

THE
ENCYCLOPÆDIA BRITANNICA

LATEST EDITION

A DICTIONARY OF ARTS, SCIENCES, AND
GENERAL LITERATURE

*NEW MAPS AND MANY ORIGINAL AMERICAN ARTICLES BY EMINENT AUTHORS
FULLY ILLUSTRATED, WITH OVER TEN THOUSAND PORTRAITS, PLATES, AND ENGRAVINGS*

ORIGINAL NINTH EDITION IN TWENTY-FIVE VOLUMES EDITED BY
PROFS. SPENCER BAYNES, LL.D., AND W. ROBERTSON SMITH, LL.D.
ASSISTED BY OVER ONE THOUSAND CONTRIBUTORS

IN THIRTY VOLUMES WITH
NEW AMERICAN SUPPLEMENT

EDITED UNDER THE PERSONAL SUPERVISION OF
DAY OTIS KELLOGG, D.D.
Formerly Professor of English Literature and History, Kansas State University, etc., etc.
ASSISTED BY A CORPS OF EXPERIENCED WRITERS

TWENTIETH CENTURY EDITION
REVISED, WITH LARGE ADDITIONS, TO JANUARY 1, 1901

VOLUME XVIII

THE WERNER COMPANY
NEW YORK AKRON, OHIO CHICAGO

1902

Encyclopædia Britannica.

VOL. XVIII.—(ORN—PHT).

Total number of Articles, 554.

PRINCIPAL CONTENTS.

ORNITHOLOGY. ALFRED NEWTON, F.R.S., Professor of Zoology, University of Cambridge.

OTTER. Prof. W. H. FLOWER, F.R.S.

OTWAY. RICHARD GARNETT, LL.D.

OVID. W. Y. SELLAR, LL.D., Professor of Humanity, University of Edinburgh.

OXFORD. FALCONER MADAN, M.A., Sub-Librarian of the Bodleian Library, Oxford.

OXUS. Lieut.-General WALKER, R.E., C.B.

OYSTER. J. T. CUNNINGHAM, B.A.

INDUSTRY. G. BROWN GOODE, U.S. National Museum, Washington.

PACIFIC OCEAN. JOHN MURRAY, Director of the "Challenger" Expedition Commission.

PAINTING. GEORGE REID, R.S.A.

PALÆOGRAPHY. E. MAUNDE THOMPSON, LL.D.

Keeper of Manuscript Department, British Museum

PALESTINE. Prof. ALBRECHT SOGIN, University of Tübingen.

PALEY. Prof. A. SETH, University College, Cardiff.

PALL. REINHOLD ROST, Ph.D., LL.D.

PALM. MAXWELL T. MASTERS, M.D., F.R.S.

PALMERSTON.

PALMYRA. Prof. W. ROBERTSON SMITH, LL.D.

PAMPHLETS. H. R. TEDDER, F.S.A., Librarian, Athenæum Club, London.

PANTOMIME. Prof. A. W. WARD.

PAPER. E. MAUNDE THOMPSON and R. C. MENZIES.

PARAFFIN. Prof. W. DITTMAR and JAMES PATON.

PARALLAX. DAVID GILL, LL.D., F.R.S., Astronomer-Royal, Cape of Good Hope.

PARALYSIS. J. O. AFFLECK, M.D.

PARASITISM—

ANIMAL. PATRICK GEDDES, F.R.S.E.

VEGETABLE. G. R. MILNE MURRAY, Botanical Department, British Museum.

IN MEDICINE. CHARLES CREIGHTON, M.A., M.D.

PARIS. GASTON MEISSAS and ANTHYME ST PAUL.

PARKER, MATTHEW. J. BASS MULLINGER, M.A.

PARKER, THEODORE. Rev. J. F. SMITH.

PARLIAMENT. The Right Hon. Lord FARNBOROUGH, D.C.L., late Clerk of the House of Commons, London.

PARTNERSHIP. JAMES WILLIAMS, M.A., B.C.L., Barrister at Law.

PASCAL. GEORGE SAINTSBURY, M.A., and Prof. CHRYSTAL.

PASSOVER. Prof. W. R. SMITH.

PASTON LETTERS. RICHARD GARNETT, LL.D.

PASTORAL. E. W. GOSSE, Author of "Studies in the Literature of Modern Europe."

PATENTS. J. HENRY JOHNSON, Solicitor, London.

PATHOLOGY. CHARLES CREIGHTON, M.A., M.D.

PATRICK, ST. WM. K. SULLIVAN, Ph.D., D.Sc., President, Queen's College, Cork.

PAUL. Rev. EDWIN HATCH, D.D., Vice-Principal, St. Mary Hall, Oxford.

PEEL. GOLDWIN SMITH, LL.D., and C. S. PARKER, M.P.

PEERAGE. Prof. E. A. FREEMAN, LL.D.

PEITING. Prof. R. K. DOUGLAS.

PELAGIUS. Rev. MARCUS DODS, D.D.

PENANCE. Rev. R. F. LITLEDALE, LL.D., D.C.L.

PENN. OSMUND AIRY.

PENNSYLVANIA. Prof. J. P. LESLEY, State Geologist, and Rev. C. G. AMES, Philadelphia.

PENTATEUCH. Prof. JULIUS WELHAUSEN, D.D.

PEPPER. E. M. HOLMES, F.R.S.

PEPYS. OSMUND AIRY.

PERFUMERY. C. H. PIESSE, F.C.S.

PERIODICALS. H. R. TEDDER.

PERIPATETICS. Prof. SETH.

PERJURY. JAMES WILLIAMS, M.A., B.C.L.

PERPETUAL MOTION. Prof. CHRYSTAL.

PERSIA—

ANCIENT HISTORY. Prof. NÜLDEKE, Strasburg, and Prof. A. VON GUTSCHMID, Tübingen.

MODERN HISTORY AND GEOGRAPHY. Major-General Sir FREDERICK GOLDSMID, K.C.S.I.

LANGUAGE. Prof. K. GELDNER, Tübingen.

LITERATURE. Prof. HERMANN ETHÉ, Ph.D.

PERSIUS. Prof. SELLAR.

PERSONAL ESTATE. J. WILLIAMS.

PERU. CLEMENTS R. MARKHAM, C.B., F.R.S., Author of "War between Peru and Chili."

PESSIMISM. WM. WALLACE, M.A., Whyte's Professor of Moral Philosophy, University of Oxford.

PETER. Rev. E. HATCH, D.D.

PETRARCH. J. A. SYMONDS.

PETROLEUM. Prof. S. F. PECKHAM, M.A., U.S. Census Commissioner.

PHARMACOPŒIA. E. M. HOLMES.

PHILADELPHIA. C. H. HART, Philadelphia.

PHILIPPIANS. Rev. E. HATCH, D.D.

PHILIPPINE ISLANDS. H. A. WEBSTER.

PHILISTINES. Prof. W. R. SMITH.

PHILO. Prof. E. SCHÜRER, University of Giessen.

PHILOLOGY. W. D. WHITNEY, Professor of Sanskrit, Yale College, Conn.

ARYAN LANGUAGES. Prof. L. SIEVERS, Tübingen.

PHILOSOPHY. Prof. SETH.

PHENICIA. Profs. A. SOGIN and A. VON GUTSCHMID.

PHONETICS. A. J. ELLIS.

PHOSPHORUS. Prof. W. DITTMAR.

PHOTOGRAPHY. Captain WM. DE W. ARNEY, R.E. F.R.S., Author of "Instructions in Photography."

PHOTOMETRY. Prof. CHARLES PRITCHARD, D.D.

PHRENOLOGY. Prof. A. MACALISTER, M.D.

PHYRGIA. Prof. W. M. RAMSAY.

PHTHISIS. J. O. AFFLECK, M.D.

ENCYCLOPÆDIA BRITANNICA.

ORNE

ORNE, a department of the north-west of France, about half of which formerly belonged to the province of Normandy and the rest to the duchy of Alençon and to Perche, lies between $48^{\circ} 10'$ and $48^{\circ} 58'$ N. lat., and between 1° E. and $0^{\circ} 50'$ W. long., and is bounded N. by Calvados, N.E. by Eure, S.E. by Eure-et-Loir, S. by Sarthe and Mayenne, and W. by Manche. The greatest length from east to west is 87 miles, and the area 2635 square miles. The population in 1881 numbered 376,126. Geologically there are two distinct regions: to the west of the Orne and the railway from Argentan to Alençon lie primitive rocks connected with those of Brittany; to the east begin the Jurassic and Cretaceous formations of Normandy. The latter district is agriculturally the richest part of the department; in the former the poverty of the soil has led the inhabitants to seek their subsistence from industrial pursuits. Between the northern portions, draining to the Channel, and the southern portion, belonging to the basin of the Loire, stretch the hills of Perche and Normandy, which generally have a height of from 800 to 1000 feet. The highest point in the department, situated in the forest of Écouves north of Alençon, reaches 1378 feet. The department gives birth to three Seine tributaries—the Eure, its affluent the Iton, and the Rille, which passes by Laigle. The Touques, passing by Vimoutier, the Dives, and the Orne fall into the English Channel,—the last passing Sées and Argentan, and receiving the Noireau with its tributary the Vere, which runs past Flers. Towards the Loire flow the Huisne, a feeder of the Sarthe passing by Mortagne, the Sarthe, which passes by Alençon, and the Mayenne, some of whose affluents rise to the north of the dividing range and make their way through it by the most picturesque defiles. Nearly the whole department, indeed, with its beautiful forests containing oaks several centuries old, its green meadows peopled with herds, its limpid streams, its deep gorges, its stupendous rocks, is one of the most picturesque of all France, though neither bathed by the sea nor possessing a truly mountainous character. In the matter of climate Orne belongs to the Seine region. The mean temperature is 50° Fahr.; the summer heat is never extreme; the west winds are the most frequent; the rainfall, distributed over about a hundred days in the year, amounts to

nearly 3 feet, or half as much again as the average for France.

Arable land occupies seven-twelfths of the surface, woods one-eighth, and pasture land almost as much. The live stock comprises 70,000 horses, 4000 asses, 122,000 sheep (35,500 high-bred), yielding in 1878 660,000 lb of wool of the value of nearly £25,000, 53,000 pigs, 2800 goats, 210,000 horned cattle, 30,000 dogs, 700,000 fowls, 53,000 geese, and 15,800 beehives, each producing on the average 2 lb of wax and 20 lb of honey. Horse-breeding is the most flourishing business in the rural districts; there are three breeds—those of Perche, Le Merlerault (a cross between Norman and English horses), and Brittany. The great Government stud of Le Pin is situated between Le Merlerault and Argentan. Several horse-training establishments exist in the department. A large number of lean cattle are bought in the neighbouring departments to be fattened; the farms in the vicinity of Vimoutier, on the borders of Calvados, produce the famous Camembert cheese, and others excellent butter. In 1882 Orne produced 3,288,000 bushels of wheat, meslin 431,000, rye 315,700, barley 1,510,000, oats 3,410,000, buckwheat 600,000, potatoes 654,000, beetroot 939,000 cwt., colza seed 5000 cwt., hemp 8300 cwt., besides fodder in great quantity and variety, pulse, flax, fruits, &c. The variety of production is due to the great natural diversity of the soils. Small farms are the rule, and the fields in those cases are surrounded by hedges relieved by pollard trees. Along the roads or in the enclosures are planted numerous pear and apple trees (nearly 3,000,000), yielding 58,000,000 gallons of cider and perry, part of which is manufactured into brandy. Beech, oak, birch, and pine are the chief timber trees in the extensive forests of the department, of which a third belongs to the state. Orne contains iron ore of poor quality, granite quarries employing from 400 to 500 workmen, and a kind of smoky quartz known as Alençon diamond. Its most celebrated mineral waters are those of the hot springs of Bagnoles, which contain salt, sulphur, and arsenic, and are employed for tonic and restorative purposes in cases of general debility. In the forest of Bellême is the chalybeate spring of L. Hesse, which was used by the Romans. The other mineral springs of the department are chalybeate

sulphurous. Cotton and linen weaving forms the staple industry of Orne, 51 establishments (123,000 spindles and 12,170 looms) being devoted to cotton, 2 establishments (500 spindles) to wool, and 3 establishments (2400 spindles and 2800 looms) to linen. Flers manufactures ticking, table-linen, furniture satin, cotton cloth, and thread, employs 28,000 workmen, and produces to the annual value of £1,520,000. La Ferté Macé employs 10,000 workmen in the hand-loom manufacture of cotton. Alençon and Vimoutier are engaged in the production of linen and canvas, and have also dye-works and bleacheries. About 2000 workmen are employed at Alençon in the making of the lace which takes its name from the town. Foundries, wire-works, and one blast furnace also exist in the denartment, and cutlery, boilers, and articles in copper,

zinc, and lead are manufactured. Tin wares, pins, and needles are produced at Laigle. Glass-works give employment to 600 workmen, and turn out glass to the value of more than £100,000. There are flourishing paper-mills, tanneries (the waters of the Orne giving a special quality to the leather), and glove-works. There are in all 133 establishments making use of steam (2128 horse-power). There are 348 miles of railway. The department consists of four arrondissements (Alençon, Argentan, Domfront, and Mortagne), 36 cantons, and 511 communes, forms the diocese of Sées, depends on the Caen court of appeal, and is included in the corps d'armée of Le Mans. The communes with more than 5000 inhabitants are Alençon (17,237), Flers (12,304), La Ferté Macé (9396), Argentan (6300), and Laigle (5303).

ORNITHOLOGY

ORNITHOLOGY¹ in its proper sense is the methodical study and consequent knowledge of Birds with all that relates to them; but the difficulty of assigning a limit to the commencement of such study and knowledge gives the word a very vague meaning, and practically procures its application to much that does not enter the domain of Science. This elastic application renders it impossible in the following sketch of the history of Ornithology to draw any sharp distinction between works that are emphatically ornithological and those to which that title can only be attached by courtesy; for, since Birds have always attracted far greater attention than any other group of animals with which in number or in importance they can be compared, there has grown up concerning them a literature of corresponding magnitude and of the widest range, extending from the recondite and laborious investigations of the morphologist and anatomist to the casual observations of the sportsman or the schoolboy. The chief cause of the disproportionate amount of attention which Birds have received plainly arises from the way in which so many of them familiarly present themselves to us, or even (it may be said) force themselves upon our notice. Trusting to the freedom from danger conferred by the power of flight, most Birds have no need to lurk hidden in dens, or to slink from place to place under shelter of the inequalities of the ground or of the vegetation which clothes it, as is the case with so many other animals of similar size. Besides this, a great number of the Birds which thus display themselves freely to our gaze are conspicuous for the beauty of their plumage; and there are very few that are not remarkable for the grace of their form. Some Birds again enchant us with their voice, and others administer to our luxuries and wants, while there is scarcely a species which has not idiosyncrasies that are found to be of engaging interest the more we know of them. Moreover, it is clear that the art of the fowler is one that must have been practised from the very earliest times, and to follow that art with success no inconsiderable amount of acquaintance with the haunts and habits of Birds is a necessity. Owing to one or another of these causes, or to the combination of more than one, it is not surprising that the observation of Birds has been from a very remote period a favourite pursuit among nearly all nations, and this observation has by degrees led to a study more or less framed on methodical principles, finally reaching the dignity of a

science, and a study that has its votaries in almost all classes of the population of every civilized country. In the ages during which intelligence dawned on the world's total ignorance, and even now in those districts that have not yet emerged from the twilight of a knowledge still more imperfect than is our own at present,² an additional and perhaps a stronger reason for paying attention to the ways of Birds existed, or exists, in their association with the cherished beliefs handed down from generation to generation among many races of men, and not unfrequently interwoven in their mythology.³

Moreover, though Birds make a not unimportant appearance in the earliest written records of the human race, the painter's brush has preserved their counterfeit presentment for a still longer period. What is asserted—and that, so far as the writer is aware, without contradiction—by Egyptologists of the highest repute to be the oldest picture in the world is a fragmentary fresco taken from a tomb at Maydoom, and happily deposited, though in a decaying condition, in the Museum at Boolak. This picture is said to date from the time of the third or fourth dynasty, some three thousand years before the Christian era. In it are depicted with a marvellous fidelity, and thorough appreciation of form and colouring (despite a certain conventional treatment), the figures of six Geese. Four of these figures can be unhesitatingly referred to two species (*Anser albifrons* and *A. ruficollis*) well known at the present day; and if the two remaining figures, belonging to a third species, were re-examined by an expert they would very possibly be capable of determination with no less certainty.⁴ In later ages the representations of Birds of one sort or another in Egyptian paintings and sculptures become countless, and the *bassi-relievi* of Assyrian monuments, though mostly belonging of course to a subsequent period, are not without them. No figures of Birds, however, seem yet to have been found on the incised stones, bones, or ivories of the prehistoric races of Europe.

It is of course necessary to name ARISTOTLE (born B.C. 385, died B.C. 322) as the first serious author on Ornithology with whose writings we are acquainted, but even he had,

² Of the imperfection of our present knowledge more must be said presently.

³ For instances of this among Greeks and Romans almost any dictionary or treatise of "Classical Antiquities" may be consulted, while as regards the superstitions of barbarous nations the authorities are far too numerous to be here named.

⁴ The portion of the picture containing the figures of the Geese has been figured by Mr. LOFTIE (*Ride in Egypt*, p. 209), and the present writer owes to that gentleman's kindness the opportunity of examining a copy made on the spot by an accomplished artist, as well as the information that it is No. 988 of Mariette's *Catalogue*. See *ART. MURAL DECORATION*, vol. xvii. p. 39, fig. 7.

¹ *Ornithologia*, from the Greek *ὄρνιθ*, crude form of *ὄρνις*, a bird, and *-λογία*, allied to *λόγος*, commonly Englished a discourse. The earliest known use of the word Ornithology seems to be in the third edition of Blount's *Glossographia* (1670), where it is noted as being "the title of a late Book." See Prof. Skeat's *Etymological Dictionary of the English Language*.

as he tells us, predecessors; and, looking to that portion of his works on animals which has come down to us, one finds that, though more than 170 sorts of Birds are mentioned,¹ yet what is said of them amounts on the whole to very little, and this consists more of desultory observations in illustration of his general remarks (which are to a considerable extent physiological or bearing on the subject of reproduction) than of an attempt at a connected account of Birds. Some of these observations are so meagre as to have given plenty of occupation to his many commentators, who with varying success have for more than three hundred years been endeavouring to determine what were the Birds of which he wrote; and the admittedly corrupt state of the text adds to their difficulties. One of the most recent of these commentators, the late Prof. Sundevall—equally proficient in classical as in ornithological knowledge—was, in 1863, compelled to leave more than a score of the Birds unrecognized. Yet it is not to be supposed that in what survives of the great philosopher's writings we have more than a fragment of the knowledge possessed by him, though the hope of recovering his Ζωικά or his Ἀνατομικά, in which he seems to have given fuller descriptions of the animals he knew, can be hardly now entertained. A Latin translation by Gaza of Aristotle's existing zoological work was printed at Venice in 1503. Another version, by Scaliger, was subsequently published. Two wretched English translations have appeared.

Next in order of date, though at a long interval, comes CAIUS PLINIUS SECUNDUS, commonly known as PLINY the Elder, who died A.D. 79, author of a general and very discursive *Historia Naturalis* in thirty-seven books, of which Book X. is devoted to Birds. A considerable portion of Pliny's work may be traced to his great predecessor, of whose information he freely and avowedly availed himself, while the additions thereto made cannot be said to be, on the whole, improvements. Neither of these authors attempted to classify the Birds known to them beyond a very rough and for the most part obvious grouping. Aristotle seems to recognize eight principal groups:—(1) *Gamponyches*, approximately equivalent to the *Accipitres* of Linnæus; (2) *Scolecophaga*, containing most of what would now be called *Oscines*, excepting indeed the (3) *Acanthophaga*, composed of the Goldfinch, Siskin, and a few others; (4) *Scnipophaga*, the Woodpeckers; (5) *Peristeroide*, or Pigeons; (6) *Schizopoda*, (7) *Steganopoda*, and (8) *Barea*, nearly the same respectively as the Linnæan *Grallæ*, *Anseres*, and *Gallinæ*. Pliny, relying wholly on characters taken from the feet, limits himself to three groups—without assigning names to them—those which have “hooked talons, as Hawkes; or round long claws, as Hennes; or else they be broad, flat, and whole-footed, as Geese and all the sort in manner of water-foule”—to use the words of Philemon Holland, who, in 1601, published a quaint and, though condensed, yet fairly faithful English translation of Pliny's work.

Ælian. About a century later came ÆLIAN, who died about A.D. 140, and compiled in Greek (though he was an Italian by birth) a number of miscellaneous observations on the peculiarities of animals. His work is a kind of commonplace book kept without scientific discrimination. A considerable number of Birds are mentioned, and something said of almost each of them; but that something is too often nonsense—according to modern ideas—though occasionally a fact of interest may therein be found. It contains numerous references to former or contemporary writers whose works have perished, but there is nothing to shew that they were wiser than Ælian himself.

The twenty-six books *De Animalibus* of ALBERTUS MAGNUS (GROOT), who died A.D. 1282, were printed in 1478; but were apparently already well known from manuscript copies. They are founded on the works of Aristotle, many of whose statements are almost literally repeated, and often without acknowledgment. Occasionally Avicenna, or some other less-known author, is quoted; but it is hardly too much to say that the additional information is almost worthless. The twenty-third of these books is *De Avibus*, and therein a great number of Birds' names make their earliest appearance, few of which are without interest from a philologist's if not an ornithologist's point of view, but there is much difficulty in recognizing the species to which many of them belong. In 1485 was printed the first dated copy of the volume known as the *Ortus Sanitatis*, to the popularity of which many editions testify. Though said by its author, JOHANN WONNECKE VON CAUB (Latinized as JOHANNES DE CUBA),² to have been composed from a study of the collections formed by a certain nobleman who had travelled in Eastern Europe, Western Asia, and Egypt—possibly Breidenbach, an account of whose travels in the Levant was printed at Mentz in 1486—it is really a medical treatise, and its zoological portion is mainly an abbreviation of the writings of Albertus Magnus, with a few interpolations from Isidorus of Seville (who flourished in the beginning of the seventh century, and was the author of many works highly esteemed in the Middle Ages) and a work known as *Physiologus* (q.v.). The third *tractatus* of this volume deals with Birds—including among them Bats, Bees, and other flying creatures; but as it is the first printed book in which figures of Birds are introduced it merits notice, though most of the illustrations, which are rude woodcuts, fail, even in the coloured copies, to give any precise indication of the species intended to be represented. The scientific degeneracy of this work is manifested as much by its title (*Ortus* for *Hortus*) as by the mode in which the several subjects are treated;³ but the revival of learning was at hand, and WILLIAM TURNER, a Northumbrian, while residing abroad to avoid persecution at home, printed at Cologne in 1544 the first commentary on the Birds mentioned by Aristotle and Pliny conceived in anything like the spirit that moves modern naturalists.⁴ In the same year and from the same press was issued a *Dialogus de Avibus* by GYBERTUS LONGOLIUS, and in 1570 CAIUS brought out in London his treatise *De rariorum animalium atque stirpium historia*. In this last work, small though it be, ornithology has a good share; and all three may still be consulted with interest and advantage by its votaries.⁵ Meanwhile the study received a great impulse from the appearance, at Zurich in 1555, of the third book of the illustrious CONRAD GESNER's *Historia Animalium* Gesner. “*qvi est de Avium natura*,” and at Paris in the same year

² On this point see G. A. Fritzel, *Botan. Zeitung*, 1846, pp. 785-790; and *Thes. Literat. Botanica* (Lipsie: 1851), pp. 349-352.

³ Absurd as much that we find both in Albertus Magnus and the *Ortus* seems to modern eyes, if we go a step lower in the scale and consult the “Bestiaries” or treatises on animals which were common from the twelfth to the fourteenth century we shall meet with many more absurdities. See for instance that by PHILIPPE DE THAUN (PHILIPPUS TAONENSIS), dedicated to Adelheid or Alice, queen of Henry I. of England, and probably written soon after 1121, as printed by the late Mr Thomas Wright, in his *Popular Treatises on Science written during the Middle Ages* (London: 1841).

⁴ This was reprinted at Cambridge in 1823 by the late Dr George Thackeray.

⁵ The Seventh of WOTTON's *De differentiis animalium Libri Decem*, published at Paris in 1552, treats of Birds; but his work is merely a compilation from Aristotle and Pliny, with references to other classical writers who have more or less incidentally mentioned Birds and other animals. The author in his preface states—“*Veterum scriptorum sententias in unam quasi cumulum coarctavi, de meo nihil adjici*.” Nevertheless he makes some attempt at a systematic arrangement of Birds, which, according to his lights, is far from despicable.

¹ This is Sundevall's estimate; Drs Aubert and Wimmer in their excellent edition of the *Ἱστορία περὶ ζῴων* (Leipzig: 1868) limit the number to 126.

Belon. of Pierre BELON'S (BELLONTIUS) *Histoire de la nature des Oyseaux*. Gesner brought an amount of erudition, hitherto unequalled, to bear upon his subject; and, making due allowance for the times in which he wrote, his judgment must in most respects be deemed excellent. In his work, however, there is little that can be called systematic treatment. Like nearly all his predecessors since Ælian, he adopted an alphabetical arrangement,¹ though this was not too pedantically preserved, and did not hinder him from placing together the kinds of Birds which he supposed (and generally supposed rightly) to have the most resemblance to that one whose name, being best known, was chosen for the headpiece (as it were) of his particular theme, thus recognizing to some extent the principle of classification.² Belon, with perhaps less book-learning than his contemporary, was evidently no mean scholar, and undoubtedly had more practical knowledge of Birds—their internal as well as external structure. Hence his work, written in French, contains a far greater amount of original matter; and his personal observations made in many countries, from England to Egypt, enabled him to avoid most of the puerilities which disfigure other works of his own or of a preceding age. Besides this, Belon disposed the Birds known to him according to a definite system, which (rude as we now know it to be) formed a foundation on which several of his successors were content to build, and even to this day traces of its influence may still be discerned in the arrangement followed by writers who have faintly appreciated the principles on which modern taxonomers rest the outline of their schemes. Both his work and that of Gesner were illustrated with woodcuts, many of which display much spirit and regard to accuracy.

Belon, as has just been said, had a knowledge of the anatomy of Birds, and he seems to have been the first to institute a direct comparison of their skeleton with that of Man; but in this respect he only anticipated by a few years the more precise researches of VOLCHER COITER, a Frisian, who in 1573 and 1575 published at Nuremberg two treatises, in one of which the internal structure of Birds in general is very creditably described, while in the other the osteology and myology of certain forms is given in considerable detail, and illustrated by carefully-drawn figures. The first is entitled *Externarum et internarum principalium humani corporis Tabulæ*, &c., while the second, which is the most valuable, is merely appended to the *Lectiones Gabrielis Fallopii de partibus similaribus humani corporis*, &c., and thus, the scope of each work being regarded as medical, the author's labours were wholly overlooked by the mere natural-historians who followed, though Coiter introduced a table, "*De differentiis Avium*," furnishing a key to a rough classification of such Birds as were known to him, and this as nearly the first attempt of the kind deserves notice here.

Contemporary with these three men was ULYSSES ALDROVANDUS, a Bolognese, who wrote an *Historia Naturalium* in sixteen folio volumes, most of which were not printed till after his death in 1605; but those on Birds appeared between 1599 and 1603. The work is almost wholly a compilation, and that not of the most discriminative kind, while a peculiar jealousy of Gesner is continuously displayed, though his statements are very constantly quoted—nearly always as those of "Ornithologus," his name appearing but few times in the text, and not at all in the list of authors

cited. With certain modifications in principle not very important, but characterized by much more elaborate detail, Aldrovandus adopted Belon's method of arrangement, but in a few respects there is a manifest retrogression. The work of Aldrovandus was illustrated by copper-plates, but none of his figures approach those of his immediate predecessors in character or accuracy. Nevertheless the book was eagerly sought, and several editions of it appeared.³

Mention must be made of a medical treatise by CASPAR SCHWENCKFELD, published at Liegnitz in 1603, under the title of *Theriotropheum Silesiæ*, the fourth book of which consists of an "Aviarius Silesiæ," and is the earliest of the works we now know by the name of Fauna. The author was well acquainted with the labours of his predecessors, as his list of over one hundred of them testifies. Most of the Birds he describes are characterized with accuracy sufficient to enable them to be identified, and his observations upon them have still some interest; but he was innocent of any methodical system, and was not exempt from most of the professional fallacies of his time.⁴

Hitherto, from the nature of the case, the works aforesaid treated of scarcely any but the Birds belonging to the *orbis veteribus notus*; but the geographical discoveries of the sixteenth century began to bear fruit, and many animals of kinds unsuspected were, about one hundred years later, made known. Here there is only space to name BONTIUS, CLUSIUS, HERNANDEZ (or FERNANDEZ), MARCGRAVE, NIEREMBERG, and PISO,⁵ whose several works describing the natural products of both the Indies—whether the result of their own observation or compilation—together with those of OLINA and WORM, produced a marked effect, since they led up to what may be deemed the foundation of scientific Ornithology.⁶

This foundation was laid by the joint labours of FRANCIS WILLUGHBY (born 1635, died 1672) and JOHN RAY (born 1628, died 1705), for it is impossible to separate their share of work in Natural History more than to say that, while the former more especially devoted himself to zoology, botany was the favourite pursuit of the latter. Together they studied, together they travelled, and together they collected. Willughby, the younger of the two, and at first the other's pupil, seems to have gradually become the master; but, he dying before the promise of his life was fulfilled, his writings were given to the world by his friend Ray, who, adding to them from his own stores, published the *Ornithologia* in Latin in 1676, and in English with many emendations in 1678. In this work Birds generally were grouped in two great divisions—"Land-Fowl" and "Water-Fowl,"—the former being subdivided into those which have a crooked beak and talons and those which have a straighter bill and claws, while the latter was separated into those which frequent waters and watery places and those that swim in the water—each subdivision being further broken up into many sections, to the whole of which a key was given. Thus it became possible for almost any diligent reader without much chance of error to refer to its

³ The *Historia Naturalis* of JOHANNES JOHNSTONUS, said to be of Scottish descent but by birth a Pole, ran through several editions during the seventeenth century, but is little more than an epitome of the work of Aldrovandus.

⁴ The *Hierozoicon* of Bochart—a treatise on the animals named in Holy Writ—was published in 1619.

⁵ For Lichtenstein's determination of the Birds described by Marcgrave and Piso see the *Abhandlungen* of the Berlin Academy for 1817 (pp. 155 sq.).

⁶ The earliest list of British Birds seems to be that in the *Pinax Rerum Naturalium* of CHRISTOPHER MERRETT, published in 1667. In the following year appeared the *Onomasticon Zoonon* of WALTER CHARLTON, which contains some information on ornithology. An enlarged edition of the latter, under the title of *Exercitationes* &c., was published in 1677; but neither of these writers is of much authority. In 1684 SIBBALD in his *Scotia illustrata* published the earliest Fauna of Scotland.

¹ Even at the present day it may be shrewdly expected that not a few ornithologists would gladly follow Gesner's plan in their despair of seeing, in their own time, a classification which would really deserve the epithet scientific.

² For instance, under the title of "Accipiter" we have to look, not only for the Sparrow-Hawk and Gos-Hawk, but for many other Birds of the Family (as we now call it) removed comparatively far from those species by modern ornithologists.

Colter.

Aldro-
vandus.

proper place nearly every bird he was likely to meet with. Ray's interest in ornithology continued, and in 1694 he completed a *Synopsis Methodica Avium*, which, through the fault of the booksellers to whom it was entrusted, was not published till 1713, when Derham gave it to the world.¹

Two years after Ray's death, LINNÆUS, the great reformer of Natural History, was born, and in 1735 appeared the first edition of the celebrated *Systema Naturæ*. Successive editions of this work were produced under its author's supervision in 1740, 1748, 1758, and 1766. Impressed by the belief that verbosity was the bane of science, he carried terseness to an extreme which frequently created obscurity, and this in no branch of zoology more than in that which relates to Birds. Still the practice introduced by him of assigning to each species a diagnosis by which it ought in theory to be distinguishable from any other known species, and of naming it by two words—the first being the generic and the second the specific term, was so manifest an improvement upon any thing which had previously obtained that the Linnæan method of differentiation and nomenclature established itself before long in spite of all opposition, and in principle became almost universally adopted. The opposition came of course from those who were habituated to the older state of things, and saw no evil in the cumbrous, half-descriptive half-designative titles which had to be employed whenever a species was to be spoken of or written about. The supporters of the new method were the rising generation of naturalists, many of whose names have since become famous, but among them were some whose admiration of their chief carried them to a pitch of enthusiasm which now seems absurd. Careful as Linnæus was in drawing up his definitions of groups, it was immediately seen that they occasionally were made to comprehend creatures whose characteristics contradicted the prescribed diagnosis. His chief glory lies in his having reduced, at least for a time, a chaos into order, and in his shewing both by precept and practice that a name was not a definition. In his classification of Birds he for the most part followed Ray, and where he departed from his model he seldom improved upon it.

In 1745 BARRERE brought out at Perpignan a little book called *Ornithologiæ Specimen novum*, and in 1752 MÖHRING published at Aurich one still smaller, his *Avium Genera*. Both these works (now rare) are manifestly framed on the Linnæan method, so far as it had then reached; but in their arrangement of the various forms of Birds they differed greatly from that which they designed to supplant, and they deservedly obtained little success. Yet as systematists their authors were no worse than KLEIN, whose *Historiæ Avium Prodromus*, appearing at Lübeck in 1750, and *Stemmata Avium* at Leipzig in 1759, met with considerable favour in some quarters. The chief merit of the latter work lies in its forty plates, whereon the heads and feet of many Birds are indifferently figured.²

But, while the successive editions of Linnæus's great work were revolutionizing Natural History, and his example of precision in language producing excellent effect on scientific writers, several other authors were advancing the study of Ornithology in a very different way—a way that pleased the eye even more than his labours were pleasing the mind. Between 1731 and 1743 MARK CATESBY brought out in

London his *Natural History of Carolina*—two large folios containing highly-coloured plates of the Birds of that colony, Florida, and the Bahamas—the forerunners of those numerous costly tomes which will have to be mentioned presently at greater length.³ ELEAZAR ALBIN between 1738 and 1740 produced a *Natural History of Birds* in three volumes of more modest dimensions, seeing that it is in quarto; but he seems to have been ignorant of Ornithology, and his coloured plates are greatly inferior to Catesby's. Far better both as draughtsman and as authority was GEORGE EDWARDS, who in 1743 began, under the same title as Albin, a series of plates with letter-press, which was continued by the name of *Gleanings in Natural History*, and finished in 1760, when it had reached seven parts, forming four quarto volumes, the figures of which are nearly always quoted with approval.⁴

The year which saw the works of Edwards completed was still further distinguished by the appearance in France, where little had been done since Belon's days,⁵ in six quarto volumes, of the *Ornithologie* of MATHURIN JACQUES BRISSON—a work of very great merit so far as it goes, for as a descriptive ornithologist the author stands even now unsurpassed; but it must be said that his knowledge, according to internal evidence, was confined to books and to the external parts of Birds' skins. It was enough for him to give a scrupulously exact description of such specimens as came under his eye, distinguishing these by prefixing two asterisks to their name, using a single asterisk where he had only seen a part of the Bird, and leaving unmarked those that he described from other authors. He also added information as to the Museum (generally Réaumur's, of which he had been in charge) containing the specimen he described, acting on a principle which would have been advantageously adopted by many of his contemporaries and successors. His attempt at classification was certainly better than that of Linnæus; and it is rather curious that the researches of the latest ornithologists point to results in some degree comparable with Brisson's systematic arrangement, for they refuse to keep the Birds-of-Prey at the head of the Class *Aves*, and they require the establishment of a much larger number of "Orders" than for a long while has been thought advisable. Of such "Orders" Brisson had twenty-six, and he gave Pigeons and Poultry precedence of the Birds which are plunderers and scavengers. But greater value lies in his generic or sub-generic divisions, which, taken as a whole, are far more natural than those of Linnæus, and consequently capable of better diagnosis. More than this, he seems to be the earliest ornithologist, perhaps the earliest zoologist, to conceive the idea of each genus possessing what is now called a "type"—though such a term does not occur in his work; and, in like manner, without declaring it in so many words, he indicated unmistakably the existence of subgenera—all this being effected by the skilful use of names. Unfortunately he was too soon in the field to avail himself, even had he been so minded, of the convenient mode of nomenclature brought into use by Linnæus. Immediately on the completion of his *Règne Animale* in 1756, Brisson set about his *Ornithologie*, and it is only in the last two volumes of the latter that any reference is made to the tenth edition of the *Systema Naturæ*, in which the binomial method

¹ To this was added a supplement by PETIVER on the Bird of Madras, taken from pictures and information sent him by one Edward Buckley of Fort St George, being the first attempt to catalogue the Birds of any part of the British possessions in India.

² After Klein's death his *Prodromus*, written in Latin, had the unwonted fortune of two distinct translations into German, published in the same year 1760, the one at Leipzig and Lübeck by BEHN, the other at Danzig by RYOKER—each of whom added more or less to the original.

³ Several Birds from Jamaica were figured in SLOAN's *Voyage*, &c. (1705–1725), and a good many exotic species in the *Thesaurus*, &c., of SEBA (1734–1765), but from their faulty execution these plates had little effect upon Ornithology.

⁴ The works of Catesby and Edwards were afterwards reproduced at Nuremberg and Amsterdam by SELIGMANN, with the letterpress in German, French, and Dutch.

⁵ Birds were treated of in a worthless fashion by one D. B. in a *Dictionnaire raisonné et universel des animaux*, published at Paris in 1759.

was introduced. It is certain that the first four volumes were written if not printed before that method was promulgated, and when the fame of Linnæus as a zoologist rested on little more than the very meagre sixth edition of the *Systema Naturæ* and the first edition of his *Fauna Suecica*. Brisson has been charged with jealousy of if not hostility to the great Swede, and it is true that in the preface to his *Ornithologie* he complains of the insufficiency of the Linnæan characters, but, when one considers how much better acquainted with Birds the Frenchman was, such criticism must be allowed to be pardonable if not wholly just. Brisson's work was in French, with a parallel translation in Latin, which last was reprinted separately at Leyden two years afterwards.

In 1767 there was issued at Paris a book entitled *L'histoire naturelle éclaircie dans une de ses parties principales, l'Ornithologie*. This was the work of SALERNE, published after his death, and is often spoken of as being a mere translation of Ray's *Synopsis*, but is thereby very inadequately described, for, though it is confessedly founded on that little book, a vast amount of fresh matter, and mostly of good quality, is added.

The success of Edwards's very respectable work seems to have provoked competition, and in 1765, at the instigation of Buffon, the younger D'AUBENTON began the publication known as the *Planches Enluminées d'histoire naturelle*, which appearing in forty-two parts was not completed till 1780, when the plates¹ it contained reached the number of 1008—all coloured, as its title intimates, and nearly all representing Birds. This enormous work was subsidized by the French Government; and, though the figures are utterly devoid of artistic merit, they display the species they are intended to depict with sufficient approach to fidelity to ensure recognition in most cases without fear of error, which in the absence of any text is no small praise.²

Buffon
and
Mont-
Beillard.

But BUFFON was not content with merely causing to be published this unparalleled set of plates. He seems to have regarded the work just named as a necessary precursor to his own labours in Ornithology. His *Histoire Naturelle, générale et particulière*, was begun in 1749, and in 1770 he brought out, with the assistance of GUÉNAU DE MONTBEILLARD,³ the first volume of that grand undertaking relating to Birds, which, for the first time since the days of Aristotle, became the theme of one who possessed real literary capacity. It is not too much to say that Buffon's florid fancy revelled in such a subject as was now that on which he exercised his brilliant pen; but it would be unjust to examine too closely what to many of his contemporaries seemed sound philosophical reasoning under the light that has since burst upon us. Strictly orthodox though he professed to be, there were those, both among his own countrymen and foreigners, who could not read his speculative indictments of the workings of Nature without a shudder; and it is easy for any one in these days to frame a reply, pointed with ridicule, to such a chapter as he wrote on the wretched fate of the Woodpecker. In the nine volumes devoted to the *Histoire Naturelle des Oiseaux* there are passages which will for ever live in the memory of those

that carefully read them, however much occasional expressions, or even the general tone of the author, may grate upon their feelings. He too was the first man who formed any theory that may be called reasonable of the Geographical Distribution of Animals, though this theory was scarcely touched in the ornithological portion of his work, and has since proved to be not in accordance with facts. He proclaimed the variability of species in opposition to the views of Linnæus as to their fixity, and moreover supposed that this variability arose in part by degradation.⁴ Taking his labours as a whole, there cannot be a doubt that he enormously enlarged the purview of naturalists, and, even if limited to Birds, that, on the completion of his work upon them in 1783, Ornithology stood in a very different position from that which it had before occupied. Because he opposed the system of Linnæus he has been said to be opposed to systems in general; but that is scarcely correct, for he had a system of his own; and, as we now see it, it appears neither much better nor much worse than the systems which had been hitherto invented, or perhaps than any which was for many years to come propounded. It is certain that he despised any kind of scientific phraseology—a crime in the eyes of those who consider precise nomenclature to be the end of science; but those who deem it merely a means whereby knowledge can be securely stored will take a different view—and have done so.

Great as were the services of Buffon to Ornithology in one direction, those of a wholly different kind rendered by our countryman JOHN LATHAM must not be overlooked. In 1781 he began a work the practical utility of which was immediately recognized. This was his *General Synopsis of Birds*, and, though formed generally on the model of Linnæus, greatly diverged in some respects therefrom. The classification was modified, chiefly on the old lines of Willughby and Ray, and certainly for the better; but no scientific nomenclature was adopted, which, as the author subsequently found, was a change for the worse. His scope was co-extensive with that of Brisson, but Latham did not possess the inborn faculty of picking out the character wherein one species differs from another. His opportunities of becoming acquainted with Birds were hardly inferior to Brisson's, for during Latham's long lifetime there poured in upon him countless new discoveries from all parts of the world, but especially from the newly-explored shores of Australia and the islands of the Pacific Ocean. The British Museum had been formed, and he had access to everything it contained in addition to the abundant materials afforded him by the private Museum of Sir Ashton Lever.⁵ Latham entered, so far as the limits of his work would allow, into the history of the Birds he described, and this with evident zest, whereby he differed from his French predecessor; but the number of cases in which he erred as to the determination of his species must be very great, and not unfrequently the same species is described more than once. His *Synopsis* was finished in 1785; two supplements were added in 1787 and 1802,⁶ and in 1790 he produced an abstract of the work under the title of *Index Ornithologicus*, wherein he assigned names on the Linnæan method to all the species described. Not to recur again to his labours, it may be said here that between 1821 and 1828 he published at Winchester, in eleven volumes, an enlarged edition of his original work, entitling it *A General History of Birds*; but his defects as

¹ They were drawn and engraved by MARTINET, who himself began in 1787 a *Histoire des Oiseaux* with small coloured plates which have some merit, but the text is worthless. The work seems not to have been finished and is rare. For the opportunity of seeing a copy the writer is indebted to Mr Gurney.

² Between 1767 and 1776 there appeared at Florence a *Storia Naturale degli Uccelli*, in five folio volumes, containing a number of ill-drawn and ill-coloured figures from the collection of Giovanni Gerini, an ardent collector who died in 1751, and therefore must be acquitted of any share in the work, which, though sometimes attributed to him, is that of certain learned men who did not happen to be ornithologists (cf. Savi, *Ornitologia Toscana*, i. Introduzione, p. 7).

³ He retired on the completion of the sixth volume, and thereupon Buffon associated Bexon with himself.

⁴ See Prof. Mivart's address to the Section of Biology, *Rep. Brit. Association* (Sheffield Meeting), 1879, p. 356.

⁵ In 1792 SHAW began the *Museum Leverianum* in illustration of this collection, which was finally dispersed by sale, and what is known to remain of it found its way to Vienna. Of the specimens in the British Museum described by Latham it is to be feared that scarcely any exist. They were probably very imperfectly prepared.

⁶ A German translation by Bechstein subsequently appeared.

a compiler, which had been manifest before, rather increased with age, and the consequences were not happy.¹

About the time that Buffon was bringing to an end his studies of Birds, MAUDUYT undertook to write the *Ornithologie* of the *Encyclopédie Méthodique*—a comparatively easy task, considering the recent works of his fellow-countrymen on that subject, and finished in 1784. Here it requires no further comment, especially as a new edition was called for in 1790, the ornithological portion of which was begun by BONNATERRE, who, however, had only finished three hundred and twenty pages of it when he lost his life in the French Revolution; and the work thus arrested was continued by VIEILLOT under the slightly changed title of *Tableau encyclopédique et méthodique des trois règnes de la Nature*—the *Ornithologie* forming volumes four to seven, and not completed till 1823. In the former edition Mauduyt had taken the subjects alphabetically; but here they are disposed according to an arrangement, with some few modifications, furnished by D'Aubenton, which is extremely shallow and unworthy of consideration.

Several other works bearing upon Ornithology in general, but of less importance than most of those just named, belong to this period. Among others may be mentioned the *Genera of Birds* by THOMAS PENNANT, first printed at Edinburgh in 1773, but best known by the edition which appeared in London in 1781; the *Elementa Ornithologica* and *Museum Ornithologicum* of SCHAEFFER, published at Ratisbon in 1774 and 1784 respectively; PETER BROWN'S *New Illustrations of Zoology* in London in 1776; HERMANN'S *Tabulæ Affinitatum Animalium* at Strasburg in 1783, followed posthumously in 1804 by his *Observationes Zoologicae*; JACQUIN'S *Beytraege zur Geschichte der Voegel* at Vienna in 1784, and in 1790 at the same place the larger work of SPALOWSKY with nearly the same title; SPARRMAN'S *Museum Carolinianum* at Stockholm from 1786 to 1789; and in 1794 HAYES'S *Portraits of rare and curious Birds* from the menagerie of Child the banker at Osterley near London. The same draughtsman (who had in 1775 produced a *History of British Birds*) in 1822 began another series of *Figures of rare and curious Birds*.²

The practice of Brisson, Buffon, Latham, and others of neglecting to name after the Linnæan fashion the species they described gave great encouragement to compilation, and led to what has proved to be of some inconvenience to modern ornithologists. In 1773 P. L. S. MÜLLER brought out at Nuremberg a German translation of the *Systema Naturæ*, completing it in 1776 by a *Supplement* containing a list of animals thus described, which had hitherto been technically anonymous, with diagnoses and names on the Linnæan model. In 1783 BODDAERT printed at Utrecht a *Table des Planches Enluminées*,³ in which he attempted to refer every species of Bird figured in that extensive series to its proper Linnæan genus, and to assign it a scientific name if it did not already possess one. In like manner in 1786, SCOPOLI—already the author of a little book published

at Leipzig in 1769 under the title of *Annus I. Historico-naturalis*, in which are described many Birds, mostly from his own collection or the Imperial vivarium at Vienna—was at the pains to print at Pavia in his miscellaneous *Delicia Floræ et Faunæ Insultricæ a Specimen Zoologicum* containing diagnoses, duly named, of the Birds discovered and described by SONNERAT in his *Voyage aux Indes orientales* and *Voyage à la Nouvelle Guinée*, severally published at Paris in 1772 and 1776. But the most striking example of compilation was that exhibited by J. F. GMELIN, who in 1788 commenced what he called the Thirteenth Edition of the celebrated *Systema Naturæ*, which obtained so wide a circulation that, in the comparative rarity of the original, the additions of this editor have been very frequently quoted, even by expert naturalists, as though they were the work of the author himself. Gmelin availed himself of every publication he could, but he perhaps found his richest booty in the labours of Latham, neatly condensing his English descriptions into Latin diagnoses, and bestowing on them binomial names. Hence it is that Gmelin appears as the authority for so much of the nomenclature now in use. He took many liberties with the details of Linnæus's work, but left the classification, at least of the Birds, as it was—a few new genera excepted.⁵

During all this time little had been done in studying the internal structure of Birds since the works of Cæsar already mentioned⁶; but the foundations of the science of Embryology had been laid by the investigations into the development of the chick by the great HARVEY. Between 1666 and 1669 PERRAULT edited at Paris eight accounts of the dissection by DU VERNEY of as many species of Birds, which, translated into English, were published by the Royal Society in 1702, under the title of *The Natural History of Animals*. After the death of the two anatomists just named, another series of similar descriptions of eight other species was found among their papers, and the whole were published in the *Mémoires* of the French Academy of Sciences in 1733 and 1734. But in 1681 GERARD BLASIUS had brought out at Amsterdam an *Anatome Animalium*, containing the results of all the dissections of animals that he could find; and the second part of this book, treating of *Volatilia*, makes a respectable show of more than one hundred and twenty closely-printed quarto pages, though nearly two-thirds is devoted to a treatise *De Ovo et Pullo*, containing among other things a reprint of Harvey's researches, and the scientific rank of the whole book may be inferred from Bats being still classed with Birds. In 1720 VALENTINI published, at Frankfort-on-the-Main, his *Amphitheatrum Zootomicum*, in which again most of the existing accounts of the anatomy of Birds were reprinted. But these and many other contributions,⁷ made until nearly the close of the eighteenth century, though highly meritorious, were unconnected as a whole, and it is plain that no conception of what it was in the power of Comparative Anatomy to set forth had occurred to the most diligent dissectors. This privilege was reserved for GEORGES COUVIER, who in 1798 published at Paris his *Tableau Élémentaire de l'histoire naturelle des Animaux*, and thus laid the foundation of a thoroughly and hitherto unknown

Gerard Blasius.

¹ He also prepared for publication a second edition of his *Index Ornithologicus*, but this was never printed, and the manuscript is now in the present writer's possession.

² *The Naturalist's Miscellany* or *Vivarium Naturale*, in English and Latin, of SHAW and NODDER, the former being the author, the latter the draughtsman and engraver, was begun in 1789 and carried on till Shaw's death, forming twenty-four volumes. It contains figures of more than 280 Birds, but very poorly executed. In 1814 a sequel, *The Zoological Miscellany*, was begun by LEACH, Nodder continuing to do the plates. This was completed in 1817, and forms three volumes with 149 plates, 27 of which represent Birds.

³ Of this work only fifty copies were printed, and it is one of the rarest known to the ornithologist. Only two copies are believed to exist in England, one in the British Museum, the other in private hands. It was reprinted in 1874 by Mr Tegetmeier.

⁴ This was reprinted in 1882 by the Willughby Society.

⁵ DAUDIN'S unfinished *Traité élémentaire et complet d'Ornithologie* appeared at Paris in 1800, and therefore is the last of these general works published in the eighteenth century.

⁶ A succinct notice of the older works on Ornithotomy is given by Prof. SELENKA in the introduction to that portion of Dr Bronn's *Klassen und Ordnungen des Thierreichs* relating to Birds (pp. 1-9) published in 1869; and Prof. CARUE'S *Geschichte der Zoologie*, published in 1872, may also be usefully consulted for further information on this and other heads.

⁷ The treatises of the two BARTHOLINIS and BORRICHUS published at Copenhagen deserve mention if only to record the activity of Danish anatomists in those days.

Pennant.

P. L. S. Müller.

Boddaert.

mode of appreciating the value of the various groups of the Animal Kingdom. Yet his first attempt was a mere sketch.¹ Though he made a perceptible advance on the classification of Linnæus, at that time predominant, it is now easy to see in how many ways—want of sufficient material being no doubt one of the chief—Cuvier failed to produce a really natural arrangement. His principles, however, are those which must still guide taxonomers, notwithstanding that they have in so great a degree overthrown the entire scheme which he propounded. Confining our attention here, as of course it ought to be confined, to Ornithology, Cuvier's arrangement of the Class *Aves* is now seen to be not very much better than any which it superseded. But this view is gained by following the methods which Cuvier taught. In the work just mentioned few details are given; but even the more elaborate classification of Birds contained in his *Leçons d'Anatomie Comparée* of 1805 is based wholly on external characters, such as had been used by nearly all his predecessors; and the *Règne Animal* of 1817, when he was in his fullest vigour, afforded not the least evidence that he had ever dissected a couple even of Birds² with the object of determining their relative position in his system, which then, as before, depended wholly on the configuration of bills, wings, and feet. But, though apparently without such a knowledge of the anatomy of Birds as would enable him to apply it to the formation of that natural system which he was fully aware had yet to be sought, he seems to have been an excellent judge of the characters afforded by the bill and limbs, and the use he made of them, coupled with the extraordinary reputation he acquired on other grounds, procured for his system the adhesion for many years of the majority of ornithologists, and its influence though waning is still strong. Regret must always be felt by them that his great genius was never applied in earnest to their branch of study, especially when we consider that had it been so the perversion of energy in regard to the classification of Birds witnessed in England for nearly twenty years, and presently to be mentioned, would most likely have been prevented.³

Hitherto mention has chiefly been made of works on General Ornithology, but it will be understood that these were largely aided by the enterprise of travellers, and as there were many of them, who published their narratives in separate forms their contributions have to be considered. Of those travellers then the first to be here especially named is MARSIGLI, the fifth volume of whose *Danubius Pannonico-Mysicus* is devoted to the Birds he met with in the valley of the Danube, and appeared at the Hague in 1725, followed by a French translation in 1744.⁴ Most of the many pupils whom Linnæus sent to foreign countries submitted their discoveries to him, but KALM, HASSELVIST, and OSBECK published separately their respective travels

in North America, the Levant, and China.⁵ The incessant journeys of PALLAS and his colleagues—FALK, GEORGI, S. G. GMELIN, GÜLDENSTÄDT, LEPECHIN, and others—in the exploration of the recently extended Russian empire supplied not only much material to the *Commentarii* and *Acta* of the Academy of St Petersburg, but more that is to be found in their narratives,—all of it being of the highest interest to students of Palearctic or Nearctic Ornithology. Nearly the whole of their results, it may here be said, were summed up in the important *Zoographia Rosso-Asiatica* of the first-named naturalist, which saw the light in 1811,—the year of its author's death,—but, owing to circumstances over which he had no control, was not generally accessible till twenty years later. Of still wider interest are the accounts of Cook's three famous voyages, though unhappily much of the information gained by the naturalists who accompanied him on one or more of them seems to be irretrievably lost: the original observations of the elder FORSTER^{The Forster} were not printed till 1844, and the valuable collection of zoological drawings made by the younger FORSTER still remains unpublished in the British Museum. The several accounts by JOHN WHITE, COLLINS, PHILLIPS, HUNTER, and others of the colonization of New South Wales at the end of the last century ought not to be overlooked by any Australian ornithologist. The only information at this period on the Ornithology of South America is contained in the two works on Chili by MOLINA, published at Bologna in 1776 and 1782. The travels of LE VAILLANT in South Africa^{Le Vaillant} having been completed in 1785, his great *Oiseaux d'Afrique* began to appear in Paris in 1790; but it is hard to speak properly of this work, for several of the species described in it are certainly not, and never were in his time, inhabitants of that country, though he sometimes gives a long account of the circumstances under which he observed them.⁶

From travellers who employ themselves in collecting the animals of any distant country the zoologists who stay at home and study those of their own district, be it great or small, are really not so much divided as at first might appear. Both may well be named "Faunists," and of the latter there were not a few who having turned their attention more or less to Ornithology should here be mentioned, and first among them RZACZYNSKI, who in 1721 brought out at Sandomirsk the *Historia naturalis curiosa regni Poloniæ*, to which an *Auctuarium* was posthumously published at Danzig in 1742. This also may be perhaps the most proper place to notice the *Historia Avium Hungariæ* of GROSSINGER, published at Posen in 1793. In 1734 J. L. GÜSSNER, FRISCH began the long series of works on the Birds of Germany with which the literature of Ornithology is enriched, by his *Vorstellung der Vögel Deutschlands*, which was only completed in 1763, and, its coloured plates proving very attractive, was again issued at Berlin in 1817. The little fly-sheet of ZORN⁷—for it is scarcely more—on the Birds of the Hercynian Forest made its appearance at Pappenheim in 1745. In 1756 KRAMER published at Vienna a modest *Elenchus* of the plants and animals of Lower Austria, and J. D. PETERSEN produced at Altona, in 1766 a *Verzeichniss balthischer Vögel*; while in 1791 J. B. FISCHER's *Versuch einer Naturgeschichte von Livland* appeared at Königsberg, next year BESEKE brought out at Mitau his *Beytrag zur Naturgeschichte der Vögel Kurlands*,^{Kramer.}

¹ It had no effect on LACÉPÈDE, who in the following year added a *Tableau Méthodique* containing a classification of Birds to his *Discours d'Ouverture* (*Mém. de l'Institut*, iii. pp. 454-468, 503-519).

² So little regard did he pay to the Osteology of Birds that, according to De Blainville (*Jour. de Physique*, xcii. p. 187, note), the skeleton of a Powl to which was attached the head of a Hornbill was for a long time exhibited in the Museum of Comparative Anatomy at Paris! Yet, in order to determine the difference of structure in their organs of voice, Cuvier, as he says in his *Leçons* (iv. p. 464), dissected more than one hundred and fifty species of Birds. Unfortunately for him, as will appear in the sequel, it seems not to have occurred to him to use any of the results he obtained as the basis of a classification.

³ It is unnecessary to enumerate the various editions of the *Règne Animal*. Of the English translations, that edited by Griffiths and Pidgeon is the most complete. The ornithological portion of it contained in these volumes received many additions from JOHN EDWARD GRAY, and appeared in 1829.

⁴ Though much later in date, the *Iter per Posenam Sclavoniam* of PILLER and MITTERPACHER, published at Buda in 1783, may perhaps be here most conveniently mentioned.

⁵ The results of FORSKÆL's travels in the Levant, published after his death by Niebuhr, require mention, but the ornithology they contain is but scant.

⁶ It has been charitably suggested that, his collection and notes having suffered shipwreck, he was induced to supply the latter from his memory and the former by the nearest approach to his lost specimens that he could obtain. This explanation, poor as it is, fails, however, in regard to some species.

⁷ His earlier work under the title of *Petinotheologie* can hardly be deemed scientific.

and in 1794 SIEMSEN'S *Handbuch* of the Birds of Mecklenburg was published at Rostock. But these works, locally useful as they may have been, did not occupy the whole attention of German ornithologists, for in 1791 BECHSTEIN reached the second volume of his *Gemeinnützige Naturgeschichte Deutschlands*, treating of the Birds of that country, which ended with the fourth in 1795. Of this an abridged edition by the name of *Ornithologisches Taschenbuch* appeared in 1802 and 1803, with a supplement in 1812; while between 1805 and 1809 a fuller edition of the original was issued. Moreover in 1795 J. A. NAUMANN humbly began at Cöthen a treatise on the Birds of the principality of Anhalt, which on its completion in 1804 was found to have swollen into an Ornithology of Northern Germany and the neighbouring countries. Eight supplements were successively published between 1805 and 1817, and in 1822 a new edition was required. This *Naturgeschichte der Vögel Deutschlands*, being almost wholly rewritten by his son J. F. NAUMANN, is by far the best thing of the kind as yet produced in any country. The fulness and accuracy of the text, combined with the neat beauty of its coloured plates, have gone far to promote the study of Ornithology in Germany, and while essentially a popular work, since it is suited to the comprehension of all readers, it is throughout written with a simple dignity that commends it to the serious and scientific. Its twelfth and last volume was published in 1844—by no means too long a period for so arduous and honest a performance, and a supplement was begun in 1847; but, the editor—or author as he may be fairly called—dying in 1857, this continuation was finished in 1860 by the joint efforts of J. H. BLASIUS and Dr BALDANUS. In 1800 BORKHAUSEN with others commenced at Darmstadt a *Deutsche Ornithologie* in folio which appeared at intervals till 1812, and remains unfinished, though a reissue of the portion published took place between 1837 and 1841.

Other countries on the Continent, though not quite so prolific as Germany, bore some ornithological fruit at this period; but in all Southern Europe only four faunistic products can be named:—the *Saggio di Storia Naturale Bresciana* of PILATI, published at Brescia in 1769; the *Ornithologia dell' Europa Meridionale* of BERNINI, published at Parma between 1772 and 1776; the *Uccelli di Sardegna* of CETTI, published at Sassari in 1776; and the *Romana Ornithologia* of GILIUS, published at Rome in 1781—the last being in great part devoted to Pigeons and Poultry. More appeared in the North, for in 1770 Amsterdam sent forth the beginning of NOZEMAN'S *Nederlandsche Vogelen*, a fairly illustrated work in folio, but only completed by HOUTTUYN in 1829, and in Scandinavia most of all was done. In 1746 the great LINNÆUS had produced a *Fauna Svecica*, of which a second edition appeared in 1761, and a third revised by RETZIUS in 1800. In 1764 BRÜNNICH published at Copenhagen his *Ornithologia Borealis*, a compendious sketch of the Birds of all the countries then subject to the Danish crown. At the same place appeared in 1767 LEEM'S work *De Lapponibus Finmarchie*, to which GUNNERUS contributed some good notes on the Ornithology of Northern Norway, and at Copenhagen and Leipzig was published in 1780 the *Fauna Groenlandica* of OTTO FABRICIUS.

Of strictly American origin can here be cited only BARTRAM'S *Travels through North and South Carolina* and BARTON'S *Fragments of the Natural History of Pennsylvania*,¹ both printed at Philadelphia, one in 1791, the other in 1799; but J. R. FORSTER published a *Catalogue of the Animals of North America* in London in 1771, and the

following year described in the *Philosophical Transactions* a few Birds from Hudson's Bay.² A greater undertaking was PENNANT'S *Arctic Zoology*, published in 1785, with a supplement in 1787. The scope of this work was originally intended to be limited to North America, but circumstances induced him to include all the species of Northern Europe and Northern Asia, and though not free from errors it is a praiseworthy performance. A second edition appeared in 1792. The Ornithology of Britain naturally demands greater attention. The earliest list of British Birds we possess is that given by MERRETT in his *Pinax Rerum Naturalium Britannicarum*, printed in London in 1667.³ In 1677 PLOT published his *Natural History of Oxfordshire*, which reached a second edition in 1705, and in 1686 that of *Staffordshire*. A similar work on *Lancashire, Cheshire, and the Peak* was sent out in 1700 by LEIGH, and one on *Cornwall* by BORLASE in 1758—all these four being printed at Oxford. In 1766 appeared PENNANT'S *British Zoology*, a well-illustrated folio, of which a second edition in octavo was published in 1768, and considerable additions (forming the nominally third edition) in 1770, while in 1777 there were two issues, one in octavo the other in quarto, each called the fourth edition. In 1812, long after the author's death, another edition was printed, of which his son-in-law Hanmer was the reputed editor, but he received much assistance from Latham, and through carelessness many of the additions herein made have often been ascribed to Pennant. In 1769 BERKENHOUT gave to the world his *Berkenhout. Outlines of the Natural History of Great Britain and Ireland*, which reappeared under the title of *Synopsis* of the same in 1795. TUNSTALL'S *Ornithologia Britannica*, which Tunstall appeared in 1771, is little more than a list of names.⁴ In 1781 NASH'S *Worcestershire* included a few ornithological notices; and WALCOTT in 1789 published an illustrated *Walcott Synopsis of British Birds*, coloured copies of which are rare. In 1791 J. HEYSHAM added to Hutchins's *Cumberland* a list of Birds of that county, and in 1794 DONOVAN began *Donovan a History of British Birds* which was only finished in 1819—the earlier portion being reissued about the same time. In 1800 LEWIN brought out a very worthless work with *Lewin the same title*.

All the foregoing publications yield in importance to two that remain to be mentioned, a notice of which will fitly conclude this part of our subject. In 1767 Pennant, several of whose works have already been named, entered into correspondence with GILBERT WHITE, receiving from Gilbert White him much information, almost wholly drawn from his own observation, for the succeeding editions of the *British Zoology*. In 1769 White began exchanging letters of a similar character with Barrington. The epistolary intercourse with the former continued until 1780 and with the latter until 1787. In 1789 White's share of the correspondence, together with some miscellaneous matter, was published as *The Natural History of Selborne*—from the name of the village in which he lived. Observations on Birds form the principal though by no means the whole theme of this book, which may be safely said to have done more to promote a love of Ornithology in this country than any other work that has been written, nay more than all the other works (except one next to be mentioned) put together. It has passed through a far greater number of

² Both of these treatises have also been reprinted by the Willughby Society.

³ In this year there were two issues of this book; one, nominally a second edition, only differs from the first in having a new title-page. No real second edition ever appeared, but in anticipation of it Sir THOMAS BROWNE prepared in or about 1671 (?) his "Account of Birds found in Norfolk," of which the draught, now in the British Museum, was printed in his collected works by Wilkin in 1835. If a fair copy was ever made its resting-place is unknown.

⁴ It has been republished by the Willughby Society.

editions than any other work in Natural History in the whole world, and has become emphatically an English classic—the graceful simplicity of its style, the elevating tone of its spirit, and the sympathetic chords it strikes recommending it to every lover of Nature, while the severely scientific reader can scarcely find an error in any statement it contains, whether of matter of fact or opinion. It is almost certain that more than half the zoologists of the British Islands for the past seventy years or more have been infected with their love of the study by Gilbert White; and it can hardly be supposed that his influence will cease.¹

The other work to the importance of which on Ornithology in this country allusion has been made is BEWICK'S *History of British Birds*. The first volume of this, containing the Land-Birds, appeared in 1797²—the text being, it is understood, by Beilby—the second, containing the Water-Birds, in 1804. The woodcuts illustrating this work are generally of surpassing excellence, and it takes rank in the category of artistic publications. Fully admitting the extraordinary execution of the engravings, every ornithologist may perceive that as portraits of the Birds they are of very unequal merit. Some of the figures were drawn from stuffed specimens, and accordingly perpetuate all the imperfections of the original; others represent species with the appearance of which the artist was not familiar, and these are either wanting in expression or are caricatures;³ but those that were drawn from live Birds, or represent species which he knew in life, are worthy of all praise. It is well known that the earlier editions of this work, especially if they be upon large paper, command extravagant prices; but in reality the copies on smaller paper are now the rarer, for the stock of them has been consumed in nurseries and schoolrooms, where they have been torn up or worn out with incessant use. Moreover, whatever the lovers of the fine arts may say, it is nearly certain that the "Bewick Collector" is mistaken in attaching so high a value to these old editions, for owing to the want of skill in printing—indifferent ink being especially assigned as one cause—many of the earlier issues fail to shew the most delicate touches of the engraver, which the increased care bestowed upon the edition of 1847 (published under the supervision of Mr John Hancock) has revealed,—though it must be admitted that certain blocks have suffered from wear of the press so as to be incapable of any more producing the effect intended. Of the text it may be said that it is respectable, but no more. It has given satisfaction to thousands of readers in time past, and will, it may be hoped, give satisfaction to thousands in time to come.

The existence of these two works explains the widely-spread taste for Ornithology in this country, which is to foreigners so puzzling, and the zeal—not always according to knowledge, but occasionally reaching to serious study—with which that taste is pursued.

Having thus noticed, and it is to be hoped pretty thoroughly, the chief ornithological works begun if not completed prior to the commencement of the present cen-

tury, together with their immediate sequels, those which follow will require a very different mode of treatment, for their number is so great that it would be impossible for want of space to deal with them in the same extended fashion, though the attempt will finally be made to enter into details in the case of works constituting the foundation upon which apparently the superstructure of the future science has to be built. It ought not to need stating that much of what was, comparatively speaking, only a few years ago regarded as scientific labour is now no longer to be so considered. The mere fact that the principle of Evolution, and all its admission carries with it, has been accepted in some form or other by almost all naturalists, has rendered obsolete nearly every theory that had hitherto been broached, and in scarcely any branch of zoological research was theory more rife than in Ornithology. One of these theories must presently be noticed at some length on account of the historical importance which attaches to its malefic effects in impeding the progress of true Ornithology in Britain; but charity enjoins us to consign all the rest as much as possible to oblivion.

On reviewing the progress of Ornithology since the end of the last century, the first thing that will strike us is the fact that general works, though still undertaken, have become proportionally fewer, and such as exist are apt to consist of mere explanations of systematic methods that had already been more or less fully propounded, while special works, whether relating to the ornithic portion of the Fauna of any particular country, or limited to certain groups of Birds—works to which of late years the name of "Monograph" has become wholly restricted—have become far more numerous. But this seems to be the natural law in all sciences, and its cause is not far to seek. As the knowledge of any branch of study extends, it outgrows the opportunities and capabilities of most men to follow it as a whole; and, since the true naturalist, by reason of the irresistible impulse which drives him to work, cannot be idle, he is compelled to confine his energies to narrower fields of investigation. That in a general way this is for some reason to be regretted is true; but, like all natural operations, it carries with it some recompense, and the excellent work done by so-called "specialists" has over and over again proved of the greatest use to advancement in different departments of science, and in none more than in Ornithology.⁴

Another change has come over the condition of Ornithology, as of kindred sciences, induced by the multiplication of learned societies which issue publications as well as of periodicals of greater or less scientific pretension—the latter often enjoying a circulation far wider than the former. Both kinds increase yearly, and the desponding mind may fear the possibility of its favourite study expiring through being smothered by its own literature. Without anticipating such a future disaster, and looking merely to what has gone before, it is necessary here to premise that, in the observations which immediately follow, treatises which have appeared in the publications of learned bodies or in other scientific periodicals must, except they be of prime importance, be hereinafter passed unnoticed; but their omission will be the less felt because the more recent of those of a "faunal" character have generally been mentioned in a former dissertation (*BIRDS*, vol. iii. pp. 737-764) under the different Regions or

¹ Next to the original edition, that known as Bennett's, published in 1837, which was reissued in 1875 by Mr Harting, was long deemed the best; but it must give place to that of Bell, which appeared in 1877, and contains much additional information of great interest. But the editions of Markwick, Herbert, Blyth, and Jardine all possess features of merit. An elaborately prepared edition, issued of late years under the management of one who gained great reputation as a naturalist, only shews his ignorance and his vulgarity.

² There were two issues—virtually two editions—of this with the same date on the title-page, though one of them is said not to have been published till the following year. Among several other *indicia* this may be recognized by the woodcut of the "Sea Eagle" at page 11 bearing at its base the inscription "Wycliffe, 1791," and by the additional misprint on page 145 of *Saheniclus* for *Scheniclus*.

³ This is especially observable in the figures of the Birds-of-Prey.

⁴ The truth of the preceding remarks may be so obvious to most men who have acquaintance with the subject that their introduction here may seem unnecessary; but it is certain that the facts they state have been very little appreciated by many writers who profess to give an account of the progress of Natural History during the present century.

countries with which they deal, while reference to the older of these treatises is usually given by the writers of the newer. Still it seems advisable here to furnish some connected account of the progress made in the ornithological knowledge of those countries in which the readers of the present volume may be supposed to take the most lively interest—for example, the British Islands and those parts of the European continent which lie nearest to them or are most commonly sought by travellers, the Dominion of Canada and the United States of America, South Africa, India, together with Australia and New Zealand. The more important Monographs, again, will usually be found cited in the series of special articles on Birds contained in this work, though, as will be immediately perceived, there are some so-styled Monographs, which by reason of the changed views of classification that at present obtain have lost their restricted character, and for all practical purposes have now to be regarded as general works.

It will perhaps be most convenient to begin by mentioning some of these last, and in particular a number of them which appeared at Paris very early in this century. First in order of them is the *Histoire Naturelle d'une partie d'Oiseaux nouveaux et rares de l'Amérique et des Indes*, a folio volume¹ published in 1801 by LE VAILLANT. This is devoted to the very distinct and not nearly-allied groups of Hornbills and of birds which for want of a better name we must call "Chatterers," and is illustrated, like those works of which a notice immediately follows, by coloured plates, done in what was then considered to be the highest style of art and by the best draughtsmen procurable. The first volume of a *Histoire Naturelle des Perroquets*, a companion work by the same author, appeared in the same year, and is truly a Monograph, since the Parrots constitute a Family of birds so naturally severed from all others that there has rarely been anything else confounded with them. The second volume came out in 1805, and a third was issued in 1837–38 long after the death of its predecessor's author, by BOUJOT ST-HILAIRE. Between 1803 and 1806 Le Vaillant also published in just the same style two volumes with the title of *Histoire Naturelle des Oiseaux de Paradis et des Rolliers, suivie de celle des Toucans et des Barbous*, an assemblage of forms, which, miscellaneous as it is, was surpassed in incongruity by a fourth work on the same scale, the *Histoire Naturelle des Promerops et des Guépriers, des Couroucous et des Touracos*, for herein are found Jays, Waxwings, the Cock-of-the-Rock (*Rupicola*), and what not besides. The plates in this last are by Barraband, for many years regarded as the perfection of ornithological artists, and indeed the figures, when they happen to have been drawn from the life, are not bad: but his skill was quite unable to vivify the preserved specimens contained in Museums, and when he had only these as subjects he simply copied the distortions of the "bird-stuffer." The following year, 1808, being aided by Temminck of Amsterdam, of whose son we shall presently hear more, Le Vaillant brought out the sixth volume of his *Oiseaux d'Afrique*, already mentioned. Four more volumes of this work were promised; but the means of executing them were denied to him, and, though he lived until 1824, his publications ceased.

A similar series of works was projected and begun about the same time as that of Le Vaillant by AUDEBERT and VIEILLOT, though the former, who was by profession a painter and illustrated the work, was already dead more than a year before the appearance of the two volumes, bearing date 1802, and entitled *Oiseaux dorés ou a reflets métalliques*, the effect of the plates in which he sought to heighten by the lavish use of gilding. The first volume

¹ There is also an issue of this, as of the same author's other works, on large quarto paper.

contains the "Colibris, Oiseaux-mouches, Jacamars et Promerops," the second the "Grimpereaux" and "Oiseaux de Paradis"—associations which set all the laws of systematic method at defiance. His colleague, Vieillot, brought out in 1805 a *Histoire Naturelle des plus beaux Chanteurs de la Zone Torride* with figures by Langlois of tropical Finches, Grosbeaks, Buntings, and other hard-billed birds; and in 1807 two volumes of a *Histoire Naturelle des Oiseaux de l'Amérique Septentrionale*, without, however, paying much attention to the limits commonly assigned by geographers to that part of the world. In 1805 ANSELME DESMAREST published a *Histoire naturelle des Tangaras, des Manakins et des Todiers*, which, though belonging to the same category as all the former, differs from them in its more scientific treatment of the subjects to which it refers; and, in 1808, TEMMINCK, whose father's aid to Le Vaillant has already been noticed, brought out at Paris a *Histoire Naturelle des Pigeons* illustrated by Madame Knip, who had drawn the plates for Desmarest's volume.²

Since we have begun by considering these large illustrated works in which the text is made subservient to the coloured plates, it may be convenient to continue our notice of such others of similar character as it may be expedient to mention here, though thereby we shall be led somewhat far afield. Most of them are but luxuries, and there is some degree of truth in the remark of Andreas Wagner in his *Report on the Progress of Zoology* for 1843, drawn up for the Ray Society (p. 60), that they "are not adapted for the extension and promotion of science, but must inevitably, on account of their unnecessary costliness, constantly tend to reduce the number of naturalists who are able to avail themselves of them, and they thus enrich ornithology only to its ultimate injury." Earliest in date as it is greatest in bulk stands AUDUBON'S cgrégious *Birds of America* in four volumes, containing four hundred and thirty-five plates, of which the first part appeared in London in 1827 and the last in 1838. It does not seem to have been the author's original intention to publish any letter-press to this enormous work, but to let the plates tell their own story, though finally, with the assistance, as is now known, of WILLIAM MACOILLIVRAY, a text, on the whole more than respectable, was produced in five large octavos under the title of *Ornithological Biography*, of which more will be said in the sequel. Audubon has been greatly extolled as an ornithological artist; but he was far too much addicted to representing his subjects in violent action and in postures that outrage nature, while his drawing is very frequently defective.³ In 1866 Mr D. G. ELLIOT began, and in 1869 finished, a sequel to Audubon's great work in two volumes, on the same scale—*The New and Hitherto unfigured Species of the Birds of North America*, containing life-size figures of all those which had been added to its fauna since the completion of the former.

In 1830 JOHN EDWARD GRAY commenced the *Illustrations of Indian Zoology*, a series of plates of vertebrated animals, but mostly of Birds, from drawings it is believed by native artists in the collection of General HARDWICKE, whose name is therefore associated with the work. Scientific

² Temminck subsequently reproduced, with many additions, the text of this volume in his *Histoire Naturelle des Pigeons et des Gallinacées*, published at Amsterdam in 1813–15, in 3 vols. 8vo. Between 1833 and 1848 M. FLORENT-PROVOST brought out at Paris a further set of illustrations of Pigeons by Mme. Knip.

³ On the completion of these two works, for they must be regarded as distinct, an octavo edition in seven volumes under the title of *The Birds of America* was published in 1840–44. In this the large plates were reduced by means of the "camera lucida," the text was revised, and the whole systematically arranged. Other reprints have since been issued, but they are vastly inferior both in execution and value. A sequel to the octavo *Birds of America*, corresponding with it in form, was brought out in 1853–55 by CASSIN as *Illustrations of the Birds of California, Texas, Oregon, British and Russian America*.

names are assigned to the species figured; but no text was ever supplied. In 1832 Mr LEAR, afterwards well known as a painter, brought out his *Illustrations of the Family of Psittacidae*, a volume which deserves especial notice from the extreme fidelity to nature and the great artistic skill with which the figures were executed.

This same year (1832) saw the beginning of the marvellous series of illustrated ornithological works by which the name of JOHN GOULD is likely to be always remembered. *A Century of Birds from the Himalaya Mountains* was followed by *The Birds of Europe* in five volumes, published between 1832 and 1837, while in the interim (1834) appeared *A Monograph of the Ramphastidae*, of which a second edition was some years later called for, then the *Icones Avium*, of which only two parts were published (1837-38), and *A Monograph of the Trogonidae* (1838), which also reached a second edition. Sailing in 1838 for New South Wales, on his return in 1840 he at once commenced the greatest of all his works, *The Birds of Australia*, which was finished in 1848 in seven volumes, to which several supplementary parts, forming another volume, were subsequently added. In 1849 he began *A Monograph of the Trochilidae or Humming-birds* extending to five volumes, the last of which appeared in 1861, and has since been followed by a supplement now in course of completion by Mr SALVIN. *A Monograph of the Odontophorinæ or Partridges of America* (1850); *The Birds of Asia*, in seven volumes, the last completed by Mr SHARPE (1850-83); *The Birds of Great Britain*, in five volumes (1862-73); and *The Birds of New Guinea*, begun in 1875, and, after the author's death in 1881, undertaken by Mr Sharpe, make up the wonderful tale consisting of more than forty folio volumes, and containing more than three thousand coloured plates. The earlier of these works were illustrated by Mrs Gould, and the figures in them are fairly good; but those in the later, except when (as he occasionally did) he secured the services of Mr WOLF, are not so much to be commended. There is, it is true, a smoothness and finish about them not often seen elsewhere; but, as though to avoid the exaggerations of Audubon, Gould usually adopted the tamest of attitudes in which to represent his subjects, whereby expression as well as vivacity is wanting. Moreover, both in drawing and in colouring there is frequently much that is untrue to nature, so that it has not uncommonly happened for them to fail in the chief object of all zoological plates, that of affording sure means of recognizing specimens on comparison. In estimating the letterpress, which was avowedly held to be of secondary importance to the plates, we must bear in mind that, to ensure the success of his works, it had to be written to suit a very peculiarly composed body of subscribers. Nevertheless a scientific character was so adroitly assumed that scientific men—some of them even ornithologists—have thence been led to believe the text had a scientific value, and that of a high class. However it must also be remembered that, throughout the whole of his career, Gould consulted the convenience of working ornithologists by almost invariably refraining from including in his folio works the technical description of any new species without first publishing it in some journal of comparatively easy access.

An ambitious attempt to produce in England a general series of coloured plates on a large scale was Mr FRASER'S *Zoologia Typica*, the first part of which bears date 1841-42. Others appeared at irregular intervals until 1849; when the work, which seems never to have received the support it deserved, was discontinued. The seventy plates (forty-six of which represent birds) composing, with some explanatory letterpress, the volume are by C. Cousens and H. N. Turner,—the latter (as his publications prove) a zoologist of much promise who in 1851 died, a victim to

his own zeal for investigation, of a wound received in dissecting. The chief object of the author, who had been naturalist to the Niger Expedition, and curator to the Museum of the Zoological Society of London, was to figure the animals contained in its gardens or described in it. *Proceedings*, which until the year 1848 were not illustrated.

The publication of the *Zoological Sketches* of Mr WOLF, from animals in the gardens of the Zoological Society, was begun about 1855, with a brief text by MITCHELL, at that time the Society's secretary, in illustration of them. After his death in 1859, the explanatory letterpress was rewritten by Mr SCLATER, his successor in that office, and a volume was completed in 1861. Upon this a second series was commenced, and brought to an end in 1868. Though a comparatively small number of species of Birds are figured in this magnificent work (seventeen only in the first series, and twenty-two in the second), it must be mentioned here, for their likenesses are so admirably executed as to place it in regard to ornithological portraiture at the head of all others. There is not a single plate that is unworthy of the greatest of all animal painters.

Proceeding to illustrated works generally of less pretentious size but of greater ornithological utility than the books last mentioned, which are fitter for the drawing-room than the study, we next have to consider some in which the text is not wholly subordinated to the plates, though the latter still form a conspicuous feature of the publication. First of these in point of time as well as in importance is the *Nouveau Recueil des Planches Coloriées d'Oiseaux* of TEMMINCK and LAUGIER, intended as a sequel to the *Planches Enluminées* of D'Aubenton before noticed (page 6), and like that work issued both in folio and quarto size. The first portion of this was published at Paris in 1820, and of its one hundred and two *livraisons*, which appeared with great irregularity (*Ibis*, 1868, p. 500), the last was issued in 1839, containing the titles of the five volumes that the whole forms, together with a "Tableau Méthodique" which but indifferently serves the purpose of an index. There are six hundred plates, but the exact number of species figured (which has been computed at six hundred and sixty-one) is not so easily ascertained. Generally the subject of each plate has letterpress to correspond, but in some cases this is wanting, while on the other hand descriptions of species not figured are occasionally introduced, and usually observations on the distribution and construction of each genus or group are added. The plates, which shew no improvement in execution on those of Martinet, are after drawings by Huet and Prêtre, the former being perhaps the less bad draughtsman of the two, for he seems to have had an idea of what a bird when alive looks like, though he was not able to give his figures any vitality, while the latter simply delineated the stiff and dishevelled specimens from museum shelves. Still the colouring is pretty well done, and experience has proved that generally speaking there is not much difficulty in recognizing the species represented. The letterpress is commonly limited to technical details, and is not always accurate; but it is of its kind useful, for in general knowledge of the outside of Birds Temminck probably surpassed any of his contemporaries. The "Tableau Méthodique" offers a convenient concordance of the old *Planches Enluminées* and its successor, and is arranged after the system set forth by Temminck in the first volume of the second edition of his *Manuel d'Ornithologie*, of which something must presently be said.

The *Galérie des Oiseaux*, a rival work, with plates by OUDART, seems to have been begun immediately after the former. The original project was apparently to give a figure and description of every species of Bird; but that was soon found to be impossible; and, when six parts had

Temminck
and
Laugier.

been issued, with text by some unnamed author, the scheme was brought within practicable limits, and the writing of the letterpress was entrusted to VIEILLOT, who, proceeding on a systematic plan, performed his task very creditably, completing the work, which forms two quarto volumes, in 1825, the original text and fifty-seven plates being relegated to the end of the second volume as a supplement. His portion is illustrated by two hundred and ninety-nine coloured plates that, wretched as they are, have been continually reproduced in various text-books—a fact possibly due to their subjects having been judiciously selected. It is a tradition that, this work not being favourably regarded by the authorities of the Paris Museum, its draughtsman and author were refused closer access to the specimens required, and had to draw and describe them through the glass as they stood on the shelves of the cases.

In 1825 JARDINE and SELBY began a series of *Illustrations of Ornithology*, the several parts of which appeared at long and irregular intervals, so that it was not until 1839 that three volumes containing one hundred and fifty plates were completed. Then they set about a Second Series, which, forming a single volume with fifty-three plates, was finished in 1843. These authors, being zealous amateur artists, were their own draughtsmen to the extent even of lithographing the figures. In 1828 JAMES WILSON (author of the article ORNITHOLOGY in the 7th and 8th editions of the present work) began, under the title of *Illustrations of Zoology*, the publication of a series of his own drawings (which he did not, however, himself engrave) with corresponding letterpress. Of the thirty-six plates illustrating this volume, a small folio, twenty are devoted to Ornithology, and contain figures, which, it must be allowed, are not very successful, of several species rare at the time.

Though the three works last mentioned fairly come under the same category as the *Planches Enluminées* and the *Planches Coloriées*, no one of them can be properly deemed their rightful heirs. The claim to that succession was made in 1845 by DES MURS for his *Iconographie Ornithologique*, which, containing seventy-two plates by Prévot and Oudart¹ (the latter of whom had marvellously improved in his drawings since he worked with Vieillot), was completed in 1849. Simultaneously with this DES BUS began a work on a plan precisely similar, the *Esquisses Ornithologiques*, illustrated by Severeys, which, however, stopped short in 1849 with its thirty-seventh plate, while the letterpress unfortunately does not go beyond that belonging to the twentieth. In 1866 the succession was again taken up by the *Exotic Ornithology* of MESSRS SLATER and SALVIN, containing one hundred plates, representing one hundred and four species, all from Central or South America, which are neatly executed by Mr Smit. The accompanying letterpress is in some places copious, and useful lists of the species of various genera are occasionally subjoined, adding to the definite value of the work, which, forming one volume, was completed in 1869.

Lastly here must be mentioned ROWLEY'S *Ornithological Miscellany* in three quarto volumes, profusely illustrated, which appeared between 1875 and 1878. The contents are as varied as the authorship, and, most of the leading English ornithologists having contributed to the work, some of the papers are extremely good, while in the plates, which are in Mr Kulemans's best manner, many rare species of Birds are figured, some of them for the first time.

All the works lately named have been purposely treated at some length, since being very costly they are not easily accessible. The few next to be mentioned, being of smaller size (octavo), may be within reach of more persons, and

therefore can be passed over in a briefer fashion without detriment. In many ways, however, they are nearly as important. SWAINSON'S *Zoological Illustrations* in three volumes, containing one hundred and eighty-two plates, whereof seventy represent Birds, appeared between 1820 and 1821, and in 1829 a Second Series of the same was begun by him, which, extending to another three volumes, contained forty-eight more plates of Birds out of one hundred and thirty-six, and was completed in 1833. All the figures were drawn by the author, who as an ornithological artist had no rival in his time. Every plate is not beyond criticism, but his worst drawings shew more knowledge of bird-life than do the best of his English or French contemporaries. A work of somewhat similar character, but one in which the letterpress is of greater value, is the *Centurie Zoologique* of LESSON, a single volume that, though bearing the date 1830 on its title page, is believed to have been begun in 1829,² and was certainly not finished until 1831. It received the benefit of Isidore Geoffroy St-Hilaire's assistance. Notwithstanding its name it only contains eighty plates, but of them forty-two, all by Prêtre and in his usual stiff style, represent Birds. Concurrently with this volume appeared Lesson's *Traité d'Ornithologie*, which is dated 1831, and may perhaps be here most conveniently mentioned. Its professedly systematic form strictly relegates it to another group of works, but the presence of an "Atlas" (also in octavo) of one hundred and nineteen plates to some extent justifies its notice in this place. Between 1831 and 1834 the same author brought out, in continuation of his *Centurie*, his *Illustrations de Zoologie* with sixty plates, twenty of which represent Birds. In 1832 KITTLITZ began to publish some *Kupfertafeln zur Naturgeschichte der Vögel*, in which many new species are figured; but the work came to an end with its thirty-sixth plate in the following year. In 1845 REICHENBACH commenced with his *Praktische Naturgeschichte der Vögel* the extraordinary series of illustrated publications which, under titles far too numerous here to repeat, ended in or about 1855, and are commonly known collectively as his *Vollständigste Naturgeschichte der Vögel*.³ Herein are contained more than nine hundred coloured and more than one hundred uncoloured plates, which are crowded with the figures of Birds, a large proportion of them reduced copies from other works, and especially those of Gould.

It now behoves us to turn to general and particularly systematic works in which plates, if they exist at all, form but an accessory to the text. These need not detain us for long, since, however well some of them may have been executed, regard being had to their epoch, and whatever repute some of them may have achieved, they are, so far as general information and especially classification is concerned, wholly obsolete, and most of them almost useless except as matters of antiquarian interest. It will be enough merely to name DUMÉRIL'S *Zoologie Analytique* (1806) and GRAVENHORST'S *Vergleichende Uebersicht des linneischen und einiger neuern zoologischen Systeme* (1807); nor need we linger over SHAW'S *General Zoology*, a pretentious compilation continued by STEPHENS. The last seven of its fourteen volumes include the Class *Aves*, and the first part of them appeared in 1809, but, the original author dying in 1815, when only two volumes of Birds were published, the remainder was brought to an end in 1826 by his successor, who afterwards became well known as an entomologist. The engravings which these volumes contain are mostly bad copies, often of bad figures,

¹ In 1828 he had brought out, under the title of *Manuel d'Ornithologie*, two handy duodecimos which are very good of their kind.

² Technically speaking they are in quarto, but their size is so small that they may be well spoken of here. In 1879 Dr A. B. Meyer brought out an *Index* to them.

³ On the title page credit is given to the latter alone, but only two-thirds of the plates (from pl. 25 to the end) bear his name.

though many are piracies from Bewick, and the whole is a most unsatisfactory performance. Of a very different kind is the next we have to notice, the *Prodromus Systematis Mammalium et Avium* of ILLIGER, published at Berlin in 1811, which must in its day have been a valuable little manual, and on many points it may now be consulted to advantage—the characters of the Genera being admirably given, and good explanatory lists of the technical terms of Ornithology furnished. The classification was quite new, and made a step distinctly in advance of anything that had before appeared.¹ In 1816 VIEILLOT published at Paris an *Analyse d'une nouvelle Ornithologie élémentaire*, containing a method of classification which he had tried in vain to get printed before, both in Turin and in London.² Some of the ideas in this are said to have been taken from Illiger; but the two systems seem to be wholly distinct. Vieillot's was afterwards more fully expounded in the series of articles which he contributed between 1816 and 1819 to the Second Edition of the *Nouveau Dictionnaire d'Histoire Naturelle* containing much valuable information. The views of neither of these systematizers pleased TEMMINCK, who in 1817 replied rather sharply to Vieillot in some *Observations sur la Classification méthodique des Oiseaux*, a pamphlet published at Amsterdam, and prefixed to the second edition of his *Manuel d'Ornithologie*, which appeared in 1820, an *Analyse du Système Général d'Ornithologie*. This proved a great success, and his arrangement, though by no means simple,³ was not only adopted by many ornithologists of almost every country, but still has some adherents. The following year RANZANI of Bologna, in his *Elementi di Zoologia*—a very respectable compilation—came to treat of Birds, and then followed to some extent the plan of De Blainville and Merrem (concerning which much more has to be said by and by) placing the Struthious Birds in an Order by themselves. In 1827 WAGLER brought out the first part of a *Systema Avium*, in this form never completed, consisting of forty-nine detached monographs of as many genera, the species of which are most elaborately described. The arrangement he subsequently adopted for them and for other groups is to be found in his *Natürliches System der Amphibien* (pp. 77–128), published in 1830, and is too fanciful to require any further attention. The several attempts at system-making by KAUP, from his *Allgemeine Zoologie* in 1829 to his *Ueber Classification der Vögel* in 1849, were equally arbitrary and abortive; but his *Skizzirte Entwicklungs-Geschichte* in 1829 must be here named, as it is so often quoted on account of the number of new genera which the peculiar views he had embraced compelled him to invent. These views he shared more or less with Vigors and Swainson, and to them attention will be immediately especially invited, while consideration of the scheme gradually developed

from 1831 onward by CHARLES LUCIEN BONAPARTE, and Bonaparte still not without its influence, is deferred until we come to treat of the rise and progress of what we may term the reformed school of Ornithology. Yet injustice would be done to one of the ablest of those now to be called the old masters of the science if mention were not here made of the *Conspectus Generum Avium*, begun in 1850 by the naturalist last named, with the help of SCHLEGEL, and Schlegel unfortunately interrupted by its author's death six years later.⁴ The systematic publications of GEORGE ROBERT GRAY, so long in charge of the ornithological collection of the British Museum, began with *A List of the Genera of Birds* published in 1840. This, having been closely, though by no means in a hostile spirit, criticized by STRICKLAND (*Ann. Nat. History*, vi. p. 410; vii. pp. 26 and 159), was followed by a Second Edition in 1841, in which nearly all the corrections of the reviewer were adopted, and in 1844 began the publication of *The Genera of Birds*, beautifully illustrated—first by MITCHELL and afterwards by Mr WOLF—which will always keep Gray's name in remembrance. The enormous labour required for this work seems scarcely to have been appreciated, though it remains to this day one of the most useful books in an ornithologist's library. Yet it must be confessed that its author was hardly an ornithologist but for the accident of his calling. He was a thoroughly conscientious clerk, devoted to his duty and unsparing of trouble. However, to have conceived the idea of executing a work on so grand a scale as this—it forms three folio volumes, and contains one hundred and eighty-five coloured and one hundred and forty-eight uncoloured plates, with references to upwards of two thousand four hundred generic names—was in itself a mark of genius, and it was brought to a successful conclusion in 1849. Costly as it necessarily was, it has been of great service to working ornithologists. In 1855 Gray brought out, as one of the Museum publications, *A Catalogue of the Genera and Subgenera of Birds*, a handy little volume, naturally founded on the larger works. Its chief drawback is that it does not give any more reference to the authority for a generic term than the name of its inventor and the year of its application, though of course more precise information would have at least doubled the size of the book. The same deficiency became still more apparent when, between 1869 and 1871, he published his *Hand-List of Genera and Species of Birds* in three octavo volumes (or parts, as they are called). Never was a book better named, for the working ornithologist must almost live with it in his hand, and though he has constantly to deplore its shortcomings, one of which especially is the wrong principle on which its index is constructed, he should be thankful that such a work exists. Many of its defects are, or perhaps it were better said ought to be, supplied by GIEBEL's *Thesaurus Ornithologiae*, also in three volumes, published between 1872 and 1877, a work admirably planned, but the execution of which, whether through the author's carelessness or the printer's fault, or a combination of both, is lamentably disappointing. Again and again it will afford the enquirer who consults it valuable hints, but he must be mindful never to trust a single reference in it until it has been verified. It remains to warn the reader also that, useful as are both this work and those of Gray, their utility is almost solely confined to experts.

With the exception to which reference has just been made, scarcely any of the ornithologists hitherto named indulged their imagination in theories or speculations. Nearly all were content to prosecute their labours in a plain fashion consistent with common sense, plodding

¹ Illiger may be considered the founder of the school of nomenclatural purists. He would not tolerate any of the "barbarous" generic terms adopted by other writers, though some had been in use for many years.

² The method was communicated to the Turin Academy, 10th January 1814, and was ordered to be printed (*Mém. Ac. Sc. Turin*, 1813–14, p. xxviii); but, through the derangements of that stormy period, the order was never carried out (*Mem. Accad. Sc. Torino*, xxiii. p. xcvi). The minute-book of the Linnean Society of London shows that his *Prologo* was read at meetings of that Society between 15th November 1814 and 21st February 1815. Why it was not at once accepted is not told, but the entry respecting it, which must be of much later date, in the "Register of Papers" is "Published already." It is due to Vieillot to mention these facts, as he has been accused of publishing his method in haste to anticipate some of Cuvier's views, but he might well complain of the delay in London. Some reparation has been made to his memory by the reprinting of his *Analyse* by the Willughby Society.

³ He recognized sixteen Orders of Birds, while Vieillot had been content with five, and Illiger with seven.

⁴ To this very indispensable work a good index was supplied in 1865 by Dr Fiasch.

steadily onwards in their efforts to describe and group the various species of Birds, as one after another they were made known. But this was not always to be, and now a few words must be said respecting a theory which was promulgated with great zeal by its upholders during the end of the first and early part of the second quarter of the present century, and for some years seemed likely to carry all before it. The success it gained was doubtless due in some degree to the difficulty which most men had in comprehending it, for it was enwrapped in alluring mystery, but more to the confidence with which it was announced as being the long looked-for key to the wonders of creation, since its promoters did not hesitate to term it the discovery of "the Natural System," though they condescended, by way of explanation to less exalted intellects than their own, to allow it the more moderate appellation of the Circular or Quinary System.

A comparison of the relation of created beings to a number of intersecting circles is as old as the days of NIEREMBERG, who in 1635 wrote (*Historia Naturæ*, lib. iii. cap. 3)—"Nullus hiatus est, nulla fractio, nulla dispersio formarum, invicem connexa sunt velut annulus annulo"; but it is almost clear that he was thinking only of a chain. In 1806 FISCHER DE WALDHEIM, in his *Tableaux Synoptiques de zoognosie* (p. 181), quoting Nieremberg, extended his figure of speech, and, while justly deprecating the notion that the series of forms belonging to any particular group of creatures—the *Mammalia* was that whence he took his instance—could be placed in a straight line, imagined the various genera to be arrayed in a series of contiguous circles around Man as a centre. Though there is nothing to show that Fischer intended, by what is here said, to do anything else than illustrate more fully the marvellous interconnexion of different animals, or that he attached any realistic meaning to his metaphor, his words were eagerly caught up by the prophet of the new faith. This was WILLIAM SHARPE MACLEAY, a man of education and real genius, who in 1819 and 1821 brought out a work under the title of *Horæ Entomologicae*, which was soon after hailed by VIGORS as containing a new revelation, and applied by him to Ornithology in some "Observations on the Natural Affinities that connect the Orders and Families of Birds," read before the Linnean Society of London in 1823, and afterwards published in its *Transactions* (xiv. pp. 395-517). In the following year Vigors returned to the subject in some papers published in the recently established *Zoological Journal*, and found an energetic condisciple and coadjutor in SWAINSON, who, for more than a dozen years—to the end, in fact, of his career as an ornithological writer—was instant in season and out of season in pressing on all his readers the views he had, through Vigors, adopted from Macleay, though not without some modification of detail if not of principle. What these views were it would be manifestly improper for a sceptic to state except in the terms of a believer. Their enunciation must therefore be given in Swainson's own words, though it must be admitted that space cannot be found here for the diagrams, which it was alleged were necessary for the right understanding of the theory. This theory, as originally propounded by Macleay, was said by Swainson in 1835 (*Geogr. and Classific. of Animals*, p. 202) to have consisted of the following propositions:—

"1. That the series of natural animals is continuous, forming, as it were, a circle; so that, upon commencing at any one given point, and thence tracing all the modifications of structure, we shall be imperceptibly led, after passing through numerous forms, again to the point from which we started.

"2. That no groups are natural which do not exhibit, or show an evident tendency to exhibit, such a circular series.

"3. That the primary divisions of every large group are ten, five of which are composed of comparatively large circles, and five of smaller: these latter being termed *osculant*, and being intermediate between the former, which they serve to connect.

"4. That there is a tendency in such groups as are placed at the opposite points of a circle of affinity 'to meet each other.'

"5. That one of the five larger groups into which every natural circle is divided 'bears a resemblance to all the rest, or, more strictly speaking, consists of types which represent those of each of the four other groups, together with a type peculiar to itself.'

As subsequently modified by Swainson (*loc. cit.* pp. 224, 225), the foregoing propositions take the following form:—

"1. That every natural series of beings, in its progress from

a given point, either actually returns, or evinces a tendency to return, again to that point, thereby forming a circle.

"II. The primary circular divisions of every group are three actually, or five apparently.

"III. The contents of such a circular group are symbolically (or analogically) represented by the contents of all other circles in the animal kingdom.

"IV. That these primary divisions of every group are characterized by definite peculiarities of form, structure, and economy, which, under diversified modifications, are uniform throughout the animal kingdom, and are therefore to be regarded as the PRIMARY TYPES OF NATURE.

"V. That the different ranks or degrees of circular groups exhibited in the animal kingdom are NINE in number, each being involved within the other."

Though, as above stated, the theory here promulgated owed its temporary success chiefly to the extraordinary assurance and pertinacity with which it was urged upon a public generally incapable of understanding what it meant, that it received some support from men of science must be admitted. A "circular system" was advocated by the eminent botanist FRIES, and the views of Macleay met with the partial approbation of the celebrated entomologist KIRBY, while at least as much may be said of the imaginative OKEA, whose mysticism far surpassed that of the Quinarians. But it is obvious to every one who nowadays indulges in the profitless pastime of studying their writings that, as a whole, they failed in grasping the essential difference between *homology* (or "affinity," as they generally termed it) and *analogy* (which is only a learned name for an uncertain kind of resemblance)—though this difference had been fully understood and set forth by Aristotle himself—and, moreover, that in seeking for analogies on which to base their foregone conclusions they were often put to hard shifts. Another singular fact is that they often seemed to be totally unaware of the tendency if not the meaning of some of their own expressions: thus Macleay could write, and doubtless in perfect good faith (*Trans. Linn. Society*, xvi. p. 9, note), "Naturalists have nothing to do with mysticism, and but little with *a priori* reasoning." Yet his followers, if not he himself, were ever making use of language in the highest degree metaphorical, and were always explaining facts in accordance with preconceived opinions. FLEMING, already the author of a harmless and extremely orthodox *Philosophy of Zoology*, pointed out in 1829 in the *Quarterly Review* (xli. pp. 302-327) some of the fallacies of Macleay's method, and in return provoked from him a reply, in the form of a letter addressed to Vigors *On the Dying Struggle of the Dichotomous System*, couched in language the force of which no one even at the present day can deny, though to the modern naturalist its invective power contrasts ludicrously with the strength of its ratiocination. But, confining ourselves to what is here our special business, it is to be remarked that perhaps the heaviest blow dealt at these strange doctrines was that delivered by RENNIE, who, in an edition of Montagu's *Ornithological Dictionary* (pp. xxxiii-iv), published in 1831 and again issued in 1833, attacked the Quinary System, and especially its application to Ornithology by Vigors and Swainson, in a way that might perhaps have demolished it, had not the author mingled with his undoubtedly sound reasoning much that is foreign to any question with which a naturalist, as such, ought to deal—though that herein he was only following the example of one of his opponents, who had constantly treated the subject in like manner, is to be allowed. This did not hinder Swainson, who had succeeded in getting the ornithological portion of the first zoological work ever published at the expense of the British Government (namely, the *Fauna Boreali-Americana*) executed in accordance with his own opinions, from maintaining them more strongly than ever in several of the volumes treating of Natural History which he contributed to the *Cabinet Cyclopædia*—among others that from which we have just given some extracts—and in what may be deemed the culmination in England of the Quinary System, the volume of the "Naturalist's Library" on *The Natural Arrangement and History of Flycatchers*, published in 1838, of which unhappy performance mention has already been made in this present work (vol. ix. p. 350, note). This seems to have been his last attempt; for, two years later, his *Bibliography of Zoology* shows little trace of his favourite theory, though nothing he had uttered in its support was retracted. Appearing almost simultaneously with this work, an article by STRICKLAND (*Mag. Nat. History*, ser. 2, iv. pp. 219-226) entitled *Observations upon the Affinities and Analogies of Organized Beings* administered to the theory a shock from which it never recovered, though attempts were now and then made by its adherents to revive it; and, even ten years or more later, KAUP, one of the few foreign ornithologists who had embraced Quinary principles, was by mistaken kindness allowed to publish *Mono-graphs of the Birds-of-Prey* (Jardine's *Contributions to Ornithology*, 1849, pp. 68-75, 96-121; 1850, pp. 51-50; 1851, pp. 119-130; 1852, pp. 163-122; and *Trans. Zool. Society*, iv. pp. 201-260), in which its absurdity reached the climax.

The mischief caused by this theory of a Quinary System was

¹ We prefer giving them here in Swainson's version, because he seems to have set them forth more clearly and concisely than Macleay ever did, and, moreover, Swainson's application of them to Ornithology—a branch of science that lay outside of Macleay's proper studies—appears to be more suitable to the present occasion.

very great, but was chiefly confined to Britain, for (as has been already stated) the extraordinary views of its adherents found little favour on the continent of Europe. The purely artificial character of the System of Linnaeus and his successors had been perceived, and men were at a loss to find a substitute for it. The new doctrine, loudly proclaiming the discovery of a "Natural" System, led away many from the steady practice which should have followed the teaching of Cuvier (though he in Ornithology had not been able to act up to the principles he had laid down) and from the extended study of Comparative Anatomy. Moreover, it veiled the honest attempts that were making both in France and Germany to find real grounds for establishing an improved state of things, and consequently the labours of DE BLAINVILLE, ÉTIENNE, GEOFFROY ST-HILAIRE, and L'HERMINIER, of MERREM, JOHANNES-MÜLLER, and NITZSCH—to say nothing of others—were almost wholly unknown on this side of the Channel, and even the value of the investigations of British ornithologists of high merit, such as MACARTNEY and MACGILLIVRAY, was almost completely overlooked. True it is that there were not wanting other men in these islands whose common sense refused to accept the metaphorical doctrine and the mystical jargon of the Quinarians, but so strenuously and persistently had the latter asserted their infallibility, and so vigorously had they assailed any who ventured to doubt it, that most peaceable ornithologists found it best to bend to the furious blast, and in some sort to acquiesce at least in the phraseology of the self-styled interpreters of Creative Will. But, while thus lamenting this unfortunate perversion into a mistaken channel of ornithological energy, we must not over-blame those who caused it. Macleay indeed never pretended to a high position in this branch of science, his tastes lying in the direction of Entomology; but few of their countrymen knew more of Birds than did Swainson and Vigors; and, while the latter, as editor for many years of the *Zoological Journal*, and the first Secretary of the Zoological Society, has especial claims to the regard of all zoologists, so the former's indefatigable pursuit of Natural History, and conscientious labour in its behalf—among other ways by means of his graceful pencil—deserve to be remembered as a set-off against the injury he unwittingly caused.

Faunæ.

It is now incumbent upon us to take a rapid survey of the ornithological works which come more or less under the designation of "Faunæ";¹ but these are so numerous that it will be necessary to limit this survey, as before indicated, to those countries alone which form the homes of English people, or are commonly visited by them in ordinary travel.

New Zealand.

Beginning with our Antipodes, it is hardly needful to go further back than Mr Buller's beautiful *Birds of New Zealand* (4to, 1827-73), with coloured plates by Mr Keulemans, since the publication of which the same author has issued a *Manual of the Birds of New Zealand* (8vo, 1832), founded on the former; but justice requires that mention be made of the labours of G. R. Gray, first in the Appendix to Dieffenbach's *Travels in New Zealand* (1843) and then in the ornithological portion of the *Zoology of the Voyage of H.M.S. "Erebus" and "Terror"*, begun in 1863, but left unfinished from the following year until completed by Mr Sharpe in 1876. A considerable number of valuable papers on the Ornithology of the country by Drs Hector and Von Haast, Prof. Hutton, Mr Potts, and others are to be found in the *Transactions and Proceedings of the New Zealand Institute*.

Passing to Australia, we have the first good description of some of its Birds in the several old voyages and in Latham's works before mentioned (pages 6 and 8). Shaw's *Zoology of New Holland* (4to, 1794) added those of a few more, as did J. W. Lewin's *Natural History of the Birds of New South Wales* (4to, 1822), which reached a third edition in 1833. Gould's great *Birds of Australia* has been already named, and he subsequently reproduced with some additions the text of that work under the title of *Handbook to the Birds of Australia* (2 vols. 8vo, 1865). In 1866 Mr Diggles commenced a similar publication, *The Ornithology of Australia*, but the coloured plates, though fairly drawn, are not comparable to those of his predecessor. This is still incomplete, though the parts that have appeared have been collected to form two volumes and issued with title-pages. Some notices of Australian Birds by Mr Ramsay and others are to be found in the *Proceedings of the Linnean Society of New South Wales* and of the *Royal Society of Tasmania*.

Coming to our Indian possessions, and beginning with Ceylon, we have Kelaart's *Prodromus Faunæ Zeylanicæ* (8vo, 1852), and the admirable *Birds of Ceylon* by Capt. Legge (4to, 1878-80), with coloured plates by Mr Keulemans of all the peculiar species. It is hardly possible to name any book that has been more conscientiously executed than this. In regard to continental India many

of the more important publications have been named in a former article (BIRDS, iii. pp. 762, 763), and since that was written the chief work that has appeared is Blyth's *Mammals and Birds of Burma* (8vo, 1875).² Jerdon's *Birds of India* (8vo, 1862-64; reprinted 1877) still reigns supreme as the sole comprehensive work on the Ornithology of the Peninsula. A very fairly executed compilation on the subject by an anonymous writer is to be found in a late edition of the *Cyclopædia of India* published at Madras. It is needless to observe that *Stray Feathers*, an ornithological journal for India and its dependencies, and maintained with much spirit by Mr A. O. Hume, contains many interesting and some valuable papers.

In regard to South Africa, besides the well-known work of Le Vaillant already mentioned, there is the second volume of Sir Andrew Smith's *Illustrations of the Zoology of South Africa* (4to, 1838-42), which is devoted to birds. This is an important but cannot be called a satisfactory work. Its one hundred and fourteen plates by Ford truthfully represent one hundred and twenty-two of the mounted specimens obtained by the author in his explorations into the interior. Mr Layard's handy *Birds of South Africa* (8vo, 1867), though by no means free from faults, has much to recommend it. A so-called new edition of it by Mr Sharpe has since appeared (1875-84), but is executed on a plan so wholly different that it must be regarded as a distinct work. Andersson's *Notes on the Birds of Danara Land* (8vo, 1872) has been carefully edited by Mr Gurney, whose knowledge of South-African ornithology is perhaps greater than that of any one else. It is much to be regretted that of the numerous sporting books that treat of this part of the world so few give any important information respecting the Birds.

Of special works relating to the British West Indies, Waterton's *West well-known Wanderings* has passed through several editions since its first appearance in 1825, and must be mentioned here, though, strictly speaking, much of the country he traversed was not British territory. To Dr Cabanis we are indebted for the ornithological results of Richard Schomburgk's researches given in the third volume (pp. 662-765) of the latter's *Reisen im Britisch-Guiana* (8vo, 1848), and then in Léotaud's *Oiseaux de l'île de la Trinidad* (8vo, 1866). Of the Antilles there is only to be named Mr Gosse's excellent *Birds of Jamaica* (12mo, 1847), together with its *Illustrations* (sm. fol., 1849) beautifully executed by him. A nominal list, with references, of the Birds of the island is contained in the *Handbook of Jamaica* for 1881 (pp. 103-117).

So admirable a "List of Faunal Publications relating to North American Ornithology" up to the year 1878 has been given by Dr Coues as an appendix to his *Birds of the Colorado Valley* (pp. 567-784) that nothing more of the kind is wanted except to notice the chief separate works which have since appeared. These may be said to be Mr Stearns's *New England Bird Life* (2 vols. 8vo, 1881-83), revised by Dr Coues, and the several editions of his own *Check List of North American Birds* (8vo, 1882), and *Key to North American Birds* (1884); while it may be added that the concluding volumes of the *North American Birds* of Prof. Baird, the late Dr Brewer, and Mr Ridgway (the first three of which were published in 1874) are expected to be issued about the time that these lines will meet the reader's eye. Yet some of the older works are still of sufficient importance to be especially mentioned here, and especially that of Alexander Wilson, whose *American Ornithology*, originally published between 1808 and 1814, has gone through more editions than there is room to specify, though mention should be made of those issued in Great Britain, by Jameson (4 vols. 16mo, 1831), and Jardine (3 vols. 8vo, 1832). The former of these has the entire text, but no plates; the latter reproduces the plates, but the text is in places much condensed, and excellent notes are added. A continuation of Wilson's work, under the same title and on the same plan, was issued by Bonaparte between 1825 and 1833, and most of the later editions include the work of both authors. The works of Audubon, with their continuations by Cassin and Mr Elliot, and the *Fauna Boreali-Americana* of Richardson and Swainson have already been noticed (pages 11 and 15); but they need naming here, as also does Nuttall's *Manual of the Ornithology of the United States and of Canada* (2 vols., 1832-34; 2d ed., 1840); the *Birds of Long Island* (8vo, 1844) by Giraud, remarkable for its excellent account of the habits of shore-birds; and of course the *Birds of North America* (4to, 1858) by Prof. Baird, with the co-operation of Cassin and Mr Lawrence, which originally formed a volume (ix.) of what are known as the "Pacific Railroad Reports." Apart from these special works the scientific journals of Boston, New York, Philadelphia, and Washington contain innumerable papers on the Ornithology of the country, while in 1876 the *Bulletin of the Nuttall Ornithological Club* began to appear and continued until 1884, when it was superseded by *The Auk*, established solely for the promotion of Ornithology in America, and

¹ A very useful list of more general scope is given as the Appendix to an address by Mr Selater to the British Association in 1875 (*Report*, pt. ii. pp. 114-133).

² This is a posthumous publication, nominally forming an extra number of the *Journal of the Asiatic Society*; but, since it was separately issued, it is entitled to notice here.

numbering among its supporters almost every American ornithologist of repute, its editors being Messrs Allen, Coues, Ridgway, Brewster, and Chamberlain.

Returning to the Old World, among the countries whose Ornithology will most interest British readers we have first Iceland, the fullest—indeed the only full—account of the Birds of which is Faber's *Prodromus der isländischen Ornithologie* (8vo, 1822), though the island has since been visited by several good ornithologists, —Proctor, Kripper, and Wolley among them. A list of its Birds, with some notes, bibliographical and biological, has been given as an Appendix to Mr Baring-Gould's *Iceland, its Scenes and Sagas* (8vo, 1862); and Mr Shepherd's *North-west Peninsula of Iceland* (8vo, 1867) recounts a somewhat profitless expedition made thither expressly for ornithological objects. For the Birds of the Feroes there is Herr H. C. Müller's *Færøernes Fuglefauna* (8vo, 1862), of which a German translation has appeared.¹ The Ornithology of Norway has been treated in a great many papers by Herr Collett, some of which may be said to have been separately published as *Norges Fugle* (8vo, 1863; with a supplement, 1871), and *The Ornithology of Northern Norway* (8vo, 1872)—this last in English. For Scandinavia generally the latest work is Herr Collin's *Skandinavien Fugle* (8vo, 1873), being a greatly better edition of the very moderate *Danmarks Fugle* of Kjerföbling; but the ornithological portion of Nilsson's *Skandinavisk Fauna, Fuglarna* (3d ed., 2 vols. 8vo, 1858) is of great merit; while the text of Sundevall's *Svenska Fuglarna* (obl. fol., 1856-73), unfortunately unfinished at his death, and Herr Holmgren's *Skandinavien Fuglar* (2 vols. 8vo, 1866-75) deserve naming.

Works on the Birds of Germany are far too numerous to be recounted. That of the two Naumanns, already mentioned, and yet again to be spoken of, stands at the head of all, and perhaps at the head of the "Faunal" works of all countries. For want of space it must here suffice simply to name some of the ornithologists who in this century have elaborated, to an extent elsewhere unknown, the science as regards their own country:—Altum, Baldamus, Bechstein, Blasius (father and two sons), Bolle, Borggreve, whose *Vogel-Fauna von Norddeutschland* (8vo, 1869) contains what is practically a bibliographical index to the subject, Brehm (father and sons), Von Droste, Gätke, Gloger, Hintz, Alexander and Eugen von Homeyer, Jäckel, Koch, König-Wart-hausen, Krüper, Kutter, Landbeck, Landois, Leisler, Von Maltzan, Bernard Meyer, Von der Mühl, Neumann, Tobias, Johann Wolf, and Zander.² Were we to extend the list beyond the boundaries of the German empire, and include the ornithologists of Austria, Bohemia, and the other states subject to the same monarch, the number would be nearly doubled; but that would overpass our proposed limits, though Herr von Pelzeln must be named.³ Passing onward to Switzerland, we must content ourselves by referring to the list of works, forming a *Bibliographia Ornithologica Helvetica*, drawn up by Dr Stölker for Dr Fatio's *Bulletin de la Société Ornithologique Suisse* (ii. pp. 90-119). As to Italy, we can but name here the *Fauna d'Italia*, of which the second part, *Ucelli* (8vo, 1872), by Count Salvadori, contains an excellent bibliography of Italian works on the subject, and the posthumously published *Ornithologia Italiana* of Savi (3 vols. 8vo, 1873-77).⁴ Coming to the Iberian peninsula, we must in default of separate works depart from our rule of not mentioning contributions to journals, for of the former there are only Col. Irby's *Ornithology of the Straits of Gibraltar* (8vo, 1875) and Mr A. C. Smith's *Spring Tour in Portugal*⁵ to be named, and these only partially cover the ground. However, Dr A. E. Brehm has published a list of Spanish Birds (*Allgem. deutsche Naturhist. Zeitung*, iii. p. 431), and *The Ibis* contains several excellent papers by Lord Lilford and by Mr Saunders, the latter of whom there records (1871, p. 55) the few works on Ornithology by Spanish authors, and in the *Bulletin de la Société Zoologique de France* (i. p. 315; ii. pp. 11, 89, 185) has given a list of the Spanish Birds known to him.

