Flaccum*, M. ii. 517-544) and (4) *Περὶ ἀρετῶν καὶ πρεσβίας πρὸς Γάϊον* (*De legatione ad Caium*, M. ii. 545-600). These two works have a very intimate connexion. In the first Philo relates how the Roman governor Flaccus in Alexandria, towards the beginning of the reign of Caligula, allowed the Alexandrian mob, without interference, to insult the Jews of that city in the grossest manner and even to persecute them to the shedding of blood. In the second he tells how the Jews had been subjected to still greater sufferings through the command of Caligula that divine honours should be everywhere accorded to him, and how the Jews of Alexandria in vain sought relief by a mission to Rome which was headed by Philo. But both together were only parts of a larger work, in five books, of which the first two and the last have perished. For it is clear from the introduction to the *Adversus Flaccum* that it had been preceded by another book in which the Jewish persecutions by Sejanus, under the reign of Tiberius, were spoken of, and the *Chronicon* of Eusebius (ed. Schoene, vol. ii. pp. 150, 151) informs us that these persecutions of Sejanus were related in the second book of the work now under discussion. But from the conclusion of the *Legatio ad Caium*, which we still possess, we learn that it was also followed by another book which exhibited the *παλινοδία*, or change of Jewish fortunes for the better. Thus we make out five books in all,—the number actually given by Eusebius (*H. E.*, ii. 5, 1). (5) *Περὶ προνοίας* (*De providentia*). This work has reached us only in an Armenian translation, which has been edited, with a Latin translation, by Aucher (see below). It is mentioned by its Greek title in Eusebius (*H. E.*, ii. 18, 6; *Præp. Ev.*, vii. 20 fin., viii. 13 fin., ed. Gaisford). The Armenian text gives two books, but of these the first, if genuine at all, at any rate appears only in an abridged and somewhat revised state.¹ Eusebius (*Præp. Ev.*, viii. 14) quotes from the second book to an extent that amounts to a series of excerpts from the whole. The short passage in *Præp. Ev.*, vii. 21, is also taken from this book; and it appears that Eusebius knew nothing at all about the first. (6) *Ἀλεξάνδρος ἢ περὶ τοῦ λόγον εἶναι τὰ ἔλλογα ζῶα* (*De Alexandro et quod propriam rationem multa animalia habeant*; so Jerome, *De Vir. Ill.*, c. 11); the Greek title is given in Euseb., *H. E.*, ii. 18, 6. This also now exists only in an Armenian translation, which has been edited by Aucher. Two small Greek fragments occur in the *Florilegium* of Leontius and Johannes (Mai, *Scr. vet. nov. coll.*, vii. 1, pp. 99, 100a). (7) *Τροπικὰ*, a writing now known to us only through fragments preserved in Euseb., *Præp. Ev.*, viii. 6, 7. The title, as Bernays² has shown, means "Counsels," "Recommendations," the references being to such laws of the Jews as can be recommended also to non-Jewish readers. (8) *Περὶ Ἰουδαίων*, a title met with in Euseb., *H. E.*, ii. 18, 6. The writing is no doubt the same as *Ἡ ὑπὲρ Ἰουδαίων ἀπολογία*, from which a quotation is given in Euseb., *Præp. Ev.*, viii. 11. To this place also, perhaps, belongs the *De nobilitate* (M. ii. 437-444), which treats of that true noblesse of wisdom in which the Jewish people also is not wanting.³

(V.) *Spurious works* ascribed to Philo. (1) *Περὶ βίαις θεωρητικῶν ἢ ἡμετέρας ἀρετῶν* (*De vita contemplativa*, M. ii. 471-486). That the Therapeutic life here praised is that of Christian monks was seen by Euseb., *H. E.*, ii. 17 (who, however, accepted the book as Philo's), and the same view was long prevalent in the church.⁴ But, if the Therapeutæ are monks, the book cannot be genuine; see especially Lucius, *Die Therapeuten und ihre Stellung in der Gesch. der Askese*, Strassburg, 1879. There are, however, so many other objections to its genuineness that the book is now given up even by such as do not admit that the Therapeutæ are monks.⁵ (2) *Περὶ ἀφάρπτης κέρμου* (*De incorruptibilitate mundi*, M. ii. 487-516). Bernays, who first showed that the received text is disordered by misplacement of leaves (*Monatsb. Berl. Akad.*, 1863, p. 34 sq.), published a corrected text with German version in *Abh. Berl. Akad.*, 1876. An unfinished commentary of the same critic was posthumously published in the Berlin *Abhandlungen*, 1882. (3) *Περὶ κέρμου* (*De mundo*, M. ii. 601-624). That this collection of extracts from Philo, and especially from the *De incorruptibilitate*, is spurious has been long recognized. (4) Two orations, *De Sampson* and *De Jona*, pub-

¹ See Diels, *Doxographi Græci*, 1879, pp. 1-4; Zeller, *Phil. d. Gr.*, iii. 2, p. 340 (3d ed.).

² *Monatsb. d. Berl. Akad.* (1876), pp. 589-603.

³ This conjecture is Dalme's, *Theol. Stud. u. Krit.* (1833), pp. 990, 1087.

⁴ So still Montfaucon, the learned notes to whose French translation are still valuable (Paris, 1709).

⁵ Nicolas, in *Rev. Théol.*, Strassburg, 1869, p. 25 sq.; Kurnen, *Godsmans*, ii. 446-444; Weingarten, "Mönchtum," in *Herzog-Platt, R. F.*, x.

lished from the Armenian by Aucher in 1826, are generally held to be spurious.¹ (5) The lexicon of Hebrew proper names with Greek interpretations (*Ἑβραϊστικὰ ὀνόματα*), which Origen completed by adding the New Testament names, and which Jerome rewrote, was often ascribed to Philo. It appears from ancient testimonies that it bore no author's name, so that Philo's part in it is at least very problematical; nor does its original form seem to be extant (see Orig., *Comm. in Joan.*, vol. ii. c. 27; Euseb., *H. E.*, ii. 18, 7; Jerome in the preface to his recension of the book). Various Greek and Latin recensions are given by Vallarsi and in Lagarde's *Onomastica sacra*, 1870; see also on this class of literature as a whole Fabricius-Harles, *Bib. Gr.*, iv. 742 sq., vi. 199 sq., vii. 226 sq. (6) On a Latin work, *De biblicis antiquitatibus*, ascribed to Philo, see Fabr.-Harl., iv. 743. (7) For the pseudo-Philonic *Breviarium temporum*, a forgery of Annianus of Viterbo, see *ibid.* (8) The book *On Virtue*, published as Philo's by Mai (*Phil. Jud. de virt. ejusque partibus*, 1816), is a work of Gemistus Pletho.

Editions.—The first, very imperfect, edition of the Greek text of Philo is by Turnebus (Paris, 1552). Some additional pieces were given by Höschel (Frankfort, 1587; Augsburg, 1614). Other editions are those of Geneva, 1618; Paris, 1640; Frankfurt, 1691 (a page-for-page reprint of the Paris edition); but the best is still that of Mangey (2 vols., London, 1742), which alone is based on a number of MSS. and gives a critical apparatus. Pfeiffer's unfinished edition, vols. i.-v., appeared at Erlangen in 1785-95, 2d ed. 1820. An important supplement to Mangey is given by Aucher's publications from the Armenian—*Phil. Jud. sermones tres inediti*, Venice, 1822. *Phil. Jud. paralipomena Armenica*, Venice, 1826. The Greek pieces newly published since Mangey are less extensive. The editions by Mai, Grossmann, and Tischendorf have been already noticed. Aucher's publications and Mai's of 1818 are contained in the convenient edition of Richter (Leipsic, 1828-30) and in the Tauchnitz stereotype edition (1851-53). Of editions of particular works, J. G. Müller's *Des Juden Philo Buch v. d. Weltchöpfung* (Berlin, 1841), with commentary, claims special notice. Compare further for the editions and versions, Furst, *Bibl. Jud.*; Grasse, *Trésor de livres rares et précieux*, v. 269-271 (1864); and Eng. tr. by Yonge, 4 vols., London, 1854-55.

Literature.—(A.) On Philo's writings in general. Fabricius-Harles, *Bib. Gr.*, iv. 721-750. On the order of Philo's works, Gröber, *Philo und die Alexandrinische Theosophie*, i. (1831); Dahne, in *Stud. und Krit.*, 1833, p. 984 sq.; Grossmann, *De Phil. Jud. operum continuæ serie et ordine chronol.*, pts. i., ii., Leipsic, 1841-42. On the text, Creuzer, in *Stud. und Krit.*, 1832, p. 8 sq. J. G. Müller, *Texteskritik der Schr. des Juden Philo*, Basel, 1839, reprinted in his edition of the *Weltchöpfung*, 1841. On Philo's language, method, and influence on posterity, see Siegfried, *Philo von Alex. als Ausleger des A. T.*, Jena, 1875. On his knowledge of Palestinian legal tradition, B. Ritter, *Philo und die Halacha*, Leipsic, 1879. (B.) On Philo's teaching. Gröber, *op. cit.*; Dahne, *Gesch. Darstellung der jud.-alex. Religionsphilosophie*, Halle, 1834; Zeller, *Phil. d. Griechen*, pt. iii. sect. ii. (3d ed., 1881)—this is on the whole the best general sketch; Gröber and Dahne give fuller material. On special points, see Keferstein, *Philo's Lehre von dem göttlichen Mittelwesen*, Leipsic, 1846; Heinze, *Lehre vom Logos*, 1872; Soulier, *La doctrine du Logos chez Philon*, Turin, 1876. (E. S.')

PHILO. A Jewish Hellenist of this name is the author of an epic poem in Greek hexameters on the History of Jerusalem, and lived at an earlier date than the philosopher, Alexander Polyhistor quoting several passages of his book about 80-60 B.C. From Alexander Eusebius derives these extracts from the poem (*Præp. Ev.*, ix. 20, 24, 37). This is probably the Philo who is mentioned by Clemens Alexandrinus (*Strom.*, i. 21, 141) and Josephus (*C. Ap.*, i. 23). See Philippson's work on the Jewish poets Ezechiel and Philo (1830) and Müller, *Fr. Hist. Gr.*, iii. 213 sq.

PHILO BYBLIUS, i.e., Philo of Byblus (Gabal, Jubeil), was born, according to Suidas, in 42 A.D., and lived into the reign of Hadrian, about which he wrote a book now wholly lost. He was a grammarian by profession and author of many books, of which those oftenest cited are: (1) a work *About Cities and the Famous Men they have produced*, which was epitomized by Serenus, and (2) *Phœnician History*. Of the latter there are very considerable fragments, chiefly preserved by Eusebius in the *Præparatio Evangelica*, and presenting a Euhemeristic *réchauffé* of Phœnician theology and mythology which is represented as translated from the Phœnician of Sanchuniathon. The fragments of Philo are collected in Müller, *Fr. Hist. Gr.*, iii. 560 sq. To the literature there cited add Ewald's essay in the *Abhandlungen of the Royal Society of Göttingen*, vol. v (1853); Renan's in *Mém. Acad. des Inscriptions*, vol. xxiii. (1858); and Baudissin, *Studien zur semitischen Religionsgeschichte*, i. 3 sq.

PHILO OF BYZANTIUM, author of a treatise on mechanics, of which only two books now remain, flourished in the 2d or 3d century A.D. The extant books, which refer to machines used in war and to siege works, are

edited with a German translation in Köchly and Rüstow's *Griechische Kriegsschriftsteller*, vol. i. (Leipsic, 1853).

For a list of other Philos, see Fabricius, *Bibl. Græca*, iv. p. 750 sq., ed. Harl.

PHILOLAUS, next to Archytas the most illustrious of the Pythagorean philosophers, was born at Tarentum or, according to Diogenes Laertius, at Crotona.² He was said to have been intimate with Democritus, and was probably one of his teachers. After the death of Pythagoras great dissensions prevailed in the cities of lower Italy, which were allayed only after the lapse of many years through the intervention of the Achæans. According to some accounts Philolaus was obliged to flee, and owed his escape to his youthful energy. He took refuge first in Lucania, then in Greece; he lived at Thebes, where he had for pupils Simmias and Cebes, who subsequently, being still young men (*νεανίσκοι*), were present at the death of Socrates. Prior to this Philolaus had left Thebes and returned to Italy, where he was the teacher of Archytas. Pythagoras published nothing, nor did the other early Pythagoreans; the members of the brotherhood, moreover, piously referred their discoveries back to their master, hence many doctrines have been attributed to Pythagoras which were first propounded later in the school. He entered deeply into the number-theory, which constituted the distinctive feature of the Pythagorean philosophy, and in particular dwelt on the properties inherent in the decad—the sum of the first four numbers, consequently the fourth triangular number, the tetractys—which he called great, all-powerful, and all-producing. The discovery of the regular solids is attributed to Pythagoras by Eudemus, and Empedocles is stated to have been the first who maintained that there were four elements. Philolaus, connecting these ideas, held that the elementary nature of bodies depended on their form, and assigned the tetrahedron to fire, the octahedron to air, the icosahedron to water, and the cube to earth; the dodecahedron he assigned to a fifth element, æther, or, as some think, to the universe. This theory indicates considerable knowledge of geometry on the part of its author; it gave, moreover, a great impulse to the study of that science, and many important results were arrived at, so that Aristæus, who lived before Euclid, was able to write a book on the comparison of the five regular solids.

Philolaus was the first to propound the doctrine of the motion of the earth; some, however, attribute this doctrine to Pythagoras, but there is no evidence in support of their view. Philolaus supposed that the sphere of the fixed stars, the five planets, the sun, moon, and earth, all moved round the central fire, which he called the hearth of the universe, the house of Zeus, and the mother of the gods; but as these made up only nine revolving bodies he conceived, in accordance with his number-theory, a tenth, which he called counter-earth, *ἀντίχθων*. He was the first who published a book on the Pythagorean doctrines, a treatise of which Plato made use in the composition of his *Timæus*. This work of the Pythagorean, to which the mystical name *Βάκχαι* is sometimes given, seems to have consisted of three books: (1) *Περὶ κόσμου*, containing a general account of the origin and arrangement of the universe; (2) *Περὶ φύσεως*, an exposition of the nature of numbers; (3) *Περὶ ψυχῆς*, on the nature of the soul.

See Boeckh, *Philolaos des Pythagoreers Lehren nebst den Bruchstücken seines Werkes* (Berlin, 1819); also Fabricius, *Bibliotheca Græca*; Zeller, *History of Greek Philosophy*; and Chaignet, *Pythagore et la Philosophie Pythagoricienne, contenant les Fragments de Philolaos et d'Archytas* (1873).

² Boeckh places his life between the 70th and 95th Olympiads (496-396 B.C.). He was a contemporary of Socrates and Democritus, but senior to them, and was probably somewhat junior to Empedocles, so that his birth may be placed at about 480.

¹ See Dähne, *Stud. und Krit.*, 1833, p. 987 sq.; Freudenthal, *Die Fl. Joseph, beigelegte Schrift über die Herrschaft der Vernunft*, 1869, pp. 9 sq., 141 sq.

PHILOLOGY

PART I.—SCIENCE OF LANGUAGE IN GENERAL.

PHILOLOGY is the generally accepted comprehensive name for the study of the word; it designates that branch of knowledge which deals with human speech, and with all that speech discloses as to the nature and history of man. Philology has two principal divisions, corresponding to the two uses of "word" or "speech," as signifying either what is said or the language in which it is said, as either the thought expressed—which, when recorded, takes the form of literature—or the instrumentality of its expression: these divisions are the literary and the linguistic. Not all study of literature, indeed, is philological: as when, for example, the records of the ancient Chinese are ransacked for notices of astronomical or meteorological phenomena, or the principles of geometry are learned from the text-book of a Greek sage; while, on the other hand, to study Ptolemy and Euclid for the history of the sciences represented by them is philological more than scientific. Again, the study of language itself has its literary side: as when the vocabulary of a community (say of the ancient Indo-Europeans or Aryans) is taken as a document from which to infer the range and grade of knowledge of its speakers, their circumstances, and their institutions. The two divisions thus do not admit of absolute distinction and separation, though for some time past tending toward greater independence. The literary is the older of the two; it even occupied until recently the whole field, since the scientific study of language itself has arisen only within the present century. Till then, literary philology included linguistic, as a merely subordinate and auxiliary part, the knowledge of a language being the necessary key to a knowledge of the literature written in that language. When, therefore, instead of studying each language by itself for the sake of its own literature, men began to compare one language with another, in order to bring to light their relationships, their structures, their histories, the name "comparative philology" naturally enough suggested itself and came into use for the new method; and this name, awkward and trivial though it may be, has become so firmly fixed in English usage that it can be only slowly, if at all, displaced. Continental usage (especially German) tends more strongly than English to restrict the name philology to its older office, and to employ for the recent branch of knowledge a specific term, like those that have gained more or less currency with us also: as glottic, glossology, linguistics, linguistic science, science of language, and the like. It is not a question of absolute propriety or correctness, since the word philology is in its nature wide enough to imply all language-study, of whatever kind; it is one, rather, of the convenient distinction of methods that have grown too independent and important to be any longer well included under a common name.

Philology, in all its departments, began and grew up as classical; the history of our civilization made the study of Greek and Latin long the exclusive, still longer the predominant and regulating, occupation of secular scholarship. The Hebrew and its literature were held apart, as something of a different order, as sacred. It was not imagined that any tongue to which culture and literature did not lend importance was worthy of serious attention from scholars. The first essays in comparison, likewise, were made upon the classical tongues, and were as erroneous in method and fertile in false conclusions as was to be expected, considering the narrowness of view and the controlling prejudices of those who made them; and the

admission of Hebrew to the comparison only added to the confusion. The change which this century has seen has been a part of the general scientific movement of the age which has brought about the establishment of so many new branches of knowledge, both historical and physical, by the abandonment of shackling prejudices, the freedom of inquiry, the recognition of the dignity of all knowledge, the wide-reaching assemblage of facts and their objective comparison, and the resulting constant improvement of method. Literary philology has had its full share of advantage from this movement; but linguistic philology has been actually created by it out of the crude observations and wild deductions of earlier times, as truly as chemistry out of alchemy, or geology out of diluvianism. It is unnecessary here to follow out the details of the development, but we may well refer to the decisive influence of one discovery, the decisive action of one scholar. It was the discovery of the special relationship of the Aryan or Indo-European languages, depending in great measure upon the introduction of the Sanskrit as a term in their comparison, and demonstrated and worked out by the German scholar Bopp, that founded the science of linguistic philology. While there is abundant room for further improvement, it yet appears that the grand features of philologic study, in all its departments, are now so distinctly drawn that no revolution of its methods, but only their modification in minor respects, is henceforth probable. How and for what purposes to investigate the literature of any people (philology in the more proper sense), combining the knowledge thus obtained with that derived from other sources; how to study and set forth the material and structure and combinations of a language (grammar), or of a body of related languages (comparative grammar); how to co-ordinate and interpret the general phenomena of language, as variously illustrated in the infinitely varying facts of different tongues, so as to exhibit its nature as a factor in human history, and its methods of life and growth (linguistic science),—these are what philology teaches. The first two subjects are mainly disposed of in this work in the various articles devoted to countries and races, with their literatures and dialects; the last was briefly touched upon in the article ANTHROPOLOGY, but requires fuller treatment here, along with a general view of the classification of languages, as thus far effected.

The study of language is a division of the general science of anthropology, and is akin to all the rest in respect of its objects and its methods. Man as we now see him is a twofold being: in part the child of nature, as to his capacities and desires, his endowments of mind and body; in part the creature of education, by training in the knowledge, the arts, the social conduct, of which his predecessors have gained possession. And the problem of anthropology is this: how natural man has become cultivated man; how a being thus endowed by nature should have begun and carried on the processes of acquisition which have brought him to his present state. The results of his predecessors' labours are not transmuted for his benefit into natural instincts, in language or in anything else. The child of the most civilized race, if isolated and left wholly to his own resources, aided by neither the example nor the instruction of his fellows, would no more speak the speech of his ancestors than he would build their houses, fashion their clothes, practise any of their arts, inherit their knowledge or wealth. In fact, he would

possess no language, no arts, no wealth, but would have to go to work to acquire them, by the same processes which began to win them for the first human beings. One advantage he would doubtless enjoy: the descendant of a cultivated race has an enhanced aptitude for the reception of cultivation; he is more cultivable; and this is an element that has to be allowed for in comparing present conditions with past, as influencing the rate of progress, but nothing more. In all other respects, it is man with the endowments which we now find him possessed of, but destitute of the gradually accumulated results of the exercise of his faculties, whose progress we have to explain. And it is, as a matter of necessity, by studying recent observable modes of acquisition, and transferring them, with due allowance for different circumstances, to the more primitive periods, that the question of first acquisition or origin is to be solved, for language as for tools, for arts, for family and social organization, and the rest. There is just as much, and just as little, reason for assuming miraculous interference and aid in one of these departments as in another. If men have been left to themselves to make and improve instruments, to form and perfect modes of social organization, by implanted powers directed by natural desires, and under the pressure of circumstances, then also to make and change the signs that constitute their speech. All expressions, as all instruments, are at present, and have been through the known past, made and changed by the men who use them; the same will have been the case in the unknown or prehistoric past. And we command now enough of the history of language, with the processes of its life and growth, to determine with confidence its mode of origin—within certain limits, as will appear below.

Cause of
language-
making.

It is beyond all question, in the first place, that the desire of communication was the only force directly impelling men to the production of language. Man's sociality, his disposition to band together with his fellows, for lower and for higher purposes, for mutual help and for sympathy, is one of his most fundamental characteristics. To understand those about one and to be understood by them is now, and must have been from the very beginning, a prime necessity of human existence; we cannot conceive of man, even in his most undeveloped state, as without the recognition of it. Communication is still the universally recognized office of speech, and to the immense majority of speakers the only one; the common man knows no other, and can only with difficulty and imperfectly be brought to see that there is any other; of the added distinctness and reach of mental action which the possession of such an instrumentality gives him, he is wholly unconscious: and it is obvious that what the comparatively cultivated being of to-day can hardly be made to realize, can never have acted upon the first men as a motive to action. It may perhaps be made a question which of the two uses of speech, communication or the facilitation of thought, is the higher; there can be no question, at any rate, that the former is the broader and the more fundamental. That the kind and degree of thinking which we do nowadays would be impossible without language-signs is true enough; but so also it would be impossible without written signs. That there was a time when men had to do what mental work they could without the help of writing, as an art not yet devised, we have no difficulty in realizing, because the art is of comparatively recent device, and there are still communities enough that are working without it; it is much harder to realize that there was a time when speaking also was an art not yet attained, and that men had to carry on their rude and rudimentary thinking without it. Writing too was devised for conscious purposes of communication only; its esoteric uses, like

those of speech, were at first unsuspected, and incapable of acting as an inducement; they were not noticed until made experience of, and then only by those who look beneath the surface of things. There is no analogy closer and more instructive than this, between speech and writing. But analogies are abundant elsewhere in the history of human development. Everywhere it is the lower and more obvious inducements that are first effective, and that lead gradually to the possession of what serves and stimulates higher wants. All the arts and industries have grown out of men's effort to get enough to eat and protection against cold and heat—just as language, with all its uses, out of men's effort to communicate with their fellows. As a solitary man now would never form even the beginnings of speech, as one separated from society unlearns his speech by disuse and becomes virtually dumb, so early man, with all his powers, would never have acquired speech, save as to those powers was added sociality with the needs it brought. We might conceive of a solitary man as housing and dressing himself, devising rude tools, and thus lifting himself a step from wildness toward cultivation; but we cannot conceive of him as ever learning to talk. Recognition of the impulse to communication as the efficient cause of language-making is an element of primary importance in the theory of the origin of language. No one who either leaves it out of account or denies it will, however ingenious and entertaining his speculations, cast any real light on the earliest history of speech. To inquire under what peculiar circumstances, in connexion with what mode of individual or combined action, a first outburst of oral expression may have taken place, is, on the other hand, quite futile. The needed circumstances were always present when human beings were in one another's society; there was an incessant drawing-on to attempts at mutual understanding which met with occasional, and then ever more frequent and complete success. There inheres in most reasoning upon this subject the rooted assumption, governing opinion even when not openly upheld or consciously made, that conceptions have real natural names, and that in a state of nature these will somehow break forth and reveal themselves under favouring circumstances. The falsity of such a view is shown by our whole further discussion.

The character of the motive force to speech determined the character of the beginnings of speech. That was first signified which was most capable of intelligible signification, not that which was first in order of importance, as judged by any standard which we can apply to it, or first in order of conceptional development. All attempts to determine the first spoken signs by asking what should have most impressed the mind of primitive man are and must be failures. It was the exigencies and possibilities of practical life, in conditions quite out of reach of our distinct conception, that prescribed the earliest signs of communication. So, by a true and instructive analogy, the beginnings of writing are rude depictions of visible objects; it is now thoroughly recognized that no alphabet, of whatever present character, can have originated in any other way; everything else is gradually arrived at from that—as, indeed, in the ingeniously shaping hands of man, from any central body of signs, though but of small extent, all else is attainable by processes of analogy and adaptation and transfer. Now what is it that is directly signifiable in the world about us? Evidently, the separate acts and qualities of sensible objects, and nothing else. In writing, or signification to the eye, the first element is the rude depiction of the outline of an object, or of that one of the sum of its characteristic qualities which the eye takes note of and the hand is capable of intelligibly reproducing; from that the mind understands the whole

complex object itself, and then whatever further may in the circumstances of its use be suggested by it. So, for example, the picture of a tree signifies primarily a tree, then perhaps wood, something made of wood, and so on; that of a pair of outstretched wings signifies secondarily flight, then soaring, height, and whatever else these may lead to. No concrete thing is signifiable in its totality, or otherwise than by a facile analysis of its constituent qualities, and a selection of the one which is both sufficiently characteristic in itself and capable of being called up by a sign before the mind addressed.

And what quality shall be selected depends in great measure upon the instrumentality used for its signification. Of such instrumentalities, men are possessed of a considerable variety. We must leave out of account that of depiction, as just instanced, because its employment belongs to a much more advanced state of cultivation, and leads the way to the invention not of speech but of the analogous and auxiliary art of writing. There remain gesture, or changes of position of the various parts of the body, especially of the most mobile parts, the arms and hands; grimace, or the changes of expression of the features of the countenance (in strictness, a variety of the preceding); and utterance, or the production of audible sound. It cannot be doubted that, in the first stages of communicative expression, all these three were used together, each for the particular purposes which it was best calculated to serve. The nearest approach to such action that is now possible is when two persons, wholly ignorant of one another's speech, meet and need to communicate—an imperfect correspondence, because each is trained to habits of expression, and works consciously, and with the advantage of long experience, towards making himself understood; yet it is good for its main purpose. What they do, to reach mutual comprehension, is like what the first speechless men, unconsciously and infinitely more slowly, learned to do: face, hands, body, voice, are all put to use. It is altogether probable that gesture at first performed the principal part, even to such extent that the earliest human language may be said to have been a language of gesture-signs; indeed, there exist at the present day such gesture-languages, as those in use between roving tribes of different speech that from time to time meet one another (the most noted example is that of the gesture-language, of a very considerable degree of development, of the prairie tribes of American Indians); or such signs as are the natural resort of those who by deafness are cut off from ordinary spoken intercourse with their fellows. Yet there never can have been a stage or period in which all the three instrumentalities were not put to use together. In fact, they are still all used together; that is even now an ineffective speaking to which grimace and gesture ("action," as Demosthenes called them) are not added as enforcers; and the lower the grade of development and culture of a language, the more important, even for intelligibility, is their addition. But voice has won to itself the chief and almost exclusive part in communication, inasmuch that we call all communication "language" (i.e., "tonguiness") just as a race of mutes might call it "handiness," and talk (by gesture) of a handiness of grimace. This is not in the least because of any closer connexion of the thinking apparatus with the muscles that act to produce audible sounds than with those that act to produce visible motions; not because there are natural uttered names for conceptions, any more than natural gestured names. It is simply a case of "survival of the fittest," or analogous to the process by which iron has become the exclusive material of swords; and gold and silver of money: because, namely, experience has shown this to be the material best adapted to this special use. The advantages of voice are numerous

and obvious. There is first its economy, as employing a mechanism that is available for little else, and leaving free for other purposes those indispensable instruments the hands. Then there is its superior perceptibility: its nice differences impress themselves upon the sense at a distance at which visible motions become indistinct; they are not hidden by intervening objects; they allow the eyes of the listener as well as the hands of the speaker to be employed in other useful work; they are as plain in the dark as in the light; and they are able to catch and command the attention of one who is not to be reached in any other way. We might add as the third advantage a superior capability of variation and combination on the part of spoken sounds; but this is not to be insisted on, inasmuch as we hardly know what a gesture-language might have become if men's ingenuity in expression had been expended through all time upon its elaboration; and the superiority, however real, can hardly have been obvious enough to serve as a motive: certainly, there are spoken languages now existing whose abundance of resources falls short of what is attainable by gesture. Oral utterance is the form which expression has inevitably taken, the sum of man's endowments being what it is; but it would be a mistake to suppose that a necessity of any other kind is involved in their relation. The fundamental conditions of speech are man's grade of intellectual power and his social instinct; these being given, his expression follows, availing itself of what means it finds best suited to its purpose; if voice had been wanting, it would have taken the next best. So, in certain well-known cases, a marked artistic gift, on the part of individuals deprived of the use of hands, has found means of exercise in the feet instead. But men in general have hands, instruments of exquisite tact and power, to serve the needs of their intellect; and so voice also, to provide and use the tools of thought; there is no error in maintaining that the voice is given us for speech, if only we do not proceed to draw from such a *dictum* false conclusions as to the relation between thought and utterance. Man is created with bodily instruments suited to do the work prescribed by his mental capacities; therein lies the harmony of his endowment.

It is through imitation that all signification becomes directly suggestive. The first written signs are (as already noticed) the depictions of visible objects, and could be nothing else; and, by the same necessity, the first uttered signs were the imitations of audible sounds. To reproduce any sound of which the originating cause or the circumstances of production are known, brings up of course before the conception that sound, along with the originator, or circumstances of origination, or whatever else may be naturally associated with it. There are two special directions in which this mode of sign-making is fruitful: imitation of the sounds of external nature (as the cries of animals, and the noises of inanimate objects when in motion or acted on by other objects) and imitation of human sounds. The two are essentially one in principle, although by some held apart, or even opposed to each other, as respectively the imitative or onomatopoeic and the exclamatory or interjectional beginnings of speech; they differ only in their spheres of significance, the one being especially suggestive of external objects, the other of inward feelings. There are natural human tones, indicative of feeling, as there are natural gestures, poses, modes of facial expression, which either are immediately intelligible to us (as is the warning cry of the hen to the day-old chicken), or have their value taught us by our earliest experiences. If we hear a cry of joy or a shriek of pain, a laugh or a groan, we need no explanation in words to tell us what it signifies, any more than when we see a sad face or a drooping attitude. So also the characteristic cry

or act of anything outside ourselves, if even rudely imitated, is to us an effective reminder and awakener of conception. We have no reason to question that such were the suggestions of the beginnings of uttered expression. The same means have made their contributions to language even down to our own day; we call words so produced "onomatopoeic" (i.e., "name-making"), after the example of the Greeks, who could not conceive that actually new additions to language should be made in any other way. What and how wide the range of the imitative principle, and what amount of language-signs it was capable of yielding, is a subject for special investigation—or rather, of speculation, since anything like exact knowledge in regard to it will never be attained; and the matter is one of altogether secondary consequence; it is sufficient for our purpose that enough could certainly be won in this way to serve as the effective germs of speech.

All the natural means of expression are still at our command, and are put to more or less use by us, and their products are as intelligible to us as they have been to any generation of our ancestors, back to the very first. They are analogous also to the means of communication of the lower animals; this, so far as we know, consists in observing and interpreting one another's movements and natural sounds (where there are such). But language is a step beyond this, and different from it. To make language, the intent to signify must be present. A cry wrung out by pain, or a laugh of amusement, though intelligible, is not language; either of them, if consciously reproduced in order to signify to another pain or pleasure, is language. So a cough within hearing of any one attracts his attention; but to cough, or to produce any other sound, articulate or inarticulate, for the purpose of attracting another's attention, is to commit an act of language-making, such as in human history preceded in abundance the establishment of definite traditional signs for conceptions. Here begins to appear the division between human language and all brute expression; since we do not know that any animal but man ever definitely took this step. It would be highly interesting to find out just how near any come to it; and to this point ought to be especially directed the attention of those who are investigating the communication of the lower animals in its relation to human communication. Among the animals of highest intelligence that associate with man and learn something of his ways, a certain amount of sign-making expressly for communication is not to be denied; the dog that barks at a door because he knows that somebody will come and let him in is an instance of it; perhaps, in wild life, the throwing out of sentinel birds from a flock, whose warning cry shall advertise their fellows of the threat of danger, is as near an approach to it as is anywhere made.

But the actual permanent beginnings of speech are only reached when the natural basis is still further abandoned, and signs begin to be used, not because their natural suggestiveness is seen in them, but by imitation, from the example of others who have been observed to use the same sign for the same purpose. Then for the first time the means of communication becomes something to be handed down, rather than made anew by each individual; it takes on that traditional character which is the essential character of all human institutions, which appears not less in the forms of social organization, the details of religious ceremonial, the methods of art and the arts, than in language. That all existing speech, and all known recorded speech, is purely traditional, cannot at all be questioned. It is proved even by the single fact that for any given conception there are as many different spoken signs as there are languages—say a thousand (this number is rather far within than beyond the truth) each of them intelli-

gible to him who has learned to use it and to associate it with the conception to which it belongs, but unintelligible to the users of the nine hundred and ninety-nine other signs, as these are all unintelligible to him; unless, indeed, he learn a few of them also, even as at the beginning he learned the one that he calls his own. What single sign, and what set of signs, any individual shall use, depends upon the community into the midst of which he is cast, by birth or other circumstances, during his first years. That it does not depend upon his race is demonstrated by facts the most numerous and various; the African whose purity of descent is attested by every feature is found all over the world speaking just that language, or jargon, into the midst of which the fates of present or former slavery have brought his parents; every civilized community contains elements of various lineage, combined into one by unity of speech; and instances are frequent enough where whole nations speak a tongue of which their ancestors knew nothing: for example, the Celtic Gauls and the Germanic Normans of France speak the dialect of a geographically insignificant district in central Italy, while we ourselves can hardly utter a sentence or write a line without bringing in more or less of that same dialect. There is not an item of any tongue of which we know anything that is "natural" expression, or to the possession of which its speaker is brought by birth instead of by education; there is even very little that is traceably founded on such natural expression: everywhere *θεός* or human attribution reigns supreme, and the original *φύσις* or natural significance has disappeared, and is only to be found by theoretic induction (as we have found it above). It seems to some as if a name like *cuckoo* (one of the most striking available cases of onomatopœia) were a "natural" one; but there is just as much *θεός* in it as in any other name; it implies the observation of an aggregate of qualities in a certain bird, and the selection of one among them as the convenient basis of a mutual understanding when the bird is in question; every animal conspicuous to us must have its designation, won in one way or another; and in this case, to imitate the characteristic cry is the most available way. If anything but convenience and availability were involved, all our names for animals would have to be and to remain imitations of the sounds they make. That the name of *cuckoo* is applied also to the female and young, and at other than the singing season, and then to related species which do not make the same sound—all helps to show the essentially conventional character of even this name. An analogous process of elimination of original meaning, and reduction to the value of conventional designation merely, is to be seen in every part of language, throughout its whole history. Since men ceased to derive their names from signs having a natural suggestiveness, and began to make them from other names already in use with an understood value, every new name has had its etymology and its historical occasion—as, for example, the name *quarantine* from the two-score (*quarantaine*) of days of precautionary confinement, or *volume* from its being rolled up, or *book* from a beech-wood staff, or *copper* from Cyprus, or *lunacy* from a fancied influence of the moon, or *priest* from being an older (*πρεσβύτερος*) person, or *butterfly* from the butter-yellow colour of a certain common species: every part of our language, as of every other, is full of such examples—but, when once the name is applied, it belongs to that to which it is applied, and no longer to its relatives by etymology: its origin is neglected, and its form may be gradually changed beyond recognition, or its meaning so far altered that comparison with the original shall seem a joke or an absurdity. This is a regular and essential part of the process of name-making in all human speech, and from

the very beginning of the history of speech: in fact (as pointed out above), the latter can only be said to have begun when this process was successfully initiated, when uttered signs began to be, what they have ever since continued to be, conventional, or dependent only on a mutual understanding. Thus alone did language gain the capacity of unlimited growth and development. The sphere and scope of natural expression are narrowly bounded; but there is no end to the resources of conventional sign-making.

It is well to point out here that this change of the basis of men's communication from natural suggestiveness to mutual understanding, and the consequent purely conventional character of all human language, in its every part and particle, puts an absolute line of demarcation between the latter and the means of communication of all the lower animals. The two are not of the same kind, any more than human society in its variety of organization is of the same kind with the instinctive herding of wild cattle or swarming of insects, any more than human architecture with the instinctive burrowing of the fox and nest-building of the bird, any more than human industry and accumulation of capital with the instinctive hoarding of bees and beavers. In all these cases alike, the action of men is a result of the adaptation of means at hand to the satisfaction of felt needs, or of purposes dimly perceived at first, but growing clearer with gradually acquired experience. Man is the only being that has established institutions—gradually accumulated and perfected results of the exercise of powers analogous in kind to, but greatly differing in degree from, those of the lower animals. The difference in degree of endowment does not constitute the difference in language, it only leads to it. There was a time when all existing human beings were as destitute of language as the dog; and that time would come again for any number of human beings who should be cut off (if that were practicable) from all instruction by their fellows: only they would at once proceed to re-create language, society, and arts, by the same steps by which their own remote ancestors created those which we now possess; while the dog would remain what he and his ancestors have always been, a creature of very superior intelligence, indeed, as compared with most, of infinite intelligence as compared with many, yet incapable of rising by the acquisition of culture, through the formation and development of traditional institutions. There is just the same *saltus* existent in the difference between man's conventional speech and the natural communication of the lower races as in that between men's forms of society and the instinctive associations of the lower races; but it is no greater and no other; it is neither more absolute and characteristic nor more difficult to explain. Hence those who put forward language as the distinction between man and the lower animals, and those who look upon our language as the same in kind with the means of communication of the lower animals, only much more complete and perfect, fail alike to comprehend the true nature of language, and are alike wrong in their arguments and conclusions. No addition to or multiplication of brute speech would make anything like human speech; the two are separated by a step which no animal below man has ever taken; and, on the other hand, language is only the most conspicuous among those institutions the development of which has constituted human progress, while their possession constitutes human culture.

With the question of the origin of man, whether or not developed out of lower animal forms, intermediate to the anthropoid apes, language has nothing to do, nor can its study ever be made to contribute anything to the solution of that question. If there once existed creatures above the apes and below man, who were extirpated by primitive

man as his especial rivals in the struggle for existence, or became extinct in any other way, there is no difficulty in supposing them to have possessed forms of speech, more rudimentary and imperfect than ours. At any rate, all existing human speech is one in the essential characteristics which we have thus far noted or shall hereafter have to consider, even as humanity is one in its distinction from the lower animals; the differences are in non-essentials. All speech is one in the sense that every human being, of whatever race he may be, is capable of acquiring any existing tongue, and of using it for the same purposes for which its present possessors use it, with such power and effect as his individual capacity allows, and without any essential change in the mental operations carried on by means of speech—even as he may acquire any other of the items of culture belonging to a race not his own. The difference between employing one language and another is like that between employing one instrument and another in mechanical arts; one instrument may be better than another, and may enable its user to turn out better work, but the human ingenuity behind both is the same, and works in the same way. Nor has the making of language anything whatever to do with making man what he is, as an animal species having a certain physical form and intellectual endowment. Being what he is by nature, man has by the development of language and other institutions become what he is by culture. His acquired culture is the necessary result of his native endowment, not the contrary. The acquisition of the first stumbling beginnings of a superior means of communication had no more influence to raise him from a simian to a human being than the present high culture and perfected speech of certain races has to lift them up to something more than human, and specifically different from the races of inferior culture. It cannot be too absolutely laid down that differences of language, down to the possession of language at all, are differences only in respect to education and culture.

How long man, after he came into being such as he now is, physically and intellectually, continued to communicate with imitative signs of direct significance, when the production of traditional signs began, how rapidly they were accumulated, and how long any traces of their imitative origin clave to them—these and the like questions it is at present idle to try to answer even conjecturally: just as it is to seek to determine when the first instruments were used, how soon they were shaped instead of being left crude, at what epoch fire was reduced to service, and so on. The stages of development and their succession are clear enough; to fix their chronology will doubtless never be found practicable. There is much reason for holding, as some do, that the very first items of culture were hardest to win and cost most time, the rate of accumulation (as in the case of capital) increasing with the amount accumulated. Beyond all reasonable question, however, there was a positively long period of purely imitative signs, and a longer one of mixed imitative and traditional ones, the latter gradually gaining upon the former, before the present condition of things was reached, when the production of new signs by imitation is only sporadic and of the utmost rarity, and all language-signs besides are traditional, their increase in any community being solely by variation and combination, and by borrowing from other communities.

Of what nature, in various respects, this earliest language-material was is sufficiently clear. The signs, in the first place, were of the sort that we call "roots." By this is only meant that they were integral signs, significant in their entirety, not divisible into parts, of which one signified one thing and another another thing, or of which one gave the main significance, while another was an added sign of kind or relation. In a language of

Develop-
ment of
language
signs.

developed structure like our own, we arrive at such "roots" mainly by an artificial stripping-off of the signs of relation which almost every word still has, or can be shown to have once had. In *un-cost-li-ness*, for example, *cost* is the centrally significant element; so far as English is concerned, it is a root, about which cluster a whole body of forms and derivatives; if we could follow its history no farther, it would be to us an ultimate root, as much so as *bind* or *sing* or *mean*. But we can follow it up, to the Latin compound *con-sta*, a root *sta* with a prefixed formative element *con*. Then *sta*, which in slightly varied forms we find in a whole body of related tongues called "Aryan," having in them all the same significance "stand," is an Aryan root, and to us an ultimate one, because we can follow its history no farther; but there always remains the possibility that it is as far from being actually original as is the English root *cost*: that is to say, it is not within our power ever to get back to the really primitive elements of speech, and to demonstrate their character by positive evidence. The reason for accepting a primitive root-stage of language is in great part theoretical: because nothing else is reconcilable with any acceptable view of the origin of language. The law of the simplicity of beginnings is an absolute one for everything of the nature of an institution, for every gradually developed product of the exercise of human faculties. That an original speech sign should be of double character, one part of it meaning this and another part that, or one part radical and the other formative, is as inconceivable as that the first instruments should have had handles, or the first shelters a front room and a back one. But this theoretical reason finds all the historical support which it needs in the fact that, through all the observable periods of language-history, we see formative elements coming from words originally independent, and not from anything else. Thus, in the example just taken, the *-li-* of *costliness* is a suffix of so recent growth that its whole history is distinctly traceable; it is simply our adjective *like*, worn down in both form and meaning to a subordinate value in combination with certain words to which it was appended, and then added freely as a suffix to any word from which it was desired to make a derivative adjective—or, later but more often, a derivative adverb. The *ness* is much older (though only Germanic), and its history obscurer; it contains, in fact, two parts, neither of them of demonstrable origin; but there are equivalent later suffixes, as *ship* in *hardship* and *dom* in *wisdom*, whose derivation from independent words (*shape*, *doom*) is beyond question. The *un-* of *uncostliness* is still more ancient (being Aryan), and its probably pronominal origin hardly available as an illustration; but the comparatively modern prefix *be-*, of *become*, *believe*, &c., comes from the independent preposition *by*, by the same process as *-ly* or *-li-* from *like*. And the *con* which has contributed its part to the making of the quasi-root *cost* is also in origin identical with the Latin preposition *cum* "with." By all the known facts of later language-growth, we are driven to the opinion that every formative element goes back to some previously existing independent word; and hence that in analysing our present words we are retracing the steps of an earlier synthesis, or following up the history of our formed words toward the unformed roots out of which they have grown. The doctrine of the historical growth of language-structure leads by a logical necessity to that of a root-stage in the history of all language; the only means of avoiding the latter is the assumption of a miraculous element in the former.

Of what phonetic form were the earliest traditional speech-signs is, so far as essentials are concerned, to be inferred with reasonable certainty. They were doubtless

articulate: that is to say, composed of alternating consonant and vowel sounds, like our present speech; and they probably contained a part of the same sounds which we now use. All human language is of this character; there are no sounds in any tongue which are not learned and reproduced as easily by children of one race as of another; all dialects admit a like phonetic analysis, and are representable by alphabetic signs; and the leading sounds, consonant and vowel, are even practically the same in all; though every dialect has its own (for the most part, readily definable and imitable) niceties of their pronunciation, while certain sounds are rare, or even met with only in a single group of languages, or in a single language. Articulate sounds are such as are capable of being combined with others into that succession of distinct yet connectable syllables which is the characteristic of human speech-utterance. The name "articulate" belongs to this utterance, as distinguished from inarticulate human sounds and cries, and from the sounds made by the lower animals. The word itself is Latin, by translation from the Greek, and, though very widely misunderstood, and even deliberately misapplied in some languages to designate all sound, of whatever kind, uttered by any living creature, is a most happily chosen and truly descriptive term. It signifies "jointed," or broken up into successive parts, like a limb or stem; the joints are the syllables; and the syllabic structure is mainly effected by the alternation of closer or consonant sounds with opener or vowel sounds. The simplest syllabic combination (as the facts of language show) is that of a single consonant with a following vowel; and there are languages even now existing which reject any other. Hence there is much plausibility in the view that the first speech-signs will have had this phonetic form, and been monosyllabic, or dissyllabic only by repetition (reduplication) of one syllable, such as the speech of very young children shows to have a peculiar ease and naturalness. The point, however, is one of only secondary importance, and may be left to the further progress of phonetic study to settle, if it can; the root-theory, at any rate, is not bound to any definite form or extent of root, but only denies that there can have been any grammatical structure in language except by development in connexion with experience in the use of language. What particular sounds, and how many, made up the first spoken alphabet, is also a matter of conjecture merely; they are likely to have been the closest consonants and the openest vowels, medial utterances being of later development.

As regards their significant value, the first language-signs must have denoted those physical acts and qualities which are directly apprehensible by the senses; both because these alone are directly significant, and because it was only they that untrained human beings had the power to deal with or the occasion to use. Such signs would then be applied to more intellectual uses as fast as there was occasion for it. The whole history of language, down to our own day, is full of examples of the reduction of physical terms and phrases to the expression of non-physical conceptions and relations; we can hardly write a line without giving illustrations of this kind of linguistic growth. So pervading is it, that we never regard ourselves as having read the history of any intellectual or moral term till we have traced it back to a physical origin. And we are still all the time drawing figurative comparisons between material and moral things and processes, and calling the latter by the names of the former. There has never been any difficulty in providing for new knowledge and more refined thought by putting to new uses the earlier and grosser materials of speech.

As a matter of course, whatever we now signify by our simple expressions for simple acts, wants, and the like,

was intended to be signified through the first speech-signs by the users of them. But to us, with our elaborated apparatus of speech, the sentence, composed of subject and predicate, with a verb or special predicative word to signify the predication, is established as the norm of expression, and we regard everything else as an abbreviated sentence, or as involving a virtual sentence. With a view to this, we must have "parts of speech": that is, words held apart in office from one another, each usable for such and such a purpose and no other, and answering a due variety of purposes, so that when they are combined they fit together, as parts composing a whole, and the desired meaning is made clear. Inflexions, too, lend their aid; or else auxiliary words of various kinds answering the same purpose—namely, of determining the relations of the members of the sentence. But all our success in understanding the earliest stages of language depends upon our power to conceive a state of things where none of these distinctions were established, where one speech-sign was like another, calling up a conception in its indefinite entirety, and leaving the circumstances of the case to limit its application. Such a language is far below ours in explicitness; but it would suffice for a great deal of successful communication; indeed (as will be shown farther on), there are many languages even now in existence which are little better off. So a look of approval or disgust, a gesture of beckoning or repulsion, a grunt of assent or inquiry, is as significant as a sentence, means a sentence, is translatable into a sentence, and hence may even in a certain way be called a sentence; and in the same way, but only so, the original roots of language may be said to have been sentences. In point of fact, between the holophrastic gesture or uttered sign and the sentence which we can now substitute for it—for example, between the sign of beckoning and the equivalent sentence, "I want you to come here"—lies the whole history of development of inflective speech.

What has been this history of development, how the first scanty and formless signs have been changed into the immenso variety and fulness of existing speech, it is of course impossible to point out in detail, or by demonstration of facts, because nearly the whole process is hidden in the darkness of an impenetrable past. The only way to cast any light upon it is by careful induction from the change and growth which are seen to have been going on in the recent periods for which we have recorded evidence, or which are going on at the present time. Of some groups of related languages we can read the life for three or four thousand years back, and by comparison can infer it much farther; and the knowledge thus won is what we have to apply to the explanation of periods and languages otherwise unknown. Nothing has a right to be admitted as a factor in language-growth of which the action is not demonstrable in recorded language. Our own family of languages is the one of whose development most is known, by observation and well-warranted inference; and it may be well here to sketch the most important features of its history, by way of general illustration.

Apparently the earliest class-distinction traceable in Aryan speech is that of pronominal roots, or signs of position, from the more general mass of roots. It is not a formal distinction, marked by a structural difference, but, so far as can be seen, is founded only on the assignment by usage of certain elements to certain offices. Formal distinction began with combination, the addition of one element to another, their fusion into a single word, and the reduction of the one part to a subordinate value, as sign of a certain modification of meaning of the other. Thus, doubtless by endings of pronominal origin, were made the first verb-forms, or words used only when predication was intended (since that is all that makes a verb),

conveying at first a distinction of persons only, then of persons and numbers, while the further distinctions of tense and mode were by degrees added. To the nouns, which became nouns by the setting up of the separate and special class of verbs, were added in like manner distinctions of case, of number, and of gender. With the separation of noun and verb, and the establishment of their respective inflexion, the creative work of language-making is virtually done; the rest is a matter of differentiation of uses. For the noun (noun substantive) and the adjective (noun adjective) become two parts of speech only by a gradually deepened separation of use; there is no original or formal distinction between them; the pronouns merely add the noun-inflexion to a special set of stems; adverbs are a part of the same formation as noun-cases; prepositions are adverbs with a specialized construction, of secondary growth; conjunctions are the products of a like specialization; articles, where found at all, are merely weakened demonstratives and numerals.⁹

To the process of form-making, as exhibited in this history, belong two parts: the one external, consisting in the addition of one existing element of speech to another and their combination into a single word; the other internal, consisting in the adaptation of the compound to its special use and involving the subordination of one element to the other. Both parts appear also abundantly in other departments of language-change, and throughout the whole history of our languages; nothing has to be assumed for the earliest formations which is not plainly illustrated in the latest. For example, the last important addition to the formative apparatus of English is the common adverb-making suffix *-ly*, coming, as already pointed out, from the independent adjective *like*. There was nothing at first to distinguish a compound like *godly* (*godlike*) from one like *storm-tossed*, save that the former was more adaptable than the other to wider uses; resemblance is an idea easily generalized into appurtenance and the like, and the conversion of *godlike* to *godly* is a simple result of the processes of phonetic change described farther on. The extension of the same element to combination with adjectives instead of nouns, and its conversion to adverb-making value, is a much more striking case of adaptation, and is nearly limited to English, among the Germanic languages that have turned *like* into a suffix. A similar striking case, of combination and adaptation, is seen in the Romanic adverb-making suffix *mente* or *ment*, coming from the Latin ablative *mente*, "with mind." So, to make a Romanic future like *donnerai*, "I shall give," there was needed in the first place the pre-existing elements *donner*, "to give," and *ai*, "I have," and their combination; but this is only a part; the other indispensable part is the gradual adaptation of a phrase meaning "I have [something before me] for giving" to the expression of simple futurity, "*donabo*." So far as the adaptation is concerned, the case is quite parallel to that of *j'ai donné*, "I have given," &c. (equivalent phrases or combinations are found in many languages), where the expression of possession of something that is acted on has been in like manner modified into the expression of past action. Parallel in both combination and adaptation is the past tense *loved*, from *love-did*, while we have again the same adaptation without combination in the equivalent phrase *did love*.

That these are examples of the process by which the whole inflective structure of Aryan language was built up admits of no reasonable question. Our belief that it is so rests upon the solid foundation that we can demonstrate no other process, and that this one is sufficient. It is true that we can prove such an origin for our formative elements in only a small minority of instances; but this is just what was to be expected, considering what we know

of the disguising processes of language-growth. No one would guess in the mere *y* of *ably* (for *able-ly*) the presence of the adjective *like*, any more than in the altered final of *sent* and the shortened vowel of *led* the effect of a *did* once added to *send* and *lead*. The true history of these forms can be shown, because there happen to be other facts left in existence to show it; where such facts are not within reach, we are left to infer by analogy from the known to the unknown. The validity of our inference can only be shaken by showing that there are forms incapable of having been made in this way, or that there are and have been other ways of making forms. Of the former there is evidently but small chance; if a noun-form meaning "with mind" can become the means of conversion of all the adjectives of a language into adverbs, and a verb meaning "have" (and, yet earlier, "seize") of signifying both future and past time, there is obviously nothing that is impossible of attainment by such means. As regards the latter, no one appears to have even attempted to demonstrate the genesis of formative elements in any other way during the historical periods of language; it is simply assumed that the early methods of language-making will have been something different from and superior in spontaneity and fruitfulness to the later ones; that certain forms, or forms at certain periods, were made out-and-out, as forms; that signs of formal distinction somehow exuded from roots and stems; that original words were many-membered, and that a formative value settled in some member of them—and the like. Such doctrines are purely fanciful, and so opposed to the teachings both of observation and of sound theory that the epithet absurd is hardly too strong to apply to them. If the later races, of developed intelligence, and trained in the methods of a fuller expression, can only win a new form by a long and gradual process of combination and adaptation, why should the earlier and comparatively untrained generations have been able to do any better? The advantage ought to be, if anywhere, on our side. The progress of language in every department, accompanying and representing the advance of the race, on the whole, in the art of speaking as in other arts, is from the grosser to the more refined, from the physical to the moral and intellectual, from the material to the formal. The conversion of compounds into forms, by the reduction of one of their elements to formative value, is simply a part of the general process which also creates auxiliaries and form-words and connectives, all the vocabulary of mind, and all the figurative phraseology that gives life and vigour to our speech. If a copula, expressive of the grammatical relation of predication, could be won only by attenuation of the meaning of verbs signifying "grow," "breathe," "stand," and the like; if our auxiliaries of tense and mode all go traceably back to words of physical meaning (as *have* to "seize," *may* to "be great or strong," *shall* to "be under penalty," and so on); if *of* comes from the comparatively physical *off*, and *for* from "before, forward"; if relative pronouns are specialized demonstratives and interrogatives; if *right* means etymologically "straight," and *wrong* means "twisted"; if *spirit* is "blowing," and *intellect* a "picking out among," and *understanding* a "getting beneath," and *development* an "unfolding"; if an event *takes place* or *comes to pass*, and then *drops out* of mind and is *forgotten* (opposite of *gotten*)—then it is of no avail to object to the grossness of any of the processes by which, in earlier language or in later, the expression of formal relations is won. The mental sense of the relation expressed is entirely superior to and independent of the means of its expression. He who, to express the plural of *man*, says what is equivalent to *man-man* or *heap-man* (devices which are met with in not a few languages) has just as good a sense of plurality

as he who says *men* or *homines*; that sense is no more degraded in him by the coarseness of the phrase he uses to signify it than is our own sense of eventuality and of pastness by the undisguised coarseness of *take place* and *have been*. In short, it is to be laid down with the utmost distinctness and confidence, as a law of language-growth, that there is nothing formal anywhere in language which was not once material; that the formal is made out of the material, by processes which began in the earliest history of language and are still in action.

We have dropped here the restriction to our own or Aryan language with which we began, because it is evident that what is true of this family of speech, one of the most highly organized that exist, may also be true of the rest—must be true of them, unless some valid evidence be found to the contrary. The unity of human nature makes human speech alike in the character of its beginnings and in the general features of its after-history. Everywhere among men, a certain store of expression, body of traditional signs of thought, being given, as used by a certain community, it is capable of increase on certain accordant lines, and only on them. In some languages, and under peculiar circumstances, borrowing is a great means of increase; but it is the most external and least organically important of all. Out-and-out invention (which, so far as we can see, must be of the kind called by us onomatopoeic) is found to play only a very insignificant part in the historical periods of language,—clearly because there are other and easier modes of gaining new expression for what needs to be expressed. In the course of phonetic change, a word sometimes varies into two (or more) forms, and makes so many words, which are differently turned to account. Everything beyond this must be the product of combination; there is no other way, so far as concerns the externals of speech. Then, partly as accompanying and aiding this external growth, partly as separate from and supplementing it, there is in all language an internal growth, making no appearance in the audible part of speech, consisting in multiplication of meanings, their modification in the way of precision or comprehension or correctness, the restriction of words to certain uses, and so on. Along with these, too, a constant change of phonetic form constitutes an inseparable part of the life of language. Speech is no more stable with respect to the sounds of which it is composed than with respect to its grammatical forms, its vocabulary, or the body of conceptions signified by it. Even nearly related languages differ as much in their spoken alphabets and the combinations of sounds they admit, and in their uttered forms of words historically the same, as in any other part; and the same is true of local dialects, and of class dialects within the same community. Phonetic change has nothing whatever to do with change of meaning; the two are the product of wholly independent tendencies. Sometimes, indeed, they chance to coincide, as in the distinction of *minute* "small," and *minute* "moment"; but it is only by chance, as the spoken accordance of *second* in its two meanings ("next" and "sixtieth of a minute") shows; words that maintain their identity of value most obstinately, like the numerals, are liable to vary indefinitely in form (so *four*, *fidvor*, *quatuor*, *τέσσαρες*, &c., from an original *katuvar*; *five*, *quinque*, *πέντε*, *coic*, &c., from *penka*—while, on the other hand, *two* and *three* show as striking an accordance of form as of meaning through all the same languages); what is far the most common is that the word becomes very unlike its former self in both respects, like *priest* from the Greek *πρεσβύτερος* (*presbyter*), literally "older man." Human convenience is, to be sure, the governing motive in both changes; but it is convenience of two different kinds: the one mental, depending on the fact

All
formal
elements
once
material.

(pointed out above) that a name when once applied belongs to the thing to which it is applied, to the disregard of its etymological connexions, does not need to be changed when the thing changes, and is ready for new application to anything that can be brought into one class with the latter; and the other physical, depending on the organs of speech and their successive movements, by which the sounds that make up the word are produced. * Phonetic convenience is economy of effort on the part of those organs; and to no other law than that of economy of utterance have any of the phenomena of phonetic change been found traceable (though it is also to be noted that some phenomena have not hitherto been successfully brought under it, and that the way of effecting this is still unclear). * "Euphony," which used to be appealed to as explanation, is a false principle, except so far as the term may be made an idealized synonym of economy. The ear finds that agreeable which the organs of utterance find facile. Economy in utterance is no isolated tendency; it is the same that plays its part in all other kinds of human action, and in language appears equally in the abbreviation of the sentence by leaving out parts that can be spared without loss of intelligibility. It is an insidious tendency, always lying in wait, like gravitation, to pull down what is not sufficiently held up,—the holding-up force in language being the faithfulness of tradition, or accurate reproduction by the learner and user of the signs which he has acquired. No generation of men has any intention to speak otherwise than as its predecessor has spoken, or any consciousness that it is doing so; and yet, from generation to generation, words are shortened, sounds are assimilated to one another, and one element passes out of use while a new one is introduced. Abbreviation and assimilation are the most conspicuous departments of phonetic change, and those in which the nature of the governing tendency is most plainly seen. Taken by itself, one sound is as easy as another to the person who has accustomed himself to it from childhood; and those which the young child most easily acquires are not those which in the history of speech are least liable to alteration; it is especially in the combinations and transitions of rapid speaking that the tongue, as it were, finds out for itself easier ways of performing its task, by dropping and slurring and adapting. To trace out the infinitely varied items of this change, to co-ordinate and compare them and discover their reasons, constitutes a special department of language-study, which is treated under the head of SPEECH SOUNDS. It only needs to be pointed out here that phonetic change plays a necessary part in the structural development of language, by integrating compound words through fusion and loss of identity of their component parts, and, what is of yet more importance, by converting them into forms, through disguise of identity of one of the parts and its phonetic subordination to the other part. It is this that turns, for example, the compound *god-like* into the derivative *godly*, the compound *love-did* into the verbal form *loved*. And yet one further result sometimes follows: an internal change is wrought by phonetic influence in the body of a word, which change then may in the further history of the word be left as the sole means of distinction between one form and another. It is thus that, in the most recent period, the distinction of *led* from *lead* and *met* from *meet* and so on has been made; the added auxiliary which originally made these preterites induced a shortening of the root-vowel, and this was left behind when the auxiliary disappeared by the usual process of abbreviation. It is in the same way that the distinctions of *men* from *man*, of *were* from *was*, of *set* from *sit*, with all their analogues, were brought about: by a modification of vowel-sound (Ger. *Umlaut*) occasioned by the presence

in the following syllable of an *i*-vowel, which in the older stages of the language is still to be seen there. * And the distinctions of *sing*, *sang*, *sung*, and *song*, of *bind*, *bound*, *band*, and *bond*; are certainly of the same kind, though they go back so far in the history of our family of languages that their beginnings are not yet clearly demonstrable; they were in their origin phonetic accidents, inorganic, mere accompaniments and results of external combinations which bore the office of distinction of meaning and were sufficient to it; in some of our languages they have been disregarded and effaced, in others they have risen to prominent importance. * To regard these internal changes as primary and organic is parallel with assuming the primariness of the formative apparatus of language in general; like this, it ignores the positive evidence we have of the secondary production of such differences; they are, like everything else in linguistic structure, the outcome of combination and adaptation.

Borrowing, or the taking-in of material out of another language, has been more than once referred to above as sometimes an important element in language-history, though less deep-reaching and organic than the rest. * There is nothing anomalous about borrowing; it is rather in essential accordance with the whole process of language-acquisition. All our names were adopted by us because they were already in use by others; and a community is in the same way capable of taking a new name from a community with which it comes in contact as an individual from individuals. Not that it seeks or admits in this way new names for old things; but it accepts new things along with the names that seem to belong to them. Hence any degree of intercourse between one community and another, leading to exchange of products or of knowledge, is sure to lead also to some borrowing of names; and there is hardly a language in the world, except of races occupying peculiarly isolated positions, that does not contain a certain amount of foreign material thus won, even as our English has elements in its vocabulary from half the other tongues in the world. * The scale of borrowing is greatly increased when one people becomes the pupil of another in respect of its civilization: hence the abundant classical elements in all the European tongues, even the non-Romanic; hence the Arabic material in Persian and Turkish and Malay; hence the Chinese in Japanese and Korean; and, as a further result, even dead languages, like the Greek and Latin and the Sanskrit, become stores to be drawn upon in that learned and conscious quest of new expression which in the school-stage of culture supplements or even in a measure replaces the unconscious growth of natural speech. So, in mixture of communities, which is a highly-intensified form of contact and intercourse, there follows such mixture of speech as the conditions of the case determine; yet not a mixture on equal terms, through all the departments of vocabulary and grammar; the resulting speech (just as when two individuals learn to speak alike) is essentially that of the one constituent of the new community, with more or less material borrowed from that of the other. What is most easily taken in out of another language is the names of concrete things; every degree of removal from this involves additional difficulty—names of abstract things; epithets, verbs, connectives, forms. Indeed, the borrowing of forms in the highest sense, or forms of inflexion, is well-nigh or quite impossible; no example of it has been demonstrated in any of the historical periods of language, though it is sometimes adventurously assumed as a part of prehistoric growth. How nearly it may be approached is instanced by the presence in English of such learned plurals as *phenomena* and *strata*. This extreme resistance to mixture in the department of inflexion is the ground on which some deny the possibility of mixture in

language, and hence the existence of such a thing as a mixed language. The difference is mainly a verbal one; but it would seem about as reasonable to deny that a region is inundated so long as the tops of its highest mountains are above water. According to the simple and natural meaning of the term, nearly all languages are mixed, in varying degree and within varying limits, which the circumstances of each case must explain.

These are the leading processes of change seen at work in all present speech and in all known past speech, and hence to be regarded as having worked through the whole history of speech. By their operation, every existing tongue has been developed out of its rudimentary radical condition to that in which we now see it. The variety of existing languages is well-nigh infinite, not only in their material but in their degree of development and the kind of resulting structure. Just as the earlier stages in the history of the use of tools are exemplified even at the present day by races which have never advanced beyond them, so is it in regard to language also—and, of course, in the latter case as in the former, this state of things strengthens and establishes the theory of a gradual development. There is not an element of linguistic structure possessed by some languages which is not wanting in others; and there are even tongues which have no formal structure, and which cannot be shown ever to have advanced out of the radical stage. The most noted example of such a rudimentary tongue is the Chinese, which in its present condition lacks all formal distinction of the parts of speech, all inflexion, all derivation; each of its words (all of them monosyllables) is an integral sign, not divisible into parts of separate significance; and each in general is usable wherever the radical idea is wanted, with the value of one part of speech or another, as determined by the connexion in which it stands: a condition parallel with that in which Aryan speech may be regarded as existing prior to the beginnings of its career of formal development briefly sketched above.* And there are other tongues, related and unrelated to Chinese, of which the same description, or one nearly like it, might be given. To call such languages radical is by no means to maintain that they exhibit the primal roots of human speech, unchanged or only phonetically changed, or that they have known nothing of the combination of element with element. Of some of them, the roots are in greater or less part dissyllabic; and we do not yet know that all dissyllabism, and even that all complexity of syllable beyond a single consonant with following vowel, is not the result of combination or reduplication. But all combination is not form-making; it needs a whole class of combinations, with a recognized common element in them producing a recognized common modification of meaning, to make a form. The same elements which (in Latin, and even to some extent in English also) are of formal value in *con-stant* and *pre-dict* lack that character in *cost* and *preach*; the same *like* which makes adverbs in *tru-ly* and *right-ly* is present without any such value in *such* and *which* (from *so-like* and *who-like*); *cost* and *preach*, and *such* and *which*, are as purely radical in English as other words of which we do not happen to be able to demonstrate the composite character. And so a Chinese monosyllable or an Egyptian or Polynesian dissyllable is radical, unless there can be demonstrated in some part of it a formative value; and a language wholly composed of such words is a root-language. Neither is the possibility to be denied that a language like Chinese may have had at some period of its history the weak beginnings of a formal development, since extinguished by the same processes of phonetic decay which in English have wiped out so many signs of a formal character, and brought back so considerable a part of the

vocabulary to monosyllabism; but it remains thus far a possibility merely; and the development would need to have been of the scantiest character to be so totally destroyed by phonetic influences. In languages thus constituted, the only possible external alteration is that phonetic change to which all human speech, from the very beginning of its traditional life, is liable; the only growth is internal, by that multiplication and adaptation and improvement of meanings which is equally an inseparable part of all language-history. This may include the reduction of certain elements to the value of auxiliaries, particles, form-words, such as play an important part in analytical tongues like English, and are perhaps also instanced in prehistoric Aryan speech by the class of pronominal roots. Phrases take the place of compounds and of inflexions, and the same element may have an auxiliary value in certain connexions while retaining its full force in others, like, for instance, our own *have*. It is not easy to define the distinction between such phrase-collocations and the beginnings of agglutination; yet the distinction itself is in general clearly enough to be drawn (like that in French between *donnerai* and *ai donné*), when the whole habit of the language is well understood.

Such languages, constituting the small minority of human tongues, are wont to be called "isolating," i.e., using each element by itself, in its integral form. All besides are "agglutinative," or more or less compounded into words containing a formal part, an indicator of class-value. Here the differences, in kind and degree, are very great; the variety ranges from a scantiness hardly superior to Chinese isolation up to an intricacy compared with which Aryan structure is hardly fuller than Chinese. Some brief characterization of the various families of language in this respect will be given farther on, in connexion with their classification. The attempt is also made to classify the great mass of agglutinating tongues under different heads: those are ranked as simply "agglutinative" in which there is a general conservation of the separate identity of root or stem on the one hand, and of formative element, suffix or prefix, on the other; while the name "inflective," used in a higher and pregnant sense, is given to those that admit a superior fusion and integration of the two parts, to the disguise and loss of separate identity, and, yet more, with the development of an internal change as auxiliary to or as substitute for the original agglutination. But there is no term in linguistic science so uncertain of meaning, so arbitrary of application, so dependent on the idiosyncrasy of its user, as the term "inflective." Any language ought to have the right to be called inflective that has inflexion: that is, that not merely distinguishes parts of speech and roots and stems formally from one another, but also conjugates its verbs and declines its nouns; and the name is sometimes so used. If, again, it be strictly limited to signify the possession of *inner flexion*, of roots and stems (as if simply agglutinated forms could be called "exfective"), it marks only a difference of degree of agglutination, and should be carefully used as so doing. As describing the fundamental and predominant character of language-structure, it belongs to only one family of languages, the Semitic, where most of the work of grammatical distinction is done by internal changes of vowel, the origin of which thus far eludes all attempts at explanation. By perhaps the majority of students of language it is, as a generally descriptive title, restricted to that family, and one other, the Indo-European or Aryan; but such a classification is not to be approved, for, in respect to this characteristic, Aryan speech ranks not with Semitic but with the great body of agglutinative tongues. To few of these can the name be altogether denied, since there is hardly a body of related dialects in existence that does

not exhibit some items of "inflective" structure, the Aryan is only the one among them that has most to show. Outside the Semitic, at any rate, one should not speak of inflective and non-inflective languages, but only of languages more inflective and less inflective.

To account for the great and striking differences of structure among human languages is beyond the power of the linguistic student, and will doubtless always continue so. We are not likely to be able even to demonstrate a correlation of capacities, saying that a race which has done this and that in other departments of human activity might have been expected to form such and such a language. Every tongue represents the general outcome of the capacity of a race as exerted in this particular direction, under the influence of historical circumstances which we can have no hope of tracing. There are striking apparent anomalies to be noted. The Chinese and the Egyptians have shown themselves to be among the most gifted races the earth has known; but the Chinese tongue is of unsurpassed jejuneness, and the Egyptian, in point of structure, little better, while among the wild tribes of Africa and America we find tongues of every grade, up to a high one, or to the highest. This shows clearly enough that mental power is not measured by language-structure. But any other linguistic test would prove equally insufficient. On the whole, the value and rank of a language are determined by what its users have made it do. The reflex action of its speech on the mind and culture of a people is a theme of high interest, but of extreme difficulty, and apt to lead its investigators away into empty declamation; taking everything together, its amount, as is shown by the instances already referred to, is but small. The question is simply one of the facilitation of work by the use of one set of tools rather than another; and a poor tool in skilful hands can do vastly better work than the best tool in unskilful hands—even as the ancient Egyptians, without steel or steam, turned out products which, both for colossal grandeur and for exquisite finish, are the despair of modern engineers and artists. In such a history of development as that of human speech a fortunate turn may lead to results of unforeseen value; the earlier steps determine the later in a degree quite beyond their own intrinsic importance. Everything in language depends upon habit and analogy; and the formation of habit is a slow process, while the habit once formed exercises a constraining as well as a guiding influence. Hence the persistency of language-structure: when a certain sum and kind of expression is produced, and made to answer the purposes of expression, it remains the same by inertia; a shift of direction becomes of extreme difficulty. No other reason can at present be given why in historical time there has been no marked development out of one grade of structure into another; but the fact no more shakes the linguistic scholar's belief in the growth of structure than the absence of new animal species worked out under his eyes shakes the confidence of the believer in animal development. The modifying causes and their modes of action are clearly seen, and there is no limit to the results of their action except what is imposed by circumstances.

It is in vain to attempt to use dates in language-history, to say when this or that step in development was taken, and how long a period it cost, especially now that the changed views as to the antiquity of man are making it probable that only a small part of the whole history is brought within the reach even of our deductions from the most ancient recorded dialects. At any rate, for aught that we know or have reason to believe, all existing dialects are equally old; every one alike has the whole immeasurable past of language-life behind it, has reached its present condition by advance along its own line of growth and

change from the first beginnings of human expression. Many of these separate lines we clearly see to converge and unite, as we follow them back into the past; but whether they all ultimately converge to one point is a question quite beyond our power to answer. If in this immensity of time many languages have won so little, if everywhere language-growth has been so slow, then we can only differ as to whether it is reasonably certain, or probable, or only possible, that there should have been a considerable first period of human existence without traditional speech, and a yet more considerable one before the fixation of so much as should leave abiding traces in its descendants, and that meanwhile the race should have multiplied and scattered into independent communities. And the mere possibility is enough to exclude all dogmatic assertion of the unity of origin of human speech, even assuming unity of origin of the human race. For to prove that identity by the still existing facts of language is utterly out of the question; the metamorphosing effect of constant change has been too great to allow it. In point of fact, taking languages as they now exist, only those have been shown related which possess a common structure, or have together grown out of the more primitive radical stage, since structure proves itself a more constant and reliable evidence than material. And this is likely ever to be the case; at any rate, to trace all the world's languages so far back toward their beginnings as to find in them evidences of identity is beyond the wildest hope. We must be content with demonstrating for those beginnings a unity of kind as alike a body of formless roots. But, on the other hand, since this unity is really demonstrated, since all structure is the result of growth, and no degree of difference of structure, any more than of difference of material, refuses explanation as the result of discordant growth from identical beginnings, it is equally inadmissible to claim that the diversities of language prove it to have had different beginnings. That is to say, the question of the unity of speech, and yet more that of the unity of the race, is beyond the reach of the student of language; the best view he can attain is the hypothetical one, that, if the race is one, the beginnings of speech were perhaps one—but probably not, even then. This negative conclusion is so clearly established as to leave no excuse for the still oft-repeated attempts to press language into service on either side of the controversy respecting human unity of race.

That all making and changing of language is by the act of its speakers is too obvious to call for discussion. No other force capable of acting and of producing effects is either demonstrable or conceivable as concerned in the work. The doctrine that language is an organism, growing by its own inherent powers, exempt from the interference of those who use it, is simply an indefensible paradox. Every word that is uttered is so by an act of human will, at first in imitation of others, then more and more by a formed and controlling habit; it is accessible to no change except by influences working in the speaker's mind, and leading him to make it otherwise. Not that he is aware of this, or directs his action knowingly to that end. The whole process is unconscious. If any implication of reflective or intended action can be shown to inhere in any doctrine of linguistic science, it vitiates that doctrine. The attitude of the ordinary speaker towards his language is that of unreasoning acceptance; it seems to him that his names for things are their real names, and all others unintelligent nicknames; he thinks himself to possess his speech by the same tenure as his sight or hearing; it is "natural" to him (or, if he reasons about it, he attributes it to a divine origin, as races beginning to philosophize are wont to ascribe their various social institutions to their

Unconscious growth through individual acts.

gods); he knows nothing of its structure and relations; it never occurs to him to find fault with it, or to deem it insufficient and add to or change it; he is wholly unaware that it does change. He simply satisfies his social needs of communication by means of it; and if he has anything to express that is different from what has been expressed before, he takes the shortest way to a provision for the need; while any relaxation of the energy of utterance tends to a variation in the uttered combinations; and thus changes come by his act, though without his knowledge. His sole object is, on the basis of what language he has, to make known his thought in the most convenient way to his fellow; everything else follows with and from that. Human nature and circumstances being what they are, what follows actually is, as already shown, incessant growth and change. For it we have not to seek special disturbing causes in the history of the speakers; although such may come in to heighten and quicken the change; we know that even in a small community, on a narrow ~~islet~~, cut off from all intercourse with other communities, the speech would grow different—as certainly, if not as rapidly, as anywhere in the world—and only by the action of its speakers: not that the speakers of a language act in unison and simultaneously to produce a given change. This must begin in an individual, or more or less accordantly in a limited number of individuals, and spread from such example through the community. Initiation by one or a few, acceptance and adoption by the rest,—such is the necessary method of all linguistic change, and to be read as plainly in the facts of change now going on among ourselves as in those of former language. The doctrine of the inaccessibility of language to other action than that of its speakers does not imply a power in the individual speaker to create or alter anything in the common speech, any more than it implies his desire to do so. What he suggests by his example must be approved by the imitation of his fellows, in order to become language. The common speech is the common property, and no one person has any more power over it than another. If there are, for example, a thousand speakers of a certain dialect, each one wields in general a thousandth part of the force required to change it—with just so much more as may belong to his excess of influence over his fellows, due to recognized superiority of any kind on his part. His action is limited only by their assent; but this is in effect a very narrow limitation, insuring the adoption of nothing that is not in near accordance with the already existing; though it is also to be noted that he is as little apt to strike off into startling change as they to allow it; since the governing power of already formed habits of speech is as strong in him as in them. That change to which the existing habits naturally lead is easy to bring about; any other is practically impossible. It is this tendency on the part of the collective speakers of a language to approve or reject a proposed change according to its conformity with their already subsisting usages that we are accustomed to call by the fanciful name “the genius of a language.”