Returning northwards, we have of the Birds of the whole of France nothing of real importance more recent than the volume

Oiseaux in Vieillot's Faune Française (8vo, 1822-29); but there is a great number of local publications of which Mr Saunders has furnished (*Zoologist*, 1878, pp. 95-99) a catalogue. Some of these seem only to have appeared in journals, but many have certainly been issued separately. Those of most interest to English ornithologists naturally refer to Brittany, Normandy, and Picardy, and are by Bailion, Benoist, Blandin, Bureau, Canivet, Chesnon, Degland, Denarie, De Norguet, Gentil, Hardy, Lemetteil, Lemou-nier, Lesauvage, Maignon, Maféotte, Nourry, and Taslé, while perhaps the *Ornithologie Parisienne* of M. René Paquet, under the pseudonym of Nérée Quépat, should also be named. Of the rest the most important are the *Ornithologie Provençale* of Roux (2 vols. 4to, 1825-29);⁶ *Risso's Histoire naturelle . . . des environs de Nice* (5 vols. 8vo, 1826-27); the *Ornithologie du Dauphiné* of Bouteille and Labatie (2 vols. 8vo, 1843-44); the *Faune Méditerranéale* of Crespon (2 vols. 8vo, 1844); the *Ornithologie de la Savoie* of Bailly (4 vols. 8vo, 1853-54), and *Les Richesses ornithologiques du midi de la France* (4to, 1859-61) of MM. Ljubert and Barthélemy-Lapommière. For Belgium the *Faune Belge* of Baron De Selys-Longchamps (8vo, 1842), old as it is, remains the classical work, though the *Planches coloriées des Oiseaux de la Belgique* of M. Dubois (8vo, 1851-60) is so much later in date. In regard to Holland we have Schlegel's *De Vogels van Nederland* (3 vols. 8vo, 1854-58; 2d ed., 2 vols., 1878), besides his *De Dieren van Nederland: Vogels* (8vo, 1861).

Before considering the ornithological works relating solely to the British Islands, it may be well to cast a glance on a few of those that refer to Europe in general, the more so since most of them are of Continental origin. First we have the already-mentioned *Manuel d'Ornithologie* of Temminck, which originally appeared as a single volume in 1815,⁶ but that was speedily superseded by the second edition of 1820, in two volumes. Two supplementary parts were issued in 1835 and 1840 respectively, and the work for many years deservedly maintained the highest position as the authority on European Ornithology—indeed in England it may almost without exaggeration be said to have been nearly the only foreign ornithological work known; but, as could only be expected, grave defects are now to be discovered in it. Some of them were already manifest when one of its author's colleagues, Schlegel (who had been employed to write the text for Susemihl's plates, originally intended to illustrate Temminck's work), brought out his bilingual *Revue critique des Oiseaux d'Europe* (8vo, 1844), a very remarkable volume, since it correlated and consolidated the labours of French and German, to say nothing of Russian, ornithologists. Of Gould's *Birds of Europe* (5 vols. fol., 1832-37) nothing need be added to what has been already said. The year 1849 saw the publication of Degland's *Ornithologie Européenne* (2 vols. 8vo), a work fully intended to take the place of Temminck's; but of which Bonaparte, in a caustic but by no means ill-deserved *Revue Critique* (12mo, 1850), said that the author had performed a miracle since he had worked without a collection of specimens and without a library. A second edition, revised by M. Gerbe (2 vols. 8vo, 1867), strove to remedy, and to some extent did remedy, the grosser errors of the first, but enough still remain to make few statements in the work trustworthy unless corroborated by other evidence. Meanwhile in England Dr Bree had in 1858 begun the publication of *The Birds of Europe not observed in the British Isles* (4 vols. 8vo), which was completed in 1863, and in 1875 reached a second and improved edition (5 vols.). In 1862 M. Dubois brought out a similar work on the "Espèces non observées en Belgique," being supplementary to that of his above named. In 1870 Dr Fritsch completed his *Naturgeschichte der Vögel Europas* (8vo, with atlas in folio); and in 1871 Messrs Sharpe and Dresser began the publication of their *Birds of Europe*, which was completed by the latter in 1879 (8 vols. 4to), and is unquestionably the most complete work of its kind, both for fulness of information and beauty of illustration—the coloured plates being nearly all by Mr Keulemans, or when not by him from the hardly inferior hand of Mr Neale. In so huge an undertaking mistakes and omissions are of course to be found if any one likes the invidious task of seeking for them; but many of the errors imputed to this work prove on investigation to refer to matters of opinion and not to matters of fact, while many more are explicable if we remember that while the work was in progress Ornithology was being prosecuted with unprecedented activity, and thus statements which were in accordance with the best information at the beginning of the period were found to need modification before it was ended. As a whole European ornithologists are all but unanimously grateful to Mr Dresser for the way in which he performed the enormous labour he had undertaken.

Coming now to works on British Birds only, the first of the present century, that requires remark is Montagu's *Ornithological Dictionary* (2 vols. 8vo, 1802; supplement 1813), the merits of which have been so long and so fully acknowledged both abroad and at home, that no further comment is here wanted. In 1831

¹ *Journal für Ornithologie*, 1869, pp. 107, 341, 351. One may almost say an English translation also, for Major Feilden's contribution to the *Zoologist* for 1872 on the same subject gives the most essential part of Herr Müller's information.

² This is of course an complete list of German ornithologists. Some of the most eminent of them have written scarcely a line on the Birds of their own country, as Cabanis (editor since 1853 of the *Journal für Ornithologie*), Finsch, Hartlaub, Prince Max of Wied, A. B. Meyer, Nathusius, Nehrkorn, Reichenbach, Reichenow, and Schadow among others.

³ A useful ornithological bibliography of the Austrian-Hungarian dominions was printed in the *Verhandlungen der Zoologischen und Botanischen Society of Vienna* for 1878, by Victor Ritter von Tschusi zu Schmidhofen. A similar bibliography of Russian Ornithology by Alexander Brandt was printed at St Petersburg in 1877 or 1878.

⁴ A useful compendium of Greek and Turkish Ornithology by Drs Krüper and Hartlaub is contained in Mommsen's *Griechische Jahrzeiten* for 1875 (Heft III.). For other countries in the Levant there are Canon Tristram's *Fauna and Flora of Palestine* (4to, 1884) and Capt. Shelley's *Handbook to the Birds of Egypt* (8vo, 1872).

⁵ In the final chapter of this work the author gives a list of Portuguese Birds, including besides those observed by him those recorded by Prof. Borboza da Belega in the *Gazeta Médica de Lisboa*, 1861, pp. 17-21.

⁶ Copies are said to exist bearing the date 1814.

Rennell brought out a modified edition of it (reissued in 1833), and Newman another in 1866 (reissued in 1883); but those who wish to know the author's views had better consult the original. Next in order come the very inferior *British Ornithology* of Graves (3 vols. 8vo, 1811-21), and a work with the same title by Hunt (3 vols. 8vo, 1815-22), published at Norwich, but never finished. Then we have Selby's *Illustrations of British Ornithology*, two folio volumes of coloured plates engraved by himself, between 1821 and 1833, with letterpress also in two volumes (8vo, 1825-33), a second edition of the first volume being also issued (1833), for the author, having yielded to the pressure of the "Quinarian" doctrines then in vogue, thought it necessary to adjust his classification accordingly, and it must be admitted that for information the second edition is best. In 1828 Fleming brought out his *History of British Animals* (8vo), in which the Birds are treated at considerable length (pp. 41-146), though not with great success. In 1835 Mr Jenyns (now Blomefield) produced an excellent *Manual of British Vertebrate Animals*, a volume (8vo, executed with great scientific skill, the Birds again receiving due attention (pp. 49-286), and the descriptions of the various species being as accurate as they are terse. In the same year began the *Coloured Illustrations of British Birds and their Eggs* of H. L. Meyer (4to), which was completed in 1843, whereof a second edition (7 vols. 8vo, 1842-50) was brought out, and subsequently (1852-57) a reissue of the latter. In 1836 appeared Eyton's *History of the rarer British Birds*, intended as a sequel to Bewick's well-known volumes, to which no important additions had been made since the issue of 1821. The year 1837 saw the beginning of two remarkable works by Macgillivray and Yarrell respectively, and each entitled *A History of British Birds*. Of the first, undoubtedly the more original and in many respects the more minutely accurate; mention will again have to be made (page 24), and, save to state that its five volumes were not completed till 1852, nothing more needs now to be added. The second has unquestionably become the standard work on British Ornithology, a fact due in part to its numerous illustrations, many of them indeed ill drawn, though all carefully engraved, but much more to the breadth of the author's views and the judgment with which they were set forth. In practical acquaintance with the internal structure of Birds, and in the perception of its importance in classification, he was certainly not behind his rival; but he well knew that the British public in a Book of Birds not only did not want a series of anatomical treatises, but would even resent their introduction. He had the art to conceal his art, and his work was therefore a success, while the other was unhappily a failure. Yet with all his knowledge he was deficient in some of the qualities which a great naturalist ought to possess. His conception of what his work should be seems to have been perfect, his execution was not equal to the conception. However, he was not the first nor will he be the last to fall short in this respect. For him it must be said that, whatever may have been done by the generation of British ornithologists now becoming advanced in life, he educated them to do it; nay, his influence even extends to a younger generation still, though they may hardly be aware of it. Of Yarrell's work in three volumes, a second edition was published in 1845, a third in 1856, and a fourth, begun in 1871, and almost wholly rewritten, is still unfinished. Of the compilations based upon this work, without which they could not have been composed, there is no need to speak. One of the few appearing since, with the same scope, that are not borrowed is Jardine's *Birds of Great Britain and Ireland* (4 vols. 8vo, 1838-43), forming part of his *Naturalist's Library*; and Gould's *Birds of Great Britain* has been already mentioned.¹

A considerable number of local works deserving of notice have also to be named. The first three volumes of Thompson's *Natural History of Ireland* (8vo, 1849-51) contain an excellent account of the Birds of that island, and Mr Watters's *Birds of Ireland* (8vo, 1853) has also to be mentioned. For North Britain there is Mr Robert Gray's *Birds of the West of Scotland* (8vo, 1871), which virtually is an account of those of almost the whole of that part of the kingdom. To these may be added Dunn's *Ornithologist's Guide to Orkney and Shetland* (8vo, 1837), the unfinished *Historia Naturalis Orcanensis* of Baikie and Heddle (8vo, 1848), and Saxby's *Birds of Shetland* (8vo, 1874), while the sporting works of Charles St John contain much information on the Ornithology of the Highlands.² The local works on English Birds are still more numerous, but among them may be especially named Dillwyn's *Fauna and Flora of Swansea* (1848), Mr Knox's *Ornithological Rambles in Sussex* (1849), Mr Stevensen's *Birds of Norfolk* (1866-70), Mr Cecil Smith's *Birds of Somerset* (1869) and *Birds of*

Guernsey (1879), Mr Cordeaux's *Birds of the Humber District* (1872), Mr John Hancock's *Birds of Northumberland and Durham* (1874), *The Birds of Nottinghamshire* by Messrs Sterland and Whitaker (1879), Rodd's *Birds of Cornwall* edited by Mr Harting (1880), and the *Vertebrate Fauna of Yorkshire* (1881) of which the "Birds" are by Mr W. E. Clarke.

The good effects of "Faunal" works such as those named in the foregoing rapid survey none can doubt. "Every kingdom, every province, should have its own monographer," wrote Gilbert White more than one hundred years ago, and experience has proved the truth of his assertion. In a former article (*BIRDS*, iii. pp. 736-764) the attempt has been made to shew how the labours of monographers of this kind, but on a more extended scale, can be brought together, and the valuable results that thence follow. Important as they are, they do not of themselves constitute Ornithology as a science; and an enquiry, no less wide and far more recondite, still remains. By whatever term we choose to call it—Classification, Arrangement, Systematizing, or Taxonomy—that enquiry which has for its object the discovery of the natural groups into which Birds fall, and the mutual relations of those groups, has always been one of the deepest interest, and to it we must now recur.

But nearly all the authors above named, it will have been seen, trod the same ancient paths, and in the works of scarcely one of them had any new spark of intelligence been struck out to enlighten the gloom which surrounded the investigator. It is now for us to trace the rise of the present more advanced school of ornithologists whose labours, preliminary as we must still regard them to be, yet give signs of far greater promise. It would probably be unsafe to place its origin further back than a few scattered hints contained in the "Pterographische Fragmente" of CHRISTIAN LUDWIG NITZSCH, published in the *Nitzsch Magazin für den neuesten Zustand der Naturkunde* (edited by Voigt) for May 1806 (xi. pp. 393-417), and even these might be left to pass unnoticed, were it not that we recognize in them the germ of the great work which the same admirable zoologist subsequently accomplished. In these "Fragments," apparently his earliest productions, we find him engaged on the subject with which his name will always be especially identified, the structure and arrangement of the feathers that form the proverbial characteristic of Birds. But, though the observations set forth in this essay were sufficiently novel, there is not much in them that at the time would have attracted attention, for perhaps no one—not even the author himself—could have then foreseen to what important end they would, in conjunction with other investigations, lead future naturalists; but they are marked by the same close and patient determination that eminently distinguishes all the work of their author; and, since it will be necessary for us to return to this part of the subject later, there is here no need to say more of them. In the following year another set of hints—of a kind so different that probably no one then living would have thought it possible that they should ever be brought in correlation with those of Nitzsch—are contained in a memoir on Fishes contributed to the tenth volume of the *Annales du Muséum d'histoire naturelle de Paris* by ÉTIENNE GEOFFROY ST-HILAIRE in 1807.³ Here we have it stated as a general truth (p. 100) that young birds have the sternum formed of five separate pieces—one in the middle, being its keel, and two "annexes" on each side to which the ribs are articulated—all, however, finally uniting to form the single "breast bone." Further on (pp. 101, 102) we find observations as to the number of ribs which are attached to each of the "annexes"—there being some-

¹ Though contravening our plan, we must for its great merits notice here Mr More's series of papers in *The Ibis* for 1865, "On the Distribution of Birds in Great Britain during the Nesting Season."

² Did our scheme permit us, we should be glad to mention in detail the various important communications on Scottish Birds of Alston, Messrs Buckley, Harvie-Brown, Lumsden, and others.

³ In the *Philosophie Anatomique* (i. pp. 69-101, and especially pp. 135, 136), which appeared in 1818, Geoffroy St-Hilaire explained the views he had adopted at greater length.

times more of them articulated to the anterior than to the posterior, and in certain forms no ribs belonging to one, all being applied to the other. Moreover, the author goes on to remark that in adult birds trace of the origin of the sternum from five centres of ossification is always more or less indicated by sutures, and that, though these sutures had been generally regarded as ridges for the attachment of the sternal muscles, they indeed mark the extreme points of the five primary bony pieces of the sternum.

In 1810 appeared at Heidelberg the first volume of TIEDEMANN'S carefully-wrought *Anatomie und Naturgeschichte der Vögel*—which shews a remarkable advance upon the work which Cuvier did in 1805, and in some respects is superior to his later production of 1817. It is, however, only noticed here on account of the numerous references made to it by succeeding writers, for neither in this nor in the author's second volume (not published until 1814) did he propound any systematic arrangement of the Class. More germane to our present subject are the *Osteographische Beiträge zur Naturgeschichte der Vögel* of Nitzsch, printed at Leipzig in 1811—a miscellaneous set of detached essays on some peculiarities of the skeleton or portions of the skeleton of certain Birds—one of the most remarkable of which is that on the component parts of the foot (pp. 101–105) pointing out the aberration from the ordinary structure exhibited by the Goatsucker (*Caprimulgus*) and the Swift (*Cypselus*)—an aberration which, if rightly understood, would have conveyed a warning to those ornithological systematists who put their trust in Birds' toes for characters on which to erect a classification, that there was in them much more of importance, hidden in the integument, than had hitherto been suspected; but the warning was of little avail, if any, till many years had elapsed. However, Nitzsch had not as yet seen his way to proposing any methodical arrangement of the various groups of Birds, and it was not until some eighteen months later that a scheme of classification in the main anatomical was attempted.

This scheme was the work of BLASIUS MERREM, who, in a communication to the Academy of Sciences of Berlin on the 10th December 1812, which was published in its *Abhandlungen* for the following year (pp. 237–259), set forth a *Tentamen Systematis naturalis Avium*, no less modestly entitled than modestly executed. The attempt of Merrem must be regarded as the virtual starting-point of the latest efforts in Systematic Ornithology, and in that view its proposals deserve to be stated at length. Without pledging ourselves to the acceptance of all its details—some of which, as is only natural, cannot be sustained with our present knowledge, resulting from the information accumulated by various investigators throughout more than seventy years—it is certainly not too much to say that Merrem's merits are almost incomparably superior to those of any of his predecessors as well as to those of the majority of his successors for a long time to come; while the neglect of his treatise by many (perhaps it would not be erroneous to say by most) of those who have since written on the subject seems inexcusable save on the score of inadvertence. Premising then that the chief characters assigned by this ill-appreciated systematist to his several groups are drawn from almost all parts of the structure of Birds, and are supplemented by some others of their more prominent peculiarities, we present the following abstract of his scheme:—

I. AVES CARINATÆ.

1. Aves aeræ.

A. Rapaces.—a. Accipitres—*Vultur, Falco, Sagittarius*.
b. Strix.

B. Hymenopodes.—a. Chelidonæ: a. C. nocturnæ—*Caprimulgus*; β. C. diurnæ—*Hirundo*.

b. Oscines: a. O. conirostres—*Loxia, Fringilla, Emberiza, Tangara*; β. O. tenuirostres—*Alauda, Motacilla, Muscicapa, Todus, Lanius, Ampelis, Turdus, Paradisea, Buphaga, Sturnus, Oriolus, Gracula, Coracias, Corvus, Pipra, Parus, Sitta, Certhia quædam*

C. Mellisugæ.—*Trochilus, Certhia et Upupa plurimæ*.

D. Dendrocolaptæ.—*Picus, Yunz*.

E. Brevilingues.—a. *Upupa*; b. *Ispidæ*.

F. Leuirostræ.—a. *Ramphastus, Scythrops* 1; b. *Psittacus*.

G. Coceyges.—*Cuculus, Trogon, Bucco, Crotophaga*.

2. Aves terrestres.

A. *Columba*.

B. *Gallinæ*.

3. Aves aquaticæ.

A. Odontorhynchi: a. Boscades—*Anas*; b. *Mergus*; c. *Phaenicopterus*.

B. Platyrrhynchi.—*Pelicanus, Phaeton, Plotus*.

C. *Aptenodytes*.

D. Urinatrices: a. *Cephi—Alca, Colymbi pedibus palmatis*; b. *Podiceps, Colymbi pedibus lobatis*.

E. Stenorrhynchi.—*Procellaria, Diomedea, Larus, Sterna, Rhynchops*.

4. Aves palustres.

A. Rusticolæ: a. *Phalarides—Rallus, Fulica, Parra*; b. *Limosugæ—Numenius, Scolopaz, Tringa, Charadrius, Recurvirostra*.

B. Grallæ: a. *Erodii—Ardeæ ungue intermedio serrato, Cancroma*; b. *Pelargi—Ciconia, Mycteria, Tantalid quidam, Scopus, Platalea*; c. *Gerani—Ardeæ cristatæ, Grues, Psophia*.

C. *Otis*.

II. AVES RATITÆ.—*Struthio*.

The most novel feature, and one the importance of which most ornithologists of the present day are fully prepared to admit, is of course the separation of the Class *Aves* into two great Divisions, which from one of the most obvious distinctions they present were called by its author *Carinata*² and *Ratita*,³ according as the sternum possesses a keel (*crista* in the phraseology of many anatomists) or not. But Merrem, who subsequently communicated to the Academy of Berlin a more detailed memoir on the "flat-breasted" Birds,⁴ was careful not here to rest his Divisions on the presence or absence of their sternal character alone. He concisely cites (p. 238) no fewer than eight other characters of more or less value as peculiar to the Carinate Division, the first of which is that the feathers have their barbs furnished with hooks, in consequence of which the barbs, including those of the wing-quills, cling closely together; while among the rest may be mentioned the position of the furcula and coracoids,⁵ which keep the wing-bones apart; the limitation of the number of the lumbar vertebra to fifteen, and of the carpals to two; as well as the divergent direction of the iliac bones,—the corresponding characters peculiar to the Ratite Division being (p. 259) the disconnected condition of the barbs of the feathers, through the absence of any hooks whereby they might cohere; the non-existence of the furcula, and the coalescence of the coracoids with the scapula (or, as he expressed it, the extension of the scapula to supply the place of the coracoids, which he thought were wanting); the lumbar vertebrae being twenty and the carpals three in number; and the parallelism of the iliac bones.

² From *carina*, a keel.

³ From *rates*, a raft or flat-bottomed barge.

⁴ "Beschreibung der Gerippes eines Casuars nebst einigen beiläufigen Bemerkungen über die flachbrüstigen Vögel"—*Abhandl. der Berlin. Akademie, Phys. Klasse*, 1817, pp. 179–193, tabb. i–iii.

⁵ Merrem, as did many others in his time, calls the coracoids "*claviculae*"; but it is now well understood that in Birds the real *claviculae* form the furcula or "merry-thought."

¹ The names of the genera are, he tells us, for the most part those of Linnæus, as being the best-known, though not the best. To some of the Linnæan genera he dare not, however, assign a place, for instance, *Buceros*, *Hæmatopus*, *Merops*, *Glareola* (Gmelin's genus, by the bye), and *Palamedea*.

As for Merrem's partitioning of the inferior groups there is less to be said in its praise as a whole, though credit must be given to his anatomical knowledge for leading him to the perception of several affinities, as well as differences, that had never before been suggested by superficial systematists. But it must be confessed that (chiefly, no doubt, from paucity of accessible material) he overlooked many points, both of alliance and the opposite, which since his time have gradually come to be admitted. For instance, he seems not to have been aware of the distinction, already shown by Nitzsch (as above mentioned) to exist, between the Swallows and the Swifts; and, by putting the genus *Coracias* among his *Oscines Tenuirostres*¹ without any remark, proved that he was not in all respects greatly in advance of his age; but on the other hand he most righteously judged that some species hitherto referred to the genera *Certhia* and *Upupa* required removal to other positions, and it is much to be regretted that the very concise terms in which his decisions were given to the world make it impossible to determine with any degree of certainty the extent of the changes in this respect which he would have introduced. Had Merrem published his scheme on an enlarged scale, it seems likely that he would have obtained for it far more attention, and possibly some portion of acceptance. He had deservedly attained no little reputation as a descriptive anatomist, and his claims to be regarded as a systematic reformer would probably have been admitted in his lifetime. As it was his scheme apparently fell flat, and not until many years had elapsed were its merits at all generally recognized.

Notice has next to be taken of a Memoir on the Employment of Sternal Characters in establishing Natural Families among Birds, which was read by DE BLAINVILLE before the Academy of Sciences of Paris in 1815,² but not published in full for more than five years later (*Journal de Physique . . . et des Arts*, xcii. pp. 185-215), though an abstract forming part of a *Prodrome d'une nouvelle distribution du Règne Animal* appeared earlier (*op. cit.*, lxxxiii. pp. 252, 253, 258, 259; and *Bull. Soc. Philomath. de Paris*, 1816, p. 110). This is a very disappointing performance, since the author observes that, notwithstanding his new classification of Birds is based on a study of the form of the sternal apparatus, yet, because that lies wholly within the body, he is compelled to have recourse to such outward characters as are afforded by the proportion of the limbs and the disposition of the toes—even as had been the practice of most ornithologists before him! It is evident that the features of the sternum on which De Blainville chiefly relied were those drawn from its posterior margin, which no very extensive experience of specimens is needed to show are of comparatively slight value; for the number of "*échancrures*"—notches as they have sometimes been called in English—when they exist, goes but a very short way as a guide, and is so variable in some very natural groups as to be even in that short way occasionally misleading.³ There is no appearance of his having at all taken into consideration the far more trustworthy characters furnished by the anterior part of the sternum, as well as by the coracoids and the furcula. Still De Blainville made some advance in a right direction, as for instance by elevating the Parrots⁴ and the Pigeons as "*Ordres*," equal in rank to that of the Birds-of-Prey and some others.

¹ He also placed the genus *Todus* in the same group, but it must be borne in mind that in his time a great many Birds were referred to that genus which (according to modern ideas) certainly do not belong to it, and it may well have been that he never had the opportunity of examining a specimen of the genus as nowadays restricted.

² Not 1812, as has sometimes been stated.

³ Cf. *Philos. Transactions*, 1869, p. 337, note.

⁴ This view of them had been long before taken by Willughby, but abandoned by all later authors.

According to the testimony of L'Herminier (for whom see later) he divided the "*Passereaux*" into two sections, the "*faux*" and the "*vrais*"; but, while the latter were very correctly defined, the former were most arbitrarily separated from the "*Grimpeurs*." He also split his *Grallatores* and *Natatores* (practically identical with the *Grallæ* and *Anseres* of Linnæus) each into four sections; but he failed to see—as on his own principles he ought to have seen—that each of these sections was at least equivalent to almost any one of his other "*Ordres*." He had, however, the courage to act up to his own professions in collocating the Rollers (*Coracias*) with the Bee eaters (*Merops*), and had the sagacity to surmise that *Menura* was not a Gallinaceous Bird. The greatest benefit conferred by this memoir is probably that it stimulated the efforts, presently to be mentioned, of one of his pupils, and that it brought more distinctly into sight that other factor, originally discovered by Merrem, of which it now clearly became the duty of systematizers to take cognizance.

Following the chronological order we are here adopting, we next have to recur to the labours of NITZSCH, who, in 1820, in a treatise on the Nasal Glands of Birds—a subject that had already attracted the attention of JACOBSON (*Nouv. Bull. Soc. Philomath. de Paris*, iii. pp. 267-269)—first put forth in Meckel's *Deutsches Archiv für die Physiologie* (vi. pp. 251-269) a statement of his general views on ornithological classification which were based on a comparative examination of those bodies in various forms. It seems unnecessary here to occupy space by giving an abstract of his plan,⁵ which hardly includes any but European species, because it was subsequently elaborated with no inconsiderable modifications in a way that must presently be mentioned at greater length. But the scheme, crude as it was, possesses some interest. It is not only a key to much of his later work—to nearly all indeed that was published in his lifetime—but in it are founded several definite groups (for example, *Passerinae* and *Picariæ*) that subsequent experience has shown to be more or less natural; and it further serves as additional evidence of the breadth of his views, and his trust in the teachings of anatomy; for it is clear that, if organs so apparently insignificant as these nasal glands were found worthy of being taken into account, and capable of forming a base of operations, in drawing up a system, it would almost follow that there can be no part of a Bird's organization that by proper study would not help to supply some means of solving the great question of its affinities. This seems to the present writer to be one of the most certain general truths in Zoology, and is probably admitted in theory to be so by most zoologists, but their practice is opposed to it; for, whatever group of animals be studied, it is found that one set or another of characters is the chief favourite of the authors consulted—each generally taking a separate set, and that to the exclusion of all others, instead of effecting a combination of all the sets and taking the aggregate.⁶

That Nitzsch took this extended view is abundantly proved by the valuable series of ornithological observations which he must have been for some time accumulating,

⁵ This plan, having been repeated by Schöps in 1829 (*op. cit.*, xii. p. 73), became known to Sir R. Owen in 1835, who then drew to it the attention of Kirby (*Seventh Bridgewater Treatise*, ii. pp. 444, 445), and in the next year referred to it in his own article "*Aves*" in Todd's *Cyclopædia of Anatomy* (i. p. 266), so that Englishmen need no excuse for not being aware of one of Nitzsch's labours, though his more advanced work of 1829, presently to be mentioned, was not referred to by Sir R. Owen.

⁶ A very remarkable instance of this may be seen in the *Systema Avium*, promulgated in 1830 by Wagler (a man with great knowledge of Birds) in his *Natürliches System der Amphibien* (pp. 77-128). He took the tongue as his chief guide, and found it indeed an unruly member

and almost immediately afterwards began to contribute to the younger Naumann's excellent *Naturgeschichte der Vögel Deutschlands*, already noticed above (page 9). Besides a concise general treatise on the Organization of Birds to be found in the Introduction to this work (i. pp. 23-52), a brief description from Nitzsch's pen of the peculiarities of the internal structure of nearly every genus is incorporated with the author's prefatory remarks, as each passed under consideration, and these descriptions being almost without exception so drawn up as to be comparative are accordingly of great utility to the student of classification, though they have been so greatly neglected. Upon these descriptions he was still engaged till death, in 1837, put an end to his labours, when his place as Naumann's assistant for the remainder of the work was taken by Rudolph Wagner; but, from time to time, a few more, which he had already completed, made their posthumous appearance in it, and, even in recent years, some selections from his unpublished papers have through the care of Giebel been presented to the public. Throughout the whole of this series the same marvellous industry and scrupulous accuracy are manifested, and attentive study of it will shew how many times Nitzsch anticipated the conclusions at which it has taken some modern taxonomers fifty years to arrive. Yet over and over again his determination of the affinities of several groups even of European Birds was disregarded; and his labours, being contained in a bulky and costly work, were hardly known at all outside of his own country, and within it by no means appreciated so much as they deserved¹—for even Naumann himself, who gave them publication, and was doubtless in some degree influenced by them, utterly failed to perceive the importance of the characters offered by the song-muscles of certain groups, though their peculiarities were all duly described and recorded by his coadjutor, as some indeed had been long before by Cuvier in his famous dissertation² on the organs of voice in Birds (*Leçons d'anatomie comparée*, iv. pp. 450-491). Nitzsch's name was subsequently dismissed by Cuvier without a word of praise, and in terms which would have been applicable to many another and inferior author, while Temminck, terming Naumann's work an "*ouvrage de luxe*,"—it being in truth one of the cheapest for its contents ever published,—effectually shut it out from the realms of science. In Britain it seems to have been positively unknown until quoted some years after its completion by a catalogue-compiler on account of some peculiarities of nomenclature which it presented.³

Now we must return to France, where, in 1827, L'HERMINIER, a creole of Guadeloupe and a pupil of De Blainville's, contributed to the *Actes* of the Linnæan Society of Paris for that year (vi. pp. 3-93) the "*Recherches sur l'appareil sternal des Oiseaux*," which the precept and example of his master had prompted him to undertake, and Cuvier had found for him the means of executing. A second and considerably enlarged edition of this very remarkable treatise was published as a separate work in the following year. We have already seen that De Blainville, though fully persuaded of the great value of sternal features as a method of classification, had been compelled to fall back upon the old pedal characters so often employed before; but now the scholar had learnt to excel his teacher, and not only to form an at least provi-

sional arrangement of the various members of the Class, based on sternal characters, but to describe these characters at some length, and so give a reason for the faith that was in him. There is no evidence, so far as we can see, of his having been aware of Merrem's views; but like that anatomist he without hesitation divided the Class into two great "*coupes*," to which he gave, however, no other names than "*Oiseaux Normaux*" and "*Oiseaux Anomaux*,"—exactly corresponding with his predecessor's *Cuviniæ* and *Ratitæ*—and, moreover, he had a great advantage in founding these groups, since he had discovered, apparently from his own investigations, that the mode of ossification in each was distinct; for hitherto the statement of there being five centres of ossification in every Bird's sternum seems to have been accepted as a general truth, without contradiction, whereas in the Ostrich and the Rhea, at any rate, L'Herminier found that there were but two such primitive points,⁴ and from analogy he judged that the same would be the case with the Cassowary and the Emu, which, with the two forms mentioned above, made up the whole of the "*Oiseaux Anomaux*" whose existence was then generally acknowledged.⁵ These are the forms which composed the Family previously termed *Cursores* by De Blainville; but L'Herminier was able to distinguish no fewer than thirty-four Families of "*Oiseaux Normaux*," and the judgment with which their separation and definition were effected must be deemed on the whole to be most creditable to him. It is to be remarked, however, that the wealth of the Paris Museum, which he enjoyed to the full, placed him in a situation incomparably more favourable for arriving at results than that which was occupied by Merrem, to whom many of the most remarkable forms were wholly unknown, while L'Herminier had at his disposal examples of nearly every type then known to exist. But the latter used this privilege wisely and well—not, after the manner of De Blainville and others subsequent to him, relying solely or even chiefly on the character afforded by the posterior portion of the sternum, but taking also into consideration those of the anterior, as well as of the in some cases still more important characters presented by the pre-sternal bones, such as the furcula, coracoids, and scapulæ. L'Herminier thus separated the Families of "*Normal Birds*":—

- | | |
|---|--|
| 1. "Accipitres" — <i>Accipitres</i> , Linn. | 18. "Passereaux" — <i>Passeres</i> , Linn. |
| 2. "Serpentaires" — <i>Gypogeryx</i> , Illiger. | 19. "Pigeons" — <i>Columba</i> , Linn. |

¹ Their value was, however, understood by Gloger, who in 1834, as will presently be seen, expressed his regret at not being able to use them.

² Cuvier's first observations on the subject seem to have appeared in the *Magasin Encyclopédique* for 1795 (ii. pp. 330, 358).

³ However, to this catalogue-compiler the present writer's gratitude is due, for thereby he became acquainted with the work and its merits.

⁴ This fact in the Ostrich appears to have been known already to Geoffroy St-Hilaire from his own observation in Egypt, but does not seem to have been published by him.

⁵ Considerable doubts were at that time, as said elsewhere (KIWI, vol. xiv. p. 104), entertained in Paris as to the existence of the *Apteryx*.

The preceding list is given to shew the very marked agreement of L'Herminier's results compared with those obtained fifty years later by another investigator, who approached the subject from an entirely different, though still osteological, basis. The sequence of the Families adopted is of course open to much criticism; but that would be wasted upon it at the present day; and the cautious naturalist will remember that it is generally difficult and in most cases absolutely impossible to deploy even a small section of the Animal Kingdom into line. So far as a linear arrangement will permit, the above list is very creditable, and will not only pass muster, but cannot easily be surpassed for excellence even at this moment. Experience has shewn that a few of the Families are composite, and therefore require further splitting; but examples of actually false grouping cannot be said to occur. The most serious fault perhaps to be found is the intercalation of the Ducks (No. 30) between the Pelicans and the Grebes—but every systematist must recognize the difficulty there is in finding a place for the Ducks in any arrangement we can at present contrive that shall be regarded as satisfactory. Many of the excellencies of L'Herminier's method could not be pointed out without too great a sacrifice of space, because of the details into which it would be necessary to enter; but the trenchant way in which he showed that the "Passereaux"—a group of which Cuvier had said "Son caractère semble d'abord purement négatif," and had then failed to define the limits—differed so completely from every other assemblage, while maintaining among its own innumerable members an almost perfect essential homogeneity, is very striking, and shews how admirably he could grasp his subject. Not less conspicuous are his merits in disposing of the groups of what are ordinarily known as Water-birds, his indicating the affinity of the Rails (No. 22) to the Cranes (No. 23), and the severing of the latter from the Herons (No. 24). His union of the Snipes, Sandpipers, and Plovers into one group (No. 26) and the alliance, especially dwelt upon, of that group with the Gulls (No. 27) are steps which, though indicated by Merrem, are here for the first time clearly laid down; and the separation of the Gulls from the Petrels (No. 28)—a step in advance already taken, it is true, by Illiger—is here placed on indefeasible ground. With all this, perhaps on account of all this, L'Herminier's efforts did not find favour with his scientific superiors, and for the time things remained as though his investigations had never been carried on.¹

Two years later Nitzsch, who was indefatigable in his endeavour to discover the Natural Families of Birds, and had been pursuing a series of researches into their vascular system, published the result, at Halle in Saxony, in his *Observationes de Anum arteria carotide communi*, in which is included a classification drawn up in accordance with the variation of structure which that important vessel presented in the several groups that he had opportunities of examining. By this time he had visited several of the principal museums on the Continent, among others Leyden (where Temminck resided) and Paris (where he had frequent intercourse with Cuvier), thus becoming acquainted with a considerable number of exotic forms that had hitherto been inaccessible to him. Consequently his labours had attained to a certain degree of completeness in this direction, and it may therefore be expedient here to name the different groups which he thus thought himself entitled to consider established. They are as follows:—

¹ With the exception of a brief and wholly inadequate notice in the *Edinburgh Journal of Natural History* (i. p. 90), the present writer is not aware of attention having been directed to L'Herminier's labours by British ornithologists for several years after; but considering how they were employing themselves at the time (as is shown in another place) this is not surprising.

I. AVES CARINATÆ [L'H. Oiseaux Normaux "].

A. Aves Carinatæ aerem.

1. *Accipitrinæ* [L'H. 1, 2 partim, 3]; 2. *Passerinæ* [L'H. 18]; 3. *Macrochiræ* [L'H. 6, 7]; 4. *Cuculinæ* [L'H. 8, 9, 10 (qu. 11, 12)]; 5. *Picinæ* [L'H. 15, 16]; 6. *Psittacinæ* [L'H. 5]; 7. *Lipoglossæ* [L'H. 13, 14, 17]; 8. *Amphibolæ* [L'H. 4].

B. Aves Carinatæ terrestres.

1. *Columbinæ* [L'H. 19]; 2. *Gallinacæ* [L'H. 20].

C. Aves Carinatæ aquaticæ.

Grallæ.

1. *Alectorides* (= *Dicholophus* + *Otis*) [L'H. 2 partim, 26 partim]; 2. *Gruinæ* [L'H. 23]; 3. *Fulicaræ* [L'H. 22]; 4. *Herodiæ* [L'H. 24 partim]; 5. *Pelargi* [L'H. 24 partim, 25]; 6. *Odontoglossi* (= *Phœnicopterus*) [L'H. 26 partim]; 7. *Limicolæ* [L'H. 26 pæne omnes].

Palmatæ.

8. *Longipennes* [L'H. 27]; 9. *Nasutæ* [L'H. 28]; 10. *Unguistrores* [L'H. 30]; 11. *Steganopodes* [L'H. 29]; 12. *Pyropodes* [L'H. 31, 32, 33, 34].

II. AVES RATIÆ [L'H. "Oiseaux Anomalous "].

To enable the reader to compare the several groups of Nitzsch with the Families of L'Herminier, the numbers applied by the latter to his Families are suffixed in square brackets to the names of the former; and, disregarding the order of sequence, which is here immaterial, the essential correspondence of the two systems is worthy of all attention, for it obviously means that these two investigators, starting from different points, must have been on the right track, when they so often coincided as to the limits of what they considered to be, and what we are now almost justified in calling, Natural Groups.² But it must be observed that the classification of Nitzsch, just given, rests much more on characters furnished by the general structure than on those furnished by the carotid artery only. Among all the species (188, he tells us, in number) of which he examined specimens, he found only four variations in the structure of that vessel, namely:—

1. That in which both a right carotid artery and a left are present. This is the most usual fashion among the various groups of Birds, including all the "aerial" forms excepting *Passerinæ*, *Macrochiræ*, and *Picinæ*.

2. That in which there is but a single carotid artery, springing from both right and left trunk, but the branches soon coalescing, to take a midway course, and again dividing near the head. This form Nitzsch was only able to find in the Bittern (*Ardea stellaris*).

3. That in which the right carotid artery alone is present, of which, according to our author's experience, the Flamingo (*Phœnicopterus*) was the sole example.

4. That in which the left carotid artery alone exists, as found in all other Birds examined by Nitzsch, and therefore as regards species and individuals much the most common—since into this category come the countless thousands of the Passerine Birds—a group which outnumbers all the rest put together.

Considering the enormous stride in advance made by L'Herminier, it is very disappointing for the historian to have to record that the next inquirer into the osteology of Birds achieved a disastrous failure in his attempt to throw light on their arrangement by means of: comparison of their sternum. This was BERTHOLD, who devoted a long chapter of his *Beiträge zur Anatomie*, published at Göttingen in 1831, to a consideration of the subject. So far as his introductory chapter went—the development of the sternum—he was, for

² Whether Nitzsch was cognizant of L'Herminier's views is in no way apparent. The latter's name seems not to be even mentioned by him, but Nitzsch was in Paris in the summer of 1827, and it is almost impossible that he should not have heard of L'Herminier's labours, unless the relations between the followers of Cuvier, to whom Nitzsch attached himself, and those of De Blainville, whose pupil L'Herminier was, were such as to forbid any communication between the rival schools. Yet we have L'Herminier's evidence that Cuvier gave him every assistance. Nitzsch's silence, both on this occasion and afterwards, is very curious; but he cannot be accused of plagiarism, for the scheme given above is only an amplification of that foreshadowed by him (as already mentioned) in 1820—a scheme which seems to have been equally unknown to L'Herminier, perhaps through linguistic difficulty.

his time, right enough and somewhat instructive. It was only when, after a close examination of the sternal apparatus of one hundred and thirty species, which he carefully described, that he arrived (pp. 177-183) at the conclusion—astonishing to us who know of L'Hermier's previous results—that the sternum of Birds cannot be used as a help to their classification on account of the egregious anomalies that would follow the proceeding—such anomalies, for instance, as the separation of *Cypselus* from *Hirundo* and its allies with *Trochilus*, and the grouping of *Hirundo* and *Fringilla* together. He seems to have been persuaded that the method of Linnaeus and his disciples was indisputably right, and that any method which contradicted it must therefore be wrong. Moreover, he appears to have regarded the sternal structure as a mere function of the Bird's habit, especially in regard to its power of flight, and to have wholly overlooked the converse position that this power of flight must depend entirely on the structure. Good descriptive anatomist as he certainly was, he was false to the anatomist's creed; but it is plain, from reading his careful descriptions of sternums, that he could not grasp the essential characters he had before him, and, attracted only by the more salient and obvious features, had not capacity to interpret the meaning of the whole. Yet he did not amiss by giving many figures of sternums hitherto unrepresented. We pass from him to a more lively theme.

At the very beginning of the year 1832 Cuvier laid before the Academy of Sciences of Paris a memoir on the progress of ossification in the sternum of Birds, of which memoir an abstract will be found in the *Annales des Sciences Naturelles* (xxv. pp. 260-272). Herein he treated of several subjects with which we are not particularly concerned at present, and his remarks throughout were chiefly directed against certain theories which Étienne Geoffroy St-Hilaire had propounded in his *Philosophie Anatomique*, published a good many years before, and need not trouble us here; but what does signify to us now is that Cuvier traced in detail, illustrating his statements by the preparations he exhibited, the progress of ossification in the sternum of the Fowl and of the Duck, pointing out how it differed in each, and giving his interpretation of the differences. It had hitherto been generally believed that the mode of ossification in the Fowl was that which obtained in all Birds—the Ostrich and its allies (as L'Hermier, we have seen, had already shewn) excepted. But it was now made to appear that the Struthious Birds in this respect resembled, not only the Duck, but a great many other groups—Waders, Birds-of-Prey, Pigeons, Passerines, and perhaps all Birds not Gallinae, so that, according to Cuvier's view, the five points of ossification observed in the *Gallina*, instead of exhibiting the normal process, exhibited one quite exceptional, and that in all other Birds, so far as he had been enabled to investigate the matter, ossification of the sternum began at two points only, situated near the anterior upper margin of the side of the sternum, and gradually crept towards the keel, into which it presently extended; and, though he allowed the appearance of detached portions of calcareous matter at the base of the still cartilaginous keel in Ducks at a certain age, he seemed to consider this an individual peculiarity. This fact was fastened upon by Geoffroy in his reply, which was a week later presented to the Academy; but was not published in full until the following year, when it appeared in the *Annales du Muséum* (ser. 3, ii. pp. 1-22). Geoffroy here maintained that the five centres of ossification existed in the Duck just as in the Fowl, and that the real difference of the process lay in the period at which they made their appearance, a circumstance, which, though virtually proved by the preparations Cuvier had used, had been by him overlooked or misinterpreted. The Fowl possesses all five ossifications at birth, and for a long while the middle piece forming the keel is by far the largest. They all grow slowly, and it is not until the animal is about six months old that they are united into one firm bone. The Duck on the other hand, when newly hatched, and for nearly a month after, has the sternum wholly cartilaginous.

Then, it is true, two lateral points of ossification appear at the margin, but subsequently the remaining three are developed, and when once formed they grow with much greater rapidity than in the Fowl, so that by the time the young Duck is quite independent of its parents, and can shift for itself, the whole sternum is completely bony. Nor, argued Geoffroy, was it true to say, as Cuvier had said, that the like occurred in the Pigeons and true Passerines. In their case the sternum begins to ossify from three very distinct points—one of which is the centre of ossification of the keel. As regards the Struthious Birds, they could not be likened to the Duck, for in them at no age was there any indication of a single median centre of ossification, as Geoffroy had satisfied himself by his own observations made in Egypt many years before. Cuvier seems to have acquiesced in the corrections of his views made by Geoffroy, and attempted no rejoinder; but the attentive and impartial student of the discussion will see that a good deal was really wanting to make the latter's reply effective, though, as events have shewn, the former was hasty in the conclusions at which he arrived, having trusted too much to the first appearance of centres of ossification, for, had his observations in regard to other Birds been carried on with the same attention to detail as in regard to the Fowl, he would certainly have reached some very different results.

In 1834 GLOGER brought out at Breslau the first (and unfortunately the only) part of a *Vollständiges Handbuch der Naturgeschichte der Vögel Europa's*, treating of the Land-birds. In the Introduction to this book (p. xxxviii., note) he expressed his regret at not being able to use as fully as he could wish the excellent researches of Nitzsch which were then appearing (as has been above said) in the successive parts of Naumann's great work. Notwithstanding this, to Gloger seems to belong the credit of being the first author to avail himself in a book intended for practical ornithologists of the new light that had already been shed on Systematic Ornithology; and accordingly we have his second Order of his arrangement, the *Aves Passerinae*, divided into two Suborders:—Singing Passerines (*meloduse*), and Passerines without an apparatus of Song-muscles (*anomalæ*)—the latter including what some later writers called *Picariæ*. For the rest his classification demands no particular remark; but that in a work of this kind he had the courage to recognize, for instance, such a fact as the essential difference between Swallows and Swifts lifts him considerably above the crowd of other ornithological writers of his time.

An improvement on the old method of classification by purely external characters was introduced to the Academy of Sciences of Stockholm by SUNDEVALL in 1835, and was published the following year in its *Handlingar* (pp. 43-130). This was the foundation of a more extensive work of which, from the influence it still exerts, it will be necessary to treat later at some length, and there will be no need now to enter much into details respecting the earlier performance. It is sufficient here to remark that the author, even then a man of great erudition, must have been aware of the turn which taxonomy was taking; but, not being able to divest himself of the older notion that external characters were superior to those furnished by the study of internal structure, and that Comparative Anatomy, instead of being a part of Zoology, was something distinct from it, he seems to have endeavoured to form a scheme which, while not running wholly counter to the teachings of Comparative Anatomists, should yet rest ostensibly on external characters. With this view he studied the latter most laboriously, and in some measure certainly not without success, for he brought into prominence several points that had hitherto escaped the notice of his predecessors. He also admitted among his characteristics a physiological consideration (apparently derived from Oken¹) dividing the class *Aves* into two sections *Altrices* and *Præoces*, according as the young were fed by their parents or, from the first, fed themselves. But at this time he was encumbered with the hazy doctrine of analogies, which, if it did not act to his detriment, was assuredly of no service to him. He prefixed an "Idem Systematis" to his "Expositio"; and the former, which appears to represent his real opinion, differs in arrangement very considerably from the latter. Like Gloger, Sundevall in his ideal system separated the true Passerines from all other Birds, calling them *Folivores*; but he took a step further, for he assigned to them the highest rank, wherein

¹ He says from Oken's *Naturgeschichte für Schulen*, published in 1821, but the division is to be found in that author's earlier *Lehrbuch der Zoologie* (ii. p. 571), which appeared in 1816.

nearly every recent authority agrees with him; out of them, however, he chose the Thrushes and Warblers to stand first as his ideal "Centrum"—a selection which, though in the opinion of the present writer erroneous, is still largely followed.

The points at issue between Cuvier and Étienne Geoffroy St-Hilaire before mentioned naturally attracted the attention of L'HERMINIER, who in 1836 presented to the French Academy the results of his researches into the mode of growth of that bone which in the adult Bird he had already studied to such good purpose. Unfortunately the full account of his diligent investigations was never published. We can best judge of his labours from an abstract printed in the *Comptes Rendus* (iii. pp. 12-20) and reprinted in the *Annales des Sciences Naturelles* (ser. 2, vi. pp. 107-115), and from the report upon them by ISIDORE GEOFFROY ST-HILAIRE, to whom with others they were referred. This report is contained in the *Comptes Rendus* for the following year (iv. pp. 565-574), and is very critical in its character. It were useless to conjecture why the whole memoir never appeared, as the reporter recommended that it should; but, whether, as he suggested, the author's observations failed to establish the theories he advanced or not, the loss of his observations in an extended form is greatly to be regretted, for no one seems to have continued the investigations he began and to some extent carried out; while, from his residence in Guadeloupe, he had peculiar advantages in studying certain types of Birds not generally available, his remarks on them could not fail to be valuable, quite irrespective of the interpretation he was led to put upon them. L'Herminier arrived at the conclusion that, so far from there being only two or three different modes by which the process of ossification in the sternum is carried out, the number of different modes is very considerable—almost each natural group of Birds having its own. The principal theory which he hence conceived himself justified in propounding was that instead of *five* being (as had been stated) the maximum number of centres of ossification in the sternum, there are no fewer than *nine* entering into the composition of the perfect sternum of Birds in general, though in every species some of these nine are wanting, whatever be the condition of development at the time of examination. These nine theoretical centres or "pieces" L'Herminier deemed to be disposed in *three* transverse series (*rangées*), namely the anterior or "prosternal," the middle or "mesosternal," and the posterior or "metasternal"—each series consisting of *three* portions, one median piece and two side-pieces. At the same time he seems, according to the abstract of his memoir, to have made the somewhat contradictory assertion that sometimes there are more than three pieces in each series, and in certain groups of Birds as many as six.¹ It would occupy more space than can here be allowed to give even the briefest abstract of the numerous observations which follow the statement of his theory and on which it professedly rests. They extend to more than a score of natural groups of Birds, and nearly each of them presents some peculiar characters. Thus of the first series of pieces he says that when all exist they may be developed simultaneously, or that the two side-pieces may precede the median, or again that the median may precede the side-pieces—according to the group of Birds, but that the second mode is much the commonest. The same variations are observable in the second or middle series, but its side-pieces are said to exist in all groups of Birds without exception. As to the third or posterior series, when it is complete the three constituent pieces are developed almost simultaneously;

but its median piece is said often to originate in two which soon unite, especially when the side-pieces are wanting. By way of examples of L'Herminier's observations, what he says of the two groups that had been the subject of Cuvier's and the elder Geoffroy's contest may be mentioned. In the *Gallinæ* the five well-known pieces or centres of ossification are said to consist of the two side-pieces of the second or middle series, and the three of the posterior. On two occasions, however, there was found in addition, what may be taken for a representation of the first series, a little "*noyau*" situated between the coracoids—forming the only instance of all three series being present in the same Bird. As regards the Ducks, L'Herminier agreed with Cuvier that there are commonly only two centres of ossification—the side-pieces of the middle series; but as these grow to meet one another a distinct median "*noyau*," also of the same series, sometimes appears, which soon forms a connexion with each of them. In the Ostrich and its allies no trace of this median centre of ossification ever occurs; but with these exceptions its existence is invariable in all other Birds. Here the matter must be left; but it is undoubtedly a subject which demands further investigation, and naturally any future investigator of it should consult the abstract of L'Herminier's memoir, and the criticisms upon it of the younger Geoffroy.

Hitherto it will have been seen that our present business has lain wholly in Germany and France, for, as is elsewhere explained, the chief ornithologists of Britain were occupying themselves at this time in a very useless way—not but that there were several distinguished men in this country who were paying due heed at this time to the internal structure of Birds, and some excellent descriptive memoirs on special forms had appeared from their pens, to say nothing of more than one general treatise on ornithic anatomy.² Yet no one in Britain seems to have attempted to found any scientific arrangement of Birds on other than external characters until, in 1837, WILLIAM MACGILLIVRAY issued the first volume of his *History of British Birds*, wherein, though professing (p. 19) "not to add a new system to the many already in partial use, or that have passed away like their authors," he propounded (pp. 16-18) a scheme for classifying the Birds of Europe at least founded on a "consideration of the digestive organs, which merit special attention, on account, not so much of their great importance in the economy of birds, as the nervous, vascular, and other systems are not behind them in this respect; but because, exhibiting great diversity of form and structure, in accordance with the nature of the food, they are more obviously qualified to afford a basis for the classification of the numerous species of birds" (p. 52). Experience has again and again exposed the fallacy of this last conclusion, but it is no disparagement of its author, writing nearly fifty years ago, to say that in this passage, as well as in others that might be quoted, he was greater as an anatomist than as a logician.

¹ We shall perhaps be justified in assuming that this apparent inconsistency, and others which present themselves, would be explicable if the whole memoir with the necessary illustrations had been published.

² Sir Richard Owen's celebrated article "Aves," in Todd's *Cyclopedia of Anatomy and Physiology* (i. pp. 265-358), appeared in 1836, and, as giving a general view of the structure of Birds, needs no praise here; but its object was not to establish a classification, or throw light especially on systematic arrangement. So far from that being the case, its distinguished author was content to adopt, as he tells us, the arrangement proposed by Kirby in the *Seventh Bridgewater Treatise* (ii. pp. 445-474), being that, it is true, of an estimable zoologist, but of one who had no special knowledge of Ornithology. Indeed it is, as the latter says, that of Linnæus, improved by Cuvier, with an additional modification of Illiger's—all these three authors having totally ignored any but external characters. Yet it was regarded "as being the one which facilitates the expression of the leading anatomical differences which obtain in the class of Birds, and which therefore may be considered as the most natural."

He was indeed thoroughly grounded in anatomy,¹ and though undoubtedly the digestive organs of Birds have a claim to the fullest consideration, yet Macgillivray himself subsequently became aware of the fact that there were several other parts of their structure as important from the point of view of classification. He it was, apparently, who first detected the essential difference of the organs of voice presented by some of the New-World Passerines (subsequently known as *Clamatores*), and the earliest intimation of this seems to be given in his anatomical description of the Arkansas Flycatcher, *Tyrannus verticalis*, which was published in 1838 (*Ornithol. Biography*, iv. p. 425), though it must be admitted that he did not—because he then could not—perceive the bearing of their difference, which was reserved to be shown by the investigation of a still greater anatomist, and of one who had fuller facilities for research, and thereby almost revolutionized, as will presently be mentioned, the views of systematists as to this Order of Birds. There is only space here to say that the second volume of Macgillivray's work was published in 1839, and the third in 1840; but it was not until 1852 that the author, in broken health, found an opportunity of issuing the fourth and fifth. His scheme of classification, being as before stated partial, need not be given in detail. Its great merit is that it proved the necessity of combining another and hitherto much-neglected factor in any natural arrangement, though vitiated as so many other schemes have been by being based wholly on one class of characters.

But a bolder attempt at classification was that made in 1838 by BLYTH in the New Series (Mr Charlesworth's) of the *Magazine of Natural History* (ii. pp. 256–268, 314–319, 351–361, 420–426, 589–601; iii. pp. 76–84). It was limited, however, to what he called *Insessores*, being the group upon which that name had been conferred by Vigors (*Trans. Linn. Society*, xiv. p. 405) in 1823 (see above, p. 15), with the addition, however, of his *Raptores*, and it will be unnecessary to enter into particulars concerning it, though it is as equally remarkable for the insight shewn by the author into the structure of Birds as for the philosophical breadth of his view, which comprehends almost every kind of character that had been at that time brought forward. It is plain that Blyth saw, and perhaps he was the first to see it, that Geographical Distribution was not unimportant in suggesting the affinities and differences of natural groups (pp. 258, 259); and, underterred by the precepts and practice of the hitherto dominant English school of Ornithologists, he declared that “anatomy, when aided by every character which the manner of propagation, the progressive changes, and other physiological data supply, is the only sure basis of classification.” He was quite aware of the taxonomic value of the vocal organs of some groups of Birds, presently to be especially mentioned, and he had himself ascertained the presence and absence of *cacæ* in a not inconsiderable number of groups, drawing thence very justifiable inferences. He knew at least the earlier investigations of

L'Herminier, and, though the work of Nitzsch, even if he had ever heard of it, must (through ignorance of the language in which it was written) have been to him a sealed book, he had followed out and extended the hints already given by Temminck as to the differences which various groups of Birds display in their moult. With all this it is not surprising to find, though the fact has been generally overlooked, that Blyth's proposed arrangement in many points anticipated conclusions that were subsequently reached, and were then regarded as fresh discoveries. It is proper to add that at this time the greater part of his work was carried on in conjunction with Mr BARTLETT, the present Superintendent of the Zoological Society's Gardens, and that, without his assistance, Blyth's opportunities, slender as they were compared with those which others have enjoyed, must have been still smaller. Considering the extent of their materials, which was limited to the bodies of such animals as they could obtain from dealers and the several menageries that then existed in or near London, the progress made in what has since proved to be the right direction is very wonderful. It is obvious that both these investigators had the genius for recognizing and interpreting the value of characters; but their labours do not seem to have met with much encouragement; and a general arrangement of the Class laid by Blyth before the Zoological Society at this time² does not appear in its publications, possibly through his neglect to reduce his scheme to writing and deliver it within the prescribed period. But even if this were not the case, no one need be surprised at the result. The scheme could hardly fail to be a crude performance—a fact which nobody would know better than its author; but it must have presented much that was objectionable to the opinions then generally prevalent. Its line to some extent may be partly made out—very clearly, for the matter of that, so far as its details have been published in the series of papers to which reference has been given—and some traces of its features are probably preserved in his *Catalogue* of the specimens of Birds in the Museum of the Asiatic Society of Bengal, which, after several years of severe labour, made its appearance at Calcutta in 1849; but, from the time of his arrival in India, the onerous duties imposed upon Blyth, together with the want of sufficient books of reference, seem to have hindered him from seriously continuing his former researches, which, interrupted as they were, and born out of due time, had no appreciable effect on the views of systematizers generally.

Next must be noticed a series of short treatises communicated by JOHANN FRIEDRICH BRANDT, between the years 1836 and 1839, Brandt to the Academy of Sciences of St Petersburg, and published in its *Mémoires*. In the year last mentioned the greater part of these was separately issued under the title of *Beiträge zur Kenntniss der Naturgeschichte der Vögel*. Herein the author first assigned anatomical reasons for rearranging the Order *Anseres* of Linnaeus and *Natatores* of Illiger, who, so long before as 1811, had proposed a new distribution of it into six Families, the definitions of which, as was his wont, he had drawn from external characters only. Brandt now retained very nearly the same arrangement as his predecessor; but, notwithstanding that he could trust to the firmer foundation of internal framework, he took at least two retrograde steps. First he failed to see the great structural difference between the Penguins (which Illiger had placed as a group, *Impeones*, of equal rank to his other Families) and the Auks, Divers, and Grebes, *Pygopodes*—combining all of them to form a “Typus” (to use his term) *Urinatores*; and secondly he admitted among the *Natatores*, though as a distinct “Typus” *Podoidae*, the genera *Podoa* and *Fulica*, which are now known to belong to the *Rallidae*—the latter indeed (see Coar, vol. vi. p. 341) being but very slightly removed from the *MOORHEN* (vol. xvi. p. 808). At the same time he corrected the error made by Illiger in associating the *PHALAROPES* (*g.v.*) with these forms, rightly declaring their

¹ This is not the place to expatiate on Macgillivray's merits; but the writer may perhaps be excused for here uttering the opinion that, after Willughby, Macgillivray was the greatest and most original ornithological genius save one (who did not live long enough to make his powers widely known) that this island has produced. The exact amount of assistance he afforded to Audubon in his *Ornithological Biography* will probably never be ascertained; but, setting aside “all the anatomical descriptions, as well as the sketches by which they are sometimes illustrated,” that on the latter's own statement (*op. cit.*, iv., Introduction, p. xxiii) are the work of Macgillivray, no impartial reader can compare the style in which the *History of British Birds* is written with that of the *Ornithological Biography* without recognizing the similarity of the two. On this subject some remarks of Prof. Coar (*Bull. Nutt. Ornithol. Club*, 1880, p. 201) may well be accepted.

² An abstract is contained in the Minute-book of the Scientific Meetings of the Zoological Society, 26th June and 10th July 1838. The Class was to contain fifteen Orders, but only three were dealt with in any detail.

relationship to *Tringa* (see SANDPIPER), a point of order which other systematists were long in admitting. On the whole Brandt's labours were of no small service in asserting the principle that consideration must be paid to osteology; for his position was such as to gain more attention to his views than some of his less favourably placed brethren had succeeded in doing.

In the same year (1839) another slight advance was made in the classification of the true Passerines. KEYSERLING and BLASIUS briefly pointed out in the *Archiv für Naturgeschichte* (v. pp. 332-334) that, while all the other Birds provided with perfect song-muscles had the "planta" or hind part of the "tarsus" covered with two long and undivided horny plates, the LARKS (vol. xiv. p. 316) had this part divided by many transverse sutures, so as to be scutellated behind as well as in front; just as is the case in many of the Passerines which have not the singing-apparatus, and also in the HOOPOE (vol. xii. p. 154). The importance of this singular but superficial departure from the normal structure has been so needlessly exaggerated as a character that at the present time its value is apt to be unduly depreciated. In so large and so homogeneous a group as that of the true Passerines, a constant character of this kind is not to be despised as a practical mode of separating the Birds which possess it; and, more than this, it would appear that the discovery thus announced was the immediate means of leading to a series of investigations of a much more important and lasting nature—those of Johannes Müller to be presently mentioned.

Again we must recur to that indefatigable and most original investigator NITZSCH, who, having never intermitted his study of the particular subject of his first contribution to science, long ago noticed, in 1833 brought out at Halle, where he was Professor of Zoology, an essay with the title *Pterylographix Avium Pars prior*. It seems that this was issued as much with the object of inviting assistance from others in view of future labours, since the materials at his disposal were comparatively scanty, as with that of making known the results to which his researches had already led him. Indeed he only communicated copies of this essay to a few friends, and examples of it are comparatively scarce. Moreover, he stated subsequently that he thereby hoped to excite other naturalists to share with him the investigations he was making on a subject which had hitherto escaped notice or had been wholly neglected, since he considered that he had proved the disposition of the feathered tracts in the plumage of Birds to be the means of furnishing characters for the discrimination of the various natural groups as significant and important as they were new and unexpected.¹ There was no need for us here to quote this essay in its chronological place, since it dealt only with the generalities of the subject, and did not enter upon any systematic details. These the author reserved for a second treatise which he was destined never to complete. He kept on diligently collecting materials, and as he did so

¹ It is still a prevalent belief among nearly all persons but well-informed ornithologists, that feathers grow almost uniformly over the whole surface of a Bird's body; some indeed are longer and some are shorter, but that is about all the difference perceptible to most people. It is the easiest thing for anybody to satisfy himself that this, except in a few cases, is altogether an erroneous supposition. In all but a small number of forms the feathers are produced in very definite clumps or tracts, called by Nitzsch *pterylae* (πτερόν, *penna*, ἵλη, *sylvæ*), a rather fanciful term it is true, but one to which no objection can be taken. Between these *pterylae* are spaces bare of feathers, which he named *apteria*. Before Nitzsch's time the only men who seem to have noticed this fact were the great John Hunter and the accurate Macartney. But the observations of the former on the subject were not given to the world until 1836, when Sir R. Owen introduced them into his *Catalogue* of the Museum of the College of Surgeons in London (vol. iii. pt. ii. p. 311), and therein is no indication of the fact having a taxonomical bearing. The same may be said of Macartney's remarks, which, though subsequent in point of time, were published earlier, namely, in 1819 (Rees's *Cyclopædia*, xiv., art. "Feathers"). Ignorance of this simple fact has led astray many celebrated painters, among them Sir Edwin Landseer, whose pictures of Birds nearly always shew an unnatural representation of the plumage that at once betrays itself to the trained eye, though of course it is not perceived by spectators generally, who regard only the correctness of attitude and force of expression, which in that artist's work commonly leave little to be desired. Every draughtsman of Birds to be successful should study the plan on which their feathers are disposed.

was constrained to modify some of the statements he had published. He consequently fell into a state of doubt, and before he could make up his mind on some questions which he deemed important he was overtaken by death.² Then his papers were handed over to his friend and successor Prof. BURMEISTER, now and for many years past of Buenos Aires, who, with much skill elaborated from them the excellent work known as Nitzsch's *Pterylographie*, which was published at Halle in 1840. There can be no doubt that Prof. Burmeister (fortunately yet spared to us) discharged his editorial duty with the most conscientious scrupulosity; but, from what has been just said, it is certain that there were important points on which Nitzsch was as yet undecided—some of them perhaps of which no trace appeared in his manuscripts, and therefore as in every case of works posthumously published, unless (as rarely happens) they have received their author's "imprimatur," they cannot be implicitly trusted as the expression of his final views. It would consequently be unsafe to ascribe positively all that appears in this volume to the result of Nitzsch's mature consideration. Moreover, as Prof. Burmeister states in his preface, Nitzsch by no means regarded the natural sequence of groups as the highest problem of the systematist, but rather their correct limitation. Again the arrangement followed in the *Pterylographie* was of course based on pterylographical considerations, and we have its author's own word for it that he was persuaded that the limitation of natural groups could only be attained by the most assiduous research into the species of which they are composed from every point of view. The combination of these three facts will of itself explain some defects, or even retrogressions, observable in Nitzsch's later systematic work when compared with that which he had formerly done. On the other hand some manifest improvements are introduced, and the abundance of details into which he enters in his *Pterylographie* render it far more instructive and valuable than the older performance. As an abstract of that has already been given, it may be sufficient here to point out the chief changes made in his newer arrangement. To begin with, the three great sections of Aerial, Terrestrial, and Aquatic Birds are abolished. The "Accipitres" are divided into two groups, Diurnal and Nocturnal; but the first of these divisions is separated into three sections:—(1) the Vultures of the New World, (2) those of the Old World, and (3) the genus *Falco* of Linnæus. The "Passerine," that is to say, the true *Passeres*, are split into eight Families, not wholly with judgment;³ but of their taxonomy more is to be said presently. Then a new Order "*Picariæ*" is instituted for the reception of the *Macrochires*, *Cuculiniæ*, *Piciniæ*, *Psittaciniæ*, and *Amphibolæ* of his old arrangement, to which are added three⁴ others—*Caprimulginiæ*, *Todidæ*, and *Lipoglossæ*—the last consisting of the genera *Buceros*, *Upupa*, and *Alcedo*. The association of *Alcedo* with the

² Though not relating exactly to our present theme, it would be improper to dismiss Nitzsch's name without reference to his extraordinary labours in investigating the insect and other external parasites of Birds, a subject which as regards British species was subsequently elaborated by DENNY in his *Monographia Anoplurorum Britannicæ* (1842) and in his list of the specimens of British *Anoplura* in the collection of the British Museum.

³ A short essay by Nitzsch on the general structure of the Passerines; written, it is said, in 1836, was published in 1862 (*Zeitschr. Ges. Naturwissenschaft*, xix. pp. 389-408). It is probably to this essay that Prof. Burmeister refers in the *Pterylographie* (p. 102, note; English translation, p. 72, note) as forming the basis of the article "Passeriniæ" which he contributed to Ersch and Gruber's *Encyclopædie* (sect. iii. bd. xiii. pp. 139-144), and published before the *Pterylographie*.

⁴ By the numbers prefixed it would look as if there should be four new members of this Order; but that seems to be due rather to a slip of the pen or to a printer's error.

other two is no doubt a misplacement, but the alliance of *Buceros* to *Upupa*, already suggested by Gould and Blyth in 1838¹ (*Mag. Nat. History*, ser. 2, ii. pp. 422 and 589), though apparently unnatural, has been corroborated by many later systematizers; and taken as a whole the establishment of the *Picariæ* was certainly a commendable proceeding. For the rest there is only one considerable change, and that forms the greatest blot on the whole scheme. Instead of recognizing, as before, a Subclass in the *Ratitæ* of Merrem, Nitzsch now reduced them to the rank of an Order under the name "*Platysternæ*," placing them between the "*Gallinacæ*" and "*Grallæ*," though admitting that in their pterylosis they differ from all other Birds, in ways that he is at great pains to describe, in each of the four genera examined by him—*Struthio*, *Rhea*, *Dromæus*, and *Casuarus*.² It is significant that notwithstanding this he did not figure the pterylosis of any one of them, and the thought suggests itself that, though his editor assures us he had convinced himself that the group must be here shoved in (*eingeschoben* is the word used), the intrusion is rather due to the necessity which Nitzsch, in common with most men of his time (the Quinarians excepted), felt for deploying the whole series of Birds into line, in which case the proceeding may be defensible on the score of convenience. The extraordinary merits of this book, and the admirable fidelity to his principles which Prof. Burmeister shewed in the difficult task of editing it, were unfortunately overlooked for many years, and perhaps are not sufficiently recognized now. Even in Germany, the author's own country, there were few to notice seriously what is certainly one of the most remarkable works ever published on the science, much less to pursue the investigations that had been so laboriously begun.³ Andreas Wagner, in his report on the progress of Ornithology, as might be expected from such a man as he was, placed the *Pterylographie* at the summit of those publications the appearance of which he had to record for the years 1839 and 1840, stating that for "*Systematik*" it was of the greatest importance.⁴ On the other hand Oken (*Isis*, 1842, pp. 391–394), though giving a summary of Nitzsch's results and classification, was more sparing of his praise, and prefaced his remarks by asserting that he could not refrain from laughter when he looked at the plates in Nitzsch's work, since they reminded him of the plucked fowls hanging in a poulterer's shop—it might as well be urged as an objection to the plates in many an anatomical book that they called to mind a butcher's—and goes on to say that, as the author always had the luck to engage in researches of which nobody thought, so had he the luck to print them where nobody sought them. In Sweden

Sundevall, without accepting Nitzsch's views, accorded them a far more appreciative greeting in his annual reports for 1840–42 (i. pp. 152–160); but of course in England and France⁵ nothing was known of them beyond the scantiest notice, generally taken at second hand, in two or three publications. Thanks to Mr Selater, the Ray Society was induced to publish, in 1867, an excellent translation by Mr Dallas of Nitzsch's *Pterylography*, and thereby, however tardily, justice was at length rendered by British ornithologists to one of their greatest foreign brethren.⁶

The treatise of KESSLER on the osteology of Birds' feet, published in the *Bulletin* of the Moscow Society of Naturalists for 1841, next claims a few words, though its scope is rather to shew differences than affinities; but treatment of that kind is undoubtedly useful at times in indicating that alliances generally admitted are unnatural; and this is the case here, for, following Cuvier's method, the author's researches prove the artificial character of some of its associations. While furnishing—almost unconsciously, however—additional evidence for overthrowing that classification, there is, nevertheless, no attempt made to construct a better one; and the elaborate tables of dimensions, both absolute and proportional, suggestive as is the whole tendency of the author's observations, seem not to lead to any very practical result, though the systematist's need to look beneath the integument, even in parts that are so comparatively little hidden as Birds' feet, is once more made beyond all question apparent.

It has already been mentioned that MACGILLIVRAY contributed to Audubon's *Ornithological Biography* a series of descriptions of some parts of the anatomy of American Birds, from subjects supplied to him by that enthusiastic naturalist, whose zeal and prescience, it may be called, in this respect merits all praise. Thus he (prompted very likely by Macgillivray) wrote:—"I believe the time to be approaching when much of the results obtained from the inspection of the exterior alone will be laid aside; when museums filled with stuffed skins will be considered insufficient to afford a knowledge of birds; and when the student will go forth, not only to observe the habits and haunts of animals, but to preserve specimens of them to be carefully dissected" (*Ornith. Biography*, iv., Introduction, p. xxiv). As has been stated, the first of this series of anatomical descriptions appeared in the fourth volume of his work, published in 1838, but they were continued until its completion with the fifth volume in the following year, and the whole was incorporated into what may be termed its second edition, *The Birds of America*, which appeared between 1840 and 1844 (see p. 11). Among the many species whose anatomy Macgillivray thus partly described from autopsy were at least half a dozen⁷ of those now referred to the Family *Tyrannidae* (see KING-BIRD, vol. xiv. p. 80), but then included, with many others, according to the irrational, vague, and rudimentary notions of classification of the time, in what was termed the Family "*Muscicapinæ*." In all these species he found the vocal organs to differ essentially in structure from those of other Birds of the Old World, which we now call Passerine, or, to be still more precise, Oscinian. But by him these last were most arbitrarily severed, dissociated from their allies, and wrongly combined with other forms by no means nearly related to them (*Brit. Birds*, i. pp. 17, 18) which

Macgillivray and Audubon.

¹ This association is one of the most remarkable in the whole series of Blyth's remarkable papers on classification in the volume cited above. He states that Gould suspected the alliance of these two forms "from external structure and habits alone;" otherwise one might suppose that he had obtained an intimation to that effect on one of his Continental journeys. Blyth "arrived at the same conclusion, however, by a different train of investigation," and this is beyond doubt.

² He does not mention *Apteryx*, at that time so little known on the Continent.

³ Some excuse is to be made for this neglect. Nitzsch had of course exhausted all the forms of Birds commonly to be obtained, and specimens of the less common forms were too valuable from the curator's or collector's point of view to be subjected to a treatment that might end in their destruction. Yet it is said, on good authority, that Nitzsch had the patience so to manipulate the skins of many rare species that he was able to ascertain the characters of their pterylosis by the inspection of their inside only, without in any way damaging them for the ordinary purpose of a museum. Nor is this surprising when we consider the marvellous skill of Continental and especially German taxidermists, many of whom have elevated their profession to a height of inconceivable to most Englishmen, who are only acquainted with the miserable mockery of Nature which is the most sublime result of all but a few "bird-stuffers."

⁴ *Archiv für Naturgeschichte*, vii. 2, pp. 60, 61.

⁵ In 1836 JACQUEMIN communicated to the French Academy (*Comptes Rendus*, ii. pp. 374, 375, and 472) some observations on the order in which feathers are disposed on the body of Birds; but, however general may have been the scope of his investigations, the portion of them published refers only to the Crow, and there is no mention made of Nitzsch's former work.

⁶ The Ray Society had the good fortune to obtain the ten original copper-plates, all but one drawn by the author himself, wherewith the work was illustrated. It is only to be regretted that the Society did not also stick to the quarto size in which it appeared, for by issuing their English version in folio they needlessly put an impediment in the way of its common and convenient use.

⁷ These are, according to modern nomenclature, *Tyrannus carolinensis* and (as before mentioned) *T. verticalis*, *Myiarchus crinitus*, *Sayornis fuscus*, *Contopus virens*, and *Empidonax acadicus*.

he also examined; and he practically, though not literally,¹ asserted the truth, when he said that the general structure, but especially the muscular appendages, of the lower larynx was "similarly formed in all other birds of this family" described in Audubon's work. Macgillivray did not, however, assign to this essential difference any systematic value. Indeed he was so much prepossessed in favour of a classification based on the structure of the digestive organs that he could not bring himself to consider vocal muscles to be of much taxonomic use, and it was reserved to JOHANNES MÜLLER to point out that the contrary was the fact. This the great German comparative anatomist did in two communications to the Academy of Sciences of Berlin, one on the 26th June 1845 and the other on the 14th May 1846, which, having been first briefly published in the Academy's *Monatsbericht*, were afterwards printed in full, and illustrated by numerous figures, in its *Abhandlungen*, though in this latter and complete form they did not appear in public until 1847. This very remarkable treatise forms the groundwork of almost all later or recent researches in the comparative anatomy and consequent arrangement of the *Passeres*, and, though it is certainly not free from imperfections, many of them, it must be said, arise from want of material, notwithstanding that its author had command of a much more abundant supply than was at the disposal of Nitzsch. Carrying on the work from the anatomical point at which he had left it, correcting his errors, and utilizing to the fullest extent the observations of Keyserling and Blasius, to which reference has already been made, Müller, though hampered by mistaken notions of which he seems to have been unable to rid himself, propounded a scheme for the classification of this group, the general truth of which has been admitted by all his successors, based, as the title of his treatise expressed, on the hitherto unknown different types of the vocal organs in the *Passerines*. He freely recognized the prior discoveries of, as he thought, Audubon, though really, as has since been ascertained, of Macgillivray; but Müller was able to perceive their systematic value, which Macgillivray did not, and taught others to know it. At the same time Müller shewed himself, his power of discrimination notwithstanding, to fall behind Nitzsch in one very crucial point, for he refused to the latter's *Picariæ* the rank that had been claimed for them, and imagined that the groups associated under that name formed but a third "Tribe"—*Picarii*—of a great Order *Insectores*, the others being (1) the *Oscines* or *Polymyodi*—the Singing Birds by emphasis, whose inferior larynx was endowed with the full number of five pairs of song-muscles, and (2) the *Tracheophones*, composed of some South-American Families. Looking on Müller's labours as we now can, we see that such errors as he committed are chiefly due to his want of special knowledge of Ornithology, combined with the absence in several instances of sufficient materials for investigation. Nothing whatever is to be said against the composition of his first and second "Tribes"; but the third is an assemblage still more heterogeneous than that which Nitzsch brought together under a name so like that of Müller—for the fact must never be allowed to go out of sight that the extent of the *Picarii* of the latter is not at all that of the *Picariæ* of the former.² For instance, Müller places in his

third "Tribe" the group which he called *Ampelidæ*, meaning thereby the peculiar forms of South America that are now considered to be more properly named *Cotingidæ*, and herein he was clearly right, while Nitzsch, who (misled by their supposed affinity to the genus *Ampelis*—peculiar to the Northern Hemisphere, and a purely *Passerine* form) had kept them among his *Passerina*, was as clearly wrong. But again Müller made his third "Tribe" *Picarii* also to contain the *Tyrannidæ*, of which mention has just been made, though it is so obvious as now to be generally admitted that they have no very intimate relationship to the other Families with which they are there associated. There is no need here to criticize more minutely his projected arrangement, and it must be said that, notwithstanding his researches, he seems to have had some misgivings that, after all, the separation of the *Insectores* into those "Tribes" might not be justifiable. At any rate he wavered in his estimate of their taxonomic value, for he gave an alternative proposal, arranging all the genera in a single series, a proceeding in those days thought not only defensible and possible, but desirable or even requisite, though now utterly abandoned. Just as Nitzsch had laboured under the disadvantage of never having any example of the abnormal *Passeres* of the New World to dissect, and therefore was wholly ignorant of their abnormality, so Müller never succeeded in getting hold of an example of the genus *Pitta* for the same purpose, and yet, acting on the clew furnished by Keyserling and Blasius, he did not hesitate to predict that it would be found to fill one of the gaps he had to leave, and this to some extent it has been since proved to do.

The result of all this is that the *Oscines* or true *Passeres* are found to be a group in which the vocal organs not only attain the greatest perfection, but are nearly if not quite as uniform in their structure as is the sternal apparatus; while at the same time each set of characters is wholly unlike that which exists in any other group of Birds. In nearly all Birds the inferior larynx, or syrinx, which is, as proved long ago by the experiments of Cuvier, the seat of their vocal powers, is at the bottom of the trachea or windpipe, and is formed by the more or less firm union of several of the bony rings of which that tube is composed. In the *Ratitæ*, the genus *Rhea* excepted, and in one group of *Carinata*, the American Vultures *Cathartidæ*, but therein it is believed only, there is no special modification of the trachea into a syrinx;³ but usually, at a little distance from the lungs, the trachea is somewhat enlarged, and here is found a thicker and stouter bony ring, which is bisected axially by a *septum* or partition extending from behind forwards, and thus dividing the pipe,⁴ each half of which swells out below the ring and then rapidly contracts to enter the lung on its own side. The halves of the pipe thus formed are the *Bronchi*, tubes whose inner side is flattened and composed of the *membrana tympaniformis*, on the change of form and length of which some of the varieties of intonation depend, while the outer and curved side is supported by bony half-hoops, connected by membrane just as are the entire hoops of the upper part of the trachea. The whole of this apparatus is extremely flexible, and is controlled by muscles, the real vocal muscles of which mention has previously been so frequently made. These vary in number in different groups of Birds, and reach their maximum in the *Oscines*, which have always five pairs, or even more according to some authorities.⁵ But supposing five to be the number of pairs, as it is generally allowed to be in this group of them, two pairs have a common origin about the middle of the trachea, and, descending on its outside, divide at a short distance above the lower end of the tube; one of them, the *tensor posterior longus*, being directed downward and backward, is inserted at the extreme posterior end of the first half-ring of the bronchus, while its counterpart, the *tensor anterior longus*, passing from the place of separation downward and forward, is inserted below the extreme point of the last ring of the trachea. Within the angle formed by the divergence of each of these pairs of muscles, a third slender muscle—the *sterno-trachealis*—is given off

¹ Not literally, because a few other forms such as the genera *Polioptila* and *Ptilogonys*, now known to have no relation to the *Tyrannidæ*, were included, though these forms, it would seem, had never been dissected by him. On the other hand he declares that the American Redstart, *Muscicapa*, or, as it now stands, *Setophaga ruticilla*, when young, has its vocal organs like the rest—an extraordinary statement which is worthy the attention of the many able American ornithologists.

² It is not needless to point out this fine distinction, for more than one modern author would seem to have overlooked it.

³ See BIRDS, vol. iii. p. 726; but cf. Forbes, *Proc. Zool. Society*, 1881, pp. 778, 788.

⁴ In a few forms belonging to the *Spheniscidæ* and *Procellariidæ*, this *septum* is prolonged upwards, to what purpose is of course unknown. On the other hand, the Parrots have no *septum* (see BIRDS, *ut supra*).

⁵ See BIRDS, vol. iii. p. 726.

on each side and is attached to the sternum.¹ The fourth pair, the *tensores posteriores breves*, is the smallest of all, and, arising near the middle of the lower end of the trachea, has its fibres inserted on the extremity of the first of the incomplete rings of the bronchi. The fifth pair, the *tensores anteriores*, originates like the last from the middle of the trachea, but is somewhat larger and thicker, appearing as though made up of several small muscles in close contact, and by some ornithologists is believed to be of a composite nature. Its direction is obliquely downward and forward, and, attached by a broad base to the last ring of the trachea and cartilago immediately below, reaches the first or second of the half-rings of the bronchi—in the normal *Oscines* at their extremity; but, in another section of that group, which it will be necessary to mention later, it is found to be attached to their middle. There is no question of its being by the action of the syringeal muscles just described that the expansion of the bronchi, both as to length and diameter, is controlled, and, as thereby the sounds uttered by the Bird are modified, they are properly called the Song-muscles.

It must not be supposed that the muscles just defined were first discovered by Müller; on the contrary they had been described long before, and by many writers on the anatomy of Birds. To say nothing of foreigners, or the authors of general works on the subject, an excellent account of them had been given to the Linnean Society by YARRELL in 1829, and published with elaborate figures in its *Transactions* (xvi. pp. 305–321, pls. 17, 18), an abstract of which was subsequently given in the article "Raven" in his *History of British Birds*, and Macgillivray also described and figured them with the greatest accuracy ten years later in his work with the same title (ii. pp. 21–37, pls. x–xii.), while Blyth and Nitzsch had (as already mentioned) seen some of their value in classification. But Müller has the merit of clearly outstriking his predecessors, and with his accustomed perspicuity made the way even plainer for his successors to see than he himself was able to see it. What remains to add is that the extraordinary celebrity of its author actually procured for the first portion of his researches notice in England (*Ann. Nat. History*, xvii. p. 499), though it must be confessed not then to any practical purpose; but more than thirty years after there appeared an English translation of his treatise by Prof. Jeffrey Bell, with an appendix by Garrod containing a summary of the latter's own continuation of the same line of research, and thus once more Mr Selater, for it was at his instigation that the work was undertaken, had the satisfaction of rendering proper tribute to one who by his investigations had so materially advanced the study of Ornithology.²

It is now necessary to revert to the year 1842, in which Dr CORNAY of Rochefort communicated to the French Academy of Sciences a memoir on a new Classification of Birds, of which, however, nothing but a notice has been preserved (*Comptes Rendus*, xiv. p. 164). Two years later this was followed by a second contribution from him on the same subject, and of this only an extract appeared in the official organ of the Academy (*ut supra*, xvi. pp. 94, 95), though an abstract was inserted in one scientific journal (*L'Institut*, xii. p. 21), and its first portion in another (*Journal des Découvertes*, i. p. 256). The *Revue Zoologique* for 1847 (pp. 360–369) contained the whole, and enabled naturalists to consider the merits of the author's project, which was to found a new Classification of Birds on the form of the anterior palatal bones, which he declared to be subjected more evidently than any other to certain fixed laws. These laws, as formulated by him, are that (1) there is a coincidence of form of the anterior palatal and of the cranium in Birds of the same Order; (2) there is a likeness between the anterior palatal bones in Birds of the same Order; (3) there are relations of likeness between the anterior palatal bones in groups of Birds which are near to one another. These laws, he added, exist in regard to all

parts that offer characters fit for the methodical arrangement of Birds, but it is in regard to the anterior palatal bone that they unquestionably offer the most evidence. In the evolution of these laws Dr Cornay had most laudably studied, as his observations prove, a vast number of different types, and the upshot of his whole labours, though not very clearly stated, was such as to wholly subvert the classification at that time generally adopted by French ornithologists. He of course knew the investigations of L'Hermier and De Blainville on sternal formation, and he also seems to have been aware of some pterylogical differences exhibited by Birds—whether those of Nitzsch or those of Jacquemin is not stated. True it is the latter were never published in full, but it is quite conceivable that Dr Cornay may have known their drift. Be that as it may, he declares that characters drawn from the sternum or the pelvis—hitherto deemed to be, next to the bones of the head, the most important portions of the Bird's framework—are scarcely worth more, from a classificatory point of view, than characters drawn from the bill or the legs; while pterylogical considerations, together with many others to which some systematists had attached more or less importance, can only assist, and apparently must never be taken to control, the force of evidence furnished by this bone of all bones—the anterior palatal.

That Dr Cornay was on the brink of making a discovery of considerable merit will by and by appear; but, with every disposition to regard his investigations favourably, it cannot be said that he accomplished it. No account need be taken of the criticism which denominated his attempt "unphilosophical and one-sided," nor does it signify that his proposals elicited no attention or were generally received with indifference. Such is commonly the fate of any deep-seated reform of classification proposed by a comparatively unknown man, unless it happen to possess some extraordinarily taking qualities, or be explained with an abundance of pictorial illustration. This was not the case here. Whatever proofs Dr Cornay may have had to satisfy himself of his being on the right track, these proofs were not adduced in sufficient number nor arranged with sufficient skill to persuade a somewhat stiff-necked generation of the truth of his views—for it was a generation whose leaders, in France at any rate, looked with suspicion upon any one who professed to go beyond the bounds which the genius of Cuvier had been unable to overpass, and regarded the notion of upsetting any of the positions maintained by him as verging almost upon profanity. Moreover, Dr Cornay's scheme was not given to the world with any of those adjuncts that not merely please the eye but are in many cases necessary, for, though on a subject which required for its proper comprehension a series of plates, it made even its final appearance unadorned by a single explanatory figure, and in a journal, respectable and well-known indeed, but one not of the highest scientific rank. Add to all this that its author, in his summary of the practical results of his investigations, committed a grave sin in the eyes of rigid systematists by ostentatiously arranging the names of the forty types which he selected to prove his case wholly without order, and without any intimation of the greater or less affinity any one of them might bear to the rest. That success should attend a scheme so inconclusively elaborated could not be expected.

The same year which saw the promulgation of the crude scheme just described, as well as the publication of the final researches of Müller, witnessed also another attempt at the classification of Birds, much more limited indeed in scope, but, so far as it went, regarded by most ornithologists of the time as almost final in its operation. Under the vague title of "Ornithologische Notizen" Prof. Cabanis of Berlin contributed to the *Archiv für Naturgeschichte* (xiii. 1, pp. 186–256, 308–352) an essay in two parts, wherein, following the researches of Müller³ on the syrinx, in the course of which a correlation had been shewn to exist between the whole or divided condition of the *planta* or hind part of the "tarsus," first noticed, as has been said, by Keyserling and Blasius, and the presence or absence of the perfect song-apparatus, the younger author found an agreement which seemed almost invariable in this respect, and he also pointed out that the *planta* of the different groups of Birds in which it is divided is divided in different modes, the mode of division being generally characteristic of the group. Such a coincidence of the internal and external features of Birds was naturally deemed a discovery of the greatest value by those ornithologists who thought most highly of the latter, and it was unquestionably of no little practical utility. Further examination also revealed the fact that

¹ According to Blyth (*Mag. Nat. History*, ser. 2, ii. p. 264), Yarrell ascertained that this pair of muscles was wanting in "the mina genus" (qu. *Gracula*!), a statement that requires attention either for confirmation or contradiction.

² The title of the English translation is *Johannes Müller on Certain Variations in the Vocal Organs of the Passeres that have hitherto escaped notice*. It was published at Oxford in 1878. By some unaccountable accident, the date of the original communication to the Academy of Berlin is wrongly printed. It has been rightly given above.

³ On the other hand, Müller makes several references to the labours of Prof. Cabanis. The investigations of both authors must have been proceeding simultaneously, and it matters little which actually appeared first.

⁴ This seems to have been made known by Prof. Cabanis the preceding year to the *Gesellschaft der Naturforschender Freunde* (cf. Müller, *Stimmorganen der Passerinen*, p. 65). Of course the variation to which the number of primaries was subject had not escaped the observation of Nitzsch, but he had scarcely used it as a classificatory character.

in certain groups the number of "primaries," or quill-feathers growing from the *manus* or distal segment of the wing, formed another characteristic easy of observation. In the *Oscines* or *Polymyodi* of Müller the number was either nine or ten—and if the latter the outermost of them was generally very small. In two of the other groups of which Prof. Cabanis especially treated—groups which had been hitherto more or less confounded with the *Oscines*—the number of primaries was invariably ten, and the outermost of them was comparatively large. This observation was also hailed as the discovery of a fact of extraordinary importance; and, from the results of these investigations, taken altogether, Ornithology was declared by Sundevall, undoubtedly a man who had a right to speak with authority, to have made greater progress than had been achieved since the days of Cuvier. The final disposition of the "Subclass *Inscissores*"—all the perching Birds, that is to say, which are neither Birds-of-Prey nor Pigeons—proposed by Prof. Cabanis, was into four "Orders," as follows:—

1. *Oscines*, equal to Müller's group of the same name;
2. *Clamatores*, being a majority of that division of the *Picariæ* of Nitzsch, so called by Andreas Wagner, in 1841,¹ which have their feet normally constructed;
3. *Strisores*, a group now separated from the *Clamatores* of Wagner, and containing those forms which have their feet abnormally constructed; and
4. *Scansores*, being the *Grinpeurs* of Cuvier, the *Zygodactyli* of several other systematists.

The first of these four "Orders" had been already indefensibly established as one perfectly natural, but respecting its details more must presently be said. The remaining three are now seen to be obviously artificial associations, and the second of them, *Clamatores*, in particular, containing a very heterogeneous assemblage of forms, but it must be borne in mind that the internal structure of some of them was at that time still more imperfectly known than now. Yet even then enough had been ascertained to have saved what are now recognized as the Families *Todidæ* and *Tyrannidæ* from being placed as "Subfamilies" in the same "Family *Coleopteridæ*"; and several other instances of unharmonious combination in this "Order" might be adduced were it worth while to particularize them. More than that, it would not be difficult to shew, only the present is not exactly the place for it, that some groups or Families which in reality are not far distant from one another are distributed, owing to the dissimilarity of their external characters, throughout these three Orders. Thus the *Podarginæ* are associated with the *Ceraciidæ* under the head *Clamatores*, while the *Caprimulgidæ*, to which they are clearly most allied, if they do not form part of that Family (GOATSUCKER, vol. x. p. 711), are placed with the *Strisores*; and again the *Musophagidæ* also stand as *Strisores*, while the *Cuculidæ*, which modern systematists think to be their nearest relations, are considered to be *Scansores*.

But to return to the *Oscines*, the arrangement of which in the classification now under review has been deemed its greatest merit, and consequently has been very generally followed. That by virtue of the perfection of their vocal organs, and certain other properties—though some of these last have perhaps never yet been made clear enough—they should stand at the head of the whole Class, may here be freely admitted, but the respective rank assigned to the various component Families of the group is certainly open to question, and to the present writer seems, in the methods of several systematists, to be based upon a fallacy. This respective rank of the different Families appears to have been assigned on the principle that, since by reason of one character (namely, the more complicated structure of their syrinx) the *Oscines* form a higher group than the *Clamatores*, therefore all the concomitant features which the former possess and the latter do not must be equally indicative of superiority. Now one of the features in which most of the *Oscines* differ from the lower "Order" is the having a more or less undivided *planta*, and accordingly it has been assumed that the Family of *Oscines* in which this modification of the *planta* is carried to its extreme point must be the highest of that "Order." Since, therefore, this extreme modification of the *planta* is

exhibited by the Thrushes and their allies, it is alleged that they must be placed first, and indeed at the head of all Birds. The groundlessness of this reasoning ought to be apparent to everybody. In the present state of anatomy at any rate, it is impossible to prove that there is more than a coincidence in the facts just stated, and in the association of two characters—one deeply seated and affecting the whole life of the Bird, the other superficially, and so far as we can perceive without effect upon its organism. Because the *Clamatores*, having no song-muscles, have a divided *planta*, it cannot be logical to assume that among the *Oscines*, which possess song-muscles, such of them as have an undivided *planta* must be higher than those that have it divided. The argument, if it can be called an argument, is hardly one of analogy; and yet no stronger ground has been occupied by those who invest the Thrushes, as do the majority of modern systematists, with the most dignified position in the whole Class. But passing from general to particular considerations, so soon as a practical application of the principle is made its inefficacy is manifest. The test of perfection of the vocal organs must be the perfection of the notes they enable their possessor to utter. There cannot be a question that, sing admirably as do some of the Birds included among the Thrushes,² the Larks, as a Family, infinitely surpass them. Yet the Larks form the very group which, as has been already shewn (LARK, vol. xiv. p. 314), have the *planta* more divided than any other among the *Oscines*. It seems hardly possible to adduce anything that would more conclusively demonstrate the independent nature of each of these characters—the complicated structure of the syrinx and the asserted inferior formation of the *planta*—which are in the *Alaudidæ* associated.³ Moreover, this same Family affords a very valid protest against the extreme value attached to the presence or absence of the outermost quill-feather of the wings, and in this work it has been before shewn (*ut supra*) that almost every stage of magnitude in this feather is exhibited by the Larks from its rudimentary or almost abortive condition in *Alauda arvensis* to its very considerable development in *Melanocorypha calandra*. Indeed there are many genera of *Oscines* in which the proportion that the outermost primary bears to the rest is at best but a specific character, and certain exceptions are allowed by Prof. Cabanis (p. 313) to exist. Some of them it is now easy to explain, inasmuch as in a few cases the apparently aberrant genera have elsewhere found a more natural position, a contingency to which he himself was fully awake. But as a rule the allocation and ranking of the different Families of *Oscines* by this author must be deemed arbitrary.⁴ Yet the value of his *Ornithologische Notizen* is great, not only as evidence of his extraordinarily extensive acquaintance with different forms, which is proclaimed in every page, but in leading to a far fuller appreciation of characters that certainly should on no account be neglected, though

² Prof. Cabanis would have strengthened his position had he included in the same Family with the Thrushes, which he called *Rhacnemidæ*, the Birds commonly known as Warblers, *Sylviidæ*, which the more advanced of recent systematists are inclined with much reason to unite with the Thrushes, *Turdidæ*; but instead of that he, trusting to the placard character, segregated the Warblers, including of course the Nightingale, and did not even allow them the second place in his method, putting them below the Family called by him *Sylvicolidæ*, consisting chiefly of the American forms now known as *Amniotiltidæ*, none of which as songsters approach those of the Old World.

³ It must be observed that Prof. Cabanis does not place the *Alaudidæ* lowest of the seventeen Families of which he makes the *Oscines* to be composed. They stand eleventh in order, while the *Corvidæ* are last—a matter on which something has to be said in the sequel.

⁴ By a curious error, probably of the press, the number of primaries assigned to the *Paradisidæ* and *Corvidæ* is wrong (pp. 334, 335). In each case 10 should be substituted for 19 and 14.

¹ *Archiv für Naturgeschichte*, vii. 2, pp. 93, 94. The division seems to have been instituted by this author a couple of years earlier in the second edition of his *Handbuch der Naturgeschichte* (a work not seen by the present writer), but not then to have received a scientific name. It included all *Picariæ* which had not "zygodactylous" feet, that is to say, toes placed in pairs, two before and two behind.

too much importance may easily be, and already has been, assigned to them.¹

This will perhaps be the most convenient place to mention another kind of classification of Birds, which, based on a principle wholly different from those that have just been explained, requires a few words, though it has not been productive, nor is likely, from all that appears, to be productive of any great effect. So long ago as 1831, BONAPARTE, in his *Saggio di una distribuzione metodica degli Animali Vertebrati*, published at Rome, and in 1837 communicated to the Linnean Society of London, "A new Systematic Arrangement of Vertebrated Animals," which was subsequently printed in that Society's *Transactions* (xviii. pp. 247-304), though before it appeared there was issued at Bologna, under the title of *Synopsis Vertebratorum Systematis*, a Latin translation of it. Herein he divided the Class *Aves* into two Subclasses, to which he applied the names of *Insectorum* and *Grallatorum* (hitherto used by their inventors Vigors and Illiger in a different sense), in the latter work relying chiefly for this division on characters which had not before been used by any systematist, namely, that in the former group Monogamy generally prevailed and the helpless nestlings were fed by their parents, while the latter group were mostly Polygamous, and the chicks at birth were active and capable of feeding themselves. This method, which in process of time was dignified by the title of a Physiological Arrangement, was insisted upon with more or less pertinacity by the author throughout a long series of publications, some of them separate books, some of them contributed to the memoirs issued by many scientific bodies of various European countries, ceasing only at his death, which in July 1857 found him occupied upon a *Conspectus Generum Avium*, that in consequence remains unfinished (see p. 14). In the course of this series, however, he saw fit to alter the name of his two Subclasses, since those which he at first adopted were open to a variety of meanings, and in a communication to the French Academy of Sciences in 1853 (*Comptes Rendus*, xxxvii. pp. 641-647) the denomination *Insectorum* was changed to *Alliaces*, and *Grallatores* to *Præcoes*—the terms now preferred by him being taken from Sundevall's treatise of 1835 already mentioned. The views of Bonaparte were, it appears, also shared by an ornithological amateur of some distinction, HOGG, who propounded a scheme which, as he subsequently stated (*Zoologist*, 1850, p. 2797), was founded strictly in accordance with them; but it would seem that, allowing his convictions to be warped by other considerations, he abandoned the original "physiological" basis of his system, so that this, when published in 1846 (*Edinb. N. Philosoph. Journal*, xli. pp. 50-71), was found to be established on a single character of the feet only; though he was careful to point out, immediately after formulating the definition of his Subclasses *Constrictipedes* and *Inconstrictipedes*, that the former "make, in general, compact and well-built nests, wherein they bring up their very weak, blind, and mostly naked young, which they feed with care, by bringing food to them for many days, until they are fledged and sufficiently strong to leave their nest," observing also that they "are principally monogamous" (pp. 55, 56); while of the latter he says that they "make either a poor and rude nest, in which they lay their eggs, or else none, depositing them on the bare ground. The young are generally born with their full sight, covered with down, strong, and capable of running or swimming immediately after they leave the egg-shell." He adds that the parents, which "are mostly polygamous," attend their young and direct them where to find their food (p. 63). The numerous errors in these assertions hardly need pointing out. The Herons, for instance, are much more "*Constrictipedes*" than are the Larks or the Kingfishers, and, so far from the majority of "*Inconstrictipedes*" being polygamous, there is scarcely any evidence of polygamy obtaining as a habit among Birds in a state of nature except in certain of the *Gallinæ* and a very few others. Furthermore, the young of the Goatsuckers are at hatching far more developed than are those of the Herons or the Cormorants; and, in a general way, nearly every one of the asserted peculiarities of the two Subclasses breaks down under careful examination. Yet the idea of a "physiological" arrangement on the same kind of principle found another follower, or, as he thought, inventor, in NEWMAN, who in 1850 communicated to the Zoological Society of London a plan published in its *Proceedings* for that year (pp. 46-45), and reprinted also in his own journal *The Zoologist* (pp. 2780-2782), based on exactly the same considerations, dividing Birds into two groups, "Hæstogenous"—a word so vicious in formation as to be incapable of amendment, but intended to signify those that were hatched with a clothing of down—and "Gymnogenous," or those that were hatched naked. These three systems are essentially identical; but, plausible as they may be at

the first aspect, they have been found to be practically useless, though such of their characters as their upholders have advanced with truth deserve attention. Physiology may one day very likely assist the systematist; but it must be real physiology and not a sham.

In 1856 Prof. GÉRAVAIN, who had already contributed to the *Zoologie* of M. de Castelnau's *Expédition dans les parties centrales de l'Amérique du Sud* some important memoirs describing the anatomy of the HOACTZIN (vol. xii. p. 28) and certain other Birds of doubtful or anomalous position, published some remarks on the characters which could be drawn from the sternum of Birds (*Ann. Sc. Nat. Zoologie*, ser. 4, vi. pp. 5-15). The considerations are not very striking from a general point of view; but the author adds to the weight of evidence which some of his predecessors had brought to bear on certain matters, particularly in aiding to abolish the artificial groups "Déodactyls," "Syndactyls," and "Zygodactyls," on which so much reliance had been placed by many of his countrymen; and it is with him a great merit that he was the first apparently to recognize publicly that characters drawn from the posterior part of the sternum, and particularly from the "*échancrures*," commonly called in English "notches" or "emarginations," are of comparatively little importance, since their number is apt to vary in forms that are most closely allied, and even in species that are usually associated in the same genus or unquestionably belong to the same Family,² while these "notches" sometimes become simple *foramina*, as in certain Pigeons, or on the other hand *foramina* may exceptionally change to "notches," and not unfrequently disappear wholly. Among his chief systematic determinations we may mention that he refers the Timminous to the Rails, because apparently of their deep "notches," but otherwise takes a view of that group more correct according to modern notions than did most of his contemporaries. The Bustards he would place with the "Limicoles," as also *Dromas* and *Chionis*, the SHEATH-BILL (*g.v.*) *Phaethon*, the TROPIC-BIRD (*g.v.*), he would place with the "Laridés" and not with the "Pelicanidés," which it only resembles in its feet having all the toes connected by a web. Finally Divers, Auks, and Penguins, according to him, form the last term in the series, and it seems fit to him that they should be regarded as forming a separate Order. It is a curious fact that even at a date so late as this, and by an investigator so well informed, doubt shou'd still have existed whether *Apteryx* (KIWI, vol. xiv. p. 104) should be referred to the group containing the Cassowary and the Ostrich. On the whole the remarks of this esteemed author do not go much beyond such as might occur to any one who had made a study of a good series of specimens; but many of them are published for the first time, and the author is careful to insist on the necessity of not resting solely on sternal characters, but associating with them those drawn from other parts of the body.

Three years later in the same journal (xi. pp. 11-145, pls. 2-4) BLANCHARD published some *Recherches sur les caractères ostéologiques des Oiseaux appliquées à la Classification naturelle de ces animaux*, strongly urging the superiority of such characters over those drawn from the bill or feet, which, he remarks, though they may have sometimes given correct notions, have mostly led to mistakes, and, if observations of habits and food have sometimes afforded happy results, they have often been deceptive; so that, should more be wanted than to draw up a mere inventory of creation or trace the distinctive outline of each species, zoology without anatomy would remain a barren study. At the same time he states that authors who have occupied themselves with the sternum alone have often produced uncertain results, especially when they have neglected its anterior for its posterior part; for in truth every bone of the skeleton ought to be studied in all its details. Yet this distinguished zoologist selects the sternum as furnishing the key to his primary groups or "Orders" of the Class, adopting, as Merrem had done long before, the same two divisions *Carinata* and *Ratita*, naming, however, the former *Tropidosternii* and the latter *Homalosternii*.³ Some unkind fate has hitherto hindered him from making known to the world the rest of his researches in regard to the other bones of the skeleton till he reached the head, and in the memoir cited he treats of the sternum of only a portion of his first "Order." This is the more to be regretted by all ornithologists, since he intended to conclude with what to them would have been a very great boon—the shewing in what way external characters coincided with those presented by Osteology. It was also within the scope of his plan to have continued on a more extended scale the researches on ossification begun by L'Hermier, and thus M.

² Thus he cites the cases of *Machetes pugnax* and *Scolopax rusticola* among the "Limicoles," and *Larus catartæ* among the "Laridés," as differing from their nearest allies by the possession of only one "notch" on either side of the keel. Several additional instances are cited in *Philos. Transactions*, 1869, p. 337, note.

³ These terms were explained in his great work *L'Organisation du Règne Animal, Oiseaux* (p. 16), begun in 1855, and still (1884) no further advanced than its fourth part, comprehending in all but thirty-two pages of letter-press, to mean exactly the same as those applied by Merrem to his two primary divisions.

¹ A much more extensive and detailed application of his method was begun by Prof. Cabanis in the *Museum Hœneanum*, a very useful catalogue of specimens in the collection of Herr Oberamtmann Helze, of which the first part was published at Halberstadt in 1850, and the last which has appeared, the work being still unfinished, in 1863.

Blanchard's investigations, if completed, would obviously have taken extraordinarily high rank among the highest contributions to ornithology. As it is, so much of them as we have are of considerable importance; for, in this unfortunately unfinished memoir, he describes in some detail the several differences which the sternum in a great many different groups of his *Tropidosternii* presents, and to some extent makes a methodical disposition of them accordingly. Thus he separates the Birds-of-Prey into three great groups—(1) the ordinary Diurnal forms, including the *Falconidae* and *Vulturidae* of the systematist of his time, but distinguishing the American Vultures from those of the Old World; (2) *Gypogoranus*, the SECRETARY-BIRD (*q.v.*); and (3) the Owls (*infra*, p. 83). Next he places the PARROTS (*q.v.*), and then the vast assemblage of "Passereaux"—which he declares to be all of one type, even genera like *Pipra* (MANAKIN, vol. xv. p. 455) and *Pitta*—and concludes with the somewhat heterogeneous conglomeration of forms, beginning with *Cypselus* (SWIFT, *q.v.*), that so many systematists have been accustomed to call *Picariæ*, though to them as a group he assigns no name. A continuation of the treatise was promised in a succeeding part of the *Annales*, but a quarter of a century has passed without its appearance.¹

Important as are the characters afforded by the sternum, that bone even with the whole sternal apparatus should obviously not be considered alone. To aid ornithologists in their studies in this respect, EYTON, who for many years had been forming a collection of Birds' skeletons, began the publication of a series of plates representing them. The first part of this work, *Osteologia Avium*, appeared early in 1859, and a volume was completed in 1867. A Supplement was issued in 1869, and a Second Supplement, in three parts, between 1873 and 1875. The whole work contains a great number of figures of Birds' skeletons and detached bones; but they are not so drawn as to be of much practical use, and the accompanying letter-press is too brief to be satisfactory.

That the eggs laid by Birds should offer to some extent characters of utility to systematists is only to be expected, when it is considered that those from the same nest generally bear an extraordinary family-likeness to one another, and also that in certain groups the essential peculiarities of the egg-shell are constantly and distinctively characteristic. Thus no one who has ever examined the egg of a Duck or of a Tinamou would ever be in danger of not referring another Tinamou's egg or another Duck's, that he might see, to its proper Family, and so on with many others. Yet, as has been stated on a former occasion (BIRDS, vol. iii. p. 772), the expectation held out to oologists, and by them, of the benefits to be conferred upon Systematic Ornithology from the study of Birds' eggs, so far from being fulfilled, has not unfrequently led to disappointment. But at the same time many of the shortcomings of Oology in this respect must be set down to the defective information and observation of its votaries, among whom some have been very lax, not to say incautious, in not ascertaining on due evidence the parentage of their specimens, and the author next to be named is open to this charge. After several minor notices that appeared in journals at various times, Des Murs in 1860 brought out at Paris his ambitious *Traité général d'Oologie Ornithologique au point de vue de la Classification*, which contains (pp. 529-538) a "Systema Oologicum" as the final result of his labours. In this scheme Birds are arranged according to what the author considered to be their natural method and sequence; but the result exhibits some unions as ill-assorted as can well be met with in the whole range of tentative arrangements of the Class, together with some very unjustifiable divorces. Its basis is the classification of Cuvier, the modifications of which by Des Murs will seldom commend themselves to systematists whose opinion is generally deemed worth having. Few, if any, of the faults of that classification are removed, and the improvements suggested, if not established by his successors, those especially of other countries than France, are ignored, or, as is the case with some of those of L'Herminier, are only cited to be set aside. Oologists have no reason to be thankful to Des Murs, notwithstanding his zeal in behalf of their study. It is perfectly true that in several or even in many instances he acknowledges and deprecates the poverty of his information, but this does not excuse him for making assertions (and such assertions are not unfrequent) based on evidence that is either wholly untrustworthy or needs further enquiry before it can be accepted (*Ibis*, 1860, pp. 331-335). This being the case, it would seem useless to take up further space by analysing the several proposed modifications of Cuvier's arrangement. The great merit of the work is that the author shews the necessity of taking Oology into account when investigating the classification of Birds; but it also proves that in so doing the paramount consideration lies in the thorough sifting of evidence as to the parentage of the eggs which are to serve as the building stones of the fabric to be erected. The attempt of Des Murs was

praiseworthy; but in effect it has utterly failed, notwithstanding the encomiums passed upon it by friendly critics (*Rev. de Zoologie*, 1860, pp. 176-183, 313-325, 370-373).²

Until about this time systematists, almost without exception, may be said to have been wandering with no definite purpose. At least their purpose was indefinite compared with that which they now have before them. No doubt they all agreed in saying that they were prosecuting a search for what they called the True System of Nature; but that was nearly the end of their agreement, for in what that True System consisted the opinions of scarcely any two would coincide, unless to own that it was some shadowy idea beyond the present power of mortals to reach or even comprehend. The Quinarians, who boldly asserted that they had fathomed the mystery of Creation, had been shewn to be no wiser than other men, if indeed they had not utterly befooled themselves; for their theory at best could give no other explanation of things than that they were because they were. The conception of such a process as has now come to be called by the name of Evolution was certainly not novel; but except to two men the way in which that process was or could be possible had not been revealed.³ Here there is no need to enter into details of the history of Evolution; but the annalist in every branch of Biology must record the eventful 1st of July 1858, when the now celebrated views of DARWIN and Mr WALLACE were first laid before the scientific world,⁴ and must also notice the appearance towards the end of the following year of the former's *Origin of Species*, which has effected the greatest revolution of human thought in this or perhaps in any century. The majority of biologists who had schooled themselves on other principles were of course slow to embrace the new doctrine; but their hesitation was only the natural consequence of the caution which their scientific training enjoined. A few there were who felt as though scales had suddenly dropped from their eyes, when greeted by the idea conveyed in the now familiar phrase "Natural Selection"; but even those who had hitherto believed, and still continued to believe, in the sanctity of "Species" at once perceived that their life-long study had undergone a change, that their old position was seriously threatened by a perilous siege, and that to make it good they must find new means of defence. Many bravely maintained their posts, and for them not a word of blame ought to be expressed. Some few pretended, though the contrary was notorious, that they had always been on the side of the new philosophy, so far as they allowed it to be philosophy at all, and for them hardly a word of blame is too severe. Others after due deliberation, as became men who honestly desired the truth and nothing but the truth, yielded wholly or almost wholly to arguments which they gradually found to be irresistible. But, leaving generalities apart, and restricting ourselves to what is here our proper business, there was possibly no branch of Zoology in which so many of the best informed and consequently the most advanced of its workers sooner accepted the principles of Evolution than Ornithology, and of course the effect upon its study was very marked. New spirit was given to it. Ornithologists now felt they had something before them that was really worth investigating. Questions of Affinity, and the details of Geographical Distribution, were endowed with a real interest, in comparison with

² In this historical sketch of the progress of Ornithology it has not been thought necessary to mention other oological works, since they have not a taxonomic bearing, and the chief of them have been already named (BIRDS, vol. iii. p. 774, note 1).

³ Neither Lamarck nor Robert Chambers (the now acknowledged author of *Vestiges of Creation*), though thorough evolutionists, rationally indicated any means whereby, to use the old phrase, "the transmutation of species" could be effected.

Eyton.

Darw
and
Wallac

¹ M. Blanchard's animadversions on the employment of external characters, and on trusting to observations on the habits of Birds, called forth a rejoinder from Mr Wallace (*Ibis*, 1864, pp. 36-41), who successfully shewed that they are not altogether to be despised.

which any interest that had hitherto been taken was a trifling pastime. Classification assumed a wholly different aspect. It had up to this time been little more than the shuffling of cards, the ingenious arrangement of counters in a pretty pattern. Henceforward it was to be the serious study of the workings of Nature in producing the beings we see around us from beings more or less unlike them, that had existed in bygone ages and had been the parents of a varied and varying offspring—our fellow-creatures of to-day. Classification for the first time was something more than the expression of a fancy, not that it had not also its imaginative side. Men's minds began to figure to themselves the original type of some well-marked genus or Family of Birds. They could even discern dimly some generalized stock whence had descended whole groups that now differed strangely in habits and appearance—their discernment aided, may be, by some isolated form which yet retained undeniable traces of a primitive structure. More dimly still visions of what the first Bird may have been like could be reasonably entertained; and, passing even to a higher antiquity, the Reptilian parent whence all Birds have sprung was brought within reach of man's consciousness. But, relieved as it may be by reflexions of this kind—dreams some may perhaps still call them—the study of Ornithology has unquestionably become harder and more serious; and a corresponding change in the style of investigation, followed in the works that remain to be considered, will be immediately perceptible.