On the relation of the part played in language-change by the individual to that by the community, in combination with the inevitableness of change, rests the explanation of the dialectic variation of language. If language were stable there would of course be no divarication; but since it is always varying, and by items of difference that proceed from individuals and become general by diffusion, there can be uniformity of change only so far as diffusion goes, or as the influences of communication extend. Within the limits of a single community, small or large, whatever change arises spreads gradually to all, and so becomes part of the general speech; but let that community become divided into two (or more) parts, and then

the changes arising in either part do not spread to the other, and there begins to appear a difference in linguistic usage between them. It is at first slight, even to insignificance; not greater than exists between the dialects of different localities or ranks or occupations in the same community, without detriment to the general unity of speech. This unity, namely, rests solely on mutual intelligibility, and is compatible with no small amount of individual and class difference, in vocabulary, in grammar, and in pronunciation; indeed, in the strictest sense, each individual has a dialect of his own, different from that of every other, even as he has a handwriting, a countenance, a character of his own. And every item of change, as it takes place, must have its season of existence as a local or class or trade peculiarity, before it gains universal currency; some of them linger long in that condition, or never emerge from it. All these differences in the speech of different sub-communities within the same community are essentially dialectic; they differ not in kind, but only in degree, from those which separate the best-marked dialects; they are kept down by general communication within the limit of general mutual intelligibility. Where that restraining influence ceases, the limit is gradually but surely overpassed, and real dialects are the result. From what we know of the life of language we can say positively that continued uniformity of speech without continued community is not practicable. If it were possible to divide artificially, by an impassable chasm or wall, a people one for ages, and continuing to occupy the same seats, the language of the divided parts would at once begin to be dialectically different; and after sufficient time had elapsed, each would have become unintelligible to the other. That is to say, whenever a community of uniform speech breaks up, its speech breaks up also; nor do we know of any other cause of dialectic diversity.

In applying this explanation of dialectic growth we have to allow for modifying circumstances of various nature, which alter not indeed the fact but the rate and kind of divarication. Some languages grow and change much more rapidly than others, with a corresponding effect upon divarication, since this is but a result of discordant growth. Usually, when there is division of a community, the parts get into different external circumstances, come in contact or mingle with different neighbouring communities, and the like; and this quickens and increases their divergence of speech. But the modifying factor of by far the highest importance, here as elsewhere in the history of language, is civilization. Civilization in its higher forms so multiplies the forces of communication as to render it possible that the widely-divided parts of one people, living in circumstances and under institutions of very different character, should yet maintain a substantial oneness of speech; of this there is no more striking example than the two great divisions of the English-speaking people on opposite sides of the Atlantic. On the other hand, a savage people cannot spread even a little without dialectic disunity; there are abundant examples to be met with now of mutually unintelligible speech between the smallest subdivisions of a race of obviously kindred tongue—as the different clusters of huts on the same coral islet. It is with linguistic unity precisely as it is with political unity, and for the same reasons. Before the attainment of civilization the human race, whether proceeding from one centre of dispersion or from several, was spread over the earth in a state of utter disintegration; but every centre of civilization becomes also a centre of integration; its influences make for unity of speech as of all other social institutions. Since culture has become incontestably the dominant power in human history, the unifying forces in language have also been

stronger than the diversifying; and with culture at its full height, and spread equally to every land and race, one universal language, like one universal community, is not an absurdity or theoretic impossibility, but only a Utopian or millennial dream.

Dialectic variation is thus simply a consequence of the movements of population. As the original human race or races, so the divisions or communities of later formation, from point to point through the whole life of man on the earth, have spread and separated, have jostled and interfered, have conquered and exterminated or mingled and absorbed; and their speech has been affected accordingly. Hence something of these movements can be read in the present condition of languages, as in a faithful though obscure record—more, doubtless, than can be read in any other way, however little it may be when viewed absolutely. Dialectic resemblances point inevitably back to an earlier unity of speech, and hence of community; from what we know of the history of speech, they are not to be accounted for in any other way. The longer the separation that has produced the diversity, the greater its degree. With every generation, the amount of accordance decreases and that of discordance increases; the common origin of the dialects is at first palpable, then evident on examination, then to be made out by skilled research, then perhaps no longer demonstrable at all; for there is plainly no limit to the possible divergence. So long, now, as any evidence of original unity is discoverable we call the languages "related dialects," and combine them into a "family." The term "family" simply signifies a group of languages which the evidence thus far at command, as estimated by us, leads us to regard as descended by the ordinary processes of dialectic divarication from one original tongue. That it does not imply a denial of the possibility of wider relationship is obvious from what has been said above. That there is abundant room for error in the classification represented by it is also clear, since we may take purely accidental resemblances, or the results of borrowing, for evidence of common descent, or may overlook or wrongly estimate real evidences, which more study and improved method will bring to light. Grouping into families is nothing more than the best classification attainable at a given stage in the progress of linguistic science; it is in no small part provisional only, and is always held liable to modification, even sweeping, by the results of further research. Of some families we can follow the history by external evidences a great way back into the past; their structure is so highly developed as to be traced with confidence everywhere; and their territory is well within our reach: such we regard with the highest degree of confidence, hardly allowing for more than the possibility that some other dialect, or group, or now-accepted family even, may sometime prove its right to be added on. But these are the rare exceptions; in the great majority of cases we have only the languages as they now exist, and in more or less scanty collections, of every degree of trustworthiness; and even their first grouping is tentative and incomplete, and involves an adjournment of deeper questions to the day of more light. To complete and perfect the work of classification by relationship, or the establishment of families and their subdivisions, is the first object of the comparative study of languages. No other classification has a value in the least comparable with it; that by grade of structure is a mere recreation, leading to nothing; that by absolute worth is of no account whatever, at any rate in the present state of our knowledge. On genetic relationship, in the first place, is founded all investigation of the historical development of languages; since it is in the main the comparison of related dialects, even in the case of families having a long recorded history, and

elsewhere only that, that gives us knowledge of their earlier condition, and enables us to trace the lines of change. In the second place, and yet more obviously, with this classification is connected all that language has to teach as to the affinities of human races; whatever aid linguistic science renders to ethnology rests upon the proved relationships of human tongues.

That a classification of languages, to which we have now to proceed, is not equivalent to a classification of races, and why this is so, is evident enough from the principles which have been brought out by our whole discussion of languages, and which, in their bearing upon this particular point, may well be recapitulated here. No language is a race-characteristic, determined by the special endowments of a race; all languages are of the nature of institutions, parallel products of powers common to all mankind—the powers, namely, involved in the application of the fittest available means to securing the common end of communication. Hence they are indefinitely transferable, like other institutions—like religions, arts, forms of social organization, and so on—under the constraining force of circumstances. As an individual can learn any language, foreign as well as ancestral, if it be put in his way, so also a community, which in respect to such a matter is only an aggregate of individuals. Accordingly, as individuals of very various race are often found in one community, speaking together one tongue, and utterly ignorant of any other, so there are found great communities of various descent, speaking the dialects of one common tongue, which at some period historical circumstances have imposed upon them. The conspicuous example, which comes into every one's mind when this subject is discussed, is that of the Romanic countries of southern Europe, all using dialects of a language which, 2500 years ago, was itself the insignificant dialect of a small district in central Italy; but this is only the most important and striking of a whole class of similar facts. Such are the results of the contact and mixture of races and languages. If language-history were limited to growth and divarication, and race-history to spread and dispersion, it would be a comparatively easy task to trace both backward toward their origin; as the case is, the confusion is inextricable and hopeless. Mixture of race and mixture of speech are coincident and connected processes; the latter never takes place without something of the former; but the one is not at all a measure of the other, because circumstances may give to the speech of the one element of population a greatly disproportionate preponderance. Thus, there is left in French only an insignificant trace of the Celtic dialects of the predominant race-constituent of the French people; French is the speech of the Latin conquerors of Gaul, mixed perceptibly with that of its later Frankish conquerors; it was adopted in its integrity by the Norse conquerors of a part of the land, then brought into Britain by the same Norsemen in the course of their further conquests, this time only as an element of mixture, and thence carried with English speech to America, to be the language of a still further mixed community. Almost every possible phase of language-mixture is traceable in the history of the abundant words of Latin origin used by American negroes. What events of this character took place in prehistoric time we shall never be able to tell. If any one chooses to assert the possibility that even the completely isolated dialect of the little Basque community may have been derived by the Iberian race from an intrusive minority as small as that which made the Celts of Gaul speakers of Latin, we should have to admit it as a possibility—yet without detriment to the value of the dialect as indicating the isolated race-position of its speakers. In strictness, language is never a proof of race.

either in an individual or in a community; it is only a probable indication of race, in the absence of more authoritative opposing indications; it is one evidence, to be combined with others, in the approach towards a solution of the confessedly insoluble problems of human history. But we must notice, as a most important circumstance, that its degree of probability is greatest where its aid is most needed, in prehistoric periods and among uncultivated races; since it is mainly civilization that gives to language a propagative force disproportionate to the number of its speakers. On the whole, the contributions of language to ethnology are practically far greater in amount and more distinct than those derived from any other source.

The genetical classification of languages, then, is to be taken for just what it attempts to be, and no more: primarily as a classification of languages only; but secondarily as casting light, in varying manner and degree, on movements of community, which in their turn depend more or less upon movements of races. It is what the fates of men have left to represent the tongues of men—a record imperfect even to fragmentariness. Many a family once as important as some of those here set down has perhaps been wiped out of existence, or is left only in an inconspicuous fragment; one and another has perhaps been extended far beyond the limits of the race that shaped it,—which, we can never tell to our satisfaction.

We begin with the families of highest importance and nearest to ourselves.

1. *Aryan (Indo-European, Indo-Germanic) Family.*—To this family belongs incontestably the first place, and for many reasons: the historical position of the peoples speaking its dialects, who have now long been the leaders in the world's history; the abundance and variety and merit of its literatures, ancient and modern, which, especially the modern, are wholly unapproached by those of any other division of mankind; the period covered by its records, hardly exceeded in duration by any other; and, most of all, the great variety and richness of its development. These advantages make of it an illustration of the history of human speech with which no other family can bear a moment's comparison as to value, however important various other families may be in their bearing on one and another point or department of history, and however necessary the combination of the testimony of all to a solution of the problems involved in speech. These advantages have made Aryan language the training-ground of comparative philology, and its study will always remain the leading branch of that science. Many matters of importance in its history have been brought up and used as illustrations in the preceding discussion; but as its constitution and ascertained development call for a fuller and more systematic exposition than they have found here, a special section is devoted to the subject (see p. 781 *sq.* below).

2. *Semitic Family.*—This family also is beyond all question the second in importance, on account of the part which its peoples (Hebrews, Phœnicians, Assyrians, Syrians, Arabs, Abyssinians, &c.) have played in history, and of the rank of its literatures. For a special treatment of it see SEMITIC. Some of the peculiarities of the language have been alluded to above; in the monotony and rigidity of its triliteral roots, and in the extended use which it makes of internal vowel-change ("inflection" in the special sense of that term) for the purposes of grammatical distinction, it is more peculiar and unlike all the other known families of language than these are unlike one another. There are, and perhaps will always be, those to whom the peculiarities just mentioned will seem original; but if the views of language and its history taken above are in the main true, then that opinion is untenable; Semitic language must have grown into its present forms out of beginnings accordant in kind, if not identical in substance, with those of other families; and the only question remaining to be solved is, through what processes and under what governing tendencies Semitic speech should have arrived at its present state. And with this solution is most obviously and incontestably bound up that of the other interesting and much discussed question, whether the Semitic family can be shown to be related with other families, especially with our own Aryan. To some the possession in common of grammatical gender, or of the classification of objects in general as masculine and feminine, is of itself enough to prove such relationship; but, though the fact is a striking one, and of no small importance as an indication, this degree of value can by no means be attributed to it in the present state of our knowledge—any more than to any other single item of structure among the infinite variety

of such, distributed among the multitude of human tongues. Many others compare the Semitic and Aryan "roots" with one another, and believe themselves to find there numerous indications of identity of material and signification; but these also must pass for insufficient, until it shall prove possible by their aid to work out an acceptable theory of how Semitic structure should have grown out of such radical elements as underlie Aryan structure, or out of the accordant initial products of a structural growth that afterwards diverged into two so discordant forms. To show that, both the material and the method have been hitherto wanting, and any confident decision is at least premature; but present probabilities are strongly against the solubility of the question. While many general considerations favour the ultimate unity of these two great civilized and civilizing white races of neighbouring homes, and no discordance of speech (as was shown above) can ever be made to prove their diversity of origin, it seems in a high degree unlikely that the evidence of speech will ever be made to prove them one. As regards the often-claimed relationship of Semitic with Hamitic language, see the following section.

3. *Hamitic Family.*—The prominent importance of this family, is due to a single one of its members, the Egyptian; in all other respects it is quite insignificant. It occupies the north-eastern corner of Africa, with the border-lands of that continent stretching westward along the whole shore of the Mediterranean, and southward to beyond the equator. It falls into three principal divisions: (1) the ancient Egyptian, with its descendant, the more modern Coptic (itself now for some centuries extinct; see EGYPT, COPTS); (2) the Libyan or Berber languages of northern Africa; (3) the Ethiopic languages of eastern Africa. Its situation thus plainly suggests the theory of its intrusion from Asia, across the isthmus of Suez, and its gradual spread from that point; and the theory is strongly favoured by the physical character of the Hamites, and the historical position especially of the Egyptians, so strikingly different from that of the African races in general. Linguistic evidences of the relationship of Hamite with Semite have also been sought, and by many believed to be found; but the maintenance of the two families in their separateness is an indication that those evidences have not yet been accepted as satisfactory; and such is indeed the case. The Egyptian is a language of extreme simplicity of structure, almost of no structure at all. Its radical words are partly monosyllabic, partly of more than one syllable, but not in the latter case any more than in the former showing traceable signs of extension by formative processes from simpler elements. It has no derivative apparatus by which noun-stems are made from roots; the root is the stem likewise; there is nothing that can be properly called either declension or conjugation; and the same pronominal particles or suffixes have now a subjective value, indicating use as a verb, and now a possessive, indicating use as a noun. There is no method known to linguistic science by which the relationship of such a tongue as this with the highly and peculiarly inflective Semitic can be shown, short of a thorough working out of the history of development of each family taken by itself, and a retracing in some measure of the steps by which each should have arrived at its present position from a common starting-point; and this has by no means been done. In short, the problem of the relation of Semitic with Hamitic, not less than with Aryan, depends upon that of Semitic growth, and the two must be solved together. There are striking correspondences between the pronouns of the two families, such as, if supported by evidences from other parts of their material, would be taken as signs of relationship; but, in the absence of such support, they are not to be relied upon, not till it can be shown to be possible that two languages could grow to be so different in all other respects as are Egyptian and Hebrew, and yet retain by inheritance corresponding pronouns. And the possession of grammatical gender by Aryan, Semitic, and Hamitic speech, and by them almost alone, among all human languages, though an extremely noteworthy fact, is (as was pointed out above) in the present condition of linguistic science quite too weak a basis for a belief in the original identity of the three families.

Egyptian is limited to the delta and valley of the Nile, and is the only Hamitic language which has ancient records: of the others the existing forms alone are known.

The Libyan or Berber division of the family occupies the inhabitable part of northern Africa, so far as it has not been displaced by intrusive tongues of other connexion—in later times the Arabic, which since the Mohammedan conquest has been the cultivated tongue of the Mediterranean coast, while the earlier Vandal, Latin, and Punic have disappeared, except in the traces they may have left in Berber dialectic speech. The principal dialects are the Kabyle, the Shilha, and the Tuarek or Tamashek, corresponding nearly to the ancient Numidian, Mauretanian, and Gætulian respectively. Some authorities add the Haussa, from farther south, while by others this is considered a Semitic and by yet others a negro tongue.

The third or Ethiopic division includes as its chief members the Beja or Bisharin, the Saho, the Dankali, the Somali, and the more

inland Galla; the first two lying along the Red Sea north of Semitic Abyssinia, the others south of it, to the equator. By some authorities (Lepsius, Bleek) there is added to the Hamitic family as a fourth division a group from extreme southern Africa, the Hottentot and Bushman languages. The ground of this classification is the possession by the Hottentot of the distinction of grammatical gender, and even its designation by signs closely corresponding to those used in the Ethiopic division. Others deny the sufficiency of this evidence, and rank the Hottentot as a separate group of African dialects, adding to it provisionally the Bushman, until better knowledge of the latter shall show whether it is or is not a group by itself. If the Hottentot be Hamitic, we shall have to suppose it cut off at a very remote period from the rest of the family, and forced gradually southward, while all the time suffering mixture both of speech and of blood with the negro races, until the physical constitution of its speakers has become completely metamorphosed, and of its original speech no signs are left save those referred to above; and while such exceptional phonetic peculiarities have been worked out as the use of the clicks or clucking sounds (see HOTTENTOTS): and this must be regarded as at least extremely difficult.

4. *Monosyllabic or South-eastern Asiatic Family.*—This body of languages may well enough be the next taken up; and here again (as was the case with the preceding family) on account of the prominent importance of one of its dialects and of the people speaking it—the Chinese people and language. The territory of the family includes the whole south-eastern corner of Asia: China on the north-east, Farther India in the south, and the high plateau of Tibet, with the neighbouring Himalayan regions, to the westward. The ultimate unity of all these languages rests chiefly upon the evidence of their form, as being all alike essentially monosyllabic and isolating, or destitute of formal structure; the material correspondences among them, of accordant words, are not sufficient to prove them related. The Chinese itself can be followed up, in contemporary records, to a period not far from 2000 B.C., and the language, the people, and their institutions, are then already in the main what they have ever since continued to be (see CHINA); the other leading tongues come into view much later, as they receive culture and religion from China on the one hand (the Anamites), or from India on the other (the Tibetans, Burmese, Siamese); and the territory includes great numbers of wild tribes unknown until our own times, whose race-relations and language-relations are as yet very obscure. Current opinion tends to regard the Anamites, Peguans, and Cambodians as forming a more nearly related group or division of the family, and as having been the earlier population of Farther India, in part dispossessed and driven forward by the later intrusion from the north of Siamese and Burmese, of whom the former are more nearly related to the Chinese, and the latter to the Tibetans; but these groupings rest as yet upon too slender evidence to be accepted with confidence.

The character of the languages of this family, especially as instanced by its most important member, the Chinese, has been pretty fully set forth in the general discussions above. They are languages of roots: that is to say, there is not demonstrable in any of their words a formative part, limiting the word, along with others similarly characterized, to a certain office or set of offices in the formation of the sentence. That the words are ultimate roots, come down from the first period of language-making, we have no reason whatever to believe; and they may possibly have passed through processes of growth which equipped them with some scanty supply of forms; but no evidence to that effect has yet been produced. The indications relied on to show an earlier polysyllabism in the family (though already in Chinese reduced to monosyllabism before the earliest historical appearance of the language, some 4000 years ago) are the comparatively recent loss of certain final mutes in Chinese words, and the presence on a considerable scale in Tibetan spelling of added initial and final consonants, now silent in the literary dialect, but claimed to be still uttered in some parts of the country. If the theory connecting these phenomena be established, the Tibetan will approve itself to be by far the most primitive of the dialects of the family, furnishing the key to the history of the rest.

For further details respecting the various tongues of the monosyllabic family, the articles on the different divisions of its territory (BURMAN, CHINA, SIAM, TIBET, &c.) may be consulted. The languages all alike show an addition to the resources of distinction possessed by languages in general, in the use of tones: that is to say, words of which the alphabetic elements are the same differ in meaning according as they are uttered in a higher or a lower tone, with the rising or the falling inflexion, and so on. By this means, for example, the monosyllabic elements of the literary Chinese, numbering but 500 as we should write them, are raised to the number of about 1500 words.

5. *Ural-Altaic (Scythian, Turanian) Family.*—China and Tibet are bordered on the north and west by the eastern branches of another immense family, which stretches through central and

northern Asia into Europe, overlapping the European border in Turkey, and reaching across it in Russia and Scandinavia to the very shore of the Atlantic. Usage has not so definitely determined as in the case of most other families by what name it shall be called; Turanian is perhaps the commonest appellation, but also the most objectionable. Five principal branches are generally reckoned as composing the family. The two easternmost are the Tungusian, with the Manchu for its principal division, and the Mongol (see MONGOLS). Of these two the language is exceedingly simple in structure, being raised but little above the formlessness of the Chinese. The three others are: the Turkish or Tatar, the dialects of which reach from the mouth of the Lena (Yakut) to Turkey in Europe; the Samoyed, from the Altai down to the arctic shore of Asia, and along this to the White Sea—an unimportant congeries of barbarous tribes; and the Finno-Hungarian, including the tongues of the two cultivated peoples from which it takes its name, and also those of a great part of the population of northern and central Russia, to beyond the Ural Mountains, and finally the Lappish, of northern Scandinavia. The nearer relation of the Samoyed is with the Finno-Hungarian. The Turkish is a type of a well-developed language of purely agglutinative structure: that is, lacking that higher degree of integration which issues in internal change. Whether this degree is wholly wanting in Finnish and Hungarian is made a question; at any rate, the languages named have no reason to envy the tongues technically called "inflective." Of a value not inferior to that of inflective characteristics is one that belongs to all the Ural-Altaic tongues, in varying measure and form, and helps to bind them together into a single family—the harmonic sequence of vowels, namely, as between root and endings, or a modification of the vowels of the endings to agree with that of the root or its final syllable.

While the physical race-characteristics known as Mongolian are wanting in the speakers of the western dialects of this family, they are conspicuously present in the people of Japan and Corea; and hence the tendency of scholars to endeavour to connect the languages of the two latter countries, since they also are of agglutinative structure (see JAPAN and COREA), with the family now under treatment, as also with one another. Neither connexion, however, can at present be regarded as proved.

Other languages of north-eastern Asia, too little known to group, and too unimportant to treat as separate families, may be mentioned here by way of appendix to their neighbours of the most diversified and widespread Asiatic family. They are the Aino, of Yezo and the Kurile Islands with part of the neighbouring coast; the Kamchatkan; and the Yukagir and Tchukchei, of the extreme north-east.

The opinion was recently held by many scholars that the agglutinative dialects—Accadian, Sumirian, &c.—of the presumed founders of Mesopotamian culture and teachers of the Assyrian Semites (see BABYLONIA) belonged to the Ural-Altaic family, and specifically to its Finno-Hungarian branch; but it is believed to be now generally abandoned. The mere possession of an agglutinative structure cannot be taken as proving anything in the way of relationship.

6. *Dravidian or South-Indian Family.*—This is an important body of nearly and clearly related tongues, spoken by about 50,000,000 people, doubtless representing the main population of all India at the time when the intrusive Aryan tribes broke in from the north-west, and still filling most of the southern peninsula, the Deccan, together with part of Ceylon. In an earlier article (see INDIA) the names of the dialects have been given, with indication of their locality and relative importance, and with some account of their leading features. They are languages of a high grade of structure, and of great power and euphony; and the principal ones have enjoyed a long cultivation, founded on that of the Sanskrit. As they obviously have no Aryan affinities, the attempt has been made to connect them also with the Ural-Altaic or Turanian family, but altogether without success, although there is nothing in their style of structure that should make such connexion impossible.

Not all the tribes that make up the non-Aryan population of India speak Dravidian dialects. The Santals and certain other wild tribes appear to be of another lineage, and are now generally known as Kolarian.

7. *Malay-Polynesian Family.*—The islands, greater and smaller, lying off the south-eastern coast of Asia and those scattered over the Pacific, all the way from Madagascar to Easter Island, are filled with their own peculiar families of languages, standing in no known relationship with those of the mainland. The principal one among them is the great Malay-Polynesian family. It falls into two principal divisions, Malayan and Polynesian. The Malayan includes, besides the Malay proper (see MALAYA), which occupies the Malaccan peninsula (yet doubtless not as original home of the division, but by immigration from the islands), the languages also of Sumatra, Java, Borneo, &c., of the Philippine Islands, of Formosa, and of Madagascar, together with the coasts of Celebes and other islands occupied in the interior by Papuans. The Polynesian division includes most of the tongues of the remaining scattered groups of

islands, and that of New Zealand. Probably to these are to be added, as a third division, the Melanesian dialects of the Melanesian Archipelago, of which both the physical and the linguistic peculiarities would in that case be ascribed to mixture with the black Papuan races. All these languages are extremely simple in phonetic form, and of a low grade of structure, the Polynesian branch being in both respects the lowest, and some of the Malayan dialects having reached a development considerably more advanced. The radical elements are much oftener of two syllables than of one, and reduplication plays an important part in their extension and variation. Malay literature goes back as far as to the 13th century, and there are Javan records even from the early centuries of our era, the result of religion and culture introduced into that island from Brahmanic India; but none of these have yet been utilized, as they doubtless in time will be, for tracing out the special laws of historical development prevailing in the family.

8. *Other Oceanic Families.*—At least two other families, unconnected with the preceding and with one another, are found among the Pacific islands, and only there. The continental island of Australia, with its dependency Tasmania (where, however, the native tongue has now become extinct), has its own body of probably related dialects, as its own physical type. They have been but imperfectly investigated, their importance, except to the professed student of language, being nothing; but they are not destitute of a rude agglutinative structure of their own. Still less known are the Papuan or Negrito languages, belonging to the black race with frizzled hair inhabiting most of New Guinea, and found also in the interior of some of the other islands, having been driven from the coasts by superior intruders of the Malay race.

9. *Caucasian Languages.*—Of the existing languages of Asia there remain to be mentioned only those of the Caucasian mountains and highlands, between the Black and Caspian Seas, pressed upon the north by Slavonians and Turks, upon the south by Armenians and Kurds and Turks. Its situation makes of the Caucasus a natural eddy in all movements of emigration between Asia and Europe; and its linguistic condition is as if remnants of many families otherwise extinct had been stranded and preserved there. The dialects north of the principal range—Circassian, Mitsjehian, Lesghian, &c.—have not been proved to be related either to one another or to those of the south. Among the latter, the Georgian is much the most widespread and important (see GEORGIA), and, alone among them all, possesses a literature. The Caucasian dialects present many exceptional and difficult features, and are in great part of so high a grade of structure as to have been allowed the epithet inflective by those who attach special importance to the distinction thus expressed.

10. *Remnants of Families in Europe.*—The Basque people of the western Pyrenees, at the angle of the Bay of Biscay, are shown by their speech to be an isolated remnant of some race which was doubtless once much more widely spread, but has now everywhere else lost its separate identity; as such it is of extreme interest to the ethnologist. The Basque language appears to be unrelated to any other on earth. It is of a very highly agglutinative structure, being equalled in intricacy of combination only by a part of the American dialects. Limited as it is in territory, it falls into a number of well-marked dialects, so that it also may not be refused the name of a "family."

The only other case of the kind worth noting is that of the Etruscan language of northern central Italy, which long ago became extinct, in consequence of the conquest and absorption of Etruria by Rome, but which still exists in numerous brief inscriptions (see ETRURIA). Many attempts have been made to connect the language with other families, and it has even quite recently been pronounced Aryan or Indo-European, of the Italian branch, by scholars of high rank; yet it is altogether likely to be finally acknowledged, like the Basque, as an isolated fragment.

In order to complete this review of the languages of the Old World it only remains to notice those of Africa which have not been already mentioned. They are grouped under two heads: the languages of the south and those of the centre of the continent.

11. *South-African or Bantu Family.*—This is a very extensive and distinctly marked family, occupying (except the Hottentot and Bushman territory) the whole southern peninsula of the continent from some degrees north of the equator. It has been already partly described under KAFFRARIA, and will be treated more in detail under the head of ZULU. It is held apart from all other known families of language by a single prominent characteristic—the extent to which it makes use of prefixes instead of suffixes as the apparatus of grammatical distinction; its inflexion, both declensional and conjugational, is by appended elements which precede the stem or root. The most conspicuous part of this is the variety of prefixes, different in singular and plural, by which the various classes or genders (not founded on sex; the ground of classification is generally obscure) of nouns are distinguished; these then reappear in the other members of the sentence, as adjectives and verbs and pronouns, which are determined by the noun, thus producing an alliterative concord that runs through the sentence.

The pronominal determinants of the verb, both subject and object, also come before it; but the determinants of mode of action, as causative, &c., are mostly suffixed. The language in general is rich in the means of formal distinction. Those dialects which border on the Hottentots have, apparently by derivation from the latter, the clicks or clucking-sounds which form a conspicuous part of the Hottentot spoken alphabet.

12. *Central African Languages.*—The remaining languages of Africa form a broad band across the centre of the continent, between the Bantu on the south and the Hamitic on the east and north. They are by no means to be called a family, but rather a great mass of dialects, numbering by hundreds, of varying structure, as to the relations of which there is great discordance of opinion even among the most recent and competent authorities. It is no place here to enter into the vexed questions of African linguistics, or even to report the varying views upon the subject; that would require a space wholly disproportioned to the importance of African speech in the general sum of human language. There is no small variety of physical type as well as of speech in the central belt; and, partly upon the evidence of lighter tint and apparently higher endowment, certain races are set off and made a separate division of; such is the Nuba-Fulah division of F. Müller, rejected by Lepsius. The latter regarded all the varieties of physical and linguistic character in the central belt as due to mixture between pure Africans of the south and Hamites of the north and east; but this is at present a hypothesis only, and a very improbable one, since it implies modes and results of mixture to which no analogies are quotable from languages whose history is known; nor does it appear at all probable that the collision of two races and types of speech should produce such an immense and diverse body of transitional types. It is far from impossible that the present prominence of the South-African or Bantu family may be secondary, due to the great expansion under favouring circumstances of a race once having no more importance than belongs now to many of the Central-African races, and speaking a tongue which differed from theirs only as theirs differed from one another. None of the Central-African languages is a prefix-language in the same degree as the Bantu, and in many of them prefixes play no greater part than in the world's languages in general; others show special forms or traces of the prefix-structure; and some have features of an extraordinary character, hardly to be paralleled elsewhere. One group in the east (Oigob, &c.) has a gender distinction, involving that of sex, but really founded on relative power and dignity: things disparaged, including women, are put in one class; things extolled, including men, are put in the other. This is perhaps the most significant hint anywhere to be found of how a gender distinction like that in our own Aryan languages, which we usually regard as being essentially a distinction of sex, while in fact it only includes such, may have arisen. Common among the African languages, as among many other families, especially the American, is a generic distinction between animate beings and inanimate things.

13. *American Languages.*—With these the case is closely the same as with the Central-African languages: there is an immense number of dialects, of greatly varied structure, of which as yet even the nearer groupings are only in part made out, while the grade and kind of relationship between the groups, if such there exist, is wholly unclear. Some general statements respecting American languages have been given under AMERICA, and a detailed list and classification of them in the article INDIANS; hence it is unnecessary to go over the subject again in this place. What we most need to note is the very narrow limitation of our present knowledge. Even among neighbouring families like the Algonquin, Iroquois, and Dakota, whose agreement in style of structure (polysynthetic), taken in connexion with the accordant race-type of their speakers, forbids us to regard them as ultimately different, no material correspondence, agreement in words and meanings, is to be traced; and there are in America all the degrees of polysyntheticism, down to the lowest, and even to its entire absence. Such being the case, it ought to be evident to every one accustomed to deal with this class of subjects that all attempts to connect American languages as a body with languages of the Old World are and must be fruitless; in fact, all discussions of the matter are at present unscientific, and are tolerably certain to continue so through all time to come.

Literature.—Many of the theoretic points discussed above are treated by the writer with more fulness in his *Language and the Study of Language* (1867) and *Life and Growth of Language* (1875). Other English works to consult are M. Müller's *Lectures on the Science of Language*; Farrar's *Chapters on Language*; Wedgwood's *Origin of Language*; Sayce's *Principles of Philology and Introduction to the Science of Language*, &c. In German, see Paul's *Prinzipien der Sprachgeschichte* (Halle, 1880); Delbrück's *Einleitung in das Sprachstudium* (Leipzig, 1880; there is also an English version); Schleicher's *Deutsche Sprache*; also the works of W. von Humboldt and of H. Steinthal. As to the classification and relationships of languages, see Hovelacque's *La Linguistique* (Paris, 1876), and F. Müller's *Grundriss der Sprachwissenschaft* (Vienna, still in progress). As to the history of the study, see Lersch's *Sprachphilosophie der Alten* (1840); Steinthal's *Geschichte der Sprachwissenschaft bei den Griechen und Römern* (1863); Benfey's *Geschichte der Sprachwissenschaft und Orientalischen Philologie in Deutschland* (1869). (W. D. W.)

PART II.—COMPARATIVE PHILOLOGY OF THE ARYAN LANGUAGES.

The study of Aryan comparative philology has from its outset necessarily been in close connexion with the study of Sanskrit, a language unparalleled amongst its cognates in antiquity and distinctness of structure, and consequently the natural basis of comparison in this field. It is therefore not to be wondered at that we find no clear views of the mutual relationship of the individual members of the Aryan family or their position with regard to other languages until Sanskrit began to attract the attention of European philologists, or that the introduction of Sanskrit as an object of study was closely followed by the discovery of the original community of a vast range of languages and dialects hitherto not brought into connexion at all, or only made the objects of baseless speculations. We meet with the first clear conception of this idea of an Indo-European community of languages in the distinguished English scholar Sir William Jones, who, as early as 1786, expressed himself as follows: "The Sanskrit language, whatever may be its antiquity, is of wonderful structure; more perfect than the Greek, more copious than the Latin, and more exquisitely refined than either, yet bearing to both of them a stronger affinity, both in the roots of verbs and in the forms of grammar, than could have been produced by accident; so strong that no philologer could examine all the three without believing them to have sprung from some common source which, perhaps, no longer exists. There is a similar reason, though not quite so forcible, for supposing that both the Gothic and the Celtic, though blended with a different idiom, had the same origin with the Sanskrit."¹ But neither Sir William Jones nor any of his older contemporaries who had arrived at similar conclusions ever raised this important discovery from a brilliant *aperçu* into a valid scientific theory through a detailed and systematic comparison of the languages in question. To have achieved this is the undoubted merit of the German, Franz BOPP (*q.v.*), the founder of scientific philology of the Aryan languages, and subsequently through this example also the founder of comparative philology in general. Next to him Jacob GRIMM (*q.v.*) must be mentioned here as the father of historical grammar. The first part of his famous *Deutsche Grammatik* appeared in 1819, three years after Bopp had published his first epoch-making book, *Ueber das Conjugationssystem der Sanskritsprache*. Bopp's results were here at once utilized, yet Grimm's whole system was entirely independent of that of Bopp, and had no doubt been worked out before Grimm knew of his illustrious predecessor. In fact, their scientific aims and methods were totally different. Bopp's interest was not concentrated in comparison as such, but chiefly inclined towards the explanation of the origin of grammatical forms, and comparison to him was only a means of approaching that end.

In this more or less speculative turn of his interest Bopp showed himself the true son of a philosophical period when general linguistics received its characteristic stamp from the labours and endeavours of men like the two Schlegels and Wilhelm von Humboldt. Jacob Grimm's aims were of a less lofty character than those of Bopp, whose work, to his own mind, was crowned by his theory of the origin of inflexion through agglutination. In confining his task to a more limited range than the vast field of Aryan languages embraced in Bopp's researches, and thus fixing his attention on a group of idioms exhibiting a striking regularity in their mutual relationship, both where

they coincide and where they differ, he made it his foremost object to investigate and illustrate the continuous progress, subject to definite laws, by which these languages had been developed from their common source. He thus raised the hitherto neglected study of the development of sounds to an equal level with the study of grammatical forms, which had so far almost exclusively absorbed all the interest of linguistic research. Grimm's discovery of the so-called "Lautverschiebung," or Law of the Permutation of Consonants in the Teutonic languages (which, however, had been partly found and proclaimed before Grimm by the Danish scholar Rask), became especially important as a stimulus for further investigation in this line. Grimm's influence on comparative philology (which is secondary only to that of Bopp, although he was never a comparative philologist in the sense that Bopp was, and did not always derive the benefit from Bopp's works which they might have afforded him) is clearly traceable in the work of Bopp's successors, amongst whom Friedrich August Pott is universally judged to hold the foremost rank. In his great work, *Etymologische Forschungen auf dem Gebiete der indo-germanischen Sprachen, mit besonderem Bezug auf die Lautumwandlung im Sanskrit, Griechischen, Lateinischen, Litauischen, und Gothischen* (Lemgo, 1833-36), we find Indo-Germanic etymology for the first time based on a scientific investigation of general Indo-Germanic phonology. Amongst Pott's contemporaries Theodor Benfey² deserves mention on account of his *Griech.-Benfey*

² Theodor Benfey was born on 28th January 1809 at Nörten, Hanover, the son of a Jewish tradesman who had gained some reputation as an acute and learned Talmudic scholar. At the early age of sixteen he entered the university of Göttingen (which he afterwards exchanged for Munich) to devote himself to the study of classical philology. It was not until after 1830, when he had settled in Frankfurt-on-the-Main as a private teacher, that his attention was drawn towards the study of Sanskrit. In 1834 he went back to Göttingen and began lecturing as a privat-docent. For some time his lectures extended over various branches of classical philology as well as of Oriental and comparative philology, but he soon began to concentrate himself on the latter departments. After he had joined the Christian church he received, in 1848, an extraordinary professorship, and in 1862 he was appointed ordinary professor of Sanskrit and comparative philology. He died on 26th June 1881. Benfey also began his long and brilliant literary career in the field of classica. Besides his dissertation *Observationes ad Anacreontis fragmenta genuina* (Göttingen, 1829), his translation of the comedies of Terence (Stuttgart, 1837) deserves special notice. This was followed by his *Wurzellexikon* in 1839, and his quarto volume on "India" in Ersch and Gruber's *Encyclopädie*, 1840. Through these he at once gained a position of authority both in comparative and Indian philology. Of his other writings the more important are, *Ueber die Monatsnamen einiger alten Völker, insbesondere der Perser, Cappadocier, Juden, Syrer* (written in conjunction with A. Stern), Berlin, 1836; *Ueber das Verhältniss der ägypt. Sprache zum semit. Sprachstamm*, Leipzig, 1844; *Die pers. Keilschriften, mit Uebersetzung und Glossar*, Leipzig, 1847; *Die Hymnen des Samaveda*, Leipzig, 1848; *Vollständige Grammatik der Sanskritsprache*, Leipzig, 1852; *Chrestomathie aus Sanskritwerken*, Leipzig, 1853; *Pantschatantra*, 2 vols., Leipzig, 1859; *Geschichte der Sprachwissenschaft und oriental. Philologie in Deutschland*, Munich, 1869. Of his numerous contributions to the various scientific periodicals of the time, those published in the *Abhandlungen der Göttinger Gesellschaft der Wissenschaften* are especially meritorious:—"Ueber die indog. Endungen des Gen. Sing.," vol. xix.; "Einleitung in die Grammatik der ved. Sprache," vol. xix.; "Die quantitätsverchiedenheiten in den Samhita- und Padatexten der Veden," vols. xix.-xxvii.; "Das indog. Thema des Zahlworts 'Zwei' ist 'du,'" vol. xxi.; "Hermes, Minos, Tartaros," vol. xxii.; "Altpers. mazdāh = Zend mazdāh = Skr. medhās," vol. xxiii.; "Einige Derivate des indog. Verbums *ambh* = *nabh*," and "Ueber einige Wörter mit dem Bindesvocal *i* im Rīgveda," vol. xxiv.; "Behandlung des auslautenden *a* in ná 'wie' und ná 'nicht' im Rīgveda, nebst Bemerkungen über die urspr. Aussprache und Accentuierung der Wörter im Veda," vol. xxvi. Some of his smaller articles in the *Göttinger Gelehrte Anzeigen* were reprinted under the titles of *Vedica und Verwandtes*, Strasburg, 1877, and *Vedica und Linguistica*, ibid., 1880. As the preceding list shows, Benfey's interest had become more and more concentrated on Vedic studies towards the end of his days, and indeed he had planned, as the crowning work of his life, an extensive grammar of Vedic Sans-

¹ For this quotation and the following historical sketch in general see Th. Benfey, *Geschichte der Sprachwissenschaft*, p. 438, Munich, 1869, and especially B. Delbrück, *Introduction to the Study of Language*, p. 1. Leipzig, 1882 (a second German edition appeared in 1881).

isches Wurzellexicon (Berlin, 1839), a work equally remarkable for copiousness of contents and power of combination, yet showing no advance on Bopp's standpoint in its conception of phonetic changes.

A third period in the history of Indo-Germanic philology is marked by the name of August Schleicher, whose *Compendium der vergleichenden Grammatik der indo-germanischen Sprachen* first appeared in 1861. In the period subsequent to the appearance of Pott's *Etymologische Forschungen*, a number of distinguished scholars, too large to be recorded here individually,¹ had devoted their labours to the different branches of Aryan philology, especially assisted and promoted in their work by the rapidly progressing Vedic (and Avestic) studies that had been inaugurated by Rosen, Roth, Benfey, Westergaard, Müller, Kuhn, Aufrecht, and others. Moreover, new foundations had been laid for the study of the Slavonic languages by Miklosich and Schleicher, of Lithuanian by Kurschat and Schleicher, of Celtic by Zeuss. Of the classical languages Greek had found a most distinguished representative in Curtius, while Corssen, Mommsen, Aufrecht, Kirchhoff, &c., had collected most valuable materials towards the elucidation of Latin and the cognate Italic idioms. In his *Compendium*, Schleicher undertook and solved the difficult task of sifting down the countless details amassed since the days of Bopp and Grimm, and thus making the individual languages stand out clearly on their common background, while Bopp's attention had been especially occupied with what was common to all Indo-Germanic tongues. There are two prominent features which characterize this part of Schleicher's work,—his assumption and partial reconstruction of a prehistoric parent-speech, from which the separate Indo-Germanic languages were supposed to have sprung, and the establishment of a long series of phonetic laws, regulating the changes by which that development of the individual idioms had taken place. On Schleicher's views of and contributions towards general comparative philology (which he erroneously proposed to consider as a branch of natural science) we need not enter here.

For some time after Schleicher's premature death (in 1868) Indo-Germanic philology continued in paths indicated by him and Curtius, with the exception, perhaps, of the school founded by Benfey, who had always stood on independent ground. The difference between the two schools, however, was less strikingly marked in their writings, because it chiefly concerns general views of language and the Indo-Germanic languages in particular, although the characteristic task of the period alluded to was that of working out the more minute details of comparison; but behind all this the general interest still clung to Bopp's old glottogonic problems. Lately, however, a new movement has begun, and a younger school of linguists has sprung up who are united in their opposition to many theories of the older generation, yet often differ materially

krit. Death, however, prevented him from completing more than the above-mentioned preliminary studies by means of which he had intended to open the field for his greater work. (For fuller biographical details see Bezenberger, in his *Beiträge*, viii. 239 sq.)

¹ The extensive progress made in this period is best illustrated by the foundation of two periodicals especially devoted to Aryan comparative philology, Kuhn's *Zeitschrift für vergleichende Sprachforschung*, Berlin, from 1851 (now 27 vols.), and Kuhn's *Beiträge zur vergleichenden Sprachforschung*, Berlin, from 1858 (8 vols.). Benfey's school is more especially represented by the contributors to Benfey's *Orient und Occident*, Göttingen (3 vols.), from 1862, and subsequently through Bezenberger's *Beiträge zur Kunde der indogermanischen Sprachen*, Göttingen (8 vols.), from 1877. France possesses two periodicals of the same kind, the *Revue de Linguistique*, Paris, from 1868, and the *Mémoires de la Société de Linguistique de Paris*, also from 1868, while England is represented by the *Proceedings and Transactions of the Philological Society*, and America by the *Transactions of the American Philological Association* (from 1868)

both with regard to method and the solution of individual problems. In its present state this younger school (often branded with the name of Neo-Grammarians, "Junggrammatiker," by its opponents real and imaginary) is marked by certain distinct tendencies. In the first place, they are inclined more or less to abandon glottogonic problems as insoluble, if not for ever, yet for the present and with the scanty means that Aryan philology alone can furnish for this purpose. In this they are in opposition to the whole of the older school. In the second place, they object to the use of all misleading metaphorical comparisons of processes in the history of language with processes of organic development,—comparisons used at all times, but especially cherished by Schleicher. In the third place—and this has been of the greatest practical importance—they hold that our general views of language and our methods of comparison should be formed after a careful study of the living languages, because these alone are fully controllable in every minute detail, and can therefore alone give us a clear insight into the working of the different motive forces which shape and modify language, and that the history of earlier periods of language, consequently, can only be duly illustrated by tracing out the share which each of these forces has had in every individual case of change. Of these forces two are found to be especially prominent—phonetic variation and formation by analogy. They generally work in turns and often in opposition to one another, the former frequently tending to differentiation of earlier unities, the latter to abolition of earlier differences, especially to restoration of conformity disturbed by phonetic change. There are, however, other important differences in the action of the two forces. Phonetic change affects exclusively the pronunciation of a language by substituting one sound or sound-group for another. From this simple fact it is self-evident that phonetic changes as such admit of no exceptions. Pronunciation—that is, the use of certain sounds in certain combinations—is perfectly unconscious in natural unstudied speech, and every speaker or generation of speakers has only one way of utterance for individual sounds or their combinations. If, therefore, a given sound was once changed into another under given circumstances, the new sound must necessarily and unconsciously replace its predecessor in every word that falls under the same rules, because the older sound ceases to be practised and therefore disappears from the language. Thus, for instance, the sound of the short so-called Italian *a* in English has become exchanged for the peculiarly English sound in *man*, *hat*, &c., which is so exclusively used and practised now by English speakers that they feel great difficulty in pronouncing the Italian sound, which at an earlier period was almost as frequent in English as in any other language that has preserved the Italian sound up to the present day. Again, the sound of the so-called long English *a* in *make*, *paper*, &c., although once a monophthong, is now pronounced as a diphthong, combining the sounds of the English short *e* and *i*, and no trace of the old monophthong is left, except where it was followed by *r*, as in *hare*, *mare* (also *air*, *their*, *where*, &c.), where the *a* has a broader sound somewhat approaching that of the short *a* in *lat*. This last instance may at the same time serve to illustrate the restrictions made above as to sounds changing their pronunciation in certain groups or combinations, or under given circumstances only. We may learn from it that phonetic change need not always affect the same original sound in the same way in all its combinations, but that neighbouring sounds often influence the special direction in which the sound is modified. The different sounds of the English *a* in *make* and *hare* are both equivalents of the same Old English sound *ǣ* (= the Italian short *a*) in *macian*, *hara*. The latter sound has

been split in two, but this process again has taken place with perfect regularity, the one sound appearing before *r*, the other before all other consonants. It is easy to see that the common practice of comprising the history of the Old English *ā* in the one rule,—that it was changed into the sound of the *a* in *make* except when followed by an *r*,—can only be defended on the practical ground that this rule is convenient to remember, because the words exhibiting the former change are more numerous than the instances of the latter; apart from this there is nothing to justify the assumption that one of these changes is the rule and the other the exception. The fact is, that we have two independent cases of change, which ought to be stated in two distinct and independent rules according to the different positions in which the original *ā* stood before the splitting began. It is also easy to observe that the variety of modifying influences may be much more manifold than in the present instance of *make* and *hare*, and that the number of special phonetic rules in such cases must be increased in proportion to the progress made in the investigation of the said modifying powers. In this respect much still remains to be done, but what has been achieved is more than sufficient to prove the correctness of the statement from which we started above, that phonetic rules in themselves are without exceptions, however often phonetic processes may have been crossed and more or less effaced by non-phonetic influences in actual (especially literary) language, such as mixture of dialects, formation by analogy, and the like.

Analogue change, on the other hand, does not affect the pronunciation of a language as a whole in the way phonetic change does, but is confined to the formation and inflexion of single words or groups of words, and therefore very apt to bear an entirely arbitrary and irregular character. A few instances will be sufficient to illustrate this. In Old English a certain number of substantives formed their plurals by mutation of the root-vowels, as *fōt*—*fēt* or *bōc*—*bēc*. In Modern English this system of inflexion has been preserved in some cases, as in *foot*—*feet*, and altered in others as *book*—*books*. Now, while *foot*, *feet*, and *book* are the regular modern phonetic equivalents of the old *fōt*, *fēt*, *bōc*, the plural *books* can in no way be phonetically traced back to the old *bēc*, the phonetical equivalent of which in Modern English would be **beech*. The only possible explanation of a form like *books* is that the older *bēc* was at some date given up and replaced by an entirely new formation, shaped after the analogy of the numerous words with a plural in *-s* without modification of the root-vowel. That this should have been done in the case of *book*, but not in that of *foot*, is an accident, which must be accepted as a fact not allowing of any special explanation. Let us now take another instance from the English verb. In Old English the different persons of the preterite indicative in the so-called strong (irregular) verbs were generally distinguished by different root-vowels; *ridan*, "to ride," thus *ic rād*, *þú ride*, *hē rād*, *wē*, *gē*, *hiē ridon*, and *ic band*, *þú bunde*, *hē band*, *wē*, *gē*, *hiē bundon*. In Modern English this difference in the root-vowels has been abandoned, and *rode*, *bound* now stand for all persons, *rode* being the modern phonetic equivalent of the 1st and 3d sing. *rād*, while *bound* represents the *u*-forms of *bindan*. Inasmuch as a similar process of levelling has been carried through in all preterites of Modern English, regularity prevails even here. But when we look to its results in the individual verbs we soon find that the choice amongst the different forms which might have served as starting-points has been entirely arbitrary. It is indeed impossible to say why the old singular form should have been chosen as a model in one case, as in *rode*, and the old plural form in

another, as in *bound*. From these and numerous similar instances we must draw the conclusion that it is beyond our power to ascertain whence analogical changes may start, and to what extent they may be carried through when once begun. All we can do is to carefully classify the single cases that come under our observation, and in this way to investigate where such changes are especially apt to take place and what is their general direction. As to the latter points, it has been observed before that levelling of existing differences is one of the chief features in analogical change (as in the case of *rode* and *bound*). As to the former, it must be borne in mind that, before any analogical change can take place, some mental connexion must exist between the words or forms serving as models and those which are remodelled after the types suggested to the mind of the speakers through the former. Of such natural mental combinations two classes deserve especial notice: the mutual relationship in which the different, say inflexional, forms of the same word stand to each other, and the more abstract analogies between the inflexional systems of word-groups bearing a similar character, as, for instance, the different declensions of nouns and pronouns, or the different conjugations of verbs. The instance of *rode*, *bound* may serve to illustrate the former category, that of *books* the latter. In the first case a levelling has taken place between the different forms of the root-vowels once exhibited in the different preterite forms of *ridan* or *bindan*, which clearly constitute a natural group or mental unity in consequence of their meaning. The form of *rode* as a plural has simply been taken from the old singular, that of *bound* as a singular from the old plural. In the case of *book*—*looks* for *bōc*—*bēc*, this explanation would fall short. Although we might say that the vowel of the singular here was carried into the plural, yet this would not explain the plural *-s*. So it becomes evident that the old declension of *bōc*—*bēc* was remodelled after the declension of words like *arm*—*arms*, which had always formed their plurals in *-s*. Isolated words or forms, on the other hand, which are no part of natural groups or systems, inflexional or formative, must be regarded as commonly safe from alterations through analogy, and are therefore of especial value with regard to establishing rules of purely phonetic development.

It is true that the distinction between phonetic and analogical change has always been acknowledged in comparative philology. At the same time it cannot be denied that analogical changes were for a long time treated with a certain disdain and contempt, as deviations from the only course of development then allowed to be truly "organic" and natural, namely, that of gradual phonetic change (hence the epithet "false" so constantly attached to analogy in former times). Amongst those who have recently contributed most towards a more correct evaluation of analogy as a motive-power in language, Professor Whitney must be mentioned in the first place. In Germany Professor Scherer (*Zur Geschichte der deutschen Sprache*, 1868) was the first to apply analogy as a principle of explanation on a larger scale, but in a wilful and unsystematic way. Hence he failed to produce an immediate and lasting impression, and the merit of having introduced into the practice of modern comparative philology a strictly systematic consideration of both phonetic and analogic change as co-ordinate factors in the development of language rests with Professor Leskien of Leipzig, and a number of younger scholars who had more or less experienced his personal influence. Amongst these Brugmann, Osthoff, and Paul rank foremost as the most vigorous and successful defenders of the new method, the correctness of which has since been practically acknowledged by most of the leading philologists of all shades.

who in point of fact follow it in their investigations, in spite of the lively theoretical protest which some of them continue to maintain against it, and in spite of the general feeling of hostility and inclination towards mutual distrust often but too clearly visible in recent linguistic publications, from whatever side they may come.¹

From this historical sketch we may now proceed to a short examination of some of the chief results of Aryan comparative philology.

The most prominent achievement of the researches of Bopp and his followers was to prove that the majority of the European languages and dialects, together with a certain number of important languages spoken in Asia, form one great family,—that is, that they have sprung from one common source or parent-language. The name now mostly used in England for this community is *Aryan languages*. American and French scholars generally prefer to say *Indo-European languages*, while the name of *Indo-Germanic languages* is still almost universally used in Germany. It is hard to decide for or against any of these names from a scientific point of view. The word *Indo-Germanic* was not inappropriately coined by combining the names of the most easterly and westerly members of the family, the Indian and the Germanic or Teutonic group.² *Indo-European* seems to be a less lucky invention, as this combination of geographical names would erroneously point to all the languages of India and Europe as the constituents of our family, while a large number both of Indian and European idioms belong to entirely unrelated groups of languages. *Aryan* would no doubt be the best name in itself, for it seems that the primitive forefathers of the Aryan nations used the word *Āria* as a national name themselves. We find at least the Sanskrit *Ārya* thus used in India, and similarly the Old Persian *Ārya* (in the cuneiform inscriptions of Darius), Zend *Airya* in Persia (whence the later *Ērān*, *Īrān*), and perhaps *Ériu*, gen. *Éirenn*, as the national name for Ireland.³ But before the word *Aryan* came to be applied in the sense defined above it had for some time been used, and it is still largely used, in a more restricted sense as the special collective name for the languages of the Indian and Persian or Iranian groups of the Indo-Germanic family. This ambiguity renders the use of the word *Aryan* less recommendable than it would be had its meaning been properly fixed from the beginning. It seems that outside of England *Aryan* will hardly gain ground; some recent attempts to introduce the name into Germany have utterly failed, and in the same way the other nations who share in scientific research in this demesne cling to the older names.

This large Indo-Germanic or Aryan family, then, to revert to our principal task, consists of ten groups or sub-

families of languages, three of which are located in Asia while the rest belong to Europe.⁴

1. The *Indian Family*, in which Sanskrit, especially in its oldest form, preserved in the Vedic texts, stands foremost in rank. Of the older stages of the language Prākṛit and Pāli may be mentioned here,—the former, in its various branches being the mother of the modern Indian dialects of Aryan descent (including also the Gipsy language), the latter (see above, p. 183) the idiom of the sacred books of the southern Buddhists.⁵

2. The *Iranian or Persian Family*, represented in the earliest period by Old Persian, scanty remnants of which have come down to us in the Achæmænian cuneiform inscriptions, and Zend, or, as it is also called, Old Bactrian, the language of the *Zend-Avesta*, the sacred books of the Zoroastrians. The chief modern representatives of this group are Persian, Afghan, Kurdish, and Ossetic.⁶

3. The *Armenian Family*, consisting of the different living dialects of Armenian. Armenian has but recently been proved to be an independent member of the Aryan family. It partakes of many peculiarities of the Iranian group, but at the same time shares several important characteristics of the European languages, so that it cannot be classed as a subdivision of either of these groups.⁷

4. The *Greek Family*, comprising the various old dialects of Greek, and the modern Romaine idioms, which have been developed out of the later κοινή that had gradually superseded the old dialectal varieties.⁸

5. A fifth family, which may once have had a far larger extension, is now only represented by one surviving member, the *Albanian language*. As we have no old sources for this idiom, and only know it in its modern state of utter decay, it is extremely difficult to obtain definite results concerning its origin and position relatively to the surrounding languages. Bopp seems to have proved, however, that Albanian actually is an Aryan idiom.⁹ It is also certain that it belongs to the European type of Aryan, yet it is not particularly closely allied with Greek, as has often been assumed, but shows some remarkable coincidences with the northern European languages.¹⁰

6. The *Italic Family*. Its most important representative is Latin, from which the modern Romance languages have sprung. Closely connected with Latin was the Faliscan dialect, which is preserved in a few inscriptions only. A second branch of Italic is formed by Umbrian and Oscan, both of which soon became extinct through the overpowering influence of Latin, like the other less widely diffused idioms once spoken in Italy.¹¹

⁴ The fullest, yet now somewhat antiquated, account of all the members of the Aryan family will be found in the article "Indo-germanischer Sprachstamm," by A. F. Pott, in Ersch and Gruber's *Encyclopædie* (Leipsic, 1840). See also especially Th. Benfey, *Geschichte der Sprachwissenschaft*, pp. 601-683.

⁵ For further particulars see SANSKRIT.

⁶ See the articles PAHLAVI (*supra*, p. 134 sq.) and PERSIA (*supra*, p. 653 sq.), and for the linguistic characteristics of this group H. Hübschmann, in *Zeitschrift für vergl. Sprachforschung*, xxiv. p. 372 sq.

⁷ See H. Hübschmann, "Ueber die Stellung des Armenischen im Kreise der indo-germanischen Sprachen," in *Zeitschr. vergl. Sprachf.*, xxiii. p. 5 sq., where further references to earlier treatments of this question are given.

⁸ See GREECE, vol. xi. p. 129 sq. An exhaustive summary of all prior contributions towards linguistic elucidation of Greek is given in Gustav Meyer's excellent *Griechische Grammatik*, Leipsic, 1880, which must now be considered the standard book on Greek grammar, together with the well-known works of G. Curtius, quoted at vol. xi. p. 136.

⁹ Bopp, "Ueber das Albanesische in seinen verwandtschaftlichen Beziehungen," Berlin, 1855, in *Abhandl. Berl. Akad.*

¹⁰ See especially G. Meyer, "Die Stellung des Albanesischen im Kreise der indo-germ. Sprachen," in Bezenberger's *Beiträge*, viii. p. 185 sq., and *Albanesische Studien*, Vienna, 1883. For other references, cp. Benfey, *Geschichte der Sprachwissenschaft*, p. 643 sq.

¹¹ A sketch of the history of Latin is given under LATIN LANGUAGE; a list of the chief books concerning the other dialects will be found in the appendix to Sayce's *Intr. to the Science of Lang.*, vol. ii.

¹ The fullest systematical treatment of these questions of method will be found in Paul's *Prinzipien der Sprachgeschichte*, Halle, 1880. See also Osthoff, *Das physiologische und psychologische Moment in der sprachlichen Formenbildung*, Berlin, 1879, and Misteli, "Lautgesetz und Analogie," in *Zeitschrift für Völkerpsychologie*, xi. p. 365 sq. Of those who on principle stand in theoretical opposition, the several schools of Benfey (now especially represented by Fick), Scherer, and Johannes Schmidt may be mentioned.

² The word *Indo-Germanic*, it is true, was invented before the Celtic languages were known to belong to the same family. But even after that discovery it was unnecessary to substitute the name *Indo-Celtic* as some authors have tried to do; for certainly the most westerly branch of Indo-Germanic in Europe (disregarding the Aryan colonies in America) is Icelandic, an undoubtedly Germanic language. Other names, such as *Japhetic* or *Sanskritic*, have hardly found any use in scientific literature.

³ For particulars see Professor Max Müller's *Lect. on the Science of Ling.*, lect. vi. (first series), and ARYAN, vol. ii. p. 672 sq.; for this etymology of *Ériu* see especially H. Zimmer, "Arisch," in Bezenberger's *Beitr. z. Kunde der indogerm. Sprachen*, iii. p. 137 sq.

7. The *Celtic Family*, once covering a large part of western Europe, but now reduced to comparatively scanty remnants in the north-west of France and in the British islands. Among its extinct members the language of the Galatians in Asia Minor may be mentioned, of which little more is known than that it was Celtic. The earliest documents of Celtic speech we possess are some inscriptions in the idiom of the Gallic inhabitants of France and northern Italy. The surviving branches of Celtic show a clear division into two groups: the Northern or Gaelic group, formed by Irish, Gaelic or Scotch, and Manx, and a Southern or Britannic group, consisting of Welsh or Cymric, Cornish (extinct since 1778), and Armorican or Bas Breton in Brittany. The fundamental authority for the comparative study of Celtic grammar is Zeuss, *Grammatica Celtica*, 1853 (2d ed. by H. Ebel, 1871). After Zeuss, Stokes and Rhŷs in England, Ascoli in Italy, Ebel, Windisch, and Zimmer in Germany, and D'Arbois de Jubainville and H. Gaidoz in France have been the chief contributors to this field of research. The last-named is also the editor of a periodical especially devoted to Celtic studies, the *Revue Celtique* (Paris, from 1870).¹

8. The *Germanic or Teutonic Family*. This well-developed family is divided into two main groups, which are now commonly denoted Eastern and Western Germanic. The members of the former are Gothic (see *GOthic LANGUAGE*, vol. x. p. 852 sq.) and Scandinavian, with an eastern and a western subdivision, the former comprising Swedish and Danish, the latter Norse and Icelandic. Western Germanic, on the other hand, consists of English, Frisian (these two seem to form a separate branch), Saxon or Low German, Frankish (including Dutch), and Upper German (see article *GERMAN LANGUAGE*). The dialects of the numerous other Teutonic tribes not mentioned here have died out without leaving sufficient materials for linguistic classification.

9. The *Baltic Family*, comprising three distinct idioms—Prussian, Lithuanian, and Lettish. Prussian became extinct in the 16th century. The few specimens of this highly interesting language which have been preserved are collected by Nesselmann, *Die Sprache der alten Preussen* (Königsberg, 1845), and *Ein deutschpreussisches Vocabularium* (*ibid.*, 1868). The same author has also published a dictionary, *Thesaurus linguæ Prussicæ* (Berlin, 1873). Amongst other contributions to Prussian grammar, Bopp's essay, *Ueber die Sprache der Altpreussen* (Berlin, 1853), is especially noteworthy. Of the two other branches, Lithuanian is the more important for comparative philology. The chief grammars are those by Schleicher (*Handbuch der litauischen Sprache*, 2 vols., Prague, 1856-57) and Kurschat (*Litauische Grammatik*, Halle, 1876); the best dictionary is by Kurschat (*Wörterbuch der lit. Sprache*, 2 vols., Halle, 1878-83). Some of the oldest texts are now being reprinted by Bezzenberger.² For Lettish, Bielenstein's grammar (*Die lettische Sprache*, 2 vols., Berlin, 1863-64) and Ulmann's dictionary (*Lettisches Wörterbuch*, Riga, 1872) are the first books to be consulted.

10. The *Slavonic Family*. There are two main branches of Slavonic. The so-called Southern or South-Eastern branch embraces Russian, Ruthenian (in Galicia), Bulgarian; Servian, Croatian, and Slovenian. The second branch is generally designated by the name of Western Slavonic. It is chiefly represented by Cechish or Bohemian and Polish. With the former the Serbian dialects spoken

in Lusatia are very closely connected. Polish, again, is subdivided into Eastern Polish or Polish Proper and Western Polish, a few remnants of which now survive in the Kasubian dialects of Prussia. About the extinct members of this last group, which are generally comprehended under the name of Polabian dialects, Schleicher's *Laut- und Formenlehre der polabischen Sprache* (St Petersburg, 1871) and an article by Leskien in *Im neuen Reich*, ii. p. 325, may be consulted. The oldest Slavonic texts, some of which go as far back as the 10th century, are a number of books destined for the use of the church. From this circumstance the peculiar dialect in which they are written is often called Church Slavonic. Schleicher and others identify this dialect with Old Bulgarian, while Miklosich thinks it should be classed as Old Slovenian. For comparative purposes as well as for Slavonic philology this idiom is the most important. The chief grammars are Schleicher, *Formenlehre der kirchenslavischen Sprache* (Bonn, 1852); Miklosich, *Laut- und Formenlehre der altslovenischen Sprache* (Vienna, 1850); and Leskien, *Handbuch der albulgarischen Sprache* (Vienna, 1871). The fundamental works on comparative Slavonic philology are Miklosich, *Vergleichende Grammatik der slavischen Sprachen* (4 vols., Vienna, 1852-68; 2d ed. of vol. i., *Lautlehre*, 1879), and *Lexicon Palæoslovenico-Græco-Latinum* (Vienna, 1862-65). A large number of special contributions are collected in Jagić, *Archiv für slavische Philologie* (Berlin, from 1876).

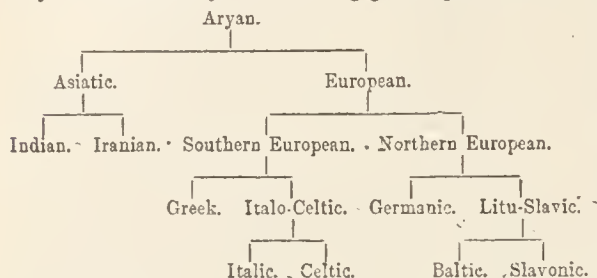

The mutual relationship of these ten families may be shortly characterized by saying that they are dialects of the primitive Aryan parent-speech, which at an early period of its existence must have formed a linguistic unity, but subsequently became dissolved into these subdivisions. This fundamental view now seems to be universally admitted to be correct. But it is extremely difficult to go beyond it in attempts to trace out the history of the process of dissolution. One problem offering itself at the very outset of such an attempt (although more of an ethnological than philological character) must at once be dismissed as insoluble,—the question of the original home of our Aryan forefathers and the directions of the wanderings that brought the single members of the great original tribe to the seats occupied in historical times by the several Aryan nations. There exist indeed no means for deciding whether they came from the north-eastern part of the Iranian plateau near the Hindu-Kush Mountains, as was once generally assumed, or whether Europe may boast of being the mother of the Aryan nationality, as some authors are now inclined to believe.³ The chief philological difficulty lies in the fact that some of these ten families stand in closer relationship with certain others than with the rest, so that they seem to form separate independent groups, and yet these groups cannot be severed from the rest without overlooking important linguistic facts which seem to speak for the existence of a closer connexion between single members of one group and single members or the whole of another. Before attention was drawn to this latter point it was easy enough to account for the origin of the grouping alluded to. If everything that is common to all Aryan languages must have originated in the common parent-speech—and the correctness of this assumption can hardly be doubted—then everything that is common to all the families of one particular group, but strange to the others, must be assigned to a period when these families formed a unity by themselves and were disconnected with the other stock. The fact, for instance, that all the European languages possess the three vowels *a*, *e*, *o*, where the Indian and Iranian group show the uniform *a*, which was then believed to be the primitive

¹ For further particulars see article *CELTIC LITERATURE*, and the very exhaustive critical and bibliographical study by Windisch, "Keltische Sprachen," in Ersch and Gruber's *Encyclopædie*.

² *Litauische und Lettische Drucke des 16ten Jahrhunderts*, Göttingen, 1878 sq.; cp. also *Beiträge zur Geschichte der lit. Sprache*, Göttingen, 1877, by the same author.

³ On this much vexed question see especially O. Schrader, *Sprachvergleichung und Urgeschichte*, Jena, 1883, *passim*.

sound, seemed to indicate that the primitive Aryan stock had once been split into two halves, one of which remained in Asia and retained the primitive *a*-sound, while the other half emigrated to Europe and there developed the new vowel-system, before any new divisions took place. The Aryan parent-speech would thus appear to have been split into a European and an Asiatic "base-language." Similar facts in the history of the single European languages then led to the further assumption of a southern European base as the parent of Greek, Italic, and Celtic, and a northern European base for Germanic, Baltic, and Slavonic, and, with further subdivision, an Italo-Celtic and a Litu-Slavic base for Italic and Celtic on the one hand and for Baltic and Slavonic on the other. The prehistoric development of Aryan, according to this genealogical theory (which makes division of language dependent on division of nations), may be illustrated by the following genealogical table.¹

It may still be admitted that at least the mutual position of the ten families is not the same in all cases. It cannot be doubted that Indian and Iranian resemble each other more than either of them does any other family. The same may also be said of Baltic and Slavonic, and even of Italic and Celtic, however different the latter two may appear to be at first sight.² But it is impossible to carry this system of genealogical grouping through. It will be observed that not all the ten families are represented in the genealogical tree given above; Albanian and Armenian have not found a place in it, nor could they be introduced without disturbing the entire table. If we look at Armenian, for instance, we find that its structure and phonology on the whole follow the Asiatic type, and yet Armenian shares the European vowel-system alluded to before; compare, for instance, Armenian *berem*, "I bear," with Greek *φέρω*, Latin *fero*, Old Irish *berimm* (and *dobiur* for **do-beru*), Gothic *baira* (pronounced *bēra*), Lith. *berù*, Slavonic *bera*, against Sanskrit *bhārāmi*, Zend *barāmi*. Armenian, then, is half European, half Asiatic, and if such an intermediate idiom exists it is impossible to make a strict distinction between Asiatic and European. Let us take another instance. All the Asiatic languages have changed the original palatal *k* into sibilants, and the same change we find again in Slavonic and Baltic, both of which otherwise clearly belong to the European type; compare, for instance, Sanskrit and Zend *daṇa*, "ten," Armenian *tasn*, Slavonic *desetī*, Lith. *dėszimt*, with Greek *δέκα*, Latin *decem*, Old

Irish *deich* (for **dekim*), Gothic *taihun*. In a similar way Litu-Slavic and Germanic are connected by the formation of a plural dative in *n*, as in Gothic *wulfam*, Lith. *vilkams*, Slavonic *vlukomū*, against the Sanskrit *-bhyas*, Latin *-bus*, Irish *-b*; and so all round. The consequence is that every attempt at grouping the Aryan families of speech on the genealogical basis must fail, because it would have to cut asunder some of the natural ties that hold the single families together. It is true that some of the coincidences falling under this head may be due to mere chance, especially those in phonology; for we often see the same phonetic processes going on in languages which stand in no connexion whatever at the time. Yet in the case before us the number of the actual coincidences is too large to allow of such an explanation, and the fact of their existence is made all the more striking from the circumstance that it is each pair of *neighbouring* families which shows these connecting links. If they prove anything (and it cannot be doubted that they do), we must necessarily come to the conclusion that every such link is a witness for at least a temporary connexion between the two languages or families it holds together. To assume such temporary connexions in the time after a true division of nations had taken place (that is, to assume, for instance, that Slavonic had come into contact with the Asiatic languages after the Europeans had migrated from Asia to Europe, or the forefathers of the present Asiatic nations from Europe to Asia, as the case may be) seems impossible. It is likewise highly improbable that connexions intimate enough to leave distinct marks in language existed at a time when the original tribe had spread over the wide regions now covered by the Aryans, even supposing this spreading to have been so gradual as not to cause any break in the continuity of the Aryan population. And, even if we concede this, how are we to account for the fact that we have no longer the supposed continuity of speech, but well-defined single languages, whose separation must, after all, be due to breaks in the continuity of intercourse between the respective speakers? These and similar reasons point to the assumption that the origin of the phenomena alluded to must be sought in a remote period, when the Aryan tribe had an extension small enough to permit continuity of intercourse, and yet large enough to allow of dialectic variations in its different districts. In other words, when the actual break-up of the Aryan tribe into different nations came to pass the Aryan parent-speech was no longer a homogeneous idiom, but the development of dialects had begun. On their following wanderings, then, those tribes or clans would naturally cling together which had until then lived in the closest connexion both of intercourse and dialect (for community of intercourse and of speech always go together), or, as we might also say, the old unity would naturally be broken up into as many parts as there had been dialectic centres. Transition dialects, which might have been spoken in the outlying parts of the old dialectic districts, would also naturally be then reduced to a common level in consequence of the general mixture of speakers that could not but have taken place on wanderings so extensive as those of the Aryan tribes must have been.

Such an assumption would indeed solve most of the difficulties mentioned above, especially the peculiar way in which the single families of Aryan are linked together. Each of these would then correspond to one of the main dialects of the parental language, and their mutual affinities would therefore be of the same kind as those of neighbouring dialects, say, of any living speech. And in these nothing is more common, nay even more characteristic, than the gradual transition from one to the other, so that each dialect of an intermediate position partakes of some

¹ This pedigree is the one ultimately given by Schleicher. Others have assumed more or less different degrees of relationship. Greek and Italic, for instance, were for a long time believed to be particularly near relations. A totally contrary view would come nearer the truth. Greek and Latin are about as different, both in phonology and grammatical structure, as any two members of the Aryan family; indeed there is nothing to recommend their combination but the intimate connexion in which the two nations and their literatures have stood within historical times, and the custom derived therefrom of studying the two classical languages together from our schooldays.

² Amongst the characteristics of these two groups the general resemblance in the declension, and in the verb the formation of a future in *b* or *f* (Latin *amabo*, Old Irish *carfa*, *ruo charb*) and of a passive in *r* (Latin *fertur*, Old Irish *carthir*, &c.), are the most important.

of the peculiarities of its neighbours to the right and left. In Old English the Kentish dialect, for instance, in some respects goes with West Saxon against Mercian, in others with Mercian against West Saxon, sometimes West Saxon and Mercian combine against Kentish, and sometimes each of them stands by itself, as the following table will show.

| West Saxon. | Kentish. | Mercian. |
|---------------|---------------|------------------------------|
| <i>hīlpð</i> | <i>hīlpð</i> | <i>helpeð</i> (he) helps. |
| <i>lēht</i> | <i>lēht</i> | <i>lēht</i> light. |
| <i>dæd</i> | <i>dæd</i> | <i>dæd</i> deed. |
| <i>hīerde</i> | <i>hīorde</i> | <i>hīorde</i> (shep-)herd. |
| <i>dæl</i> | <i>dæl</i> | <i>dæl</i> deal. |
| <i>gylden</i> | <i>gylden</i> | <i>gylden</i> golden. |
| <i>fēlð</i> | <i>fēlð</i> | <i>fālled</i> (he) falls. |
| <i>wierpð</i> | <i>wecorð</i> | <i>wecorpeð</i> (he) throws. |

If the inhabitants of the old kingdoms of Wessex, Kent, and Mercia had separately left their English abodes and wandered back to different parts of the Continent after their dialects had developed in the way illustrated above, would not their dialects have gradually developed into independent languages exhibiting the same characteristic features of mutual relationship as those found in the Indo-Germanic idioms?¹

It remains to give a short review of the main characteristics of Indo-Germanic, both phonetic and structural.

A. Phonology.—The consonant system of the Aryan parent-language was chiefly characterized by the prevalence of stopped (explosive) sounds and the scarcity of spirants. The only representatives of the latter class were *s*, and in a few cases *z*, while there is no trace of sounds so common in modern languages as the English *f*, *th*, *sn*, or the German *ch*. Besides stops and spirants the system comprised nasals, liquids, and semi-vowels.

The stops were either voiceless (surd), like the English *p*, *t*, *k*, or voiced (sonant), like the English *b*, *d*, *g*, and either pure (unaspirated) or aspirated. By combining these two distinctions we arrive at four chief varieties of stops, which are generally thus symbolized: *p*, *ph*, *b*, *bh* for the labial, *t*, *th*, *d*, *dh* for the dental class, &c. Here the *p*, *t*, *k* denote unaspirated voiceless stops, *ph*, *th*, *kh* their aspirates; *b*, *d*, *g* voiced stops, and *bh*, *dh*, *gh* their aspirates. In pronouncing these sounds English readers should be careful not to give the Aryan *p*, *t*, *k* the value of the English *p*, *t*, *k*, because these are always slightly aspirated. The true unaspirated sound is still found in the Romance and the Slavonic languages, in modern Greek, &c. The aspirates *ph*, *th*, *kh* should be sounded with a strong escape of breath after the explosion of the stop, inserting a distinct *h* between the initial *p*, *t*, *k* and the following sound (as is often done in Irish pronunciation; initial *p*, *t*, *k* in Danish may also be taken as examples). In the so-called media *b*, *d*, *g* the voice should always be distinctly audible, as in French, or in English medial *b*, *d*, *g* (initial *b*, *d*, *g* in English are often voiceless). The pronunciation of the voiced aspirates *bh*, *dh*, *gh* is a very vexed question, as these sounds have disappeared from all the living Aryan languages except the modern Indian dialects, and these seem to show differences in the pronunciation of the aspirates which have not yet been sufficiently cleared up. The old Indian grammarians made their aspirates out to be voiced stops followed by a corresponding, that is voiced, aspiration, and this description seems to correspond with the observations of Mr Alex. Ellis,² who found that in the Benares pronunciation of Sanskrit *bha*, *dha*, *gha* are distinguished from *ba*, *da*, *ga* merely by a somewhat stronger pronunciation of the vowel. It seems, however, that another pronunciation exists in the west, and that *bha*, for instance, in Bombay is actually pronounced as a distinctly voiced *b* followed by a common *h*; the voice is broken off simultaneously with the opening of the lips, so that no vocalic sound is inserted between the *b* and the *h*. If this pronunciation was not original in Aryan, it seems to have come in at an early period; for it would be extremely difficult to explain the transition of original *bh*, *dh*, *gh* into the Greek voiceless

aspirates *φ*, *θ*, *χ* (as in Greek *φῆρσ*, originally pronounced *p-hérσ*, compared with Sanskrit *bhārāmi*), unless we start from a voiceless aspiration.

With regard to their positions, the labials *p*, *ph*, *b*, *bh* do not seem to have differed from the common European labials of the present day. The so-called dentals *t*, *th*, *d*, *dh* were really dental, that is, formed by touching the lower rim or back of the upper teeth with the tip of the tongue (in the pronunciation of the English *t*, *d* the tongue is raised towards the upper gums). This purely dental pronunciation is still preserved in most of the Asiatic and some European languages. The supradental class represented in the Indian languages by the so-called cerebrals or linguals *ṭ*, *ṭh*, *ḍ*, *ḍh* seems not to have existed in primitive Aryan, but was most probably imported into Indian from the Dravidian idioms of southern India, where these sounds are very common. Of back consonants Aryan possessed two distinct parallel sets, now generally symbolized by *k*¹, *kh*¹, *g*¹, *gh*¹ and *k*², *kh*², *g*², *gh*² respectively.³ They may be characterized as front and back gutturals, or possibly as palatals and gutturals proper (compare the Semitic distinction of *ṭ* and *p*). The distinction of the two series is best preserved in the Asiatic languages and Litu-Slavic, where the front gutturals or palatals passed into spirants, while the back gutturals (at least originally) retained their character of explosives. In the other languages the difference is less clearly marked, as will be seen from the following table of correspondences.⁴

| Aryan. | Sans. | Zend. | Arm. | Slav. | Lith. | Greek. | Lat. | Irish. | Germ. |
|------------------------|----------------------|---|-----------------------|--------------------------------|---------------------|----------------------------------|---------------------|----------------------|--|
| <i>k</i> ¹ | <i>ç</i> | <i>s</i> | <i>s</i> | <i>s</i> | <i>sz</i> | <i>κ</i> | <i>c</i> | <i>c</i> , <i>ch</i> | <i>h</i> (<i>g</i>) |
| <i>g</i> ¹ | <i>j</i> | <i>z</i> | <i>ts</i> | <i>z</i> | <i>z</i> | <i>γ</i> | <i>g</i> | <i>g</i> | <i>k</i> |
| <i>gh</i> ¹ | <i>h</i> | | <i>z</i> , <i>dz</i> | | | <i>χ</i> | <i>h</i> , <i>g</i> | <i>g</i> | <i>g</i> |
| <i>k</i> ² | <i>k</i> , <i>c</i> | <i>k</i> , <i>c</i> (<i>χ</i> , <i>δ</i>) | <i>k</i> , <i>kh</i> | <i>k</i> , <i>č</i> , <i>c</i> | <i>k</i> | <i>κ</i> , <i>π</i> (<i>τ</i>) | <i>q</i> , <i>c</i> | <i>c</i> , <i>ch</i> | <i>hw</i> , <i>h</i> (<i>u</i> , <i>g</i>) |
| <i>g</i> ² | <i>g</i> , <i>j</i> | <i>g</i> , <i>j</i> | <i>g</i> , <i>gh</i> | <i>g</i> , <i>g</i> | <i>g</i> | <i>γ</i> (<i>β</i> , <i>δ</i>) | <i>g</i> | <i>g</i> | <i>g</i> |
| <i>gh</i> ² | <i>gh</i> , <i>h</i> | <i>gh</i> , <i>h</i> | <i>g</i> (<i>z</i>) | <i>g</i> , <i>z</i> | <i>g</i> , <i>z</i> | <i>χ</i> (<i>θ</i>) | <i>h</i> , <i>g</i> | <i>g</i> , <i>b</i> | <i>g</i> (<i>g</i>) <i>w</i> |

Of nasals there were four, corresponding to the four classes of stops, Nasals *m*, *n*, and two guttural ones, which may be written *ṃ*¹ and *ṅ*²; the latter only occur before the corresponding explosives. Of liquids we find *r* and *l* in the individual languages, but frequently interchanging. It has been assumed, therefore, that Aryan had only one sound instead of the two, which was afterwards developed into either *r* or *l*. There seems to be sufficient reason, however, to believe that the later distinction of *r* and *l* was founded on some parallel distinction in Aryan; most probably we have to assume the coexistence of two varieties of *r*-sounds; the one which, at a later period, passed into *r* may have been a distinct trilled *r*, while the second, the antecedent of *l*, may have been an untrilled variety. We find a similar distinction in the semi-vowels *y* and *w*, each of which must have Sem- had two distinct varieties. The first variety of *y* is in Greek vowels represented by *ι*, the second by *υ*, as in *δς*, *ζυγόν*, compared with Sanskrit *yds* and *yugdm*, &c.; from these correspondences it would seem that the first *y* was a real semi-vowel, like the English *y*—that is, a non-syllabic *i*—and the second a more spirant sound, like the North-German *j*. As to the *w*, the existence of a double sound Other seems to follow from the different way in which initial *v* is treated in Sanskrit reduplication; compare perfects like *uvāca*, 3d plural *uācis* with *vavārdha*, pl. *vavārdhis*.⁵ Here the transition of *v* into *u* points to a semi-vocalic pronunciation, as in English *w*. The other sound, which remains unaltered, may have been more like the spirant English *v*. The sound of the sibilant *s* cannot be fixed exactly; it may have been dental either like the French *s*, or more supradental as in English. The voiced *z* is of extremely rare occurrence; it was confined to combinations of a sibilant with a voiced mute, such as *zd*, *zdḥ*, *zg*; compare, for instance, Aryan *mizdho*,

¹ A detailed history of the different views expressed with regard to the mutual relationships of the Indo-Germanic languages has been given by O. Schrader, *Sprachvergleichung und Culturgeschichte*, p. 66 sq.; cp. especially Joh. Schmidt, *Die Verwandtschaftsverhältnisse der indog. Sprachen*, Vienna, 1872; A. Fick, *Die ehemalige Sprach-einheit der Indogermanen Europas*, Göttingen, 1873 (reviewed by Schmidt, in *Jenaer Literaturzeitung*, 1874, p. 401 sq.); A. ² On *Early English Pronunciation*, iv. p. 1135 sq.

³ This fact was first discovered by Ascoli, *Corsi di glottologia*, 1870, p. 51 sq., and Fick, *Die chem. Sprachtheorie der Indo-germanen Europas*, p. 3 sq.; cp. also Joh. Schmidt, in *Jenaer Lit.-Zeitung*, 1874, p. 201 sq., and *Zeitschr. f. vergl. Sprachf.*, xxv. p. 1 sq.; H. Hübschmann, in *Zeitschr. f. vergl. Sprachf.*, xxiii. pp. 20 sq., 385 sq., xlv. p. 372 sq.; H. Müller, *Die palatale Reihe der indog. Grundsprache im Germanischen*, Leipzig, 1875; H. Collitz, in *Bezenberger's Beitr.*, iii. p. 177 sq.; F. Kluge, *Beiträge zur Geschichte der german. Conjugation*, Strassburg, 1879, p. 42 sq.

⁴ The voiceless aspirates are left out here because they are hardly frequent enough to enable us to make out exact rules of correspondence. It may be noticed here that in Sanskrit and Greek the old aspirates have been replaced by the corresponding unaspirated sounds (that is, *b*, *d*, *g*, *j* and *π*, *τ*, *χ* respectively) whenever they were followed by another aspirate. See especially Grassmann, in *Zeitschr. f. vergl. Sprachf.*, xli. p. 81 sq.

⁵ Compare also the parallel of Sanskrit *iyāja*, perfect of *√yaj*, and Greek *ἱϋαγ*, *ἱγος*, with initial *h*. The discovery of the two *y*-sounds was first made by G. Schulze, *Ueber das Verhältnis des *z* zu den entsprechenden Lauten der verwandten Sprachen*, Göttingen, 1867.

Sanskrit *mīdha*, Zend *mīdha*, Greek *μῆδης*, Slavonic *mīzda*, Gothic *mīzō*.¹

Up to a very recent date the Aryan vowel-system was considered not to have contained more than the three "primitive" vowels *a*, *i*, *u*, and the diphthongs *ai* and *au* (regardless of quantity). The sounds of *e* and *o*, which are frequent in the European languages (and also in Armenian, as has been pointed out before), but do not occur in Sanskrit,² were regarded as later developments from the original *a*. We know now that these views were erroneous. Aryan not only had the five common vocalic sounds *a*, *e*, *o*, *i*, *u*, both long and short, but also often used the liquids and nasals *r*, *l*, *m*, *n*, *ṇ*, as vowels, that is, with syllabic value (as, for instance, in English *buttle*, *bottom*, *mutton*, pronounced *bat-tl*, *bot-tm*, *mut-tn*), also both short and long. Besides these simple vocalic sounds, there were twelve diphthongs proper, *ai*, *ei*, *oi*, *au*, *eu*, *ou*, and *āi*, *ēi*, *ōi*, *āu*, *ēu*, *ōu*, setting aside the similar combinations of *a*, *e*, *o*, &c., with liquids and nasals. It will be observed at a glance that the Greek vowels and diphthongs

| | | | | | | | | | |
|----|----|----|---|---|----|----|----|---|---|
| ā | ε | ο | ι | υ | ā | η | ω | ι | υ |
| αι | ει | οι | | | α | η | ω | | |
| αυ | ευ | ου | | | αυ | ηυ | ωυ | | |

are exactly those of the Aryan system. The only case, indeed, where Greek has changed the Aryan sounds is that of the syllabic liquids and nasals, as will be shown hereafter.

Primitive
a, *e*, *o*.

The first proofs for the priority of the European *a*, *e*, *o* in comparison with the uniform Indo-Iranian *a* were discovered independently by Amelung and Brugmann.³ Since then the number of proofs has been considerably increased. The most striking of all is perhaps the observation, made independently by Verner and Collitz,⁴ that the original back gutturals of Aryan are changed into palatals in Indo-Iranian when followed by *i*, *y*, or an *a* corresponding to a European *e*, but are preserved without alteration when followed by other sounds, especially an *a* corresponding to a European *a* or *o*. We thus find not only forms like Sanskrit *cīd* corresponding to Greek *τι*, Latin *quid*, but also Sanskrit *ca*, *pañca*, *janas*, &c., corresponding to Greek *τε*, *πέντε*, Latin *que*, *quinque*, *genus*, while the old guttural is kept in words like Sanskrit *kalara*, *garbha* = Greek *κῆρος* (Ionian *kōrepos*), Slavonic *kotoryj*, Gothic *hwalhar*, and German *kalb*. A special instance of this Indo-Iranian law of palatalization is exhibited in the formation of the reduplicative perfect, where initial gutturals are changed into palatals before the vowel of the reduplicative syllable, which is *e* in Greek and elsewhere; compare Sanskrit perfects like *akāra*, *jaṅgrābha* with Greek *τέρεφα*, *λέλανα*, &c. If, then, the Indo-Iranian *a* (European *e*) once had the same influence on preceding gutturals as the palatal vowel and semi-vowel *i* and *y*, it must necessarily itself have had a similar palatal, that is *e*-like, pronunciation distinguishing it from the other *a*'s that go along with the non-palatal European *a* and *o*. The proofs for the coexistence of *a* and *e* in primitive Aryan are no less convincing than those for the existence of the palatal "a-vowel," that is *e*, but they are too complicated to be discussed here.⁵

Syllabic
r and *l*.

The Aryan syllabic liquids and nasals were also discovered by Brugmann. In Sanskrit the short syllabic liquids are preserved in the so-called *r*-vowel and *l*-vowel, as in *kṛtā*, *klptā*; the long ones have passed over into *īr* or *ūr*, as in *stīrnā*, *pūrnā*, and *gūrthi*. These Sanskrit vocalic *r* and *l* are the only direct remnants of the whole class. In all other cases the original system has been more or less destroyed. Thus, to give only a few instances, the syllabic nasals appear as *a* in Sanskrit and Greek, as in Sanskrit *tātā*, Greek *τάρως* for *τῆν* (past part. of *τείν*, in Sanskrit *tanōmi*, Greek *τείνω* for **τενίω*), Sanskrit *çātd*, Greek *ἐκατόν*, "hundred" (for *k'ntō-m*); or as *a* before vowels, as in Sanskrit *tanā*, "thin," Greek *τάρως*, for dissyllabic *tn-ā*. In Latin and Celtic an *e* has been developed before

¹ See Osthoff, in *Zeitschr. f. vergl. Sprachf.*, xxiii. p. 87, and Kluge, *ibid.*, xxv. p. 313.

² It must be borne in mind that the Sanskrit sounds generally transcribed by *e* and *o* were originally diphthongs, — *ai* and *au*.

³ See A. Amelung, *Die Bildung der Tempusformen durch Vocalsteigerung*, Berlin, 1871, also in *Zeitschr. f. vergl. Sprachf.*, xxii. p. 209, and *Zeitschr. f. deutsches Alterthum*, xviii. p. 161 sq.; and Brugmann, in Curtius's *Studien*, ix. pp. 257, 363. In his earlier publications Brugmann wrote *a*₁, *a*₂, *a*₃ for *e*, *o*, *a* respectively; *A* was then substituted for *a*₃ by De Saussure; others, again, introduced *a'* and *a''* for Brugmann's *a*₁ and *a*₂, and simple *a* for his *a*₃. The spelling *e*, *o*, *a*, now generally adopted, was first proposed by Collitz.

⁴ H. Collitz, in Bezenberger's *Beiträge*, iii. p. 177 sq.; Verner's discovery was communicated by Osthoff, in *Morphologische Untersuchungen*, I. p. 116, and by Hubschmann, in *Zeitschr. f. vergl. Sprachf.*, xxiv. p. 409. See also the full discussion of this problem by Joh. Schmidt, *ibid.*, xxv. p. 1 sq.

⁵ Besides the references given above, compare for this and the following especially F. Kluge, *Beitr. zur Geschichte der german. Conjugation*, Strassburg, 1879; P. Masung, *Das Verhältniss der griech. Vocalabstufung zur Sanskritischen*, St. Petersburg, 1879; F. de Saussure, *Mémoire sur le système primitif des voyelles dans les langues indo-européennes*, Leipsic, 1879; G. Mahlow, *Die langen Vocale ā, ē, ō in den europ. Sprachen*, Berlin, 1879; Osthoff and Brugmann, *Morphologische Untersuchungen auf dem Gebiete der indog. Sprachen*, 4 vols., Leipsic, 1878, eq.; O. Meyer, *Griechische Grammatik*, Leipsic, 1880; and a long series of articles by K. Verner, Brugmann, Meyer, Osthoff, Joh. Schmidt, in *Zeitschr. f. vergl. Sprachf.*, vol. xxiii. sq., and by Bezenberger, Collitz, and Fick, in Bezenberger's *Beiträge*, vol. ii. sq.; also Fick in *Göttinger gelehrte Anzeigen*, 1880, i. p. 417, and 1881, ii. p. 1418; Paul, in Paul and Branne, *Beiträge zur Geschichte der deutschen Sprache und Literatur*, vi. p. 103; H. Müller, *ibid.*, vii. p. 482.

the nasal, Latin *centum*, *tenu-is*, Irish *cé* (for **cent*), in Germanic *a* *u*, Gothic *hund*, Old High German *dunni*. Original syllabic *r* and *l* are in the same way represented by Greek *pa* (*ap*) and *la* (*al*), as in *ἐπακον*, *βραδύς* (for **μπαδύς*), *πλᾶνός* (= Sanskrit *dāṛcam*, *mṛdā*, *prthā*), and in Germanic by *ur*, *ul* (more seldom *ru*, *lu*), as in Gothic *thaursus*, "dry" (for **thursus*), *wulfs*, "wolf" (= Sanskrit *trshū*, *vṛka*), and so forth.

The most brilliant result, however, of these recent researches was not the more exact fixing of the phonetic values of the single Aryan vowels, and of the rules of correspondence between these and the vowels of the individual languages, but the discovery that the system of etymological vowel-change which pervades the whole of Aryan word-formation and inflexion, and which had until then generally borne the name of vowel-gradation, was chiefly developed under the influence of stress and pitch. It is well known how the theory by which the old Sanskrit grammarians tried to explain vowel-differences in words or forms derived from the same "root" considered the shortest form of a root-syllable discernible in all its derivations as the most primitive shape of the root, and let the fuller forms be developed from it through a process of increase, which Sanskrit grammar is accustomed to call *guna* and *vrddhi*. Taking, for instance, the inflexions of perfects like *vēda*, *vētha*, *vēda* (originally pronounced *vāda*, &c.), plur. *vidmā*, *vidā*, *vidīs*, or *akāra*, *akārtha*, *akāra*, plur. *akarmā*, *akārā*, *akrīs*, past part. *kṛtā*, they would start from *vid* and *k-* as "roots," and say that *red-* (*void-*) and *kar-* in *vēda* (*vāda*) and *akara*, &c., were derived from these through *guna*, that is, through the insertion of an *a* before the original root-vowels *i* and *r*. This doctrine has been adopted by Bopp, and thus become one of the fundamental theories of comparative philology, although the objections that can be raised against it are both numerous and obvious. Even if we pass over the difficulty of giving a satisfactory phonetic explanation of the assumed process of insertion, how are we to account for the fact that in cases like *yājāmi*, past part. *iṣṭhā*, or perfects like *jaṅgrābha*, plur. *jaṅgrbhā*, the "inserted" *a* stands after the "root-vowel" instead of before it? Or, if we look at forms like *paptimā*, perf. plur. of *ptāmi*, "I fly," or *emās*, *sthā*, *sānti*, plur. of *āsmi*, "I am," must we not take *pt* and *s* as the original roots, and is it possible to imagine that such roots could ever have existed? All such difficulties disappear by assuming the new theory, that the fuller forms are more original. As the above instances show, the fuller forms appear wherever the "root-syllable" is accented, *Function* that is, stressed; the shorter ones are confined to stressless syllables, of stress. What, then, more natural than to assume that the *a* of the fuller forms was the original "root-vowel," and that it was dropped in the shorter forms on account of their being unaccentuated? Loss of stressless vowels is one of the most frequent phonetic phenomena in all languages, and we have only to look to modern English pronunciation to find the most striking analogies to the processes assumed above. Every-day pronunciations like *p'tato*, *S'ptember* for the written *potato*, *September* are exact parallels to the Sanskrit *pa-p'timā*, and the common *mīlōrd*, *mīlādy* against the usual full *mī* to the Sanskrit *vidmā* against *vāda*; even the *r*-vowel is quite well known in rapid speech in forms like *I prpōse*, or *histry*, *natshtal* for the written *propose*, *history*, *natural*.

So far the new theory of vowel-gradation may be summed up as follows. Every root-syllable originally contained one of the three primitive vowels *a*, *e*, *o*, either short or long; *i*, *u*, the liquids and nasals, only occurred as semi-vowels or consonants, that is, forming monosyllabic (diphthongic) combinations with these vowels, which may either precede or follow the consonants. Thus, taking the combinations with the short vowels as an instance, we get the following table—

| | | | | | | |
|----|----|----|-----|----|----|----|
| ai | ei | oi | and | ya | ye | yo |
| au | eu | ou | ,, | wa | we | wo |
| ar | er | or | ,, | ra | re | ro |
| an | en | on | ,, | na | ne | no |

&c. In originally stressless syllables long vowels were shortened and short vowels dropped. If the original short vowel were surrounded by mutes, the mutes would come into contact through the loss of the vowel, as in Sanskrit *pap-timā* from **papatimā*, or Greek *ἐπ-τόμῃ* from *πέτομα*, or *ἐπ-χον* from *ἐχων* (for **σέχων*). If, however, the root-vowel were combined with a semi-vowel (*i*, *u*, or *y*, *w*), liquid or nasal, the latter would, on account of their vowel-like character, become syllabic (that is, vocalic) if followed by another consonant, but remain consonants if followed by a vowel; compare the following instances taken from Sanskrit (for the sake of distinctness we write the original *ai*, *au* for the common *ē*, *ō*).

| | | |
|-------------------------------|---|-------------------------------------|
| <i>vāda</i> — <i>vidā</i> | <i>tutāda</i> — <i>tutudis</i> | <i>daddra</i> — <i>dadrē</i> |
| <i>yājāmi</i> — <i>iṣṭhā</i> | <i>vaktum</i> — <i>uktā</i> | <i>jaṅgrābha</i> — <i>jaṅgrbhīs</i> |
| <i>jigāya</i> — <i>jigyus</i> | <i>tatāna</i> — <i>tātā</i> (for <i>tntā</i> , see above) | <i>akāra</i> — <i>akrīs</i> |
| | ,, | <i>-tatnirē</i> |

In the same way we find in Greek *σῖδα* — *lδειν*, *φείγω* — *φυνγείν*, *ἐδρακομαι* — *ἐδρακον* (for **ἐδρακον* = Sanskrit *dāṛcam*; see above), *τρέπω* — *ἐτραπον* (for **ἐτραπον*), &c., and correspondingly in the other languages.

It is obvious that through these rules the existence of *i*, *ū*, *ī*, *ī*, *ī* cannot be explained, and yet they do exist. Osthoff has suggested the explanation that they represent intermediate stages of shortening between the full diphthongs and the short *i*, *u*, &c., which were sometimes kept under the influence of a sort of half-stress.¹ They may just as well be subsequent lengthenings of the shorts due to some reason as yet unknown; but this whole chapter is still very obscure, and it may be doubted if the point will ever be sufficiently elucidated.

The principle of explanation by presence or absence of stress in "roots" is also applicable to derivative or inflexional syllables. It is evident that forms like the Greek *πόλις* (for **πόλις*)—*πόλις*, or *γλοκίς* (for **γλοκίς*)—*γλοκίς*, or *πατέρα*, *πατέρες*—*πατράσι*—*πατρῶν* follow the same rule as *λείπω*—*λείπειν*, *φείγω*—*φίγειν*, *δέρκομαι*—*δέρκω*, &c. But analogy and change of stress from one syllable to another (which even in root-syllables have often somewhat obscured the original state of things) have done much to render the working of the old laws indistinct, so that no more than this short hint can be given here.

There are yet other interchanges of vowels in Aryan, quite as important as those which find their explanation in presence or absence of stress, which do not seem to fall under the principle applied here. Amongst these the change of *e* and *o* or *ē* and *ō*, both in roots and derivative syllables, is the most frequent. Thus we have in Greek *λέγω*—*εἶλοχα*, *λόγος*; *λείπω*—*λέλοιπα*, *λοιπός*; *ἐλεῖν*—*ἐλάνθησα*; *δέρκομαι*—*δέδορκα*; *τρέπω*—*τέτρουφα*; *ρήγνυμι*—*ῥήγω*; or *λόγος*—*λόγος*; *γένος*—*γένεος* (for **γένεος*); *φέρο*—*μὲν*—*φέρει*—*τε*; *πατήρ*—*Εὐπάτωρ*, *φράτωρ*; *ποιμήν*—*ἄκμων*, &c. It is absolutely incredible that difference of stress could have changed either *e* into *o*, or *o* into *e*; for the greater or less effort in pronouncing a vowel can have nothing to do with the quality of the vowel uttered, as vowel-quality is only regulated by the position of the tongue and lips. If, then, any distinguishing principle in the utterance of human speech governs these changes—and that assumption is inevitable—it must have been difference of pitch. This explanation was suggested independently by Fick and Möller² some years ago, but has not found its due share of attention, although it recommends itself both upon physiological and philological grounds. There is a natural physiological connexion between the palatal *e* and high pitch and between the guttural *o* and low pitch; for in uttering a high tone we generally raise the larynx above its normal level, and consequently push the tongue forward with it towards a more palatal position; for a low tone the larynx is lowered, and the tongue follows this movement by sliding backwards, that is, towards the position of the guttural vowels (as can easily be observed in singing the vowel *a* on different notes). On the other hand, we know that in Sanskrit the stress syllables were uttered in a high tone (*udātta*), and regularly followed by a low-pitch syllable (*svarita*). This combination of high tone + low tone again corresponds with the sequel of *e* + *o* observable in a great many types of Aryan words or forms, such as *λέγω*, *γένος*, *δέδορκα*; compare also *Εὐπάτωρ* against *πατήρ*, *ἄκμων* against *ποιμήν*, &c. So far this theory seems very probable; yet several difficulties still remain. In the first place, the additional hypothesis must be made, that not all "accentuated," that is stressed, syllables had the high tone; if *o* is the characteristic vowel of low-pitch syllables, words like *λόγος*, *φῶρος* must have had low pitch on their first syllable, while the *e* of *λέγω*, *φέρω* was uttered with the high tone. Strange as such an accentuation might sound to English or German ears, it involves no practical difficulty; for there are at least some living Aryan idioms which possess similar distinctions: in Serbian, for instance, the nominative *vođa* is pronounced with a high rising tone on the first and a falling tone on the second, the stress being nearly equally divided between the two syllables; the accusative *vođu*, again, has a well-marked stress on the first syllable, but is pronounced in a low falling tone.³ In the second place, this theory requires a supplementary inquiry into the relations of pitch and stress in Aryan, for it seems evident that stress and high pitch did not always go together. That the reduplicated perfects like the Sanskrit *dadārca*, Greek *dédorke*, for instance, originally had the stress on the root-syllable is certain from the evidence of Germanic, yet that same root-syllable has the low-pitch vowel *o*, while the unstressed reduplicative syllable shows the high-pitch vowel *e*. The original pronunciation of Aryan *dedorke*, therefore, must

have been something like *ḑēdōrke*, while afterwards the stress was attracted by the high-tone syllable in Greek and the high tone by the old stress-syllable in Sanskrit. In this direction the investigations of Fick and Möller cannot be considered more than an opening of the field for further research; and the same must be said of what has been done hitherto with regard to an explanation of other vowel-changes of a similar character.

B. *Grammatical Structure.*—A few short remarks must suffice here, as a full characteristic of Aryan morphology cannot be given without entering into a mass of more or less minute details.

Since the days of Bopp comparative philologists have on the whole accepted the theory of the old Sanskrit grammarians, that all Indo-Germanic words and forms must be traced back to simple, no longer divisible, monosyllabic elements, which have been called *roots*. We cannot undertake here to discuss the question how far this theory, which has never been uncontested and is beginning to be doubted more and more, is historically correct. However, so much may be conceded that, after removing all the elements which seem to serve in the formation of single words or forms, or the formation of groups of such only in contrast with the whole mass of a system of cognate words or forms, there generally remains a monosyllable, which for practical purposes we may take as a philological starting-point, without asking whether these preparations of the philological laboratory ever had an actual existence of their own or whether they are mere abstractions. The general means by which words and forms are derived from these "roots," or from other ready-made words and forms, are partly external, partly internal. On the whole, Indo-Germanic derivation and inflexion, looked at from this point of view, are based on a system of suffixes, that is, individualizing formative elements added at the end of less compound and less individualized formations. Infixes instead of suffixes occur only by exception, the chief instance being the insertion of a nasal, especially in certain verbal formations (as in Latin *ju-n-go* against *jugum*, Greek *λα-μ-βάνω* against *ἐλαβον*, Sanskrit *yu-ná-jmi*, *yu-ñ-jmās* against *yugám*). The third external element we meet is reduplication. Prefixes in the proper sense do not seem to occur; even the verbal augment, which is the only case of an apparently real prefix, most likely was once an independent word, so that augmentation must be reckoned among the numerous cases of composition. As means of internal change we may mention the shifting of stress and pitch over the different syllables of words and forms, and the vowel-changes which, as we have seen, originally followed these variations of accent, yet may soon have become independent formative principles.

As to inflexion, Indo-Germanic is known to hold the foremost inflexion rank among all inflexive languages. The distinction of nouns, of nouns, pronouns, and verbs is fully developed. In the nouns the introduction in the substantives of grammatical gender is especially noteworthy. Substantives and adjectives were inflected in the same way, though some of the individual languages have deviated from this rule; the pronouns, at least, in many cases had their own inflexions; otherwise they agree with the nouns in the distinction of numbers and cases. There were three numbers—singular, dual, and plural. The number of original cases cannot be settled with certainty. The highest number we find distinguished in any language is seven—nominative, accusative, genitive, dative, instrumental, and locative (besides the vocative or interjectional case). But, judging from the fact that the same cases often have different endings in different declensions, one might be inclined to think that once a still greater variety of case-distinctions had existed. The single declensions are distinguished according to the various stem-suffixes immediately preceding the case-endings. The two chief subdivisions accordingly are the declensions of vocalic and consonantal stems. It may be noticed in passing that the so-called *i* and *u* stems follow the type of the consonantal declension; this, however, appears but natural if we consider that the final *i* and *u* of these stems most probably are reductions of older diphthongs ending in a semi-vocalic or consonantal element. For declensional distinctions only one of the general external formative principles is used, namely, that of combining ready-made stems with suffixal endings, at the same time expressing case and number.

The verb, too, has in like manner its inflexional endings to express the distinctions of number and person; but it also makes use of all the other formative principles, both internal and external. The shifting of accent and the vowel-changes connected therewith are nowhere more distinctly traceable than in the verb. Besides, we find the use of special suffixes for the distinction of tenses and moods, sometimes the infixion of a nasal in the formation of tense-stems, then again on a larger scale the use of reduplication, and lastly, the use of the augment as a common sign for the different tenses of the past. None of the individual languages seems to have preserved the original stock of Aryan verbal forms to its full extent. The oldest Sanskrit seems to come nearest to Aryan. Greek has also been very conservative in one way; it has lost hardly anything that was original, but has, like Latin, created a host of apparently new forms, some of which still continue to baffle all attempts at an explanation. Germanic may serve as a type of the opposite character; it has lost all but the old present and the old reduplicated perfect, but supplied the loss by the extensive employment of auxiliaries. The differences thus exhibited by the different languages make it a difficult task to determine which formations belong to the primitive Aryan stock and which were added at later periods. General consent, however, seems to take the following points for settled. Of the three voices distinguished in Greek,

¹ *Morphologische Untersuchungen*, vol. iv., which treats of the Aryan *i* and *u*.

² Fick, in *Gottinger gelehrte Anzeigen*, 1880, t. p. 417 sq., and Möller, in *Paul and Braune, Deutsche Grammatik*, vol. p. 462 sq.

³ See L. Masini, "Die Hauptformen des serbisch-chorwatischen Accents," in *Acta Slavica*, St. Petersburg, 1879.

only two are of primitive growth, the active and the middle voice, the passive voice being a later specialization of the middle. There were three moods, an indicative, a subjunctive, and an optative; the difference of the latter two from the indicative lay partly in the inflexional endings, partly in the addition of a special mood-suffix before these terminations. There was also an imperative. The distinction of numbers was the same as in declension,—singular, dual, plural, each of which had three persons. The tenses may be divided into three groups. The first group comprises the present and perfect, the former of which is supposed to have been used originally as a general predicative form, being neither past, present, nor future, while the perfect was used to indicate the completion of the action signified by the root. The present is rarely formed direct from the root, but more generally from a special tense-stem derived from the root by the addition of some special tense suffix or infix, or reduplication. Of the different formations of the perfect met with in the individual languages only that through reduplication of the root-syllable is believed to be of Aryan origin. The second group is that of the past tenses, the imperfect and two aorists. In all these the past sense is marked by the augment. The imperfect is regularly formed from the present stem, and the

aorist either from the root simple or reduplicated (root-aorist, corresponding to the so-called second aorist in Greek), or by inserting an *s* between the root and the inflexional endings (sibilant, or sigmatic aorist, the first aorist of Greek). The existence of a pluperfect derived from the perfect in a way similar to the derivation of the imperfect from the present is doubtful and not generally admitted. The last division is formed by the future, which, like the first aorist, inserts a sibilant after the root-syllable. None of the other formations of the future occurring here and there is believed to have existed in the parent-speech. Of participles there were three sets, belonging to the present, the perfect, and the aorist respectively. An infinitive had not yet been developed; its place in Aryan was supplied by the use of verbal nouns.

C. Comparative *Syntax*,¹ to conclude with, is the youngest branch of Aryan philology. Its chief object so far has been to settle the original meanings and the primitive rules of use of the different cases, moods, and tenses. Some attempts have also been recently made to fix the rules of primitive word-order. About all these questions we must refer the reader to the original investigations of the different authors who have more especially cultivated this branch of research. (E. SI.)

PHILOMELA. See NIGHTINGALE, vol. xvii. p. 499.

PHILOPŒMEN, "the last of the Greeks" as he was called by an admiring Roman, was a leading champion of the Achæan League, which preserved in Peloponnesus a last shred of Greek freedom. Sprung from an illustrious Arcadian family, he was born at Megalopolis in Arcadia in 252 B.C. His father Craugis dying in his infancy, Philopœmen was brought up by his father's friend Cleander, an exile from Mantinea. In his youth he associated with Eodemus and Megalophanes, who had studied the Academic philosophy under Arcesilaus, and had proved themselves friends of freedom by helping to rid Megalopolis and Sicyon of tyrants. Philopœmen soon distinguished himself in war and the chase. Hard-featured but of an iron frame, simple and hardy in his way of life, blunt and straightforward in speech and manner,² he was a born soldier, delighting in war and careless of whatever did not bear on it. Thus he would not practise wrestling because the athlete's finely-strung habit of body is ill-fitted to bear the strain of a soldier's life. He read books of a martial and stirring tone, like the poems of Homer, together with works on military history and tactics. Epaminondas was his pattern, but he could not school his hot temper into the unruffled patience of the Theban. Indeed we miss in this rugged soldier that union of refinement at home with daring in the field which had stamped the soldier-citizens of the best age of Greece. His leisure was devoted to the chase or to the cultivation of his farm, where he worked like one of his hinds. In 222, when Cleomenes king of Sparta made himself master of Megalopolis by a night attack, Philopœmen secured by his valour the retreat of the main body of the citizens to Messene, and encouraged them to refuse the insidious invitation of Cleomenes to return to their homes on condition of renouncing their connexion with the Achæan League. Thus baffled, Cleomenes laid the city in ruins and retired. At the battle of Sellasia (early summer 221), where Cleomenes was defeated by the combined Achæan and Macedonian forces under Antigonos, king of Macedonia, Philopœmen greatly distinguished himself by charging, without orders, at the head of the Megalopolitan cavalry and thus saving from defeat the wing on which he fought. His conduct won the admiration of Antigonos, who offered him a command in the Macedonian army, but he declined it and went to the wars in Crete. Returning after some time with fresh laurels, he was at once chosen to command the Achæan cavalry, which, from an ill-mounted, raw, and cowardly

body he soon turned into a highly-trained and thoroughly efficient force; at the head of it he overthrew the Ætolian and Elean horse, and slew their commander with his own hand (209). He was elected general of the Achæan League for the first time in 208. In this, the highest dignity of the confederacy, he infused greater vigour and independence into the councils of the League than had been shown by Aratus, who had leaned on Macedonia and trusted to diplomacy rather than the sword. Philopœmen entirely changed the equipment and tactics of the troops of the League, substituting complete armour, long lances and large shields for the lighter arms hitherto in use, and adopting the Macedonian phalanx as the fighting order. But he did more: by example and precept he turned a nation of dandies into a nation of soldiers, who now spent on arms and accoutrements the wealth they had before lavished on dinners and dress. With the army thus transformed he defeated Machanidas, tyrant of Sparta, at the battle of Mantinea. The tyrant fell by Philopœmen's hand, Tegea was taken, and Laconia ravaged. A bronze statue representing Philopœmen slaying Machanidas was set up at Delphi by the Achæans. At the Nemean festival which followed the battle Philopœmen, then general for the second time, was hailed by the people as the liberator of Greece. Jealous of the degree of independence to which Philopœmen had raised the League, Philip king of Macedonia sent emissaries to murder him, but they were foiled. So great was the terror of his name that at the bare report that he was coming the Bœotians raised the siege of Megara and fled. When Nabis, successor of Machanidas in the tyranny of Sparta, seized Messene, Philopœmen, though he held no office at the time and the general of the League refused to stir, collected his fellow-townsmen and drove out the tyrant. In his third generalship (201-200) he mustered the Achæan forces with great secrecy at Tegea and, invading Laconia, defeated the troops of Nabis. The Romans were now about to cross the sea for the war with Philip of Macedonia, and Philopœmen was the means of preventing the Achæans from concluding an alliance with Philip against Rome. At the expiry of his year of office he sailed once more to Crete, where he successfully led the troops of the Gortynians, beating the Cretans with their own weapons of craft and surprise. Philopœmen did not return to Peloponnesus till after the Romans under Flamininus had conquered Philip. He found the Romans and Achæans making war on Nabis and was again elected to the generalship (192). Nabis was besieging Gythium, which with the other towns on the Laconian coast had been wrested from him by the Romans, handed over by them to the Spartan exiles, and attached to the Achæan League. Being defeated in an attempt to relieve Gythium

¹ A list of books concerning Aryan syntax will be found in the appendix to Sayce's *Introduction to the Science of Language*, vol. ii.

² The simplicity of his manners is illustrated by a tale like that of Alfred and the cakes, Plut., *Phil.*, 2.

by sea, Philopœmen landed and surprised a part of the tyrant's forces not far from that town, burned their camp, and slew many. After ravaging Laconia he marched on Sparta in the hope of compelling Nabis to raise the siege. But Nabis took Gythium and awaited the Achæans in a pass. Philopœmen was surprised, but by skilful generalship he not only extricated himself but routed the Spartans and cut off most of the fugitives. When Nabis was assassinated Philopœmen hastened to Sparta and induced it to join the Achæan League. In the same year (192) Antiochus, king of Asia, crossed into Greece to fight the Romans. By the advice, or at least with the concurrence, of Philopœmen the Achæans rejected the king's proposal that they should remain neutral, and declared war against him and his allies the Ætolians. In the following year Diophanes, general of the League, hearing that Sparta showed signs of revolt, marched against it accompanied by Flamininus. Philopœmen had remonstrated in vain against this step, and he now boldly threw himself into Sparta, composed the disturbances, and closed the gates against Diophanes and Flamininus. The grateful Spartans offered Philopœmen a splendid present, but he bade them keep such bribes for their enemies. In 189 Philopœmen, again general, proposed and carried in an assembly, which he summoned at Argos, a decree that the general assembly of the League should meet in all the cities of the League in rotation, instead of, as hitherto, at Ægeum only. This measure was obviously meant to deprive Achæa of its position as head of the League, and to make the allied cities more equal. In the same year the Spartans made an unsuccessful attack on one of the maritime towns occupied by the exiles. As these towns were under Achæan protection the League required Sparta to surrender the authors of the attack. Far from complying, the Spartans put to death thirty partisans of Philopœmen and renounced their connexion with the League. The Achæans declared war, and in the following spring (188) Philopœmen, having been re-elected general, marched against Sparta, which was forced to pull down its walls, to expel the foreign mercenaries and the slaves whom the tyrants had freed, to exchange the laws and institutions of Lycurgus for those of the Achæans, and, lastly, to receive back the exiles. It would seem that on this occasion Philopœmen allowed his hatred of the old enemy of Megalopolis to overpower his judgment; his conduct was as unwise as it was cruel, for it afforded the Romans—what Philopœmen had hitherto been careful not to furnish them with—a pretext for meddling in the affairs of Greece. His treatment of Sparta was censured by the senate, and Roman officers in Greece remonstrated with the League on the subject. In 183, the last year of his life, Philopœmen was general for the eighth time (his seventh generalship perhaps fell in 187, but this is uncertain). He lay sick of a fever at Argos when word came that Messene, under Dinocrates, had revolted from the League. At first he despatched his friend and partisan Lyeortas to put down the revolt, then growing impatient, in spite of the fever and his seventy years, he hurried in a single day to Megalopolis, and, taking with him the cavalry of his native town, entered Messenia and routed Dinocrates. But, the enemy being reinforced, he was compelled to fall back over broken ground. In his anxiety to cover the retreat of his troopers he was left alone, and, his horse stumbling, he was thrown to the ground and taken prisoner. He was conducted with his arms pinioned through the streets of Messene and cast into a dungeon. At nightfall on the second day an executioner was sent to him with a cup of poison. Seeing the light and the executioner standing by, Philopœmen sat up with difficulty, for he was weak, and, taking the cup in his hand, he asked the man, What tidings of the

cavalry? Being told that they had mostly escaped, he bowed his head and said that it was well. Then he drained the cup and lay down to die. Swift vengeance overtook his murderers. The indignant Achæans, under Lyeortas, ravaged Messenia, and when the capital surrendered all who had had part in the murder of Philopœmen were obliged to kill themselves. Dinocrates had already committed suicide. The body of Philopœmen was burned, and his bones conveyed to Megalopolis with every mark of respect and sorrow, the urn, almost hidden in garlands, being borne by his fellow-townsmen, the historian Polybius. Numerous statues were set up and honours decreed to him in the cities of the League. After the destruction of Corinth by Mummius some one proposed to destroy the statues of a man who had been no friend of the Romans; but the Roman general rejected the base proposal.

Philopœmen's lot was cast in evil days. Hardly were the Achæans freed by him from Macedonia when they had to submit to Rome. His policy towards the Romans was marked by a prudence and moderation hardly to be expected from one of his passionate nature. He saw that the final subjugation of Greece was inevitable, but he did his best to delay it, not by a war which would only have precipitated the catastrophe, but by giving the Romans no ground for interference, and by resisting their encroachments, so far as this could be done, by an appeal to reason and justice.

Our authorities for the life of Philopœmen are Polybius, Livy, Plutarch, and Pausanias. Polybius's work on Philopœmen was in three books, but it is lost. Plutarch's biography, like the account in Pausanias (viii. 49-51), is based on Polybius. (J. G. FR.)

PHILOSOPHY is a term whose meaning and scope have varied very considerably according to the usage of different authors and different ages; and it would hardly be possible, even having regard to the present time alone, to define and divide the subject in such a way as to command the adhesion of all the philosophic schools. The aim of the present article will be, however, leaving controversial details as far as possible in the background, to state generally the essential nature of philosophy as distinguished from the special sciences, and to indicate the main divisions into which, as matter of historical fact, its treatment has fallen.

Historical Use of the Term.—The most helpful introduction to such a task is afforded by a survey of the steps by which philosophy differentiated itself, in the history of Greek thought, from the idea of knowledge and culture in general. These steps may be traced in the gradual specification of the term. The tradition which assigns the first employment of the word to Pythagoras has hardly any claim to be regarded as authentic; and the somewhat self-conscious modesty to which Diogenes Laërtius attributes the choice of the designation is, in all probability, a piece of etymology crystallized into narrative. It is true that, as a matter of fact, the earliest uses of the word (the verb *φιλοσοφῶ* occurs in Herodotus and Thucydides) imply the idea of the *pursuit* of knowledge; but the distinction between the *σοφός*, or wise man, and the *φιλόσοφος*, or lover of wisdom, appears first in the Platonic writings, and lends itself naturally to the so-called Socratic irony. The same thought is to be found in Xenophon, and is doubtless to be attributed to the historical Socrates. But the word soon lost this special implication. What is of real interest to us is to trace the progress from the idea of the philosopher as occupied with any and every department of knowledge to that which assigns him a special kind of knowledge as his province. A specific sense of the word first meets us in Plato, who defines the philosopher as one who apprehends the essence or reality of things in opposition to the man who dwells in appearances and the shows of sense. The philosophers, he says, "are those who are able to grasp the eternal and immutable"; they are "those who set the"

affections on that which in each case really exists" (*Rep.*, 480). In Plato, however, this distinction is applied chiefly in an ethical and religious direction; and, while it defines philosophy, so far correctly, as the endeavour to express what things are in their ultimate constitution, it is not yet accompanied by a sufficient differentiation of the subsidiary inquiries by which this ultimate question may be approached. Logic, ethics, and physics, psychology, theory of knowledge, and metaphysics are all fused together by Plato in a semi-religious synthesis. It is not till we come to Aristotle—the encyclopædist of the ancient world—that we find a demarcation of the different philosophic disciplines corresponding, in the main, to that still current. The earliest philosophers, or "physiologers," had occupied themselves chiefly with what we may call cosmology; the one question which covers everything for them is that of the underlying substance of the world around them, and they essay to answer this question, so to speak, by simple inspection. In Socrates and Plato, on the other hand, the start is made from a consideration of man's moral and intellectual activity; but knowledge and action are confused with one another, as in the Socratic doctrine that virtue is knowledge. To this correspond the Platonic confusion of logic and ethics and the attempt to substitute a theory of concepts for a metaphysic of reality. Aristotle's methodic intellect led him to separate the different aspects of reality here confounded. He became the founder of logic, psychology, ethics, and æsthetics as separate sciences; while he prefixed to all such (comparatively) special inquiries the investigation of the ultimate nature of existence as such, or of those first principles which are common to, and presupposed in, every narrower field of knowledge. For this investigation Aristotle's most usual name is "first philosophy"; but there has since been appropriated to it, apparently by accident, the title "metaphysics." "Philosophy," as a term of general application, was not, indeed, restricted by Aristotle or his successors to the disciplines just enumerated. Aristotle himself includes under the title, besides mathematics, all his physical inquiries. It was only in the Alexandrian period, as Zeller points out, that the special sciences attained to independent cultivation. Nevertheless, as the mass of knowledge accumulated, it naturally came about that the name "philosophy" ceased to be applied to inquiries concerned with the particulars as such. The details of physics, for example, were abandoned to the scientific specialist, and philosophy restricted itself in this department to the question of the relation of the physical universe to the ultimate ground or author of things. This inquiry, which was long called "rational cosmology," may be said to form part of the general science of metaphysics, or at all events a pendant to it. By the gradual sifting out of the special sciences philosophy thus came to embrace primarily the inquiries grouped as "metaphysics" or "first philosophy." These would embrace, according to the scheme long current, ontology proper, or the science of being as such, with its branch sciences of (rational) psychology, cosmology, and (rational or natural) theology. Subsidiary to metaphysics, as the central inquiry, stand the sciences of logic and ethics, to which may be added æsthetics, constituting three normative sciences,—sciences, that is, which do not, primarily, describe facts, but rather prescribe ends. It is evident, however, that if logic deals with conceptions which may be considered constitutive of knowledge as such, and if ethics deals with the harmonious realization of the highest known form of existence, both sciences must have a great deal of weight in the settling of the general question of metaphysics.

Modern modifications of the above scheme will be presently considered; but it is sufficiently accurate as a starting-point, and its acceptance by so many generations of

thinkers is a guarantee for its provisional intelligibility. Accordingly, we may say that "philosophy" has been understood, during the greater part of its history, to be a general term covering the various disciplines just enumerated. It has frequently tended, however, and still tends, to be used as specially convertible with the narrower term "metaphysics." This is not unnatural, seeing that it is only so far as they bear on the one central question of the nature of existence that philosophy spreads its mantle over psychology, logic, or ethics. The organic conditions of perception and the associative laws to which the mind, as a part of nature, is subjected, are nothing to the philosopher; and therefore the handing over of (empirical) psychology to special investigators, which is at present taking place, can be productive of none but good results. Similarly, logic, so far as it is an art of thought or a doctrine of fallacies, and ethics, so far as it is occupied with a natural history of impulses and moral sentiments, do neither of them belong, except by courtesy, to the philosophic province. But, although this is so, it is perhaps hardly desirable to deprive ourselves of the use of two terms instead of one. It will not be easy to infuse into so abstract and bloodless a term as "metaphysics" the fuller life (and especially the inclusion of ethical considerations) suggested by the more concrete term "philosophy."

We shall first of all, then, attempt to differentiate philosophy from the special sciences, and afterwards proceed to take up one by one what have been called the philosophical sciences, with the view of showing how far the usual subject-matter of each is really philosophical in its bearing, and how far it belongs rather to the domain of science strictly so called. We shall also see in the course of this inquiry in what these various philosophical disciplines differ from one another, and how far they merge into another, or have, as a matter of fact, been confused at different periods in the history of philosophy. The order in which, for clearness of exposition, it will be most convenient to consider these disciplines will be psychology, epistemology or theory of knowledge, and metaphysics, then logic, æsthetics, and ethics. Finally, the connexion of the last-mentioned with politics (or, to speak more modernly, with jurisprudence and sociology) and with the philosophy of history will call for a few words on the relation of these sciences to general philosophy.

Philosophy and Science.—In distinguishing philosophy from the sciences, it may not be amiss at the outset to guard against the possible misunderstanding that philosophy is concerned with a subject-matter different from, and in some obscure way transcending, the subject-matter of the sciences. Now that psychology, or the observational and experimental study of mind, may be said to have been definitively included among the positive sciences, there is not even the apparent ground which once existed for such an idea. Philosophy, even under its most discredited name of metaphysics, has no other subject-matter than the nature of the real world, as that world lies around us in everyday life, and lies open to observers on every side. But if this is so, it may be asked what function can remain for philosophy when every portion of the field is already lotted out and enclosed by specialists? Philosophy claims to be the science of the whole; but, if we get the knowledge of the parts from the different sciences, what is there left for philosophy to tell us? To this it is sufficient to answer generally that the synthesis of the parts is something more than that detailed knowledge of the parts in separation which is gained by the man of science. It is with the ultimate synthesis that philosophy concerns itself; it has to show that the subject-matter which we are all dealing with in detail really is a whole, consisting of articulated members. Evidently, therefore, the relation existing be-

tween philosophy and the sciences will be, to some extent, one of reciprocal influence. The sciences may be said to furnish philosophy with its matter, but philosophical criticism reacts upon the matter thus furnished, and transforms it. Such transformation is inevitable, for the parts only exist and can only be fully, *i.e.*, truly, known in their relation to the whole. A pure specialist, if such a being were possible, would be merely an instrument whose results had to be co-ordinated and used by others. Now, though a pure specialist may be an abstraction of the mind, the tendency of specialists in any department naturally is to lose sight of the whole in attention to the particular categories or modes of nature's working which happen to be exemplified, and fruitfully applied, in their own sphere of investigation; and in proportion as this is the case it becomes necessary for their theories to be co-ordinated with the results of other inquirers, and set, as it were, in the light of the whole. This task of co-ordination, in the broadest sense, is undertaken by philosophy; for the philosopher is essentially what Plato, in a happy moment, styled him, *συνοπτικός*, the man who insists on seeing things together. The aim of philosophy (whether attainable or not) is to exhibit the universe as a rational system in the harmony of all its parts; and accordingly the philosopher refuses to consider the parts out of their relation to the whole whose parts they are. Philosophy corrects in this way the abstractions which are inevitably made by the scientific specialist, and may claim, therefore, to be the only concrete science, that is to say, the only science which takes account of all the elements in the problem, and the only science whose results can claim to be true in more than a provisional sense.

For it is evident from what has been said that the way in which we commonly speak of "facts" is calculated to convey a false impression. The world is not a collection of individual facts existing side by side and capable of being known separately. A fact is nothing except in its relations to other facts; and as these relations are multiplied in the progress of knowledge the nature of the so-called fact is indefinitely modified. Moreover, every statement of fact involves certain general notions and theories, so that the "facts" of the separate sciences cannot be stated except in terms of the conceptions or hypotheses which are assumed by the particular science. Thus mathematics assumes space as an existent infinite, without investigating in what sense the existence or the infinity of this "Unding," as Kant called it, can be asserted. In the same way, physics may be said to assume the notion of material atoms and forces. These and similar assumptions are ultimate presuppositions or working hypotheses for the sciences themselves. But it is the office of philosophy, or theory of knowledge, to submit such conceptions to a critical analysis, with a view to discover how far they can be *thought out*, or how far, when this is done, they refute themselves, and call for a different form of statement, if they are to be taken as a statement of the ultimate nature of the real.¹ The first statement may frequently turn out to have been merely provisionally or relatively true; it is then superseded by, or rather inevitably merges itself in, a less abstract account. In this the same "facts" appear differently, because no longer separated from other aspects that belong to the full reality of the known world. There is no such thing, we have said, as an individual fact; and the nature of any fact is not fully known unless we know it in all its relations to the

system of the universe, or, in Spinoza's phrase, "*sub specie eternitatis*." In strictness, there is but one *res completa* or concrete fact, and it is the business of philosophy, as science of the whole, to expound the chief relations that constitute its complex nature.

The last abstraction which it becomes the duty of philosophy to remove is the abstraction from the knowing subject which is made by all the sciences, including, as we shall see, the science of psychology. The sciences, one and all, deal with a world of objects, but the ultimate fact as we know it is the existence of an object for a subject. Subject-object, knowledge, or, more widely, self-consciousness with its implicates—this unity in duality is the ultimate aspect which reality presents. It has generally been considered, therefore, as constituting in a special sense the problem of philosophy. Philosophy may be said to be the explication of what is involved in this relation, or, in modern phraseology, a theory of its possibility. Any would-be theory of the universe which makes its central fact impossible stands self-condemned. On the other hand, a sufficient analysis here may be expected to yield us a statement of the reality of things in its last terms, and thus to shed a light backwards upon the true nature of our subordinate conceptions.

Psychology, Epistemology, and Metaphysics.—This leads to the consideration of our first group of subsidiary-sciences—PSYCHOLOGY (*q.v.*), epistemology (theory of knowledge, Erkenntnisstheorie), and metaphysics (ontology; see METAPHYSIC). A special relation has always existed between psychology and systematic philosophy, but the closeness of the connexion has been characteristic of modern and more particularly of English thought. The connexion is not difficult to explain, seeing that in psychology, or the science of mind, we study the fact of intelligence (and moral action), and have, so far, in our hands the fact to which all other facts are relative. From this point of view we may even agree with Sir W. Hamilton when he quotes Jacobi's dictum—"Nature conceals God; man reveals God." In other words, as has just been said, the ultimate explanation of things cannot be given by any theory which excludes from its survey the intelligence in which nature, as it were, gathers herself up. But knowledge, or the mind as knowing, willing, &c., may be looked at in two different ways. It may be regarded simply as a fact, in which case the evolutions of mind may be traced and reduced to laws in the same way as the phenomena treated by the other sciences. This study gives us the science of empirical psychology, or, as it is now termed, psychology *sans phrase*. In order to give an adequate account of its subject-matter, psychology may require higher or more complex categories than are employed in the other sciences, just as biology, for example, cannot work with mechanical categories alone, but introduces the conception of development or growth. But the affinities of such a study are manifestly with the sciences as such rather than with philosophy; and it has been already pointed out that the division of labour in this respect is proceeding rapidly. Since it has been taken up by specialists, psychology is being established on a broader basis of induction, and with the advantage, in some departments, of the employment of experimental methods of measurement. But it is not of mind in this aspect that such assertions can be made as those quoted above. Mind, as studied by the psychologist—mind as a mere fact or phenomenon—grounds no inference to anything beyond itself. The distinction between mind viewed as a succession of "states of consciousness" and the further aspect of mind which philosophy considers is very clearly put in a recent article by Professor Croom Robertson, who also makes a happy suggestion of two terms to designate the double point of view.

¹ The revisional office which philosophy here assumes constitutes her the critic of the sciences. It is in this connexion that the meaning of the definition of philosophy as "the science of principles" can best be seen. This is perhaps the most usual definition, and, though vague, one of the least misleading.

"We may view knowledge as mere subjective function, but it has its full meaning only as it is taken to represent what we may call objective fact, or is such as is named (in different circumstances) real, valid, true. As mere subjective function, which it is to the psychologist, it is best spoken of by an unambiguous name, and for this there seems none better than *Intellektion*. We may then say that psychology is occupied with the natural function of *Intellektion*, seeking to discover its laws and distinguishing its various modes (perception, representative imagination, conception, &c.) according to the various circumstances in which the laws are found at work. Philosophy, on the other hand, is theory of *Knowledge* (as that which is known)."—"Psychology and Philosophy," *Mind*, 1883, pp. 15, 16.

The confusion of these two points of view has led, and still leads, to serious philosophical misconception. It is hardly an exaggeration to say that, in the English school since Hume, psychology superseded properly philosophical inquiry. The infusion of epistemological matter into the numerous analyses of the human mind rendered the substitution plausible and left men satisfied. And we find even a thinker with a wider horizon like Sir W. Hamilton encouraging the confusion by speaking of "psychology or metaphysics,"¹ while his lectures on metaphysics are mainly taken up with what belongs in the strictest sense to psychology proper, with an occasional excursus (as in the theory of perception) into epistemology. That this confusion is on the way to be obviated for the future is largely due to the Kantian impulse which has been strongly felt of late in English thought, and which has acted in this matter on many who could not, by any laxity of terminology, be numbered as Kantians or Neo-Kantians. The distinction between psychology and theory of knowledge was first clearly made by Kant, who repeatedly insisted that the *Critique of Pure Reason* was not to be taken as a psychological inquiry. He defined his problem as the *quid juris* or the question of the validity of knowledge, not its *quid facti* or the laws of the empirical genesis and evolution of intellection (to use Professor Robertson's phraseology). Since Kant philosophy has chiefly taken the form of theory of knowledge or of a criticism of experience. Not, indeed, a preliminary criticism of our faculties or conceptions such as Kant himself proposed to institute, in order to determine the limits of their application; such a criticism *ab extra* of the nature of our experience is essentially a thing impossible. The only criticism which can be applied in such a case is the immanent criticism which the conceptions or categories exercise upon one another. The organized criticism of these conceptions is really nothing more than the full explication of what they mean and of what experience in its full nature or notion is. This constitutes the theory of knowledge, and lays down, in Kantian language, the conditions of the possibility of experience. These conditions are the conditions of knowledge as such, of self-consciousness in general, or, as it may be put, of objective consciousness. The inquiry is, therefore, logical or transcendental in its nature, and does not entangle us in any decision as to the conditions of the genesis of such consciousness in the individual. When we inquire into subjective conditions, we are thinking of facts causing other facts. But the logical or transcendental conditions are not causes or even factors of knowledge; they are the statement of its idea. Hence the dispute at the present time between evolutionist and transcendentalist rests, in general, on an *ignoratio elenchi*; for the history of the genesis of an idea (the historical or genetic method) does not contain an answer to—though it may throw light on—the philosophic question of its truth or validity. Speaking of this transcendental consciousness, Kant goes so far as to say that it is not

of the slightest consequence "whether the idea of it be clear or obscure (in empirical consciousness), no, not even whether it really exists or not. But the possibility of the logical form of all knowledge rests on its relation to this apperception as a faculty or potentiality" (*Werke*, ed. Hartenstein, iii. 578 note). Or, if we return to the distinction between epistemology and psychology, by way of illustrating the nature of the former, we may take the summing up of Mr Ward in a valuable article on "Psychological Principles" recently contributed to *Mind* (April 1883, pp. 166, 167). "Comparing psychology and epistemology, then, we may say that the former is essentially genetic in its method, and might, if we had the power to revise our existing terminology, be called biology; the latter, on the other hand, is essentially devoid of everything historical, and treats, *sub specie aternitatis*, as Spinoza might have said, of human knowledge, conceived as the possession of mind in general."

Kant's problem is not, in its wording, very different from that which Locke set before him when he resolved to "inquire into the original, certainty, and extent of human knowledge together with the grounds and degrees of belief, opinion, and assent." Locke's *Essay* is undoubtedly, in its intention, a contribution to the theory of knowledge, as any one may verify for himself by turning to the headings of the chapters in the fourth book. But, because time had not yet made the matter clear, Locke suffered himself to digress in his second book into the purely psychological question of the origin of our ideas, or, as Kant called it, the *physiology of the human mind*. Appearing thus, first, as the problem of perception (in Locke and his English successors), widening its scope and becoming, in Kant's hands, the question of the possibility of experience in general, epistemology may be said to have passed with Hegel into a completely articulated "logic," that claimed to be at the same time a metaphysic, or an ultimate expression of the nature of the real. This introduces us to the second part of the question we are seeking to determine, namely, the relation of epistemology to metaphysics.

It is evident that philosophy as theory of knowledge must have for its complement philosophy as metaphysics or ontology. The question of the truth of our knowledge, and the question of the ultimate nature of what we know, are in reality two sides of the same inquiry; and therefore our epistemological results have to be ontologically expressed. But it is not every thinker that can see his way with Hegel to assert in set terms the identity of thought and being. Hence the theory of knowledge becomes with some a theory of human ignorance. This is the case with Herbert Spencer's doctrine of the unknowable, which he advances as the result of epistemological considerations in the philosophical prolegomena to his system. Very similar positions were maintained by Kant and Comte; and, under the name of "agnosticism," the theory has popularized itself of late in the outer courts of philosophy, and on the shifting borderland of philosophy and literature. The truth is that the habit of thinking exclusively from the standpoint of the theory of knowledge tends to beget an undue subjectivity of temper. And the fact that it has become usual for men to think from this standpoint is very plainly seen in the almost universal description of philosophy as an analysis of "experience," instead of its more old-fashioned designation as an inquiry into "the nature of things." Now it is matter of universal agreement that the problem of being must be attacked indirectly through the problem of knowledge; and therefore this substitution certainly marks an advance, in so far as it implies that the fact of experience, or of self-conscious existence, is the chief fact to be dealt with. But if so, then self-consciousness must really be treated as existing,

¹ It is true that he afterwards modifies this misleading identification by introducing the distinction between empirical psychology or the phenomenology of mind and inferential psychology or ontology, i.e., metaphysics proper. But he continues to use the terms "philosophy," "metaphysics," and "mental science" as synonymous.

and as organically related to the rest of existence. If self-consciousness be treated in this objective fashion, then we pass naturally from epistemology to metaphysics or ontology. (For, although the term "ontology" has been as good as disused, it still remains true that the aim of philosophy must be to furnish us with an ontology or a coherent and adequate theory of the nature of the existent.) But if, on the other hand, knowledge and existence be *ab initio* opposed to one another—if consciousness be set on one side as over against existence, and merely holding up a mirror to it—then it follows with equal naturalness that the truly objective must be something which lurks unrevealed behind the subject's representation of it. Hence come the different varieties of a so-called phenomenism. The upholders of such a theory would, in general, deride the term "metaphysics" or "ontology"; but it is evident, none the less, that their position itself implies a certain theory of the universe and of our own place in it, and philosophy with them will consist, therefore, in the establishment of this theory.

Without prejudice, then, to the claims of epistemology to constitute the central philosophic discipline, we may simply note its liability to be misused. The exclusive preoccupation of men's minds with the question of knowledge during the last quarter of a century or more drew from Lotze the caustic criticism that "the continual sharpening of the knife becomes tiresome, if, after all, we have nothing to cut with it." Stillingfleet's complaint against Locke was that he was "one of the gentlemen of this new way of reasoning that have almost discarded substance out of the reasonable part of the world." The same may be said with greater truth of the devotees of the theory of knowledge; they seem to have no need of so old-fashioned a commodity as reality. Yet, after all, Fichte's dictum holds good that knowledge *as* knowledge—i.e., so long as it is looked at as knowledge—is, *ipso facto*, not reality. The result of the foregoing, however, is to show that, as soon as epistemology draws its conclusion, it becomes metaphysics; the theory of knowledge passes into a theory of being. The ontological conclusion, moreover, is not to be regarded as something added by an external process; it is an immediate implication. The metaphysic is the epistemology from another point of view—regarded as completing itself, and explaining in the course of its exposition that relative or practical separation of the individual known from the knowable world which it is a sheer assumption to take as absolute. This, not the so-called assumption of the implicit unity of being and thought, is the really unwarrantable postulate; for it is an assumption which we are obliged to retract bit by bit, while the other offers the whole doctrine of knowledge as its voucher.

Logic, Aesthetics, and Ethics.—If the theory of knowledge thus takes upon itself the functions discharged of old by metaphysics, it becomes somewhat difficult to assign a distinct sphere to logic. It has already been seen how the theory of knowledge, when it passed out of Kant's hands, and tried to make itself (a) complete and (b) presuppositionless, became for Hegel a logic that was in reality a metaphysic. This is the comprehensive sense given to logical science in the article *Logic* (*q.v.*) in this work; and it is there contended that no other definition can be made consistent with itself. It is, of course, admitted that this is not the traditional use of the term (see vol. xiv. p. 802). Ueberweg's definition of logic as "the science of the regulative laws of thought" (or "the normative science of thought") comes near enough to the old sense to enable us to compare profitably the usual subject-matter of the science with the definition and end of philosophy. The introduction of the term "regulative" or "normative" is intended to differentiate the science from psychology as the

science of mental events. In this reference logic does not tell us how our intellections connect themselves as mental phenomena, but how we ought to connect our thoughts if they are to realize truth (either as consistency with what we thought before or as agreement with observed facts). Logic, therefore, agrees with epistemology (and differs from psychology) in treating thought not as mental fact but as knowledge, as idea, as having meaning in relation to an objective world. To this extent it must inevitably form a part of the theory of knowledge. But, if we desire to keep by older landmarks and maintain a distinction between the two disciplines, a ground for doing so may be found in the fact that all the main definitions of logic point to the investigation of the laws of thought in a subjective reference,—with a view, that is, by an analysis of the operation, to ensure its more correct performance. According to the old phrase, logic is the art of thinking. Moreover, the fact that ordinary logic investigates its laws primarily in this reference, and not disinterestedly as immanent laws of knowledge or of the connexion of conceptions, brings in its train a limitation of the sphere of the science as compared with the theory of knowledge. We find the logician uniformly assuming that the process of thought has advanced a certain length before his examination of it begins; he takes his material full-formed from perception, without, as a rule, inquiring into the nature of the conceptions which are involved in our perceptive experience. Occupying a position, therefore, within the wider sphere of the general theory of knowledge, ordinary logic consists in an analysis of the nature of general statement, and of the conditions under which we pass validly from one general statement to another. But the logic of the schools is eked out by contributions from a variety of sources (*e.g.*, from grammar on one side and from psychology on another), and cannot claim the unity of an independent science.

ÆSTHETICS (*q.v.*) may be treated as a department of psychology or physiology, and in England this is the mode of treatment that has been most general. To what peculiar excitation of our bodily or mental organism, it is asked, are the emotions due which make us declare an object beautiful or sublime? And, the question being put in this form, the attempt has been made in some cases to explain away any peculiarity in the emotions by analysing them into simpler elements, such as primitive organic pleasures and prolonged associations of usefulness or fitness. But, just as psychology in general can in no sense do duty for a theory of knowledge, so it holds true of this particular application of psychology that a mere reference of these emotions to the mechanism and interactive play of our faculties cannot be regarded as an account of the nature of the beautiful. The substitution of the one inquiry for the other may doubtless be traced in part to the latent assumption—standing very much in need of proof—that our faculties are constructed on some arbitrary plan, without reference to the general nature of things. Perhaps by talking of "emotions" we tend to give an unduly subjective colour to the investigation; it would be better to speak of the *perception* of the beautiful. Pleasure in itself is unqualified, and affords no differentia. In the case of a beautiful object the resultant pleasure borrows its specific quality from the presence of determinations essentially intellectual in their nature, though not reducible to the categories of science. We have a *prima facie* right, therefore, to treat beauty as an objective determination of things. The question of æsthetics would then be formulated—What is it in things that makes them beautiful, and what is the relation of this aspect of the universe to its ultimate nature, as that is expounded in metaphysics? The answer constitutes the substance of æsthetics. *coul*

sidered as a branch of philosophy. But it is not given simply in abstract terms; aesthetics includes also an exposition of the concrete phases of art, as these have appeared in the history of the world, relating themselves to different stages of the spirit's insight into itself and into things.

Of *ETHICS* (*q.v.*) it may also be said that many of the topics commonly embraced under that title are not strictly ethical at all, but are subjects for a scientific psychology employing the historical method with the conceptions of heredity and development, and calling to its aid, as such a psychology will do, the investigations of ethnology, and all its subsidiary sciences. To such a psychology must be relegated all questions as to the origin and development of moral ideas. Similarly, the question debated at such length by English moralists as to the nature of the moral faculty (moral sense, conscience, &c.) belongs entirely to psychology. This is more generally admitted in regard to the controversy concerning the freedom of the will, though that still forms part of most ethical treatises. If we exclude such questions in the interest of systematic correctness, and seek to determine for ethics a definite subject-matter, the science may be said to fall into two departments. The first of these deals with the notion of duty, as such, and endeavours to define the ultimate end of action; the second lays out the scheme of concrete duties which are deducible from, or which, at least, are covered by, this abstractly-stated principle. The second of these departments is really the proper subject-matter of ethics considered as a separate science; but it is often conspicuous by its absence from ethical treatises. However moralists may differ on first principles, there seems to be remarkably little practical divergence when they come to lay down the particular laws of morality. Hence, as it must necessarily be a thankless task to tabulate the commonplaces of conduct, the comparative neglect of this part of their subject is perhaps sufficiently explained. It may be added that, where a systematic account of duties is actually given, the connexion of the particular duties with the universal formula is in general more formal than real. It is only under the head of "casuistry" that ethics has been much cultivated as a separate science. The first department of ethics, on the other hand, is the branch of the subject in virtue of which ethics forms part of philosophy. As described above, it merges in general metaphysics or ontology, and ought rather to be called, in Kant's phrase, the metaphysic of ethics. A theory of obligation is ultimately found to be inseparable from a metaphysic of personality. The connexion of ethics with metaphysics will be patent as a matter of fact, if it be remembered how Plato's philosophy is summed up in the idea of the good, and how Aristotle also employs the essentially ethical notion of end as the ultimate category by which the universe may be explained or reduced to unity. But the necessity of the connexion is also apparent, unless we are to suppose that, as regards the course of universal nature, man is altogether an *imperium in imperio*, or rather (to adopt the forcible phrase of Marcus Aurelius) an abscess or excrescence on the nature of things. If, on the contrary, we must hold that man is essentially related to "a common nature," as the same writer puts it, then it is a legitimate corollary that in man as intelligence we ought to find the key of the whole fabric. At all events, this method of approach must be truer than any which, by restricting itself to the external aspect of phenomena as presented in space, leaves no scope for inwardness and life and all that, in Lotze's language, gives existence "value." Historically we may be said in an intelligible sense to explain the higher by showing its genesis from the lower. But in philosophy it is exactly the reverse; the lower is always to be explained by the higher. In the ethical

reference it has been customary to argue, as Sir W. Hamilton does, from man's moral being to "an Intelligent Creator and Moral Governor of the Universe." It is evident that the argument *ex analogia hominis* may sometimes be carried too far; but if a "chief end of man" be discoverable—*ἀνθρώπων ἀγαθόν*, as Aristotle wisely insisted that the ethical end must be determined—then it may be assumed that this end cannot be irrelevant to that ultimate "meaning" of the universe which, according to Lotze, is the quest of philosophy. If "the idea of humanity," as Kant called it, has ethical perfection at its core, then a universe which is organic must be ultimately representable as a moral order or a spiritual kingdom such as Leibnitz named, in words borrowed from Augustine, a city of God.

Politics, Sociology, Philosophy of History.—In Aristotle we can observe how ethics is being differentiated from politics, but this differentiation does not, and ought not to, amount to a complete separation. The difficulty, already hinted at, which individualistic systems of ethics experience in connecting particular duties with the abstract principle of duty is a proof of the failure of their method. For the content of morality we are necessarily referred, in great part, to the experience crystallized in laws and institutions and to the unwritten law of custom, honour, and good breeding, which has become organic in the society of which we are members. The development of society is therefore brought within the scope of philosophy. So far as this development is traced in a purely historical spirit, it will be simply a sequence of efficient causes, in which, starting with a b c, we eventually arrive at A B C. But, if this sequence is to be philosophized, it must be shown that we have no means of knowing what a b c is except in its relation to A B C, its resultant. We interpret the process, therefore, as the realization of an immanent end. The state, as the organism in whose play morality is realized, becomes an interest of reason; and the different forms of state-organization are judged according to the degree in which they realize the reconciliation of individual freedom and the play of cultured interests with stable objectivity of law and an abiding consciousness of the greater whole in which we move. So far as the course of universal history can be truly represented as an approximation to this reconciliation by a widening and deepening of both the elements, we may claim to possess a philosophy of history. (A. SE.)

PHILOSTRATUS, the eminent Greek sophist, was probably born in Lemnos between 170 and 180 A.D. From his incidental statements respecting himself we learn that he studied at Athens, and was afterwards attached to the court of the empress Julia Domna, consort of Severus. Since he does not speak of her as living, while mentioning her as his patroness in his *Life of Apollonius of Tyana*, this work was probably written after her death. From some passages in it and his *Lives of the Sophists*, he would seem to have been in Gaul with Caracalla, and he may probably have accompanied that emperor on his progress through his dominions. The only other fixed date we possess for his life is afforded by his dedication of the *Lives of the Sophists* to Antonius Gordianus as proconsul. Gordianus was consul in 230, and his proconsulship must have been between that year and 234. It seems to be implied that Philostratus resided in Rome, and, according to Suidas, he lived until the reign of Philip (244-249). His works now extant are a biography of Apollonius of Tyana, *Lives of the Sophists*, *Heroicon*, *Imagines*, and *Epistles*.

The *Life of Apollonius of Tyana* has been partly discussed under *APOLLONIUS*. It may be compared to the *Cyropædia*, of Xenophon as a romance founded on fact, treating of a distinguished historical person, not in an historical spirit, but as an ideal model for imitation. While, however, the

incidents of Xenophon's romance were mostly his own invention, Philostratus was indebted for his to the narrative attributed to Damis, Apollonius's travelling companion; and many of the sayings ascribed to Apollonius, such as his bon-mots against Domitian and his protest against gladiatorial combats, are probably authentic. The rest of the work testifies to the increasing fondness of the age for the marvellous, which Lucian had vainly endeavoured to stem in the preceding generation, and to the tendency to set up semi-mythical sages like Pythagoras as prophets, at the expense of sober reasoners like Zeno and Epicurus. Philostratus, however, is careful to disclaim all connexion of his hero with mere vulgar thaumaturgy. The sorcerer, he expressly says, is a miserable person. Apollonius is the sage who foreknows the future not by incantations but by wisdom and conformity to the will of the gods,—a new Pythagoras, the prototype, we can now see, of Apuleius, Plotinus, and the other later Platonists, who, without wholly discarding philosophical method, coquetted with ecstasy and revelation. Philosophy, in truth, had become bankrupt, physical science did not yet exist, and the best minds of the time were necessarily thrown back on the supernatural. Philostratus gives this tendency of the age a concrete expression, and there is no reason to conceive that his work was composed in any spirit of antagonism to Christianity, whose Founder, equally with Apollonius himself, was venerated by his patron Alexander Severus. Though a mass of fiction, it is still very valuable as delineating the ideal of the philosophic character as recognized in the 3d century. It is full of errors in geography and chronology, but possesses great literary merit, being varied, entertaining, animated, and lively and accurate in its pictures of character. *Sophisticæ certe artis egregium dedit in hoc libro specimen*, says Kayser. The distinction between a philosopher and a sophist is clearly laid down by Philostratus himself in his next important work, the *Lives of the Sophists*. The philosopher investigates truth independently; the sophist embellishes the truth, which he takes for granted. The distinction is much the same as that between the theologian and the preacher, or the jurist and the advocate. Philostratus, though by no means attempting detailed biography after the fashion of Diogenes Laertius, has given us interesting sketches of a number of distinguished ornaments of the sophistical profession, mostly his immediate predecessors or contemporaries. He thus affords a lively picture of the intellectual standard of an age full of curiosity and intelligence, but unable to make progress in knowledge for want of a scientific method or a scientific spirit, living on old literary models which it was unable to emulate or vary, and hence compelled to prefer show to substance, and manner to matter. The *Heroicon* is a good specimen of the popular literature of the day. It may have arisen out of Caracalla's visit to Ilion, and the games celebrated by him in honour of Achilles. The subject is the injustice of Homer to Palamedes, which is expounded to a Phœnician merchant by a Thracian vine-dresser on the authority of the latter's tutelary dæmon, the hero Protesilaus. It was probably a common theme of declamation in the schools, to which Philostratus has contributed an elegant and graceful setting. The *Imagines*, after the life of Apollonius the most entertaining of Philostratus's writings, is perhaps the most valuable of any from the light it throws on ancient art. The writer is introduced as living in a villa near Naples, which contains a collection of choice paintings. To please the son of his host and his young companions he undertakes to describe and explain the pictures, which are sixty-four in all, including mythological, historical, allegorical, and landscape subjects. The descriptions are exceedingly good, and reveal the skilful word-painter no less than the accomplished

connoisseur of art. As pointed out by M. Bougot, they either actually are or are intended to be taken for improvisations, which explains some irregularities in the style. It has been much disputed whether they are genuine descriptions of actually existing works of art. The affirmative has been maintained by Goethe and Welcker, the negative by Heyne. In our days the controversy has been revived by two eminent German archæologists, Friederichs and Brunn, the former impugning, the latter maintaining the actual existence of the pictures. Their arguments are reviewed in a recent and valuable work by E. Bertrand, who sides with Brunn, as also does Helbig. Perhaps the point is not of such extreme moment, for, if Philostratus had not actual pictures in his mind, he must nevertheless have described such as his hearers or readers were in the habit of seeing. The traces of improvisation, however, pointed out by M. Bougot afford a strong argument that he was lecturing upon a visible collection, and in any case his work is a most valuable guide to the manner in which heroic figures were delineated in ancient paintings, to the general grouping and arrangement of such works, and to the qualities which they were expected to possess. Philostratus's *Epistles* are entirely artificial, and mostly amatory. The style is good, and the originals of some pretty conceits appropriated by modern poets may be found in them.¹

The first complete edition of the works of Philostratus was published by F. Morel, Paris, 1608. It is not much esteemed. That by Olearius (Leipsic, 1709) is much better; but the chief restorer of the text is C. F. Kayser, who, after having edited most of the writings of Philostratus, separately published a collective edition at Zurich in 1844, reissued in 1853, and again at Leipsic in 1870-71. There is a very good edition, with a Latin translation, by Westermann (Paris, 1849); this also contains Eunapius's *Lives of the Sophists* and the declamations of Himerius. The first two books of the *Life of Apollonius* were translated into English by the celebrated and unfortunate Charles Blount in 1680; but the unorthodox nature of the commentary, attributed in part to Lord Herbert of Cherbury, occasioned the work to be prohibited, and it was not continued. A complete translation by E. Berwick, an Irish clergyman, was published in 1809. A French translation by Chassang (*Le Merveilleux dans l'Antiquité*, Paris, 1862) contains some valuable notes. The most important works on the *Imagines* are: Friederichs, *Die Philostratischen Bilder*, 1866; Brunn, *Die Philostratischen Gemälde*, 1861; A. Bougot, *Une galerie antique*, 1881; and E. Bertrand, *Un critique d'art dans l'antiquité: Philstrate et son école*, 1882. (R. G.)