That this was the case is undeniably shewn by some remarks of Canon TRISTRAM, who, in treating of the *Alaudidæ* and *Saxicolinæ* of Algeria (whence he had recently brought a large collection of specimens of his own making), stated (*Ibis*, 1859, pp. 429-433) that he could "not help feeling convinced of the truth of the views set forth by Messrs Darwin and Wallace," adding that it was "hardly possible, I should think, to illustrate this theory better than by the Larks and Chats of North Africa." It is unnecessary to continue the quotation; the few words just cited are enough to assure to their author the credit of being (so far as is known) the first ornithological specialist who had the courage publicly to recognize and receive the new and at that time unpopular philosophy.¹ But greater work was at hand. In June 1860 Prof. PARKER broke, as most will allow, entirely fresh ground, and ground that he has since continued to till more deeply perhaps than any other zoologist, by communicating to the Zoological Society a memoir "On the Osteology of *Balaniceps*," subsequently published in that Society's *Transactions* (iv. pp. 269-351). Of this contribution to science, as of all the rest which have since proceeded from him, may be said in the words he himself has applied (*ut supra*, p. 271) to the work of another labourer in a not distant field:—"This is a model paper for unbiased observation, and freedom from that pleasant mode of *supposing* instead of *ascertaining* what is the true nature of an anatomical element."² Indeed the study of this memoir, limited though it be in scope, could not fail to convince any one that it proceeded from the mind of one who taught with the authority derived directly from original knowledge, and not from association with the scribes—a conviction that has become strengthened as, in a series of successive memoirs, the stores of more than twenty years' silent observation and unremitting research

were unfolded, and, more than that, the hidden forces of the science of Morphology were gradually brought to bear upon almost each subject that came under discussion. These different memoirs, being technically monographs, have strictly no right to be mentioned in this place; but there is scarcely one of them, if one indeed there be, that does not deal with the generalities of the study; and the influence they have had upon contemporary investigation is so strong that it is impossible to refrain from noticing them here, though want of space forbids us from enlarging on their contents.³ Moreover, the doctrine of Descent with variation is preached in all—seldom, if ever, conspicuously, but perhaps all the more effectively on that account. There is no reflective thinker but must perceive that Morphology is the lamp destined to throw more light than that afforded by any other kind of study on the obscurity that still shrouds the genealogy of Birds as of other animals; and, though as yet its illuminating power is admittedly far from what is desired, it has perhaps never shone more brightly than in Prof. Parker's hands. The great fault of his series of memoirs, if it may be allowed the present writer to criticize them, is the indifference of their author to formulating his views, so as to enable the ordinary taxonomer to perceive how far he has got, if not to present him with a fair scheme. But this fault is possibly one of those that are "to merit near allied," since it would seem to spring from the author's hesitation to pass from observation to theory, for to theory at present belong, and must for some time belong, all attempts at Classification. Still it is not the less annoying and disappointing to the systematist to find that the man whose life-long application would enable him, better than any one else, to declare the effect of the alliances and differences that have been shewn to exist among various members of the Class should yet be so reticent, or that when he speaks he should rather use the language of Morphology, which those who are not morphologists find difficult of correct interpretation, and wholly inadequate to allow of zoological deductions.⁴

¹ It may be convenient to our readers that a list of Prof. Parker's works which treat of ornithological subjects, in addition to the two above mentioned, should here be given. They are as follows:—In the Zoological Society's *Transactions*, 25th November 1862, "On the Osteology of the Gallinaceous Birds and Tinamous," v. pp. 149-241; 12th December 1865, "On some fossil Birds from the Zebbug Cave," vi. pp. 119-124; 9th January 1868, "On the Osteology of the Kagu," vi. pp. 501-521; 18th February 1873, "On the *Agithognathous* Birds," Pt. I. ix. pp. 289-352; 15th February 1876, "On the Skull of the *Agithognathous* Birds," Pt. II. x. pp. 251-314. In the *Proceedings* of the same Society, 8th December 1863, "On the systematic position of the Crested Screecher," pp. 511-518; 25th February 1865, "On the Osteology of *Microglossa alcyon*," pp. 235-238. In the *Philosophical Transactions of the Royal Society*, 9th March 1865, "On the Structure and Development of the Skull in the Ostrich Tribe," pp. 113-183; 11th February 1869, "On the Structure and Development of the Skull of the Common Fowl," pp. 755-807. In the Linnean Society's *Transactions*, 2d April 1874, "On the Morphology of the Skull in the Woodpeckers and Wrynecks," ser. 2, Zoology, i. pp. 1-22; 16th December 1875, "On the Structure and Development of the Bird's Skull," *tom. cit.*, pp. 99-154. In the *Monthly Microscopical Journal* for 1872, "On the Structure and Development of the Crow's Skull," pp. 217-253; for 1873, "On the Development of the Skull in the genus *Turdus*," pp. 102-107, and "On the Development of the Skull in the Tit and Sparrow Hawk," parts i. and ii., pp. 6-11, 45-50. There is besides the great work published by the Ray Society in 1868, *A Monograph on the Structure and Development of the Shoulder-girdle and Sternum*, of which pp. 142-191 treat of these parts in the Class *Aves*; and our readers will hardly need to be reminded of the article *BIRDS* in the present work (vol. iii. pp. 699-728). Nearly every one of this marvellous series of contributions is copiously illustrated by plates from drawings made by the author himself.

² As an instance, take the passages in which *Turnix* and *Thinocorus* are apparently referred to the *Agithognathæ* (*Trans. Zool. Society*, ix. pp. 291 *et seq.*; and *supra*, vol. iii. p. 700), a view which, as shewn by the author (*Transactions*, x. p. 310), is not that really intended by him.

¹ Whether Canon Tristram was anticipated in any other, and if so in what, branch of Zoology will be a pleasing inquiry for the historian of the future.

² It is fair to state that some of Prof. Parker's conclusions respecting *Balaniceps* were contested by the late Prof. J. T. Reinhardt (*Overs. K. D. Vid. Selsk. Forhandling*, 1861, pp. 135-154; *Ibis*, 1862, pp. 158-175), and as it seems to the present writer not ineffectually. Prof. Parker replied to his critic (*Ibis*, 1862, pp. 297-299).

For some time past rumours of a discovery of the highest interest had been agitating the minds of zoologists, for in 1861 ANDREAS WAGNER had sent to the Academy of Sciences of Munich (*Sitzungsberichte*, pp. 146-154; *Ann. Ndt. History*, ser. 3, ix, pp. 261-267) an account of what he conceived to be a feathered Reptile (assigning to it the name *Griphosaurus*), the remains of which had been found in the lithographic beds of Solenhofen; but he himself, through failing health, had been unable to see the fossil. In 1862 the slabs containing the remains were acquired by the British Museum, and towards the end of that year Sir R. OWEN communicated a detailed description of them to the *Philosophical Transactions* (1863, pp. 33-47), proving their Bird-like nature, and referring them to the genus *Archæopteryx* of Hermann von Meyer, hitherto known only by the impression of a single feather from the same geological beds. Wagner foresaw the use that would be made of this discovery by the adherents of the new Philosophy, and, in the usual language of its opponents at the time, strove to ward off the "misinterpretations" that they would put upon it. His protest, it is needless to say, was unavailing, and all who respect his memory must regret that the sunset of life failed to give him that insight into the future which is poetically ascribed to it. To Darwin and those who believed with him scarcely any discovery could have been more welcome; but that is beside our present business. It was quickly seen—even by those who held *Archæopteryx* to be a Reptile—that it was a form intermediate between existing Birds and existing Reptiles—while those who were convinced by Sir R. Owen's researches of its ornithic affinity saw that it must belong to a type of Birds wholly unknown before, and one that in any future for the arrangement of the Class must have a special rank reserved for it.¹ It has been already briefly described and figured in this work (BIRDS, vol. iii, pp. 728, 729).

It behoves us next to mention the "Outlines of a Systematic Review of the Class of Birds," communicated by Prof. LILLJEBORG to the Zoological Society in 1866, and published in its *Proceedings* for that year (pp. 5-20), since it was immediately after reprinted by the Smithsonian Institution, and with that authorization has exercised a great influence on the opinions of American ornithologists. Otherwise the scheme would hardly need notice here. This paper is indeed little more than an English translation of one published by the author in the annual volume (*Årsskrift*) of the Scientific Society of Upsala for 1860, and belonging to the pre-Darwinian epoch should perhaps have been more properly treated before, but that at the time of its original appearance it failed to attract attention. The chief merit of the scheme perhaps is that, contrary to nearly every precedent, it begins with the lower and rises to the higher groups of Birds, which is of course the natural mode of proceeding, and one therefore to be commended. Otherwise the "principles" on which it is founded are not clear to the ordinary zoologist. One of them is said to be "irritability," and, though this is explained to mean, not "muscular strength alone, but vivacity and activity generally,"² it does not seem to form a character that can be easily appreciated either as to quantity or quality; in fact, most persons would deem it quite immeasurable, and, as such, removed from practical consideration. Moreover, Prof. Lilljeborg's scheme, being actually an adaptation of that of Sundevall, of which we shall have to speak at some length almost immediately, may possibly be left for the present with these remarks.

In the spring of the year 1867 Prof. HUXLEY, to the delight of an appreciative audience, delivered at the Royal College of Surgeons of England a course of lectures on Birds, and it is much to be regretted that his many engagements hindered him from publishing in its entirety his elucidation of the anatomy of the Class, and the results

which he drew from his investigations of it; for never assuredly had the subject been attacked with greater skill and power, or, since the days Buffon, had Ornithology been set forth with greater eloquence. To remedy, in some degree, this unavoidable loss, and to preserve at least a portion of the fruits of his labours, Prof. Huxley, a few weeks after, presented an abstract of his researches to the Zoological Society, in whose *Proceedings* for the same year it will be found printed (pp. 415-472) as a paper "On the Classification of Birds, and on the taxonomic value of the modifications of certain of the cranial bones observable in that Class." Starting from the basis (which, undeniably true as it is, not a little shocked many of his ornithological hearers) "that the phrase 'Birds are greatly modified Reptiles' would hardly be an exaggerated expression of the closeness" of the resemblance between the two Classes, which he had previously brigaded under the name of *Sauropsida* (as he had brigaded the *Pisces* and *Amphibia* as *Ichthyopsida*), he drew in bold outline both their likenesses and their differences, and then proceeded to inquire how the *Aves* could be most appropriately subdivided into Orders, Suborders, and Families. In this course of lectures he had already dwelt at some length on the insufficiency of the characters on which such groups as had hitherto been thought to be established were founded; but for the consideration of this part of his subject there was no room in the present paper, and the reasons why he arrived at the conclusion that new means of philosophically and successfully separating the Class must be sought are herein left to be inferred. The upshot, however, admits of no uncertainty: the Class *Aves* is held to be composed of three "Orders"—(I.) SAURURÆ, Hæckel; (II.) RATITÆ, Merrem; and (III.) CARINATÆ, Merrem. The *Saururæ* have the metacarpals well developed and not ancylosed, and the caudal vertebræ are numerous and large, so that the caudal region of the spine is longer than the body. The furcula is complete and strong, the feet very Passerine in appearance. The skull and sternum were at the time unknown, and indeed the whole Order, without doubt entirely extinct, rested exclusively on the celebrated fossil, then unique, *Archæopteryx* (BIRDS, vol. iii, pp. 728, 729). The *Ratitæ* comprehend the Struthious Birds, which differ from all others now extant in the combination of several peculiarities, some of which have been mentioned in the preceding pages. The sternum has no keel, and ossifies from lateral and paired centres only; the axes of the scapula and coracoid have the same general direction; certain of the cranial bones have characters very unlike those possessed by the next Order—the vomer, for example, being broad posteriorly and generally intervening between the basisphenoidal rostrum and the palatals and pterygoids; the barbs of the feathers are disconnected; there is no syrinx or inferior larynx; and the diaphragm is better developed than in other Birds.³ The *Ratitæ* are divided into five groups, separated by very trenchant characters, principally osteological, and many of them afforded by the cranial bones. These groups consist of (i.) *Struthio* (OSTRICH, *infra*, p. 62), (ii.) *RHEA* (*q.v.*), (iii.) *Casuarus* and *Dromæus* (ÉMEU, vol. viii. 171), (iv.) *Dinornis*, and (v.) *Apteryx* (KIWI, vol. xiv. p. 104); but no names are here given to them. The *Carinatæ* comprise all other existing Birds. The sternum has more or less of a keel, and is said to ossify, with the possible exception of *Strigops* (KAKAPO, vol. xiii. p. 825), from a median centre as well as from paired and lateral centres. The axes of the scapula and coracoid meet at an acute, or, as in *Didus* (DODO, vol. vii. p. 321) and *Ocydromus* (OCYDROME, vol. xvii. p. 222), at a slightly obtuse angle, while the vomer is

¹ This was done shortly afterwards by Prof. Hæckel, who proposed the name *Saururæ* for the group containing it.

² On this ground it is stated that the *Passeres* should be placed highest in the Class. But those who know the habits and demeanour of many of the *Limicolæ* would no doubt rightly claim for them much more "vivacity and activity" than is possessed by most *Passeres*.

³ This peculiarity had led some zoologists to consider the Struthious Birds more nearly allied to the *Mammalia* than any others.

comparatively narrow and allows the pterygoids and palatals to articulate directly with the basisphenoidal rostrum. The *Carinatae* are divided, according to the formation of the palate, into four "Suborders," and named (i.) *Dromæognathæ*, (ii.) *Schizognathæ*, (iii.) *Desmognathæ*, and (iv.) *Ægithognathæ*.¹ The *Dromæognathæ* resemble the *Ratitæ*, and especially the genus *Dromæus*, in their palatal structure, and are composed of the TINAMOUS (*q.v.*). The *Schizognathæ* include a great many of the forms belonging to the Linnæan Orders *Gallinæ*, *Grallæ*, and *Anseres*. In them the vomer, however variable, always tapers to a point anteriorly, while behind it includes the basisphenoidal rostrum between the palatals; but neither these nor the pterygoids are borne by its posterior divergent ends. The maxillo-palatals are usually elongated and lamellar, uniting with the palatals, and, bending backward along their inner edge, leave a cleft (whence the name given to the "Suborder") between the vomer and themselves. Six groups of *Schizognathæ* are distinguished with considerable minuteness:—(1) *Charadriomorphæ*, containing *Charadriidæ* (PLOVER, *q.v.*), *Otididæ* (BUSTARD, vol. iv. p. 578), and *Scolopacidæ*; (2) *Geranomorphæ*, including *Gruidæ* (CRANE, vol. vi. p. 546) and *Rallidæ*, between which *Psophiidæ* and *Rhinocetidæ* are intermediate, while the *SERIEMA* (*q.v.*) would also seem to belong here; (3) *Cecomorphæ*, comprising *Laridæ* (GULL, vol. xi. p. 274), *Procellariidæ* (PETREL, *q.v.*), *Colymbidæ* (DIVER, vol. vii. p. 292), and *Alcidæ* (GUILLEMOT, vol. xi. p. 262); (4) *Spheniscomorphæ*, composed of the PENGUINS (*q.v.*); (5) *Alectoromorphæ* (FOWL, vol. ix. p. 491), being all the *Gallinæ* except the Tinamous; and finally (6) *Peristeromorphæ*, consisting of the DOVES (vol. vii. p. 379) and PIGEONS (*q.v.*). In the third of these Suborders, the *Desmognathæ*, the vomer is either abortive or so small as to disappear from the skeleton. When it exists it is always slender, and tapers to a point anteriorly. The maxillo-palatals are bound together (whence the name of the "Suborder") across the middle line, either directly or by the ossification of the nasal septum. The posterior ends of the palatals and anterior of the pterygoids articulate directly with the rostrum. The groups of *Desmognathæ* are characterized as carefully as are those of the preceding "Suborder," and are as follows:—(1) *Chenomorphæ*, consisting of the *Anatidæ* (DUCK, vol. vii. p. 505; GOOSE, vol. x. p. 777) with *Palamedea*, the SCREAMER (*q.v.*); (2) *Amphimorphæ*, the FLAMINGOES (vol. ix. p. 286); (3) *Pelargomorphæ*, containing the *Ardeidæ* (HERON, vol. xi. p. 760), *Ciconiidæ* (STORK, *q.v.*), and *Tantalidæ*; (4) *Dysporomorphæ*, the CORMORANTS (vol. vi. p. 407), FRIGATE-BIRDS (vol. ix. p. 786), GANNETS (vol. x. p. 70), and PELICANS (*q.v.*); (5) *Actomorphæ*, comprising all the Birds-of-Prey; (6) *Psittacomorphæ*, the PARROTS (*q.v.*); and lastly (7) *Coccygomorphæ*, which are held to include four groups, viz., (a) *Coliidae* (MOUSE-BIRD, vol. xvii. p. 6); (b) *Musophagidæ* (PLANTAIN-EATERS and TOURACOOS, *q.v.*) *Cuculidæ* (CUCKOO, vol. vi. p. 685), *Buconidæ*, *Rhamphastidæ* (TOUCANS, *q.v.*), *Capitonidæ*, *Galbuidæ* (JACAMAR, vol. xiii. p. 531); (c) *Alcedinidæ* (KING-FISHER, xiv. p. 81), *Bucerotidæ* (HORNBILL, xii. p. 169), *Upupidæ* (HOOPOE, xii. p. 154), *Meropidæ*, *Momotidæ* (MOTMOT, xvii. p. 3), *Coraciidæ* (ROLLER, *q.v.*); and (d) *Trogonidæ* (TROGON, *q.v.*). Next in order come the *Celeomorphæ* or WOODPECKERS (*q.v.*), a group respecting the exact position of which Prof. Huxley was uncertain,²

though he inclined to think its relations were with the next group, *Ægithognathæ*, the fourth and last of his "Suborders," characterized by a form of palate in some respects intermediate between the two preceding. The vomer is broad, abruptly truncated in front, and deeply cleft behind, so as to embrace the rostrum of the sphenoid; the palatals have produced postero-external angles; the maxillo-palatals are slender at their origin, and extend obliquely inwards and forwards over the palatals, ending beneath the vomer in expanded extremities, not united either with one another or with the vomer, nor does the latter unite with the nasal septum, though that is frequently ossified. Of the *Ægithognathæ* two divisions are made—(1) *Cypselomorphæ*, including *Trochilidæ* (HUMMING-BIRD, vol. xii. p. 357), *Cypselidæ* (SWIFT, *q.v.*), and *Caprimulgidæ* (GOAT-SUCKER, vol. x. p. 711); and (2) *Coracomorphæ*, which last are separable into two groups, one (a) formed of the genus *Menura* (LYRE-BIRD, vol. xv. p. 115), which then seemed to stand alone, and the other (b) made up of *Polymyodæ*, *Tracheophonæ*, and *Oligomyodæ*, sections founded on the syringeal structure, but declared to be not natural.

The above abstract³ shews the general drift of this very remarkable contribution to Ornithology, and it has to be added that for by far the greater number of his minor groups Prof. Huxley relies solely on the form of the palatal structure, the importance of which Dr Cornay, as already stated (p. 29), had before urged, though to so little purpose. That the palatal structure must be taken into consideration by taxonomers as affording hints of some utility there can no longer be a doubt; but the present writer is inclined to think that the characters drawn thence owe more of their worth to the extraordinary perspicuity with which they have been presented by Prof. Huxley than to their own intrinsic value, and that if the same power had been employed to elucidate in the same way other parts of the skeleton—say the bones of the sternal apparatus or even of the pelvic girdle—either set could have been made to appear quite as instructive and perhaps more so. Adventitious value would therefore seem to have been acquired by the bones of the palate through the fact that so great a master of the art of exposition selected them as fitting examples upon which to exercise his skill.⁴ At the same time it must be stated this selection was not premeditated by Prof. Huxley, but forced itself upon him as his investigations proceeded.⁵ In reply to some critical remarks (*Ibis*, 1868, pp. 85–96), chiefly aimed at shewing the inexpediency of relying solely on one set of characters, especially when those afforded by the palatal bones were not, even within the limits of Families, wholly diagnostic, the author (*Ibis*, 1868, pp. 357–362) announced a slight modification of his original scheme, by introducing three more groups into it, and concluded by indicating how its bearings upon the great question of "Genetic Classification" might be represented so far as the different groups of *Carinatae* are concerned:—

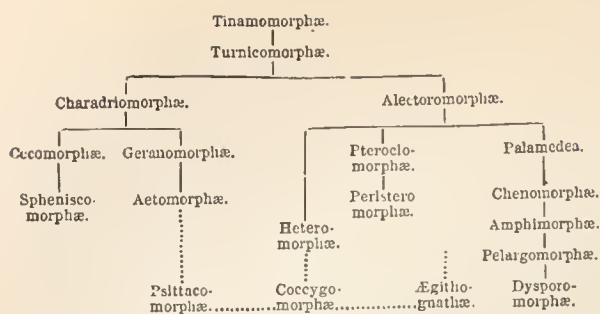

¹ This is adapted from that given in the *Record of Zoological Literature* (iv. pp. 46–49), which is believed to have not inadequately represented the author's views.

² The notion of the superiority of the palatal bones to all others for purposes of classification has pleased many persons, from the fact that these bones are not unfrequently retained in the dried skins of Birds sent home by collectors in foreign countries, and are therefore available for study, while such bones as the sternum and pelvis are rarely preserved. The common practice of ordinary collectors, until at least very recently, has been tersely described to the present writer as being to "shoot a bird, take off its skin, and throw away its characters."

³ Perhaps this may be partially explained by the fact that the Museum of the College of Surgeons, in which these investigations were chiefly carried on, like most other museums of the time, contained a much larger series of the heads of Birds than of their entire skeletons, or of any other portion of the skeleton. Consequently the materials available for the comparison of different forms consisted in great part of heads only.

¹ These names are compounded respectively of *Dromæus*, the generic name applied to the Emeu, *σχιζα*, a split or cleft, *δίσμα*, a bond or tying, *αψιδος*, a Finch, and, in each case, *γράδος*, a jaw.

² Prof. Parker subsequently advanced the Woodpeckers to a higher rank under the name of *Sauvognathæ* (*Monthly Microscop. Journal*, 1872, p. 219, and *Tr. Linn. Soc.*, ser. 2, Zoology, i. p. 2).

The above scheme, in Prof. Huxley's opinion, nearly represents the affinities of the various Carinate groups,—the great difficulty being to determine the relations to the rest of the *Coccygomorphæ*, *Psittacomorphæ*, and *Ægithognathæ*, which he indicated "only in the most doubtful and hypothetical fashion." Almost simultaneously with this he expounded more particularly before the Zoological Society, in whose *Proceedings* (1868, pp. 294–319) his results were soon after published, the groups of which he believed the *Alectoromorphæ* to be composed and the relations to them of some outlying forms usually regarded as Gallinaeous, the *Turnicidæ* and *Pteroclidæ*, as well as the singular *HOACTZIN* (vol. xii. p. 28), for all three of which he had to institute new groups—the last forming the sole representative of his *Heteromorphæ*. More than this, he entered upon their Geographical Distribution, the facts of which important subject are here, almost for the first time, since the attempt of Blyth already mentioned,¹ brought to bear practically on Classification, as has been previously hinted (*BIRDS*, vol. iii. pp. 736, 737); but, that subject having been already treated at some length, there is no need to enter upon it here.

Nevertheless it is necessary to mention here the intimate connexion between Classification and Geographical Distribution as revealed by the palæontological researches of Prof. ALPHONSE MILNE-EDWARDS, whose magnificent *Oiseaux Fossiles de la France* began to appear in 1867, and was completed in 1871—the more so, since the exigencies of his undertaking compelled him to use materials that had been almost wholly neglected by other investigators. A large proportion of the fossil remains the determination and description of which was his object were what are very commonly called the "long bones," that is to say, those of the limbs. The recognition of these, minute and fragmentary as many were, and the referring them to their proper place, rendered necessary an attentive study of the comparative osteology and myology of Birds in general, that of the "long bones," whose sole characters were often a few muscular ridges or depressions, being especially obligatory. Hence it became manifest that a very respectable Classification can be found in which characters drawn from these bones play a rather important part. Limited by circumstances as is that followed by M. Milne-Edwards, the details of his arrangement do not require setting forth here. It is enough to point out that we have in his work another proof of the multiplicity of the factors which must be taken into consideration by the systematist, and another proof of the fallacy of trusting to one set of characters alone. But this is not the only way in which the author has rendered service to the advanced student of Orni-

thology. The unlooked-for discovery in France of remains which he has referred to forms now existing it is true, but existing only in countries far removed from Europe, forms such as *Collocalia*, *Leptosomus*, *Psittacus*, *Serpentarius*, and *Trogon*, is perhaps even more suggestive than the finding that France was once inhabited by forms that are wholly extinct, of which, as has been already mentioned (*BIRDS*, vol. iii. pp. 730, 731), in the older formations there is abundance. Unfortunately none of these, however, can be compared for singularity with *Archæopteryx* or with some American fossil forms next to be noticed, for their particular bearing on our knowledge of Ornithology will be most conveniently treated here.

In November 1870 Prof. MARSH, by finding the imperfect fossilized tibia of a Bird in the Middle Cretaceous shale of Kansas, began a series of wonderful discoveries which will ever be associated with his name,² and, making us acquainted with a great number of forms long since vanished from among the earth's inhabitants, has thrown a comparatively broad beam of light upon the darkness that, broken only by the solitary spark emitted on the recognition of *Archæopteryx*, had hitherto brooded over our knowledge of the genealogy of Birds, and is even now for the most part palpable. Subsequent visits to the same part of North America, often performed under circumstances of discomfort and occasionally of danger, brought to this intrepid and energetic explorer the reward he had so fully earned. Brief notices of his spoils appeared from time to time in various volumes of the *American Journal of Science and Arts* (Silliman's), but it is unnecessary here to refer to more than a few of them. In that *Journal* for May 1872 (ser. 3, iii. p. 360) the remains of a large swimming Bird (nearly 6 feet in length, as afterwards appeared) having some affinity, it was thought, to the *Colymbidæ* were described under the name of *Hesperornis regalis*, and a few months later (iv. p. 344) a second fossil Bird from the same locality was indicated as *Ichthyornis dispar*—from the fish-like, biconcave form of its vertebræ. Further examination of the enormous collections gathered by the author, and preserved in the Museum of Yale College at New Haven in Connecticut, shewed him that this last Bird, and another to which he gave the name of *Apatornis*, had possessed well-developed teeth implanted in sockets in both jaws, and induced him to establish (v. pp. 161, 162) for their reception a "Subclass" *Odontornithes* and an Order *Ichthyornithes*. Two years more and the originally found *Hesperornis* was discovered also to have teeth, but these were inserted in a groove. It was accordingly regarded as the type of a distinct Order *Odontolæ* (x. pp. 403–408), to which were assigned as other characters vertebræ of a saddle-shape and not biconcave, a keelless sternum, and wings consisting only of the humerus. In 1880 Prof. Marsh brought out a grand volume, *Odontornithes*, being a monograph of the extinct toothed Birds of North America. Herein remains, attributed to no fewer than a score of species, which were referred to eight different genera, are fully described and sufficiently illustrated, and, instead of the ordinal name *Ichthyornithes* previously used, that of *Odontotormæ* was proposed. In the author's concluding summary he remarks on the fact that, while the *Odontolæ*, as exhibited in *Hesperornis*, had teeth inserted in a continuous groove—a low and generalized character as shewn by Reptiles, they had, however, the strongly differentiated saddle-shaped vertebræ such as all modern Birds possess. On the other hand the *Odontotormæ*, as exemplified in *Ichthyornis*, having the primitive biconcave vertebræ, yet possessed the highly

¹ It is true that from the time of Buffon, though he scorned any regular Classification, Geographical Distribution had been occasionally held to have something to do with systematic arrangement; but the way in which the two were related was never clearly put forth, though people who could read between the lines might have guessed the secret from Darwin's *Journal of Researches*, as well as from his introduction to the *Zoology of the "Beagle" Voyage*.

² It will of course be needless to remind the general zoologist of Prof. Marsh's no less wonderful discoveries of wholly unlooked-for types of Reptiles and Mammals.

specialized feature of teeth and distinct sockets. *Hesperornis* too, with its keelless sternum, had aborted wings but strong legs and feet adapted for swimming, while *Ichthyornis* had a keeled sternum and powerful wings, but diminutive legs and feet. These and other characters separate the two forms so widely as quite to justify the establishment of as many Orders for their reception, and the opposite nature of the evidence they afford illustrates one fundamental principle of evolution, namely, that an animal may attain to great development of one set of characters and at the same time retain other features of a low ancestral type. Prof. Marsh states that he had fully satisfied himself that *Archæopteryx* belonged to the *Odontornithes*, which he thought it advisable for the present to regard as a Subclass, separated into three Orders—*Odontolæ*, *Odontoræ*, and *Saururæ*—all well marked, but evidently not of equal rank, the last being clearly much more widely distinguished from the first two than they are from one another. But that these three oldest-known forms of Birds should differ so greatly from each other unmistakably points to a great antiquity for the Class. All are true Birds; but the Reptilian characters they possess converge towards a more generalized type. He then proceeds to treat of the characters which may be expected to have occurred in their common ancestor, whose remains may yet be hoped for from the Palæozoic rocks if not from the Permian beds that in North America are so rich in the fossils of a terrestrial fauna. Birds, he believes, branched off by a single stem, which gradually lost its Reptilian as it assumed the Ornithic type; and in the existing *Ratitæ* we have the survivors of this direct line. The lineal descendants of this primal stock doubtless at an early time attained feathers and warm blood, but, in his opinion, never acquired the power of flight, which probably originated among the small arboreal forms of Reptilian Birds. In them even rudimentary feathers on the fore-limbs would be an advantage, as they would tend to lengthen a leap from branch to branch, or break the force of a fall in leaping to the ground. As the feathers increased, the body would become warmer and the blood more active. With still more feathers would come increased power of flight as we see in the young Birds of to-day. A greater activity would result in a more perfect circulation. A true Bird would doubtless require warm blood, but would not necessarily be hot-blooded, like the Birds now living. Whether *Archæopteryx* was on the true Carinate line cannot as yet be determined, and this is also true of *Ichthyornis*; but the biconcave vertebrae of the latter suggest its being an early offshoot, while it is probable that *Hesperornis* came off from the main "Struthious" stem and has left no descendants.

Bold as are the speculations above summarized, there seems no reason to doubt the probability of their turning out to be, if not the exact truth, yet something very like it.

From this bright vision of the poetic past—a glimpse, some may call it, into the land of dreams—we must relapse into a sober contemplation of the prosaic present—a subject quite as difficult to understand. The former efforts at classification made by Sundevall have already several times been mentioned, and a return to their consideration was promised. In 1872 and 1873 he brought out at Stockholm a *Methodi Naturalis Avium Dispendiarum Tentamen*, two portions of which (those relating to the Diurnal Birds-of-Prey and the "*Cichlomorphæ*," or forms related to the Thrushes) he found himself under the necessity of revising and modifying in the course of 1874, in as many communications to the Swedish Academy of Sciences (*K. V.-Ak. Förhandlingar*, 1874, No. 2, pp. 21-30; No. 3, pp. 27-30). This *Tentamen*, containing the

latest complete method of classifying Birds in general, has naturally received much attention, the more so perhaps, since, with its appendices, it was nearly the last labour of its respected author, whose industrious life came to an end in the course of the following year. From what has before been said of his works it may have been gathered that, while professedly basing his systematic arrangement of the groups of Birds on their external features, he had hitherto striven to make his schemes harmonize if possible with the dictates of internal structure as evinced by the science of anatomy, though he uniformly and persistently protested against the inside being better than the outside. In thus acting he proved himself a true follower of his great countryman Linneus; but, without disparagement of his efforts in this respect, it must be said that when internal and external characters appeared to be in conflict he gave, perhaps with unconscious bias, a preference to the latter, for he belonged to a school of zoologists whose natural instinct was to believe that such a conflict always existed. Hence his efforts, praiseworthy as they were from several points of view, and particularly so in regard to some details, failed to satisfy the philosophic taxonomer when generalizations and deeper principles were concerned, and in his practice in respect of certain technicalities of classification he was, in the eyes of the orthodox, a transgressor. Thus instead of contenting himself with terms that had met with pretty general approval, such as Class, Subclass, Order, Suborder, Family, Subfamily, and so on, he introduced into his final scheme other designations, "Agmen," "Cohors," "Phalanx," and the like, which to the ordinary student of Ornithology convey an indefinite meaning, if any meaning at all. He also carried to a very extreme limit his views of nomenclature, which were certainly not in accordance with those held by most zoologists, though this is a matter so trifling as to need no details in illustration. It is by no means easy to set forth briefly, and at the same time intelligibly, to any but experts, the final scheme of Sundevall, owing to the number of new names introduced by him, nevertheless the attempt must be made; but it must be understood that in the following paradigm, in which his later modifications are incorporated, only the most remarkable or best-known forms are cited as examples of his several groups, for to give the whole of them would, if any explanations were added, occupy far more space than the occasion seems to justify, and without such explanations the list would be of use only to experts, who would rather consult the original work.

First, Sundevall would still make two grand divisions ("Agmina") of Birds, even as had been done nearly forty years before; but, having found that the names, *Altrices* and *Præcoces*, he had formerly used were not always applicable, or the groups thereby indicated naturally disposed, he at first distinguished them as *Psilopædes* and *Ptilopædes*. Then, seeing that the great similarity of these two words would produce confusion both in speaking and writing, he changed them (p. 158) into the equivalent *Gymnopædes* and *Dasypædes*, according as the young were hatched naked or clothed. The *Gymnopædes* are divided into two "Orders"—*Oscines* and *Volucres*—the former intended to be identical with the group of the same name established by older authors, and, in accordance with the observations of Keyserling and Blasius already mentioned, divided into two "Series"—*Laminiplantares*, having the hinder part of the "tarsus" covered with two horny plates, and *Scutelliplantares*, in which the same part is scutellated. These *Laminiplantares* are composed of six Cohorts as follows:—

Cohors 1. *Cichlomorphæ*.

Phalanx 1. *Ocreatæ*.—7 Families: the Nightingales standing first, and therefore at the head of all Birds, with the Redbreast, Redstart, and the American Blue-bird; after them the Chats,

Thrushes proper, Dippers, Water-Chats (*Henicurus*), Bush-Chats, and (under the name of *Euciniæ*) the singular group commonly known as Pittas or Water-Thrushes.

Phalanx 2. *Novempennatæ*.—6 Families. Pipits, Wagtails, American Fly-catching Warblers, and Australian Diamond-birds (*Pardalotus*).

Phalanx 3. *Sylviiformes*.—17 Families: divided geographically (†) into two groups—the Old-World forms, and those of the New. The first is further broken up into three sections—(a) 4 Families with moderately long wings and a slender bill, containing what may be called perhaps the normal Warblers, as the Willow-Wrens, Whitethroats, Sedge-birds, and others; (b) 5 Families, with short wings and a slender bill, what are often called by Indian and African writers Bush-babblers (*Bradypterus*, *Crateropus*, and others); (c) 3 Families, with a somewhat stout or blunt bill, the Thick-heads of some writers (*Pachycephalus*) and Titmouse Family. The second or American group comprehends 5 Families, Vireos, Cat-birds, Wrens (not, by the way, peculiar to America), and some other forms for which it is impossible to find names that will pass as English.

Phalanx 4. *Brachypteræ*.—3 Families: the short-winged Wren-Warblers, with long tails, of the Australian (*Malurus*), Indian, and Ethiopian Regions.

Phalanx 5. *Latirostræ*.—7 Families: the true Flycatchers (*Muscicapa*), and several others of fly-catching habits.

Phalanx 6. *Brachypodæ*.—8 Families: Waxwings, Orioles, Swallow-Flycatchers (*Artamus*), Catnapper-catchers (*Campophaga*), and Drongos (*Dicrurus*).

Phalanx 7. *Dentirostræ* or *Laniiformes*.—3 Families: Shrikes. Puff-backed Shrikes.

Phalanx 8. *Subcorviformes*.—1 Family: Bower-birds and some others.

Cohors 2. *Conirostræ*.

Phalanx 1. *Decempennatæ*.—3 Families: Weaver-birds (*Ploceus*), Whydah-birds (*Vidua*), and Hedge-Sparrows (*Accentor*).

Phalanx 2. *Amphipalatales*.—2 Families: Grosbeaks. true Finches.

Phalanx 8. *Arctipalatales*.—6 Families: Crossbills, Buntings, Rice-birds, and many hard-billed forms which are usually placed among the Tanagers.

Phalanx 4. *Simplici-rostræ*.—4 Families: Tanagers.

Cohors 3. *Coliormorphæ*.

Phalanx 1. *Novempennatæ*.—3 Families: Grackles or American Starlings.

Phalanx 2. *Humilinares*.—4 Families: True Starlings, Oxpeckers, Choughs.

Phalanx 3. *Altinæres*.—3 Families: Nutcrackers, Jays, Crows.

Phalanx 4. *Idiodactylæ*.—5 Families: Crow-Shrikes. Birds-of-Paradise.

Cohors 4. *Certhiormorphæ*.—3 Families: Tree-creepers, Nut-hatches.

Cohors 5. *Cinnymorphæ*.—5 Families: Sun-birds, Honey-suckers.

Cohors 6. *Chelidonormorphæ*.—1 Family: Swallows.

The *Scutellipiantares* include a much smaller number of forms, and, with the exception of the first "Cohort" and a few groups of the fourth and fifth, all are peculiar to America.

Cohors 1. *Holaspideæ*.—2 Families: Larks, Hoopoes.

Cohors 2. *Endaspideæ*.—3 Families—all Neotropical: Oven-birds (*Furnarius*), *Synallaxis*, and the Piculules (*Dendrocolaptes*).

Cohors 3. *Ezaspideæ*.—4 Families: the first two separated as *Lysodactylæ*, including the King-birds or Tyrants, of which twelve groups are made; the remaining two as *Syndactylæ*, composed of the Todies and Manakins.

Cohors 4. *Pycnaspideæ*.—3 Families: Cocks-of-the-Rock (*Rupicola*), to which the Indian genus *Calyptomena*, *Eurylamus*, and some others are supposed to be allied, the Chatterers and Fruit-Crows (*Chasmorhynchus*, *Cephalopterus*, and others), as well as *Tityra* and *Lipaugus*.

Cohors 5. *Taxaspideæ*.—5 Families: the very singular Madagascar form *Philopitta*; the Bush-Shrikes (*Thamnopophilus*), Ant-Thrushes (*Formicarius*), and Tapaculos (*Pteroptochus*) of the Neotropical Region; and the Australian Lyre-bird.

We then arrive at the Second Order *Volucres*, which is divided into two "Series." Of these the first is made to contain, under the name *Zygodactyli*,

Cohors 1. *Psittaci*.—6 Families: Parrots;

Cohors 2. *Pici*.—6 Families: Woodpeckers, Piculets (*Picumnus*), and Wrynecks;

Cohors 3. *Coccygæ*.—12 Families: divided into two groups—(1) *Altinæres*, containing the Honey-Guides, Barbets, Toucans, Jacamars, Puff-birds, and the Madagascar genus *Leptosomus*; and (2) *Humilinares*, comprising all the forms commonly known as *Cuculidæ*, broken up, however, into three sections;

while to the second "Series" are referred, as *Anisodactyli*,

Cohors 4. *Cenormorphæ*.—4 Families: Plantain-eaters or Touracous, Mouse-birds, Rollers, and the peculiar Madagascar forms *Atelornis* and *Brachypteracias*;

Cohors 5. *Ampligulares*.—4 Families: Trogons, Goatsuckers, and Swifts;

Cohors 6. *Longilingues* or *Mellisugæ*.—12 Families: Humming-birds, arranged in three "Series";

Cohors 7. *Syndactylæ*.—4 Families: Bee-eaters, Motmots and Fishers, and Hornbills;

Cohors 8. *Peristeroidæ*.—3 Families: *Didunculus*, with the Dodo Pigeons, and the Crowned Pigeons (*Goura*) separated from the last.

The *Dasyptædes* of Sundevall are separated into six "Orders"; but these will occupy us but a short while.

The first of them, *Accipitres*, comprehending all the Birds-of-Prey, were separated into 4 "Cohorts" in his original work, but these were reduced in his appendix to two—

Nyctarpages or Owls with 4 Families divided into 2 series, and *Hemerocharpages* containing all the rest, and comprising 10 Families (the last of which is the Seriemæ,

Dicholophus) divided into 2 groups as *Rapaces* and *Saprophagi*—the latter including the Vultures. Next

stands the Order *Gallinæ* with 4 "Cohorts":—(1) *Tetraonomorphæ*, comprising 2 Families, the Sand-Grouse (*Pterocles*)

and the Grouse proper, among which the Central-American *Oreophasis* finds itself; (2) *Phasianomorphæ*, with 4

Families, Pheasants, Peacocks, Turkeys, Guinea Fowls, Partridges, Quails, and Hemipodes (*Turnix*); (3) *Macro-*

nyches, the Megapodes, with 2 Families; (4) the *Duodecim-*

pennatæ, the Curassows and Guans, also with 2 Families

(5) the *Struthioniformes*, composed of the Tinamous; and

(6) the *Subgrallatores* with 2 Families, one consisting of the curious South-American genera *Thinocorus* and *Attagis* and

the other of the Sheathbill (*Chionis*). The Fifth Order

(the third of the *Dasyptædes*) is formed by the *Grallatores*

divided into 2 "series"—(1) *Altinæres*, consisting of 2

"Cohorts," *Herodii* with 1 Family, the Herons, and *Pelargi*

with 4 Families, Spoonbills, Ibises, Storks, and the

Umbre (*Scopus*), with *Balaniceps*; (2) *Humilinares*, also

consisting of 2 "Cohorts," *Limicola* with 2 Families

Sandpipers and Snipes, Stilts and Avocets, and *Cursore*

with 8 Families, including Plovers, Bustards, Cranes

Rails, and all the other "Waders." The Sixth Order

Natatores, consists of all the Birds that habitually swim

and a few that do not, containing 6 Cohorts:—

Longipennes and *Pygopodes* with 3 Families each; *Toti-*

palmatæ with 1 Family; *Tubinares* with 3 Families

Impennes with 1 Family, Penguins; and *Lamelli-rostræ*

with 2 Families, Flamingoes and Ducks. The Seventh

Order, *Proceres*, is divided into 2 Cohorts—*Veri* with 2

Families, Ostriches and Emeus; and *Subnobiles*, consisting

of the genus *Apteryx*. The Eighth Order is formed by

the *Saururæ*.

Such then is Sundevall's perfected system, which has in

various quarters been so much praised, and has been

partially recognized by so many succeeding writers, that

it would have been impossible to pass it over here, though

the present writer is confident that the best-informed

ornithologists will agree with him in thinking that the com-

pilation of the above abstract has been but so much waste

of time, and its insertion here but so much waste of space

Without, however, some such abstract its shortcomings

could not be made apparent, and it will be seen to

what little purpose so many able men have laboured in

arrangement and grouping so manifestly artificial—the

latter often of forms possessing no real affinity—can pass

as a natural method. We should be too sanguine to hope

that it may be the last of its kind, yet any one accustomed

to look deeper than the surface must see its numerous

defects, and almost every one, whether so accustomed or

not, ought by its means to be brought to the conclusion

that, when a man of Sundevall's knowledge and experience

could not, by trusting only to external characters, do better than this, the most convincing proof is afforded of the inability of external characters alone to produce anything save ataxy. The principal merits it possesses are confined to the minor arrangements of some of the *Oscines*; but even here many of the alliances, such, for instance, as that of *Pitta* with the true Thrushes, are indefensible on any rational grounds, and some, as that of *Accentor* with the Weaver-birds and Whydah-birds, verge upon the ridiculous, while on the other hand the interpolation of the American Fly-catching Warblers, *Mniotiltidae*, between the normal Warblers of the Old World and the Thrushes is as bad—especially when the genus *Mniotilta* is placed, notwithstanding its different wing-formula, with the Tree-creepers, *Certhiidae*. The whole work unfortunately betrays throughout an utter want of the sense of proportion. In many of the large groups the effect of very slight differences is to keep the forms exhibiting them widely apart, while in most of the smaller groups differences of far greater kind are overlooked, so that the forms which present them are linked together in more or less close union. Thus, regarding only external characters, great as is the structural distinction between the Gannets, Cormorants, Frigate-birds, and Pelicans, it is not held to remove them from the limits of a single Family; and yet the Thrushes and the Chats, whose distinctions are barely sensible, are placed in separate Families, as are also the Chats and the Nightingales, wherein no structural distinctions at all can be traced. Again, even in one and the same group the equalization of characters indicative of Families is wholly neglected. Thus among the Pigeons the genera *Didus* and *Didunculus*, which differ, so far as we know it, in every external character of their structure, are placed in one Family, and yet on the slightest pretext the genus *Goura*, which in all respects so intimately resembles ordinary Pigeons, is set apart as the representative of a distinct Family. The only use of dwelling upon these imperfections here is the hope that thereby students of Ornithology may be induced to abandon the belief in the efficacy of external characters as a sole means of classification, and, by seeing how unmanageable they become unless checked by internal characters, be persuaded of the futility of any attempt to form an arrangement without that solid foundation which can only be obtained by a knowledge of anatomy. Where Sundevall failed no one else is likely to succeed; for he was a man gifted with intelligence of a rare order, a man of cultivation and learning, one who had devoted his whole life to science, who had travelled much, studied much and reflected much, a man whose acquaintance with the literature of his subject probably exceeded that of any of his contemporaries, and a man whose linguistic attainments rendered him the envy of his many friends. Yet what should have been the crowning work of his long life is one that all who respected him, and that comprehends all who knew him, must regret.

Of the very opposite kind was the work of the two men next to be mentioned—GARROD and FORBES—both cut short in a career of promise¹ that among students of Ornithology has rarely been equalled and perhaps never surpassed. The present writer finds it difficult to treat of the labours of two pupils and friends from whose assistance he had originally hoped to profit in the preparation of this very article, the more so that, while fully recognizing the brilliant nature of some of their researches, he is compelled very frequently to dissent from the conclusions at which

they arrived, deeming them to have often been of a kind that, had their authors survived to a maturer age, they would have greatly modified. Still he well knows that learners are mostly wiser than their teachers; and, making due allowance for the haste with which, from the exigencies of the post they successively held, their investigations had usually to be published, he believes that much of the highest value underlies even the crudest conjectures contained in their several contributions to Ornithology. Putting aside the monographical papers by which each of them followed the excellent example set by their predecessor in the office they filled—Dr MURIE²—and beginning with Garrod's,³ those having a more general scope, all published in the Zoological Society's *Proceedings*, may be briefly considered. Starting from the level reached by Prof. Huxley, the first attempt made by the younger investigator was in 1873, "On the value in Classification of a Peculiarity in the anterior margin of the Nasal Bones in certain Birds." Herein he strove to prove that Birds ought to be divided into two Subclasses—one, called "Holorhinal," in which a straight line drawn transversely across the hindmost points of the external narial apertures passes in front of the posterior ends of the nasal processes of the premaxillæ, and the other, called "Schizorhinal," in which such a line passes behind those processes. If this be used as a criterion, the validity of Prof. Huxley's group *Schizognathæ* is shaken; but there is no need to enlarge upon the proposal, for it was virtually abandoned by its author within little more than a twelvemonth. The next subject in connexion with Systematic Ornithology to which Garrod applied himself was an investigation of the Carotid Arteries, and here, in the same year, he made a considerable advance upon the labours of Nitzsch, as might well be expected, for the opportunities of the latter were very limited, and he was only able, as we have seen (page 22), to adduce four types of structure in them, while Garrod, with the superior advantages of his situation, raised the number to six. Nevertheless he remarks that their "disposition has not much significance among Birds, there being many Families in which, whilst the majority of the species have two, some have only one carotid." The exceptional cases cited by him are quite sufficient to prove that the condition of this artery has nearly no value from the point of view of general classification. If relied upon it would split up the Families *Bucerotidae* and *Cypselidae*, which no sane person would doubt to be homogeneous and natural. The femoral vessels formed another subject of investigation, and were found to exhibit as much exceptional conformation as those of the neck—for instance in *Centropus phasianus*, one of the Birds known as Coucals, the femoral artery accompanies the femoral vein, though it does not do so in another species of the genus, *C. rufipennis*, nor in any other of the *Cuculidae* (to which Family the genus *Centropus* has been always assigned) examined by Garrod. Nor are the results of the very great labour which he bestowed upon the muscular conformation of the thigh in Birds any more conclusive when they come to be impartially and carefully considered. Myology was with him always a favourite study, and he

² Dr Murie's chief papers having a direct bearing on Systematic Ornithology are:—in the Zoological Society's *Transactions* (vii. p. 465), "On the Dermal and Visceral Structures of the Kagu, Sun-Bittern, and Boatbill"; in the same Society's *Proceedings*—(1871, p. 647) "Additional Notice concerning the Powder-Downs of *Rhinocetus jubatus*," (1872, p. 664) "On the Skeleton of *Todus* with remarks as to its Allies," (1879, p. 552) "On the Skeleton and Linage of *Fregilupus varius*," in *The Ibis*—(1872, p. 262) "On the genus *Cotius*," (1872, p. 383) "Motmots and their affinities," (1873, p. 181) "Relationships of the *Upupidae*."

³ Garrod's *Scientific Papers* have been collected and published in a memorial volume, edited by Forbes. There is therefore no need to give a list of them here. Forbes's papers are to be edited by Prof. F. J. Bell.

¹ Alfred Henry Garrod, Prosecutor to the Zoological Society of London, died of consumption in 1879, aged thirty-three. His successor in that office, William Alexander Forbes, fell a victim to the deadly climate of the Niger in 1883, and in his twenty-eighth year.

may be not unreasonably supposed to have a strong feeling as to its efficacy for systematic ends. It was in favour of an arrangement based upon the muscles of the thigh, and elaborated by him in 1874, that he gave up the arrangement he had published barely more than a year before based upon the conformation of the nostrils. Nevertheless it appears that even the later of the two methods did not eventually content him, and this was only to be expected, though he is said by Forbes (*Ibis*, 1881, p. 28) to have remained "satisfied to the last as to the naturalness of the two main groups into which he there divided birds"—*Homalognatæ* and *Anomalognatæ*. The key to this arrangement lay in the presence or absence of the *ambiens* muscle, "not because of its own intrinsic importance, but because its presence is always associated with peculiarities in other parts never found in any *Anomalognatous* bird." Garrod thought that so great was the improbability of the same combination of three or four different characters (such as an accessory femoro-caudal muscle, a tufted oil-gland, and *cæca*) arising independently in different Birds that similar combinations of characters could only be due to blood-relationship. The ingenuity with which he found and expressed these combinations of characters is worthy of all praise; the regret is that time was wanting for him to think out all their consequences, and that he did not take also into account other and especially osteological characters. Every osteologist must recognize that the neglect of these makes Garrod's proposed classification as unnatural as any that had been previously drawn up, and more unnatural than many. So much is this the case that, with the knowledge we have that ere his death he had already seen the need of introducing some modifications into it, its reproduction here, even in the briefest abstract possible, would not be advisable. Two instances, however, of its failure to shew natural affinities or differences may be cited. The first Order *Galliformes* of his Subclass *Homalognatæ* is made to consist of three "Cohorts"—*Struthionæ*, *Gallinæ*, and *Psittaci*—a somewhat astonishing alliance; but even if that be allowed to pass, we find the second "Cohort" composed of the Families *Palamedeidae*, *Gallinæ*, *Rallidae*, *Otididae* (containing two Subfamilies, the Bustards and the Flamingoes), *Musophagidae*, and *Cuculidae*. Again the Subclass *Anomalognatæ* includes three Orders—*Piciformes*, *Passeriformes*, and *Cypseliformes*—a preliminary to which at first sight no exception need be taken; but immediately we look into details we find the *Alcedinidae* placed in the first Order and the *Meropidae* in the second, together with the *Passeres* and a collection of Families almost every feature in the skeleton of which points to a separation. Common sense revolts at the acceptance of any scheme which involves so many manifest incongruities. With far greater pleasure we would leave these investigations, and those on certain other muscles, as well as on the Disposition of the deep plantar Tendons, and dwell upon his researches into the anatomy of the Passerine Birds with the view to their systematic arrangement. Here he was on much safer ground, and it can hardly be doubted that his labours will stand the test of future experience, for, though it may be that all his views will not meet with ultimate approval, he certainly made the greatest advance since the days of Müller, to the English translation of whose classical work he added (as already mentioned) an excellent appendix, besides having already contributed to the Zoological Proceedings between 1876 and 1878 four memoirs replete with observed facts which no one can gainsay. As his labours were continued exactly on the same lines by Forbes, who, between 1880 and 1882, published in the same journal six more memoirs on the subject, it will be convenient here to state generally, and

in a combined form, the results arrived at by these two investigators.

Instead of the divisions of Passerine Birds instituted by Müller, Garrod and Forbes having a wider range of experience consider that they have shewn that the *Passeres* consist of two primary sections, which the latter named respectively *Desmodactyli* and *Eleutherodactyli*, from the facts discovered by the former that in the *Eurylemidae*, or Broadbills, a small Family peculiar to some parts of the Indian Region, and consisting of some nine or ten species only, there is a strong band joining the muscles of the hind toe exactly in the same way as in many Families that are not Passerine, and hence the name *Desmodactyli*, while in all other Passerines the hind toe is free. This point settled, the *Eleutherodactyli* form two great divisions, according to the structure of their vocal organs; one of them, roughly agreeing with the *Clamatores* of some writers, is called *Mesomyodi*, and the other, corresponding in the main, if not absolutely, with the *Oscines*, *Polymyodi*, or true *Passeres* of various authors, is named *Acromyodi*—"an *Acromyodian* bird being one in which the muscles of the syrinx are attached to the extremities of the bronchial semi-rings, a *Mesomyodian* bird being one in which the muscles of the syrinx join the semi-rings in their middle." Furthermore, each of these groups is subdivided into two: the *Acromyodi* into "normal" and "abnormal," of which more presently; the *Mesomyodi* into *Homœomeri* and *Heteromeri*, according as the sciatic or the femoral artery of the thigh is developed—the former being the usual arrangement among Birds and the latter the exceptional. Under the head *Heteromeri* come only two Families the *Cotingidae* (Chatterers) and *Pipridæ* (MANAKINS, vol. xv. p. 455) of most ornithologists, but these Garrod was inclined to think should not be considered distinct. The *Homœomeri* form a larger group, and are at once separable, on account of the structure of their vocal organs, into *Tracheophonæ* (practically equivalent to the *Tracheophones* of Müller) and *Haplophonæ* (as Garrod named them)—the last being those *Passeres* which were by Müller erroneously included among his *Picarii*, namely, the *Tyrannidae* (see KING-BIRD, vol. xiv. p. 80) with *Rupicola*, the Cocks-of-the-Rock. To these are now added Families not examined by him,—but subsequently ascertained by Forbes to belong to the same group,—*Pittidae*, *Philepittidae*, and *Xenicidae* (more properly perhaps to be called *Acanthisittidae*); and it is remarkable that these last three Families are the only members of the *Mesomyodi* which are not peculiar to the New World—nay more, if we except the *Tyrannidae*, which in North America occur chiefly as migrants,—not peculiar to the Neotropical Region. The *Tracheophonæ* are held to contain five Families—*Furnariidae* (Oven-birds), *Pteroptochidae* (TAPACULOS, *q.v.*), *Dendrocolaptidae* (Piculules), *Conopophagidae*, and *Formicariidae* (Ant-Thrushes). Returning now to the *Acromyodi*, which include, it has just been said, a normal and an abnormal section, the latter consists of birds agreeing in the main, though not absolutely, as to the structure of the syrinx with that of the former, yet differing so considerably in their osteology as to be most justifiably separated. At present only two types of these abnormal *Acromyodi* are known—*Menura* (the LYRE-BIRD, vol. xv. p. 115) and *Atrichia* (the SCRUB-BIRD, *q.v.*), both from Australia, while all the remaining *Passeres*, that is to say, incomparably the greater number of Birds in general, belong to the normal section. Thus the whole scheme of the *Passeres*,¹ as worked out by Garrod and Forbes, can be

¹ It is right to observe that this scheme was not a little aided by a consideration of palatal characters, as well as from the disposition of some of the tendons of the wing-muscles.

briefly expressed as below; and this expression, so far as it goes, is probably very near the truth, though for simplicity's sake some of the intermediate group-names might perhaps be omitted:—

PASSERES,

ELEUTHERODACTYLI.

ACROMYODI,

NORMALES,

ABNORMALES, *Menura*, *Atrichia*.

MESOMYODI,

HOMOMERI,

Tracheophonæ,

Furnariidæ, *Pteroptochidæ*, *Dendrocolaptidæ*, *Conopophagidæ*, *Formicariidæ*.

Haplophonæ,

Tyrannidæ, *Rupicolæ*, *Pittidæ*, *Philepittidæ*, *Xenicidæ*.

HETEROMERI, *Cotingidæ*, *Pipridæ*.

DESMODACTYLI,

Eurylæmidæ.

It will be seen that no attempt is here made to separate the Normal Acromyodians into Families. Already, in *The Ibis* for 1874 (pp. 406–416), Mr WALLACE had published a plan, which, with two slight modifications that were manifestly improvements, he employed two years later in his great work on *The Geographical Distribution of Animals*, and this included a method of arranging the Families of this division. Being based, however, wholly on alar characters, it has of course a great similarity to the schemes of Dr Cabanis and of Sundevall, and, though simpler than either of those, there is no need here to enter much into its details. The Birds which would fall under the category of Garrod's *Acromyodi normales* are grouped in three series:—A. "Typical or Turdoid *Passeres*," having a wing with ten primaries, the first of which is always more or less markedly reduced in size, and to this 21 Families are allotted; B. "Tanagroid *Passeres*," having a wing with nine primaries, the first of which is fully developed and usually very long, and containing 10 Families; and C. "Sturnoid *Passeres*," having a wing with ten primaries, the first of which is "rudimentary," with only 4 Families. The remaining Families, 10 in number, which are not normally acromyodian are grouped as Series D. and called "Formicaroid *Passeres*."

In *The Ibis* for 1880 (pp. 340–350, 399–411) Mr SCLATER made a laudable attempt at a general arrangement of Birds,¹ trying to harmonize the views of ornithotomists with those taken by the ornithologists who only study the exterior; but, as he explained, his scheme is really that of Prof. Huxley reversed, with some slight modifications mostly consequent on the recent researches of Prof. Parker and of Garrod, and (he might have added) a few details derived from his own extensive knowledge of the Class. Adopting the two Subclasses *Carinatae* and *Ratitæ*, he recognized 3 "Orders" as forming the latter and 23 the former—a number far exceeding any that had of late years met with the approval of ornithologists. It is certainly difficult in the present state of our knowledge to get on with much fewer groups; whether we call them "Orders" or not is immaterial. First of them comes the *Passeres*, of which Mr Sclater would make four Suborders:—(1) the *Acromyodi normales* of Garrod under the older name of *Oscines*, to the further subdivision of which we must immediately return; (2) under Prof. Huxley's term *Oligomyodi*, all the *Haplophonæ*, *Heteromeri*, and *Desmodactyli* of Garrod, comprehending 8 Families—*Oxyrhamphidæ*,² *Tyrannidæ*, *Pipridæ*, *Cotingidæ*, *Phytotomidæ*,³ *Pittidæ*, *Philepittidæ*, and *Eurylæmidæ*; (3) *Tracheophonæ*,

containing the same groups as in the older scheme, but here combined into 3 Families only—*Dendrocolaptidæ*, *Formicariidæ*, and *Pteroptochidæ*; and (4) the *Acromyodi abnormales* of Garrod, now elevated to the rank of a Suborder and called *Pseudoscines*.⁴ With regard to the *Acromyodi normales* or *Oscines*, Mr Sclater takes what seems to be quite the most reasonable view, when he states that they "are all very closely related to one another, and, in reality, form little more than one group, equivalent to other so-called families of birds," going on to remark that as there are some 4700 known species of them "it is absolutely necessary to subdivide them," and finally proceeding to do this nearly on the method of Sundevall's *Tentamen* (see above pp. 37, 38), merely changing the names and position of the groups in accordance with a plan of his own set forth in the *Nomenclator Avium Neotropicalium*, which he and Mr Salvin printed in 1873, making, as did Sundevall, two divisions (according as the hind part of the "tarsus" is plated or scaled), A. *Laminiplantares* and B. *Scutelliplantares*—but confining the latter to the *Alaudidæ* alone, since the other Families forming Sundevall's *Scutelliplantares* are not Oscinian, nor all even Passerine. The following table shews the comparative result of the two modes as regards the *Laminiplantares*, and, since the composition of the Swedish author's groups was explained at some length, may be found convenient by the reader:—

| Mr Sclater, 1880. | Sundevall, 1872–73. |
|--|--------------------------------|
| 1. Dentiostres, ⁵ —practically equal to | 1. Cichlomorphæ. |
| 2. Latiostres, ⁶ " | 6. Chelidonomorphæ. |
| 3. Curviostres, " | 4. Certhiomorphæ. ⁷ |
| 4. Tenuiostres, " | 5. Cinyrimorphæ. |
| 5. Coniostres, " | 2. Coniostres. |
| 6. Cultriostres, " | 3. Coliomorphæ. |

These six groups Mr Sclater thinks may be separated without much difficulty, though on that point the proceedings of some later writers (a notable instance of which he himself cites) shew that doubt may still be entertained; but he rightly remarks that, "when we come to attempt to subdivide them, there is room for endless varieties of opinion as to the nearest allies of many of the forms," and into further details he does not go. It will be perceived that, like so many of his predecessors, he accords the highest rank to the *Dentiostres*, which, as has before been hinted, seems to be a mistaken view that must be considered in the sequel.

Leaving the *Passeres*, the next "Order" is *Picariæ*, of which Mr Sclater proposes to make six Suborders:—(1) *Pici*, the Woodpeckers, with 2 Families; (2) *Cypseli*, with 3 Families,⁷ practically equal to the *Macrochires* of Nitzsch; (3) *Anisodactylæ*, with 12 Families—*Colidæ* (MOUSE-BIRD, vol. xvii. p. 6), *Alcedinidæ* (KINGFISHER, vol. xiv. p. 81), *Bucerotidæ* (HORNBILL, vol. xii. p. 169), *Upupidæ* (HOOPOE, vol. xii. p. 154), *Irrisoridæ*, *Meropidæ*, *Momotidæ* (MOTMOT, vol. xvii. p. 3), *Todidæ* (TODY, q.v.), *Coraciidæ* (ROLLER, q.v.), *Leptosomidæ*, *Podargidæ*, and *Steatornithidæ* (GUACHARO, vol. xi. p. 227); (4) *Heterodactylæ*, consisting only of the TROOONS (q.v.); (5) *Zygodactylæ* with 5 Families, *Galbulidæ* (JACAMAR, vol. xiii. p. 531), *Buconidæ* (PUFF-BIRD, q.v.), *Rhamphastidæ* (TOUCAN, q.v.), *Capitonidæ*, and *Indicatoridæ* (HONEY-GUIDE, vol. xii. p. 139); and (6) *Coccygæ*, composed of the two Families *Cuculidæ* and *Musophagidæ*. That all these may be most conveniently

⁴ A term unhappily of hybrid origin, and therefore one to which purists may take exception.

⁵ These are not equivalent to Sundevall's groups of the same names.

⁶ Mr Sclater (p. 348) inadvertently states that no species of Sundevall's *Certhiomorphæ* is found in the New World, having omitted to notice that in the *Tentamen* (pp. 46, 47) the genera *Mniotilta* (peculiar to America) as well as *Certhia* and *Sitta* are therein placed.

⁷ Or 2 only, the position of the *Caprimulgidæ* being left undecided, but in 1883 (see next note) put here.

¹ An abstract of this was read to the British Association at Swansea in the same year, and may be found in its *Report* (pp. 606–609).

² Not recognized by Garrod.

³ To these Mr Sclater would now doubtless add Forbes's *Xenicidæ*.

associated under the name *Picariæ* seems likely enough, and the first two "Suborders" are probably natural groups, though possibly groups of different value. In regard to the rest comment is for the present deferred. The *Psittaci*, *Striges*, and *Accipitres*, containing respectively the PARROTS (*q.v.*), OWLS (*q.v.*), and diurnal Birds-of-Prey, form the next three "Orders"—the last being held to include 3 Families, *Falconidæ*, *Cathartidæ*, and *Serpentariidæ*, which is perhaps the best that can be done with them—the difficult question as to the position of *Cariama* (*SERIEMA*, *q.v.*) being decided against the admission of that form to the last Family, notwithstanding its remarkable resemblance to *Serpentarius* (*SECRETARY-BIRD*, *q.v.*). We have then the *Steganopodes* to make the Sixth "Order," consisting of the 5 Families usually grouped together as by Braudt (*supra*, p. 25) and others, and these are followed naturally enough by the HERONS (vol. xi. p. 760) under the name of *Herodiones*, to which the 3 Families *Ardeidæ*, *Ciconiidæ* (*STORK*, *q.v.*), and *Plataleidæ* (*SPOONBILL*, *q.v.*) are referred; but the FLAMINGOES (vol. ix. p. 286), under Prof. Huxley's title *Odontoglossæ*, form a distinct "Order." The Ninth "Order" is now erected for the *Palamedæ* (*SCREAMER*, *q.v.*), which precede the *Anseres*—a group that, disencumbered from both the last two, is eminently natural, and easily dealt with. A great break then occurs, and the new series is opened by the Eleventh "Order," *Columbæ*, with 3 Families, *Carpophagidæ*, *Columbidæ*, and *Gouridæ*, "or perhaps a fourth," *Didunculidæ*,¹—the DOOS (vol. vii. p. 321) being "held to belong to quite a separate section of the order." The Twelfth "Order" is formed by the *Pterocletes*, the Sand-Grouse; and then we have the very natural group *Gallinæ* ranking as the Thirteenth. The next two are the *Opisthocomi* and *Hemipodii* for the HOACTZIN (vol. xii. p. 28) and the *Turnicidæ* (often known as Button-Quails) respectively, to which follow as Sixteenth and Seventeenth the *Fulicaridæ* and *Alectoridæ*—the former consisting of the Families *Rallidæ* (*RAIL*, *q.v.*) and *Helionithidæ*, and the latter of what seems to be a very heterogeneous compound of 6 Families—*Aramidæ*, *Eurypygidæ* (*SUN BITTERN*, *q.v.*), *Gruidæ* (*CRANE*, vol. vi. p. 546), *Psophiidæ* (*TRUMPETER*, *q.v.*), *Cariamidæ* (*SERIEMA*, *q.v.*), and *Otididæ*² (*BUSTARD*, vol. iv. p. 578). It is confessedly very puzzling to know how these varied types, or some of them at least, should be classed; but the need for the establishment of this group, and especially the insertion in it of certain forms, is not explained by the author. Then we have "Orders" Eighteen and Nineteen, the *Limicolæ*, with 6 Families, and *Gariæ*, consisting only of *Laridæ* (*GULL*, vol. xi. p. 274), which taken in their simplest condition do not present much difficulty. The last are followed by *Tubinares*, the PETRELS (*q.v.*), and these by *Pygopodes*, to which only 2 Families *Colymbidæ* (*DIVER*, vol. vii. p. 292) and *Alcidæ* are allowed—the GREBES (vol. xi. p. 79) being included in the former. The *Impennes* or PENGUINS (*q.v.*) form the Twenty-second, and TINAMOUS (*q.v.*) as *Crypturi* complete the Carinate Subclass. For the *Ratidæ* only three "Orders" are allotted—*Apteryges*, *Casuarii*, and *Struthiones*.

As a whole it is impossible not to speak well of the scheme thus sketched out; nevertheless it does seem in some parts to be open to amendment, though the task of attempting to suggest any modifications of it by way of improvement is one that the present writer approaches with reluctance and the utmost diffidence. Yet the task, it appears, must be undertaken. From the preceding

pages, recounting the efforts of many system-makers—good, bad, and indifferent—it will have been seen what a very great number and variety of characters need to be had in remembrance while planning any scheme that will at all adequately represent the results of the knowledge hitherto attained, and the best lesson to be learnt from them is that our present knowledge goes but a very little way in comparison with what we, or our successors, may hope to reach in years to come. Still we may feel pretty confident that we are on the right track, and, moreover, that here and there we can plant our feet on firm ground, however uncertain, not to say treacherous, may be the spaces that intervene. Now that geographical exploration has left so small a portion of the earth's surface unvisited, we cannot reasonably look for the encountering of new forms of ornithic life that, by revealing hitherto unknown stepping stones, will quicken our course or effectively point out our path. Indeed, as a matter of fact, the two most important and singular types of existing Birds—*Balaniceps* and *Rhinocetus*—that in later years have rewarded the exertions of travelling naturalists, have proved rather sources of perplexity than fountains of inspiration. Should fortune favour ornithologists in the discovery of fossil remains, they will unquestionably form the surest guide to our faltering steps; but experience forbids us to expect much aid from this quarter, however warmly we may wish for it, and the pleasure of any discovery of the kind would be enhanced equally by its rarity as by its intrinsic worth. However, it is now a well accepted maxim in zoology that the mature forms of the past are repeated in the immature forms of the present, and that, where Palæontology fails to instruct us, Embryology may be trusted to no small extent to supply the deficiency. Unhappily the embryology of Birds has been as yet very insufficiently studied. We have indeed embryological memoirs of a value that can scarcely be rated too highly, but almost all are of a monographic character. They are only oases in a desert of ignorance, and a really connected and continuous series of investigations, such as the many morphological laboratories, now established in various countries, would easily render possible, has yet to be instituted. No methodical attempt at this kind of work seems to have been made for nearly half a century, and, with the advantage of modern appliances, no one can justifiably doubt the success of a renewal of such an attempt any more than he can possibly foresee the precise nature of the revelations that would come of it.

The various schemes for classifying Birds set forth by the authors of general text-books of Zoology do not call for any particular review here, as almost without exception they are so drawn up as to be rather of the nature of a compromise than of a harmony. The best and most notable is perhaps that by Prof. CARUS in 1868 (*Handbuch der Zoologie*, i. pp. 191-368); but it is of course now antiquated. The worst scheme is one of the most recent, that by Prof. CLAUS in 1882 (*Grundzüge der Zoologie*, ii. pp. 318-388). Of most other similar text-books that have come under the writer's notice, especially those issued in the United Kingdom, the less said the better. It is unfortunate that neither Prof. Gegenbaur nor the late Prof. F. M. Balfour should have turned their attention to this matter; but an improvement may be expected from Dr Gadow, who is engaged in completing the ornithological portion of Bronn's *Thierreich*, so long left unfinished.

Birds are animals so similar to Reptiles in all the most essential features of their organization that they may be said to be merely an extremely modified and aberrant Reptilian type. These are almost the very words of Prof. Huxley twenty years ago,³ and there are now but few zoologists to dissent from his statement, which by another man of science has been expressed in a phrase even more

¹ In the eighth edition of the *List of Vertebrated Animals* in the Zoological Gardens, which, being published in 1883, may be taken as expressing Mr. Slater's latest views, the first two Families only are recognized, the last two being placed under *Columbidæ*.

² Wrongly spelt *Otidæ*.

³ *Lectures on the Elements of Comparative Anatomy*, p. 69; see also Carus, *Handbuch der Zoologie*, i. p. 192.

pitly—"Birds are only glorified Reptiles." It is not intended here to enter upon their points of resemblance and differences. These may be found summarized with more or less accuracy in any text-book of zoology. We shall content ourselves by remarking that by the naturalist just named Birds and Reptiles have been brigaded together under the name of *Sauropsida* as forming one of the three primary divisions of the *Vertebrata*—the other two being *Ichthyopsida* and *Mammalia*. Yet Birds have a right to be considered a Class, and as a Class they have become so wholly differentiated from every other group of the Animal Kingdom that, among recent and even the few fossil forms known to us, there is not one about the assignation of which any doubt ought now to exist, though it is right to state that some naturalists have even lately refused a place among *Aves* to the singular *Archæopteryx*, of which the remains of two individuals—most probably belonging to as many distinct forms¹—have been discovered in the quarries of Solenhofen in Bavaria. Yet one of them has been referred, without much hesitation, by Prof. Vogt to the Class *Reptilia* on grounds which seem to be mistaken, since it was evidently in great part if not entirely clothed with feathers.² The peculiar structure of *Archæopteryx* has already been briefly mentioned and partly figured in this work (BIRDS, vol. iii. p. 728-9), and, while the present writer cannot doubt that its Bird-like characters predominate over those which are obviously Reptilian, he will not venture to declare more concerning its relations to other Birds, and accordingly thinks it advisable to leave the genus as the sole representative as yet known of the Sub-class *Saururæ*,³ established for its reception by Prof. Hæckel, trusting that time may shew whether this provisional arrangement will be substantiated. The great use of the discovery of *Archæopteryx* to naturalists in general is well known to have been the convincing testimony it afforded as to what is well called "the imperfection of the Geological Record." To ornithologists in particular its chief attraction is the evidence it furnishes in proof of the evolution of Birds from Reptiles; though, as to the group of the latter from which the former may have sprung, it tells us little that is not negative. It throws, for instance, the Pterodactyls—so often imagined to be nearly related to Birds, if not to be their direct ancestors—completely out of the line of descent. Next to this its principal advantage is to reveal the existence at so early an epoch of Birds with some portions of their structure as highly organized as the highest of the present day, a fact witnessed by its foot, which, so far as can be judged by its petrified relics,

might well be that of a modern Crow. The fossil remains of many other Birds, for example Prof. SEELEY's *Endiornis* (*Quart. Journ. Geol. Society*, 1876, pp. 496-512), Sir R. OWEN's *Odontopteryx* (BIRDS, vol. iii. p. 729), *Gastornis*, Prof. COPE's *Diatryma* (*Proc. Acad. N. Sc. Philadelphia*, April 1876), and some more, are too fragmentary to serve the purposes of the systematist; but the grand discoveries of Prof. Marsh, spoken of above, afford plentiful hints as to the taxonomy of the Class, and their bearing deserves the closest consideration. First of all we find that, while Birds still possess the teeth they had inherited from their Reptilian ancestors, two remarkable and very distinct types of the Class had already made their appearance, and we must note that these two types are those which persist at the present day, and even now divide the Class into *Ratitæ* and *Carinatæ*, the groups whose essentially distinct characters were recognized by Merrem. Furthermore, while the Ratite type (*Hesperornis*) presents the kind of teeth, arrayed in grooves, which indicate (in Reptiles at least) a low morphological rank, the Carinate type (*Ichthyornis*) is furnished with teeth set in sockets, and shewing a higher development. On the other hand this early Carinate type has vertebræ whose comparatively simple, biconcave form is equally evidence of a rank unquestionably low; but the saddle-shaped vertebræ of the contemporary Ratite type as surely testify to a more exalted position. Reference has been already made to this complicated if not contradictory state of things, the true explanation of which seems to be out of reach at present. It has been for some time a question whether the Ratite is a degraded type descended from the Carinate, or the Carinate a superior development of the Ratite type. Several eminent zoologists have declared themselves in favour of the former probability, and at first sight most people would be inclined to decide with them; for, on this hypothesis, the easiest answer to the question would be found. But the easiest answer is not always the true one; and to the present writer it seems that before this question be answered, a reply should be given to another—Was the first animal which any one could properly call a "Bird," as distinguished from a "Reptile," possessed of a keeled sternum or not? Now Birds would seem to have been differentiated from Reptiles while the latter had biconcave vertebræ, and teeth whose mode of attachment to the jaw was still variable. There is no reason to think that at that period any Reptile (with the exception of Pterodactyls, which, as has already been said, are certainly not in the line of Birds' ancestors) had a keeled sternum. Hence it seems almost impossible that the first Bird should have possessed one; that is to say, it must have been practically of the Ratite type. Prof. Marsh has shown that there is good reason for believing that the power of flight was gradually acquired by Birds, and with that power would be associated the development of a keel to the sternum, on which the volant faculty so much depends, and with which it is so intimately correlated that in certain forms which have to a greater or less extent given up the use of their fore-limbs the keel though present has become proportionally aborted. Thus the Carinate type would, from all we can see at present, appear to have been evolved from the Ratite. This view receives further support from a consideration of the results of such embryological research as has already been made—the unquestionable ossification of the Ratite sternum from a smaller number of paired centres than the Carinate sternum, in which (with the doubtful exception of the *Anatidæ*) an additional, unpaired centre makes its appearance. Again the geographical distribution of existing, or comparatively recent, Ratite forms points to the same conclusion. That these forms—Moa, Kiwi, Emu and Cassowary, Rhea, and finally Ostrich—

¹ See Prof. Seeley's remarks on the differences between the two specimens, in the *Geological Magazine* for October 1881.

² Prof. Vogt lays much stress on the absence of feathers from certain parts of the body of the second example of *Archæopteryx* now, thanks to Dr Werner Siemens, in the museum of Berlin. But Prof. Vogt himself shews that the parts of the body devoid of feathers are also devoid of skin. Now it is well known that amongst most existing Birds the ordinary "contour-feathers" have their origin no deeper than the skin, and thus if that decayed and were washed away the feathers growing upon it would equally be lost. This has evidently happened (to judge from photographs) to the Berlin specimen just as to that which is in London. In each case, as Sir R. Owen most rightly suggested of the latter, the remains exactly call to mind the very familiar relics of Birds found on a seashore, exposed perhaps for weeks or even months to the wash of the tides so as to lose all but the deeply-seated feathers, and finally to be embedded in the soft soil. Prof. Vogt's paper is in the *Revue Scientifique*, ser. 2, ix. p. 241, and an English translation of it in *The Ibis* for 1880, p. 431.

³ Prof. Hæckel seems first to have spelt this word *Sauriuræ*, in which form it appears in his *Allgemeine Entwicklungsgeschichte der Organismen*, forming the second volume of his *Generelle Morphologie* (pp. xi. and cxxxix.), published at Berlin in 1866, though on plate vii. of the same volume it appears as *Sauriuri*. Whether the masculine or feminine termination be preferred matters little, though the latter is come into general use, but the interpolation of the *i* in the middle of the word appears to be against all the laws of orthography.

must have had a common ancestor nearer to them than is the ancestor of any Carinate form seems to need no proof. If we add to these the *Epyornis* of Madagascar, the fossil *Ratitæ* of the Siwalik rocks,¹ and the as yet but partially recognized *Struthiolithus* of Southern Russia,² to say nothing of *Gastornis*, the evidence is stronger still. Scattered as these Birds have been or are throughout the world, it seems justifiable to consider them the survivals of a very ancient type, which has hardly undergone any essential modification since the appearance of Bird-life upon the earth—even though one at least of them has become very highly specialized.

No doubt the difficulty presented by the biconcave vertebrae of the earliest known representative of the Carinate type is a considerable obstacle to the view just taken. But in the *American Journal of Science* (April 1879), and again in his great work (pp. 180, 181), Prof. MARSH has shewn that in the third cervical vertebra of *Ichthyornis* "we catch nature in the act as it were" of modifying one form of vertebra into another, for this single vertebra in *Ichthyornis* is in vertical section "moderately convex, while transversely it is strongly concave, thus presenting a near approach to the saddle-like articulation"; and he proceeds to point out that this specialized feature occurs at the first bend of the neck, and, greatly facilitating motion in a vertical plane, is "mainly due originally to its predominance." The form of the vertebra would accordingly seem to be as much correlated with the mobility of the neck as is the form of the sternum with the faculty of flight. If therefore the development of the saddle shape be an indication of development, as well may be the outgrowth of a keel. However, the solution of this perplexing problem, if a solution be ever found, must remain for future palæontological or embryological discoverers. The present writer is far from attempting to decide a question so complicated, though he does not hesitate to say, notwithstanding the weight of authority on the other side, that according to present evidence the probability is in favour of the Carinate having been evolved from a mere ancient Ratite type. One thing only is certain, and that is the independent and contemporaneous existence of each of these great divisions at the earliest period when Birds at all like recent forms are known to have lived. The facts that each of these types was provided with teeth, and that the teeth were of a different pattern, are of comparatively secondary importance.

The three
Sub-
classes.

It seems therefore quite justifiable to continue, after the fashion that has been set, to separate the Class *Aves* into three primary groups:—I. *Saururæ*, II. *Ratitæ*, III. *Carinatæ*—the earliest members of the two last, as well as possibly all of the first, being provided with teeth. These three primary groups we may call "Subclasses."³ Thus we shall have:—

SAURURÆ, Hæckel. *Archæopteryx* the only known form.
RATITÆ, Merrem. a. with teeth;

a'. with biconcave vertebrae—as yet unknown;

b'. with saddle-shaped vertebrae—*Hesperornis*.

b. without teeth—recent and existing forms.

¹ For notice of these see the papers by Mr Davies in the *Geological Magazine* (new series, decade ii., vol. vii. p. 18), and Mr Lydekker in the *Records of the Geological Survey of India* (xii. p. 52).

² *Bull. Acad. Sc. St. Petersburg*, xviii. p. 158; *Ibis*, 1874, p. 4.

³ Prof. Huxley has termed them "Orders"; but it is more in accordance with the practice of ornithological writers to raise them to a higher rank, and to call the secondary groups "Orders." There is a good deal to be said in behalf of either view; but, as in most cases of mere terminology, the matter is not worth wasting words over it, so long as we bear in mind that what here is meant by an "Order" of *Aves* is a very different thing from an "Order" of *Reptilia*.

CARINATÆ, Merrem. a. with teeth;
a'. with biconcave vertebrae—*Ichthyornis*;
b'. with saddle-shaped vertebrae—as yet unknown.
b. without teeth—recent and existing forms.

We have now to consider the recent and existing forms of toothless *Ratitæ*. These were shewn beyond doubt by Prof. Huxley to form five separate groups, which we shall here dignify by the name of Orders,⁴ adding to them a sixth, though little is as yet known of its characteristics. Of this, which contains the great extinct Birds of Madagascar, he did not take cognizance, as it is here necessary to do. In the absence of any certain means of arranging all of these orders according to their affinities, it will be best to place their names alphabetically, thus:—

EPYORNITHES. Fam. *Epyornithidæ*.

APTERYGES. Fam. *Apterygidæ* (KIWI, vol. xiv. p. 104).

IMMANES. Fam. i. *Dinornithidæ*; Fam. ii. *Palaapterygidæ*.⁵

MEGISTANES. Fam. i. *Casuariidæ*; Fam. ii. *Dromæidæ* (EMEU, vol. viii. p. 171).

RHEÆ. Fam. *Rheidæ* (RHEA, q.v.).

STRUTHIONES. Fam. *Struthionidæ* (OSTRICH v. 62 *infra*).

Some systematists think there can be little question of the *Struthiones* being the most specialized and therefore probably the highest type of these Orders, and the present writer is rather inclined to agree with them. Nevertheless the formation of the bill in the *Apteryges* is quite unique in the whole Class, and indicates therefore an extraordinary amount of specialization. Their functionless wings, however, point to their being a degraded form, though in this matter they are not much worse than the *Megistanes*, and are far above the *Immanes*—some of which at least appear to have been absolutely wingless, and were thus the only members of the Class possessing but a single pair of limbs.

Turning then to the third Subclass, the *Carinatæ*, their subdivision into Orders is attended with a considerable amount of difficulty; and still greater difficulty is presented if we make any attempt to arrange these Orders so as in some way or other to shew their respective relations—in other words, their genealogy. In regard to the first of these tasks, a few groups can no doubt be at once separated without fear of going wrong. For instance, the *Crypturi* or Tinamous, the *Impennes* or Penguins, the *Striges* or Owls, the *Psittaci* or Parrots, and the *Passeres*, or at least the *Oscines*, seem to stand as groups each quite by itself, and, since none of them contains any hangers-on about the character of which there can any longer be room to hesitate, there can be little risk in setting them apart. Next comes a category of groups in which differentiation appears not to have been carried so far, and, though there may be as little doubt as to the association in one Order of the greater number of forms commonly assigned to each, yet there are in every case more or fewer outliers that do not well harmonize with the rest. Here we have such groups as those called *Pygopodes*, *Gaviæ*, *Limicolæ*, *Gallinæ*, *Columbæ*, *Anseres*, *Herodiones*, *Steganopodes*, and *Accipitres*. Finally there are two groups of types presenting characteristics so diverse as to defy almost any definition, and, if it were not almost nonsense to say so, agreeing in little more than in the differences. These two groups are those known as *Picariæ* and *Alectorides*; but, while the majority

⁴ See *Ann. Nat. History*, ser. 4, x. pp. 499, 500.

⁵ On the supposition that the opinions of Dr Von Haast (*Trans. and Proc. N. Zeal. Institute*, vi. pp. 426, 427) can be substantiated; but they have since been disputed by Prof. Hutton (*op. cit.*, ix. pp. 363–365), and for the present it is advisable to suspend our judgment.

of Families or genera usually referred to the former plainly have some features in common, the few Families or genera that have been clubbed together in the latter make an assemblage that is quite artificial, though it may be freely owned that with our present knowledge it is impossible to determine the natural alliances of all of them.¹

That our knowledge is also too imperfect to enable systematists to compose a phylogeny of Birds, even of the Carinate Subclass, and draw out their pedigree, ought to be sufficiently evident. The uncertainty which still prevails among the best-informed ornithologists as to the respective origin of the *Ratitæ* and *Carinatæ* is in itself a proof of that fact, and in regard to some groups much less widely differentiated the same thing occurs. We can point to some forms which seem to be collaterally ancestral (if such a phrase may be allowed), and among them perhaps some of those which have been referred to the group "*Alectorides*" just mentioned, and from a consideration of their Geographical Distribution and especially Isolation it will be obvious that they are the remnants of a very ancient and more generalized stock which in various parts of the world have become more or less specialized. The very case of the New-Caledonian Kagu (*Rhinocetus*), combining features which occasionally recall the Sun-Bittern (*Eurypyga*), and again present an unmistakable likeness to the *Limicolæ* or the *Rallidæ*, shews that it is without any very near relation on the earth, and, if convenience permitted, would almost justify us in placing it in a group apart from any other, though possessing some characteristics in common with several.

It is anything but the desire of the present writer to invent a new arrangement of Birds. Such acquaintance as he possesses with the plans which have been already propounded warns him that until a great deal more labour has been expended, and its results made clearly known, no general scheme of Classification will deserve to be regarded as final. Nevertheless in the best of modern systems there are some points which, as already hinted, seem to be well established, while in them there are also some dispositions and assignments which he is as yet unable to accept, while he knows that he is not alone in his mistrust of them, and he thinks it his duty here to mention them in the hope that thereby attention may be further directed to them, and his doubts either dispelled or established—it matters not which. The most convenient way of bringing them to the notice of the reader will perhaps be by considering in succession the different groups set forth by the latest systematist of any authority—Mr Sclater—a sketch of whose method has been above given.

If we trust to the results at which Prof. Huxley arrived, there can be little doubt as to the propriety of beginning the Carinate Subclass with his *Dromæognathæ*, the *Crypturi* of Illiger and others, or Tinamous, for their resemblance to the *Ratitæ* is not to be disputed; but it must be borne in mind that nothing whatever is known of their mode of development, and that this may, when made out, seriously modify their position relatively to another group, the normal *Anseres*, in which the investigations of Cuvier and L'Hermier have already shewn that there is some resemblance to the *Ratitæ* as regards the ossification of the sternum. It will be for embryologists to determine whether this asserted resemblance has any real meaning; but of the sufficient standing of the *Crypturi* as an Order there can hardly be a question.

We have seen that Prof. Huxley would derive all other existing Carinate Birds from the *Dromæognathæ*; but of course it must be understood in this, as in every other similar case, that it is not thereby implied that the modern representatives of the *Dromæognathous* type (namely, the Tinamous) stand in the line of ancestry.

Under the name *Impennes* we have a group of Birds, the Penguins, smaller even than the last, and one over which until lately systematists have been sadly at fault; for, though we as yet know little if anything definite as to their embryology, no one, free from bias, can examine any member of the group, either externally or internally, without perceiving how completely different it is from any others of the Carinate division. There is perhaps scarcely a feather or a bone which is not diagnostic, and nearly every character hitherto observed points to a low morphological rank. It may even be that the clothing of *Hesperornis* was not very dissimilar to the "plumage" which now covers the *Impennes*, and the title of an Order can hardly be refused to them.

The group known as *Pygopodes* has been often asserted to be closely akin to the *Impennes*, and we have seen that Brandt combined the two under the name of *Urinatores*, while Mr Sclater thinks the *Pygopodes* "seem to form a natural transition between" the Gulls and the Penguins. The affinity of the *Alcidæ* or Auks (and through them the Divers or *Colymbidæ*) to the Gulls may be a matter beyond doubt, and there appears to be ground for considering them to be the degraded offspring of the *Laridæ*; but to the present writer it appears questionable whether the Grebes, *Podicipidæ*, have any real affinity to the two Families with which they are usually associated, and this is a point deserving of more attention on the part of morphologists than it has hitherto received. Under the name of *Gaviæ* the Gulls and their close allies form a very natural section, but it probably hardly merits the rank of an Order more than the *Pygopodes*, for its relations to the large and somewhat multiform though very natural group *Limicolæ* have to be taken into consideration. Prof. PARKER long ago observed (*Trans. Zool. Society*, v. p. 150) that characters exhibited by Gulls when young, but lost by them when adult, are found in certain Plovers at all ages, and hence it would appear that the *Gaviæ* are but more advanced *Limicolæ*. The Limicoline genera *Dromas* and *Chionis* have many points of resemblance to the *Laridæ*; and on the whole the proper inference would seem to be that the *Limicolæ*, or something very like them, form the parent-stock whence have descended the *Gaviæ*, from which or from their ancestral forms the *Alcidæ* have proceeded as a degenerate branch. If this hypothesis be correct, the association of these three groups would constitute an Order, of which the highest Family would perhaps be *Otididæ*, the Bustards; but until further research shows whether the view can be maintained it is not worth while to encumber nomenclature by inventing a new name for the combination. On the other hand the Petrels, which form the group *Tubinæræ*, would seem for several reasons to be perfectly distinct from the *Gaviæ* and their allies, and possibly will have to rank as an Order.

Considerable doubt has already been expressed as to the existence of an Order *Alectorides*, which no one can regard as a natural group, and it has just been proposed to retransfer to the *Limicolæ* one of the Families, *Otididæ*, kept in it by Mr Sclater. Another Family included in it by its founder is *Cariamida*, the true place of which has long been a puzzle to systematizers. The present writer is inclined to think that those who have urged its affinity to the *Accipitres*, and among them taxonomers starting from bases so opposite as Sundevall and Prof. Parker, have more nearly hit the mark, and accordingly would

¹ Heterogeneous as is the group as left by the latest systematist, it is nothing to its state when first founded by Illiger in 1811; for it then contained in addition the genera *Glareola* and *Cercopis*, but the last was restored to its true place among the *Anseres* by Temminck. The *Alectridæ* of Duméril have nothing in common with the *Alectorides* of Illiger, and the latter is a name most unfortunately chosen, since the group so called does not include any Cock-like Bird.

Gaviæ
and their
allies.

now relegate it to that Order. It is doubtless an extremely generalized form,¹ the survival of a very ancient type, whence several groups may have sprung; and, whenever the secret it has to tell shall be revealed, a considerable step in the phylogeny of Birds can scarcely fail to follow.² Allusion has also been made to the peculiarities of two other forms placed with the last among the *Alectorides*—*Eurypyga* and *Rhinocetus*—being each the sole type of a separate Family. It seems that they might be brought with the *Gruide*, *Psophiide*, and *Aramide* into a group or Suborder *Grues*,—which, with the *Fulicariæ*³ of Nitzsch and Mr Sclater as another Suborder, would constitute an Order that may continue to bear the old Linnæan name *Grallæ*. It must be borne in mind, however, that some members of both these Suborders exhibit many points of resemblance to certain other forms that it is at present necessary to place in different groups—thus some *Rallidæ* to the *Gallinæ*, *Grus* to *Otis*, and so forth; and it is as yet doubtful whether further investigation may not shew the resemblance to be one of affinity, and therefore of taxonomic value, instead of mere analogy, and therefore of no worth in that respect.

Gallinæ. We have next to deal with a group nearly as complicated. The true *Gallinæ* are indeed as well marked a section as any to be found; but round and near them cluster some forms very troublesome to allocate. The strange Hoactzin (*Opisthocomus*) is one of these, and what seems to be in some degree its arrested development makes its position almost unique,⁴—but enough has already been said of it before (see vol. xii. p. 28, and *supra* p. 36). It must for the present at least stand alone, the sole occupant of a single Order. Then there are the Hemipodes or Button-Quails, which have been raised to equal rank by Prof. Huxley as *Turnicomorphæ*; but, though no doubt the osteological differences between them and the normal *Gallinæ*, pointed out by him as well as by Prof. Parker, are great, they do not seem to be more essential than are found in different members of some other Orders, nor to offer an insuperable objection to their being classed under the designation *Gallinæ*. If this be so there will be no necessity for removing them from that Order, which may then be portioned into three Suborders—*Hemipodii* standing somewhat apart, and *Alectoropodes* and *Peristeropodes*, which are more nearly allied—the latter comprehending the *Megapodiidæ* and *Cracidæ*, and the former consisting of the normal *Gallinæ*, of which it is difficult to justify the recognition of more than a single Family, though in that two types of structure are discernible.

Pteroclidæ. The Family of Sand-Grouse, *Pteroclidæ*, is perhaps one of the most instructive in the whole range of Ornithology. In Prof. HUXLEY's words (*Proceedings*, 1853, p. 303), they are "completely intermediate between the *Alectoromorphæ* [i.e., *Gallinæ*] and the *Peristeromorphæ* [the Pigeons]. They cannot be included within either of these groups without destroying its definition, while they are perfectly definable themselves." Hence he would make them an independent group of equal value with the other two. Almost the same result has been reached by Dr GADOW

(*op. cit.*, 1882, pp. 331, 332). No doubt there are strong and tempting reasons for taking this step; but peradventure the real lesson taught by this aggregation of common characters is rather the retention of the union of the *Gallinæ* and *Columbæ* into a single group, after the fashion of by-gone years, under the name, however meaningless, of *Rasores*. Failing that, the general resemblance of most parts of the osteology of the Sand-Grouse to that of the Pigeons, so well shewn by M^r. Milne-Edwards, combined with their Pigeon-like pterylosis, inclines the present writer to group them as a Suborder of *Columbæ*; but the many important points in which they differ from the more normal Pigeons, especially in the matter of their young being clothed with down, and their coloured and speckled eggs,⁵ must be freely admitted. Young Sand-Grouse are described as being not only "*Dasyptædes*" but even "*Præcoces*" at birth, while of course every one knows the helpless condition of "*Pipers*"—that is, Pigeons newly-hatched from their white eggs. Thus the opposite condition of the young of these two admittedly very near groups inflicts a severe blow on the so-called "*physiological*" method of dividing Birds before mentioned, and renders the *Pteroclidæ* so instructive a form. The *Columbæ*, considered in the wide sense just suggested, would seem to have possessed another and degenerate Suborder in the Dodo and its kindred, though the extirpation of those strange and monstrous forms will most likely leave their precise relations a matter of some doubt; while the third and last Suborder, the true *Columbæ*, is much more homogeneous, and can hardly be said to contain more than two Families, *Columbidæ* and *Didunculidæ*—the latter consisting of a single species peculiar to the Samoa Islands, and having no direct connexion with the *Dididæ* or *Dodos*,⁶ though possibly it may be found that the Papuan genus *Otidiphaps* presents a form linking it with the *Columbidæ*.

The *Gallinæ* would seem to hold a somewhat central position among existing members of the Carinate division,⁷ whence many groups diverge, and one of them, the *Opisthocomi* or *Heteromorphæ* of Prof. Huxley, indicates, as he has hinted, the existence of an old line of descent, now almost obliterated, in the direction of the *Musophegidæ*, and thence, we may not unreasonably infer, to the *Coccygomorphæ* of the same authority. But these "*Coccygomorphs*" would also appear to reach a higher rank than some other groups that we have to notice, and therefore, leaving the former, we must attempt to trace the fortunes of a more remote and less exalted line. It has already been stated that the *Gaviæ* are a group closely allied to though somewhat higher than the *Limicolæ*, and that at least two forms of what have here been called *Grallæ* present an affinity to the latter. One of them, *Rhinocetus*, has been several times thought to be connected through its presumed relative *Eurypyga* (from which, however, it is a good way removed both as regards distribution and structure) with the *Heriodiones*, Herons. On the other hand the *Gaviæ* would seem to be in like manner related through *Phaethon* (the TROPIC-BIRD, *q.v.*) with the *Steganopodes* or *Dysporomorphæ* of Prof. Huxley, among which it is usually placed, though according to Prof. MIVART (*Trans. Zool. Society*, x. pp. 364, 365) wrongly. These supposed affinities lead us to two other groups of Birds that have, it has been proved, some common characters; and from one or the other (no one yet can say which) the *Accipitres* would seem to branch off—

¹ *Cariama* is the oldest name for the genus, but being a word of "barbarous" origin it was set aside by Illiger and the purists in favour of *Dicholophus*, under which name it has been several times mentioned in the foregoing pages.

² A brief description of the egg and young of *Cariama cristata* produced in the Jardin des Plantes at Paris is given in the Zoological Society's *Proceedings* for 1881, p. 2.

³ This group would contain three families—*Rallidæ*, *Helionithidæ* (the Finfoots of Africa and South America), and the *Mesitidæ* of Madagascar—whose at least approximate place has been at last found for them by M. A. Milne-Edwards (*Ann. Sc. Naturelles*, ser. 6. vii. No. 6).

⁴ *Mesites*, just mentioned, presents a case which may, however, be very similar.

⁵ This fact tells in favour of the views of Dr Gadlow and those who hold the Sand-Grouse to be allied to the Plovers; but then he places the Pigeons between these groups, and their eggs tell as strongly the other way.

⁷ Cf. Prof. Parker's remarks in the *Philosophical Transactions* for 1869, p. 755.

possibly from some ancestral type akin to and now most directly represented by the enigmatical *Cariama*—possibly in some other way which we can only dimly foreshadow. The *Herodiones* are commonly partitioned into three groups—*Ardeæ*, *Ciconiæ*, and *Plataleæ*, the last including the Ibises—which may certainly be considered to be as many Suborders. The second of them, the Storks, may perhaps be regarded as the point of departure for the *Accipitres* in the manner indicated,¹ as well as, according to Prof. Huxley, for the Flamingoes, of which he would make a distinct group, *Amphimorphæ*, equivalent to the *Odontoglossæ* of Nitzsch, intermediate between the *Pelargomorphæ* and the *Chenomorphæ*, that is, between the Storks and the Geese. When the embryology of the *Phœnicopteridæ* is investigated their supposed relationship may perhaps be made out. At present it is, like so much that needs to be here advanced, very hypothetical; but there is so much in the osteology of the Flamingoes, besides other things, that resembles the *Anseres* that it would seem better to regard them as forming a Subclass of that group to rank equally with the true *Anseres* and with the *Palamedæ* (SCREAMER, *q.v.*), which last, notwithstanding the opinion of Garrod, can hardly from their osteological similarity to the true *Anseres* be removed from their neighbourhood.

Whatever be the alliances of the genealogy of the *Accipitres*, the Diurnal Birds-of-Prey, their main body must stand alone, hardly divisible into more than two principal groups—(1) containing the *Cathartidæ* or the Vultures of the New World, and (2) all the rest, though no doubt the latter may be easily subdivided into at least two Families, *Vulturidæ* and *Falconidæ*, and the last into many smaller sections, as has commonly been done; but then we have the outliers left. The African *Serpentariidæ*, though represented only by a single species,² are fully allowed to form a type equivalent to the true *Accipitres* composing the main body; but whether to the Secretary-bird should be added the often-named *Cariama*, with its two species, must still remain an open question.

It has so long been the custom to place the Owls next to the Diurnal Birds-of-Prey that any attempt to remove them from that position cannot fail to incur criticism. Yet when we disregard their carnivorous habits, and certain modifications which may possibly be thereby induced, we find almost nothing of value to indicate relationship between them. That the *Striges* stand quite independently of the *Accipitres* as above limited can hardly be doubted, and, while the *Psittaci* or Parrots would on some grounds appear to be the nearest allies of the *Accipitres*, the nearest relations of the Owls must be looked for in the multifarious group *Picariæ*. Here we have the singular *Steatornis* (GUACHARO, vol. ix. p. 227), which, long confounded with the *Caprimulgidæ* (GOATSUCKER, vol. ix. p. 711), has at last been recognized as an independent form, and one cannot but think that it has branched off from a common ancestor with the Owls. The Goatsuckers may have done the like,³ for there is really not much to ally them to the Swifts and Humming-birds, the *Macrochires* proper, as has often been recommended. However, the present writer would not have it supposed that he would place the *Striges* under the *Picariæ*, for the

last are already a sufficiently heterogeneous assemblage, and one with which he would not meddle. Whether the Woodpeckers should be separated from the rest is a matter of deeper consideration after the deliberate opinion of Prof. Parker, who would lift them as *Saurognothæ* to a higher rank than that in which Prof. Huxley left them as *Celeomorphæ*, indeed to be the peers of *Schizognathæ*, *Desmognathæ*, and so forth; but this advancement is based solely on the characters of their palatal structure, and is unsupported by any others. That the *Pici* constitute a very natural and easily defined group is indisputable; more than that, they are perhaps the most differentiated group of all those that are retained in the "Order" *Picariæ*; but it does not seem advisable at present to deliver them from that chaos when so many other groups have to be left in it.

Lastly we arrive at the *Passeres*, and here, as already mentioned, the researches of Garrod and Forbes prove to be of immense service. It is of course not to be supposed that they have exhausted the subject even as regards their *Mesomyodi*, while their *Acromyodi* were left almost untouched so far as concerns details of arrangement; but the present writer has no wish to disturb by other than very slight modifications the scheme they put forth. He would agree with Mr Selater in disregarding the distinctions of *Desmodactyli* and *Eleutherodactyli*, grouping the former (*Eurylamidæ*) with the *Heteromeri* and *Haplophonæ*, which all together then might be termed the their Suborder *Oligomyodi*. To this would follow as a second orders. Suborder the *Tracheophonæ* as left by Garrod, and then as a third Suborder the abnormal *Acromyodi*, whether they are to be called *Pseudoscines* or not, that small group containing, so far as is known at present, only the two Families *Atrichidæ* and *Menuridæ*. Finally we have the normal *Acromyodi* or true *Oscines*.

This last and highest group of Birds is one which, as *Oscines*, before hinted, it is very hard to subdivide. Some two or three natural, because well-differentiated, Families are to be found in it—such, for instance, as the *Hirundinidæ* or Swallows, which have no near relations; the *Alaudidæ* or Larks, that can be unfailingly distinguished at a glance by their scutellated *planta*, as has been before mentioned; or the *Meliphagidæ* with their curiously constructed tongue. But the great mass, comprehending incomparably the greatest number of genera and species of Birds, defies any sure means of separation. Here and there, of course, a good many individual genera may be picked out capable of the most accurate definition; but genera like these are in the minority, and most of the remainder present several apparent alliances, from which we are at a loss to choose that which is nearest. Four of the six groups of Mr Selater's "Laminipantar" *Oscines* seem to pass almost imperceptibly into one another. We may take examples in which what we may call the Thrush-form, the Tree-creeper-form, the Finch-form, or the Crow-form is pushed to the most extreme point of differentiation, but we shall find that between the outposts thus established there exists a regular chain of intermediate stations so intimately connected that no precise lines of demarcation can be drawn cutting off one from the other.

Still one thing is possible. Hard though it be to find definitions for the several groups of *Oscines*, whether we make them more or fewer, it is by no means so hard, if we go the right way to work, to determine which of them is the highest, and, possibly, which of them is the lowest. It has already been shewn (page 30) how, by a woeeful want of the logical apprehension of facts, the *Turdidæ* came to be accounted the highest, and the position accorded to them has been generally acquiesced in by those who have followed in the footsteps of Keyserling and

¹ Garrod and Forbes suggest a "Ciconiiform" origin for the *Tubinares* (Zool. Voy. "Challenger," pt. xi. pp. 62, 63).

² It was long suspected that the genus *Polyboroides* of South Africa and Madagascar, from its general resemblance in plumage and outward form, might come into this group, but that idea has now been fully dispelled by M. A. Milne-Edwards in his and M. Grandidier's magnificent *Oiseaux de Madagascar* (vol. i. pp. 50-66).

³ The great resemblance in coloration between Goatsuckers and Owls is of course obvious, so obvious indeed as to make one suspicious of their being akin; but in reality the existence of the likeness is no bar to the affinity of the groups; it merely has to be wholly disregarded.

Blasius, of Prof. Cabanis and of Sundevall. To the present writer the order thus prescribed seems to be almost the very reverse of that which the doctrine of Evolution requires, and, so far from the *Turdidæ* being at the head of the *Oscines*, they are among its lower members. There is no doubt whatever as to the intimate relationship of the Thrushes (*Turdidæ*) to the Chats (*Saxicolinæ*), for that is admitted by nearly every systematizer. Now most authorities on classification are agreed in associating with the latter group the Birds of the Australian genus *Petræca* and its allies—the so-called “Robins” of the English-speaking part of the great southern communities. But it so happens that, from the inferior type of the osteological characters of this very group of Birds, Prof. PARKER has called them (*Trans. Zool. Society*, v. p. 152) “Struthious Warblers.” Now if the *Petræca*-group be, as most allow, allied to the *Saxicolinæ*, they must also be allied, only rather more remotely, to the *Turdidæ*—for Thrushes and Chats are inseparable, and therefore this connexion must drag down the Thrushes in the scale. Let it be granted that the more highly-developed Thrushes have got rid of the low “Struthious” features which characterize their Australian relatives, the unbroken series of connecting forms chains them to the inferior position, and of itself disqualifies them from the rank so fallaciously assigned to them. Nor does this consideration stand alone. By submitting the Thrushes and allied groups of Chats and Warblers to other tests we may try still more completely their claim to the position to which they have been advanced.

Without attaching too much importance to the systematic value which the characters of the nervous system afford, there can be little doubt that, throughout the Animal Kingdom, where the nervous system is sufficiently developed to produce a brain, the creatures possessing one are considerably superior to those which have none. Consequently we may reasonably infer that those which are the best furnished with a brain are superior to those which are less well endowed in that respect, and that this inference is reasonable is in accordance with the experience of every Physiologist, Comparative Anatomist, and Palæontologist, who are agreed that, within limits, the proportion which the brain bears to the spinal marrow in a vertebrate is a measure of that animal's morphological condition. These preliminaries being beyond contradiction, it is clear that, if we had a series of accurate weights and measurements of Birds' brains, it would go far to help us in deciding many cases of disputed precedency, and especially such a case as we now have under discussion. To the dispraise of Ornithotomists this subject has never been properly investigated, and of late years seems to have been wholly neglected. The present writer can only refer to the meagre lists given by TIEDEMANN (*Anat. und Naturgesch. der Vögel*, i. pp. 18–22), based for the most part on very ancient observations; but, so far as those observations go, their result is conclusive, for we find that in the Blackbird, *Turdus merula*, the proportion which the brain bears to the body is lower than in any of the eight species of *Oscines* there named, being as 1 is to 67. In the Redbreast, *Erithacus rubecula*, certainly an ally of the *Turdidæ*, it is as 1 to 32; while it is highest in two of the Finches—the Goldfinch, *Carduelis elegans*, and the Canary-bird, *Serinus canarius*, being in each as 1 to 14. The signification of these numbers needs no comment to be understood.

Evidence of another kind may also be adduced in proof that the high place hitherto commonly accorded to the *Turdidæ* is undeserved. Throughout the Class *Aves* it is observable that the young when first fledged generally assume a spotted plumage of a peculiar character—nearly each of the body-feathers having a light-coloured spot at

its tip—and this is particularly to be remarked in most groups of *Oscines*, so much so indeed, that a bird thus marked may, in the majority of cases, be set down without fear of mistake as being immature. All the teachings of morphology go to establish the fact that any characters which are peculiar to the immature condition of an animal, and are lost in its progress to maturity, are those which its less advanced progenitors bore while adult, and that in proportion as it gets rid of them it shews its superiority over its ancestry. This being the case, it would follow that an animal which at no time in its life exhibits such marks of immaturity or inferiority must be of a rank, compared with its allies, superior to those which do exhibit these marks. The same may be said of external and secondary sexual characters. Those of the female are almost invariably to be deemed the survival of ancestral characters, while those peculiar to the male are in advance of the older fashion, generally and perhaps always the result of sexual selection.¹ When both sexes agree in appearance it may mean one of two things—either that the male has not lifted himself much above the condition of his mate, or that, he having raised himself, the female has successfully followed his example. In the former alternative, as regards Birds, we shall find that neither sex departs very much from the coloration of its fellow-species; in the latter the departure may be very considerable. Now, applying these principles to the Thrushes, we shall find that without exception, so far as is known, the young have their first plumage more or less spotted; and, except in some three or four species at most,² both sexes, if they agree in plumage, do not differ greatly from their fellow-species.

Therefore as regards capacity of brain and coloration of plumage priority ought not to be given to the *Turdidæ*. It remains for us to see if we can find the group which is entitled to that eminence. Among Ornithologists of the highest rank there have been few whose opinion is more worthy of attention than Macgillivray, a trained anatomist and a man of thoroughly independent mind. Through the insufficiency of his opportunities, his views on general classification were confessedly imperfect, but on certain special points, where the materials were present for him to form a judgment, one may generally depend upon it. Such is the case here, for his work shews him to have diligently exercised his genius in regard to the Birds which we now call *Oscines*. He belonged to a period anterior to that in which questions that have been brought uppermost by the doctrine of Evolution existed, and yet he seems not to have been without perception that such questions might arise. In treating of what he termed the Order *Vagatores*,³ including among others the Family *Corvidæ*—the Crows, he tells us (*Brit. Birds*, i. pp. 485, 486) that they “are to be accounted among the most perfectly organized birds,” justifying the opinion by stating the reasons, which are of a very varied kind, that led him to it. In one of the earlier treatises of Prof. PARKER, he has expressed (*Trans. Zool. Society*, v. p. 150) his approval of Macgillivray's views, adding that, “as that speaking, singing, mocking animal, Man, is the culmination of the Mammalian series, so that bird in which the gifts of speech, song, and mockery are combined must be considered as the top and crown of the bird-class.” Any doubt as to which Bird is here intended is dispelled by another passage, written ten

¹ See Darwin, *Descent of Man*, chaps. xv., xvi.

² According to Mr Seebohm (*Cat. Birds Brit. Museum*, v. p. 232) these are in his nomenclature *Merula nigrescens*, *M. fuscata*, *M. gigas*, and *M. gigantea*.

³ In this Order he included several groups of Birds which we now know to be but slightly if at all allied; but his intimate acquaintance was derived from the *Corvidæ* and the allied Family we now call *Sturnidæ*.

years later, wherein (*Monthly Microsc. Journal*, 1872, p. 217) he says, "The Crow is the great sub-rational chief of the whole kingdom of the Birds; he has the largest brain; the most wit and wisdom;" and again, in the Zoological Society's *Transactions* (ix. p. 300), "In all respects, physiological, morphological, and ornithological, the Crow may be placed at the head, not only of its own great series (birds of the *Crow-form*), but also as the unchallenged chief of the whole of the 'Carinatae.'"

It is to be supposed that the opinion so strongly expressed in the passage last cited has escaped the observation of recent systematizers; for he would be a bold man who would venture to gainsay it. Still Prof. Parker has left untouched or only obscurely alluded to one other consideration that has been here brought forward in opposing the claim of the *Turdidae*, and therefore a few words may not be out of place on that point—the evidence afforded by the coloration of plumage in young and old. Now the *Corvidae* fulfil as completely as is possible for any group of Birds to do the obligations required by exalted rank. To the magnitude of their brain beyond that of all other Birds Prof. Parker has already testified, and it is the rule for their young at once to be clothed in a plumage which is essentially that of the adult. This plumage may lack the lustrous reflexions that are only assumed when it is necessary for the welfare of the race that the wearer should don the best apparel, but then they are speedily acquired, and the original difference between old and young is of the slightest. Moreover, this obtains even in what we may fairly consider to be the weaker forms of the *Corvidae*—the Pies and Jays. In one species of *Corvus*, and that (as might be expected) the most abundant, namely, the Rook, *C. frugilegus*, very interesting cases of what would seem to be explicable on the theory of Reversion occasionally though rarely occur. In them the young are more or less spotted with a lighter shade, and these exceptional cases, if rightly understood, do but confirm the rule.¹ It may be conceded that even among *Oscines*² there are some other groups or sections of

groups in which the transformation in appearance from youth to full age is as slight. This is so among the *Paridae*; and there are a few groups in which the young, prior to the first moult, may be more brightly tinted than afterwards, as in the genera *Phylloscopus* and *Anthus*. These anomalies cannot be explained as yet, but we see that they do not extend to more than a portion, and generally a small portion, of the groups in which they occur; whereas in the Crows the likeness between young and old is, so far as is known, common to every member of the Family. It is therefore confidently that the present writer asserts, as Prof. Parker, with far more right to speak on the subject, has already done, that at the head of the Class *Aves* must stand the Family *Corvidae*, of which Family no one will dispute the superiority, of the genus *Corvus*, nor in that genus the pre-eminence of *Corvus corax*—the widely-ranging Raven of the Northern Hemisphere, the Bird perhaps best known from the most ancient times, and, as it happens, that to which belongs the earliest historical association with man. There are of course innumerable points in regard to the Classification of Birds which are, and for a long time will continue to be, hypothetical as matters of opinion, but this one seems to stand a fact on the firm ground of proof.

During the compilation of much of the present article the writer flattered himself with the hope that he might at its conclusion have been able to give a graphic illustration of the way in which the various groups of Birds may be conceived to be related to one another in the form of a map, such as has been so usefully furnished by several of his more gifted brethren in regard to other Classes or portions of Classes of the Animal Kingdom. This hope he has been reluctantly constrained to abandon,—whether from the inherent difficulty, perhaps impossibility, of at present executing the task, or from his own want of cartographical skill, it is not for him to say. He may, however, be allowed to express the belief that there is no group in Animated Nature that more assuredly deserves the further attention of the highest zoological intellects than Birds; and, looking to the perplexities which on all sides beset their scientific study, there is no department of Zoology that will better repay the application of those intellects than Ornithology.

(A. N.)

ORNITHORHYNCHUS. See PLATYPUS.

ORONTES. See SYRIA.

OROPUS, a Greek seaport, on the Euripus, in the district *Περαϊκή*, opposite Eretria. It was a border city between Boeotia and Attica, and its possession was a continual source of dispute between the two countries; but at last it came into the final possession of Athens, and is always alluded to under the Roman empire as an Attic town. The actual harbour, which was called Delphinium, was at the mouth of the Asopus, about a mile north of the city. The famous oracle of Amphiaraus was situated in the territory of Oropus, 12 stadia from the city. A village still called Oropo occupies the site of the ancient town.

OROSIUS, PAULUS, author of the once widely read *Historiarum adversum Paganos Libri VII.*, was born in Spain towards the close of the 4th century; that he was a native of Tarragona is a somewhat precarious inference from his manner of referring to "Tarraco nostra" in *Hist.* vii. 22. Having entered the Christian priesthood, he naturally took an interest in the Priscillianist controversy then going on in his native country, and it was in connexion with this that he went (or was sent) to consult Augustine at Hippo in 413 or 414. After staying for some time in Africa as the disciple of Augustine, he was sent by him in 415 to Palestine with a letter of introduction to Jerome, then at Bethlehem. The ostensible purpose of his mission (apart, of course, from those of pilgrimage and perhaps relic hunting) was that he might gain further instruction from Jerome on the points raised by the Priscillianists and Origenists; but in reality, it would seem, his business was to stir up and assist Jerome and others against Pelagius, who, since the synod of Carthage in 411, had been living in Palestine, and finding some acceptance there. The result of his arrival was that John, bishop of Jerusalem, was induced to summon at his capital in June 415 a synod at which Orosius communicated the decisions of Carthage and read such of Augustine's writings against Pelagius as had at that time appeared. Success, however,

was scarcely to be hoped for amongst Orientals who did not understand Latin; and whose sense of reverence was unshocked by the question of Pelagius "et quis est mihi Augustinus?" All that Orosius succeeded in obtaining was John's consent to send letters and deputies to Innocent of Rome; and, after having waited long enough to learn the unfavourable decision of the synod of Diospolis or Lydda in December of the same year, he returned to north Africa, where he is believed to have died. According to Gennadius he carried with him recently discovered relics of the protomartyr Stephen from Palestine to the West.

The earliest work of Orosius, *Consultatio sive Commonitorium ad Augustinum de errore Priscillianistarum et Origenistarum*, explains its object by its title; it was written soon after his arrival in Africa, and is usually printed in the works of Augustine along with the reply of the latter, *Contra Priscillianistas et Origenistas Liber ad Orosium*. His next treatise, *Liber Apologeticus de arbitrii libertate*, was written during his stay in Palestine, and in connexion with the controversy which engaged him there. It occurs in the *Biblioth. Max. Patr.*, and also in Hardouin and Mansi. The *Historia adversum Paganos* was undertaken at the suggestion of Augustine, to whom it is dedicated. When Augustine proposed this task he had already planned and made some progress with his own *De Civitate Dei*; it is the same argument that is elaborated by his disciple, namely, the evidence from history that the circumstances of the world had not really become worse since the introduction of Christianity. The work, which is thus a pragmatical chronicle of the calamities that have happened to mankind from the fall down to the Gothic period, has little accuracy or learning, and even less of literary charm to commend it; but its purpose gave it value in the eyes of the orthodox, and the *Historia*, or *Ornista* (Or[osii] M[undi] Hist[oria]), as it was called, speedily attained a wide popularity. A free abridged translation by King Alfred is still extant (Old English text, with original in Latin, edited by H. Sweet, 1883). The *editio princeps* of the original appeared at Augsburg (1471); that of Havercamp (Leyden, 1738 and 1767) has now been superseded by Zangemeister, who has edited the *Hist.* and also the *Lib. Apol.* in vol. v. of the *Corp. Scr. Eccl. Lat.* (Vienna, 1882). The "sources" made use of by Orosius have been investigated by Mörmr (*De Orosii vita ejusque hist. libr. VII. adversum Paganos*, 1844); besides the Old and New Testaments, he appears to have consulted Livy, Justin, Tacitus, Suetonius, Florus, and a cosmography, attaching also great value to Jerome's translation of the *Chronicles* of Eusebius.

ORPHEUS, a very important figure in Greek legend. The name is an ancient Indo-European one; the original *Arbhu* can be traced in the *Ribhu* of the Rigveda and the *Alp* or *Elf* of Teutonic folklore. It is, however, impossible to establish any connexion between the Orpheus legend in the highly developed form which alone has come down to us and the beliefs entertained about Ribhu and Elf. In Greece, Orpheus was always associated with the early Thracian race, which was supposed to have inhabited the neighbourhood of Mount Helicon, the district of Pieria in Macedonia, and the coasts and country generally on the north of the Ægean Sea. The religion of the Muses and the religion of Dionysus, with both of which Orpheus is connected, are intimately associated with this race (see MUSES). Orpheus was son of the river god Egeus and the Muse Calliope. He played so divinely on the lyre that all nature stopped to listen to his music. When his wife Eurydice died, he went after her to Hades, and the strains of his lyre softened even the stern gods of the dead. Eurydice was released, and followed him to the upper world, but he looked back towards her before she was clear of the world of death and she vanished again from his sight. The Thracian women, jealous of his unconquerable love for his lost wife, tore him to pieces during the frenzy of the Bacchic orgies; his head and his lyre floated "down the swift Hebrus to the Lesbian shore," where a shrine of Orpheus was built near Antissa. The legend, with all its melancholy, its love, and its sympathy with nature, has obviously taken shape in the hands of an early school of lyric poetry, associated with the worship of the Muses; the ancient Thracian *oidoi* are recognized as the earliest singers in Greece, but their art and their Muse-religion have passed to Lesbos, which was the chief seat of Greek lyric poetry in the 7th and 6th centuries B.C. The tragic death of Orpheus is obviously connected with the Bacchic ritual (see ORGIES). Orpheus is the representative of the god torn to pieces every year by the envious powers of nature, a ceremony that was duly enacted by the Bacchæ, in earlier times with a human victim, afterwards with a bull to represent the bull-formed god.

The Orpheus legend is closely analogous with that of Marsyas. Orpheus and Marsyas are embodiments of the supposed origin of music in Thrace and in Phrygia, countries inhabited by kindred races, viz., the influences of nature (both being closely connected with river-worship) and the teaching or gift of a goddess. The melancholy history of both must have its origin in the character of the Thracio-Phrygian people: the divine gift brings sorrow as well as power. Each uses the musical instrument that characterized his country.

The name of Orpheus is equally important in the religious history of Greece; and in this respect also it is associated with Thrace. He was the mythic founder of a religious school or sect, with a code of rules of life, a mystic eclectic theology, a system of purificatory and expiatory rites, and peculiar mysteries. This school is first observable under the rule of Pisistratus at Athens in the 6th century B.C. Its doctrines are founded on two elements—(1) the Thracio-Phrygian religion of Bacchus with its enthusiastic orgies, its mysteries, and its purifications, and (2) the tendency to philosophic speculation on the nature and mutual relations of the numerous gods, developed at this time by intercourse with Egypt and the East, and by the quickened intercourse between different tribes and different religions in Greece itself. These causes produced similar results in different parts of Greece. The close analogy between Pythagoreanism and Orphism has been recognized from Herodotus (ii. 81) to the latest modern writers. Both inculcated a peculiar kind of ascetic life; both had a mystical speculative

theory of religion, with purificatory rites, abstinence from beans, &c.; but Orphism was more especially religious, while Pythagoreanism, at least originally, inclined more to be a political and philosophical creed.

The rules of the Orphic life (*βίος Ὀρφικός*) prescribed abstinence from beans, flesh, certain kinds of fish, &c., the wearing of a special kind of clothes, and numerous other practices and abstinences, for all of which reasons were given in religious myths (*ἱεροὶ λόγοι*). The ritual of worship was peculiar, not admitting bloody sacrifices. The belief was taught in the homogeneity of all living things, in the transmigration of souls, in the view that the soul is imprisoned in the body, and that it may gradually attain perfection during connexion with a series of bodies. It is not possible here to treat of the Orphic mysteries (see Lobeck, *Aglaophamus*). The influence of Orphism on the Eleusinian mysteries has been described under MYSTERIES, and points of similarity and diversity noted. Greek literature was always hostile to the Orphic religion (cf. Eur., *Hipp.*, 952 sq.; Plato, *Rep.*, ii. 364; Theophr., *Char.*, 25).

A large number of writings in the tone of the Orphic religion existed and were ascribed to Orpheus, as the poems of the Trojan and Theban cycles to Homer and Hesiod. The real names of the authors of these works were in many cases known to those who inquired into the matter, though the common people believed that all were written before the time of Homer by Orpheus (Herod., ii. 53). Aristotle declared that there had never been a poet Orpheus. The names of poets of the Orphic cycle can be traced as early as 550 B.C. Onomacritus is the most famous of them all (see ONOMACRITUS). These poems were recited at rhapsodic contests alongside of Homeric and Hesiodic works (Plato, *Ion*, 536). Orphic hymns were used in the mysteries at Phlya and Eleusis (Paus., ix. 27, 2; 30, 5; i. 14). The poems were a favourite subject of study for the Alexandrian grammarians. Again in the controversies between Christian and pagan writers in the 3d and 4th centuries after Christ the Orphic religious poems played a great part: pagan writers quoted them to show the real meaning of the multitude of gods, while Christians retorted by reference to the obscene and disgraceful fictions by which they degraded the gods.

The Orphic literature was united in a *corpus*, entitled τὰ Ὀρφικά, or τὰ ἐς Ὀρφέα ἀναφερόμενα; the different parts were connected, and the whole prefaced by a dedication to Musæus as son and first initiate of Orpheus. The chief poem was ἡ τοῦ Ὀρφέου θεολογία or μυθοποιία, which existed in several versions, showing considerable variations. There was also a collection of Orphic hymns, containing numerous liturgic songs used in the mysteries and in exoteric ceremonial; also practical treatises, *Ἔργα καὶ Ἡμέραι*, and poems on stones, herbs, and plants, &c. These works have been lost, except fragments collected by Lobeck. There exist several poems called Orphic (*Argonautica*, *Hymns*, *Lithica*). These are very late works, composed at the time when paganism was passing away before Christianity.

The story of Orpheus, as was to be expected of a legend told both by Ovid and Boetius (bk. iii. cap. xxxv.), retained its popularity throughout the Middle Ages and was transformed into the likeness of a northern fairy tale. In English mediæval literature it appears in three somewhat different versions:—*Sir Orpheo*, a "lay of Brittany" printed from the Harleian MS. in Ritson's *Ancient English Metrical Romances*, vol. ii.; *Orpheo and Heurodis* from the Auchinleck MS. in David Laing's *Select Remains of the Ancient Popular Poetry of Scotland*; and *King Orfeo* from the Ashmolean MS. in Halliwell's *Illustrations of Fairy Mythology* (Shakespeare Soc., 1842). The poems bear trace of French influence.

ORPIMENT (*auripigmentum*), the trisulphide of arsenic, As₂S₃, or yellow realgar, occurs in small quantities as a native mineral of a brilliant golden-yellow colour in Bohemia, Peru, &c. For industrial purposes an artificial orpiment is manufactured by subliming one part of sulphur with two of arsenious acid. The sublimate varies in colour from yellow to red, according to the intimacy of the combination of the ingredients; and by varying the relative

quantities used many intermediate tones may be obtained. These artificial preparations all contain free arsenious acid, and are therefore highly poisonous. Formerly, under the name of king's yellow, a preparation of orpiment was in considerable use as a pigment, but now it has been largely superseded by chrome-yellow. It was also at one time used in dyeing and calico-printing, and for the unhairing of skins, &c.; but safer and equally efficient substitutes have been found.

ORRERY, EARLS OF. See BOYLE.

ORRIS-ROOT consists of the rhizomes or underground stems of three species of *Iris*, *I. germanica*, *I. florentina*, and *I. pallida*, closely allied plants growing in subtropical and temperate latitudes, but principally identified with North Italy. The three plants are indiscriminately cultivated in the neighbourhood of Florence as an agricultural product under the name of "ghiaggiuolo." The rhizomes form joints of annual growth from 3 to 4 inches long; they branch and give off rootlets at the joints, and when these attain five years of age they begin to decay. When taken out of the ground the branches and rootlets are trimmed off, the brown bark removed, and the separated joints are put up to dry and mature. In its fresh condition orris-root contains an acrid juice and has an earthy odour, but it is quite destitute of the fragrance which ultimately characterizes the substance, and which develops fully only after a lapse of about two years, probably by fermentation. As it comes into the market, orris-root is in the form of contorted sticks and irregular knobby pieces up to 4 inches in length, of a compact chalky appearance, having a delicate but distinct odour of violets. By distillation with water a crystalline body known as orris-camphor or oil of orris, possessing the fragrant properties of orris-root, is obtained. It is present in exceedingly small quantity, from 0.10 to 0.80 per cent., and Professor Flückiger has demonstrated that the crude distillate consists only of myristic acid impregnated with or scented by the essential oil of orris, a body which may never be isolated owing to the necessarily minute quantities in which it could be produced. Orris-root has been a well-known and esteemed perfume from early Greek times. It is principally powdered for use in dentifrices and other scented dry preparations; but to some extent the crude oil is distilled for general perfumery purposes. It is also used in small pellets as issue peas.

ORSINI, FELICE (1819–1858), Italian patriot, was born in December 1819 at a small town in the Roman states not far from Forlì. He was educated for the church, but soon abandoned that career, and joined Mazzini's Young Italy Society in 1838. For engaging in revolutionary projects he was arrested 1st May 1844, and sentenced at Rome to the galleys for life, but by the amnesty proclaimed on the accession of Pius IX. he was restored to liberty. In 1848 he became leader of a band of youthful Romagnoli, distinguishing himself greatly at Vicenza and Treviso; and in 1849 he was chosen a deputy to the Roman parliament. After the suppression of the revolution he became one of the most active agents of Mazzini, and while engaged in a mission to Hungary he was in December 1854 arrested at Hermannstadt and imprisoned at Mantua. A few months afterwards he made his escape by sawing through the bars of his cell, and in 1856 he published a narrative of his prison experiences under the title *Austrian Dungeons in Italy*. Some time after a rupture with Mazzini he went to Paris with the determination to assassinate Napoleon III., whom he regarded as the chief stumbling-block in the way of Italian independence, and the principal cause of the anti-liberal reaction in Europe. While the emperor and empress were returning from the opera on the evening of January 14, 1858, bombs were exploded at their carriage,

but without inflicting any injury on either. In the attempt Orsini had three associates, Pieri, Rudio, and Gomez. Gomez was pardoned, the sentence against Rudio was commuted on the scaffold, but Orsini and Pieri were executed 13th March 1858. Orsini, whose action had an important influence in precipitating the campaign of 1859 (see vol. ix. p. 624), met his fate with great dignity and stoicism.

See *Memoirs and Adventures of Felice Orsini written by himself*, translated by George Carbonel, Edinburgh, 1857; *Lettere Edite ed Inedite di Felice Orsini*, 2 vols., Milan, 1861; *I Contemporanei Italiani—Felice Orsini*, by Enrico Montazio, Turin, 1862; *La Verità sur Orsini, par un ancien Proscrit*, 1879.

ORSK (*Yaman-kala* of the Kirghiz), a district town of Orenburg, Russia, 155 miles to the east-south-east of the capital of the government, on the right bank of the Ural, was originally founded in 1735 as the principal Russian fort against the attacks of the Kirghiz. Though this was afterwards transferred to Orenburg, the town of Orsk has increased rapidly within the last few years, owing to the fertility of the surrounding country, to immigration, and to the growth of trade with the Kirghiz. The population, only 6000 some fifteen years ago, reached 14,350 in 1880, and has since become larger.

ORTELIUS, ORTELL, or OERTEL, ABRAHAM, next to Mercator the greatest geographer of his age, was born at Antwerp in 1527, and died in the same city on June 28, 1598. He visited various parts of the Netherlands and Germany (1575), England and Ireland (1577), and Italy on several occasions. His *Theatrum Orbis Terrarum* (published at Antwerp in 1570, and reissued in a revised form five times during his lifetime) was the first modern atlas, Mercator having, it is said, delayed the appearance of his collection out of consideration for his friend. Most of the maps were admittedly reproductions, and no attempt was made to reconcile discrepancies of delineation or nomenclature. To the modern eye even England and Scotland appear with amusing distortions (the Mons Grampius, e.g., lies between the Forth and the Clyde); but, taken as a whole, the noble folio, with its well-nigh one hundred maps, and its careful accompaniment of text, was a monument of rare erudition and industry; and the author well deserved the appointment to be cosmographer to Philip II. bestowed upon him in 1575. A few years later he laid the basis of a critical treatment of ancient geography by his *Synonymia geographica* (Antwerp, 1578), reissued as *Thesaurus geographicus* in 1596. Other works from his pen are *Itinerarium per nonnullas Galliae Belgicae partes*, 1584 (reprinted in Hegenitius, *Itin. Frisio-Holl.*); *Deorum dearumque capita*, 1573 (reprinted in Gronovius, *Thes. Gr. Ant.*, vol. vii.).

See Macedo in *Annales des Voyages*, ii., and Gérard in *Bull. de la soc. géogr. d'Anvers*, 1880.

ORTHONYX, the scientific name given in 1820, by Temminck, to a little bird, which, from the straightness of its claws,—a character somewhat exaggerated by him,—its large feet and spiny tail, he judged to be generically distinct from any other form. Concerning its affinities much doubt has long prevailed, and this has been only lately set at rest. The typical species, *O. spinicauda*, is from south-eastern Australia, where it is said to be very local in its distribution, and strictly terrestrial in its habits. In the course of time two other small birds from New Zealand, where they are known as the "Whitehead" and "Yellowhead," were referred to the genus, under the names of *O. albicilla* and *O. ochrocephala*, and then the question of its affinity became more interesting. By some systematists it was supposed to belong to the otherwise purely Neotropical *Dendrocolaptidae*, and in that case would have been the sole representative of the *Tracheo-*

¹ It may be charitably conjectured that the nomenclator intended to write *albicilla*.

phone *Passeres* in the Australian Region. Others considered it one of the nearest relatives of *Menura*, and if that view were correct it would add a third form to the small section of *Pseudoscines* (see LYRE-BIRD, vol. xv. p. 115); while Sundevall, in 1872, placed it not far from *Timelia*, among a group the proper sorting of which will probably for years tax the ingenuity of ornithologists. The late Mr W. A. Forbes shewed (*Proc. Zool. Soc.*, 1882, p. 544) that this last position was the most correct, as *Orthonyx spinicauda* proved on dissection to be one of the true *Oscines*, but yet to stand, so far as is known, alone among birds of that group, or any other group of *Passeres*, in consequence of the superficial course taken by the (left) carotid artery, which is nowhere contained in the subvertebral canal. Whether this discovery will require the segregation of the genus as the representative of a separate Family *Orthonycidae*—which has been proposed by Mr Salvin (*Catal. Coll. Strickland*, p. 294)—remains to be seen. Forbes also demonstrated that one at least of the two New-Zealand species above mentioned, *O. ochrocephala*, had been wrongly referred to this genus, and they therefore at present stand as *Clitonyx*. This is a point of some little importance in its bearing on the relationship of the fauna of the two countries, for *Orthonyx* was supposed to be one of the few genera of Land-birds common to both.

The typical species of *Orthonyx*—for the scientific name has been adopted in English—is rather larger than a Skylark, coloured above not unlike a Hedge-Sparrow. The wings are, however, barred with white, and the chin, throat, and breast are in the male pure white, but of a bright reddish-orange in the female. The remiges are very short, rounded, and much incurved, showing a bird of weak flight. The rectrices are very broad, the shafts stiff, and towards the tip divested of barbs. Two other species that seem rightly to belong to the genus have been described—*O. spaldingi* from Queensland, of much greater size than the type, and with a jet-black plumage, and *O. novæ-guinæ*, from the great island of that name, which seems closely to resemble *O. spinicauda*. (A. N.)

ORTOLAN (French, *Ortolan*), the *Emberiza hortulana* of Linnæus, a bird so celebrated for the delicate flavour of its flesh as to have become proverbial. A native of most European countries—the British Islands (in which it occurs but rarely) excepted—as well as of western Asia, it emigrates in autumn presumably to the southward of the Mediterranean, though its winter quarters cannot be said to be accurately known, and returns about the end of April or beginning of May. Its distribution throughout its breeding-range seems to be very local, and for this no reason can be assigned. It was long ago said in France, and apparently with truth, to prefer wine-growing districts; but it certainly does not feed upon grapes, and is found equally in countries where vineyards are unknown—reaching in Scandinavia even beyond the arctic circle—and then generally frequents corn-fields and their neighbourhood. In appearance and habits it much resembles its congener the YELLOW-HAMMER (*q.v.*), but wants the bright colouring of that species, its head for instance being of a greenish-grey instead of a lively yellow. The somewhat monotonous song of the cock is also much of the same kind; and, where the bird is a familiar object to the country people, who usually associate its arrival with the return of fair weather, they commonly apply various syllabic interpretations to its notes, just as our boys do to those of the Yellow-hammer. The nest is placed on or near the ground, but the eggs seldom shew the hair-like markings so characteristic of those of most Buntings. Ortolans are netted in great numbers, kept alive in an artificially lighted or darkened room, and fed with oats and other seeds. In a very short time they become enormously fat,

and are then killed for the table. If, as is supposed, the Ortolan be the *Miliaria* of Varro, the practice of artificially fattening birds of this species is very ancient. In French the word *Ortolan* is used so as to be almost synonymous with the English "Bunting"—thus the *Ortolan-de-neige* is the Snow-Bunting (*Plectrophanes nivalis*), the *Ortolan-de-riz* is the Rice-bird or "Bobolink" of North America (*Doichonyx oryzivorus*), so justly celebrated for its delicious flavour; but the name is also applied to other birds much more distantly related, for the *Ortolan* of some of the Antilles, where French is spoken, is a little Ground-Dove of the genus *Chamæpelia*.

In Europe the *Beccafico* (Figeater) shares with the Ortolan the highest honours of the dish, and this may be a convenient place to point out that the former is a name of equally elastic signification. The true *Beccafico* is said to be what is known in England as the Garden-Warbler (the *Motacilla salicaria* of Linnæus, the *Sylvia hortensis* of many writers); but in Italy any soft-billed small bird that can be snared or netted in its autumnal emigration passes under the name in the markets and cook-shops. The "Beccafico," however, is not as a rule artificially fattened, and on this account is preferred by some sensitive tastes to the Ortolan. (A. N.)

ORVIETO, a town in Umbria, Italy, on the main road from Florence to Rome, situated on an almost isolated volcanic rock, about 770 feet above the plain. It is now the capital of a province, the seat of a bishop, and in 1881 had a population of 8626. The town is of Etruscan origin, and is said to have joined the Volscians in their war against Rome; it is the *Urbibentum* of Procopius (with which the *Herbanum* of Pliny has been conjecturally identified), and the mediæval *Urbs Velus* (whence the modern name). Owing to the strong Guelphic sympathies of the inhabitants, and the inaccessible nature of the site, Orvieto has been constantly used as a place of refuge by the popes, of whom no less than thirty-two have at different times found shelter there. The town is very picturesque, both from its magnificent position and also from the unusually large number of fine 13th-century houses and palaces which still exist in its streets. The chief glory of the place is its splendid cathedral, dedicated to the Virgin; it was founded in 1290 by Nicholas IV. on the site of an older church; it was designed by Lorenzo Maitani, a Siennese architect, and from the 13th till the 16th century was enriched by the labours of a whole succession of great Italian painters and sculptors (see ORCAGNA). The exterior is covered with black and white marble; the interior is of grey limestone with bands of a dark basaltic stone. The plan consists of large rectangular nave, with semicircular recesses for altars, opening out of the aisles, north and south. There are two transeptal chapels, and a short choir. The most magnificent part of the exterior is the west façade, built of richly-sculptured marble, divided into three gables with intervening pinnacles, much resembling the front of Siena cathedral, the work of the same architect. The mosaics are modern, and the whole church has suffered greatly from recent "restoration." The four wall-surfaces that flank the three western doorways are decorated with very beautiful sculpture in relief, once ornamented with colour, the work mainly of pupils of Niccolò Pisano, at the end of the 13th century. This at least is Vasari's statement. Giovanni Pisano, Arnolfo del Cambio, and Fra Guglielmo da Pisa were the chief of these. The subjects are scenes from the Old and New Testaments, and the Final Doom, with Heaven and Hell. In the interior on the north, the Cappella del Corporale possesses a large silver shrine, enriched with countless figures in relief and subjects in translucent coloured enamel—one of the most important specimens of early silver

smith's work that yet exists in Italy. It was begun by Ugolino Veri of Siena in 1338, and was made to contain the Holy Corporal from Bolsena, which, according to the legend, became miraculously stained with blood during the celebration of mass to convince a sceptical priest of the truth of the doctrine of transubstantiation. This is supposed to have happened in the middle of the 13th century, while Urban IV. was residing at Orvieto; and it was to commemorate this miracle that the existing cathedral was built. On the south side is the chapel of S. Brizio, separated from the nave by a fine 14th-century wrought-iron screen. The walls and vault of this chapel are covered with some of the best-preserved and finest frescos in Italy—among the noblest works of Fra Angelico, his pupil Benozzo Gozzoli, and Luca Signorelli, mainly painted between 1450 and 1501,—the latter being of especial importance in the history of art owing to their great influence on Michelangelo in his early days (see Symonds, *Renaissance in Italy—Fine Arts*, pp. 278–291). The choir stalls are fine and elaborate specimens of *tarsia* and rich wood-carving—the work of various Sienese artists in the 14th century. In 16th-century sculpture the cathedral is especially rich, containing many statues, groups, and altar-reliefs by Simone Mosca, Ippolito Scalza, and Gian di Bologna,—some of them well designed and carefully executed, but all showing strongly the rapid decay into which the art of that time was falling. The well, now disused, called Il pozzo di S. Patrizio, is one of the chief curiosities of Orvieto. It is 180 feet deep to the water-level and 46 feet in diameter, cut in the rock, with a double winding inclined plane, so that oxen could ascend and descend to carry up the water from the bottom. It was begun by the architect San Gallo in 1527 for Clement VII., who fled to Orvieto after the sack of Rome, and was finished by Simone Mosca under Paul III. It resembles in many respects the "Well of Joseph" (Saladin) in the citadel of Cairo. The Palazzo Faina has an interesting collection of objects found in Etruscan tombs, of which a large number exist in the neighbourhood of Orvieto. The church of S. Domenico contains one of the finest works in sculpture by Arnolfo del Cambio. This is the tomb with recumbent effigy of the Cardinal Brago or De Braye (1282), with much beautiful sculpture and mosaic. It is signed HOC OPVS FECIT ARNVLFVS. It was imitated by Giovanni Pisano in his monument to Pope Benedict XI. at Perugia.

For Etruscan remains see Dennis, *Cities of Etruria*, ii. p. 36, 1878.

ORYEKHOFF-ZUYEFF, or ORYEKHOVSKIY POGOST, a village of European Russia, in the Pokroff district of the Vladimir government, 12 miles west of Pokroff by rail, on the Klyazma, a tributary of the Volga. A great cotton factory in the vicinity has become the centre of a new town, which is called after the village, but also frequently Nikolskoye. About 12,600 hands are employed in the cotton manufacture itself, and about 6000 in digging peats and making bricks for the firm. There are forty-two steam engines (978 horse-power), and goods were manufactured to the value of 8,328,000 roubles in 1881 (2,590,000 in 1861). The cotton is procured from Asia and western Europe, and the goods are sold throughout southern and south-eastern Russia.

OSBORN, SHERARD (1822–1875), English admiral and explorer, was the son of Lieutenant-Colonel Osborn of the Madras army, and was born 25th April 1822. Entering

the navy as a first-class volunteer in 1837, he was in the following year entrusted, though only a midshipman, with the command of a gunboat, the "Emerald," at the attack on Kedah. He was present at the reduction of Canton in 1841, and at the capture of the batteries of Woosung in the following year. Having passed lieutenant in 1844, he was in the same year appointed gunnery mate of the "Collingwood," under Sir George Seymour in the Pacific. On account of his interest in the fate of many of his friends and messmates, he took a prominent part in advocating a new search expedition for Sir John Franklin. When it was agreed upon he was appointed to the command of one of the ships, and performed a remarkable sledge journey to the western extremity of Prince of Wales Island, of which he published an account entitled *Stray Leaves from an Arctic Journal*, 1852. In the new expedition fitted out in the spring of that year he also took part as commander of the "Pioneer," and, after spending two trying winters up Wellington Channel, returned home in 1855. In 1856 he published the journals of Robert McClure, giving a narrative of the discovery of the North-West Passage. Shortly after his return he was called to active service in connexion with the Russian war; and in command of a light squadron of gunboats on the Sea of Azoff he distinguished himself in the destruction of the stores of the enemy at various points on the coast. Receiving post rank, he was appointed to the "Medusa," in which he continued to command the Sea of Azoff squadron until the conclusion of peace. As commander of the "Furious" he took a prominent part in the second Chinese war, during which he performed the remarkable feat of proving the navigability of the Yang-tze, by taking the "Furious" as far up the river as Hankow, 600 miles from the sea. In 1859 he returned to England in broken health, and to support his family engaged in literary pursuits, contributing many important articles to *Blackwood's Magazine*, and publishing in December of that year *The Career, Last Voyage, and Fate of Sir John Franklin*. In 1864 he was appointed to the command of the "Royal Sovereign," to assist Captain Coles in his experiments regarding the turret system of shipbuilding. Retiring soon afterwards on half pay, he was in 1865 appointed agent to the Great Indian Peninsula Railway Company, and in 1867 managing director of the Telegraph Construction and Maintenance Company, for the construction of a submarine system of telegraphy between Great Britain and her Eastern and Australian dependencies. In 1873 he was promoted rear-admiral. Continuing to interest himself in Arctic exploration, he induced A. H. Markham to visit Baffin's Bay in a whaler to report on the possibility of ice-navigation with the aid of steam. A record of his observations was published under the title of a *Whaling Cruise to Baffin's Bay* in 1873, with the result that a new Arctic expedition was fitted out in 1874. Osborn died 6th May 1875.

OSCANS, or OPICANS, was the name given both by Greeks and Romans to one of the ancient nations of central Italy. There can be no doubt that the original form of the name was Opscus, which, as we learn from Festus, was still used by Ennius. This the Greeks softened into Opicus, while the Latin writers always used Oscus as a national appellation, though they occasionally employ the term "opicus" in the sense of barbarous or ignorant. It is singular that, though there can be no doubt the name was a national one, it is not found in history as the name of any particular nation. No mention occurs of the Oscans among the populations of Italy that were successively reduced by the Roman arms; but we learn incidentally from a passage in Livy (x. 20) that the language of the Samnites and Campanians was Oscan; and it is cer-

tain that this continued to be the vernacular tongue of the people of Italy until long after the Roman conquest. Of the ethnical affinities or origin of the Oscans we know nothing, except what may be gathered philologically from the remains of their language; and their relations with the Samnites and other Sabellian tribes, whom we find during the historical period settled in this part of Italy, are extremely obscure. Perhaps the most plausible theory is that they were in very early times the inhabitants of the regions subsequently occupied by a race of invaders from the north, who were known as Sabines, Samnites, and Sabellians, but who, being comparatively few in numbers, and in an inferior stage of civilization, gradually adopted the language of the conquered race (see ITALY, vol. xiii. p. 445).

It is certain that the Oscan language continued in common use as a vernacular dialect till the close of the Roman republic. Ennius boasted that he was possessed of three tongues because he could speak Latin, Greek, and Oscan (Gell. xvii. 17); and at the time of the Social War (88 B.C.) the allies made an attempt to introduce it as the official language, and struck coins with Oscan inscriptions bearing the names of Vitellius (for Italia), Safinim, &c. After the failure of that movement there can be no doubt that the language was never again employed for official purposes, though it would linger long in use among the rustic populations of the mountains. Nor was it altogether without a literature, for the *Fabula Atellanæ*, a kind of rude farces popular among the Romans, not only derived their names and origin from the Oscan district of Campania, but were undoubtedly in the first instance composed and recited in the Oscan dialect. The monuments of the language which have been preserved to us by inscriptions are much more numerous than those of any other ancient Italian dialect. The principal of them are enumerated in the article above referred to, and they are all collected and examined in detail by Professor Mommsen in his *Unter-Italischen Dialekte* (Leipsic, 1850). The general result is that the Oscan language must have resembled the Latin much more closely than any other of the Italian dialects, but wanted almost entirely the Greek or Pelagic element which is found so distinctly in the more cultivated language, and which formed the basis of the Messapian and other dialects of the southern part of the Italian peninsula.

See HUSCHKE, *Die Oskischen und Sabellischen Denkmäler*, Elberfeld, 1856.

OSHKOSH, a city of the United States, capital of Winnebago county, Wisconsin, stretches from the west side of Lake Winnebago for about 3 miles up Fox River to Lake Buttes des Morts, and covers an area of about 8 square miles. By rail the distance from Milwaukee is 84 miles. Oshkosh is the seat of the United States district court for the eastern district of Wisconsin; and, besides the court-house, it contains the State normal school, a fine high school, and two opera-houses. The leading industry is the manufacture of sashes, doors, and blinds. Lumber shingles, matches, trunks, and carriages are also manufactured, and there are foundries, match-factories, flour-mills, and breweries. The population was 6085 in 1860, 12,663 in 1870, and 15,748 in 1880. Oshkosh may be said to date from 1836; it was incorporated in 1853. In 1859, 1866, 1874, and 1875 it suffered severely from conflagrations.

OSIANDER, ANDREAS (1498–1552), German Reformer, was born at Gunzenhausen, near Nuremberg, on December 19, 1498. His German name was Heiligmann, or, according to others, Hosemann. After studying at Leipsic, Altenburg, and Ingolstadt, he was ordained in 1520 to the priesthood, when he became Hebrew tutor in the Augus-

tinian convent at Nuremberg. Two years afterwards he was appointed preacher in the St Lorenz Kirche, and about the same time he publicly joined the Lutheran party, taking a prominent part in the discussion which ultimately led to the adoption of the Reformation by the city. He married in 1525. As a theologian of recognized ability and influence, he was present at the Marburg conference in 1529, at the Augsburg diet in 1530, and at the signing of the Smalkald articles in 1537, and took part in other public transactions of importance in the history of the Reformation; if he had an exceptionally large number of personal enemies the circumstance can be readily explained by his vehemence, coarseness, and arrogance as a controversialist. The introduction of the Augsburg Interim in 1548 necessitated his departure from Nuremberg; he went first to Breslau, and afterwards settled at Königsberg as professor in the new university there at the call of Duke Albert of Prussia. Here in 1550 he published two disputations, the one *De Lege et Evangelio* and the other *De Justificatione*, which aroused a vehement controversy that was not brought to a close by his death in 1552 (October 17). The nature of the dispute has been indicated elsewhere (see LUTHERANS, vol. xv. p. 85). The party was afterwards led by Funk, Osiander's son-in-law, but disappeared after his execution for high treason in 1566.

Osiander, besides a number of controversial writings, published a corrected edition of the Vulgate, with notes, in 1522, and a *Harmony of the Gospels*—the first work of its kind—in 1537. His son Lukas Osiander (1534–1604), a prominent ecclesiastic in Würtemberg, published a *Biblia Latina ad fontes Hebr. text. emendata cum brevī et perspicua expositione illustrata* (1573–86) in seven quarto volumes, which was highly appreciated in its day, an *Institutio Christianæ Religionis* (1576), and, his best-known work, an *Epitome of the Magdeburg Centuries*. Several other Osianders, also descendants of Andreas, figure with more or less prominence in the theological literature of Germany.

OSIRIS. See EGYPT, vol. vii. p. 716.

OSKALOOSA, a city of the United States, capital of Mahaska county, Iowa, about 55 miles south-east of Des Moines. It lies on high ground between the Des Moines and the South Skunk, in a fine agricultural district, with coal and iron mines in the vicinity; and it contains two colleges—Oskaloosa College (1861), belonging to the "Disciples," and Penn College (1873), a Quaker institution—flour-mills, wool-factories, iron and brass foundries, lumber yards, &c., and an artesian well 2900 feet deep. The population, 3204 in 1870 and 4598 in 1880, is estimated at over 7000 in 1884.

OSMAN. This transcription of the Arabic name 'Othmān (which first appears in history as borne by the famous companion of Mohammed, and third caliph, see vol. xvi. pp. 548, 563) corresponds to the pronunciation of the Persians and Turks, and is therefore commonly used in speaking of Osman I. Ghāzi, the founder of the dynasty of Osmanli or Ottoman Turks. He took the title of sultan in 699 A.H. (1299 A.D.), ruled in Asia Minor, and died in 726 A.H. Osman II., the sixteenth Ottoman sultan, came to the throne in 1616 A.D., and was strangled in a sedition of the Janissaries in 1621. See TURKEY.

OSMIUM. See PLATINUM.

OSNABRÜCK, a prosperous manufacturing town of Prussia, the see of a Roman Catholic bishop, and the capital of a district of its own name in the province of Hanover, is pleasantly situated on the Hase, 70 miles to the west of the town of Hanover. The older streets are narrow and crooked, containing many interesting examples of Gothic and Renaissance domestic architecture, while the substantial houses of the modern quarters testify to the present well-being of the town. The old fortifications have been converted into promenades. The Roman Catholic cathedral, with its three towers, is a spacious building of the 12th century, partly in the Romanesque and partly in

the Transitional style; but it is inferior in architectural interest to the Marienkirche, a fine Gothic structure of the 14th century. The town-house contains portraits of the plenipotentiaries engaged in concluding the peace of Westphalia, the negotiations for which were partly carried on here. Among the other principal buildings are the episcopal residence, the law courts, the two gymnasia, the commercial school, and various other educational and charitable institutions. The museum contains antiquities and objects of natural history. The lunatic asylum on the Gertrudenberg occupies the site of an ancient nunnery. Linen was formerly the staple product of Osnabrück, but no longer takes so prominent a position among its manufactures, which now include paper, dyes, chemicals, machinery, nails, pianos, tobacco, and cotton. There are also large iron and steel works and a rolling mill. A brisk trade is carried on in grain, drugs, linen, and Westphalian hams, and important cattle and horse fairs are held here at regular intervals. Osnabrück contains (1880) 32,812 inhabitants, one-third of whom are Roman Catholics. The patriotic writer and philanthropist Julius Möser (1720–94) was a native of Osnabrück, and has a statue in the cathedral square.

Osnabrück is a place of very ancient origin, and in 888 received the right to establish a mint, an annual fair, and a custom-house. It was surrounded with walls towards the close of the 11th century. The bishopric to which it gave name was founded by Charlemagne after the subjugation of the Saxon inhabitants of the district (c. 790), and embraced what was afterwards the south-west part of the kingdom of Hanover. The town maintained a very independent attitude towards its nominal rulers, the bishops, and joined the Hanseatic League. It reached the height of its prosperity in the 15th century, but the decay inaugurated by the dissensions of the Reformation was accelerated by the trials of the Thirty Years' War. The peace of Westphalia decreed that the bishopric of Westphalia should be held alternately by a Roman Catholic and a Protestant bishop, and this curious state of affairs lasted down to its secularization in 1803. The last bishop was the late duke of York. Since 1859 Osnabrück has again been the seat of a Roman Catholic bishop, who, of course, has no territorial jurisdiction. The revived prosperity of the town dates from the middle of last century.

OSORIO, GERONYMO (1506–1580), "the Cicero of Portugal," belonged to a noble family, and was born at Lisbon in 1506. After studying languages at Salamanca, philosophy at Paris, and theology at Bologna, he rose through successive ecclesiastical dignities to the bishopric of Sylves. He evaded the necessity of accompanying Dom Sebastian on his first African expedition (which he did all in his power to discourage) only by setting out for Rome, where he was well received by Gregory XIII. The disaster which overtook the Portuguese arms at Alcázquivir in 1578 had a serious effect on Osorio's health and spirits; he withdrew into solitude, and died at Tavira on August 20, 1580.

His principal work, a history of the reign of King Emanuel I. (*De rebus Emmanuelis Lusitanis regis invictissimi virtute et auspicio domi forisque gestis libri XII.*, 1571), undertaken at the request of Cardinal Henry, entitles him to considerable literary rank, not only by pure Latinity and artistic arrangement, but also by historical accuracy and insight, as well as by impartiality and elevation of tone. An English translation appeared in 1752; and versions in French, German, and Dutch also exist. Osorio's *De gloria libri V.* (1552), and his double treatise *De nobilitate civili et de nobilitate Christiana* (1542) have been often reprinted; of the former D'Alembert is reported to have declared that it was really a production of Cicero's palmed off by the modern as his own. Osorio also published *De regis institutione et disciplina libri VIII.* (1574) and a large mass of theological matter, including commentaries on the Epistle to the Romans, the Gospel according to John, and some of the minor prophets. His *Admonitio et Epistola* to Queen Elizabeth of England are polemical treatises. The *Opera Omnia* of Osorio were collected and published at Rome by his nephew in 1592 (4 vols. folio).

OSPREY, or OSPRAY, a word said to be corrupted from "Ossifrage," in Latin *Ossifraga* or bone-breaker. The *Ossifraga* of Pliny (*H. N.*, x. 3) and some other classical writers seems, as already said, to have been the LÄMMERGEYER (vol. xiv. p. 244); but the name, not inapplicable

in that case, has been transferred—through a not uncommon but inexplicable confusion—to another bird which is no breaker of bones, save incidentally those of the fishes it devours.¹ The Osprey is a rapacious bird, of middling size and of conspicuously-marked plumage, the white of its lower parts, and often of its head, contrasting sharply with the dark brown of the back and most of its upper parts when the bird is seen on the wing. It is the *Falco haliæetus* of Linnæus, but unquestionably deserving generic separation was, in 1810, established by Savigny (*Ois. de l'Égypte*, p. 35) as the type of a new genus which he was pleased to term *Pandion*—a name since pretty generally accepted. It has commonly been kept in the Family *Falconidæ*, but of late regarded as the representative of a separate Family, *Pandionidæ*, for which view not a little can be said.² *Pandion* differs from the *Falconidæ* not only pterylogically, as long ago observed by Nitzsch, but also osteologically, as pointed out by M. Alphonse Milne-Edwards (*Ois. Foss. France*, ii. pp. 413, 419), and it is a curious fact that in some of the characters in which it differs structurally from the *Falconidæ*, it agrees with certain of the Owls; but the most important parts of its internal structure, as well as of its pterylosis, quite forbid a belief that there is any near alliance of the two groups.

The Osprey is one of the most cosmopolitan Birds-of-Prey. From Alaska to Brazil, from Lapland to Natal, from Japan to Tasmania, and in some of the islands of the Pacific, it occurs as a winter-visitant or as a resident. The countries which it does not frequent would be more easily named than those in which it is found—and among the former are Iceland and New Zealand. Though migratory in Europe at least, it is generally independent of climate. It breeds equally on the half-thawed shores of Hudson's Bay and on the cays of Honduras, in the dense forests of Finland and on the barren rocks of the Red Sea, in Kamchatka and in West Australia. Where, through abundance of food, it is numerous—as in former days was the case in the eastern part of the United States—the nests of the Fish-Hawk (to use its American name) may be placed on trees to the number of three hundred close together. Where food is scarcer and the species accordingly less plentiful, a single pair will occupy an isolated rock, and jealously expel all intruders of their kind, as happens in Scotland.³ The lover of birds cannot see many more enjoyable spectacles than an Osprey engaged in fishing—poising itself aloft, with upright body, and wings beating horizontally, ere it plunges like a plummet beneath the water, and immediately after reappears shaking a shower of drops from its plumage. The feat of carrying off an Osprey's eggs is often difficult, and attended with some risk, but has more than once tempted the most daring of birds' nesters. Apart from the dangerous situation not unfrequently chosen by the birds for their eyry,—a steep rock in a lonely lake, only to be reached after a

¹ Another supposed old form of the name is "Orfraie"; but that is said by M. Rolland (*Faune popul. France*, ii. p. 9, note), quoting M. Suchier (*Zeitschr. Röm. Philol.*, i. p. 432), to arise from a mingling of two wholly different sources:—(1) *Oripelargus*, *Oriperagus*, *Orprais*, and (2) *Ossifraga*. "Orfraie" again is occasionally interchanged with *Effraie* (which, through such dialectical forms as *Fresaie*, *Fressaie*, is said to come from the Latin *præsaia*), the ordinary French name for the Barn-Owl, *Aluco flammeus* (see OWL, *infra*, p. 91); but the subject is too complex for any but an expert philologist to treat. According to Prof. Skeat's *Dictionary* (i. p. 408), "Asprey" is the oldest English form; but "Osprey" dates from Cotgrave at least.

² Mr Sharpe goes further, and makes a "Suborder" *Pandiones*; but the characters on which he founds such an important division are obviously inadequate. The other genus associated with *Pandion* by him has been shown by Mr Gurney (*Ibis*, 1878, p. 455) to be nearly allied to the ordinary Sea-Eagles (*Haliæetus*), and therefore one of the true *Falconidæ*.

³ Two good examples of the different localities chosen by this bird for its nest are illustrated in *Ootheca Wolleyana*, pls. B. & H.

long swim through chilly water, or the summit of a very tall tree,—their fierceness in defence of their eggs and young is not to be despised. Men and boys have had their head gashed by the sharp claw of the angry parent, and this happening when the robber is already in a precarious predicament, and unable to use any defensive weapon, renders the enterprise formidable. But the prize is worthy of the danger. Few birds lay eggs so beautiful or so rich in colouring: their white or pale ground is spotted, blotched, or marbled with almost every shade of purple, orange, and red—passing from the most delicate lilac, buff, and peach-blossom, through violet, chestnut, and crimson, to a nearly absolute black. A few years ago some of the best informed ornithologists were led to think that persecution had exterminated the Osprey from Great Britain, except as a chance visitant. This opinion proved to be incorrect, and at the present time the bird is believed still to breed in at least two counties of Scotland, but the secret of its resorts is carefully guarded by those who wish to retain it as a member of the country's fauna, for publication would doubtless speedily put an end to its occupancy. (A. N.)

OSRHOENE, or ORRHOENE, the district of western Mesopotamia of which Edessa was the capital (see MESOPOTAMIA, vol. xvi. p. 47). It may be here added that the older form of the name appears to be Chosroene (Chosdroene). Edessa or Orrhoi thus appears to have been "the city of Chosrau," implying an early Parthian influence. See G. Hoffmann in *Z. D. M. G.*, xxxii. 743.

OSSETT-CUM-GAWTHORPE, a township and urban sanitary district in the West Riding of Yorkshire, including the contiguous hamlets of Ossett, South Ossett, and Gawthorpe, is situated about 3 miles west-north-west of Wakefield, and $1\frac{1}{2}$ north-west from the Horbury station on the Lancashire and Yorkshire Railway. The Great Northern Railway has two stations in the township. The church of the Holy Trinity, a fine cruciform structure in the Early Decorated style, was erected in 1865 at a cost of £20,000. There are woollen cloth and mungo mills, and in the neighbourhood extensive collieries. The population of the township (3105 acres) in 1871 was 9190, and in 1881 it was 10,957.

OSSIAN, or OISIN. See CELTIC LITERATURE, vol. v. pp. 311, 313, and GAELIC LITERATURE, vol. x. p. 13.

OSSOLI, SARAH MARGARET FULLER, MARCIONESS, (1810–1850), an American authoress, was the eldest child of Timothy Fuller, a lawyer and politician of some eminence, and was born at Cambridge Port, Massachusetts, 23d May 1810. Her education was conducted by her father, who, she states, made the mistake of thinking to "gain time by bringing forward the intellect as early as possible," the consequence being "a premature development of brain that made her a youthful prodigy by day, and by night a victim of spectral illusions, nightmare, and somnambulism." At six years she began to read Latin, and at a very early age she had selected as her favourite authors Shakespeare, Cervantes, and Molière. Soon the great amount of study exacted of her ceased to be a burden, and reading became a habit and a passion. Having made herself familiar with the masterpieces of French, Italian, and Spanish literature, she in 1833 began the study of German, and within the year had read some of the masterpieces of Goethe, Körner, Novalis, and Schiller. Her father dying in 1835, she went in 1836 to Boston to teach languages, and in 1837 she was chosen principal teacher in the Green Street school, Providence, Rhode Island, where she remained till 1839. From this year until 1844 she stayed at different places in the immediate neighbourhood of Boston, forming an intimate acquaintance with the colonists of Brook Farm, and number-

ing among her closest friends R. W. Emerson, Nathaniel Hawthorne, and W. E. Channing. In 1839 she published a translation of Eckermann's *Conversations with Goethe*, which was followed in 1841 by a translation of the *Letters of Günderode and Bettina*. Aided by R. W. Emerson and George Ripley, she in 1840 started *The Dial*, a poetical and philosophical magazine representing the opinions and aims of the New England Transcendentalists. This journal she continued to edit for two years, and while in Boston she also conducted conversation classes for ladies in which philosophical and social subjects were discussed with a somewhat over accentuated earnestness, and which may be regarded as perhaps the beginning of the modern movement in behalf of women's rights. R. W. Emerson, who had met her as early as 1836, thus describes her appearance:—"She was then twenty-six years old. She had a face and frame that would indicate fullness and tenacity of life. She was rather under the middle height; her complexion was fair, with strong fair hair. She was then, as always, carefully and becomingly dressed, and of ladylike self-possession. For the rest her appearance had nothing prepossessing. Her extreme plainness, a trick of incessantly opening and shutting her eyelids, the nasal tone of her voice, all repelled; and I said to myself we shall never get far." On fuller acquaintance this unprepossessing exterior seemed, however, to melt away, and her inordinate self-esteem to be lost in the depth and universality of her sympathy. She possessed an almost irresistible power of winning the intellectual and moral confidence of those with whom she came in contact, and "applied herself to her companion as the sponge applied itself to water." She obtained from each the best they had to give. It was indeed more as a conversationalist than as a writer that she earned the title of the Priestess of Transcendentalism. It was her intimate friends who admired her most. Smart and pungent though she is as a writer, any originality that seems to characterize her views partakes more of wayward eccentricity than either intellectual depth or imaginative vigour. In 1844 she removed to New York to become contributor to *The Tribune*, and in 1846 she published a selection from her criticisms on contemporary authors in Europe and America, under the title *Papers on Art and Literature*. The same year she paid a visit to Europe, passing some time in England and France, and finally taking up her residence in Italy. There she was married in December 1847 to the Marquis Giovanni Angelo Ossoli, a friend of Mazzini. During 1848–49 she was present with her husband in Rome, and when the city was besieged she, at the request of Mazzini, took charge of one of the two hospitals while her husband fought on the walls. In May 1850, along with her husband and infant son, she embarked at Leghorn for America, but when they had all but reached their destination the vessel was wrecked on Fire Island beach, and the Ossolis were among the passengers who perished.

The *Autobiography of Margaret Fuller Ossoli*, with additional Memoirs by J. F. Clarke, R. W. Emerson, and W. E. Channing, was published in 1852, the last edition being that of 1874. See also *Margaret Fuller (Marchesa Ossoli)*, by Julia Ward Howe, 1883, in the Eminent Women Series. Her collected works were also published in 1874.

OSTADE. The Ostades are Dutch painters of note, whose ancestors were settled at Eyndhoven, near the small village of Ostaden, from which they took their name. Early in the 17th century Jan Hendriex, a weaver, moved with his family from Eyndhoven to Haarlem, where he married and founded a large family. The eldest and youngest of his sons became celebrated artists.

I. ADRIAN OSTADE (1610–1685), the first of Jan Hendriex's boys, was born at Haarlem shortly before the 20th December 1610, when he was christened in presence

of several witnesses. His death took place on the 27th April, his burial on the 2d May 1685, at Haarlem. According to Houbraeken he was taught by Frans Hals, at that time master of Adrian Brouwer. At twenty-six he joined a company of the civic guard at Haarlem; at twenty-eight he married his first wife, who lived till 1642. He speedily married again, but again became a widower in 1666. Persons curious of matters connected with the lives of famous men may visit the house in the Königsstraat at Haarlem where Adrian Ostade lived in 1657, or that of the Ridderstraat which he occupied in 1670. He took the highest honours of his profession, the presidency of the painters' guild at Haarlem, in 1662. Amongst the treasures of the Louvre collection, a striking picture represents the father of a large family sitting in state with his wife at his side in a handsomely furnished room, surrounded by his son and five daughters, and a young married couple. It is an old tradition that Ostade here painted himself and his children in holiday-attire; yet the style is much too refined for the painter of boors, and pitiless records tell us that Ostade had but one daughter. The number of Ostade's pictures is given by Smith at three hundred and eighty-five. It is probable that he painted many more. At his death the stock of his unsold pieces was over two hundred. His engraved plates were put up to auction, with the pictures, and fifty etched plates—most of them dated 1647-48—were disposed of in 1686. At the present time it is easy to trace two hundred and twenty pictures in public and private collections, of which one hundred and four are signed and dated, seventeen are signed with the name but not with the date, and the rest are accepted as genuine by modern critics.

Adrian Ostade is the contemporary of David Teniers and Adrian Brouwer. Like them he spent his life in the delineation of the homeliest subjects—tavern scenes, village fairs, and country quarters. Between Teniers and Ostade the contrast lies in the different condition of the agricultural classes of Brabant and Holland, and the atmosphere and dwellings that were peculiar to each region. Brabant has more sun, more comfort, and a higher type of humanity; Teniers, in consequence, is silvery and sparkling; the people he paints are fair specimens of a well-built race. Holland, in the vicinity of Haarlem, seems to have suffered much from war; the air is moist and hazy, and the people, as depicted by Ostade are short, ill-favoured, and marked with the stamp of adversity on their features and dress. Brouwer, who painted the Dutch boor in his frolics and passion, imported more of the spirit of Frans Hals into his delineations than his colleague; but the type is the same as Ostade's, only more animated and vicious. How was it that the disciples of Hals should have fallen into this course, whilst Hals himself drew people of the gentle classes with such distinction? It was probably because of his superiority and the monopoly which he and a few colleagues at Haarlem enjoyed that his pupils were forced into a humbler walk, and into this walk Hals was able to lead them, because he was equally able in depicting the strolling waif or fishwife, or the more aristocratic patrician who strutted about in lace collar, with his rapier at his side. But the practice of Hals in this form was confined to the city, or to those wanderers from the country who visited towns. Brouwer and Ostade went to the country itself and lived in the taverns and cottages of peasants, where they got the models for their pictures. Neither of them followed the habits of the artists of the Hague, who took sitters into their studios and made compositions from them. Their sitters were people, unconscious that they sat, taken on the spot and from life, and transferred with cunning art to pictures.

There is less of the style of Hals in Adrian Ostade than in Brouwer, but a great likeness to Brouwer in Ostade's early works. During the first years of his career, Ostade displayed the same tendency to exaggeration and frolic as his comrade. He had humour and boisterous spirits, but he is to be distinguished from his rival by a more general use of the principles of light and shade, and especially by a greater concentration of light on a small surface in contrast with a broad expanse of gloom. The key of his harmonies remains for a time in the scale of greys. But his treatment is dry and careful, and in this style he shuns no difficulties of detail, representing cottages inside and out, with the vine leaves covering the poorness of the outer side, and nothing inside to deck the patch-work of rafters and thatch, or tumble-down chimneys and ladder staircases, that make up the sordid interior of the Dutch rustic of those days. His men and women, attuned to these needy surroundings, are invariably dressed in the poorest clothes. The hard life and privations of the race are impressed on their shapes and faces, their shoes and hats, worn at heel and battered to softness, as if they had descended from generation to generation, so that the boy of ten seems to wear the cast-off things of his sire and grandsire. It was not easy to get poetry out of such materials. But the greatness of Ostade lies in the fact that he often caught the poetic side of the life of the peasant class, in spite of its ugliness and stunted form and misshapen features. He did so by giving their vulgar sports, their quarrels, even their quieter moods of enjoyment, the magic light of the sunbeam, and by clothing the wreck of cottages with gay vegetation.

It was natural that, with the tendency to effect which marked Ostade from the first, he should have been fired by emulation to rival the masterpieces of Rembrandt. His early pictures are not so rare but that we can trace how he glided out of one period into the other. Before the dispersion of the Gsell collection at Vienna in 1872, it was easy to study the steel-grey harmonies and exaggerated caricature of his early works in the period intervening between 1632 and 1638. There is a picture of Rustics, dated 1632, in the Kosloff collection at St Petersburg; a Countryman having his Tooth Drawn, in the Belvedere of Vienna, of a similar date though unsigned; a Bagpiper of 1635 in the Lichtenstein gallery at Vienna; Cottage Scenes of 1635 and 1636, in the museums of Carlsruhe, Darmstadt, and Dresden; Smokers in the House of Count Berchem at Munich; and Card Players of 1637 in the Lichtenstein palace at Vienna, which make up for the loss of the Gsell collection. The same style marks most of those pieces. About 1638 or 1640 the influence of Rembrandt suddenly changed his style, and he painted the Annunciation of the Brunswick museum, where the angels appearing in the sky to Dutch boors half asleep amidst their cattle, sheep, and dogs, in front of a cottage, at once recall the similar subject by Rembrandt, and his effective mode of lighting the principal groups by rays propelled to the earth out of a murky sky. But Ostade was not successful in this effort to vulgarize Scripture. He might have been pardoned had he given dramatic force and expression to his picture; but his shepherds were only boors without much emotion, passion, or surprise. His picture was a mere effect of light, as such masterly, in its sketchy rubbings, of dark brown tone relieved by strongly impasted lights, but without the very qualities which made his usual subjects attractive. When, in 1642, he painted the beautiful interior at the Louvre, in which a mother tends her child in a cradle at the side of a great chimney near which her husband is sitting, the darkness of a country loft is dimly illumined by a beam from the sun that shines on the easement; and one might think the painter intended to depict the Nativity, but that there is nothing holy in all the surroundings, nothing attractive indeed except the wonderful Rembrandtesque transparency, the brown tone, and the admirable keeping of the minutest parts. The sparkle of Brouwer is not there; nor as yet the concentrated evenness of such pictures of Rembrandt as the Meditative Philosopher at the Louvre. Yet there is perhaps more conscientiousness of detail. Ostade was more at home in a similar effect applied to the commonplace incident of the Slaughtering of a Pig, one of the masterpieces of 1643, once in the Gsell collection at Vienna. In this and similar subjects of previous and succeeding years, he returned to the homely subjects in which his power and wonderful observation made him a master. He never seems to have gone back to gospel illustrations till 1667, when he produced the admirable Nativity of Mr Walter of Bearwood, which is only surpassed as regards

arrangement and colour by Rembrandt's Carpenter's Family at the Louvre, or the Woodcutter and Children in the gallery of Cassel. Innumerable almost are the more familiar themes to which he devoted his pencil during this interval, from small single figures, representing smokers or drinkers, to vulgarized allegories of the five senses (Hermitage and Brunswick galleries), half-lengths of fish-mongers and bakers, and cottage brawls, or scenes of gambling, or itinerant players and quacks, and nine-pin players in the open air. The humour in some of these pieces is contagious, as in the Tavern Scene of the Lacaze collection (Louvre, 1653), where a boor squeezes the empty beer-pot in his hands to show that the last drop has been sucked out of it. It would be tedious to enumerate the masterpieces of this kind. But those who have no other opportunities may study with pleasure and advantage the large series of dated pieces which adorn every European capital, from St Petersburg to London. Buckingham Palace has a large store, and many and many a good specimen lies hid in the private collections of England. But if we should select a few as peculiarly worthy of attention, we might point to the Rustics in a Tavern of 1662 at the Hague, the Village School of the same year at the Louvre, the Tavern Court-yard of 1670 at Cassel, the Sportsmen's Rest of 1671 at Amsterdam, and the Fiddler and his Audience of 1673 at the Hague. At Amsterdam we have the likeness of a painter, in a red bonnet and violet coat, sitting with his back to the spectator, at his easel. The colour-grinder is at work in a corner, a pupil prepares a palette, and a black dog sleeps on the ground. The same picture, with the date of 1666, is in the Dresden gallery. Both specimens are supposed to represent Ostade himself. But unfortunately we see the artist's back and not his face. Ostade painted with equal vigour at all times. Two of his latest dated works, the Village Street and Skittle Players in the Ashburton and Ellesmere collections, were executed in 1676 without any sign of declining powers. The prices which he received are not known, but those of the present day are telling when compared with those of the close of last century. Early pictures, which may have been sold by the painter for a few shillings, now fetch £200. Later ones, which were worth £40 in 1750, are now worth £1000, and Earl Dudley gave £4120 for a cottage interior in 1876. The signatures of Ostade vary at different periods. But the first two letters are generally interlaced. Up to 1635 Ostade writes himself Ostaden,—e.g., in the Bagpiper of 1635 in the Lichtenstein collection at Vienna. Later on he uses the long s (ſ), and occasionally he signs in capital letters (Strauss collection, Vienna, 1647; and Hague museum, 1673). His pupils are his own brother Isaac, Cornelis Bega, Cornelis Dusart, and Richard Brakenburg.

II. ISAAC OSTADE (1621–1649) was christened on the 2d of June 1621, at Haarlem. He began his studies under Adrian, with whom he remained till 1641, when he started on his own account. At an early period he felt the influence of Rembrandt, and this is apparent in a Slaughtered Pig of 1639, in the gallery of Augsburg. But he soon reverted to a style more suited to his pencil. He produced pictures in 1641–42 on the lines of his brother,—amongst these, the Five Senses, which Adrian afterwards represented by a Man Reading a Paper, a Peasant Tasting Beer, a Rustic Smearing his Sores with Ointment, and a Countryman Sniffing at a Snuff-box. The contract for these pieces was made before 1643, when Leendert, a dealer, summoned him for a breach of his agreement before the burgomaster of Haarlem. The matter was referred to the guild, and evidence was adduced to prove that Isaac had promised in 1641 to deliver six pictures and seven rounds, including the Five Senses, for 27 florins. Isaac, in his defence, urged that he had finished two of the pictures and two of the rounds, which Leendert had seen, but neglected to fetch; that he had begun the remainder of the series, but that in the meanwhile the value of his works had risen, so that he thought that on that ground alone he was freed from the obligations he had assumed. The guild decided that Isaac was bound to furnish the pictures before Easter 1643. But they reduced the number of the rounds to five, and assessed the price of the whole at 50 florins. A specimen of Isaac's work at this period may be seen in the Laughing Boor with a Pot of Beer, in the museum of Amsterdam; the cottage interior, with two peasants and three children near a fire, in the Berlin museum; a Concert, with people listening to singers accompanied by a piper and flute player, and a Boor Stealing a Kiss from a Woman, in the

Lacaze collection at the Louvre. The interior at Berlin is lighted from a casement in the same Rembrandtesque style as Adrian's interior of 1643 at the Louvre. The value of these panels, which we saw estimated in 1643 at two florins apiece, was greatly enhanced in the following century, when the Laughing Boor at Amsterdam was sold for 56 florins. But the low price fixed by the guild of Haarlem must have induced Isaac to give up the practice, in which he could only hope to remain a satellite in the orbit of Adrian, and accordingly we find him gradually abandoning the cottage subjects of his brother for landscapes in the fashion of Esaias Van de Velde and Salomon Ruysdael. Once only, in 1645, he seems to have fallen into the old groove, when he produced the Slaughtered Pig, with the boy puffing out a bladder, in the museum of Lille. But this was a mere accident. Isaac's progress in the new path which he had cut out for himself was greatly facilitated by his previous experience as a figure painter; and, although he now selected his subjects either from village high streets or frozen canals, he was enabled to give fresh life and animation to the scenes he depicted by groups of people full of movement and animation, which he relieved in their coarse humours and sordid appearance by a refined and searching study of picturesque contrasts. Unfortunately he did not live long enough to bring his art to the highest perfection. He died at twenty-eight, on the 16th October 1649.

The first manifestation of Isaac's surrender of Adrian's style is apparent in 1644 when the skating and sledging scenes were executed which we see in the Lacaze collection and the galleries of the Hermitage, Antwerp, and Lille. Three of these examples bear the artist's name, spelt Isack van Ostade, and the dates of 1644 and 1645. The road-side inns, with halts of travellers, form a compact series from 1646 to 1649. In this, the last form of his art, Isaac has very distinct peculiarities. The air which pervades his composition is warm and sunny, yet mellow and lazy, as if the sky were veiled with a vapour coloured by meek smoke. The trees are rubbings of umber, in which the prominent foliage is tipped with touches hardened in a liquid state by amber varnish mediums. The same principle applied to details such as glazed bricks or rents in the mud lining of cottages gives an unreal and conventional stamp to those particular parts. But these blemishes are forgotten when one looks at the broad contrasts of light and shade and the masterly figures of steeds and riders, and travellers and rustics, or quarrelling children and dogs, poultry, and cattle, amongst which a favourite place is always given to the white horse, who seems as invariable an accompaniment as the grey in the skirmishes and fairs of Wouvermans. But it is in winter scenes that Isaac displays the best qualities. The absence of foliage, the crisp atmosphere, the calm air of cold January days, unsullied by smoke or vapour, preclude the use of the brown tinge, and leave the painter no choice but to ring the changes on opal tints of great variety, upon which the figures come out with masterly effect on the light background upon which they are thrown. Amongst the road-side inns which will best repay attention we should notice those of Buckingham Palace, the National Gallery, the Wallace, Ellesmere, Ashburton, Holford, Roberts, and Bearwood collections in England, and those of the Louvre, Berlin, Hermitage, and Rotterdam museums and the Rothschild collections at Vienna on the Continent. The finest of the ice scenes is the famous one at the Louvre. (J. A. C.)

OSTASHKOFF, a town of Tver, Russia, 163 miles by rail south-east from the capital of that government, on Lake Seliger, has a population of 12,500. The fisheries, which still employ a considerable number of the inhabitants, attracted settlers at an early date, but it is not till 1500 that the Ostashkoff villages are mentioned in Russian annals. The advantageous site, the proximity of the Smolenskiy Jitnyi monastery, a pilgrim-resort on an island of the lake, and the early development of certain petty trades, combined to bring prosperity to Ostashkoff; and its cathedral (1672–85) still contains rich offerings, as also do two other churches of the same century. About 200,000 pairs of boots are now manufactured annually; hatchets, scythes, shears, and similar implements are also made; and tanning is another important industry.

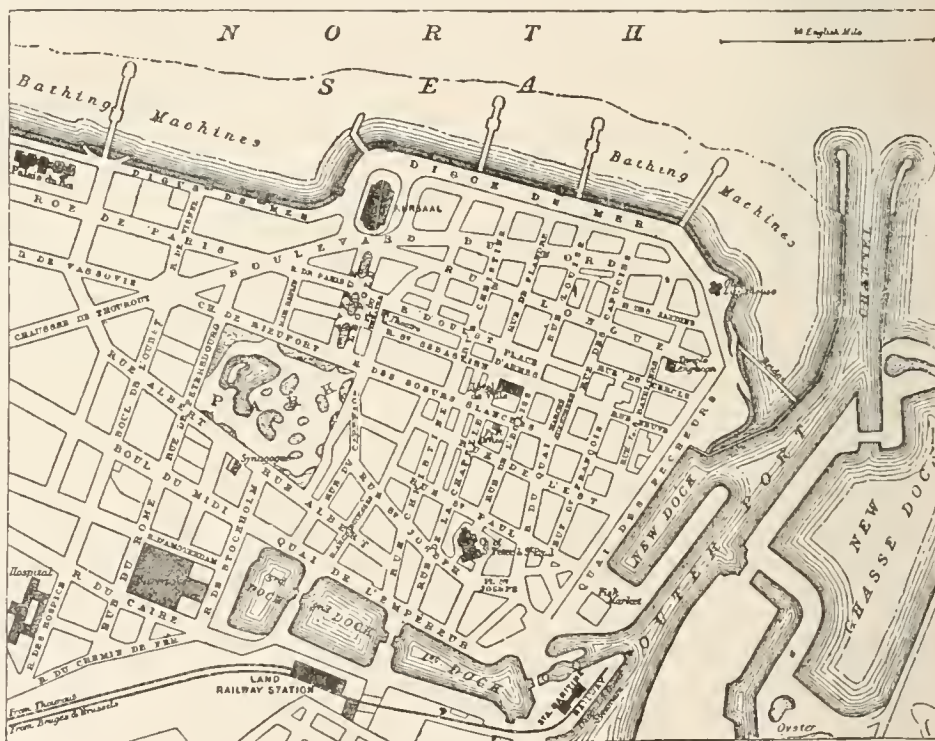

OSTEND, a seaport of Belgium, in the province of West Flanders, 70 miles west-north-west from Brussels, is surrounded on the north and west by the sea; its site is an extensive plain, lying below high-water level, the town and surrounding country being protected by a sea-wall built of granite with a brick revetment, upon which the waves generally exhaust their force even in the roughest weather, though the town has occasionally been inundated through a combination of westerly gales and unusually high tides. The port is dangerous in unfavourable weather; the channel leading into the two interior basins (which are calculated to hold more than a thousand vessels) is formed by two long wooden piers, and at its mouth has a width of only 165 yards. The rise of the tide in the harbour is about 15 feet, and as the bed of the sluice lies 3 feet under low-water mark, the depth at high water should amount to 18 feet; but the entrance to the harbour is obstructed by sandbanks, which frequently shift their position under the influence of wind and tide, and leave a free depth of only about 9 feet. At the north-west extremity of the sea-wall (digue de mer) is a lighthouse erected in 1771, and subsequently modernized, with a light visible at a distance of 45 miles. The town has an active trade in refined salt, ropes, sails, soap, tobacco, lace, and wool. The imports greatly exceed the exports. In 1883 1345 vessels entered with 175,987 tons cargo, and 1342 cleared with 32,010.

The large fishing population is chiefly occupied in the cod or herring fisheries; the trade in oysters is important, these being brought over in large quantities from the English coast, principally about Harwich or Colchester, and fattened in the Ostend oyster-beds. There are no manufactures of any consequence; and, unlike other Flemish cities, Ostend has no monument or building in any way worthy of notice. The town owes its repute and prosperity chiefly to its sea-beach, which is admirably adapted for bathing purposes, being composed of perfectly smooth sands, firm, level, and of great extent. Ostend is the yearly resort, from August to October, of many thousand visitors, comprising not only members of the fashionable society of Brussels and the larger provincial towns of Belgium, but also foreigners, principally Germans and Russians. During the season the digue and piers are crowded; entertainments and festivities are offered to guests at the Kursaal, Casino, &c.; a good deal of private and promiscuous gambling is carried on. The influx of bathers and pleasure-seekers has led to the development of some quieter resorts in the immediate vicinity, such as Blankerbergh (lately a mere fishing village), Heyst, Middelkerk, and others. In 1880 the population of the town was 16,823.

In the 10th century Ostend was but a cluster of fishermen's huts. In 1072 Robert I. of Flanders built a church there in honour of St Peter. The place thenceforth grew in importance, and the

harbour became noted. Margaret of Constantinople, countess of Flanders, raised it to the rank of a city in 1267. In 1445 Philip the Good caused it to be walled round, but the prince of Orange was the first to fortify it in earnest (1583); and a short time afterwards it sustained a memorable siege, during the reign of Albert and Isabella, being invested on the 5th of July 1601, and taken by Spinola on the 14th of September 1604, after a resistance of more than three years. It was then in a state of almost absolute ruin, but was speedily rebuilt by the archduke, who granted the citizens many privileges. The prosperity of Ostend, however, was constantly impeded by rivalries and dissensions. In the beginning of the 18th century it appeared in a fair way to attain commercial eminence, the emperor Charles VI. having selected it as the seat of the East Indian Company; but the interference of powerful neighbours, and principally of England and Holland, caused a stop to be put to this by the treaty of Vienna in 1732. Ostend was taken by the French in 1794, and belonged to the republic until 1814, after which it formed part of the Netherlands, and subsequently, since 1830, of the kingdom of Belgium.

OSTERVALD, JEAN FRÉDÉRIC (1663-1747), Swiss Protestant theologian, was born at Neuchâtel on November 25, 1663, was educated at Zurich and at Saumur (where

Plan of Ostend.

he graduated), studied theology at Orleans, Paris, and Geneva, and was ordained to the ministry in his native place in 1683. As preacher, pastor, lecturer, and author, he attained a position of great influence in his day, he and his friends J. A. Turretin of Geneva and S. Werenfels of Basel forming what was once called the "Swiss triumvirate." He died on April 14, 1747.

His principal works are *Traité des sources de la corruption qui règne aujourd'hui parmi les Chrétiens* (1700), practically a plea for a more ethical and less doctrinal type of Christianity; *Catéchisme ou Instruction dans la Religion Chrétienne*, 1702; *Traité contre l'Impureté*, 1707; *Sermons sur divers Textes*, 1722-24; *Theologiæ Compendium*, 1739; and *Traduction de la Bible*, 1724. All his writings attained great popularity among French Protestants; many were translated into various languages; and "Ostervald's Bible," in particular, was long well known and much valued in Britain. A *Life* by Durand was published in London in 1778.

OSTIA, a city of ancient Latium, situated at the mouth of the Tiber, from which circumstance it obviously derived its name. Owing to this position it became from an early period the port of Rome, but its foundation as a regular colony of that city is ascribed by ancient authors to Ancus

Marcus, who is said to have at the same time established there extensive salt-works, which long continued to supply Rome and its neighbourhood with that necessary article. As the wealth and importance of Rome itself increased, the prosperity of Ostia naturally rose with it, and it continued throughout the period of the Roman republic to be at once the principal emporium of trade in this part of Italy and the permanent station of the Roman fleet. It was, however, at no period a really good port, and the natural disadvantages of its position were not merely felt the more keenly as its commercial importance increased, but they were continually aggravated by natural causes,—the alluvial matter continually brought down by the Tiber having filled up the port, and at the same time in great measure blocked the mouth of the river, so as to render it inaccessible to the larger class of vessels. Strabo gives a lively picture of the difficulties with which these had to contend in his time, and which were only surmounted on account of the great pecuniary advantages arising from its proximity to the capital. The necessity of taking some steps to obviate these evils had indeed already presented itself to the dictator Cæsar, who had proposed to construct an artificial port at Ostia, with all the appurtenances requisite for so extensive a trade, but no steps were taken towards the execution of this project till the reign of the emperor Claudius, who constructed an entirely new basin or artificial port at a distance of about two miles north of Ostia, and communicating by an artificial channel with the Tiber on one side and the sea on the other. These works were afterwards largely augmented by Trajan, so that the port came to be known as the Portus Trajani, and the channel from thence to the sea was called the Fossa Trajani. This was undoubtedly the same with what is now become the right branch of the Tiber, entering the sea at Fiumicino. From this time the great mass of the trade was transferred to the new port, while that of Ostia continually diminished, though the city itself continued to be a populous and flourishing place throughout the period of the Roman empire. It was not till the close of the western empire that Ostia itself, which was unprotected by walls, and consequently exposed to the attacks of the barbarians, fell into decay; and after it was plundered by the Saracens in the 9th century the site became altogether abandoned, the modern village of Ostia (a very poor place) being situated at a distance of about half a mile from the ruins of the ancient city. The extent and variety of these, as well as the beauty of the works of art discovered on the site, confirm the accounts given by ancient writers of the opulence and prosperity of Ostia in the days of the empire; while those of Porto, as the port of Trajan is still called, are of great interest as exhibiting not only the artificial basin of the port, with its quays and the remains of the surrounding magazines, but a large part of the circuit of walls and towers by which it was protected. Such was the importance of Portus under the Roman empire that it became an episcopal see, and still gives that title to one of the cardinals of Rome.

The continual advance of the coast-line, owing to the alluvial deposits brought down by the Tiber, has left the ruins of Ostia more than two miles from the sea. Those of Portus are separated from it by an equal interval, and even the tower of Fiumicino, which was built in the last century at the entrance of the right branch of the Tiber—the only one now navigable—is already a considerable distance inland.

For a detailed account of the history and topography of Ostia and the neighbouring Portus, as well as of the changes in the coast-line and channel of the Tiber, the reader may consult Nibby, *Dintorni di Roma*, vol. ii. p. 426-474, 602-660; and an elaborate paper by Preller in the *Berichte der Sächsischen Gesellschaft* for 1849.

OSTIAKS, or OSTYAKS, a tribe of Finnish origin, who inhabit the basin of the Obi in western Siberia; a few hundreds also are nomads in the basin of the lower Yenisei. Plano Carpini and Marco Polo in the 13th century knew them on the flat lands of the Obi, and the best investigators (Castrén, Lerberg, A. Schrenck) consider the trans-Uralian Ostiaks and Samoyedes as identical with the Yugra of the Russian annals. During the Russian conquest their abodes extended much farther south than now, and they had numerous settlements on the basin of the Obi, no less than forty-one of their fortified places having been destroyed by the Cossacks in 1501, in the region of Obdorsk alone. Remains of these "towns" are still to be seen at the Kunovat river, on the Obi 20 miles below Obdorsk, and elsewhere. The total number of the Ostiaks may be estimated at a little over 27,000. Those on the Irish are mostly settled, and have adopted the manner of life of Russians and Tartars. Those on the Obi are mostly nomads; along with 8000 Samoyedes in the districts of Beryozoff and Surgut, they own 93,600 reindeer. The Obi Ostiaks are Russified to a great extent. They live almost exclusively by fishing, buying from Russian merchants corn for bread, the use of which has become widely diffused.

The Ostiaks call themselves Ass-yakh (people of the Obi), and it is supposed that their present designation is a corruption of this name. By language they belong (Castrén, *Reiseberichte, Reisebriefe*; Ahlqvist, *Öfvers. af Finska Vet.-Soc. Förh.*, xxi.) to the Ugrian branch of the eastern Finnish stem,—a classification confirmed by a grammar of their language, compiled in 1875, in Hungarian, by Hunfalvy. All the Ostiaks speak the same language, mixed to some extent with foreign elements; but three or four leading dialects can be distinguished.

The Ostiaks are middle-sized, or of low stature, mostly meagre, and not ill made, however clumsy their appearance in winter, in their thick fur-clothes. The extremities are fine, and the feet are usually small. The skull is brachycephalic, mostly of moderate size and height. The hair is dark and soft for the most part, fair and reddish individuals being rare; the eyes are dark, generally narrow; the nose is flat and broad; the mouth is large and with thick lips; the beard is scanty. The younger men and women are sometimes of an agreeable appearance. The Mongolian type is more strongly pronounced in the women than in the men. On the whole, the Ostiaks are not a pure race; the purest type is found among the fishers on the Obi, the reindeer-breeders of the tundra being largely intermixed with Samoyedes (see Castrén; Dr Finckh's *Reise nach West-Sibirien*, &c.).

Investigators are unanimous in describing them as very kind, gentle, and honest; rioting is almost quite unknown among them, as also theft, this last occurring only in the vicinity of Russian settlements, and the only penalty enforced being the restitution twofold of the property stolen. The farther they are removed from contact with Russian dealers and traders the higher do their moral qualities become (Middendorff and Castrén).

They are very skilful in the arts they practise, especially in carving wood and bone, tanning (with egg-yolk and brains), preparation of implements from birch bark, &c. Some of their carved or decorated bark implements (like those figured in Middendorff's *Sibirische Reise*, iv. 2) show great artistic skill. Only a few have guns, the great majority continuing to hunt with bow and arrows.

Their folk-lore, like to that of other Finnish stems, is imbued with a deep feeling of natural poetry, and reflects also the sadness, or even the despair, which has been noticed among them. The number of those who are considered Christians reaches 2000; but their Shamanism is still retained, hardly anything being borrowed from Christianity beyond the worship of St Nicholas, who is a most popular saint among them.

OSTRACISM, a peculiar political institution in Athens, designed by Clisthenes as a safeguard against any citizen acquiring too great power and aspiring to make himself tyrant of the state. Before it could be carried into effect, a decree of the people had to be passed that ostracism was necessary. If this was done, the voting was fixed for a special day in the agora. The votes were given according to tribes; and each citizen wrote on an oyster shell (ὄστρακον) the name of the person who he thought should be ostracized. The person who obtained the majority was exiled for ten years, provided the votes against him were

6000. If no person were designated on so many shells, the proceedings were at an end. The ostracized person might return at the end of his term of banishment, having then the full rights of citizenship, or his term might be shortened by a special vote of the people. The institution was intended as a precaution in view of the weakness of the central Government, which, having no standing army at its disposal, was liable to be disturbed or overturned by a sudden attack arranged by a powerful partisan. When party strife ran high, ostracism was frequently resorted to with the consent of the two parties, in order to test their strength; but when an ostracism had been arranged in 416 B.C. the parties subsequently compromised their dispute and directed their votes against an insignificant person named Hyperbolus. After this the institution fell into disuse. According to Aristotle and Philochorus, the people were required every year in the first assembly of the sixth prytany to determine whether or not an ostracism should take place. The same institution is said to have been in use at Argos, Miletus, and Megara, and a similar one called *petalismus* was employed at Syracuse for a short time during the 5th century B.C.; the latter was named from the olive leaves (*πέραλα*) used instead of oyster-shells.

OSTRICH (Old English, *Estridge*; French, *Autruche*; Spanish, *Avestruz*; Latin, *Avis struthio*). Among exotic birds there can be hardly one better known by report than the strange, majestic, and fleet-footed creature that "scorneth the horse and his rider," or one that from the earliest times to the present has been oftener more or less fully described; and there must be few persons in any civilized country unacquainted with the appearance of this, the largest of living birds, whose size is not insignificant in comparison even with the mightiest of the plumed giants that of old existed upon the earth, since an adult male will stand nearly 8 feet in height, and weigh 300 lb.

As to the ways of the Ostrich in a state of nature, not much has been added of late years to the knowledge acquired and imparted by former travellers and naturalists, many of whom enjoyed opportunities that will never again occur of discovering its peculiarities, for even the most favourably-placed of their successors in recent years seem to content themselves with repeating the older observations, and to want either leisure or patience to make additions thereto, their personal acquaintance with the bird not amounting to more than such casual meetings with it as must inevitably fall to the lot of those who traverse its haunts. Thus there are still several dubious points in its natural history. On the other hand we unquestionably know far more than our predecessors respecting its geographical distribution, which has been traced with great minuteness in the *Vögel Ost-Afrikas* of Drs Finsch and Hartlaub, who have therein given (pp. 597-607) the most comprehensive account of the bird that is to be found in the literature of ornithology.¹ As with most birds, the Ostrich is disappearing before the persecution of man, and this fact it is which gives the advantage to older travellers, for there are many districts, some of wide extent, known to have been frequented by the Ostrich within the present century, especially towards the extremities of its African range—as on the borders of Egypt and the Cape Colony—in which it no longer occurs, while in Asia there is evidence, more or less trustworthy, of its former existence in most parts of the south-western desert-tracts, in few of which it

is now to be found. Xenophon's notice of its abundance in Assyria (*Anabasis*, i. 5) is well known. It is probable that it still lingers in the wastes of Kirwan in eastern Persia, whence examples may occasionally stray northward to those of Turkestan,² even near the Lower Oxus; but the assertion, often repeated, as to its former occurrence in Baloochistan or Sindh, though not incredible, seems to rest on testimony as yet too slender for acceptance. Apparently the most northerly limit of the Ostrich's ordinary range at the present day cannot be further than that portion of the Syrian Desert lying directly to the eastward of Damascus; and, within the limits of what may be called Palestine, Canon Tristram (*Fauna and Flora of Palestine*, p. 139) regards it as but a straggler from central Arabia, though we have little information as to its appearance and distribution in that country. Africa, however, is still, as in ancient days, the continent in which

Ostrich.

the Ostrich most flourishes, and from the confines of Barbary to those of the European settlements in the south it appears to inhabit every waste sufficiently extensive to afford it the solitude it loves, and in many wide districts, where the influence of the markets of civilization is feebly felt, to be still almost as abundant as ever. Yet even there it has to contend with deadly foes in the many species of *Carnivora* which frequent the same tracts and prey upon its eggs and young—the latter especially; and Lichtenstein long ago remarked that if it were not for its numerous enemies "the multiplication of Ostriches would be quite unexampled." The account given of the habits of the species by this naturalist, who had excellent opportunities of observing it during his three years'

¹ A good summary of it is contained in the *Ostriches and Ostrich Farming* of Messrs De Mosenthal and Harting, from which the accompanying figure is, with permission, taken. Von Heuglin, in his *Ornithologie Nordost-Afrika's* (pp. 925-935), has given more particular details of the Ostrich's distribution in Africa.

² Drs Finsch and Hartlaub quote a passage from Remusat's *Remarques sur l'extension de l'Empire Chinoise*, stating that in about the seventh century of our era a live "camel-bird" was sent as a present with an embassy from Turkestan to China.

travels in South Africa, is perhaps one of the best we have, and since his narrative¹ has been neglected by most of its more recent historians we may do well by calling attention thereto. Though sometimes assembling in troops of from thirty to fifty, and then generally associating with zebras or with some of the larger antelopes, Ostriches commonly, and especially in the breeding season, live in companies of not more than four or five, one of which is a cock and the rest are hens. All the latter lay their eggs in one and the same nest, a shallow pit scraped out by their feet, with the earth heaped around to form a kind of wall against which the outermost circle of eggs rest. As soon as ten or a dozen eggs are laid, the cock begins to brood, always taking his place on them at nightfall surrounded by his wives, while by day they relieve one another, more it would seem to guard their common treasure from jackals and small beasts-of-prey than directly to forward the process of hatching, for that is often left wholly to the sun.² Some thirty eggs are laid in the nest, and round it are scattered perhaps as many more. These last are said to be broken by the old birds to serve as nourishment for the newly-hatched chicks, whose stomachs cannot bear the hard food on which their parents thrive. The greatest care is taken by them not only to place the nest where it may not be discovered, but to avoid being seen when going to or from it, and their solicitude for their tender young is no less. Andersson in his *Lake Ngami* (pp. 253-269) has given a lively account of the pursuit by himself and Mr Francis Galton of a brood of Ostriches, in the course of which the father of the family flung himself on the ground and feigned being wounded to distract their attention from his offspring. Though the Ostrich ordinarily inhabits the most arid districts, it requires water to drink; more than that, it will frequently bathe, and sometimes even, according to Von Heuglin, in the sea.

The question whether to recognize more than one species of Ostrich, the *Struthio camelus* of Linnæus, has been for some years agitated without leading to a satisfactory solution. It has long been known that, while eggs from North Africa present a perfectly smooth surface, those from South Africa are pitted (see BIRDS, vol. iii. p. 775, note 1). It has also been observed that northern birds have the skin of the parts not covered with feathers flesh-coloured, while this skin is bluish in southern birds, and hence the latter have been thought to need specific designation as *S. australis*. Still more recently examples from the Somali country have been described as forming a distinct species under the name of *S. molybdophanes* from the leaden colour of their naked parts.

The genus *Struthio* forms the type of one group of the Subclass *Ratitæ*, which differs so widely from the rest, in points that have been concisely set forth by Prof. Huxley (*Proc. Zool. Society*, 1867, p. 419), as to justify us in regarding it as an Order, to which the name *Struthionæ* may be applied (see ORNITHOLOGY, p. 44); but that term, as well as *Struthionidæ*, has been often used in a more general sense by systematists, even to signify the whole of the *Ratitæ*, and hence for the present caution must be

exercised as to whether certain fossil remains from the Sivalik formation, referred to "*Struthionidæ*," be regarded as true Ostriches or not. The most obvious distinctive character presented by the Ostrich is the presence of two toes only, the third and fourth, on each foot,—a character absolutely peculiar to the genus *Struthio*.

The great mercantile value of Ostrich-feathers, and the increasing difficulty, due to the causes already mentioned, of procuring them from wild birds, has led to the formation in the Cape Colony and elsewhere of numerous "Ostrich-farms," on which these birds are kept in confinement, and at regular intervals of time deprived of their plumes. In favourable localities and with judicious management these establishments are understood to yield very considerable profit; while, as the ancient taste for wearing Ostrich-feathers shows no sign of falling off, but seems rather to be growing, it is probable that the practice will yet be largely extended.

Among the more important treatises on this bird may be mentioned:—E. D'Alton, *Die Skelete der Straussartigen Vögel abgebildet und beschrieben*, folio, Bonn, 1827; P. L. Selater, "On the Struthion Birds living in the Zoological Society's Menagerie," *Transactions*, iv. p. 353, containing the finest representation (pl. 67), by Mr Wolf, ever published of the male *Struthio camelus*; Prof. Mivart, "On the Axial Skeleton of the Ostrich," *op. cit.*, viii. p. 285; Prof. Haughton, "On the Muscular Mechanism of the Leg of the Ostrich," *Ann. Nat. History*, ser. 3, xv. pp. 262-272; and Prof. Macalister, "On the Anatomy of the Ostrich," *Proc. R. Irish Academy*, ix. pp. 1-24. (A. N.)

OSTUNI, a city of Italy, in the province of Lecce, 23 miles by rail north-west of Brindisi. It is a bishop's see, has a cathedral of the 15th century with a fine Romanesque façade, several other churches of some interest, a municipal library with a collection of antiquities, and a technical school. The population was 14,422 in 1871 and 15,199 in 1881, that of the commune being 16,295 and 18,226.

OSUNA, a town of Spain, in the province of Seville, distant 48 miles by road and 57 by rail east-south-east from that city, is built in a semicircular form on the slope of a hill, at the edge of a fertile plain watered by the Salado, a sub-tributary of the Guadalquivir. On the top of the hill, which commands an extensive view, stands the collegiate church, a mixed Gothic and cinquecento building, containing several good specimens of Ribera, which, however, as well as the sculptures over the portal, suffered considerably during the occupation of the place by Soult. The vaults, which are supported by Moorish arches, contain the tombs of the Giron family, by one of whom, Don Juan Tellez, the church was founded in 1534. The university of Osuna, founded also by him in 1549, was suppressed in 1820; but the large building is still used as a secondary school. A great number of the inhabitants of Osuna are engaged in agriculture, and the making of esparto mats employs many of the poorer people. Earthenware, bricks, oil, soap, linen, hats, are also manufactured; and barley, oil, and wheat are sent in large quantities to Seville and Malaga. The population of the ayuntamiento in 1877 was 17,211.

Osuna, the *Uso* of Ilirius, where the Pompeians made their last stand, was afterwards called by the Romans *Gemina Urbanorum*, from the fact, it is said, that two urban legions were simultaneously quartered there. The place was taken from the Moors in 1239, and given by Alphonso the Wise to the knights of Calatrava in 1264. Don Pedro Giron appropriated it to himself in 1445. One of his descendants founded the university, and another, Don Pedro Tellez, was made duke of Osuna by Philip II. (1562).

OSWALD (c. 604-642), "most Christian king of the Northumbrians," was the son of King Ethelfrith, and was born about 604. On the death of his father on the battlefield in 617, he and his brothers were compelled to take refuge among the northern Celts, where they are said to have received baptism. The fall of King Edwin in 633 permitted their return, and after the death of Eanfrid

¹ M. H. K. Liechtenstein, *Reise im südlichen Africa*, II. pp. 42-45 (Berlin, 1812).

² By those whose experience is derived from the observation of captive Ostriches this fact has been often disputed. But, to say nothing of the effects of the enforced monogamy in which such birds live, the difference of circumstances under which they find themselves, and in particular their removal from the heat-retaining sands of the desert and its burning sunshine, is quite enough to account for the change of habit. Von Heuglin also (p. 933) is explicit on this point. That the female Ostriches while on duty crouch down to avoid detection is only natural, and this habit seems to have led hasty observers to suppose they were really brooding.

who had received Deira, and of Osric, who had been chosen to Bernicia, Oswald was called to the throne of the united kingdoms, and established his claim to it by his great victory over Ceadwalla at Heavenfield near Hexham in 635. His beneficent reign, which was chiefly devoted to the establishment of Christianity throughout his dominions, was brought to an end by his defeat and death on August 5, 642 (see NORTHUMBERLAND). The cross erected by Oswald on the scene of his victory in 635 was afterwards the scene or the instrument of many miracles, and gradually his name found a place in the calendar, August 5th being the day sacred to his memory. A German "Spießmannsgedicht" of the 12th or 13th century takes its name from St Oswald, but the narrative has no relation to anything recorded about the hero in authentic history (see monographs by Zingerle, 1856; Strobl, 1870; and Edzardi, 1876). Oswald, bishop of Winchester, who died February 29, 992, is also commemorated as a saint (October 15).

OSWALDTWISTLE, a township of Lancashire, England, is situated on the Leeds and Liverpool Canal and the East Lancashire Railway, $3\frac{1}{2}$ miles east-south-east of Blackburn and 24 north of Manchester. It possesses cotton-mills, printworks, bleachworks, and chemical works, and in the neighbourhood there are collieries, stone quarries, and potteries. The population of the township and urban sanitary district (area 4883 acres) in 1871 was 10,283, and in 1881 it was 12,206.

OSWEGO, a city and port of entry of the United States, capital of Oswego county, New York, stretches between 2 and 3 miles along the south-east shore of Lake Ontario, on the low bluffs and hilly ground near the mouth of the Oswego river, which divides it into two nearly equal portions, and is spanned by three iron drawbridges. By the Delaware, Lackawanna, and Western Railroad it is 305 miles from New York, and by the New York, Ontario, and Western Railway 326 miles. The Oswego Canal connects at Syracuse with the Erie Canal. The situation of the city is a beautiful and healthful one: most of the streets are 100 feet wide, and there are two finely-shaded public parks, one on each side of the river. Among the more conspicuous buildings are the conjunct custom-house, post-office, and United States court-house, erected in 1858 at a cost of \$120,000, the city-hall, the county court-house, the State armoury, the church of the Evangelists, the large Roman Catholic church in Mohawk Street, the public library (10,000 volumes), the normal and training schools, the city almshouse (2 miles outside the city limits), and the orphan asylum. Falling 34 feet in its passage through the city, Oswego river furnishes a good supply of water-power, rendered available by a canal on each side. Besides the Oswego starch factory (founded in 1848, and now probably the largest in the world, occupying 10 acres of ground, partly with fireproof buildings seven stories high, and producing 35 tons of starch daily), the manufactories of Oswego comprise flour-mills, large iron-works (making steam-engines, steam-shovels, dredges, &c.), knitting works, shade-cloth factories, railway carriage works and repair shops, box factories, planing-mills, and a large number of subsidiary establishments. In the extent of its trade Oswego is the principal United States port on Lake Ontario, importing vast quantities of grain and timber, and exporting coal, flour, and salt. The annual duties on imports average over \$1,000,000. The inner harbour, formed by the river mouth being enclosed by jetties, has about 3 miles of wharfage, and a depth at low water of from 9 to 13 feet; and the outer harbour, formed by the construction since 1871 of a breakwater 5700 feet long, has about 4 miles of wharfage, and a depth of 20 feet. Fort Ontario, rebuilt by the United States Government in

1839, guards the entrance to the harbour; it is a place of some strength. The population of Oswego was 12,205 in 1850, 20,910 in 1870, and 21,112 in 1880.

Oswego was visited by Champlain in 1615, by the Jesuits Le Mayne in 1654, and by other early explorers. In 1722 the English established a trading post here, and in 1727 Governor William Burnet (son of Bishop Burnet) erected Fort Oswego. A body of about 700 men, left here by Governor Shirley, constructed in 1755-56 two other forts—Fort Ontario on the east and Oswego New Fort on the west side of the river. In 1756 the place was bombarded and captured by Montcalm; but between 1757 and 1759 new works were constructed by the English, who kept possession till Oswego was transferred to the United States by the Jay treaty in 1796. In 1814 Sir James Yeo took the fortress after a bombardment of three hours. The little hamlet of Oswego, commenced by Neil M'Mullen, rapidly increased after the introduction of steam navigation on the lake (1816) and the construction of the Welland and the Oswego Canal (1823). In 1823 it was incorporated as a village, in 1848 as a city.

OSWESTRY, a market-town and municipal borough in Shropshire, England, on the borders of Wales, on two railway lines and near the Shropshire Canal, 18 miles north-west of Shrewsbury and 16 north from Welshpool. It is a well-built town with wide and regular streets, although some of the old wooden houses still remain. There are still some traces of the ancient castle erected in the reign of Stephen. The church of St Oswald, originally conventual, has been very much altered, the original structure having been more than once damaged, and the tower taken down by the Royalists in 1644. It was restored in 1872 at a cost of £10,000. For the free grammar school, founded in the reign of Henry IV., a new building was erected in 1810, which was enlarged in 1863 and 1878. Among the other public buildings are the public hall, the Victoria Rooms, the guildhall, the general market-hall, the literary institute, the union workhouse, and the cottage hospital. The town possesses locomotive repairing works, steam-engine, threshing machine, and agricultural implement works, steam printing works, corn mills, malting works, breweries, and a leather factory. In the vicinity are coal-mines and limestone quarries. The population of the municipal borough (area 1888 acres) in 1871 was 7306, and in 1881 it was 7847.

Oswestry was called by the Britons Tre'r Cadeiriau, the town of chairs or seats commanding an extensive view, in reference to the eminences in the neighbourhood. It existed in the 4th century, and, having been given in the 5th century by Cunedda Wledig, prince of North Wales, to his son Oswael, it received the name of Oswelling and subsequently Maserfield. After a battle in 642 between Oswald the Christian king of Northumbria, and Penda the pagan king of Mercia, in which the former was slain, the name was changed to Oswaldstre (Welsh, *Croes Oswallt*), which was gradually corrupted into Oswestry. On the spot where Oswald was slain a monastery was afterwards erected, and near its site there is a spring still called Oswald's well. In 777 Oswestry was disjoined from Powis and added to Mercia. It stands between Offa's and Wat's dykes. About a mile from the town is an old British earthwork, known as Old Port, a corruption of Old Fort (Welsh, *Hên Dinas*), and sometimes called Old Oswestry, from a tradition that Oswestry originally occupied its site. Oswestry is not mentioned in Domesday. The castle is said to have been built about 1149 by Madoc, the ruler of Powis Vadog. It was burned in 1216 and in 1233. Edward I. began in 1277 to surround the town with walls, which were about one mile in circumference and had four gates. During invasions of the Welsh the town was burned in 1400 and 1403; it also suffered severely from a similar cause in 1542, 1544, and 1567, and in 1550 it was devastated by the plague. Oswestry was garrisoned for the Royalists, but surrendered 22d June 1644, and a few years afterwards the castle was demolished. The town obtained the grant of a fair from Henry III. It received its first charter from William Fitz-Alan in the reign of Henry II., and a royal charter from Richard II. Its present charter was granted by Charles II.

See Price, *History of Oswestry*, 1815; Cathrall, *History of Oswestry and Topography of the Borough*, 1855; Pennant, *Tour*; Eytton, *Antiquities of Shropshire*.

OTAHEITE, or TAHITI. See SOCIETY ISLANDS

OTHO, MARCUS SALVIUS, Roman emperor from January 15 to April 15, 69 A.D., was born April 28, 32 A.D. He belonged to an ancient and noble Etruscan

family, settled at Ferentinum in Etruria. His grandfather had been a senator and held the prætorship; his father had added to the family honours the dignity of a consulship. Otho himself first appears in history as one of the most reckless and extravagant of the young nobles who surrounded Nero and shared his revels. But his friendship with that emperor was brought to an abrupt close in 58 A.D., when Otho was only twenty-six years old, by his refusal to divorce his beautiful wife Poppæa Sabina at the bidding of Nero, who was enslaved by her charms. The emperor, impatient as usual of anything that hindered the gratification of his passions, at once removed Otho from the scene by appointing him governor of the remote province of Lusitania. In this honourable exile Otho remained for ten years, and, contrary to all expectation, his administration was marked by a moderation unusual at the time. When in 68 his neighbour Galba, the governor of Hispania Tarraconensis, rose in revolt against Nero, Otho at once joined him and accompanied him to Rome. Resentment at the treatment he had received from Nero may very well have impelled him to this course, but to this motive was added before long that of personal ambition. Galba was far advanced in years, and Otho, encouraged by the predictions of astrologers, aspired to succeed him, and, as a preliminary step, to be adopted as his heir by the emperor himself. With this object in view he set himself to win the affections of the soldiery and the populace in Rome, who, disgusted by Galba's old-fashioned parsimony and severity, were easily brought to look favourably upon a claimant for the imperial purple whose open-handed generosity and easy manners promised a return of the golden years of Nero. But in January 69 his hopes in this direction were dissipated by Galba's formal adoption of L. Calpurnius Piso as the fittest man to succeed him. Nothing now remained for Otho but to strike a bold blow for the prize which seemed to be slipping from his grasp. Desperate as was the state of his finances, thanks to his previous extravagance, he found money enough to purchase the services of some three-and-twenty soldiers of the prætorian guard, with whom he arranged his plan of operations. On the morning of January 15, five days only after the adoption of Piso, Otho attended as usual to pay his respects to the emperor, and then hastily excusing himself on the score of private business hurried from the Palatine to meet his slender band of accomplices in the forum. By them he was escorted to the prætorian camp, where, after a few moments of surprise and indecision, he was saluted imperator by the assembled troops. At the head of an imposing force he returned to the forum, and at the foot of the Capitol encountered Galba himself, who, alarmed by vague rumours of treachery, was making his way through a dense crowd of wondering citizens towards the barracks of the guard. The cohort on duty at the Palatine, which had accompanied the emperor, instantly deserted him; Galba himself was brutally murdered by the fierce prætorians, and his fate was shared by his adopted heir Piso, and by his chief confidants and advisers. The brief struggle over, Otho returned in triumph to the camp. Towards sunset on the same day he proceeded to the senate-house, and there was duly invested by the senators with the name of Augustus, the tribunician power, and the other dignities belonging to the principate. Otho had owed his success largely, not only to the resentment felt by the prætorian guards at Galba's well-meant attempts to curtail their privileges in the interests of discipline, but also to the attachment felt in Rome for the memory of Nero; and his first acts as emperor showed that he was not unmindful of the fact. He accepted, or appeared to accept, the cognomen of Nero conferred upon him by the shouts of the populace, whom

his comparative youth and the effeminacy of his appearance reminded of their lost favourite. Nero's statues were again set up, his freedmen and household officers reinstalled in their places, and the intended completion of the Golden House announced. At the same time the fears of the more sober and respectable citizens were allayed by Otho's liberal professions of his intention to govern equitably, and by his judicious clemency towards Marius Celsus, consul-designate, a devoted adherent of Galba. These favourable symptoms were eagerly seized upon as promising better things than could have been hoped for from one who was only known as yet in Rome as a passionate and reckless profligate and spendthrift.

But any further development of Otho's policy was speedily checked by the news which reached Rome shortly after his accession, that the army in Germany had declared for Vitellius, the commander of the legions on the lower Rhine, and were already advancing upon Italy under the command of Vitellius's two lieutenants, Fabius Valens and Alienus Cæcina. After in vain attempting to conciliate Vitellius by the offer of a share in the empire, Otho, with unexpected vigour, prepared for war. His resources were not contemptible. From the remoter provinces, indeed, which had acquiesced in his accession little help was to be expected; but the legions of Dalmatia, Pannonia, and Mœsia were eager in his cause, the prætorian cohorts were in themselves a formidable force, and an efficient fleet gave him the mastery of the Italian seas. Nor was he himself wanting in promptitude. The fleet was at once despatched to secure Liguria, and on March 14 Otho, undismayed by omens and prodigies, started northwards at the head of his troops, in the hopes of preventing the entry of the Vitellian troops into Italy. But for this he was too late. Both Valens and Cæcina had already crossed the Alps,—the former by the Cottian, the latter by the Pennine passes,—and all that could be done was to throw troops into Placentia and hold the line of the Po. The campaign opened favourably for Otho. His advanced guard successfully defended Placentia against Cæcina, and compelled that general to fall back on Cremona. But the arrival of Valens altered the aspect of affairs. The Vitellian commanders now resolved to bring on a decisive battle, and their designs were assisted by the divided and irresolute counsels which prevailed in Otho's camp. The more experienced officers urged the importance of avoiding a battle, until at least the legions from Dalmatia had arrived. But the inconsiderate rashness of the emperor's brother Titianus and of Proculus, prefect of the prætorian guards, added to Otho's feverish impatience of prolonged suspense, overruled all opposition, and an immediate advance was decided upon, Otho himself remaining behind with a considerable reserve force at Brixellum, on the southern bank of the Po. At the time when this decision was taken the Othonian forces had already crossed the Po and were encamped at Bedriacum, a small village on the Via Postumia, and on the route by which the legions from Dalmatia would naturally arrive. Leaving a strong detachment to hold the camp at Bedriacum, the Othonian forces advanced along the Via Postumia in the direction of Cremona. At a short distance from that city they unexpectedly encountered the Vitellian troops, and a battle at once ensued. The Othonians, though taken at a disadvantage, fought desperately, but were finally defeated at all points and forced to fall back in disorder upon their camp at Bedriacum. Thither on the next day the victorious Vitellians followed them, but only to come to terms at once with their disheartened enemy, and to be welcomed into the camp as friends. More unexpected still was the effect produced by the news of the battle at Brixellum. Otho was still in command of a formidable force—the Dalmatian legions had already reached Aquileia; and the spirit of his soldiers and their officers was still unbroken. But he was resolved to accept the verdict of the battle which his own impatience had hastened. He had made a bold throw for success and had failed. He was weary of the suspense and anxieties of a protracted struggle, and he may even have been sincere in his professed unwillingness to cause further bloodshed. In a dignified speech he bade farewell to those about him, and then retiring to rest slept soundly for some hours. Early in the morning he stabbed himself to the heart with a dagger which he had concealed under his pillow, and died as his attendants entered the tent. His funeral was celebrated at once, as he had wished, and not a few of his soldiers followed their master's example by killing themselves at his pyre. A plain tomb was erected in his honour at Brixellum, with the simple inscription "Diis Manibus Marci Othonis." At the time of his death (April 15, 69) he was only in his thirty-eighth year, and had reigned just three months. In all his life nothing became him so well as his manner of leaving it; but the nothing he then showed, even if it was not merely the courage of despair, cannot blind us to the fact that he was little better than a reckless

and vicious spendthrift, who was not the less dangerous because his fiercer passions were concealed beneath an affectation of effeminate dandyism. (H. F. P.)

OTHO I. (912-973), called 'The Great, Holy Roman emperor, was born in 912. After the death of his father, Henry, king of Germany, he was elected and crowned king in 936 at Aix-la-Chapelle; and he occupied the throne upwards of thirty-six years. His reign was one of the most momentous in mediæval history, its chief incident being his assumption of the imperial crown, whereby he rendered impossible the growth of a compact German monarchy. Otho was a man of great ambition, stern and resolute; and soon after his coronation as king of Germany his leading vassals saw that he intended to claim from them something more than nominal allegiance. First he had to suppress a rebellion headed by Eberhard, duke of Franconia, in association with Thankmar, a son of King Henry by a marriage which had been declared invalid. When this insurrection was put down, Thankmar having died, there was a more formidable rising, in which Eberhard secured the alliance of Otho's younger brother Henry, of Giselbert, duke of Lorraine, of Frederick, archbishop of Mainz, and of other powerful prelates. The king was again triumphant, and on this occasion he strengthened his position by retaining Franconia in his own hands, and by granting Lorraine to his supporter Conrad, who married Otho's daughter Liudgard. To his brother Henry, whom he pardoned, he gave Bavaria; and over Swabia, after the death of its duke, he placed his own son Ludolf. His native duchy, Saxony, was entrusted to Count Hermann, called Billung, a brave noble who had distinguished himself in wars on the eastern borders of Germany. Thus all the great offices of the state were held by Otho's kinsmen and friends; and he exercised more direct control over his subjects than any sovereign, except Charlemagne, had done before him. In wars with the Bohemians, the Wends, and the Danes Otho was not less successful. In 951 he crossed the Alps to help Queen Adelaide, and, having conquered Berengar II., he married her and became king of Lombardy. On his return to Germany his son Ludolf rebelled against him, and was aided by Duke Conrad, by Archbishop Frederick of Mainz, and by many discontented magnates. In the midst of the struggle Germany was attacked by the Magyars, whom Duke Conrad had summoned to his aid. This common danger led to the establishment of internal peace, and Otho succeeded in defeating the Magyars. When in 955 they returned in greater numbers than ever, he inflicted on them so decisive a defeat that they did not again invade Germany. In 961, in response to the appeal of Pope John XII., Otho returned to Italy to punish his rebellious vassal Berengar; and on the 2d February 962 he was crowned emperor by the pope, for the deposition of whom he soon afterwards summoned a council. At this time Otho remained two years in Italy, and a later visit extended over six years, during which he not only maintained his authority in Lombardy, but sought to assert it in southern Italy. In Germany his policy was directed chiefly to the strengthening of the church, which was to act as a counterpoise to the influence of the secular nobles. He died on the 7th May 973, at Memleben, and was buried in Magdeburg, which he had made the seat of an archbishopric.

See Köpke and Dürmmer, *Kaiser Otto der Grosse*, 1876.

OTHO II. (955-983), Holy Roman emperor, son of Otho I. and Adelaide, was born in 955. In the lifetime of his father he was twice crowned, in 961 as king of Germany, and in 967 (at Rome) as emperor. He became sole ruler after the death of Otho I. in 973. Early in his reign he had to suppress a great conspiracy organized by

his cousin, Duke Henry of Bavaria; and at the same time he was repeatedly attacked by Harold, king of the Danes. In 978, when his authority had been in some measure re-established, he was confronted by a new danger, for Lothair, king of France, suddenly invaded Lorraine. Otho hastily assembled an army, drove Lothair from Lorraine, and pushed on to Paris, which he unsuccessfully besieged. In the treaty by which peace was concluded, France formally recognized the right of Germany to Lorraine. Otho next went to restore order in Rome, from which Pope Benedict VII. had been expelled by Crescentius. In southern Italy Otho (who, in virtue of his wife, Theophano, claimed Apulia and Calabria) waged war with the Saracens, and defeated them in a great battle. On the 13th July 982, however, he himself was defeated, and was very nearly taken prisoner. At a diet in Verona, attended by German and Italian princes, his son Otho, three years of age, was chosen to be his successor, and arrangements were made for a new campaign in the south. On the 7th December 983 Otho II. died, leaving the empire in a state of confusion, the Danes and the Wends, encouraged by his defeat, having risen against German supremacy. Although warlike and impetuous, Otho II. was a man of refined and scholarly tastes, which had been carefully cultivated by his mother.

See Giesebrecht, *Geschichte der deutschen Kaiserzeit*.

OTHO III. (980-1002), Holy Roman emperor, son of Otho II. and Theophano, was born in 980, and crowned king of Germany at Aix-la-Chapelle in 983. After his coronation his kinsman, Duke Henry of Bavaria, who had been imprisoned by Otho II. in Utrecht, made his escape and seized the young king, in whose name he proposed to govern the empire. His pretensions were resisted, however, and he agreed to submit on condition of being reinstated in his dukedom. During Otho's minority public affairs were administered, with the aid of Willegis, archbishop of Mainz, by his mother Theophano, his grandmother Adelaide, and his aunt Matilda, sister of Otho II. and abbess of Quedlinburg. Otho was a dreamy and imaginative youth of brilliant talents, which were carefully developed by Gerbert, the greatest scholar of the age. In 996, when Otho was declared to have reached his majority, he went to Rome, where Crescentius had made himself supreme. After the death of Pope John XV. Otho caused Bruno, who was related to the Saxon dynasty, to be elected to the holy see; and by him (Gregory V.) Otho was crowned emperor on the 21st May 996. After Otho's departure Crescentius again rose, drove Gregory V. from Rome, and set up an anti-pope. Otho immediately returned, and Crescentius, with twelve of his supporters, was executed. On the death of Gregory V., Otho's tutor, Gerbert, archbishop of Ravenna, was appointed pope; and, in part through his influence, the emperor began to form great plans, deciding to make Rome the centre of the secular as well as of the spiritual world. At the approach of the year 1000, when it was commonly supposed that the earth was about to be destroyed, Otho returned to Germany and made a pilgrimage to the tomb of St Adalbert at Gnesen. Afterwards, in Aix-la-Chapelle, he entered the vault in which the body of Charlemagne sat upon a throne, and took away the golden cross which hung on the mighty emperor's breast. In 1001 Otho went back to Italy for the purpose of carrying out his far-reaching schemes; but popular disturbances in Rome compelled him to quit the city; and on the way to Ravenna, where he proposed to wait for a German army, he died at Paterno, near Viterbo, on the 21st January 1002.

See Wilmans, *Jahrbücher des deutschen Reichs unter Kaiser Otto III.*; Giesebrecht, *Geschichte der deutschen Kaiserzeit*.

* OTHO IV. (c. 1174–1218), Holy Roman emperor, the second son of Henry the Lion, duke of Saxony and Bavaria, of the house of Guelph, was born about 1174. After the banishment of his father to England in 1180, Otho was educated at the court of Richard I., whose sister Matilda was Otho's mother. Otho distinguished himself in the war between England and France, and in 1196 Richard I. made him duke of Aquitaine and count of Poitou. In 1197, when the majority of the German princes, disregarding the previous election of Frederick II., offered the crown to Philip of Swabia, a party in the Rhine country, headed by the archbishop of Cologne, set up Otho as anti-king, and he was crowned at Aix-la-Chapelle. The result was a civil war which lasted about ten years, Philip being supported by most of the German princes and by the king of France, Otho by the kings of England and Denmark. For some time Pope Innocent hesitated to take part with either side, but at last he declared for Otho, who promised to make over certain fiefs claimed by the holy see. Notwithstanding the pope's aid, Otho's cause did not prosper; but in 1208 Philip was murdered by Otho of Wittelsbach, and then Otho IV. was universally acknowledged as king. On the 27th September 1209, at Rome, he was crowned emperor by the pope, to whom he had made new and more important concessions. Otho gave deadly offences to Innocent by seizing Ancona and Spoleto, which had been united to the papal territories; and, when the emperor, having conquered Apulia, was about to cross to Sicily, the pope excommunicated him, released the German princes from their oath of allegiance, and recognized the right of Frederick II. to the throne. In 1212 Otho returned to Germany, where he acted with so much vigour that he seemed to be capable of defying the papacy; but he immediately lost ground when Frederick II., a youth of brilliant genius, appeared as his rival. After the battle of Bouvines (July 27, 1214), in which Otho, with King John of England, was defeated by the French, the discredited emperor had no chance of recovering his position. He made some ineffectual attempts to assert his claims, but ultimately he contented himself with the principality of Brunswick, which he had inherited when the Guelphic territories were divided in 1202. On the 19th of May 1218 he died at the Harzburg.

See Langerfeldt, *Kaiser Otto IV.*, 1872; Winkelmann, *Philipp von Schwaben und Otto IV.*, 1873.

OTHO OF FREISING, German historian, was the son of Leopold IV., margrave of Austria, and of Agnes, the daughter of the emperor Henry IV. He became a priest, and was made provost of the monastery of Neuburg, which had been founded by his father. Soon afterwards he went to Paris to prosecute his studies; and on his way back he joined the Cistercian order in the monastery of Morimont, in Burgundy, of which he became abbot. In 1137 he was elected bishop of Freising, and this position he held until his death on September 22, 1158.

He was the author of two important works, a universal history, in which he brought the record down to 1146, and a history of the reign of the emperor Frederick I. The first of these works was continued (to 1209) by Otho of St Blasien, the second by Ragewin. Otho was not a very accurate historian, but he was much more than a mere chronicler, his materials being clearly and effectively arranged, and his narrative giving evidence of a penetrating and philosophical judgment. A critical edition of his writings was presented for the first time in the *Monumenta Germaniae*, and this was afterwards separately published with the title, *Othonis Episcopi Frisingensis Opera*, 1867.

OTIS, JAMES (1724–1783), was born at Barnstable, Massachusetts, U.S., on February 5, 1724 (o.s.). He graduated with honours at Harvard in 1743, and for a year or two afterwards devoted himself to the study of literature before reading law. He had been a dozen years at the bar, and had risen to professional distinction, when in 1760 he

published a *Rudiments of Latin Prosody*, a book long ago out of print as well as out of date, but of authority in its time. He wrote also a similar treatise upon Greek prosody; but that was never published, because, as he said, there was not a fount of Greek letters in the country, nor, if there were, a printer who could have set it up. These, however, were his first and last works upon any other subject than politics. As the long war between Great Britain and France drew towards its close in 1762, measures were taken to enforce anew, in the British colonies in America, the commercial laws which had been in a measure lost sight of. The relaxation had taught the colonists that the burden was heavier than they thought when they bent beneath it; now the war had given them confidence in their own power, and the time had come, therefore, when resistance was inevitable. A trade with the West Indies in colonial vessels had been specially developed. This was in violation of the navigation laws, and to break it up an order in council was sent from England in 1760 directing the issue of writs of assistance, which would authorize the custom-officers to enter any man's house on suspicion of concealment of smuggled goods. The legality of a measure which would put so dangerous a power into the hands of irresponsible men was questioned, and the superior court consented to hear argument. Otis was a law-officer under the crown, and it was his duty to appear on behalf of the Government. He refused, resigned his office, and appeared for the people against the issue of the writs. His plea was profound for its legal lore, fearless in its assertion of the rights of colonial Englishmen, and so fervid in its eloquence that it was said he "was a flame of fire." Though it failed to convince a court where the lieutenant-governor, Hutchinson, sat as chief justice, Otis was from that moment a man of mark. John Adams, who heard him, said, "American independence was then and there born." The young orator was soon afterwards unanimously elected a representative from Boston to the Colonial Assembly. To that position he was re-elected nearly every year of the remaining active years of his life, serving there with his father, who was usually a member, and often speaker, of that body. Of most of the important state papers addressed to the colonies to enlist them in the common cause, or sent to the Government in England to uphold the rights or set forth the grievances of the colonists, the younger Otis was the author. His influence at home in controlling and directing the movement of events which led to the revolution was universally felt and acknowledged; and abroad no American was so frequently quoted, denounced, or applauded in parliament and the English press, as the recognized head and chief of the rebellious spirit of the colonies.¹ In 1765 Massachusetts sent him as one of her representatives to the first Continental Congress, where he was a conspicuous figure. Four years later his brilliant public career was brought to a close. In consequence of a newspaper controversy with some Tory office-holders in Boston, he was attacked in a darkened room in a public coffee-house by a dozen men, and wounded by a blow upon the head from which he never recovered. His health gave way, and he was subject to frequent attacks of insanity. He was killed by lightning on the 23d May 1783.

A biography of Otis by William Tudor appeared in 1823; and a much briefer one, by Francis Bowen, in 1844.

¹ The political writings of Otis were chiefly controversial, and were published in the Boston newspapers. His more important pamphlets were *A Vindication of the Conduct of the House of Representatives of the Province of Massachusetts Bay*, published in 1763; *The Rights of the British Colonies Asserted and Proved*, 1764; *A Vindication of the British Colonies against the Aspersions of the Halifax Gentlemen, in his Letter to a Rhode Island Friend*,—a letter known at the time as the "Halifax Libel," 1765; *Considerations on Behalf of the Colonists in a Letter to a Noble Lord*, published in England the same year.

OTLEY, a market-town in the West Riding of Yorkshire, is picturesquely situated on the south bank of the Wharfe, at the foot of the precipitous Chevin Hill, 10 miles north of Bradford and 9 south-west of Harrogate. The river is crossed by a stone bridge of seven arches. The church of All Saints contains what is said to be a Saxon doorway belonging to the original building, and several interesting monuments. A free grammar school took its origin from a bequest by Thomas Cave in 1602, and was named in honour of Henry, prince of Wales, son of James I. A mechanics' institute was erected in 1869 in the Italian style, and a court-house in 1875. Worsted spinning and weaving, machine making, tanning and leather dressing, organ-building, and paper-making are the principal industries. Otley is a very old town. It is mentioned in Domesday, the name being possibly derived from Othelai—the field of Otho. The population of the town and urban sanitary district (area 2370 acres) was 5855 in 1871 and 6806 in 1881.