PHILOXENUS, one of the last of the dithyrambic poets of Greece, was born in 435 B.C., in the island of Cythera. When the island was conquered by the Athenians in 424 Philoxenus was sold as a slave to Agesylas, who gave him the name of Myrmex ("ant"). On the death of Agesylas he was bought by the dithyrambic poet Melanippides, who educated him, no doubt in his own profession. Philoxenus afterwards resided in Sicily, at the court of Dionysius, tyrant of Syracuse, whose bad verses he declined to praise, and was in consequence sent to work in the quarries. Being fetched back again and asked by the tyrant how he liked his verses now, the poet made no reply but "Take me away to the quarries." He is said to have quitted Sicily in disgust at the luxury and vulgarity of the people, abandoning an estate which he owned in the island. From Sicily he seems to have gone to Tarentum, and thence perhaps to Corinth. He visited Colophon in Asia Minor and died at Ephesus in 380. According to Suidas, Philoxenus composed twenty-four dithyrambs and a lyric poem on the genealogy of the Æacidae. In his hands the dithyramb seems to have been a burlesque drama in verse, which was acted and sung to the accompaniment of elaborate instrumental music and enlivened

¹ A younger Philostratus, also called the Lemnian, is several times mentioned by the elder as a contemporary sophist. He speaks of him as a friend, but does not say that he was a kinsman. Another and much inferior collection of *Imagines* is ascribed under the name of this writer, who claims relationship with the elder Philostratus. It is probably a supposititious work.

with the dance,—in short, it was a sort of comic opera. The music, which Philoxenus himself composed, appears to have been of a debased, Offenbachian character. His masterpiece was the *Cyclops* or *Galatea*, a pastoral burlesque on the love of the Cyclops for the fair Galatea. Its general style may probably be gathered from the sixth idyl of Theocritus. The work must have been well known before 388, for it was parodied by Aristophanes in his play the *Plutus*, performed in that year. Another work of Philoxenus, sometimes attributed to a notorious parasite and glutton of the same name, is the *Δείπνον* (Dinner), of which considerable fragments have been preserved by Athenæus. This poem, of which the text is very obscure and corrupt, is little more than an elaborate bill of fare put into verse, and, as such, possesses more interest for cooks than scholars. In the time of Aristotle it was the one book read by the Athenian quidnuncs. The great popularity enjoyed by Philoxenus is attested not only by the allusions to him in the comic poets of his day but also by a complimentary resolution passed by the Athenian senate in 393 on the motion of the dithyrambic poet Cinesias. The intention of the decree was doubtless mainly political—to propitiate Dionysius—but the poet was included in it. Nor was his popularity transient: the poet Antiphanes of the Middle Comedy spoke of Philoxenus as a god among men; Alexander the Great had his poems sent to him in Asia along with the tragedies of Æschylus, Sophocles, and Euripides; the Alexandrian grammarians received him into the canon; and down to the time of Polybius his works were regularly learned and annually acted by the Arcadian youth. The scanty fragments of his works are to be found in Bergk's *Poetæ Lyrici Græci*, vol. iii.

PHLEGON, of Tralles in Asia Minor, a Greek writer of the 2d century, was a freedman of the emperor Hadrian. His chief work was the *Olympiads* (chronicles, or collection of Olympic victories and chronicles), a universal history in sixteen books, from the 1st down to the 229th Olympiad (776 B.C. to 137 A.D.). If we may judge from the sample preserved by Photius, the work contained lists of the victors in the Olympic games together with a bare and disjointed summary of the chief historical events; it is probable, however, that Photius quoted from an epitome in eight books which we know to have existed, and which, together with another epitome in two books, is ascribed by Suidas to Phlegon himself. Portions of another work of Phlegon, *On Marvels*, along with parts of another *On Long-lived Persons*, and the opening part of his *Olympiads*, are extant in a Heidelberg MS. of the 10th century.

The book *On Marvels* contains some ridiculous stories about ghosts, prophecies, and monstrous births. The work *On Long-lived Persons* includes a list, extracted by Phlegon from the Roman censuses, of persons who had lived a hundred years and upwards. He mentions two men aged 136 years each, one of whom he professes to have seen. Other works ascribed to Phlegon by Suidas are a description of Sicily, a work on the Roman festivals in three books, and a topography of Rome. Ælius Spartianus tells us that a life of Hadrian was published in Phlegon's name, but that it was written by the emperor himself. A work on *Women Wise and Brave in War* has sometimes been wrongly attributed to Phlegon. From his remains Phlegon is seen to have been credulous and superstitious to absurdity, but his literary style deserves the remark of Photius that, without being pure Attic, it is not very bad. The complaint of Photius, that Phlegon wearied his readers by the numerous oracles which he dragged in, is fully borne out by the remains of his works. These remains are collected by Westermann in his *Scriptores rerum mirabilium Græci* (1839) and by Müller in his *Fragmenta Historicorum Græcorum*, vol. iii.

PHLOX, a considerable genus of *Polemoniaceæ*, chiefly consisting of North-American perennial plants, with entire, usually opposite, leaves and showy flowers generally in terminal clusters. Each flower has a tubular calyx with five lobes, and a salver-shaped corolla with a long slender

tube and a flat limb. The five stamens are given off from the tube of the corolla at different heights and do not protrude beyond it. The ovary is three-celled with one to two ovules in each cell; it ripens into a three-valved capsule. Many of the species are cultivated for the beauty of their flowers; and the forms obtained by cross-breeding and selection are innumerable. The garden varieties fall under three groups,—the annuals, including the lovely *P. Drummondii* from Texas and its many forms; the perennials, including a dwarf section of alpine plants (forms of *P. subulata*), suitable, by reason of their prostrate habit and neat mode of growth, for the rockery; and the taller-growing decussate phloxes which contribute so much to the beauty of gardens in late summer, and which have probably originated from *P. paniculata*. The range of colour in all the groups is from white to rose and lilac.

PHOCÆA, in ancient geography, was one of the cities of Ionia, on the western coast of Asia Minor. It was the most northern of the Ionian cities, and was situated on the coast of the peninsula that separates the Gulf of Cyme, which was occupied by Æolian settlers, from the Hermæan Gulf, on which stood Smyrna and Clazomenæ.¹ Its advantageous position between two good harbours, called Naustathmus and Lampter, is pointed out by Livy (xxxvii. 31), and was probably the cause which led the inhabitants to devote themselves from an early period to maritime pursuits. We are expressly told by Herodotus that the Phocæans were the first of all the Greeks who undertook distant voyages and made known to their countrymen the coasts of the Adriatic, as well as those of Tyrrhenia and Spain. In the latter country they established friendly relations with Arganthonius, king of Tartessus, who even invited them to emigrate in a body to settle in his dominions, and, on their declining this offer, presented them with a large sum of money. This they employed in constructing a strong wall of fortification around their city, a defence which stood them in good stead when the Ionian cities were attacked by Cyrus in 546. On that occasion they refused to submit when besieged by Harpagus, the general of Cyrus; but, mistrusting their power of ultimate resistance, they determined to abandon their city, and, embarking their wives and children and most valuable effects, to seek a new home in the western regions, where they had already founded several flourishing colonies, among others those of Alalia in Corsica and the important city of Massilia in the south of Gaul. A large part of the emigrants, however, relented, and, after having proceeded only as far as Chios, returned to Phocæa, where they submitted to the Persian yoke. The rest, however, having bound themselves by a solemn oath never to return, proceeded to Corsica, where they settled for a time; but, being afterwards expelled from the island, they founded the colony of Velia or Elea in southern Italy.

Phocæa continued to exist under the Persian government, but greatly reduced in population and commerce, so that, although it joined in the revolt of the Ionians against Persia in 500, it was only able to send three ships to the combined fleet that fought at Lade. Nor did it ever again assume a prominent part among the Ionian cities, and it is rarely mentioned in Greek history. But at a later period it was sufficiently powerful to oppose a vigorous resistance to the Roman prætor Æmilius during the war against Antiochus in 191. On that occasion the town was taken and plundered, but it continued to survive, and we learn from its coins that it was a place of some importance throughout the Roman empire. The ruins still visible on the site bear the name of Palea Foggia, but they are of little interest. A small town in the immediate neighbourhood, known as Nova Foggia, appears to date only from Byzantine times.

¹ It was said to have been founded by a band of emigrants from Phocis, under the guidance of two Athenian leaders, named Philogenes and Damon, but it joined the Ionian confederacy by accepting the government of Athenian rulers of the house of Codrus.

PHOCAS, emperor of the East from 602 to 610, was a Cappadocian of humble origin, and was still but a centurion when chosen by the army of the Danube to lead it against Constantinople. A revolt within the city soon afterwards resulted in the abdication of the reigning emperor MAURICE (*q.v.*) and in the speedy elevation of Phocas to the vacant throne (23d November 602). The secret of his popularity is hard to discover, but perhaps it is to be sought in the sheer recklessness of his audacity; courage is nowhere imputed to him, and he is known to have been ignorant, brutal, and deformed. "Without assuming the office of a prince he renounced the profession of a soldier; and the reign of Phocas afflicted Europe with ignominious peace, and Asia with desolating war." By the representations of Theodosius, Maurice's supposed son, and of Narses, the Byzantine commander-in-chief on the Persian frontier, Chosroes (Khosrau) II. was induced to take up arms against the emperor in 604 (see PERSIA, above, p. 614). The failures of the generals of Phocas could not but tend to weaken his always insecure tenure of the imperial crown, and the appearance of the Persian armies as far west as Chalcedon in 609-610 made his deposition by HERACLIUS (*q.v.*) an easy task. He was beheaded by his successful rival on 4th October 610.

PHOCION, an Athenian statesman, whose private virtues won him the surname of "the Good," but whose mistaken policy fatally contributed to the downfall of Athens, was born about 402 B.C. His father, Phocus, was a pestlemaker, but would seem to have been a man of means, for Phocion in his youth was a pupil of Plato. If Plutarch is right in saying that he afterwards studied under Xenocrates, this implies that he kept up his philosophical studies in later life, for Xenocrates was his junior and did not succeed to the headship of the Academy until 339. As men of kindred character, they may well have been friends; we find them on one occasion serving on the same embassy. It was perhaps from the Academic philosophy that Phocion learned that contempt for luxury and that truly Socratic simplicity and bardiness which characterized him throughout life. From Plato too he may have caught that scorn for the Athenians of his day which he often betrayed—a scorn harmless, perhaps, in the study, but fatal in the council and the camp. His words, though few, were pithy and forcible, his wit keen and caustic. Many of his trenchant sayings have been preserved by Plutarch. He was the only orator whom Demosthenes feared; when Phocion rose to speak Demosthenes used to whisper to his friends, "Here comes the chopper of my speeches." Gruff in manner, he was kind at heart, ever ready to raise the fallen and succour those in peril, even when they were his enemies. Being once reproached for pleading the cause of a bad man, he replied that the good had no need of help. When other generals were sent by Athens to the allies, the people closed their gates against them and prepared for a siege, but if it was Phocion they went out to meet him and conducted him in joyful procession into their midst. In his youth he saw service under the distinguished general Chabrias, whose temper, by turns sluggish and impetuous, he alternately stimulated and repressed. He thus won the regard of his good-natured commander, and was introduced by him to public notice and employed on important services. When Chabrias defeated the Spartans in the sea-fight off Naxos (September 376) Phocion commanded with distinction the left wing of the Athenian fleet. After the death of Chabrias (357) Phocion cared for the relatives of his patron, patiently endeavouring to tram to virtue his wild and wayward son. A consistent advocate of peace, he was yet a good officer, and held the annual office of general no less than forty-five times, though he never sought election.

He was amongst the last of the Athenian leaders who combined the characters of statesman and soldier. In 351 Phocion and Evagoras, lord of the Cyprian Salamis, were sent by Idrieus, prince of Caria, with a military and naval force to put down a revolt which had broken out against the Persians in Cyprus. The task was successfully accomplished. Next year¹ Phocion commanded a force which the Athenians sent to Eubœa in support of the tyrant Plutarch of Eretria. For a time the Athenians were in a dangerous position, but Phocion extricated himself and defeated the enemy on the heights above Tamynæ. After the battle he humanely dismissed all his Greek prisoners, fearing the vengeance which the Athenians too often wreaked on their fallen foes. In 341 he returned to the island and put down Clitarchus, whom Philip, king of Macedonia, had set up as tyrant of Eretria. Demosthenes had long warned the Athenians against Philip, but there is nothing to show that in this he was backed by Phocion. On the contrary, from the opposition which he so often offered to Demosthenes, as well as from his subsequent policy, we may infer that Phocion discredited rather than corroborated the warnings of his contemporary. But, when Philip laid siege to Byzantium, the Athenians, at last thoroughly aroused to their danger, sent Chares with an expedition to relieve it. He failed to do so, and Phocion took his place (340). The Byzantines had refused to admit Chares into their city, but they welcomed Phocion. Athenians and Byzantines fought side by side, and Philip was compelled to raise the siege and retire from the Hellespont. Phocion afterwards retaliated on the king's territory by raids, in one of which he was wounded. When the Megarians appealed to Athens for help,² Phocion promptly marched to their aid, fortified the port Nisæa, and connected it with the capital by two long walls, thus securing Megara and its port against attacks by land.³ In spite of the successful issue of his expedition to Byzantium Phocion advised the Athenians to make peace with Philip. But the war party led by Demosthenes prevailed, and the battle of Chæronea (August 338), in which Philip overthrew the united armies of Athens and Thebes, converted Greece into a province of Macedonia. This brought Phocion and the peace party into power, but Phocion consulted the dignity of Athens so far as to advise the people not to take part in the congress of the Greek states summoned by Philip to meet at Corinth until they knew what terms Philip meant to propose. The Athenians soon had reason to regret that they did not follow this advice. When the

¹ Diodorus (xvi. 46) speaks of Phocion as still in Cyprus in 350. But this can hardly be true if Phocion led the expedition to Eubœa in Anthesterion (end of February and beginning of March) 350. See next note.

² The dates and even the order of the events from the Cyprian down to the Megarian expedition are variously given by modern writers. The order in the text is that of Plutarch and Diodorus. The dates assigned to the Cyprian, second Eubœan, and Megarian expeditions are those of Diodorus. The first expedition to Eubœa (as to the date of which see Clinton's *Fasti Hellenici*, vol. ii.) and that to Megara are not mentioned by Diodorus. Plutarch mentions the Megarian after the Byzantine expedition. But the siege of Byzantium was not raised till the earlier half of 339, and Phocion afterwards spent some time in Macedonian waters. Thus he could hardly have been at Megara before midsummer 339. But Elatea was seized by Philip in the winter of 339/338, and its seizure was the occasion of a league between Athens and Thebes. Hence, as the motive assigned for the Megarian expedition was distrust of Thebes, that expedition cannot have taken place after the seizure of Elatea. But the six months between midsummer and winter 339 would hardly suffice for the construction of the Long Walls. Perhaps, then, Plutarch has misplaced the expedition to Megara, and it ought to be dated earlier. Thirlwall assigns it to 343.

³ The Athenians had rendered the same service to the Megarians more than a century before, but these first Long Walls had been destroyed by the Megarians themselves in the Peloponnesian War (424).

news of Philip's assassination reached Athens (336) Phocion vainly dissuaded the people from publicly expressing what he termed a dastardly joy.

After the revolt of Thebes and its destruction by Philip's son and successor Alexander the Great, Athens, having been implicated in the movement, was called on by Alexander to surrender the orators of the anti-Macedonian party, including Demosthenes (335). Phocion advised the men to give themselves up, but nevertheless by his intercession he induced the conqueror to relent.¹ Alexander conceived a high opinion of Phocion, and ever afterwards treated him with marked respect. He would have loaded him with presents, but Phocion steadily declined them, the only favour he asked being the release of some prisoners. When Harpalus, a Macedonian officer who had betrayed the confidence reposed in him by Alexander, fled for refuge to Athens, Phocion, though he contemptuously refused the bribes which Harpalus offered him, nevertheless resisted the proposal to surrender the fugitive (324); and, after the death of Harpalus, Phocion and his son-in-law cared for his infant daughter. The wild joy which the death of Alexander (323) roused at Athens was not shared by Phocion, and he had nothing better than scorn for that heroic effort to shake off the Macedonian yoke known as the Lamian War (323-322). When the news of Leosthenes's victory over Antipater, the regent of Macedonia, was greeted at Athens with enthusiasm (323), Phocion sneeringly asked, "When shall we have done conquering?" Still, when a body of Macedonian and mercenary troops under Micion landed in Attica and ravaged the country, Phocion led out a force and defeated them with loss. After the battle of Crannon (322) Phocion's personal influence induced the victorious Antipater to spare Attica the misery of invasion, but he could not prevent the occupation of Munychia (one of the ports of Athens) by a Macedonian garrison. However, Menyllus, the commander of the garrison, was a friend of Phocion and respected the feelings of the Athenians. Further, the Athenians were required by Antipater to surrender the chief members of the anti-Macedonian party, amongst them Demosthenes and Hyperides, and to restrict their franchise by a property qualification. In consequence Hyperides was executed, Demosthenes died by his own hand, and over 12,000 citizens lost the franchise, many of them going into exile. These disfranchised citizens had afterwards an important influence on Phocion's fate. For some years Athens dwelt in peace, if not in honour, under the shadow of Macedonia. Phocion had the direction of affairs and filled the magistracies with respectable men. By his intercession with Antipater he procured for many of the exiles a repeal or mitigation of their sentence, but he declined to petition Antipater to withdraw the garrison from Munychia. The presents offered him by Antipater and Menyllus he refused. In 318 Antipater died, leaving as his successor in the regency of Macedonia the veteran general Polysperchon, instead of his own son Cassander. The new regent, finding himself isolated and wishing to strengthen himself against his enemies, tried to attach the Greeks to his cause by proclaiming in the name of the young king Philip Arrhidaeus that the oligarchies established by Antipater in the Greek cities should be abolished and the democracies restored, and that all exiles, with a few exceptions, should be allowed to return. A special letter to Athens in the king's name announced the restoration of the democracy. But Cassander was not to be set aside lightly; he was naturally supported by all who

had benefited by his father's measures, i.e., by the oligarchical and Macedonian party in the Greek states. Before the news of the death of Antipater got abroad Cassander sent Nicanor, an adherent of his own, to relieve Menyllus of the command in Munychia. Menyllus unsuspectingly resigned the command to him, and Nicanor held the place for Cassander. When, a few days later, the death of Antipater became known, there were angry murmurs at Athens that Phocion had been a party to the deception. Phocion heeded them not, but, following his usual policy, propitiated Nicanor in favour of Athens. But the people were excited by the promises of Polysperchon; Phocion could no longer hold them in. In a public assembly at which Nicanor was present an attempt was made to seize the obnoxious Macedonian, but he escaped. Warnings now poured in on Phocion to beware of him, but he confided in Nicanor's good intentions and would take no precaution. So Nicanor was enabled to seize and intrench himself in Piræus, the chief port of Athens. The irritation against Phocion was intense. An attempt to treat with Nicanor failed; he simply referred the envoys, of whom Phocion was one, to Cassander. The arrival in Attica of Alexander, son of Polysperchon, revived the hopes of the Athenians. He came at the head of an army and brought in his train a crowd of the exiles, and it was thought that, along with the constitution, he would restore Munychia and Piræus to Athens. Far from doing so, it soon appeared that his intention was to seize and hold these ports for Polysperchon, and rumour said that to this step he was instigated by Phocion. The people were furious. In a public assembly they deposed the existing magistrates, filled their places with the most pronounced democrats, and sentenced all who had held office under the oligarchy to exile or death. Among these was Phocion. With some of his companions in misfortune he fled to Alexander, who received the fugitives courteously and sent them to Polysperchon and the king, who were with an army in Phocis. Thither, too, came an embassy from Athens to accuse Phocion and his fellows before the king and to demand the promised independence. Polysperchon resolved to propitiate the Athenians with blood; so, after an audience disgraceful to all who took part in it except to Phocion, the refugees were packed in carts and sent to Athens to be tried by what Polysperchon called the now free people. A savage mob filled the theatre where the trial was to take place; the returned exiles mustered in force, and with them were women, aliens, and slaves. The prisoners were charged with having betrayed their country in the Lamian War and overturned the democracy. Every attempt Phocion made to defend himself was drowned in a storm of hooting. At last, renouncing the attempt, he was heard to say that for himself he pleaded guilty, but the rest were innocent. "Why," he asked, "will you kill them?" He was answered with a great shout, "Because they are your friends." Then Phocion was silent. All were condemned to die, the multitude rising to their feet like one man to give the verdict. A howling rabble followed them with curses to the prison. Phocion was the last to die (317), for he allowed his best friend Nicocles, as a last token of regard, to die before him. His old disdainful wit did not desert him. When his turn came there was not poison enough left, and he had to pay for more, remarking that at Athens a man could not even die for nothing. His body was cast out of Attic territory, but his faithful wife² secretly brought back his bones and interred them by the hearth. Afterwards the

¹ So Plutarch, *Phocion*, c. 17. But Diodorus (xvii. 15) and Plutarch himself elsewhere (*Demosth.*, c. 23) ascribe to Demades the credit of having mollified Alexander. Phocion's name is not mentioned in this connexion by Arrian (*Anab.*, i. 10) nor by Justin (xi. 4).

² The story that this service was rendered by a Megarian woman rests on a false reading in Plutarch, *Phoc.*, c. 37, Μεγαρικὴ before γυνὴ being the interpolation of an ignorant copyist who mistook the preceding τῆς Μεγαρικῆς.

repentant Athenians buried them with public honours and raised a bronze statue to his memory.

The chief authorities for the life of Phocion are Diodorus (xvi. 42, 46, 74, xvii. 15, xviii. 18, 64-67) and the biographies of Plutarch and Nepos. (J. G. F. R.)

PHOCIS was in ancient times the name of a district of central Greece, between Bœotia on the east and the land of the Ozolian Locrians on the west. It adjoined the Gulf of Corinth on the south, while it was separated on the north from the Malian gulf by the ridge of Mount Cnemis and the narrow strip of territory occupied by the Epimenidian and Opuntian Locrians. In early times, indeed, a slip of Phocian territory extended between these two Locrian tribes to the sea, and the port of Daphnus, opposite to the Cenean promontory in Eubœa, afforded the Phocians an opening in this direction; but in the time of Strabo Daphnus had ceased to exist, and its territory was incorporated with Loeris (Strabo, ix. 3, § 1).

Phocis was for the most part a rugged and mountainous country. In the centre of it rose the great mountain mass of Parnassus, one of the most lofty in Greece, attaining to the height of 8068 feet, and an underfall of this, Mount Cirphis (4130 feet), sweeps round to the Gulf of Corinth on the south, separating the Gulf of Crissa from that of Anticyra, both of which were included in the Phocian territory. The range of Mount Cnemis on its northern frontier was of less elevation (about 3000 feet), but rugged and difficult of access, while the upper valley or plain of the Cephissus, which intervened between this and the northern slopes of Mount Parnassus, constituted the only considerable tract of fertile and level country comprised within the limits of Phocis. The little basin adjoining the Crissæan gulf, though fertile, was of very limited extent, and the broad valley leading into the interior from thence to Amphissa (now Salona) belonged to the Ozolian Locrians. Besides the Cephissus, the only river in Phocis was the Pleistus, a mere torrent, which rose in Mount Parnassus, and, after flowing past Delphi, descended through a deep ravine to the Crissæan gulf.

Phocis possessed great importance in a military point of view, not only from its central position with regard to the other states of northern Greece and its possession of the great sanctuary of Delphi, but from its command of the pass which led from the Malian gulf across Mount Cnemis to Elatea in the valley of the Cephissus, and afforded the only access for an invader who had already passed Thermopylæ into Bœotia and Attica. Hence the alarm of the Athenians in 339 when it was suddenly announced that Philip had occupied Elatea. Again, the only practicable communication from Bœotia with Delphi and the western Locrians lay through a narrow pass known as the Schiste Hodos, between Mount Cirphis and the underfalls of Mount Helicon. From this point another deep valley branches off to the Gulf of Anticyra, and the Triodos or junction of the three ways was the spot celebrated in Greek story as the place where Œdipus met and slew his father.

The most important city in Phocis after Delphi was Elatea, the position of which has already been described; next to this came Abæ, also in the valley of the Cephissus, near the Bœotian frontier, celebrated for its oracle of Apollo. In the same neighbourhood stood Daulis and Ambrysus; while farther south, towards the Corinthian gulf, lay Anticyra, on the gulf of the same name. Crissa, which had been in early times one of the chief cities of Phocis, and had given name to the Crissæan gulf, was destroyed by order of the Amphictyonic council in 591, and never rebuilt. The other towns of Phocis were places of no importance, and their names scarcely appear in history.

The whole extent of Phocis did not exceed half that of Bœotia, but it was broken up into a number of small townships—twenty-

two in all—forming a confederacy, the deputies of which used to meet in a "synedrion" or council-chamber near Daulis. But from an early period the predominance of Delphi, owing to the influence of its celebrated oracles, threw all the others into the shade. At first (as has been already stated in the article DELPHI) the Phocians were masters of the oracle, and of the town that had grown up on its site; but after the first Sacred War in 595 B.C., and the destruction of Crissa, Delphi became an independent city, and from this period a strong feeling of hostility subsisted between the Delphians and the Phocians. The latter, however, thus deprived of their chief city, sank into a position of insignificance, and played but an unimportant part in the affairs of Greece. During the Persian War of 480 their territory was ravaged by the invader, and several of their small cities destroyed. In the Peloponnesian War they were zealous allies of the Athenians, and for a short time recovered possession of Delphi, which was, however, soon after wrested from them; and it maintained its independence from the peace of Nicias in 421 till the outbreak of the Sacred War in 357. On this occasion the Phocians, who had been sentenced by the Amphictyons to the payment of a heavy fine, rose in arms against the decree, which they attributed to the hostile influence of the Thebans, and, under the command of Philomelus, made themselves masters of Delphi, and seized on the sacred treasures of the temple. With the assistance of these resources they were able to maintain the contest, under the command of Onomarchus, Phayllus, and Phalæcus, for a period of ten years, not only against the Thebans and their allies but even after the accession of Philip, king of Macedonia, to the side of their adversaries. This was the only occasion on which the Phocians bore a prominent part in Greek history. After their final defeat by Philip a decree was passed by the Amphictyons, in 346, that all the Phocian towns except Abæ should be destroyed, and the inhabitants dispersed in villages. Notwithstanding the ruin thus brought upon their country, many of their towns seem to have been subsequently rebuilt, and the Phocians were able to take part with the Athenians in the final struggle for Greek independence at Chæronea, and in the Samian War. Their last appearance in history was in defence of Delphi against the attack of the Gauls in 279; but they still continued to subsist as a separate though obscure people in the days of Strabo.

Of the origin of the Phocians as a people we have no information. The earliest traditions connect them with the pre-Hellenic Leleges, as was the case also with the Locrians, and this statement was probably intended to convey the fact that the two nations were tribes of the same race. They first appear under the name of Phocians in the Homeric catalogue as having joined the Greek armament against Troy under the command of the two sons of Iphitus (*Iliad*, ii. 517) and were restored amongst the Æolie division of the northern Greeks.

For the ancient geography of Phocis, see Strabo (ix. 3) and Pausanias (x.). The country and the existing remains of antiquity are described by Dodwell (vol. i. chaps. 6 and 7) and Leake (*Northern Greece*, vol. ii.).

PHŒBUS (φῶιβος, the bright or pure), a common epithet of APOLLO (*q.v.*). Artemis in like manner is called Phœbe, and in the Latin poets and their modern followers "Phœbus" and "Phœbe" are often used simply for the sun and the moon respectively.

PHŒNICIA (Gr. Φοινίκη) forms part of the seaboard of SYRIA (*q.v.*), extending along the Mediterranean (sometimes called the Phœnician Sea) from the mouth of the Eleutherus in the north to Mount Carmel in the south, a distance of rather more than two degrees of latitude. In early times Phœnicians were settled beyond this district, but for the Persian period Dor may be taken approximately as the limit towards the south. In the north a strip of country on the other side of the Eleutherus (Nahr al-Kebîr) was frequently reckoned to Phœnicia. Formed partly by alluvium carried down by perennial streams from the mountains to the east, and fringed by great sand dunes thrown up by the sea, Phœnicia is covered by a very fertile vegetable soil. It is only at Eleutherus in the north, and near Acre (Akka) in the south, that this strip of coastland widens out into plains of any extent; a smaller plain is found at Beirût (Beyrout). For the most part the mountains approach within not many miles of the coast, or even close to it, leaving only a narrow belt of lowland, which from remote antiquity has been traversed by a caravan-route. To the south of Tyre the cliffs sometimes advance so close to the sea that a passage for the road had to be hewn out of the rocks, as at Scala Tyriorum (Ras an-

Nakura), and farther north at Promontorium Album (Ras al-Abyad). It is not known how far inland the Phœnician territory extended; the limit was probably different at different times. Both the maritime district, partly under artificial irrigation, and the terraces, laid out with great care on the mountain-sides, were in antiquity in a high state of cultivation; and the country—more especially that portion which lies north of the Kāsīmye (Litāni) along the flanks of Lebanon—still presents some of the richest and most beautiful landscapes in the world, in this respect far excelling the Italian Riviera. The lines of the limestone mountains, running for the most part parallel to the sea, are pierced by deep river-valleys; those that debouch to the south of the Kāsīmye have already been mentioned in the article PALESTINE; the most important of those to the north are the Nahr Zaherani, Al-Auwali, Damur (Tamyras), Nahr Beirūt, Nahr al-Kelb (Lycus), Nahr Ibrahim (Adonis), Nahr Abu Ali (Kaddisha). The mountains are not rich in mineral products; but it may be mentioned that the geologist Fraas has recently discovered indubitable traces of amber-digging on the Phœnician coast. The purple-shell (*Murex trunculus* and *brandaris*) is still found in large quantities. The harbours on the Phœnician coast which played so important a part in antiquity are nearly all silted up, and, with the exception of that of Beirūt, there is no safe port for the large vessels of modern times. A few bays, open towards the north, break the practically straight coast-line; and there are a certain number of small islands off the shore. It was, in the main, such points as these that the Phœnicians chose for their towns; since, while affording facilities for shipping, they also enabled the Phœnicians to protect themselves from attacks from the mainland, which was subject to them within but narrow limits.

Race.—The ethnographic relations of the Phœnicians have been the subject of much debate. As in Gen. x., Sidon, the firstborn of Canaan, is classed with the Hamites, many investigators are still of opinion that, in spite of their purely Semitic language, the Phœnicians were a distinct race from the Hebrews. They attach great weight to the peculiarities that mark the course of Phœnician civilization, and, above all, to their political organization and colonizing habits, which find no analogies among the Semites. In favour of the opposite and more probable view, that the Phœnicians, like the Canaanites, are an early offshoot from the Semitic stock, it may be urged (1) that the account in Gen. x. is not framed on strict ethnographic lines, and (2) that the absence from Phœnicia of all trace of an original non-Semitic form of speech cannot be reconciled with the theory of an exchange of language. The close connexion which existed from an early period between the Phœnicians and the Egyptians accounts for many coincidences in the matter of religion. Phœnician civilization, being on the whole of but little originality, may have been that of a Semitic people, who, from their situation on the narrow strip of country at the east end of the Mediterranean, were naturally addicted to trade and colonization.

Language.—Inscriptions, coins, topographical names preserved by classical writers, proper names of persons, and the Punic passages in the *Pœnulus* of Plautus combine to show that the Phœnician language, like Hebrew, belonged to the north Semitic group. Even the Phœnician which survived as a rustic dialect in north Africa till the 5th century of our era was very closely akin to Hebrew. Though it retained certain old forms obsolete in Hebrew, Phœnician, as we know, represents on the whole a later stage of grammatical structure than the language of the Old Testament. Its vocabulary, in like manner, apart from a few archaisms, coincides most nearly with later Hebrew. At a very early period Semitic words were

adopted into Greek from Phœnician; and it is also quite certain that the Phœnicians had at least a great share in the development and diffusion of the alphabetic character which forms the foundation of all European alphabets. We possess, however, only a few Phœnician inscriptions and coins of very early date. The longest and most important of the inscriptions—that on King Eshmun'azar's tomb—is in letters which, while very ancient in certain of their features, present a series of important modifications of the original type of the Semitic alphabet, as it can be fixed by comparison of the oldest documents. Still more divergent from the ancient characters are the forms of the letters on the Phœnician, *i.e.*, Punic, monuments of north Africa. (A. so.)

Religion.—Considering the great part which the Phœnicians played in the movements of ancient civilization, it is singular how fragmentary are our sources of knowledge for all the most essential elements of their history. What we are told of their religion is only in appearance an exception to this rule. Eusebius in the *Preparatio Evangelica* cites at length from the Greek of Philo of Byblus a cosmogony and theogony professedly translated from a Berytian Sanchuniathon, who wrote 1221 B.C. But that this work is a forgery appears from the apocryphal authorities cited, and the affinity displayed with the system of Euhemerus. The forger was Philo himself, for the writer borrows largely from Hesiod and was therefore a Greek; he gives Byblus the greatest prominence in a history professedly Berytian, and was therefore a Byblian; and finally Philo was a fanatical Euhemerist, and the admitted object of the work was to make converts to that system. The materials used by Philo were, however, in all probability mainly genuine, but so cut and clipped to fit his system that they must be used with great caution and constantly controlled by the few scattered data that can be gathered from authentic sources.

The two triads of Hannibal's oath to Philip of Macedon (Polyb., vii. 9, 2)—Sun, Moon, and Earth, and Rivers, Meadows, and Waters—contain the objects on which all Phœnician worship is based. Rivers were generally sacred to gods, trees to goddesses; mountains, too, were revered as nearer than other places to heaven; and bœtylia or meteoric stones were held sacred as divine messengers.

Philo's second generation of men (Genos and Genea) first worshipped the plants of the earth, till a drought ensued and they stretched out their hands towards the sun as the Lord of Heaven or Beelsamen (Baal-Shamaim),—an indication that the worship of heavenly bodies was regarded as a later development of religion. Baudissin, on the other hand, has lately maintained that all Phœnician deities were astral and only manifested themselves in the terrestrial sphere, that the things holy to them on earth were symbols, not dwelling-places, of the gods. And there seems to be little doubt that this was the theory of later Phœnician theology, as appears in the legend of the fiery star of the queen of heaven that fell into the holy stream at Aphaca (Sozom., ii. 5, 5), in the coincidence of the names of sacred rivers with those of the celestial gods, and in the name Ζεύς Θαλάσσιος (Hesych.) for a Sidonian sea-god. But surely this theory was devised to remove a contradiction which theologians felt to be involved in the popular religion. In the latter logical consistency is not necessarily to be presumed, and astral and terrestrial worships might well exist side by side. In historical times the astral element had the ascendancy; the central point in religion, and the starting-point in all Phœnician mythology, was the worship of the Sun, who has either the Moon or (as the sun-god is also the heaven-god) the Earth for wife. In Byblus, for which alone we possess some details of the local cult, ʿĒl was the founder and

lord of the town, and therefore of course had the pre-eminence in religion; and so the Byblian Philo makes ʿĒl to be the highest god and the other ʿĒlim or ʿelōhim subordinate to him. In the other towns also the *numen patrium* was a form of the sun-god, or else his wife, and enjoyed somewhat exclusive honour—a step in the direction of monotheism similar to the Moabite worship of Chemosh (cp. the Mesha stone). ʿĒl is represented as the first to introduce circumcision and the first who sacrificed an only son or a virgin daughter to the supreme god. He wanders over all the earth, westward towards the setting sun, and leaves Byblus to his spouse Baaltis—this is meant to explain why she had the chief place in the cult of Byblus; her male companion Eliūn, Shadid (or μέγιστος θεός), is conceived as her youthful lover, and ʿĒl is transformed into a hostile god, who slays Shadid with the sword. According to another legend the youthful god is killed by a boar while hunting, and the mourning for him with the finding of him again make up a chief part of Byblian worship, which at an early date was enriched with elements borrowed from Egypt and the myth of Osiris. In other places we find as spouse of the highest god the moon-goddess Astarte with the cow's horns, who in Tyre was worshipped under the symbol of a star as queen of heaven. With her worship as with that of Baaltis were associated wild orgies; and traces of the like are not lacking even at Carthage (Aug., *Civ. Dei*, ii. 4), where theology had given a more earnest and gloomy character to the goddess. Astarte was viewed as the mother of the Tyrian sun-god Melkarth (Eudoxus, in Athen., ix. p. 392 D), or, as his full title runs, “our lord Melkarth the Baal of Tyre” (*C.I.S.*, No. 122). On account of his regular daily course the Sun is viewed as the god who works and reveals himself in the world, as son of the god who is above the world, and as protector of civil order. But, again, as the Sun engenders the fruitfulness of the earth, he becomes the object of a sensual nature-worship, one feature of which is that men and women interchange garments. A chief feast to his honour in Tyre was the “awaking of Heracles” in the month Peritius (February/March; Menander of Eph., in Jos., *Ant.*, viii. 5, 3), a festival of the returning power of the sun in spring, probably alluded to in the sarcasm of Elijah (1 Kings xviii. 27). Peculiar to Berytus is the worship of Poseidon and other sea-gods, who are connected genealogically with Zeus Belus, a son of ʿĒl, born beyond the Euphrates, and perhaps therefore connected with the Babylonian fish-gods. Berytus was also a chief seat of the worship of the Cabiri, the seven nameless sons of Sydek, with their brother Eshmūn, who is the eighth and greatest of the Cabiri. Philo supplies for them a genealogy which is an attempt to present the growth of man from rude to higher civilization, and presents analogies, long since observed, to the genealogy of the sons of Cain in Genesis. Not only their half-divine ancestors but the Cabiri themselves belong to a comparatively recent stage of religious development. They are the patron deities of manual arts and civil industry, and as such are the great gods of the Phœnician land, specially worshipped in the federal centre Tripolis. On coins of this town they are called Syrian (i.e., perhaps Assyrian) gods,¹ which seems to imply that the Phœnicians themselves regarded as not primitive the many Egyptian elements which were quite early introduced into the religion of the Cabiri, and especially of Eshmūn. On the other hand, a figure allied to Eshmūn, Taaut, the inventor of the alphabet, is certainly borrowed from the Egyptian Tehuti. So, too, Onka (Steph., s.v. “Ὀγκαίαι”) is probably the Anuke of Sais, and it is possible that the whole

cycle of gods who revealed and interpreted the sacred books is Egyptian; some of the latter have the form of a serpent.

The Phœnicians did not set up anthropomorphic statues of the gods, but symbolic pillars of stone, or, in the case of the queen of heaven, of wood (ashērāh). If an actual image was used, likeness to man was avoided by fantastic details: the god had two heads or wings, or some animal emblem, or was dwarfish or hermaphrodite, and so on. The sacrifices were of oxen and other male domestic animals—as expiatory offerings also stags²—and for minor offerings birds. Human sacrifices were exceptionally offered by the state to avert great disasters; the victim was chosen from among the citizens and must be innocent, wherefore children were chosen, and by preference firstborn or only sons. The same idea that the godhead demanded the holiest and most costly gift explains the prostitution of virgins at certain feasts in the sacred groves of the queen of heaven, and the temporary consecration of maidens or maîtres as *kēdēshōth* (ιερόδουλοι). For this custom, as for that of human sacrifice, substitutes were by and by introduced in many places; thus at Byblus it was held sufficient that the women cut off their hair at the feast of Adonis (*De Dea Syr.*, c. 6).

Origin of the Phœnicians.—The oldest towns were held to have been founded by the gods themselves, who presumably also placed the Phœnicians in them. Imitating the Egyptians, the race claimed an antiquity of 30,000 years (Africanus, in Syncellus, p. 31), yet they retained some memory of having migrated from older seats on an Eastern sea. Herodotus (vii. 89) understood this of the Persian Gulf; the companions of Alexander sought to prove by learned etymologies that they had actually found here the old seats of the Phœnicians. But all this rested on a mere blunder, and the true form of the tradition is preserved by Trogus (Just., xviii. 3, 3), who places the oldest seats of the Phœnicians on the Syrian stagnum or Dead Sea—with which the Greeks before the time of the Diadochi had no acquaintance—and says that, driven thence by an earthquake, they reached the coast, and founded Sidon. This earthquake Bunsen has ingeniously identified with that which destroyed Sodom and Gomorrah, and with which Genesis itself connects the migrations of Lot. Perhaps it played much such a part in the mythic history of the peoples of Canaan as the breach of the dam of Marib does in the history of the Arabs.

In historical times the Phœnicians called themselves Canaanites and their land Canaan (Kēna'an, Kēna'; *Xiv* in Hecateus, fr. 254), the latter applying equally to the coast which they themselves held and the inland highlands which the Israelites occupied. The Greeks call people and land Φοίνικες, Φοινίκη; the former is the older word, which in itself disposes of the idea that Phœnicia means the land of the date-palm, which the Greeks called φοίνιξ, i.e., Phœnician.³ In truth, Φοίνικες, with an antique termination used in forming other names of nations (Αἰθίοκες, Ὀρήκες), is derived from φοινός, “blood-red,” probably in allusion to the dark complexion of the race.

When the southern part of the coast of Canaan was occupied by the Philistines the region of Ekron became the boundary of Phœnicia to the south (Josh. xiii. 3); the northern boundary in the time of the Persians was the town of Posidium and the mouth of the Orontes (Herod., iii. 91; Pseudo-Scylax, § 104). Under the Seleucids these limits contracted, the southern boundary being the Chorseus (Ptol., Codd. B. E., Pal. 1), which falls into the sea north of the tower of Straton, and the northern the river

² For stags offered to Tanit see Clermont-Ganneau. *Journ. As.*, ser. 7, vol. xl. p. 232 sq., 444 sq.

³ In reality the date-palm is not aboriginal in these regions. Heuz. *Kulturpflanzen*, &c., 3d ed., p. 233.

Eleutherus, so that Orthosia was the last town of Phœnicia and the whole region of Aradus was excluded.¹ Under the Roman empire the southern boundary was unchanged, but the northern advanced to a little south of Balanea.² A still narrower definition of Canaan is that in Gen. x. 19 and Josh. xiii. 2-6, where Sidon or its territory is the northern limit; but the reference is only to the land destined to be occupied by Israel, for a younger hand has added to Sidon (the firstborn of Canaan) and Heth a list of other nations, sons of Canaan, extending northwards as far as Hamath.³

It is a singular fact that alike in the Old Testament and in Homer, in the time of Tyre's greatest might, we constantly read of Sidonians and not of Tyrians. The explanation that Sidonians is a synonym of Phœnicians in general is defended on 1 Kings v. 1 [15] compared with ver. 6 [20], but is not adequate; the same chapter distinguishes between the Sidonians and the Gîblites or men of Byblus (E.V., "stone squarers," ver. 18 [32]). And in Gen. x. we have besides Sidon the peoples of Arce, Sinna, Aradus, and Simyra enumerated in order from south to north—mostly unimportant towns afterwards absorbed in the land of Aradus—and yet Tyre is lacking, though one fancies that we could better miss even Aradus, which was a colony from Sidon (Strabo, xvi. p. 753), only Aradus was founded by fugitives, and so must, from the first, have been independent. Hence we may conjecture that the list in Genesis is political in principle; and this gives us a solution of the whole difficulty, viz., that, during the flourishing period of Phœnicia, Sidon and Tyre formed a single state whose kings reigned first in Sidon and then in Tyre, but whose inhabitants continued to take their name from the old metropolis. The first unambiguous example of two distinct kings in Tyre and Sidon is in the end of the 8th century B.C., on an inscription of Sennacherib (Schrader, *K.A.T.*, 2d ed., p. 286 sq.), and there is every reason to think that the revolt of Sidon from Tyre about 726 spoken of by Menander (Jos., *Ant.*, ix. 14, 2) was a revolt not from Tyrian hegemony but from the Tyrian kingdom. The several Phœnician cities had lists of their kings back to a very early date. Abedbalus⁴ reigned at Berytus in the time which Philo had ciphered out as that of the judge Jerubbaal, i.e., about the beginning of the 13th century B.C., and in Sidon there is word of kings at the time to which the Greeks referred the rape of Europa (15th century; see Lætus, in Tatian, *Adv. Græcos*, 58). The leading Phœnician towns are mentioned in connexion with the Syrian wars of the Pharaohs of the XVIIIth, XIXth, and XXth Dynasties (16th-13th century); thus under Thothmes III. we read of Berytus, Ace, Joppe, and repeatedly of Aradus, which is commonly spoken of along with Haleb (Aleppo) and other eastern districts. The mention of Tyre is less certain, as there were two cities which the Egyptians called T'ar; but there is no mistake as to the city on the sea called "T'aru the haven" in the journey of an Egyptian of the 14th century (*Rec. of the Past*, ii. 107 sq.),—"water is carried to it in barks, it is richer in fish than in sands"; the noble aqueducts therefore, of which the ruins are still seen, were not yet constructed.

The oldest parts of Tyre were taken to be the town on the mainland, afterwards known as Palætyrus, and the so-called temple of Hercules built on a rocky islet, which Hiram by and by united with the insular part of the town. According to native historians this temple was more properly one of Olympian Zeus, that is, of Baal-Shamain, the Lord of Heaven.⁵ Herodotus, after inquiries made

on the spot, fixes the founding of the city in 2756 B.C.; but Tyre did not attain great importance till the later island city was built. According to Trogus (Justin, xviii. 3, 5) the Phœnicians (not the people of Sidon, as the passage is often misread to mean), who had been subdued by the king of Ascalon, took ship and founded Tyre a year before the taking of Troy. This goes well with the spread of the Philistine power in the time of the later judges and with the fact that Ascalon was still a Canaanite town under Ramesses II. (c. 1335 B.C.), while in the eighth year of Ramesses III. (c. 1246) the Philistines made a raid into Egypt.⁶ Philistus (in Euseb., *Can.*, No. 803) gives us without knowing it the era used in Tyre and in early times also in Carthage when he says that Zorus (i.e., Çôr, Tyre) and Carchedon built Carthage in 1213 B.C., or rather, according to a very good MS. (Regin.), in 1209, which agrees with the date 1208 for the fall of Troy on the Parian marble, and also may be reconciled with the notice (taken from Philistus) in Appian, *Punica*, i., that the founding of Zorus and Carchedon was fifty years before the fall of Troy, if we suppose that Philistus took for the latter event the latest date we know of, viz., that assigned by Democritus.⁷ Now Josephus (*Ant.*, viii. 3, 1) counts 229 years from the building of Tyre to Hiram, and places the foundation of Carthage (*Cont. Ap.*, i. 18) in the 155th year from Hiram's accession. The best authority for the last-named event is Timæus, who puts it in 814 B.C. This gives us for the founding of Tyre a date twelve years later than that of Philistus, but it is probable that Josephus in summing up the individual reigns between Hiram and the building of Carthage as given by Menander departed from the intention of his author in assuming that the twelve years of Astartus and the twelve of the contemporaneous usurper were not to be reckoned separately.⁸ This hypothesis enables us to give a restored chronology which cannot be far from the truth (see *infra*).

Manufactures and Inventions.—The towns of the Phœnician coast were active from a very early date in various manufactures. Glass work, for which the sands of the Belus gave excellent material, had its chief seat in Sidon; embroidery and purple-dyeing were favoured by the prevalence of the purple-giving murex all along the coast. The ancients ascribed to the Phœnicians the invention of all three industries, but glass-making seems to have been borrowed from Egypt, where this manufacture is of immemorial antiquity; and several circumstances indicate that the other two arts probably came from Babylon—in particular, the names of the two main tints of purple—dark red (argamān) and dark blue (tēkhēleth)—seem not to be Phœnician. The Phœnicians, however, brought these arts to perfection and spread the knowledge of them. In other particulars also the ancients looked on the Phœnicians as the inventive people *par excellence*: to them as the great trading nation was ascribed the invention of arithmetic, measure, and weight, which are really Babylonian in origin, and also of writing, although it is not even quite certain that it was the Phœnicians who adapted the Egyptian hieroglyphic alphabet to Semitic use.⁹ Yet here again the Phœnicians have undisputedly the scarcely inferior merit of having communicated the art to all the nations of the Mediterranean basin.

Navigation, Trade, Colonies.—The beginnings of navigation lie beyond all human memory, but it is not hard to understand how the ancients made this also an invention of the Phœnicians, whose skill as seamen was never matched by any ancient people before or after them. Even in later times Greek observers noted with admiration the exact order kept on board Phœnician ships, the skill with which every corner of space was utilized, the careful disposition of the cargo, the vigilance of the steersmen and their mates (Xen., *Æc.*, viii. 11 sq.). They steered by the pole-star, which the Greeks therefore called the Phœnician star (Hyginus, *Po. Ast.*, ii. 2); and all their

⁶ See Brugsch, *Geschichte Aegyptens*, pp. 516, 598.

⁷ If Democritus was born in 470 (Thrasylus), his date for the fall of Troy is 1160.

⁸ He is contemporaneous on the reading Μεθ' οὗ Ἀστυριος given by Theophilus, *Ad Autol.*, iii. 19. If Josephus took it ~~22~~, then according to the best readings he would get exactly 155 years.

⁹ That the Semitic alphabet did not come from cuneiform writing may be taken as certain; but also it is not probable that it came from the hieratic character of the Egyptians.

⁵ This appears by comparing Herod., ii. 44, with the mention of the same golden stele by Menander (Jos., *Cont. Ap.*, i. 18).

vessels, from the common round γαῦλος, to the great Tarshish ships, the East-Indiamen—so to speak—of the ancient world, had a speed which the Greeks never rivalled. Of the extent of the Phœnicians' trade in the last days of Tyre's glory Ezekiel (xxvii. 12-25) has left a lively picture, which shows how large was the share they had in overland as well as in naval commerce. It was they, in fact, who from the earliest time distributed to the rest of the world the wares of Egypt and Babylon (Herod., i. 1). To the lands of the Euphrates and Tigris there were two routes: the more northerly passed obliquely through Mesopotamia and had on it the trading places of Haran (Carrhæ), Caneh (Cenæ), and Eden; the other, more southerly, had Sheba (Sabæa) for its goal, and led down the Euphrates, passing Asshur (Sura) and Chilmad (Charmande). There were other routes in the Persian and Macedonian period, but they do not belong to the present history.

Actual inland settlements of the Phœnicians seem to have been few; we know of one near the head of the northern trade road, Laish, which was lost to the Danites in the time of the judges (Judges xviii.), and one on the southern route, Eddana on the Euphrates (Steph. B., s.v.), which corresponds in name with Eden, but is not the same place, but perhaps rather the Giddan of Isidore of Charax (§ 1). In the Arabian caravan trade in perfume, spices, and incense for worship the Phœnicians had a lively interest (Herod., iii. 107). These wares were mainly produced not in Arabia but in eastern Africa and India; but Sheba in Yemen was the emporium of the whole trade, and the active commerce of this rich and powerful state in the times before the Persian is seen better than by any direct testimony from the exact knowledge of the Sabæan lands shown in Gen. x., from the many references to Arabia and Sheba in the Assyrian monuments, and from such facts as Euting's discovery at Taimā in the heart of Arabia of an Aramaic inscription of the 6th century B.C., composed by a man with an Egyptian name.¹

In Egypt Phœnician trade and civilization soon took firm root; they alone were able to maintain their Egyptian trade and profits in the anarchic times of the XXIIIrd to the XXVth Dynasties (825-650 B.C.), times like those of the Mameluke beys, in which all other foreign merchants were frightened away and the Greek legend of the inhospitable Busiris originated.² The Tyrians had their own quarter in old Memphis (Herod., ii. 112), but there never were real colonies of the Phœnicians in Egypt.

That in matters economic Syria and Palestine depended on Phœnicia might have been inferred even if we had not the express testimony of Ezekiel that these lands were included in the sphere of Tyrian trade; so too was Togarmah, an Armenian district.

Cilicia was important to the Phœnicians as the natural point of shipment for wares from the Euphrates regions; and the opposite island of Cyprus attracted them by its store of timber for shipbuilding, and of copper. Both these countries were originally peopled by the non-Semitic Kittim, who have left their name in the Cilician district Cetis and the Cyprian city Citium; but they came under profound Semitic influences, mainly those of the Phœnicians, who on the mainland had settlements at Myriandus (Xen., *Anab.*, i. 4, 6) and Tarsus,³ while in Cyprus Citium—which to the last remained the chief seat of the Phœnician tongue and culture—was held to have its foundation from Belus (Steph., s.v. "Λάπηθος"), and Carpasia from Pygmalion (Id., s.v.). Pseudo-Scylax (§ 103),

writing in 346 B.C., knows Carpasia, Cerynea, and Lapethus as Phœnician; but the view that Phœnician sway in Cyprus was very ancient and that the Phœnicians were gradually driven back by the Greeks appears not to be sound. On the contrary, the balance of power seems to have varied greatly; the Assyrian tribute-lists of 673 and 667 (Schrader, *A.A.T.*, p. 354 sq.) contain but two names of Phœnician cities in Cyprus, Sillū (Soli) and Kartihadast (probably New Paphos); not one of the later Phœnician kingdoms is mentioned, so that presumably none of them then existed, and not one of the ten Cyprian kings mentioned appears to be Phœnician by name. Menander tells us (Jos., *Ant.*, ix. 14, 2) that the kings of Tyre ruled over Cyprus at the close of the 8th century; but a very clear proof that there was no ancient and uninterrupted political connexion with Phœnicia lies in the fact that the Cyprian Greeks took the trouble to frame a Greek cuneiform character modelled on the Assyrian.

The Homeric poems represent the Phœnicians as present in Greek waters for purposes of traffic, including the purchase and capture of slaves, but not as settlers. Tradition (see especially Thucyd., i. 8) is unanimous in representing the Carians and Phœnicians as having occupied the islands of the Ægean before the migrations of the Greeks to Asia Minor, but so far as the Phœnicians are concerned this holds only of the southern islands—afterwards occupied by Dorians—where they had mining-stations, and also establishments for the capture of the murex and purple-dyeing.⁴ The most northerly of the Cyclades on which we can prove a Phœnician settlement is OIarus (Steph., s.v.), which was occupied by Sidonians, probably with a view to the use of the marble quarries of Paros, which lies opposite. Similarly the Byblians occupied Melos (Steph., s.v.), which produced a white pigment (Melian earth), alumi, and sulphur. Two great islands were held as main seats of the purple trade, Cythera (Herod., i. 105) and Thera, with the neighbouring Anaphe (Herod., iv. 147; Steph., s.v. "Μεμβλλιαρος"),—as also the town Itanus at the eastern extremity of Crete (Steph., s.v.). Specially famous was the purple of the Laconian waters,—the isles of Elishah of Ezekiel xxvii. 7. Farther east the Phœnicians were settled in Rhodes.⁵ The Greek local tradition about the Phœnicians seems, in Thera and Rhodes, to embody real historical reminiscences, and it is confirmed for Thera and Melos by the discoveries of Phœnician pottery and ornaments in the upper strata of the tuff, and for other places by peculiar cults which survived among the later Dorian settlers. Thus the Aphrodite Urania of Cythera was identical with the Oriental goddess of love at Paphos, and Herodotus (i. 105) makes her temple to be founded from Ascalon; the coins of Itanus (Mionnet, ii. 284 sq.) show a fish-tailed deity; in Rhodes human sacrifices to Cronus were long kept up (Porph., *De Abs.*, ii. 54). The legends of Rhodes and Crete have a character quite distinct from that of other Greek myths, and so give lasting testimony to the deep influence in both islands of even the most hideous aspects of Phœnician religion; it is enough to refer in this connexion to the stories of the eight children of Ilios in Rhodes, of Europa, the Minotaur, and the brazen Talos in Crete. The pre-Hellenic inhabitants of the islands, the Carians and their near kinsmen the Eteocretans or Mnōtæ (probably identical with the PHILISTINES, q.v.), had no native civilization, and were therefore wholly under the influence of the higher culture of the Phœnicians. But on the Greeks too the Phœnicians had no small influ

¹ Noldeke, in *Sitzb. Berl. Ak.*, 1894, p. 813 sq.

² Ξάλαγες, the herald of Busiris, is simply כלב, "dog."

³ Tarsus was founded by Aradians, Dio Chr., xxxiii. 40. Αἴξ, a city of the Phœnicians in Hecateus, fr. 259, is probably not Ægæ but Gaza.

⁴ As an enormous supply of murex was needed for this industry, the conjecture of Duncker is probably sound, that the purple stations were the object of all Phœnician settlements.

⁵ Rodanum, 1 Chron. i. 7, by which Dodanum in Gen. x. 4 must be corrected, see Ergas (?) and Polyzelus, in Athen., viii. p. 360 D.

ence, as appears even from the many Phœnician loan-words for stuffs, utensils, writing materials, and similar things connected with trade.¹ From the Phœnicians the Greeks derived their weights and measures; *μνᾶ*, the Hebrew *maneh*, became a familiar Greek word. From Phœnicia too they had the alphabet which unanimous tradition connects with the name of Cadmus, founder of Thebes. Hence Cadmus has been taken to mean "eastern" (from קדם), and Thebes viewed as a Phœnician colony; but the Greeks did not speak Phœnician, and the Phœnicians would not call themselves Easterns. Further, an inland colony of Phœnicians is highly improbable; and all other traces seem to connect Cadmus with the north. But the Cadmeans, who traced their descent to Cadmus, colonized Thera, and it was they who, mingling with the Phœnicians left on the island, learned the alphabet. It was in Thera, where the oldest Greek inscriptions have been found, that the invention of letters was ascribed to the mythic ancestor, and that he was made out to be a Phœnician. We now know better than we did a few years ago how much the oldest Greeks depended before the migrations on the movements of Eastern civilization, and can well believe that the Phœnicians played a very important part in this connexion. Thus in the tombs of Mycenæ we find Phœnician idols, objects of amber, and an ostrich egg side by side with rich jewels of gold, Oriental decoration, and images of Eastern plants and animals; thus too the rock-tombs of Hymettus closely resemble those of Phœnicia; and above all we find on the Isthmus of Corinth, that most ancient seat of commerce, the worship of the Tyrian Melkarth under the name of Melicertes. Yet with all these proofs of a lively trade there is no trace of Phœnician settlements on the Greek mainland and the central islands of the Ægean; but in the north Thasus was occupied for the sake of its gold mines (Herod., vi. 47), and so probably was Galepsus on the opposite Thracian coast (Harpocr., s.v.), where also it was Phœnicians (Strabo, xiv. p. 680; from Callisthenes) who opened the gold mines of Pangæus. Beyond these points their settlements in this direction do not seem to have extended; the Tyrians, indeed, according to Ezekiel, traded in slaves and bronze-ware with the Greeks of Pontus (Javan), the Tibareni (Tubal), and Moschi (Meshech); but all supposed traces of actual settlements on these coasts prove illusory, and Pronectus on the Gulf of Astacus, which Stephanus attributes to the Phœnicians, lies so isolated that it was perhaps only a station of their fleet in Persian times.

The great centre of Phœnician colonization was the western half of the Mediterranean and the Atlantic coasts to the right and left of the straits. In especial the trade with Tarshish, that is, the region of the Tartessus (Gualquivir), was what made the commercial greatness of the Phœnicians; for here they had not only profitable fisheries (tunny and *muræna*) but above all rich mines of silver and other metals, to which the navigable rivers Gnadiana and Gualquivir gave easy access. The untutored natives had little idea of the value of the metals; for long there was no competition, and so the profits were enormous; it was said that even the anchors were of silver in ships returning from Spain (Diod., v. 35). Next the Phœnicians ventured farther on the ocean and drew tin from the mines of north-west Spain or the richer deposits of Cornwall; the tin islands (Cassiterides) were reached from Brittany, and are always distinguished from the British mainland, so that the old view which makes them the Scilly Islands is probably right. The tin was supposed to be produced where it was exchanged,—a very common case.² Amber too was brought in very early times from the farthest north; amber ornaments are often mentioned by Homer,

and have been found in the oldest tombs of Cumæ and in those by the Lion gate at Mycenæ. The Phœnicians can hardly have fetched the amber themselves from the Baltic or even from the North Sea (where it scarcely can have ever been common); it came to them by two trade routes, one from the Baltic to the Adriatic, the other up the Rhine and down the Rhone. But indeed a deposit of amber has been found in the Lebanon not far from Sidon,³ and perhaps the Phœnicians worked this and only concealed, after their manner, the origin of the precious ware. Certainly the ancients knew of Syrian amber, and knew also that amber could be dug from the ground.⁴ The rich trade with Spain led to the colonization of the west (Diod., *ut supra*). Strabo (i. 48) dates the settlements beyond the Pillars of Hercules soon after the Trojan War, in the time, that is, of Tyre's first expansion. Lixus in Mauretania was older than Gades (Pliny, xix. 63) and Gades a few years older than Utica (Vell., i. 2), which again was founded 1101 B.C. (Pseudo-Arist., *Mir. ausc.*, 134; Bocchus, in *Plin.*, xvi. 216). Most of the African colonies were no doubt younger; we have dates for Aoz (887-855, Menander) and Carthage (814, Timæus). Here, as generally in like cases, the farthest points were settled first and the need for intermediate stations to secure connexion was felt later. The colonization was carried out on a great scale. Ophelas (Strabo, xvii. 826) may exaggerate when he speaks of 300 cities on the Mauritanian coast beyond the Pillars of Hercules; but the colonists and the Carthaginians after them stamped west Africa with a thoroughly Phœnician character, and their language was dominant, at least in the cities, far beyond the limits of their nationality, just as was the case with Latin and Arabic in later times. It is most likely that so great a mass of colonists was not wholly drawn from the narrow bounds of Phœnicia, but that the inland Canaanites, pushed back by Hebrews and Philistines, furnished many recruits; the supposed testimonies to this fact, however, are late, and certainly apocryphal.

Surveying the great settlements of the Phœnicians from east to west, we find them first in Sicily, occupying, in a way typical of the commencement of all their settlements, projecting headlands and neighbouring islets, from which they traded with the Siculi (Thucyd., vi. 2). Their chief seat seemingly was Macara (Heraclides, *Polit.*, 29), on the south coast, רש כלקרת on coins, Heraclea Minoa of the Greeks. Before the Greeks they retired to the north coast, where they held Motye, Panormus, and Soloeis, supported by their alliance with and influence over the Elymi, and by the neighbourhood of Carthage, which here and elsewhere succeeded to the heritage of Tyre, and gave protection to the Phœnician colonies. The islands between Sicily and Africa—Melite, with its excellent harbour and commanding position on the naval highway, Gaulus, and Cossura—were also occupied (Diod., v. 12), and a beginning was made with the colonization of Sardinia (*ib.*, v. 35), where Caralis is said to be a Tyrian foundation (Claudian, *E. Gild.*, 520); but real sovereignty over this island and Corsica was first exercised by the Carthaginians.⁵ It is uncertain if Phœnician trade with and influence on the Etruscans is older than the political alliance of the latter with Carthage; there were, at least, no Phœnician colonies in Italy. On the east coast of Spain Barcino (Auson., *Epist.*, xxiv. 68) and Old Carthage (Ptol., ii. 6, 64) are settlements apparently older than the Spanish empire of Carthage, but their origin is not therefore necessarily Phœnician, especially as Old Carthage lies inland; they may date from the conflicts of Carthage and the Massaliotes. In Tartessus, on the other hand, or Turdetania, as it was called later, all the important coast towns were Phœnician (Strabo, iii. 151, 156 sq., 169 sq.)—Abdera, Sex (which was regarded as one of the oldest of the Tyrian settlements in Spain), Malaca, Carteia, and, most famous of all, Gades, with its most holy shrine of Hercules; it lay on an islet which had not even drinking water, but the position was a commanding one. Still farther off lay Onoba, where the Tyrians are said to have settled before they were in Gades. In Africa the most easterly settlement was Great Leptis, which is the only colony ascribed to Sidonians, driven from their home by

⁴ Pliny, *N.H.*, xxxvii. 37, 40, reading with Detlefsen *ex humo*.

⁵ The Greeks of the 6th century had a very fantastic idea of the value of these islands (Herod., i. 170, v. 106, 124).

¹ See A. Müller, in *Beitr. z. K. d. indog. Spr.*, i. 273 sq.

² See *Lit. Centrbl.*, 1871. p. 528.

civil troubles (Sallust, *Jug.*, 78), and is therefore presumably one of the oldest. Less certain are the accounts that the sister cities Œa and Sabratha were founded, the former by Phœnicians from Sicily, the latter from Tyre (Sil. Ital., iii. 256 sq.). The district Emporia on the Lesser Syrtis was named from its many Phœnician trading towns. Here, on the river Cinyps, corn produced three-hundredfold, and a great trade-road led inland to the land of the Garamantes. That the commercial town of Tacape (Kābis) and the island of Meninx (Jirba), with its purple-dyeing trade, were Phœnician is proved by inscriptions, and Capsa, in inland Numidia, was deemed a foundation of the Tyrian Hercules (Oros., v. 15). Among the Phœnician towns in Africa proper Achulla was Melitan (Steph., *c.v.* "Ἀχόλλα"), Lesser Leptis and Hadrumetum Tyrian (Pliny, v. 76; Solin., 27, 9), as was also Azoa (Menander), that is, rather the Uzita of Strabo and Ptolemy (cp. Wilmanns on *C.I.L.*, viii. 68), 5½ miles inland from Leptis, than Auzia in inland Mauretania. On the north coast Carthage and Utica are Tyrian colonies, and probably also Hippo Zarytus, though Sidon, on a coin, claims it, rather the Uzita of Strabo and Ptolemy (cp. Wilmanns on *C.I.L.*, ii. 2, p. 134). The unidentified town of Canthele and the island Endeipne are called Liby-Phœnician (Steph., *s.v.*), and this name in later times denoted the Phœnicians in Africa apart from and in contrast to Carthage. The Semitic populations were thickly sown over all this region, but we cannot generally distinguish Phœnician colonies, Carthaginian foundations, and native settlements that had become Punic. Chalce, on the coast east of Oran, in the country of the Masesyli, was Phœnician, but their great domain was the Atlantic coast of Mauretania. Tingis and Zelis, if originally Berber, became thoroughly Phœnician cities (Mela, ii. 6, 9; Strabo, iii. 140); the chief colony here was Lixus (Ps.-Scylax, § 112), a city accounted greater than Carthage. Southward, on the so-called Κόλπος Ἐκτοριεύς, and onwards to the mouth of the Dra river Tyrian colonies lay thick, and here a great trade-route went inland to the country of the Blacks. These colonies were ruined by the invasion of the Pharusii and Nigritæ (Strabo, xvii. 826), who spread destruction just as did the Almoravids when they issued from the same region in the 11th century; the Carthaginians saved the remnant of their kinsmen by sending Hanno to found the new colony of Thymiatium and plant 30,000 Liby-Phœnicians in the old ports of Karikon Teichos, Gytte, Aera, Melitta, and Aramby. The most westerly point reached by the Phœnicians was the Fortunate Island (the largest of the Canaries, probably), which later fancy painted in glowing colours after intercourse with so distant a region had ceased (Diod., v. 20).

The trading connexions of the Phœnicians reached far beyond their most remote colonies, and it must have been their knowledge of Africa which encouraged Pharaoh Necho to send a Phœnician expedition to circumnavigate Africa. This greatest feat of ancient seamanship was actually accomplished in 611-605 B.C., at a time when the mother-country had already lost its independence, and the colonial empire bad but a shadow of its former splendour. The power of Tyre rested directly on her colonies, which, unlike the Greek colonies, remained subject to the mother-city; we read of rebellions in Utica and Citium which were put down by arms. The colonies paid tithes of all their revenues and sometimes also of booty taken in war to the Tyrian Hercules, and sent envoys to Tyre for his chief feast. But Tyre was too remote long to exercise as effective a control over her dependencies as was possible to the more favourably placed Carthage; the relation gradually became looser, and the more substantial obligations of the colonies ceased to be discharged; yet Carthage certainly paid tithes to the Tyrian Hercules as late as the middle of the 6th century B.C.

Fragments of History.—Josephus (*Ant.*, viii. 5, 3, and *Ap.*, i. 17, 18) has fortunately preserved extracts of two Hellenistic historians, Dios and Menander of Ephesus, which supply at least the skeleton of the history of the golden age of Tyre. From them we learn that Hiram (or rather Hirōm) I., son of Abibal, reigned from 980 to 916 B.C. He enlarged the insular town to the east by filling up the so-called ἐκπόρπον, united the temple of Baal-Shamaim with the main island by a mole, placed in it a golden pillar, and splendidly renewed the temples of Hercules¹ and Astarte. The inhabitants of Utica—so the text must be corrected

(Ἱερκαίος)—having ceased to pay tribute, Hiram reduced them in a victorious expedition, after which he founded the feast of the awaking of Hercules in the month Peritius. The Tyrian annals also mentioned the connexion of Hiram with Solomon king of Jerusalem. The relations of Phœnicians and Israelites had been generally friendly before this; it appears from Judges v. 17, Gen. xlix. 13, 20, that Asher, Zebulun, and Dan acknowledged some dependence on Sidon, and had in return a share in its commerce; and the only passage in the older period of the judges which represents Israelites as subject to Sidonians, and again casting off the yoke, is Judges x. 12, which perhaps refers to the time of power of the Canaanites of Hazor (Graetz, i. 412). The two nations drew closer together under the kings. Hiram built David's palace (2 Sam. v. 11), and also gave Solomon cedar and fir-trees, as well as workmen for his palace and temple, receiving in exchange large annual payments of oil and wine, and finally the cession of a Galilaean district (Cabal), in return for the gold he had supplied to decorate the interior of the temple. The temple was quite in Phœnician style, as appears particularly in the two pillars Jachin and Boaz. We may also judge that it was Hiram's temples that led Solomon to propose to himself a similar work.² One commercial result of the alliance with Solomon was the united expedition from Eziongeber on the Gulf of Akaba to Ophir (Malabar).³ The oldest known Phœnician inscription (*C.I.S.*, No. 5) is of a servant of "Hiram king of the Sidonians," a title which, as we have seen, is quite suitable for the king of Tyre. Hiram's grandson Abdastarte I. (929-920) was murdered by his foster-brothers, and the eldest took the regal title (920-908), but in the last twelve years of his reign he shared his throne with a scion of the old house, [Abd]Astarte II. (908-896). His brother Astharym or Abdastharym (896-887) was murdered by a third brother Phelles, who, in turn, after a reign of but eight months, was slain by Ithobal I., priest of Astarte, whose reign (887-855) marks a return to more settled rule. Ithobal was beloved of the gods, and his intercession put an end to a year of drought which Josephus recognized as that which is familiar to us in the history of Elijah and Ahab. In 1 Kings xvi. 31 Ithobal appears as Ethbaal, king of the Sidonians. At this time the Tyrians still continued to expand mightily. Botrys in Phœnicia and Azoa in Africa are foundations of Ithobal; the more famous Carthage owed its foundation to the civil discords that followed on the death of King Metten I. (849-820). According to the legend current in later Carthage (Justin, xviii. 4, 3-6, 9), Metten's son Phygmalion (820-773), who began to reign at the age of nine, slew, when he grew up, his uncle Sicularbas, the priest of Hercules and second man in the kingdom, in order to seize his treasures. The wife of Sicularbas was Elissa, Phygmalion's sister, and she fled and founded Carthage. Truth and fable in this legend are not easy to disentangle, but as Elissa is named also in the Tyrian annals she is probably historical.

From the time of Ithobal downwards the further progress of Phœnicia was threatened by a foreign power. The older campaigns of the empires of the Euphrates and Tigris against the Mediterranean coast had left no abiding results—neither that of the Chaldeans in 1535 or 1538 (Eus., *Can.*, No. 481), nor that of Tiglath Pileser I., c. 1120 B.C.⁴

² The date 11 or 12 Hiram which Josephus gives for the building of the temple (*Ant.*, viii. 3, 1; *Ap.*, i. 18) must in the Tyrian annals have referred to the cutting of wood in Lebanon for the native temples, which Josephus then misinterpreted by 1 Kings v. 6[20] sq.

³ So Caldwell, *Comp. Gram. of Dravidian Languages*, p. 66; Barnell, *Indian Antiquary*, 1872, p. 230. The decisive argument is that the Hebrew word for "peacocks" can only be the Tamil *tōkei* [see, however, OPHIN].

⁴ He had the control of the ships of the Aradians; Menaat, *Ann. des rois d'Assyrie*, p. 50.

¹ This is the Agenorium at the northern extremity of the island (Arr., ii. 24). Except in this point the topography of Renan (*Miss. de Phén.*, p. 546 sq., and Pl. lxxix.) is here followed.

More serious was the new advance of the Assyrians under Ashurnācipal (c. 870), when this prince took tribute from the lords of Tyre, Sidon, Byblus, Mahallat, Maiz, Kaiz, the Westland, and the island Aradus. A king of Aradus was one of the allies of Rammānidri of Damascus whom Shalmaneser III. smote at Karkar in 854; thereafter the Assyrian took tribute of Tyre in 842 and 839, and in the latter year also from Byblus. Again in 803 Rammānirāru boasted of exacting tribute from Tyre and Sidon, but thereafter there was a respite until Tiglath Pileser II., the real founder of the Assyrian empire, to whom Tyre paid tribute in 741, and again along with Byblus in 738. In Tiglath Pileser's Philistine campaign of 734 Byblus and Aradus paid tribute, but a heavy contribution had to be exacted from Metten of Tyre by an Assyrian captain. For the history of Elulæus, who reigned in Tyre under the name of Pylas¹ (c. 728-692), we have a fragment of Menander. He subdued a revolt of the Cittæi in Cyprus, but thereafter was attacked by Shalmaneser IV.,² to whom Sidon, Ace, Palætyrus, and many other cities submitted, revolting from Tyre. A new kingdom was thus formed under a king [E]luli, whose name makes it likely that he was a relative of the Tyrian prince, and who presently appears on the monuments as lord of Great Sidon (the same name as in Josh. xix. 28), Lesser Sidon (=Palætyrus?), and other cities. But insular Tyre did not yield, and Shalmaneser had to make a second expedition against it, for which the jealous particularism of the other Phœnician cities supplied the ships. With much inferior forces the Tyrians gained a naval victory and the king drew off. But the blockade was continued, and seems to have ended after five years in a capitulation. This siege probably began about the same time with that of Samaria, and may be dated 724-720. About 715 Ionian sea-rovers attacked Tyre and were repulsed by Sargon (Schrader, *K.A.T.*, p. 169), an affair in which we may find the historical basis of such legends as that in the *Cyclic Cypris*, that Sidon was taken by Priam's son Alexander. [E]luli did not prove a faithful subject; Sennacherib attacked him, and he had to flee to Cyprus, Ithobal being set in his place (701). Among the Phœnician kings who appeared to do homage to Sennacherib a prince of Tyre does not appear. One sees from all this how barbarous and ill-consolidated the Assyrian power in the west was; after the retreat of Sennacherib it was even for a time seriously threatened by the Ethiopian dynasty which then held Egypt; and this may explain the revolt of Abdimilkut, king of Sidon, which was visited by Esarhaddon with the destruction of the city, the captivity of part of the inhabitants, and the execution of the rebel king (680 B.C., Ménant, p. 241 *sq.*). Further unsuccessful revolts of Tyre (Baal I. being king, 662 or later) and of Aradus are recorded in the reign of Ashurbanipal; but at last the war of this monarch with his brother seems to have enabled Phœnicia to throw off the yoke without a contest (c. 650).

The Assyrians had proved their inability to create anything; but their talent for destruction was brilliantly exhibited in Phœnicia, and the downfall of Tyre was occasioned, if not caused, by their intervention in the west. For what Justin (xviii. 3, 6 *sq.*) relates of the Tyrians, that they were so reduced in number by protracted war with the Persians that, though they were at last victorious, their slaves were able to overpower and slay them to a man, all save Straton, whom a faithful servant saved, and whom the slaves chose, on account of his wisdom, to be king and founder of a new dynasty (Abdāstarte III.), is only to be understood by reading Assyrians for Per-

sians.³ The catastrophe must have occurred soon after the events already noticed; and in the same period falls the decay of the colonial power of Tyre, which we cannot follow in detail, though we can recognize some of its symptoms. After reaching the Mediterranean the Assyrians established themselves in Cyprus (709); in the Greek islands farther west the Phœnicians had before this time been gradually displaced by the Dorian migration, which, however, must not be taken to be a single movement eastward in the 11th century, but a long course of colonizing expeditions, starting from Argos and continued for generations, about which we can only say that the whole was over by the middle of the 8th century. Thasus, the most northern settlement in the Ægean, was already deserted by the Phœnicians when the father of the poet Archilochus led a Parian colony thither in 708. But the loss of the more western colonies seems to have been contemporary with the fall of Tyrian independence. About 701 Isaiah looks for a revolt of Tartessus (xxiii. 10), and the first Greek visitor, the Samian Colæus (639), found no trace of Phœnician competition remaining there (Herod., iv. 152). These circumstances seem to justify us in understanding what the contemporary poet Anacreon (fr. 8) says of the hundred and fifty years' reign of Arganthonius over Tartessus as really applying to the duration of the kingdom; and as he died in 545 the kingdom will date from 695. In Sicily the Phœnicians began to be pushed back from the time of the founding of Gela (690); and Himera (648) and Selinus (628) mark the limits of Greek advance towards the region on the north-west coast, which the Phœnicians continued to hold. In 654 the Carthaginians occupied the island Ebusus, on the sea-way to Spain (Diod., v. 16), a step obviously directed to save what could still be saved. Soon after this, when Psammetichus opened Egypt to foreigners (650), the Greeks, whose mental superiority made them vastly more dangerous rivals than the Assyrians, supplanted the Phœnicians in their lucrative Egyptian trade; it is noteworthy that Egypt is passed over in silence in Ezekiel's full list of the trading connexions of Tyre.