OTRANTO, a city of Italy in the province of Lecce (Terra d'Otranto), 53½ miles by rail south of Brindisi on the coast of the Adriatic, within sight on a clear day of the mountains of Albania. Though at present a small place with a communal population of only 2333 (1881), it was formerly one of the most celebrated cities of southern Italy, and the seat of an archbishop who bore the title of primate of the Salentines.

Probably of Greek origin, Hydruntum or Hydrus, as it was called, seems for a time to have suffered from the prosperity of Brundisium, but by the 4th century it had become the regular port for travellers bound for the East by Apollonia and Dyrrachium. It remained in the hands of the Greek emperors till its second capture by Robert Guiscard in 1068. In 1480 the Turkish fleet under Achmet, grand-vizier of Mohammed II., destroyed the city and massacred or enslaved the inhabitants; and, though Otranto was recovered for Ferdinand by Alphonso, duke of Calabria, and fortified by King Alphonso and Charles V., it never rose to its former importance. During the war of the League of Cambray, Ferdinand of Aragon expelled the Venetians, who had been for some time in possession of the city. In 1810 Napoleon made Fouché duke of Otranto. The cathedral (S. Annunziata), a three-aisled basilica ending in three apses, contains a mosaic floor dating from 1163, greatly injured by the Turkish horses; and the castle still stands which gave its title to Walpole's well-known novel, *The Castle of Otranto*.

OTTAWA, the capital of the Dominion of Canada, the seat of the supreme court, and the residence of the governor-general, of the Church of England bishop of Ontario, and of the Roman Catholic bishop of Ottawa, is situated in 45° 25' 59" N. lat. and 75° 42' 4" W. long., in the province of Ontario, on the south bank of the Ottawa (which forms the boundary between Ontario and Quebec), about 90 miles above its junction with the St Lawrence. By the Canadian Pacific Railway, which here crosses from the north to the south side of the Ottawa valley, the city is 120 miles west of Montreal (by the Canada Atlantic Railway the distance is 116 miles), and from Prescott on the Grand Trunk Railway and opposite Ogdensburg in New York it is distant 54 miles. The site of Ottawa is sufficiently remarkable, extending as it does for about 2 miles along the Ottawa from the Chaudière Falls (where the river, narrowed to 200 feet, rushes down about 40 feet over a broken ledge of rock) to the falls at the mouth of the Rideau (a right-hand tributary), and rising about midway into a cluster of hills—Parliament or Barrack Hill (160 feet), Major's Hill, &c.—which front the river with bold bluffs. The Rideau Canal, which skirts the east side of Parliament Hill, separates what is known as the higher from the lower town. To the south of Parliament Hill is the more commercial part of the city, stretching westward to the suburb of Rochesterville and the lumber district round the Chaudière Falls. Major's Hill, east of the canal, is laid out as a public park; and

Sandy Hill, to the south of the lower town, forms a residential quarter. Beyond the Rideau river lies the suburban village of New Edinburgh, with the official residence of the governor-general, Rideau Hall. The city of Hull too, on the opposite side of the Ottawa, in the province of Quebec, may be regarded as a suburb of the capital, with which it is connected by a suspension bridge. The Government buildings, which give the name to Parliament Hill, rank among the finest specimens of architecture in North America. The central pile, or Parliament House, is in Italian Gothic of the 13th century,—the material mainly Potsdam sandstone from Nepean. The main (south) front is 470 feet long and 40 feet high, and in the middle over the principal entrance stands Victoria Tower, 180 feet high, and surmounted by a great iron crown. In the centre of the north front is a semi-detached polygonal (almost circular) hall, 90 feet in diameter, appropriated to the library. The corner stone of the building was laid by the Prince of Wales in 1860. The total cost was about £1,000,000.

Plan of Ottawa.

(For ground plan and elevation see *The Builder*, 1859 and 1860.) Two extensive blocks of departmental buildings are placed like detached wings forming the sides of the quadrangle in front. Ottawa also contains a Roman Catholic cathedral (Notre Dame) with twin spires 200 feet high, the Gray Nunnery (the mother-house of the province of Ontario), the Black Nunnery, two convents, a Roman Catholic college (Ottawa University), a Roman Catholic hospital, a Protestant hospital, a Protestant ladies' college, a city-hall, a custom-house, the Government normal school for central Canada, the museum of the geological survey, &c. Besides being a great seat of the lumber trade, with saw-mills and match-works, it manufactures flour, cast-iron wares, leather, and bricks. The exports were valued at \$1,683,148 in the fiscal year ending June 1874, and at \$2,444,723 in the fiscal year 1883,—the imports at the same dates amounting to \$1,495,169 and \$1,562,344. The revenue arising from customs duties amounts to about £260,000 annually. The population of the city (about half being Roman Catholics and half Protestants) was 14,669 in 1861, 21,545 in 1871, and 27,412 in 1881. A mayor and board of aldermen constitute the municipal government, and the city is divided into five wards—Wellington, Victoria, St George's, By, and Ottawa.

Steamers ply in summer down to Montreal, and for about 200 miles up the river above the falls, as well as through the Rideau Canal to Kingston.

Philemon Wright of Woburn, in Massachusetts, settled in 1800 at the foot of the portage round the Chaudière Falls on the site of Hull, and some twenty years later he transferred his claim to the hills on the other side of the river to a teamster named Sparks, who would have preferred the \$200 due to him. Sparks Street is now the fashionable commercial street of Ottawa. In 1827 the Rideau Canal was constructed at a cost of \$2,500,000 to connect lower Canada with Kingston on Lake Ontario, and in that way prevent the necessity of gun-boats, &c., passing up the St. Lawrence exposed to the enemy's fire; and soon afterwards a town sprang up at the Ottawa end, called Bytown after Colonel By, R.E., who had surveyed the canal. At its incorporation as a city in 1854 Bytown received the name of Ottawa. In 1858 the queen, to whom the matter was referred, selected Ottawa as the capital of the Dominion of Canada, partly because of the advantages of its site, and partly to avoid invidious preference among the rival claims of Quebec, Montreal, Kingston, and Toronto. The first session of parliament in Ottawa was opened in 1855.

OTTAWA, a city of the United States, capital of La Salle county, Illinois, on both sides of the Illinois above and below the mouth of the Fox river (which furnishes abundant water-power by a fall of 29 feet), on the Illinois and Michigan Canal, and at the junction of the Fox river branch of the Chicago, Burlington, and Quincy Railway with the Chicago, Rock Island, and Pacific Railway, 84 miles south-west of Chicago. Ottawa ships large quantities of produce and live stock, and has manufactories of agricultural implements, carriages, glass, and clothing. The more conspicuous buildings are those occupied by the county courts and jail, and the supreme court for the northern division of the State. Near the south bank of the Illinois there are mineral springs possessing important medicinal properties. In 1880 the population was 7834 (811 in South Ottawa).

OTTENSEN, a town of Prussia, in the province of Schleswig-Holstein, lies on the right bank of the Elbe, immediately below Altona, of which it practically forms a part. It contains numerous villas of Hamburg merchants, and carries on manufactures of machinery, tobacco, soap, gilt frames and cornices, glass, iron, and other articles. Ottensen, which received its municipal charter in 1871, contained 15,375 inhabitants at the census of 1880. The three "Graves of Ottensen," besung by the poet Rückert, are those of 1138 citizens, who were expelled from Hamburg by Marshal Davoust in 1813-14, and perished here, of Charles, duke of Brunswick, who died at Ottensen of wounds received at the battle of Jena, and of Klopstock and his wife Meta. The last alone now remains.

OTTER, a group of animals belonging to the family *Mustelidae*, of the order *Carnivora* (see MAMMALIA, vol. xv. p. 439), distinguished from their allies by their aquatic habits. The true otters constitute the genus *Lutra* of zoologists, of which the common species of the British Isles, *L. vulgaris*, may be taken as the type. It has an elongated, low body, short limbs, short broad feet, with five toes on each, connected together by webs, and all with short, moderately strong, compressed, curved, pointed claws. Head rather small, broad, and flat; muzzle very broad; whiskers thick and strong; eyes small and black; ears short and rounded. Tail a little more than half the length of the body and head together, very broad and strong at the base, and gradually tapering to the end, somewhat flattened horizontally. The fur is of very fine quality, consisting of a short soft under fur of a whitish grey colour, brown at the tips, interspersed with longer, stiffer, and thicker hairs, very shining, greyish at the base, bright rich brown at the points, especially on the upper parts and outer surface of the legs; the throat, cheeks, under parts and inner surface of the legs brownish grey throughout. Individual otters vary much in size. The total length from the nose to the end of the tail averages about

3½ feet, of which the tail occupies 1 foot 3 or 4 inches. The weight of a full size male is from 18 to 24 lb, that of a female about 4 lb less.

As the otter lives almost exclusively on fish, it is rarely met with far from water, and usually frequents the shores of brooks, rivers, lakes, and, in some localities, the sea itself. It is a most expert swimmer and diver, easily overtaking and seizing fish in the water, but when it has captured its prey it brings it to shore to devour it. When lying upon the bank it holds the fish between its fore-paws, commences at the head and then eats gradually towards the tail, which it is said always to leave. The female produces three to five young ones at a time, in the month of March or April, and brings them up in a nest formed of grass or other herbage, usually placed in a hollow place in the bank of a river, or under the shelter of the roots of some overhanging tree. The Common Otter is found in localities suitable to its habits throughout Great Britain and Ireland, though far less abundantly than formerly, for, being very destructive to fish, and thus coming into keen competition with those who pursue the occupation of fishing either for sport or for gain, it is rarely allowed to live in peace when once its haunts are discovered. Otter hunting with packs of hounds of a special breed, and trained for the purpose, was formerly a common pastime in the country. When hunted down and brought to bay by the dogs, the otter is finally despatched by long spears carried for the purpose by the huntsmen.

The Common Otter ranges throughout the greater part of Europe and Asia. A closely allied but larger species, *L. canadensis*, is extensively distributed throughout North America, where it is systematically pursued by professional trappers for the value of its fur. An Indian species, *L. nair*, is regularly trained by the natives of some parts of Bengal to assist them in fishing, by driving the fish into the nets. In China also otters are taught to catch fish, being let into the water for the purpose attached to a long cord.

Otters are widely distributed over the earth, and, as they are much alike in size and coloration, their specific distinctions are by no means well defined. Besides those mentioned above, the following have been described, *L. californica*, North America; *L. felina*, Central America, Peru, and Chili; *L. brasiliensis*, Brazil; *L. maculicollis*, South Africa; *L. whiteleyi*, Japan; *L. chinensis*, China and Formosa, and other doubtful species. A very large species from Demerara and Surinam, with a prominent flange-like ridge along each lateral margin of the tail, *L. sandbachii*, constitutes the genus *Pteronura* of Gray. Others, with the feet only slightly webbed, and the claws exceedingly small or altogether wanting on some of the toes, and also with some difference in dental characters, are with better reason separated into a distinct genus called *Aonyx*. These are *A. inunguis* from South Africa and *A. leptonyx* from Java and Sumatra.

More distinct still is the Sea-Otter (*Enhydra lutris*). It differs from all other known *Carnivora* in having but two incisors on each side of the lower jaw, the one corresponding to the first (very small in the true otters) being constantly absent. Though the molar teeth resemble those of *Lutra* in their proportions, they differ very much in the exceeding roundness and massiveness of their crowns and bluntness of their cusps. The fore feet are very small, with five short webbed toes, and naked palms; the hind feet are altogether unlike those of the true otters, but approaching those of the seals, being large, flat, palmated, and furry on both sides. The outer toe is the largest and stoutest, the rest gradually diminishing in size to the first. The tail is about one-fourth of the length of the head and body, cylindrical and obtuse. The entire length of the animal from nose to end of tail is about 4 feet, so that the body is considerably larger and more massive than that of the English otter. The skin is peculiarly loose, and stretches when removed from the animal so as to give the idea of a still larger creature than it really is. The fur is remarkable for the preponderance of the beautifully soft woolly under fur, the longer stiffer hairs being very scanty. The general colour is a deep liver-brown, everywhere silvered or frosted with the hoary tips of the longer stiff

hair. These are, however, removed when the skin is dressed for commercial purposes.

Sea-otters are only found upon the rocky shores of certain parts of the North Pacific Ocean, especially the Aleutian Islands and Alaska, extending as far south on the American

The Sea-Otter (*Enhydra lutris*). From Wolf in the *Proceedings of the Zoological Society of London*, 1865, pl. vii.

coast as Oregon; but, owing to the unremitting persecution to which they are subjected for the sake of their skins, which rank among the most valuable known to the furrier, their numbers are greatly diminishing, and, unless some restriction can be placed upon their destruction, such as that which protects the fur seals of the Pribyloff Islands, the species is threatened with extermination, or, at all events, excessive scarcity. When this occurs, the occupation of five thousand of the half-civilized natives of Alaska, who are dependent upon sea-otter hunting as a means for obtaining their living, will be gone. The principal hunting grounds at present are the little rocky islets and reefs around the island of Seanach and the Chernobours, where they are captured by spearing, clubbing, or nets, and recently by the more destructive rifle bullet. They do not feed on fish, like the true otters, but on clams, mussels, sea-urchins, and crabs, and the female brings forth but a single young one at a time, apparently at no particular season of the year. They are excessively shy and wary, and all attempts to rear the young ones in captivity have hitherto failed.

See Elliott Coues, *Monograph of North American Fur-bearing Animals*, 1877. (W. H. F.)

OTTOMAN EMPIRE. See TURKEY.

OTTUMWA, a city of the United States, capital of Wapello county, Iowa, lies on the Des Moines river (here spanned by a bridge), 75 miles north-west of Burlington by the main line of the Chicago, Burlington, and Quincy Railroad. An important railway junction, in the heart of the coal-region of Iowa, and in possession of good water-power, Ottumwa, whose existence as a city dates from 1856, is growing in commercial and industrial activity. There is a large pork-packing establishment, killing 100,000 hogs annually. Among the manufactures are waggons and carriages, ploughs, sewing machine attachments, table-cutlery, corn-starch, linseed oil, harness, and furniture. The population was 1632 in 1860, 5214 in 1870, and 9004 in 1880.

OTWAY, THOMAS (1651–1685), the best English tragic poet of the classical school, was the son of the Rev. Humphrey Otway, rector of Woolbeding, near Midhurst in Sussex, and was born at the adjoining village of Trotton, March 3, 1651. He acknowledges his obligations to the care and education of his parents. He went to

school at Wickham, near Winchester, and in 1669 proceeded to Christ Church, Oxford. In 1671 he appeared at the Duke's Theatre, Lincoln's Inn Fields, in the *Forced Marriage*, a new play by Aphra Behn, but failed ignominiously. Declining to take orders, he quitted the university in 1674, and obtained a cornetcy in a troop of horse. Within a twelvemonth he sold his commission, and came to London as a literary adventurer. In 1675 his *Alcibiades*, a poor play, was performed with indifferent success at the Duke's Theatre. In the following year *Don Carlos*, a vigorous rhymed tragedy, puerile in conception and showing little knowledge of human nature, but full of declamatory energy, took the town fairly by storm. He followed it up with translations of Racine's *Berenice* and Molière's *Fourberies de Scapin*, and with a very dull and indecent comedy of his own, *Friendship in Fashion*. He next went as a volunteer to the wars in Flanders, an unfortunate expedition which pointed the merciless lampoons of Rochester, to whom *Berenice* had been dedicated, but with whom he had now quarrelled. It also prompted his mediocre but not uninteresting play, *The Soldier's Fortune* (1679), in which he has turned his military experience to account. Next year he produced *The Orphan*, founded upon a novel called *English Adventures*, one of the two plays which have placed him in the first rank of English tragic poets; and *Caius Marius*, a wholesale but acknowledged plagiarism from *Romeo and Juliet*. In 1682 appeared his masterpiece, *Venice Preserved*, the plot of which is taken from Saint Réal's *Histoire de la Conjuración du Marquis de Bedemar*. Its success was decisive, but it brought little pecuniary advantage to the author, who was already sinking into abject poverty, and, as appears by some letters attributed by Mr Gosse to this date, was further tormented by a hopeless passion for the beautiful Mrs Barry, the principal female performer in his plays. Some of his letters to her were first published with Rochester's works, and subsequently included in his own. Desponding and broken-hearted, he seems to have given himself up to dissipation, and produced but one more insignificant play, *The Atheist*, a second part of the *Soldier's Fortune* (1684). On April 14, 1685, he died on Tower Hill, under most melancholy circumstances if the tradition can be believed that he was choked by a piece of bread begged from a passer by. There is no absolute confirmation of this sad story, or of a later account which attributes his death to a fever caught by over-exertion in pursuing a robber. Whatever the exact manner of his decease, he certainly expired in obscurity and want. A tragedy called *Heroic Friendship* was published under his name in 1719. It has generally been regarded as wholly spurious; but Mr Gosse, his most sympathetic critic, recognizes some traces of his hand.

Otway's strong point is pathos. In this respect, though in no other, he is the Euripides of the English stage. When he would excite compassion he is irresistible. Unlike Shakespeare's, however, his pathos springs entirely out of the situation. His characters in themselves are not interesting, but the circumstances in which they are placed afford scope for the most moving appeals, and merit and demerit are altogether lost sight of in the contemplation of human suffering. The love scenes between Jaffier and Belvidera cannot be surpassed; and no plot more skilfully calculated to move the emotions than that of *Venice Preserved* was ever contrived by dramatist. It is to be regretted that modern fastidiousness has banished from the stage *The Orphan*, in which Johnson saw no harm. In everything but pathos Otway is mediocre: he has no deep insight into the human heart; his ideas are circumscribed and commonplace; and his attempted eloquence is frequently mere rant. Even the affecting madness of Belvidera verges dangerously on burlesque, and is no

doubt parodied in Sheridan's *Critic*. His boyish *Alcibiades* is positively absurd, and even *Don Carlos* produces much the same effect in the closet, though its rattling vigour carried it off well in the theatre at a time when nature was little regarded. It was probably not unknown to Schiller. The comedies and melodramas are simply tiresome, although a certain interest attaches to the military scenes in the *Soldier's Fortune*. There has hardly been another instance of a poet whose best and whose worst are at such an immeasurable distance from each other as Otway's; but his supreme excellence in one of the most difficult branches of the dramatic art must always be held to entitle him to an exalted place as a tragic poet. It has been remarked that Dryden, with all his splendour, has but one truly pathetic passage in the whole range of his dramas. Otway, writing simply from the heart, reached at a bound an eminence inaccessible to the laborious efforts of the greater poet. His miscellaneous poems are only interesting in so far as they illustrate his life and character. Of the latter little is known. He was a man about town in a dissipated age; but his references to his parents and friends, and his letters to the object of his unfortunate passion show that he possessed deep and refined feeling.

OU DENARDE, or **OU DENAERDE**, a small town of Belgium, in the province of East Flanders, on the Scheldt, 17 miles south-south-west from Ghent, with a population (1880) of 5880. It has manufactures of cotton and woollen fabrics, lace, tobacco, and starch, dyeing and bleaching establishments, salt refineries, distilleries, and so on. The town-hall, built in 1530 by Van Pede, is remarkable for the elegance of its architecture and the profusion of its ornament; the portal of the council chamber is a masterpiece of wood-carving, executed in 1534 by Paul van der Schelden. Among other buildings of interest are the old church of St Walburga, of the 10th century, partly rebuilt in the 14th, and that of Our Lady of Pamele, an example, rare in Belgium, of the transition Gothic style. A monument was erected at Oudenarde in 1867 to the memory of the Belgians who fell in Mexico at the battle of Zacaucuro.

The origin of Oudenarde is unknown; it appears to have been a stronghold of some importance under the Romans. A fortress was erected there by Count Baldwin of Flanders in 1053. It was besieged in 1452 by the citizens of Ghent, who were repulsed by Simon de Lalaing after a memorable siege. Alexander Farnese took the town in 1581. Close to its walls was fought, on July 11, 1708, the battle of Oudenarde, in which the French were defeated by the allied army under the command of Marlborough and Prince Eugene. It was retaken by the French in 1745.

ODUH, a province of British India, now under the political administration of the lieutenant-governorship of the North-Western Provinces, but in respect of its land and courts still a distinct chief-commissionership. Lying between 25° 34' and 28° 42' N. lat. and between 79° 44' and 83° 9' E. long., it is bounded on the N.E. by Nepál, on the N.W. by the Rohilkhand division, on the S.W. by the Ganges river, on the E. and S.E. by the Benares division. The administrative headquarters of the province are at Lucknow.

Physical Aspects.—Oudh forms the central portion of the great Gangetic plain, sloping downwards from the Nepál Himalayas in the north-east to the Ganges on the south-west. For 60 miles along the northern border of Gonda and Bahraich districts the boundary extends close up to the lower slopes of the Himalayas, embracing the damp and unhealthy sub-montane region known as the *taráí*. To the westward of this, the northern boundary recedes a little from the mountain tract, and the *taráí* in

this portion of the range has been for the most part ceded to Nepál. With the exception of a belt of Government forest along the northern frontier, the rest of the province consists of a fertile and densely peopled monotonous plain. The greatest elevation (600 feet) is attained in the jungle-clad plateau of Khairigarh in Kheri district, while the extreme south-east frontier is only 230 feet above sea-level. Four great rivers traverse or skirt the plain of Oudh in converging courses—the Ganges, the Gumti, the Gogra, and the Ráptí. Numerous smaller channels seam the whole face of the country, carrying off the surplus drainage in the rains, but drying up in the hot season. All the larger rivers, except the Gumti, as well as most of the smaller streams, have beds hardly sunk below the general level; and in time of floods they burst through their confining banks and carve out new channels for themselves. Numerous shallow ponds or *jhils* mark the former beds of the shifting rivers. These *jhils* have great value, not only as preservatives against inundation, but also as reservoirs for irrigation. The soil of Oudh consists of a rich alluvial deposit, the detritus of the Himálayan system, washed down into the Ganges valley by ages of fluvial action. Usually a light loam, it passes here and there into pure clay, or degenerates occasionally into barren sand. The uncultivable land consists chiefly of extensive *usar* plains, found in the southern and western districts, and covered by the deleterious saline efflorescence known as *reh*. Oudh possesses no valuable minerals. Salt was extensively manufactured during native rule, but the British Government has prohibited this industry for fiscal reasons. Nodular limestone (*kankar*) occurs in considerable deposits and is used as road metal.

The general aspect of the province is that of a rich expanse of waving and very varied crops, interspersed by numerous ponds or lakes. The villages lie thickly scattered, consisting of low thatched cottages, and surrounded by patches of garden land, or groves of banyan, *pápal*, and *pákar* trees. The dense foliage of the mango marks the site of almost every little homestead,—no less an area than 1000 square miles being covered by these valuable fruit-trees. Tamarinds overhang the huts of the poorer classes, while the neighbourhood of a wealthy family may be recognized by the graceful clumps of bamboo. Plantains, guavas, jack-fruit, limes, and oranges add further beauty to the village plots. The flora of the Government reserved forests is rich and varied. The *sál* tree yields the most important timber; the finest logs are cut in the Khairigarh jungles and floated down the Gogra to Bahramghát, where they are sawn. The hard wood of the *shisham* is also valuable; and several other timber-trees afford materials for furniture or roofing shingle. Among the scattered jungles in various parts of the province, the *mahúd* tree is prized alike for its edible flowers, its fruits, and its timber. The *jhils* supply the villages with wild rice, the roots and seeds of the lotus, and the *singhára* water-nut. The fauna comprises most of the animals and birds common to the Gangetic plain; but many species, formerly common, have now almost, if not entirely, disappeared. The wild elephant is now practically unknown, except when a stray specimen loses its way at the foot of the hills. Tigers are now only found in any numbers in the wilds of Khairigarh. Leopards still haunt the cane-brakes and thickets along the banks of the rivers; and *nilgai* and antelopes abound. Game birds consist of teal and wild duck, snipe, jungle fowl, and peacock.

Climate.—The climate of Oudh is less damp than that of Lower Bengal, and has greater varieties of temperature. The year falls naturally into three seasons—the rainy, from the middle of June to the beginning of October; the cold weather, from October to February or March; and the

hot season, from March to June. The mean temperature at Lucknow for the thirteen years ending 1880 was 78°; in 1881 it was the same, the maximum temperature on any one day during the year being 111°, and the minimum 35°. The heat proves most oppressive in the rainy season. The heaviest downpours occur in July and September, but are extremely capricious. The average annual rainfall at Lucknow for the fourteen years ending 1881 amounted to 37·57 inches.

Population.—Oudh is probably more densely peopled than any other equal rural area in the world. The census of 1881 returned the population at 11,387,741 (5,851,555 males and 5,536,086 females), distributed over an area of 24,245 square miles. The following table exhibits the areas and populations of the districts separately.

| Divisions. | Districts. | Area in Square Miles. | Population (1881). |
|------------------------|-------------------------|-----------------------|--------------------|
| Lucknow.. | Lucknow..... | 989 | 696,824 |
| | Unao..... | 1,747 | 899,069 |
| | Bara Bánki..... | 1,768 | 1,026,788 |
| Sitápur.... | Sitápur..... | 2,251 | 958,251 |
| | Hardoi..... | 2,312 | 987,630 |
| | Kheri..... | 2,992 | 831,922 |
| Faizábád (Fyzabad). | Faizábád..... | 1,689 | 1,081,419 |
| | Bahráich (Bharáich).... | 2,741 | 878,048 |
| | Gonda..... | 2,875 | 1,270,926 |
| Rái Bareli | Rái Bareli..... | 1,738 | 951,905 |
| | Sultánpur..... | 1,707 | 957,912 |
| | Partágarh (Pratágarh) | 1,436 | 847,047 |
| Total..... | | 24,245 | 11,387,741 |

Divided according to religion, the population consisted of 9,942,411 Hindus, 1,433,443 Mohammedans, 1154 Sikhs, 9060 Christians, and 1673 others. The Mohammedans are subdivided into the four classes of Sayyids, Shaikhs, Patháns, and Mughals, but they have lost greatly in social prestige since the downfall of the royal line. In the higher rank they still number seventy-eight *tálukdárs*. Some of these, as the rájás of Utraula and Nánpara, trace their descent from local Mohammedan chieftains. Others belong to ancient Hindu families. The Mohammedans still furnish the ablest public servants in the province, and supply almost entirely the native bar. The lower orders make industrious cultivators and weavers. Among the Hindu population, the Bráhmans preponderate, numbering 1,364,783, about one-eighth of the entire population. They include, however, only six *tálukdárs* in the whole province, and two of these acquired their wealth during the later days of Mohammedan rule. Large numbers of them follow agriculture, but they make undesirable tenants,—most of them refusing to hold the plough, and cultivating their fields by hired labour. They supply good soldiers, however, and many are employed in trade. The Kshattriyas, or Rájputs, form the great landholding class, but the majority are now in decayed circumstances. The Mohammedans, Bráhmans, and Kshattriyas compose the higher social stratum of society, and number altogether about a fourth of the entire population. Amongst the lower Hindus, the Káyasths, or clerk and scrivener class, number 147,432. The Súdrias or lowest class of Hindus include 1,185,512 Ahirs, cattle graziers and cultivators. The best tenantry and most industrious cultivators are to be found amongst the Kurmis, who number nearly 800,000. Of the aboriginal or semi-Hinduized tribes some, such as the Pásis, who number 718,906, make good soldiers, and furnish the greater part of the rural police. Others, like the Bhars and Tharus, live in small isolated groups on the outskirts of the jungle or the hill country, and hold no communication with the outer world. The Nats and Kanjárs wander like gipsies over the country, with their small movable villages or wigwams of matting and leaf-screens. The Koris and Chamárs, weavers and leather-cutters, reach the lowest depth of all. In the northern districts many still practically occupy the position of serfs, bound to the soil, having seldom spirit enough to avail themselves of the remedy afforded by the courts of law. They hold the plough for the Bráhman or Kshattriya master, and dwell with the pigs in a separate quarter of the village, apart from their purer neighbours.

Fifteen towns in the province have a population exceeding 10,000 persons, according to the census of 1881, namely—Lucknow, 239,773; Faizábád, 38,828; Lucknow Cantonment, 21,530; Bahráich, 19,439; Sháhábád, 18,510; Tánda, 16,594; Sandila, 14,865; Khairábád, 14,217; Nawabganj, 13,933; Ajudhia, 11,643; Rudauli, 11,394; Bilgram, 11,067; Malláwan, 10,970; Lahárpur, 10,437; Hardoi, 10,026. Thirty-six other towns have a population exceeding 5000. The general population is essentially rural, spread over the surface of the country in small cultivating communities. Over 90 per cent. of the population belong to the rural class.

Agriculture.—There are three harvests, reaped respectively in September, December, and March, while sugar-cane comes to maturity in February, cotton in May, and *sáncán* in almost any month of the year. The principal September crops are rice, Indian corn, and millets. Fine rice, transplanted in August from nurseries near the village sites, forms the most valuable item of the December harvest, the other staples being mustard-seed and pulses. Wheat forms the main spring crop. Sugar-cane occupies the land for an entire year; it requires much labour and several waterings, but the result in ordinary years amply repays the outlay.

At the date of the annexation of Oudh in 1856, 23,500 villages, or about two-thirds of the entire area of the province, were in the possession of the great *tálukdárs*, heads of powerful clans and representatives of ancient families, a feudal aristocracy, based upon rights in the soil, which went back to traditional times, and which were heartily acknowledged by the subordinate holders. The new settlement paid no regard to their claims, and many landholders were stripped of almost their entire possessions. The mutiny of 1857 suddenly put a stop to this work of disinheritance, and it is hardly to be wondered at that throughout Oudh, the whole *tálukdár*, with a very few isolated exceptions, joined the scyops. On the restoration of order the principle adopted was to restore to the *tálukdárs* all that they had formerly possessed, but in such a manner that their rights should depend upon the immediate grant of the British Government. About two-thirds of the number accepted an invitation to come to Lucknow, and there concluded political arrangements with the Government. On the one hand, the *tálukdárs* bound themselves to level all forts, give up arms, and act loyally, to pay punctually the revenue assessed upon them and the wages of the village officials, and to assist the police in keeping order. On the other hand, the British Government conferred a right of property unknown alike to Hindu and to Mohammedan law, comprising full power of alienation by will, and succession according to primogeniture in case of intestacy. The land revenue demand was fixed at one-half the gross rental; subordinate tenured holders were confirmed in their ancient privileges; and a clause was introduced to protect the actual cultivators from extortion. Such were the main features of the *sanads* issued by Sir C. Wingfield in October 1859, which constitute the land system of Oudh to the present day, subject to a few minor modifications. The detailed operations for giving effect to this settlement were carried out by a revenue survey, conducted both by fields and villages, begun in 1860, and finished in 1871. The total assessed area in 1881–82 was 14,877,020 acres, the total assessment as land revenue being £1,449,147, or an average of 1s. 11½d. per acre. The total cultivated area is 8,274,560 acres; cultivable and grazing lands are set down at 4,035,351 acres; and uncultivable waste at 2,567,105 acres.

The estates on the revenue roll are divided into three classes:—(1) those held under the *tálukdár* rules described above; (2) those held by ordinary *zamindari* tenure; and (3) those held in fee-simple. There are altogether about 400 *tálukdárs* in the province; of whom about two-thirds, with an area of about 2½ million acres, hold their estate under the rule of primogeniture. The *zamindari* estates, locally known by the name of *mufrád*, may be the undivided property of a single owner; but far more commonly they are owned by a coparcenary community who regard themselves as descendants of a common ancestor. The fee-simple estates, which are very few in number, consist of land sold under the Waste Land Rules. The sub-tenures under the above estates are—(1) sub-settled villages comprised within *tálukdár* estates; (2) lands known as *str*, *daswant*, *nánkán*, and *dihdár*, held by proprietors who have been unable to prove their right to the sub-settlement of a whole village; (3) groves held by cultivators, who, according to immemorial custom, give the landlord a certain share of the produce; (4) lands granted, either by sale or as gifts, for religious endowments; and (5) lands held rent-free by village servants and officials.

Commerce and Manufactures.—Under native rule the only exports were salt and saltpetre, while the imports were confined to articles of luxury required for the Lucknow court. Since the introduction of British authority, although Lucknow has declined, countless small centres of traffic have sprung up throughout the country. The staple exports consist of wheat and other food grains, and oil-seeds; the main imports are cotton piece goods, cotton twist, and salt. Cawnpur, though lying on the southern bank of the Ganges within the North-Western Provinces, is, in fact, the emporium for the whole trade of Oudh, by rail, road, and river. The enormous exports of wheat and oil-seeds from Cawnpur represent to a great extent the surplus harvest of the Oudh cultivator. A brisk trade is also carried on with Nepal, along the three frontier districts of Kheri, Bahráich, and Gonda. The policy of the Nepal court is to compel this traffic to be transacted at marts within its own dominions. At all of these a considerable number of Oudh merchants are permanently settled, whereas Nepális rarely cross the frontier to trade except for the purchase of petty necessities. The principal exports from Oudh into Nepal are Indian and European piece goods, salt, sugar

tobacco, spices, and enameleds. The imports from Nepal, which considerably exceed the exports in value, consist chiefly of rice, oil-seeds, ghee or clarified butter, metal-ware, timber, spices, drugs, and cattle.

No province of India is more destitute of wholesale manufactures than Oudh. Almost all manufactured articles of any nicety require to be imported. The only specialties are gold and silver lace-work, silver chasing, and rich embroidery, all confined to Lucknow, and the weaving of a peculiar class of cotton goods, which still flourishes at Tanda.

Communication.—The Oudh and Rohilkhand Railway forms the great trunk of communications. A branch runs from Lucknow through Unao to Cawnpur; and another diverges at Bāra Bānki for Bahramghāt on the Gogra. The whole railway forms a loop-line between the East Indian and the Sind, Punjab, and Delhi systems. Good roads connect all the principal towns, and much traffic passes along the rivers.

Administration.—The administration belongs to the non-regulation system, under which a single officer discharges both fiscal and judicial functions. The province contains twelve districts, each under a deputy-commissioner. The chief-commissionership is now amalgamated with the governorship of the North-Western Provinces. The high court, presided over by the judicial commissioner, forms the ultimate court of appeal. The principal items of revenue consist of the land revenue, which stands at about £1,400,000; stamps, £116,770; excise, £100,411; forests, £31,114; and cesses over £101,000. In 1881 the total police force numbered 7634 officers and men, maintained at a cost of £95,815.

History.—At the dawn of history Oudh appears as a flourishing kingdom, ruled over from Srāvasti by a powerful sovereign. In its capital Sakya Muni (Buddha) began his labours, and the city long remained a seat of learning for Buddhist disciples. For six centuries Srāvasti maintained a high position among the states of northern India, but in the 1st century of our era the Buddhist monarch of Kashmir was defeated by the Brāhmanical king of Ujjain, who restored the fane and holy places of Ajodhya, the Hindu sacred city, which had fallen into decay. A long struggle between Buddhism and Brāhmanism followed, and when the Chinese pilgrim Fa Hian (c. 400 A.D.) visited Srāvasti, as one of the most famous historical places of his religion, he found the once populous city still marked by lofty walls, enclosing the ruins of numerous temples and palaces, but inhabited only by a few destitute monks and devotees. In the 7th century the desolation was complete. According to local tradition, about the 8th or 9th century the Thārus, an aboriginal tribe, descended from the hills and began to clear the jungle which had overgrown the deserted kingdom, as far as the sacred city of Ajodhya. To the present day these aborigines are the only people who can withstand the influence of malaria, and so become the pioneers of civilization in the jungle tracts. About a century later, a family of Sombansi lineage, from the north-west, subjected the wild settlers to their sway. The new dynasty belonged to the Jain faith, and still ruled at or near the ruins of Srāvasti at the time of the invasion of Mahmūd's famous general, Sayyid Sālār. Towards the close of the 11th century Oudh was added to the kingdom of Kanauj by conquest. After its downfall Shahab-ud-din Ghori, or his lieutenant, overran Oudh in 1194. Mohammed Bakhtiyār Khilji was the first Mohammedan to organize the administration, and establish in Oudh a base for his military operations, which extended to the banks of the Brahmaputra. On the death of Kutub-ud-din he refused allegiance to Altamsh as a slave, and his son Ghiyās-ud-din established an hereditary governorship of Bengal. Oudh, however, was wrested from the Bengal dynasty, and remained an outlying province of Delhi. Although nominally ruled in the name of the Delhi empire by great Mohammedan vassals from Bahraich or Mānikpur, Oudh continued to be a congeries of Rājput principalities and baronies, which made war, collected revenues, and administered justice within their territories at their own pleasure. During the early days of Mohammedan supremacy the Hindu chiefs of southern Oudh were engaged in a desultory warfare with the receding Bhārs, an aboriginal tribe who had obtained a temporary ascendancy after the first Moslem invasions. Upon their subjection the Mohammedan kingdom of Jaunpur arose in the valley of the Ganges. Ibrāhīm Shāh Shārkī, the ablest of the Jaunpur rulers, turned his attention to the fruitful province which lay in the direct path between his capital and Delhi. He attempted thoroughly to reduce Oudh to the condition of a Moslem country, and, as long as he lived, the people sullenly acquiesced. But on his death the national spirit successfully reasserted itself under the leadership of Rājā Tilok Chānd, probably a descendant of the Kanauj sovereigns; and for a hundred years the land had peace.

During the troubled times which followed the death of Bābar, the first Mughal emperor of Delhi, Oudh became a focus of disaffection against the reigning house. After the final defeat of the Afghan dynasty at Panipat, and the firm establishment of Akbar's rule, the province settled down into one of the most important among the imperial vicerealties. Under the Mughal dynasty in

its flourishing days, the Hindu chieftains accepted their position without difficulty. But when the rise of the Mahrattā power broke down the decaying empire of Aurangzeb, the chieftains of Oudh again acquired an almost complete independence. About 1732 Saadat Ali Khān, a Persian merchant, received the appointment of governor of Oudh, and founded the Mohammedan dynasty which ruled over Oudh down to our own days. Before his death, in 1743, Oudh had become practically an independent kingdom, the rulers retaining the title of nawāb wazīr, or chief minister of the empire. Saadat Khān was succeeded by his brother-in-law, Saifdar Jang, under whose wise rule the country enjoyed internal prosperity, although exposed to constant attacks from the Rohillās on one side and the Mahrattās on the other. The next nawāb, Shujā-ud-daulā, who succeeded his father Saifdar Jang in 1753, attempted to take advantage of the war in Bengal between the British and Mir Kāsim to acquire for himself the rich province of Behar. He therefore advanced upon Patnā, taking with him the fugitive emperor Shāh Alam and the exiled nawāb of Bengal. The enterprise proved a failure, and Shujā-ud-daulā retired to Baxar, where, in October 1764, Major Munro won a decisive victory, which laid the whole of upper India at the feet of the Company. The nawāb fled to Bareilly (Bareilly), while the unfortunate emperor joined the British camp.

By the treaty of 1765 Korah and Allahābād, which had hitherto formed part of the Oudh vicerealty, were made over to the emperor for the support of his dignity and expenses, all the remaining territories being restored to Shujā-ud-daulā, who had thrown himself upon the generosity of the British. A few years later, in 1771, the titular Mughal emperor, Shāh Alam, was a virtual prisoner in the hands of the Mahrattās, who extorted from him the cession of Korah and Allahābād. This was considered to be contrary to the terms of the treaty of 1765, and, as the emperor had abandoned possession of them, the British sold them to the Oudh nawāb. Saadat Ali Khān, threatened by Sindhiā on the advance of Zamān Shāh to the Indus, concluded a new treaty with the British in 1801, by which he gave up half his territories in return for increased means of protection. Rohilkhand thus passed under British rule, and the nawāb became still more absolute within his restricted dominions. Saadat's son, Ghāzi-ud-din Haidar (1814), was the first to obtain the title of king. In 1847 Wajid Ali Shāh, the last king, ascended the throne. The condition of the province had long attracted the attention of the British Government. The king's army, receiving insufficient pay, recouped itself by constant depredations upon the people. The Hindu chiefs, each isolated in his petty fort, had turned the surrounding country into a jungle as a means of resisting the demands of the court and its soldiery. Before 1855 the chronic anarchy and oppression had reduced the people of Oudh to extreme misery.

A treaty was proposed to the king in 1856, which provided that the sole civil and military government of Oudh should be vested in the British Government for ever, and that the title of king of Oudh should be continued to him and his heirs male, with certain privileges and allowances. He refused to sign the treaty, and on the 18th February 1856 the British Government assumed the administration of the province, Oudh thus becoming an integral part of the British empire. A provision of 12 lakhs a year was made to the king, who resides in a palace at Garden Reach, a few miles south of Calcutta. Wajid Ali Shāh has been allowed to retain the title of king of Oudh, but on his death the title will cease absolutely, and the allowance will not be continued on its present scale.

Immediately after annexation in 1856, Oudh was constituted into a chief-commissionership, and organized on the ordinary British model. In March 1857 Sir Henry Lawrence assumed the administration at Lucknow; and on the 30th of May five of the native regiments broke into mutiny. The remainder of the events connected with the siege and recovery of the capital have been narrated in the article on Lucknow. Since 1858 the province has been administered without further vicissitudes. On the 17th of January 1877 Oudh was partially amalgamated with the North-Western Provinces by the unification of the two offices of chief-commissioner and lieutenant-governor.

UDINOT, CHARLES NICOLAS (1767-1847), duke of Reggio, one of the most distinguished of Napoleon's marshals, came of a good bourgeois family in Lorraine, and was born at Bar-le-duc on April 25, 1767. From his youth he had a passion for a military career, and served in the regiment of Médoc from 1784 to 1787, when he retired with the rank of sergeant, and the knowledge that as a bourgeois he could never obtain a commission. The Revolution changed his fortunes, and in 1792, on the outbreak of war, he was elected lieutenant-colonel of the 3d battalion of the volunteers of the Meuse. His gallant defence of the little fort of Bitche in the Vosges in 1792

arrested attention to him; he was transferred to the regular army in November 1793, and after serving in all the numerous actions on the Belgian frontier he was promoted general of brigade in June 1794 for his conduct at the battle of Kaiserslautern. He continued to serve with the greatest distinction on the German frontier under Hoche, Pichegru, and Moreau, and was repeatedly wounded and once (in 1795) made prisoner. He was Masséna's right hand all through the great Swiss campaign of 1799—first as a general of division, to which grade he was promoted in April, and then as chief of the staff—and was instrumental in winning the battle of Zurich. He was present under Masséna at the defence of Genoa, and so distinguished himself at the combat of Monzambano that Napoleon presented him with a sword of honour. On the declaration of the empire he was given the Grand Cross of the Legion of Honour, but was not included in the first creation of marshals. In the same year he received the command of ten battalions of the army of the reserve, which he formed into the famous division of the "grenadiers Oudinot," and with which he won the battle of Ostrolenka and decided the fate of at least three great battles—Austerlitz, Friedland, and Wagram. A week after the last-named battle he was promoted to the rank of marshal, and he was made Duc de Reggio in the following month. He administered the government of Holland from 1810 to 1812, and commanded the 2d corps of the grand army in the Russian campaign. He was present at Lützen and Bautzen, and when holding the independent command of the corps directed to take Berlin was defeated at Gross Beeren. He was then superseded by Ney, but the mischief was too great to be repaired, and Napoleon was utterly defeated at Leipsic. Though superseded, Oudinot was not disgraced, and held an important command throughout the campaign of 1814. On the abdication of Napoleon he rallied to the new Government, and was made a peer by Louis XVIII., and, unlike many of his old comrades, he remained faithful to his new sovereign, and did not desert to his old master in 1815. He died on September 13, 1847.

Oudinot's son, Charles Nicolas Victor, second duke of Reggio (1791-1863), served through the later campaigns of Napoleon from 1809 to 1814, but is chiefly known by his capture of Rome from Garibaldi in 1849.

UGHTRED, WILLIAM (1574-1660), an eminent mathematician, was born at Eton in 1574, and educated there and at King's College, Cambridge, of which he became fellow. Being admitted to holy orders, he left the university about 1603, and was presented to the rectory of Aldbury, near Guildford in Surrey; and about 1628 he was appointed by the earl of Arundel to instruct his son in mathematics. He corresponded with some of the most eminent scholars of his time on mathematical subjects; and his house was generally full of pupils from all quarters. It is said that he expired in a sudden transport of joy upon hearing the news of the vote at Westminster for the restoration of Charles II.

He published, among other mathematical works, *Clavis Mathematica*, in 1631; *A Description of the Double Horizontal Dial*, in 1636; and *Opuscula Mathematica*, in 1676.

OUNCE. See MAMMALIA, vol. xv. p. 435.

OURO PRETO, a city of Brazil, the chief town of the extensive province of Minas Geraes, lies 170 miles north by west of Rio de Janeiro, in the upper part of the Rio São Francisco basin, at a height of 3757 feet above the sea. A steep hill to the north of the peak of Itacolúmi (5740) is broken up by ravines into a number of distinct plateaus; and it is round these plateaus, generally crowned by a church, that most of the houses of Ouro Preto cluster in irregular and almost independent groups. The streets run up and down hill in such a way as to

make riding on horseback hazardous and the use of carriages impossible. The stream which passes through the town and was formerly the scene of the most extensive gold washing operations, the Ribeirão de Ouro Preto or Do Carmo, is a tributary of the São Francisco. Besides the churches, the prominent buildings are the president's palace, the town-house, and the prison, all fronting the principal square, the treasury, the theatre (the oldest in Brazil, and restored in 1861-62), and the hospital. The botanical garden, dating from 1825, used to distribute specimens of different kinds of tea, but is now practically defunct. A public library has been in existence since before 1865. At present the importance of Ouro Preto is almost entirely administrative; formerly it was one of the great mining centres of Brazil. Its population is about 8000.

The first "prospectors," finding the hills full of a gold ore which, from the presence of silver alloy, turned black on exposure to the air, called them Serra do Ouro Preto, and the village, built in 1701 by Antonio Dias of Taubate, bore at first the same name (meaning Black Gold). In 1711 the settlement was formally constituted as the city of Villa Rica, and for sixty or seventy years it continued to deserve its new title,—the population amounting to 25,000 or 30,000, and 12,000 slaves being employed in its gold mines. When in 1720 Minas Geraes was separated from the captaincy of S. Paulo, Villa Rica was made the capital of the new province. In 1788 it was the centre of the disastrous attempt made by Tiradentes, the poet Gonzaga, &c., to found an independent republic in Brazil with São João d'el Rei as its capital and Villa Rica as its university town (see GONZAGA); and in 1821 it took a vigorous part in the successful revolution. A comarca of Ouro Preto was created in 1823, and Villa Rica received back its original name.

OUSEL, or OUZEL, Anglo-Saxon *Osle*, equivalent of the German *Amsel* (a form of the word found in several old English books, and perhaps yet surviving in some parts of the country), apparently the ancient name for what is now more commonly known as the Blackbird, the *Turdus merula* of ornithologists, but at the present day not often applied to that species, though, as will immediately be seen, used in a compound form for two others. In many parts of Britain the Blackbird is still called the Merle, a name had directly from the French, and abbreviated from the Latin *Merula*, which has the same meaning. The adult male of this beautiful and well-known species scarcely needs any other description than that of the poet:—

"The Ouzel-cock, so black of hue
With orange-tawny bill."

—*Midsummer Night's Dream*, act iii. sc. 1.

But the female is of an uniform umber-brown above, has the chin, throat, and upper part of the breast orange-brown, with a few dark streaks, and the rest of the plumage beneath of a hair-brown. The young of both sexes resemble the mother. The Blackbird is found in every country of Europe, even breeding—though rarely—beyond the arctic circle, and in eastern Asia, as well as in Barbary and the Atlantic islands. Resident in Britain as a species, its numbers yet receive considerable accession of passing visitors in autumn, and in most parts of its range it is very migratory. The song of the cock has a peculiarly liquid tone, which makes it much admired, but it is rather too discontinuous to rank the bird very high as a musician. The species is very prolific, having sometimes as many as four broods in the course of the spring and summer. The nest, generally placed in a thick bush, is made of coarse roots or grass, strongly put together with earth, and is lined with fine grass. Herein are laid from four to six eggs of a light greenish-blue closely mottled with reddish-brown. Generally vermivorous, the Blackbird will, when pressed for food, eat grains and seeds, while berries and fruits in their season are eagerly sought by it, thus earning the enmity of gardeners. More or less allied to and resembling the Blackbird are many other species which inhabit most parts of the world, excepting the Ethiopian Region, New Zealand and Australia proper, and

North America. Some of them have the legs as well as the bill yellow or orange; and, in a few of them, both sexes alike display a uniformly glossy black. The only other species that need here be mentioned is the Ring-Ousel, *Turdus torquatus*, which differs from the Blackbird in the dark colour of its bill, and in possessing a conspicuous white gorget—whence its name. It has also very different habits, frequenting wild and open tracts of country, shunning woods, groves, and plantations, and preferring the shelter of rocks to that of trees. Its distribution is accordingly much more local, and in most parts of England it is only known as a transitory migrant in spring and autumn—from and to its hardly as yet ascertained winter quarters. It does not seem to have an extensive range to the eastward, though it has been recorded from Persia.

The Water-Ousel, or Water-Crow, now commonly named the "Dipper,"—a term apparently invented and bestowed in the first edition of Bewick's *British Birds* (ii. pp. 16, 17),—not, as is commonly supposed, from the bird's habit of entering the water in pursuit of its prey, but because "it may be seen perched on the top of a stone in the midst of the torrent, in a continual dipping motion, or short courtesy often repeated." This, the *Cinclus aquaticus* of most ornithologists, is the type of a small but remarkable group of birds, the position of which many taxonomers have been at their wits' end to determine. It would be useless here to recount the various suppositions that have been expressed; suffice it to say that almost all ornithologists are now agreed in regarding the genus *Cinclus*¹ as

Cinclus mexicanus.

differing so much from other birds that, though essentially one of the true *Passeres* (i.e., *Oscines*), it forms a distinct Family, *Cinclidæ*, which has no very near allies. That some of its peculiarities (for instance, the sternum in adult examples having the posterior margin generally entire, and the close covering of down that clothes the whole body—a character fully recognized by Nitzsch) are correlated with its aquatic habit is probably not to be questioned; but this fact furnishes no argument for associating it, as has often been done, with the Thrushes (*Turdidæ*), the Wrens (*Troglodytidæ*), or much less with other groups to which it has undoubtedly no affinity. The Dipper haunts rocky streams, into which it boldly enters, generally by deliberately wading, and then by the strenuous combined action of its wings and feet makes its way along the bottom in quest of its living prey—freshwater mollusks, and aquatic insects in their larval or mature condition. By the careless and ignorant it is accused of feeding on the spawn of fishes, and it has been on that account subjected to much persecution. Innumerable examinations of the contents of its stomach have not only proved that the charge is baseless, but that the bird clears off many of the worst enemies of the precious product. Short and squat of stature, active and

restless in its movements, silky black above, with a pure white throat and upper part of the breast, to which succeeds a broad band of dark bay, it is a familiar figure to most fishermen on the stream it frequents, while the cheerful song of the cock, often heard in the hardest frost, helps to make it a favourite with them in spite of the obloquy under which it labours. The Water-Ousel's nest is a very curious structure,—outwardly resembling a Wren's, but built on a wholly different principle,—an ordinary cup-shaped nest of grass lined with dead leaves, placed in some convenient niche, but encased with moss so as to form a large mass that covers it completely except only a small hole for the bird's passage. The eggs laid within are from four to six in number, and are of a pure white. These remarks refer to the Water-Ousel of central and western Europe, including the British Islands; but, except as regards plumage, it is believed that they will apply to all the other species, about a dozen in number, which have been described. These inhabit suitable places throughout the whole Palearctic Region as well as the southern slopes of the Himalaya and the hill-country of Formosa, besides the Rocky Mountains and a great part of the Andes. Mr Salvin, in a very philosophical paper on the genus (*Ibis*, 1867, pp. 109–122), refers these species—some of which are wholly black and one slate-coloured—to five well-marked forms, of which the other members are either "representative species" or merely "local races"; but all seem to occupy distinct geographical areas,—that which is represented in the accompanying woodcut having a wide range along the mountainous parts of North America to Mexico; and it is quite possible that their number may yet be increased, for the general habits of the birds preclude any invasion of territory, and thus produce practical isolation. (A. N.)

OUSELEY, SIR WILLIAM (1769–1842), Orientalist, was the eldest son of Captain Ralph Ouseley, of an old Irish family, and was born in Monmouthshire in 1769. After a private education he went to Paris, in 1787, to perfect himself in French, and in the following year became cornet in the 8th regiment of dragoons. After obtaining the grade of lieutenant he, on the conclusion of the campaign of 1794, sold his commission in order to devote his attention to the study of Oriental literature, especially Persian. In 1795 he published *Persian Miscellanies*; in 1797, *Oriental Collections*; in 1799, *Epitome of the Ancient History of Persia*; in 1801, *Tales of Bakhtyar and Observations on Some Medals and Gems*; and in 1804, *The Oriental Geography of Ebn Haukal*. He received the degree of LL.D. from the university of Dublin in 1797, and in 1800 he was knighted by the Marquis Cornwallis. On his brother, Sir Gore Ouseley, being appointed ambassador to Persia in 1810, Sir William accompanied him as secretary. He returned to England in 1813, and in 1819–23 published, in three volumes, *Travels in Various Countries of the East, especially Persia*, in 1810, 1811, and 1812. He also published editions of the *Travels and Arabian Proverbs* of Burckhardt. He was a member of various learned societies, and contributed a number of important papers to the *Transactions of the Royal Society of Literature*. He died at Boulogne in September 1842.

OUTLAW, in English law, is a person put out of the protection of the law by process of outlawry. A woman is properly said to be waived rather than outlawed. Outlawry was usually the result of non-appearance of the defendant or accused at the trial, and involved deprivation of all civil rights. It was finally abolished in civil proceedings in 1879 by 42 & 43 Vict. c. 59, § 3. In criminal proceedings it has become practically obsolete, and the Criminal Code, § 458, proposes to formally abolish it.

¹ Some writers have used for this genus the name *Hydrobatæ*.

In Scotland outlawry or fugitation may be pronounced by the supreme criminal court in the absence of the panel on the day of trial. In the United States outlawry never existed in civil cases, and in the few cases where it existed in criminal proceedings it has become obsolete.

OUTRAM, SIR JAMES (1803–1863), English general, was the son of Benjamin Outram of Butterley Hall, Derbyshire, civil engineer, and was born 29th January 1803. His father died in 1805, and his mother, a daughter of Dr James Anderson, the Scottish writer on agriculture, removed in 1810 to Aberdeenshire. From Uduy school the boy went in 1818 to Marischal College, Aberdeen; and in 1819 an Indian cadetship was given him. Soon after his arrival in India his remarkable energy attracted notice, and in July 1820 he became acting adjutant to the first battalion of the 12th regiment on its embodiment at Poona, an experience which he found to be of immense advantage to him in his after career. In 1825 he was sent to Khandesh, where he succeeded in training a light infantry corps, formed of the wild robber Bhils, gaining over them a marvellous personal influence, and employing them with great success in checking outrages and plunder. Their loyalty to him had its principal source in their boundless admiration of his hunting achievements, which in their cool daring and hairbreadth escapes have perhaps never been equalled. Originally a "puny lad," and for many years after his arrival in India subject to constant attacks of sickness, Outram seemed to win strength by every new illness, acquiring a constitution of iron, "nerves of steel, shoulders and muscles worthy of a six-foot Highlander." In 1835 he was sent to Gujerat to make a report on the Mahi Kanthā district, and for some time he remained there as political agent. On the outbreak of the Afghan war in 1838 he was appointed extra aide-de-camp on the staff of Sir John Keane, and besides many other brilliant deeds performed an extraordinary exploit in capturing a banner of the enemy before Ghazni. After conducting various raids against different Afghan tribes, he was in 1839 promoted major, and appointed political agent in Lower Sind, and later in Upper Sind. On his return from a short visit to England in 1843, he was, with the rank of brevet lieutenant-colonel, appointed to a command in the Mahratta country, and in 1847 he was transferred from Satara to Baroda. In 1854 he became chief-commissioner of Oudh, and in 1856 he received the honour of knighthood. Appointed in 1857, with the rank of lieutenant-general, to command an expedition against Persia, he defeated the enemy with great slaughter at Khushab, and otherwise conducted the campaign with such rapid decision that peace was shortly afterwards concluded, his brilliant services being rewarded by the Grand Cross of the Bath. From Persia he was summoned in June to India, with the brief explanation,—"We want all our best men here." Immediately on his arrival in Calcutta he was appointed to command the two divisions of the Bengal army, occupying the country from Calcutta to Cawnpur; and to the military control was also joined the commissioner-ship of Oudh. Already the rebellion had assumed such proportions as to compel Havelock to fall back on Cawnpur, which he only held with difficulty, although a speedy advance was necessary to save the garrison at Lucknow. On arriving at Cawnpur with reinforcements, Outram, "in admiration of the brilliant deeds of General Havelock," conceded to him the glory of relieving Lucknow, and, waiving his rank, tendered his services to him as a volunteer. During the advance he commanded a troop of volunteer cavalry, and performed exploits of great brilliancy at Mangalwar, and in the attack at the Alam-bagh; and in the final conflict he led the way, charging through a very tempest of fire. Resuming supreme com-

mand, he then held the town till the arrival of Sir Colin Campbell, after which he conducted the evacuation of the residency so as completely to deceive the enemy. In the second capture of Lucknow, on the commander-in-chief's return, Outram was entrusted with the attack on the side of the Gumti, and afterwards, having recrossed the river, he advanced "through the Chattar Manzil to take the residency," thus, in the words of Sir Colin Campbell, "putting the finishing stroke on the enemy." After the capture of Lucknow he was gazetted lieutenant-general. In February 1858 he received the special thanks of both Houses of Parliament, and in the same year the dignity of baronet with an annuity of £1000. When, on account of shattered health, he returned finally to England in 1860, a movement was set on foot to mark the sense entertained, not only of his military achievements, but of his constant exertions in behalf of the natives of India, whose "weal," in his own words, "he made his first object." The movement resulted in the presentation of a public testimonial and the erection of statues in London and Calcutta. He died 11th March 1863, and was buried in Westminster Abbey, where the marble slab on his grave bears the pregnant epitaph "The Bayard of India."

See *James Outram, a Biography*, by Major-General Sir F. J. Goldsmid, C.B., K.C.S.I., 2 vols., 1880, 2d ed., 1881.

OVAR, a town of Portugal, in the district of Aveiro (Beira), with a station on the railway 20 miles south of Oporto, lies at the northern end of the Aveiro lagoon, —an extremely unhealthy position. It contains 10,022 inhabitants (1878), and carries on a brisk trade with the colonies and northern Africa.

OVATION, an honour awarded in Rome to victorious generals. It was less distinguished than the triumph (see **TRIUMPH**), and was awarded either when the campaign, though victorious, had not been important enough for the higher honour, or when the general was not of rank sufficient to give him the right to a triumph. The ceremonial was on the whole similar in the two cases, but in an ovation the general walked or more commonly rode on horseback.

OVEN, a close chamber or compartment in which a considerable degree of heat may be generated either from internal or from external sources. In English the term is generally restricted to a chamber for baking bread and other food substances, being equivalent to the French *four* or the German *Backofen*; but the chambers in which coal is coked are termed coke ovens. See **BAKING**, vol. iii. 257, and **COKE**, vol. vi. 118.

OVERBECK, JOHANN FRIEDRICH (1789–1869), the reviver and leader of "Christian art" in the 19th century, was born in Lübeck 4th July 1789. His ancestors for three generations had been Protestant pastors; his father was doctor of laws, poet, mystic pietist, and burgomaster of Lübeck. Within stone's throw of the family mansion in the Königstrasse stood the gymnasium, where the uncle, doctor of theology and a voluminous writer, was the master; there the nephew became a classic scholar and received instruction in art.

The young artist left Lübeck in March 1806, and entered as student the academy of Vienna, then under the direction of F. H. Füger, a painter of some renown, but of the pseudo-classic school of the French David. Here was gained thorough knowledge, but the teachings and associations proved unendurable to the sensitive, spiritual-minded youth. Overbeck wrote to a friend that he had fallen among a vulgar set, that every noble thought was suppressed within the academy, and that losing all faith in humanity he turned inwardly on himself. These words are a key to his future position and art. It seemed to him that in Vienna, and indeed throughout Europe, the pure springs of

Christian art had been for centuries diverted and corrupted, and so he sought out afresh the living source, and, casting on one side his contemporaries, took for his guides the early and pre-Raphaelite painters of Italy. At the end of four years, differences had grown so irreconcilable that Overbeck and his band of followers were expelled from the academy. True art, he writes, he had sought in Vienna in vain—"Oh! I was full of it; my whole fancy was possessed by Madonnas and Christs, but nowhere could I find response." Accordingly he left for Rome, carrying his half-finished canvas Christ's Entry into Jerusalem, as the charter of his creed—"I will abide by the Bible; I elect it as my standing-point."

Overbeck in 1810 entered Rome, which became for fifty-nine years the centre of his unremitting labour. He was joined by a goodly company, including Cernelius, Wilhelm Schadow, and Philip Veit, who took up their abode in the old Franciscan convent of San Isidoro on the Pincian Hill, and were known among friends and enemies by the descriptive epithets—"the Nazarites," "the pre-Raphaelites," "the new-old school," "the German-Roman artists," "the church-romantic painters," "the German patriotic and religious painters." Their precept was hard and honest work and holy living; they eschewed the antique as pagan, the Renaissance as false, and built up a severe revival on simple nature and on the serious art of Perugino, Pinturicchio, Francia, and the young Raphael. The characteristics of the style thus educed were nobility of idea, precision and even hardness of outline, scholastic composition, with the addition of light, shade, and colour, not for allurements, but chiefly for perspicuity and completion of motive. Overbeck was mentor in the movement; a fellow-labourer writes:—"No one who saw him or heard him speak could question his purity of motive, his deep insight and abounding knowledge; he is a treasury of art and poetry, and a saintly man." But the struggle was hard and poverty its reward. Helpful friends, however, came in Niebuhr, Bunsen, and Frederick Schlegel. Overbeck in 1813 joined the Roman Catholic Church, and thereby he believed that his art received Christian baptism.

Faith in a mission begat enthusiasm among kindred minds, and timely commissions followed. The Prussian consul, Bartholdi, had a house on the brow of the Pincian, and he engaged Overbeck, Cornelius, Veit, and Schadow to decorate a room 24 feet square with frescos from the Story of Joseph and his Brethren. The subjects which fell to the lot of Overbeck were the Seven Years of Famine and Joseph Sold by his Brethren. These tentative wall-pictures, finished in 1818, produced so favourable an impression among the Italians that in the same year Prince Massimo commissioned Overbeck, Cornelius, Veit, and Schnorr to cover the walls and ceilings of his garden pavilion, near St John Lateran, with frescos illustrative of Tasso, Dante, and Ariosto. To Overbeck was assigned, in a room 15 feet square, the illustration of Tasso's *Jerusalem Delivered*; and of eleven compositions the largest and most noteworthy, occupying one entire wall, is the Meeting of Godfrey de Bouillon and Peter the Hermit. The completion of the frescos—very unequal in merit—after ten years' delay, the overtaxed and enfeebled painter delegated to his friend Joseph Führich. The leisure thus gained was devoted to a thoroughly congenial theme, the Vision of St Francis, a wall-painting 20 feet long, figures life size, finished in 1830, for the church of Sta Maria degli Angeli near Assisi. Overbeck and the brethren set themselves the task of recovering the neglected art of fresco and of monumental painting; they adopted the old methods, and their success led to memorable revivals throughout Europe.

Fifty years of the artist's laborious life were given to

oil and easel paintings, of which the chief, for size and import, are the following:—Christ's Entry into Jerusalem (1824), in the Marien Kirche, Lübeck; Christ's Agony in the Garden (1835), in the great hospital, Hamburg; Lo Sposalizio (1836), Raczynski gallery, Berlin; the Triumph of Religion in the Arts (1840), in the Städel Institut, Frankfurt; Pietà (1846), in the Marien Kirche, Lübeck; the Incredulity of St Thomas (1851), in the possession of Mr Beresford Hope, London; the Assumption of the Madonna (1855), in Cologne Cathedral; Christ Delivered from the Jews (1858), tempera, on a ceiling in the Quirinal Palace,—a commission from Pius IX., and a direct attack on the Italian temporal government, therefore now covered by a canvas adorned with Cupids. All the artist's works are marked by religious fervour, careful and protracted study, with a dry, severe handling, and an abstemious colour.

Overbeck belongs to eclectic schools, and yet was creative; he ranks among thinkers, and his pen was hardly less busy than his pencil. He was a minor poet, an essayist, and a voluminous letter-writer. His style is wordy and tedious; like his art it is borne down with emotion and possessed by a somewhat morbid "subjectivity." His pictures were didactic, and used as propagandas of his artistic and religious faith, and the teachings of such compositions as the Triumph of Religion and the Sacraments he enforced by rapturous literary effusions. His art was the issue of his life: his constant thoughts, cherished in solitude and chastened by prayer, he transposed into pictorial forms, and thus were evolved countless and much-prized drawings and cartoons, of which the most considerable are the Gospels, forty cartoons (1852); Via Crucis, fourteen water-colour drawings (1857); the Seven Sacraments, seven cartoons (1861). Overbeck's compositions, with few exceptions, are engraved. His life-work he sums up in the words—"Art to me is as the harp of David, whereupon I would desire that psalms should at all times be sounded to the praise of the Lord." He died in Rome in 1869, aged eighty, and lies buried in San Bernardo, the church wherein he worshipped. (J. B. A.)

OVER DARWEN, a municipal borough of Lancashire, is situated in the vale of the Darwen river, shut in by heath-covered hills, and on the Lancashire and Yorkshire Railway, 3 miles south from Blackburn and 9 north from Bolton. There are four ecclesiastical parishes, each of which has a handsome church; and among the other public buildings are the market-house, the Liberal and Conservative club-houses, a free public library with 10,000 volumes, and the Peel baths, erected in memory of Sir Robert Peel. The town possesses cotton factories, iron and brass foundries, machine works, paper mills, paper-staining works—the first and probably the largest of their kind. In the neighbourhood there are collieries and stone quarries. The population of the municipal borough (area 5918 acres) in 1881 was 29,744. It includes part of Lower Darwen and Eccleshill, with 2118 inhabitants. The postal designation is Darwen.

Over Darwen was at one time included in Walton-le-dale, which was granted by Henry de Laey to Robert Banastre in the reign of Henry II. In the 4th of Edward II. (1310) it is mentioned along with Livesey and Tockholes, the three containing a carucate of land in fee of the castle of Clitheroe. In 38 Edward III. (1364) a moiety of the manor of Over Darwen was held by Thomas Molyneux, the other moiety being held by the Osbaldeston family. Subsequently the whole manor became the property of the Traffords, of whom it was purchased in 1810 by the present owners the Duckworths. Over Darwen was incorporated as a municipal borough in 1878, and a commission of the peace was granted in 1881.

OVERTURE. See MUSIC, vol. xvii. p. 95 sq.

OVERYSSEL, or OVERIJSEL, a province of Holland, bounded N.W. by the Zuyder Zee, N. by Friesland and

Drenthe, N.E. by Hanover (Prussia), S.E. by Westphalia (Prussia), and S. and S.W. by Guelderland, with an area of 1291 square miles. The southern district belongs to the basin of the Yssel; the northern is watered by the Vecht and various small streams falling into the Zwartewater, the river which was for so many generations the object of dispute between Zwolle and Hasselt. A large proportion of the surface is a sandy flat relieved by hillocks, rising at times to a height of 230 feet above the sea. Husbandry, stock-raising, and dairy-farming are the principal means of subsistence in the province, though the fisheries, turf-cutting, the shipping trade, and a number of manufacturing industries are also of importance. In the district of Twenthe (towards the east) more especially there are a great many cotton-mills and bleaching-works; brick and tile making is prosecuted in the neighbourhood of the Yssel; and along the coast a good many people are engaged in making mats and besoms. During the present century the province has been opened up by the construction of several large canals—the Dedemsvaart, the Noord-Willemsvaart (between the Yssel and the Zwartewater), the "Overyssele canals" (running near the eastern frontier), &c.; and a fairly complete railway system has come into existence. The province is divided into the three administrative districts of Zwolle, Deventer, and Almelo. Its population, 234,376 in 1859 and 263,008 in 1875 (134,201 males, 128,807 females), was 247,136 in 1879. Of the total for 1875, 181,863 were Protestants, 76,891 Roman Catholics, and 4018 Jews. The chief town, Zwolle, had in 1879 a communal population of 22,759, and there were fourteen other communes with more than 2000 inhabitants, including Deventer, 19,162; Kampen, 17,444; Almelo, 7758; Hengelo, 6502.

Both the present name Overyssele and the older designation Overzicht are explained by the fact that the province lies mainly on the other side of the Yssel from Utrecht, with which it long constituted an episcopal principality. Vollenhove was bestowed on the bishops in 943, Oldenzaal in 970, the land north-east of Vollenhove in 1042, Deventer in 1046, a part of Salland in 1226, the countship of Goor in 1248, the lordship of Diepenheim in 1331, and that of Almelo in 1406. In 1527 Bishop Henry of Bavaria advised the recognition of Charles V. as protector and ruler of the district, and Overzicht became Overyssele. It was the sixth province to join the Union in 1579. During the French occupation it bore the name of the department of Bouches de l'Issel.

OVID (P. OVIDIUS NASO) was the last in order of time of the poets of the Augustan age, whose works have given to it the distinction of ranking among the great eras in the history of human culture. As is the case with most other Roman writers, his personal history has to be gathered almost entirely from his own writings. The materials for his life are partly the record of the immediate impressions of the time in which they were written contained in the *Amores*; partly the reminiscences of his happier days, to which his mind constantly recurred in the writings from his place of exile.

His life is almost coincident in extent with that of the Augustan age. The year of his birth, 43 B.C.,—the year of the consulship of Hirtius and Pansa, which intervened between the death of Julius Cæsar and the partition of the Roman world among the Triumvirs,—may be regarded as the last year of the republic. It was the year of the death of Cicero, which marks the close of the republican literature. Thus the only form of political life known to Ovid was that of the ascendancy and absolute rule of Augustus and his successor. His character was neither strengthened nor sobered, like that of his older contemporaries, by personal recollection of the crisis through which the republic passed into the empire. There is no sense of political freedom in any of his writings. The spirit inherited from his ancestors was that of the Italian country districts and *municipia*, not that of Rome. He

was sprung from the Peligni, one of the four small mountain peoples whose proudest memories were of the part they had played in the Social War. They had no old race-hostility with Rome, such as that which made the most powerful representative of the Sabellian stock remain till the last her implacable enemy; and their opposition to the senatorian aristocracy in the Social War would predispose them to accept the empire. Ovid belonged by birth to the same social class as Tibullus and Propertius, that of old hereditary landowners; but he was more fortunate than they in the immunity which his native district enjoyed from the confiscations made by the triumvirs. His native town and district, Sulmo, lay high among the Apennines, and is described by Mr Hare as "grandly situated on an isolated platform, backed by snowy mountains." The poet himself describes this district as remarkable for the abundance of its streams and for its salubrity—

"Parva, sed irriguis ora salubris aquis;"

and he recalls the fresh charm of its scenery from the desolate waste of his Scythian exile. To his early life in such a district he may have owed his eye for natural beauty, and that interest in the common sights of the country which relieves the monotony of his life of pleasure in Rome and the dreary record of the life spent within the walls of Tomi, and enables him to add the charm of natural scenery to the romantic creations of his fancy. The pure air of this mountain home may have contributed to the vigorous vitality which prevented the life of pleasure from palling on him, and which beats strongly even through all the misery of his exile. But if this vitality—with its natural accompaniment, a keen capacity for enjoyment—was a gift due to his birthplace, it was apparently a gift transmitted to him by inheritance; for he tells us that his father lived till the age of ninety, and that he performed the funeral rites to his mother after his father's death. While he mentions both with the piety characteristic of the old Italian, he tells us little more about them than that "their thrift curtailed his youthful expenses,"¹ and that his father did what he could to dissuade him from poetry, and to force him into the more profitable career of the law courts. He had one brother, exactly a year older than himself, who, after showing promise as a speaker, died at the age of twenty. The tone in which Ovid speaks of him is indicative of sincere affection, but not of such depth of feeling as was called forth in Catullus by a similar loss. The two brothers had been brought early to Rome for their education, where they attended the lectures of the most eminent rhetoricians of their time. Education had become more purely rhetorical and literary, less philosophical and political, than it had been in a previous generation. Ovid is said to have attended these lectures eagerly, and to have shown in his exercises that his gift was poetical rather than oratorical, and that he had a distaste for the severer processes of thought. Like Pope, "he lisped in numbers," and he wrote and destroyed many verses before he published anything. The earliest edition of the *Amores*, which first appeared in five books, and the *Heroides* were given by him to the world at an early age. He courted the society of the older and younger poets of his time, and formed one among those friendly coteries who read or recited their works to one another before they gave them to the world. "He had only seen Virgil"; but Virgil's friend and contemporary Æmilius Macer used in his advanced years to read his didactic epic to him; and, although there is no indication in the works of either the reigning or the rising poet of any intimacy between them, even the fastidious Horace sometimes delighted his ears

¹ *Ex Ponto*, i. 8, 42.

with the music of his verse. He had a closer bond of intimacy with the younger poets of the older generation, Tibullus, whose death he laments in one of the few pathetic pieces among his earlier writings, and Propertius, to whom he describes himself as united in the close ties of comradeship. The name of Mæcenas occurs nowhere in his poems. The time of his paramount influence both on public affairs and on literature was past before Ovid entered on his poetical career, but Messala and Fabius Maximus, whose name is mentioned by Juvenal along with that of Mæcenas as the type of a munificent patron of letters in the Augustan age, encouraged his earliest efforts. With their sons he lived in intimacy in after years, and, as he speaks of having known the younger Fabius in his cradle, his friendship with his family must have begun early in his career. He enjoyed also the intimacy of poets and men of literary accomplishment belonging to a younger generation; and with one of them, Macer, he travelled for more than a year. It is not mentioned whether he travelled immediately after the completion of his education, or in the interval between the publication of his earlier poems and that of the *Medea* and *Ars Amatoria*; but it is in his later works, the *Fæsti* and *Metamorphoses*, that we seem chiefly to recognize the impressions of the scenes he visited. In one of the epistles written from Pontus to his fellow-traveller there is a vivid record of the pleasant time they had passed together. Athens was to a Roman of that time what Rome is to an educated Englishman of the present day. Ovid speaks of having gone there under the influence of literary enthusiasm ("studiosus"); but the impression of his visit which remains on his writings is not of the wisdom taught "among the woods of Academus," but of the flowers that grow on the neighbouring Hymettus. A similar impulse induced him to visit the supposed site of Troy. The two friends saw together the splendid cities of Asia, which had inspired the enthusiasm of travel in Catullus, and had become familiar to Cicero and Horace during the years they passed abroad. They spent nearly a year in Sicily, which attracted him, as it had attracted Lucretius¹ and Virgil,² by its manifold charm of climate, of sea-shore and inland scenery, and of legendary and poetical association,—a charm which has found its most enduring expression in some of his most delightful tales. He recalls with a fresh sense of pleasure the incidents of their tour (which they made sometimes in a pinnace or yacht, sometimes in a light carriage), and the endless delight which they had in each other's conversation. We would gladly exchange the record of his life of pleasure in Rome for more of these recollections. The highest type of classic culture realized in ancient Rome—the type realized in such men as Cicero and Catullus, Virgil and Horace, Ovid and Germanicus—shows its affinity to a type which is the result of essentially similar studies in modern times by nothing more clearly than the enthusiasm for travel among lands famous for their natural beauty, their monuments of art, and their historical associations.

When settled at Rome, although a public career, leading to senatorian position, was open to him, and, although he filled various judicial offices, and claims to have filled them well, he had no ambition for such distinction, and looked upon pleasure and poetry as the occupations of his life. He tells us that he was married, when little more than a boy, to a wife for whom he did not care, who, he implies, was not worthy of him, and from whom he was soon

separated, and afterwards to a second wife, with whom his union, although through no fault of hers, did not last long. But he had other objects of his volatile affections, and one of them, Corinna, after the example of his predecessors Gallus, Propertius, and Tibullus, and their Alexandrian prototypes Callimachus, Philetas, &c., he makes the heroine of his love elegies. It is doubtful whether, like Lesbia, Delia, and Cynthia, she belonged to the class of Roman ladies of recognized position, or to that to which the Chloes and Lalages of Horace's artistic fancy evidently belong. If trust can be placed in the later apologies for his life, in which he states that he had never given occasion for any serious scandal, it is probable that she belonged to the class of "libertinæ." Ovid is not only a less constant but he is a much less serious lover than Catullus, Tibullus, or Propertius. His tone is that either of mere sensual self-regarding feeling or of persiflage. That tone is in many ways offensive to modern taste, but in nothing is it more characteristic of his age than in his light-hearted justification of his choice both of a theme and of a career. In his complete emancipation from all sense of restraint or wish for better things, Ovid goes beyond all his predecessors, although Tibullus and Propertius, and even Horace in the ironical disclaimers of his earlier *Odes*, give indication of the same state of feeling. In this Ovid reflects the tastes and tone of fashionable, well-born, and wealthy Roman society between the years 20 B.C. and the beginning of our era. The memory of the civil wars no longer weighed on the world. The career of ambition was so far from attracting men that they had to be urged and coerced into filling official places and carrying on the routine duties of the senate. Society was bent simply on amusement. There was less of coarseness in the pursuit of pleasure than had prevailed among the contemporaries of Catullus. We find little trace in Ovid of the convivial pleasures which Horace celebrates in his lighter odes, or of the excesses of which Propertius makes confession. Ovid says of himself that he drank scarcely anything but water, and from what he tells us of his appearance and constitution he was evidently not of the temperament to which convivial excesses bring any temptation.³ But probably it was not the fashion of the time to live intemperately. As a result of the loss of political interests, women came to play a more important and brilliant part in society, and the tone of fashionable conversation and literature was adapted to them. Julia, daughter of the emperor, was by her position, her brilliant gifts, and her reckless laxity of character the natural leader of such a society. The awakening of the Roman world out of this fool's paradise of pleasure was due to the discovery of her intrigue with Iulus Antonius, son of Mark Antony, and to the open and violent display of anger with which Augustus resented what was at once a shock to his affections and a blow to his policy. Nearly coincidently with the publicity given to this scandal appeared the famous *Ars Amatoria* of Ovid, perhaps the most immoral and demoralizing work ever written, at least in ancient times, by a man of genius. Ovid was the favourite poet of the fashionable world; he lived on terms of intimacy with its leading members, the younger representatives of the old nobility, who had survived the proscriptions and the fatal day of Philippi. His poetical accomplishment would naturally recommend him to Iulus Antonius, of whose gifts Horace has spoken so eulogistically. His marriage with his third wife, a lady of the great Fabian house, and a friend of the empress Livia, had probably taken place before this time. It thus seems likely that he may have been admitted into the intimacy of the

¹ Cf. Lucret., l. 726—

"Quæ cum magna modis multis miranda videtur
Gentibus humanis regio visendaque fertur."

² "Quamquam secessu Campaniæ Siciliæque plurimum uteretur."
—Donat.

³ Compare *Am.*, ii. 23—

"Graciles, non sunt sine viribus artus;
Pondere, non nervis, corpora nostra carent."

younger society of the Palatine, although in the midst of his most fulsome flattery he does not claim ever to have enjoyed the favour of Augustus. Whether he was in any way mixed up with this intrigue is not known. But that the work which appeared coincidentally with it excited deep resentment in the mind of the emperor, as the pander to the passions by which the dignity of his family had been outraged and his state policy thwarted, is shown by his edict, issued ten years later, against the book and its author. Augustus had the art of dissembling his anger; and Ovid appears to have had no idea of the storm that was gathering over him. He still continued to enjoy the society of the court and of the fashionable world; he passed before the emperor in the annual procession among the ranks of the equites; he filled a more important judicial place; and he had developed a richer vein of genius than he had shown in his youthful prime. But he was aware that public opinion had been shocked, or professed to be shocked, by his last work; and after writing a kind of apology for it, called the *Remedia Amoris*, he directed his genius into other channels, and wrote during the next ten years the *Metamorphoses* and the *Fasti*. He had already written one work, the *Heroides*, in which he had imparted a modern and romantic interest to the heroines of the old mythology,¹ and a tragedy, the *Medea*, which must have afforded greater scope for the dramatic and psychological treatment of the passion with which he was most familiar. In the *Fasti* Ovid assumes the position of a national poet² by imparting poetical life and interest to the ceremonial observances of Roman religion; but it is as the brilliant narrator of the romantic tales that have got so strangely blended with the realistic annals of Rome that he succeeds in the part assumed by him. The *Metamorphoses* professed to trace the relations of the gods with human affairs from the reign of Chaos to the deification of Augustus; and in the later books that work also may claim something of a national character. But it consists for the most part of a series of tales of the love adventures of the gods with nymphs and heroines, told in a tone of mixed irony and romance. This work, which he regards as his most serious claim to immortality, had not been finally revised at the time of his disgrace, and he committed it to the flames; but other copies were in existence, and the book was given to the world in his absence. He often regrets that it had not obtained his final revisal. The *Fasti* also was broken off by his exile, after the completion and publication of the first six books, treating of the first six months of the year.

The actual offence which gave occasion for his banishment is not exactly known. In his frequent references to it he wavers between assertions of his innocence of anything beyond simplicity and error and the admission that, though he had done nothing, he yet deserved his punishment. He had witnessed something which was a cause of pain and offence to the emperor. In a letter to one of his intimate friends, to whom he had been in the habit of confiding all his secrets, he says that had he confided this one he would have escaped condemnation. In writing to another friend in reference to his disgrace, he warns him against the danger of courting too high society—"prælustria vita." The cause which excited or renewed the anger of Augustus was connected with the old offence of writing and publishing the *Ars Amatoria*. All this points to his having been in some way mixed up with some scandal affecting the imperial family. He distinctly disclaims the idea that he had anything to do with any treasonable plot; and he

certainly appears to have been the last man who ever could have been made the confederate of a serious conspiracy. All this seems to connect him with one event, coincident in time with his disgrace,—the intrigue of the younger Julia, granddaughter of the emperor, with Silanus, mentioned by Tacitus in the third book of the *Annals*. Tacitus tells us how deeply Augustus felt these family scandals, looking upon them as acts of treason and sacrilege. It seems, at first sight, strange that the chief punishment fell, not on the real offenders, but on Ovid, who at the worst could only have been the confidant of their intrigue, perhaps may have lent his house as a place of rendezvous for the lovers. To Julia herself was assigned the lighter penalty of seclusion in one of the towns of Italy, and Silanus had no other punishment than that of exclusion from the court. Augustus must have regarded Ovid and his works as, if not the corrupter of the age, yet the most typical representative of that corruption which in its effects on his own family might be regarded as the nemesis attending on, as it was, the direct consequence of, the outward success of his policy. The date of this scandal must have been 7 or early in 8 A.D., as Tacitus, under the date 28 A.D., mentions the death of Julia after twenty years of seclusion.

A delay of nearly two years seems to have taken place between the disgrace and the sentence passed on Ovid, and it must have been during this interval that he visited his friend Fabius at Elba,³ probably with the view of inducing him to intercede for him. At last the edict, dictated by relentless policy rather than personal vindictiveness, was published. He was left in the enjoyment of the rights of citizenship and in the possession of his property (perhaps through the exercise of the influence of Livia in favour of his wife), but was ordered to leave Rome on a particular day, and to settle at the very outskirts of civilization,—in the semi-Greek semi-barbaric town of Tomi, near the mouth of the Danube. He tells vividly the story of the agony of his last night at Rome, of the dangers and hardships of his winter voyage down the Adriatic, and of his desolate feelings on his first arrival at his new abode. But this was merely the beginning of his miseries. For eight years he bore up in his solitude, in the dreariest circumstances, suffering from the unhealthiness of the climate and exposed to constant alarm from the incursions of the neighbouring barbarians. He continued to be buoyed up by hopes first of a remission of his sentence, afterwards of at least a change to another place of exile. He wrote his complaints first in a series of books sent successively to Rome, afterwards in a number of poetical epistles, also collected into books, addressed to all his friends who were likely to have influence at court. He believed that Augustus had softened towards him before his death, but his successor was inexorable to his complaints. Perhaps the person who most deeply resented the offence was the one who exercised the greatest influence over both, the empress Livia, whose life and example were a protest against the laxity of the age, and who was an unsympathetic stepmother to the members of the imperial family. His chief consolation was the exercise of his art, and the only expression of a worthy feeling of resistance to his misery is in a letter to his daughter Perilla, in which he asserts that over his genius Augustus had no control:—

"Ingenio tamen ipso meo comitorque furorque:

Cæsar in hoc potuit juris habere nihil."

—*Tristia*, iii. 7, 47.

Yet as time goes on he is painfully conscious of failure in power; and of the absence of all motive to perfect his work. He had access to no books except such as he may have brought with him, and the zest for reading, as for all

¹ The essentially modern character of the work appears in his making a heroine of the time of the Trojan war speak of visiting "learned" Athens (*Heroid.*, ii. 83).

² "Animos ad publica carmina flexi" (*Trist.*, v. 23).

³ *Ex Ponto*, ii. 3, 83.

other pleasure, was gone. He recalls the memories of the happy days he had spent at Rome; and the chief relief to the misery of his exile was the receipt of letters from his friends. M. Gaston Boissier says that he left his genius behind him at Rome; and it is true that the works written in exile have not the brilliant versatility, the buoyant spirit, or the finished art of his earlier writings. They harp eternally on the same theme. All his faults of diffuseness and self-repetition appear in an exaggerated form. But there is the same power of vivid realization and expression, the same power of making his thought, feeling, and situation immediately present to the reader. What they lose in art they gain in personal interest. They have, like the letters of Cicero to Atticus, the fascination exercised by those works which have been given to the world under the title of *Confessions*; and they are the sincerest expression in literature of the state of mind produced by a unique experience,—that of a man, when well advanced in years, but still retaining extraordinary sensibility to pleasure and pain, withdrawn from a most brilliant position in the centre of social and intellectual life and material civilization, and cast upon his own resources in a place and among people affording the dreariest contrast to all that had gratified his eye, heart, and mind through the whole of his previous life. How far these letters and confidences are to be regarded as equally sincere expressions of his affection or admiration for his correspondents is another question, which need not be pressed. Even in those addressed to his wife, in which he might be supposed to pour out his heart naturally, there may perhaps be detected a certain ring of insincerity. He pays her compliments, addresses her in the studied language of gallantry, and compares her to Penelope and Laodamia and the other famous heroines of ancient legend. Had she been a Penelope or a Laodamia she would have accompanied him in his exile, as we learn from Tacitus was done by other wives¹ in the more evil days of which he wrote the record. There is a note of truer affection in the one letter to his daughter Perilla, of whose genius and beauty he was proud, and who in her tastes and character was more in sympathy with him. This is one of several points of resemblance in the position, feelings, and fortunes of Ovid with one whose career and character were so essentially different—Cicero. He shows a regard for many of his friends, and dependence on their sympathy and appreciation, and he recalls with some bitterness the coldness with which some of those in whom he had trusted treated him when his disgrace first overtook him. He was moved by the persistent hostility of one whom he had regarded as a friend to an act of retaliation for which neither his temper nor his genius was adapted,—the composition of a lampoon, the *Ibis*, in imitation of a poem of Callimachus, called by the same name. His affections, like his genius, were diffused widely rather than strongly concentrated, and he seems to have had rather a large circle of intimate acquaintances than any close friends to whom he was attached as Cicero was to Atticus, Horace to Mæcenas, Catullus to Calvus and Verannius. He was evidently a man of gentle and genial manners; and, as his active mind induced him to learn the language of the new people among whom he was thrown, his active interest in life enabled him to gain their regard and various marks of honour. One of the last acts of his literary career was to revise the *Fasti* and re-edit it with a dedication to Germanicus. The last lines of the *Ex Ponto* sound like the despairing sigh of a drowning man who had long struggled alone with the waves:—

"Omnia perdidimus, tantum modo vita relicta est
Præbeat ut sensum materiamque malis."

Shortly after these words were written the poet died, at the

¹ "Comitatus profugos liberos matres, secutos maritos in exilia conjuges" (Tac. *Hist.*, i. 3).

age of sixty-one, in the year 17 A.D., the third year of the reign of Tiberius.

The natural temperament of Ovid, as indicated in his writings, has more in common with the suppleness and finesse of the modern Italian than with the strength and direct force of the ancient Roman. That stamp of her own character and understanding which Rome impressed on the genius of those other races, Italian, Celtic, or Iberian, which she incorporated with herself, is fainter in Ovid than in any other great writer. He ostentatiously disclaims the manliness which in the republican times was regarded as the birthright not of Romans only but of the Sabellian races from which he sprung. He is as devoid of dignity in his abandonment to pleasure as in the weakness with which he meets calamity. He has no depth of serious conviction, no vein of sober reflexion, and is sustained by no great or elevating purpose. Although the beings of a supernatural world fill a large place in his writings, they appear stripped of all sanctity and mystery. It is difficult to say whether the tone in which the adventures of the gods and goddesses of mythology are told, or his prayer offered to the gods of heaven and of the sea, when in danger of shipwreck,

"Pro superi viridesque dei, quibus æquora cura,"

implies a kind of half-believing return to the most childish elements of paganism, or is simply one of mocking unbelief. He has absolutely no reverence, and consequently almost alone among the greater poets of Greece or Rome (the "sancti" of Lucretius, the "pii vates" of Virgil) he inspires no reverence in his reader. With all a poet's feeling for the life, variety, and subtlety of nature, he has no sense of her mystery and majesty. Though he can give dramatic expression to pathetic emotion, the profound melancholy of Lucretius, the spiritual sadness, half-relieved by dim spiritual hopes, of Virgil, the thoughtful renunciation with which Horace fronts "the cloud of mortal destiny," are states of mind which were seemingly inconceivable by him. Nor is he more capable of sounding the deeper sources of joy than of sorrow. The love which he celebrates is sensual and superficial—a matter of vanity as much as of passion. He prefers the piquant attraction of falsehood and fickleness to the charm of truth and constancy. Even where he follows Roman tendencies in his art he perverts them. Didactic poetry has set before itself many false ends in ancient Roman as in modern English literature; but the pedantry of systematic teaching has never been so strangely misapplied, as it never has been so strangely combined with brilliant power of execution, as in the methodical teaching of the art—"corrumpere et corrumpi." The *Fasti* is a work conceived in the prosaic spirit of Roman antiquarianism. But this conception might have been made poetical had it been penetrated by the religious and patriotic spirit in which Virgil treats the origin of ancient ceremonies, or the serious, half mystic spirit in which he accepts the revelations of science. The contrast between the actual trivialities of ancient science and ancient ceremonial, on the one hand, and the new meaning which both were capable of receiving from a reverential treatment, could not be more effectually enforced than by a comparison of passages in the *Georgics* and *Æneid* treating the astronomical fancies and religious ceremonies of early ages with the literal definiteness or the light persiflage of the *Fasti*.

These grave defects in strength and gravity of character had an important effect on the artistic result of Ovid's writings. Though he wanted neither diligence, perseverance, nor literary ambition, he seems incapable of conceiving a great and serious whole. Though his mind works very actively in the way of observing and reflecting on

the superficial aspects of life, yet he has added no great thoughts or maxims to the moral or intellectual heritage of the world. With a more versatile dramatic faculty than any of his countrymen, he has created no great character, comparable either with the grand impersonations of Greek tragedy, or with the Dido and Turnus of Virgil. He has both the psychological power of reading and the rhetorical power of expressing passion and emotion of different kinds; but he has not a genuine and consistent sense of human greatness or heroism. He represents with impartial sympathy the noble heart of Laodamia and the unhallowed lust of Myrrha. His spirit seems thoroughly ironical or indifferent in regard to the higher ideals or graver convictions of men.

But with all the laxity and levity of his character he must have had qualities which made him, if not much esteemed, yet much liked in his own day, and which have perpetuated themselves in the genial amiability of his writings. He claims for himself two social virtues, highly prized by the Romans, "fides" and "candor,"—the qualities of social honour and kindly sincerity, the qualities which made a man a pleasant member of society and a friend who might be relied on in the ordinary relations of life. There is no indication of anything base, anything ungenerous, or anything morose in his relations to others. The literary quality of "candor," the generous appreciation of all sorts of excellence, he possesses in a remarkable degree. He heartily admires everything in the literature of the past, Greek or Roman, that had any merit. In him more than in any of the other Augustan poets we find words of admiration more than once applied to the rude genius of Ennius and the high spirit of Accius. It is by him, not by Virgil or Horace, that Lucretius is first named and the sublimity of his genius is first acknowledged. The image of Catullus that most haunts the imagination is that of the poet who died so early—

... "hedera juvenalia cinctus
Tempora,"

as he is represented by Ovid coming to meet the shade of the young Tibullus in Elysium. To his own contemporaries, known and unknown to fame, he is as liberal in his words of recognition. He enjoyed society too in a thoroughly amiable and unenvious spirit. He lived on a friendly footing with a large circle of men of letters, poets, critics, grammarians, &c., but he showed none of that sense of superiority which is manifest in Horace's estimate of the "tribes of grammarians" and the poetasters of his day. Like Horace, too, he courted the society of the great, and probably he did not maintain an equally independent attitude towards it; but unlike Horace he expresses no contempt for the profane world outside. With his gifts of irony and knowledge of the world one might have expected him to be the social satirist of the later phase of the Augustan age. But he wanted the censorious and critical temper necessary for a social, and the admixture of gall in his disposition necessary for a successful personal satirist.

"Candidus a salibus suffusus felle refugi"

is a claim on our regard which he is fully justified in making. In his exile, and in imitation of his model Callimachus, he did retaliate on one enemy and persistent detractor; but the *Ibis* is a satire more remarkable for irrelevant learning than for epigrammatic sting.

But his chief personal endowment was his vivacity, and his keen interest in and enjoyment of life. He had no grain of discontent in his composition. He had no regrets for an ideal past nor longings for an imaginary future. The age in which his lot was cast was, as he tells us, that in which more than any other he would have wished to live.¹

He is its most gifted representative, but he does not rise above it. The great object of his art was to amuse and delight it by the vivid picture he presented of its actual fashions and pleasures, and by creating a literature of romance which reflected these fashions and pleasures, and which could stimulate the curiosity and fascinate the fancy of a society too idle and luxurious for serious intellectual effort. The sympathy which he felt with the love adventures and intrigues of his contemporaries, to which he probably owed his fall, quickened his creative power to the composition of the *Heroides* and the romantic tales of the *Metamorphoses*. Catullus, by his force of concentration, makes the actual life of his age more immediately present; but none of the Roman poets can people a purely imaginary world with such spontaneous fertility of fancy as Ovid. In heart and mind he is inferior to Lucretius and Catullus, to Virgil and Horace, perhaps to Tibullus and Propertius; but in the power and range of imaginative vision he is surpassed by no ancient and by few modern poets. This power of vision is the counterpart of his lively sensuous nature. He has a keener eye for the apprehension of outward beauty, for the life and colour and forms of nature, than any Roman or perhaps than any Greek poet. This power, acting upon the wealth of his varied reading, gathered with eager curiosity and received into a singularly retentive mind, has enabled him to body forth scenes of the most varied and picturesque beauty in all the lands of Europe and Asia famous in ancient song and story. If his tragedy the *Medea*, highly praised by ancient critics, had been preserved, we should have been able to judge whether Roman art was capable of producing a great drama. In many of the *Heroides*, and in several speeches attributed to his imaginary personages, he gives evidence of true dramatic creativeness. Catullus, in his *Ariadne* and his *Attis*, has given a voice to deeper and more powerful feeling, and he presents an idyllic picture of the heroic age with a purer charm. But the range and variety of his art were limited by the shortness as well as the turmoil of his life. Catullus is unsurpassed as the author of an epic idyll. Ovid is not idyllic in his art, or whatever there is of idyllic in it is lost in the rapid movement of his narrative. But he is one, among the poets of all times, who can imagine a story with most vivid inventiveness and tell it with most unflagging animation. An ideal world, poetical and supernatural, but never fantastic or grotesque, of beings rich with the beauty and fulness of youth, playing their part in scenes of picturesque beauty, is brought before us in verse and diction of apparently inexhaustible resource and unimpeded flow, partly created or rising up spontaneously for the occasion, partly borrowed boldly and freely from all his predecessors in Latin poetry, but always full of genuine life and movement. The faults of his verse and diction are those which arise from the vitality of his temperament,—too facile a flow, too great exuberance of illustration. He has as little sense of the need of severe restraint in his art as in his life. He is not without mannerism, but he is quite unaffected, and, however far short he might fall of the highest excellence of verse or style, it was not possible for him to be rough or harsh, dull or obscure.

As regards the school of art to which he belongs, he may be described as the most brilliant representative of Roman Alexandrinism. The latter half of the Augustan age was, in its social and intellectual aspects, more like the Alexandrian age than any other era of antiquity. The Alexandrian age was like the Augustan, one of refinement and luxury, of outward magnificence and literary dilettanteism flourishing under the fostering influence of an absolute monarchy. Poetry was the only important branch of literature cultivated, and the chief subjects of

¹ *Ars Amatoria*, iii. 121, &c.

poetry were mythological tales, various phases of the passion of love, the popular aspects of science, and some aspects of the beauty of nature. These, too, were the chief subjects of the later Augustan poetry. The higher feelings and ideas which found expression in the poetry of Virgil, Horace, Varius, and the writers of an older generation no longer acted on the Roman world. It was to the private tastes and pleasures of individuals and society that Roman Alexandrinism had appealed both in the poetry of Catullus, Cinna, Calvus, &c., and in that of Gallus, Tibullus, and Propertius. Ovid was the last of this school of writers; he profited at the very entrance on his poetical career by the artistic accomplishment in form, metre, and diction which had been gained by the slow labours of his predecessors; his fancy was much more active and brilliant than that of any of them; and his spirit was more unreservedly satisfied with the conditions imposed both by the art to which he devoted himself and the political and social circumstances by which he was surrounded. Like all his countrymen, he wanted power to create a new form of art and a new vehicle of expression. But if he could have foreseen his future fame his literary ambition would have been completely satisfied by the consciousness that he had not only immeasurably surpassed, but had, for all after time, practically superseded his Greek models. He has confined himself to two vehicles of expression—the elegiac metre and the hexameter. In the first the great mass of his poetry is written,—the *Heroides*, the *Amores*, the *Ars Amatoria*, the *Remedia Amoris*, the *Fasti*, the *Tristia*, the *Ex Ponto*, the *Ibis*, the *Medicamina Faciei*; in the hexameter we have the work which he regarded as that on which his hope of immortality was based, the *Metamorphoses*, and a fragment of a didactic poem written in the style of the Alexandrians, probably with the mere desire to kill time in the place of his exile, called the *Halieutica*. Of the first metre he is the acknowledged master. He brought it to its highest perfection, and all the immense mass of elegiac verse published and written in modern times has merely endeavoured to reproduce the echo of his rhythm and manner. In the direct expression and illustration of feeling, his elegiac metre has much more ease, vivacity, and sparkle than that of any of his predecessors, while he alone has communicated to it, without altering its essential characteristic of recurrent and regular pauses, a fluidity and rapidity of movement which makes it an admirable vehicle for tales of pathetic and picturesque interest. It was impossible for him to give to the hexameter a greater perfection than it had already attained, but he imparted to it also a new character, wanting indeed the weight, and majesty, and intricate harmonies of Virgil, but rapid, varied, animated, and in complete accord with the swift, versatile, and fervid movement of his imagination. One other proof he gave of his irrepressible energy and vitality by composing, during his exile, a poem in the Gothic language, in praise of Augustus,—the loss of which, whatever it may have been to literature, is one much to be regretted in the interests of philological science.

Ovid would, in any previous century since the revival of classical studies, have been regarded as a more important representative of ancient life and feeling, and as a greater poet, than he is in the present day. During the earlier period of this revival, the beauty and refinement of ancient literature, and of the life to which that literature is the key, were better appreciated than their moral and intellectual greatness. As the representative writer of an age of great material civilization and luxury, he gained the attention of a time and a class struggling towards a similar civilization and animated by the same love of pleasure. It was in his writings that the world of romance and wonder, created by the early Greek imagination, was first revealed to the modern world. The vivid, sensuous fancy through which he reproduced the tales and beings of mythology, as well as the transparent lucidity, the unflinching truthfulness, the ease and directness of the medium through which

this is done, made his works the most accessible and among the most attractive of the recovered treasures of antiquity. His influence was first felt in the literature of the Italian Renaissance. But in the most creative periods of English literature he seems to have been more real than any other ancient poet, not even excepting Virgil; and it was on the most creative minds, such as those of Marlowe, Spenser, Shakespeare,¹ Milton, and Dryden, that he acted most powerfully. The continuance of his influence is equally unmistakable during the classical era of Addison and Pope. The most successful Latin poetry of modern times has been written in imitation of him; and the accomplishment by which the faculty of literary composition and the feeling for ancient Roman culture were most developed in the great schools of England and France was the writing of Ovidian elegiacs. His works gave also a powerful stimulus and supplied abundant materials to the great painters who flourished during and immediately subsequent to the Renaissance. The mythological figures and landscapes which crowd the great galleries of Europe reproduce on canvas the forms, life, colour, and spirit which first were clothed in words and metre in his *Elegies* and *Metamorphoses*.

But, whatever charm individual readers of ancient literature may still find in him, no one would claim for him anything like the same influence on literature, art, and education in the present day as he formerly enjoyed. Judged by the attention given to their works by professional scholars and also in current criticism, not only Virgil and Horace, but Lucretius and Catullus, appear to be more in esteem than Ovid. This may perhaps be due as much to a loss in imagination as to a gain in critical power. Although the spirit of antiquity is better understood now than it was in the 16th and 17th centuries, yet in the capacity of appreciating works of brilliant fancy we can claim no superiority over the centuries which produced Spenser, Shakespeare, and Milton, nor over those which produced the great Italian, French, and Flemish painters. Still, whatever be the cause of the change in taste, Ovid is not one of those poets who seem to have much to teach us, or much power to move and interest us now. Perhaps the very liveliness and clearness of his style and manner, which made him the most accessible of ancient authors in times of less exact learning, have tended to deaden curiosity about him in the present day. There is no deep or recondite meaning to be extracted from him. The sensuous and more superficial aspects of the later phase of ancient civilization, of which he is the most brilliant exponent, have much less interest for us than the heroic aspects of its earlier phase, and the spiritual, ethical, and political significance of its maturity. The art which chiefly ministers to pleasure, though it had its place in the great ages of antiquity, had then only a subordinate one; and it is to that place that it has been relegated by the permanent judgment of the world. It is of that art that Ovid is the chief master, and it is that with which he is identified. There might almost seem to be some danger of his falling into the neglect which has deservedly overtaken the authors of the epics of the Flavian era. It is therefore perhaps worth while to indicate some of the grounds on which his works must continue to hold an important place in any comprehensive study of Roman literature or human culture.

His first claim on the attention of modern readers is that already indicated—the influence which he exercised on the earlier development of modern art and literature. Just as certain Greek poets and literary periods (the Alexandrian for instance) claim attention as much on account of their influence on the development of Roman literature as on their own account, so, if for no other reason, the works of Ovid must always retain an importance, second only to those of Virgil and Horace, as one of the chief media through which the stream of ancient feeling and fancy mingled with the great river of modern literature.

He is interesting further as the sole contemporary exponent of the last half of the Augustan age. The whole of that age is a time of which the outward show and the inner spirit are known from the works, not of contemporary historians or prose-writers, but of its poets. The successive phases of feeling and experience through which the world passed during the whole of this critical period of human affairs are revealed in the poetry of Virgil, Horace, and Ovid. Virgil throws an idealizing and religious halo around the hopes and aspirations of the first rise of the empire. His aim seems to be to bring the new régime into living connexion with the past, not of Rome only but of the civilized world. Horace presents the most complete image of his age in its most various aspects, realistic and ideal. Ovid, in all his earlier writings, reflects the life of the world of wealth and fashion under the influence of the new court. It is a life of material prosperity, splendour, refinement, of frivolity and intrigue, of dilettanteism in literature, of decay in all the nobler energies, of servility and adulation. He is the most characteristic painter such a time could have found. For the continuous study

¹ The influence of Ovid on Shakespeare is shown conclusively in the interesting papers on "What Shakespeare learned at School," contributed to *Fraser's Magazine* (1879, 1880) by Prof. Baynes.

of the Roman world in its moral and social relations, his place is important as marking a stage of transition between the representation of Horace, in which the life of pleasure and amusement has its place, but one subordinate to the life of reflexion and of serious affairs, and the life which reveals itself in the cynicism of Martial and the morose disgust of Juvenal.

From the times of Ennius and Lucilius, Roman poetry occupied itself much with the lives, pursuits, and personal feelings of its authors, and this is one element of interest which it has in common with such works as the *Letters* of Cicero and of Pliny. Few poets of any age or country bring themselves into such close relation with their readers as Catullus, Horace, Ovid, and Martial. Ovid is in mind and character perhaps the least interesting of the four. But an exceptional interest attaches to his history. He attracts curiosity by having a secret, which, though it may be guessed with an approach to certainty, is not fully revealed. He excites also personal sympathy by the contrast presented in his writings between the unclouded gaiety of his youth and prime and the long heart-break of his exile. If we knew him only from the personal impression which he makes in the *Amores* and the *Ars Amatoria*, it would be allowed that few men of equal genius had so little claim on the esteem of the world. In the ten books of complaint which he pours out from his place of exile, though he shows no sign of a manlier temper than when he wrote his "imbelles elegi," yet by the vividness with which he realizes the contrast between his past and present, by his keen capacity for pleasure and pain, by the unreserve with which he exposes all his feelings, he forces himself on our intimacy, and awakens those sympathies which all sincere and passionate confessions create, where there is nothing base or malignant in the temper of their author to alienate them. Though his fate does not rouse the powerful interest inspired by the "fiery courage" and "Titanic might" with which Byron struggled during his self-imposed exile, yet to it, too, apply the sympathetic words of Virgil—"Mentem mortalia tangunt."

But it was not owing to the historical and personal interest of his works that he gained his great name among his countrymen and the readers of a former generation, nor is it on that ground solely that he claims attention now. He is the last true poet of the great age of Roman literature,—which begins with Lucretius and closes with him,—of the age which drew the most powerful stimulus from the genius and art of Greece, from the sentiment inspired by Rome, and from the Italian love of nature. Among the five or six great poets of that time Ovid is distinguished both as a brilliant artist who brought one branch of poetry to the highest perfection and also as a poet in whom one rich vein of the genius of Italy most conspicuously manifested itself. It is mainly through his reproduction of the forms, metres, and materials of the chief Alexandrian poets that these have maintained an enduring place in literature. But, great as he was in art and imitative faculty, his spontaneous gifts of genius were still more remarkable. If his works had perished we should have had a most inadequate idea of what the fervid Italian genius could accomplish in ancient times. No other Roman poet can invent and tell a story and make an outward scene and dramatic situation present to the eye and mind with such vivid power. If he does not greatly move the deeper sources of emotion, he has the power of lightly stirring many of them. No Roman poet writes with such ease, life, and rapidity of movement. None is endowed with such fertility of fancy, such quickness of apprehension. In respect of his vivacity and fertility we recognize in him the countryman of Cicero and Livy. But the type of genius of which he affords the best example is more familiar in modern Italian than in ancient Roman literature. While the serious spirit of Lucretius and Virgil reappeared in Dante, the qualities attributed by his latest and most accomplished critic to Ariosto may be said to reproduce the light-hearted gaiety and the brilliant fancy of Ovid.

There were several editions of Ovid's collected works in the 16th and 17th centuries, the time in which he enjoyed his greatest popularity. Recent editions of the text have been published by R. Merkel and A. Riese. The most important aids to the study of Ovid recently made in England are the editions of the *Hexa* by Mr Robinson Ellis, and those of the *Heroides* by Mr A. Falmer. Much light is thrown on the diction of Ovid by Zingerle in his *Ovidius und sein Verhältniss zu den Vorgängern*. The most interesting discussion on the cause of his exile is that of M. Gaston Boissier, which originally appeared in the *Revue des Deux Mondes*, and now forms part of his volume entitled *L'Opposition sous les Césars*. (W. Y. S.)

OVIEDO, a city in the north of Spain, capital of a province of the same name,¹ stands on a gentle northern slope, about 72 miles by rail and diligence to the north

of Leon, and 14 miles to the south of the Bay of Biscay. About a mile to the north-west is the Sierra de Naranco, a Red Sandstone hill 1070 feet above the sea and about 470 above the town, which is thus sheltered from the north wind, but subject in consequence to a large rainfall. Most of the town was burnt in 1521, and the reconstruction, till recently, has been irregular. The four main streets are formed by the roads connecting Gijon and Leon (north and south) and Grado and Santander (east and west), which cross each other in a central square, the Plaza Mayor. The streets are clean and well lighted; the projecting roofs of the houses give a characteristic effect, and some portions of the old Calle de la Plateria are highly picturesque. In the Plaza Mayor are the handsome Casas Consistoriales, dating from the 17th century; one or two deserted mansions of the nobility are architecturally interesting. The university, founded by Philip III. in 1604, is lodged in a plain building, 180 feet square; connected with it are a small library and physical and chemical museums. The cathedral, an elegant Perpendicular building of the 14th century, occupies the site of an earlier edifice, founded in the 8th century, of which only the Camara Santa remains. The west front has a fine portico of ornamented arches between the two towers. Of these one, very richly adorned, has been completed, and is 284 feet high; the other, which is larger, does not as yet rise above the nave. The interior has some fine stained glass, but has been much disfigured with modern rococo additions. The Capilla del Rey Santo (Alphonso II., who died in Oviedo in 843) contains the remains of many successive princes of the house of Pelayo; and the Camara Santa (dating from 802) preserves in an arca the crucifix, sundarium, and other relics saved by Don Pelayo in his flight. The cathedral library has some curious old MSS., mostly from Toledo. On the Sierra de Naranco is the ancient Santa Maria de Naranco, originally built by Ramiro in 850 as a palace, and afterwards turned into a church. Higher up the hill is San Miguel de Lino, also of the 9th century; and on the road to Gijon, about a mile outside the town, is the Santullano or church of St Julian, also of very early date. The modern town has the usual equipments in the way of hospitals, schools, theatre, casino, and the like; and in the neighbourhood are some pleasant paseos or promenades (San Francisco, Bombe, Jardin Botanico). The industries of the town include hat-making and tanning, and there is also a manufactory of arms. The population of the ayuntamiento in 1877 was 34,460.

Oviedo, founded in the reign of Fruela (762), became the fixed residence of the kings of the Asturias in the time of Alphonso the Chaste, and continued to be so until about 924, when the advancing reconquest led them to remove their capital to Leon. From that date the history of the city was comparatively uneventful. It was twice plundered during the war of independence—by Ney in 1809 and by Bonnet in the following year.

OVIEDO Y VALDEZ, GONZALO FERNANDEZ DE (1478–1557), an early historian of Spanish America, was born at Madrid, of noble Asturian descent, in 1478. He was brought up at the court of Ferdinand and Isabella as one of the pages of Prince John; in this capacity he was present at the surrender of Granada in 1492, and saw Columbus at Barcelona on his first return from America in 1493. In 1514 he was sent out to San Domingo as supervisor of the gold-smeltings. He only occasionally afterwards visited his native country and the American mainland. Among other offices subsequently added to his original appointment was that of historiographer of the Indies, in the discharge of which he produced, besides some unimportant chronicles, two large works of abiding interest and value—*La general y natural Historia de las Indias* and *Quincuagenas de los Notables de España*. He died at Valladolid in 1557.

¹ The province of Oviedo, corresponding to the ancient province and principality of ASTURIAS (*q.v.*), has an area of 4091 square miles and a population (1877) of 576,352. At that census the ayuntamientos (besides the capital) having a population exceeding 10,000 were—Cangas de Tinéo, 22,212; Cudillero, 10,113; Gijon, 30,591; Grado, 20,255; Langreo, 12,832; Lena, 11,657; Llanes, 18,637; Miéres, 12,614; Piloña, 18,648; Salas, 16,394; Siero, 21,494; Tinéo, 21,414; Valdés, 22,014; and Villaviciosa, 20,179.

The *History of the Indies* first appeared at Madrid in the form of a *Sumario* in 1526. Of the full work, consisting of fifty books, the first twenty-one were published at Seville in 1535 (Eng. transl. by Eden, 1555; Fr. transl. by Poleur, 1556). The whole has recently been published for the first time by the Madrid Royal Academy of History (4 vols. fol., 1851-55). It contains a large mass of valuable information, but written in a loose rambling moralizing style which makes it somewhat difficult to use. According to Las Casas, it is "as full of lies almost as pages," but the judgment of the humane ecclesiastic was, necessarily perhaps, somewhat prejudiced. The *Quincuagenas*, devoted to reminiscences of the principal characters who had figured in Spain during his lifetime, consists of a series of imaginary conversations full of gossip and curious anecdote of great interest to the student of history. Several MSS. are extant, but the work has never been printed.

OWEGO, a post village and township of the United States, capital of Tioga county, New York, lies at the mouth of Owego Creek, on the north side of the Susquehanna (here crossed by a bridge), 237 miles north-west of New York by the New York, Erie, and Western Railroad, which here connects with the Delaware, Lackawanna, and Western and the Southern Central Railroads. The village, built at the foot of a considerable hill in the heart of a fine agricultural district, is a pleasant place with broad maple-shaded side-walks along its principal streets. Grist-mills, soap-works, marble-works, a piano factory, and carriage-works are among the industrial establishments. The population of the village was 4756 in 1870 and 5525 in 1880; that of the whole township 9442 and 9984 respectively.

OWEN, JOHN (*Owenus* or *Audoenus*) (1560-1622), a writer of Latin epigrams, once very popular all over Europe, was of Welsh extraction, and was born at Armon, Caernarvonshire, in 1560. He was educated under Dr Bilson at Wykeham's School, Winchester, and afterwards studied at New College, Oxford, where he received a fellowship in 1584, and took the degree of bachelor of laws in 1590. Throwing up his fellowship during the following year, he turned schoolmaster, and taught successively at Tryleggh, near Monmouth, and at Warwick, where he was master of the free school founded by Henry VIII. He soon became distinguished for his perfect mastery of the Latin language, and for the humour, felicity, and point of his epigrams. As a writer of Latin verse he takes rank with Buchanan and Cowley. Those who, with Dryden, place the epigram "at the bottom of all poetry" will not estimate Owen's poetical genius very high; yet the Continental scholars and wits of the day used to call him "the British Martial." "In one respect he was a true poet," says a biographer; "namely, he was always poor." He was a staunch Protestant besides, and could not resist the temptation of turning his wit against Popery occasionally. This practice caused his book to be placed on the *Index Prohibitorius* of the Roman Church in 1654, and, what was yet more serious, led a rich old uncle of the Roman Catholic communion, from whom he had "great expectations," to cut the epigrammatist out of his will. When the poet died in 1622, his countryman and relative, Bishop Williams of Lincoln, had him buried at St Paul's Cathedral, London, where he erected a monument to his memory bearing an elegant epitaph in Latin.

Owen's *Epigrammata* are divided into twelve books, of which the first four were published in 1606, and the rest at four different times. Owen frequently adapts and alters to his own purpose the lines of his predecessors in Latin verse, and one such borrowing has become celebrated as a quotation, though few know where it is to be found. It is the first line of this epigram:—

"Tempora mutantur, nos et mutamur in illis:
 no modo? si semper tempore peior homo."
 (Lib. I. ed. Edoardum Neel, epig. 68.)

This first line is altered from an epigram by Matthew Borbonius, one of a series of mottoes for various emperors, this one being for Lothario I.

"Omnia mutantur, nos et mutamur in illis:
 Illa vices quasdam res habet, illa vices."

There are editions of the *Epigrammata* by Elzevir and by Didot;

the best is that edited by Renouard (2 vols., Paris, 1795). Translations into English, either in whole or in part, have been made by Vicens, 1619; by Pecke, in his *Parnassi Puerperium*, 1659; and by Harvey in 1677, which is the most complete. La Torre, the Spanish epigrammatist, owed much to Owen, and translated his works into Spanish in 1674. French translations of the best of Owen's epigrams have been published by A. L. Lebrun, 1709, and by Kérivalant, 1819.