In the last crisis of the dying power of Assyria the Egyptians for a short time laid their hand on Phœnicia, but after the battle of Carchemish (605) the Chaldæans took their place. Apries made an attempt to displace the Chaldæans, took Sidon by storm, gained over the other cities, and defeated the king of Tyre, who commanded the Phœnician and Cyprian fleet (Herod., ii. 161; Diod., i. 68). The party hostile to Chaldæa now took the rule all through Phœnicia. The new king of Tyre, Ithobal II., was on the same side (589), and after the fall of Jerusalem Nebuchadnezzar laid siege to the great merchant-city, which was still rich and strong enough to hold out for thirteen years (587-574).⁴ Ezekiel says that Nebuchadnezzar and his host had no reward for their heavy service against Tyre, and the presumption is that the city capitulated on favourable terms, for Ithobal's reign ends with the close of the siege, and the royal family is subsequently found in Babylon, obviously as cards that might on occasion be played against the actual princes of Tyre.⁵ The king appointed by Nebuchadnezzar was Baal II. (574-564), on whose death a republic was formed under a single suffet. This form of government lasted a year, and then after three months' interregnum under the high priest Abbar there were for six years

¹ So Codd. Samb. Big. The name may be Pil-eser.

² The best MSS.—Paris, 1421, and Oxon.—offer (according to a private communication of Professor Niese) traces pointing to the reading *ἐν τούτῳ Σελάμψας*.

³ There was no Straton, king of Tyre, between 587 and 480; a war between Tyrians and Persians between 480 and 390 is nowhere heard of, and is highly improbable, and Straton, from what we learn of his descendants, cannot have reigned later than this.

⁴ See the Tyrian sources in Jos., *Ap.*, i. 21, compared with Ezek. xvi. 1 *sq.*, xxix. 17 *sq.*

⁵ See Winer's "Pflanzprogramm": *De Nebuc. exp. Tyr. ad B.* xvi. xxviii. (Leipsic, 1848).

two suffets—presumably one for the island and one for Old Tyre—after which an elected king, Balatorus, ruled for a year (557-556). The next two kings (556-532) were brought from Babylon. Under the second of these, Hiram III., Phœnicia passed in 538 from the Chaldeans to the Persians; at the same time Amasis of Egypt occupied Cyprus (Herod., ii. 182). There seems to have been no struggle, the great siege and the subsequent civil disorders had exhausted Tyre completely, and the city now becomes second to Sidon. Accordingly about this time Carthage asserted her independence; the political activity of Hanno the Great, the real founder of the Carthaginian state, falls in the years 538-521.¹ Of Hanno it is said that he made his townsmen Africans instead of Tyrians (Dio Chrys., *Or.*, xxv. 7). The old dependence was changed for a mere relation of piety.

Constitution.—As Carthage was of old a republic, and its constitution underwent many changes, it is not safe to infer from the two Carthaginian suffets that Tyre also stood in the oldest time under two such magistrates. All Canaanite analogy speaks for kingship in the several cities as the oldest form of Phœnician government. The royal houses claimed descent from the gods, and the king could not be chosen outside their members (Curt., iv. 1, 17). The land belonged to the king, who was surrounded by much splendour (Ezek. xxviii. 13), but the highly-developed independent activity of the citizens limited his actual power more than in ordinary Oriental realms; it was possible for war or peace to be decided at Tyre in the king's absence, and in Sidon against his will (Arrian, ii. 15, 16; Curt., iv. 1, 16). In Tyre the high priest of Hercules was the second man in the state (Just., xviii. 4, 5), and so the office was by preference given to a kinsman of the king. The sovereign had a council of elders, who in Sidon were in number a hundred; of these the most distinguished were the ten First whom we find at Marathus and Carthage (Diod., ii. 628; Just., xviii. 6, 1),—originally, it may be supposed, heads of the most noble houses. The third estate was the people; the freemen, however, were much outnumbered by the slaves, as we have seen in Tyre. Under the Persians there was a federal bond between the cities, which we may suppose to be due to that great organizer Darius I. The federation comprised Sidon, Tyre, and Aradus—Sidon being chief—and contributed 300 triremes to the Persian fleet (Herod., vii. 89-99); the contingents of the lesser towns were under the command of the great cities, which probably had the rule in other matters also. This holds for Marathus, Sigon, Mariammé, which belonged to Aradus (Arr., ii. 13), even for Byblus also, which had its own kings in the Persian period, and seems from the number of its coins and inscriptions to have been very flourishing. We know the names of sixteen kings of Sidon, ten of Byblus, eight of Aradus, but none of Berytus in historical times; presumably it formed with Byblus a single kingdom, and in later times the capital was moved to the latter. Tripolis was a bond of three cities, Sidonian, Tyrian, and Aradian, a stadium distant from one another (Diod., xvi. 41). Here sat the federal council under the kings of the three leading states, who were accompanied to Tripolis by their senators (probably 300 in all). Among the chief concerns of this council were the relations to the Persian Government, which was represented at the meetings.

Under Persian Rule.—Phœnicia, Palestine, and Syria formed the fifth satrapy, paying a tribute of £99,296. The Phœnicians were favoured subjects for the sake of

¹ This date is got from Justin, who in xix. 1, 1 says of his Mago the same thing that others say of Hanno; for the defeat spoken of in xviii. 7, 1 is the battle against the Phœnicians in 538, and the war with a Spartan prince in Sicily (xix. 1, 7) is the war with Dorieus (510). Taking into account the eleven years of Hasdrubal's dictatorship we get Hanno's date as above.

their indispensable fleet; and having also common interests against Greece they were amongst the most loyal subjects of the empire. Sidon, as we have seen, was now the chief city; its king at the time of the expedition of Xerxes was Tetramnestus. Among his descendants was the youthful Eshmun'azar, whose inscription on the great sarcophagus in Egyptian style now in the Louvre, taken with other notices, enables us to make out the following fragment of a genealogical table with much probability.²

Reckoning back from Straton II., and remembering that Eshmun'azar II. died as a minor under the regency of his mother, we may place the death of the latter c. 400 B.C.; the gift of Dor and Japho, which he received from the great king, may have been a reward for fidelity in the rebellion of the younger Cyrus. Certainly it was not Eshmun'azar who led the eighty ships that joined Conon in 396 (Diod., xiv. 79), an event which may have been the beginning of the friendly relations between Sidon and Athens, indicated in a decree of "proxenia" for Straton I. (*C. I. Gr.*, No. 87). Tyre was then quite weak; between 391 and 386 it was stormed by Evagoras of Salamis (Isocr., *Paneg.*, 161, and *Evag.*, 23, 62; Diod., xv. 2), who had already made the Greek element dominant over the Phœnician in Cyprus. Straton was friendly with Evagoras's son Nicoteles; they rivalled one another in debauchery, and both found an unhappy end through their implication in the great revolt of the satraps (Ath., xii. 531). When Tachos entered Phœnicia Straton joined him, and on his failure (361) was about to fall into the hands of the foe when his wife slew him first and then herself (Jerome, ii. 1, 311 Vall.). A new revolt of Sidon against Persia took place under Tennes II. on account of insults offered to the Sidonians at the federal diet at Tripolis. Again they joined the Egyptian Nectanebus II., carried the rest of Phœnicia with them, and with the aid of Greek mercenaries from Egypt drove the satraps of Syria and Cilicia out of Phœnicia. Tennes, however, whose interests were not identical with those of the citizens at large, betrayed his people and opened the city to Artaxerxes III. The Sidonians, to the number of 40,000, are said to have burned themselves and their families within their houses (345 B.C., Diod., xvi. 41-45). Tennes himself was executed after he had served the ends of the great king. The *Periplus* ascribed to Scylax (§ 104) describes the respective possessions of Tyre and Sidon in the year before this catastrophe; Sidon had the coast from Leontopolis to Ornithopolis, an Aradus near the later Sycaminon, and Dor; Tyre had Sarepta and Exope (†) in the district of the later Calamon, farther south a town seemingly called Cirtha, and, strangely enough, the important Ascalon. Tyre now again for a short time took the first place. When, however, Alexander entered Phœnicia after Issus and the kings were absent with the fleet, Aradus, Byblus, and Sidon joined him, the last-named showing special zeal against Persia. The Tyrians also offered submission, but refused to allow Alexander to enter the city and sacrifice in the temple of Hercules. Alexander was determined to make an example of the first sign of opposition that did not proceed from Persian officials, and

² See for details Gutschmid, in *Jahrb. f. Phil. u. Pädag.*, 1857, p. 672.

at once began the siege. It lasted seven months, and, though the king, with enormous toil, drove a mole from the mainland to the island, he made little progress till the Persians were mad enough to dismiss the fleet and give him command of the sea through his Cyprian and Phœnician allies. The town was at length forced in July 332; 8000 Tyrians were slain, 30,000 inhabitants sold as slaves, and only a few notables, the king Azemileus, and the Carthaginian festival envoys, who had all taken shelter in the fane of Hercules, were spared (Arr., ii. 13, 15 sq.). Tyre thus lost its political existence, and the foundation of Alexandria presently changed the lines of trade and gave a blow perhaps still more fatal to the Phœnician cities. The Phœnicians thenceforth ceased to be a great nation, though under the Greeks Tyre and Sidon were still wealthy towns, the seats of rich merchants.

Sources and Helps.—The only at all continuous records of ancient tradition are the account of Phœnician mythology by Philo of Byblus, the extracts of the Tyrian annals by Josephus from Menander of Ephesus, and what Justin in the 18th book of his abridgment of Pompeius Trogus has taken from Timæus. Everything else has to be pieced together in a mosaic fashion. The chief help is Movers's unfinished work; *Die Phönizier*, i., ii. 1-3 (Bonn, 1841-56), which must be compared with his article "Phœnizien," in Ersch and Gruber (1878). Both works are learned and indispensable, but to be used with caution wherever the author's judgment on his material is involved, especially in the treatment of the mythology, which is merely syncretistic, whereas it is essential to a right understanding of this subject to distinguish the peculiarities of the several Semitic nations. Selden, *De diis Syris* (London, 1617), is still a valuable mine. The best recent contributions are those of Baudissin, *Studien zur semitischen Religionsgeschichte* (Leipzig, 1876, 1878). For the colonial history Bochart's monumental *Chanaan* (Caen, 1666) is not superseded even by Movers, who, as has been wittily observed, has created with the help of etymology Phœnician *chambres de réunion*; and, though Olshausen (*N. Rhein. Mus.*, 1853, p. 321 sq.) does not go quite so far, both he and Müllenhoff (*Deutsche Alterthumskunde*, i., 1870) follow the steps of Movers much too closely. A good corrective is given by Meltzer (*Gesch. d. Karthager*, i., 1879), though he, again, is sometimes too sceptical. Movers is best on the history proper; and the admirable sketch in Grote's *History of Greece* should also be consulted. See also Duncker, *Gesch. des Alterthums*, and Maspero, *Hist. anc. de l'Orient*. (A. v. G.)

Art.—Of Phœnician buildings few remains now exist on Phœnician soil; the coast has always been, and still is, densely peopled, and the builders of successive generations, like those of the present day, have regarded ancient edifices as their most convenient quarries. Phœnician architecture had its beginning in the widening and adaptation of caves in the rocks; the independent buildings of later times, constructed of great blocks of unhewn stone, are direct imitations of such cave-dwellings. As Syrian limestone (which is the material employed) does not admit of the chiselling of finer details, the Phœnician monuments are somewhat rough and irregular. Not a vestige remains of the principal sanctuary of this ancient people, the temple of Melkart at Tyre; but Renan discovered a few traces of the temple of Adonis near Byblus: and a peculiar mausoleum, Burj al-Bezzak, still remains near Amrit (Marathus). It may also be conjectured that the conduits of Ras al-Ain, south of Tyre, are of ancient date. Various notices that have come down to us render it probable that the Phœnician temples, in the erection of which great magnificence was undoubtedly displayed, were in many respects similar to the temple at Jerusalem; and confirmatory evidence is afforded by the remarkable remains of a sanctuary near Amrit, in which there is a cella in the midst of a large court hewn out of the rock, and other buildings more of an Egyptian style. In the domain of art originality was as little a characteristic of the Phœnicians as of the Hebrews; they followed foreign and especially Egyptian models. This influence is mainly evident in sculptured remains, in which Egyptian *motifs* such as the Uraeus frieze and the winged sun-disk not unfrequently

occur. It was in the time of the Persian monarchy that Phœnician art reached its highest development; and to this period belong the oldest remains, numismatic as well as other, that have come down to us. The whole artistic movement may be divided into two great periods: in the first (from the earliest times to the 4th century B.C.) Egyptian influence is predominant, but the national Phœnician element is strongly marked; while in the second Greek influence has obtained the mastery, and the Phœnician element, though always making itself felt, is much less obtrusive. In the one period works of art, as statues of the gods and even sculptured sarcophagi, were sometimes imported direct from Egypt (such statues of the gods have been found even in the western colonies); in the other Greek works were procured mainly from Rhodes. The Phœnicians also adopted from the Egyptians the custom of depositing their dead in sarcophagi. The oldest examples of those anthropoid stone coffins are made after the pattern of Egyptian mummy-cases; they were painted in divers colours, and at first were cut in low relief; afterwards, however, towards and during the Greek period, the contours of the body began to be shown in stronger relief on the cover. Modern excavations show that, besides stone coffins (in marble or basalt), which indeed cannot be considered the oldest kind of receptacle, the Phœnicians employed coffins of wood, clay, and lead, to which were often attached metal plates or, at times it may be, decorations in carved wood. Embalming also seems to have been frequently practised as well as covering the body with stucco. Great care was bestowed by the Phœnicians on their burial-places, and their cemeteries are the most important monuments left to us. The tombs are subterranean chambers of the most varied form: the walls and roof are not always straight; sometimes there are two tiers of tombs one above the other, often several rows one behind the other: While in early times a mere perpendicular shaft led to the mouth of these excavations, at a later date regular stairs were constructed. The dead were deposited either on the floor of the chamber (often in a sarcophagus) or, according to the later custom, in niches. The mouths of the tombs were walled up and covered with slabs, and occasionally cippi were set up. The great sepulchral monuments (popularly called *maghâzil*, "spindles") which have been found above the tombs near Amrit are very peculiar: some are adorned with lions at the base and at the top with pyramidal finials. Besides busts (which belong generally to the Greek period), the smaller objects usually discovered are numerous earthen pitchers and lamps, glass wares, such as tear-bottles, tesserae, and gems. Unrifed tombs are seldom met with.

Literature.—For topography and art, see Renan, *Mission de Phénicie* (Paris, 1846); for language, Schröder, *Die phönizische Sprache* (Halle, 1869), and Stade in *Morgenländische Forschungen* (1875, p. 167); and for inscriptions, *Corp. Inscr. Sem.* (Paris, 1881, and following years). (A. SO.)

PHŒNIX. Herodotus (ii. 73), speaking of the animals in Egypt, mentions a sacred bird called "phœnix," which he had only seen in a picture, but which the Heliopolitans said visited them once in five hundred years on the death of its father. The story was that the phœnix came from Arabia, bearing its father embalmed in a ball of myrrh, and buried him in the temple of the sun. Herodotus did not believe this story, but he tells us that the picture represented a bird with golden and red plumage, and closely resembling an eagle in size and shape. The story of the phœnix is repeated with variations by later writers, and was a favourite one with the Romans. There is only one phœnix at a time, says Pliny (*N.H.*, x. 2), who, at the close of his long life, builds himself a nest with twigs of cassia and frankincense, on which he dies; from his corpse is generated a worm which grows into the young

phoenix. The young bird lays his father on the altar in the city of the sun, or burns him there, as Tacitus has it (*Ann.*, vi. 28). The story of the birth and death of the phoenix has several other forms. According to Horapollon (ii. 57) he casts himself on the ground and receives a wound, from the ichor of which the new phoenix springs; but the most familiar form of the legend is that in the *Physiologus*, where the phoenix is described as an Indian bird which subsists on air for 500 years, after which, lading his wings with spices, he flies to Heliopolis, enters the temple there, and is burned to ashes on the altar. Next day the young phoenix is already feathered; on the third day his pinions are full-grown, he salutes the priest and flies away. The period at which the phoenix reappears is very variously stated, some authors giving as much as 1461 or even 7006 years, but 500 years is the period usually named; and Tacitus tells us that the bird was said to have appeared first under Sesostris, then under Amasis, again under Ptolemy III., and once more in 34 A.D., after an interval so short that the genuineness of the last phoenix was suspected. The phoenix that was shown at Rome in the year of the secular games, A.U.C. 800, was universally admitted to be an imposture.¹

The form and variations of these stories characterize them as popular tales rather than official theology; but they evidently must have had points of attachment in the mystic religion of Egypt, and indeed both Horapollon and Tacitus speak of the phoenix as a symbol of the sun. Now we know from the *Book of the Dead* and other Egyptian texts that a bird called the "bennu" was one of the sacred symbols of the worship of Heliopolis, and Wiedemann (*Ztsch. f. Aeg. Sprache*, xvi. p. 89 sq.) has made it tolerably clear that the bennu was a symbol of the rising sun, whence it is represented as "self-generating" and called "the soul of Ra (the sun)," "the heart of the renewed Sun." All the mystic symbolism of the morning sun, especially in connexion with the doctrine of the future life, could thus be transferred to the bennu, and the language of the hymns in which the Egyptians praised the luminary of dawn as he drew near from Arabia, delighting the gods with his fragrance and rising from the sinking flames of the morning glow, was enough to suggest most of the traits materialized in the classical pictures of the Phoenix. That the bennu is the prototype of the phoenix is further confirmed by the fact that the former word in Egyptian means also "palm-tree," just as the latter does in Greek. How far the Egyptian priests translated the symbolism of the bennu into a legend it would be vain to conjecture; that the common people did so is only what we should expect; and it is to be observed that the monuments have not yet shown any trace of the element in the classical legend which makes the phoenix a prodigy instead of a symbol—its actual appearance at long intervals. The very various periods named make it probable that the periodical return of the phoenix belongs only to vulgar legend, materializing what the priests knew to be symbolic. The hieroglyphic figure of the bennu is that of a heron

( bennu, or  bāh), and the gorgeous colours and plumed head spoken of by Pliny and others would be least inappropriate to the purple heron (*Ardea purpurea*),

with which, or with the allied *Ardea cinerea*, it has been identified by Lepsius and Peters (*Älteste Texte des Töln-buchs*, 1867, p. 51). But it must be remembered that the bennu in the Egyptian texts is really a mere symbol, having the very vaguest connexion with any real bird, and the golden and purple hues described by Herodotus may be the colours of sunrise rather than the actual hues of the purple heron. How Herodotus came to think that the bird was like an eagle is quite unexplained; perhaps this is merely a slip of memory.

Many commentators still understand the word *חֵן*, *chōl*, in Job xxix. 18 (A.V. "sand") of the phoenix. This interpretation is perhaps as old as the (original) Septuagint, and is current with the later Jews, whose appetite for fable, however, is often greater than their exegetical sagacity. Compare Eisenmenger's *Entdecktes Judenthum*, vol. i. *passim*. Among the Arabs the story of the phoenix was confused with that of the salamander; and the samand or samandal (Damiri, ii. 36 sq.) is represented sometimes as a quadruped, sometimes as a bird. It was firmly believed in, for the incombustible cloths woven of flexible asbestos were popularly thought to be made of its hair or plumage, and were themselves called by the same name (comp. Yāqūt, i. 529, and Dozy, s.v.). The 'ankā (Pers. *simurgh*), a stupendous bird like the roc (rikh) of Marco Polo and the *Arabian Nights*, also borrows some features of the phoenix. According to Kazwini (i. 420) it lives 1700 years, and when a young bird is hatched the parent of opposite sex burns itself alive. In the book of Kalilah and Dimnah the *simūr* or 'ankā is the king of birds, the Indian garuda on whom Vishnu rides.

PHOENIXVILLE, a borough in the United States, in Schuylkill township, Chester county, Pennsylvania, is situated 27½ miles north-west of Philadelphia by the Philadelphia and Reading Railroad, on the right bank of the Schuylkill river, which is there joined by French Creek, crossed by eight fine bridges. Phoenixville is best known as the seat of the blast-furnaces and mills of the Phoenix Iron Company, which had its origin in a rolling and slitting mill erected in 1790 by Benjamin Longstreth, and long ranked as the largest in the States. The works cover 150 acres and employ sometimes 2500 men. Phoenixville also contains a pottery, a sash and planing mill, a shirt-factory, and needle works; and iron, copper, and lead are all mined in the neighbourhood. The vicinity of the borough is noted for its large number of magnificent iron bridges. The population was 2670 in 1850, 4886 in 1860, 5292 in 1870, and 6682 in 1880.

PHONETICS (τὰ φωνητικά, the matters pertaining to the voice, φωνή) is the science and art of the production of sounds, including cries, by means of the organs of speech in man and their analogues in other animals.

This very extensive subject may be divided into the following three parts. (1) *Anatomical*, the accurate description of all the organs employed, emissive (lungs, with the muscles acting on them, trachea, larynx, pharynx, mouth and its parts, nose and its passages, with its closing valve the uvula) and receptive (the ear, external and internal, and parts of the brain with which the auditory nerve communicates). As all voice-sounds are produced by imitation, defects in the receptive organs entail defects in the action of the emissive. The congenitally deaf are consequently mute. (2) *Physiological*, the co-ordinated action of the parts just referred to in hearing and uttering sounds, and especially expiration and inspiration, with laryngeal, oral, and nasal actions, and the relation of these actions to the will (on these see Voice). (3) *Acoustical*, with especial reference to the action of double membranous reeds, as in the glottis; the effects of resonance chambers, both fixed and variable in shape and size, open and closed, single and combined, and of the passage of air, more or less in a state of sonorous vibration, through tubes of variable lengths and widths, with walls of variable hardness, and with or without the interposition of semi-viscous fluids, as well as of flapping, smacking, or vibrating parts, and of other obstructions; also investigations into the nature, pro-

¹ Some other ancient accounts may be here referred to. That ascribed to Hecateus is, in the judgment of Cobet (*Memnosync*, 1883), stolen from Herodotus by a late forger. The poem of the Jew Ezechiel quoted by Eusebius (*Præp. Ev.*, ix. 29, 30) appears to refer to the phoenix. Here the sweet song is first mentioned,—a song which, according to the poem on the phoenix ascribed to Lactantius, accompanies the rising sun. The bird is often spoken of in Latin poetry, and is the subject of an idyl by Claudian. See also Solinus, cap. xxxiii., with Salmasius's *Exercitationes*; Tertullian, *De resur. carnis*, c. 33; Clemens Rom., *Ep. i.* ch. xxv.

duction, and appreciation of qualities of tone, and their gradual but rapid gliding one into another, as well as into the nature of sympathetic vibration, not only of the different cavities filled with air in the organs of speech but of the solid bony parts, and also the softer cartilages, sinews, and muscles connecting and supporting them. This part of the subject, which is far from having been fully investigated at present, has two main subdivisions—(a) *musical*, regarding the nature and properties of musical sound, and especially song, with their varieties due to force, pitch, and quality, as partly investigated in Helmholtz's *Sensations of Tone*; (b) *rhetorical*, regarding the mechanism of speaking as distinct from singing, the blending and differentiation of qualities of tone, partly musical and partly unmusical, with constantly variable and ill-defined pitch and force, influenced by feeling; this subdivision embraces speech in particular, its special sounds for conveying thought and feeling, with their constantly-shifting characters, and also cries of joy and pain, as well as, properly speaking, the cries of the lower animals by which they communicate with those of the same kind; hence it comprehends also language, elocution, and philology in their fundamental constitution.

In a more restricted sense, applied solely to human beings and to articulate significant sounds (that is, exclusive of cries of pain and pleasure, or the inarticulate and often unconscious noises of snoring, snuffing, gargling, panting, laughing, crying, sobbing, sneezing, and the like), the term "phonetics" is used to designate a work on the enumeration, evaluation, relations, classification, analysis, and synthesis of SPEECH-SOUNDS (*q.v.*),—that is, of the sounds actually used in speech for conveying and recording thought by different nations and tribes, together with a means of fixing them by visible signs. The alphabet has followed speech-sounds with very halting steps. It is only in quite recent times that sufficient knowledge of the nature of speech has been obtained to enable us in some measure to understand and unravel the mysteries of the old enigmatic forms, and thus to construct a securer basis for philology than the guesses on which it once rested.

In a still more restricted and popular sense the term "phonetics" has been recently used for attempts to construct a new practical alphabet for English or other individual languages, or for several such languages simultaneously, with a view either of superseding the alphabets at present in use, or of improving their employment, or, at any rate, of facilitating the generally very difficult tasks of teaching and learning to read and write. Attempts of this kind are by no means recent: witness Loys Meigret, *Traité touchant le commun usage de l'écriture françoise* (1545); Sir Thomas Smith, *De recta et emendata linguæ Anglicæ scriptione* (1568); J. Hart, *An orthographie, conteyning the due order and reason, howe to write or painte thimage of mannes voice, most like to the life or nature* (1569); [William] Bullokar's *Booke at large for the Amendment of Orthographie for English speech* (1580); Alexander Gill (master of St Paul's school, London, when Milton was there), *Logonomia Anglica: quâ gentis sermo faciliùs addiscitur* (1619 and 1621); Charles Butler, *The English Grammar, or the Institution of Letters, Syllables, and Words in the English tongue* (1633). All these works are more or less printed in the orthography proposed, and each orthography is different. They are described and illustrated in A. J. Ellis's *Early English Pronunciation*, parts i. and iii. It is, however, not necessary in this place to go beyond attempts made by persons still living. In 1847, after three years of experiments, Isaac Pitman and Alexander John Ellis brought out their phonotypy, consisting of twenty-three old types and seventeen new ones, with which, among much other matter, the *Bible*

and the *Phonetic News* newspaper were printed in 1849, and extensive experiments were made, showing that reading in this alphabet could be rapidly taught, and that when children had learned to read phonotypy well they could easily learn to read in ordinary spelling. The new letters were subsequently much and frequently altered in meaning by Pitman, who in 1884 still produced a *Phonetic Journal* weekly in his present phonotypy. Very numerous forms of phonotypy, following either the old or the new edition, have also appeared in America. Many other systems have been tried by accenting, italicizing, supernumbering, or diacritically marking the letters to make the ordinary letters of English spelling convey their sounds. Almost every new "pronouncing dictionary" has its own method. This last plan has been, on the whole, successfully applied for teaching to read by many writers. In order to avoid new types, or even accented letters, and yet have a practical phonetic alphabet for English and its dialects, Ellis prefixed to part iii. of his *Early English Pronunciation* (1871) an account of "Glossic, a new system of spelling intended to be used concurrently with the existing English orthography, in order to remedy some of its defects without detracting from its value." This has been extensively used by the English Dialect Society and in Ellis's works on *Pronunciation for Singers* (1877) and *Speech in Song* (1878), in which it is fully explained and used in complete practical accounts of the phonology of English, German, French, Italian, and Spanish. Henry Sweet, in his *Handbook of Phonetics* (Oxford, 1878), proposed his "Broad Romic," admitting, however, a few inverted letters. Subsequently, the English Spelling Reform Association was started, and great numbers of new attempts at phonetic alphabets for English only were made, which will be found described and illustrated at full length in W. R. Evans's *Spelling Experimenter and Phonetic Investigator* (2 vols., September 1880 to April 1883). There is also an American spelling reform association. But neither association has as yet agreed upon a new alphabet. In 1881 the Philological Society of London approved of certain "partial corrections of English spelling" submitted by Sweet, and these are more or less used in the *Proceedings* of that society, as edited by Sweet, and are generally approved by the American association, but they are not by any means an entirely phonetic scheme. In the books referred to, and particularly Evans's, the whole of this special branch of the subject of phonetics, so far as English is concerned, may be sufficiently examined. (A. J. E*.)

PHORMIUM, or NEW ZEALAND FLAX (also called "New Zealand hemp"), is a fibre obtained from the leaves of *Phormium tenax* (ord. *Liliaceæ*). The plant is a native of New Zealand, the Chatham Islands, and Norfolk Island; it is now cultivated as an ornamental garden-plant in Europe, and for economic purposes it has been introduced into the Azores. The leaves grow from 3 to 6 and even 9 feet in height and from 2 to 3 inches in breadth, springing from the extremity of a rhizome. After the tuft of leaves has continued growing for about three years a flowering stalk springs up to the height of about 16 feet, and when it comes to maturity the whole plant dies down. Meantime, however, lateral branches or fans have been given off from the main rhizome, and thus the life of the plant is continued by stem as well as seed. Phormium has been treated as a cultivated plant in New Zealand, though only to a limited extent, and with no promising results; for the supplies of the raw material dependence has been principally placed on the abundance of the wild stocks and on sets planted as hedges and boundaries by the Maoris. Among these people the fibre has always been an article of considerable importance, yielding cloaks, mats, cordage,

fishing-lines, &c., its valuable properties having attracted the attention of traders even before colonists settled in the islands. The leaves, for fibre-yielding purposes, come to maturity in about six months, and the habit of the Maoris is to cut them down twice a year, rejecting the outer and leaving the central immature leaves. Phormium is prepared with great care by native methods, only the mature fibres from the under-side of the leaves being taken. These are collected in water, scraped over the edge of a shell to free them from adhering cellular tissue and epidermis, and more than once washed in a running stream, followed by renewed scraping till the desired purity of fibre is attained. This native process is exceedingly wasteful, not more than one-fourth of the leaf-fibre being thereby utilized. But up till 1860 it was only native-prepared phormium that was known in the market, and it was on the material so carefully, but wastefully, selected that the reputation of the fibre was built up. The troubles with the Maoris at that period led the colonists to engage in the industry, and the sudden demand for all available fibres caused soon afterwards by the Civil War in America greatly stimulated their endeavours. Machinery was invented for disintegrating the leaves and freeing the fibre; and at the same time experiments were made with the view of obtaining it by water-retting and by means of alkaline solutions and other chemical agencies. But the fibre produced by these rapid and economical means was very inferior in quality to the product of Maori handiwork, mainly because weak and undeveloped strands are, by machine preparation, unavoidably intermixed with the perfect fibres, which alone the Maoris select, and so the uniform quality and strength of the material are destroyed. No means have yet been devised for producing by mechanical or chemical means fibre in the perfect condition it shows when selected and prepared by Maoris. Phormium is a cream-coloured fibre with a fine silky gloss, capable of being spun and woven into many of the heavier textures for which flax is used, either alone or in combination with flax. It is, however, principally a cordage fibre, and in tensile strength it is second only to Manila hemp; but it does not bear well the alternations of wet and dry to which ship-ropes are subject. It is largely used as an adulterant of Manila hemp in rope-making, and recently it has come into use as a suitable material for the bands of self-binding reaping-machines. Between 1864 and 1876 there were exported from New Zealand 26,434 tons of phormium, valued at £592,218; in 1881 the exports were 1307 tons, of the value of £26,285.

PHOSPHORESCENCE, a name given to a variety of phenomena due to different causes, but all consisting in the emission of a pale more or less ill-defined light, not obviously due to combustion. The word was first used by physicists to describe the property possessed by many substances of themselves becoming luminous after exposure to light. Such bodies were termed "phosphori," and the earliest known appears to have been barium sulphide, which was discovered by Vincenzo Cascardiolo, a cobbler of Bologna, at the beginning of the 17th century. See PHOSPHORUS. Subsequently, when certain animals were observed to be similarly endowed, the word "phosphorescent" was applied to them also. It is clear, however, that the light derived from previous exposure to light, which thus becomes, as it were, stored up, is hardly comparable with that which is produced by living protoplasm and evidently under the control of the nervous system. It has been suggested that this latter should have a special name appropriated to it, and here it will certainly be convenient to divide the subject into two heads in accordance with this distinction.

A. PHOSPHORESCENCE IN MINERALS.—In addition to the phosphorescence after insolation already alluded to

(see LIGHT, vol. xiv. p. 603) many minerals exhibit this property under other circumstances: (a) on heating to a temperature much below what is known as "red heat" (fluorspar, lepidolite, quinine)—this being often attended with a change in molecular structure or in specific heat; (b) on friction, as in the case of fused calcium chloride (Homberg's phosphorus); (c) on cleavage, a property manifested by mica, the two split portions becoming electrified—the one positive, the other negative; (d) on crystallization, as boracic acid after fusion, or water on rapid freezing.¹

A few meteorological phenomena may here be mentioned. Rain has been seen to sparkle on striking the ground, and waterspouts and meteoric dust have presented a luminous appearance. The *ignis fatuus*, or will-o'-the-wisp, seen in marshy districts, has given rise to much difference of opinion: Kirby and Spence suggest that it may be due to luminous insects; but this explanation will certainly not apply in all cases, and it is perhaps on the whole more reasonable to believe that the phenomenon is caused by the slow combustion of marsh gas (methyl hydride).

B. PHOSPHORESCENCE IN ORGANISMS.—The vegetable kingdom has furnished few instances of the property under consideration; the earliest on record took place in the year 1762, when a daughter of Linnæus saw luminous emanations from a species of *Tropæolum*, since which time a like appearance has been noticed in *Helianthus annuus*, *Lilium bulbiferum*, *Calendula officinalis*, *Tagetes patula*, and *T. erecta*, all of which are red or orange-coloured flowers. A few cryptogams have been seen to shine in the dark, e.g., *Schistostega osmundacea* among the liverworts; *Rhizomorpha subterranea*, *Fungus igneus* in Amboyna, and other fungi in Brazil and Italy; and the mycelium (thread-like fibres) of other species growing in decayed wood is also occasionally luminous. There are also a number of small marine phosphorescent organisms² (*Pyrocystis*, *Peridinium*), concerning which it is impossible to say with certainty whether they should be referred to the animal or the vegetable kingdom. But the most brilliant as well as the most varied and interesting cases of phosphorescence belong to the animal world, and there is not one of the larger groups which does not furnish some instances of it.

Nature of the Light.—The light emitted by different animals varies very much in colour: green has been noticed in the glow-worm, fire-flies, some brittle-stars, centipedes, and annelids; blue is seen in the Italian fire-fly (*Luciola italica*); and this and light green are the predominant colours exhibited by marine animals, although the beautiful Girdle of Venus and some species of *Salpa* and *Cleodora* appear red, and *Pavonaria* and other gorgonoids lilac. The curious lantern-fly (*Fulgora pyrorhynchus*) has a purple light. One very remarkable instance is mentioned of an *Appendicularia* in which the same individual appeared first red, then blue, and finally green.³ In comparatively few cases has the light been examined by the spectroscope. Panceri⁴ states that in every instance observed by him it was monochromatic, the spectrum consisting of a continuous band without any separate bright lines; in *Pholas* this band extended from the line E of the solar spectrum to a little beyond F; in *Umbellula*, examined on the voyage of the "Challenger," it was sharply included between the lines b and D.⁵

Luminous Organs.—In the lowest forms of life and in

many jelly-fish there seem to be no organs specially set apart for the production of light, this being emitted from the whole surface of the body; but even in the latter group a degree of specialization is found, for in some it is only the marginal sense-organs, in others the radial canals and ovaries, that are luminous. In other groups of animals the localization of the photogenic property in certain organs or tissues is universal, and these present the utmost variety in structure and situation. In the sea-peus (*Pennatula*) every polyp has eight luminous bands on the outer surface of the stomach; when the colony is touched the light commences at the point irritated and then spreads to other portions. *Pyrosoma*, a colonial free-swimming ascidian, has two small patches of cells at the base of each inhalent tube; the cells have no nucleus, but contain a material which appears from its chemical relations to be fatty; as in *Pennatula*, the light spreads from the irritated point. In the transparent pelagic mollusc (*Phyllirrhoe*) there are rounded cells connected with the nerve-twigs from which, as also from the ordinary cells of the nerve-ganglia, the light emanates. Several annelids (*Chaetopterus*, *Tomopteris*) have luminous organs at the bases of lateral processes of the body. The rock-boring mollusc (*Pholas*), whose phosphorescent properties were known as long ago as the time of Pliny, has three distinct luminous organs—(1) a curved band along the anterior border of the mantle, (2) two small triangular patches at the entrance of the anterior siphon, and (3) two long parallel cords situated within this latter; these are all covered with ciliated epithelium, like that of other parts of the mantle, but having granular contents.¹

The glow-worm (*Lampyrus splendidula*) has been investigated by Max Schultze;² he finds that the male has a pair of organs in each of the two segments preceding the last in the abdomen; each organ consists of a pale transparent superficial layer, which gives off the light, and a deep opaque layer, whose function is less obvious, but which may serve as a reflector.³ Quite recently Emery⁴ has examined the Italian fire-fly, in which both male and female are luminous. As in the glow-worm, the organ consists of two layers: the dorsal contains large quantities of uric acid salts; while in the ventral layer there are clear cells arranged in cylindrical lobules, which surround vertically-disposed tracheal limbs—a structure comparable to the stellate tracheal cells of Schultze. The luminous organs are regarded as homologous to the "fat body" so common in insects. The ultimate branches of the tracheae ramify in these and terminate in peculiar star-like cells; nerve-fibres are also present. The Mexican fire-flies (*Pyrophorus*) are in most respects similar to the glow-worm, but have a pair of organs in the thorax and one in the abdomen, whilst the lantern-flies (*Fulgora*) carry their light at the extremity of a long curved proboscis. Many crustaceans are luminous, but in most cases it has not been observed from what part of the body the light emanates; in some instances, however (*Thysanopoda* [*Nyctiphanes norvegica*, *Euphausia pellucida*, &c.], there are small globular phosphorescent organs, which have often been described as eyes, beneath the thorax and between the abdominal swimmerets. Sars⁵ states that "these globules . . . constitute a highly complicated luminous apparatus, the lenticular body of the organs, generally described as a true eye-lens, acting as a condenser, which . . . enables the animal to produce at will a very bright flash of light in a given direction." Mr John Murray in the same place records the occurrence

of a very brilliant display of this phosphorescence during the "Triton" expedition in the Faroe Channel.

Many deep-sea fish possess round shining bodies imbedded in the skin, either in the vicinity of the eye or along the sides of the body; some of these resemble modified eyes, whilst the structure of others recalls a glandular organ without the usual duct,⁶ and it is supposed that some or all of these are luminous organs, the lens in the former group acting as a bull's eye (see ICHTHYOLOGY, vol. xii. p. 684).

Dead and putrescent animals are not unfrequently phosphorescent; this fact has most commonly been observed in fish, though instances are not wanting in which the property has been manifested by molluscs and other animals, and even by the human body. Furthermore, a few startling but apparently well-authenticated instances are on record in which human beings have been luminous while yet alive owing to certain states of disease.⁷

Causes of Phosphorescence.—On this head it is at present impossible to write with certainty; it seems likely, however, from the variety of the effects produced by different chemical and physical agents, that the causes are manifold. In many instances light is only emitted after stimulation, either mechanically, chemically (by fresh water, milk, ammonia), or by electricity, though there are cases in which this last has no effect whatever. The fact that the nervous system is so often closely connected with the luminous organs indicates that the exhibition of the light is either dependent on the volition of the animal or is the reflex result of the stimulation of sensory nerves (Panceri). In the glow-worm the distribution of tracheae (air-tubes) throughout the photogenic apparatus, and the fact that carbonic acid extinguishes the light while oxygen intensifies it, suggest that it is due to some form of slow combustion, while the fatty contents of the luminous cells of this and many other animals point to the probability that a fat containing free phosphorus is the active agent in the process. Since a large number of luminous organs retain their power after the death of the animal, and even after desiccation and subsequent moistening, there seems no necessity to adopt the theory that we have to deal with an instance of the direct transformation of vital into radiant energy.

The well-known phosphorescence of the sea is due to the animals which inhabit it, except in a few cases in which it has been ascribed to putrescent matter. This was known as long ago as 1749, when Vianelli⁸ discovered in the waters of the Adriatic a luminous animalcule which was named by him *Nereis noctiluca*, and was probably the creature now known as *Noctiluca miliaris*. This minute animal swarms in countless myriads on the surface of the sea not very far from land, and is the commonest cause of a diffuse luminosity, although other low forms of life such as *Peridinium* (*Ceratium*) contribute in no small degree; and in mid-ocean another organism, *Pyrocystis*, which has often been mistaken for *Noctiluca*, appears to replace it, and is very abundant. The brilliant sparkling phosphorescence more rarely seen is caused by the presence of copepoda and other small surface crustaceans.

Uses of Phosphorescence.—The service rendered by this property to its possessors is in many cases by no means obvious; indeed it would seem certain that to crustacean larvae and other surface-organisms surrounded by voracious enemies phosphorescence must be a "perilous gift." It is possessed by so many anthozoa and jelly-fish, which have also stinging organs, that fish have perhaps learned to shun instinctively all phosphorescent animals; fishermen state that fishes avoid nets in which phosphorescent *Medusae* have become entangled; if such be the case, it would be possible for animals otherwise defenceless to obtain protection by acquiring this property.⁹ A similar hypothesis has been propounded with respect to the Italian fire-fly,¹⁰ although, as regards the glow-worm, it has been generally believed that the light serves to attract the opposite sex, and the same has been stated with respect to the earth-worm. The fact that so many deep-sea animals are phosphorescent, coupled with the discovery that many fish from those regions have large and normally-developed eyes whilst others have organs which appear to be adapted for the production of light, has led to the belief that this source of light becomes of great importance in the depths of the ocean where no sunlight penetrates,—an hypothesis which is known as the "abyssal theory of light." (W. E. HO.)

PHOSPHORUS AND PHOSPHATES. "Phosphorus" (*φωσφόρος*, light-bringer) had currency in chemistry as a generic term for all substances which shine in the dark without burning, until the name came to be monopolized by a peculiar kind of "phosphorus" which was discovered, some time previous to 1678, by the German alchemist Brand of Hamburg. Brand, hoping to obtain thereby an essence for the "ennobling" of silver into gold, subjected urine-solids to dry distillation. In lieu of the hoped-for essence he obtained as part of the distillate a wax-like, easily fusible solid which, besides being phosphorescent, readily caught fire, to burn with a dazzling light into a white solid acid. The new phosphorus naturally excited universal interest; but it was, and remained, only a rather costly chemical curiosity until Scheele, in 1771, starting from the discovery of Gahn that bone-ash is the lime-salt of a peculiar non-volatile acid, proved that this acid is identical with the one formed in the combustion of phosphorus, and that the latter, being only "phlogisticated" bone-ash acid, can be obtained from it by distillation with charcoal at a high temperature. This method of Scheele's is used to the present day for the manufacture of phosphorus, and even the theoretical notion on which it rests is recognized as correct as far as it goes, anhydrous bone-ash acid being a compound of phosphorus with oxygen the formation of which involves the liberation of part of the *energy* ("phlogiston") of each in the kinetic form of heat. That phosphorus is an elementary substance was originally a surmise, which, however, has been confirmed by all subsequent experiences. In comparatively recent times it was found that Brand's phosphorus is susceptible of passing (by mere loss of energy) into two allotropic modifications, known as "red" and "metallic" phosphorus respectively, so that the name "phosphorus" has again come to assume a generic meaning, being used for these three substances and the element as such conjointly.

Manufacture.—For the manufacture of ordinary phosphorus any kind of phosphate of lime might be used, and in fact mineral phosphates are used occasionally, though as a rule the bones of domestic animals are employed as a raw material. Such bones (apart from a large percentage of water and a small admixture of fats and other subsidiary organic components) consist essentially of two things, namely, (1) *osseine*—a nitrogenous organic compound, insoluble in water, but convertible by long treatment with hot water into a solution of "glue"—and (2) an infusible and incombustible part,—the two being united together (perhaps chemically) into a cellular tissue. The following analysis of the humerus of an ox gives an idea of the constitution of the second part and its ratio to the whole.

The percentages, however, in bones generally are subject to great variation. When bones are heated to redness in the absence of air the organic part is destroyed, and there remains ultimately a cellular tissue of bone-phosphate impregnated, so to speak, with finely-divided charcoal. This black residue, known as "bone-black," is used largely for the decoloration of sugar-syrup, and, after having been exhausted in this direction, forms a cheap material for the manufacture of bone-ash and consequently of phosphorus; but, as a rule, the phosphorus-manufacturer makes his bone-ash direct from bones, by burning them in a furnace (constructed and wrought pretty much like a limekiln) between alternate layers of coal.

The burned bones (which retain their original shape)

are ground up into granules of about the size of lentils, and these are then placed in a wooden tank coated inside with lead, to be decomposed by means of about their own weight of chamber-acid, i.e., sulphuric acid containing about 60 per cent. of real H_2SO_4 . To accelerate the action the bone-meal is mixed with boiling water previous to the addition of acid, and steam may be passed into the magma when its temperature threatens to fall too low. The acid readily decomposes the carbonate of the bone-ash, and then acts, more slowly, on the phosphate, the process being completed in about twenty-four hours; and the result, in regard to the latter, is that about two-thirds of the phosphate are decomposed into sulphate of lime (gypsum), which separates out as a precipitate, and phosphoric acid, which unites with the residual one-third of the phosphate and the water into a solution of superphosphate of lime—

To eliminate the gypsum the mass is diluted with water, allowed to settle, and the solution drawn off with lead syphons, then the residue is washed by decantation, and ultimately filtered off through a bed of straw contained in a cask with a perforated bottom. The spent heat of the distillation-furnace is utilized to concentrate the united liquors to about 1.45 specific gravity, when a remnant of gypsum separates out, which must be removed. The clarified liquor is then mixed with about one-tenth of its weight of granulated charcoal, and the whole evaporated in an iron basin until the mass is sufficiently dry to be passed through a copper sieve and granulated. The granules are heated cautiously over a fire, to be dehydrated as far as possible without loss of phosphorus (as phosphuretted hydrogen); and the dry mass is then transferred to fire-clay retorts—either pear-shaped with bent-down necks, or cylinders, about 18 inches long and 4 inches in diameter, with straight necks—arranged within a powerful furnace. The condensers are made of earthenware, and must be so arranged that loss of phosphorus by combustion is avoided as far as possible; its condensation takes care of itself. One construction is to give the condenser the form of a bell-jar resting in a saucer containing water; lateral orifices in the bell serve to couple every two bells into one, to unite each with its retort-neck, and to send the vapour (of phosphuretted hydrogen, carbonic oxide, and other poisonous gases) into a chimney, where they take fire spontaneously, and the products are carried away by the draught. While the condensers are being adjusted the fire is kindled and raised very slowly, but ultimately forced up to the highest temperature which the retorts can stand, and maintained at this pitch until the appearance of the flames of the escaping vapours proves the absence from them of phosphorus, free or combined. This takes from thirty-six to forty-eight hours. The reduction-process, though in reality very complex, is in its principal features easily understood. The acid-phosphate behaves as if it were a mere mixture of $\frac{2}{3} \times P_2O_5 + \frac{1}{3} \times P_2O_5 \cdot 3CaO$ (bone-phosphate). The quasi-free acid ($\frac{2}{3}P_2O_5$) is reduced by the charcoal with formation of carbonic oxide and phosphorus-vapour, one-third of the phosphorus remaining in its original form of bone-phosphate.

The distillation of phosphorus is rather a dangerous operation, because the connecting pipes at the condensers are apt to get blocked up with frozen phosphorus, and consequently must be cleared from lime by copper or iron wires being pushed through them (at a certain risk to the operator). Another difficulty is that, although a retort may be quite whole in the ordinary sense, it may, and as a rule does, admit of the perspiration of phosphorus-vapour. To render retorts as nearly as possible impermeable to the

vapour they are being provided with two or three coats of some kind of cement, such as a mixture of slaked lime and borax, or a magma of clay, horse-dung, and water. In the collecting and further manipulation of the phosphorus the dangerous inflammability of the substance demands that all operations be conducted under water.

As soon as the retorts have cooled down sufficiently the condensers are detached and their tubuli bunged up to prevent access of air to the inside. The necks of the retorts are knocked off and thrown into water to save the phosphorus which has condensed within them and to unite it with that of the condensers. From the analysis of the ox-bone quoted we calculate that its ash contains 17.6 per cent. of phosphorus, of which two-thirds ($= 11.7$ per cent.) should be recoverable as free phosphorus; according to Fleck, the yield of phosphorus is 8 per cent., while Payen puts it down at 8 to 10 per cent. But this crude phosphorus is largely contaminated with blown-over bone-ash and charcoal and with "red" phosphorus. Its purification used to be effected everywhere by melting it under water of about 60°C ., and pressing it through chamois leather by means of a force-pump. In certain French works porous fireclay serves as a filtering medium, while superheated steam supplies at the same time the necessary heat and pressure. By the addition of coarsely-powdered charcoal to the phosphorus the clogging-up of the pores of the fireclay septum is precluded. A more effectual method of purification is to re-distil the crude (or perhaps the previously filtered) phosphorus from out of cast-iron retorts, the necks of which dip half an inch deep into water contained in a bucket. A chemical method of purification is that of Böttcher, who fuses the crude phosphorus (100 parts) under water, with addition of 3.5 parts of oil of vitriol and 3.5 parts of bichromate of potash. The phosphorus passes, with a feeble gas-evolution, into an almost colourless liquid, with a loss of only 4 per cent. of its weight, as against the 10 to 15 per cent. unavoidably involved in the distillation process. To bring the purified phosphorus into the traditional form of sticks it is fused under water and sucked up into slightly conical glass tubes about two-fifths of an inch wide and a foot long; the tubes are closed below with the finger and immersed in cold water to cause the contents to freeze. The solid stick is then pushed out by means of a rod, and cut into pieces with a pair of scissors. For emission into commerce the sticks are put into cylindrical wide-necked glass bottles, or into tin canisters, full of water, which latter had better be mixed with a sufficiency of alcohol or glycerin to prevent freezing (and bursting) in winter time.

Seubert, about 1844, invented an ingenious apparatus for the continuous casting of phosphorus-sticks, consisting of a funnel-shaped vessel of copper, terminating below in a long horizontal copper tube, the outer end of which lies within a tank full of cold water. The phosphorus is placed in the funnel, covered with water, and the whole up to the cold-water tank raised (by means of a water-bath and steam-pipes) to a suitable temperature, matters being arranged so that the phosphorus freezes just on arriving at the exit end of the tube. The workman then catches the protruding button of phosphorus and pulls out an endless stick, which is cut up into pieces of the desired length. This ingenious apparatus, however, has not been found to work satisfactorily, and has been given up again in favour of some form of the old method. The loss of one-third of the phosphorus contained in the bone-ash, which is unavoidably involved in the ordinary method of phosphorus-making, can be avoided, according to Wöhler, by adding finely-powdered quartz to the mixture which goes into the retorts. The superphosphate is then completely decomposed with formation of a residue of silicate, instead of

phosphate, of lime. An improvement by Fleck aims at the utilization of the organic part of the bones. He proposes to recover the fat from the bones by boiling them with water and then the gelatin by digesting them in hydrochloric acid of 1.05 specific gravity. The gelatin remains in a coherent form; the phosphate passes into solution as mono-calcic salt, which is recovered by evaporation in crystals and then reduced by distillation with charcoal. None of these (and other) proposals have been much heeded; the manufacture of phosphorus at present, in fact, is almost a monopoly, the bulk of what occurs in commerce being produced by two firms, viz., Albright and Wilson of Oldbury, near Birmingham, and Coignet and Son in Lyons. According to E. Kopp, the production in 1874 amounted to 1200 tons.

Recently purified phosphorus is a slightly yellowish or colourless solid of about the consistence of beeswax. At low temperatures it is brittle; specific gravity $= 1.83$ at 10°C . It fuses at 44.3°C . into a strongly light-refracting liquid of 1.743 (Kopp) specific gravity. Neither in the solid nor in the liquid state does it conduct electricity. When heated further (in an inert atmosphere such as hydrogen or carbonic-acid gas) it boils at 290°C ., and assumes the form of a colourless vapour which at 1040°C . is 4.5 times as heavy as air or 65.1 times as heavy as hydrogen, whence it follows that its molecular weight is $2 \times 65.1 = 130.2 =$ very nearly four times the atomic weight of phosphorus (31.0). Phosphorus is insoluble in water, more or less sparingly soluble in alcohol, ether, fatty oils, and oil of turpentine, and very abundantly soluble in bisulphide of carbon. When exposed to the air, and especially to moist air, it suffers gradual oxidation into phosphorous and phosphoric acids with evolution of a feeble light. Phosphorus does not phosphoresce in the absence of oxygen. Singularly, it does not phosphoresce in pure oxygen either, unless the tension of the gas be reduced to some point considerably below one atmosphere (Graham). Phosphorus is a most dangerous poison; doses of as little as 0.1 gramme ($= 1.5$ grains) are known to have been fatal to adults. The heads of a few lucifer matches may suffice to kill a child. Phosphorus is used chiefly for the manufacture of lucifer matches (see MATCHES, vol. xv. pp. 625, 626) and also in the manufacture of iodide of methyl and other organic preparations used as auxiliary agents in the tar-colour industry. Phosphorus-paste, made by working up a small proportion of phosphorus melted under water in a hot mortar with flour, is used as poison for vermin.

Red Phosphorus.—A red infusible solid which is always produced when ordinary phosphorus is made to burn in an insufficient supply of air, and also by the long-continued action of sunlight on phosphorus-sticks kept under water, used to be taken for a lower oxide of the element, until A. v. Schrötter of Vienna showed, in 1845, that it is nothing but an allotropic modification of the elementary substance. A given mass of ordinary phosphorus can be converted almost completely into the red modification by keeping it at 240° to 250°C . in the absence of air for a sufficient time. The addition of a trace of iodine to phosphorus at 200°C . brings about the conversion suddenly with large evolution of heat (Brodie). Red phosphorus is now an article of chemical manufacture. The phosphorus is simply heated, and kept at the requisite temperature, within a large iron pot which communicates with the atmosphere by only a narrow pipe. At a very slight expense of the material the air within the apparatus is quickly deoxygenated and converted into (inert) nitrogen. The requisite steady temperature is maintained by means of a bath of molten solder. By the mere effect of the heat the phosphorus becomes more and more viscid and darker and darker in colour, and is at last completely converted into a dark-red opaque infusible solid. This, however, always includes a small proportion of the ordinary modification, which is most readily extracted by powdering the crude product and exhausting it with bisulphide of carbon, which does not affect the red kind. A less expensive method is to boil the powdered raw product with successive quantities of caustic-soda ley, when the ordinary phosphorus only is dissolved as hypophosphite with evolution of phosphuretted hydrogen. The residue is washed and

dried and then sent out in bottles or canisters like any ordinary chemical preparation. It is not at all affected by even moist air, nor by aerated water, hence it is neither phosphorescent nor poisonous. When heated in air to about 260° C. it begins to pass into the ordinary modification and consequently burns, readily enough, into the same phosphoric acid P_2O_5 as ordinary phosphorus does. But its combustion-heat amounts to only 5070 Centigrade-units per unit-weight of fuel as against the 5953 units produced in the combustion of ordinary phosphorus. The balance of 883 units is the equivalent of the surplus of energy contained in the yellow as compared with the red modification. This accounts for the relative chemical inertness of the latter. The specific gravity of red phosphorus is 2.089 to 2.106 at 17° C.; its electric conductive power is about .000,000,1 of that of silver wire (Matthiessen). It is used in making safety-matches.

Metallic Phosphorus.—This, discovered by Hittorf, is obtained by heating ordinary phosphorus with lead in sealed-up tubes to redness for forty hours. After removal of the lead by nitric acid metallic phosphorus remains, partly in the shape of dark resplendent plates, partly in the form of microscopic rhombohedra. It requires a temperature of 358° to be converted into ordinary phosphorus-vapour. The specific gravity is 2.24 at 15° C.

Detection of Phosphorus.—The detection of (ord.) phosphorus in medico-legal cases offers no difficulty as long as the phosphorus has not disappeared, by oxidation. In the case of a mass of food or the contents of a stomach the first step is to spread out the mass on a plate and view it in the dark. A very small admixture of phosphorus becomes visible by its phosphorescence. Failing this, the mass is distilled with water from out of a glass flask connected with a glass Liebig's condenser in a dark room. The minutest trace of phosphorus suffices to impart phosphorescence to the vapours at some stage of the distillation. Should this second test fail we must search for phosphorous acid, which may be there as a product of the oxidation of phosphorus originally present as such. To test for phosphoric acid would be of no use, as salts of this acid are present in all animal and vegetable juices and tissues. Phosphorous acid, if present, can be detected by treating the mass, in a properly constructed gas-evolution apparatus, with pure hydrochloric acid and zinc. The hydrogen gas evolved must be purified by passing it over pieces of solid caustic potash, and made to stream out of a narrow platinum nozzle. If the reagents are pure and phosphorous acid is absent the gas burns with a colourless flame, which remains so even when depressed by means of a porcelain plate; in the presence of phosphorous acid the gas contains phosphuretted hydrogen, which causes the flame of the gas to exhibit a green core, at least when depressed by means of a porcelain plate. The test is very delicate, but in interpreting a positive result it must be remembered that it applies likewise to hypophosphorous acid, and that certain salts of this acid are recognized medicinal agents.

Of all phosphorus compounds ortho-phosphates are the commonest, and they can be detected by the tests given below under "Phosphates." All other phosphorus compounds, when fused with carbonate of alkali and nitre, or heated in sealed-up tubes with strong nitric acid to a sufficient temperature, are changed so that the phosphorus assumes the form of ortho-phosphoric acid, which is easily detected. Either of the two operations named (by the mere action of the alkali or of the acid *qua* acid) converts what may be present of meta-phosphoric or pyro-phosphoric into ortho-phosphoric acid.

Phosphor-Bronze.—This name has been given to a class of useful metallic substances produced by the chemical union of either pure copper or of copper alloys with phosphorus. Most commercial copper is contaminated with a small proportion of its own sub-oxide, which, in the case of an otherwise pure metal, detracts from its tenacity and plasticity; and all ordinary bronze is subject to a similar contamination, because, whatever kind of copper may have been used in making it, the tin is sure to suffer partial oxidation, and some of this oxide, as Montefiori-Levi and Künzel found, remains diffused throughout the casting, and diminishes its homogeneity and solidity. Experience shows that both in the case of copper and bronze the oxygen present as metallic oxide can be removed by introduction into the fused metal of a judiciously limited proportion of phosphorus, which takes out the oxygen (and itself) into the slag as phosphate, and thus produces a purely metallic and consequently superior metal. A small excess of phosphorus in either case effects further improvement. A phosphor-copper containing 0.1 to 0.5 per cent. of the non-metallic element has all the plasticity of the pure metal coupled with higher degrees of hardness and solidity. An alloy of from 0.5 to 2.0 per cent. gives good castings, because, unlike the pure metal, it does not form blisters on solidifying. In the case of phosphorized bronze the presence of somewhat more than 0.5 per cent. of phosphorus (in the finished alloy) produces a warmer tone of colour (more gold-like than that of the plain alloy), a finer grain (similar to that of steel), a higher degree of elasticity, and a higher breaking-strain. The latter may be more than double that of the corresponding plain bronze. By

increasing or diminishing the proportion of phosphorus the mechanical properties of a phosphor-bronze can be modified at will, within wide limits. By its fine colour and its perfect fluidity when molten it lends itself particularly well for the casting of artistic or ornamental articles. The introduction of phosphorus into the metal is best effected by fusing it with the proper proportion of a rich phosphor-copper. A phosphor-copper containing about 9 per cent. of phosphorus can be produced as follows. A kind of potential phosphorus ("phosphorus mass") is made by mixing superphosphate of lime with 20 per cent. of charcoal, and dehydrating the mixture at a dull red heat. Six hundred parts of this mass are mixed with 975 of copper-turnings and 75 of charcoal, and kept at copper-fusion heat for sixteen hours within a graphite crucible. The phosphor-copper is obtained in the form of detached granules, which are picked out, re-fused, and cast out into cast-iron moulds. Phosphor-bronze has only come to be popularly known during the last decade or two; but as early as 1848 A. & H. Parkes of Birmingham took out a patent for phosphoriferous metallic alloys.

Phosphuretted Hydrogens.—Of these three are known, namely, (1) phosphine, a gas of the composition and specific gravity PH_3 , (2) a volatile liquid of the composition and vapour-density P_2H_4 , and (3) a yellow solid of the probable composition P_2H_2 . The liquid compound (No. 2) at once takes fire when it comes into contact with air, and a small admixture of its vapour to any inflammable gas, such as coal-gas, renders the latter self-inflammable. The most important and best known of the three hydrides is phosphine, PH_3 . This gas is formed when (syrupy) phosphorous acid is heated—thus, $4PH_3O_3 = 3PH_3O_4 + PH_3$; also when phosphorus is being dissolved in hot solutions of caustic potash, soda, or baryta,

also by the action of water on the phosphides of highly basilius metals. The gas evolved by any of these processes is impure; that obtained by the second or third invariably includes vapour of P_2H_4 , and consequently is self-inflammable. Pure phosphine can be obtained only by decomposing solid iodide of phosphonium with concentrated caustic potash-ley in a suitable gas-evolution bottle previously filled with hydrogen to avoid explosions. It is a colourless gas, smelling intensely like putrid fish, and very poisonous. It is slightly soluble in water, and takes fire in air only beyond 100° C. It may be mixed with pure oxygen without change; but when the mixture is suddenly expanded it explodes violently. Notwithstanding its analogy to ammonia (NH_3), phosphine is only very feebly basic. It unites with gaseous hydriodic or hydrobromic acid into solid phosphonium salts PH_4I or Br ; but these are both decomposed by water into the respective acids and phosphine. Pure phosphine is little known; chemists are more familiar with the (impure) gas which is evolved when "phosphide of calcium" is thrown into water, and which, containing vapour of P_2H_4 , at once catches fire when it bubbles out of the water into the air, with formation of steam and a smoke of meta-phosphoric acid, which latter, in a still atmosphere, assumes the form of an exquisite vortex-ring. During the last decade or so this reaction has come to be pretty extensively utilized in navigation for producing a light on the surface of the sea at night, in case of accidents, and for other purposes. A British patent for this useful application of phosphide of calcium was granted (as No. 1828) to the agent of Silas and Pegot Ogier of Paris on the 8th of August 1859, but allowed to lapse in 1863, to be subsequently wrought by others. The manufacture of the phosphide is now (1884) being chiefly carried on by one firm (in Warrington, England), and through the courtesy of their chemist, Mr W. C. Johnston, the writer is enabled to give the following details. The preparation of the phosphide is effected within a crucible standing on a support within a furnace, and divided by a perforated false bottom into two compartments. The lower is charged with pieces of phosphorus, the upper, up to the closely-fitting lid, with fragments of quicklime. The firing is conducted so that the lime is red hot before the phosphorus, through the radiation and conduction of the heat applied above, begins to volatilize. A charge yielding 20 lb of product is finished in from five to eight hours. The reaction is very complex, but it is easy to see through its general course; part of the phosphorus deoxidizes lime with formation of P_2O_5 , which unites with other lime into phosphate, and of calcium, which combines with other phosphorus into phosphides. Of the latter, PCa seems to predominate, and consequently the product, when thrown into water, should yield chiefly the hydride P_2H_4 ; but this latter very readily breaks up into phosphine and solid hydride P_2H_2 . The crude phosphide forms a brown stone-like mass, which must at once be secured in air-tight receptacles. But most of it is immediately worked up into "lights" of various kinds, of which the "life-buoy light" may be selected as an example. It consists of a cylindrical tinued-iron box, the upper half of which is taken up by an inverted hollow box, which serves as a float when the light is in the water. The lower half contains

some 16 oz. of fragments of phosphide of calcium. Two small circular portions of the top and bottom respectively consist of soft metal (lead). These are pierced with an appended pricker before the apparatus goes overboard along with the buoy, to which it is attached by means of a cord. The water penetrates through the lower hole and the gas comes out through the upper and burns with a brilliant flame, which is from 9 to 13 inches high and lasts for about half an hour. A larger similar contrivance, intended to be accommodated within a bucket full of water on deck, serves as an inextinguishable night-signal to ships in distress. By the British Merchant Shipping Act, 1876, Vict. 21, every sea-going passenger-steamer and every emigrant-ship must be provided with arrangements for inextinguishable distress-lights and life-buoy lights. In the British navy a peculiar form of the phosphide of calcium light is used in connexion with torpedo-practice.

Phosphorus Bases.—This is a generic name for organic bases which are related to phosphine (PH_3), as the "compound ammonias" are to NH_3 . See CHEMISTRY, vol. v. p. 516 sq.; also METHYL, vol. xvi. p. 197. Tri-ethyl phosphine $\text{P}(\text{C}_2\text{H}_5)_3$, a colourless self-inflammable liquid, readily unites with bisulphide of carbon into a red crystalline compound, and consequently is available as a delicate reagent for the detection of the vapour of this compound in coal-gas.

PHOSPHATES.

"Phosphates," in chemistry, is a generic term for the salts formed by the union of the acid-anhydride P_2O_5 with bases or water or both. As explained in CHEMISTRY (vol. v. pp. 517, 518) there are three classes of phosphates customarily distinguished by the prefixes ortho, pyro, and meta. The last two nowhere occur in nature, and are hardly known to the arts; hence in this article only the ortho-compounds will be noticed, and their specific prefix will be dropped except where it is needed for definiteness. Combined phosphoric acid is universally diffused throughout the three kingdoms of nature, and (it is perhaps as well to add) to the practical, if not absolute, exclusion of all other phosphorus compounds. All organic tissues and juices contain it: of animal matters bones and blood-solids, of vegetable the seeds of cereals, may be referred to as being exceptionally rich in phosphates. Of mineral phosphates the following may be here referred to:—pyro-morphite, $3(\text{P}_2\text{O}_5 \cdot 3\text{PbO}) + \text{PbCl}_2$, where the chlorine may be replaced partially by fluorine; wavelite, $2(\text{Al}_2\text{O}_3 \cdot \text{P}_2\text{O}_5) + \text{Al}_2\text{O}_3 \cdot 3\text{H}_2\text{O} + 9\text{Aq}$ (this is a crystalline mineral; an amorphous or massive phosphate of alumina, known as "rotundominal," occurs as a large deposit on a West Indian island); vivianite, $\text{P}_2\text{O}_5 \cdot 3\text{FeO} + 8\text{H}_2\text{O}$. All these and any others that might be named are rare minerals compared with apatite and its derivatives.

Apatite.—This exists in a variety of forms, but, as long as undecomposed, always answers the formula $3(\text{P}_2\text{O}_5 \cdot 3\text{CaO}) + (\text{CaX}_2)$. In the fluor-apatites the X₂ is wholly F₂ (fluorine); in the chlor-apatites it stands for $(\text{Cl}_2, \text{F})_2$, i.e., chlorine and fluorine coming up conjointly to two equivalents. See vol. xvi. p. 407.

Phosphorite.—Phosphorite is the name given to many impure forms of amorphous or massive apatite, modified more or less by disintegration. It occurs (a) in massive, irregular, corroded-looking nodules embedded in limestone or other kinds of soft rock near Amberg (Bavaria), in Baden, Württemberg, the Weser hills, and in the Teutoburger Wald, and contains from 40 to 80 per cent. of phosphate and up to 3 per cent. of fluoride of calcium; the phosphorite nodules in the sandstone of Kursk and Voronezh, the "South Carolina phosphate," and the "Lot phosphate" belong to the same category. It is met with (b) in more or less extensive beds, as "kidneys," as stalactites, or as a connective cement in breccias; such phosphorite, of which large quantities are found in the Lahn valley, generally contains only from 25 to 60 per cent. of phosphate of lime, and includes large percentages of clay or marl, and more or less of the phosphates of iron and alumina. Another variety is (c) black phosphorite slate. A deposit containing 20 per cent. of P_2O_5 occurs in the Coal-measures of Hörde (Westphalia), also in Wales; an earthy deposit is found in the "braunkohle" of Pilgrimsreuth in the Fichtelgebirge. Phosphorite is also found (d) in veins, as a stone of very varying structure, generally intermixed with quartz,—for instance at Logrosan in Estremadura (65 to 80 per cent. of phosphate and up to 14 per cent. of fluoride of calcium), also in the Silurian slate of the Dniester.

Coprolites.—According to Buckland, coprolites are derived from the excrements of extinct animals. They consist of highly impure phosphate of lime. All native phosphate of calcium being fluoriferous, we need not wonder at the constant occurrence of traces of phosphates in the bones of vertebrate animals; the wonder is that the fluorine in these amounts to only '005 per cent.¹

Preparation.—For the preparation of phosphates the oxide P_2O_5 affords a natural starting-point. This substance is produced when phosphorus burns in an abundant supply of oxygen or air. Apparatus for the convenient execution of the process on a preparative scale are described in the handbooks of chemistry. Phosphoric anhydride forms a snow-white, loose, inodorous powder, which,

when heated in a hard glass tube to redness, sublimes slowly. It is extremely hygroscopic. When thrown into water it hisses like a red-hot iron and passes into the meta-acid, most of which, in spite of its abundant solubility, separates out as a sticky precipitate, which is rather slow in dissolving. It is the most energetic of all dehydrating agents; even sulphuric acid, when distilled with an excess of it, suffers dehydration, and passes into SO_3 . The preparation is liable to be contaminated with red phosphorus and phosphorous anhydride (P_2O_3), also with "white arsenic," because most commercial phosphorus, being made by means of pyrites-vitriol, is arseniferous. A freshly-prepared solution of the anhydride in water, being one of the meta-acid, coagulates albumen (as HNO_3 does) and gives a white precipitate with nitrate of silver. But, when the solution is allowed to stand, the dissolved meta-acid gradually passes into pyro-acid ($\text{P}_2\text{O}_5 \cdot 2\text{H}_2\text{O}$), and this latter again gradually passes into ortho-acid ($\text{P}_2\text{O}_5 \cdot 3\text{H}_2\text{O}$), the highest hydrate. At a boiling heat, especially if a little nitric acid be added, the whole of the dissolved P_2O_5 is converted into ortho-acid in the course of one or two hours. The solution then does not coagulate albumen; it gives no precipitate with nitrate of silver unless the mixture be neutralized with an alkali, when a yellow precipitate of the salt $\text{P}_2\text{O}_5 \cdot 3\text{Ag}_2\text{O}$ comes down. The aqueous ortho-acid, when evaporated at temperatures not exceeding 160°C ., and ultimately dried at this temperature, leaves its substance $\text{P}_2\text{O}_5 \cdot 3\text{H}_2\text{O}$ as a thick syrup, which, when left to itself in a dry atmosphere, slowly freezes into crystals. At 215°C . the ortho-acid loses one-third of its water and becomes pyro-acid; at a red-heat it is reduced to a "glass" of meta-acid, $\text{P}_2\text{O}_5 \cdot \text{H}_2\text{O}$, which retains its water even at the highest temperatures. The substance known in pharmacy as "acidum phosphoricum glaciale" is very impure meta-acid.

Ortho-Phosphoric Acid, H_3PO_4 .—The synthetical method described in the last paragraph is not so easy in practice as it appears on paper; hence it is generally preferred to prepare this substance by the oxidation of ordinary phosphorus with nitric acid. An acid of 1.2 specific gravity works best; weaker acid acts too slowly; if stronger it may act with dangerous violence. One part of phosphorus is placed in a large tubulated retort, connected with an ordinary globular receiver, and treated therein, at a carefully regulated heat, with ten or twelve parts of the acid. When about half the acid has distilled over, it is poured back and the operation resumed and kept on until all the phosphorus is dissolved. The excess of nitric acid is then distilled over as far as conveniently possible and thus recovered. Towards the end of the distillation a fresh gas-evolution sets in through the conversion of previously produced phosphorous acid (H_2PO_3) into phosphoric. The residual liquid in the retort is now poured out into a Berlin porcelain (or, what is better, a platinum) basin, and, if it still contains phosphorous acid, fully oxidized by evaporation with occasional addition of strong nitric acid. Phosphorous acid, if present, is easily detected by the following tests: (1) its solution, when mixed with nitrate of silver and excess of ammonia, gives a black precipitate of metallic silver; (2) when heated with a solution of corrosive sublimate, HgCl_2 it produces a white precipitate of calomel, Hg_2Cl_2 ; (3) when heated to boiling with excess of aqueous sulphurous acid it gives a precipitate of sulphur, or, if arsenious acid is present, of sulphide of arsenic. When the final oxidation is accomplished the acid needs only be freed of the remnant of nitric acid by repeated evaporation with water to be ready for use if arsenic be absent. As a rule, however, this impurity is present and must be removed by diluting the acid, passing in sulphuretted hydrogen first at 70°C ., and then in the cold, and allowing to stand for twenty-four hours, when all the arsenic is converted into sulphide, which, after elimination of the excess of sulphuretted hydrogen by continued exposure to air at a gentle heat, is filtered off. In practice, as a rule, the filtrate is being concentrated to some predetermined specific gravity and preserved as aqueous phosphoric acid, which preparation is official, and used besides for the cleansing of metallic surfaces, in lithography, and for other purposes. The British pharmacopœia prescribes for the official acid a strength corresponding to 10 per cent. of P_2O_5 .

Hager has published a complete table showing the dependence of the specific gravity, taken at $17^\circ \cdot 5^\circ \text{C}$., on the strength of the acid. From it the following is extracted.

| Spec. Grav. | Percentages of | | Spec. Grav. | Percentages of | |
|-------------|------------------------|-------------------------|-------------|------------------------|-------------------------|
| | P_2O_5 | H_3PO_4 | | P_2O_5 | H_3PO_4 |
| 1.209 | 68.0 | 93.7 | 1.271 | 26.6 | 41.3 |
| 1.267 | 60.0 | 82.7 | 1.213 | 25.0 | 34.4 |
| 1.521 | 50.0 | 63.9 | 1.169 | 20.0 | 27.6 |
| 1.448 | 45.0 | 62.0 | 1.122 | 15.0 | 20.7 |
| 1.853 | 40.0 | 55.1 | 1.079 | 10.0 | 13.8 |
| 1.325 | 35.0 | 48.2 | 1.037 | 5.0 | 6.9 |

Aqueous phosphoric acid has all the properties of a decided acid, but, for a mineral acid, the exceptional qualities of an agreeably sour taste and of non-poisonousness. Phosphoric is the only mineral acid which might be used as a condiment in place of vinegar.

¹ Some books (Nicklès) quote as high percentages as 1 or 1.5, but these are based on erroneous analyses.

or citric acid; but the writer is far from recommending the substitution. Professor Gamgee has made the very surprising discovery that meta-phosphoric and pyro-phosphoric, although so closely allied to ortho-phosphoric acid, are poisons, as phosphorous acid is.

Phosphoric acid readily combines with and neutralizes alkalis, even when these are given as carbonates. The concentrated acid, when heated in porcelain or glass, strongly attacks either material; hence its concentration ought always to be effected in platinum. In former times, when phosphorus was expensive, the acid, or rather an apology for the same, used to be prepared from bone-ash.

Alkaline Phosphates.—Of these the di-sodic salt is of the greatest practical importance. It is prepared by somewhat more than neutralizing the hot aqueous acid with carbonate of soda. A cheaper (manufacturing) process is to prepare a solution of "super-phosphate" from bone-ash by the action of vitriol; and, after elimination of the gypsum, to supersaturate the liquid with carbonate of soda and filter off the phosphate of lime produced (see p. 815 *supra*, where the process is explained indirectly). The salt, from sufficiently strong hot solutions, separates out in large transparent crystals of the composition $\text{PO}_4\text{HNa}_2 \cdot 12\text{H}_2\text{O}$, which lose their crystal-water on exposure to dry air, even at ordinary temperatures, and very quickly at 100°C . The residue, $\text{PO}_4\text{HNa}_2 = \frac{1}{2}(\text{P}_2\text{O}_5 \cdot 2\text{Na}_2\text{O} \cdot \text{H}_2\text{O})$, when heated to redness, loses its remnant of water and becomes pyro-phosphate, which latter retains its specific character on being dissolved in water. A solution of the (original) salt in water has a mild taste (hence its preferential application as a pleasant purgative); it colours red litmus-paper intensely blue, and does not act upon alkaline carbonate. But, when evaporated with the calculated proportion of carbonate of soda (Na_2CO_3 per P_2O_5) to dryness at, ultimately, a red heat, it yields a residue of tri-sodic salt (PO_4Na_3) as a white mass, infusible at the highest temperature producible within a platinum crucible over a glass blowpipe. The solution of this salt in water has all the properties of a mixed solution of $\text{PO}_4\text{Na}_2\text{H} + \text{NaOH}$; yet it is capable of depositing crystals of the composition $\text{PO}_4\text{Na}_3 \cdot 12\text{H}_2\text{O}$. The mono-sodic salt (PO_4HNa), producible by mixing together solutions containing the quantities H_3PO_4 and Na_2HPO_4 , is of no importance. Of the three *potash* salts, the mono-metallic salt (PO_4KH) is the most readily produced. It forms beautiful anhydrous quadratic crystals which at a red heat lose their H_2O and become meta-phosphate, PO_3K .

Ammonia Salts.—A strong solution of the acid, when supersaturated with ammonia, deposits on cooling crystals of the diammoniac salt $\text{PO}_4(\text{NH}_4)_2\text{H}$, liable to be contaminated with the mono-ammoniac salt. The tri-ammoniac salt is very unstable, and hardly known.

The double salt $\text{PO}_4(\text{NH}_4)\text{NaH} + 4\text{H}_2\text{O}$ was known to the alchemists as "*sal microcosmicum urinae*," and is interesting historically as having served Brand as a raw material for the making of phosphorus. It is easily prepared, either by mixing the solution of the two quantities $\text{PO}_4\text{Na}_2\text{HPO}_4$ and $\text{PO}_4(\text{NH}_4)_2\text{HPO}_4$ together and allowing to crystallize, or by dissolving the former along with NH_4Cl parts of sal-ammoniac in water, and removing the chloride of sodium produced by crystallization *in the heat*. Microcosmic salt, when heated to redness, leaves a viscid glass of meta-phosphate of soda, which dissolves all basic metallic oxides pretty much as fused borax does, with formation of glasses which often exhibit colours characteristic of the dissolved oxides. Hence its application in blowpipe analysis.

Phosphates of Lime.—The normal salt $\text{P}_2\text{O}_5 \cdot 3\text{CaO}$ or PO_4Ca_3 , where $\text{Ca} = \frac{1}{2}\text{Ca}$ = one equivalent of calcium, or perhaps a compound of it and carbonate of lime, forms the predominating component of bone-ash. A hydrate of the salt is produced by precipitating chloride of calcium solution with excess of ordinary phosphate of soda, mixed with enough of ammonia to produce (virtually) tri-alkaline salt, as a gelatinous precipitate similar in appearance and behaviour on filtration to precipitated alumina. A suspension of this precipitate in water, when mixed with a carefully adjusted quantity of hydrochloric acid, gradually passes into a mass of microscopic crystals of di-calcic salt, $\text{PO}_4\text{Ca}_2\text{H} + x\text{Aq}$, which latter is used medicinally. A solution of the di-calcic or tri-calcic salt, in the proper proportion of hot aqueous hydrochloric acid, deposits on cooling crusts of crystals of the mono-calcic salt $\text{PO}_4\text{H}_2\text{Ca}$, which is soluble in about 700 parts of cold water, but is decomposed, by hot water or by prolonged contact with a proportion of cold water insufficient to dissolve it, into free acid and a precipitate of di-calcic salt, $2\text{PO}_4\text{CaH}_2 = \text{PO}_4\text{H}_2 + \text{PO}_4\text{Ca}_2\text{H}$. A very impure form of this salt, known as "superphosphate," enters into the composition of many artificial manures. Such superphosphate is made industrially by treating broken-up bones, or powdered bone-ash, or powdered phosphorite, or coprolite, or occasionally apatite with chamber-acid, meaning vitriol of about 60 per cent., as it comes out of the chamber. The phosphate is mixed with the acid in a lead-lined trough by means of machinery, when a rather lively reaction sets in, involving the evolution of vapour of water mixed with hydrofluoric acid, and fluoride of silicon if mineral phosphate is used, possibly also with traces of fluoride or chloride of arsenic, and, in any case, with stinking volatile organic substances. The

vapour, therefore, must be removed by means of suitable draught arrangements. The mass passes from the trough into a (ventilated) chamber, where the reaction gradually accomplishes itself with ultimate formation of a porous friable mass, dry to the touch. This is superphosphate as it goes out into commerce or is used as an ingredient in making more complex manures. Its value is determined chiefly by its percentage of "soluble phosphoric acid," meaning the percentage of P_2O_5 extractable as PO_4H_2 or PO_4CaH_2 by a certain large proportion of cold water. This percentage is liable to decrease on long-continued storing, especially in the case of mineral superphosphate, through a gradual formation of (or regeneration of originally present) phosphate of iron and alumina, partly, perhaps, also through the spontaneous decomposition of some of the mono-calcic salt into insoluble di-calcic salt and free acid. The portion of the P_2O_5 which has thus become insoluble is designated "reduced" phosphoric acid. In regard to other phosphates than those named reference may be made to the handbooks of chemistry.

Analysis.—Phosphoric acid, when given in any form, *soluble in solution of ammonia*, can be detected and determined by "magnesia mixture" (a solution of chloride of magnesium and sal-ammoniac, $\text{MgCl}_2 \cdot 2\text{NH}_4\text{Cl}$, strongly alkalinized by addition of aqueous ammonia). The phosphoric acid is very gradually, but at last completely, precipitated in microscopic crystals of the salt $\text{PO}_4\text{MgNH}_4 \cdot 6\text{H}_2\text{O}$, which, though slightly soluble in water, can be washed pure, without loss, with dilute ammonia. All other acids except arsenic acid (As_2O_3)—which behaves like phosphoric, and, if present, must be removed by sulphuretted hydrogen—remain dissolved. The precipitate, when kept at a red heat, assumes the composition $\text{P}_2\text{O}_5 \cdot 2\text{MgO}$, and from the weight of the ignited precipitate that of the phosphoric acid present is easily calculated. Phosphates soluble in acids, and reprecipitated from their solutions as such by ammonia—as phosphate of lime or alumina, or ferric oxide—used to give great difficulties to the analysts until Sonnenschein founded an excellent quantitative method for their analysis upon a reaction discovered by Swanberg and Struve, which is explained under *MOLYBDENUM* (vol. xvi. p. 697). The phosphate is dissolved in nitric acid (hydrochloric is less to be recommended) and the solution mixed, and kept for some hours at 40°C , with a large excess of a solution of molybdate of ammonia in excess of nitric acid. The phosphoric acid (along with any arsenic acid that may be present) comes down as yellow crystalline phospho-molybdate of ammonia, soluble in phosphoric acid and slightly in water, but insoluble in *dilute* nitric acid in the presence of a sufficiency of nitrate of ammonia. The precipitate is soluble in aqueous ammonia, and from the solution its P_2O_5 can be precipitated by magnesia mixture as above explained. Neither of the two methods applies directly to meta-phosphates or pyrophosphates. Regarding these, see the last paragraph of the section "phosphorus" above. (W. D.)

PHOTIUS, patriarch of Constantinople from 857 to 867 and again from 877 to 886 A.D., the most eminent literary and ecclesiastical character of his age, was probably born between 820 and 825. If we could credit the assertions of his adversaries, his father, an official of the imperial court, named Sergius, was of heathen extraction, and his mother, Irene, a faithless nun. It is more certain that he displayed from an early age the most extraordinary talent and appetite for knowledge, and that, having mastered whatever Greek literature could give him (Latin and Hebrew he never acquired), he began to teach with distinguished success grammar, rhetoric, divinity, and philosophy. The way to public life was probably opened for him by the brilliant marriage of his maternal uncle to the princess Irene, sister of the empress Theodora, who, upon the death of her husband Theophilus in 842, had assumed the regency of the empire. Photius became captain of the guard and subsequently first imperial secretary. Somewhere about 850 he was entrusted with a mission to the "Assyrians," by whom the Saracens must be meant, possibly to the court of the caliph of Baghdad. Just previous to his departure on this mission he compiled his *Bibliotheca*, or *Myriobiblion*, the noblest monument of his erudition, and, from the number of classical authors whose writings it has partially preserved, by much the most important of his works.

Some time after his return from this embassy an unexpected path was opened to Photius's ambition by the dissensions between the patriarch Ignatius and Bardas, the uncle of the youthful emperor Michael III., who had succeeded to the regency on the disgrace of Theodora. Ignatius

a man of austere morals and apparently not exempt from spiritual pride, had excommunicated Bardas on the ground of an alleged incestuous connexion with his daughter-in-law. Bardas retorted by an accusation of a conspiracy. Ignatius was arrested and imprisoned (November 857), and upon his refusing to resign was illegally deposed, when Photius, receiving all the necessary sacerdotal orders within six days, was installed as patriarch in his place. This sudden elevation of a layman to the highest ecclesiastical office could not but provoke scandal, even though the laic, as was actually the case, might be the first theologian of his age. Ignatius, continuing to refuse the abdication which could alone have given it a semblance of legality, was treated with extreme severity, and a violent persecution broke out against his adherents. Photius urged clemency in his epistles to Bardas, probably with sincerity, but shrank from taking the only step which could have effectually repressed the persecution and healed the schism,—the resignation of the patriarchate. In judging his conduct, however, two circumstances have to be borne in mind,—the fact that the party of Ignatius dwindled away so rapidly as to flatter Photius with the hope of its extinction, and the espousal of his competitor's cause by Nicholas, bishop of Rome, in a manner highly offensive to the independent feeling of the Eastern Church. Photius felt himself the champion of Eastern Christianity against Latin pretensions; and, when in 863 Nicholas finally anathematized and deposed him, he replied by a counter-excommunication. He also sought to ally himself with Western bishops who had been displaced or suspended by the arrogant Nicholas, and with the latter's secular adversaries, while at the same time he was more honourably engaged in endeavours to reunite the Armenians to the Eastern Church, in combating the Paulicians, and in successful missions to the Russians and Bulgarians. While these transactions were proceeding the situation was suddenly changed by the murder of Photius's patron, Caesar Bardas, by order of the emperor Michael, who was himself assassinated by his colleague Basil in the following year (867). The fall of Photius immediately ensued, but the attendant circumstances are exceedingly obscure. According to Georgius Hamartolus, or rather his continuator, the cause was Photius's stern reproof of the crime by which Basil had obtained the throne. As the only definite testimony of any kind, this statement cannot be wholly disregarded, but it is certainly difficult to reconcile it with the general suppleness of Photius in his relations with the Byzantine court. Whatever the cause, Photius was removed from his office and banished about the end of September 867, a few days after the accession of Basil, and the deposed Ignatius, brought back from his exile, was reinstated on 23d November. The convocation of a general council followed, to give the restoration of Ignatius a character of indisputable legality. This synod, regarded by the Latins as the eighth oecumenical council, but rejected as such by the Greeks, met in October 869. The attendance of Eastern bishops was relatively very small; Photius's friends and creatures generally remained faithful to him; and the ostentatious patronage of Pope Hadrian must have been irritating to the Orientals. Photius, when brought before the assembly, maintained a dignified silence, which perplexed his accusers, but could not avert his condemnation. It seems, nevertheless, to have been generally felt that the proceedings of the council were entitled to little moral weight. The usurper, for such he unquestionably was, had successfully identified himself with the cause of his church and nation. In his captivity, which, notwithstanding his complaints, the extent of his correspondence proves to have been mild, he maintained the same unbending spirit, and rejected all overtures of compromise. About

876 he was suddenly recalled to Constantinople and entrusted with the education of Basil's children. A tale of his having regained favour by forging an illustrious genealogy for the upstart emperor may be dismissed without hesitation as an invention of his enemies. The cause was in all probability Basil's recognition of the fact that he had disgraced and banished the ablest man in his dominions, and the best qualified to fill the patriarchate upon the decease of the aged Ignatius. This event soon occurred, probably in October 877, and after a decent show of reluctance Photius again filled the patriarchal throne. According to his own account, which there seems no reason to discredit, he had become fully reconciled to his predecessor, and had shown him much kindness. Photius now proceeded to obtain the formal recognition of the Christian world. In November 879 a synod, considered by the Greeks as the eighth oecumenical council, and far more numerous attended than the one by which he had been deposed, was convened at Constantinople. The legates of Pope John VIII attended, prepared to acknowledge Photius as legitimate patriarch, a concession for which John was so much censured by Latin opinion that Baronius rather fancifully explains the legend of Pope Joan by the contempt excited by his want of spirit. John, however, was firm on the other two points which had long been contested between the Eastern and Western Churches, the ecclesiastical jurisdiction over Bulgaria and the introduction of the "filioque" clause into the creed. He disowned his legates, who had shown a tendency to yield, again excommunicated Photius, and thus kindled smouldering ill-will into the open hostility which has never been appeased to this day. Strong in the support of the council, Photius simply ignored him. He has been accused of interpolating John's letters, a charge not improbable in itself, but which can neither be proved nor disproved at this date. At the height of glory and success he was suddenly precipitated from his dignity by another palace revolution. Archbishop Theodore Santabaren, his confidant and favourite, had accused Basil's son, Leo, of a conspiracy against his father. Leo owed his liberty and eyesight to Photius's entreaties; nevertheless, on his accession in 886, he involved his benefactor in the ruin of his accuser. Arrested, degraded from the patriarchate, banished to the monastery of Bordi in Armenia, Photius, as if by magic, disappears from history. No letters of this period of his life are extant, which leads to the inference that his imprisonment was severe. The precise date of his death is not known, but it is said to have occurred on 6th February 891.

For long after Photius's death his memory was held in no special honour by his countrymen. His literary merits were obscured by the growing barbarism of the times, and the anarchy and apparent decrepitude of the Roman Church made his protest against its pretensions seem superfluous. But, when, in the crusading age, the Greek Church and state were alike in danger from Latin encroachments, Photius became a national hero, and is at present regarded as little short of a saint. To this character he has not the least pretension. Few men, it is probable, have been more atrociously calumniated; but, when every specific statement to his prejudice has been rejected, he still appears on a general review of his actions worldly, crafty, and unscrupulous. Yet, however short he may fall of the standard of an Athanasius or a Luther, he shows to no little advantage when regarded as an ecclesiastical statesman. His firmness was heroic, his sagacity profound and far-seeing; he supported good and evil fortune with equal dignity; and his fall was on both occasions due to revolutions beyond his control. If his original elevation to the patriarchate was unquestionably irregular, his re-enthronement was no less certainly legal; he began as a usurper and ended as a patriot. His zeal for the promotion of learning, education, and missions was most genuine, and fruitful in good. In erudition, literary power, and force and versatility of intellect he far surpassed every contemporary. The records of his actions are so imperfect or so prejudiced that in endeavouring to judge his personal character we have to rely principally upon the internal evidence of his own letters. With every allowance for their *ex parte* and rhetorical character and the writer's manifest desire to display

himself in the most favourable light, they nevertheless seem to afford sufficient testimony of a magnanimous spirit and a feeling heart.

The most important of the works of Photius is his renowned *Myriobiblion*, a collection of extracts from and abridgments of 280 volumes of classical authors, the originals of which are now to a great extent lost. Dictated in haste immediately before his departure on his Eastern embassy, it is open to the charges of imperfect recollection and hasty criticism, but these are as nothing in comparison with its merits. It is especially rich in extracts from historical writers. To Photius we are indebted for almost all we possess of Ctesias, Memnon, Conon, the lost books of Diodorus Siculus, and the lost writings of Arrian. Theology and ecclesiastical history are also very fully represented. The best edition is Bekker's (Berlin, 1824-25), which, however, has neither notes nor a Latin version. The next of his works in importance is the *Amphilochia*, a collection of 333 questions and answers on difficult points in Scripture, addressed to Amphilochius, archbishop of Cyzicus. This valuable work has exposed Photius to charges of plagiarism, which, as he does not claim entire originality, are wholly undeserved. The only complete edition is that published by Sophocles Economus at Athens in 1858. Photius is further

author of a *Lexicon* (London, 1822), of a *Nomocanon* or harmony of the ecclesiastical canons with the imperial edicts relating to the discipline of the church, a work of great authority, but based on the labours of his predecessors, and of numerous theological writings. The more important of these are his treatise *Against the Paulicians*, in four books, and his controversy with the Latins on the procession of the Holy Spirit. His *Epistles* are valuable from their contents, but the style is often affected or unsuitable to the subject. The most complete edition is Val'tta's (London, 1864). Many of Photius's works yet remain in manuscript. The only complete edition is Bishop Malou's in Migne's *Patrologia Græca*, and this is very imperfect and unsatisfactory.

After the allusions in his own writings the chief contemporary authority for the life of Photius is his bitter enemy Nicetas the Paphlagonian, the biographer of his rival Ignatius. In modern times his life has been written with great prejudice and animosity by Baronius, and by Weguelin in the *Memoirs of the Berlin Academy*, and more fairly by Hankins (*De Eyzantinarum Rerum Scriptibus*, pt. 1). But all previous writers are superseded by the classical work of Cardinal Hergenröther, *Photius, Patriarch von Constantinopel* (3 vols., Ratisbon, 1857-60). As a dignitary of the Roman Catholic Church Cardinal Hergenröther is inevitably biased against Photius as an ecclesiastic, but his natural candour and sympathy with intellectual eminence have made him just to the man, while his investigation of all purely historical and literary questions is industrious and exhaustive in the highest degree. (R. G.)

PHOTOGRAPHY

IT would be somewhat difficult to fix a date when what we now know as "photographic action" was first recorded. No doubt the tanning of the skin by the sun's rays was what was first noticed, and this is as truly the effect of solar radiation as is the darkening of the sensitive paper which is now in use in photographic printing operations. We may take it that Scheele, the Swedish chemist, was the first to enter upon a scientific investigation of the darkening action of sunlight on silver chloride. He found by experiment that when silver chloride was exposed to the action of light beneath water there was dissolved in the fluid a substance which, on the addition of caustic (silver nitrate), caused the precipitation of new silver chloride, and that on applying liquor ammonia to the blackened chloride an insoluble residue of metallic silver was left behind. He also noticed that of the rays of the spectrum the violet most readily blackened the silver chloride. In Scheele, then, we have the first who applied combined chemical and spectrum analysis to the science of photography. Senebier repeated Scheele's experiments, and found that in fifteen seconds the violet rays blackened silver chloride as much as the red rays did in twenty minutes.¹ About twenty years later than Scheele's experiments Count Rumford contributed a paper to the *Philosophical Transactions* of the Royal Society (1798) entitled "An inquiry concerning the chemical properties that have been attributed to light," in which he tried to demonstrate that all effects produced on metallic solutions could be brought about by a temperature somewhat less than that of boiling water. Robert Harrup in 1802, however, conclusively showed in *Nicholson's Journal* that, at all events, salts of mercury were reduced by visible radiation and not by change of temperature. In 1801 we come to the next decided step in the study of photographic action, when Ritter proved the existence of rays lying beyond the violet limit of the spectrum, and found that they had the power of blackening silver chloride. Such a discovery naturally gave a direction to the investigations of others, and Seebeck (between 1802 and 1808) and Bérard turned their attention to this particular subject, eliciting information which at the time was of a valuable nature. We need only mention two or three other cases where the influence of light was noticed at the beginning of this century. Wollaston observed the conversion of yellow gum guaiacum into a green tint by the violet rays, and the restoration of the colour by the red rays,—both of which, he it observed,

are the effect of absorption of light, the original yellow colour of the gum absorbing the violet rays, whilst the green colour to which it is changed absorbs the red rays. Davy found that puce-coloured oxide of lead, when damp, became red in the red rays, whilst it blackened in the violet rays, and that the green oxide of mercury became red in the red rays,—again an example of the necessity of absorption to effect a molecular or chemical change in a substance. Desmoutiens in 1801 observed the change effected in Prussian blue, and Böckman noted the action of the two ends of the spectrum on phosphorus, a research which, it may be mentioned, Draper extended further in America at a later date.

To England belongs the honour of first producing a Wedgwood photograph by the utilization of Scheele's observations on the chloride of silver. In June 1802 Wedgwood published in the *Journal* of the Royal Institution the paper—"An account of a method of copying paintings upon glass and of making profiles by the agency of light upon nitrate of silver, with observations by H. Davy." He remarks that white paper or white leather moistened with a solution of nitrate of silver undergoes no change when kept in a dark place, but on being exposed to the daylight it speedily changes colour, and, after passing through various shades of grey and brown, becomes at length nearly black. The alteration of colour takes place more speedily in proportion as the light is more intense.

"In the direct beam of the sun two or three minutes are sufficient to produce the full effect, in the shade several hours are required, and light transmitted through different-coloured glasses acts upon it with different degrees of intensity. Thus it is found that red rays, or the common sunbeams passed through red glass, have very little action upon it; yellow and green are more efficacious, but blue and violet light produce the most decided and powerful effects."

Wedgwood then goes on to describe the method of using this prepared paper by throwing shadows on it, and inferentially by what we now call "contact printing." He states that he has been unable to fix his prints, no washing being sufficient to eliminate the traces of the silver salt which occupied the unexposed or shaded portions. Davy in a note states that he has found that, though the images formed by an ordinary camera obscura were too faint to print out in the solar microscope, the images of small objects could easily be copied on such paper.

"In comparing the effects produced by light upon muriate of silver (silver chloride) with those upon the nitrate it seemed evident that the muriate was the most susceptible, and both were more readily acted upon when moist than when dry—a fact long ago known. Even in the twilight the colour of the moist muriate of silver, spread upon paper, slowly changed from white to faint

¹ It may here be remarked that had he used a pure spectrum he would have found that the red rays did not blacken the material in the slightest degree.

violet; though under similar circumstances no intermediate alteration was produced upon the nitrate. . . . Nothing but a method of preventing the unshaded parts of the delineations from being coloured by exposure to the day is wanting to render this process as useful as it is elegant."

In this method of preparing the paper lies the germ of the silver-printing processes which are practised at the present time (1884), and it was only by the spread of chemical knowledge that the hiatus which was to render the "process as useful as it is elegant" was filled up—when hyposulphite of soda, discovered by Chaussier in 1799, or three years before Wedgwood published his paper, was used for making the print permanent. Here we must call attention to an important observation by Dr Seebeck of Jena in 1810. In the *Farbenlehre* of Goethe he says:

"When a spectrum produced by a properly constructed prism is thrown upon moist chloride of silver paper, if the printing be continued for from fifteen to twenty minutes, whilst a constant position for the spectrum is maintained by any means, I observe the following. In the violet the chloride is a reddish brown (sometimes more violet, sometimes more blue), and this coloration extends well beyond the limit of the violet; in the blue the chloride takes a clear blue tint, which fades away, becoming lighter in the green. In the yellow I usually found the chloride unaltered; sometimes, however, it had a light yellow tint; in the red and beyond the red it took a rose or lilac tint. This image of the spectrum shows beyond the red and the violet a region more or less light and uncoloured. This is how the decomposition of the silver chloride is seen in this region. Beyond the brown band, . . . which was produced in the violet, the silver chloride was coloured a grey-violet for a distance of several inches. In proportion as the distance from the violet increased, the tint became lighter. Beyond the red, on the contrary, the chloride took a feeble red tint for a considerable distance. When moist chloride of silver, having received the action of light for a time, is exposed to the spectrum, the blue and violet behave as above. In the yellow and red regions, on the other hand, it is found that the silver chloride becomes paler; . . . the parts acted upon by the red rays and by those beyond take a light coloration."

This has been brought prominently forward by Dr J. M. Eder as being undoubtedly the first record we have of photographic action lending itself to production of natural colours, a fact which, in describing the history of photographic phenomena, has been more or less overlooked. We shall see later on that this observation of Seebeck was allowed to lie fallow for many years, until it was again taken up and published as a novelty. In photography perhaps, above all other technical applications of science, there has been a great flood of rediscovery, owing, no doubt, in the first instance to the fact that much published in one country has remained unknown in others, and also to the fact that it is difficult to boil down photographic literature and to ascertain what is really scientifically true and what is merely the result of unscientific use of the imagination. Photography has suffered greatly also from the fact that those who follow it are usually artists rather than scientific men, and fall into mistakes of theory which must of necessity lead to wrong conclusions.

The first to found a process of photography which gave pictures that were subsequently unaffected by light was Nicéphore de NIEPCE (*q.v.*). His process, which he called provisionally "héliographie, dessins, et gravures," consists in coating the surface of a metallic plate with a solution of asphaltum in oil of lavender and exposing it to a camera image. In his description he recommends that the asphaltum be powdered and the oil of lavender dropped upon it in a wine-glass, and that it be then gently heated. A polished plate is covered with this varnish, and, when dried, is ready for employment in the camera. After requisite exposure, which is very long indeed, a very faint image, requiring development, is seen. Development is effected by diluting oil of lavender with ten parts by volume of white petroleum. After this mixture has been allowed to stand two or three days it becomes free from turbidity and is ready to be used. The plate is placed in a dish

and covered with the solvent. By degrees the parts unaffected by light dissolve away, and the picture, formed of modified asphaltum, is developed. The plate is then lifted from the dish, as much as possible of the solvent being allowed to drain away. It is next placed on an inclined support and carefully freed from all the remaining solvents by washing in water. Subsequently, instead of using oil of lavender as the asphaltum solvent, Niepce employed an animal oil, which gave a deeper colour and more tenacity to the surface-film than did his original agent.

Later still, Daguerre and Niepce used as a solvent the brittle residue obtained from evaporating the essential oil of lavender dissolved in ether or alcohol,—a transparent solution of a lemon-yellow colour being formed. This solution was used for covering glass or silver plates, which, when dried, could be used in the camera. The time of exposure varied somewhat in length. Daguerre remarked that "the time required to procure a photographic copy of a landscape is from seven to eight hours, but single monuments, when strongly lighted by the sun, or which are themselves very bright, can be taken in about three hours." Perhaps there is no sentence which could be quoted that illustrates more forcibly the advance made in photography from the days when this process was described. The ratio of three hours to $\frac{1}{250}$ th of a second is a fair estimate of the progress made since Niepce. The development was conducted by means of petroleum-vapour, which dissolved the parts not acted upon by light. As a rule silver plates seem to have been used, and occasionally glass; but it does not appear whether the latter material was chosen because an image would be projected through it or whether simply for the sake of effect. Viewed in the light of present knowledge, a more perfectly developable image in half-tone would be obtained by exposing the film through the back of the glass. The action of light on most organic matter is apparently one of oxidation. In the case of asphaltum or bitumen of Judæa the oxidation causes a hardening of the material and an insolubility in the usual solvents. Hence that surface of the film is generally hardened first which first feels the influence of light. Where half-tones exist, as in a landscape picture, the film remote from the surface first receiving the image is not acted upon at all, and remains soluble in the solvent. It is thus readily seen that, in the case of half-tone pictures, or even in copying engravings, if the action were not continued sufficiently long when the surface of the film farthest from the glass was first acted upon, the layer next the glass would in some places remain soluble, and on development would be dissolved away, carrying the top layer of hardened resinous matter with it, and thus give rise to imperfect pictures. In carbon-printing development from the back of the exposed film is absolutely essential, since it depends on the same principles as does heliography, and in this the same mode of procedure is advisable. It would appear that Niepce began his researches as early as 1814, but it does not appear that he was very successful in his first endeavours: it was not till 1827 that he had any success worth recounting. At that date he communicated a paper to Dr Bauer of Kew, the secretary of the Royal Society of London, with a view to its presentation to that society. Its publication, however, was prevented because the process, of which examples were shown, was a secret one. There lies before the present writer an authentic MS. copy of Niepce's "Mémoire," dated "Kew, le 8 Décembre 1827," in which he says it will be found that "in his framed drawings made on tin the tone is too feeble, but that by the use of chemical agents the tone may be darkened." This shows that Niepce was familiar with the idea of using some darkening medium even with his photographs taken on tin plates.

Daguerreotype.—We have already noticed in the joint process of Daguerre and Niepce that polished silver plates were used, and we know from the latter that amongst the chemical agents tried iodine suggested itself. Iodine vapour or solution applied to a silvered plate would cause the formation of silver iodide on those parts not acted upon by light. The removal of the resinous picture would leave an image formed of metallic silver, whilst the black parts of the original would be represented by the darker silver iodide. This was probably the origin of the daguerreotype process. Such shrewd observers as Niepce and Daguerre, who had formed a partnership for prosecuting their researches, would not have thus formed iodide of silver without noticing that it changed in colour when exposed to the light. What parts respectively Daguerre and Niepce played in the development of the daguerreotype, which we shall shortly describe, will probably never be known with absolute accuracy, but in a letter from Dr Bauer to Dr Bennett, F.R.S., dated 7th May 1839, the former says:

"I received a very interesting letter from Mons. Isidore Niepce, dated 12th March [about a month after the publication of the daguerreotype process], and that letter fully confirms what I suspected of Daguerre's manoeuvres with poor Nicéphore, but Mr Isidore observes that for the present that letter might be considered confidential."

Dr Bauer evidently knew more of "poor Nicéphore's" work than most people, and at that early period he clearly thought that an injustice had been done to Niepce at the hands of Daguerre. It should be remarked that Nicéphore de Niepce died in 1833, and a new agreement was entered into between his son Isidore de Niepce and Daguerre to continue the prosecution of their researches. It appears further that Niepce communicated his process to Daguerre on 5th December 1829. At his death some letters from Daguerre and others were left by him in which the use of iodine, sulphur, phosphorus, &c., is mentioned as having been used on the metal plates, and their sensitiveness to light, when thus treated, commented upon. We are thus led to believe that a great part of the success in producing the daguerreotype is due to the elder Niepce; and indeed it must have been thought so at the time, since, on the publication of the process, life-pensions of 6000 francs and 4000 francs were given to Daguerre and to Isidore Niepce respectively. In point of chronology the publication of the discovery of the daguerreotype process was made subsequently to the Talbot-type process. It will, however, be convenient to continue the history of the daguerreotype, premising that it was published on 6th February 1839, whilst Talbot's process was given to the world on 25th January of the same year.

Daguerreotype pictures were originally taken on silver-plated copper, and even at the present day the silvered surface thus prepared serves better than electro-deposited silver of any thickness. An outline of the operations is as follows. A brightly-polished silver plate is cleaned by means, first of finely-powdered pumice and olive oil then of dilute nitric acid, and a soft buff is employed to give it a brilliant polish, the slightest trace of foreign matter or stain being fatal to the production of a perfect picture. The plate, thus prepared, is ready for the iodizing operation. Small fragments of iodine are scattered over a saucer, covered with gauze. Over this the plate is placed, face downwards, resting on supports, and the vapour from the iodine is allowed to form upon it a surface of silver iodide, which is the sensitive compound. It is essential to note the colour of the surface-formed iodide at its several stages, the varying colours being due to interferences caused by the different thicknesses of the minutely thin film of iodide of silver. The stage of maximum sensitiveness is obtained when it is of a golden orange colour. In this

state the plate is withdrawn and removed to the dark slide of the camera, ready for exposure. A plan frequently adopted to give an even film of iodide was to saturate a card with iodine and hold the plate a short distance above the card. Long exposures were required, varying in Paris from three to thirty minutes. The length of the exposure was evidently a matter of judgment, more particularly as over-exposure introduced an evil which was called "solarization," but which was in reality due to the oxidation of the iodide, itself altered by prolonged exposure to light. As a matter of history it may be interesting to remark that the development of the image by means of mercury-vapour is said to be due to a chance discovery of Daguerre. It appears that for some time previous to the publication of the daguerreotype method he had been experimenting with iodized silver plates, producing images by what would now be called the "printing out" process. This operation involved so long an exposure that he sought some means of reducing it by the application of different reagents. Having on one occasion exposed such a plate to a camera-image, he accidentally placed it in the dark in a cupboard containing various chemicals, and found after the lapse of a night that he had a perfect image developed. By the process of exhaustion he arrived at the fact that it was the mercury-vapour, which even at ordinary temperatures volatilizes, that had caused this intensification of the almost invisible camera-image. It was this discovery that enabled the exposures to be very considerably shortened from those which it was found necessary to give in mere camera-printing. The development of the image was effected by placing the exposed plate over a slightly heated (about 75° C.) cup of mercury. The vapour of mercury condensed on those places where the light had acted in an almost exact ratio to the intensity of its action. This produced a picture in an amalgam of mercury, the vapour of which attached itself to the altered iodide of silver. Proof that such was the case was subsequently afforded by the fact that the mercurial image could be removed by heat. The developing box was so constructed that it was possible to examine the picture through a yellow glass window whilst the image was being brought out. The next operation was to fix the picture by dipping it in a solution of hyposulphite of soda. The image produced by this method is so delicate that it will not bear the slightest handling, and has to be protected from accidental touching.

The first great improvement in the daguerreotype process was the resensitizing of the iodized film by bromine vapour. Mr Goddard published his account of the use of bromine in conjunction with iodine in 1840, and M. Claudet employed a combination of iodine and chlorine vapour in 1841. In 1844 Daguerre published his improved method of preparing the plates, which is in reality based on the use of bromine with iodine. That this addition points to additional sensitiveness will be readily understood when we remark that so-called instantaneous pictures of yachts in full sail, and of large size, have been taken on plates so prepared,—a feat which is utterly impossible with the original process as described by Daguerre. The next improvement to be noticed in the process was toning or gilding the image by a solution of gold, a practice introduced by M. Fizeau. Gold chloride is mixed with hyposulphite of soda, and the levelled plate, bearing a sufficient quantity of the fluid, is warmed by a spirit-lamp until the required vigour is given to the image, as a consequence of which it is better seen in most lights. Nearly all the daguerreotypes extant have been treated in this manner, and no doubt their permanence is in a great measure due to this operation. Images of this class can be copied by taking electrotypes from them, as shown by Grove and others. These reproductions are admirable in every way, and furnish a posi-

tive proof, if any were needed, that the daguerrean image is a relief.

Fox-Talbot Process.—In January 1839 Fox Talbot described the first of his processes, photogenic drawing, in a paper to the Royal Society. He states that he began experimenting in 1834, and that in the solar microscope he obtained an outline of the object to be depicted in full sunshine in half a second. We must turn, however, to the *Philosophical Magazine* for the account of the full details of his method, which consisted essentially in soaking paper in common salt, brushing one side only of it with about a 12 per cent. solution of silver nitrate in water, and drying at the fire. Fox Talbot stated that by repeating the alternate washes of the silver and salt—always ending, however, with the former—greater sensitiveness was attained. This is the same in every respect as the method practised by Wedgwood in 1802; but, when we come to the next process, which he called “calotype” or “beautiful picture,” we have a distinct advance. This process Talbot protected by a patent in 1841. It may be briefly described as the application of iodide of silver to a paper support. Carefully-selected paper was brushed over with a solution of silver nitrate (100 grains to the ounce of distilled water), and dried by the fire. It was then dipped into a solution of potassium iodide (500 grains being dissolved in a pint of water), where it was allowed to stay two or three minutes until silver iodide was formed. In this state the iodide is scarcely sensitive to light, but is sensitized by brushing “gallo-nitrate of silver” over the surface to which the silver nitrate had been first applied. This “gallo-nitrate” is not a chemical compound, but merely a mixture, consisting of 100 grains of silver nitrate dissolved in 2 oz. of water, to which is added one-sixth of its volume of acetic acid, and immediately before applying to the paper an equal bulk of a saturated solution of gallic acid in water. The prepared surface is then ready for exposure in the camera, and, after a short insolation in the dark, develops itself, or the development may be hastened by a fresh application of the “gallo-nitrate of silver.” The picture is then fixed by washing it in clean water and drying slightly in blotting paper, after which it is treated with a solution of potassium bromide, and again washed and dried. Here there is no mention made of hyposulphite of soda as a fixing agent, that having been first used by Sir J. Herschel in February 1840. In a strictly historical notice it ought to be mentioned that development by means of gallic acid and nitrate of silver was first known to Rev. J. B. Reade. When impressing images in the solar microscope he employed gallic acid and silver in order to render more sensitive the chloride of silver paper that he was using, and he accidentally found that the image could be developed without the aid of light. The priority of the discovery was claimed by Fox Talbot; and his claim was sustained after a lawsuit, apparently on the ground that Reade’s method had never been legally published. It would be beyond the scope of the present article to give the slight improvements which Talbot afterwards made in the process. In one of his patents he recognizes the value of the proper fixing of his photogenic drawings by the use of hyposulphite of soda, and also the production of positive prints from the calotype negatives. We pass over his application of albumen to porcelain and its subsequent treatment with iodine vapour, as also his application of albumen in which iodide of silver was held in suspension to a glass plate, since in this he was undoubtedly preceded by Niepce de St Victor in 1848.

Albumen Process on Glass.—It was a most decided step in advance when Niepce de St Victor, a nephew of Nicéphore de Niepce, employed a glass plate and coated it with iodized albumen. The originator of this method did not

meet with much success. In the hands of M. Blanquart Evrard it became more practicable; but it was carried out in its greatest perfection by M. Le Gray. The outline of the operations is as follows. The whites of five fresh eggs are mixed with about one hundred grains of potassium iodide, about twenty grains of potassium bromide, and ten grains of common salt. The mixture is beaten up into a froth with an egg-whisk or fork, and allowed to settle for twenty-four hours, when the clear liquid is decanted off. A circular pool of albumen is poured on a glass plate, and a straight ruler (its ends being wrapped with waxed paper to prevent its edge from touching the plate anywhere except at the margins) is drawn over the plate, sweeping off the excess of albumen, and so leaving an even film. The plate is first allowed to dry spontaneously, a final heating being given to it in an oven or before the fire. The heat hardens the albumen, and it becomes insoluble and ready for the nitrate of silver bath. One of the difficulties is to prevent crystallization of the salts held in solution, and this can only be effected by keeping them in defect rather than in excess. The plate is sensitized for five minutes in a bath of nitrate of silver, acidified with acetic acid, and exposed whilst still wet, or it may be slightly washed and again dried and exposed whilst in its desiccated state. The image is developed by gallic acid in the usual way. After the application of albumen many modifications were introduced in the shape of starch, serum of milk, gelatin, all of which were intended to hold iodide *in situ* on the plate; and the development in every case seems to have been by gallic acid. At one time the waxed-paper process subsequently introduced by Le Gray was a great favourite. Paper that had been made translucent by white wax was immersed in a solution of potassium iodide until impregnated with it, after which it was sensitized in the usual way, development being by gallic acid. This procedure is still followed in some meteorological observatories for obtaining transparent magnetograms, barograms, &c. Reflexion will show that in images obtained by this process the high lights are represented by metallic silver, whilst the shadows are translucent. Such a print is technically called a “negative.” When chloride of silver paper is darkened by the passage of light through a negative, we get the highest lights represented by white paper and the shadows by darkened chloride. A print of this kind is called a “positive.”

Collodion Process.—A great impetus was given to photography in 1850, rendering it easy of execution and putting it into the hands of the comparatively untrained. This was the introduction of collodion, a vehicle which up to the present day holds its own against the more rapid processes on account of the facility with which the plates are prepared, and also because it is a substance totally unaffected by silver nitrate, which is not the case when any organic substance is employed, and, it may be said, inorganic as well in many instances. Thus albumen forms a definite silver compound, as do gelatin, starch, and gum. The employment of collodion for use in photography was first suggested by Le Gray, who has been already mentioned in connexion with the albumen process. He does not appear to have gone beyond suggestion, and it remained for Archer of London, closely followed by Fry, to make a really practical use of the discovery. Collodion is a solution of cotton or cellulose in which some atoms of its hydrogen have been replaced by NO_2 by treatment with a more or less dilute mixture of sulphuric and nitric acids. The action of the sulphuric acid is to take up the molecules of water formed by elimination of the hydrogen from the cotton, which combines with oxygen from the nitric acid, the latter acid supplying the cotton with NO_2 . According to the temperature of the acids and

their dilution a tri-nitro or di-nitro cellulose is said to be formed, one of which is the explosive gun-cotton, insoluble in ether and alcohol, whilst the other, though inflammable, is readily soluble in a mixture of these two solvents. When collodion is poured on a glass plate it leaves on drying a hard transparent film which under the microscope is slightly reticulated. Before drying, the film is gelatinous and perfectly adapted for holding *in situ* salts soluble in ether and alcohol. Where such salts are present they crystallize out when the film is dried, hence such a film is only suitable where the plates are ready to be immersed in the silver bath. As a rule, about five grains of the soluble cotton are dissolved in an ounce of a mixture of equal parts of ether and alcohol, both of which must be of low specific gravity, .725 and .805 respectively. If the alcohol or ether be much diluted with water the cotton (pyroxylin) precipitates, but, even if less diluted, it forms a film which is "crapey" and uneven. Such was the material with which Le Gray proposed to work, and which Archer actually brought into practical use. The opaque silver plate with its one impression was abandoned; and the paper support of Talbot, with its inequalities of grain and thickness, followed suit, though not immediately. When once a fine negative had been obtained with collodion on a glass plate—the image showing high lights by almost complete opacity and the shadows by transparency (as was the case, too, in the calotype process)—any number of impressions could be obtained by means of the silver-printing process introduced by Fox Talbot, and they were found to possess a delicacy and refinement of detail that certainly eclipsed the finest print obtained from a calotype negative. To any one who had practised the somewhat tedious calotype process, or the waxed-paper process of Le Gray with its still longer preparation and development, the advent of the collodion method must have been extremely welcome, since it effected a saving in time, money, and uncertainty. The rapidity of photographic action, was much increased, and the production of pictures became possible to hundreds who previously had been excluded from this art-science by force of circumstances. We can merely give an outline of the procedure, referring the reader for further information to the manuals of photography. A glass plate is carefully cleaned by the application of a detergent such as a cream of tripoli powder or spirits of wine (to which a little ammonia is often added), then wiped with a soft rag, and finally polished with a silk handkerchief or chamois leather previously freed from grease. A collodion containing soluble iodides and bromides is made to flow over the plate, all excess being drained off when it is covered. A good standard formula for the collodion may be taken to be as follows,—55 grains of pyroxylin, 5 oz. of alcohol, 5 oz. of ether; and in this liquid are dissolved $2\frac{1}{2}$ grains of ammonium iodide, 2 grains of cadmium iodide, and 2 grains of cadmium bromide. When the collodion is set, *i.e.*, when it is in a gelatinous condition, the plate is immersed in a bath of nitrate of silver—a vertical form being that mostly used in Britain, whilst a horizontal dish is used on the Continent—a good formula for which is 350 grains of silver nitrate with 10 oz. of water. The plate is steadily lowered into this solution without pause, and moved in it until all the repellent action between the aqueous solution of the silver and the solvents of the collodion is removed, when it is allowed to rest for a couple of minutes, after which period it is taken out and placed in the dark slide ready for exposure in the camera. After undergoing proper exposure the plate is withdrawn, and in a room lighted with yellow light the developing solution is applied, which originally was a solution of pyrogallie acid in water restrained in its action by the addition of acetic acid. One of the old formulae

employed by Delamotte was 9 grains of pyrogallie acid, 2 drachms of glacial acetic acid, and 3 oz. of water. The image gradually appears after the application of this solution, building itself up from the silver nitrate clinging to the film, which is reduced to the metallic state by degrees. Should the density be insufficient a few drops of nitrate of silver are added to the pyrogallie-acid solution and the developing action continued.

In 1844 Hunt introduced another reducing agent, which has continued to be the favourite down to the present time, *viz.*, ferrous sulphate. By its use the time of necessary exposure of the plate is reduced, and the image develops with great rapidity. A sample of this developing solution is 20 grains of ferrous sulphate, 20 minims of acetic acid, with 1 oz. of water. This often leaves the image thinner than is requisite for the formation of a good print, and it is intensified with pyrogallie acid and silver. There are other intensifiers used to increase the deposit on a plate by means of mercury or uranium, followed by other solutions to still further darken the double salts formed on the film; but into these it is not necessary to enter here. Such intensifying agents have to be applied to the image after the plate is fixed, which is done by a concentrated solution of hyposulphite of soda or by cyanide of potassium, the latter salt having been first introduced by Martin and Gaudin in 1853 (*La Lumière*, 23d April 1853). Twenty-five grains of cyanide of potassium to one ounce of water is the strength of the solution usually employed. The reaction of both these fixing agents is to form with the sensitive salts of silver double hyposulphites or cyanides, which are soluble in water, not, as is often considered to be the case, to merely dissolve the silver salt itself. It may be well to remark that the utility of bromides in the collodion process seems to have been recognized in its earliest days, Archer (1852) and Bingham (1850, both mentioning it. We notice this, since as late as the year 1866 a patent-right in its use was sought to be enforced in America, the patent being taken out by James Cutting in July 1854.

Positive Pictures by the Collodion Process.—In the infancy of the collodion process it was shown by Mr Horne that a negative image could be made to assume the appearance of a positive by whitening the metallic silver deposit. This he effected by using with the pyrogallie acid developer a small quantity of nitric acid. A better result was obtained by Mr Fry with ferrous sulphate and ferrous nitrate, whilst Dr Diamond gave effect to the matter in a practical way. Mr Archer used mercuric chloride to whiten the image. To Mr Hunt, however, must be awarded the credit of noticing the action of this salt on the image, in his paper in the *Philosophical Transactions* of 1843. The whitened picture may be made to stand out against black velvet, or black varnish may be poured over the film to give the necessary black background, or, as has been done more recently, the positive pictures may be produced on japanned iron plates (ferrotype plates) or on japanned leather. This process is still practised by some photographers, and from the number of ferrotype plates sold the number of portraits taken by it must be still very large.

Moist Collodion Process.—From what has been stated above it will be seen that for the successful working of the collodion process it was necessary that the plate should be exposed very shortly after its preparation; this was a drawback, inasmuch as it necessitated taking a heavy equipment into the field. In May 1851 Messrs Spiller and Crookes published in the *Philosophical Magazine* a process whereby they were enabled to keep a film moist (so as to prevent crystallization of the silver nitrate) several days, enabling plates to be prepared at home, exposed in the field, and then developed in the dark room. The plate

was prepared in the usual way and a solution of zinc nitrate and silver nitrate in water was made to flow over it. The hygroscopic nature of the zinc salt kept sufficient moisture on the plate to attain the desired end. Various modifications in procedure have been made since, but it is scarcely necessary to record them here; for details the reader may consult the volumes of the *Photographic Journal*, 1854-55.

Dry Plates.—It would appear that the first experiments with collodion dry plates were due to M. Gaudin. In *La Lumière* of 22d April and 27th May 1854 he describes his researches on the question; whilst in England Mr G. R. Muirhead, on the 4th August 1854, stated that light acts almost as energetically on a dry surface as on a wet after all the silver has been washed away from the former previous to desiccation. Dr Taupenot, however, seems to have been the first to use a dry-plate process that was really workable. His original plan was to coat a plate with collodion, sensitize it in the ordinary manner, wash it, cause a solution of albumen to flow over the surface, dry it, dip it in a bath of silver nitrate, acidified with acetic acid, and wash and dry it again. The plate was then in a condition to be exposed, and was to be developed with pyrogallie acid and silver. In this method we have a double manipulation, which is long in execution, though perfectly effective, as we know from experience.

Alkaline
develop-
oper.

A great advance was made in all dry-plate processes by the introduction of what is known as the "alkaline developer," which is, however, inapplicable to all plates on which silver nitrate is present in the free state. It will be remembered that the developers previously described, either for collodion or paper processes, were dependent on the reduction of metallic silver by some such agent as ferrous sulphate, the reduction taking place gradually and the reduced particles aggregating on those portions of the film which had been acted upon by light. The action of light being to reduce the silver iodide, bromide, or chloride to the state of sub-salts (e.g., sub-iodide of silver), these reduced particles really acted as nuclei for the crystallized metal. It will be evident that in such a method of development the molecular attraction acts at distances relatively great compared with the diameters of the molecules themselves. If it were possible to reduce the altered particles it was plain that development would be more rapid, and also that the number of molecules reduced by light would be smaller if the metallic silver could be derived from silver compounds within shorter distances of the centres of molecular attraction. Alkaline development accomplished this to a very remarkable extent; but the method is only really practicable when applied to films containing bromide and chloride of silver, as iodide is only slightly amenable to the alkaline body. We have not been able to trace the exact date of the introduction of this developer. It is believed to be of American origin; and it is known that in the year 1862 Major Russell used it with the dry plates he introduced. An alkaline developer consists of an alkali, a reducing agent, and a restraining agent. These bodies, when combined and applied to the solid bromide or chloride of silver, after being acted upon by light, as when a plate was exposed to the camera image, were able to reduce the sub-bromide or sub-chloride, and to build up an image upon it, leaving the unaltered bromide intact, except so far as it was used in the building up. In 1877 Abney investigated this action and was able to demonstrate what actually occurred during the development. One of the experiments will show on what grounds this conclusion was arrived at. A dry plate was prepared by the bath process in the usual manner (to be described below), and exposed in the camera. The exposed film was covered with another film of collodion-bromide emulsion, which of course had not seen the light.

An image was obtained from the double film by means of the developer, which penetrated through the upper unexposed film, and the development was prolonged until an image appeared through the same film, when the plate was fixed, washed, and dried. A piece of gelatinous paper was cemented on the upper film, and a similar piece on the lower after both had been stripped off the glass. When quite dry the two papers were forcibly separated, a film adhering to each. The upper film, *although never exposed to light*, showed an image in some cases more intense than the under film. The action of the alkaline developer was here manifest: the bromide of silver in close contiguity to the exposed particles was reduced to the metallic state. Hence, from this and similar experiments Abney was able to announce that silver bromide could not exist in the presence of freshly precipitated or reduced metallic silver, and that a sub-bromide was immediately formed. Thus $\text{Ag}_2\text{Br}_2 + \text{Ag}_2 = 2\text{Ag}_2\text{Br}$. From this it will be seen that the deposited silver is well within the sphere of molecular attraction, and that consequently a less exposure (i.e., the reduction of fewer molecules of the sensitive salt) would give a developable image.

The alkalis used embraced the alkalis themselves and the mono-carbonates. The sole reducing agent up till recent times was pyrogallie acid. In the year 1880 Abney found that hydrokinone was even more effective than pyrogallie acid, its reducing power being stronger. Various other experimentalists tried other kindred substances, but without adding to the list of really useful agents. In 1884, however, Herr Egli and Arnold Spiller brought out hydroxylamin as a reducing agent, which promises to be of great use if it can be prepared cheaply enough.

Another set of developers for dry plates dependent on the reduction of the silver bromide and the metallic state is founded on the fact that certain organic salts of iron can be utilized. In 1877 Mr Carey Lea of Philadelphia and Mr William Willis announced almost simultaneously that a solution of ferrous oxalate in neutral potassium oxalate was effective as a developer, and from that time it has been universally acknowledged as a useful agent in that capacity; and it is a rare favourite, more especially amongst Continental photographers. In 1881 Abney showed that the addition of a small quantity of sodium hyposulphite very greatly increased its rapidity of action by reducing the time of exposure necessary to get a developable image. In 1882 Dr Eder demonstrated that gelatin chloride of silver plates could be developed with ferrous citrate, which could not be so readily accomplished with ferrous oxalate. The exposure for chloride plates when developed by the latter was extremely prolonged. In the same year Abney showed that if ferrous oxalate were dissolved in potassium citrate a much more powerful agent was formed, which allowed not only gelatino-chloride plates to be readily developed but also collodio-chloride plates. These, it may be said, were undevelopable except by the precipitation method until the advent of the agents last-mentioned; the chloride being as readily reduced as the sub-chloride rendered the development of an image impracticable.

Amongst the components of an alkaline developer we mentioned a restrainer. This factor, generally a bromide or chloride of an alkali, serves probably to form a compound with the silver salt which has not been acted upon by light, and which is less easily reduced than is the silver salt alone,—the altered particles being left intact. The action of the restrainer is regarded by some as due to its combination with the alkali. But whichever theory is correct the fact remains that the restrainer does make the primitive salt less amenable to reduction. Such restrainers as the bromides of the alkalis act through chemical means; but there are others which act through physical means, an

Other
dry-plate
develop-
opers.

example of which we have in the preparation of a gelatin plate. In this case the gelatin wraps up the particles of the silver compound in a colloidal sheath, as it were, and the developing solution only gets at them in a very gradual manner, for the natural tendency of all such reducing agents is to attack the particles on which least work has to be expended. In the case of bromide of silver the developer has only to remove one atom of bromine, whereas it has to remove two in the case of sub-bromide of silver. The sub-bromide formed by light and that subsequently produced in the act of development are therefore reduced. A large proportion of gelatin compared with the silver salt in a film enables an alkaline developer to be used without any chemical restrainer; but when the gelatin bears a small proportion to the silver such a restrainer has to be used. With collodion films the particles of bromide are more or less unenveloped, and hence in this case some kind of chemical restrainer is absolutely necessary. We may say that the organic iron developers require less restraining in their action than do the alkaline developers.

Alkaline development was first used by Major Russell in a dry-plate process in which the collodion was merely bromized by means of bromides soluble in alcohol. The plate was prepared by immersion in a strong solution of silver nitrate and then washed and a preservative applied. The last-named agent executes two functions, one being to absorb the halogen liberated by the action of light and the other to preserve the film from atmospheric action. Tannin, which Major Russell employed, if we mistake not, is a good absorbent of the halogens, and acts as a varnish to the film. Other collodion dry-plate processes carried out by means of the silver-nitrate bath were very numerous at one time, many different organic bodies being also employed. In most cases ordinary iodized collodion was made use of, a small percentage of soluble bromide being as a rule added to it. When plates were developed by the alkaline method this extra bromide induced density, since it was the silver bromide alone which was amenable to it, the iodide being almost entirely unaffected by the weak developer which was at that time in general use.

One of the most successful bath dry-plate processes was introduced by Mr. R. Manners Gordon and was a really beautiful process. The plate was given an edging of albumen and then coated with ordinary iodized collodion to which one grain per ounce of cadmium bromide had been added. It was kept in the silver-nitrate bath for ten minutes, after which it was washed thoroughly. The following preservative was then applied:—

| | | |
|----|-------------------|---------|
| 1. | Gum arabic | 20 grs. |
| | Sugar candy | 5 " |
| | Water | 6 dr. |
| 2. | Gallic acid | 3 grs. |
| | Water | 2 dr. |

These ingredients were mixed just before use and, after filtering, applied for one minute to the plate, which was allowed to drain and set up to dry naturally. Great latitude is admissible in the exposure; it should rarely be less than four times or more than twenty times that which would be required for a wet plate under ordinary circumstances. The image may be developed with ferrous sulphate restrained by a solution of gelatin and glacial acetic acid, to which a solution of silver nitrate is added just before application, or by the following alkaline developer:—

| | | |
|----|--------------------------|---------|
| 1. | Pyrogallie acid | 96 grs. |
| | Alcohol | 1 oz. |
| 2. | Potassium bromide | 12 grs. |
| | Water | 1 oz. |
| 3. | Ammonium carbonate | 80 grs. |
| | Water | 1 oz. |

The development of the image requires 6 minims of No. 1, $\frac{1}{2}$ drachm of No. 2, with 3 drachms of No. 3. If properly

exposed the image appears rapidly and gradually gains in intensity, and when all action from the developer ceases the plate is washed and further intensified with pyrogallie acid and silver as is a wet plate. The image is finally fixed in sodium hyposulphite.

In photographic processes not only has the chemical condition of the film to be taken into account but also the optical. When light falls on a semi-opaque or translucent film it is scattered by the particles in it and passes through the glass plate to the back. Here the rays are partly transmitted and partly reflected, a very small quantity of them being absorbed by the material of the glass. Theory points out that the strongest reflexion from the back of the glass should take place at the vertical angle. In 1875 Abney investigated the subject and proved that practice agreed with theory in every respect, and that the image of a point of light in development on a plate was surrounded by a ring of reduced silver caused by the reflexion of the scattered light from the back surface of the glass, and that this ring was shaded inwards and outwards in such a manner that the shading varied with the intensity of the light reflected at different angles. To avoid "halation," as this phenomenon is called, it was usual for photographers to cover the back of their dry plates with some material which should be in optical contact with it, and which at the same time should absorb all the photographically active rays, and only replace those which were incapable of reducing the silver salt. This was called "backing a plate."

Collodion Emulsion Processes.—In 1864 Bolton and Sayce published the germ of a process which revolutionized photographic manipulations, and by a subsequent substitution of gelatin for collodion gave an impetus to photography which has carried it to that state of perfection at which it has arrived at the present time (1884). In the ordinary collodion process it will be recollected that a sensitive film is procured by coating a glass plate with collodion containing the iodide and bromide of some soluble salt, and then, when set, immersing it in a solution of silver nitrate in order to form iodide and bromide of silver in the film. The question that presented itself to Bolton and Sayce was whether it might not be possible to get the sensitive salts of silver formed in the collodion whilst liquid, and a sensitive film given to a plate by merely letting this collodion, containing the salts in suspension, flow over the glass plate. Gaudin had attempted to do this with chloride of silver, and later G. W. Simpson had succeeded in perfecting a printing process with collodion containing chloride of silver, citric acid, and nitrate of silver; but the chloride until recently has been considered a slow working salt, and nearly incapable of development. Up to the time of Bolton and Sayce's experiments iodide of silver had been considered the staple of a sensitive film; and, though bromide had been used by Major Russell and others, it had not met with so much favour as to lead to the omission of the iodide. At the date mentioned the suspension of iodide of silver in collodion was not thought practicable, and the inventors of the process turned their attention to bromide of silver, which they found could be secured in such a fine state of division that it remained suspended for a considerable time in collodion, and even when precipitated could be resuspended by simple agitation. The outline of the method was to dissolve a soluble bromide in plain collodion, and add to it drop by drop an alcoholic solution of silver nitrate, the latter being in excess or defect according to the will of the operator. To prepare a sensitive surface the collodion containing the emulsified sensitive salt was poured over a glass plate, allowed to set, and washed till all the soluble salts resulting from the double decomposition of the soluble bromide and the silver nitrate, together with the unaltered soluble

bromide or silver nitrate, were removed, when the film was exposed wet, or allowed to dry and then exposed. The rapidity of these plates was not in any way remarkable, but the process had the great advantage of doing away with the sensitizing nitrate of silver bath, and thus avoiding a tiresome operation. The plates were developed by the alkaline method, and gave images which, if not primarily dense enough, could be intensified by the application of pyrogallie acid and silver nitrate as in the wet collodion process. Such was the crude germ of a method which was destined to effect a complete change in the aspect of photographic negative taking;¹ but for some time it lay dormant. In fact there was at first much to discourage trial of it, since the plates often became veiled on development. Mr Carey Lea of Philadelphia, and Mr W. Cooper, jun., of Reading, may be said to have given the real impetus to the method. Mr. Carey Lea, by introducing an acid into the emulsion, established a practicable collodion emulsion process, which was rapid and at the same time gave negative pictures free from veil. To secure the rapidity Carey Lea employed a fair excess of silver nitrate, and Colonel Wortley gained further rapidity by a still greater increase of it; the free use of acid was the only means by which this could be effected without hopelessly spoiling the emulsion. It may be well to mention that the effect of the addition of the mineral acids such as Carey Lea employed is to prevent the formation of (or to destroy when formed) any sub-bromide or oxide of silver, either of which acts as a nucleus on which development can take place. Captain Abney first showed the theoretical effect of acids on the sub-bromide, as also the effect of oxidizing agents on both the above compounds (see below). A more valuable modification was introduced in 1874 by Mr W. B. Bolton, one of the originators of the process, who allowed the ether and the alcohol of the collodion to evaporate, and then washed away all the soluble salts from the gelatinous mass formed of pyroxylin and sensitive salt. After washing for a considerable time, the pellicle was dried naturally or washed with alcohol, and then the pyroxylin redissolved in ether and alcohol, leaving an emulsion of silver bromide, silver chloride, or silver iodide, or mixtures of all suspended in collodion. In this state the plate could be coated and dried at once for exposure. Sometimes, in fact generally, preservatives were used, as in the case of dry plates with the bath, in order to prevent the atmosphere from rendering the surface of the film spotty or insensitive on development. This modification had the great advantage of allowing a large quantity of sensitive salt to be prepared of precisely the same value as to rapidity of action and quality of film. A great advance in the use of the collodion bromide process was made by Colonel Stuart Wortley, who in June 1873 made known the powerful nature of a *strongly* alkaline developer as opposed to the weak one which up to that time had usually been employed. The brief exposure necessary for a collodion emulsion plate, or indeed any dry plate, had not been recognized till the introduction of this developer. This at once placed in the hands of photographers an instrument which by judicious use enabled them to shorten the time of exposure of their plates and to render possible effects which had before been considered out of the question. As an example of the preparation of a collodion emulsion and the developer usually employed with it we give the following,—2½ oz. of alcohol, 5 oz. of ether, 75 grains of pyroxylin. In 1 oz. of alcohol are dissolved 200 grains of zinc bromide;² it is then acidulated with 4 or 5 drops

of nitric acid, and added to half the above collodion. In 2 drachms of water are dissolved 330 grains of silver nitrate, 1 oz. of alcohol being added. The silvered alcohol is next poured into the other half of the collodion and the brominized collodion dropped in, care being taken to shake between the operations. An emulsion of bromide of silver is formed in suspension; and it is in every case left for 10 to 20 hours to what is technically called "ripen," or, in other words, to become creamy when poured out upon a glass plate. When the emulsion has ripened it may be used at once or be poured out into a flat dish and the solvents allowed to evaporate till the pyroxylin becomes gelatinous. In this state it is washed in water till all the soluble salts are carried away. After this it may be either spread out on a cloth and dried or treated with two or three doses of alcohol, and then redissolved in equal parts of alcohol (specific gravity, '805) and ether (specific gravity, 720). In this condition it is a washed emulsion, and a glass plate can be coated with it and the film dried, or it may be washed and a preservative applied. An excellent preservative introduced by Colonel Stuart Wortley is as follows:—

1. Salycin, a saturated solution in water.
2. { Tannin 60 grs.
Distilled water 1 oz.
3. { Gallic acid 48 grs.
Water 1 oz.

To make the preservative, take 2 oz. of No. 1, 1 oz. of No. 2, ½ oz. of No. 3, 40 grains of sugar, and 7 oz. of water. The plates are immersed in this solution and dried. It is often necessary to give the plate a previous coating with very dilute albumen or gelatin in order to make the film of collodion adhere during development, which can be effected by the strong alkaline developer, or by the ferrous oxalate developer, previously noticed.

The type of a useful alkaline developer is as follows:—

1. { Pyrogallie acid 96 grs.
Alcohol 1 oz.
2. { Potassium bromide 12 grs.
Water distilled 1 oz.
3. { Ammonium carbonato 80 grs.
Water 1 oz.

To develop the plate 6 minims of No. 1, ½ drachm of No. 2, and 3 drachms of No. 3 are mixed together and made to flow over the plate after washing the preservative off under the tap. Sometimes the development is conducted in a flat dish, sometimes the solution is poured on the plate.³ The unreduced salts are eliminated by either cyanide of potassium or sodium hyposulphite. Intensity may be given to the image, if requisite, either before or after the "fixing" operation. Where resort is had to ferrous oxalate development, the developer is made in one of two ways—(1) by saturating a saturated solution of neutral potassium oxalate with ferrous oxalate, and adding an equal volume of a solution (10 grains to 1 oz. of water) of potassium bromide to restrain the action, or (2) by mixing, according to Eder's plan, 3 volumes by measure of a saturated solution of the potassium oxalate with 1 volume by measure of a saturated solution of ferrous sulphate, and adding to the ferrous oxalate solution thus obtained an equal bulk of the above solution of potassium bromide. The development is conducted in precisely the same manner as indicated above, and the image is fixed by one of the same agents.

Gelatin Emulsion Process.—The facility with which collodion emulsion plates could be prepared had turned all investigation into this channel, and collodion was not the only vehicle that was tried for holding the sensitive salts in suspension. As early as September 1871 Dr R. L.

¹ An account of Mr Sayce's process is to be found in the *Photographic News* of October 1865, or the *Photographic Journal* of the same date.

² The advantages of this salt were pointed out by Mr. Warnerke in 1875.

³ For further details the reader is referred to *Instruction in Photography*, p. 99.

Maddox had tried emulsifying the silver salt in gelatin, and had produced negatives of rare excellence, as the present writer can testify from personal knowledge. In November 1873 Mr King described a similar process, getting rid of the soluble salts by washing. Efforts had also been made in this direction by Mr Burgess in July 1873. Mr R. Kennett in 1874 may be said to have been the first to put forward the gelatin emulsion process in a practical and workable form, as he then published a formula which gave good and quick results. It was not till 1878, however, that the great capabilities of silver bromide when held in suspension by gelatin were fairly known; in March of that year Mr C. Bennett showed that by keeping the gelatin solution liquid at a low temperature for as long as seven days extraordinary rapidity was conferred on the sensitive salt. The molecular condition of the silver bromide seemed to be altered, and to be amenable to a far more powerful developer than had hitherto been dreamt of. In 1874 the Belgian chemist Stas had shown that various modifications of silver bromide and chloride were possible, and it seemed that the green molecular condition (one of those noted by Stas) of the bromide was attained by prolonged warming. It may in truth be said that the starting-point of rapid plates was 1878, and that the full credit of this discovery should be allotted to Mr C. Bennett. Both Kennett and Bennett got rid of the soluble salts from the emulsion by washing; and in order to attain success it was requisite that the bromide should be in excess of that necessary to combine with the silver nitrate used to form the emulsion. In June 1879 Abney showed that a good emulsion might be formed by precipitating a silver bromide by dropping a solution of a soluble bromide into a dilute solution of silver nitrate. The supernatant liquid was decanted, and after two or three washings with water the precipitate was mixed with the proper amount of gelatin. Dr van Monckhoven of Ghent, in experimenting with this process, hit upon the plan of obtaining the emulsion by splitting up silver carbonate with hydrobromic acid, leaving no soluble salts to be extracted. He further, in August 1879, announced that he had obtained great rapidity by adding to the bromide emulsion a certain quantity of ammonia. This addition rapidly altered the bromide of silver from its ordinary state to the green molecular condition referred to above. At this point we have the branching off of the gelatin emulsion process into two great divisions, viz., that in which rapidity was gained by long-continued heating, and the other in which it was gained by the use of ammonia—a subdivision which is maintained to the present day. Photographers' opinions as to the respective merits of the two methods are much divided, some maintaining that the quality of the heated emulsion is better than that produced by alkalinity, and *vice versa*. We may mention that in 1881 Dr Herschell introduced a plan for making an alcoholic gelatin emulsion with the idea of inducing rapid drying of the plates, and in the same year Dr H. Vogel of Berlin brought forward his ideas for combining gelatin and pyroxylin together by means of a solvent which acted on the gelatin and allowed the addition of alcohol in order to dissolve the pyroxylin. This method was called "collodio-gelatin emulsion," and apparently was only a shortlived process, which is not surprising, since its preparation involved the inhalation of the fumes of acetic acid.

The warming process introduced by Bennett was soon superseded. Colonel Stuart Wortley in 1879 announced that, by raising the temperature of the vessel in which the emulsion was stewed to 150° Fahr., instead of days being required to give the desired sensibility only a few hours were necessary. A further advance was made by boiling the emulsion, first practised, we believe, by Mr Mansfield

in 1879. Another improvement was effected by Mr W. B. Bolton by emulsifying the silver salt in a small quantity of gelatin and then raising the emulsion to boiling point, boiling it for from half an hour to an hour, when extreme rapidity was attained. It would be impossible to enumerate many minor improvements in this process that have from time to time been made; it is sufficient to have stated in historical sequence the different important stages through which it has passed. It may be useful to give an idea of the relative rapidities of the various processes we have described.

| | |
|---------------------------------|--------------------------|
| Daguerreotype, originally | half an hour's exposure. |
| Calotype | 2 or 3 minutes' " |
| Collodion | 10 seconds' " |
| Collodion emulsion | 15 seconds' " |
| Rapid gelatin emulsion | 1/10th second " |

By this it will be seen what advances have been made in the art of photography during the forty-five years of its existence.

The following is an outline of two representative processes. All Gelatin operations should be conducted in light which can act but very emulsifyingly on the sensitive salts employed, and this is more necessary now, with this process than with others on account of the extreme ease with which the equilibrium of the molecules is upset in giving rise to the molecule which is developable. The light to work with, and which is safe, is gaslight or candlelight passing through a sheet of Chance's stained red glass backed by orange paper. Stained red glass allows but few chemically effective rays to pass through it, whilst the orange paper diffuses the light. If daylight be employed, it is as well to have a double thickness of orange paper. The following should be weighed out:—

| | |
|---|--------|
| 1. Potassium iodide | 5 gra/ |
| 2. Potassium bromide | 135 " |
| 3. Nelson's No. 1 photographic gelatin | 30 " |
| 4. Silver nitrate | 175 " |
| 5. { Autotype or other hard gelatin.....100 " | |
| { Nelson's No. 1 gelatin | 100 " |

Nos. 3 and 5 are rapidly covered with water or washed for a few seconds under the tap to get rid of any adherent dust. No. 2 is dissolved in 1½ oz. of water, and a little tincture of iodine added till it assumes a light sherry colour. No. 1 is dissolved in 60 minims of water. No. 4 is dissolved in ½ oz. of water, and No. 3 is allowed to swell up in 1 oz. of water, and is then dissolved by heat. All the flasks containing these solutions are placed in water at 150° Fahr. and carried into the "dark room," as the orange-lighted chamber is ordinarily called; Nos. 3 and 4 are then mixed together in a jar or flask, and No. 2 added drop by drop till half its bulk is gone, when No. 1 is added to the remainder, and the double solution is dropped in as before. When all is added there ought to be formed an emulsion which is very ruddy when examined by gaslight, or orange by daylight. The flask containing the emulsion is next placed in boiling water, which is kept in a state of ebullition for about three-quarters of an hour. It is then ready, when the contents of the flask have cooled down to about 100° Fahr., for the addition of No. 5, which should in the interval be placed in 2 oz. of water to swell and finally be dissolved. The gelatin emulsion thus formed is placed in a cool place to set, after which it is turned into a piece of coarse canvas or mosquito-netting made into a bag. By squeezing, threads of gelatin containing the sensitive salt can be made to fall into cold water; by this means the soluble salts are extracted. This is readily done in two or three hours by frequently changing the water, or by allowing running water to flow over the emulsion-threads. The gelatin is next drained by straining canvas over a jar and turning out the threads on to it, after which it is placed in a flask, and warmed till it dissolves, half an ounce of alcohol being added. Finally, it is filtered through chamois leather or swansdown calico. In this state it is ready for the plates.

The other method of forming the emulsion is with ammonia. The same quantities as before are weighed out, but the solutions of Nos. 2 and 3 are first mixed together and No. 4 is dissolved in 1 oz. of water, and strong ammonia of specific gravity '880 added to it till the oxide first precipitated is just redissolved. This ammoniacal solution is then dropped into Nos. 2 and 3 as previously described, and finally No. 1 is added. In this case no boiling is required; but to secure rapidity it is as well that the emulsion should be kept an hour at a temperature of about 90° Fahr., after which half the total quantity of No. 5 is added. When set the emulsion is washed, drained, and redissolved as before; but in order to give tenacity to the gelatin the remainder of No. 5 is added before the addition of the alcohol, and before filtering.

Coating the Plates.—Glass plates are best cleaned with nitric acid, rinsed, and then treated with potash solution, rinsed again,

and dried with a clean cloth. They are then ready for receiving the emulsion, which, after being warmed to about 120° Fahr., is poured on them in sufficient quantity to cover well the surface. This being done, the plates are placed on a level shelf and allowed to stay there till the gelatin is thoroughly set; they are then put in a drying cupboard, through which, by a simple contrivance, a current of warm air is made to pass. It should be remarked that the warmth is only necessary to enable the air to take up the moisture from the plates. They ought to be dry in about twelve hours, and they are ready for immediate use.

Exposure.—With a good emulsion and on a bright day the exposure of a plate to a landscape, with a lens whose aperture is one-sixteenth that of the focal distance, should not be more than one-half to one-fifth of a second. This time depends, of course, on the nature of the view; if there be foliage in the immediate foreground it will be longer. In the portrait-studio, under the same circumstances, an exposure with a portrait-lens may be from half a second to four or five seconds.

Development of the Plate.—To develop the image either a ferrous oxalate solution or alkaline pyrogallol acid may be used. The former is conveniently prepared as described on p. 826. No chemical restrainer such as bromide of potassium is necessary, since the gelatin itself acts as a physical restrainer. If the alkaline developer be used, the following may be taken as a good standard:—

1. { Pyrogallol 50 grs.
Citric acid 10 "
Water 1 oz.
2. { Potassium bromide 10 grs.
Water 1 oz.
3. { Ammonia, '880 1 dr.
Water 9 "

One drachm of each of these is taken and the mixture made up to 2 oz. with water. The plate is placed in a dish and the above poured over it without stoppage, whereupon the image gradually appears and, if the exposure has been properly timed, gains sufficient density for printing purposes. It is fixed in a solution of hyposulphite of soda, as in the other processes already described, and then thoroughly washed for two or three hours to eliminate all the soluble salt. This long washing is necessary on account of the nature of the gelatin.

Intensifying the Negative.—Sometimes it is necessary to intensify the negative, which can be done in a variety of ways with mercury salts. An excellent plan, introduced by the Platinotype Company, is to use a saturated solution of mercuric chloride in water, and a subsequent addition of 2 grains to the ounce of platonic chloride. This is put in a dish and the metallic solution allowed to act till sufficient density is obtained. With most other methods with mercury the image is apt to become yellow and to fade; with this apparently it is not.

Varnishing the Negative.—The negative is usually protected by receiving first a film of plain collodion and then a coat of shellac or other photographic varnish. This protects the gelatin from moisture and also from becoming stained with the silver nitrate owing to contact with the sensitive paper used in silver printing.

Printing Processes.

The first printing process may be said to be that of Fox Talbot (see above, p. 824), which has continued to be generally employed to the present day (with the addition of albumen to give a surface to the print,—an addition first made, we believe, by Fox Talbot). Paper for printing is prepared by mixing 150 parts of ammonium chloride with 240 parts of spirits of wine and 2000 parts of water, though the proportions vary with different manufacturers. These ingredients are dissolved, and the whites of fifteen fairly-sized eggs are added and the whole beaten up to a froth. In hot weather it is advisable to add a drop of carbolic acid to prevent decomposition. The albumen is allowed two or three days to settle, when it is filtered through a sponge placed in a funnel, or through two or three thicknesses of fine muslin, and transferred to a flat dish. The paper is cut of convenient size and allowed to float on the solution for about a minute, when it is taken off and dried in a warm room. For dead prints, on which colouring is to take place, plain salted paper is useful. It can be made of the following proportions—80 parts of ammonium chloride, 100 parts of sodium citrate, 10 parts of gelatin, 5000 parts of distilled water. The gelatin is first dissolved in hot water and the remaining components are added. It is next filtered, and the paper allowed to float on it for three minutes, then withdrawn and dried.

Sensitizing Bath.—To sensitize the paper it is made to float on a 10 per cent. solution of silver nitrate for three minutes. It is then hung up and allowed to dry, after which it is ready for use. To print the image the paper is placed in a printing-frame over a negative and exposed to light. It is allowed to print till such time as the image appears rather darker than it should finally appear.

Toning and Fixing the Print.—The next operation is to tone and fix the print. In the earlier days this was accomplished by means of a bath of sel d'or,—a mixture of hyposulphite of soda and auric chloride. This gilded the darkened parts of the print which light

had reduced to the semi-metallic state; and on removal of the chloride by means of hyposulphite an image composed of metallic silver, an organic salt of silver, and gold was left behind. There was a suspicion, however, that part of the coloration was due to a combination of sulphur with the silver, not that pure sulphide of silver is in any degree fugitive, but the sulphuretted organic salt of silver seems to be liable to change. This gave place to a method of alkaline toning, or rather, we should say, of neutral toning, by employing auric chloride with a salt, such as the carbonate or acetate of soda, chloride of lime, borax, &c. By this means there was no danger of sulphurization during the toning, to which the method by sel d'or was prone owing to the decomposition of the hyposulphite. The substances which can be employed in toning seem to be those in which an alkaline base is combined with a weak acid, the latter being readily displaced by a stronger acid, such as nitric acid, which must exist in the paper after printing. This branch of photography owes much to the Rev. T. F. Hardwich, he having carried on extensive researches in connexion with it during 1854 and subsequent years. MM. Davanne and Girard, a little later, also investigated the matter with fruitful results.

The following may be taken as two typical toning-baths:—

| | |
|------------------------------|-------------|
| { Auric chloride | 1 part. |
| { Sodium carbonate | 10 parts. |
| { Water | 5000 " |
| { (a) { Borax | 100 " |
| { Water | 4000 " |
| { (β) { Auric chloride | 1 part. |
| { Water | 4000 parts. |

In the latter (α) and (β) are mixed in equal parts immediately before use. Each of these is better used only once. A third bath is:—

| | |
|------------------------|---------|
| Auric chloride | 2 parts |
| Chloride of lime | 2 " |
| Chalk | 40 " |
| Water | 8000 " |

These are mixed together, the water being warmed. When cool the solution is ready for use. In toning prints there is a distinct difference in the *modus operandi* according to the toning-bath employed. Thus in the first two baths the print must be thoroughly washed in water to enable all free silver nitrate to be carried away from the image, that salt forming no part in the chemical reactions. On the other hand, where free chlorine is used, the presence of free silver nitrate or some active chlorine absorbent is a necessity. In 1872 Abney showed that with such a toning-bath free silver nitrate might be eliminated, and if the print were immersed in a solution of a salt such as lead nitrate the toning action proceeded rapidly and without causing any fading of the image whilst toning, which was not the case when the free silver nitrate was totally removed and no other chlorine absorbent substituted. This was an important factor in the matter, and one which had been overlooked. In the third bath the free silver nitrate should only be partially removed by washing. The print, having been partially washed or thoroughly washed, as the case may be, is immersed in the toning-bath till the image attains a purple or bluish tone, after which it is ready for fixing. The solution used for this purpose is a 20 per cent. solution of hyposulphite of soda, to which it is best to add a few drops of ammonia in order to render it alkaline. About ten minutes suffice to effect the conversion of the chloride into hyposulphite of silver, which is soluble in hyposulphite of soda and can be removed by washing. The organic salts of silver seem, however, to form a different salt, which is partially insoluble, but which the ammonia just recommended helps to remove. If it is not removed, there is a sulphur compound left behind, according to Spiller, which by time and exposure becomes yellow.

The use of potassium cyanide for fixing prints is to be avoided, as this reagent attacks the organic coloured oxide which, if removed, would render the print a ghost. The washing of silver prints should be very complete, since it is said that the least trace of hyposulphite left behind renders the fading of the image a mere matter of time. Whether this be due to the hygroscopic nature of the hyposulphite and its reaction on the organic salt of silver, or to the destruction of the hyposulphite and sulphurizing of the black organic salt, seems at present to be an undetermined question. The stability of a print has been supposed to be increased by immersing it, after washing, in a solution of alum. The alum, like any other acid body, decomposes the hyposulphite into sulphur and sulphurous acid. If this be the case, it seems probable that the destruction of the hyposulphite by time is not the occasion of fading, but that its hygroscopic character is. This, however, as has already been said, is a moot point. It is usual to wash the prints some hours in running water. We have found that half a dozen changes of water, and between successive changes the application of a sponge to the back of each print separately, are equally or more efficacious. On drying, the print assumes a darker tone than what it has after leaving the fixing-bath.

Different tones can thus be given to a print by different toning-baths; and the gold itself may be deposited in a ruddy form or in a blue form. The former molecular condition gives the red and sepia tones, and the latter the blue and black tones. The degree

of minute subdivision of the gold may be conceived when it is stated that, on a couple of sheets of albuminized paper, fully printed, the gold necessary to give a decided tone does not exceed half a grain.