OWEN, JOHN (1616-1683), theologian, was born of Puritan parents at Stadham in Oxfordshire in 1616. At twelve years of age he was admitted at Queen's College, Oxford, where he took his B.A. degree in 1632 and M.A. in 1635. During these years he worked with such diligence that he allowed himself but four hours sleep a night, and damaged his health by this excessive labour. In 1637 he was driven from Oxford by his refusal to comply with the requirements of Laud's new statutes. Having taken orders shortly before, he became chaplain and tutor in the family of Sir Robert Dormer of Ascot in Oxfordshire. At the outbreak of the civil troubles he adopted Parliamentary principles, and thus lost both his place and the prospects of succeeding to his uncle's fortune. For a while he lived in Charterhouse Yard, in great unsettlement of mind on religious questions, which was removed at length by a sermon which he accidentally heard at St Michael's in Wood Street.

His first publication, in 1642, *The Display of Arminianism*, dedicated to the committee of religion, gained him the living of Fordham in Essex, from which a "scandalous minister" had been ejected. Here he was married, and by his marriage he had eleven children.

Although he was thus formally united to Presbyterianism, Owen's views were originally inclined to those of the Independents, and, as he acquainted himself more fully with the controversy, he became more resolved in that direction. He represented, in fact, that large class of persons who, falling away from Episcopacy, attached themselves to the very moderate form of Presbyterianism which obtained in England as being that which came first in their way. His views at this time are shown by his *Duty of Pastors and People Distinguished*. At Fordham he remained until 1646, when, the old incumbent dying, the presentation lapsed to the patron, who gave it to some one else. He was now, however, coming into notice, for on April 29 he preached before the Parliament. In this sermon, and still more in his *Thoughts on Church Government*, which he appended to it, his tendency to break away from Presbyterianism is displayed.

The people of Coggeshall in Essex now invited him to become their pastor. Here he declared his change by founding a church on Congregational principles, and, in 1647, by publishing *Eshcol*, as well as various works against Arminianism. He made the friendship of Fairfax while the latter was besieging Colchester, and urgently addressed the army there against religious persecution. He was chosen to preach to Parliament on the day after the execution of Charles, and succeeded in fulfilling his task without mentioning that event, and again on April 19, when he spake thus:—"The time shall come when the earth shall disclose her slain, and not the simplest heretic shall have his blood unrevenged; neither shall any atonement or expiation be allowed for this blood, while a toe of the image, or a bone of the beast, is left unbroken."

He now became acquainted with Cromwell, who carried him off to Ireland in 1649 as his chaplain, that he might regulate the affairs of Trinity College; while there he began the first of his frequent controversies with Baxter by writing against the latter's *Aphorisms of Justification*. In 1650 he accompanied Cromwell to Scotland, and returned to Coggeshall in 1651. In March Cromwell, as chancellor, gave him the deanery of Christ Church, and made him

vice-chancellor in September 1652. In 1651, October 24, after Worcester, he preached the thanksgiving sermon before Parliament. In October 1653 he was one of several ministers whom Cromwell, probably to sound their views, summoned to a consultation as to church union. In December in the same year he had the honour of D.D. conferred upon him by his university. In the Parliament of 1654 he sat, but only for a short time, as member for Oxford university, and, with Baxter, was placed on the committee for settling the "fundamentals" necessary for the toleration promised in the Instrument of Government. He was, too, one of the Triers, and appears to have behaved with kindness and moderation in that capacity. As vice-chancellor he acted with readiness and spirit when a general rising in the west seemed imminent in 1655; his adherence to Cromwell, however, was by no means slavish, for he drew up, at the request of Desborough and Pride, a petition against his receiving the kingship (see Ludlow's *Memoirs*, ed. 1751, p. 224). During the years 1654-58 his chief controversial works were *Divina Justitia*, *The Perseverance of Saints* (against Goodwin), and *Vindiciæ Evangelicæ* (against the Socinians). In 1658 he took a leading part in the conference which drew up the Savoy Declaration.

Baxter declares that at the death of Cromwell Owen joined the Wallingford House party. This, though supported by the fact that under the Restoration he had among his congregation a large number of these officers, Owen himself utterly denied. He appears, however, to have assisted in the restoration of the Rump Parliament, and, when Monk began his march into England, Owen, in the name of the Independent churches, to whom Monk was supposed to belong, and who were keenly anxious as to his intentions, wrote to dissuade him from the enterprise.

In March 1660, the Presbyterian party being uppermost, Owen was deprived of his deanery, which was given back to Reynolds. He retired to Stadham, where he wrote various controversial and theological works, in especial the laborious *Theologoumena Pantodapa*, a history of the rise and progress of theology. In 1661 was published the celebrated *Fiat Lux*, a work in which the oneness and beauty of Roman Catholicism are contrasted with the confusion and multiplicity of Protestant sects. At Clarendon's request Owen answered this in 1662 in his *Animadversions*; and this led of course to a prolonged controversy. Clarendon now offered Owen preferment if he would conform. Owen's condition for making terms was liberty to all who agree in doctrine with the Church of England; nothing therefore came of the negotiation.

In 1663 he was invited by the Congregational churches in Boston, New England, to become their minister, but declined. The Conventicle and Five Mile Acts soon drove him to London; and in 1666, after the Fire, he, as did other leading Nonconformist ministers, fitted up a room for public service and gathered a congregation, composed chiefly of the old Commonwealth officers. Meanwhile he was incessantly writing; and in 1667 he published his *Catechism*, which led to a proposal from Baxter for union. Various papers passed, and after a year the attempt was closed by the following laconical note from Owen: "I am still a well-wisher to these mathematics." It was now, too, that he published the first part of his vast work upon the Epistle to the Hebrews.

In 1669 Owen wrote a spirited remonstrance to the Congregationalists in New England, who, under the influence of Presbyterianism, had shown themselves persecutors. At home, too, he was busy in the same cause. In 1670 Parker attacked the Nonconformists in his own style of clumsy intolerance. Owen answered him; Parker

repeated his attack; Marvell wrote *The Rehearsal Transposed*; and Parker is remembered by this alone.

At the revival of the Conventicle Acts in 1670, Owen was appointed to draw up a paper of reasons which was submitted to the House of Lords in protest. In this or the following year Harvard university invited him to become their president; he received similar invitations from some of the Dutch universities.

When Charles issued his Declaration of Indulgence in 1672, Owen drew up an address of thanks. This indulgence gave the dissenters an opportunity for increasing their churches and services, and Owen was one of the first preachers at the weekly lectures which the Independents and Presbyterians jointly held in Plummer's Hall. He was held in high respect by a large number of the nobility (one of the many things which point to the fact that Congregationalism was by no means the creed of the poor and insignificant), and during 1674 both Charles and James held prolonged conversations with him in which they assured him of their good wishes to the dissenters. Charles gave him 1000 guineas to relieve those upon whom the severe laws had chiefly pressed. In 1674 Owen was attacked by one Dr Sherlock, whom he easily vanquished, and from this time until 1680 he was engaged upon his ministry and the writing of religious works. In 1680, however, Stillingfleet having on May 11 preached his sermon on "The Mischief of Separation," Owen defended the Nonconformists from the charge of schism in his *Brief Vindication*. Baxter and Howe also answered Stillingfleet, who replied in *The Unreasonableness of Separation*. Owen again answered this, and then left the controversy to a swarm of eager combatants. From this time to his death he was occupied with continual writing, disturbed only by an absurd charge of being concerned in the Rye House Plot. His most important work was his *Treatise on Evangelical Churches*, in which were contained his latest views regarding church government. During his life he issued more than eighty separate publications, many of them of great size. Of these a list may be found in Orme's *Memoirs of Owen*. For some years before his death Owen had suffered greatly from stone and asthma. He died quietly, though after great pain, at Ealing, on August 24, 1683, and was buried on September 4th in Bunhill Fields, being followed to the grave by a large procession of persons of distinction. "In younger age a most comely and majestic form; but in the latter stages of life, depressed by constant infirmities, emaciated with frequent diseases, and above all crushed under the weight of intense and unremitting studies, it became an incommensurable mansion for the vigorous exertions of the spirit in the service of its God."

For engraved portraits of Owen see first edition of Palmer's *Nonconformists' Memorial and Vertue's Sermons and Tracts*, 1721. The chief authorities for the life are Owen's *Works*; Orme's *Memoirs of Owen*; Wood's *Athenæ Ozonienses*; Baxter's *Life*; Neal's *History of the Puritans*; Edwards's *Gangræna*; and the various histories of the Independents. (O. A.)

OWEN, ROBERT (1771-1858), philanthropist, and founder of English socialism, was born at the village of Newtown, Montgomeryshire, in North Wales. His father had a small business in Newtown as saddler and ironmonger, and there young Owen received all his school education, which terminated at the age of nine. At ten he went to Stamford, where he served in a draper's shop for three or four years, and, after a short experience of work in a London shop, removed to Manchester. His success at Manchester was very rapid. When only nineteen years of age he became manager of a cotton mill, in which five hundred people were employed, and by his administrative intelligence, energy, industry, and steadiness soon made it one of the very best establishments of the kind in Great Britain. In this factory Owen used the best bags of

American sea-island cotton ever imported into the country; it was the first cotton obtained from the Southern States of America. Owen also made remarkable improvement in the quality of the cotton spun; and indeed there is no reason to doubt that at this early age he was the first cotton-spinner in England, a position entirely due to his own capacity and knowledge of the trade, as he had found the mill in no well-ordered condition, and was left to organize it entirely on his own responsibility. Owen had become manager and one of the partners of the Chorlton Twist Company at Manchester, when he made his first acquaintance with the scene of his future philanthropic efforts at New Lanark. During a visit to Glasgow he had fallen in love with the daughter of the proprietor of the New Lanark mills, Mr Dale. Owen induced his partners to purchase New Lanark; and after his marriage with Miss Dale he settled there, as manager and part owner of the mills (1800). Encouraged by his great success in the management of cotton factories in Manchester, he had already formed the intention of conducting New Lanark on higher principles than the current commercial ones.

The factory of New Lanark had been started in 1784 by Dale and Arkwright, the water-power afforded by the falls of the Clyde being the great attraction. Connected with the mills were about two thousand people, five hundred of whom were children, brought, most of them, at the age of five or six from the poorhouses and charities of Edinburgh and Glasgow. The children especially had been well treated by Dale, but the general condition of the people was very unsatisfactory. Many of them were the lowest of the population, the respectable country people refusing to submit to the long hours and demoralizing drudgery of the factories; theft, drunkenness, and other vices were common; education and sanitation were alike neglected; most families lived only in one room. It was this population, thus committed to his care, which Owen now set himself to elevate and ameliorate. He greatly improved their houses, and by the unsparing and benevolent exertion of his personal influence trained them to habits of order, cleanliness, and thrift. He opened a store, where the people could buy goods of the soundest quality at little more than cost price; and the sale of drink was placed under the strictest supervision. His greatest success, however, was in the education of the young, to which he devoted special attention. He was the founder of infant schools in Great Britain; and, though he was anticipated by Continental reformers, he seems to have been led to institute them by his own views of what education ought to be, and without hint from abroad. In all these plans Owen obtained the most gratifying success. Though at first regarded with suspicion as a stranger, he soon won the confidence of his people. The mills continued to be a great commercial success, but it is needless to say that some of Owen's schemes involved considerable expense, which was displeasing to his partners. Tired at last of the restrictions imposed on him by men who wished to conduct the business on the ordinary principles, Owen formed a new firm, who, content with 5 per cent. of return for their capital, were ready to give freer scope to his philanthropy (1813). In this firm Jeremy Bentham and the well-known Quaker, William Allen, were partners. In the same year Owen first appeared as an author of essays, in which he expounded the principles on which his system of educational philanthropy was based. From an early age he had lost all belief in the prevailing forms of religion, and had thought out a creed for himself, which he considered an entirely new and original discovery. The chief points in this philosophy were that man's character is made not by him but for him; that it has been formed by circumstances over which he had no control; that he

is not a proper subject either of praise or blame,—these principles leading up to the practical conclusion that the great secret in the right formation of man's character is to place him under the proper influences—physical, moral, and social—from his earliest years. These principles—of the irresponsibility of man and of the effect of early influences—are the keynote of Owen's whole system of education and social amelioration. As we have said, they are embodied in his first work, *A New View of Society, or Essays on the Principle of the Formation of the Human Character*, the first of these essays (there are four in all) being published in 1813. It is needless to say that Owen's new views theoretically belong to a very old system of philosophy, and that his originality is to be found only in his benevolent application of them. For the next few years Owen's work at New Lanark continued to have a national and even a European significance. His schemes for the education of his workpeople attained to something like completion on the opening of the institution at New Lanark in 1816. He was a zealous supporter of the factory legislation resulting in the Act of 1819, which, however, greatly disappointed him. He had interviews and communications with the leading members of Government, including the premier, Lord Liverpool, and with many of the rulers and leading statesmen of the Continent. New Lanark itself became a much-frequented place of pilgrimage for social reformers, statesmen, and royal personages, including Nicholas, afterwards emperor of Russia. According to the unanimous testimony of all who visited it, the results achieved by Owen were singularly good. The manners of the children, brought up under his system, were beautifully graceful, genial, and unconstrained; health, plenty, and contentment prevailed; drunkenness was almost unknown, and illegitimacy was extremely rare. The most perfect good feeling subsisted between Owen and his workpeople, and all the operations of the mill proceeded with the utmost smoothness and regularity; and the business was a great commercial success.

Hitherto Owen's work had been that of a philanthropist, whose great distinction was the originality and unwearying unselfishness of his methods. His first departure in socialism took place in 1817, and was embodied in a report communicated to the Committee of the House of Commons on the Poor Law. The general misery and stagnation of trade consequent on the termination of the great war was engrossing the attention of the country. After clearly tracing the special causes connected with the war which had led to such a deplorable state of things, Owen pointed out that the permanent cause of distress was to be found in the competition of human labour with machinery, and that the only effective remedy was the united action of men, and the subordination of machinery. His proposals for the treatment of pauperism were based on these principles. He recommended that communities of about twelve hundred persons each should be settled on quantities of land of from 1000 to 1500 acres, all living in one large building in the form of a square, with public kitchen and mess-rooms. Each family should have its own private apartments, and the entire care of the children till the age of three, after which they should be brought up by the community, their parents having access to them at meals and all other proper times. These communities might be established by individuals, by parishes, by counties, or by the state; in every case there should be effective supervision by duly qualified persons. Work, and the enjoyment of its results, should be in common. The size of his community was no doubt partly suggested by his village of New Lanark; and he soon proceeded to advocate such a scheme as the best form for the reorganization of society in general. In its fully developed form—and it cannot be said to have

changed much during Owen's lifetime—it was as follows. He considered an association of from 500 to 3000 as the fit number for a good working community. While mainly agricultural, it should possess all the best machinery, should offer every variety of employment, and should, as far as possible, be self-contained. "As these townships," as he also called them, "should increase in number, unions of them federatively united shall be formed in circles of tens, hundreds, and thousands,"¹ till they should embrace the whole world in a common interest.

His plans for the cure of pauperism were received with great favour. *The Times* and *The Morning Post* and many of the leading men of the country countenanced them; one of his most steadfast friends was the duke of Kent, father of Queen Victoria. He had indeed gained the ear of the country, and had the prospect before him of a great career as a social reformer, when he went out of his way at a large meeting in London to declare his hostility to all the received forms of religion. After this defiance to the religious sentiment of the country, Owen's theories were in the popular mind associated with infidelity, and were henceforward suspected and discredited. Owen's own confidence, however, remained unshaken; and he was anxious that his scheme for establishing a community should be tested. At last, in 1825, such an experiment was attempted under the direction of his disciple, Abram Combe, at Orbiston near Glasgow; and in the same year Owen himself commenced another at New Harmony in Indiana, America. After a trial of about two years both failed completely. Neither of them was a pauper experiment; but it must be said that the members were of the most motley description, many worthy people of the highest aims being mixed with vagrants, adventurers, and crotchety, wrong-headed enthusiasts. After a long period of friction with William Allen and some of his other partners, Owen resigned all connexion with New Lanark in 1828. On his return from America he made London the centre of his activity. Most of his means having been sunk in the New Harmony experiment, he was no longer a flourishing capitalist, but the head of a vigorous propaganda, in which socialism and secularism were combined. One of the most interesting features of the movement at this period was the establishment in 1832 of an equitable labour exchange system, in which exchange was effected by means of labour notes, the usual means of exchange and the usual middlemen being alike superseded. The word "socialism" first became current in the discussions of the Association of all Classes of all Nations, formed by Owen in 1835. During these years also his secularistic teaching gained such influence among the working classes as to give occasion for the statement in the *Westminster Review* (1839) that his principles were the actual creed of a great portion of them. His views on marriage, which were certainly lax, gave just ground for offence. At this period some more communistic experiments were made, of which the most important were that at Ralahine, in the county of Clare, Ireland, and that at Tytherly in Hampshire. It is admitted that the former (1831) was a remarkable success for three and a half years, till the proprietor, having ruined himself by gambling, was obliged to sell out. Tytherly, begun in 1839, was an absolute failure. By 1846 the only permanent result of Owen's agitation, so zealously carried on by public meetings, pamphlets, periodicals, and occasional treatises, was the co-operative movement, and for the time even that seemed to have utterly collapsed. In his later years Owen became a firm believer in spiritualism. He died at his native town at the age of eighty-seven.

¹ The exposition and criticism of Owen's socialism and of his socialistic experiments belong to the general subject (see SOCIAL-

ISM). Robert Owen was essentially a pioneer, whose work and influence it would be unjust to measure by their tangible results. Apart from his socialistic theories, it should, nevertheless, be remembered that he was one of the foremost and most energetic promoters of many movements of acknowledged and enduring usefulness. He was the founder of infant schools in England; he was the first to introduce reasonably short hours into factory labour, and zealously promoted factory legislation—one of the most needed and most beneficial reforms of the century; and he was the real founder of the co-operative movement. In general education, in sanitary reform, and in his sound and humanitarian views of common life, he was far in advance of his time. Still he had many serious faults; all that was quixotic, crude, and superficial in his views became more prominent in his later years; and by the extravagance of his advocacy of them he did vital injury to the cause he had at heart. In his personal character he was without reproach—frank, benevolent, and straightforward to a fault; and he pursued the altruistic schemes in which he spent all his means with more earnestness than most men devote to the accumulation of a fortune.

Of R. Owen's numerous works in exposition of his system, the most important are the *New View of Society*, already mentioned; the *Report* communicated to the Committee on the Poor Law; the *Book of the New Moral World*; and *Revolution in the Mind and Practice of the Human Race*. See *Life of Robert Owen* written by himself, London, 1857, and *Threading my Way*, *Twenty-seven Years of Autobiography* by Robert Dale Owen, his son, London, 1874. There are also *Lives of Owen* by A. J. Booth (London, 1869) and by W. L. Sargant (London, 1860). For works of a more general character see G. J. Holyoake, *History of Co-operation in England*, London, 1875; Reybaud, *Etudes sur les réformateurs modernes*, Paris, 1856; Adolf Held, *Zwei Bücher zur sozialen Geschichte Englands*, Leipzig, 1881. (T. K.)

OWENSBOROUGH, a city of the United States, capital of Daviess county, Kentucky, on the Ohio, 160 miles below Louisville. It engages extensively in the manufacture of whisky and the curing of tobacco, and has waggon factories, flour-mills, and foundries. The population, 6231 in 1880, exceeded 11,000 in 1883.

OWL, the Anglo-Saxon *Ule*, Swedish *Uggla*, and German *Eule*—all allied to the Latin *Ulu*, and evidently of imitative origin—the general English name for every nocturnal Bird-of-prey,¹ of which group nearly two hundred species have been recognized. The Owls form a very natural assemblage, and one about the limits of which no doubt has for a long while existed. Placed by nearly all systematists for many years as a Family of the Order *Accipitres* (or whatever may have been the equivalent term used by the particular taxonomers), there has been of late a disposition to regard them as forming a group of higher rank. On many accounts it is plain that they differ from the ordinary diurnal Birds-of-prey, more than the latter do among themselves; and, though in some respects Owls have a superficial likeness to the GOATSUCKERS (vol. x. p. 711), and a resemblance more deeply seated to the GUACHARO (vol. xi. p. 227), even the last has not been made out to have any strong affinity to them. A good deal is therefore to be said for the opinion which would regard the Owls as forming an independent Order, or at any rate Sub-order, *Striges*. Whatever be the position assigned to the group, its subdivision has always been a fruitful matter of discussion, owing to the great resemblance obtaining among all its members, and the existence of safe characters for its division has only lately been at all generally recognized. By the older naturalists, it is true, Owls were divided, as was first done by Willughby, into two sections—one in which all the species exhibit tufts of feathers on the head, the so-called "ears" or "horns," and the second in which the head is not tufted. The artificial and therefore untrustworthy nature of this distinction was shewn by Isidore Geoffroy St-Hilaire (*Ann. Sc. Naturelles*, xxi. pp. 194-203) in 1830; but he did not do much good in the

¹ The poverty of the English language—generally so rich in synonyms—is here very remarkable. Though four well-known if not common species of Owls are native to Britain, to say nothing of half a dozen others which occur with greater or less frequency, none of them has ever acquired an absolutely individual name, and various prefixes have to be used to distinguish them. In Greece and Italy, Germany and France, almost each indigenous species has had its own particular designation in the vulgar tongue. The English Owlet or Howlet is of course a simple diminutive only.

arrangement of the Owls which he then proposed; and it was hardly until the publication ten years later of Nitzsch's *Pterylographie* that rational grounds on which to base a division of the Owls were adduced. It then became manifest that two very distinct types of pterylosis existed in the group, and further it appeared that certain differences, already partly shewn by Berthold (*Beitr. zur Anatomie*, pp. 166, 167), of sternal structure coincided with the pterylogical distinctions. By degrees other significant differences were pointed out, till, as summed up by Prof. Alphonse Milne-Edwards (*Ois. foss. de la France*, ii. pp. 474-492), there could no longer be any doubt that the bird known in England as the Screech-Owl or Barn-Owl, with its allies, formed a section which should be most justifiably separated from all the others of the group then known. Space is here wanting to state particularly the pterylogical distinctions which will be found described at length in Nitzsch's classical work (English translation, pp. 70, 71), and even the chief osteological distinctions must be only briefly mentioned. These consist in the Screech-Owl-section wanting any manubrial process in front of the sternum, which has its broad keel joined to the clavicles united as a furcula, while posteriorly it presents an unbroken outline. In the other section, of which the bird known in England as the Tawny or Brown Owl is the type, there is a manubrial process; the furcula, far from being joined to the keel of the sternum, often consists but of two stylets which do not even meet one another; and the posterior margin of the sternum presents two pairs of projections, one pair on each side, with corresponding fissures between them. Furthermore the Owls of the same section shew another peculiarity in the bone usually called the tarsus. This is a bony ring or loop bridging the channel in which lies the common extensor tendon of the toes—which does not appear in the Screech-Owl section any more than in the majority of birds. The subsequent examination by M. Milne-Edwards (*Novv. Arch. du Muséum*, ser. 2, i. pp. 185-200) of the skeleton of an Owl known as *Phodilus* (more correctly *Photodilus*) *badius*, hitherto attached to the Screech-Owl section, shews that, though in most of its osteological characters it must be referred to the Tawny Owl section, in several of the particulars mentioned above it resembles the Screech-Owls, and therefore we are bound to deem it a connecting link between them. The pterylogical characters of *Photodilus* seem not to have been investigated, but it is found to want the singular bony tarsal loop, as well as the manubrial process, while its clavicles are not united into a furcula and do not meet the keel, and the posterior margin of the sternum has processes and fissures like those of the Tawny Owl section. *Photodilus* having thus to be removed from the Screech-Owl section, Prof. Milne-Edwards has been able to replace it by a new form *Heliodilus* from Madagascar, described at length by him in M. Grandidier's great work on the natural history of that island (*Oiseaux*, i. pp. 113-118). The unexpected results thus obtained preach caution in regard to the classification of other Owls, and add to the misgivings that every honest ornithologist must feel as to former attempts to methodize the whole group—misgivings that had already arisen from the great diversity of opinion displayed by previous classifiers, no two of whom seem able to agree. Moreover, the difficulties which beset the study of the Owls are not limited to their respective relations, but extend to their scientific terminology, which has long been in a state so bewildering that nothing but the strictest adherence to the very letter of the laws of nomenclature, which are approved in principle by all but an insignificant number of naturalists, can clear up the confusion into which the matter has been thrown by heed-

less or ignorant writers—some of those who are in general most careful to avoid error being not wholly free from blame in this respect.

A few words are therefore here needed on this most unprofitable subject.¹ Under the generic term *Strix* Linnæus placed all the Owls known to him; but Brisson most justifiably divided that genus, and in so doing fixed upon the *S. stridula*—the aforesaid Tawny Owl—as its type, while under the name of *Asio* he established a second genus, of which his contemporary's *S. otus*, afterwards to be mentioned, is the type. Some years later Savigny, who had very peculiar notions on nomenclature, disregarding the act of Brisson, chose to regard the Linnæan *S. flammea*—the Screech-Owl before spoken of—as the type of the genus *Strix*, which genus he further dissevered, and his example was largely followed until Fleming gave to the Screech-Owl the generic name of *Aluco*,² by which it had been known for more than three hundred years, and reserved *Strix* for the Tawny Owl. He thus anticipated Nitzsch, whose editor was probably unacquainted with this fact when he allowed the name *Hybris* to be conferred on the Screech-Owl. No doubt inconvenience is caused by changing any general practice; but, as will have been seen, the practice was not universal, and such inconvenience as may arise is not chargeable on those who abide by the law, as it is intended in this article to do. The reader is therefore warned that the word *Strix* will be here used in what is believed to be the legitimate way, for the genus containing the *Strix stridula* of Linnæus, while *Aluco* is retained for that including the *S. flammea* of the same naturalist.

Except the two main divisions already mentioned, any further arrangement of the Owls must at present be deemed tentative, for the ordinary external characters, to which most systematists trust, are useless if not misleading.³ Several systematizers have tried to draw characters from the orifice of the ear, and the parts about it; but hitherto these have not been sufficiently studied to make the attempts very successful. If it be true that the predominant organ in any group of animals furnishes for that group the best distinctive characters, we may have some hope of future attempts in this direction,⁴ for we know that few birds have the sense of hearing so highly developed as the Owls, and also that the external ear varies considerably in form in several of the genera which have been examined. Thus in *Surnia*, the Hawk-Owl, and in *Nyctea*, the Snowy Owl, the external ear is simple in form, and, though proportionally larger than in most birds, it possesses no very remarkable peculiarities,—a fact which may be correlated with the diurnal habits of these Owls—natives of the far north, where the summer is a season of constant daylight, and to effect the capture of prey the eyes are perhaps more employed than the ears.⁵ In *Bubo*, the Eagle-Owl, though

¹ It has been dealt with at greater length in *The Ibis* for 1876 (pp. 94-105).

² The word seems to have been the invention of Gaza, the translator of Aristotle, in 1503, and is the Latinized form of the Italian *Allocco*.

³ It is very much to be regretted that a very interesting form of Owl, *Sceloglaux albigacies*, peculiar to New Zealand, should be rapidly becoming extinct, without any effort, so far as is known, being made to ascertain its affinities. It would seem to belong to the Strigine section, and is remarkable for its very massive clavicles, that unite by a kind of false joint, which in some examples may possibly be wholly ankylosed, in the median line.

⁴ This hope is strengthened by the very praiseworthy essay on the Owls of Norway by Herr Collett in the *Forhandlinger* of Christiania for 1881.

⁵ But this hypothesis must not be too strongly urged; for in *Carine*, a more southern form of nocturnal (or at least crepuscular) habits, the external ear is perhaps even more normal. Of course by the ear the real organ of hearing is here meant, not the tuft of feathers often so called in speaking of Owls.

certainly more nocturnal in habit, the external ear, however, has no very remarkable development of conch, which may perhaps be accounted for by the ordinary prey of the bird being the larger rodents, that from their size are more readily seen, and hence the growth of the bird's auditory organs has not been much stimulated. In *Strix* (as the name is here used), a form depending greatly on its sense of hearing for the capture of its prey, the ear-conch is much enlarged, and it has, moreover, an elevated flap or operculum. In *Asio*, containing the Long-eared and Short-eared Owls of Europe, Asia, and America, the conch is enormously exaggerated, extending in a semicircular direction from the base of the lower mandible to above the middle of the eye, and is furnished in its whole length with an operculum.¹ But what is more extraordinary in this genus is that the entrance to the ear is asymmetrical—the orifice on one side opening downwards and on the other upwards. This curious adaptation is carried still further in the genus *Nyctala*, containing two or three small species of the Northern hemisphere, in which the asymmetry that in *Asio* is only skin-deep extends, in a manner very surprising, to several of the bones of the head, as may be seen in the Zoological Society's *Proceedings* (1871, pp. 739-743), and in the large series of figures given by Messrs Baird, Brewer and Ridgway (*N. Am. Birds*, iii. pp. 97-102).

Among Owls are found birds which vary in length from 5 inches—as *Glaucidium cobanense*, which is therefore much smaller than a Skylark—to more than 2 feet, a size that is attained by many species. Their plumage, none of the feathers of which possesses an aftershaft, is of the softest kind, rendering their flight almost noiseless. But one of the most characteristic features of this whole group is the ruff, consisting of several rows of small and much-curved feathers with stiff shafts—originating from a fold of the skin, which begins on each side of the base of the beak, runs above the eyes, and passing downwards round and behind the ears turns forward, and ends at the chin—and serving to support the longer feathers of the “disk” or space immediately around the eyes, which extend over it. A considerable number of species of Owls, belonging to various genera, and natives of countries most widely separated, are remarkable for exhibiting two phases of coloration—one in which the prevalent browns have a more or less rusty-red tinge, and the other in which they incline to grey. Another characteristic of nearly all Owls is the reversible property of their outer toes, which are not unfrequently turned at the bird's pleasure quite backwards. Many forms have the legs and toes thickly clothed to the very claws; others have the toes, and even the tarsi, bare, or only sparsely beset by bristles. Among the bare-legged Owls those of the Indian *Ketupa* are conspicuous, and this feature is usually correlated with their fish-catching habits; but certainly other Owls that are not known to catch fish present much the same character.

Among the multitude of Owls there is only room here to make further mention of a few of the more interesting. First must be noticed the Tawny Owl—the *Strix stridula* of Linneus, the type, as has been above said, of the whole group, and especially of the Strigine section as here understood. This is the *Syrnium aluco* of some authors, the *Chat-huant* of the French, the species whose tremulous hooting “tu-whit, to-who,” has been celebrated by Shakespeare, and, as well as the plaintive call, “keewick,” of the young after leaving the nest, will be familiar sounds to many readers, for the bird is very generally distributed throughout most parts of Europe, extending its range through Asia Minor to Palestine, and also to Barbary—but not belonging to the Ethiopian Region or to the eastern half of the Palearctic. It is the largest of the species indigenous to Britain, and is strictly a woodland bird, only occasionally choosing any other place for its nest than a hollow tree. Its food consists almost entirely of small mammals, chiefly rodents;

but, though on this account most deserving of protection from all classes, it is subject to the stupid persecution of the ignorant, and is rapidly declining in numbers.² Its nearest allies in North America are the *S. nebulosa*, with some kindred forms, one of which, the *S. occidentalis* of California and Arizona, is figured below; but none of them seem to have the “merry note” that is uttered by the

FIG. 1.—*Strix occidentalis*.

European species. Common to the most northerly forest-tracts of both continents (for, though a slight difference of coloration is observable between American examples and those from the Old World, it is impossible to consider it specific) is the much larger *S. cinerea* or *S. lapponica*, whose iron-grey plumage, delicately mottled with dark brown, and the concentric circles of its facial disks make it one of the most remarkable of the group. Then may be noticed the genus *Bubo*—containing several species which from their size are usually known as Eagle-Owls. Here the Nearctic and Palearctic forms are sufficiently distinct—the latter, *B. ignavus*,³ the *Duc* or *Grand Duc* of the French, ranging over the whole of Europe and Asia north of the Himalayas, while the former, *B. virginianus*, extends over the whole of North America. A contrast to the generally sombre colour of these birds is shown by the Snowy Owl, *Nyctea scandiaca*, a circumpolar species, and the only one of its genus, which disdains the shelter of forests and braves the most rigorous arctic climate, though compelled to migrate southward in winter when no sustenance is left for it. Its large size and white plumage, more or less mottled with black, distinguish this from every other Owl. Then may be mentioned the birds commonly known in English as “Horned” Owls—the *Hibou*s of the French, belonging to the genus *Asio*. One, *A. otus* (the *Otus vulgaris* of some authors), inhabits woods, and, distinguished by its long tufts, usually borne erected, would seem to be common to both America and Europe—though experts profess their ability to distinguish between examples from each country. Another species, *A. accipitrinus* (the *Otus brachyotus* of many authors), has much shorter tufts on its head, and they are frequently carried depressed so as to escape observation. This is the “Woodcock-Owl” of English sportsmen, for, though a good many are bred in Great Britain, the majority arrive in autumn from Scandinavia, just about the time that the immigration of Woodcocks occurs. This species frequents heaths, moors, and the open country generally, to the exclusion of woods, and has an enormous geographical range, including not only all Europe, North Africa, and northern Asia, but the whole of America,—reaching also to the Falklands, the Galapagos, and the Sandwich Islands,—for the attempt to

² All Owls have the habit of casting up the indigestible parts of the food swallowed in the form of pellets, which may often be found in abundance under the Owl-roost; and reveal without any manner of doubt what the prey of the birds has been. The result in nearly every case shows the enormous service they render to man in destroying rats and mice. Details of many observations to this effect are recorded in the *Bericht über die XIV. Versammlung der Deutschen Ornithologen-Gesellschaft* (pp. 30-34).

³ This species bears confinement very well, and propagates freely therein. To it belong the historic Owls of Arundel Castle.

¹ Figures of these different forms are given by Macgillivray (*Brit. Birds*, iii. pp. 396, 403, and 427).

separate specifically examples from those localities only shews that they possess more or less well-defined local races. Commonly placed near *Asio*, but whether really akin to it cannot be stated, is the genus *Scops*, of which nearly forty species, coming from different parts of the world, have been described; but this number should probably be reduced by one half. The type of the genus, *S. giu*, the *Petit Duc* of the French, is a well-known bird in the south of Europe, about as big as a Thrush, with very delicately pencilled plumage, occasionally visiting Britain, emigrating in autumn across the Mediterranean, and ranging very far to the eastward. Further southward, both in Asia and Africa, it is represented by other species of very similar size, and in the eastern part of North America by *S. asio*, of which there is a tolerably distinct western form, *S. kennicotti*, besides several local races. *S. asio* is one of the Owls that especially exhibits the dimorphism of coloration above mentioned, and it was long before the true state of the case was understood. At first the two forms were thought to be distinct, and then for some time the belief obtained that the ruddy birds were the young of the greyer form which was called *S. nœvia*; but now the "Red Owl" and the "Mottled Owl" of the older American ornithologists are known to be one species.¹ One of the most remarkable of American Owls is *Speotyto cunicularia*, the bird that in the northern part of the continent inhabits the burrows of the prairie dog, and in the southern those of the biscacha, where the latter occurs—making holes for itself, says Darwin, where that is not the case,—rattlesnakes being often also joint tenants of the same abodes. The odd association of these animals, interesting as it is, cannot here be more than noticed, for a few words must be said, ere we leave the Owls of this section, on the species which has associations of a very different kind—the bird of Pallas Athene, the emblem of the city to which science and art were so welcome. There can be no doubt, from the many representations on coins and sculptures, as to their subject being the *Carine noctua* of modern ornithologists, but those who know the grotesque actions and ludicrous expression of this veritable buffoon of birds can never cease to wonder at its having been seriously selected as the symbol of learning, and can hardly divest themselves of a suspicion that the choice must have been made in the spirit of sarcasm. This Little Owl (for that is its only name—though it is not even the smallest that appears in England), the *Chevalche* of the French, is spread throughout the greater part of Europe, but it is not a native of Britain. It has a congener in *C. brama*, a bird well known to all residents in India.

Finally, we have Owls of the second section, those allied to the Screech-Owl, *Aluco flammeus*, the *Efrait*² of the French. This,

FIG. 2.—*Aluco flammeus*.

with its discordant scream, its snoring, and its hissing, is far too well known to need description, for it is one of the most widely-spread of birds, and is the Owl that has the greatest geographical range, inhabiting almost every country in the world,—Sweden and Norway, America north of lat. 45°, and New Zealand being the principal exceptions. It varies, however, not inconsiderably, both in size and intensity of colour, and several ornithologists have tried

¹ See the remarks of Mr Ridgway in the work before quoted (*B. N. America*, iii. pp. 9, 10), where also response is made to the observations of Mr Allen in the *Harvard Bulletin* (ii. pp. 338, 339).

² Through the dialectic forms *Fresac* and *Presaie*, the origin of the word is easily traced to the Latin *præsaia*—a bird of bad omen; but it has also been confounded with *Orfraie*, a name of the Osprey (vide *supra*, p. 56).

to found on these variations more than half a dozen distinct species. Some, if not most of them, seem, however, hardly worthy to be considered geographical races, for their differences do not always depend on locality. Mr Sharpe, with much labour and in great detail, has given his reasons (*Cat. B. Brit. Museum*, ii. pp. 291–309; and *Ornith. Miscellany*, i. pp. 269–298; ii. pp. 1–21) for acknowledging four "subspecies" of *A. flammeus*, as well as five other species. Of these last, *A. tenebriosus* is peculiar to Australia, while *A. norve-hollandia* inhabits also New Guinea, and has a "subspecies," *A. castanops*, found only in Tasmania; a third, *A. candidus*, has a wide range from Fiji and northern Australia through the Philippines and Formosa to China, Burmah, and India; a fourth, *A. capensis*, is peculiar to South Africa; while *A. thomensis* is said to be confined to the African island of St Thomas. To these may perhaps have to be added a species from New Britain, described by Count Salvadori as *Strix aurantha*, but it may possibly prove on further investigation not to be an Alucine Owl at all. (A. N.)

OX. See CATTLE.

OXALIC ACID, an organic acid of the formula $(\text{COOH})_2$, which, in a general scientific sense, excites our interest chiefly by its almost universal diffusion throughout the vegetable kingdom. Traces of oxalates are contained in the juices of, probably, all plants at certain stages of their growth; but so are lime-salts, which, in solutions, can coexist with the former only in the presence of free acid. Hence the frequent occurrence in plant-cells of those crystals of oxalates of lime with which all microscopists are familiar. In certain algæ, if they grow on calcareous soils, this salt, according to Bracannot, may form as much as one-half of the total dry solids. Of phanerogamic tissues, the roots of the officinal kinds of rhubarb may be named as being peculiarly rich in oxalate of lime-crystals. It is perhaps as well to add that the juicy stems of the garden rhubarb, although not free of oxalic, owe their sourness chiefly to malic acid. The strongly sour juices of certain species of *Rumex* and *Acetosella*, on the other hand, are exceptionally rich in acid oxalates. The juice of *Oxalis Acetosella*, when concentrated by evaporation, deposits on cooling a large crop of crystals of bin-oxalate of potash. This salt, as an educt from the plant juice named, has been known for some three centuries as "sal acetosellæ" or "salt of sorrel." Oxalic acid and all soluble oxalates are dangerous poisons, which almost implies that they cannot occur, under normal conditions, in the juices of the higher animals. Yet human urine always contains traces of oxalate of lime, which, when the urine is or becomes alkaline, forms on standing a micro-crystalline deposit. In certain diseased conditions of the system the oxalate is formed more largely, and may be deposited within the bladder in crystals or even develop into calculi.

The discovery of oxalic acid must be credited to Scheele, who obtained it in 1776 by the oxidation of sugar with nitric acid, and called it saccharic acid. In 1784 he proved its identity with the acid of sal acetosellæ. Our knowledge of the elementary composition of oxalic acid is the result of the independent labours of Berzelius, Döbereiner, and Dulong (1814–21).

Its artificial synthesis can be effected in various ways. Thus, for instance, (1) cyanogen, when dissolved in aqueous hydrochloric acid, gradually assimilates $4\text{H}_2\text{O}$ per N_2C_2 and becomes oxalate of ammonia, $\text{C}_2\text{O}_4(\text{NH}_4)_2$ (Liebig). Or (2) moist carbonic acid is reduced by potassium to formic acid, $\text{CO}_2 + \text{H}_2\text{O} - \text{O} = \text{CH}_2\text{O}_2$, which, of course, assumes the form of potash salt (Kolbe). This latter, when heated beyond its fusing point, breaks up into oxalate and hydrogen, $2\text{CHKO}_2 = \text{H}_2 + \text{C}_2\text{O}_4\text{K}_2$ (Erlenmeyer). At 350° dry CO_2 and sodium unite into oxalate $\text{C}_2\text{O}_4\text{Na}_2$ (Drechsel).

Sugar, starch, and many other organic bodies of the "fatty" series, when boiled with nitric acid, yield oxalic acid as a penultimate product of oxidation. In this manner oxalic acid used to be produced, industrially, from

star or molasses; but this method, though not by any means obsolete, is almost superseded by a new process which we owe to Mr Dale of Manchester.

Mr Dale's process is founded upon the old observation of Gay-Lussac's that cellulose, by fusion with caustic potash, is oxidized into oxalate with evolution of (impure) hydrogen. In Mr Dale's works (at Warrington) sawdust and wood-shavings do service as cellulose, while a mixed caustic alkali lye of 1.34 to 1.35 specific gravity, containing 1KHO for every 3NaHO, serves as a reagent. Unmixed caustic soda gives no or little oxalate. The wood-shavings are soaked in a quantity of lye equal to 30 to 40 per cent. of their weight of dry alkali, and the mixture is evaporated down on iron plates at about 200° C. with constant agitation, until it is converted into a homogeneous brown mass completely soluble in water. This mass (which is as yet very poor in oxalate) is then dried up fully at a somewhat lower temperature, and thus converted into a crude oxalate equivalent to 28 to 30 per cent. of its weight of oxalic acid crystals. Messrs Roberts, Dale, & Co. have come, latterly, to substitute for the iron plates an iron pipe passing slantingly through a heated chamber and provided inside with a revolving screw, which draws in the mixture of wood and alkali below, and conveys it along at such a rate that it comes out above as finished product. The crude oxalate is lixiviated with cold water, when the bulk of the oxalic acid remains as soda salt, while the rest of the alkali passes into solution as, substantially, carbonate. The oxalate, after having been washed with the least sufficient quantity of water, is boiled with a dilute milk of lime and thus converted into a precipitate of oxalate of lime, while caustic soda passes in to solution, which is added to the liquors produced in the separation of the oxalate of soda from the surplus alkali. The oxalate of lime is washed and then decomposed by boiling it with three times the calculated amount of dilute sulphuric acid, the sulphate of lime filtered off, and the solution evaporated to crystallization. The yield as oxalic acid crystals amounts to 50 to 60 per cent. of the weight of the wood-shavings. The united alkali-liquors are causticized with lime, and thus (apart from the unavoidable losses) the originally employed caustic alkali is recovered in its entirety.

Commercial (oxalic) acid is contaminated chiefly with sulphuric acid and alkali, of which the latter cannot be removed by recrystallization from water, but, according to Stolha, easily and exhaustively by recrystallization from 10 to 15 per cent. hydrochloric acid.

Crystallized oxalic acid forms colourless needles of the composition $C_2O_4H_2 + 2H_2O$. It melts at 98° C., and when kept at about this temperature readily loses its crystal-water, but at 110° the dry acid $C_2O_4H_2$ already begins to volatilize. The latter sublimes most readily at 165° C., without previous fusion, in needles. At higher temperatures it breaks up, more or less completely, into CO_2 + formic acid, CH_2O_2 (or $CO + H_2O$). The crystallized acid dissolves in 10.5 parts of water of 14°5, also in alcohol. The solution readily neutralizes basic hydrates and carbonates; in the case of the alkalies and alkaline earths, the point of neutrality to litmus corresponds to the normal salt, i.e., to the ratio $CO_2H : RHO$, where $R = K, Na, (NH_4), \frac{1}{2}Ba$, &c. The normal salt CO_2R combines with $1CO_2H$ into "binoxalate," and, in the case of $R = K$ or NH_4 , also with $3CO_2H$ into "quadxalate." Alkaline oxalates are soluble in water—the soda and ammonia salts rather sparingly; of the rest of oxalates, as far as they are normal salts, the majority are insoluble or difficultly soluble in water, and therefore most conveniently produced, by double decomposition, as precipitates.

Potash Salts.—The normal salt, $C_2O_4K_2 + H_2O$, is soluble in 3 parts of water of 16° C. The binoxalate (salt of sorrel) is generally anhydrous, but occasionally $C_2O_4KH + \frac{1}{2}H_2O$, the latter soluble in 26.2 parts of water of 8° C. The elsewhere extinct industry of manufacturing this salt from sorrel-juice survives in the Black Forest. It is used habitually for removing ink and rust-stains from linen, though oxalic acid is better and cheaper. The quadroxalate, $C_2O_4KH + C_2O_4H_2 + 2H_2O$, soluble in 20 parts of water at 20° C., is often sold as salt of sorrel.

Soda Salts.—The normal salt, $C_2O_4Na_2$, generally forms small

imperfect crystals, soluble in 31.6 parts of water of 13° C. The acid salt, $C_2O_4NaH + H_2O$, is soluble in 67.6 parts of water at 10° C.

Ammonium Salts.—The normal salt, $C_2O_4(NH_4)_2 + H_2O$, found native in guano, crystallizes in needles, and is soluble in 23.7 parts of water of 15° C. It is much used in the laboratory as a most delicate precipitant for lime salts. The binoxalate, $C_2O_4(NH_4)H + H_2O$, dissolves in 16 parts of water of 11°5. There is a quadroxalate, $C_2O_4(NH_4)H + C_2O_4H_2 + 2H_2O$.

Other Salts.—The normal lime salt, as obtained by precipitation of lime salts with alkaline oxalates or oxalic acid, and found in plant cells, is $C_2O_4Ca + 3H_2O$; but $2H_2O$ are easily lost below 110°; the remaining $1H_2O$ is expelled only above 200° C. Ferrous oxalate, $C_2O_4Fe + 2H_2O$, obtainable by precipitation of ferrous sulphate with oxalic acid, is a yellow crystalline powder. When heated it breaks up into CO_2 and finely divided metallic iron, which latter at once burns into red ferric oxide of a state of aggregation which fits it pre-eminently for the polishing of optical glasses. Ferric oxalate dissolves in oxalic acid, the solution, when exposed to the light, giving off CO_2 with precipitation of ferrous oxalate. Draper recommends it for measuring the chemical intensity of light.

Industrially oxalic acid chiefly serves the calico printers as a discharge for certain colours, which, unlike the otherwise equivalent mineral acids, does not attack the tissue. Minor quantities are used, as solution, for cleaning metallic surfaces. It has been recommended for the metallurgic precipitation of NICKEL (*q.v.*).

Analysis.—Solid metallic oxalates, when heated, are decomposed without noteworthy elimination of carbon. When heated with oil of vitriol they give off the components of the anhydride C_2O_3 , as carbonic oxide and carbonic acid gases, without blackening. Oxalate solutions are precipitated by chloride of calcium; the precipitate ($C_2O_4Ca \cdot xH_2O$) is insoluble in water, ammonia, ammonia salts, and acetic (though soluble in hydrochloric) acid. Even a mixture of free oxalic acid and gypsum solution deposits oxalate of lime. Oxalic acid is readily oxidized into carbonic acid by the conjoint action of dilute sulphuric acid and binoxide of manganese or permanganate of potash. In the latter case this reaction, even with small quantities, becomes visible by the discharge of the intensely violet colour of the reagent; the change, however, is slow at first; it becomes more and more rapid as the $MnSO_4$ formed increases, and consequently goes on promptly from the first, if ready made $MnSO_4$ be added along with the reagent. The permanganate test is readily translatable into a titrimetric method for the determination of oxalic acid in solutions. (W. D.)

OXENSTIERNA, AXEL, COUNT OF (1583–1654), Swedish statesman, was born at Fanö in Upland on the 16th of June 1583. He studied theology at Rostock, Wittenberg, and Jena; and in 1602, having spent some time in visiting German courts, he returned to Sweden to take the oath of allegiance to Charles IX., whose service he entered. In 1606 he was sent as ambassador to the court of Mecklenburg, and in 1609 he became a member of the Swedish senate. When Gustavus Adolphus succeeded to the throne, in 1611, Oxenstierna was appointed chancellor, and in 1613 he was plenipotentiary in the negotiations for the conclusion of peace between Sweden and Denmark. In 1614 he went with the king to Livonia, and helped to bring about the cessation of hostilities between Sweden and Russia. After the intervention of Gustavus in the Thirty Years' War, Oxenstierna was made governor-general of all the districts in Prussia which had been overrun by the Swedes; and, when the Imperialists were preparing to besiege Stralsund, he negotiated with the duke of Pomerania for the substitution of Swedish for Danish troops in the town, going subsequently to Denmark to obtain the sanction of the Danish king. While Gustavus pushed on to Franconia and Bavaria, Oxenstierna was entrusted with the supreme direction of affairs, both political and military, in the Rhine country, and he took up his headquarters at Mainz. In 1632, when Gustavus fell at the battle of Lützen, the responsibility for the maintenance of the Protestant cause fell chiefly upon Oxenstierna; and in one of the greatest crises in the history of the world he displayed splendid courage, discretion, and resource. At a congress held in Heilbronn he was appointed director of the evangelical confederation, and in this capacity he went

to France and Holland to secure the aid of these countries against the emperor. On his return he found the Protestants in a very desponding mood. The battle of Nördlingen had been lost; the allies distrusted one another; the troops were dissatisfied and resented any attempt to subject them to strict discipline. Oxenstierna laboured indefatigably to restore the confidence of his party, and to a large extent he succeeded. He then returned, in 1636, to Sweden, where he resigned his exceptional powers and resumed his place in the senate as chancellor of the kingdom. He acted also as one of five guardians of Queen Christina, whom he carefully instructed in what seemed to him the true methods of administration. Oxenstierna had the reputation of being one of the wisest statesmen of his age, and during his absence from his country he had drawn up the scheme of a system of government which had been accepted in 1634 by the Swedish estates. Abroad he upheld vigorously the honour of Sweden, and at home he maintained strict economy in public expenditure, while encouraging, according to the ideas of his time, the development of industry and the arts. In 1645, when he went back to Sweden after taking part in the negotiations with Denmark at Brömsebro, he was raised to the rank of count by the queen. He died on the 28th of August 1654.

See Lundblad, *Svensk Plutarch*, 1824.

OXFORD, or OXON, an inland county of England, is bounded N.E. by Northamptonshire, N.W. by Warwickshire, W. by Gloucestershire, S.S.W. and S.E. by Berks, and E. by Bucks. In shape it is very irregular, its breadth varying from about 7 to 27½ miles, and its greatest length being about 52 miles. The total area is 483,621 acres, or about 756 square miles. The character of the scenery varies greatly in different districts. The Chiltern Hills cross the south-western extremity of the county from north-east to south-west. On the west side of the ridge Nettlebed Hill expands into Nettlebed Common, an extensive table-land, reaching at some points nearly 700 feet above sea-level. The Chiltern district is supposed to have been at one time covered by forest, and there are still many fine beeches, as well as oak and ash trees, although for the most part the district is now utilized as a sheep-walk or as arable land. Camden mentions the woods of Oxfordshire as a special feature of the county. The forest of Wychwood extended to 3735 acres of forest proper. In the district of Staunton St John there are considerable traces of natural woodland. The most extensive of the recent plantations is the great belt at Blenheim. Immediately to the east of the city of Oxford a range of hills stretches between the valleys of the Thames and Cherwell, the highest point being Shotover Hill, 560 feet. In the central district the surface is less varied, and along the rivers there are extensive tracts of flat land, but the finely cultivated fields and the abundance of wood lend an aspect of richness to the landscape. The northern part of the county is flat and bare, its bleakness and monotony being increased in some districts by the stone fences. Wychwood has been recently disafforested by statute.

Oxfordshire abounds in streams and watercourses, the majority of which belong to the basin of the Thames, which skirts the whole southern border of the county, forming for the most part of its course the boundary with Berks. In the earlier part of its course it is called the Isis. Before reaching the city of Oxford it receives the Windrush, and the united waters of the Evenlode and Glyme. It then divides into various channels, but these soon unite, and the river flowing round the city receives the united streams of the Cherwell and the Ray, and passes south-east to Dorchester, where it is joined by the Thame. From this point it is called the Thames. The

Windrush and Evenlode both flow south-east from Gloucestershire; the Cherwell traverses the whole length of the county south from Northamptonshire; and the Thame crosses its south-east corner from Bucks. The Thames is navigable for small craft to Gloucestershire, and for vessels of considerable burden to Oxford. The Oxford Canal, 91 miles long, begun in 1769 and finished in 1790, enters the north-eastern extremity of the county near Claydon, and following the course of the Cherwell passes south to the city of Oxford.

Geology.—The low ground in the north-west, along the vale of Moreton, on the banks of the Cherwell as far as Steeple Aston, and along the banks of the Evenlode, is occupied by the blue clays of the Lower Lias, the higher regions being occupied by the Middle Lias. The Lower Lias contains beds of hard shelly limestone called Banbury marble, which is worked into chimneypieces; and associated with the blue limestone of the Middle Lias there is a valuable deposit of brown hæmatite iron which is largely worked at Adderbury near Banbury, the total quantity obtained in 1882 being 8614 tons, valued at £1507. At one time the marlstone was covered by the Upper Lias clays, but these are now found only in isolated strips and patches. Beds of Oolite, called Northampton Sands, rest on the higher ridges above the Upper Lias, and the Great Oolite is exposed on both sides of the Evenlode and extensively quarried for building purposes, the upper beds forming also a white limestone containing numerous fossils. Forest marble occupies the greater part of Wychwood Forest, Blenheim Park, and adjoining regions. A wide extent of flat uninteresting country in the south-west, stretching as far east as the city of Oxford, belongs to the Oxford clay. Coral rag, Kimmeridge clay, and white limestone occur at different places in the neighbourhood of the Thames. There are also various outliers of Upper and Lower Greensand. At the junction of the Chalk with the Greensand there is a line of springs which have determined the sites of numerous villages. Chalk forms the ridges of the Chiltern Hills, and Upper Chalk with flint extends eastward a considerable distance beyond them. In the northern and eastern districts there are large accumulations of drift along all the old river valleys; and a considerable breadth of flat country on the banks of the Thames and Cherwell is occupied by alluvial deposits. Ochre of remarkably fine quality is obtained from Shotover Hill.

Climate, Soil, and Agriculture.—The climate is salubrious and dry, but generally colder than the other southern districts of England, especially in the bleak and exposed regions of the Chilterns. Crops are later in the uplands than in more northerly situations at a lower elevation. Agriculture is in a fairly advanced condition, but the possibilities of improvement are not by any means exhausted, as the soil is on the whole above the average in fertility. In the northern districts there is a strong yet friable loam, well adapted for all kinds of crops. The centre of the county is occupied for the most part by a good friable but not so rich soil, formed of decomposed sandstone, chalk, and limestone. A large district in the south-east is occupied by the chalk of the Chiltern Hills, at one time covered by a forest of beech, but now partly arable and partly used as sheep-walks. The remainder of the county is occupied by a variety of miscellaneous soils ranging from coarse sand to heavy tenacious clay, and occasionally very fertile.

According to the agricultural returns of 1883, as many as 417,509 acres, or about eight-ninths of the total of the county, were under cultivation, corn crops occupying 152,437 acres, green crops 52,451, rotation grasses 44,472, and permanent pasture 153,898. Wheat and barley, with 51,796 acres and 47,611 acres respectively, occupy the largest areas among corn crops, and oats and beans come next with 31,771 and 14,389. Potatoes are not much grown, but turnips occupy as many as 34,618 acres. The most common course of crops on lighter soils is a four years' rotation, sometimes lengthened to six years with pease, oats, or similar crops. On heavier soils the course is first turnips or other roots, second barley or oats, third three or more years of clover and grass seed, fourth wheat, and finally beans. Along the smaller streams there are very rich meadows for grazing, but those on the Thames and Cherwell are subject to floods. On the

hills there are extensive sheep pastures. Horses in 1883 numbered 17,454, of which 13,716 were used solely for purposes of agriculture. The number of cattle was 50,209, of which 16,914 were cows and heifers in milk or in calf. The dairy system prevails in many places, but the milk is manufactured into butter, little cheese being made. The improved shorthorn is the most common breed, but Alderney and Devonshire cows are largely kept. Sheep numbered as many as 270,288, of which 157,243 were one year old and upwards. Southdowns are kept on the lower grounds, and Leicesters and Cotswolds on the hills. Pigs in 1883 numbered 44,682, the county being famous for its "brawn."

According to the latest return, the land was divided among 10,177 proprietors, possessing 452,232 acres, at an annual value of £1,073,246, an average per acre of about £2. 7s. Of the owners, 6833 possessed less than one acre, and the following 10 upwards of 5000 acres, viz., the duke of Marlborough, 21,945; earl of Ducie, 8799; earl of Abingdon, 8174; M. P. W. Boulton, 7946; Sir H. W. Dashwood, 7515; earl of Jersey, 7043; Edward W. Harcourt, 5721; earl of Macclesfield, 5491; Viscount Dillon, 5444; and Lord F. G. Churchill, 5352. Upwards of 30,000 acres were held by various colleges of Oxford, the largest owner being Christ Church, 4837 acres.

Manufactures.—Blankets are manufactured at Witney, and tweeds, girths, and horsecloths at Chipping Norton. There are paper mills at Hampton-Gay, Shiplake, Sandford-on-Thames, Woolvercot, and Eynsham. Agricultural implements and portable engines are made at Banbury, and gloves at Woodstock, where the polished steel work has long ago ceased. A large number of women and girls are employed in several of the towns and villages in the lace manufacture.

Railways.—The county is traversed by several branches of the Great Western, which skirts its borders, and by the East Gloucestershire and the London and North-Western Railways.

Administration and Population.—Oxfordshire comprises fourteen hundreds, the municipal boroughs of Banbury (3600) and Chipping Norton (4167), the greater part of the city of Oxford, of which the remainder is in Berkshire, and a small portion of the municipal borough of Abingdon, of which the remainder is also in Berkshire. It has one court of quarter sessions, and is divided into ten petty and special sessional divisions. The boroughs of Abingdon and Banbury and the city of Oxford have commissions of the peace and separate courts of quarter sessions. For parliamentary purposes the county is not divided; it returns three members, having previous to the Reform Act of 1832 returned only two. The borough of Woodstock returns one member; and there are parts of four other boroughs within the county, Oxford city returning two members, and Abingdon, Banbury, and Wallingford one each. The university of Oxford also returns two members. The county contains 292 civil parishes, with parts of seven others. It is almost entirely in the diocese of Oxford. The population in 1801 was 111,977, which by 1841 had increased to 163,143, by 1851 to 170,439, by 1871 to 177,975, and by 1881 to 179,559, of whom 88,025 were males and 91,534 females. The average number of persons to an acre was 0.37, and of acres to a person 2.69.

History and Antiquities.—At the Roman invasion the district was inhabited by the Dobuni. To this early British period probably belong the circle of stones and cromlech near Chipping Norton, the cromlech called the "Hoarstone" at Enstone, and the scattered stones called the Devil's Quoits at Stanton-Harcourt. Icknield Street crossed the centre of the county from Goring in the south-west to Chinnor in the north-east, and joined Watling Street in Northamptonshire. Akeman Street crossed the county from east to west, entering it from Bucks at Ambrosden, and passing through Chesterton, Kirtlington, Blenheim Park, Stonesfield, and Asthall to Gloucestershire. Between Mongewell and Nuffield there is a vallum with embankment $2\frac{1}{2}$ miles in length called Grimes Dyke or Devil's Ditch; and there are remains of another with the same name between the Glyme and the Evenlode near Ditchley. Traces still exist of Roman and British camps, and on the east side of the Cotswolds the square and the round camps lie together in pairs. Numerous Roman coins have been found at Dorchester, and tessellated pavements at Great Tew and Stonesfield. For a long time Oxford was the residence of the monarchs of Mercia. Cuthred of Wessex in 752 disowned the overlordship of Ethelbald of Mercia, whom he defeated at Burford. From this time a portion of Oxfordshire seems to have been subject to Wessex, but Offa of Mercia inflicted in 779 a severe defeat on the West Saxons under yne-wulf, after which Oxfordshire probably became Mercian. The district of Oxford was frequently the scene of conflict during the long contests between the Saxons and the Danes, the latter of whom reduced the city of Oxford four times to ashes, and in the 11th century occupied nearly the whole region. In 1387 the insurgent nobles defeated the earl of Oxford at Radcot Bridge near Bampton. In 1469 the farmers and peasants of Yorkshire, to the number of 15,000, under the leadership of Robin of Redesdale, marched to Banbury, and defeated and captured the earl of Pembroke at Danes Moor on the borders of Oxford. During the civil wars the county

was frequently entered by the armies both of the Parliament and the king, the more important incidents being the seizing of Oxford, Banbury, and Broughton by the Royalists; the assembling of the adherents of the king at the city of Oxford in 1644; the capture of the city by Fairfax in 1646; the surprise of the Parliamentarians by Rupert at Caversham; their repulse at Chalgrove Field, where Hampden received his death-wound; and the defeat of the Royalist forces by Cromwell at Islip Bridge.

Some portions still remain of the old Norman castle at Oxford; there are traces of a moat at Banbury; of the castle at Bampton, the seat of Aylmer de Valence in 1313, there are a chamber and other fragments; and Broughton Castle is a good moated house of various periods. Among old mansions, mention may be made of Shirburn Castle, Mapledurham House, Chastleton House, Rousham Park, Crowsley Park, Hardwick House, Shipton Court, Stonor Park, Stanton-Harcourt Manor House, and Wroxton Abbey. In regard to Burford Priory, the High Lodge at Blenheim Park, and the old manor houses of Helton and Minster Lovell, the interest is chiefly historical. The most interesting churches, in addition to those in the city of Oxford, are Ilfley, Norman, one of the finest specimens of early ecclesiastical architecture in England; Thame, with tombs and brasses; Bampton, mostly transitional from Early English and Decorated; Kidlington, Decorated, with a chancel and tower of earlier date; Ewelme, Perpendicular; Adderbury, with a chancel built by William of Wykeham; Bloxham, with spire said to have been erected by Wolsey; Burford, Norman and later; Chipping Norton, with brasses of the 14th century; Dorchester, once an abbey church; Stanton-Harcourt, with Early English chancel; Witney, Early English and Decorated, with Norman doorway. Among the religious foundations in addition to those in the city were a college and hospital at Banbury; an abbey of Austin canons at Bicester; a Cistercian abbey at Briern; a hospital at Burford; an Austin cell at Caversham; an alien priory at Charlton-on-Otmoor; a Gilbertine priory at Clattercote; an alien priory of Black monks at Coggs; an Austin priory at Cold Norton; a hospital at Crommarsh; a priory of Austin canons at Dorchester; a hospital at Ewelme; a Benedictine abbey at Eynsham; a priory of Austin nuns at Goring; a preceptory at Gosford; a Benedictine house at Milton; an alien priory at Minster Lovell; an abbey of Austin canons at Osney; a preceptory at Sandford-on-Thames; a Cistercian abbey at Thame; an establishment of the Mathurins at Tuffield; a hospital at Woodstock; and a house of Austin canons at Wroxton. There was a bishopric at Dorchester as a West Saxon see from 634 to 705, which was restored towards the close of the 9th century as a Mercian see. The bishopric was transferred to Lincoln in 1067, from which Oxfordshire was separated and erected into a see in 1545. The diocese was enlarged by the addition of Berks in 1836 and of Bucks in 1846.

See Plot, *Natural History of Oxfordshire*, 1677; Walker, *Flora of Oxfordshire*, 1833; Skelton, *Antiquities of Oxfordshire*, 1823; *Domesday Book Facsimile*, 1862; Davenport, *Lords Lieutenant and High Sheriffs of Oxford*, 1863; Id., *Oxfordshire Annals*, 1869; Phillips, *Geology of Oxford and the Thames Valley*, 1871.

OXFORD, the county town of Oxfordshire, a cathedral city, a municipal and parliamentary borough, and the seat of a famous university, is situated at a distance of 45 miles west-north-west from London, in the centre of the south midland district. It lies for the most part on a low ridge between the rivers Thames (locally called the Isis) and Cherwell, immediately above their junction. The soil is gravel lying over extensive beds of Oxford clay. From some points of view the city seems to be surrounded with hills, a line of which runs from Wytham Hill (539 feet) to Cumnor Hurst (515 feet) and Stonesfield (535 feet) on the west of the Thames valley, while on the east Headington Hill approaches still closer, with Shotover (566 feet) behind it. The river bed is about 180 feet above sea-level. Both the Thames and Cherwell valleys are liable to floods, especially in winter and spring.

University and City Buildings.—The view of the city, whether from the Abingdon road and Hinksey Hills, or from the old approach from London by Headington, or from the top of the Radcliffe, is a sight not to be forgotten. The towers and spires, numerous and yet varied in character, the quadrangles old and new with their profusion of carved stonework, the absence of large factories and tall chimneys, the groves and avenues of trees, the quiet college gardens, the well-watered valleys and encircling hills—all these combine to make Oxford the fairest city in England. The first place in importance as well as grandeur is taken by the buildings of the university, which will be briefly described in order.

First among the institutions ranks the Bodleian Library (see LIBRARIES, vol. xiv. p. 519). This noble home of study consists in the first place of the quadrangle once known as the "Schools"—containing a Jacobean gateway tower, erected 1613–18, which exemplifies the so-called five orders of architecture—and the upper part of an H-shaped building immediately adjoining. In this older part the manuscripts and most of the printed books are preserved; the fabric of the central part of the H dates from the 15th century, when it housed the library given by Humphrey, duke of Gloucester; while the contents and fittings, even to the readers' seats, have been hardly altered since the days of Charles I. The present library, founded by Sir Thomas Bodley in 1602, has since 1610 had the right to receive a copy of every book published in the United Kingdom, and its growth has been accelerated by donations from Selden, Rawlinson, Malone, Gough, Douce, and others. The modern books

are contained in the adjacent circular building known as the "Camera Bodleiana" or "Radcliffe," built 1737–49 by James Gibbs with money left by Dr Radcliffe to erect and endow a scientific library. The Radcliffe Library proper was removed in 1861 to the New Museum. The height of the dome is 140 feet. The Bodleian at present gives a home to the Pomfret and Arundel marbles, including the famous Parian Chronicle, to a number of models and pictures, to the Hope collection of 200,000 engraved portraits, and in the tower to the archives of the university. The Divinity School, immediately below the older reading-room of the Bodleian, with its beautiful roof and pendants of carved Caen stone, was finished in 1480, and is still the finest room in Oxford. The Proscholium, a rare example of an original ambulatory, adjoins it on the east, and the Convocation House on the west. To the north of these is the Sheldonian Theatre, built at the expense of Archbishop Sheldon from the designs of Sir Christopher Wren, and opened in 1669. The annual Act or "Encenia," a commemoration of benefactors, accompanied by the recitation of prize compositions and the conferment of honorary degrees, has almost invariably been held in this building. It contained also the University Press from 1669 until, in 1713, the Clarendon Building, a conspicuous object in Broad Street, was erected to contain the growing establishment, which was finally moved in 1830 to the present Clarendon Press; the Building is now used for university offices. The Ashmolean Museum, which also faces Broad Street, is an unpretentious edifice, the first public museum of curiosities in the kingdom,—founded by Elias Ashmole, and opened in 1683. The nucleus was formed by the collections of John Tradescant, and not till lately has the museum been made to serve a scientific purpose.

It contains models, ethnographical collections, English and Egyptian antiquities, and miscellaneous curiosities. The last and not the least of this central group of university buildings is the church of St Mary the Virgin in the High Street, which derives peculiar interest from its long connexion with academic history. Here were held the disputations preparatory to a degree; here, time out of mind, the university sermons have been preached; and the north-east corner is the ancient seat of the Houses of Convocation and Congregation. Round it were the earliest lecture-rooms, and its bell was the signal for the gathering of the students, as St Martin's for the townsmen. It has memories too of Wickliffe, of Cranmer, Latimer, and Ridley, of Laud, of Newman, and of Pusey. The tower and spire, of which the height is about 190 feet, date from 1400, the chancel and nave from the succeeding century. The design of the porch was the ground of one of the articles

Plan of Oxford

in the impeachment of Laud. Farther down on the south side of the High Street (the curve of which, lined with colleges and churches in its course from the centre of the city at Carfax, leads with beautiful effect to Magdalen tower and bridge) is an extensive building completed in 1882, known as the New Examination Schools, on the site of the old Angel Hotel. The architect was Mr T. G. Jackson, the style Jacobean Gothic. The size and elaborate decoration of the rooms, which form three sides of an oblong quadrangle with an entrance hall opening on the street, well adapt them for the lighter as well as the graver uses of the university. Farther on, and close to the Cherwell, is the Botanic Garden, the first of its kind in England, opened in 1683, the design having been supplied by Inigo Jones. The study of plants is unfortunately carried on at a great distance from the home of the other branches of natural history and science, the New Museum, which was built between 1855 and 1860 in the south-west

corner of the Park. The architects were Deane and Woodward, and the cost about £150,000. In it are gathered the numerous scientific collections of the university, from the time of Tradescant and Ashmole to that of the munificent donations of Mr Hope. The general plan is a central hall covered by a glass roof resting on iron columns. The lecture-rooms and Radcliffe Library surround this on both floors. The chief adjuncts to this building are to the south-west a laboratory, an imitation of the shape of the Glastonbury Kitchen, to the south a chemical laboratory, and to the north-west the Clarendon laboratory of physical science. At a short distance to the east in the Park is the University Observatory (1873), consisting of two dome-shaped buildings connected by lecture-rooms (see OBSERVATORY). The Clarendon Press in Walton Street is probably the best appointed of provincial establishments. Founded partly with the profits arising from the copyright of Clarendon's *History of the Rebellion*, the Press was for long, as we have seen, established in the Clarendon Building. Of the present classical building, completed from Robertson's designs in 1830, the chief part forms a large quadrangle. The south side is entirely devoted to the printing of Bibles and prayer-books. All the subsidiary processes of type-founding, stereotyping, electrotyping, and the like are done at the Press, and the paper is supplied from the University Mills at Wolvercote. Printing in Oxford dates from "1468" (1478?), but ceased after 1486 until 1585, except in 1517, 1518, and 1519. The first university printer was Joseph Barnes, in 1585. The Press is to a large extent a commercial firm, in which the university has a preponderating influence, as well as prior claims in the case of its own works. It is managed by the partners, and governed by eleven delegates. Returning towards the centre of the city by St Giles's, we pass on the right the Taylor Building, partly devoted to the university gallery of pictures, which contains more than two hundred and seventy sketches and drawings by Michelangelo and Raphael, besides a Turner collection and individual paintings of interest. The rest of the building is divided between the Ruskin School of Drawing and the Taylor Library, which consists chiefly of books in modern European languages. The plan and architecture is Grecian, designed by Cockerell, and completed in 1849. Close by is the Martyrs' Memorial (1841), commemorating the burning of Cranmer, Latimer, and Ridley. It resembles in shape the Eleanor crosses, and is 73 feet in height; it was the first work which brought Sir George Gilbert Scott into notice.

Taylor
Building.

All Souls.

The colleges may now be described, and for convenience of reference in alphabetical order (see also UNIVERSITIES). All Souls College (*Collegium Omnium Animarum*) occupies a central position, with fronts to Radcliffe Square and the High Street. The chief points of interest are the magnificent reredos in the chapel, coeval with the college, but lost sight of since the Reformation until discovered and restored in 1872-76; the Codrington Library, chiefly of works on jurisprudence; and the turrets (1720) designed by Hawksmoor. The west front is due to Sir Christopher Wren. Founded in 1437 by Archbishop Chichele, with sixteen law fellows out of a foundation of forty, the college has always had a legal character which, combined with an almost entire absence of undergraduates, sufficiently marks it off from all the others. The name records the ancient duty of praying for all who fell in the French wars of the early 15th century. Balliol College, at present the largest in numbers, is also among the oldest. In 1282 the Lady Dervorgilla, widow of John de Balliol, gave effect to his wishes by issuing statutes to a body of students in Oxford who two years later settled on the present site of the college. The buildings are diverse in

style and date, the two most striking being the newest, the chapel built in 1856-57, in modern Gothic, by Butterfield, and the handsome hall erected by Waterhouse in 1876. The King's Hall and College of Brasenose (*Collegium Aenei Nasi*) is the combined work of William Smith, bishop of Lincoln, and Sir Richard Sutton. The front quadrangle is among the most regular and, taken in connexion with the Radcliffe and St Mary's church, among the most picturesque in Oxford, remaining exactly as it was built at the foundation of the college in 1509, except that the third story was added, as in several other colleges, in the time of James I. The library and chapel date from the Restoration; the roof of the latter shows some rich wooden fan-tracery. The name is that of one of the old halls absorbed into the new foundation, and probably signifies brew-house (from *bracinum*, malt, and *-house*), but is popularly connected with a brazen knocker above the gate, said to have been brought from Stamford after the migration of the university thither in 1334; it is, however, first found in the 13th century. Christ Church (*Aedes Christi*), the greatest and most imposing college, and projected on a still larger scale as Cardinal College by its first founder, Wolsey, was established by Henry VIII. in 1525. It is of a peculiar dual character, the cathedral being wholly within its precincts, and partly used as the chapel of the house, while the cathedral chapter shares in the government of the whole society. The dean presides over both institutions. The lower part of the great gateway known as Tom Tower is Wolsey's design, the upper and incongruous part is by Wren; the large bell, weighing 7 tons 12 cwt., daily gives the signal for closing all the college gates by one hundred and one strokes at 9.5 P.M. The chief quadrangle, measuring 264 feet by 261 feet, was designed to have cloisters. The present classical buildings of Peckwater quadrangle are not of earlier date than 1705; the library on the south side was built in 1716-61. The latter contains valuable pictures and engravings not yet sufficiently known, as well as extensive collections of books. The hall (built in 1529), from its size (115 feet by 40 feet), the carving of the oak roof, the long lines of portraits, and the beauty of the entrance staircase, is one of the sights of Oxford. The meadow buildings were erected in 1862-66. It is commonly said that the three great English religious revivals sprang from Christ Church, Wickliffe having been warden of Canterbury Hall, now part of the house, John Wesley a member of the college, and Pusey a canon. Corpus Christi College was founded in 1516 by Bishop Richard Fox, who expressly provided for the study of Greek and Latin; nor have classical traditions ever left the "garden of bees," as the first statutes term it. The chief ornament of the college is the library, which is rich in illuminated and early English MSS., and in early printed books. Exeter College may be said to have been founded (as Stapeldon Hall) in 1314, by Walter de Stapeldon, bishop of Exeter; but Sir William Petre in 1566 largely added to the original endowment. Most of the buildings date from the present century; the chapel, the proportions of which resemble those of the Sainte Chapelle at Paris, was built in 1856-59 by Sir G. Gilbert Scott, the hall in 1818, the Broad Street front in 1855-58. The secluded gardens are beautifully situated beneath the shadow of the Divinity School and Bodleian. Hertford College, founded in 1874, is on a site of old and varied history. From the 13th century until 1740 it was occupied by Hart or Hertford Hall; at the latter date Dr Richard Newton refounded the hall with special statutes of his own framing as Hertford College. In 1822 the society of Magdalen Hall, after the fire at their buildings near Magdalen College, migrated thither, and finally the

Christ
Church.

Corpus
Christi.

hall was merged in the new college which owes its existence to the munificence of Mr T. C. Baring. The Welsh College, Jesus, dates from 1571, having been founded by Dr Hugh Price. Sir Leoline Jenkins, principal at the Restoration, was a conspicuous benefactor. The present buildings are of various dates. The direct connexion with the Principality extends to a moiety of the fellows and a majority of the scholars. Keble College is a testimony to the wide-felt reverence for the character and principles of the Rev. John Keble, who died in 1866. In his memory the college was founded with a special view to economical life and Christian training, based on the principles of the Church of England. Since its opening in 1870 its growth has been continuous. The buildings are the design of Keble's friend Butterfield; the richly ornamented chapel, the gift of Mr William Gibbs, was completed in 1876, and the library and hall in 1878. The style is Italian Gothic, the material to a large extent red brick relieved by white stone, and in the chapel by marble and mosaics. Bishop Richard Flemmyng founded Lincoln College in 1427, with the object, it is believed, of opposing the doctrines of Wickliffe. Like Exeter and Jesus it boasts a second founder in Thomas de Rotherham, also bishop of Lincoln, in 1478. The library is of considerable value, both for MSS. and books. The painted windows in the chapel were procured from Italy in the 17th century. Magdalen College is the most beautiful and the most complete in plan of all the colleges. The extensive water-walks in the Cherwell meadows, the deer park, the cloisters with their ivy-grown walls and quaint emblematic sculptures, the rich new buildings of pure Gothic, and, above all, the tower, combine in this conspicuous result. William Patten, better known as William of Waynflete, bishop of Winchester, established the college in 1456 for a president, forty fellows, and thirty scholars with chaplains and a full choir. The cloister quadrangle was first built in 1473, and the chapel in 1474-80; the latter has a decorated interior, an altarpiece of Christ bearing the Cross similar to that in Bolton Abbey, and painted windows. The tower, of exquisite proportions and harmony of detail, was commenced in 1492, and reached its full height of 145 feet in 1505; it stood for a few years isolated as a campanile. The custom of singing a hymn on the top at 5 A.M. on May-day has been kept up by the choir since the time of Henry VII. The meadow buildings date from 1733. The muniments and library are valuable, the former containing some 14,000 deeds, chiefly of religious houses suppressed at the Reformation. The high-handed attempt of James II. to force a president on the college in 1688 is matter of history. Merton College is in a very definite sense the oldest; the earliest extant statutes were given in 1264 by Walter de Merton, and before 1274 it was settled in Oxford. The statutes were a model for all the more ancient colleges both in Oxford and Cambridge. The founder's special intention was to benefit the order of secular priests, and the first century of his society was more prolific of great names than any similar period in any college. The fine chapel, which is also the parish church of St John the Baptist, rose gradually between 1330 and 1450, the tower belonging to the later part. The hall, of the 14th century, was thoroughly restored in 1872. The library, built about 1349, is the oldest existing library in England. To the east lie the quiet well-wooded gardens, still bounded on two sides by the city wall. New College, or more properly the college of St Mary Winton, is the magnificent foundation of William of Wykeham, who closely connected it with his other great work Winchester School. Its name is still significant, for the first statutes marked a new departure, in the adaptation of monastic buildings and

rules to the requirements of a less fettered body of students; and they, like those of Merton, were imitated by succeeding societies. The foundation-stone was laid in 1380, and the hall, chapel, and front quadrangle are of that period, except that the third story of the latter was added in 1674. The chapel is noteworthy for the west window, designed by Sir Joshua Reynolds, and the Flemish windows on the south side; the roof was renewed in 1880. The tower is built on one of the bastions of the city wall, and faces the new buildings in Holywell Street, erected in 1872-75. The gardens and cloisters are among the most picturesque sights of Oxford, the former encompassed on the north and east by the city wall, still almost perfect. Oriel College was founded by Adam de Brome in 1324, and reconstituted by Edward II. in 1326. The present buildings chiefly date from the first half of the 17th century. The Tractarian movement is closely connected with the college of Newman and Keble. Pembroke College (1624) derives its name from the chancellor of the university at the time when it was established by Richard Wightwick, partly by means of a legacy from Thomas Tesdale. The library contains many memorials of Dr Johnson, who was a member of the college. Queen's College, so called from its first patroness, Queen Philippa, was founded in 1340 by Robert de Eglesfield, whose name is commemorated yearly in the custom of presenting a needle and thread ("aiguille et fil," a rebus) to each fellow on New-Year's Day. The present buildings are not older than the Restoration, while the front dates from the middle of the last century, and the west part of the front quadrangle was rebuilt after a disastrous fire in 1778. The interior of the chapel, which is classical in style, with an apse, exhibits some fine wood-carving and windows. Queen's possesses the largest and most valuable collegiate library of printed books, chiefly owing to the munificence of Bishop Barlow in 1691 and of Dr Robert Mason in 1841. On Christmas Day a boar's head is brought into the hall to the accompaniment of an ancient carol. St John the Baptist's College was the work of Sir Thomas White, a London merchant, in June 1555. Archbishop Laud was closely connected with it, and built, almost entirely at his own expense, the second quadrangle, including the library; his body rests within the college. The chapel and other parts of the buildings belonged to the earlier foundation of St Bernard's College. The large gardens are skilfully laid out in alternate lawns and groves. Trinity College, founded in February 1555 by Sir Thomas Pope, was the first post-Reformation college and the first established by a layman. The library is the original one of Durham College, in which Richard de Bury's books were deposited in the 14th century. The gardens are extensive, including a fine lime-tree avenue. University College, the proper title of which is the Great Hall of the University (*Collegium Magnæ Aulae Universitatis*), is generally accounted the oldest college, although its connexion with Alfred is wholly legendary. It received the first endowment given to students at Oxford in 1249 from William of Durham, but its first statutes date from 1280, and its tenure of the present site from about 1340. None of the present buildings are older than the 17th century. The detached library was built in 1860. Wadham College was founded in 1610 by Dorothy Wadham, in pursuance of the designs of her husband Nicholas, who died in 1609. The college buildings, made of exceptionally firm stone, have been less altered than those of any other college. The chapel exhibits a surprisingly pure Gothic style considering its known date, the early part of the 17th century. The meetings held in this college after the Restoration by Dr Wilkins, Bishop Sprat, Sir Christopher Wren, and others directly led to the institu-

St John's

Trinity.

University.

tion of the Royal Society. The gardens lie to the north and east. Worcester College, which has recently celebrated the sixcentenary of its first building in 1283 as Gloucester Hall, was at first a place of study for Benedictines from all parts of the country, until it was dissolved at the Reformation, when the buildings passed to the see of Oxford. In 1560 the founder of St John's College reopened it as St John the Baptist's Hall, but after changing fortunes, and an attempt in 1689 to form it into a college for students of the Greek Church, it came in 1714 into the hands of the trustees of Sir Thomas Cookes, who founded the present college. The garden front still retains the antique style of Gloucester Hall, looking over the extensive gardens and pond. The other buildings rose at various periods in the 18th century, while the splendid interior decoration of the chapel, with its profusion of marble, inlaid wood, and painted panel-work, designed by Burgess, was completed in 1870.

Halls.

Until Laud's time the number of private halls was considerable; by him five only were allowed to survive:—Magdalen Hall, now merged in Hertford College; St Mary Hall, founded in 1333, now destined to be absorbed into Oriel, as New Inn Hall into Balliol, and St Alban Hall into Merton; and St Edmund Hall, which, though closely connected with Queen's College, is likely to maintain a separate existence.

City buildings.

The public buildings of the city, as distinct from the university, do not require a detailed notice. The town-hall dates from 1752, the corn exchange and post-office from 1863 and 1882 respectively. The chief hospital is the Radcliffe Infirmary, opened in 1770, and due to the same liberal benefactor who has been mentioned in connexion with the Radcliffe Library, and who left funds for the erection of the large and important Radcliffe Observatory, completed in 1795. There are two ladies' halls, Lady Margaret's and Somerville, and High Schools for boys and girls. Port Meadow is a large pasture to the north-west of the city, which has belonged from time immemorial to the freemen of the city. An extensive system of drainage has been recently carried out, involving the formation of a sewage farm at Littlemore. Water is supplied from large covered tanks on Headington Hill, into which the water is forced from reservoirs at New Hinksey. The University Park, comprising 80 acres, is beautifully situated on the banks of the Cherwell.

Cathedral.

The diocese of Oxford now includes the three "home counties" of Berkshire (originally in the diocese of Wessex, then till 1836 in that of Sherborne or Salisbury), Buckinghamshire (until 1845 under the see of Lincoln), and Oxfordshire (formerly in the dioceses of Dorchester, Winchester, or Lincoln). The patents for the formation of the bishopric bear dates of 1542 and 1546. The cathedral, already mentioned as part of Christ Church, was at first the church of St Frideswide, begun so far as the present buildings are concerned in about 1160, and forming "a fine example of Late Norman and Transitional work of early character." The nave is pure Norman; the choir, with its richer ornament and delicate pendants, is the Transitional part; the present remarkable east end, having a circular window over two smaller round-headed ones, is believed to be a restoration of the original design. Part of the western end of the nave was destroyed by Wolsey to allow the large quadrangle to be formed. Within the cathedral the most noteworthy objects are the 15th century "shrine of St Frideswide," the modern reredos, and the bishop's throne, a memorial of Bishop Wilberforce. The stained glass is of different styles. The octagonal spire, 144 feet high, is of a peculiar pitch. The chapter-house on the south side of the nave, and the fine doorway leading from it to the cloisters, are early 13th-century

work. Of the numerous parish churches some have already been noticed. All Saints' was built early in the 18th century, from designs by Dean Aldrich, in a classical style, but with much originality of detail; St Philip and St James's and St Barnabas's are among the most recent, the latter being in imitation of Italian style with separate campanile. The Roman Catholic church of St Aloysius in St Giles's was opened in 1875.

History.—The legends connecting the city with Brute the Trojan, Mempric, and the Druids are not found before the 14th century, and are absolutely without foundation. The name, which is found in the 10th century as *Oxenaford*, and in the 11th as *Oxenford*, the Welsh (more modern) *Rhydychain*, points to a ford for oxen across the shallow channels of the divided river near Folly Bridge, though many on theoretical grounds connect the first part of the word with a Celtic root signifying water, comparing it with *Onse*, *Oseney*, *Exford*, and even *Isis*. The nucleus of the town was probably a nunnery, afterwards a house of secular canons, founded in honour of St Frideswide in or before the 9th century, on the site of the present cathedral. After the peace of Wedmore (886) Oxford became a border town between Mercia and Wessex, and coins of Alfred with the legend *OKSNAFORDA* (on some types *ORSNAFORDA*) seem to prove that a mint was established there before the close of that century. The earliest undoubted mention of the city is in the English Chronicle under the year 912, when Edward the Elder made London and Oxford a part of his own kingdom of Wessex. To this period probably belongs the castle mound, still a conspicuous object on the New Road between the railway stations and the city, and similar to those found at Warwick and Marlborough. The subsequent notices of Oxford in the Chronicle before the Conquest prove the rapidly increasing importance of the place, both strategically as the chief stronghold of the valley of the upper Thames—as when the Danes attacked and burned it in 1009 and Sweyn took hostages from it and Winchester in 1013—and politically as a meeting-place for gemots in which the interests of north and south England were alike affected. Witenagemots were held there in 1015, when two Danish thegns were treacherously murdered; in 1036, when Harold was chosen king; and in 1065. In 1018, when Cnut first became king of all England, he selected the same spot for the confirmation by Danes and English of "Edgar's law." But the murder of King Edmund in 1016 and the death of Harold in 1039 seem to have given rise to the saying that it was ill-omened for the kings of England to enter or reside at Oxford. The Domesday survey of Oxford (c. 1086) is more than usually complete, and from it we gather that about six-sevenths of the town was held in equal proportions by ecclesiastical owners, by Norman followers of the king, and by citizens, one-seventh being in the king's hands. The priory church of St Frideswide, and the churches of St Mary the Virgin, St Michael, St Peter in the East, and St Ebbe are mentioned; from other sources it is known that St Martin's at Carfax was in existence, and not less than seven more before the close of the century. It is a curious fact that, while two hundred and forty-three houses (*domi*) paid tax, no less than four hundred and seventy-eight were waste (*waste*), and even of the *mansiones* one hundred and ninety-one were habitable and not fewer than one hundred and six waste. Oxford grew steadily when governed by the strong hand of Robert d'Oili (1070?–1119?). The existing remains which may be attributed to his building are the castle tower containing the church of St George and a crypt, the crypt and part of the church of St Peter's in the East, and the tower of St Michael's; but it is known that he repaired other churches and built bridges. His nephew founded the abbey of Oseney, for Augustinian canons, in 1129. During the 12th century Beaumont Palace, built by Henry I. outside the north wall of the city, was a favourite royal residence, and the birthplace both of Richard I. and of John. In the charter granted by Henry I. the privileges of the town rank with those of London, and a large Jewry was formed near the site of the present town-hall. The flight of the empress Matilda from the castle over the ice-bound river to Abingdon in 1142, when besieged by Stephen, is a well-known incident. If we may trust the Oseney Chronicle it is in 1133 that we find the first traces of organized teaching in Oxford, the germ of the great university which was destined to far outstrip the city in privileges, wealth, and fame (see *UNIVERSITIES*). During the 13th century parliaments were often held in the town, notably the Mad Parliament in 1258, which led to the enactment of the "Provisions of Oxford." But this time also witnessed the beginning of the long struggle between the town and university, which produced serious riots, culminating on St Scholastica's day in 1354, and finally subjected the former to serious curtailment of its powers and jurisdiction. History has preserved the names of several heroes in the struggle for civic independence, but the issue was never doubtful, and the annals of the city in succeeding centuries admit of briefer narration. The religious orders found their way early

into Oxford:—in 1221 the Dominicans (whose settlement near the site of the present gas-works is still attested by Blackfriars Street, Preacher's Bridge, and Friar's Wharf); in 1224 the Franciscans (who built their house near Paradise Square); soon after 1240 the Carmelites (near Worcester College, to which Friar's Entry led); and in 1252 the Austin Friars, who settled near what is now Wadham College. The greater orders were not less firmly established,—the Cistercians at Rewley Abbey (*de Regali loco*, founded about 1280), the Benedictines scarcely later at Gloucester Hall and Durham College, now Worcester and Trinity Colleges respectively. In the 13th and 14th centuries, as the university grew, an increasing number of students gathered in Oxford, filling the numerous halls and swelling the size, if not the wealth, of the place. The total of students in Henry III.'s time was placed at thirty thousand in contemporary records seen by Thomas Gascoigne, but this can only be an exaggeration or a mistake. The town was frequently ravaged by plagues, and generally shared in the exhaustion and inactivity which marked the 15th century. The Reformation was unaccompanied by important incidents other than those which affected the university and the see; but after the troubles of Mary's reign Oxford again began to revive under the personal favour of Elizabeth, which was continued by the Stuart kings. In the civil war Oxford becomes suddenly prominent as the headquarters of the Royalist party and the meeting-place of the king's parliament. It was hither that the king retired after Edgehill, the two battles of Newbury, and Naseby; from here Prince Rupert made his dashing raids in 1643. In May 1644 the earl of Essex and Waller first approached the city, from the east and south, but failed to enclose the king, who escaped to Worcester, returning once more after the engagement at Cropredy Bridge. The final investment of the city, when the king had lost every other stronghold of importance, and had himself escaped in disguise, was in May 1646; and on June 20 it surrendered to Fairfax. Throughout the war the secret sympathies of the citizens were Parliamentary, but there was no conflict within the walls. In October 1644 a destructive fire burnt down almost every house between George Street and St Aldate's church. Charles II. held the last Oxford parliament in 1681, the House of Lords sitting in Christ Church Hall, the Commons in the Schools. In the first year of George I.'s reign there were serious Jacobite riots, but from that time the city becomes Hanoverian in opposition to the university, the feeling coming to a head in 1754 during a county election, which was ultimately the subject of a parliamentary inquiry. The public works which distinguish the last century have been already mentioned; the general history of the city proper presents few features of interest. Since the first railway (from Didcot) in 1844 its rate of progress has been accelerated, and it has at length vindicated for itself a vigorous and independent municipal life.

Oxford grew up, as has been seen, on the slope leading from the ford near Folly Bridge to Carfax. Its earliest trade must have been twofold, partly with London by way of the Thames, and partly with the west by the ford. No Roman road of importance passed within three miles of the future town, and the Chiltern Hills prevented a direct road to the metropolis. The first mention of townsmen is "*eco buruwaru*" in the English Chronicle *sub anno* 1013, and of its trade in the toll paid to the abbot of Abingdon by passing barges from the 11th century (*Abingdon Chron.*, vol. ii. p. 119). When the Domesday survey was made all the churches except St Mary Magdalen were within the line of walls. Mr James Parker estimates the population at that time to have been "not more than 1700," occupying one hundred and ninety-one mansions and two hundred and forty-three houses. By the close of the 11th century the castle had been partly built, and the walls enclosed a space roughly of the shape of a parallelogram, its greater length lying nearly east and west, dominated by the castle at its western extremity. In Elizabeth's time, as Ralph Agas's view shows, nine-tenths of the city was still intra-mural. In 1789 the population was about 8300, but more than half lived outside the walls; in 1831, 20,650; in 1881 the municipal borough comprised 35,264, the local board district 38,289, exclusive of about 3000 members of the university. The chief extensions have been towards the north, including both the fashionable quarter beyond the parks and the poorer suburb of Jericho, and on the south-east, where St Clement's and Cowley St John have greatly increased. The newly built low-lying districts of Osney town with Botley in the west, and Grandpont with New Hinksey to the south, are comparatively unhealthy, contrasting in that respect with the houses rising on Headington Hill. The trade of the city has always been varied rather than extensive; there has never been a staple produce, and the few manufactures are of recent introduction. Oxford being an agricultural centre has an important market, but the alternations of university terms and vacations affect the steadiness of general business. The first charter known is one of Henry I., not now extant, mentioning a merchants' guild (*gilda mercatoria*). That of Henry II. specially connects the citizens with London, *quia ipsi et cives Londonienses sunt de una et eadem consuetudine et lege et libertate*. They were to be butlers with the latter at the king's

coronation—a privilege still retained by their representative. The earliest governing body was the mayor and burgesses; aldermen were added in 1255, and the full institution from 1605 until 1835 consisted of a mayor, two bailiffs, four aldermen, eight assistants, and twenty-four common council men, together with a high steward, recorder, town-clerk, and inferior officers. At present the government is in the hands of a high steward, recorder, sheriff, and corporation, the latter consisting of a mayor, ten aldermen, and thirty councillors. For the election of the last two classes the city is divided into five wards. There is a local board of forty-seven members and a school board of seven. From the earliest times the city has been represented by two burgesses in parliament.

The chief authorities for the general history of Oxford are the works of Antony Wood, viz., the *Hist. and Antiqu. of the University*, 1792-98 (in Latin, 1674), *Hist. and Antiqu. of the Colleges and Halls*, 1785-90, and the *Ancient and Present State of the City*, 1773; and Ingram, *Memorials of Oxford*, 1837 and 1847. There are good local directories and guides. Of a more special kind are James Parker's sketch of the early *History of Oxford*, 1871; Turner, *Selections from the Records of the City*, 1879; Phillips, *Geology of Oxford*, 1871; and the accounts of All Souls, Exeter, and Magdalen Colleges by Burrows, Boase, and Bloxam respectively. The Oxford Historical Society publishes works bearing on the history of the place. The history of the university will be found under UNIVERSITIES. (F. M.)

OXFORD, ROBERT HARLEY, FIRST EARL OF (1661-1724), the eldest son of Sir Edward Harley, a prominent landowner in Herefordshire, was born in Bow Street, Covent Garden, London, 5th December 1661. His school days were passed near Burford, in Oxfordshire, in a small school which produced at the same time a lord high treasurer, a lord high chancellor, and a lord chief justice of the common pleas. The principles of Whiggism and Nonconformity were instilled into his mind at an early age, and if he changed the politics of his ancestors he never formally abandoned their religious opinions. At the Revolution of 1688 Sir Edward and his son raised a troop of horse in support of the cause of William III., and took possession of the city of Worcester in his interest. The family zeal for the Revolution recommended Robert Harley to the notice of the Boscawen family, and led to his election, in April 1689, as the parliamentary representative of Tregony, a borough under their control. He remained its member for one parliament, when he was elected by the constituency of New Radnor, and he continued to represent it until his elevation to the peerage in 1711. From the first he gave great attention to the conduct of public business, bestowing especial care upon the study of the forms and ceremonies of the House, and acquiring from his labours that distinction which a knowledge of parliamentary precedents always bestows. This reputation marked him out as a fitting person to preside over the debates of the House, and from the general election of February 1701 until the dissolution of 1705 he held with general approbation the office of speaker. For a part of this period, from 18th May 1704, he combined with the speakership the duties of a principal secretary of state, displacing in that office the Tory earl of Nottingham, a circumstance which may have impelled that haughty peer to join the Whigs, some years later, in opposition to the treaty of Utrecht. At the time of his appointment as secretary of state Harley had given no outward sign of dissatisfaction with the Whigs, and it was mainly through Marlborough's good opinion of his abilities that he was admitted to the ministry. For some time, so long indeed as the victories of the great English general cast a glamour over the policy of his friends, and the constituencies were enthusiastic in support of a war policy, Harley continued to act loyally with his colleagues. But in the summer of 1707 it became evident to Godolphin that some secret influence behind the throne was opposing his wishes and shaking the confidence of the queen in her ministers. The sovereign had resented the intrusion into the administration of the impetuous earl of Sunderland, and had persuaded herself that the safety of the church depended on the fortunes of the Tories. These convictions were strengthened in her mind by the new favourite Abigail

Hill (a relative of the duchess of Marlborough through her mother, and of Harley on her father's side), whose soft and silky ways contrasted only too favourably in the eyes of the queen with the haughty manners of her old friend, the duchess of Marlborough. Both the duchess and Godolphin communicated to Marlborough their belief that this change in the disposition of the queen was due to the sinister conduct of Harley and his relatives, and the persistent protestations of the accused persons to the contrary were accepted with an ill grace. Although Harley was for the present permitted to remain in his office, subsequent experience convinced the chiefs of the Government of the necessity for his dismissal, and an occurrence which showed the remissness of his official conduct, if it did not prove his treachery to the nation, furnished them with an opportunity for carrying out their wishes. An ill-paid and poverty-stricken clerk in Harley's office was detected in furnishing the enemy with copies of many documents which should have been kept from the knowledge of all but the most trusted advisers of the court, and it was found that through the carelessness of the head of the department the contents of such papers became the common property of all in his service. The queen was thereupon informed that Godolphin and Marlborough could no longer serve in concert with a minister whom they distrusted, and of whose incapacity there were such proofs. They did not attend her next council, and when Harley proposed to proceed with the business of the day one of their friends drew attention to their absence, when the queen found herself forced (11th February 1708) to accept the resignation of her secret adviser. At that time it seemed as if Harley's fortunes had sunk for ever.

Harley went out of office, but his cousin, who had now become Mrs Masham, remained by the side of the queen, and contrived to convey to her mistress the views of the ejected minister. Every device which the defeated ambition of a man whose strength lay in his aptitude for intrigue could suggest for hastening the downfall of his adversaries was employed without scruple, and not employed in vain. The cost of the protracted war with France, the danger to the national church, the chief proof of which lay in the prosecution of Sacheverell, were the weapons which he used to influence the masses of the people. Marlborough himself could not be dispensed with, but his proud spirit was insulted in a thousand ways, and his relations were dismissed from their posts in turn. When the greatest of these, Lord Godolphin, was sent into private life, five commissioners to the treasury were appointed (10th August 1710), and among them figured Harley as chancellor of the exchequer. It was the aim of the new chancellor to frame an administration from the moderate members of both parties, and to adopt with but slight changes the policy of his predecessors; but his efforts were doomed to disappointment. The Whigs refused to join in an alliance with the man whose rule began with the retirement from the treasury of the finance minister idolized by the city merchants, and the Tories, who were successful beyond their wildest hopes at the polling booths, could not understand why their leaders should pursue a system of government which copied the faults of their political opponents. The clamours of the wilder spirits of the party, the country members who met at the "October Club," began to be re-echoed even by those who were attached to the person of Harley, when, through an unexpected event, his popularity was restored at a bound. A French refugee, the ex-abbé de la Bourlie (better known by the name of the marquis de Guiscard), was being examined before the privy council on a charge of treachery to the nation which had befriended him, when he stabbed Harley in the breast with a penknife (March

1711). To a man in good health the wounds would not have been serious, but the minister had been for some time indisposed—a few days before the occurrence Swift had penned the prayer "Pray God preserve his health, everything depends upon it"—and the joy of the nation on his recovery knew no bounds. Both Houses presented an address to the crown, suitable response came from the queen, and on Harley's reappearance in the Lower House the speaker made an oration which was spread broadcast through the country. On the 24th May 1711 the minister became Baron Harley of Wigmore and earl of Oxford and Mortimer; before the month was ended he was created lord treasurer, and in the following year he became a knight of the Garter. Well might his friends exclaim that he had "grown by persecutions, turnings out, and stabbings."

With the sympathy which this attempted assassination had evoked, and with the skill which the lord treasurer possessed for conciliating the calmer members of either political party, he passed through several months of office without any loss of reputation. He rearranged the nation's finances, and continued to support her generals in the field with ample resources for carrying on the campaign, though his emissaries were in communication with the French king, and were settling the terms of a peace independently of England's allies. After many weeks of vacillation and intrigue, when the negotiations were frequently on the point of being interrupted, the preliminary peace was signed, and in spite of the opposition of the Whig majority in the Upper House, which was met by the creation of twelve new peers, the much-vexed treaty of Utrecht was at last brought to a conclusion. While these negotiations were under discussion the friendship between Oxford and St John was fast changing into hatred. The latter had resented the rise in fortune which the stab of Guiscard had secured for his colleague, and when he was raised to the peerage with the title of Baron St John and Viscount Bolingbroke, instead of with an earldom, his resentment knew no bounds. The royal favourite, whose husband had been called to the Upper House as Baron Masham, deserted her old friend and relation for his more vivacious rival. The Jacobites found that, although the lord treasurer was profuse in his expressions of good will for their cause, no steps were taken to ensure its triumph, and they no longer placed reliance in promises which were repeatedly made and repeatedly broken. Even Oxford's friends began to complain of his habitual dilatoriness, and to find some excuse for his apathy in ill health, aggravated by excess in the pleasures of the table and by the loss of his favourite child. By slow degrees the confidence of Queen Anne was transferred from Oxford to Bolingbroke; on the 27th July 1714 the former surrendered his staff as lord treasurer, and on the 1st August the queen died.

On the accession of George I. the defeated minister retired to Herefordshire, but a few months later his impeachment was decided upon and he was committed to the Tower. After an imprisonment of nearly two years the prison doors were opened, and he was allowed to resume his place among the peers, but he took little part in public affairs, and died almost unnoticed 21st May 1724. Harley's political fame may now be dimmed by time, his statesmanship may seem but intrigue and finesse, but his character is set forth in the brightest colours in the poems of Pope and the prose of Swift. The Irish dean was his discriminating friend in the hours of prosperity, his unswerving advocate in adversity. The books and manuscripts which the first earl of Oxford and his son collected were among the glories of their age. The manuscripts became the property of the nation; the books were sold to a bookseller called Osborne, and described in

a printed catalogue of four volumes, part of which was the work of Dr Johnson. In the recollection of the Harleian manuscripts, the Harleian library, and the *Harleian Miscellany*, the family name will never die. (W. P. C.)

OXUS. This river rises in the lofty table-lands which are intercepted between the two great mountain ranges of central Asia, the Thian Shán and the Hindú Kúsh, in the region where they approach each other most closely. It flows westwards through a broad valley, receiving numerous affluents from the mountain ranges on either side; then bending to the north-west it traverses the arid deserts of western Turkestan on the borders of Bokhara, descends into and fertilizes the rich oasis of Khiva, and finally disembogues at the southern extremity of the Sea of Aral. Its course is roughly parallel to that of its sister river the Jaxartes, which rises to the north of the Thian Shán water-parting, and disembogues at the northern extremity of the Sea of Aral.

The name Oxus is that by which the river is mentioned in the writings of the ancient Greek historians. In the older traditions of the Parsi books it is named the Veh-rúd, in some form of which originates the classical name which we find it most convenient to use, and also it may be presumed the names of various territories on the banks of its upper waters, such as Wakhan, Wakhsh, and Washgird, which are no doubt identical in formation, if not in application, with the classical Oxiani, Oxii, and Oxi-Petra. The classical names have long ceased to be known to the inhabitants of the country. In early Mohammedan history the river was usually styled Al-Nahr, whence the title Ma wará'l Nahr, or "beyond the river," which came to be bestowed on a province of Persia lying to the north of the Oxus, and which in modern use has been rendered Transoxiana. In subsequent Mohammedan writings Al-Nahr gives place to Jaihún, corresponding to the Gihon of the Mosaic garden of Eden. And now the river is known by Asiatics as the Amú Daria, a name of which the origin is uncertain.¹

In the most remote ages to which written history carries us, the regions on both sides of the Oxus were subject to the Persian monarchy. Of their populations Herodotus mentions the Bactrians, Chorasmians, Sogdians, and Sacæ as contributing their contingents to the armies of the great King Darius. The Oxus figures in Persian romantic history as the limit between Iran and Turan, but the substratum of settled population to the north as well as the south was probably of Iranian lineage. The valley is connected with many early Magian traditions, according to which Zoroaster dwelt at Balkh, where, in the 7th

Sketch Map of the Oxus.

century B.C., his proselytizing efforts first came into operation. Buddhism eventually spread widely over the Oxus countries, and almost entirely displaced the religion of Zoroaster in its very cradle. The Chinese traveller Hwen Tsang, who passed through the country in 630-644 A.D., found Termedh, Khúlín, Balkh, and above all Bamian, amply provided with monasteries, stirpas, and

colossal images, which are the striking characteristics of prevalent Buddhism; even the Pamir highlands had their monasteries.

Christianity penetrated to Khorásán and Bactria at an early date; episcopal sees are said to have existed at Merv and Samarkand in the 4th and 5th centuries, and Cosmas (c. 545) testifies to the spread of Christianity among the Bactrians and Iluns.

Bactria was long a province of the empire which Alexander the Great left to his successors, but the Greek historians give very little information of the Oxus basin and its inhabitants. About 250 B.C. Theodotus, the "governor of the thousand cities of Bactria," declared himself king, simultaneously with the revolt of Arsaces which laid the foundation of the Parthian monarchy. The Græco-Bactrian dominion was overwhelmed entirely about 126 B.C. by the Yüehi, a numerous people of Tibet who had been driven westwards from their settlements on the borders of China by the Hiongnu, the Huns of Deguignes. From the Yüehi arose, about the Christian era, the great Indo-Scythian dominion which extended across the Hindú Kúsh southwards, over Afghanistan and Sind. The history of the next five centuries is a blank. In 571 the Háiáthalah of the Oxus, who are supposed to be descendants of the Yüehi, were shattered by an invasion of the Turkish khakan; and in the following century the Chinese pilgrim Hwen Tsang found the former empire of the Háiáthalah broken up into a great number of small states, all acknowledging the supremacy of the Turkish khakan, and several having names identical with those which still exist. The whole group of states he calls Tukhára, by which name in the form Tokháristan, or by that of Háiáthalah, the country continued for centuries to be known to the Mohammedans. At the time of his pilgrimage Chinese influence had passed into Tokháristan and Transoxiana. Yezdegird, the last of the Sasanian kings of Bokhara, who died in 661, when defeated and hard pressed by the Saracens, invoked the aid of China; the Chinese emperor, Taitsung, issued an edict organizing the whole country from Ferghana to the borders of Persia into three Chinese administrative districts, with 126 military cantonments, an organization which, however, probably only existed on paper.

In 711-12 Mohammedan troops were conducted by Kotaiba, the governor of Khorásán, into the province of Khwárizm (Khiva), after subjugating which they advanced on Bokhara and Samarkand, the ancient Sogdiana, and are said to have even reached Ferghana and Kashgar, but no occupation then ensued. In 1016-25 the government of Khwárizm was bestowed by Sultan Mahmud of Ghazni upon Altúnshah, one of his most distinguished generals.

Tokháristan in general formed a part successively of the empires of the Sasanian dynasty of Bokhara (terminated 999 A.D.), of the Ghaznavi dynasty, of the Seljukian princes of Persia and of Khorásán, of the Ghorí or Shansabanya kings, and of the sultans of Khwárizm. The last dynasty ended with Sultan Jalál-ud-din, during whose reign (1221-31) a division of the Moghul army of Jenghiz Khan first invaded Khwárizm, while the khan himself was besieging Bamian; Jalál-ud-din, deserted by most of his troops, retired to Ghazni, where he was pursued by Jenghiz Khan, and again retreating towards Hindustán was overtaken and driven across the Indus.

The commencement of the 16th century was marked by the rise of the Uzbek rule in Turkestan. The Uzbeks were no one race, but an aggregation of fragments from Turke, Mongols, and all the great tribes constituting the hosts of Jenghiz and Batú. They held Kúndúz, Balkh, Khwárizm, and Khorásán, and for a time Badakhshán also; but Badakhshán was soon won by the emperor Baber, and in 1529 was bestowed on his cousin Sulaimán, who by 1555 had established his rule over much of the region between the Oxus and the Hindú Kúsh. The Moghul emperors of India occasionally interfered in these provinces, notably Shah Jehán in 1646; but, finding the difficulty of maintaining so distant a frontier, they abandoned it to the Uzbek princes. About 1765 the wazir of Ahmed Sháh Abdali of Cabul invaded Badakhshán, and from that time until now the domination of the countries on the south bank of the Oxus from Wakhan to Balkh has been a matter of frequent struggles between Afghans and Uzbeks.

The Uzbek rule in Turkestan has during the last twenty years been rapidly dwindling before the growth of Russian power. In 1863 Russia invaded the Khokand territory, taking in rapid succession the cities of Turkestan, Chemkend and Tashkend. In 1866 Khojend was taken, the power of Khokand was completely crushed, a portion was incorporated in the new Russian province of Turkestan, while the remainder was left to be administered by a native chief almost as a Russian feudatory; the same year the Bokharians were defeated at Irdjar. In 1867 an army assembled by the amir of Bokhara was attacked and dispersed by the Russians, who in 1868 entered Samarkand, and became virtually rulers of Bokhara. In 1873 Khiva was invaded, and as much of the khanate as lay on the right bank of the Oxus was incorporated into the Russian empire, a portion being afterwards made over to Bokhara. Russia acquired the right of the free navigation of the Oxus throughout its entire course, on the borders of both Khiva and Bokhara. The administration of the whole of the states on the right bank of the Oxus, down to the Russian boundary line at Ichke

¹ Natives of western India hold that it implies "mother" of rivers, in correlation with Abi-sán or "father of rivers," a title which is frequently given to its great southern neighbour, the river Indus.

Yar, is now in the hands of Bokhara, including Karategin—which the Russians have transferred to it from Khokand—and Darwáz at the entrance to the Pamir highlands. At the present time the states on the left bank of the Oxus, from its sources in the Panjah river down to the town and ferry of Khwāja Saleh, are mainly subject to Afghanistan; from Khwāja Saleh to the frontiers of Khiva and Russia at Ichka Yar the left bank of the Oxus is subject to Bokhara; from the same point the Afghan boundary is supposed to stretch across the Dasht-i-chul plains of the Turkomans, above Maimána, to Sarakhs, where it meets the Persian frontier.

The regions in which the Oxus takes its birth, and through which it passes until it becomes lost in the Sea of Aral, may be divided into upper, middle, and lower: the upper is constituted by the highlands between the Thián Shán and the Hindú Kúsh ranges, and the middle by the plains and uplands which are situated in the broad valley between the western prolongations of the same ranges; the lower lies in the plains of western Turkestan. Descriptions of the chief provinces and states in the middle and lower regions will be found under *AFGHAN TURKESTAN* (vol. i. p. 241), including the eastern khanates of Kúndúz, Khúlím, Balkh, and Akcha, and the Chahár Wilayat, or Four Domains, viz., the western khanates of Sir-i-púl, Shibghán, Andkhúí, and Maimána; also under *BADAKHSHÁN, KARATEGIN, HISSAR, BOKHARA, and KHIVA*; accounts have also been already given of *BACTRIA, BALKH, and BAMIAN*. Here we shall only treat of the highland regions of the Oxus, and the river itself in its downward course to the Sea of Aral, postponing all other matter to the article *TURKESTAN* (see also the map of Turkestan).

For a right understanding of the highland region, notice must be taken of its position relatively to the two great longitudinal systems of mountains, the Thián Shán and the Indian Caucasus, and their respective prolongations east and west, which form such a prominent feature in the physical geography of the continent of Asia. These mountain systems include between them a belt of tablelands of varying breadth, and generally of considerable altitude. The forces of nature by which both the mountains and the intermediate tablelands were primarily evolved from the earth's crust appear to have acted concurrently over the entire region, but with greatest elevating effect along the northern edge of the Caucasus; for, though the highest peaks of the Hindú Kúsh and the Himalayan ranges are more frequently met with on spurs some distance to the south than on the northern water-parting, the elevated masses are here of greatest magnitude; here there are mountains whose peaks rise to great altitudes above the sea-level, but which are comparatively insignificant differentially, the visible height above the surrounding tablelands being rarely more than a third, and often less than a tenth, of the height above the sea; and here there are passes across great ranges of which the level is barely distinguishable from that of the surrounding tablelands, so that the traveller may cross a great water-parting without being aware of it, a tussock of grass deciding the course of the waters, whether towards the frontiers of China or of Europe or towards the Indian Ocean.

The elevated mass which forms a bridge between the Thián Shán and the Hindu Caucasus, in the quarter where they approach each other most closely, constitutes the governing geographical and political feature of these regions, and gives birth to all the principal sources of the Oxus. A happy instinct has led the inhabitants to call it the *Bam-i-dúniá*, or Roof of the World; modern European geographers have called it the "heart of Asia," the "central boss of Asia." It is the Tsungling of Chinese writers, the northern Imaus of Ptolemy, the Mountain Parnassus of Aristotle, "the greatest of all that exist toward the winter sunrise." The geographical indications of the *Pūranas*, considered in any but a fabulous light,

point to it as Méru, the scene of the primeval Aryan paradise. Old Parsi traditions point to it as the origin and nucleus of the Aryan migrations. And it is here that the Mohammedan invaders are shown, by their identification of the great rivers with the Gihon and Pison of the Mosaic narrative, to have believed that the terrestrial paradise, the cradle of the human race, was situated.

Few regions can present claims to interest and just curiosity so strong and various as this one. Its past history is interwoven with that of all the great Asiatic conquerors, and its position on the rapidly narrowing borderland between the British and the Russian dominions gives it additional interest at the present time. But its geography is most intricate and complicated, and has long been a fruitful subject of controversy. The region is intersected with mountain ridges and depressed river beds which are alike difficult to cross; its altitude is unfavourable for the growth of cereals, and it mostly lies buried in snow for half the year; it is, moreover, sparsely inhabited, and does not produce sufficient food for the requirements of the inhabitants. It interposes a formidable barrier between eastern and western Turkestan across the ancient highway from Europe to China; and, though this barrier has been repeatedly crossed, the extant narratives of the journeys and descriptions of the routes present only occasional glimmerings of truth amidst a mass of error and confusion, and are at times barely available for sober inquiry; genuine facts of observation have been so mixed up with erroneous information that it has become impossible to reconcile conflicting statements or separate the true from the false. Thus within the last quarter of a century maps have been published by eminent geographers in England and Germany in which the great cities of eastern Turkestan are placed 3° to 4°, or over 200 miles, too far to the west, and the limits of the "heart of Asia" are materially narrowed.

The interest attaching to the region has even led to the fabrication of spurious documents which have darkened the mist already enveloping it, and have betrayed eminent geographers into error and confusion.¹

While geography remained under the spell of these mischievous fictions, research was impeded, and an insurmountable obstacle placed in the way of the true delineation of the region; doubt was even thrown on the accuracy of the work of genuine explorers. But within the last decade the mist in which the "Roof of the World" had so long been enveloped has been largely dispelled by the labours of Russian and British officers, and also by natives of India trained to geographical exploration and employed in connexion with the operations of the Great Trigonometrical Survey of India. In some parts there is still much doubt and uncertainty, but enough is now known to furnish the geographical student with a fairly accurate idea of the general course of the rivers and configuration of the tablelands and mountains.

Two systems of rivers give birth to the sources of the

¹ Thus early in the present century certain papers were lodged in the secret archives of the Russian Foreign Office which purported to give an account of two unpublished records of exploration in this obscure region, one by a German traveller, Georg Ludwig von —, said to have been an employé of the Anglo-Indian Government, the other by a Chinese traveller. They were brought to light in 1861, and excited the curiosity of all who were interested in the geography of this region. A few years afterwards it was discovered that a parallel mass of papers, embodying much of the same peculiar geography and nomenclature, but purporting to be the report of a Russian expedition sent through Central Asia to the frontiers of India, existed in the London Foreign Office. All three documents bear indubitable traces of having been fabricated for sale to the British and the Russian Governments by an acute geographer who, while availing himself of such genuine data as were actually within his reach, did not scruple to draw on his own imagination for the filling up of all blanks.