Collodio-chloride Silver Printing Process.—In the history of the emulsion processes we have already stated that Gaudin had attempted to use silver chloride suspended in collodion, but it was not till the year 1864 that any practical use was made of the suggestion so far as silver printing is concerned. In the autumn of that year Mr George Wharton Simpson worked out a method which has been more or less successfully employed, and is still one of the best with which we are acquainted. The formula appended is the original one which Mr Simpson published:—

| | |
|-------------------------------|----------|
| 1. { Silver nitrate | 60 parts |
| { Distilled water | 60 " |
| 2. { Strontium chloride | 64 " |
| { Alcohol | 1000 " |
| 3. { Citric acid | 64 " |
| { Alcohol | 1000 " |

To every 1000 parts of plain collodion 30 parts of No. 1, previously mixed with 60 parts of alcohol, are added; 60 parts of No. 2 are next mixed with the collodion, and finally 30 parts of No. 3. This forms an emulsion of silver chloride and also contains citric acid and silver nitrate. The defect of this emulsion is that it contains a large proportion of soluble salts, which are apt to crystallize out on drying, more particularly if it be applied to glass plates. The addition of the citric acid and the excess of silver nitrate is the key to the whole process; for, unless some body were present which on exposure to light was capable of forming a highly-coloured organic oxide of silver, no vigour would be obtained in printing. If pure chloride be used, though an apparently strong image would be obtained, yet on fixing only a feeble trace of it would be left, and the print would be worthless. The collodio-chloride emulsion may be applied to glass, as before stated, or to paper, and the printing carried on in the usual manner. The toning takes place by means of the chloride-of-lime bath or by ammonium sulpho-cyanide and gold, which is practically a return to the sel d'or bath. The organic salt formed in this procedure does not seem so prone to be decomposed by keeping as does that formed by albumen, and the washing can be more completely carried out. This is a beautiful process, and deserving of more attention than has hitherto been given to it.

Gelatino-citro-chloride Emulsion.—A modified emulsion printing process was introduced by Abney in 1881, which consisted in suspending silver chloride and silver citrate in gelatin, there being no excess of silver present. The formula of producing it is as follows:—

| | |
|----------------------------|----------|
| 1. { Sodium chloride | 40 parts |
| { Potassium citrate | 40 " |
| { Water | 500 " |
| 2. { Silver nitrate | 150 " |
| { Water | 500 " |
| 3. { Gelatin | 300 " |
| { Water | 1700 " |

Nos. 2 and 3 are mixed together whilst warm, and No. 1 is then gently added, the gelatin solution being kept in brisk agitation. This produces the emulsion of citrate and chloride of silver. The gelatin containing the suspended salts is heated for five minutes at boiling point, when it is allowed to cool and subsequently slightly washed, as in the gelatino-bromide emulsion. It is then ready for application to paper or glass. The prints are of a beautiful colour, and seem to be fairly permanent. They may be readily toned by the borax or by the chloride of lime toning-bath, and are fixed with the hyposulphite solution of the strength before given.

Printing with Salts of Uranium.—The sensitiveness of the salts of uranium to light seems to have been discovered by Niepce, and the fact was subsequently applied to photography by Burnett in England. One of the original formulæ consisted of 20 parts of uranic nitrate with 600 parts of water. Paper, which is better if slightly sized previously with gelatin, is floated on this solution. When dry it is exposed beneath a negative, and a very faint image is produced; but it can be developed into a strong one by 6 to 10 per cent. solution of silver nitrate to which a trace of acetic acid has been added, or by a 2 per cent. solution of auric chloride. In both these cases the silver and gold are deposited in the metallic state. Another developer is a 2 per cent. solution of ferro-cyanide of potassium to which a trace of nitric acid has been added, sufficient to give a red coloration. The development takes place most readily by letting the paper float on these solutions.

Wothly Type.—A variation was introduced in the uranium process by Herr Wothly in 1864, when he employed uranic nitrate with other salts in the collodion, and then coated starched paper with the product. The paper was printed until it assumed a bluish-black image, which was subsequently intensified by means of gold. The most generally used Wothly-type formula, however, consisted of a triple salt of silver nitrate, uranic nitrate, and ammonic nitrate, which were dissolved in collodion. This compound was applied to paper sized with arrowroot, and, after drying, the printing proceeded in the usual manner, the image being subsequently fixed

with hyposulphite of soda. The prints produced by this method were very beautiful, but for some reason they found no great favour with the public.

Printing with Chromates.—The first mention of the use of potassium bichromate for printing purposes seems to have been made by Mungo Ponton in May 1839, when he stated that paper, if saturated with this salt and dried, and then exposed to the sun's rays through a drawing, would produce a yellow picture on an orange ground, nothing more being required to fix it than washing it in water, when a white picture on an orange ground was obtained. In 1840 M. E. Becquerel announced that paper sized with iodide of starch and soaked in bichromate of potash was, on drying, more sensitive than unsized paper. Joseph Dixon of Massachusetts, in the following year, produced copies of bank-notes by using gum arabic with bichromate of potash spread upon a lithographic stone, and, after exposure of the sensitive surface through a bank-note, by washing away the unaltered gum and inking the stone as in ordinary lithography. The same process, with slight modifications, has been used quite recently by Simonet and Toovey of Brussels, and is capable of producing most excellent results. Dixon's method, however, was not published till 1854, when it appeared in the *Scientific American*, and consequently, as regards priority of publication, it ranks after Fox Talbot's photo-engraving process (see below), which was published in 1852. On 13th December 1855 M. Alphonse Poitevin took out a patent in England, in which he vaguely described a method of taking a direct carbon-print by rendering gelatin insoluble through the action of light on bichromate of potash. This idea was taken up by Mr Pouncey of Dorchester, who perhaps was the first to produce veritable carbon-prints, notwithstanding that Testud de Beauregard took out a somewhat similar patent to Poitevin's at the end of 1857.

Mr Pouncey published his process on 1st January 1859; but, as described by him, it was by no means in a perfect state, half-tones being wanting. The cause of this was first pointed out by Abbé Laborde in 1858, whilst describing a kindred process in a note to the French Photographic Society. He says, "In the sensitive film, however thin it may be, two distinct surfaces must be recognized—an outer, and an inner which is in contact with the paper. The action of light commences on the outer surface; in the washing, therefore, the half-tones lose their hold on the paper and are washed away." Mr J. C. Burnett in 1858 was the first to endeavour to get rid of this defect in carbon-printing. In a paper to the Photographic Society of London he says, "There are two essential requisites . . . (2) that in printing the paper should have its unprepared side (and not its prepared side, as in ordinary printing) placed in contact with the negative in the pressure frame, as it is only by printing in this way that we can expect to be able afterwards to remove by washing the unacted-upon portions of the mixture. In a positive of this sort printed from the front or prepared side the attainment of half-tones by washing away more or less depth of the mixture, according to the depth to which it has been hardened, is prevented by the insoluble parts being on the surface and in consequence protecting the soluble part from the action of the water used in washing; so that either nothing is removed, or by steeping very long till the inner soluble part is sufficiently softened the whole depth comes bodily away, leaving the paper white." This method of exposing through the back of the paper was crude and unsatisfactory, and in 1860 Fargier patented a process in which, after exposure to light of the gelatin film which contained pigment, the surface was coated with collodion, and the print placed in warm water, where it separated from the paper support and could be transferred to glass. Poitevin opposed this patent, and his opposition was successful, for he had used this means of detaching the films in his powder-carbon process, in which ferric chloride and tartaric acid were used. Fargier at any rate gave an impetus to carbon-printing, and J. W. Swan (to whom electric lighting owes so much) took up the matter, and in 1864 secured a patent. One of the great features in Swan's innovations was the production of what is now known as "carbon-tissue," made by coating paper with a mixture of gelatin, sugar, and colouring matter, and rendered sensitive to light by means of bichromate of potash or ammonia. After exposure to light Swan placed the printed carbon-tissue on an india-rubber surface, to which it was made to adhere by pressure. The print was immersed in hot water, the paper backing stripped off, and the soluble gelatin containing colouring matter washed away. The picture could then be re-transferred to its final support of paper. In 1869 J. R. Johnson of London took out a patent in which he claimed that carbon-tissue which had been soaked in water for a short period, by its tendency to swell further, would adhere to any waterproof surface such as glass, metal, waxed paper, &c., without any adhesive material being applied. This was a most important and fruitful improvement. Johnson also added soap to the gelatin to prevent its excessive brittleness on drying, and made his final support of gelatinized paper, rendered insoluble by chromo alum. In 1874 J. R. Sawyer patented a flexible support for developing on; this was a sized paper coated with gelatin and treated with an ammoniacal solution of

shellac in berax, on which wax or resin was rubbed. The advantage of this flexible support is that the dark parts of the picture have no tendency to contract from the lighter parts, which they were apt to do when a metal plate was used, as was the case in Johnson's original process. With this patent, and minor improvements made since, carbon-printing has arrived at the state of perfection in which we find it to-day.

According to Liesegang, the carbon-tissue when prepared on a large scale consists of from 120 to 150 grains of gelatin (a soft kind), 15 grains of soap, 21 grains of sugar, and from 4 to 8 grains of dry colouring matter. The last-named may be of various kinds, from lamp-black pigment to soluble colours such as alizarin. The gelatin, sugar, and soap are put in water and allowed to stand for an hour, and then melted, the liquid afterwards receiving the colours, which have been ground with a mallet on a slab. The mixture is filtered through fine muslin. In making the tissue in large quantities the two ends of a piece of roll-paper are pasted together and the paper hung on two rollers; one of wood about 5 inches in diameter is fixed near the top of the room and the other over a trough containing the gelatin solution, the paper being brought into contact with the surface of the gelatin by being made to revolve on the rollers. The thickness of the coating is proportional to the rate at which the paper is drawn over the gelatin: the slower the movement, the thicker the coating. The paper is taken off the rollers, cut through, and hung up to dry on wooden lathes. If it be required to make the tissue sensitive at once, 120 grains of potassium dichromate should be mixed with the ingredients in the above formula. The carbon-tissue when prepared should be floated on a sensitizing bath consisting of one part of potassium dichromate in forty parts of water. This is effected by turning up about 1 inch from the end of the sheet of tissue (cut to the proper size), making a roll of it, and letting it unroll along the surface of the sensitizing solution, where it is allowed to remain till the gelatin film feels soft. It is then taken off and hung up to dry in a dark room through which a current of dry warm air is passing. Tissue dried quickly, though not so sensitive, is more manageable to work than if more slowly dried. As the tissue is coloured, it is not possible to ascertain by inspection of it whether the printing operation is sufficiently carried out, and in order to ascertain this it is usual to place a piece of ordinary silvered paper in an "actinometer," or "photometer," alongside the carbon-tissue to ascertain the amount of light that has acted on it. There are several devices for ascertaining this amount, the simplest being an arrangement of a varying number of thicknesses of gold-beater's skin. The value of 1, 2, 3, &c., thicknesses of the skin as a screen to the light is ascertained by experiment. Supposing it is judged that a sheet of tissue under some one negative ought to be exposed to light corresponding to a given number of thicknesses, chloride of silver paper is placed alongside the negative beneath the actinometer and allowed to remain there until it takes a visible tint beneath a number of thicknesses equivalent to the strength of the negative. After the tissue is removed from the printing-frame—supposing a double transfer is to be made—it is placed in a dish of cold water, face downwards, along with a piece of Sawyer's flexible support (already described). When the edges of the tissue begin to curl up, its surface and that of the flexible support are brought together and placed flat. The water is pressed out with an india-rubber squeezer called a "squeegee" and the two surfaces adhere. About a couple of minutes later they are placed in warm water of about 90° to 100° Fahr., and the paper of the tissue, loosened by the gelatin solution next it becoming soluble, can be stripped off, leaving the image (reversed as regards right and left) on the flexible support. An application of warm water removes the rest of the soluble gelatin and pigment. When dried, the image is transferred to its permanent support. This usually consists of white paper coated with gelatin and made insoluble with chromic alum, though it may be mixed with barium sulphate or other similar pigments. This transfer-paper is made to receive the image by being soaked in hot water till it becomes slimy to the touch; and the surface of the dampened print is brought in contact with the surface of the retransfer-paper in the same manner as was done with the flexible support and the carbon-tissue. When dry the retransfer-paper bearing the gelatin image can be stripped off the flexible support, which may be used again as a temporary support for other pictures.

Such is a brief outline of carbon-printing as practised at the present day, subject, of course, to various modifications which need not be entered into here. We ought, however, to mention that if a reversed negative be used the image may be transferred at once to its final support instead of to the temporary flexible support, which is a point of practical value, since single-transfer are better than double-transfer prints.

Printing with Salts of Iron.—Sir John Herschel and Mr Hunt in sundry papers and publications entered into various methods of printing with salts of iron. At the present time there are two or three which are practised, being used in draughtsmen's offices for copying tracings. When a ferric salt is exposed to light it becomes reduced to the ferrous state, and when this latter compound

is treated with potassium ferri-cyanide a blue compound is formed. If, therefore, a solution of a ferric salt be brushed over a paper, and the latter be dried, and then exposed behind a tracing, the parts of the ferric salt on the paper exposed beneath the white ground are converted into a ferrous salt, and if potassium ferri-cyanide be brushed over the paper, or the paper floated upon it, the tracing shows white lines on a blue ground. Another method is to mix ferri-cyanide of potassium with a ferric salt, and expose it behind a tracing or drawing. Where the light acts, the mixture is converted into a blue compound. The resulting print is the same as the foregoing. Another method of producing blue lines on a white ground is to expose paper coated with gum and a ferric salt to light, and then treat it with potassium ferro-cyanide. This body forms an insoluble blue compound with the ferric salt, whilst the ferrous salt is inactive, or only gives a soluble body. A further development of printing with salts of iron is the beautiful platinotype process. Sized paper is coated with a solution of ferric oxalate and a platinous salt, and exposed behind a negative. It is then floated on a hot solution of neutral potassium oxalate, when the image is formed of platinum black. This process was introduced by Mr W. Willis in 1874. The rationale of it is that a ferrous salt when in solution is capable of reducing a platinum salt to metallic platinum. In this case the ferrous salt is dissolved by the potassium oxalate, and at the moment of solution the platinum salt is reduced and forms the image.

Photo-mechanical Printing Processes.—Allusion has already been Photo- made to the invention of Poitevin, who claimed to have discovered mechanism that a film of gelatin impregnated with bichromate of potash, cal print after being acted upon by light and damping, would receive greasy ink. ink on those parts which had been affected by light. But Paul Oreloth seems to have made the discovery previous to 1854, for in his patent of that year he states that his designs were inked with printing ink before being transferred to stone or zinc. Tessie de Motay (in 1865) and Marechal of Metz, however, seem to have been the first to produce half-tones from gelatin films by means of greasy ink. Their general method of procedure consisted in coating metallic plates with gelatin impregnated with bichromate or trichromate of potash or ammonia and mercuric chloride, then treating with oleate of silver, exposing to light through a negative, washing, inking with a lithographic roller, and printing from the plates as for an ordinary lithograph. The half-tints by this process were very good, and illustrations executed by it are to be found in several existing works. The method of producing the plates, however, was most laborious, and it was not long before it was simplified by Albert of Munich. He had been experimenting for many years, endeavouring to make the gelatin films more durable than those of Tessie de Motay. He added gum-resins, alnm, tannin, and other such matters, which had the property of hardening gelatin; but the difficulty of adding sufficient to the mass in its liquid state before the whole became coagulated rendered these unmanageable. It at last occurred to him that if the hardening action of light were utilized by exposing the surface next the plate to light after or before exposing the front surface of the film and the image, the necessary hardness might be given to the gelatin without adding any chemical hardeners to it. In Tessie de Motay's process the hardening was almost absent, and the plates were consequently not durable. It is evident that to effect this one of two things had to be done: either the metallic plate used by Tessie de Motay must be abandoned, or else the film must be stripped off the plate and exposed in that manner. Albert adopted the transparent plate, and his success was assured, since instead of less than a hundred impressions being pulled from one plate he was able to take over a thousand. This occurred about 1867, but the formula was not published for two or three years afterwards, when it was divulged by Ohm and Grossman, one of whom had been employed by Albert of Munich, and had endeavoured to introduce a process which resembled Albert's earlier efforts. The name of "Lichtdruck" was given about this time to these surface-printing processes, and Albert may be considered, if not the inventor, at all events the perfecter of the method. Another modification of "Lichtdruck" was patented in England by Ernest Edwards under the name of "heliotype." This consisted in coating a glass plate, the surface of which was very finely ground, with bichromated gelatin to which a certain amount of chrome alum had been added. The film itself was much thicker than that of the Albert type, since it had to be detached from the surface of the glass by stripping, which was rendered possible by the previous application of a waxing solution to the plate. After the film was stripped off it was exposed under a negative for the time necessary to give a good image with printing ink, after which the inner side was exposed to light for almost the same length of time. The gelatin sheet was then transferred to a pewter plate, to which it was cemented by thick india-rubber cement and soaked in water till all the soluble bichromate was extracted. After this it was placed in a type printing-press and inked with a lithographic or gelatin roller, and an impression pulled on paper in the same manner as in printing with type, save that a greater pressure was brought to bear on the surface. This pressure was necessary

for two reasons,—the relief of the image would be too great if only a moderate pressure were used, and the entire surface was so large that a heavy pressure was requisite to make the paper bite on the ink. Between each pull the gelatin film was dampened, the surface moisture taken off with a dry cloth, and the inking proceeded with. The drawback to this process is undoubtedly the great relief that is given from the film being so thick, but it is a more manageable process in some respects than that of Albert, since the support is unbreakable. We should mention that Edwards also patented the use of two or more inks of different degrees of stiffness. The stiffest, which was generally black, adhered to the most deeply printed parts of the image, the next stiffest to the next most deeply printed parts, and so on. By this means the least deeply printed parts acquired a different tone from that of the deeper printed parts, which was an advantage as regards artistic effect. The same method of inking could be applied to Albert's process with the same results. Since the time of the heliotype patent many improvements have been made in the minor details of the operations, and various firms now produce prints in greasy ink very little if at all inferior to silver prints.

Woodbury Type.—This process was invented by Mr W. Woodbury about the year 1864, though we believe that Mr J. W. Swan had been working independently in the same direction about the same time. In October 1864 a description of the invention was given in the *Photographic News*. M. Gaudin claimed the principle of the process, insisting that it was old, and basing his pretensions on the fact that he had printed with translucent ink from intaglio blocks engraved by hand; but at the same time he remarked that the application of the principle might lead to important results. It was just these results which Mr Woodbury obtained, and for which he was entitled to the fullest credit. Woodbury type is a combination of the principle upon which intaglio printing is based with that upon which a carbon-print is obtained. The general features of the procedure will be understood from the foregoing description of the carbon-process. An image is obtained on bichromatized gelatin from a negative of the usual kind by exposing a thick layer of gelatin to light and then washing away all its soluble parts from the back of the exposed print. This is the mould which it is necessary to obtain. At first Woodbury made electrotypes from the mould, from which he could obtain prints mechanically. The intaglio was placed on a specially devised printing-press, and the mould filled with gelatin containing colouring matter such as Indian ink. A piece of paper perfectly even in thickness was placed in contact with the mould, and a piece of flat glass under pressure brought down upon this. The excess of pigmented gelatin was squeezed out, and, when slightly set, it adhered to the paper and was brought away from the mould. After drying, a perfect picture was obtained in pigment, the image being reversed as regards right and left; but that difficulty was surmounted by using a reversed negative, and also by a modification of the process subsequently introduced by Mr Woodbury. The gelatin relief was made as before; and then by means of very heavy pressure in a hydraulic press the mould was squeezed into soft metal, from which the prints could be afterwards taken off. This is the same principle as that on which nature-printing is conducted, and at first sight it seems strange that material such as gelatin should be able to impress metal. Mr Woodbury found that it made very little if any difference in the sharpness of the image if the relief was reversed and the back of the relief pressed into the mould. This of course made the print correct as regards right and left. He has not, however, been content with his original operations, but has further simplified them, the outcome being what is known as the "autotype process." In 1860 he read a description of it before the French Photographic Society. The modification consisted in taking a mould in gelatin from a positive on glass. The mould, when hardened by chemical means (as was indeed the case with the original Woodbury-type process), was attached to a sheet of flat glass, and then covered by the foil and passed through a rolling press the cylinders of which were covered with thick india-rubber. This forced the tinfoil into every crevice of the mould, yielding a block impervious to moisture and ready to have gelatin impressions taken from it. At first Mr Woodbury took an electrotype from the relief, covered with tinfoil, obtained from a negative, but he abandoned this for a simpler plan. He took a positive on glass in the ordinary manner adopted by photographers, from which he made a mould in gelatin. This he covered with tinfoil and printed direct from it.

Photo-Lithography.

Reference has already been made to the effect of light on gelatin impregnated with bichromate of potash, whereby the gelatin becomes insoluble, and also incapable of absorbing water where the action of the light has had full play. It is this last phenomenon which occupies such an important place in photo-lithography. In the spring of 1859 Asser of Amsterdam produced photographs on a paper

basis in printer's ink. Being anxious to produce copies of such prints mechanically, he conceived the idea of transferring the greasy ink impression to stone, and multiplying the impressions by mechanical lithography. Following very closely upon Asser, J. W. Osborne of Melbourne made a similar application; his process is described by himself in the *Photographic Journal* for April 1860 as follows. "A negative is produced in the usual way, bearing to the original the desired ratio. . . . A positive is printed from this negative upon a sheet of (gelatinized) paper, so prepared that the image can be transferred to stone, it having been previously covered with greasy printer's ink. The impression is developed by washing away the soluble matter with hot water, which leaves the ink on the lines of print of the map or engraving." The process of transferring is accomplished in the ordinary way. Early in 1860 Colonel Sir H. James, R.E., F.R.S., brought forward the Southampton method of photo-lithography, which had been carefully worked out by Captain de Courcy Scott, R.E. We give a detailed description of it as practised at Southampton.

Preparation of the Paper.—The mixture consists of 3 oz. of Nelson's "fine art" gelatin and 2 oz. of potassium bichromate dissolved in 10 oz. of water and added to the 40 oz. of water with which the gelatin, after proper soaking, has been previously mixed. Good and grainless bank post-paper (chosen on account of its toughness) of medium thickness is made to float on this solution (after it has been strained) for three minutes, when it is hung up in the dark to dry. It is again floated on the solution and hung up for desiccation by the corners opposite to those which were previously uppermost, and then passed through a copper-plate or lithographic press to obtain a smooth surface. The paper is next placed upon a negative and printed in the ordinary manner, the negative being very dense in those parts which should print white, and perfectly transparent where the black lines have to be impressed. From about two minutes' exposure in sunshine to an hour in dull light is requisite to give sufficient intensity to the prints, which are next covered with greasy printer's ink, made from lithographic printing ink, pitch, varnish, palm oil, and wax. The inking is best done by covering a lithographic stone with a fine layer by means of a roller, and then passing the paper through the press as if pulling a lithographic print,—an operation which may have to be repeated twice to ensure the whole surface being covered, and yet not too thickly. The inked print is placed face uppermost on water of a temperature of about 90° Fabr., and, when the soluble parts of the gelatin have taken up their full quantity of water, the paper is laid on a sloping glass plate, inked surface uppermost, and a gentle stream of warm water poured over it. This removes the soluble gelatin and the greasy ink lying on it, the removal being helped by the application of a very soft sponge. When all the gelatin and ink except that forming the image have been removed, the paper is allowed to dry till ready to transfer to stone. The method admits of several variations in detail, such as coating the gelatin with albumen and removing the soluble albumen by cold water, some of them being excellent, especially where the relief of the developed print is small, as relief is an enemy to the production of fine work on a lithographic stone, since the ink, in passing through the press, squeezes out and produces broad lines which should be otherwise fine.

Another method of producing a transfer, called the "papyrotype process," was published by Abney in 1870, in which the ink is put on to a surface of gelatin by means of a soft roller; and this has the great advantage that the ink can be removed at pleasure if any part is not satisfactorily inked, without the basis of the print being

destroyed. In this process tough paper is coated with a fine layer of gelatin and subsequently treated with alum or chrome alum, afterwards receiving another coating, as in the Southampton method. The printing too is carried out as in the Southampton method, but not so deeply. After withdrawing the prints from the printing-frame they are soaked in cold water, and a roller is passed over them charged with an ink made of 4 parts of best lithographic chalk ink mixed with 1 part of palm oil. A roller coated with velvet is said to be better than the ordinary composition rollers. The ink takes when the work is all clear; the transfer is exposed to light, and is ready to be put down on stone or zinc.

Photo-Engraving and Photo-Reliefs.

This may be divided into two classes, one the production of an engraved plate for printing by the copper-plate press, and the other for the production of *clichés* for printing with type. Niepce's process is still generally employed for the first when line engravings have to be reproduced. A copper plate is covered with asphaltum, a film negative placed in contact with it, and the necessary exposure given. After development with olive oil and turpentine the lines are shown as bare copper. The plate after being waxed at the back is next plunged into an acid bath and etched as are etched plates. When a half-tone negative has to be reproduced on copper Fox Talbot's method, described in his patents of 1852 and 1858, is still the simplest. A print on gelatin is transferred to a copper plate, and the surface etched by means of different strengths of ferric chloride, which renders the gelatin insoluble and impermeable; hence it will be seen that a weak solution of ferric chloride is able to reach the copper through the gelatin more readily than a strong one. In order to be successful it is necessary to give a grain to the plate; this is effected by sprinkling it with powdered resin, which is then warmed.

Relief plates for printing with type are usually made on zinc. If an ordinary photo-lithographic transfer be transferred to zinc and then sprinkled with resin, the zinc may be immersed in weak acid and the uncovered parts eaten away. The regularity of the erosion is much increased by previously immersing the plate in a weak solution of copper sulphate. The particles of metallic copper deposited on the zinc form with it and with dilute acid galvanic couples, which rapidly eat away the zinc. The etching bath should be kept in motion. The depth of the erosion is increased by littering the surface again with powdered resin, which adheres to the lines, and then heating the plate. The warmed resin runs down the eroded lines and protects them from under-cutting when again placed in acid. This process is applicable to line-engravings. Niepce's bitumen process is also applicable, but in that case a positive must be applied to the plate to be etched. There exist several methods by which half-tone negatives may be reproduced for working off in the printing-press. They depend principally on breaking up the whole surface by means of lines. Thus, if, between the surface on which the printing is to take place (and which has been coated with some sensitive medium) and the positive, a film on which a network of lines has been photographed be interposed, it is evident that the resulting print will consist of the half-tone subject together with an image of the network of lines. This can be etched in the manner described above. Most of these processes are secret, but it is believed that this is the one most generally practised.

Photographs in Natural Colours.

The first notice on record of coloured light impressing its own colours on a sensitive surface is in the passage

already quoted from the *Furbenlehre* of Goethe, where Seebeck of Jena (1810) describes the impression he obtained on paper impregnated with moist chloride of silver. In 1839 Sir J. Herschel (*Athenæum*, No. 621) gave a somewhat similar description. In 1848 Edmond Becquerel succeeded in reproducing upon a daguerreotype plate not only the colours of the spectrum but also, up to a certain point, the colours of drawings and objects. His method of proceeding was to give the silver plate a thin coating of silver chloride by immersing it in ferric or cupric chlorides. It may also be immersed in chlorine water till it takes a feeble rose tint. Becquerel preferred to chlorinize the plate by immersion in a solution of hydrochloric acid in water, attaching it to the positive pole of a voltaic couple, whilst the other pole he attached to a platinum plate also immersed in the acid solution. After a minute's subjection to the current the plate took successively a grey, a yellow, a violet, and a blue tint, which order was again repeated. When the violet tint appeared for the second time the plate was withdrawn and washed and dried over a spirit-lamp. In this state it produced the spectrum colours, but it was found better to heat the plate till it assumed a rose tint. At a later date Niepce de St Victor chlorinized by means of chloride of lime, and made the surface more sensitive by applying a solution of lead chloride in dextrin. G. W. Simpson also obtained coloured images on silver chloride emulsion in collodion, but they were less vivid and satisfactory than those obtained on daguerreotype plates. Poitevin obtained coloured images on ordinary chloride of silver paper by preparing it in the usual manner and washing it and exposing it to light. It was afterwards treated with a solution of bichromate of potash and cupric sulphate, and dried in darkness. Sheets so prepared gave coloured images from coloured pictures, which he stated could be fixed by sulphuric acid (*Comptes Rendus*, 1868, vol. lxi. p. 11). In the *Bulletin de la Société Française* (1874) St Florent describes experiments which he made with the same object. He immerses ordinary or albuminized paper in silver nitrate and afterwards plunges it into a solution of uranium nitrate and zinc chloride acidulated with hydrochloric acid; it is then exposed to light till it takes a violet, blue, or lavender tint. Before exposure the paper is floated on a solution of mercuric nitrate, its surface dried, and exposed to a coloured image.

It is supposed—though it is very doubtful if it be so—that the nature of the chloride used to obtain the chloride of silver has a great effect on the colours impressed; and Niepce in 1857 made some observations on the relationship which seemed to exist between the coloured flames produced by the metal and the colour impressed on a plate prepared with a chloride of such a metal. In 1880 (*Proc. Roy. Soc.*) Abney showed that the production of colour really resulted from the oxidation of the chloride that was coloured by light. Plates immersed in a solution of hydroxyl took the colours of the spectrum much more rapidly than when not immersed, and the size of the molecules seemed to regulate the colour. He further stated that the whole of the spectrum colours might be derived from a mixture of two or at most three sizes of molecules. In 1841, during his researches on light, Robert Hunt published some results of colour-photography by means of fluoride of silver. A paper was washed with nitrate of silver and with sodium fluoride, and afterwards exposed to the spectrum. The action of the spectrum commenced at the centre of the yellow ray and rapidly proceeded upwards, arriving at its maximum in the blue ray. As far as the indigo the action was uniform, whilst in the violet the paper took a brown tint. When it was previously exposed, however, a yellow space was occupied where the yellow

rays had acted, a green band where the green had acted, whilst in the blue and indigo it took an intense blue, and over the violet there was a ruddy brown. In reference to these coloured images on paper it must not be forgotten that pure salts of silver are not being dealt with as a rule. An organic salt of silver is usually mixed with chloride of silver paper, this salt being due to the sizing of the paper, which towards the red end of the spectrum is usually more sensitive than the chloride. If a piece of ordinary chloride of silver paper is exposed to the spectrum till an impression is made, it will usually be found that the blue colour of the darkened chloride is mixed with that due to the coloration of the darkened organic compound of silver in the violet region, whereas in the blue and green this organic compound is alone affected, and is of a different colour from that of the darkened mixed chloride and organic compound. This naturally gives an impression that the different rays yield different tints, whereas this result is simply owing to the different range of sensitiveness of the bodies. In the case of the silver chlorinized plate and of true collodio-chloride, in which no organic salt has been dissolved, we have a true coloration by the spectrum. At present there is no means of permanently fixing the coloured images which have been obtained, the effect of light being to destroy them. If protected from oxygen they last longer than if they have free access to it, as is the case when the surface is exposed to the air. That photography in colours may one day be accomplished is still possible, though the bright tints of nature can never be hoped for, since, as a rule, they are produced by sunshine, whereas on the plate they have to be viewed by diffused light.

Action of Light on Silver Salts.—The action of light on sensitive bodies has occupied the attention of many experimentalists from a very early period of photography. In 1777 Scheele, according to Hunt (*Researches in Light*), made the following experiments:—

"I precipitated a solution of silver by sal-ammoniac; then I adulcorated it and dried the precipitate and exposed it to the beams of the sun for two weeks; after which I stirred the powder, and repeated the same several times. Hereupon I poured some caustic spirit of sal-ammoniac (strong ammonia) on this, in all appearance, black powder, and set it by for digestion. This menstruum dissolved a quantity of *luna cornua* (horn silver), though some black powder remained undissolved. The powder having been washed was, for the greater part, dissolved by a pure acid of nitre (nitric acid), which, by the operation, acquired volatility. This solution I precipitated again by means of sal-ammoniac into horn silver. Hence it follows that the blackness which the *luna cornua* acquires from the sun's light, and likewise the solution of silver poured on chalk, is *silver by reduction*. . . I mixed so much of distilled water with well-adulcorated horn silver as would just cover this powder. The half of this mixture I poured into a white crystal phial, exposed it to the beams of the sun, and shook it several times each day; the other half I set in a dark place. After having exposed the one mixture during the space of two weeks, I filtrated the water standing over the horn silver, grown already black; I let some of this water fall by drops in a solution of silver, which was immediately precipitated into horn silver."

This, as far as we know, is the first intimation of the reducing action of light. From this it is evident that Scheele had found that the silver chloride was decomposed by the action of light liberating some form of chlorine. Others have repeated these experiments and found that chlorine is really liberated from the chloride; but it is necessary that some body should be present which would absorb the chlorine, or, at all events, that the chlorine should be free to escape. A tube of dried silver chloride, sealed up *in vacuo*, will not discolour in the light, but keeps its ordinary white colour. A pretty experiment is to seal up *in vacuo*, at one end of a bent tube, perfectly dry chloride, and at the other a drop of mercury. The mercury vapour vola-

tilizes to a certain extent and fills the tube. When exposed to light chlorine is liberated from the chloride, and calomel forms on the sides of the tube. In this case the chloride darkens. Again, dried chloride sealed up in dry hydrogen discolours, owing to the combination of the chlorine with the hydrogen. Poitevin and H. W. Vogel first enunciated the law that for the reduction by light of the haloid salts of silver halogen absorbents were necessary, and it was by following out this law that the present rapidity in obtaining camera images has been rendered possible. To put it briefly, then, the action of light is a reducing action, which is aided by or entirely due to the fact that other bodies are present which will absorb the halogens. There is another action which seems to occur almost simultaneously when exposure takes place in the absence of an active halogen absorbent, as is the case when the exposure is given in the air,—that is, an oxidizing action occurs. The molecules of the altered haloid salts take up oxygen and form oxides. An example of this has already been shown in the section on "photographs in natural colours." If a sensitive salt be exposed to light and then treated with an oxidizing substance, such as bichromate of potash, permanganate of potash, hydroxyl, ozone, an image is not developed, but remains unaltered, showing that a change has been effected in the compound. If such an oxidized salt be treated very cautiously with nascent hydrogen the oxygen is withdrawn, and the image is again capable of development.¹

Spectrum Effects on Silver Compounds.—The next inquiry is as to the effect of the spectrum on the different silver compounds. We have already described Seebeck's (1810) experiments on the chloride of silver with the spectrum whereby he obtained coloured photographs, but Scheele in 1777 allowed a spectrum to fall on the same material, and found that it blackened much more readily in the violet rays than in any other. Senebier's experiments have been already quoted at the beginning of this article. We merely mention these two for their historical interest, and pass on to the study of the action of the spectrum on different compounds by Sir J. Herschel which is to be found in the *Philosophical Transactions* for 1840. He there describes many interesting experiments, which became the foundations of nearly all subsequent researches of the same kind. The effects of the spectrum have been studied by various experimenters since that time, amongst whom we may mention Becquerel, Draper, Poitevin, H. W. Vogel, Schumann, and Abney. Fig. 1 (see pp. 836-38), which appeared in the *Proceedings of the Royal Society* for 1882, shows the most recent researches by the last-named experimenter as regards the action of the spectrum on the three principal haloid salts of silver. We may mention that in two instances exception has been taken to these results—(1) by H. W. Vogel, who recognizes a difference of behaviour in the spectrum in chloride and bromide of silver when precipitated in alcoholic and aqueous solutions, and (2) by Schumann to the effect of the spectrum on the double iodide and bromide, and iodide and chloride. The latter experimenter finds that when the two salts are mixed after precipitation the results are correct, but that if the precipitations of the two salts take place together the most refrangible maximum of sensitiveness disappears. The diagram (see fig. 1), however, will give a very approximate approach to the truth. Nos. 33 and 34 show the effect of the spectrum on a peculiar modification of silver bromide made by Abney, in which the silver bromide is seen to be sensitive to the infra-red rays. This modification is, and will be, largely used in investigating this part of the spectrum.

¹ See Abney, "Destruction of the Photographic Image," in *Phil. Mag.*, vol. v., 1878; also *Proc. Roy. Soc.*, vol. xxvii., 1878.

FIG. 1.—Spectrum Effects on Salts of Silver.

Effect of Dyes on Sensitive Films.—In 1874 Dr Vogel of Berlin called attention to this subject. He found that when films were stained with certain aniline and other dyes and exposed to the spectrum an increased action on development was shown in those parts of the spectrum which the dye absorbed. The dyes which produced this action he called "optical sensitizers," whilst preservatives which absorbed the halogen liberated by light he called "chemical sensitizers." A dye might, according to him, be an optical and a chemical sensitizer. He further claimed that, if a film was prepared in which the haloid soluble salt was in excess and then dyed, no action took place unless some "chemical sensitizer" were present. The term "optical sensitizer" seems a misnomer, since it is meant to imply that it renders the salts of silver sensitive to those regions of the spectrum to which they were previously insensitive, merely by the addition of the dye. The idea of the action of dyes was at first combated by many, but it was soon recognized that such an action did really exist. Abney showed in 1875 that certain dyes combined with silver and formed true coloured organic salts of silver which were sensitive to light; and Dr Amory went so far as to take a spectrum on a combination of silver with eosine, which was one of the dyes experimented upon by Major Waterhouse, who had closely followed Dr Vogel, and proved that the spectrum acted simply on those parts which were absorbed by the compound. Abney further demonstrated that, in many cases at all events, the dyes were themselves reduced by light, thus acting as nuclei on which the silver could be deposited. He further showed that even when the haloid soluble salt was in excess the same character of spectrum was produced as when the silver nitrate was in excess, though the exposure had to be prolonged. This action he concluded was due to the action of the dye. The subject has been discussed again recently owing to the production of so-called iso-chromatic films, *i.e.*, films which are supposed to be sensitive to all colours, and which are prepared on gelatin or collodion plates by dyeing them with eosine or some similar dye; and the instructions given indicate that, if a coloured picture or landscape be photographed through yellow glass, the "yellows" will be denser in the negative than will the "blues." Experiment shows if a film after preparation be dipped in a solution of "eoside of silver," made by precipitating eosine with silver nitrate, washing the precipitate, and then dissolving in water faintly alkaline, a negative taken in the usual way will give the "yellows" equally as dense as the "blues." The action of the yellow glass is to cut off the blue rays to which the normal salt is most sensitive, and to leave the yellow rays unaltered; these then expend their energy upon the organic salt of silver. The advantage of rendering the yellows of a picture most intense in a negative is that the resulting print will be more nearly true to nature, since these are the most luminous rays. Further experiment ought surely to show how this can be done without the introduction of the tinted glass.

Action of the Spectrum on Chromic Salts.—The salts most usually employed in photography

are the bichromates of the alkalis. The result of spectrum action in connexion with them is confined to its own most refrangible end, commencing in the ultra-violet and reaching as far as in the solar spectrum. The accompanying diagram (fig. 2) shows the relative action of the

FIG. 2.—The top letters have reference to the Fraunhofer lines; the bottom letters are the initials of the colours. The relative sensitiveness is shown by the height of the curve above the base-line.

various parts of the spectrum on potassium bichromate. If other bichromates are employed, the action will be found to be tolerably well represented by the figures. No. 1 is the effect of a long exposure, No. 2 of a shorter one. It should be noticed that the solution of bichromate of potash absorbs those rays alone which are effective in altering the bichromate. A reference to pp. 831, 833 will show that the change is only possible in the presence of organic matter of some kind, such as gelatin or albumen.

Action of the Spectrum on Asphaltum.—This seems to be continued into and below the red; the blue rays, however, are the most effective. The action of light on this body is to render it less soluble in its usual solvents. Compare this statement with that on p. 822.

Action of the Spectrum on Salts of Iron.—Many ferric salts have been used from time to time in the production of prints, the most common at the present time being the ferric oxalate, by which the beautiful platinotype prints are produced. We give this as a representation (fig. 3) of the spectra obtained on ferric

FIG. 3.—Same description as for fig. 2.

salts in general. Here, again, we have an example of the rigorous law that exists as to the correlation between absorption and chemical action. One of the most remarkable compounds of iron is that experimented upon by Sir J. Herschel and later by Lord Rayleigh, viz., ferrocyanide of potassium and ferric chloride. If these two be brushed over paper and the paper be then exposed to a bright solar spectrum, action is exhibited into the infra-red region. This is one of the few instances in which these light-waves of low refrangibility are capable of producing any effect. The colour of this solution is a muddy green, and analysis shows that it cuts off these rays as well as generally absorbs those of higher refrangibility.

Action of Light on Uranium.—The salts of uranium are affected by light in the presence of organic matter, and they too are only acted upon by those rays which they absorb. Thus nitrate

The following table gives the names of the observers of the action of light on different substances with the date of publication of the several observations. It is nearly identical with one given by Dr Eder in his *Geschichte der Photo-Chemie*.

of uranium, which shows, too, absorption-bands in the green blue, is affected more where these occur than in any other portion of the spectrum.

It would be going beyond our province to do more than enumerate the other metallic compounds which are amenable to chemical change by the impact of radiation; suffice it to say that some salts of mercury, gold, copper, lead, manganese, molybdenum, platinum, vanadium, are all affected, but in a less degree than those which we have discussed. In the organic world there are very few substances which do not change by the continuous action of light, and it will be found that as a rule they are affected by the blue end of the spectrum rather than by the red end. For a more detailed account we must refer the reader to *The Chemical Effects of the Spectrum* by Dr J. M. Eder (London).

THE CAMERA.

Any article descriptive of photography would be incomplete without a brief notice of the development of the camera. The inventor of the camera obscura was Giambattista della PORTA (*q.v.*), who was born at Naples about 1540. Except as a scientific toy, his apparatus was not of any practical use, though it is the parent of the apparatus which have grown up with photography. The principles which govern photographic lenses have been briefly given under LIGHT (vol. xiv. p. 593 *sq.*) and OPTICS (vol. xvii. p. 802 *sq.*), and we need only state here that the finest camera which can be manufactured is useless unless the lens with which it has to be worked gives a flat field and an approximately achromatic image.

Fig. 4.—Daguerre's Camera. M, stop of lens; J, lens; A, ground glass plate, on which the image formed by the lens is thrown, and for which the sensitive plate is substituted; B, a mirror held at 45° by means of L, on which the operator viewed the image on the ground glass. The focus was obtained by sliding the inner box D towards or from the lens.

According to Hunt (*Photography*, 4th ed., p. 39), by which it will be seen that at first the idea existed of moving the plate away from the camera.

The first camera made in England, as far as is known, was that by Mr Palmer of Newgate Street, London, on the plan of Mr Fry and for him, in 1839. It was a very primitive apparatus, and was furnished with a lens made in the same year. The ordinary form of camera was simply a box, at one end of which was a lens, and at the other a ground glass for focusing, for which could be substituted a dark slide holding a sensitive plate. The adjustment of the focus was made by a rack and pinion motion attached to the lens. The arrangement, however, subsequently introduced for obtaining a rough approximation to focus was to have a sliding inner box as in Daguerre's camera; and finally to obtain the greatest sharpness the rack and pinion motion attached to the lens was used. It is evident that this form of camera has an advantage over the single box, since it allows more than one lens to be used. Ottewill's folding camera was a great improvement, in that, for outdoor work, it enabled a cumbersome article to be folded up into a compact space. Figs. 5 and 6 show it set up for use, and folded. A still more portable form was made by Mr George Edwards of Carlton Colville (Suffolk) in 1853, and for it he obtained the medal of the Society of Arts. Its portability is shown by the fact that for a 7-inch by 5½-inch plate its weight was only 2 lb 3 oz. Broadly speaking its principle was that of a couple of frames attached by screws to a solid bar, one of

which carried the dark slide and the other the lens. The two were connected together and enclosed in a cloth bag, which in reality

Fig. 5.—Ottewill's Camera, set up for use. Fig. 6.—Ottewill's Camera, folded.

was the camera. This instrument is still used at the present day. It did not come into general use owing to its complicated arrangement of screws,—for the main point in any camera is that there should be as few loose screws as possible. The next improvement is that known as the bellows form, originally introduced, it is believed, by Captain Fowke, R.E., about 1854. Its introduction may be said to mark a new era in camera construction, and from that time to the present the bellows is to be found in nearly every improved form. After this invention the square instead of the tapering form of bellows was that most generally adopted. It is unnecessary to trace every improvement that has been introduced, but we give two typical

Fig. 7.—Hare's Camera.

ones (figs. 7 and 8), which are manufactured by Hare and Meagher respectively. It will be noticed that in both these cameras there is an arrangement by which the focusing screens can be made to tilt at an angle with the axis of the lens. This is called a swing-back arrangement, and is necessary when photographing architectural subjects to prevent vertical lines converging in the picture. When the ground glass is in a

Fig. 8.—Meagher's Camera.

vertical plane, no matter what tilt is given to the camera, vertical lines will always be shown as parallel in the picture. It will also be noticed that in these cameras there is an arrangement for focusing the lens by means of a rack and pinion motion in fig. 7, and by means of a screw in fig. 8. The gradual motion which can thus be given to the focusing screen is a great advantage, since lenses need not be constructed with rack and pinion motion. Many suggestions have been put forward for adapting

Fig. 9.—Marion & Co.'s Camera.

the camera for a developing chamber, and we believe Archer's could be used for this purpose. Mr Newton in 1852 introduced a camera in which wet plates after exposure were developed by dipping in troughs of solutions; and we might name many others who sub-

sequently worked at the same idea. It met, however, with no very great success. The introduction of dry plates was a great step for the landscape photographer, as it enabled him to carry a supply of plates in the field, and to develop them at home. To economize space and weight, what are known as "double backs" were invented. A "double back" is a dark slide in which two plates are placed back to back, being separated by an opaque plate. Each side of the slide can be drawn up or out so as to expose each plate. What are known as changing boxes answer the same purpose. They hold from one to two dozen plates, and by means of a special arrangement each plate can be conveyed to or removed from the dark slide without exposure to light. There are other plans also by which a certain number of plates can be carried in the camera itself and exposed in succession. The writer's opinion of such

instruments is that they possess no striking advantage and many disadvantages, unless for very special purposes. Even for a miniature camera for taking instantaneous street views whilst holding the apparatus in the hand the use of double backs is to be preferred. An excellent specimen is a camera made by Marion & Co. of London (see fig. 9): it is entirely of metal, and fitted with a finder and instantaneous shutter,—one which should stand any amount of rough usage. The whole apparatus, including a dozen plates, can easily be carried in the pocket. The dark slides are strongly made of metal. In the preceding sketch, brief though it is, of the successive improvements in cameras, probably enough has been said to show the very remarkable development that has taken place since the days when a cigar-box and spectacle lens were used to obtain an image on a sensitive plate. (W. DE W. A.)

PHOTOMETRY, CELESTIAL. The earliest records that have come down to us regarding the relative positions of the stars in the heavens have always been accompanied with estimations of their relative brightness. With this brightness was naturally associated the thought of the relative magnitudes of the luminous bodies from whence the light was assumed to proceed. Hence in the grand catalogue of stars published by Ptolemy (c. 150 A.D.), but which had probably been formed three hundred years before his day by Hipparchus, the 1200 stars readily visible to the naked eye at Alexandria were divided into six classes according to their lustre, though instead of that term he uses the word *μέγεθος* or "magnitude"; the brightest he designates as being of the first magnitude, and so downwards till he comes to the *minimum visibile*, to which he assigns the sixth. These magnitudes he still further divides each into three. To those stars which, though ranged in any particular order of brightness, nevertheless exceed the average of that order in lustre he attaches the letter μ , the initial letter in *μείζων* (greater), and to those in the same order which exhibit a lustre inferior to that of the average he affixes the letter ϵ , the initial letter of *ελάσσων*. With this sort of subdivision he passes through all the six orders of magnitude. He does not, indeed, tell us the precise process by which these divisions were estimated, but the principle involved is obvious. The eye was here made the natural photometer, and it is certain that even in the instances where modern instrumental appliances are called into requisition the ultimate appeal is made to perception by the eye. Moreover, it is one of the many remarkable instances of the acuteness and precision of the Greek mind that for upwards of 1500 years no real improvement was made in these estimations of lustre by any of Ptolemy's numerous successors in this field of research. Flamsteed was the first astronomer who extended the estimation of magnitude to stars visible only by the telescope, and he improved Ptolemy's notation by writing 4.3 instead of δ, μ —indicating thereby an order of magnitude brighter than the average of a fourth, but inferior to that of a third—and 3.4 for δ, ϵ , and so on. Later astronomers have sometimes adopted a more precise nomenclature by subdividing the several orders decimally, but it does not appear that by any immediate and unaided effort the eye can estimate subdivisions of lustre exceeding the thirds adopted by the Greek philosopher.

It was not till the year 1796 that any real advance was made in stellar photometry. Sir W. Herschel, instead of assigning a particular magnitude to stars, arranged them in small groups of three or four or five, indicating the order in which they differed from each other in lustre at the time of observation. This method was admirably adapted to the discovery of any variations in brightness which might occur in the lapse of time among the members of the group. Sir William observed in this way some 1400 stars, published in catalogues scattered through the *Philosophical Transactions* from 1796 to 1799; but he discontinued the work before its conclusion. It might be urged that such

a work touches on no human interests, but it rightly seemed otherwise to the philosophic mind of the great astronomer. He remarked that the sun is, after all, only one among the stars, and that what befalls them in the way of varying light as time proceeds may also befall the sun. He puts the question, "Who would not wish to know what degree of permanency we ought to ascribe to the lustre of our sun? Not only the stability of our climates, but the very existence of the whole animal and vegetable creation itself, is involved in the question. Where can we hope to receive information upon the subject but from astronomical observations?"¹ These researches of the elder Herschel were in due time followed by those of his son, Sir John, about the year 1836 at the Cape of Good Hope. He both extended and improved the methods adopted by his father at Slough, and by a method of estimated sequences of magnitude he hoped to arrange all the stars visible to the naked eye at the Cape or in England in the order of their relative lustre, and then to reduce his results into the equivalent magnitudes adopted by the universal consent of astronomers. Sir John, however, like his father, left this important labour incomplete. Not only is the work one of great and continuous effort, but the effects of ever-varying meteorological conditions greatly impede it. Moreover, there is an unsatisfactory indefiniteness attending all estimations made by the unaided eye; numerical or quantitative comparisons are out of the question, and hence we find Sir John, in the very midst of establishing his "sequences," adopting also an instrumental method which might lead him to more definite results.

In the year when Sir John Herschel concluded his photometric work at the Cape (1838) Dr Argelander commenced, and in 1843 completed, his *Uranometria Nova*, in which the magnitudes of all stars visible to the unaided eye in central Europe are catalogued with a precision and completeness previously unknown. It contains 3256 stars, and although it will probably be superseded by instrumental photometry it must ever remain a monument of intelligent patience. Argelander's labours were confined to stars visible to the naked eye; by the aid of his assistants, Dr Schönfeld and Dr Krüger, a catalogue of magnitudes and celestial coordinates was ultimately published in their well-known *Durchmusterung*, extending to the enormous number of 324,000 stars.

Dr Gould also, in his *Uranometria Argentina*, has done similar work for stars visible only in the southern hemisphere, and with the aid of his colleagues has attained to an exactness and precision in his estimations of stellar lustre certainly not hitherto surpassed. There have been other worthy labourers in the same field, each of whom has rendered efficient service, such as Dr Heis and M. Houzeau; but it is chiefly to the labours of Argelander and Gould that astronomers at present make their appeal.

It is to Sir John Herschel that we are indebted for the first successful attempt at stellar photometry by what may

¹ *Phil. Trans.*, 1796, p. 184.

be termed "artificial" means. By the aid of appliances of the simplest kind he deflected the light of the moon (by means of the internal reflexion of a rectangular prism) through a small lens 0.12 inches in diameter and of very short focus, 0.2253 inches, so as to form a sort of artificial star in its focus. By the instrumentality of strings and a wooden pole he could move this artificial star of comparison so as to be in the same line of sight with any actual star whose light he proposed to measure. Other strings enabled him to remove this microscopic lunar image to such a distance from the eye that its light was adjudged to be sensibly the same as that of the star compared. The distance of the short focused lens with the image contiguous to it was measured by a graduated tape, and the inverse squares of these distances afforded relative numerical measures of the brightness of the several stars thus brought into ocular juxtaposition with the equalized light of the tiny lunar image. In this way he proceeded with the observations of a considerable number of stars, and these, by appropriate methods, were reduced so as to afford the means of the comparison of their relative brightness when set side by side with results obtained by means of his "sequences," and with the estimated magnitudes of preceding astronomers. Sir John, however, did not go on to the formation of a complete "uranometria." While he was thus busy at the Cape of Good Hope, Steinheil at Munich had completed for Dr Seidel an instrument nearly the same in principle but more manageable in form. He divided the small object-glass of a telescope into two halves, one of which was movable in the direction of its axis. The images of two stars whose light he desired to compare were formed by the intervention of prismatic reflexion, nearly in the same line of sight, and one of the lenses was then moved until the light of the two stars near the respective foci of the semi-lenses seemed equal to the judgment of the observer's eye. The distance through which it was necessary to bring the movable lens furnished the data for comparing the relative lustre of the two stars in question. A large amount of work was thus achieved by Seidel, which for a considerable time has been, with greater or less reason, regarded as worthy of confidence in regard to precision (*Trans. Mun. Acad.*, vol. ii.). Dr Zöllner substituted the deflected and reduced image of a lamp for one of Steinheil's stars, and the intensity of this light, or artificial star, he could by means of double refraction reduce in any measurable proportion he pleased according to the well-known relations of polarized light. In this way he could equalize the light of the artificial lamp-star with that of the real star with which he compared it; and the division of the lens was thus dispensed with, but a new difficulty was introduced in the impossibility of maintaining the constancy of the flame. Dr Zöllner also availed himself of the effects of double refraction in altering at will the colour of his artificial star of comparison. This ingenious form of photometer has enjoyed considerable reputation, but no astronomer has yet persevered in producing a complete "uranometria" by its aid. The most recent and probably the most successful device for a stellar photometer on the principle of equalizing lights is that invented by Professor Pickering of Harvard College. He deflects the light of Polaris, or of some other star such as λ Ursæ Minoris, by means of prismatic reflexion, and he contrives to form an image of it contiguous to the image of any other star selected on the meridian. The equalization of the lights is then effected by the intervention of a polarizing apparatus, such as that adopted by Zöllner. Thus the artificial and in many respects objectionable lamp-star of Zöllner is dispensed with. Professor Pickering, with singular inventive power, has devised many other forms of stellar photometers on virtually the same principle; for a detailed

account of these labours the reader is referred to the *Annals of the Harvard College Observatory* (vol. xi.). Unlike his eminent predecessors, the American astronomer is persevering in the formation of a complete catalogue of star-magnitudes.

It has been already stated that mere estimations of relative brightness by the unaided eye are inadequate to the production of numerical quantitative results. In the instrumental devices explained, whether by means of the alteration of distances or by the known alteration of planes of polarization, no such defect exists. By their means it is possible to obtain a fairly exact numerical expression for the ratio of the intensities of the two lights measured. On applying a photometric measurement it is found that the ratio of the intensities of the lights in passing from one magnitude to the next, even in the conventional magnitudes of Argelander and Gould, is not by any means constant, and even hardly definite. At the suggestion of Mr Pogson it is now generally accepted by astronomers that the adopted and conventional ratio of the intensity of light in passing from one magnitude to another shall be 2.512, a convenient number because its logarithm is .4, which is easily remembered, and still more so because on the whole it agrees better than any other number with the varying light-ratio existing among the hitherto received orders of magnitude obtained by eye-estimation alone.

There remains still another principle on which a stellar photometer may be successfully formed, and which has been recently largely applied to the determination of star-magnitudes at the university observatory, Oxford. It is constructed on the principle that the absorption of light in passing through a uniform medium depends, *ceteris paribus*, upon the thickness. On this principle a thin wedge is constructed of homogeneous and nearly neutral-tinted glass, through which the images of stars formed in the focus of a telescope are viewed. Simple means are contrived for measuring with great exactness the several thicknesses at which the light of these telescopic star-images is extinguished. In this way the light of any star can be readily compared with that of Polaris (or any other selected star) at the moment of observation, and thus a catalogue of star-magnitudes can be formed. This method has been already applied by Professor Pritchard to all the brighter stars north of the equator; the results are published in the forty-seventh volume of the *Memoirs of the Royal Astronomical Society*, and are to be speedily followed by a complete catalogue, extending to all the stars in Argelander's *Uranometria Nova* north of the equator, and to a few others beyond. For the details of the processes adopted the reader must here, as in all other cases, consult the original researches.

Even in a rapid sketch of so extensive a subject some notice must be taken of the application of photometry to the determination of the relative amount of light received on the earth from the sun, the moon, and the planets. The methods by which these ratios have been obtained are as simple as they are ingenious; and for them we are mainly indebted to the labours of Bouguer and Bond. The former philosopher compared the light received from the sun with that from the moon in the following fashion in 1725. A hole one-twelfth of a Paris inch was made in the shutter of a darkened room; close to it was placed a concave lens, and in this way an image of the sun 9 inches in diameter was received on a screen. Bouguer found that this light was equal to that of a candle viewed at 16 inches from his eye. A similar experiment was repeated with the light of the full moon. The image now formed was only two-thirds of an inch in diameter, and he found that the light of this image was comparable with that of the same candle viewed at a distance of 50 feet. From

these data and a very simple calculation it followed that the light of the sun was about 256,289 times that of the moon. Other experiments followed, and the average of all the results was that the light of the sun was about 300,000 times the average light of a full moon, both being viewed in the heavens at the same altitudes. The details will be found in Bouguer's *Traité d'Optique*.¹ Wollaston in 1829 tried a series of experiments in which the ratio 801,072 was obtained; but the omission of certain necessary precautions vitiates the result (*Phil. Trans.*, 1829). Bond (*Mem. Amer. Acad.*, 1851, p. 295) adopted a different process. He formed the image of the sun on a silvered globe of some 10 inches diameter; the light of this image was reflected on to a small mercurial thermometer bulb; and then this second image was compared with a Bengal light so moved that the lights appeared to be equal. The same process was adopted with the full moon instead of with the sun. The result was that the sun's light was 470,980 times that of the moon. Seidel long before this date had compared the light of the mean full moon with that of Jupiter in mean opposition; his result is 6430. So also this light of Jupiter was found to be 4864 times that of Venus at her brightest; and Jupiter was found to give 8.2 times the light of α Lyra. If, then, these numbers could be accepted with confidence, we should have the means of comparing the light received from the sun with that received from any of the stars. Adopting these precarious numbers on the authorities of Bond and Seidel we have the following results—

| | | |
|---------------|-----------------|------------------------------|
| Sun's light = | 470,980 | that of the full moon. |
| " | = 622,600,000 | " Venus at her brightest. |
| " | = 302,835,000 | " Jupiter at mean opposition |
| " | = 5,970,500,000 | " Sirius. |

Lastly, Bouguer, by comparing the light of the full moon viewed at different altitudes with an artificial light, found that the atmosphere absorbs 1877 of the light incident on it at the zenith of any place. Professor Pritchard, from photometric measures taken at Cairo, found this number to be 157. At Oxford it was 209. Thus Bouguer's determination indicates an absorptive capacity in the atmosphere of Brittany just midway between those of Oxford and Cairo. Seidel at Munich expresses "surprise" at finding his own results so nearly accordant with Bouguer's. These numbers, therefore, may be regarded as close approximations to fact.¹

PHOTOPHONE. See TELEPHONE.

PHRENOLOGY. This name was given by Forster in 1815 to the empirical system of psychology formulated by Gall and developed by his followers, especially by Spurzheim and Combe. At first it was named "cranioscopy," "craniology," "physiognomy," or "zoonomy," but Forster's name was early adopted by Spurzheim, and became that whereby the system is now known. The principles upon which it is based are four: (1) the brain is the organ of the mind; (2) the mental powers of man can be analysed into a definite number of independent faculties; (3) these faculties are innate, and each has its seat in a definite region of the brain; (4) the size of each of these regions is the measure of the power of manifesting the faculty associated with it. While phrenology is thus, on the one hand, a system of mental philosophy, it has a second and more popular aspect as a method whereby the disposition and character of the individual may be ascertained. These two sides of the subject are distinct from each other, for,

while it can only serve as a reliable guide for reading character on the assumption of its truth as a philosophic system, yet the possibility of its practical application does not necessarily follow from the establishment of the truth of its theoretic side.

History.—That the phenomena of mind are in some measure connected with the action of the brain has been recognized from a very early age of philosophy. It is true that Aristotle² describes the brain as the coldest and most bloodless of bodily organs, of the nature of water and earth, whose chief purpose is to temper the excessive heat of the heart, as the cooler regions of the firmament condense the vapours rising from the earth. In his view, as in that of most of the earlier writers of other nations of antiquity, the heart is the seat of life; to it, not to the brain, the Hebrew writers refer thoughts and affections, while they considered judgment as seated sometimes in the head, sometimes in the kidneys.³ This was, likewise, the teaching of the ancient Egyptian philosophy; and hence, while many rites were practised and many prayers offered for the preservation of the heart of the deceased, the brains were passed over with very little precaution for their preservation.⁴ The influence of the Aristotelian teaching is traceable in that of some of the earlier classic writings on philosophy, as is that of the Hebrews in our own colloquial language; but we learn from Diogenes Laertius⁵ that much more accurate physiological views were held by Pythagoras, who believed the mind and the intellect to have their seat in the brain. The theory of Hippocrates was Pythagorean rather than Aristotelian, for, although in one passage in his work *De Corde* he expresses himself rather doubtfully, yet elsewhere he clearly states that he considers the brain to be the index and messenger of the intellect.⁶ The cerebral seat of sense-perception is also taught by Plato,⁷ who puts into the mouth of Socrates the theory that the brain is the organ affected by the senses, whereby memory and opinion arise, and from whence knowledge springs. The classic poets also notice this dependence of mind on brain; for example, in the *Clouds* (v. 1276) Strepsiades accuses Amynias of not being in his right mind, and, on being asked why, responds, "You seem to me as if you had had a concussion of the brain."

The two founders of anatomical science, Erasistratus and Herophilus, who lived in the days of Ptolemy Soter, taught not only that the brain was the seat of sensation and of intellect, but also that there was therein a certain degree of localization of function. Erasistratus believed that the sensory nerves arose from the brain-membranes, the motor from the cerebral substance. Herophilus was apparently the first who held that the vital forces resided in and circulated from the ventricles of the brain, at least so we gather from Celsus and the other authors who have preserved his views. By the influence of the writings of Galen,⁸ which directly teach that the brain is the seat of

² *De partibus animalium*, ii. c. 7 (Paris, 1629, p. 986).

³ In the Chaldee portion of Daniel (ii. 28, iv. 5, vii. 1) visions and thoughts are referred to the head. For other particulars as to early views see Nasse on the psychical relations of the heart in *Zeitschr. f. psychische Aerzte*, i., 1818. A few of the later medical writers express similar views; see Santa Cruz, *Opuscula medica*, Madrid, 1624.

⁸ *De usu partium*, ed. Kühn, iii. 700,—"τὰς μὲν οὖν ἀποδεδεῖχται τοῦ τοῦ λογιστικῆς ψυχῆς οἰκῆν ἐν ἐγκέφαλῳ, καὶ πνεῦμα ψυχικὸν ἐν

¹ Since this article was put in type, Professor Pickering at Harvard College has published his concluded results. Professor Pritchard at Oxford has also completed his photometric measures of some 2000 of the same stars. Taken as a whole, and as comprising the first complete and systematic efforts in a new and difficult line of research, the agreements of the two catalogues may fairly be regarded as very satisfactory, not to say surprising.

soul and intellect, the Pythagorean doctrine became universally received among philosophers. According to the Galenical theory of life, the animal spirits arising from the brain are conveyed thence by the arteries through the body. These animal spirits have their origin in the ventricles of the brain, and pass thence to the heart. It is true that in one place (viii. 159) he refers their origin to the cerebral substance, but the ventricular theory was that adopted by his followers. This view is held by the Greek physicians,¹ some of whom even speculated on the relation of the intellect to the shape and size of the head. The Arabians adopted the same hypothesis, so we find Averrhoes² correcting Aristotle's notion of cerebral physiology in favour of Galen's view. Rhazes³ also extended this by giving a sketch of a scheme of psychic localization; and Avicenna⁴ added to the regions recognized by previous authors by interpolating one of his own. Such of the early Christian authors as had occasion to refer in their writings to the relation of soul to body naturally adopted the teaching of Galen, and suited it to their theology, thereby conferring on it an importance which rendered correction difficult. Thomas Aquinas⁵ thus expresses his acquiescence in the theory of localization, as also in a sense does Tertullian.⁶

Early in the 13th century Albertus Magnus⁷ gave a detailed description of the distribution of mental and psychical faculties in the head. The anterior region he assigned to judgment, the middle to imagination, and the posterior to memory. A somewhat similar allocation was made by Gordon, professor of medicine in Montpellier (1296),⁸ who assigned common sensation and the reception of impressions to the anterior cornua of the lateral ventricles, *phantasia* to the posterior, this power being twofold (*imaginativa* and *cogitativa*), judgment or *æstimativa* to the third ventricle, and memory to the fourth.⁹ Figures of a similar division were given by Petrus Montagnana¹⁰ and Lodovico Dolce,¹¹ still later by Ghradelli¹² of Bologna and by Theodore Gall of Antwerp.¹³ That the "vital spirits" resided in the ventricles was doubted by many, and refuted by a few of the anatomists of the 17th century. Bauhin in 1621¹⁴ attacked the old view, and Hoffmann of Altorf

showed that, as the ventricles were closed cavities, they could not transmit any material fluid. That these spirits existed at all was doubted by Alexander Benedictus,¹⁵ Plater,¹⁶ and a few others; but they were believed in by the great majority of 17th and even of 18th century medical writers, many of whom conceived that the ventricles were "semper pleni spiritibus animalibus flammulis similibus, quorum beneficiis intelligimus, sentimus, et movemur,"¹⁷ and the opponents of this view were strongly assailed by Riolan and others as revolutionary. The grey matter of the surface of the cerebrum was first recognized as the true dynamic element by Malpighi¹⁸ and Willis.¹⁹ The latter regarded the convoluted surface of the cerebrum as the seat of the memory and the will, the convolutions being intended to retain the animal spirits for the various acts of imagination and memory. Imagination he described as seated in the corpus callosum, sense-perception in the corpus striatum, and *impetus et perturbatio* in the basal parts of the cerebrum above the crura. The thalami he regarded as the centres of sight and the cerebellum of involuntary acts. Columbus²⁰ ridiculed the idea that the convoluted surface can have anything to do with intellect, as the ass, a proverbially stupid animal, has a convoluted cerebrum. According to his view, the convolutions are for the purpose of lightening the brain and facilitating its movements. Succeeding anatomists simply varied these localizations according to their respective fancies. Lancisi placed sense-perception in the corpus callosum, Vieussens in the centrum ovale majus. Descartes supposed the soul to be seated in the pineal gland, Lotze in the pons Varolii.²¹ Meyer considered abstract ideas to arise in the cerebellum, and memory to have its seat at the roots of the nerves.²²

Of later writers three deserve special notice as having largely prepared the way for the more modern school of phrenology. Unzer of Halle in his work on physiology extended the pre-existing theories of localization. Metzger,²³ twenty years before the publication of Prochaska's work, had proposed to make a series of observations on the anatomical characters of the brains of persons of marked intellectual peculiarity; but it is not known to the present writer whether he ever carried this into effect. In a more special manner Prochaska of Vienna may be looked upon as the father of phrenology, as in his work on the nervous system, published in Vienna in 1784, are to be found the germs of the later views which were propounded in that city twelve years later.²⁴

The system formulated by Gall is thus a modern expansion of an old empirical philosophy, and its immediate parentage is easily traced, although, according to Gall's

αὐτῶ περιέχεσθαι πᾶμπον. See also v. 288, viii. 159, xv. 360. In his *Definitiones medicæ* (467, xix. 459) he says that the brain has a ψυχικὴ δύναμις, but does not specify in what part the power inheres.

¹ See Paulus Ægineta, Stephens's ed., 1567, cap. 62, col. 363, also Actuarius, *De actionibus et affectibus spiritus animalis*, Paris, 1556, p. 22, c. 7.

account,¹ it arose with him as the result of independent observations. These, he tells us, he began to make at an early age, by learning to correlate the outward appearances and mental qualities of his schoolfellows.¹ Gall's first published paper was a letter in the *Deutscher Merkur* of December 1798, but his principal expositions were oral, and attracted much popular attention, which largely increased when, in 1802, he was commanded by the Austrian Government, at the instance of the ecclesiastical authorities, to discontinue his public lectures. In 1804 he obtained the co-operation of Spurzheim (1776-1832), a native of Longwich near Treves, who became his pupil in 1800, and proved a powerful ally in promulgating the system. Master and pupil at first taught in harmony, but they found it advisable to separate in 1813; and we find Spurzheim, several years after their parting, declaring that Gall had not introduced any new improvements into his system since their separation (notes to Chenevix, p. 99). "My philosophical views," he also says, "widely differ from those of Gall."

In Paris, where he settled in 1807, Gall made many influential converts to his system. Broussais, Blainville, Cloquet, Andral, Geoffroy St-Hilaire, Vimont, and others warmly attached themselves to it, and countenanced its progress. Gall visited Great Britain, but the diffusion of phrenology there was chiefly due to Spurzheim, who lectured through the country and through America, and, with the aid of his pupil George Combe, soon attracted a large popular following. His most influential disciples were Elliotson, Andrew Combe, Mackenzie, Macnish, Laycock, and Archbishop Whately, and in America Caldwell and Godman. On the opposite side many influential men took up a strongly antagonistic position, prominent among whom were Barclay the anatomist, Roget, Sir Charles Bell, Sir W. Hamilton, Jeffrey, Brougham, T. Brown, and Sir B. Brodie. The nature of the system rendered it eminently fitted to catch public attention, and it rapidly attained to so great a degree of popularity that in 1832 there were twenty-nine phrenological societies in Great Britain, and several journals devoted to phrenology in Britain and America; of these the *Phrenological Journal*, a quarterly edited chiefly by George Combe with aid from others of the Edinburgh confraternity, notably Sir George Mackenzie and Macnish, "the modern Pythagorean," lived from 1823 to 1847, through twenty volumes. The controversy in many places was heated and often personal, and this largely increased the popular interest. In the *Edinburgh Review* the theory was severely criticized by Thomas Brown, and afterwards in a still more trenchant manner by Jeffrey. In *Blackwood* it was ridiculed by Professor Wilson. Being a subject which lent itself easily to burlesque, it was parodied cleverly in a long rhyme by two authors, "The Craniad," 87 pages long, published in 1817, while, on the other hand, verse was pressed into its service in the rhyme "Phrenology in Edinburgh" in 1824.² The best defence of the system was that by Chenevix in the third number of the *Foreign Quarterly*, afterwards reprinted with notes by Spurzheim.

The popularity of phrenology has waned, and few of the phrenological societies now survive; the cultivation of the system is confined to a few enthusiasts such as will be found attached to any cause, and some professional teachers who follow phrenology as a vocation. Like many similar systems, it has a much larger following in America than in Europe. Based, like many other artificial philosophies, on an admixture of assumption and truth,

certain parts will survive and become incorporated into scientific psychology, while the rest will in due course come to be relegated to the limbo of effete heresies.

The Faculties and their Localities.—The system of Gall was constructed by a method of pure empiricism, and his so-called organs were for the most part identified on slender grounds. Having selected the place of a faculty, he examined the heads of his friends and casts of persons with that peculiarity in common, and in them he sought for the distinctive feature of their characteristic trait. Some of his earlier studies were made among low associates, in jails, and in lunatic asylums, and some of the qualities located by him were such as tend to become perverted to crime. These he named after their excessive manifestations, mapping out organs of murder, theft, &c.; but as this cast some discredit on the system the names were changed by Spurzheim, who claimed as his the moral and religious considerations associated with it. Gall marked out on his model of the head the places of twenty-six organs as round enclosures with vacant interspaces. Spurzheim and Combe divided the whole scalp into oblong and conterminous patches (see the accompanying figures). Other methods of division and other names have been suggested by succeeding authors, especially by Cox, Sidney Smith (not Sydney), Toulmin Smith, Carus of Dresden, Don Mariano Cubi i Solar, Powell of Kentucky, Buchanan of Cincinnati, Hittel of New York. Some, like the brothers Fowler, raise the number of organs to forty-three; but the system of Spurzheim and Combe is that which has always been most popular in Britain.

Spurzheim separated the component faculties of the human mind into two great groups and subdivided these as follows.

I. Feelings, divided into—

1. Propensities, internal impulses inviting only to certain actions.
2. Sentiments, impulses which prompt to emotion as well as to action.
 - A. Lower,—those common to man and the lower animals.
 - B. Higher,—those proper to man.

II. Intellectual faculties.

1. Perceptive faculties.
2. Reflective faculties.

In the following list the locality and the circumstances of the first recognition of the organ are appended to the names, which are mostly the inventions of Spurzheim. Gall's names are placed in brackets.³

Propensities.

(1) Amativeness (*Instinct de la génération*), median, below theinion; first determined by Gall from its heat in a hysterical widow, supposed to be confirmed by many observations, and referred to the cerebellum.⁴

(2) Philoprogenitiveness (*Amour de la progéniture*), median, on the squama occipitis, and selected as the organ for the love of children because this part of the skull is usually more prominent in apes and in women, in whom the love of children is supposed to be stronger than in men.

(3) Concentrativeness, below the obelion and over the lambda. This is a region of uncertain function, unnoticed by Gall, but described as Inhabitiveness by Spurzheim, because he found it large in cats and in a clergyman fond of his home. It has since been considered by Combe to be the seat of the power of concentration, whereof he believed Inhabitiveness to be a special case.

(4) Adhesiveness (*Amitié*), over the lateral convoluted area of the lambdoidal suture. This region was prominent in a lady introduced to Gall as a model of friendship, and is said by him to be the region where persons who are closely attached put their heads together.

(5) Combativeness (*Instinct de la défense*), above the asterion; it was found by Gall by examining the heads of the most quarrelsome

¹ For a brief sketch of the life of Gall, see GALL, vol. x. p. 37.

² Other burlesque and satirical writings were published at this time, notably *The Phrenologists*, a farce by Wade, 1830; *The Headpiece*, or *Phrenology opposed to Divine Revelation*, by James the Less; and *A Helmet for the Headpiece*, or *Phrenology incompatible with Reason*, by Daniel the Seer.

³ For topographical purposes Broca's names are adopted as the most convenient for localities on the head.

⁴ Apollonius Rhodius speaking of the love of Médée for Jason (*Argonautica*, iii. 760-765) says, "δάκρυ δ' ἄν' ὀφθαλμῶν ῥέει· ἐνδοθεὶ δ' αἰὲλ τείρει δδὴν σμύχουσα διὰ χροὸς, ἀμφὶ ἀραιὰς ἵνας καὶ κεφαλῆς, ὑπὸ νηλοῦν ἰνίου ἀγρύς."

of his low companions whom he had beforehand stimulated by alcohol. It was verified by comparing this region with the same part of the head of a quarrelsome young lady.

(6) Destructiveness (*Instinct carnassier*), above the ear meatus. This is the widest part of the skulls of carnivorous animals, and was found large in the head of a student so fond of torturing animals that he became a surgeon, also large in the head of an apothecary who became an executioner.

(6a) Alimentiveness, over the temporal muscle and above the ear. Hoppe describes it as being large in a gourmand acquaintance, and he therefore supposes it to be the organ of selecting food.

(7) Secretiveness (*Ruse, Finesse*), the posterior part of the squamous suture.

(8) Acquisitiveness (*Sentiment de la propriété*), on the upper edge of the front half of the squamous suture. This part of the head Gall noticed to be prominent in the pickpockets of his acquaintance.

(9) Constructiveness (*Sens de mécanique*), on the stephanion; detected by its prominence on the heads of persons of mechanical genius. It was found large on the head of a milliner of uncommon taste and on a skull reputed to be that of Raphael.

The organ of Vitativeness, or love of life, is supposed by Combe to be seated at the base of the skull. To this locality Herophilus referred most of the intellectual powers.

Lower Sentiments.

(10) Self-esteem (*Orgueil, Fiérlé*), at and immediately over the obelion; found by Gall in a beggar who excused his poverty on account of his pride. This was confirmed by the observation that proud persons held their heads backwards in the line of the organ.

(11) Love of Approbation (*Vanité*), outside the obelion; the region in which Gall saw a protuberance on the head of a lunatic who fancied herself queen of France.

(12) Cautiousness (*Circonspection*), on the parietal eminence; placed here because an ecclesiastic of hesitating disposition and a vacillating councillor of state had both large parietal eminences.

Superior Sentiments.

(13) Benevolence (*Bonté*), on the middle of the frontal bone in front of the coronal suture; here Gall noticed a rising on the head of the highly-commended servant of a friend, as well as on a benevolent schoolmate who nursed his brothers and sisters when they were ill. To this spot Menocrates referred the intellectual powers.

(14) Veneration (*Sentiment religieux*), median at the bregma. Gall noted when visiting churches that those who prayed with the greatest fervour were prominent in this region, and it was also prominent in a pious brother.

(15) Conscientiousness, unknown to Gall; recognized by Spurzheim usually from its deficiency, and placed between the last and the parietal eminence.