Oxus, one to the north rising in and around the Alai plateau, the other to the south rising in the Pamir plateaus, of which there are several. The two systems are divided by a great chain of mountains known locally as the Kizil-yart range, but called by Fedchenko (looking from the north) the Trans-Alai range, and by recent Russian surveyors the Peter the Great range; it lies from east to west on the southern border of the Alai plateau, and throws out spurs westwards to Darwáz; its medium height above the sea-level is 18,000 or 19,000 feet, with occasional peaks rising to 25,000 feet. Of the Oxianian affluents to its north and west the principal are the Wákhsh or Súrkh-áb (= the Kizil-su = the Red River), rising in the Alai, and the Múksú and Khing-áb rivers, which join the Wákhsh in the district of Karategin.

The system of southern affluents is, however, the most important of the two politically as well as geographically, comprising as it does the water-partings which define the boundaries between China, Afghanistan, and Bokhara, and all the rivers of what is generally known as the Pamir region. The name Pamir is suggested by Bournouf to have been derived from Úpa-Mérú, meaning the lands "beyond the mountain of Meru"; a later and more probable suggestion, by Major Trotter, is that it is the Khirgiz equivalent of Bámi-dúnia. It means simply an elevated steppe or plateau. By the people of the country it is not applied, as European geographers apply it, to the entire region, which is one of mountains as well as table-lands, but to each of the plateaus with the addition of a distinctive designation. Thus there is the Pamir-Kalán (great), the Pamir-Khúrd (little), the Pamir-Alichúr, the Pamir-Khargoshi (of the hare), the Pamir-Sarez (of the water-parting), and the Pamir-Rangkúl, on which the Rangkúl lake is situated. There is also another, the Pamir-i-Shiva, which, though only recently brought prominently to the notice of European geographers, is of considerable magnitude, elevation, and importance; it lies in that part of Badakhshán which is enclosed to the north and east by the Panjah river, and to the south and west by a spur from the Hindú Kúsh range. This spur is an offshoot from the vicinity of the Tirich Mír peak (25,400 feet) north of Chitral; it lies between Faizabad and Ishkáshim, sinks to 10,900 feet at the Zebak pass, and then again, ascending to higher altitudes, trends to the north-west, and strikes the western spurs of the Kizil-yart range in the Darwáz district; it forms the water-parting between the Kokeha river of southern Badakhshán and the Panjah river. Though a spur from the main range, it is of itself an important range, and has some claim to be regarded as the western boundary of the Pamir table-lands, as it lies immediately over the Shiva Pamir; if the claim be admitted, the breadth of the elevated barrier between the plains of eastern and western Turkestan will be found to be about 250 miles, whereas geographers have hitherto accorded to the Pamir plateau a breadth of only 100 miles. The Panjah river flows downwards through the region where the spurs of this western bounding range meet those of the Kizil-yart range, passing between narrow and precipitous gorges which form a natural gateway to the highlands, though one which in many parts is barely accessible, or has to be quitted altogether for the easier mountain passes on either hand.

The most elevated portion of the highlands occurs on the north-east border, above the plains of Kashgar and Yarkand. Here a chain of mountains, interwoven with the Thián Shán and the Kizil-yart ranges, trends to the east and south-east, and throws up peaks of great height, culminating in Tagharma (25,500 feet); viewed from the plains to the east, it seems to form part of a great chain—the Belút Tágh of Humboldt—which connects the Thián Shán range with the Hindú Kúsh; but it is broken

through by rivers, and terminates over the plains of the Sarikol district. The line of water-parting which constitutes the real connexion between the Thián Shán and the Hindú Kúsh lies more to the west, in hills which, emanating from the Kizil-yart range, pass between the Rangkúl Pamir and the Kizil-yart plain, and then bending southwards strike an angle of the Hindú Kúsh range on the borders of the Sarikol and Kanjút districts; they are probably nowhere of any great altitude above the general level of the table-lands; but they are of importance in that they may be regarded as the natural boundary between the states of eastern Turkestan now subject to China, and those of western Turkestan subject to Afghanistan and Bokhara.

The best known river of the Pamir plateaus is the Panjah,¹ which receives all the other rivers of this region before it enters the plains; above Kila Panjah it has two important affluents, one from the east rising in Kanjút, and probably about 120 miles long, the other from the north-east rising in the lake of the Great Pamir (Wood's Lake Victoria), and about 80 miles long. From the point of junction to Kila-Bár-Panjah is 140 miles; here the united waters of the Sochán and Shákh-dara rivers from the east are received; 33 miles lower down, near Kila Wámar, the Bártang river, also from the east, is received. The upper source of the Bártang is the Ak-sú (white water) river, which rises in the Oikúl or Gazkúl lake of Little Pamir, and, winding round the highlands, passes through the Sarez Pamir, where its name changes to the Murghábi (water fowl), which lower down becomes Bártang (narrow passage). The Aksú-Bártang is probably the longest of the Pamir rivers; its length exceeds 330 miles, while that of the Panjah from the source of its longest affluent down to the Bártang junction is probably under 300 miles; thus it has been claimed as constituting, rather than the Panjah, the proper boundary line between Afghanistan and Bokhara. About 120 miles below Kila Wámar the Panjah debouches into the plains after receiving the Wanjáb river of Darwáz on its right bank, and the Kof (Kufau) river coming from the Shiva Pamir on its left bank. Fifty miles farther on it receives on its right bank the Yákhshú river conveying the waters of a system of valleys lying between the Panjah and the Wákhsh rivers, the courses of which are here nearly parallel; 18 miles onwards it receives (left bank) the Kokcha river of southern Badakhshán, and at this point it loses its individuality and becomes the Amú river; 80 miles to the west the Amú receives the Wákhsh or Súrkh-áb river, when the whole of the waters of the Oxianian highlands are brought together into one channel.

Returning to the highlands, we briefly notice the principal lakes. Chief of all is the Great Kárákúl—the Dragon Lake of Chinese writers; it stands in the Khargoshi Pamir, has an area of about 120 square miles, and an altitude of 12,800 feet; it was long regarded as the source of the Oxus, but has recently been found to have no outlet. The Little Kárákúl and the Búlankúl lakes, areas 15 and 8 square miles, on the Kizil-yart plateau, are probably over 13,000 feet. The Rangkúl lake, area 15 square miles, is 12,800 feet. Wood's Victoria, the lake of the Great Pamir, height 13,900 feet, has an area of 25

¹ The name Panjah is conjectured to be derived from a confluence of five rivers; but more probably it is taken from the well-known fort of the same name, which is situated a little below the junction of the two upper affluents of the river. The fort derives its name either from the circumstance of its being built on five mounds, or from a sacred edifice in the vicinity erected over a stone bearing the supposed impress of the palm and fingers (panjah) of Hazrat Ali, the son-in-law of Mohammed; lower down the river, in Shighnan, there is a fort built over a similar mark, and called the Kila-Bár-Panjah ("the fort over the panjah").

square miles. The Yashil-Kúl, area 16 square miles, height 12,550 feet, is in the Alichúr Pamir, where in 1759 the Chinese troops surprised and defeated the Khwajas of Badakshán. The great Shiva-Kúl, lately visited by Dr Regel, has, according to him, an area exceeding 100 square miles, and an altitude of 11,800 feet, and Wood alludes to it as of considerable magnitude. There are numerous small lakes, of which the most important is the Oikul (13,100 feet), the source of the Ak-sú river, in the Little Pamir.

Hill ranges crop up out of the table-lands in various quarters; their general direction is from north-east to south-west; they form the boundaries between the several Pamirs and the principal water-partings between the valleys. The portion of the Hindú Kúsh range which lies immediately to the south of this region is of very varying altitude, sinking at the Baroghil pass to 12,000 feet, or only 1000 feet above the adjoining table-lands, but rising to heights of 22,600 to 25,400 in peaks to the west of that pass.

In 1872 the Panjah river was adopted by the British and the Russian Governments as the line of boundary between Bokhara and Afghanistan. But rivers which are readily crossed, and pass through valleys both sides of which have much of life in common, rarely serve as boundaries between the people residing on the opposite banks. The Panjah river has been found to divide no less than four states, Wakhán, Shighnán, Roshán, and Darwáz, into two parts each; the first three of these are claimed by Afghanistan and the fourth by Bokhara, by whom they are administered—or at least are attempted to be administered—without regard to the conventional boundary line of the Panjah; presumably, therefore, this line will have to be abandoned for the lines of water-parting along the hill ranges which form the natural boundaries of the several states.

The Pamir plateaus are generally covered with a rich soil which affords very sweet and nourishing grasses, though at too great an altitude for husbandry; there is an unlimited extent of summer pasture lands for the Khirgiz and other nomad tribes and the herdsmen of the surrounding districts. But for the plentiful supply of food for cattle which these regions afford during several months of the year, they could never have been crossed by the great armies and hordes which are said to have passed over them. The cultivable areas are small, and are usually restricted to narrow ledges on the margins of the rivers, which, however, when well cultivated and manured yield rich returns; food stuffs have to be largely obtained from the plains below; mulberry trees thrive well and are much prized, because their unripened berries are ground to flour and form a serviceable article of food.

Wakhán contains some twenty-five scattered villages with about as many houses in each, and a population estimated at 3000 souls. Shighnán and Roshán may at present be regarded as one state, as they are governed by one ruler; the valleys of Sochán-o-Gúnd and Shakh-dara belong to the former, and that of Bártang to the latter (villages, 234; houses, 4477; souls, 22,000). Darwáz is famous for its difficult roads, called "averings," which are carried along the faces of perpendicular precipices, on planks resting on iron bolts driven into the rock; the roads are, however, said to be much improved since the state came under Bokhara. Darwáz extends over the valley of the Khingáb river to the north as well as over the valley of the lower Panjah. It has three ámlakdarates on the Khingáb—Upper Wakhia, Lower Wakhia, and Khulás—and one, Sagridasht, on an affluent of the Khingáb, containing 84 villages with 2458 habitations; it has also three subdivisions on the Panjah—south-eastern or

upper Darwáz terminating at Kila Khúm, south-western Darwáz terminating at Zigor, and lower Darwáz—which contain 31 villages with 896 habitations on the right bank, including those of the Wanjab affluent, and 45 villages with 1379 habitations on the left bank, including those of the Kufau river, which comes from the Shiva Pamir.

Russian officers have found that at the point where the Panjah enters the plains the level is about 1800 feet above the mean sea, or 12,100 feet below the sources of the river in Lake Victoria; 50 miles lower down, at the junction with the Kokcha, where the Panjah merges into the Amú Daria, the height is given as 1000 feet; at Kilif (214 miles) it is 730 feet; and at Chahárjúi (203 miles), 510 feet,—thence the length of the course of the river to the Sea of Aral is somewhat over 500 miles. The Aral is 158 feet above the mean sea-level. Thus the average slope of the Amú is about 14 inches in the mile above and 8 inches below Chahárjúi. The river has been reported to be navigable for steamers up to the junction with the Wakhsh or Surkháb; and in 1878 a Russian steamer ascended it up to Khwája Sáleh, at the junction of the boundaries of Bokhara and Afghanistan.

The testimony of antiquity is almost unanimous in representing the Oxus as having once flowed into the Caspian Sea. Herodotus asserts that in his day the Jaxartes also entered the Caspian, but this statement is so highly improbable that it throws much doubt on his geographical accuracy as regards these regions. Greek historians also mention a river Ochus to the south of the Oxus, flowing towards the Caspian, into which it is supposed to have fallen either directly or after joining a branch of the Oxus; Strabo says that both this river and the Oxus were crossed by Alexander in marching from Samarkand to Merv. Maps recently published by both English and Russian geographers show the supposed ancient beds of the two rivers in the Turkomani deserts, the Oxus flowing southwards from the province of Khiva and joining the Caspian below the Balkhan Bay, the Ochus flowing from east to west in a lower latitude, and possibly striking the Oxus before it turns towards the Caspian. The first is called the old Oxus in English and the Uzboi in Russian maps; the second is called the Ongúz in Russian and the Chahárjúi in English maps, and is sometimes drawn as if it had been a bifurcation from the Oxus at some point near Chahárjúi. But the recent explorations of the Russian engineer Lessar have shown that what hitherto has been taken for the dry bed of the Ochus is not the bed of a river, but merely a natural furrow between sand-hills, that it cannot be the continuation either of a river from the east bifurcating from the upper Oxus or of the Tejend river from the south as has been supposed, and also that it does not join the Uzboi, but ceases at a distance of fully 60 miles from the ancient bed of that river. Thus the bed of the Ochus has still to be discovered.

As regards the Oxus, some eminent geographers are of opinion that it has disembogued into the Aral Sea from time immemorial as at this day; other geographers of equal weight have asserted that the Aral has fluctuated at different periods of history between the condition of a great inland sea and that of a reedy marsh, according to the varying course of its two feeders the Jaxartes and the Oxus. Now the position and height of the head of the delta of the Oxus relatively to the Aral and the Caspian Seas are such that comparatively slight changes in the relations of the river to its banks and bed would readily divert its course from one sea to the other. Khwája-ili, at the head of the delta, is 217 feet above the mean sea; the Aral is 158 feet above and the Caspian 85 feet below the mean sea. The length of channel from Khwája-ili to the Aral is 110 miles, with a fall of 59 feet, or about 6 inches

in the mile; the length of channel from the town of Urganj near Khwāja-ili to the Caspian is about 600 miles, with a fall of (say) 300 feet, or also about 6 inches to the mile. Thus the degree of slope is much the same in both directions, and consequently the blocking of the channel towards one sea—either naturally as by an accidental deposit of silt, or artificially by the construction of dams for the diversion of the river—would most probably be soon followed by a flow of water towards the other sea. The writings of Strabo, Pliny, and Ptolemy indicate that from 500 B.C. to 600 A.D. the Oxus flowed into the Caspian. About 605 a great change is said to have taken place, which turned the full stream of the Oxus into the Aral. In subsequent years dams were constructed for irrigation purposes which prevented the stream from reverting to the Caspian. In 1221, during the siege of Urganj by the Turks, the dams were purposely broken down, and the stream was allowed to find its way back to the Uzboi, which had been deserted for several centuries. But by 1643 the Oxus is said to have been again debouching into the Aral, as at the present time.

OXYGEN. See CHEMISTRY, vol. v. p. 479 sq.

OXYHYDROGEN FLAME. Hydrogen gas readily burns in oxygen or air with formation of vapour of water. The quantity of heat evolved, according to Thomsen, amounts to 34116 units for every unit of weight of hydrogen burned, which means that, supposing the two gases were originally at the temperature of, say, 0° C., to bring the hot steam produced into the condition of liquid water of 0° C., we must withdraw from it a quantity of heat equal to that necessary to raise 34116 units of weight of liquid water from 0° to 1° C. This heat-disturbance is quite independent of the particular mode in which the process is conducted; it is the same, for instance, whether pure oxygen or air be used as a reagent, being neither more or less than the balance of energy between 1 part of hydrogen plus 8 parts of oxygen on the one hand and 9 parts of liquid water on the other. The temperature of the flame, on the other hand, does depend on the circumstances under which the process takes place. It obviously attains its maximum in the case of the firing of pure "oxyhydrogen" gas (we mean a mixture of hydrogen with exactly half its volume of oxygen, the quantity it combines with in becoming water). It becomes less when the "oxyhydrogen" is mixed with excess of one or the other of the two co-reagents or an inert gas such as nitrogen, because in any such case the same amount of heat spreads over a larger quantity of matter. To calculate the "calorific effect," we may assume that, in any case, for every 1 grain of hydrogen burned $9 \times 637 = 5733$ units of heat are spent in the conversion of the 9 grains of liquid water (theoretically imagined to be) produced into steam of 100° C., and that only the rest of $34116 - 5733 = 28383$ units is available for heating up the products of combustion. Now the specific heat of steam (from 120 to 220° C.) has been found to be equal to 0.4805 units; hence, on the basis of certain obvious (but bold) assumptions, in the firing of 9 grains of oxyhydrogen gas, as every 9×0.4805 units of heat correspond to an

increase of 1° C. in temperature, the temperature of the flame should be by $28383 \div 9$ times 0.4805 (or 6664° C.) higher than 100°, or equal to 6664° C.

Let us now consider the case of 1 grain of hydrogen mixed with the quantity of air containing 8 grains of oxygen, i.e., the case of 1 grain hydrogen mixed with 8 grains of oxygen and 26.78 grains of nitrogen. Here the temperature t of the flame will be governed by the equation, $28383 = (t - 100) \times 9 \times 0.4805 + t \times 26.78 \times 0.2438$, —the last coefficient being the specific heat of nitrogen. Thus $t = 2655°$ C., as against the 6664° obtained with pure oxygen. But one of our tacit assumptions is obviously untenable; ready-made vapour of water, if subjected to even the less of the two temperatures, would suffer far-going dissociation involving an absorption of heat and consequently a depression of temperature. Hence supposing a mass of oxyhydrogen gas to have been kindled, as soon as the temperature has passed a certain point the progress of the process of combination will be checked by that of the corresponding dissociation, which latter, as the combustion progresses, will go on at a greater and greater rate, or until it just compensates the effect of the process of combination. That is to say, as soon as through the combustion of a certain fraction of the oxyhydrogen a certain temperature (far less than 6664° C.) has been produced, there is no further increase of temperature, and the uncombined gas-residue would remain unchanged, if it were not for the practically unavoidable loss of heat by radiation and conduction, which enables it to become water.

This interesting matter was inquired into experimentally by Bunsen. He exploded fulminating gas mixtures in a close vessel constructed so that the maximum tension attained by the gas-contents during the combustion could be observed and measured, and from this value and the analytical data he calculated the maximum temperature and the proportion of gas-mixture which had assumed the form of a chemical compound at the moment when the maximum temperature prevailed. He found (a) for the case of pure oxyhydrogen gas—maximum temperature = 2844° C., fraction of burned gas at the respective moment 0.337; (b) for the case of a mixture of 1 volume of oxygen, 2 volumes of hydrogen, and 3.78 of nitrogen (very nearly the same as one volume of oxygen in the shape of air)—maximum temperature = 2024° C., burned gas corresponding = 0.547 of the potential water. Hence we see that the temperature of a pure oxyhydrogen flame is not so much above that produced in the combustion of hydrogen by air as we should have concluded from our calculations. But, whatever the exact numerical value may be, it has long been known that the calorific effect of an oxyhydrogen flame exceeds that of any furnace, and the effect has long been put to practical use in the oxyhydrogen lamp.

The most efficient form of this instrument is that which was given to it long ago by Newman, who pumps pure oxyhydrogen into a strong copper reservoir under 2 to 3 atmospheres' pressure, lets the gas stream out of a narrow nozzle, and kindles it. The nozzle in the original apparatus consisted of a glass tube about 4 inches long and of $\frac{1}{8}$ -inch bore. Newman worked long with this apparatus without any accident occurring; but when he once came to substitute a tube of $\frac{1}{8}$ -inch bore the flame travelled back and the apparatus burst like a bomb-shell. Of the many safety arrangements suggested we will mention only that of Hare, who inserts a plug of (microscopically) porous copper between reservoir and nozzle, and forces the gas through this plug by applying a sufficient pressure. The plug of course acts on the principle of the Davy lamp, and offers protection as long as it has not got heated. But it may get hot without the operator noticing it, and probably has done so occasionally. At any rate, the use of ready mixed oxyhydrogen has long been given up in favour of the very oldest form of lamp, which was invented, before Newman's, by Hare. Hare's lamp, in all essential points, is our present gas-blowpipe as used for glass-blowing. The fuel (hydrogen, or coal-gas, which works as well) streams out of the annular space between two co-

axial tubes, while oxygen is being blown into the hydrogen flame through the central tube. The calorific effect of a Hare's lamp is of course less than that of Newman's, but still exceeds that of any ordinary fire; it is inferior only to that of the electric arc. Platinum fuses in the flame with facility, and silica and alumina (though absolutely infusible in the metallurgist's sense) run into viscid glasses. Notwithstanding its enormous temperature, an oxyhydrogen flame emits only a feeble light; but this arises only from the absence in it of good radiators. We need only communicate its high temperature to some non-volatile and infusible solid, and a considerable portion of the heat is converted into radiant energy which streams forth as a dazzling white light. In the oxyhydrogen lamp as used in connexion with the magic lantern or the "solar" microscope, a bit of lime fixed to an upright wire serves as a radiator. Magnesia is said to be better, and it has been said that zirconia excels both. Now that the electric light is coming into general use, the oxyhydrogen lamp as a source of light will soon be a thing of the past. It is sure, however, to survive as a powerful producer of intense heat, and not for scientific purposes only. Thanks to the pioneering activity of Deville and Debray, it has found its way into the platinum works, and will hold its ground there until it may be superseded by the electric arc. The soldering together of the several parts of a platinum apparatus is now done "autogenically" (i.e., without the interposition of any foreign "solder") by means of the oxyhydrogen blowpipe, — a great improvement over the old process of soldering with gold, which stripped the platinum-work of its most valuable character, namely, its relative infusibility. (W. D.)

OXYNOTUS, the name of a genus of birds now ascertained to be peculiar to two of the Mascarene Islands—Mauritius and Réunion (Bourbon)—where the name of *Cuisinier* is applied to them, and remarkable for the fact, almost if not quite unique in Ornithology,¹ that, while the males of both species are almost identical in appearance, the females are wholly unlike each other. Though the habits of the Mauritian species, *O. rufiventer*, have been very fairly observed, there seems to be nothing in them that might account for the peculiarity. The genus *Oxynotus* is generally placed in the group known as *Campophagidæ*, most or all of which are distinguished from the *Laniidæ* (to which they seem nearly allied) by the feathers on the lower part of the back and on the rump having the basal portion of the shaft very stiff and the distal portion soft—a structure which makes that part of the body, on being touched by the finger, feel as though it were beset with blunt prickles. Hence the name of the genus conferred by Swainson, and intended to signify "prickly back." The males, which look rather like miniature Grey Shrikes (*Lanius excubitor* and others), are—except on close examination, when some slight differences of build and shade become discernible—quite indistinguishable; but the female of the one species has a reddish-brown back, and is bright ferruginous beneath, while the female of the other species is dull white beneath, transversely barred, as are the females of some Shrikes, with brown. Both sexes of each species, and the young of one of them, are described and figured in *The Ibis* for 1866 (pp. 275–280, pls. vii. and viii.). (A. N.)

OYER AND TERMINER, in English law, is one of the commissions by which a judge of assize sits (see **ASSIZE**). By the commission of oyer and terminer the commissioners (in practice the judges of assize, though other persons are named with them in the commission) are commanded to make diligent inquiry into all treasons, felonies, and misdemeanours whatever committed in the counties specified in the commission, and to hear and determine the same according to law. The inquiry is by means of the grand jury; after the grand jury has found the bills submitted to it, the commissioners proceed to hear and determine (oyer and terminer) by means of the petty jury. The words oyer and terminer are also used to

denote the court which has jurisdiction to try offences within the limits to which the commission of oyer and terminer extends.

By 7 Anne c. 21 the crown has power to issue commissions of oyer and terminer in Scotland for the trial of treason and misprision of treason. Three of the lords of justiciary must be in any such commission. An indictment for either of the offences mentioned may be removed by certiorari from the court of oyer and terminer into the court of justiciary.

In the United States oyer and terminer is the name given to courts of criminal jurisdiction in some States, e.g., New York, New Jersey, Pennsylvania, and Georgia.

OYSTER. The use of this name in the vernacular is equivalent to that of *Ostrea* in zoological nomenclature; there are no genera so similar to *Ostrea* as to be confounded with it in ordinary language. *Ostrea* is a genus of Lamellibranch Molluscs, belonging to the third order *Monomya*, the valves of its shell being closed by a single large adductor muscle. The degeneration produced by sedentary habits in all lamellibranchs has in the oyster reached its most advanced stage. The muscular projection of the ventral surface called the foot, whose various modifications characterize the different classes of *Mollusca*, is almost entirely aborted. The two valves of the shell are unequal in size, and of different shape; the left valve is larger, thicker, and more convex, and on it the animal rests in its natural state. This valve, in the young oyster, is attached to some object on the sea-bottom; in the adult it is sometimes attached, sometimes free. The right valve is flat, and smaller and thinner than the left. In a corresponding manner the right side of the animal's body is somewhat less developed than the left, and to this extent there is a departure from the bilateral symmetry characteristic of lamellibranchs.

The organization of the oyster, as compared with that of a typical lamellibranch such as *Anodon* (see **MOLLUSCA**), is brought about by the reduction of the anterior part of the body accompanying the loss of the anterior adductor, and the enlargement of the posterior region. The pedal ganglia and auditory organs have disappeared with the foot, at all events have never been detected; the labial ganglia are very minute, while the parieto-splanchnic are well developed, and constitute the principal part of the nervous system.

According to Spengel the pair of ganglia near the mouth, variously called labial or cerebral, represent the cerebral pair and pleural pair of a gastropod combined, and the parieto-splanchnic pair correspond to the visceral ganglia, the commissure which connects them with the cerebro-pleural representing the visceral commissure. Each of the visceral ganglia is connected or combined with an olfactory ganglion underlying an area of specialized epithelium, which constitutes the olfactory organ, the osphradium. This view (which, it may be pointed out, differs from that given under **MOLLUSCA**) alone admits of a satisfactory comparison between the lamellibranch and the gastropod; if the parieto-splanchnic were merely an olfactory ganglion its connexion by a commissure with its fellow would be an abnormality, and the olfactory ganglion in the lamellibranch would innervate the gills, adductor muscle, mantle, and rectum, parts which in gastropods are innervated from the visceral ganglia. The heart and pericardial chamber in the oyster lie along the anterior face of the adductor muscle, almost perpendicular to the direction of the gills, with which in *Anodon* they are parallel. In *Anodon* and the majority of lamellibranchs the ventricle surrounds the intestine; in the oyster the two are quite independent, the intestine passing above the pericardium. The renal organs of the oyster were discovered by Høek to agree in their morphological relations with those of other lamellibranchs.

¹ The only other instance cited by Darwin (*Descent of Man*, ii. pp. 192, 193) is that of two species of *Paradisæa*; but therein the males differ from one another to a far greater degree than do those of *Oxynotus*.

The generative organs of the oyster consist of a system of branching cavities on each side of the body lying immediately beneath the surface. All the cavities of a side are ultimately in communication with an efferent duct opening on the surface of the body a little above the line of attachment of the gills. The genital opening on each side is situated in a depression of the surface into which the renal organ also opens. The genital products are derived from the cells which line the cavities of the genital organs. The researches of Hoek have shown that in the same oyster the genital organs at one time produce ova, at another spermatozoa, and that consequently the oyster does not fertilize itself. How many times the alternation of sex may take place in a season is not known. It must be borne in mind that in what follows the species of the European coasts, *Ostrea edulis*, is under consideration. The ova are fertilized in the genital duct, and before their escape have undergone the earliest stages of segmentation. After escaping from the genital aperture they find their way into the infra-branchial part of the mantle cavity of the parent, probably by passing through the supra-branchial chamber to the posterior extremity of the gills, and then being conducted by the inhalent current caused by the cilia of the gills into the infra-branchial chamber. In the latter they accumulate, being held together and fastened to the gills by a white viscid secretion. The mass of ova thus contained in the oyster is spoken of by oyster fishers as "white spat," and an oyster containing them is said to be "sick." While in this position the ova go through the series of changes figured in vol. xvi. p. 638 (fig. 6). At the end of a fortnight the white spat has become dark-coloured from the appearance of coloured patches in the developing embryos. The embryos having then reached the condition of "trochospheres" escape from the mantle cavity and swim about freely near the surface of the water among the multitude of other creatures, larval and adult, which swarm there. The larvæ are extremely minute, about $\frac{1}{150}$ inch long and of glassy transparency, except in one or two spots which are dark brown. From the trochosphere stage the free larvæ pass into that of "veligers." How long they remain free is not known; Prof. Huxley kept them in a glass vessel in this condition for a week. Ultimately they sink to the bottom and fix themselves to shells, stones, or other objects, and rapidly take on the appearance of minute oysters, forming white disks $\frac{1}{10}$ inch in diameter. The appearance of these minute oysters constitutes what the fishermen call a "fall of spat." The experiment by which Hoek conclusively proved the change of sex in the oyster was as follows. In an oyster containing white spat microscopic examination of the genital organs shows nothing but a few unexpelled ova. An oyster in this condition was kept in an aquarium by itself for a fortnight, and after that period its genital organs were found to contain multitudes of spermatozoa in all stages of development.

The breeding season of the European oyster lasts from May to September. The rate of growth of the young oyster is, roughly speaking, an inch of diameter in a year, but after it has attained a breadth of 3 inches its growth is much slower. Prof. Möbins is of opinion that oysters over twenty years of age are rare, and that most of the adult Schleswig oysters are seven to ten years old.

The development of the American oyster, *O. virginiana*, and of the Portuguese oyster, *O. angulata*, is very similar to that of *O. edulis*, except that there is no period of incubation within the mantle cavity of the parent in the case of these two species. Hence it is that so-called artificial fertilization is possible; that is to say, the fertilization may be allowed to take place in a tank or aquarium in which the conditions are under control. But if it is possible to procure a supply of spat from the American oyster by keeping the swarms of larvæ in confinement, it ought to be pos-

sible in the case of the European oyster. All that would be necessary would be to take a number of mature oysters containing white spat and lay them down in tanks till the larvæ escape. This would be merely carrying oyster culture a step further back, and instead of collecting the newly fixed oysters, to obtain the free larvæ in numbers and so insure a fall of spat independently of the uncertainty of natural conditions.

Natural beds of oyster occur on stony and shelly bottoms at depths varying from 3 to 20 fathoms. In nature the beds are liable to variations, and, although Prof. Huxley is somewhat sceptical on this point, it seems that they are easily brought into an unproductive condition by over-dredging. Oysters do not flourish in water containing less than 3 per cent. salt; and hence they are absent from the Baltic. The chief enemies of oysters are the dog-whelk, *Purpura lapillus*, and the whelk-tingle, *Murex erinaceus*, which bore through the shells. Starfishes swallow oysters whole. *Cliona*, the boring sponge, destroys the shells and so injures the oyster; the boring annelid *Leucodora* also excavates the shell.

The wandering life of the larvæ makes it uncertain whether any of the progeny of a given oyster-bed will settle within its area and so keep up its numbers. It is known from the history of the Linnfjord beds that the larvæ may settle 5 miles from their place of birth.

The genus *Ostrea* has a world-wide distribution, in tropical and temperate seas; seventy species have been distinguished. Its nearest allies are *Anomia* among living forms, *Gryphæa* among fossils. For the so-called Pearl-Oyster see PEARL. (J. T. C.).

Oyster Industry.

The oyster industry of the world is seated chiefly in the United States and France. Great Britain has still a few natural beds remaining, and a number of well-conducted establishments for oyster culture. Canada, Holland, Italy, Germany, Belgium, Spain, Portugal, Denmark, Norway, and Russia have also oyster industries, which are comparatively insignificant, and in the case of the two countries last named, hardly worthy of consideration in a statistical statement. Recent and accurate statistics are lacking except in two or three instances. A brief review by countries in the order of their importance is here presented.

United States.—This is by far the most extensive of the fishery industries of the country, yielding products three times as valuable as those of the cod fishery and six times those of the whale fishery. In 1880 it employed 52,805 persons, and yielded 22,195,370 bushels, worth to the fishermen \$9,034,861. On 13,047,922 bushels there is a rise of value in passing from producers to market, which amounts to \$4,368,991, and results either from replanting or from packing in tin cans. The value of the capital invested in the industry is returned as \$10,583,295. There are employed 4155 vessels, valued at \$3,528,700, and 11,930 boats. The actual fishermen number 38,249, the shoremen 14,556. Fully 80 per cent. of the total yield is obtained from the waters of Chesapeake Bay.¹

France.—The oyster industry of France employed in 1881 29,431 men, women, and children in the parks, beds, and preserves. The number of such establishments upon the public domain was 32,364, with an area of 19,891 acres, and 970 establishments upon private property, with an area of 926 acres. From these 374,985,770 oysters were dredged during the season of 1880-81, from September 1 to June 15, worth 2,061,753 francs, while the total number of oysters disposed of during this period amounted to 680,372,750, worth 17,951,114 francs. This total includes the oysters dredged in the sea as well as those gathered from the artificial breeding-grounds or parks.

Great Britain.—A brief discussion of the British oyster fisheries may be found under FISHERIES, vol. ix. p. 265. A recent estimate² gives the total value of the oysters obtained from British seas at £2,000,000, worth 2d. each, or, perhaps, 240,000,000 in all. An extensive import trade is carried on with the United States, which has grown up within the past decade, as is shown by the following statement³ of import values:—1874, \$41,419;

¹ The statistical summary prepared for the Fisheries Division of the Tenth Census by Mr Ernest Ingersoll shows the details, by States, of the oyster industry of the whole country.

² Bonchon-Brandely stated in 1877 that the industry of oyster culture in France supported a maritime population of 200,000. It is difficult to reconcile this statement with the official statistics.

³ That of Mr James G. Bertram in *Brit. Quart. Rev.* for January 1883.

⁴ Derived from the records of the United States Treasury.

1875, \$38,733; 1876, \$99,012; 1877, \$21,301; 1878, \$254,815; 1879, \$306,941; 1880, \$366,403; 1881, \$414,184; 1882, \$372,111; 1883, \$371,497.

Holland.—Since 1870 the beds in the province of Zeeland have been greatly enriched by careful methods of culture and protection; and in 1881 the product amounted to 21,600,000 oysters, worth about 1,350,000 guilders.¹ About half the product of the Dutch oyster fishery is sent to England, and large quantities of the young oysters are laid down to fatten in the English oyster-beds.

Germany.—Germany has a small oyster industry on the west coast of Schleswig-Holstein.² According to Lindeman, the largest annual product of these beds has rarely exceeded 4,000,000 oysters. From 1859 to 1879 they were rented to a company in Flensburg for an annual payment of 80,000 marks. In 1879 the lease was transferred to a Hamburg firm, who paid for that year 163,000 marks.

Italy.—Oyster culture in Italy, according to Bouchon-Brandely,³ is carried on in only one locality, Taranto, though small quantities of natives are obtained from the Gulfs of Genoa and Naples, from the coasts of the Adriatic, and from the ponds of Corsica. The sea of Taranto is leased by the city to a company that pays an annual rent of 38,000 francs. The product of this body of water is estimated variously at from 6,000,000 to 10,000,000 oysters yearly. The entire annual product of Italy does not probably exceed 20,000,000 oysters, valued at about £40,000.

Belgium.—Oyster culture is carried on upon a small scale at Ostend. There being no native beds, the seed oysters are brought from England, a practice which, according to Lindeman, originated as early as 1765. The product probably does not exceed 10,000 bushels a year, and is consumed chiefly in Germany and Holland, though there is a small exportation.

Spain.—According to a recent report by Don Francisco Sola, there are forty-three establishments in Spain for the cultivation of oysters and other shell-fisheries. The amount of oysters annually produced is estimated at 167,673 kilogrammes (368,880 lb), valued at 50,296 pesetas (about £2000). These are exported to Algiers, France, Portugal, and South America.

Portugal.—There appear to be no statistics for Portugal. Considerable quantities of seed oysters are planted at present in the Bay of Arcachon and elsewhere in France, and in England the Anglo-Portuguese oyster is apparently growing in favour.

Denmark.—The very insignificant oyster fishery of Denmark has its seat chiefly in the Liimfjord and at Frederikshaven. All the oyster-beds, being Government property, are carefully protected by law. Statistics for late years are not accessible. In 1847 the product of the Frederikshaven beds was about 200,000 oysters; but the yield of late years has been much smaller. The Liimfjord beds were discovered about 1851. From 1876 to 1881 the Danish oyster fisheries were leased to a firm in Hamburg, which paid 240,000 kroner (£13,000) as yearly rental.

Russia.—Grimm states that a species of oys. *et*, *Ostrea adriatica*, is found in considerable numbers along the coast of the Crimea, and is the object of a considerable trade. Oysters brought from Theodosia cost in St Petersburg about 3s. sterling the score.

Norway.—The average value of the yield for the five years ending 1881 was 7600 kroner (£420). The quantity produced in 1881 was 267 hectolitres (735 bushels), valued at 7000 kroner (£390). The industry is seated for the most part in the districts of southern Trondhjem and Jarlsberg, the product of the latter province being nearly half that of all Norway.

Subjoined is a rough estimate of the total number of oysters obtained annually from the sea (North America, 5,572,000,000; Europe, 2,331,200,000):—

| | | | |
|----------------------------------|---------------|---------------|-----------|
| United States ⁵ | 5,550,000,000 | Germany..... | 4,000,000 |
| Canada..... | 22,000,000 | Belgium..... | 2,500,000 |
| | | Spain..... | 1,000,000 |
| France..... | 680,400,000 | Portugal..... | 800,000 |
| Great Britain..... | 1,600,000,000 | Denmark..... | 200,000 |

⁵ On basis of 250 oysters to the bushel. The number varies from 150 to 400.

The oyster industry is rapidly passing from the hands of the fisherman into those of the oyster culturist. The oyster being sedentary, except for a few days in the earliest stages of its existence, is easily exterminated in any given locality; since, although it may not be possible for the fishermen to rake up from the bottom every individual, wholesale methods of capture soon result in covering up or otherwise destroying the oyster banks or reefs, as the communities of oysters are technically termed. The main difference between the oyster industry of America and that of Europe lies in the fact that in Europe the native beds have long since been practically destroyed, perhaps not more than 6 or 7 per cent. of the oysters of Europe passing from the native beds directly into the hands of the consumer. It is probable that 60 to 75 per cent. are reared from the spat in artificial parks, the remainder having been laid down for a time to increase in size and flavour in shoal waters along the coasts. In the United States, on the other hand, from 30 to 40 per cent. are carried from the native beds directly to market. The oyster fishery is everywhere, except in localities where the natural beds are nearly exhausted, carried on in the most reckless manner, and in all directions oyster grounds are becoming deteriorated, and in some cases have been entirely destroyed. It remains to be seen whether the Government of the States will regulate the oyster fishery before it is too late, or will permit the destruction of these most important reservoirs of food. At present the oyster is one of the cheapest articles of diet in the United States; and, though it can hardly be expected that the price of American oysters will always remain so low, still, taking into consideration the great wealth of the natural beds along the entire Atlantic coast, it seems certain that a moderate amount of protection will keep the price of seed oysters far below European rates, and that the immense stretches of submerged land especially suited for oyster planting may be utilized and made to produce an abundant harvest at much less cost than that which accompanies the complicated system of culture in vogue in France and Holland.

The most elaborate system of oyster culture is that practised at Arcachon and elsewhere in France, and; to a limited extent since 1865, on the island of Hayling, near Portsmouth, in England. The young oysters, having been collected in the breeding season upon tiles or hurdles, are laid down in artificial ponds, or in troughs, where the water is supplied to them at the discretion of their proprietors. The oysters are thus kept under control like garden plants from the time they are laid down to that of delivery to commercial control. The numerous modifications of this system are discussed in various recent reports.⁶

The simplest form of oyster culture is the preservation of the natural oyster-beds. Upon this, in fact, depends the whole future of the industry, since it is not probable that any system of artificial breeding can be devised which will render it possible to keep up a supply without at least occasional recourse to seed oysters produced under natural conditions. It is the opinion of almost all who have studied the subject that any natural bed may in time be destroyed by overfishing (perhaps not by removing all the oysters, but by breaking up the colonies, and delivering over the territory which they once occupied to other kinds of animals), by burying the breeding oysters, by covering

⁶ See especially the following English parliamentary papers:—*Report of the Commissioners appointed to inquire into the Present State of the Oyster Fisheries of France, England, and Ireland, 1870*; *Report of the Select Committee appointed to inquire what are the Reasons for the Present Scarcity of Oysters, &c., 1876*; *Report on the Principal Oyster Fisheries of France, with a short description of the System of Oyster Culture pursued at some of the most important places, &c., 1878*.

up the projections suitable for the reception of spat, and by breaking down, through the action of heavy dredges, the ridges which are especially fitted to be seats of the colonies.¹ The immense oyster-beds in Pocomoke Sound, Maryland, have practically been destroyed by over-dredging, and many of the other beds of the United States are seriously damaged. The same is doubtless true of all the beds of Europe. It has also been demonstrated that under proper restriction great quantities of mature oysters, and seed oysters as well, may be taken from any region of natural oyster-beds without injurious effects. Parallel cases in agriculture and forestry will occur to every one. Möbius, in his most admirable essay *Die Auster und Die Austernwirtschaft*, has pointed out the proper means of preserving natural beds, declaring that, if the average profit from a bed of oysters is to remain permanently the same, a sufficient number of mother oysters must be left in it, so as not to diminish the capacity of maturing. He further shows that the productive capacity of a bed can only be maintained in one of two ways:—(1) by diminishing the causes which destroy the young oysters, in which case the number of breeding oysters may safely be decreased; this, however, is practicable only under such favourable conditions as occur at Arcachon, where the beds may be kept under the constant control of the oyster-culturist; (2) by regulating the fishing on the natural beds in such a manner as to make them produce permanently the highest possible average quantity of oysters. Since the annual increase of half-grown oysters is estimated by him to be four hundred and twenty-one to every thousand full-grown oysters, he claims that not more than 42 per cent. of these latter ought to be taken from a bed during a year.

The Schleswig-Holstein oyster-beds are the property of the state, and are leased to a company whose interest it is to preserve their productiveness. The French beds are also kept under Government control. Not so the beds of Great Britain and America, which are as a general rule open to all comers,² except when some close-time regulation is in force. Prof. Huxley has illustrated the futility of "close-time" in his remark that the prohibition of taking oysters from an oyster-bed during four months of the year is not the slightest security against its being stripped clean during the other eight months. "Suppose," he continues, "that in a country infested by wolves, you have a flock of sheep, keeping the wolves off during the lambing season will not afford much protection if you withdraw shepherd and dogs during the rest of the year." The old close-time laws were abolished in England in 1866, and returned to in 1876, but no results can be traced to the action of parliament in either case. Prof. Huxley's conclusions as regards the future of the oyster industry in Great Britain are doubtless just as applicable to other countries,—that the only hope for the oyster consumer lies in the encouragement of oyster-culture, and in the development of some means of breeding oysters under such conditions that the spat shall be safely deposited. Oyster culture can evidently be carried on only by private enterprise, and the problem for legislation to solve is how

to give such rights of property upon those shores which are favourable to oyster culture as may encourage competent persons to invest their money in that undertaking. Such property right should undoubtedly be extended to natural beds, or else an area of natural spawning territory should be kept under constant control and surveillance by Government, for the purpose of maintaining an adequate supply of seed oysters.

The existing legislation in the United States is thus admirably summarized by Lieutenant Francis Winslow:³—

"The fishery is regulated by the laws of the various States, the Federal Government exercising no control, and consequently the conditions under which the pursuit is followed are many and various. At the present time the laws relating to the oyster fishery may be said to be based upon one of two general principles. The first, the basis for the regulations of most of the States, considers the oyster-beds to be inalienable common property. Laws based upon this principle are generally of a protective nature, and are in reality regulations of the State, made by it in its capacity of guardian of the common property. The second principle assumes the right of the State to dispose of the area at the bottom of its rivers, harbours, and estuaries, and, having disposed of it, to consider the lessee or owner as alone responsible for the success or failure of his enterprises, and the State in no way called upon to afford him other assistance than protection in legitimate rights. In general terms, under the first principle the beds are held in common; under the second, in severalty. But one State permits the pre-emption of an unlimited tract of bottom, and the holding of it in fee—the State of Connecticut. Rhode Island leases her ground for a term of years, at \$10 per acre; but the person holding an area has no legal power of disposing of it beyond the limits of the lease. Massachusetts, New York, New Jersey, Maryland, and Virginia all permit pre-emption of small tracts by individuals for indefinite periods, and on the coast of Long Island the various towns along the shore lease tracts of considerable extent to private cultivators.

"Various restrictions are also placed upon the time and manner of conducting the fisheries. Some of the States, notably Virginia, prohibit entirely the use of the dredge or scrape; others, notably New Jersey, prohibit such use in some localities, and permit it in others. All the States, with one exception, prohibit the use of steam vessels or machinery, or fishing by other than their own inhabitants. Connecticut again forms the exception, and quite a large fleet of steam dredging vessels are employed on her beds.

"The laws of the various States have several common features. All general fishing is suspended during the summer months. No night fishing is permitted. No steamers are allowed to be used. No proprietary rights to particular areas are given beyond the right to 'plant' a limited number of oysters on bottoms adjoining land owned by the planter, and peace officers and local authorities are charged with execution of laws relating to the fishery. In a few States or localities licences are required to be obtained for each fishing vessel; and in one State, Maryland, a regular police force and fleet of vessels are maintained to support the law. These regulations are easily evaded, except those relating to the steamers and pre-emption of ground. Naturally, no one will put down oysters without being able to protect them; and steamers are too readily detected to make their illegal employment possible. In Connecticut and Rhode Island, the beds being virtually private property, there is no restriction of the fishery, except that it shall not be conducted at night."

The method of gathering oysters is simple, and much the same in all parts of the world, the implements in use being nippers or tongs with long handles, rakes, which are simply many-pronged nippers, and dredges. The subjoined account of the American method is abridged from that of Lieutenant Winslow:—

The character of the vessel or boat used depends in a measure upon the means of the fisherman and the constancy of his employment, and is also influenced by the character of the oyster ground, its location, and the laws governing the fishing. The last-named condition also decides the implement to be used; when permitted, it is the dredge—either the enormous one employed by the steamers, the smaller toothed rake-dredge, or smooth-scrape. When dredging is prohibited, the tongs, or nippers, with two handles, sometimes 30 feet long, are used. The dredges are usually worked by an apparatus termed a "winder," many forms of which are employed, the best and most recent form being so designed that if, while reeling in, the dredge should "hang," that is, become immovably fixed by some obstruction on the bottom, the drum is at once automatically thrown out of gearing, and the dredge-rope allowed to run out. Small craft use a more simple and less expensive description of winch, and frequently haul in by hand, while the steam dredgers have powerful machinery adapted for this special purpose. The number of men employed varies with the size of the craft; two, three, and four men are sufficient on board the smaller dredgers, while the larger vary ten and twelve.

While a great many oysters are transported in the shell to markets distant from the seaboard, the largest part of the inland consumption is of "opened" or "shucked" oysters, and nearly every oyster dealer along the coast employs a larger or smaller number of persons to open the oysters and pack and ship the meats. Some of these establishments are small, having as few as half a dozen people engaged; others are large buildings or sheds, and employ hundreds of "shuckers." After having been removed from their shells and thoroughly washed, the oysters thus dealt with are transferred either to small cans, holding a quart of oysters, or to barrels, kegs, or tubs; when packed in tubs, kegs, or barrels, they go in bulk, with a large piece of ice; when packed in the tin cans, the cans are arranged in two rows inside of a long box, a vacant space being left in the centre, between the rows, in which is placed a large block of ice. The cans are carefully soldered up before packing, and together with the ice are laid in sawdust. Oysters packed in this way can, in cool weather, be kept a week or more, and sent across the continent, or to the remote western towns.

The steaming process is that by which the "cove" oysters are prepared. The term "cove" is applied to oysters put up in cans, hermetically sealed, and intended to be preserved an indefinite time. The trade in cove is confined principally to the Chesapeake region, and the process of preparing them is as follows. The oysters, usually the smaller sizes, are taken from the vessels and placed in cans of iron frame-work, 6 or 8 feet long. These cans run on a light iron track, which is laid from the wharf through the "steam-chest" or "steam-box" to the shucking shed. As soon as a can is filled with oysters (in the shell) it is run into the steam-chest, a rectangular oak box, 15 to 20 feet long, lined with sheet iron and fitted with appliances for turning in steam; the doors, which work vertically and shut closely, are then let down, the steam admitted, and the oysters

¹ Even Prof. Huxley, the most ardent of all opponents of fishery legislation, while denying that oyster-beds have been permanently annihilated by dredging, practically admits that a bed may be reduced to such a condition that the oyster will only be able to recover its former state by a long struggle with its enemies and competition,—in fact that it must re-establish itself much in the same way as they have acquired possession of new grounds in Jutland, a process which, according to his own statement, occupied thirty years (Lecture at the Royal Institution, May 11, 1883, printed with additions in the *English Illustrated Magazine*, i. pp. 47-55, 112-21).

² Connecticut has within a few years greatly benefited its oyster industry by giving to oyster-culturists a fee simple title to the lands under control by them.

³ Catalogue of the Economic Mollusca exhibited by the United States National Museum at the International Fisheries Exhibition, London, 1883.

left for ten or fifteen minutes. The chest is then opened and the ears run into the shucking shed, their places in the chest being immediately occupied by other ears. In the shed the ears are surrounded by the shuckers, each provided with a knife and a can arranged so as to hook to the upper bar of the iron frame-work of the ear. The steaming having caused the oyster shells to open more or less widely, there is no difficulty in getting out the meats, and the ears are very rapidly emptied. The oysters are then washed in iced water and transferred to the "fillers'" table. The fans, having been filled, are removed to another part of the room and packed in a cylindrical iron crate or basket, and lowered into a large cylindrical kettle, called the "process kettle" or "tub," where they are again steamed. After this they are placed, crate and all, in the "cooling tub;" and when sufficiently cool to be handled, the cans are taken to the soldering table, and there "capped"—that is, are hermetically closed. From the "cappers" they are transported to another department, labelled, and packed in boxes for shipment. The whole steaming process will not occupy an hour from the time the oysters leave the vessel until they are ready for shipment.

The extension of the area of the natural beds is the second step in oyster culture. As is well known to zoologists, and as has been very lucidly set forth by Prof. Möbius in the essay already referred to, the location of oyster banks is sharply defined by absolute physical conditions. Within certain definite limits of depth, temperature, and salinity, the only requirement is a suitable place for attachment. Oysters cannot thrive where the ground is composed of moving sand or where mud is deposited; consequently, since the size and number of these places are very limited, only a very small percentage of the young oysters can find a resting-place, and the remainder perish. Möbius estimates that for every oyster brought to market from the Holstein banks, 1,045,000 are destroyed or die. By putting down suitable "cultch" or "stools" immense quantities of the wandering fry may be induced to settle, and are thus saved. As a rule the natural beds occupy most of the suitable space in their own vicinity. Unoccupied territory may, however, be prepared for the reception of new beds, by spreading sand, gravel, and shells over muddy bottoms, or, indeed, beds may be kept up in locations for permanent natural beds, by putting down mature oysters and cultch just before the time of breeding, thus giving the young a chance to fix themselves before the currents and enemies have had time to accomplish much in the way of destruction.

The collection of oyster spat upon artificial stools has been practised from time immemorial. As early as the 7th century, and probably before, the Romans practised a kind of oyster culture in Lake Avernus, which still survives to the present day in Lake Fusaro. Piles of rocks are made on the muddy bottoms of these salt-water lakes, and around these are arranged circles of stakes, to which are often attached bundles of twigs. Breeding oysters are piled upon the rookeries, and their young become attached to the stakes and twigs provided for their reception, where they are allowed to remain until ready for use, when they are plucked off and sent to the market. A similar though ruder device is used in the Poquonnock river in Connecticut. Birch trees are thrown into the water near a natural bed of oysters, and the trunks and twigs become covered with spat; the trees are then dragged out upon the shore by oxen, and the young fry are broken off and laid down in the shallows to increase in size. In 1858 the method of the Italian lakes were repeated at St Brieuc under the direction of Prof. P. Coste, and from these experiments the art of artificial breeding as practised in France has been developed. There is, however, a marked distinction between oyster culture and oyster breeding, as will be shown below. The natural beds of France in the Bay of Arcachon, near Auray in Brittany, near Cancale and Granville in Normandy, and elsewhere, are, however, carefully cultivated, as it is necessary that they should be, for the support of the breeding establishments.¹

More or less handling or "working" of the oysters is necessary both for natural and transplanted beds. The most elaborate is that which has been styled the "English system," which is carried on chiefly near the mouth of the Thames, by the Whitstable and Colchester corporations of fishermen and others. This consists in

laying down beds in water a fathom or more in depth at low water and constantly dredging over the grounds, even during the close time, except during the period when the spat is actually settling. By this means the oysters are frequently taken out of the water and put back again, and it is claimed that in this way their enemies are baffled and the ground put in better condition to receive the spat. As a matter of fact, however, the oysters have not for many years multiplied under this treatment, and the system is practically one of oyster-parking rather than one of oyster-culture. One of the advantages of the frequent handling is that the fishermen, in putting the oysters back, can assort them by sizes, and arrange them conveniently for the final gathering for market purposes.

American oyster culture, as practised in the "East River" (the western end of Long Island Sound), in eastern Connecticut, and to some extent in Long Island and New Jersey, is eminently successful and profitable, and there seems to be no reason to doubt its permanence, conducted as it is in close proximity to the natural beds, and with due regard for preservation. In the Long Island Sound alone, in 1879, the labours of 1714 men produced 997,000 bushels, or perhaps 250,000,000 of native oysters, valued at \$847,925, while all France produced in the following season 375,000, worth about \$412,000. There was also a side product of 450,000 bushels (122,000,000) of transplanted oysters, worth \$350,000, handled by the same men in the American beds, while France employed an additional force of 28,000 people to produce 303,000,000 artificially bred oysters, worth \$3,179,000. The Long Island Sound system consists simply in distributing over the grounds, just before the spawning season, quantities of old oyster shells to which the young oysters become attached, and left undisturbed for from three to five years, when, having reached maturity, they are dredged for use. Spawning oysters are frequently put down in the spring, two months before the ground is shelled; this is done even when the natural beds are near, but is not so essential as when a rather remote piece of bottom is to be colonized.²

An excellent summary of the methods of planting in different parts of the United States may be found in Winslow's paper already quoted.

The laying down or temporary deposit of dredged oysters in estuaries on floats or in tanks, to fatten, increase in size, or improve in flavour, is a concomitant of oyster culture, and may be used in connexion with any of the systems above referred to. It is in no sense oyster culture, since it has no relation to the maintenance of the supply. A system of this kind has been practised since the 16th century at Marennes and La Tremblade on the west coast of France, where oysters from natural beds are placed in shallow basins communicating with the sea during the spring tides, and where they obtain food which gives them a green colour and a peculiar flavour much esteemed by Parisian epicures.³ Similar methods of parking are practised at Cancale and Granville.

In England, brood oysters are laid down in fattening beds on the coast of Essex and in the Thames estuary, where they acquire delicacy of flavour, and to some extent, especially in the Thames, the green colour already referred to. Belgium has also, near Ostend, fattening beds supplied with foreign spat, chiefly from England.

In the United States an extensive business is carried on in laying down seed oysters from the Chesapeake Bay in the estuaries of southern New England and the Middle States.

Oyster-culturists practise in many places what is called "plumping," or puffing up oysters for market by exposing them for a short time to the effects of water fresher than that in which they grew. By this process the animal does not acquire any additional matter except the water, which is taken up in great amount, but it loses a part of its saltiness, and, in flavour, becomes more like an oyster from brackish water.

There are large oyster reservoirs at Husum in Schleswig-Holstein, and at Ostend, which serve the double purpose of fattening the oysters and of keeping a uniform supply for the markets at times unsuited to the prosecution of the fishery.

The artificial impregnation of oyster eggs has been successfully accomplished by many experimenters, and in 1883 Mr John A. Ryder of the United States Fish Commission succeeded in confining the swimming embryos in collectors until they had formed their shells and become fixed. The utility of this experiment seems to consist in the greater facility which it gives to oyster-culturists in securing a sure supply of spat, independent of the vicissitudes which currents and changes of weather entail upon those who rely upon its deposit under natural conditions. The spat thus secured can be reared either by the American, English, or French systems. It is not probable that the common European species, *Ostrea edulis*, can be so readily handled by this method as the Portuguese species, *Ostrea angulata*, or the American, *Ostrea virginica*, though this can only be determined by trial. For the details of Mr Ryder's experiment, see the *Bulletin of the United States Fish Commission*, vol. ii. pp. 281-94. (G. B. G.)

OYSTER-CATCHER, a bird's name which does not seem to occur in books until 1731, when Catesby (*Nat. Hist. Carolina*, i. p. 85) used it for a species which he observed to be abundant on the oyster-banks left bare at low water in the rivers of Carolina, and believed to feed principally upon those molluscs. In 1776 Pennant applied the name to the allied British species, which he and for nearly two hundred years many other English writers had called the "Sea-Pie." The change, in spite of the misnomer—for, whatever may be the case elsewhere, in England the bird does not feed upon oysters—met with general approval, and the new name has, at least in books, almost wholly replaced what seems to have been the older one.¹ The Oyster-catcher of Europe is the *Hematopus*² *ostralegus* of Linnæus, belonging to the group now called *Limicolæ*, and is generally included in the Family *Charadriidæ*; though some writers have placed it in one of its own, *Hematopodidæ*, chiefly on account of its peculiar bill—a long thin wedge, ending in a vertical edge. Its feet also are much more fleshy than are generally seen in the Plover Family. In its strongly-contrasted plumage of black and white, with a coral-coloured bill, the Oyster-catcher is one of the most conspicuous birds of the European coasts, and in many parts is still very common. It is nearly always seen paired, though the pairs collect in prodigious flocks; and, when these are broken up, its shrill but musical cry of "tu-lup," "tu-lup," somewhat pettishly repeated, helps to draw attention to it. Its wariness, however, is very marvellous, and even at the breeding-season, when most birds throw off their shyness, it is not easily approached within ordinary gunshot distance. The hen-bird commonly lays three clay-coloured eggs, blotched with black, in a very slight hollow on the ground, not far from the sea. As incubation goes on the hollow is somewhat deepened, and perhaps some haulm is added to its edge, so that at last a very fair nest is the result. The young, as in all *Limicolæ*, are at first clothed in down, so mottled in colour as closely to resemble the shingle to which, if they be not hatched upon it, they are almost immediately taken by their parents, and there, on the slightest alarm, they squat close to elude observation. This species occurs on the British coasts (very seldom straying inland) all the year round; but there is some reason to think that those we have in winter are natives of more northern latitudes, while our home-bred birds leave us. It ranges from Iceland to the shores of the Red Sea, and lives chiefly on marine worms, crustacea, and such molluscs as it is able to obtain. It is commonly supposed to be capable of prizing limpets from their rock, and of opening the shells of mussels out, though undoubtedly it feeds on both, further evidence as to the way in which it procures them is desirable. Mr Harting informs the writer that the bird seems to lay its head sideways on the ground, and then, grasping the limpet's shell close to the rock between the mandibles, use them as scissor-blades to cut off the mollusc from its sticking-place. The Oyster-catcher is not highly esteemed as a bird for the table.

Differing from this species in the possession of a longer

¹ It seems however very possible, judging from its equivalents in other European languages, such as the Filsian *Ostereischer*, the German *Augstermin*, *Austernfischer*, and the like, that the name "Oyster-catcher" may have been not a colonial invention but indigenous to the mother-country, though it had not found its way into print before. The French *Huttrier*, however, appears to be a word coined by Brisson. "Sea-Pie" has its analogues in the French *Pie-de-Mer*, the German *Meerelster*, *Seeelster*, and so forth.

² Whether it be the *Hematopus* whose name is found in some editions of Pliny (lib. x. cap. 47) is at best doubtful. Other editions have *Himantopus*; but Hædonin prefers the former reading. Both words have passed into modern ornithology, the latter as the generic name of the STILT (*q.v.*); and some writers have blended the two in the strange and impossible compound *Himantopus*.

bill, in having much less white on its back, in the paler colour of its mantle, and in a few other points, is the ordinary American species, already mentioned, *Hematopus palliatus*. Except that its call-note, judging from description, is unlike that of the European bird, the habits of the two seem to be perfectly similar; and the same may be said indeed of all the other species. The Falkland Islands are frequented by a third, *H. leucopus*, very similar to the first, but with a black wing-lining and paler legs, while the Australian Region possesses a fourth, *H. longirostris*, with a very long bill as its name intimates, and no white on its primaries. China, Japan, and possibly eastern Asia in general have an Oyster-catcher which seems to be intermediate between the last and the first. This has received the name of *H. osculans*; but doubts have been expressed as to its deserving specific recognition. Then we have a group of species in which the plumage is wholly or almost wholly black, and among them only do we find birds that fulfil the implication of the scientific name of the genus by having feet that may be called blood-red. *H. niger*, which frequents both coasts of the northern Pacific, has, it is true, yellow legs, but towards the extremity of South America its place is taken by *H. ater*, in which they are bright red, and this bird is further remarkable for its laterally compressed and much upturned bill. The South African *H. capensis* has also scarlet legs; but in the otherwise very similar bird of Australia and New Zealand, *H. unicolor*, these members are of a pale brick-colour. (A. N.)

OZAKA, or OSAKA, one of the three imperial cities of Japan (Kioto and Tokio or Yedo being the other two), is situated in a plain in the province of Setsu or Sesshu, measuring about 20 miles from north to south and from 15 to 20 miles east and west, and bounded, except towards the west, where it opens on Idzaminada Bay, by hills of considerable height. It lies on both sides of the Yodogawa, or rather of its headwater the Aji (the outlet of Lake Biwa), and is so intersected by river-branches and canals as to suggest a comparison with Venice or Stockholm. River steamers ply between Ozaka and its port Hiogo or Kobe, and a railway between the two places, opened in 1873, has since been extended to Kioto and farther. The streets are not very broad, but for the most part they are regular and well kept; the houses, about 20 or 25 feet in height, are all built of wood. Shin-sai Bashi Suji, the principal thoroughfare, leads from Kitahama, the district lying on the south side of the Tosabori, to the iron suspension bridge (Shin-sai Bashi) over the Dotom-bori. The foreign settlement is at Kawaguchi at the junction of the Shirinashi-gawa and the Aji-Kawa. It is almost deserted by the foreign merchants, who prefer to have their establishments at Kobe, but it is the seat of a number of European mission stations. Though the Buddhist temples of Ozaka number 1380 and the Shinto temples 538, few of them are of much note. The Buddhistic Tennoji, founded by Shotoku Tai-shi, and restored in 1664, covers an immense area at the south-east corner of the city, and has a fine pagoda from which an admirable view of the country is obtained. Two other Buddhist temples, which form a conspicuous object in the heart of the city, are occupied, one as a Government hospital and the other as a Government school. The principal secular buildings are the castle, the mint, and the arsenal. The castle was founded in 1581 by Hideyoshi; the enclosed palace, "probably the finest building Japan ever saw," survived the capture of the castle by Iyeyasu, and in 1867 and 1878 witnessed the reception of the foreign legations by the Tokugawa shoguns; but in the latter year it was fired by the Tokugawa party. Externally the whole castle is protected by a double enceinte of high and massive walls and broad moats—the outer moat from 80 to 120 yards across and

from 12 to 24 feet deep. Huge blocks of granite 40 feet by 10 or 20 feet occur in the masonry. The mint, erected by T. J. Waters, and organized by Major T. W. Kinder and twelve European officials, covers an area of 40 acres, and employs about 600 persons. It was opened in 1871. Both cannon and guns are manufactured in the arsenal. Apart from these Government establishments Ozaka is the seat of great industrial activity, possessing iron foundries, copper foundries, and rolling mills, antimony works, large glass works, paper mills, a sugar refinery, a cotton spinning mill, rice mills, an oil factory, sulphuric acid works, match factories, soap works, saké distilleries, a brewery (after the German pattern), shipyards, &c. Bronzes, sulphuric acid, and matches are among its chief exports. In the surrounding district large quantities of rape-seed are grown. The population in 1872 was 271,992; in 1877, 284,105.

Ozaka owes its origin to Ren-nio Sho-nin, the 8th head of the Shin-Shin sect, who in 1495-6 built, on the site now occupied by the castle, a temple which afterwards became the principal residence of his successors. In 1580, after ten years' successful defence of his position, Ken-nio, the 11th "abbot," was obliged to surrender; and in 1583 the victorious Hideyoshi made Ozaka his capital. The town was opened to foreign trade in 1863.

OZANAM, ANTOINE FRÉDÉRIC (1813-1853), the greatest name, as far as literary and historical criticism is concerned, of the Neo-Catholic movement in France during the first half of the 19th century, was born at Milan on April 13, 1813. His family is said (as the name suggests) to have been of Jewish extraction, and has a circumstantial though possibly fabulous genealogy of extraordinary length. At any rate it had been settled in the Lyonnais for many centuries. In the third generation before Frédéric it had reached distinction through Jacques Ozanam, a mathematician of eminence. The critic's father, Antoine Ozanam, served in the armies of the republic, but could not stomach the empire, and betook himself to commerce, teaching, and finally medicine. The boy was brought up at Lyons, and was strongly influenced by one of his masters, the Abbé Noirot. His conservative and religious instincts showed themselves early, and he published a pamphlet against Saint-Simonianism in 1831, which attracted the attention of Lamartine. He was then sent to study law in Paris, where he fell in with the Ampère family, and through them with excellent literary society. He also came under the influence of the Abbé Gerbet, the soberest and most learned member of the religious school of Lamennais and Lacordaire. Ozanam, however, though he joined with all the fervour of youth in the Neo-Catholic polemic, never underwent the uncomfortable experiences of the direct followers of Lamennais. His journal (for in those years every one was a journalist) was not the *Avenir*, but the more orthodox *Tribune Catholique* of Bailly, and he with some other young men founded the famous society of St Vincent de Paul, which was occupied in practical good works. Meanwhile he did not neglect his studies. He was called to the bar, and in 1838 won his doctor's degree in letters with a thesis on Dante, which was the beginning of his best-known book. A year later he was appointed to a professorship of commercial law at Lyons, and in another year assistant professor to Fauriel at the Sorbonne. On this latter precarious endowment he married, and visited Italy on his wedding tour. At Fauriel's death in 1844 he succeeded to the full professorship of foreign literature, and his future was thereby tolerably assured. He had, however, by no means a strong constitution, and he tried it severely by combining with his professorial work a good deal of literary occupation, while he still continued his custom of district-visiting as a member of the society of St Vincent de Paul. The short remainder of his life was extremely busy, though it was relieved at intervals by

visits to Italy, Brittany, England, and other places. He produced numerous books, and during the revolution of 1848 (of which, like not a few of his school, he took an unduly sanguine view) he once more became a journalist in the *Ère Nouvelle* and other papers for a short time. He was in London at the time of the Exhibition of 1851. In little more than two years from that date he died of consumption (which he had vainly hoped to cure by visiting Italy) on September 8, 1853, at the age of forty.

Ozanam deserves the phrase which has been attached to his name at the beginning of this article. He was more sincere, more learned, and more logical than Chateaubriand, less of a political partisan and less of a literary sentimentalist than Montalembert. Whether his conception of a democratic Catholicism was a possible one is of course a matter of opinion, and it may be frankly admitted that, well as he knew the Middle Ages, he looked at them too exclusively through the spectacles of a defender of the papacy. He confessed that his object was to "prove the contrary thesis to Gibbon's." And no doubt any historian, literary or other, who begins with the desire to prove a thesis is sure to go more or less wrong. But his pictures were not so much coloured by his prepossessions as some contemporary pictures on the other side, and he had not only a great knowledge of mediæval literature, but also a strong and appreciative sympathy with mediæval life.

His chief works (collected in 1855-58) were *Bacon et St Thomas de Cantorbéry*, 1836; *Dante et la Philosophie Catholique*, 1839 (2d ed., enlarged, 1845); *Études Germaniques*, 1847-49; *Documents inédits pour servir à l'Histoire d'Italie*, 1850; *Les Poètes Français*, 1852. There is an interesting life of him in English by K. O'Meara (2d ed., London, 1878).

OZOCERITE, or OZOKERITE (ὄζων, odour-emitting, and κηρός, wax; smelling wax, mineral wax), is a combustible mineral which may be designated as crude native PARAFFIN (*q.v.*), found in many localities in varying degrees of purity. The only commercial sources of supply however are in Galicia, principally at Boryslaff and Dzwieniasz. Hofstädter in 1854 examined an ozocerite from "Boristoff near Drohobiez," Galicia; he found it to consist chiefly of hydrocarbon which, after crystallization from alcohol, exhibited the composition CH_2 of the olefines; this, however, is quite compatible with their being really "paraffins," $\text{C}_n\text{H}_{2n+2}$, which latter formula for a large n coincides practically with C_nH_{2n} . At and near Baku and in other places about the Caspian Sea, soft oily native paraffins, known as "nefto-gil" or "nefte-degil" and "kir," are found with other petroleum products. The theory of the formation of ozocerite now generally accepted is that it is a product of the decomposition of organic substances, which was originally like petroleum, but has lost its more volatile components by volatilization. All native petroleum in fact, like crude paraffin oil, holds solid paraffin in solution.

Galician ozocerite varies in consistence from that of a rather firm and hard wax to that of a soft adherent plastic mass, and in colour from yellow to a dark (almost black) green. Its melting-point ranges from 58° to 98° C. (136° to 208° Fahr.); the extra high melting point of the paraffin extracted from it is one of its distinguishing features. Besides the earthy impurities which are always associated with the mineral as found in the "nests" containing it, it is mixed with liquid hydrocarbons, resinous oxygenated compounds, and water. In the following table columns I. and II. show the yield in two distillations of a superior quality of the ozocerite of Boryslaff, as given by Perutz.

| | I. | II. |
|--------------------------|-------|-------|
| Benzene | 5.67 | 0.27 |
| Naphtha | 3.67 | 11.00 |
| Paraffin | 82.33 | 78.32 |
| Pyrene and chrysene..... | 2.05 | ... |
| Coke and loss..... | 5.59 | 8.28 |
| Water..... | 0.33 | 2.13 |

The purified paraffin of ozocerite makes excellent candles, which are said to give more light, weight for weight, than

those made from ordinary paraffin, besides being less easily fusible. Under the name of ceresin or ozocerotin a large proportion of the high-melting paraffin extracted from the mineral goes into commerce, to be used chiefly for the adulteration of beeswax. The various methods of refining used furnish certain proportions of soft paraffin, and of heavy and light oils as by-products, which take their place in commerce beside the corresponding products from shale and petroleum.

A kind of mineral wax known as idrialine accompanies the mercury ore in Idria. According to Goldschmidt it can be extracted by means of xylol, amyl-alcohol, or turpentine, and also, without decomposition, by distillation in a current of hydrogen or carbonic acid. It is a white crystalline body, very difficultly fusible, boiling above 440°C . (824°F .), of the composition $\text{C}_{40}\text{H}_{28}\text{O}$. Its solution in glacial acetic acid, by oxidation with chromic acid, yielded to Goldschmidt a red powdery solid and a fatty acid fusing at 62°C ., and exhibiting all the characters of a mixture of palmitic and stearic acids.

OZONE has been defined and to some extent discussed under the heading CHEMISTRY, vol. v. p. 481.

From the time of Van Marum (1785) at least it was known that the passage of electric sparks through air is accompanied by the production of a peculiar smell; but the cause of this remained unknown until 1840, when Schönbein observed that a similar smell is exhibited by electrolytic oxygen (as obtained in the electrolysis of acidulated water), and also develops in the atmosphere of a vessel in which phosphorus suffers spontaneous oxidation at ordinary temperatures in the presence of water. The three kinds of odoriferous gas, he found, had the power of decomposing iodide of potassium with liberation of iodine, and they agreed also in their behaviour to other reagents, whence he concluded that in all the three cases the smell was owing to the same peculiar substance which he called *ozone* (from *ὄζειν*, to emit an odour). Numerous experiments confirmed his first impression that ozone is chemically similar to, though distinctly different from, chlorine, but he got no further towards establishing its nature. Having found, however, that dry phosphorus produces no ozone, and that ready-made ozone is destroyed by being passed through a heated glass tube, he surmised that ozone was a peroxide of hydrogen. This surmise was seemingly raised to a certainty by an investigation of Baumert's, who found that electrolytic (ozonized) oxygen, when de-ozonized by heat, yields water, and ascertained that the weight of water thus produced amounted to $\text{H}_2\text{O} = 18$ parts for every $41 = 4 \times 12.7$ parts of iodine which the same quantity of gas would have liberated if it had been de-ozonized by iodide of potassium. This, if true, would prove that ozone is H_2O_3 ,—a conclusion which passed current as an established fact, in reference to electrolytic ozone at least, until Andrews showed that Baumert's result was founded upon incorrect observations. The merit of having discovered the true elementary composition of ozone belongs to Marignac and De la Rive, who proved that it can be produced, as easily and abundantly as in any other way, by the electrification of absolutely pure oxygen gas, whence it at once followed that—unless oxygen be a compound of two or more unknown elements—ozone cannot be anything else than an allotropic modification of oxygen.

With regard to the relations of the two kinds of oxygen to one another, our present knowledge is derived mainly from the work of Andrews and Prof. Tait. The first important result which they arrived at was that the ozonization of pure oxygen gas involves a contraction, and that consequently ozone is denser than oxygen gas. Presuming (with all their contemporaries) that in the de-ozonization of oxygen by iodide of potassium all the substance of the ozone is taken up by the reagent with elimination of its equivalent of iodine, they sought to determine the density of ozone by comparing the weight of oxygen-matter which goes into the iodide of potassium with the contraction involved in the process. But they obtained variable results. As their methods became more and more perfect,

the weight of unit volume of ozone grew greater and greater, and at last stood at ∞ . In other words, what they found and established finally was that the removal of ozone from oxygen by means of iodide of potassium involves no change of volume whatever, although de-ozonization by heat always leads to a (permanent) increase of volume. This result, to them and everybody else, appeared very singular; but Andrews, after a while, found the correct explanation. Supposing at a certain temperature and pressure one volume of ordinary oxygen contains a grains of matter, then one volume of ozone, being denser, contains a greater quantity of matter, say $a + x$ grains; when the gas acts on iodide of potassium, the a grains come out as one volume of oxygen, while the x grains of surplus oxygen vanish in the iodide. In the decomposition by heat the x grains of surplus oxygen of course assume the form of x/a volumes of additional oxygen gas. It is no addition to Andrews's explanation, but merely a close translation of it into the language of Avogadro's law, to say that, if oxygen (proper) consists of molecules O_2 , ozone must consist of molecules O_{2+x} (perhaps O_{2+1}), and that in the iodide reaction this molecule breaks up into one molecule of oxygen gas and x atoms of oxygen which go to the reagent. What did constitute a new discovery was Berthelot's important observation that the conversion of ozone into ordinary oxygen involves an evolution of heat which amounts to 29,600 units for every 16 parts of oxygen matter available for the liberation of iodine from iodide of potassium. What the real density of ozone is was made out with a high degree of probability by Soret. He took two equal volumes of the same supply of ozonized oxygen, and in one determined the contraction produced by shaking with oil of turpentine (which he assumes to take away the ozone as a whole), while the other served for the (direct or indirect) determination of the expansion involved in the destruction of the ozone by heat. He found this increase to amount to half a volume for every one volume of ozone present; hence one volume of ozone contains the matter of one and a half volumes of ordinary oxygen, i.e., its density is 1.5 (if that of ordinary oxygen is taken as unity), and its molecular weight is $\frac{3}{2} \times \text{O}_2 = \text{O}_3$. To check this result Soret determined the rate at which ozone diffuses into air, and compared it with the rate, similarly determined, for carbonic acid. From the two rates, on the basis of Graham's law, he calculated the ratio of the density of ozone to that of carbonic acid, and found it in satisfactory accordance with $\text{O}_3 : \text{CO}_2 = 48 : 44$.

From the facts that ozone is destroyed (i.e., converted into O_2) at 270° (Andrews and Tait), and that this reaction is not reversible, it at once follows that it is impossible to convert oxygen completely into ozone by electric sparks. Supposing the ozonization to have gone a certain way, each additional spark, besides producing ozone, will destroy some of that previously produced.

From Clerk Maxwell's notion concerning the distribution of temperatures amongst the molecules of a gas, it would follow that ozonized oxygen, even at ordinary temperatures, will gradually relapse into the condition of plain oxygen, because, although the temperature as indicated by the thermometer may be only 20°C . (say), there are plenty of molecules at temperatures above the temperature of incipient dissociation (which of course lies below 270°), and any ozone once destroyed will never come back. But, be this as it may, the lower the temperature of the oxygen treated with sparks the greater the chance of the ozone formed to remain alive. This idea forms the basis of an important research by Hauteville and Chappuis, who, by operating upon oxygen at very low temperatures, produced unprecedentedly large percentages of ozone. By operating at 0°C . they produced a gas containing 14.9 per cent. by weight of ozone (presumably reckoned as O_3), while at -23° the percentage rose to 21.4. They subsequently (1882; *Compt. Rend.*, xciv. p. 1249) succeeded in producing even liquid ozone, by applying a pressure of 125 atmospheres to richly ozonized oxygen at -100°C . (the boiling point of liquefied ethylene). Liquid ozone is of a dark indigo-blue colour, which, as they tell us, is distinctly visible even in ordinary ozonized oxygen if it is viewed in tubes about one metre long.

According to Carius the coefficient of absorption of ozone by water of $+1^{\circ}\text{C}$. is about 0.8; that is to say, one volume of water of 1° , if shaken with excess of pure ozone at 1° and a pressure of 760 mm., would absorb 0.8 volume of ozone measured dry at 0° and 760 mm. pressure. But it is not certain that Carius's determinations are correct.

Antozone.—According to a now obsolete notion of Schönbein's, ordinary oxygen gas is a compound of two kinds of oxygen of which one is positively and the other negatively electrical. Ordinary ozone would be a mixture of the two in equal parts; but certain peroxides, according to Schönbein, contain the one kind, others the other. He supported his view by many ingenious experimental arguments. Meissner and others, while adopting Schönbein's idea, somehow drifted into the notion that Schönbein's two kinds of oxygen correspond to two different substances, of which ordinary ozone is one. They naturally searched for the other, and of course did not fail to discover it; but their "antozone," when critically looked into, turned out to be peroxide of hydrogen.

P

P is the sixteenth letter of our alphabet. In the original Phœnician form (see ALPHABET) it was not unlike a crook. In Greece it became angular (Ϟ), and later the downward strokes were made equal in length (Π), though in the old Corinthian the rounded form still occurs, closely resembling the Phœnician type. In old Latin the angular form is found, as in Greece, but also the form with which we are familiar, with the bottom of the curve joined to the straight line. The old guess that P was at first a rude sketch of a mouth must be abandoned unless we are prepared to credit the Phœnicians with having so far anticipated Mr Melville Bell's "visible speech."

The sound it denotes is a closed labial, differing from *b* as a surd from a sonant; it is heard only when the lips open; there is then a percussion as the breath escapes, which constitutes the sound. The difference between breath and voice can be easily seen in the production of the two sounds, *p* and *b*. When the lips are closed—as they must be closed (exactly in the same way) for each of the sounds—if we then try to articulate *p*, no effort can produce any kind of sound till the lips open; the chordæ vocales do not vibrate, and there is therefore nothing in the mouth but mere breath. But if we make as though we would sound *b*, while still keeping the lips shut, a certain dull sound is quite audible, produced by the vocalized breath (or voice) within the mouth; and the action of the top of the larynx in producing this sound may be distinctly felt. Of course this sound is not a *b*; that does not come till the lips part.

It is noteworthy how very small is the number of pure English words which begin with *p*. Such words correspond to words which began with *b* in Greek, Latin, and other members of the parent Aryan speech; and these are equally few. Nearly all the words which we have in English beginning with *p* are therefore borrowed, such as "pain," "pair," "police," which came to us from France; others are scientific terms, oftenest modelled upon the Greek. The reason of this deficiency of words in the parent language commencing with *b* is not easy to find.

The Latins denoted the sound of Greek φ by the double symbol *ph*; this is a *p* followed by a slight breathing, not so strong as an *h*; thus "philosophia" was pronounced not as we now pronounce it, but rather like "p'philosoph'ia." But this sound eventually passed into the *f*-sound, and it is so written in Italian (e.g., "filosofia"); French and English have kept the old spelling, but not the sound. So here, as elsewhere, we have quite unnecessarily two symbols, *ph* and *f*, expressing the same sound.

PACCHIA, GIROLAMO DEL, and PACCHIAROTTO (or PACCHIAROTTI), JACOPO. These are two painters of the Siennese school, whose career and art-work have been much misstated till late years. One or other of them produced some good pictures, which used to pass as the performance of Perugino; reclaimed from Perugino, they were assigned to Pacchiarotto; now it is sufficiently settled that the good works are by G. del Pacchia, while

nothing of Pacchiarotto's own doing transcends mediocrity. The mythical Pacchiarotto who worked actively at Fontainebleau has no authenticity.

GIROLAMO del Pacchia, son of a Hungarian cannon-founder, was born, probably in Siena, in 1477. Having joined a turbulent club named the Bardotti, he disappeared from Siena in 1535, when the club was dispersed, and nothing of a later date is known about him. His most celebrated work is a fresco of the Nativity of the Virgin, in the chapel of S. Bernardino, Siena, graceful and tender, with a certain artificiality. Another renowned fresco, in the church of St Catherine, represents that saint on her visit to St Agnes of Montepuciano, who, having just expired, raises her foot by miracle. In the National Gallery of London there is a Virgin and Child. The forms of G. del Pacchia are fuller than those of Perugino (his principal model of style appears to have been in reality Franciabigio); the drawing is not always unexceptionable; the female heads have sweetness and beauty of feature; and some of the colouring has noticeable force.

Pacchiarotto was born in Siena in 1474. In 1530 he took part in the conspiracy of the Libertini and Popolani, and in 1534 he joined the Bardotti. He had to hide for his life in 1535, and was concealed by the Observantine fathers in a tomb in the church of St John. He was stuffed in close to a new-buried corpse, and got covered with vermin and dreadfully exhausted by the close of the second day. After a while he resumed work; he was exiled in 1539, but recalled in the following year, and in that year or soon afterwards he died. Among the few extant works with which he is still credited is an Assumption of the Virgin, in the Carmine of Siena.

PACHECO, FRANCISCO (1571–1654), Spanish painter and art historian, born at Seville in 1571, was the pupil of Luis Fernandez, and a diligent and prolific workman. Favourable specimens of his style are to be seen in the Madrid picture gallery, and also in two churches at Alcalá de Guadaira near Seville; they are characterized by careful drawing and correct if somewhat feeble composition, but prove that he was no colorist. He attained great popularity, and about the beginning of the 17th century opened an academy of painting which was largely attended. Of his pupils by far the most distinguished was Velazquez, who afterwards became his son-in-law. From about 1625 he gave up painting and betook himself to literary society and pursuits; the most important of his works in this department is a treatise on the art of painting (*Arte de la Pintura: su anteguedad y grandezas*, 1649), which, although characterized by prolixity and pedantry of style, and often nonsensical enough in its theories, is of considerable value for the information it contains, especially on matters relating to Spanish art. He died in 1654.

PACHOMIUS, or PACHUMIUS. See MONACHISM, vol. xvi. pp. 699, 700.

PACHYDERMATA. See MAMMALIA.

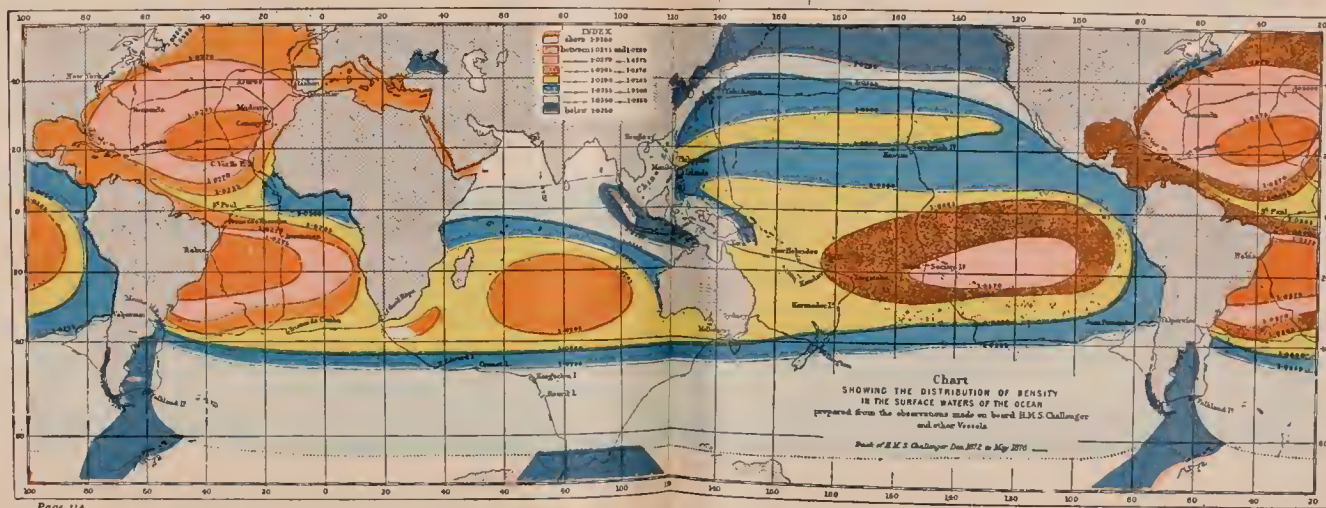

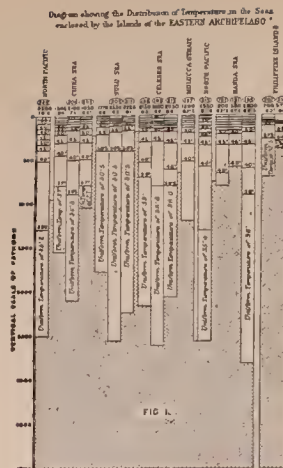

PACIFIC OCEAN

THE ancient world was ignorant of the existence of the vast expanse of water now known as the Pacific Ocean. In Ptolemy's map of the world, constructed in the 2d century of our era (see MAP, vol. xv. Pl. VII.), this fact is clearly brought out, for the only space which might possibly represent the Pacific is the Magnus Sinus,

a sea so limited in extent, and represented in such a position, that it probably stands for the Gulf of Siam in the Indian Ocean.

Vague reports of a great ocean lying beyond China were current in Europe as early as the period of Arabian supremacy in learning. Indeed an Arab merchant named

Sulaiman, who visited China in the 9th century, declared that he had sailed upon it. But for several hundred years the reports continued so uncertain, and were so loaded with the wild extravagance of travellers' tales of the period, that it is difficult to get at the facts from which they probably took their origin. During the 13th and 14th centuries Marco Polo and his successors travelled far to the East and came to an ocean of the extent of which they were ignorant, but they partially explored its western coasts. The East was the region towards which all the commerce and enterprise of the Middle Ages tended, and it was the hope of finding a safer and shorter sea route to India that led the Spanish court in 1492 to furnish Columbus with a fleet for the exploration of the Western Ocean. Although convinced of the spherical form of the earth, he greatly under-rated its size, and, accepting the popular estimate of the great breadth of the Asiatic continent, he set out on his voyage confident of soon reaching "the Indies." The glowing descriptions of his discoveries in that strange new world of the West that rose up before him to bar his advance immediately attracted the attention of adventurous Spanish mariners. Headed by Columbus himself, they cruised intrepidly amongst the Caribbean Islands, still lured by the hope of discovering some western passage to the coveted East. Columbus found that what he at first considered a labyrinthine archipelago was a continent of vast extent, but not Asia, and he died without knowing what lay beyond. Spain and Portugal were the rival maritime powers at that time, and both took up the search for new countries with great ardour. Pope Alexander VI., in 1493, fearing that the two nations would quarrel over their colonies, assigned all the new lands that might be discovered west of the Azores to Spain, and all east of those islands to Portugal. The Portuguese accepting the gift followed Vasco da Gama in opening up the road to India by the Cape of Good Hope, and pushed forward their trading and piratical excursions into the west Pacific far beyond the Spice Islands. The Spaniards confined themselves to the New World, visiting, naming, and plundering the West India Islands and the headlands of Central America. On the 29th of September 1513 Vasco Nuñez de Balbao, the leader of a Spanish party exploring the Isthmus of Panama, saw, from the summit of a mountain, a vast ocean stretching to the west—the very ocean of whose existence Columbus was certain, and which he had so long tried vainly to discover. Because he first saw it on Michaelmas day, Balbao named it the *Golfo de San Miguel*. Magellan, following the east coast of America farther to the south than any previous explorer, sailed on, in spite of terrific storms, until he found the strait which now bears his name, and, steering carefully through it, on the 27th of November 1520 he swept into the calm waters of that new sea on which he was the first to sail, and which he named the *Mar Pacifico*.

The victories of Cortez in Mexico about the same date opened the way for the exploration of the west coast of America, where Pizarro's conquest of Peru in 1526 gave the Spaniards a firm footing. From this time an intermittent trade sprang up between Europe and the Pacific through Magellan Strait, and latterly round Cape Horn. Before long English fleets, attracted more by the prospects of plundering Spanish galleons than of discovering new territories, found their way into the Pacific. Sir Francis Drake, like Balbao, saw the ocean from the Isthmus of Panama. He entered the Pacific in September 1577, being the first Englishman to sail upon it; some months later he sailed across it to the Moluccas. Alvaro de Mardana, who preceded him, had discovered the Solomon Islands in 1567.

Tasman, Roggewein, Dampier, and other explorers of the

17th century discovered Australia, New Zealand, Tasmania, and many smaller groups of islands. During the 18th century the voyages of Anson, Bass, Behring, the two Bougainvilles, Broughton, Byron, Cook, La Pérouse, and many more practically completed the geographical exploration of the Pacific Ocean. In the beginning of that century the Pacific had a curious fascination for commercial speculators, and the ill-fated Scottish colony founded at Darien in 1698 seemed only to prepare the way for the English South Sea bubble that burst in 1720. All the navigators who explored these seas believed in the existence of a north-west passage between the Atlantic and Pacific, and made attempts to find it; but its discovery baffled all enterprise until 1850, when Maclure proved that there was such a channel, but that the ice prevented its being of any commercial utility. In the present century D'Entrecasteaux, Krusenstern, Beechy, Fitzroy, and Bennet have taken the lead amongst geographical explorers in the Pacific, although the ranks contain many names scarcely less worthy of remembrance. Within recent years several purely scientific exploring expeditions and British surveying vessels have examined the Pacific, investigating its depth, the nature and form of the bottom, the temperature of the water at various depths and its density, as well as the marine fauna and flora. Of those expeditions the voyages of the "Challenger," "Gazelle," and "Tuscarora" are the most important.¹

Extent.—The Pacific Ocean² is bounded on the N. by Behring Strait and the coasts of Russia and Alaska, on the E. by the west coasts of North and South America; on the S. the imaginary line of the Antarctic Circle divides it from the Antarctic Ocean, while its western boundary is the east coast of Australia, the Malay Archipelago separating it from the Indian Ocean, and the eastern coasts of the Chinese empire. Some modern geographers place the southern limit of the Atlantic, Pacific, and Indian Oceans at the 40th parallel, and name the body of water which surrounds the earth between that latitude and the Antarctic Circle the Southern Ocean.

Although differing from the Atlantic in its general form, being more nearly land-locked to the north, the Pacific resembles it in being open to the south, forming, in fact, a great projection northwards of that vast southern ocean of which the Atlantic is another arm.

The Pacific is the largest expanse of water in the world, covering more than a quarter of its superficies, and comprising fully one-half of its water surface. It extends through 132 degrees of latitude, in other words, it measures 9000 miles from north to south. From east to west its breadth varies from about 40 miles at Behring Strait, where Asia and America come within sight of each other, to 8500 miles between California and China on the Tropic of Cancer, and to more than 10,000 miles on the Equator between Quito and the Moluccas, where the ocean is widest. The area has been variously estimated at from 50,000,000 to 100,000,000 square miles; but, defining its boundaries as above, Keith Johnston, from careful measurements, estimated it, with probably a near approach to the truth, at 67,810,000 square miles.

¹ The principal ocean tracks followed by trading vessels in the Pacific are three:—(1) round Cape Horn and along the South American coast—the great rush to California on the discovery of gold in 1847 led to the establishment of lines of fast clipper by this route and of steamers from Panamá to San Francisco; (2) from San Francisco to China a regular service was established in 1867; (3) the mails began to be carried from Australia to San Francisco in 1873 and to Panamá in 1866. The trade with the Pacific will no doubt be greatly increased when the Panama ship-canal is opened for traffic.

² Formerly called the South Sea, and sometimes still so named by the French and Germans (*la Mer du Sud*; *Südsee*, *Australocean*), with whom, however, *La Mer* (*L'Océan*) *Pacifique*, and *Grosser Ocean* or *Stilles Meer* are the more usual designations.

Coasts, Seas, &c.—The coast-line of the Pacific and Indian Oceans, taken together, only amounts to 47,000 miles; that of the Atlantic alone measures 55,000, the smaller ocean more than making up for its less extent by its numerous inland seas and inlets of smaller size. Speaking broadly, the eastern boundary of the Pacific is rugged, barren, mountainous, and singularly free from indentations, while its western shores are low, fertile, and deeply indented with gulfs and partially enclosed seas. Behring Strait unites the Arctic Ocean with the Sea of Kamchatka, or Behring Sea, which is bounded on the east by the irregular, low, swampy shores of Alaska, and on the south by the Alaskan peninsula and the Aleutian Islands. Along British North America the coast is rugged, rocky, considerably indented, and, between the parallels of 50° and 60° N. lat., fringed with islands. The largest of these are Vancouver Island in the Gulf of Georgia, Queen Charlotte Island, Prince of Wales Island, and the islands of King George III.'s Archipelago. The Gulf of California runs northwards in the Mexican coast, reaching from 23° to 32° N. lat. It is the one important inlet on the whole west coast of America,—the only others which are worth naming being the Gulf of Panama and the Gulf of Guayaquil. The Mexican shore is low, and contrasts with the coasts to the north and to the south, which are generally steep and rocky, though there are occasional sandy beaches in Peru and Chili. The breadth of the plain between the Rocky Mountains and the sea gradually diminishes towards the south, and the mountain chain of the Andes runs close along the west coast of South America to the very extremity of the continent.

A series of volcanoes, active and extinct, runs round the Pacific, commencing at Cape Horn, passing along the Andes and Rocky Mountains, crossing from the American continent by the Aleutian Islands to Kamchatka, and thence southwards by Japan and the East Indian Archipelago to New Zealand. Earthquakes are frequent all along this line.

There are few islands near the American coast north of Patagonia, and these are small and unimportant; but south of the 40th parallel there is a complete change. The end of the continent seems as if it had been shattered; there are abrupt bays and jagged chasms; archipelagos of small islands rise up in splintered fragments along the shore. The Strait of Magellan forms a tortuous channel between the mainland and the rocky storm-beaten islands of Tierra del Fuego.

The coast-line on the Asiatic side is longer and greatly diversified. In the north the Sea of Okhotsk is cut off from Behring Sea by the peninsula of Kamchatka, from the extremity of which a chain of islands extends to the borders of the Antarctic Ocean. These islands are of all sizes, ranging from small islets to the island continent of Australia. The island chain hangs in loops along the Asiatic coast, each loop including an almost land-locked sea. These partially enclosed seas are more or less completely cut off from the general oceanic circulation, and they consequently differ considerably from the open ocean as regards the temperature of the water, specific gravity, fauna and flora, and nature of the deposits. The Kurile Islands run from Kamchatka to Japan, cutting off the Sea of Okhotsk. The great Japanese Islands, with Saghalien to the north and the Chinese coast on the west, enclose the Sea of Japan, leaving it in communication with the Sea of Okhotsk by the Channel of Tartary to the north, with the ocean on the west by the Straits of La Prouse and Sangar, and on the south by the Straits of Corea. The Yellow Sea runs into the Chinese coast, and is divided from the Sea of Japan by the peninsula of

Corea. The China Sea, with the two great gulfs of Tonquin and Siam, is marked off from the Indian Ocean by the peninsula of Malacca—remarkable because it runs in the same direction as the other two peninsulas of the Pacific, Kamchatka and Corea—and the islands of Sumatra and Java, while Borneo and the Philippine Islands separate it from the Pacific. Between the south coast of China and the north of Australia the East Indian Archipelago cuts up the ocean into a network of small seas and narrow channels. The seas are named the Celebes, the Banda, the Sulu, the Java, the Flores, and the Arafura. The more important of the sea passages between the islands are the Straits and Channel of Formosa, which lead northward from the Pacific to the China Sea; the Strait of Macassar between Borneo and Celebes; Molucca Passage between Celebes, the Moluccas, and Jilolo; and Torres Strait between New Guinea and Australia. The east coast of Australia is, as a rule, steep and rocky; there are few inlets, and none of them compare in size with the Gulf of Carpentaria on the north coast. Moreton Bay and Port Jackson are two of the best harbours, and as a haven the latter has few equals in the world. The Great Barrier Reef lies off this coast for a length of more than a thousand miles, the distance between it and the shore varying from 60 to 100 miles. Bass Strait separates Australia from Tasmania on the south; and the two main islands of New Zealand, separated by Cook Strait, lie to the south-east of the continent. The Gulf of Hauraki, the Bay of Plenty, and Pegasus Bay are the chief inlets in these islands.

River-System.—The drainage area of the Pacific Ocean is estimated at 8,660,000 square miles, while that of the Atlantic amounts to more than 19,000,000; the chief reason for this disparity is that only half a million square miles of the American continent are drained into the Pacific, the remaining six and a half millions being connected with the Atlantic river-system, and it is estimated that only one-seventh of the area of the Asiatic continent drains into the Pacific Ocean. The huge wall of the Andes practically reduces the Pacific rivers of South America to the rank of mountain streams; the Biobio and the Maypu in Chili are the only ones exceeding 100 miles in length,—the former having a course of 180, the latter of 160 miles. The Rocky Mountain chain, which forms the watershed of North America, runs parallel to the Pacific coast at a distance of about 1000 miles, and the Cascade and minor ranges which skirt the shore are broken through in several places to give passage to rivers that are, in some cases, of considerable size. The Colorado rises in the State of that name, at the base of the Rocky Mountains, flows south-west through Utah and Arizona, and falls into the head of the Gulf of California. Its course measures about 1100 miles, and it drains a rugged and barren area of 170,000 square miles. California has only one river, the Sacramento, 420 miles long. The Oregon (or Columbia) is formed by the union of two streams rising in the Rocky Mountains, one in British Columbia, the other in Idaho. It is a swift-flowing river, full of rapids and cataracts, and, though it is only 750 miles long; the area which it drains is greater by one-seventh than that drained by the Colorado. The ebb and flow of the tide are perceptible for a hundred miles from the mouth of the Oregon, and the river is navigable for that distance. The Frazer, which has a length of 600 miles, flows southward through British Columbia from the Rocky Mountains, and enters the sea in the Gulf of Georgia opposite Vancouver Island, carrying off the rainfall of 98,000 square miles. The northern limit of the American mountain chains is marked by the rise of the great river Yukon, which traverses Alaska; and, after a run of more than 2000 miles, it enters

Behring Sea, opposite the island of St Lawrence. Its tributaries have not been fully explored, so the area which they intersect is unknown, but probably it is very large.

The Asiatic division of the Pacific river-system is very much more extensive than the American, and includes many streams of great size and of considerable commercial importance. In the north the Amur is more than 2000 miles long, and it receives many tributaries, which rise on the north in the Stanovoi mountains, and on the west and south on the borders of the great table-land of the Gobi, the central Asiatic desert; altogether its basin measures nearly 900,000 square miles. The Hoang-ho (Hwang-ho or Whang-ho) and the Yangtze-keang both rise near the Kuen-lun mountains of Tibet amongst the extensive terraces which form the eastern slope of the great table-land of Central Asia. The Hoang-ho has a length of 2600 miles, and in its course it sweeps in a northerly curve close to the In-Shan mountains; then, after being crossed repeatedly by the Great Wall of China, it turns sharply to the south, and finally runs due east into the Yellow Sea. The Yangtze-keang follows a southward direction from its source, but ultimately turns to the north-east and enters the Yellow Sea not far from the mouth of the Hoang-ho. It is one of the longest rivers in the world, for, including its windings, it measures 3200 miles from its source to the sea. These two rivers drain more than a million and a quarter square miles; and it is principally owing to the large amount of suspended matter which they carry down that the sea into which they fall is called the Yellow Sea. The other rivers of importance are the Choo-keang, the Mekong, and the Menam. The last two run into the Gulf of Siam, after watering the peninsula of Siam and Cochin China. Few rivers enter the Pacific on the east coast of Australia, and in consequence of the proximity of the mountains to the shore they are short and unimportant.

Atmospheric Pressure and Prevailing Winds.—When the mean atmospheric pressure for the year over the entire surface of the world is considered, it is found that there are two broad belts of high pressure which encircle the globe, one on each side of the equator. There is a wide area of slowly diminishing pressure between them, including a narrow central band along which the barometric readings attain a minimum. Two other regions of low pressure surround the poles, and extend to a considerable distance. That around the North Pole is connected with an area of still lower pressure over the North Pacific, and there is another permanent depression, which is even deeper, in the vicinity of Iceland. Atmospheric pressure is the fundamental meteorological phenomenon, and the mean pressure for the year affords a clue to the cause of all such regular and continuous phenomena as trade winds and ocean currents, and to the distribution of temperature. Similarly a study of the isobars at different seasons throws light upon all periodical occurrences in the way of winds and currents.

A low barometer is always accompanied by a high percentage of atmospheric aqueous vapour; consequently the equatorial belt of continuous low pressure is a region of almost continuous rain, excessive cloud, and constant calm or light variable winds. The effect of a difference in atmospheric pressure being established between two places is to produce a flow of air from the region of high towards that of low pressure, and the winds in their turn largely determine the surface movements or drift currents of the ocean. The region of calms between the north and south trades in the Pacific is both narrower, more irregular, and less clearly marked than the corresponding belt in the Atlantic. In the East Pacific it lies, at all seasons, considerably north of the equator; but during the southern

summer it is found south of the line in the western parts of the ocean, and disappears entirely in the northern summer, as the calms of the Indian Ocean do also. The reason of the southern position of the west end of the calm belt seems to be the simultaneous occurrence of low atmospheric pressure in the interior of Australia and an exceptionally high barometer in Asia. In the southern winter the depression over Asia and the increase of pressure over Australia form an unbroken barometric gradient, and the result is that the calms are replaced by a southerly breeze of great regularity. The region of calms included between the zones of the two trade winds, and towards which they blow, is not the only one with which they are associated; for the opposite meteorological conditions that characterize the northern border of the north-east trades and the southern margin of the south-east winds produce two fringing bands of calms. These regions are characterized by a high barometer, a sunny sky, and occasionally sudden squalls,—contrasting with the depressed barometer and dull, wet weather of the equatorial region. In January the low atmospheric pressure over the North Pacific produces winds which affect the climatological conditions of the shores in very different ways. At Vancouver Island the prevailing wind is south-west, and consequently the winter on the shores of British Columbia is mild and moist. The opposite coast of Asia is visited during the same season by northerly winds,—north-east in Alaska, north-north-east in Kamchatka, and north-west in Japan; and, as a result, the weather in these regions in winter is dry and bitterly cold. The West Pacific and the Indian Ocean are the regions of monsoons,—winds that blow as steadily as the trades, but which change their direction with the season. During the periods of transition the steady breeze gives place to variable winds, occasional calms, and sometimes terrific hurricanes. The general direction of the monsoons in the Pacific between April and October is southerly and south-easterly, and from November to April they blow from the north-east, and on nearing the continent of Asia from the north-west. Monsoonal winds are found connected with all continents; they are produced by the great differences in the temperature and pressure which prevail over the land at different seasons as compared with the adjacent ocean. The monsoons give rise to oceanic currents which flow in the same direction as the wind, and like it run opposite ways during alternate half years. Although the velocity of the wind over the open sea is always greater than that near shore or on land, it was shown by the observations of the "Challenger," in the Pacific and other oceans, that there is no distinct diurnal variation in the wind's force at sea, though very decided periods of maxima and minima were noticed in the vicinity of land (see METEOROLOGY, vol. xvi. p. 125).

Currents.—The system of surface circulation in the Pacific is much more complicated and less clearly defined than that in the Atlantic, as might be expected from the less constant character of the winds. The latter ocean has two wide channels of communication with the Arctic Sea, while, so far as currents are concerned, the Pacific is land-locked to the north—Behring Strait being narrow and shallow; consequently water enters the Pacific almost entirely from the south, where there is uninterrupted communication with the Antarctic Ocean. There is no direct information as to the movements of ocean water at depths greater than 200 or 300 fathoms; it is known, however, from indirect evidence, that movements do occur. Although the subject of under-currents at depths less than those just mentioned has been extensively studied, it is only with respect to surface currents that anything very definite is as yet known.

The vast extent of the Pacific Ocean gives full scope for the current-producing action of tides and winds, while the smooth continental boundary on its eastern side, the numerous groups of islands which break its surface, and its indented western coast, combine to modify the direction of the main streams and to produce innumerable minor currents, some permanent, and others varying from time to time in velocity and direction. The chief cause of these currents is believed to be traceable to the direct or indirect action of wind; but here it is proposed to refer merely to their general geography and physical effects, without discussing the theory of their formation.

A general surface drift of the cold waters of the Antarctic Ocean, having a temperature lower than 40° Fahr. at all seasons, bears north-east towards Cape Horn, where it divides into two branches; one, the Cape Horn current, passes on into the Atlantic, and the other sweeps northward along the west coast of South America until it strikes the Peruvian shore, which deflects it westward. The cooling effect of this current on the water all along the coast is illustrated very clearly by the abrupt northward turn of the isothermals (see METEOROLOGY, figs. 8 and 9), which is more conspicuous in the chart for the southern winter than in that for the summer. In summer, however, there is a more striking evidence of this current's cooling power to be seen in the arrangement of the isothermals. The northern line of 70° Fahr. reaches as far south as 18° N. lat., and that of 80° makes a short loop from 18° N. to the equator; but the southern isothermal of 80° does not touch the American coast at all, and that of 70° lies farther from the equator than 30° S. lat., so that the increase of temperature from the south is very gradual; so much so that at the Galapagos Islands, under the equator, the temperature of the surface water is only 70°, while a few hundred miles to the west it is over 80°. Penguins—essentially Antarctic birds—are found living on the shores of these islands. In consequence of this current, the highest surface temperature at all seasons of the year is found distinctly to the north of the equator in the eastern Pacific.

The Peruvian current forms the southern fork of the great equatorial current, which runs due west. This current is very broad, and divided by a narrow counter-current flowing in an opposite direction through its centre. The two branches of the equatorial current occupy very approximately the two areas of falling barometer between the north and south belts of high pressure and the central trough of minimum barometric readings. This difference of atmospheric pressure on each side produces the north-east and south-east trade winds, and to these the current probably owes its regularity and constant direction. The counter-current lies in the narrow belt of low barometric pressure to which the trades blow, and probably originates from the banking up of the waters to the westward. Its rate and position consequently vary greatly at different times of the year. The "Challenger," on her cruise between the Sandwich and Society Islands, found these currents to run with considerable force. In the "Narrative" of the cruise (chap. xviii.) the fact is alluded to thus:—

"From Hawaii Island to the 10th parallel the direction of the current was westerly, and its average velocity 18 miles per day, ranging from 10 to 23 miles. From the 10th to the 6th parallel the direction was easterly, and its average velocity 31 miles per day, ranging from 7 to 54 miles per day. From the 6th parallel of north latitude to the 10th parallel of south latitude the direction was again westerly, and the average velocity 35 miles per day, ranging from 17 to 70 miles per day. From thence to Tahiti the general tendency of the current was westerly, but its velocity was variable. The axis of greatest velocity of the counter-equatorial current was between the 7th and 8th parallels of north latitude. The axis of greatest velocity of the equatorial current was on the parallel of 2° north, where its speed amounted to 3 miles per hour."

The equatorial current strikes on the East Indian Archipelago, where it is split up by the narrow channels and shallow waters, and diverted into numberless minor currents. The two main divisions, which have acquired a high temperature from prolonged exposure to the tropical sun, ultimately leave the archipelago; the southern arm curves southwards, carrying its warm water to the east coast of Australia and to New Zealand, whence it is diverted towards the east, and becomes merged again in the general north-easterly antarctic drift. The north equatorial current, which varies in volume and velocity with the monsoons, strikes the coast of Asia between the Philippines and Japan, and is deflected in a north-easterly direction as the Kuro-Siwo or Japan current—wholly a warm oceanic river during the S.E. monsoon similar to the Gulf Stream of the Atlantic. The Japan current sends many branches into the inland seas and channels of the north-eastern coast of Asia, but the main body of water flows northward until it bifurcates in 40° N. lat., sending one fork among the Kurile Islands and along the Kamchatka peninsula into Behring Sea, whence it escapes by Behring Strait into the Arctic Ocean. A small counter-current of arctic water flows southward through Behring Sea, but it is not of sufficient volume to make its influence felt very decidedly on the general temperature of the surface water in the vicinity. The second and larger branch of the Japan current crosses the North Pacific, and, curving southward by Alaska and British Columbia, part of it returns as the north equatorial current, while the rest forms the variable Mexican current that runs along the coasts of California and Mexico.

The general direction of surface circulation in the Pacific may be remembered by supposing the ocean divided into a northern and southern half by the equatorial counter-current. In the northern half the water circulates in the direction of the hands of a watch, *i.e.*, it passes up the west coast and down the east, while in the southern half the rotation is in the opposite direction—down the west coast and up the east; but the latter half does not exhibit the complete cycle so distinctly as the former. The centre of each area of circulation is occupied by a small Sargasso Sea, the northern being the more clearly defined, but neither approaches the well-known Sargasso Sea of the North Atlantic either in definiteness, extent, or amount of weed.

Temperature of Surface Water.—The distribution of temperature in the surface water of the Pacific varies considerably during the year. The equatorial region is of course comparatively little affected by the change of season, but there is a general rise of temperature in the northern parts of the ocean, and a fall in the southern, during the northern summer, and a similar rise in the south and fall in the north during winter. The charts exhibit a general northward move in the isothermals during the former season, and a southward tendency in the latter. The change in the position of the lines is greatest in the temperate zones. The charts of ocean surface temperature (see METEOROLOGY, figs. 8, 9) for February and August show the direction of the isothermals at two opposite seasons; and reference to them will make it plain that in temperate regions the lines of equal temperature follow the parallels of latitude much more closely in the Pacific than in the Atlantic, while their displacement with the change of season takes place in a direction nearly north and south. There are notable instances of divergence from these rules, such as the peculiarity of the isothermal of 80° already alluded to. Another circumstance is the fact that the temperature of the surface water on the western side of a great continent is much lower than that on the eastern side in the same latitude; it seems as if the west side of

a continent attracted the isothermals, making them converge towards the equator. It has already been pointed out that these effects are due to the winds and the cold currents which strike the western continental shores and run along the coasts. The surface temperature of the Pacific, between the latitudes of 45° N. and 45° S., nowhere at any season falls below 50° . In August the southern isotherm of 50° remains close to the 50th parallel, not diverging more than a degree or two on either side. Between the 45th parallels and the northern and southern limits of the ocean the temperature is almost always below 50° . The southern isotherm of 40° is remarkable for its constant position all the year round, between latitudes 55° and 58° ,—a result brought about by the gigantic antarctic icebergs which prevent the surface temperature of the water from rising during the southern summer.

The northern and southern "isocrymes" of 68° , that is the lines which pass over water which has a mean temperature of 68° during the coldest months of the year, lie, according to Dana (*Corals and Coral Islands*, 1872), between the latitudes of 20° and 30° on each side of the equator, except in the neighbourhood of the South-American coast, where the isocryme runs north in a loop beyond the equator,—a consequence of the cooling effect of the Peruvian current. These isocrymes mark out an area of great importance; for the reef-building corals are confined within it.

The highest temperature which sea water has been observed to attain is 90° F., and water of this temperature is only met with in the Red Sea. The maximum in the Pacific in the month of August is reached in the boundary between it and the Indian Ocean (in the Malay Archipelago) and in a narrow strip along the Mexican coast; in both these regions the thermometer immersed in the surface water registers 85° as a mean. There is a considerable area which in August stretches between New Guinea and Japan, from 10° S. to nearly 30° N., where the surface temperature reaches 84° , but these are exceptional temperatures.

When the "Challenger" was cruising in the South Pacific—in 1874 and 1875—the water was found to be uniformly warmer than the air, the difference in temperature between the two averaging $1^{\circ}5$ to 2° Fahr. In the North Pacific, between the latitudes of 30° and 40° , on the other hand, the atmospheric temperature is about half a degree higher than that of the surface water. Such differences may be explained by considering the effect of warm and cold currents, which alter the temperature of the water much more rapidly than that of the air, and of warm and cold winds, which affect the atmosphere more quickly than the ocean.

Deep-Sea Temperature.—The serial temperature soundings of the "Challenger" in the Pacific give a very good idea of the distribution of temperature in the deeper waters. There seems to be a slow massive movement of water from the Antarctic Ocean into the Pacific, which is not confined to the surface currents, but affects the whole mass of water down to the bottom. The rate of this motion is quite unknown. In the open sea, far from coasts and barriers, the temperature of the water continually decreases as the depth increases. This is only true for the open ocean, fully exposed to the effects of the mass movement of the water; there is a very different distribution of temperature in enclosed seas such as those of the Western Pacific, or even in the ocean when a barrier presents itself to the moving water. The difference, which is brought out by the diagram (Plate II. fig. 1), is due to the fact that when a barrier exists it retards the motion of the lower portion of the water, which has the lowest temperature, while the higher passes on over it, and fills up the

area beyond with water at the uniform temperature of the great ocean at the point to which the top of the ridge or obstruction reaches. In the Sulu Sea, for instance, the diagram shows¹ that the temperature falls steadily and rapidly from 80° at the surface to $50^{\circ}5$ at 400 fathoms, and then continues at $50^{\circ}5$ right down to the bottom in 2500 fathoms, instead of sinking to somewhere about 35° , as it is observed to do in the open ocean at that depth. The inference is that the Sulu Sea is surrounded by a ridge rising to at least about 400 fathoms from the surface, which prevents the great ocean circulation from having its cooling effect, and soundings indicate that this is really the case. A study of the temperature phenomena, such as those just referred to, points out with considerable certainty the existence and height of barriers and ridges in many parts of the ocean, where their presence has not been detected by actual soundings.²

During the cruise of the "Challenger" the bottom temperature over the North Pacific was found to be $35^{\circ}1$; south of the Sandwich Islands it fell to 35° ; in the Low Archipelago it again rose to $35^{\circ}1$; on the 40th parallel it fell to $34^{\circ}7$ in the deep water, but rose to $35^{\circ}4$ and $35^{\circ}5$ in the shallow water of the Patagonian elevation. The thermometer registered $34^{\circ}5$ at the bottom between Australia and New Zealand; while in that part of the ocean to the north-east of Australia known as the Coral Sea, although the depth was the same (about 2500 fathoms), the bottom temperature was as high as $35^{\circ}9$. The variations of temperature in the enclosed seas of the Eastern Archipelago were found to be considerable, and nearly all those seas show the phenomenon of constant temperature from an intermediate point to the bottom, consequent on the existence of barriers. The chief details of the thermal conditions of these seas are represented graphically in the diagram (Plate II. fig. 1). Between the Caroline Islands and Japan the bottom temperature was $35^{\circ}3$. The bottom temperature in the Pacific is on the average about 1° F. lower than that in the Atlantic.

The temperature of the water at the depth of 300 fathoms is nearly the same (40° to 45°) over the whole of the North Pacific, but above 300 fathoms the water is warmer in the western than in the central portion, while below that depth it is colder in the former than in the latter. The same phenomenon is noticed between the latitudes of 34° S. and 40° S., but here 700 fathoms marks the plane of constant temperature. Between 33° N. and 40° S. the temperature of the water above 200 fathoms is higher in the North than in the South Pacific, whilst from 200 to 1500 fathoms it is lower in the North, and below the latter depth the condition reverts to what it was above 200 fathoms.