(16) Firmness (*Fermeté*), median, on the sagittal suture from behind the bregma to the front of the obelion. Lavater first pointed out that persons of determination had lofty heads.

(17) Hope, not regarded as primary by Gall, who believed hope to be akin to desire and a function of every faculty which desires, and left this territory unallocated.

(18) Wonder, said to be large in vision-seers and many psychic researchers. A second similar organ placed between this and the next is called Mysterizingness by Forster, and is said to preside over belief in ghosts and the supernatural.

(19) Ideality (*Poésie*), noted by Gall from its prominence in the busts of poets; said to be the part touched by the hand when composing poetry.

(20) Wit (*Esprit caustique*), the frontal eminence, the organ of the sense of the ludicrous, prominent in Rabelais and Swift.

(21) Imitation (*Faculté d'imiter*), disposition to mimicry, placed between Benevolence and Wonder.

Perceptive Faculties.

(22) Individuality, over the frontal sinus in the middle line; the capacity of recognizing external objects and forming ideas therefrom; said to have been large in Michelangelo, and small in the Scots.

(23) Form (*Mémoire des personnes*), capacity of recognizing faces; gives a wide interval between the eyes; found by Gall in a squinting girl with a good memory for faces.

(24) Size, over the trochlea at the orbital edge; described by Spurzheim and Vimont as the capacity of estimating space and distance.

(25) Weight, outside the last on the orbital edge and, like it, over the frontal sinus. The prominence of ridge here is due to large sinus or a projecting bone. Certain old writers, such as Strato Physicus, located the whole intellect in this ridge.

(26) Colour, also on the orbital edge external to the last.

(27) Locality (*Sens de localité*), placed above Individuality on each side, and corresponding to the upper part of the frontal sinus and to the region immediately above it.

(28) Number, on the external angular process of the frontal bone, large in a calculating boy in Vienna.

(29) Order, internal to the last, first noted by Spurzheim in an orderly idiot.

(30) Eventuality (*Mémoire des choses*), the median projection above the glabella, supposed to be the seat of the memory of events.

(31) Time, below the frontal eminence and a little in front of the temporal crest.

(32) Tune (*Sens des rapports des tons*); on the foremost part of the temporal muscle, where Gall noticed a bulge on the head of a musical prodigy of five.

(33) Language (*Sens des mots*), behind the eye. This was the first organ noticed by Gall, as a clever schoolfellow, quick at languages, had prominent eyes. Old authors have noted the connexion between prominent eyeballs and mental development; thus Gazzali and Syenensis Medicus Cyprius place the intellect and soul in and behind the eyeballs.

Reflective Faculties.

(34) Comparison (*Sagacité comparative*), median, at the top of the bare region of the forehead, where a savant friend of Gall's, fond of analogies, had a prominent boss.

(35) Causality (*Esprit métaphysique*), the eminence on each side of Comparison, noticed on the head of Fichte and on a bust of Kant; the seat of the faculty of correlating causes and effects.

The first identification of each organ was made by an induction from very limited data, but the founders and exponents of the system have collected all available instances wherein enlargements of each of these regions coexisted with increased powers of the faculty supposed to reside therein, and in some cases they have discovered coincidences of a surprising nature. When, however, such do not exist, a convenient excuse is found by reference to the indefinite article of temperament, or by a supposed explanation of the faculty in question as not simple but produced by the co-operation of other influences. Thus, as Sheridan's hump of wit was small, he is said not to have been truly witty, but to have had comparison and memory strongly developed. The girl Labrosse (described in Ferrussac's *Bulletin* for October 1831), who exhibited strong amativeness but had a rudimentary cerebellum, is said to have obliterated it by over-use. Thurtell, a cold-blooded murderer whose organ of benevolence was large, is said to have been generous, as he once gave half a guinea to a friend, &c.

The method whereby the sizes of organs are estimated is arbitrary and the boundaries of the regions indefinite. The attempts of Nicol, Straton, and Wight to devise mechanical and accurate modes of measurement have not been very successful and have not found favour with the professional phrenologist.

Anatomical Aspect of Phrenology.—The phrenological controversy served the useful purpose of stimulating research into the anatomy of the brain; but we owe very little of solid progress to the advocates of the system. Gall is the only writer of his creed in whose works original observations of value are to be found. Although the study of the surface of the cerebrum is of the essence of phrenology, yet nowhere in the circle of phrenological literature are the convolutions of the brain accurately described; our knowledge of their order and disposition comes from the morphologist, not from the phrenologist. The first real step towards their systematic description was made by Rolando,¹ who in 1830 described the fissure to which his name is attached, and very little advance was made until the publication in 1856 of Gratiolet's² and Huschke's³ memoirs. These works for the first time placed the description of the surface of the brain, imperfectly attempted by Desmoulins in 1825,⁴ on a satisfactory basis. Most of the anatomical details contained in the works on phrenology relate to controversial matters of secondary importance, and presuppose the truth of the theory; but even in connexion with these they give us no statistical details of any value. It would be important, for instance, to have tabulated a sufficiently large number of measurements of the relative thicknesses of scalp and skull in different regions, of the variations in development of the diploe, of the varying range of the frontal sinus; but of these we find no sufficient nor definite researches in the whole circle of books cited below.

As under ANATOMY (vol. i. p. 874) a careful description of the brain has been given, we need only allude to such anatomical points involved in the examination of phrenology as are not included in that account.

1. Any psychological theory which correlates brain-action and mental phenomena requires a correspondence between brain-size and mental power; and, speaking generally, we find that the brains of those whose capacities are above the average are larger than those of the general run of their fellow-men. The details of brain-weights will be found at pp. 879, 880 of the article cited.

2. Direct measurements of the relative developments of different portions of brains are difficult and troublesome to make; but their importance to phrenologists is so great that it is remarkable that no attempts to obtain any such were made by them. The series given by Wagner of the relative sizes of the cerebral lobes of four brains is almost the only record of importance in this direction, and is appended.

| Brain of | Surface of Frontal Lobe. | Surface of Parietal Lobe. | Surface of Occipital Lobe. | Surface of Temporo-Sphenoidal. | Relation of Frontal Lobe (Perceptive and Reflective Organs) to whole Surface=1. | Relation of Parietal Lobe (Sentiments) to Surface=1. | Relation of Remaining Surface (Propensities) to Surface=1. | Extent of Free Surface. | Extent of Surface of Involutions. | Total Extent of Surface. | Weight in Grammes. |
|-------------------------|--------------------------|---------------------------|----------------------------|--------------------------------|---|--|--|-------------------------|-----------------------------------|--------------------------|--------------------|
| Fuchs, clinical teacher | 143.4 | 69.5 | 59 | 67.5 | .419 | .203 | .340 | 110.7 | 231.3 | 342 | 1499 |
| Gauss, mathematician | 139 | 70.6 | 59.4 | 68.4 | .407 | .207 | .374 | 112.8 | 228.2 | 341 | 1492 |
| Workman | 113.2 | 62.3 | 50.3 | 62 | .385 | .214 | .385 | 97.4 | 193.6 | 31 | 1273 |
| Woman | 130 | 65 | 51 | 66.8 | .409 | .204 | .370 | 107.5 | 209.9 | 317.4 | 1185 |

From this it appears that the woman exceeded Gauss in perceptive and reflective organs, exceeded Fuchs in sentiment, and fell below the workman in propensities. It must be said, however, that the phrenological divisions do not accurately coincide with the anatomical. Other series constructed along these lines are very

much wanted, and it would furnish important physiological data if the brains of men distinguished for special qualities were examined in this or some comparable way.

3. It is important in relation to phrenology to ascertain the constancy of the convolutions. Many varieties in the detail of the surface-patterns have been recorded by Tenechini, Poggi, Giacomini, Rüdinger, and Sernow,⁵ but the general plan is fairly uniform. A still more important question has been recently raised by Langley, viz., how far identical spots on identical convolutions in different brains consist of nerve-cells with precisely the same connexions. The convoluted arrangement results from growth of brain-surface under constraint, hence as the different tracts of surface undergo proportional overgrowth they fold along different lines. The occurrence of small differences in the rate of overgrowth, testified to by the varieties of the resulting pattern, will cause considerable alteration in the place of definite territories of grey cells. Some method for the determination of the limits of these shiftings of place is much required.

4. The comparison of the rate of growth of brain with the development of mental faculties is important not only to the phrenologist but to the psychologist. No observations on this point were made by phrenological writers, and they simply refer to the first and rather crude observations of the earlier anatomists. We have, however, recently learned from the researches of Bischoff, Tuzee, and Exner⁶ many particulars as to the rate and progress of brain-growth. At birth the brain weighs one-tenth of the weight of the body, and averages about 11 ounces. For the first year brain-growth and consequently expansion of the skull proceed with great rapidity, the growth during a large part of this period averaging one cubic centimetre daily. This enormous increase is chiefly due to the rapid development of medullated nerve-fibres, which are deficient in the fetal brain. During the second and third years growth takes place more slowly, the occipital and parietal lobes increasing more than the frontal or temporo-sphenoidal. During these and the four succeeding years the base elongates commensurately with the increasing depth of the face. In the sixth and seventh years the frontal lobes grow faster than the parietals, and at seven the average brain has attained the weight of 1340 grammes, being to the weight of the body as 1:20. In the period between seven years and puberty growth is slight, but at puberty the whole brain grows actively, especially the frontal lobes. This activity lasts until about eighteen years of age, then diminishes; but the average brain does not reach its maximum size until about thirty, from a little after which period the brain tends to diminish towards senility.⁷ These measurements illustrate the relation between brain-growth and mental development, but are as easily explicable on any psychological theory of brain-action as on the phrenological. The relation supposed by Davaine to subsist between development of the brain and stature is not borne out by statistics.⁸

5. The estimation of the relative development of grey and white matter in the several lobes is important to any theory of cerebral dynamics which allocates functions specifically diverse to each separate part of the brain-surface; but no attempt has been made by the phrenologist to obtain precise results in this direction, nor even to determine the physical constants of the two forms of brain-matter. The recently-introduced method of Bourgoin and Danilewski, based upon the differing specific gravities of grey and white matter, promises to give definite information as to the relative amounts of these forms of brain-matter; but further experiments are needed to perfect the method.⁹

6. The relations, if any, between the alterations which take place in the shape and position of the head and alterations in brain-surface have been speculated on by the phrenologist. Broussais is reported to have said that his organ of causality had enlarged with increasing use, and a list of cases of similar alterations of head-shape is given by Deville (*Phren. Jour.*, xiv. 32), most of which are simply age-changes, of the kind described by Professor Cleland (*Phil. Trans.*, 1870). There are no exact measurements recorded which indicate the occurrence of topical increases of a normal brain in special directions coincident with the cultivation of definite faculties. All the so-called cases are given vaguely, with no measurements, and the careful measurements of George Combe in such cases as were available to him showed no appreciable alterations in adult heads even at long intervals of time (see also Andrew Combe, *Phren. Journ.* x. 414).

7. The phrenological want of knowledge of the topography of the brain-surface was necessarily correlated with ignorance of the exact relations of the convolutions to the interior of the cranial bones; these have been carefully worked out by Huschke, Heffler, Turner, and Reid. Some latitude, however, must be allowed in topography, as the exact relation of convolution to skull varies with the shape of the skull. Giaconini showed that the fissure of Rolando is perceptibly farther back from the coronal suture in dolichocephalic than in brachycephalic skulls, and it is still farther back in the extreme boat-shaped form of long-headedness. Passet shows that there is a slight topographical difference in the two sexes (*Arch. f. Anthropol.*, 1882, xiv. 89), and in the heads of those with unsymmetrically-shaped skulls there is often a want of lateral symmetry of convolution. Artificial deformations likewise alter the topographical relations of convolutions, and have served not a little to puzzle the phrenologist. Thus, the artificial dolichocephaly of the Caribs having bulged the squama occipitis, they decided that these people must be amiable lovers of children,¹ &c.

8. The existence of structural differences between different areas of cerebral surface is important to any theory of cerebral localization, but no phrenologist has given us any original information on this point. Since the investigation of Baillarger,² it has been shown that some local differentiations of structure do really exist. Thus in the convolutions around the fissure of Rolando the ganglion-cells of the fourth layer are of large size (giant-cells of Betz), and in the convolutions of the temporo-sphenoidal lobe a layer of small angular cells (granule-cells) is interposed between the larger pyramidal and the ganglion-cells; so that, while in the parts of the brain above the fissure of Sylvius the grey cortex is for the most part five-layered, below and behind that fissure it is six-layered. There is no abrupt passage from the one to the other, the only sudden transition of structure of the grey cortex being at the hippocampal sulcus; and giant-cells, although of smaller size, and less like those of the anterior cornu of the spinal cord, are scattered over other parts of the cerebral grey matter.³ In fig. 71, vol. i. p. 874, the relations of the convolutions to the internal surface of the skull are represented, and their want of accurate correlation to the phrenological areas can be seen by comparing that figure with the foregoing series.

The teachings of anatomy with regard to phrenology may be summarized thus: (1) the rate of growth of brain is concurrent with the rate of development of mental faculty; (2) there is some degree of structural differentiation as there are varying rates of development of different parts of the cerebral surface; (3) there is no accordance between the regions of Gall and Spurzheim and definite areas of cerebral surface.

Physiological Aspect.—The theory of some of the older metaphysicians, that the mind, in feeling and reflexion, makes use of no material instrument is not now accepted by psychologists. It was advanced by Brongham and Jeffrey as against the theory of phrenology; but the doctrine that the brain is the organ of the mind is now universally received. While it is probable that certain molecular changes in the grey matter are antecedents or concomitants of mental phenomena, the precise nature of these processes, to what extent they take place, or how they vary among themselves have not as yet been determined experimentally; the occurrence of the change can only be demonstrated by some such coarse method as the altered pulsation of the carotid arteries,⁴ the increase of the temperature of the head,⁵ the abstraction, during brain-action, of blood from other organs as shown by the plethysmograph, or the formation of lecithin and other products of metabolism in brain-substance. As yet not a single step has been made towards the understanding of the connexion between the molecular changes in the nerve-cell and the phenomena of thought and feeling. While our

knowledge of the anatomy of the brain, especially of the grey nuclei and of the white bands uniting them, has within the last few years become much more accurate, brain-function has not as yet been so definitely determined; indeed, much of nerve-physiology, especially that part which relates to the division of labour in the nerve-centres, is largely hypothetical and based on anatomical structure. Certain masses of grey nerve-matter situated in the spinal cord and medulla oblongata are so linked by nerve-cords to organs outside the nervous system which are set apart for the discharge of separate functions that they obviously form parts of the mechanism for the fulfilment of such functions. In the cases where these can be subjected to experiment we learn that they are nervous centres presiding over the discharge of such functions; and it has been determined by experiment, or else deduced from anatomical structure, that in those lower parts of the nervous centres which are more directly connected with the segmental elements of the body there is a certain localization of function; hence the centres of pelvic actions, of respiration, cardiac action, and inhibition of vaso-motor influence, deglutition, secretions, &c., can be mapped out in ascending series. As certain of these centres are united by bands of fibres to the larger and higher-lying grey portions of the nervous centres there is an *a priori* presumption in favour of the extension of this principle of localization. This has been premised on metaphysical as well as on anatomical grounds. Bonnet believed each portion of the brain to have a specifically separate function, and Herbert Spencer has said that "no physiologist can long resist the conviction that different parts of the cerebrum subserve different kinds of mental action. Localization of function is the law of all organization whatever; separateness of duty is universally accompanied with separateness of structure, and it would be marvellous were an exception to exist in the cerebral hemispheres. Let it be granted that the cerebral hemispheres are the seats of the higher psychical activities; let it be granted that among these higher psychical activities there are distinctions of kind which, though not definite, are yet practically recognizable, and it cannot be denied, without going in direct opposition to established physiological principles, that these more or less distinct kinds of psychical activity must be carried on in more or less distinct parts of the cerebral hemisphere."

For the results of experiment on the brain, see *PHYSIOLOGY*, section "Nervous System."

There is a large weight of evidence, which cannot be explained away, in favour of the existence of some form of localization of function. So little is known of the physical changes which underlie psychical phenomena, or indeed of the succession of the psychical processes themselves, that we cannot as yet judge as to the nature of the mechanism of these centres. So much of the psychic work of the individual life consists in the interpretation of sensations and the translation of these into motions that there are strong *a priori* grounds for expecting to find much of the material of the nerve-centres occupied with this kind of work, but in the present conflict of experimental evidence it is safer to suspend judgment. That these local areas are not centres in the sense of being indispensable parts of their respective motor apparatuses is clear, as the function abolished by ablation of a part returns, though tardily, so that whatever superintendence the removed region exercised apparently becomes assumed by another part of the brain.⁶ Experimental physiology and pathology, by suggesting other functions for much of the brain-surface, are thus directly subversive of much of the phrenology of Gall and Spurzheim.

¹ Martius tells us that the Caribs castrate their own children, fatten and eat them, an abuse of the organ of philoprogenitiveness; see also Garcilaso de la Vega, *Hist. des Incas*, i. 12.

Psychological Aspect.—The fundamental hypothesis which underlies phrenology as a system of mental science is that mental phenomena are resolvable into the manifestations of a group of separate faculties. A faculty is defined as "a convenient expression for the particular states into which the mind enters when influenced by particular organs; it is applied to the feelings as well as to the intellect, thus the faculty of benevolence means every mode of benevolence induced by the organ of benevolence" (Combe). In another work the same author says it is "used to denote a particular power of feeling, thinking, perceiving, connected with a particular part of the brain." The assumption is contained in the definition that the exercise of a faculty is the physical outcome of the activity of the organ, and in several of the standard works this is illustrated by analogies between these and other organs; thus the organs of benevolence and of firmness are said to be as distinct as the liver and pancreas. The mind, according to another author, consists of the sum of all the faculties. In this view the unity of consciousness is somewhat difficult to explain, and consequently there is assumed by others a single unifying substratum, and on this the organs are supposed to act; thus thoughts are defined as "relations of the simple substance, mind, to certain portions of the encephalon" (Welsh, *Phren. Journ.*, i. 206). Gall himself believed that there was but a single principle which saw, felt, tasted, heard, touched, thought, and willed (*Fonctions du Cerveau*, i. 243); and the American exponent of phrenology, Caldwell, says "the mind is as single in its power as it is in its substance; it is a quickening and operating principle, essential to all the mental faculties, but does not, by any means, possess them itself" (*Elements*, p. 16). It is not easy to understand the supposed relation of this hypothetical substratum to the separate faculties acting on it. It must be both immaterial and unconnected with the brain, as the whole two thousand million cells supposed to exist in the cerebral hemispheres are all parcelled out among the faculties, and none are left for the unifying *nous*.

Each organ is considered as engaged, either independently in bringing forth its own product, or collectively with others in elaborating compound mental states, and according to their several degrees of development and activity they are considered capable of perceiving, conceiving, recollecting, judging, or imagining each its own subject. This mechanical conception of the division of labour in the production of the phenomena of mind has the charm of simplicity, but is attended with the difficulty that arises in discriminating the operations of the different organs one from the other. Phrenologists are apt to be vague respecting the limits of the several faculties, as about the boundaries of the separate organs. It was pointed out by Jeffrey that the lines of demarcation between benevolence, adhesiveness, and philoprogenitiveness were indeterminate, although the organs are not very close, and the same applies to other organs.

It is unfortunate for the clearness of the definition that, although historically the faculties were the first phenomena noted, independent of and previous to their localization, yet in the definition the faculties are defined in terms of their localities.

The following arguments are adduced in favour of the fundamental separateness of the faculties: (1) analogy,—elsewhere in the animal economy division of labour is the rule; (2) the variety of mental endowment observed among children before they are influenced by education, and the inequalities in the mental endowments of individuals; (3) the phenomena of insanity, especially of monomania; (4) the varying periods at which individual faculties attain their maximum development; (5) the

phenomena of dreams, and the awakening of a limited number of faculties during them; (6) pain being felt in an organ when it is overtaxed.¹

Such faculties are supposed to be primary—(1) as exist in some animals and not in others, (2) as vary in their development in the sexes, (3) as are developed in varying proportions with regard to other faculties, (4) as may act separately from other faculties, (5) as are not necessarily simultaneous with other faculties in action, (6) as are hereditary, and (7) as may be singly diseased.

According to the development of their powers mankind may be divided into six classes: (1) those in whom the highest qualities are largely developed and the animal qualities feeble; (2) those with the reversed conditions developed, with large animal and feeble intellectual and moral faculties; (3) those in whom good and evil are in constant war, with active animal and strong intellectual faculties and sentiments; (4) those partial geniuses in whom a few qualities are unusually developed, while the rest are at or below the mediocre standard; (5) those men of moderate endowment in whom some faculties are nearly or quite deficient; (6) those with an unvarying standard of undistinguished mediocrity in all their faculties.

It is perhaps unfortunate that the word "faculty" has been used in this sense of original power by phrenologists. It would have been better to employ, as Mr Lewes suggests, the term "function" for the native activity of an organ, and to leave "faculty" for the expression of an acquired activity. "Faculty is properly limited to active power, and therefore is abusively applied to the mere passive affections of the mind" (Hamilton, *Lectures*, i. 177).

Practical Application.—"Die Schädellehre ist allerdings nicht so sehr Irrthum in der Idee als Charlatanerie in der Ausführung," says one of its most acute critics. Even though no fault could be found with the physiology and psychology of phrenology, it would not necessarily follow that the theory could be utilized as a practical method of reading character; for, although the inner surface of the skull is moulded on the brain, and the outer surface approximates to parallelism thereto, yet the correspondence is sufficiently variable to render conclusions therefrom uncertain. The spongy layer or diploe which separates the two compact tables may vary conspicuously in amount in different parts of the same skull, as in the cases described by Professor Humphry (*Journ. of Anat.*, vol. viii. p. 137). The frontal sinus, that *opprobrium phrenologicum*, is a reality, not unfrequently of large size, and may wholly occupy the regions of five organs. The centres of ossification of the frontal and parietal bones, the muscular crests of these and of the occipital bones also, differ in their prominence in different skulls. Premature synostoses of sutures mould the brain without doing much injury to its parts. Artificial malformations alter the apparent skull-shape considerably and affect the relative development of the brain but little. All these and other cogent reasons of a like kind, whose force can be estimated by those accustomed to deal with the component soft parts of the head, should lead phrenologists to be careful in predicating relative brain-development from skull-shape. Psychology, physiology, and experience alike contribute to discredit

¹ It is interesting in this connexion to note that in a case published by Professor Hamilton in *Brain* (April 1884), where a tumour existed on the occipital lobe, the pain was persistently referred to the forehead. Many similar cases are to be noticed among the records of localized brain-lesions. Bearing on this point also it is worth noting, once for all, that in nothing is the purely hypothetical nature of phrenological description better realized than in the accounts of what these authors call the "natural language of the faculties,"—that poets are snpossed to touch ideality when composing, musicians to press on tone and time, and painters on form and colour, when in the exercise of their arts! Yet we are gravely taught this in the standard works on the subject.

the system and to show how worthless the so-called diagnoses of character really are. Its application by those who are its votaries is seldom worse than amusing, but it is capable of doing positive social harm, as in its proposed application to the discrimination or selection of servants and other subordinate officials. It has even been proposed to use it for the purposes of the guarantee society and for the selection of parliamentary representatives. The sarcastic suggestion which originated with Christopher North of moulding children's heads so as to suppress the evil and foster the good was actually repeated in good faith by a writer on phrenology, but experience of the effects of malformation leads one to be sceptical as to the feasibility of this mode of producing a social Utopia. The application of phrenology to the art of painting and sculpture has been suggested, but a careful examination of some of the best pictures of the best masters, who were close observers of nature, shows that no phrenological principles were accepted by them in their works. An application to ethnology has also been proposed; but, although there are in most cases well-marked racial characters presented by the skull, yet all attempts at correlating national characteristics therewith have been groundless and worthless. For further particulars on allied subjects, see **PHYSIOGNOMY**.

PHRYGIA was the name of a large country in Asia Minor, inhabited by a race which the Greeks called Φρύγες, *Freemen*.¹ Roughly speaking, Phrygia comprised the

western part of the great central plateau of Anatolia, extending as far east as the river Halys; but its boundaries were vague,² and varied so much at different periods that a sketch of its history must precede any account of the geography. According to unvarying Greek tradition the Phrygians were most closely akin to certain tribes of Macedonia and Thrace; and their near relationship to the Hellenic stock is proved by all that is known of their language and art, and is accepted by almost every modern authority. The country named Phrygia in the better known period of history lies inland, separated from the sea by Paphlagonia, Bithynia, Mysia, and Lydia. Yet we hear of a Phrygian "thalassocracy" at the beginning of the 9th century B.C. The Troad and the district round Mount Sipylus are frequently called Phrygian, as also is the seaport Sinope; and a district on the coast between Sestus and the river Cius was regularly named Little Phrygia. Again, Abel³ has pointed to the wide currency of names like Mygdones, Doliones, and Phryges or Briges both in Asia Minor and in Europe, and many other examples might be added. The inference has been generally drawn that the Phrygians were a stock widespread in the countries which lie round the Ægean Sea. There is, however, no decisive evidence, and no agreement among modern scholars, as to whether this stock came from the East over Armenia, or whether it was European in origin and crossed the Hellespont into Asia Minor.

According to Greek tradition there existed in early time a Phrygian kingdom in the Sangarius valley, ruled by kings among whom the names Gordius and Midas were common. It was known to the ancient Greeks of Ionia and the Troad as something great and half-divine. When the goddess appeared to her favourite Anchises she represented herself as daughter of the king of Phrygia; the Phrygians were said to be the oldest people, and their language the original speech of mankind;⁴ the Phrygian kings were familiar associates of the gods, and the heroes of the land tried their skill against the gods themselves; we hear of the well-walled cities of Phrygia and of the riches of its kings. Tradition is completely corroborated by archaeological evidence. In the mountainous region on the upper waters of the Sangarius, between Kutayah and Afium Kara Hissar, there exist numerous monuments of great antiquity, showing a style of marked individuality, and implying a high degree of artistic skill among the people who produced them. On two of these monuments are engraved the names of "Midas the King" and of the goddess "Kybile the Mother." Even the title "king" (ἄναξ)⁵ appears to have been borrowed by Greek from Phrygian.

It is impossible to fix a date for the beginning of the Phrygian kingdom. It appears to have arisen on the ruins of an older civilization, whose existence is revealed to us only by the few monuments which it has left. These monuments, which are found in Lydia, Phrygia, Cappadocia, and Lycæonia, point to the existence of a homogeneous civilization over those countries; they show a singularly marked style of art, and are frequently inscribed with a peculiar kind of hieroglyphics, engraved *boustrophedon*, which have not as yet been deciphered.⁶ There can be

² The difficulty of specifying the limits gave rise to a proverb—*χωρίς τὰ Φρυγίων*, Strabo.

⁴ Herod., ii. 2; Pausan., i. 14, 2; Claudian, *In Eutrop.*, ii. 251; Apul., *Met.*, xi. p. 762.

⁵ *Φαυακί* on the Midas tomb. It is expressly recorded that *τίραννος* is a Lydian word. *Βασιλεύς* resists all attempts to explain it as a purely Greek formation, and the termination assimilates it to certain Phrygian words.

⁶ It is common to name these monuments "Hittite," but this name presupposes the truth of an historical hypothesis, namely, the conquest of Asia Minor by a race whose capital was in Syria, which has not as yet been supported by any convincing arguments.

¹ The meaning is given in Hesych., s.v. "Βρύγες."

traced in Asia Minor an ancient road-system, to which belongs the "royal road" from Sardis to the Persian capital, Susa (Herod., v. 55). The royal road followed a route so difficult and circuitous that it is quite unintelligible as the direct path from any centre in Persia, Assyria, or Syria to the west of Asia Minor. It can be understood only by reference to an imperial centre far in the north. The old trade-route from Cappadocia to Sinope, which had passed out of use centuries before the time of Strabo (pp. 540, 546), fixes this centre with precision. It must be far enough west to explain why trade tended to the distant Sinope,¹ hardly accessible behind lofty and rugged mountains, and not to Amisus by the short and easy route which was used in the Græco-Roman period. This road-system, then, points distinctly to a centre in northern Cappadocia near the Halys. Here must have stood the capital of some great empire connected with its extremities, Sardis or Ephesus on the west, Sinope on the north, the Cilician Gates on the south, by roads so well made as to continue in use for a long time after the centre of power had changed to Assyria, and the old road-system had become circuitous and unsuitable.² The precise spot on which the city stood is marked by the great ruins of Boghaz Keui, probably the ancient Pteria, of which the wide circuit, powerful walls, and wonderful rock-sculptures make the site indisputably the most remarkable in Asia Minor.

The ancient road from Pteria to Sardis crossed the upper Sangarius valley, and its course may be traced by the monuments of this early period.³ Close to its track, on a lofty plateau which overhangs the Phrygian monument inscribed with the name of "Midas the King," is a great city, inferior indeed to Pteria in extent, but surrounded by rock-sculptures quite as remarkable as those of the Cappadocian city. The plateau is between 2 and 3 miles in circumference, and presents on all sides a perpendicular face of rock 50 to 200 feet in height. In part, at least, this natural defence was crowned by a wall built of large squared stones.⁴ This city was evidently the centre of the old Phrygian kingdom of the Sangarius valley, but at least one of the monuments in it seems to belong to the older period of Cappadocian supremacy, and to prove that the city already existed in that earlier time.⁵ The Phrygian kingdom and art therefore took the place of an older civilization. It is as yet impossible to determine the relation in which the Phrygians stood to the ruling race of that older period, whether they came in from the north-west, or whether they were a primitive people taught, and for a time ruled, by foreigners from Cappadocia, but at last expelling their teachers. It is probable that the tradition of battles between the Phrygians and the Amazons on the banks of the Sangarius preserves the memory of a struggle between the two races.⁶

Of the monuments that exist around this city two classes may be confidently referred to the period of Phrygian greatness. That which is inscribed with the name of "Midas the King" is the most remarkable example of one class, in which a large perpendicular surface of rock

is covered with a geometrical pattern of squares, crosses, and mæanders, surmounted by a pediment supported in the centre by a pilaster in low relief. In some cases a floral pattern occupies part of the surface, and in one case the two sides of the pediment are filled by two sphinxes of extremely archaic type.⁷ In some of these monuments a doorway is carved in the lower part; the door is usually closed, but in one case, viz., the sphinx monument just alluded to, the valves of the door are thrown wide open and give access to a little chamber, on the back of which is sculptured in relief a rude image of the Mother-goddess Cybele, having on each side of her a lion which rests its forepaws on her shoulder and places its head against hers. Sometimes a grave has been found hidden behind the carved front; in other cases no grave can be detected, but it is probable that they are all sepulchral.⁸ The imitation of wood-work is obvious on several monuments of this kind. The second class is marked by the heraldic type of two animals, usually lions rampant, facing one another, but divided by a pillar or some other device. This type is occasionally found conjoined with the preceding; and various details common to both classes show that there was no great difference in time between them. The heraldic type is used on the monuments which appear to be the older, and the geometrical pattern is often employed on the inscribed monuments, which are obviously later than the uninscribed. Monuments of this class are carved on the front of a sepulchral chamber, the entrance to which is a small doorway placed high and inaccessible in the rocks.

Early Phrygian art stands in close relationship with the art of Cappadocia, but has such individuality, such freedom from conventionality, such power of varying and combining types learned from other peoples, as to show that the Phrygians possessed high artistic faculty very similar in character to the Greek. The monuments of the type of the Midas tomb are obviously imitated from patterns employed in cloth and carpets. Such patterns were used in Cappadocia, and the priest in the rock-sculpture at Ibriz wears an embroidered robe strikingly similar in style to the pattern on the Midas tomb; but the idea of using the pattern as the Phrygians did seems peculiar to themselves. The heraldic type of the second class is found also in the art of Assyria, and was undoubtedly adopted by the Phrygians from earlier art; but it is used so frequently in Phrygia as to be specially characteristic of that country.⁹ While Phrygian art is distinctly non-Oriental in spirit, its resemblance to archaic Greek art is a fact of the greatest importance. It is not merely that certain types are employed both in Phrygia and in Greece, but most of the favourite types in early Greek art can be traced in Phrygia, employed in similar spirit and for similar purposes. The heraldic type of the two lions is the device over the principal gateway of Mycenæ, and stamps this, the oldest great monument on Greek soil, with a distinctly Phrygian character. Mycenæ was the city of the Pelopidæ, whom Greek tradition unhesitatingly declares to be Phrygian immigrants. A study of the topography of the Argive plain leads to the conclusion that Mycenæ, Midea, and Tiryns form a group of cities founded by an immigrant people in opposition to Argos, the natural capital of the plain and the stronghold of the native race. Midea

¹ Sinope was made a Greek colony in 751 B.C., but it is said to have existed long before that time.

² When the Persians conquered Lydia they retained, at least for a time, this route, which they found in existence, and the royal messengers went first across the Halys to Pteria, and then by the road across Cappadocia to the Cilician Gates.

³ See a paper on "The Early Historical Relations between Phrygia and Cappadocia," in *Journ. Roy. As. Soc.*, 1883.

⁴ The small fortress Pishmish Kalessi is a miniature of the great city beside it; see Perrot, *Explor. Archéol.*, p. 169 and pl. viii.

⁵ A large tumulus exists in this district between Bel Keui and Ak Euren, from which one large stone, with an inscription in the usual Cappadocian hieroglyphics, has already been dug.

⁶ Abel (*l.c.*) identifies these two races, and makes the city at Boghaz Keui a Phrygian city.

⁷ Published in *Journ. Hell. Stud.*, 1884.

⁸ The monuments of Phrygia fall into two groups, which probably mark the sites of two cities about 16 miles distant from each other. One group lies round the villages of Kumbet, Yapuldak, and Bakshish; the other beside Liyen, Bel Keui, Demirtll, and Ayazin.

⁹ The heraldic type continues on gravestones down to the latest period of paganism. Carpets with geometrical patterns of the Midas-tomb style are occasionally found at the present time in the houses of the peasantry of the district.

appears to be the city of Midas,¹ and the name is one more link in the chain that binds Mycenæ to Phrygia. This connexion, whatever may have been its character, belongs to the remote period when the Phrygians inhabited the Ægean coasts. In the 8th and probably in the 9th century B.C. communication with Phrygia seems to have been maintained especially by the Greeks of Cyme, Phocæa, and Smyrna. About the end of the 8th century Midas king of Phrygia married Damodice, daughter of Agamemnon, the last king of Cyme: Gyges, the first Mermnad king of Lydia (687-653), had a Phrygian mother. The worship of Cybele spread over Phocæa to the west as far as Massilia: rock monuments in the Phrygian style and votive reliefs of an Anatolian type are found near Phocæa. Smyrna was devoted to the Phrygian Meter Sipylene. It is then natural that the lays of the Homeridæ refer to Phrygia in the terms above described, and make Priam's wife a Phrygian woman. After the foundation of the Greek colony at Sinope in 751 there can be no doubt that it formed the link of connexion between Greece and Phrygia. Phrygian and Cappadocian traders brought their goods, no doubt on camels, to Sinope, and the Greek sailors, the *ἀειναῖται* of Miletus, carried home the works of Oriental and Phrygian artisans. The Greek alphabet was carried back to Phrygia and Pteria, either from Sinope or more probably from Cyme, in the latter part of the 8th century. The immense importance of Sinope in early times is abundantly attested, and we need not doubt that very intimate relations existed at this port between the Ionic colonists and the natives. The effects of this commerce on the development of Greece were very great. It affected Ionia in the first place, and the mainland of Greece indirectly; the art of Ionia at this period is almost unknown, but it was probably most closely allied to that of Phrygia.² A striking fact in this connexion is the frequent use of a very simple kind of Ionic capital on the early Phrygian monuments, making it practically certain that the "proto-Ionic" column came to Greece over Phrygia. It is obvious that the revolution which took place in the relations between Phrygians and Greeks must be due to some great movement of races which disturbed the old paths of communication. Abel is probably correct in placing the inroads of the barbarous European tribes, Bithynians, Thyni, Mariandyni, &c., into Asia Minor about the beginning of the 9th century B.C. The Phrygian element on the coast was weakened and in many places annihilated; that in the interior was strengthened; and we may suppose that the kingdom of the Sangarius valley now sprang into greatness. The kingdom of Lydia appears to have become important about the end of the 8th century, and to have completely barred the path between Phrygia and Cyme or Smyrna. Ionian maritime enterprise opened a new way over Sinope.³

The downfall of the Phrygian monarchy can be dated with comparative accuracy. Between 680 and 670 the Cimmerians in their destructive progress over Asia Minor overran Phrygia; the king Midas in despair put an end to his own life; and from henceforth the history of Phrygia is a story of slavery, degradation, and decay, which contrasts strangely with the earlier legends. The catastrophe seems to have deeply impressed the Greek mind, and the memory of it was preserved. The date of the Cimmerian invasion is fixed by the concurrent testimony of the contemporary

poets Archilochus and Callinus, of the late chronologers Eusebius, &c., and of the inscriptions of the Assyrian king Essar-haddon. The Cimmerians were finally expelled from Asia Minor by Alyattes before his war with the Medes under Cyaxares (590-585 B.C.). The Cimmerians, therefore, were ravaging Asia Minor, and presumably held possession of Phrygia, the only country where they achieved complete success, till some time between 610 and 590. Phrygia then fell under the Lydian power, and by the treaty of 585 the Halys was definitely fixed as the boundary between Lydia and Media. The period from 675 to 585 must therefore be considered as one of great disturbance and probably of complete paralysis in Phrygia. After 585 the country was ruled again by its own princes, under subjection to Lydian supremacy. To judge from the monuments, it appears to have recovered some of its old prosperity, but the art of this later period has to a great extent lost the strongly-marked individuality of its earlier bloom. The later sepulchral monuments belong to a class which is widely spread over Asia Minor, from Lycia to Pontus. The graves are made inside a chamber excavated in the rock, and the front of the chamber imitates a house or temple. No attempt is made to conceal the entrance or render it inaccessible. The architectural details are in some cases unmistakably copied without intentional modification from the architecture of Greek temples, others point perhaps to Persian influence, while several—which are perhaps among the early works of this period—show the old freedom and power of employing in new and original ways details partly learned from abroad. This style continued in use under the Persians, under whose rule the Phrygians passed when Cyrus defeated Cræsus in 546, and probably lasted till the 3d century B.C. One monument appears to presuppose a development of Greek plastic art later than the time of Alexander.⁴ It would, however, be quite wrong to suppose that the influence of truly Hellenic art on Phrygia began with the conquest of Alexander. Under the later Mermnad kings the Lydian empire was penetrated with Greek influence, and Xanthus, the early Lydian historian, wrote his history in Greek. Under the Persian rule perhaps it was more difficult for Greek manners to spread far east; but we need not think that European influence was absolutely unfelt even in Phrygia. The probability is that Alexander found in all the large cities a party favourable to Greek manners and trade. Very little is to be learned from the ancient writers with regard to the state of Phrygia from 585 to 300. The slave-trade flourished; Phrygian slaves were common in the Greek market, and the Phrygian names Midas and Manes were stock-names for slaves. Herodotus (i. 14) records that a king Midas of Phrygia dedicated his own chair at Delphi; the chair stood in the treasury of Cypselus, and cannot have been deposited there before 680 to 660 B.C. It is not improbable that the event belongs to the time of Alyattes or Cræsus, when Greek influence was favoured throughout the Lydian empire; and it is easy to understand how the offering of a king Midas should be considered, in the time of Herodotus, as the earliest made by a foreign prince to a Greek god. The Phrygian troops in the army of Xerxes were armed like the Armenians and led by the same commander.

It is to be presumed that the cities of the Sangarius valley gradually lost importance in the Persian period. Formerly the great line of communication across Anatolia traversed the Sangarius valley, but a better and shorter path south of the Salt Desert came into use in this period, from which these cities were far distant. The final catastrophe was the invasion of the Gauls about 270 to 250; and, though the circumstances of this invasion are almost

¹ A city Midea occurs also in Boeotia, a village Midea on the Hellespont, and a city Midæum in the Sangarius valley.

² See Furtwängler, *Goldfund von Vettlersfelde*, Winckelm. Progr., 1884. The closest analogies of old Phrygian art are to be found in the earliest Greek bronze work in Olympia, Italy, and the northern lands.

³ Hipponax, fr. 36 [49], proves that a trade-route from Phrygia down the Mæander to Miletus was used in the 6th century.

⁴ A gorgoneum, on a tomb engraved in *Journ. Hell. Stud.*, vi. xxvi.

unknown, yet we may safely reckon among them the complete devastation of northern Phrygia. At last Attalus I. settled the Gauls permanently in eastern Phrygia, and a large part of the country was henceforth known as Galatia. Strabo mentions that the great cities of ancient Phrygia were in his time either deserted or marked by mere villages. The great city over the tomb of Midas has remained uninhabited down to the present day. About 5 miles west of it, near the modern Kumbet, stood Merus, a bishopric in the Byzantine time, but never mentioned under the Roman empire.

Alexander the Great placed Phrygia under the command of Antigonos, who retained it when the empire was broken up. When Antigonos was defeated and slain at the decisive battle of Ipsus, Phrygia came under the sway of Seleucus. As the Pergamenian kings grew powerful, and at last confined the Gauls in eastern Phrygia, the western half of the country was incorporated in the kingdom of Pergamum. Under the Roman empire Phrygia had no political existence under a separate government,¹ but formed part of the vast province of Asia. In autumn 85 B.C. the pacification of the province was completed by Sulla, and throughout the imperial time it was common for the Phrygians to date from this era. The imperial rule was highly favourable to the spread of Hellenistic civilization, which under the Greek kings had affected only a few of the great cities, leaving the mass of the country purely Phrygian. A good deal of local self-government was permitted: the cities struck their own bronze coins, inscribed on them the names of their own magistrates,² and probably administered their own laws in matters purely local. The western part of the country was pervaded by Græco-Roman civilization very much sooner than the central, and in the country districts the Phrygian language³ continued in common use at least as late as the 3d century after Christ.

When the Roman empire was reorganized by Diocletian at the end of the 3d century Phrygia was divided into two provinces, distinguished at first as Prima and Secunda, or Great and Little, for which the names Pacatiana and Salutaris⁴ soon came into general use. Pacatiana comprised the western half, which had long been completely pervaded by Græco-Roman manners, and Salutaris the eastern, in which the native manners and language were still not extinct. Each province was governed by a "praeses" or ἡγεμὼν about 412 A.D., but shortly after this date an officer of consular rank was sent to each province (Hierocles, *Synecd.*). About 535 Justinian made some changes in the provincial administration: the governor of Pacatiana was henceforth a "comes," while Salutaris was still ruled by a "consularis." When the provinces of the Eastern empire were reorganized and divided into "themata" the two Phrygias were broken up between the Anatolic, Opsician, and Thracasian themes, and the name Phrygia finally disappeared. Almost the whole of the Byzantine Phrygias is now included in the vilayet of Broussa or Khodavendikya, with the exception of a small part of Parorius and the district about Themisonium (Karayuk Bazar) and Ceretapa (Kayadibi), which belong to the vilayet of Koniye, and the district of Laodicea and Hierapolis, which belongs

to Aidin. The principal modern cities are Kütahya (Cotyæum), Eski Sheher (Dorylæum), Afium Kara Hissar (near Prymnessus), and Ushak (near Trajanopolis).

It is impossible to say anything definite about the boundaries of Phrygia before the 5th century. Under the Persians Great Phrygia extended on the east to the Halys and the Salt Desert; Xenophon (*Anab.*, i. 2, 19) includes Iconium on the south-east within the province, whereas Strabo makes Tyriaëum the boundary in this direction. The southern frontier is unknown: the language of Livy (xxxviii. 15) implies that Metropolis (in the Tchul Ova) belonged to Pisidia; but Strabo (p. 629) includes it in Phrygia. Celænæ, beside the later city of Apamea (Dineir), and the entire valley of the Lycus were Phrygian. The Mæander above its junction with the Lycus formed for a little way the boundary between Phrygia and Lydia. The great plateau now called the Banaz Ova was entirely or in great part Phrygian. Mount Dindymus (Murad Dag) marked the frontier of Mysia, and the entire valley of the Tembrogius or Tembris (Porsuk Su) was certainly included in Phrygia. The boundaries of the two Byzantine Phrygias were not always the same. Taking Hierocles as authority, the extent of the two provinces at the beginning of the 6th century will be readily gathered from the accompanying list, in which those towns which coined money under the Roman empire are italicized and the nearest modern village is appended.

I. PACATIANA.—1. *Laodicea* (Eski Hissar); 2. *Hierapolis* (Pambuk Kalessi); 3. *Mosyna* (Geveze); [4. *Metellopolis*, only in *Notitiæ Episcop.* (Geuzlar)]; 5. *Attuda* (Assar, south-west from Serai Keui); 6. *Trapezopolis* (perhaps between Davas Ova and Karayuk Ova); 7. *Colossæ* (near Chonas); 8. *Ceretapa Diocæsarea* (Kayadibi); 9. *Themisonium* (Karayuk Bazar); 10. *Tacina* (Yarishli); 11. *Sanaus* (Sari Kavak, in Daz Kiri); 12. *Dionysopolis* (Orta Keui); 13. *Anastasiopolis*, originally a village of the *Hyrgalis* (Uch Kuyular); 14. *Attanassus* (Eski Aidan); 15. *Lunda* (Eski Seid); 16. *Peltæ* (Karayashlar); 17. *Eumenia* (Isheki); 18. *Siblia* (Homa); 19. *Pepusa* (Yannik Euren); 20. *Bria* (Garbasan or Suretly); 21. *Sebaste* (Sivasy); 22. *Eluza* or *Aludra* (Hadjimlar); 23. *Acomia* (Ahat Keui); 24. *Alia* (Kirk); 25. *Hierocharax* (Otouarak); 26. *Dioclea* (Dola); 27. *Aristium* (Karaj Euren, in Sitchanly Ova); 28. *Cidyessus* (Cutch Eyuk); 29. *Abia* (Abia); 30. *Cotyæum* (Kutayah); 31. *Æzani* (Tchavdir Hissar); 32. *Tiberiopolis* (Altıntash); 33. *Cadæ* (Gediz); 34. *Ancyra* (Kilis Keui); 35. *Synaus* (Simav); 36. *Flaviopolis Temenothyra* (Kara Tash); 37. *Trajanopolis Grimenothyra* (Giaour Euren, near Orta Keui); 38. *Blavundus* (Suleimanly).

II. SALUTARIS.—1. *Eucarpia* (near Mentesh); 2. *Hieropolis* (Kotch Hissar); 3. *Otrous* (Tehor Hissar); 4. *Stectorium* (Emir Assar); 5. *Brutus* (Kara Sandykly); 6. *Beudus* (Aghzi Kara); 7. *Augustopolis*, formerly *Anabura* (Surmeneh); 8. *Sibidunda* (perhaps Yeni Keui); 9. *Lysias* (perhaps Bazar Agatch); 10. *Synnada* (Tchifut Cassaba); 11. *Prymnessus* (Seulun); 12. *Ipsus*, formerly *Julia* (near Sakly); 13. *Polybotus* (Bolawadun); 14. *Docimium* (Istcha Kara Hissar); 15. *Metropolis*, including *Conni* (B. Tchorgia) and *Ambasus* (Ambanaz); 16. *Merus* (Kumbet); 17. *Nacolea* (Seidi Ghazi); 18. *Dorylæum* (Eski Sheher); 19. *Midæum* (Kara Eyuk); 20. *Lycæones* (Kalejik); 21. *Aulocra* (in Dombai Ova); 22 and 23. *Amadassus* and *Prymnessus* (unknown). In later times the important fortress (and bishopric) of Acroënus was founded on the site of the present Afium Kara Hissar.

Besides these, certain cities beyond the bounds of the Byzantine Phrygias belonged under the Roman empire to the province of Asia and are usually considered Phrygian—(1) in Byzantine Pisidia, *Philomelium* (Ak Sheher), *Hadrianopolis* (Arkut Khan); (2) in Byzantine Galatia, *Amorium* (Assar near Hamza Hadji), *Oricistus* (Alikel or Alekian), *Tricomia* or *Trocnada* or *Trocnada* (Kaimaz); (3) in Byzantine Lycia, *Cibyra* (Horzum).

Phrygia contains several well-marked geographical districts. (1) *PARORIUS*, the narrow, flat, elevated valley stretching north-west to south-east between the Sultan Dag and the Emir Dag from Holmi (about Tchali) to Tyriaëum (Ilghin); its waters collect within the valley, in three lakes, which probably supply the great fountains in the Axylum, and through them the Sangarius. (2) *AXYLUM*, the vast treeless plains on the upper Sangarius; there burst forth at various points great perennial springs, the Sakaria fountains.

⁵ *Oecolia*, which is known only from coins, probably belongs to this province. Hierocles adds Theodosia, probably a name of *Daddis* (Demirji), which is usually included in Lydia. Mionnet gives coins of Mosyna, but they are falsely read and belong to the Musteni.

⁶ Nos. 1-5 were called the Phrygian "Pentapolis."

¹ An imperial officer named *Procurator Phrygiæ* is mentioned in a few inscriptions of the 2d century; but he belongs to a financial, not an administrative division.

² This liberty was not granted to the cities of any other province in Anatolia.

³ A number of inscriptions in a language presumably Phrygian have been discovered in the centre and east of the country; they belong generally to the end of the 2d and to the 3d century.

⁴ The name Salutaris is first found in Polemius Silvius about 380; in the *Notit. Dignit.*, about 412 A.D., the names Pacatiana and Salutaris are used.

her native town; the former was golden or plated with gold, the latter was of marble. It is said that at her request Praxiteles promised her the most beautiful of his works, but would not tell her which was it. Having discovered by a stratagem that of his works he prized most a statue of Love (Eros) and one of a Satyr, she asked of him the former and dedicated it in Thespiae. Being accused of impiety by Euthias, she was defended by the orator Hyperides, one of her lovers. When it seemed that the verdict was about to be against her, he rent her robe and displayed her lovely bosom, which so moved her judges that they acquitted her. According to others it was Phryne herself who thus displayed her charms. She is said to have made an attempt on the virtue of the philosopher Xenocrates, and to have signally failed.

PHRYNICHUS, the name of a number of distinguished Greeks, of whom the most prominent were the following.

1. PHRYNICHUS, one of the earliest tragic poets of Athens, was the son of Polyphradmon, and a pupil or follower of Thespis, who is commonly regarded as the founder of tragedy. But such were the improvements introduced by Phrynichus that some of the ancients regarded him as its real founder. He flourished, according to Cyrillus and Eusebius, in 483 B.C., but he gained a poetical victory (probably his first) as early as 511. His famous play the *Capture of Miletus* was probably composed shortly after the conquest of that city by the Persians (494). It moved the Athenians to tears; they fined the poet 1000 drachms for reminding them of the woes of their friends, and decreed that the play should never be used again. In 476 Phrynichus won another poetical victory, probably with his play the *Phoenissæ*, which celebrated the defeat of Xerxes at Salamis (480). The drama derived its name from the chorus of Phœnician women. On this occasion Themistocles acted as choragus, and it is probable that the play was written to revive his waning popularity by reminding the Athenians of his great deeds. The *Persians* of Æschylus (exhibited in 472) was an imitation of the *Phoenissæ* of Phrynichus. Phrynichus died in Sicily, perhaps at the court of Hiero, tyrant of Syracuse, who welcomed those other great contemporary poets Æschylus, and Pindar. The titles of his plays mentioned by Suidas and others show that he treated mythological as well as contemporary subjects; such are the titles *The Danaïdes*, *Actæon*, *Alcestis*, *Tantalus*. But in his plays, as in the early tragedies generally, the dramatic element was subordinate to the lyric element as represented by the chorus. Indeed in his earliest dramas there can only have been one actor, for the introduction of two actors was a novelty due to his younger contemporary Æschylus, who first exhibited in 499. Phrynichus was especially famous for the sweetness of his songs, which were sung by old people down to the time of Aristophanes. Connected with the predominance of the chorus in early tragedies was the prominence in them of the dance. There is an epigram ascribed to Phrynichus in which he boasts that the figures of his dances were as various as the waves of the sea. According to Suidas it was Phrynichus who first introduced female characters on the stage (played by men in masks). The few remains of his works are collected by Wagner and Nauck in their editions of the fragments of the Greek tragedians.

2. PHRYNICHUS, a poet of the Old Attic Comedy and a contemporary of Aristophanes, is said by Suidas to have been an Athenian, but according to the scholiast on Aristophanes (*Frogs*, 13) he was satirized as a foreigner. His first comedy was exhibited in 429 B.C. (according to Suidas, as corrected by Clinton and Meineke). He composed ten plays, of which the *Solitary* ("Monotropos") was exhibited in 414 along with the *Birds* of Aristophanes and gained

the third prize, and the *Muses* carried off the second prize in 405, Aristophanes being first with the *Frogs*. This poet (*Frogs*, 13) accuses Phrynichus of employing vulgar tricks to raise a laugh, and he was further charged with plagiarism and defective versification, but such accusations were too commonly bandied between rival poets to merit much attention. He was not included by the Alexandrian critics in their canon of the best poets. The remains of his works, which have been edited with the other fragments of the Attic Comedy by Meineke and Bothe, are too scanty to allow us to judge of their merits.

3. PHRYNICHUS ARABUS, a grammarian of Bithynia, lived in the reigns of the emperors Marcus Antoninus and Commodus (2d century A.D.). According to Suidas he was the author of the following works: (1) an *Atticist*, or *On Attic Words*, in two books; (2) *Τιθεμένων συναγωγή*; (3) *Σοφιστικὴ παρασκευή*, or *Sophistical Preparation*, in forty-seven or (according to others) seventy four books. We have an account of the last-mentioned work by Photius, who had read thirty-six books of it. The copy used by Photius contained only thirty-seven books, but he states that the author in a preface addressed to the emperor Commodus, to whom the work was dedicated, promised, if life lasted, to write as many more books. Separate parts of the work were dedicated to various friends, and Phrynichus excused its delays and imperfections on the ground of numerous illnesses. It consisted of a collection of Attic words and phrases, arranged in alphabetical order, and distinguished according to the purposes they were meant to serve, whether oratorical, historical, conversational, jocular, or amatory. The models of Attic style, according to Phrynichus, were Plato, Demosthenes and the other nine Attic orators (viz., Antiphon, Andocides, Lysias, Isocrates, Isæus, Æschines, Dinarchus, Lysurgus, Hyperides), Thucydides, Xenophon, Æschines the Socratic, Critias, Antisthenes, Aristophanes and the other poets of the Old Comedy, together with Æschylus, Sophocles, and Euripides. Of these, again, he assigned the highest place to Plato, Demosthenes, and Æschines the Socratic. The work was learned, but prolix and garrulous. A fragment of it, contained in a Paris MS., was published by Montfaucon, and again by Im. Bekker in the first volume of his *Anecdota Græca* (Berlin, 1814). We possess another work of Phrynichus which is not mentioned by Photius, but is, perhaps, identical with the *Atticist* mentioned by Suidas. This is the *Selection (Eclogæ) of Attic Words and Phrases*. It is dedicated to Cornelianus, a man of literary tastes, and one of the emperor's secretaries, who had invited the author to undertake the work. It is a collection of current words and forms which deviated from the Old Attic standard. Side by side with these incorrect words and forms are given the true Attic equivalents. The work is thus a "lexicon antibarbarum," and is interesting as illustrating the changes through which the Greek language had passed between the 4th century B.C. and the 2d century A.D. Phrynichus is especially severe upon Menander, and wonders what people can see in him to admire so much. The style is concise and pointed, and is occasionally relieved by touches of dry humour. The book is divided into two parts, of which the second appears in some editions as a separate work under the title of *Epitome*. Editions of it, with valuable notes, have been published by Chr. Aug. Lobeck (Leipsic, 1820) and W. G. Rutherford (London, 1881). Lobeck devotes his attention chiefly to the later, Rutherford to the earlier usages noticed by Phrynichus.

There was also an Athenian general Phrynichus in the Peloponnesian War, who took a leading part in establishing the oligarchy of the Four Hundred at Athens in 411 B.C. He was assassinated in the same year.

PHTHALIC ACID. This name was given by Laurent to a di-basic acid, $C_8H_6O_4$, which he obtained by the oxidation of naphthalin or its tetra-chloride with nitric acid. Schunck subsequently obtained the same acid by boiling alizarin with nitric acid, but failed to recognize its identity with Laurent's.

One part of naphthalin is mixed with two parts of chlorate of potash, and the mixture added cautiously to ten parts of crude muriatic acid. The product, $C_8H_6Cl_2$, is washed with water and then with "ligroin" (the more volatile fraction of petroleum). The chloride thus purified is oxidized by boiling it with ten parts of (gradually added) nitric acid of 1.45 specific gravity, evaporated to dryness, and the residue distilled to obtain the anhydride $C_8H_4O_3$, or rationally $C_6H_4CO > O$, long colourless needles fusing at $128^\circ C.$, —the boiling point being 276° . When boiled with water it becomes phthalic acid, rat. formula $C_6H_4\begin{smallmatrix} COOH \\ COOH \end{smallmatrix}$, rhombic crystals, fusing at $184^\circ C.$ with transformation into anhydride, very slightly soluble in water (100 parts at 11° dissolve 0.77 parts), more soluble in alcohol (100 of absolute dissolve 10.1 parts at 15°). Phthalic acid, when heated to redness with lime, breaks up into CO_2 and benzol; the lime salt when mixed with one equivalent $CaOH$ of lime, and kept at 330° to $350^\circ C.$, yields carbonate and benzoate—

Hence phthalic acid should be obtainable by the oxidation of di-derivatives, $C_6H_4R'R''$, of benzol ($R = CH_3, C_2H_5$, &c.), and indeed two acids, $C_6H_4(COOH)_2$, can be thus produced, but neither is identical with phthalic.

Terephthalic acid is obtained by the oxidation of ordinary cymol, $pC_6H_4\begin{smallmatrix} C_2H_5 \\ CH_3 \end{smallmatrix}$, or other similar "para" bodies with bichromate of potash and sulphuric acid. It is a white powder, quite insoluble in water, sublimable without fusion or dehydration.

Isophthalic acid is obtained similarly from "meta" derivatives, $mC_6H_4R_2$, of benzol, hair-fine needles fusing above 300° , almost insoluble in water, but pretty easily soluble in alcohol.

Ortho-bi-derivatives of benzol ought to give "ortho," i.e., Laurent's phthalic acid; but this acid itself is oxidized by the bichrome mixture into CO_2 and H_2O .

Phthalicins are a most interesting family of coloured derivatives of phthalic anhydride, which were discovered by Baeyer, and soon found their way into the colour industry. As an example we quote *phenol-phthalein*, obtained by the union of the anhydride with phenol, $C_6H_5OH = H + C_6H_4.OH = H +$ "Phen." The phthalein is

and, as will easily be understood, something widely different from the di-phenyl-phthalic ether. Phthalic anhydride and *resorcin*—one of the three di-hydroxyl derivatives, $C_6H_4(OH)_2$, of benzol—unite into "fluorescin," distinguished by the strong fluorescence of its solutions. Tetra-brom-fluorescin, a beautiful red colour, is used industrially as *eosin* (from Greek *ῥῶς*, the morning-red).

PHTHISIS (*φθίσις*) or CONSUMPTION. This term, although applicable to several forms of wasting disease, is commonly used to designate a malady having for its chief manifestations progressive emaciation of the body and loss of strength, occurring in connexion with morbid changes in the lungs and in other organs.

Few diseases possess such sad interest for humanity as consumption, both on account of its widespread prevalence and its destructive effects, particularly among the young; and in every age of medicine the subject has formed a fertile field for inquiry as to its nature, its cause, and its treatment. On all these points medical opinion has undergone numerous changes with the advance of science and the application of more accurate methods of investigation; yet, notwithstanding the many important facts which within recent years have been brought to light, it must be admitted that our knowledge of this disease is still far from complete. As regards the nature or pathology of consumption it is unnecessary in a notice like the present to refer at length to the doctrines which have from time to time been held upon the subject, further than merely to indicate in a general way the views which have been more or less widely accepted in recent times. In the early part of the present century the study of the diseases of the

chest received a great impetus from the labours of Laennec, whose discovery of the stethoscope led to greater minuteness and accuracy in investigation (see AUSCULTATION). This physician held that phthisis depended on the development of tubercles in the lungs, which, undergoing various retrograde changes, led to the breaking down and excavation of these organs,—in short, produced the whole phenomena of consumption; and, further, that this tuberculous formation affected various other parts and organs, and was the result of a morbid constitutional condition or diathesis. This doctrine, which was generally taught during the first half of the century, and even longer, was to some extent superseded by that to which the greatest prominence was given by Niemeyer and others, namely, that the majority of cases of phthisis had their origin in an inflammation of the lung (catarrhal pneumonia), but that tubercle—the existence of which was freely admitted—might occasionally be evolved out of this condition. This view has had wide acceptance, but has been modified in a variety of ways, especially by its extension to inflammation in other parts besides the lungs, the unabsorbed products of which are held to be capable of producing tubercle by infection from within the system. Still more recently there has arisen another doctrine in connexion with the discovery by Koch of the micro-organism or bacillus of tubercle, which can be cultivated and which, when inoculated, appears capable of producing tubercular disease, namely, the doctrine of the infectiveness of phthisis by means of this "microbe" received into the system from without. This view, which is supported by many striking facts and arguments, has been extensively adopted as furnishing in all probability a rational basis of the pathology of tubercular consumption. Yet it has not been universally accepted, being held by many to be insufficient to account for the origin and course of the disease in numerous instances and in certain of its forms. It is impossible to deny an important place in the course of the disease to inflammatory processes. Even in those cases where the lungs are infiltrated with tubercular deposit evidence of inflammation is abundantly present, while, on the other hand, it would seem that in not a few instances the process is inflammatory throughout. That phthisis, therefore, is not the same process in all cases, but that there are distinct varieties of the disease, is made clear by the morbid anatomy of the lungs no less than by other considerations.

Whatever be the form, the common result of the presence of these disease-products is to produce consolidations in the affected portions of the lungs, which, undergoing retrograde changes (caseation), break down and form cavities, the result being the destruction in greater or less amount of lung-substance. These changes most commonly take place at the apex of one lung, but with the advance of the disease they tend to spread throughout its whole extent and to involve the other lung as well. When the disease is confined to a limited area of a lung it may undergo arrest—even although it has advanced so far as to destroy a portion of the pulmonary tissue, and a healing process may set in and the affected part cicatrize. This is, however, exceptional, the far more common course being the progress of the destructive change either by the spread of the inflammatory process or by infection through the lymphatics, &c., from the existing foci of diseased lung-tissue. Various morbid changes affecting the lungs themselves or other organs frequently arise in the course of phthisis, complicating its progress and reducing the chance of recovery. Of these the more common are affections of the pleura, stomach, liver, kidneys, and especially the intestines, which in the later stage of the disease become ulcerated, giving rise to the diarrhoea which is so frequent and fatal a symptom at this period.

The causes influential in producing phthisis are numerous and varied, but they may for general consideration be embraced under two groups, namely, those which are *predisposing* and operate through the constitution as a whole, and those which are *exciting* and act immediately upon the organs implicated. These two sets of causes may be more or less distinctly associated in an individual case; but, on the other hand, one may appear to act in both ways—as predisposing and exciting. The following may serve to illustrate some of the conditions of a predisposing kind. A constitutional tendency to scrofula and its manifestations lends itself readily to the production of phthisis. This morbid constitution is characterized among other things by a liability to low chronic forms of inflammation affecting gland-textures, mucous membranes, &c., the products of which show little readiness to undergo absorption, but rather to degenerate. Inflammations of this character affecting the lungs, as is not uncommon, have a special tendency to lead to the breaking down of lung-texture and formation of phthysical cavities. Many high authorities hold that tubercle-formation may be evolved out of scrofulous inflammations of glands, such as those of the neck, by an infective process, like that already referred to. The mention of this constitutional state naturally suggests another powerful predisposing cause, namely, hereditary transmission. The extent to which this influence operates as a cause of consumption has been differently estimated by writers, owing probably to the various aspects in which the matter is capable of being viewed. It is impossible to deny that the children of parents one or both of whom are consumptive are liable to manifest the disease,—that is, they inherit a constitution favouring its development under suitable exciting causes. But a similar constitutional proclivity may be induced by other influences acting through the parents. Should either or both of them be enfeebled by previous disease or by any other weakening cause, they may beget children possessing a strong predisposition to consumption. Marriages of near relatives are held by some to induce a consumptive tendency,—probably, however, owing to the fact that any constitutional taint is likely to be intensified in this way. Phthisis is a disease of early life, the period between fifteen and thirty-five being that in which the great majority of the cases occur, and of these by far the larger proportion will be found to take place between the ages of twenty and thirty. The influence of sex is not marked. Occupations, habits, and conditions of life have a very important bearing on the development of the disease apart altogether from inherited tendency. Thus occupations which necessitate the inhalation of irritating particles, as in the case of stone-masons, needle-grinders, workers in minerals, in cotton, flour, straw, &c., are specially hurtful, chiefly from the mechanical effects upon the delicate pulmonary tissue of the matter inhaled. No less prejudicial are occupations carried on in a heated and close atmosphere, as is often the case with compositors, gold-beaters, sempstresses, &c. Again, habitual exposure to wet and cold or to sudden changes of temperature will act in a similar way in inducing pulmonary irritation which may lead to phthisis. Irregular and intemperate habits are known predisposing causes; and over-work, over-anxiety, want of exercise, insufficient or unwholesome food, bad hygienic surroundings such as overcrowding and defective ventilation, are all powerful agents in sowing the seeds of the disease. Consumption sometimes arises after fevers and other infectious maladies, or in connexion with any long-continued drain upon the system, as in over-lactation. The subject of climate and locality in connexion with the causation of phthisis has received considerable attention, and some interesting facts have been ascertained on this

point. That phthisis is to be met with in all climes, and it would seem fully as frequently in tropical as in temperate regions, is evidence that climate alone exercises but little influence. It is very different, however, with locality, elevation appearing to affect to a considerable extent the liability to this disease. It may be stated as generally true that phthisis is less prevalent the higher we ascend. The investigations of Dr H. J. Bowditch in New England and of Dr George Buchanan of the Local Government Board in the counties of Surrey, Kent, and Sussex agree in proving that elevated regions with dryness of soil are hostile to the prevalence of consumption, while low-lying and damp districts seem greatly to favour its development; and it has been found that the successful drainage of damp localities has occasionally had a marked effect in reducing their phthisis mortality. In all such observations, however, various modifying circumstances connected with social, personal, and other conditions come into operation to affect the general result. As regards immediate or exciting causes, probably the most potent are inflammatory affections of the respiratory passages produced as the result of exposure. The products of such attacks are liable under predisposing conditions, such as some of those already mentioned, to remain unabsorbed and undergo degenerative changes, issuing in the breaking down and excavation of the pulmonary texture. A necessary consequence of the modern doctrine of the contagious nature and inoculability of tubercle has been to bring to the front a view as to phthisis once widely prevalent and in some countries—*e.g.*, Italy—never wholly abandoned, namely, its infectiousness. By some supporters of the recent theories of tubercle it is maintained that phthisis is communicated by infection and in no other way, the infecting agent being the bacillus. Others, while holding the view of the specific nature of the disease, deny that it can be communicated by infection like a fever, and cite the experience of consumption hospitals (such as that described by Dr C. T. Williams with respect to the Brompton Hospital) as to the absence of any evidence of its spreading among the nurses and officials. Others, again, deny both its specific nature and its direct infectious character. There appears, however, to be a growing opinion that phthisis may occasionally be acquired by a previously healthy person from close association with one already suffering from it, and, if this view be well founded, it affords a strong presumption that some infecting agent (such as the tubercle bacillus) is the medium of communication. The whole subject of the infectiousness of this disease is as yet unsettled; but there appears to be sufficient reason for special care on the part of those who of necessity are brought into close contact with patients suffering from it.

Cases of phthisis differ widely as regards their severity and their rate of progress. Sometimes the disease exhibits itself as an acute or galloping consumption, where from the first there is high fever, rapid emaciation, with cough and other chest symptoms, or with the comparative absence of these, and a speedily fatal termination. In such instances there would probably be found extensive tubercularization of the lungs and other organs. In other instances, and these constitute the majority, the progress of the disease is chronic, lasting for months or years, and along with periods of temporary improvement there is a gradual progress to a fatal issue. In other cases, again, the disease is arrested and more or less complete restoration to health takes place.

It is unnecessary to describe the symptoms or course and progress of all the varieties of this malady. It will be sufficient to refer to those of the ordinary form of the disease as generally observed. The onset may be somewhat

sudden, as where it is ushered in by hæmoptysis (spitting of blood), but more commonly it is slow and insidious and may escape notice for a considerable time. The patient is observed to be falling away in flesh and strength. His appetite fails, and dyspeptic symptoms trouble him. But the most marked feature of the condition is the presence of a cough, which is either persistent or recurs at certain times, as in lying down in bed, or rising in the morning. The cough is dry or is accompanied with slight clear expectoration, and the breathing is somewhat short. Feverish symptoms are present from an early period, the temperature of the body being elevated, especially in the evening. The patient often complains of flying pains in the chest, shoulders, and back. Such symptoms occurring, especially in one who may possess by inheritance or otherwise an evident tendency to chest disease, should excite suspicion, and should be brought under the notice of the physician. They constitute what is commonly known as the first stage of phthisis and indicate the deposit of tubercle or else inflammatory consolidation in the lung.¹ Not unfrequently the disease is arrested in this stage by judicious treatment, but should it go on the symptoms characterizing the second stage (that of softening and disintegration of lung) soon show themselves. The cough increases and is accompanied with expectoration of purulent matter in which lung-tissue and the bacillus of tubercle can be detected on microscopic examination.² The symptoms present in the first stage become intensified: the fever continues and assumes a hectic character, being accompanied with copious night-sweats, while the appetite and digestion become more and more impaired and the loss of strength and emaciation more marked. Even in this stage the disease may undergo abatement, and improvement or recovery take place, though this is rare; and by careful treatment the advance of the symptoms may be in a measure held in check. The final stage (or stage of excavation), in which the lung has become wasted to such an extent that cavities are produced in its substance, is characterized by an aggravation of all the symptoms of the previous stage. In addition, however, there appear others indicating the general break-up of the system. Diarrhoea, exhausting night-perspirations, and total failure of appetite combine with the cough and other pulmonary symptoms to wear out the patient's remaining strength and to reduce his body to a skeleton. Swelling of the feet and ankles and soreness of the mouth (aphthæ) proclaim the approach of the end.³ Death usually takes place from exhaustion, but sometimes the termination is sudden from hæmorrhage, or from rupture of the pleura during a cough and the consequent occurrence of pneumothorax. A remarkable and often painful feature of the disease is the absence in many patients of all sense of the nature and

gravity of the malady from which they suffer, and their singular buoyancy of spirits (the *spes phthisica*), rendering them hopeful of recovery up till even the very end.

This description is but a brief and imperfect outline of the course and progress of an ordinary case of phthisis. It is scarcely necessary to remark that the disease is greatly modified in its course and progress and in the presence or absence of particular symptoms in individuals. Thus in some the chest-symptoms (cough, &c.) are, prominent throughout, while in others these are comparatively in abeyance, and diarrhoea or fever and exhausting perspirations or throat-troubles specially conspicuous. Nevertheless, essentially the same pathological conditions are present in each case. Further, as has been already mentioned, there are types of the disease which obviously influence alike its main features and its duration; these have been embraced under two classes, the acute and the chronic. In the former, which includes the acute tuberculous and acute inflammatory or pneumonic phthisis, the progress of the disease is marked by its rapidity and the presence of fever even more than by local chest-symptoms. Such cases run to a fatal termination in from one to three or four months, and are to be regarded as the most severe and least hopeful form. The chronic cases, of which the description above given is an example (and which embrace various chronic changes, e.g., chronic interstitial pneumonia or cirrhosis of the lung), progress with variable rapidity. Their duration has been estimated by different authorities at from two to eight or more years. Much, however, necessarily depends on the effect the disease exercises upon the patient's strength and nutrition, on his circumstances and surroundings, and on the presence or absence of weakening complications. Many cases of this class remain for long unchanged for the worse, perhaps undergoing temporary improvement, while in a few rare instances, where the disease has become well marked or has even attained to an advanced stage, what is virtually a cure takes place.

The treatment of phthisis has received much attention from physicians as well as from empirics, by the latter of whom chiefly many so-called cures for consumption have from time to time been given forth. It need scarcely be stated that no "cure" for this disease exists; but, while this is true, it is no less true that by the adoption of certain principles of treatment under enlightened medical guidance a very great deal may now be done to ward off the disease in those who show a liability to it, and to mitigate and retard, or even arrest, its progress in those who have already become affected by it. The preventive measures include careful attention to hygienic conditions, both personal and surrounding. In the case of children who may inherit a consumptive tendency or show any liability to the disease much care should be taken in bringing them up to promote their general health and strengthen their frames. Plain wholesome food with fatty ingredients, if these can possibly be taken, milk, cream, &c., are to be recommended. Exercise in the open air and moderate exercise of the chest by gymnastics and by reading aloud or singing are all advantageous. An ample supply of fresh air in sleeping apartments, schools, &c., is of great importance, while warm clothing and the use of flannel are essential, especially in a climate subject to vicissitudes. The value of the bath and of attention to the function of the skin is very great. The like general hygienic principles are equally applicable in the case of adults. When the disease has begun to show any evidence of its presence its treatment becomes a matter of first importance, as it is in the early stages that most can be done to arrest or remove it. Special symptoms, such as cough, gastric disturbances, pain, &c., must be dealt with by the physician according to the indi-

¹ The examination of the chest by the usual methods of physical diagnosis reveals in this stage the following as among the chief points. On inspection the thorax is observed to be narrow and poorly developed, or it may be quite natural. At its upper region there may be noticed slight flattening under the clavicle of one side, along with imperfect expansion of that part on full inspiration. On percussion the note may be little if at all impaired, but frequently there is dullness more or less marked at the apex of the lung. On auscultation the breath-sounds are variously altered. Thus they may be scarcely audible, or again harsher than natural, and the expiration may be unduly prolonged. Sometimes the breathing is of an interrupted or jerky character, and is occasionally accompanied with fine crepitations or râles. Pleuritic friction-sounds may be audible over the affected area.

² In this stage the physical signs are more distinctive of the disease. Thus the flattening of the chest-wall is still more marked, as is also the dullness to percussion, while on auscultation the breathing is accompanied with coarse moist sounds or râles, which become more audible on coughing. The voice-sound is broncho-phonic.

³ The physical signs now present are those of a cavity in the lung—viz., in general absolute dullness on percussion—cavernous breathing, gurgling râles, and pectoriloquy.

vidual case; but it is in this stage of the disease that the question of a change of climate in the colder seasons of the year arises among those whose circumstances render such a step practicable. There can be no doubt that as regards Great Britain the removal of patients threatened by or already suffering from consumption to some mild locality, either in the country or abroad, proves in many instances most salutary. The object aimed at is to obtain a more equable climate, where the atmosphere may have a soothing influence on the respiratory organs, and where also open-air exercise may be taken with less risk than at home. Of British health-resorts Bournemouth, Hastings, Torquay, Ventnor, Penzance, &c., in the south of England, are the best known and most frequented, and although the climate is not so certain as in places farther south in Europe they possess the advantage of home residence, and may be resorted to by persons who are unable to undertake a farther journey. The climate of the Riviera (Maritime Alps) is of superior efficacy owing to its mildness and the dry bracing character of its air, and, despite the long journey, is as a rule to be recommended as one of the best for the greater proportion of the cases of phthisis. The same may be said for Algiers and Egypt. Of recent years the air of elevated dry regions, such as Davos in the Alps and the Rocky Mountains in America, has been strongly recommended, and in not a few cases appears to be productive of good in arresting the disease at its outset, and even advantageous in chronic cases where there is no great activity in its progress. Of like value, and in a similar class of cases, are long sea-voyages, such as those to Australia or New Zealand. Nevertheless, there is no doubt that consumptive patients are often sent abroad manifestly to die. It may be stated generally (although doubtless there may be exceptions) that where the disease exhibits a decidedly acute form, even in its earlier stages, any distant change is rather to be discouraged;

while in the advanced stages, where there is great prostration of strength, with colliquative symptoms, the removal of a patient is worse than useless, and frequently hastens the end.

Throughout the whole course of the malady the nutrition of the patient forms a main part of the treatment, and tonics which promote the function of the digestive organs are especially helpful. Codliver oil has long been held to be of eminent value, as it appears not merely to possess all the advantages of a food but to exert a retarding effect on the disease. Where it is well borne, not only will the weight of the body be found to increase, but the cough and other symptoms will markedly diminish. The oil is as a rule best administered at first in small quantity. The frequently employed substitutes, such as malt extract, tonic syrups, &c., although not without their uses, are all inferior to codliver oil. The occasional employment of counter-irritation to the chest in the form of iodine or small blisters is of service in allaying cough and relieving local pains. Respirators to cover the mouth and nose, and so constructed as to contain antiseptic media through which the air is breathed, are sometimes found to lessen cough and other symptoms of chest-irritation.

Among the most serviceable drugs in the treatment of the symptoms of phthisis are the preparations of opium. Administered along with such agents as hydrocyanic acid and expectorants, they are eminently useful in soothing severe cough; along with astringents they are equally valuable in controlling diarrhoea; while with quinine, digitalis, &c., they aid in allaying fever and restlessness and in procuring sleep. But besides these many other medicinal agents, too numerous to mention here, are employed with much advantage. Each case will present its own features and symptoms calling for special attention and treatment, and details upon these points must be left to the advice of the medical attendant.