The diagram (Plate II. fig. 2) exhibits the bathymetrical distribution of temperature in a section of the Pacific from a position in $38^{\circ}9'$ N. lat. and $156^{\circ}25'$ W. long. to one in $40^{\circ}3'$ S. lat. and $132^{\circ}58'$ W. long. as determined by H.M.S. "Challenger" in 1875, and may be compared with similar diagrams of the ATLANTIC (see vol. iii. p. 23). In order to separate the isothermals in the first 200 fathoms sufficiently the scale of depths required to be made large, while in order that the length of the diagram might be kept within reasonable bounds the scale of latitude was made very much smaller. The result of this is to exaggerate the inequalities of the sea bottom, making the slopes very much steeper than they are; this effect is best seen in the way in which islands are represented. The rapid falling off of temperature in the first few hundred fathoms, and then its very slow but steady decrease to the bottom are to be observed, and the fact that latitude has a great effect on the surface temperature, but

¹ The encircled numbers in the diagrams (Plate II. figs. 1 and 2) indicate the "Challenger" stations.

² An excellent example of the existence of a submarine barrier being pointed out by a wide divergence in the temperature in contiguous areas of the ocean is met with in the Faroe Channel (see NORWEGIAN SEA, vol. xvii. p. 594, and NORTH SEA, p. 564, fig. 1).

none at considerable depths, for the isotherm of 40° is constantly between 300 and 400 fathoms, and also that depth alone determines the bottom temperature in the open ocean, the coldest water occurring as a matter of fact under the equator in the deepest troughs open to the south.

Density of the Water.—The specific gravity of ocean water is an index of its salinity, since the researches of various chemists, foremost amongst whom are Forchhammer and Dittmar, have shown conclusively that the percentage composition of the salts in sea water is the same in all parts of the ocean, so far at least as regards the principal constituents. Mr J. Y. Buchanan made continuous observations on the specific gravity of sea water during the whole voyage of the "Challenger," and has published a very valuable paper on the distribution of salt in the ocean in the "Challenger" Reports (*Phys. Chem. Chall. Exp.*, vol. i. part ii.). The chart in Plate II. showing the geographical distribution of surface density is copied from that paper. The percentage of total salts in sea water, as deduced from the specific gravity, is, according to Buchanan and Dittmar—

| | | | | |
|-----------------|--------|--------|--------|--------|
| Density..... | 1.025 | 1.026 | 1.027 | 1.028 |
| Percentage..... | 3.3765 | 3.5049 | 3.6343 | 3.7637 |

The density of the water in different parts of the ocean must obviously change to a certain extent with the season; and it is not only the surface density that is affected in this way; any cause which promotes evaporation tends to increase the salinity of surface water, while any conditions that effect condensation of aqueous vapour produce dilution. For instance, in the China Sea during the month of November, at the end of the south-west monsoon, which is a moist wind accompanied by much rain, the specific gravity observed was 1.02518, and two months later, after the dry north-east monsoon had been blowing for some time, evaporation had proceeded so far that the specific gravity had risen to 1.02534. The climate is the principal factor in determining surface salinity, and the causes which produce well-marked climatic conditions have an equally apparent effect on the density of the water. Thus there are two zones of comparatively high density encircling the globe in the region of the north-east and south-east trade winds, which are dry and promote rapid evaporation; and similarly the region of calms and rain between the trades is distinguished by the low specific gravity of the water. North and south of these areas there are two zones where the salinity maintains a mean value, in consequence of there being a balance between evaporation and condensation; and round the poles there are areas of concentration brought about by the freezing of the sea water and the separation of salt, which of course increases the salinity of the water remaining unfrozen.

The distribution of density differs considerably in the two great oceans. In the Atlantic there are two areas of high specific gravity, one in the north, the other in the south; while in the Pacific there is only one, situated in the southern division of the ocean in the neighbourhood of the Society Islands. It is neither so large as those of the Atlantic, nor has it so high a specific gravity. The density of the concentration areas in the Atlantic, taking pure water at 4° C. as unity, is 1.02750; that in the saltiest portion of the Pacific is only 1.02700. In the North Pacific the salinity is less than in the South, and its distribution is much more uniform. The density in this region never exceeds 1.02650, and the minimum, in the rainy region of the equatorial counter current, is as low as 1.02485. The South Pacific has water of a relatively high density, its maximum being 1.02750. The water of the seas of the Eastern Archipelago, in the western basin of the Pacific, although exposed to the full force of an equatorial sun, and possessed of a very high surface temperature, is yet surprisingly fresh. The specific

gravity varies considerably with the season, but the average for the year over the greater part of these seas is under 1.02550; and there is a large area surrounding the islands of Java and Sumatra where the dilution is greater, the hydrometer only indicating 1.02500. The weak salinity of these waters is largely to be attributed to the extreme humidity of the atmosphere, the frequent and heavy rains, and the fact that so many lofty and extensive islands, where the annual rainfall rises above 200 inches, drain into the seas. Water of such a degree of dilution is not met with anywhere else, except near the mouths of rivers and in the vicinity of melting ice, and, as a temporary phenomenon, after prolonged rain in the tropics.

In regions where there is decided and continuous concentration in progress, the specific gravity of the water is greatest at the surface and decreases as the depth increases, down to about 800 or 1000 fathoms, after which the density increases slowly with the depth until the bottom is reached. The density of the bottom water of the Pacific is almost the same everywhere; it only varies from 1.02570 to 1.02590; and the same value holds for the South Atlantic. The North Atlantic has denser water at the bottom, varying from 1.02616 to 1.02632. In those regions where the surface water is being constantly diluted, as is the case in the equatorial belt of calms, the density increases with the depth down to between 50 and 100 fathoms, where there is a maximum, from which the density diminishes, as in the other case, to about 1003 fathoms, and afterwards increases slowly down to the bottom. There is a striking resemblance between the direction of the isohalines, or lines of equal salinity, and of the isothermals; but the parallelism breaks down, of course, in the case of a subsurface maximum.

Depth.—For a long time the opinion that the Pacific was a comparatively shallow ocean was entertained by geographers, and it is only the recent soundings of the "Challenger," "Tuscarora," "Gazelle," and other surveying ships that have succeeded in dispelling the illusion. It is now known that the average depth of the Pacific is greater than that of the Atlantic, and that areas of deeper water occur in it than in any other part of the globe. A line running along the western shores of the two Americas and along the eastern shores of the Asiatic continent more or less closely follows a great circle of the globe. On the one side of this line there are the continental masses of the Americas and of Europe and Asia, with an average height of about 800 feet above the level of the sea; and on the other side the vast oceanic depression of the Pacific, with an average depth of about 2500 fathoms. The average level of the continental area may thus be regarded as about three miles above the Pacific depression.

The attempt to divide the ocean into sharply defined basins is more or less unsatisfactory; and for the consideration of the depth it is better to view the Pacific as marked off into two portions by an imaginary line passing through Honolulu and Tahiti, on the meridian of 150° W.

The eastern half is remarkable for the comparative absence of islands and the uniform nature of its depth. With the exception of the narrow strip of shallow water surrounding the Aleutian Islands and running along the American coast, the sounding line shows an average depth of from 2000 to 3000 fathoms undiversified by remarkable elevations or depressions, between the northern limit of the ocean and 30° S. lat. There is a great submarine plateau extending from the Patagonian coast (in 76° W. long.) in a westerly direction to 120° W. long., which rises to between 2000 and 1000 fathoms of the surface. This elevated area diminishes in breadth as it proceeds westward, but it is supposed by some authorities to be

connected with the shallow water surrounding the Low Archipelago and the Marquesas Islands (groups which are bisected by the 140th meridian of west longitude) and the Society Islands. If this be the case there is an almost continuous area of elevation stretching between Patagonia and Japan. It has been remarked that many of the submerged plateaus of the Pacific have a south-east to north-west trend. The "Challenger" examined the depth of the eastern half of the Pacific in 1875, along a line which extended from 38° N. lat. on the 160th meridian south-east to the Sandwich Islands, and then as nearly as possible along the 150th meridian to the Society Islands in 23° S. lat. From this point the course was again south-east to the 40th parallel of south latitude, which was followed eastward to the Patagonian coast, a visit to Juan Fernandez forming a northward digression. The depth was ascertained at fifty points along this route, and it was found to vary on the whole from 2000 to 3000 fathoms. There were two soundings of over 3000 fathoms between latitudes 38° and 36° N., and one a little to the south of the Sandwich Islands. Between the meridian of 120° W. and the coast of America the soundings showed the depth to vary considerably as the ship was in deep water or over the submerged Patagonian plateau. The actual numbers observed proceeding eastward from 120° W. long. were in fathoms:—2250, 1600, 2025, 2270, 1500, 1825, 1775, 1375, 2160, 2225, 1450, 1325. The soundings made by the United States ship "Tuscarora" during 1874 were much more numerous, closer together, and extended along several lines, but the general result was similar to that of the "Challenger" observations. The results of all recent observations are shown on Plate III.

The western half of the Pacific Ocean is a complete contrast to the eastern. Archipelagos and scattered islands are exceedingly numerous; the depth of the ocean is by no means uniform, for shallows and areas of unusual depth occur scattered over it at irregular intervals. Along the Asiatic coast and between the island groups there are a number of partially enclosed seas, and these are separated from the great ocean by submarine plateaus of sufficient extent and height to warrant the supposition that a moderate upheaval would extend the Asiatic continent as far south as Australia, transforming the seas into inland salt lakes. Considerations of the peculiar animal and vegetable life of New Zealand and Australia lend some degree of probability to the speculation that these islands were joined to the main continent of Asia at some very remote period; and it is even possible to trace the submerged coast-line of the great continent which then existed. This line separates the very deep water of the West Pacific from the shallower water of the inland seas and archipelagos; it runs from Kamchatka, over Japan, Formosa, the Philippines, New Guinea, to Australia and New Zealand. The most conspicuous peculiarity of the West Pacific is the very deep water lying in a crescent shape to the east of the Kurile Islands and Japan. It extends from 50° N. lat. to nearly 20° N. lat., although it is of no great breadth. The average depth of this area is nearly 4000 fathoms, and a narrow strip of still more abyssal depths runs along its western margin, like a ditch across the entrance to the Sea of Okhotsk; here the United States ship "Tuscarora" found depths of over 4600 fathoms. The course of the "Challenger" led her to explore the seas of the Eastern Archipelago pretty thoroughly, and she carried a line of soundings from the archipelago to Japan, and thence eastward across the Pacific, crossing the area of great depth about the centre, off Nippon, where two soundings of 3950 and 3625 fathoms respectively were obtained. Like the East Pacific, the western division of the ocean has an average depth of from 2000 to 3000 fathoms, although a

great number of small depressions exist where the depth is greater, and detached areas of shallower water occur still more frequently. Many of the islands rise from depths of about 3000 fathoms, forming isolated mountains springing from the bed of the ocean, and several peaks which do not rise to the surface have been detected. More usually a number of islands are bound together by submarine elevations, frequently within a few hundred fathoms of the surface, over wide areas. Although the greater part of the sea surrounding New Zealand, the north of Australia, and the adjacent islands is under 1000 fathoms in depth, there are areas of great depression amongst the islands, and some very deep channels. In 1875 when sounding in the channel between the Carolines and Ladrones, the "Challenger" met with the deepest water of the cruise, 4475 fathoms, or about five miles and a quarter; and this is the greatest depth from which a specimen of the bottom has hitherto been obtained. This abyssal depth only extends over a relatively small area, for the two nearest "Challenger" stations, one to the north and one to the south, had depths of 2300 and 1850 fathoms respectively.

The seas branching off from the Pacific are usually relatively shallow. Behring Sea on the north has extremely shallow water in its north-eastern half, where there is a depth of under 100 fathoms; in the south-western portion the depth increases rapidly to between 1000 and 2000 fathoms, except round the coasts and the Aleutian Archipelago. The Sea of Okhotsk is still shallower: much of it is within the 100 fathom line; and in its deepest part it does not attain 1000 fathoms. The Yellow Sea is entirely within the hundred fathom line; while the Sea of Japan, only separated from it by the Korean Peninsula, is not inferior in depth to the open ocean, its average depth being from 2000 to 3000 fathoms. The western portion of the Pacific, which lies between the Philippines and the Carolines and Ladrones, is also very deep, its mean depth approaching 3000 fathoms. This sea is of importance, since it is to the Pacific what the Gulf of Mexico is to the Atlantic—the source of its great northern thermal current. The fact that the temperature at 1500 fathoms over the whole of the North Pacific does not differ by more than 0°·5 F. from that at the bottom appears to indicate that this portion is cut off from the southern division by a ridge rising to within 1500 fathoms of the surface. The existence of such a barrier cannot be said to be proved, but the indications lead to the supposition that it may extend from Japan to the equator, through the Bonin, the Ladrones, and the Caroline Islands.

Taken altogether, so far as present knowledge goes, the bed of the Pacific is more uniform than that of the Atlantic, and its changes of level are less abrupt. Its depth is, on an average, greater, and appears to be more evenly distributed than in the Atlantic, but this apparent greater uniformity may be partly due to the fact that the latter ocean, both on account of its smaller size and its greater commercial importance, has been much more carefully surveyed, and its bathymetrical conditions more exactly ascertained.

DEPOSITS.

The explorations of the "Challenger," "Tuscarora," and other surveying ships have in recent years given a great amount of information respecting the nature of the deposits now forming over the floor of the ocean, and the specimens collected by these expeditions have been made the subject of a careful investigation by Messrs Murray and Renard. The great extent and depth of the Pacific Ocean make it the most suitable field for the study of the varieties of deep-sea deposits and the conditions under which they are found. The various kinds of deposits, all of which are found in the Pacific Ocean, are classed as follows:—

| | | |
|-----------------------|--------------------------|--|
| Terrigenous deposits. | Shore formations. | Found in inland seas and along the shores of continents. |
| | Blue mud. | |
| | Green mud and sand. | |
| | Red mud. | |
| Pelagic deposits. | Coral mud and sand. | Found around oceanic islands and along the shores of continents. |
| | Coralline mud and sand. | |
| | Volcanic mud and sand. | |
| | Red clay. | |
| | <i>Globigerina</i> ooze. | Found in the abyssal regions of the oceanic basins. |
| | Pteropod ooze. | |
| | Diatom ooze. | |
| | Radiolarian ooze. | |

The *terrigenous deposits* are found in more or less close proximity to the land, and are chiefly made up of the triturated fragments carried down into the ocean by rivers, or worn away from the coasts by waves or currents. Those found in the deeper water surrounding the land differ from the sands, gravels, and shingles of the shore and shallow water chiefly in the smaller size of the grains and the greater abundance of clayey matter and remains of oceanic organisms. As, however, the water becomes still deeper and the distance from land greater, the deposits assume, more and more, a deep-sea character until they pass into a true pelagic deposit.

The principal mineralogical constituents of the terrigenous deposits near continental land are isolated fragments of rocks and minerals coming from the crystalline and schisto-crystalline series, and from the clastic and sedimentary formations; according to the character of the nearest coasts they belong to granite, diorite, diabase, porphyry, &c., crystalline schists, ancient limestones, and the sedimentary rocks of all geological ages, with the minerals which come from their disintegration, such as quartz, monoclinic and triclinic feldspars, hornblende, augite, rhombic pyroxene, olivine, muscovite, biotite, titanite and magnetic iron, tourmaline, garnet, epidote, and other secondary minerals. The trituration and decomposition of these rocks and minerals give rise to materials more or less amorphous and without distinctive characters, but the origin of which is indicated by association with the rocks and minerals just mentioned.

Mixed with these are found in many places phosphatic nodules, large quantities of glauconite, and minerals arising from chemical action probably in presence of organic matter.

Blue mud is the most extensive deposit now forming around the great continents and continental islands, and in all enclosed or partially enclosed seas. It is characterized by a slaty colour, which passes in most cases into a thin layer of a reddish colour at the upper surface. These deposits are coloured blue by organic matter in a state of decomposition, and frequently give off an odour of sulphuretted hydrogen. When dried, a blue mud is greyish in colour, and rarely or never has the plasticity and compactness of a true clay. It is finely granular, and occasionally contains fragments of rocks 2 cm. in diameter; generally, however, the minerals which are derived from the continents, and are found mixed up with the muddy matter in these deposits, have a mean diameter of 0.5 mm. and less. Quartz particles, often rounded, play the principal part; next come mica, feldspar, augite, hornblende, and all the mineral species which come from the disintegration of the neighbouring lands, or the lands traversed by rivers which enter the sea near the place where the specimens have been collected. These minerals make up the principal and characteristic portion of blue muds, sometimes forming 80 per cent. of the whole deposit. Glauconite, though generally present, is never abundant. The remains of calcareous organisms are at times quite absent, but occasionally they form over 50 per cent. The latter is the case when the specimen is taken at a considerable distance from the coast and at a moderate depth. These calcareous fragments consist of bottom-living and pelagic *Foraminifera*, Molluscs, *Polyzoa*, *Serpulæ*, Echinoderms, Alcyonarian spicules, Corals, &c. The remains of Diatoms and Radiolarians are usually present. Generally speaking, as the shores are approached the pelagic organisms disappear; and, on the contrary, as we proceed seawards the size of the mineral grains diminishes, and the remains of shore and coast organisms give place to pelagic ones, till finally a blue mud passes into a true deep-sea deposit. In those regions of the ocean affected with floating ice, the colour of these deposits becomes grey rather than blue at great distances from land, and is further modified by the presence of a greater or less abundance of glaciated blocks and fragments of quartz. These deposits are found along the coasts of North and South America, and in all the enclosed and partially enclosed seas, such as the Japan Sea, China Sea, Arafura Sea, Sulu Sea, Banda Sea, Celebes Sea, Sea of Okhotsk, &c.

At some points in the same regions are found *green muds* and *sands*, which, as regards their origin, composition, and distribution near the shores of continental land, resemble the blue muds. They are largely composed of argillaceous matter and mineral particles of the same size and kind as the blue muds. Their chief characteristic is the presence of a considerable quantity of glauconitic grains, either isolated or united into concretions by a brown argillaceous matter. The *Foraminifera* and fragments of Echinoderms and other organisms in these muds are frequently filled with glauconitic substance, and beautiful casts of these organisms remain after

treatment with weak acid. At times there are few calcareous organisms in these deposits, and at other times the remains of Diatoms and Radiolarians are abundant. When these muds are dried they become earthy and of a grey-green colour. They frequently give out a sulphuretted hydrogen odour. The green colour appears sometimes to be due to the presence of organic matter, probably of vegetable origin, and to the reduction of peroxide of iron to protoxide under its influence. The green sands differ from the muds only in the comparative absence of the argillaceous and other amorphous matter, and by the more important part played by the grains of glauconite, to which the green colour is chiefly due. *Red mud* is found where quantities of ochreous matter are brought down by rivers and deposited along the coast, as in the Yellow Sea, but it is most characteristic in the Atlantic off the Brazil coast of America.

In addition to the terrigenous deposits above referred to, volcanic muds and sands and coral muds and sands are found around the shores of oceanic islands either of volcanic or coral origin. The *volcanic muds and sands* are black or grey, and when dried are rarely coherent. The mineral particles are generally fragmentary, and consist of lapilli of the basic and acid series of modern volcanic rocks, which are scoriaceous or compact, vitreous or crystalline, and usually present traces of alteration. The minerals are sometimes isolated, sometimes surrounded by their matrix, and consist principally of plagioclases, sanidine, amphibole, pyroxene, biotite, olivine, and magnetic iron; the size of the particles diminishes with distance from the shore, but the mean diameter is generally 0.5 mm. Glauconite does not appear to be present in these deposits, and quartz is also very rare or absent. The fragments of shells and rocks are frequently covered with a coating of peroxide of manganese. Shells of calcareous organisms are often present in great abundance, and render the deposit of a lighter colour. The remains of Diatoms and Radiolarians are usually present.

Coral muds frequently contain as much as 95 per cent. of Coral carbonate of lime, consisting of fragments of Corals, calcareous muds, algae, *Foraminifera*, *Serpulæ*, Molluscs, and remains of other lime-secreting organisms. There is a large amount of amorphous sand, calcareous matter, which gives the deposit a sticky and chalky character. The particles may be of all sizes according to the distance from the reefs, the mean diameter being 1 to 2 mm., but occasionally there are large blocks of coral and large calcareous concretions; the particles are white and red. Remains of siliceous organisms seldom make up over 2 or 3 per cent. of a typical coral mud. The residue consists usually of a small amount of argillaceous matter, with a few fragments of feldspar and other volcanic minerals; but off barrier and fringing reefs facing continents there may be a great variety of rocks and minerals. Beyond a depth of 1000 fathoms off coral islands the debris of the reefs begins to diminish, and the remains of pelagic organisms to increase; the deposit becomes more argillaceous, of a reddish or rose colour, and gradually passes into a *Globigerina* ooze or a red clay. *Coral sands* contain much less amorphous matter than coral muds, but in other respects they are similar, the sands being usually found nearer the reefs and in shallower water than the muds, except inside lagoons. In some regions the remains of calcareous algae predominate, and in these cases the name *coralline mud* or *sand* is employed to point out the distinction.

The extent and peculiarities of the region in which these terrigenous deposits are laid down are interesting. It extends from high-water mark down, it may be, to a depth of over 4 miles, and in a horizontal direction from 60 to perhaps 300 miles seawards, and includes all inland seas, such as the North Sea, Norwegian Sea, Mediterranean Sea, Red Sea, China Sea, Japan Sea, Caribbean Sea, and many others. It is the region of change and of variety with respect to light, temperature, motion, and biological conditions. In the surface waters the temperature ranges from 80° F. in the tropics to 28° F. in the polar regions. From the surface down to the nearly ice-cold water found at the lower limits of the region in the deep sea there is in the tropics an equally great range of temperature. Plants and animals are abundant near the shore, and animals extend in relatively great abundance down to the lower limits of the region, now marked out by these terrigenous deposits. The specific gravity of the water varies much, and this variation in its turn affects the fauna and flora. In the terrigenous region tides and currents produce their maximum effect, and these influences can in some instances be traced to a depth of 300 fathoms, or nearly 2000 feet. The upper or continental margin of the region is clearly defined by the high-water mark of the coast-line, which is constantly changing through breaker action, elevation, and subsidence. The lower or abyssal margin passes in most cases insensibly into the abyssal region, but may be regarded as ending where the mineral particles from the neighbouring continents begin to disappear from the deposits, which then pass into an organic ooze or a red clay.

The area covered by terrigenous deposits has been called the "transitional" or "critical area," and is estimated at about

two-eighths of the earth's surface, while the continents cover three-eighths, and the deep-sea deposits of the abyssal regions, which will now be considered, cover the remaining three-eighths.

The true deep-sea deposits may be divided into two classes, viz., those in which the organic elements predominate, and those in which the mineral constituents play the chief part. Belonging to the former class there are *Globigerina*, Pteropod, Diatom, and Radiolarian Oozes, and to the latter Red Clay.

Globigerina ooze is the name given to all those truly pelagic deposits containing over 40 per cent. of carbonate of lime which consist principally of the dead shells of pelagic *Foraminifera* (*Globigerina*, *Orbulina*, *Pulvinulina*, *Pullenia*, *Sphaeroidina*) and coccoliths and rhabdoliths. In some localities this deposit contains 95 per cent. of carbonate of lime. The colour is milky white, yellow, brown, or rose, the varieties of colour depending principally on the relative abundance in the deposit of the oxides of iron and manganese. This ooze is fine grained; in the tropics some of the *Foraminifera* shells are macroscopic. When dried it is pulverulent. Analyses show that the sediment contains, in addition to carbonate of lime,

phosphate and sulphate of lime, carbonate of magnesia, oxides of iron and manganese, and argillaceous matters. The residue is of a reddish-brown tinge. Lapilli, pumice, and glassy fragments, often altered into palagonite, seem always to be present, and are frequently very abundant. The mineral particles are generally angular, and rarely exceed 0.08 mm. in diameter; monoclinic and triclinic feldspars, augite, olivine, hornblende, and magnetite are the most frequent. When quartz is present, it is in the form of minute, rounded, probably wind-borne grains, often partially covered with

FIG. 1.—The finer particles of a *Globigerina* Ooze, showing, Coccoliths, Coccospheres, and Rhabdoliths.

oxide of iron. More rarely there are white and black particles of mica, bronzite, actinolite, chromite, glauconite, and cosmic dust. Siliceous organisms are probably never absent, sometimes forming 20 per cent. of the deposit, while at other times they are only recognizable after careful microscopic examination. In some regions the frustules of Diatoms predominate, in other the skeletons of Radiolarians.

FIG. 2.—*Globigerina* Ooze from 1900 fathoms.

Pteropod ooze differs in no way from a *Globigerina* ooze except in the presence of a greater number and variety of pelagic organisms, and especially in the presence of Pteropod and Heteropod shells, such as *Diacria*, *Atlanta*, *Styliola*, *Carinaria*, &c. The shells of the more delicate species of pelagic *Foraminifera* and young shells are also more abundant in these deposits than in a *Globigerina* ooze. It must be remembered that the name "Pteropod ooze" is not intended to indicate that the deposit is chiefly composed of the shells of these Molluscs, but, as their presence in a deposit is characteristic and has an important bearing on geographical and bathymetrical distribution, it is desirable to emphasize the presence of these shells in any great abundance. It may be pointed out that there is a very considerable difference between a *Globigerina* ooze or a Pteropod ooze situated near continental shores and

deposits bearing the same names situated towards the centres of oceanic areas, with respect both to mineral particles and to remains of organisms.

Diatom ooze is of a pale straw colour, and is composed principally of the frustules of Diatoms. When dry it is a dirty white siliceous flour, soft to the touch, taking the impression of the fingers, and contains gritty particles which can be recognized by the touch. It contains on an average about 25 per cent. of carbonate of lime, which exists in the deposit in the form of small *Globigerina* shells, fragments of Echinoderms and other organisms. The residue is pale white and slightly plastic; minerals and fragments of rocks are in some cases abundant; these are volcanic, or, more frequently, fragments and minerals coming from continental rocks and transported by glaciers. The fine washings consist essentially of particles of Diatoms along with argillaceous and other amorphous matter. It is estimated that the frustules of Diatoms and skeletons of siliceous organisms make up more than 50 per cent. of this deposit.

It has been already mentioned that Radiolarians are seldom, if ever, completely absent from marine deposits. In some regions they make up a considerable portion of a *Globigerina* ooze, and are also found in Diatom ooze and in the terrigenous deposits of the deeper water surrounding the land. In some regions of the Pacific, however, the skeletons of these organisms make up the principal part of the deposit, to which the name Radiolarian ooze has been given. The colour is reddish or deep brown, due to the presence of the oxides of iron and manganese. The mineral particles consist of fragments of pumice, lapilli, and volcanic minerals, rarely exceeding 0.07 mm. in diameter. There is not a trace of carbonate of lime in the form of shells in some samples of Radiolarian ooze, but other specimens contain 20 per cent. of carbonate of lime derived from the shells of pelagic *Foraminifera*. The clayey matter and mineral particles are the same as those found in the red clays, which will now be described.

FIG. 3.—Diatom Ooze from 1900 fathoms in the Antarctic Ocean.

Of all the deep-sea deposits red clay is the one which is distributed over the largest areas in the modern oceans. It might be said that it exists everywhere in the abyssal regions of the ocean basins, for the residue in the organic deposits which have been described under the names *Globigerina*, Pteropod, Diatom, and Radiolarian oozes is nothing else than the red clay. However, this deposit only appears in its characteristic form in those areas where the terrigenous minerals and calcareous and siliceous organisms disappear to a greater or less extent from the bottom. It is in the central regions of the Pacific that the typical examples are met with. Like other marine deposits, this one passes laterally, according to position and depth, into the adjacent kind of deep-sea ooze, clay, or mud.

The argillaceous matters are of a more or less deep brown tint from the presence of the oxides of iron and manganese. In the typical examples no mineralogical species can be distinguished by the naked eye, for the grains are exceedingly fine and of nearly uniform dimensions, rarely exceeding 0.05 mm. in diameter. It is plastic and greasy to the touch; when dried it forms lumps so coherent that considerable force must be employed to break them. It gives the brilliant streak of clay, and breaks down in water. The pyrognostic properties show that it is not a pure clay, for it fuses easily before the blowpipe into a magnetic bead.

Under the term red clay are comprised those deposits in which the characters of clay are not well pronounced, but which are mainly composed of minute particles of pumice and other volcanic materials.

FIG. 4.—Radiolarian Ooze from 4475 fathoms in Central Pacific.

Under the term red clay are comprised those deposits in which the characters of clay are not well pronounced, but which are mainly composed of minute particles of pumice and other volcanic materials.

which, owing to their relatively recent deposition, have not undergone great alteration. If the analyses of red clay are calculated, it will be seen, moreover, that the silicate of alumina present as clay ($2\text{SiO}_2 \cdot \text{Al}_2\text{O}_3 + 2\text{H}_2\text{O}$) comprises only a relatively small portion of the sediment; the calculation shows always an excess of free silica, which is attributed chiefly to the presence of siliceous organisms.

Microscopic examination shows that a red clay consists of argillaceous matter, minute mineral particles, and fragments of siliceous organisms. The mineral particles are for the greater part of volcanic origin, except in those cases where continental matters are transported by floating ice, or where the sand of deserts has been carried to great distances by winds. These volcanic minerals are the same constituent minerals of modern eruptive rocks enumerated in the description of volcanic muds and sands; in the great majority of cases they are accompanied by fragments of lapilli and of pumice more or less altered. Vitreous volcanic matters belonging to the acid and basic series of rocks predominate in the regions where the red clay has its greatest development; and it will be seen presently that the most characteristic decompositions which there take place are associated with pyroxenic lavas.

Associated with the red clay are almost always found concretions and microscopic particles of the oxides of iron and manganese, to which the deposit owes its colour. Again, in the typical examples of the deposit, zeolites in the form of crystals and crystalline spherules are present, along with metallic globules and silicates which are regarded as of cosmic origin. Calcareous organisms are so generally absent that they cannot be regarded as characteristic. On the other hand, the remains of Diatoms, Radiolarians, and Sponge spicules are generally present, and are sometimes very abundant. The ear-bones of various Cetaceans, as well as the remnants of other Cetacean bones and the teeth of sharks, are, in some of the typical samples far removed from the continents, exceedingly abundant, and are often deeply impregnated with, or embedded in thick coatings of, the oxides of iron and manganese. Over six hundred sharks' teeth, belonging to the genera *Carcharodon*, *Oxyrhina*, and *Lamna*, and one hundred ear-bones of whales, belonging to *Ziphius*, *Balænoptera*, *Balaena*, *Orca*, and *Delphinus*, along with fifty fragments of other bones, have been obtained in one haul of the dredge in the Central Pacific. The remains of these vertebrates have seldom been dredged in the organic oozes, and still more rarely in the terrigenous deposits.

The abyssal region, in which the true pelagic deposits above described are laid down, shows a marked contrast with the "transitional" or "critical area" where the terrigenous deposits are found. The former area comprises vast undulating plains from 2 to 5 miles beneath the surface of the sea, the average being about 3 miles, here and there interrupted by huge volcanic cones (the oceanic islands). No sunlight ever reaches these deep cold tracts. The range of temperature over them is not more than 7° , viz., from 31° to 38° F., and is apparently constant throughout the whole year in each locality. Plant life is absent, and, although animals belonging to all the great types are present, there is no great variety of form nor abundance of individuals. Change of any kind is exceedingly slow.

Leaving out of view the coral and volcanic muds and sands which are found principally around oceanic islands, the blue muds, green muds and sands, red muds, together with all the coast and shore formations, are situated along the margins of the continents and in enclosed and partially enclosed seas. The chief characteristic of these deposits is the presence in them of continental debris. The blue muds are found in all the deeper parts of the regions just indicated, and especially near the embouchures of rivers. Red muds do not differ much from blue muds except in colour, due to the presence of ferruginous matter in greater abundance, and they are found under the same conditions as the blue muds. The green muds and sands occupy, as a rule, portions of the coast where detrital matter from rivers is not apparently accumulating at a rapid rate, viz., on such places as the Agulhas Bank, off the east coast of Australia, off the coast of Spain, and at various points along the coast of America. In the tropical and temperate zones of the great oceans, which occupy about 110° of latitude between the two polar zones, at depths where the action of the waves is not felt, and at points to which the terrigenous materials do not extend, there are now forming vast accumulations of *Globigerina* and other pelagic *Foraminifera*, coccoliths, rhabdoliths, shells of pelagic Molluscs, and remains of other organisms. These deposits may perhaps be called the sediments of median depths and of warmer zones, because they diminish in great depths and tend to disappear towards the poles. This fact is evidently in relation with the surface temperature of the ocean, and shows that pelagic *Foraminifera* and Molluscs live in the superficial waters of the sea, whence their dead shells fall to the bottom. *Globigerina* ooze is not found in enclosed seas nor in polar latitudes. In the southern hemisphere it has not been met with south of the 50th parallel. In the Atlantic it is deposited upon the bottom at a very high latitude below the warm waters of the Gulf Stream, and is not observed under the cold descending polar current which

runs south in the same latitude. These facts are readily explained if it be admitted that this ooze is formed chiefly by the shells of surface organisms, which require an elevated temperature and a wide expanse of sea for their existence.

The distribution of oceanic deposits may be summarized thus. (1) The terrigenous deposits—blue muds, green muds and sands, red muds, volcanic muds and sands, coral muds and sands—are met with in those regions of the ocean nearest to land. With the exception of the volcanic muds and sands and coral muds and sands around oceanic islands, these deposits are found only lying along the borders of continents and continental islands, and in enclosed and partially enclosed seas. (2) The organic oozes and red clay are confined to the abyssal regions of the ocean basins; a Pteropod ooze is met with in tropical and subtropical regions in depths less than 1500 fathoms, a *Globigerina* ooze in the same regions between the depths of 500 and 2800 fathoms, a Radiolarian ooze in the central portions of the Pacific at depths greater than 2500 fathoms, a Diatom ooze in the Southern Ocean south of the latitude of 45° south, a red clay anywhere within the latitudes of 45° north and south at depths greater than 2200 fathoms.

As long as the conditions of the surface are the same, it might be expected that the deposits at the bottom would also remain the same. In showing that such is not the case, an agent must be taken into account which is in direct correlation with the depth. It may be regarded as established that the majority of the calcareous organisms which make up the *Globigerina* and Pteropod oozes live in the surface waters, and it may also be taken for granted that there is always a specific identity between the calcareous organisms which live at the surface and the shells of these pelagic creatures found at the bottom. *Globigerina* ooze is found in the tropical zone at depths which do not exceed 2400 fathoms, but when depths of 3000 fathoms are explored in this zone of the Atlantic and Pacific there is found an argillaceous deposit without, in many instances, any trace of calcareous organisms. Descending from the "submarine plateaus" to depths which exceed 2250 fathoms, the *Globigerina* ooze gradually disappears, passing into a greyish marl, and finally is wholly replaced by an argillaceous material which covers the bottom at all depths greater than 2900 fathoms.

The transition between the calcareous formations and the argillaceous ones takes place by almost insensible degrees, the thinner and more delicate shells disappear first. The thicker and larger shells lose little by little the sharpness of their contour and appear to undergo a profound alteration. They assume a brownish colour, and break up in proportion as the calcareous constituent disappears. The red clay predominates more and more as the calcareous element diminishes in the deposit. Recollecting that the most important elements of the organic deposits have descended from the superficial waters, and that the variations in contour of the bed of the sea cannot of themselves prevent the debris of animals and plants from accumulating upon the bottom, their absence in the red clay areas can only be explained by the hypothesis of decomposition.

Pteropod ooze, it will be remembered, is a calcareous organic deposit, in which the remains of Pteropods and other pelagic Mollusca are present, though they do not always form a preponderant constituent, and it has been found that their presence is in correlation with the bathymetrical distribution.

In studying the nature of the calcareous elements which are deposited in the abyssal areas, it has been noticed that, like the shells of the *Foraminifera*, those of the Thecosomatous *Pteropoda*, which live everywhere in the superficial waters, especially in the tropics, become fewer in number in the deposit as the depth increases. It has just been observed that the shells of *Foraminifera* disappear gradually along a series of soundings from a point where the *Globigerina* ooze has abundance of carbonate of lime, towards deeper regions; but it is also noticed that, when the sounding-rod brings up a graduated series of sediments from a declivity descending into deep water, among the calcareous shells of the Pteropods and Heteropods disappear first in proportion as the depth increases. At depths less than 1400 fathoms in the tropics a Pteropod ooze is found with abundant remains of Heteropods and Pteropods; deeper soundings then give a *Globigerina* ooze without these Molluscan remains; and in still greater depths, as has been said above, there is a red clay in which calcareous organisms are nearly, if not quite, absent.

In this manner, then, it is shown that the remains of calcareous organisms are completely eliminated in the greatest depths of the ocean. For if such be not the case, why are all these shells found at the bottom in the shallower depths, and not at all in the greater depths, although they are equally abundant on the surface at both depths, although they are equally abundant on the surface at both depths? There is reason to think that this solution of calcareous places is due to the presence of carbonic acid throughout all depths of ocean water. It is well known that this substance, dissolved in water, is an energetic solvent of calcareous matter. The investigations of Buchanan and Dittmar have shown that carbonic acid exists in a free state in sea water, and Dittmar's analyses also show

that deep-sea water contains more lime than surface water. This is a confirmation of the theory which regards carbonic acid as the agent concerned in the total or partial solution of the surface shells before or immediately after they reach the bottom of the ocean, and is likewise in relation with the fact that in high latitudes, where fewer calcareous organisms are found at the surface, their remains are removed at lesser depths than where these organisms are in greater abundance. It has been shown that sea water itself has some effect in the solution of carbonate of lime, and further it is probable that the immense pressure to which water is subjected in great depths may have an influence on its chemical activity. Objections have been raised to the explanation here advanced, on account of the alkalinity of sea water, but it may be remarked that alkalinity presents no difficulty which need be here considered (Dittmar, *Phys. Chem. Chall. Exp.*, part i., 1884).

This interpretation also explains how the remains of Diatoms and Radiolarians (surface organisms like the *Foraminifera*) are found in greater abundance in the red clay than in a *Globigerina* ooze. The action which suffices to dissolve the calcareous matter has no effect upon the silica, and so the siliceous shells accumulate. Nor is this view of the case opposed to the distribution of the Pteropod ooze. At first it would be expected that the *Foraminifera* shells, being smaller, would disappear from a deposit before the Pteropod shells; but if it be remembered that the latter are very thin and delicate, and, for the quantity of carbonate of lime present, offer a larger surface to the action of the solvent than the thicker, though smaller, *Globigerina* shells, this apparent anomaly will be explained.

The origin of these vast deposits of clay is a problem of the highest interest. It was at first supposed that these sediments were composed of microscopic particles arising from the disintegration of the rocks by rivers and by the waves on the coasts. It was believed that the matters held in suspension were carried far and wide by currents, and gradually fell to the bottom of the sea. But the uniformity of composition presented by these deposits was a great objection to this view. It can be shown that mineral particles, even of the smallest dimensions, continually set adrift upon disturbed waters must, owing to a property of sea water, eventually be precipitated at no great distance from land. It has also been supposed that these argillaceous deposits owe their origin to the inorganic residue of the calcareous shells which are dissolved away in deep water, but this view has no foundation in fact. Everything seems to show that the formation of the clay is due to the decomposition of fragmentary volcanic products, whose presence can be detected over the whole floor of the ocean.

These volcanic materials are derived from floating pumice, and from volcanic ashes ejected to great distances by terrestrial volcanoes, and carried far by the winds. It is also known that beds of lava and of tufa are laid down upon the bottom of the sea. This assemblage of pyrogenic rocks, rich in silicates of alumina, decomposes under the chemical action of the water, and gives rise, in the same way as do terrestrial volcanic rocks, to argillaceous matters, according to reactions which can always be observed on the surface of the globe, and which are too well known to need special mention here.

The universal distribution of pumice over the floor of the ocean is very remarkable, and would at first appear unaccountable; but when the fact that pieces of pumice have been known to float in sea water for a period of over three years before becoming sufficiently waterlogged to sink is taken into consideration, it will be readily understood how fragments of this material may be transported by winds and currents to an enormous distance from their point of origin before being deposited upon the bottom. Fragments of pumice are dredged in the greatest profusion in the red clay of the Central Pacific, and much less abundantly in the organic oozes and terrigenous deposits. This is owing to the rate of deposition being much slower in the former than in the latter, where the rapid accumulation of calcareous and siliceous organisms and continental debris masks their presence.

The detailed microscopic examination of hundreds of soundings has shown that the presence of pumice, of lapilli, of silicates, and of other volcanic minerals in various stages of decomposition can always be demonstrated in the argillaceous matter.

In the places where the red clay attains its most typical development, the transformation of the volcanic fragments into argillaceous matter may be followed step by step. It may be said to be the direct product of the decomposition of the basic rocks, represented by volcanic glasses, such as hyalomelan and tachylite. This decomposition, in spite of the temperature approximating to zero (32° F.), gives rise, as an ultimate product, to clearly crystallized minerals, which may be considered the most remarkable products of the chemical action of the sea upon the volcanic matters undergoing decomposition. These microscopic crystals are zeolites lying free in the deposit, and are met with in greatest abundance in the typical red-clay areas of the Central Pacific. They are simple, twinned, or spheroidal groups, which scarcely exceed half a millimetre in diameter. The crystallographic and chemical study of them shows that they must be referred to christianite. It is known how easily the zeolites crystallize in the pores of eruptive rocks in process of

decomposition; and the crystals of christianite, which are observed in considerable quantities in the clay of the centre of the Pacific

FIG. 5.—Crystals of Christianite from the deep water of the Pacific.

(fig. 5), have been formed at the expense of the decomposing volcanic matters spread out upon the bed of that ocean.

In connexion with this formation of zeolites, reference may be made to a chemical process which gives rise to the formation of nodules of manganiferous iron. These nodules are almost universally distributed in oceanic sediments, but are met with in the greatest abundance in the red clay. This association tends to show a common origin. It is exactly in those regions where there is an accumulation of pyroxenic lavas in decomposition, containing silicates with a base of manganese and iron, such for example as augite, hornblende, olivine, magnetite, and basic glasses, that manganese nodules occur in greatest numbers. In the regions where the sedimentary action, mechanical and organic, is, as it were, suspended, and where everything shows an extreme slowness of deposition,—in these calm waters favourable to chemical reactions, ferro-manganiferous substances form concretions around organic and inorganic centres.

These concentrations of ferric and manganic oxides, mixed with argillaceous materials whose form and dimensions are extremely variable, belong generally to the earthy variety or wad, but pass sometimes, though rarely, into varieties of hydrated oxide of manganese with distinct indications of radially fibrous crystallization. The interpretation necessary, in order to explain this formation of manganese nodules, is the same as that admitted in explanation of the formation of coatings of this material on the surface of terrestrial rocks. These salts of manganese and iron, dissolved in water by carbonic acid, then precipitated in the form of carbonate of protoxide of iron and manganese, become oxidized, and give rise in the calm and deep oceanic regions to more or less pure ferro-manganiferous concretions. At the same time it must be admitted that rivers may bring to the ocean a contribution of the same substances.

Among the bodies which, in certain regions where red clay predominates, serve as centres for these manganiferous nodules are the remains of vertebrates. These remains are the hardest parts of the skeleton—tympenic bones of whales, beaks of *Ziphius*, teeth of sharks; and, just as the calcareous shells are eliminated in great depths, so all the remains of the larger vertebrates are absent, except the most resistant portions. These bones often serve as a centre for the manganese iron concretions, being frequently surrounded by layers several

FIG. 6.—Section of a Manganese Nodule, enclosing tympanic bone of a whale, from 2300 fathoms, South Pacific.

¹ For the composition of these manganese nodules, see *MANGANESE*, vol. xv. p. 470.

centimetres in thickness (fig. 6). In the same dredgings in the red-clay areas some sharks' teeth and Cetacean ear-bones, some of which belong to extinct species, are surrounded with thick layers of the manganese, and others with merely a slight coating.

The cosmic spherules incidentally referred to under the description of red clay may be here described in greater detail. If a magnet be plunged into an oceanic deposit, especially a red clay from the central parts of the Pacific, particles are extracted, some of which are magnetite from volcanic rocks, to which vitreous matters are often attached; others again are quite isolated, and differ in most of their properties from the former. The latter are generally round, measuring hardly 0.2 mm., usually smaller; their surface is quite covered with a brilliant black coating having all the properties of magnetic oxide of iron; often there may be noticed clearly marked upon them cup-like depressions (figs. 7 and 8). If these spherules be broken down in an agate mortar, the brilliant black coating easily falls away and reveals white or grey metallic malleable nuclei, which may be beaten out by the pestle into thin lamellae. This metallic centre, when treated with an acid solution of sulphate of copper, immediately assumes a coppery coat, thus showing that it is native iron. But there are some malleable metallic nuclei extracted from the spherules which do not give this reaction; they do not take the copper coating.

Fig. 7.

FIG. 7.—Black Spherule with Metallic Nucleus ($\times 60$). This spherule covered with a coating of black shining magnetite represents the most frequent shape. The depression here shown is often found at the surface of these spherules. From 2375 fathoms, South Pacific.

Fig. 8.

FIG. 8.—Black Spherule with Metallic Nucleus ($\times 60$). The black external coating of magnetic oxide has been broken away to show the metallic nucleus represented by the clear part at the centre. From 3150 fathoms.

Chemical reactions show that they contain cobalt and nickel; very probably they constitute an alloy of iron and these two metals, such as is often found in meteorites, and whose presence in large quantities hinders the production of the coppery coating on the iron. G. Rose has shown that this coating of black oxide of iron is found on the periphery of meteorites of native iron, and its presence is readily understood when their cosmic origin is admitted. Indeed, these meteoric particles of native iron in their transit through the air must undergo combustion, and, like small portions of iron from a smith's anvil, be transformed either entirely or at the surface only into magnetic oxide, and in the latter case the nucleus is protected from further oxidation by the coating which thus covers it.

One may suppose that meteorites in their passage through the atmosphere break into numerous fragments, that incandescent particles of iron are thrown off all round them, and that these eventually fall to the surface of the globe as almost impalpable dust, in the form of magnetic oxide of iron more or less completely fused. The luminous train of falling stars is probably due to the combustion of these innumerable particles resembling the sparks which fly from a ribbon of iron burnt in oxygen, or the particles of the same metal thrown off when striking a flint. It is easy to show that these particles in burning take a spherical form, and are surrounded by a layer of black magnetic oxide.

Among the magnetic grains found under the same conditions as those just described are other spherules, which are referred to the *chondres*, so that, if the interpretation of a cosmic origin for the magnetic spherules with a metallic centre were not established in a manner absolutely beyond question, it almost becomes so when their association with the silicate spherules, which will now be described, is taken into account. It will be seen by the microscopic details that these spherules have quite the constitution and structure of *chondres* so frequent in meteorites of the most ordinary type, and on the other hand they have never been found, as far as is known, in rocks of a terrestrial origin; in short, the presence of these spherules in the deep-sea deposits, and their association with the metallic spherules, are matters of prime importance.

Among the fragments attracted by the magnet in deep-sea deposits are distinguished granules slightly larger than the spherules with the shining black coating above described. These are yellowish-brown, with a bronze-like lustre, and under the microscope it is noticed that the surface, instead of being quite smooth, is grooved by thin lamellae. Their dimensions never attain a millimetre, generally they are about 0.5 mm. in diameter; they

are never perfect spheres, as in the case of the black spherules with a metallic centre; and sometimes a depression more or less marked is to be observed in the periphery. When examined by the microscope it is observed that the lamellae which compose them are applied the one against the other, and have a radial eccentric disposition. It is the leafy radial-structure (*radialblatttrig*), like that of the chondres of bronzoite, which predominates in these spherules. The serial structure of the chondres with olivine is observed much less rarely, and indeed there is some doubt about the indications of this last type of structure. Fig. 9 shows the characters and texture of one of these spherules magnified 25 diameters. On account of their small dimensions, as well as of their friability due to their lamellar structure, it is difficult to polish one of these spherules, and it has been necessary to study them with reflected light, or to limit the observations to the study of the broken fragments.

These spherules break up following the lamellae, which latter are seen to be extremely fine and perfectly transparent. In rotating between crossed nicols they have the extinctions of the rhombic system, and in making use of the condenser it is seen that they have one optic axis. It is observed also that when several of these lamellae are attached they extinguish exactly at the same time, so that everything tends to show that they form a single individual.

In studying these transparent and very thin fragments with the aid of a high magnifying power, it is observed that they are dotted with brown-black inclusions, disposed with a certain symmetry, and showing somewhat regular contours; these inclusions are referred to magnetic iron, and their presence explains why these spherules of bronzoite are extracted by the magnet. It should be observed, however, that they are not so strongly magnetic as those with a metallic nucleus.

They are designated bronzoite rather than enstatite, because of the somewhat deep tint which they present; they are insoluble in hydrochloric acid. Owing to the small quantity of substance, only a qualitative analysis could be made, which showed the presence in them of silica, magnesia, and iron.

The study of deep-sea deposits suggests some interesting conclusions. It has been said that the debris carried away from the land accumulates at the bottom of the sea before reaching the abyssal regions of the ocean. It is only in exceptional cases that the finest terrigenous materials are transported several hundred miles from the shores. In place of layers formed of pebbles and elastic elements with grains of considerable dimensions, which play so large a part in the composition of emerged lands, the great areas of the ocean basins are covered by the microscopic remains of pelagic organisms, or by the deposits coming from the alteration of volcanic products. The distinctive elements that appear in the river and coast sediments are, properly speaking, wanting in the great depths far distant from the coasts. To such a degree is this the case that in a great number of soundings, from the centre of the Pacific for example, no mineral particles on which the mechanical action of water had left its imprint have been distinguished, and quartz is so rare that it may be said to be absent. It is sufficient to indicate these facts in order to make apparent the profound differences which separate the deposits of the abyssal areas of the ocean basins from the series of rocks in the geological formations. As regards the vast deposits of red clay, with its manganese concretions, its zeolites, cosmic dust, and remains of vertebrates, and the organic oozes which are spread out over the bed of the Central Pacific, Atlantic, and Indian Oceans, have they their analogues in the geological series of rocks? If it be proved that in the sedimentary strata the true pelagic sediments are not represented, it follows that deep and extended oceans like those of the present day cannot formerly have occupied the areas of the present continents, and as a corollary the great lines of the oceanic basins and continents must have been marked out from the earliest geological ages.

Without asserting that the terrestrial areas and the areas covered by the waters of the great ocean basins have had their main lines marked out since the commencement of geological history, it is a fact proved by the evidence of the pelagic sediments that these areas have a great antiquity. The accumulation of sharks' teeth, of the ear bones of Cetaceans, of manganese concretions, of zeolites, of volcanic material in an advanced state of decomposition, and of cosmic dust, at points far removed from the continents, tends to prove this. There is no reason for supposing that the parts of the ocean where

FIG. 9.—Spherule of Bronzoite ($\times 25$), from 3500 fathoms in the Central South Pacific, showing many of the peculiarities belonging to chondres of bronzoite or enstatite.

Great antiquity of oceanic areas.

these vertebrate remains are found are more frequented by sharks or Cetaceans than other regions where they are never, or only rarely, dredged from the deposits at the bottom. When it is remembered also that these ear-bones, teeth of sharks, and volcanic fragments are sometimes incrustated with two centimetres of manganese oxide, while others have a mere coating, and that some of the bones and teeth belong to extinct species, it may be concluded with great certainty that the clays of these oceanic basins have accumulated with extreme slowness. It is indeed almost beyond question that the red-clay regions of the Central Pacific contain accumulations belonging to geological ages different from our own. The great antiquity of these formations is likewise confirmed in a striking manner by the presence of cosmic fragments, the nature of which has been described. In order to account for the accumulation of all these substances in such relatively great abundance in the areas where they were dredged, it is necessary to suppose the oceanic basins to have remained the same for a vast period of time.

The sharks' teeth, ear-bones, manganese nodules, altered volcanic fragments, zeolites, and cosmic dust are met with in greatest abundance in the red clays of the Central Pacific, at that point on the earth's surface farthest removed from continental land. They are less abundant in the Radiolarian ooze, are rare in the *Globigerina*, *Diatom*, and *Pteropod* oozes, and have been dredged only in a few instances in the terrigenous deposits close to the shore. These substances are present in all the deposits, but owing to the abundance of other matters in the more rapidly forming deposits their presence is masked, and the chance of dredging them is reduced. The greater or less abundance of these materials, which are so characteristic of a true red clay, may be regarded as a measure of the relative rate of accumulation of the marine sediments in which they lie. The terrigenous deposits accumulate most rapidly; then follow in order *Pteropod* ooze, *Globigerina* ooze, *Diatom* ooze, *Radiolarian* ooze, and, slowest of all, red clay.

From the data now advanced it appears possible to deduce other conclusions important from a geological point of view. In the deposits due essentially to the action of the ocean, the great variety of sediments which may accumulate in regions where the external conditions are almost identical is very striking. Again, marine faunas and floras, at least those of the surface, differ greatly, both with respect to species and the relative abundance of individuals, in different regions of the ocean; and, as their remains determine the character of the deposit in many instances, it is legitimate to conclude that the occurrence of organisms of a different nature in several beds is not an argument against the synchronism of the layers which contain them. In this connexion may be noted the fact that in certain regions of the deep sea no appreciable formation is now taking place. Hence the absence, in the sedimentary series, of a layer representing a definite horizon must not always be interpreted as proof either of the emergence of the bottom of the sea during the corresponding period, or of an ulterior erosion.

The small extent occupied by littoral formations, especially those of an arenaceous nature, and the relatively slow rate at which such deposits are formed along a stable coast, are matters of importance. In the present state of things there does not appear to be anything to account for the enormous thickness of the clastic sediments making up certain geological formations, unless the exceptional cases of erosion which are brought into play when a coast is undergoing constant elevation or subsidence are considered. Great movements of the land are doubtless necessary for the formation of thick beds of transported matter like sandstones and conglomerates. Arenaceous formations of great thickness require seas of no great extent and coasts subject to frequent oscillations, which permit the shores to advance and retire. Along these, through all periods of the earth's history, the great marine sedimentary phenomena have taken place.

The continental geological formations, when compared with marine deposits of modern seas and oceans, present no analogues to the red clays, *Radiolarian*, *Globigerina*, *Pteropod*, and *Diatom* oozes. On the other hand, the terrigenous deposits of lakes, shallow seas, enclosed seas, and the shores of the continents reveal the equivalents of the chalks, greensands, sandstones, conglomerates, shales, marls, and other sedimentary formations. Such formations as certain Tertiary deposits of Italy and the *Radiolarian* earth from Barbados, where pelagic conditions are indicated, must be regarded as having been laid down rather along the border of a continent than in a true oceanic area. The white chalk is evidently not a deep-sea deposit, for the *Foraminifera* and fragments of other organisms of which it is largely composed are similar to those found in comparatively shallow water not far from land. The argillaceous and calcareous rocks recently discovered by Dr Guppy in the upraised coral islands in the Solomon group are identical with the deposits now forming around oceanic islands. Regions situated similarly to enclosed and shallow seas and the borders of the present continents appear to have been, throughout all geological ages, the theatre of the greatest and most remarkable changes; in short, all, or nearly all, the sedimentary rocks of the continents would seem to have been built up in areas like those now occupied by the terrigenous deposits.

During each era of the earth's history the borders of some lands have sunk beneath the sea and been covered by marine sediments, while in other parts the terrigenous deposits have been elevated into dry land, and have carried with them a record of the organisms which flourished in the sea of the time. In this transitional area there has been throughout a continuity of geological and biological phenomena.

From these considerations it will be evident that the character of a deposit is determined much more by distance from the shore of a continent than by actual depth; and the same would appear to be the case with respect to the fauna spread over the floor of the present oceans. Dredgings near the shores of continents, in depths of 1000, 2000, or 3000 fathoms, are more productive both in species and individuals than dredgings at similar depths several hundred miles seawards. Again, among the few species dredged in the abyssal areas farthest removed from land, the majority show archaic characters, or belong to groups which have a wide distribution in time as well as over the floor of the present oceans. Such are the *Hexactinellida*, *Brachiopoda*, Stalked Crinoids and other Echinoderms, &c.

As already mentioned, the "transitional area" is that which now shows the greatest variety in respect to biological and physical conditions, and in past time it has been subject to the most frequent and the greatest amount of change. The animals now living in this area may be regarded as the greatly modified descendants of those which have lived in similar regions in past geological ages, and some of whose ancestors have been preserved in the sedimentary rocks as fossils. On the other hand, many of the animals dredged in the abyssal regions are most probably also the descendants of animals which lived in the shallower waters of former geological periods, but migrated into deep water to escape the severe struggle for existence which must always have obtained in shallower waters influenced by light, heat, motion, and other favourable conditions. Having found existence possible in the less favourable and deeper water, they may be regarded as having slowly spread themselves over the floor of the ocean, but without undergoing great modifications, owing to the extreme uniformity of the conditions and the absence of competition. Or it may be supposed that, in the depressions which have taken place near coasts, some species have been gradually carried down to deep water, have accommodated themselves to the new conditions, and have gradually migrated to the regions far from land. A few species may thus have migrated to the deep sea during each geological period. In this way the origin and distribution of the deep-sea fauna in the present oceans may in some measure be explained. In like manner, the pelagic fauna and flora of the ocean is most probably derived originally from the shore and shallow water. During each period of the earth's history a few animals and plants have been carried to sea, and have ultimately adopted a pelagic mode of life.

ISLANDS.

The Pacific Ocean is distinguished from the Atlantic by the greater number of small island groups that diversify its surface. The continental islands, lying along the coasts of America and Asia, have been referred to in speaking of the coasts; the islands of the Malay Archipelago, Australia, New Zealand, and probably New Caledonia belong to the same class. The true oceanic islands on the other hand have no direct geological connexion with the continents; the older sedimentary and metamorphic rocks appear to be quite absent, the islands being either of eruptive or coral formation. The fauna and flora of the oceanic islands present a considerable amount of uniformity, though each island or important group of islands has its peculiar species. There is an entire absence of terrestrial Mammalia. The genera and species are few in number when compared with those of the continents and continental islands from which they would appear to have been originally derived by immigration, and subsequently to have undergone modification. Recent researches appear also to show that the dredgings around oceanic islands yield fewer genera and species than dredgings at similar depths along the shores of continents, although the numbers of individuals of a few species may be extraordinarily abundant.

The most northern oceanic group is the Hawaiian Archipelago or Sandwich Islands (see vol. xi. p. 528), stretching for about 340 miles between the latitudes of 18° 52' and 22° 15' N., and the meridians of 154° 42' and 160° 33' W.; it consists of eight large islands—Hawaii (Owhyhee), Maui (Mowee), Kahului (Tahooroway), Lanai

(Ranai),⁻ Molokai (Morotoi), Oahu (Woahoo), Kauai (Atooi), and Niihau (Oneehoow), and four small barren islets, the entire area being 6100 square miles. The islands of this group are mountainous, and abound in active volcanoes; the great lake of fire, Kilauea, on the east side of the Mountain of Mauna Loa (13,760 feet) in Hawaii is probably the largest active crater in the world, while one of the largest known extinct craters is that of Mauna Haleakala ("The House of the Sun") in Maui, at a height of 10,200 feet above the sea; it is 12 miles in circumference. The Hawaiian Islands being within the zone of coral formation are surrounded by fringing reefs, and there is abundant evidence that gradual upheaval has taken place over the whole area which they occupy. There are beds of coral limestone in Molokai at a height of 400 feet, and in Kauai coral sand is found at an elevation of 4000 feet above the sea; in many other islands coral and lava are found interstratified.

The three groups of the Bonin Islands known as the Parry, Beechy, and Coffin groups are composed of high rocky islets of a bold and fantastic outline, and are situated between 26° and 27° N. lat.

The Ladrões or Mariana Islands (see vol. xiv. p. 199) have a total area of 395 square miles; they stretch for nearly 450 miles between 13° and 20° N. lat. and 144° 37' and 145° 55' E. long. These islands are all of volcanic origin, and their mountains contain several active volcanoes.

The Caroline Archipelago (see vol. v. p. 125) lies about 170 miles to the south of the Ladrões, and, together with the Pelew Islands, has an area of 877 square miles. The Carolines embrace forty distinct island groups, five of which are basaltic and mountainous, though surrounded by coral reefs; the remaining thirty-five groups are entirely of coral formation, and do not rise much above the sea-level. The Pelew Islands resemble the Carolines in their physical characters; they present peculiarities in the arrangement of atolls which will be alluded to below.

The Marshall Islands (see MICRONESIA, vol. xvi. p. 256) consist of two chains running parallel to each other, and composed of fourteen and seventeen small groups respectively. They lie to the eastward of the Carolines, and are entirely of organic formation.

The Gilbert Archipelago (see vol. xvi. p. 256) is cut by the equator. It contains sixteen groups of small coral islands, low and barren, but densely populated.

In the South Pacific oceanic islands are scattered with the greatest profusion over a region between 5° and 25° S. lat. and 180° to 120° W. long. The northern part of the shallow water surrounding Australia, New Zealand, and the Malay Archipelago is occupied by the Solomon Islands, the New Hebrides, the bold rocky and mountainous islands of Fiji with fine barrier reefs, the Friendly Islands, and Samoa or the Navigators' Islands. Farther to the south there are the Society Islands, including Tahiti; they are lofty, of volcanic origin, and surrounded by very perfect barrier reefs. The Marquesas or Mendana Archipelago, farther to the north, also consists of volcanic islands, but they are not fringed by reefs.

The volcanic group of the Galapagos Archipelago is situated under the equator at a distance of 500 or 600 miles from the west coast of South America; it has been minutely described by Darwin.

The extensive Low or Paumotu Archipelago lies to the south-east of the Society Islands, and runs parallel to them. It consists of about eighty atolls, some of them of large size, and all typical examples of this form of coral island.

The total area of the islands of the Pacific is exceedingly small, especially when the vast number of groups that stud the ocean is taken into consideration.

THEORY OF CORAL ISLANDS.

The origin of coral islands was specially studied by Darwin during the voyage of the "Beagle" in 1831-36, and he shortly afterwards published a theory on the subject which has been fully detailed in the article CORAL (vol. vi. p. 377). This theory was so simple, and it appeared so complete, that it acquired universal acceptance; and the continuous action of subsidence in promoting the development of fringing reefs into barriers, and of barriers into atolls, was long unquestioned. In 1851 L. Agassiz² expressed the opinion that the theory of subsidence was insufficient to explain the formation of the coral reefs and keys of Florida. In 1863 Carl Semper stated that an attentive study of the Pelew Islands showed the complete inadequacy of this theory, and in 1868 he reiterated his convictions.²

In 1880 Mr John Murray published an abstract of his "Challenger" observations,³ and gave a theory of coral island formation which claims to account for all the phenomena without calling in the aid of subsidence. It is pointed out that, with hardly an exception, the oceanic islands are of volcanic origin, and it is assumed that the various peaks which deep-sea soundings have shown to be scattered over the bed of the ocean, and rising to within various distances of the surface, are also, primarily, of volcanic origin. There is no evidence of any extensive submerged continent or mass of land such as Darwin's theory requires. Whether built up sufficiently high to rise above the surface of the sea and thus form islands, or brought up only to varying heights below the sea-level, these volcanic eminences tend to become platforms on which coral reefs may be formed. The erosive action of waves and tides tends to reduce all volcanic summits down to the lower limit of breaker action, thus producing platforms on which barrier reefs and atolls may spring up. Again, submarine eminences may be brought up to the zone of the reef builders by the deposit of volcanic and organic detritus falling from the surface, as well as through the agency of organisms secreting lime and silica, which live in profusion at great depths, especially on the tops of submarine peaks and banks. The great profusion of life in the tropical surface waters is insisted upon, and it is pointed out that this pelagic life supplies the reef-building corals with food, and that, when these surface creatures die and their shells fall to the bottom, they carry down with them sufficient organic matter to furnish food to the animals living on the floor of the ocean. As the result of tow-net experiments in the tropics Mr Murray estimated that, in the surface waters of the ocean, there were in a mass 1 mile square by 100 fathoms, 16 tons of carbonate of lime existing in the form of shells of pelagic *Foraminifera* and Molluscs. In this way it is urged that submarine banks are continually being brought within the zone of reef-building corals. Darwin admitted that reefs not to be distinguished from atolls might be formed on such submarine banks, but the improbability of so many submerged banks existing caused him to dismiss this explanation without further consideration. He was not, however, aware of the great number of submerged cones which recent soundings have made known, nor of the enormous abundance of minute calcareous organisms—such as calcareous algae, *Foraminifera*, and Molluscs in the surface waters—and of the comparatively rapid rate at which their remains might accumulate on the sea bottom. Nor had he any idea of the comparatively great abundance of animals living at considerable depths.

Coral-reef builders starting on a bank, whether formed by elevation or subsidence, by erosion or the upward growth of deep-sea deposits composed largely of organic remains, tend ultimately to assume the atoll or barrier form. When the coral reef or colony approaches the surface, the central portions are gradually placed at a disadvantage as compared with the peripheral parts of the mass, in being farther removed from the food supply which is brought by the oceanic currents, and consequently dwindle and die. In proportion as the reef approaches the surface, the centre becomes cut off from the food supply and the conditions become increasingly uncongenial. At last an outer ring of vigorously growing reef corals encloses a central lagoon. The windward side of the reef grows most vigorously, not because of a larger supply of oxygen and greater aeration of the water, but because that is the direction in which the oceanic currents bring the food to the reef. As the atoll extends seawards from vigorous growth the lagoon becomes larger, chiefly from the removal of lime in solution by the action of the carbonic acid in sea water which flows in and out at each tide. This solvent action of sea water on dead calcareous organisms was shown by the "Challenger's" observations to be universal.

Mr Murray reverses the order of growth as given by Darwin for the groups in the Indian Ocean. He regards the Laccadive, Caroline, and Chagos archipelagos as various stages in the growth of coral reefs towards the surface, and he explains the various appear-

³ Proc. Roy. Soc. Edin., vol. x. p. 505.

ances in the Maldive group of atolls without any necessity for disavowment by oceanic currents as argued by Darwin. Precisely the same explanation is applied to the case of a barrier reef. It commences in the shallow water near the shore, and afterwards extends seawards on a talus built up of lumps of coral broken off by the surf. A very careful examination of the barrier reef at Tahiti was made by Lieutenant Swire of H.M.S. "Challenger" and Mr Murray, and they found that such an explanation was completely justified by the form and nature of the reef. There was much dead coral on the inner side of the barrier, which in many places was perpendicular or even overhanging; while, on the contrary, the outer surface was all alive, and sloped gradually seawards. A section of it, drawn to a true scale, is given in fig. 10.

FIG. 10.—Section across the Barrier Reef, Tahiti

This section shows that a ledge, over which there is a depth of from 30 to 40 fathoms of water, runs out for 250 yards from the edge of the reef. This ledge is covered with luxuriant heads and bosses of coral. Beyond it there is a steep irregular slope at an angle of about 45°, the talus being formed apparently of coral masses broken off from the ledge, and piled up; this slope is covered with living Sponges, Alcyonarians, Hydroids, *Polyzoa*, *Foraminifera*, and other forms of life. The angle of inclination then decreases to 30°, and the ground is covered with coral sand; while beyond 500 yards from the edge of the reef the declivity is

insignificant, only 6°, and there is a bed of mud containing volcanic and coral sand mixed with Rteropod and other shells, in 590 fathoms of water. The vast perpendicular wall of coral limestone descending into unfathomable depths, which has been supposed usually to mark the outside of a coral reef, has always been looked upon as a conclusive proof of great subsidence having taken place; but the depth and the slope of such limestone walls have been greatly exaggerated, and no means have been taken to ascertain beyond doubt that the rock is formed of coral throughout. The probability is that only the upper portion of such a wall is true coral limestone; and Dr Guppy has recently shown that this is actually the case in some upraised coral islands of the Solomon group. Upheaval has taken place to a considerable extent in the oceanic islands, and more extended examination of the limestone cliffs of other coral islands will probably lead to the discovery of many such cases. Mr Murray holds that the characteristic form of barrier reefs and atolls is in no way dependent on subsidence, that subsidence is not the cause of their peculiar features, that these reefs may be met with indifferently in stationary areas, in areas of subsidence, and in areas of elevation, and that elevation and subsidence only modify in a minor way the appearance of the islands.

The chief phenomena are accounted for—(1) by a physiological fact,—the very vigorous growth of the reef-forming species on the outer or seaward face of the reef where there is abundance of food, and the much less vigorous growth, and even death, of these species on the inner parts of the reefs and in the lagoons, where there is much less food, and where there are other conditions inimical to growth; and (2) by a physical and chemical fact,—the removal of lime in suspension and in solution from the inner portions of the reefs and from the lagoons, where much dead coral is exposed to the action of sea water containing carbonic acid, the result being the formation, the deepening, and the widening of lagoons and lagoon channels.

For further information on subjects referred to in this article see John Murray, "On the Structure and Origin of Coral Reefs and Islands," *Proc. Roy. Soc. Edin.*, vol. x. p. 505; Alex. Renard, "On the Microscopic Characters of Volcanic Ashes and Cosmic Dust, and their Distribution in the Deep-Sea Deposits," *Proc. Roy. Soc. Edin.*, vol. xli. p. 474. 1884. (J. MU.)

PACUVIUS, MARCUS (219–129 B.C.), was the second in order of time of the three tragic poets who wrote for the Roman stage in the 2d century B.C. His life was so long that he might be described as a contemporary of all the writers who flourished during the first period of Roman literature. He was born in 219 B.C., when Livius Andronicus and Nævius were introducing their imitations of the Greek tragic and comic drama to Roman audiences; he was recognized as the chief tragic poet about the time when Cæcilius, and after him Terence, were the flourishing authors of Latin comedy; he continued to produce his tragedies till the advent of the younger poet Accius, who lived on till the youth of Cicero; and he died in the year (129 B.C.) when Lucilius first appeared as an author. He stood in the relation of nephew as well as pupil to Ennius, by whom Roman tragedy was first raised to a position of influence and dignity. In the interval between the death of Ennius (169) and the advent of Accius, the youngest and most productive of the tragic poets, he alone maintained the continuity of the serious drama, and perpetuated the character first imparted to it by Ennius. Like Ennius he probably belonged to the Oscan stock, and was born at Brundisium, which had become a Roman colony in 244 B.C. To this origin may be attributed the fact that he never attained to that perfect idiomatic purity of style which was the special glory of the early writers of comedy, Nævius and Plautus.¹ The fame of his uncle Ennius may probably have drawn him to Rome, and may have induced him to devote himself to the composition of tragedy. But he obtained distinction also as a painter; and the elder Pliny mentions a work of his which in his time was still to be

seen in the temple of Hercules in the *forum boarium*. His relationship to the friend of the great Scipio would naturally recommend him to the consideration of the eminent men of the next generation, who fostered the new literature in his spirit; and thus Cicero, in the *De Amicitia*, represents C. Lælius as speaking of him as "hospitis et amici mei." He was less productive as a poet than either Ennius or Accius; and we hear of only about twelve of his plays, founded on Greek subjects (among them the *Antiope*, *Teucer*, *Armorum Judicium*, *Dulorestes*, *Chryses*, *Niptra*, &c., most of them on subjects connected with the Trojan cycle), and one "Prætexta," *Paulus*, written in connexion with the triumph of L. Æmilius Paulus, for his victory at Pydna, celebrated in the year 167 B.C., as the *Clastidium* of Nævius and the *Ambracia* of Ennius were written in commemoration of great military successes in their time. He continued to write tragedies till the age of eighty, when he exhibited a play in the same year as Accius, who was then thirty years of age. He retired to Tarentum for the last years of his life, and a story is told by Gellius of his being visited there by Accius on his way to Asia, who read to him one of his plays, which was famous in after times, the *Atræus*. The story is probably, like that of the visit of the young Terence to the veteran Cæcilius, due to the invention of later grammarians; but it is invented in accordance with the traditional criticism of the distinction between the two poets, the older being characterized rather by cultivated accomplishment, the younger by vigour and animation.

"Ambigitur quoties uter utro sit prior, aufert Pacuvius docti famam senis, Accius alti."

He died at the age of ninety, having lived through the long period from the beginning of the Second Punic War

¹ *Ætatis illius ista fuit laus tanquam innocentie sine Latine loquendi; nec omnium tamen; nam illorum æquales Cæcilius et Pacuvius male locutos videmus; sed omnes tum fere, qui nec extra urbem hanc vixerant nec eos aliqua barbaries domestica infuscaverat, recte loquebantur* (Cicero, *Brutus*, 74).

² Horace, *E.*, ii. 1, 54, 55.

till after the first outbreak of the revolutionary forces, in the tribunate of Tib. Gracchus, which led ultimately to the overthrow of the republic. His epitaph, said to have been composed by himself, is quoted by Aulus Gellius, with a tribute of admiration to its "modesty, simplicity, and fine serious spirit."

"Adulescens, tam etsi properas, te hoc saxum rogat
Ut se aspicias, deinde quod scriptum est legas.
Hic sunt poetæ Pacuvi Marci sita
Ossa. Hoc volebam nescius ne censes. Vale."¹

Cicero, who frequently quotes passages from him, with great admiration, appears to rank him first among the Roman tragic poets, as Ennius among the epic, and Cæcilius among the comic poets (Cic., *De Opt. Gen. Or.*, 1). If a rough parallel might be drawn between the three great original Greek tragic poets and their three Roman imitators, we might perhaps recognize in the imaginative mysticism and soldierly spirit of Ennius an affinity to Æschylus, in the mellow wisdom of Pacuvius to Sophocles, and in the oratorical talent and power of moving the passions attributed to Accius a nearer approach to the genius of Euripides. The office performed by the Roman tragic poets to Roman culture was not only to familiarize their countrymen with the creations of Greek genius, and the heroes and heroines of Greek legend, but to be the moral teachers and moral philosophers of a time before the introduction of definite ethical speculation. The fragments of Pacuvius quoted by Cicero in illustration or enforcement of his own ethical teaching appeal, by the fortitude, dignity, and magnanimity of the sentiment expressed in them, to what was noblest in the Roman temperament. They are inspired also by that fervid and steadfast glow of spirit which underlay the strong self-control of the Roman character, and which was the most powerful element in Roman oratory. They reveal also a gentleness and humanity of sentiment which it was the highest office of the new drama to blend with the severe gravity of the original Roman character. So far too as the Romans were capable of taking interest in speculative questions, the tragic poets contributed to stimulate curiosity on such subjects, and they anticipated Lucretius in using the conclusions of speculative philosophy as well as of common sense, to assail some of the prevailing forms of superstition. Among the passages quoted from Pacuvius are several which indicate a taste both for physical and ethical speculation, and others which expose the pretensions of religious imposture, e.g.—

"Nam isti qui linguam avium intelligunt,
Plusque ex alieno jecore sapient quam ex suo,
Magis audiendum quam auscultandum censeo."²

These poets aided also in developing that capacity which the Roman language subsequently displayed of being an organ of oratory, history, and moral disquisition. The literary language of Rome was in process of formation during the 2d century B.C., and it was in the latter part of this century that the series of great Roman orators, with whose spirit Roman tragedy has a strong affinity, begins. But the new creative effort in language was accompanied by considerable crudeness of execution, and the novel word-formations and varieties of inflexion introduced by Pacuvius exposed him to the ridicule of the satirist Lucilius, and, long afterwards, to that of his imitator Persius. But, notwithstanding the attempt to introduce an alien element into the Roman language, which proved incompatible with its natural genius, and his own failure to attain the idiomatic purity of Nævius, Plautus, or Terence, the fragments of his dramas are sufficient to prove the service which he rendered to the formation of the literary language of Rome, as well as to the culture and character of his contemporaries.

The best account of Pacuvius is to be found in the *kômische Tragödie* of O. Ribbeck, and the best collection of his "Fragments" in the *Tragicorum Latinorum Reliquiæ* of the same author. (Y. S.)

PADANG. See SUMATRA.

PADERBORN, an ancient town of Prussia, the seat of a Roman Catholic bishop, is situated in the province of Westphalia and district of Minden, 60 miles to the south-west of Hanover. It derives its name (Latin, *Paderæ Fontes*) from the springs of the Pader, a small affluent of the Lippe, which rise in or close to the town under the cathedral to the number of nearly two hundred, and with such force as to drive several mills within a few yards of their source. The most prominent building is the cathedral,

¹ "Young man, though thou art in haste, this stone entreats thee to look at it, and then to read what is written. Here are laid the bones of the poet M. Pacuvius. This I desired to be not unknown to thee. Farewell."

² "For they who understand the notes of birds, and derive their wisdom more from examining the livers of other beings than from their own (wit), I think should be rather heard than listened to."

the western part of which dates from the 11th, the central part from the 12th, and the eastern part from the 13th century. The exterior is imposing, but heavy, and marred by a want of harmony arising from the successive stages of its construction. Among other treasures of art it contains the silver coffin of St Liborius, a substitute for one which was coined into dollars in 1622 by Duke Christian of Brunswick. The externally insignificant chapel of St Bartholomew ranks among the most interesting buildings in Westphalia, dating as it does from 1017, and possessing the characteristic features of the architecture of that early period. The old Jesuit church and the chapel of the convent of Abdinghof are also interesting. The town-hall is a picturesque edifice of the Renaissance. Paderborn formerly possessed a university, with the two faculties of theology and philosophy, but it was closed in 1819. The Roman Catholic gymnasium, however, enjoys a considerable reputation, and there are several other schools, hospitals, and religious endowments, as well as an historical and antiquarian society. The manufactures of Paderborn are unimportant, but the trade in grain, cattle, fruit, and wool has attained considerable dimensions since the opening of the Westphalian railway. The population in 1880 was 14,689 (12,602 Roman Catholics).

Paderborn is indebted for its development to Charlemagne, who discerned the favourable situation of the village of Patrisbrunnen, and made it the capital of a bishopric. He frequently visited it, receiving the conquered Saxons here at a diet in 777 and at a later period the Saracen ambassadors from Saragossa and the suppliant Pope Leo III. Several diets were also held here by the Saxon emperors. About the year 1000 the town was enlarged by Bishop Meinwerk and surrounded with walls. It afterwards joined the Hanseatic League, received many of the privileges of a free imperial town, and endeavoured to assert its independence of the bishops. The citizens gladly embraced the doctrines of the Reformation, but the older faith was re-established by Bishop Theodore, who took the town by force in 1604. The ecclesiastical principality of Paderborn, which had an area of close on 1000 square miles, was secularized in 1803 and handed over to Prussia. The bishop, however, was allowed to retain his spiritual jurisdiction. From 1807 to 1814 the territory was included in the kingdom of Westphalia.

PADIHAM, a township of Lancashire, is situated in a wild and dreary district on the precipitous banks of the Calder, and on the Lancashire and Yorkshire Railway, 5 miles south-east from Whalley and 4 north-east from Accrington. It possesses large cotton mills, and both stone and coal are wrought in the immediate neighbourhood. The church of St Leonard, founded before 1451, was frequently altered before it was rebuilt in 1866-68, in the Perpendicular style, at a cost of £11,000. There is a national school connected with a very old endowment. Padiham in 1251 was a manor in the possession of Edmund de Laci. The population of the urban sanitary district of Padiham and Hapton (area 950 acres) in 1871 was estimated at 7361, and in 1881 it was 8974.

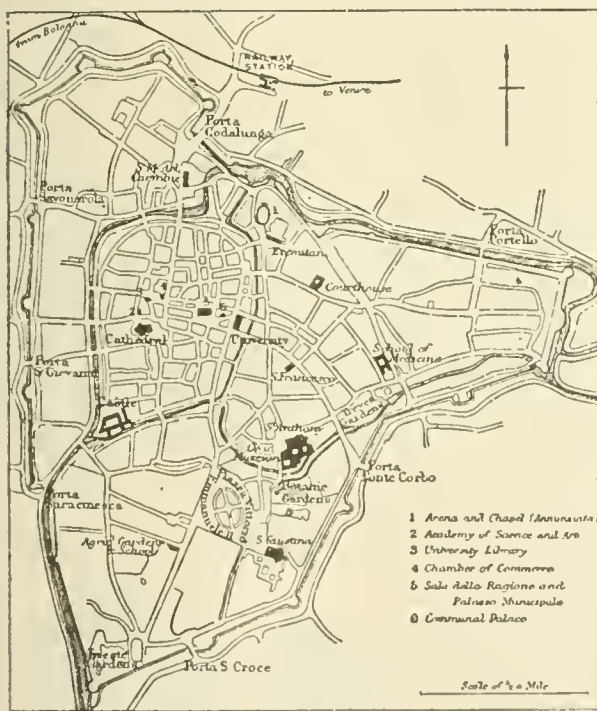

PADILLA, JUAN LOPEZ DE, insurrectionary leader in the "guerra de las comunidades" in which the commons of Castile made a futile stand against the arbitrary policy of Charles V. and his Flemish ministers, was the eldest son of the commendator of Castile, and was born in Toledo towards the close of the 15th century. After the cities, by their deputies assembled at Avila, had vainly demanded the king's return, due regard for the rights of the cortes, and economical administration; to be entrusted to the hands of Spaniards, it was resolved to resort to force, and the "holy junta" was formed, with Padilla at its head. An attempt was first made to establish a national government in the name of the imbecile Joanna, who was then residing at Tordesillas; with this view they took possession of her person, seized upon the treasury books, archives, and seals of the kingdom, and stripped Adrian of his regency. But the junta soon alienated the nobility

by the boldness with which it asserted democracy and total abolition of privilege, while it courted defeat in the field by appointing to the supreme command of its forces not Padilla but Don Pedro de Giron, who had no recommendation but his high birth. After the army of the nobility had recaptured Tordesillas, Padilla did something to retrieve the loss by taking Torrelabaton and some other towns. But the junta, which was not fully in accord with its ablest leader, neutralized this advantage by granting an armistice; when hostilities were resumed the commons were completely defeated near Villalar (April 23, 1521), and Padilla, who had been taken prisoner, was publicly executed on the following day. His wife, Doña Maria Pacheco de Padilla, bravely defended Toledo against the royal troops for six months afterwards, but ultimately was compelled to take refuge in Portugal.

PADUA (Lat., *Putaurum*; Ital., *Padova*), a city of north Italy, in 45° 24' N. lat. and 11° 50' E. long., on the river Bacchiglione, 25 miles W. of Venice and 18 miles S.E. of Vicenza, with a population in 1881 of 70,753. The city is a picturesque one, with arcaded streets and many

begun in 1493 and finished in 1526, and close by is the Palazzo del Capitano, the residence of the Venetian governors, with its great door, the work of Falconetto of Verona, 1532. The most famous of the Paduan churches is the basilica dedicated to Saint Anthony, commonly called Il Santo; the bones of the saint rest in a chapel richly ornamented with carved marbles, the work of various artists, among them of Sansovino and Falconetto; the basilica was begun about the year 1230, and completed in the following century; tradition says that the building was designed by Niccola Pisano; it is covered by seven cupolas, two of them pyramidal. On the piazza in front of the church is Donatello's magnificent equestrian statue of Erasmo da Narni, the Venetian general (1438-41). The Eremitani is an Augustinian church of the 13th century, distinguished as containing the tombs of Jacopo (1324) and Ubertino (1345) da Carrara, lords of Padua, and for the chapel of Sts James and Christopher, illustrated by Mantegna's frescos. Close by the Eremitani is the small church of the Annunziata, known as the Madonna dell' Arena, whose inner walls are entirely covered with paintings by Giotto. Padua has long been famous for its university, founded by Frederick II. in 1238. Under the rule of Venice the university was governed by a board of three patricians called the Riformatori dello Studio di Padova. The list of professors and alumni is long and illustrious, containing, among others, the names of Bembo, Sperone Speroni, Veselius, Acquapendente, Galileo, Pomponazzi, Pole, Scaliger, Tasso, and Sobieski. The place of Padua in the history of art is nearly as important as her place in the history of learning. The presence of the university attracted many distinguished artists, as Giotto, Lippo Lippi, and Donatello; and for native art there was the school of Squarcione (1394-1474), whence issued the great Mantegna (1431-1506).

Padua claims to be the oldest city in north Italy; the inhabitants pretend to a fabulous descent from the Trojan Antenor, whose relics they recognized in a large stone sarcophagus exhumed in the year 1274. Their real origin is involved in that obscurity which conceals the ethnography of the earliest settlers in the Venetian plain; but it is supposed that they were either Paphlagonians or Etruscans. Padua early became a populous and thriving city, thanks to its excellent breed of horses and the wool of its sheep. Its men fought for the Romans at Canne, and the city became so powerful that it was reported able to raise two hundred thousand fighting men. Abano in the neighbourhood was made illustrious by the birth of Livy, and Padua was the native place of Valerius Flaccus, Asconius Pedianus, and Thræsa Patus. Padua, in common with north-eastern Italy, suffered severely from the invasion of the Huns under Attila (452). It then passed under the Gothic kings Odoacer and Theodoric, but made submission to the Greeks in 540. The city was seized again by the Goths under Totila, and again restored to the eastern empire by Narses in 568. Following the course of events common to most cities of north-eastern Italy, the history of Padua falls under eight heads:—(1) the Lombard rule, (2) the Frankish rule, (3) the period of the bishops, (4) the emergence of the commune, (5) the period of the despots, (6) the period of Venetian supremacy, (7) the period of Austrian supremacy, and finally (8) the period of united Italy. (1) Under the Lombards the city of Padua rose in revolt (601) against Agilulph, the Lombard king, and, after suffering a long and bloody siege, was stormed and burned by him. The city did not easily recover from this blow, and Padua was still weak when the Franks succeeded the Lombards as masters of north Italy. (2) At the diet of Aix-la-Chapelle (828) the duchy and march of Friuli, in which Padua lay, was divided into four counties, one of which took its title from that city. (3) During the period of episcopal supremacy Padua does not appear to have been either very important or very active. The general tendency of its policy, throughout the war of investitures, was imperial and not Roman; and its bishops were, for the most part, Germans. (4) But under the surface two important movements were taking place. At the beginning of the 11th century the citizens established a constitution composed of a general council or legislative assembly and a credenza or executive; and during the next century they were engaged in wars with Venice and Vicenza for the right of water-way on the Bacchiglione and the Brenta,—so that, on the one hand, the city grew in power and self-reliance, while, on the other, the great families of Camposampiero, D'Este,

Plan of Padua.

bridges crossing the various branches of the Bacchiglione, which, once surrounded the ancient walls. The Palazzo della Ragione, with its great hall on the upper floor, is reputed to have the largest roof unsupported by columns in Europe; the hall is nearly rectangular, its length 267½ feet, its breadth 89 feet, and its height 78 feet; the walls are covered with symbolical paintings in fresco; the building stands upon arches, and the upper story is surrounded by an open loggia, not unlike that which surrounds the basilica of Vicenza; the Palazzo was begun in 1172, and finished in 1219; in 1306 Fra Giovanni, an Augustinian friar, covered the whole with one roof; originally there were three roofs, spanning the three chambers into which the hall was at first divided; the internal partition walls remained till the fire of 1420, when the Venetian architects who undertook the restoration removed them, throwing all three compartments into one, and forming the present great hall. In the Piazza dei Signori is the beautiful loggia called the Gran Guardia,

and Da Romano began to emerge and to divide the Paduan district between them. The citizens, in order to protect their liberties, were obliged to elect a podestà, and their choice fell first on one of the D'Este family (c. 1175). The temporary success of the Lombard league helped to strengthen the towns; but their ineradicable jealousy of one another soon reduced them to weakness again, so that in 1236 Frederick II. found little difficulty in establishing his vicar Ezzelino da Romano in Padua and the neighbouring cities, where he practised frightful cruelties on the inhabitants. When Ezzelino met his death, in 1259, Padua enjoyed a brief period of rest and prosperity: the university flourished; the basilica of the saint was begun; the Paduans became masters of Vicenza. But this advance brought them into dangerous proximity to Can Grande della Scala, lord of Verona, to whom they had to yield in 1311. (5) As a reward for freeing the city from the Scalas, Jacopo da Carrara was elected lord of Padua in 1318. From that date till 1405, with the exception of two years (1388–90) when Gian Galeazzo Visconti held the town, nine members of the Carrara family succeeded one another as lords of the city. It was a long period of restlessness, for the Carraresi were constantly at war; they were finally extinguished between the growing power of the Visconti and of Venice. (6) Padua passed under Venetian rule in 1405, and so remained, with a brief interval during the wars of the league of Cambray, till the fall of the republic in 1797. The city was governed by two Venetian nobles, a podestà for civil and a captain for military affairs; each of these was elected for sixteen months. Under these governors the great and small councils continued to discharge municipal business and to administer the Paduan law, contained in the statutes of 1276 and 1362. The treasury was managed by two chamberlains; and every five years the Paduans sent one of their nobles to reside as nuncio in Venice, and to watch the interests of his native town. (7 and 8) After the fall of the Venetian republic the history of Padua follows the history of Venice during the periods of French and Austrian supremacy, and must be sought for in the article ITALY. In 1866 the battle of Königgratz gave Italy the opportunity to shake off the last of the Austrian yoke, when Venetia, and with Venetia Padua, became part of the united Italian kingdom.

PADUCAH, a city of the United States, the capital of M'Cracken county, Kentucky, on the south bank of the Ohio, at the mouth of the Tennessee river, is, next to Louisville, the most important commercial point in Kentucky. It is on the Chesapeake, Ohio, and South-Western railroads, and is the terminus for five lines of steamboats plying respectively to Evansville (Ind.), Cairo (Ill.), St Louis (Mo.), Nashville (Tenn.) and Florence (Ala.), and a regular stopping point for other lines plying on the Ohio, Tennessee, and Mississippi rivers. It ships tobacco, whisky, pork, lumber, flour, and grain, and contains a number of tobacco factories and warehouses, marine-ways for the building and repair of steamboats, and manufactories of furniture, hubs and spokes, harness-leather, soap, and brooms. Laid out in 1827, Paducah was incorporated as a town in 1830, and as a city in 1856. The population was 2428 in 1830, 4590 in 1860 6866 in 1870, and 8036 in 1880.

PEONY (*Pæonia*), a genus of *Ranunculaceæ* remarkable for their gorgeous flowers, constructed almost exactly on the same lines as those of the common buttercup except as regards the pistil, which in the pæonies consists of two or more separate carpels each containing several seeds, and surrounded at the base by a fleshy cup or disk, which grows up around the carpels. The receptacle of the flower, moreover, instead of being flattish or somewhat convex, is in pæonies a little depressed in the centre, so that the stamens become somewhat perigynous as in water-lilies (*Nymphæa*) or roses (*Rosa*). The carpels when ripe form dry follicles, splitting along one edge so as to expose the numerous shining black seeds, provided with a small fleshy aril. There are but few species, natives of the northern hemisphere of the Old World, and divisible into two main groups—those with herbaceous stems dying down in winter.

and those with shrubby stems (Moutan or Tree Pæonies). The herbaceous pæonies have tuberous roots like those of a dahlia, and bold, much-divided leaves. Their magnificent cup-like flowers are, in different varieties, of all shades of colour from white to clear yellow (*P. Wittmaniana*), rose-coloured, and richest crimson. A blue pæony has yet to be introduced. There is little reason to doubt that this desideratum will be fulfilled, for in larkspurs and aconites and columbines, closely related genera, we have a similar range in colour to that of the pæony, together with intense blue. The writer has also seen a Chinese drawing representing a blue pæony, and, although too much stress must not be laid on that circumstance, yet it must be remembered that the correctness of some representations of Chinese plants formerly considered fanciful has been proved by the subsequent introduction of the plant, e.g., *Dielytra spectabilis*. The Moutan or tree pæonies have an erect bushy stem, from which the bark peels off in flakes; the foliage is divided as in the commoner kinds, and more or less glaucous. The flowers are remarkable for the extreme delicacy of tint, and botanically by the large development of the disk above mentioned. Moutan pæonies are natives of China. In gardens a large variety of pæonies are cultivated, chiefly of hybrid origin; and one of the European species, *P. corallina*, has been found naturalized on an island in the mouth of the Severn, to which it is supposed to have been introduced.

PÆSTUM (Παίστων, *Posidonia*, mod. *Pesto*), a Greek city in Lucania, Magna Græcia, near the sea, and about 5 miles south of the river Silarus (Salso). It is said by Strabo (v. p. 251) to have been founded by Trœzenian and Achæan colonists from the still older colony of Sybaris, on the Gulf of Tarentum; this probably happened not later than about 600 B.C. Herodotus (i. 167) speaks of it as being already a flourishing city in about 540 B.C. when the neighbouring city of Velia was founded. The name Posidonia was derived from Poseidon, the deity principally worshipped by the Trœzenians. For many years the city maintained its independence, though surrounded by the hostile native inhabitants of Lucania. Autonomous coins were struck, of which many specimens now exist.

Fig. 1 shows a didrachm of the 6th century B.C., an interesting example of archaic Greek art. It is struck on a broad thin flan, with guilloché pattern round the border. The obverse has a figure of Poseidon wielding his trident, with the chlamys hung across his shoulders. The reverse has the same figure *incuse*. Both sides have the legend (retrograde) in relief, ΜΟΡ ΠΟΣ.

Archaic forms of Σ and Π are used. Later silver coins (see fig. 1) have the same figure of Poseidon on the obverse, and a bull on the reverse, both in relief, with the legend ΓΟΜΕ ΣΔΑΝΣΑΤΑΜ (ΠΟΣΕΙΔΑΝΙΑΤΑΣ), in which the archaic Μ for Σ and Σ for Γ occur. Bronze coins of the Roman period have the legend ΠΑΙΣ (παίστων).

After long struggles for independence the city fell into the hands of the native Lucanians (who nevertheless did not expel the Greek colonists), and in 273 B.C. it became a municipal town under the Roman rule, the name being changed to the Latin form Pæstum. The neighbourhood was then healthy, highly cultivated, and celebrated for its flowers; the "twice blooming roses of Pæstum" are mentioned by Virgil (*Geor.*, iv. 118), Ovid (*Met.*, xv. 708), Martial (iv. 41, 10; vi. 80, 6), and other Latin poets. Its present deserted and malarious state is probably owing

to the silting up of the mouth of the Silarus, which has overflowed its bed, and converted the plain into unproductive marshy ground. Herds of buffaloes, and the few peasants who watch them, are now the only occupants of this once thickly populated and garden-like region. In the 9th century Paestum was sacked and partly destroyed by Arab invaders; in the 11th century it was further dismantled by Robert Guiscard, and in the 16th century was finally deserted. The ruins of Posidonia are, however, among the most interesting of the Hellenic world. Remains of the city wall, sufficient to indicate the whole circuit (an irregular polygon about 3 miles round), still exist. The lower part of one of the gates, a fine specimen of Greek masonry, is still fairly perfect. This is a large square tower with inner and outer doorways, and on each side a projecting bastion, semicircular in plan; the whole is skilfully arranged so as to thoroughly command the doorways. A ditch, about 40 feet outside the wall, gave additional security. The main wall is 16 feet 6 inches thick. The general design of this fortification much resembles the very perfectly preserved walls and towers of Messene in the Peloponnesus. For plan and description of this gate see a paper by T. L. Donaldson, *Museum of Classical Antiquities*, vol. i. p. 35, 1851. Outside the north gate there is a long street of tombs, some of which have been excavated, and have yielded a number of interesting arms, vases, and mural paintings, mostly now in the museum at Naples. The chief glory of Posidonia is its wonderful group of three well-preserved Doric temples.

The largest of these, conjecturally called the "Temple of Poseidon," is on the whole the most complete Greek temple now existing, and, judging from other specimens of the Doric style, can hardly be later than 500 B.C. The characteristics which point to its remote age are the shortness (comparatively speaking) of the columns, their rapid diminution, the complete absence of entasis, the great projection of the capitals, and the massiveness of the entablature. Another peculiarity is that the columns have twenty-four flutes, while other Doric examples rarely exceed twenty. The columns on the flanks are fourteen in all, about an average number for a Doric hexastyle temple. Fig. 2 gives the plan, in which there is nothing con-

except those at the angles, which measure 7 feet. The intercolumniation at the angles is closer than elsewhere, after the usual Doric rule. The height of the columns, including capitals, is 29 feet. The stylobate consists of three steps, and the cella floor is four steps above the peristyle pavement, i.e., nearly 5 feet, an unusual height. Indications still exist of the stairs leading to the roof or to the upper floor, which probably formed the internal ceiling over the aisles. The main dimensions of the building are, on the top step of the stylobate, nearly 196 feet in length by 79 feet wide, more than double the length of the celebrated temple of Ægina, though not quite double the width.

The material of which this and the other temples are built is a coarse calcareous stone from the neighbouring hills, formed by water deposit. None of this stone was, however, left exposed. The whole building, inside and out, like that at Ægina and other places, was carefully covered with a fine hard stucco formed of lime and pounded white marble, which took a high polish, and could hardly have been distinguished from real marble. On this was painted the usual coloured ornaments with which all important Greek buildings appear to have been decorated.

Archaisms of style, like those in this temple, are also to be found in the scanty remains still existing of the temples at Corinth and Ortygia (Syracuse), the latter probably an even earlier example of the Doric style. The other temples, though fine and well-preserved, are inferior both in size and interest. Though Greek in their general outline, and of the Doric order, yet the details, such as cornices, shafts, and capitals, are debased in style, and can hardly belong to the autonomous period of Posidonia; more probably they were built under the native Lucanian or Roman domination, while Hellenic traditions still lingered among the people. The larger of these, popularly called "the Basilica," is quite unique in plan (see fig. 3). It has nine columns (an unequal number) on its front, and a range of columns down the centre of the cella. It is pseudo-dipteral, and has eighteen columns on the flanks; all that is black in the plan still remains. The columns are very ungraceful in shape, with an extravagant amount of entasis, and a curious cirelet of leaves immediately under the echinus. The most probable explanation of the strange arrangement of the cella is that the temple was dedicated to two deities—each half containing one statue.

The third temple, popularly called that of Ceres, is hexastyle peripteral, about 108 feet by 48 on the top of the stylobate, with thirteen columns on the flanks. In plan it is abnormal in having an open vestibule within the peristyle. There is an opisthodomos behind the cella. Its details throughout are very debased and un-Hellenic.

Both these latter buildings offer a striking contrast to the pure and severe Doric of the great temple. Ruins and traces of several other buildings within the city wall still exist, all apparently of the Roman period. Part of an amphitheatre, and of what may have been a circus, can be distinguished, as well as ruins of an aqueduct outside the city. Various mounds and other inequalities in the ground suggest that much still remains hidden, and that Paestum would probably afford a rich harvest to the careful explorer, while a very simple system of drainage might again restore to this once fertile plain its long-lost wholesomeness of air and richness of soil.

See Strabo, v. and vi.; Wilkins, *Magna Græcia*, 1807; Piranesi, *Ville de Paestum*, Rome, 1778; Major, *Ruins of Paestum*, 1762; La Gardette, *Ruines de Paestum*, 1779; Bötticher, *Die Tektonik der Hellenen*, 1844-52, vol. ii. p. 325, and plates; Forgysson, *The Parthenon*, 1883, p. 82; Labrousse, *Les Temples de Paestum*, 1877. This last work has the best and most accurate drawings, specially executed for the Paris Ecole des Beaux Arts. (J. H. M.)

PAEZ, JOSÉ ANTONIO, one of the leaders of the struggle for South-American independence, and the first president (1830-38) of the republic of Venezuela, was born of Indian parents in the neighbourhood of Acarigua in the province of Barinas, and died in exile at New York, May 6, 1873. His military career, which began about 1810, was distinguished by the defeat of the Spanish forces at Mata de la Miel (1815), at Montecal and throughout the province of Apuro (1816), and at Puerto Cabello (1823). At first he acted in concert with BOLIVAR (*q.v.*), but in 1829 he procured the secession of Venezuela from the republic of Colombia. For his later life see VENEZUELA. His autobiography was published at New York in 1867-69, and his son Ramon Paez (otherwise known as an author) wrote *Public Life of J. A. Paez* (1864).

PAEZ, PEDRO (1564-1622), Jesuit missionary to Abyssinia, was born at Olmedo in Old Castile in 1564. Having entered the Society of Jesus, he was set apart for foreign mission service, and sent to Goa in 1588. Within a year he was despatched from that place along with a

FIG. 2. Plan of the Great Temple.

The shaded part does not now exist.

FIG. 3. Plan of the (so-called) Basilica.

jectural; the only serious loss is the absence of the greater part of the cella wall, and some of the upper range of interior columns; the seven columns of this upper order which still remain *in situ* are especially valuable, as no other temple still possesses any of them. The peristyle columns are 6 feet 10 inches in diameter at the base,

fellow missionary to Abyssinia, but having fallen into the hands of pirates at Ormuz he was detained in that neighbourhood for seven years as a galley slave. Having been redeemed by his order in 1596, he next spent some years in mission work at Diu and Camboya and other places on the west coast of India, and it was not until 1603 that he reached his original destination, landing at the port of Massowah. At the headquarters of his order in Fremona, he soon acquired the two chief dialects of the country, translated a catechism, and set about the education of some Abyssinian children. He also established a reputation as a preacher, and, having been summoned to court, succeeded in vanquishing the native priests and in converting Za-Denghel, the king, who wrote to the pope and the king of Spain for more missionaries, an act of zeal which involved him in civil war, and ultimately cost him his life (October 1604). Under the succeeding sovereign the influence of Paez became still greater, not only the king but the nobility having abjured their errors and accepted Catholicism. Paez, who is said to have been the first European to visit the Abyssinian Nile, died of fever in 1622. See *ABYSSINIA*, vol. i. p. 65.

PAGANINI, NICOLÒ (1784-1840), the most extraordinary of executants on the violin, past or present, was born at Genoa, February 18, 1784. His father, a clever amateur, imbued him with a taste for music at a very early age. He first appeared in public at Genoa, in 1793, with triumphant success. In 1795 he visited Parma for the purpose of taking lessons from A. Rolla, who, however, said that he had nothing to teach him. On returning home, he studied more diligently than ever, practising single passages for ten hours at a time, and publishing compositions so difficult that he alone could play them. After spending some years in close retirement, he started, in 1805, on a tour through Europe, astonishing the world with his matchless performances on the fourth string alone. In 1827 the pope honoured him with the Order of the Golden Spur; and, in the following year, he extended his travels to Germany, beginning with Vienna, where he created a profound sensation. He first appeared in Paris in 1831; and on June 3 in that year he played in London, at the King's Theatre. His visit to England was preluded by the most absurd and romantic stories. He was described as a political victim who had been immured for twenty years in a dungeon, where he played all day long upon an old broken violin with one string, and thus gained his wonderful mechanical dexterity. The result of this and other foolish reports was that he could not walk the streets without being mobbed. Here, as in other countries, he amassed a princely fortune, notwithstanding enormous losses caused by his unhappy propensity for speculation. In 1834 Berlioz composed for him his beautiful symphony, *Harold en Italie*. He was then at the zenith of his fame; but his health, long since ruined by excessive study, declined rapidly. In 1838 he suffered serious losses in Paris, yet generously presented Berlioz with 20,000 francs in return for his symphony. The disasters of this year increased his malady—laryngeal phthisis—and, after much suffering, he died at Nice, May 27, 1840. Paganini's style was impressive and passionate to the last degree. His *cantabile* passages moved his audience to tears, while his *tours de force* were so astonishing that a Viennese amateur publicly declared that he had seen the devil assisting him. No later violinist has as yet eclipsed his fame as an executant, though he was far from realizing the artistic perfection so nobly maintained by Spohr and Joachim. The best of his imitators was his pupil Sivori.

PAHLAVI, or PEHLEVI, the name given by the followers of Zoroaster to the character in which are written the ancient translations of their sacred books and some other

works which they preserve. The name can be traced back for many centuries; the great epic poet Firdausi (second half of the 10th Christian century) repeatedly speaks of Pahlavi books as the sources of his narratives, and he tells us among other things that in the time of the first Khosrau (Chosroes I., 531-579 A.D.) the Pahlavi character alone was used in Persia.¹ The learned Ibn Mokaffa' (8th century) calls Pahlavi one of the languages of Persia, and seems to imply that it was an official language.² We cannot determine what characters, perhaps also dialects, were called Pahlavi before the Arab period. It is most suitable to confine the word, as is now generally done, to designate a kind of writing—not only that of the Pahlavi books, but of all inscriptions on stone and metal which use similar characters and are written on essentially the same principles as these books.

At first sight the Pahlavi books present the strangest spectacle of mixture of speech. Purely Semitic (Aramaic) words—and these not only nouns and verbs, but numerals, particles, demonstrative and even personal pronouns—stand side by side with Persian vocables. Often, however, the Semitic words are compounded in a way quite unsemiotic, or have Persian terminations. As read by the modern Zoroastrians, there are also many words which are neither Semitic nor Persian; but it is soon seen that this traditional pronunciation is untrustworthy. The character is cursive and very ambiguous, so that, for example, there is but one sign for *n*, *u*, and *r*, and one for *y*, *d*, and *g*; this has led to mistakes in the received pronunciation, which for many words can be shewn to have been at one time more correct than it is now. But apart from such blunders there remain phenomena which could never have appeared in a real language; and the hot strife which raged till recently as to whether Pahlavi is Semitic or Persian has been closed by the discovery that it is merely a way of writing Persian in which the Persian words are partly represented—to the eye, not to the ear—by their Semitic equivalents. This view, the development of which began with Westergaard (*Zendavesta*, p. 20, note), is in full accordance with the true and ancient tradition. Thus Ibn Mokaffa', who translated many Pahlavi books into Arabic, tells us that the Persians had about one thousand words which they wrote otherwise than they were pronounced in Persian. For *bread* he says they wrote LHMA, i.e., the Aramaic *lahmá*, but they pronounced *nán*, which is the common Persian word for bread. Similarly BSRA, the Aramaic *besrá*, flesh, was pronounced as the Persian *gōsh*. We still possess a glossary which actually gives the Pahlavi writing with its Persian pronunciation. This glossary, which besides Aramaic words contains also a variety of Persian words disguised in antique forms, or by errors due to the contracted style of writing, exists in various shapes, all of which, in spite of their corruptions, go back to the work which the statement of Ibn Mokaffa' had in view.⁴ Thus the Persians did the same thing on a much larger scale, as when in English we write £ (libra) and pronounce "pound", or write & or & (et) and pronounce "and." No system was followed in the choice of Semitic forms. Sometimes

¹ We cannot assume, however, that the poet had a clear idea of what Pahlavi was.

² The passage, in which useful facts are mixed up with strange notions, is given abridged in *Fihrist*, p. 13, more fully by Yāqūt, iii. 925, but most fully and accurately in the unprinted *Mafātiḥ al-'alām*.

³ *Fihrist*, p. 14, l. 13 sq., comp. l. 4 sq. The former passage was first cited by Quatremère, *Jour. As.* (1835), i. 256, and discussed by Clermont-Ganneau, *Ibid.* (1866), i. 420. The expressions it uses are not always clear; perhaps the author of the *Fihrist* has condensed somewhat.

⁴ Editions by Hoshangji and Haug (Bombay, 1870), and by Salemann (Leyden, 1878). See also J. Olshausen, "Zur Würdigung der Pahlavi-glossare" in Kuhn's *Zeit. f. vergl. Sprachforsch.*, N. F. vi. 521 sq.

the Aramaic letters as naturally as they subsequently borrowed those of the Arabs. But this does not explain the strange practice of writing Semitic words in place of so many Persian words which were to be read as Persian. It cannot be the invention of an individual, for in that case the system would have been more consistently worked out, and the appearance of two or more kinds of Pahlavi side by side at the beginning of the Sāsānian period would be inexplicable. But we may remember that the Aramaic character first came to the Eranians from the region of the lower Euphrates and Tigris, where the complicated cuneiform character arose, and where it held its ground long after better ways of writing were known. In later antiquity probably very few Persians could read and write. All kinds of strange things are conceivable in an Eastern character confined to a narrow circle. Of the facts at least there is no doubt.

The Pahlavi literature embraces the translations of the holy books of the Zoroastrians, dating probably from the 6th century; and certain other religious books, especially the *Minōi-Khiradh* (see above) and the *Bundehish*.¹ The *Bundehish* dates from the Arab period. Zoroastrian priests continued to write the old language as a dead tongue and to use the old character long after the victory of a new empire, a new religion, a new form of the language (New Persian), and a new character. There was once a not quite inconsiderable profane literature of which a good deal is preserved in Arabic or New Persian versions or reproductions, particularly in historical books about the time before Islam.² Very little profane literature still exists in Pahlavi; the romance of Ardashir has been mentioned above (p. 135, note 1). The difficult study of Pahlavi is made more difficult by the corrupt state of our copies, due to ignorant and careless scribes. A Pahlavi grammar is of course an impossibility. The necessary preparation for the study is a sound knowledge of New Persian, with which one easily finds the clue to the inconsiderable grammatical variations of the older language. The lexical peculiarities of the texts are more considerable, and partly due to the peculiarities of priestly thought and speech. Of glossaries, that of West (Bombay and London, 1874) is to be recommended; the large Pahlavi, Gujarati, and English lexicon of Jamaspji Dastur Minocheherji (incomplete, 3 vols., Bombay and London, 1877-82) is very full, but has numerous false or uncertain forms, and must be used with much caution. (TH. N.)

PAINE, THOMAS (1736-1809), the author of *The Rights of Man* and *The Age of Reason*, would have had a very different kind of reputation if he had never written these works. Most of those who know him by name as a ribald scoffer against revealed religion are not aware that he has any other title to fame or infamy. But if he had never meddled with religious controversy, his name would have been remembered in the United States at least as one of the founders of their independence. He had a prominent reputation when he crossed the Atlantic to stir up the people of the Old World against monarchy and aristocracy, taking as his motto "Where liberty is *not*, there is my country." Even after he wrote *The Rights of Man*, if he had been guillotined by Robespierre, which he very narrowly escaped being, he might have been remembered in Britain as a clever but crazy and dangerous political enthusiast. The final verdict of history upon his usefulness would have turned on the question whether the United States did well to declare and fight for independence. But *The Age of Reason* brought his name into disrepute almost as much in the United States as in England. The career of Paine was a very extraordinary one. The son of a Quaker staymaker, of Thetford in Norfolk, he had emigrated to the American colonies somewhat late in life, after erratically trying various ways of making a living as a marine, an exciseman, a teacher of English, and acquiring a reputation in local political

clubs by extreme views and vigour in debate. Born in 1736, he was thirty-eight when he arrived in America, and he apparently went with a purpose, his combative temper attracted by the quarrel then reaching an acute stage, for he carried introductions with him from Franklin to the leaders of the resistance to the mother-country. His opportunity came when these leaders were dispirited and disposed to compromise. He then set the colonists in a flame with a pamphlet entitled *Common Sense*, a most telling array of arguments for separation and for the establishment of a republic, conveyed in strong direct unqualified language. There is a complete concurrence of testimony that Paine's pamphlet, issued on the 1st January 1776, was a turning-point in the struggle, that it roused and consolidated public feeling, and swept waverers along with the tide. The New York assembly appointed a committee to answer it, but the committee separated with the conclusion that it was unanswerable. When war was declared, and fortune at first went against the colonists, Paine, serving with Washington as a private soldier, composed by the light of camp fires a short hortative tract, *The Crisis*, which was read to the army, and seems to have had a wonderful effect in restoring a courage that was considerably impaired by defeat. Its opening words, "These are the times that try men's souls," became a battle-cry. This and other literary services were recognized by Paine's appointment in the first Congress to be secretary of the committee on foreign affairs. The republic finally established, another phase of his turbulent career was entered on. He determined to return to England, and "open the eyes of the people to the madness and stupidity of the Government." His chief effort in this propagandism was *The Rights of Man*, written as an answer to Burke's *Reflexions on the Revolutions in France*. The first part appeared in 1791, and had an enormous circulation before the Government took the alarm and endeavoured to suppress it, thereby exciting the most intense curiosity to see it even at the risk of heavy penalties. Those who know the book only by hearsay as the work of a furious incendiary would be surprised at the dignity, force, and temperance of the style; it was the circumstances that made it inflammatory. Pitt "used to say," according to Lady Hester Stanhope, "that Tom Paine was quite in the right, but then he would add, 'What am I to do? As things are, if I were to encourage Tom Paine's opinions, we should have a bloody revolution.'" Paine accordingly was indicted for treason, but before the trial came off he was elected by the department of Calais to the French Convention, and was allowed to pass into France followed by a sentence of outlawry. The first years that he spent in France form a curious episode in his life. As he knew little of the language, he could have had but little influence on affairs, but he was treated with great respect, and did what he could in the interests of moderation till he incurred the suspicion of Robespierre and was thrown into prison, escaping the guillotine by an accident. He completed the first part of the *Age of Reason* in the exciting interval between his accusation and his arrest, and put it into the hands of a friend on his way to prison. The publication of the work made an instant change in his position on both sides of the Atlantic, the indignation in the United States being as strong as in England. Washington, to whom he had dedicated his *Rights of Man*, declined to take any steps for his release from the prison of the Luxembourg, and he lay there for several months after the fall of Robespierre. The *Age of Reason* can now be estimated calmly. It was written from the point of view of a Quaker who did not believe in revealed religion, but who held that "all religions are in their nature mild and benign" when not associated with political

¹ The translations edited by Spiegel, the *Bundehish* by Westergaard and Justi, other Pahlavi books by Spiegel and Haug, by Hoshangji, and other Indian Pārsees.

² We have also one book, the stories of *Kalilag and Damnag*, in a Syriac version from the Pahlavi, the latter in this case being itself taken from the Sanskrit.

systems. Intermixed with the coarse unceremonious ridicule of what he considered superstition and bad faith are many passages of earnest and even lofty eloquence in favour of a pure morality founded on natural religion, fully justifying the bishop of Llandaff's saying:—"There is a philosophical sublimity in some of your ideas when speaking of the Creator of the universe." The work in short—a second part was published after his release—represents the deism of the 18th century, in the hands of a rough, ready, passionate controversialist. Paine remained in France till 1802, and then returned to America, occupying the rest of his turbulent active life with financial questions and mechanical inventions. * He died in 1809.

PAINT. See PIGMENT.

PAINTING. A general examination of the place of painting among the FINE ARTS will be found under that heading. The main SCHOOLS OF PAINTING (*q.v.*) will form the subject of a separate article. For the history of the art, see also ARCHÆOLOGY (CLASSICAL) and the notices of individual painters. The present article is limited to a few practical notes on the methods of painting in oil and water colour, other methods being dealt with under the headings ENAMEL, ENCAUSTIC PAINTING, FRESCO, and TEMPERA.

Painting-Room.—The painting-room or atelier should be of sufficient dimensions to allow the artist space to retire from his work, if it is on a scale large enough to require viewing from a distance. For large decorative paintings the room must be spacious. The size and altitude of the window is of great importance. If the opening is contracted, the light and shade on the model will be broad and intense, and the colouring sombre, especially in the shadows. If abundance of light is admitted, the tendency will be more towards brightness and purity. Painters generally prefer a window with a northern or eastern aspect.

The painting-room has a great influence in determining not only the effects in the works of individual artists, but the characteristics of whole schools. Leonardo da Vinci was among the first to show partiality to indoor effects and deep shadows. Correggio, the artists of the Bolognese school, Caravaggio, Spagnoletto, and other Neapolitan and Spanish painters followed; the Dutch painter Rembrandt perhaps carried these extreme contrasts of light and shade to the greatest length. The effects thus obtained are, however, more or less artificial, and very unlike the ordinary aspect of the open daylight face of nature.

Painters, unless there happens to be some special reason to the contrary, usually work with the light to the left to prevent the shadow cast from the brush falling inwards. Some artists who seek to represent open air effects paint from their models in glass-houses, specially constructed for the purpose. The practice has much to recommend it, the diffused light enabling them to approximate more nearly to the truth of nature.

Implements used in Painting.—The *easel* is a frame, or rest, which supports the picture during its progress. Easels are of various kinds:—the triangular, supplied with pegs for the adjustment of the height of the work; the square, or rack easel, which is much more convenient; and the French studio easel, having a screw at the back and worked by a handle in the front, by which arrangement pictures of considerable size and weight can be raised or lowered or inclined forward with great ease. There is also a variety of light portable easels used for out-door sketching.—The *palette* is the board on which the colours are arranged to paint from; it is usually either of an oval or oblong square form, of light-coloured wood, and, to avoid inconvenience being felt from its weight, it should be thin and well balanced on the thumb. It ought

to be kept clean and the colour never allowed to dry on it.—The *palette-knife* has a pliable blade, and is used for arranging the colours on the palette, mixing tints, &c. With some painters it not unfrequently takes the place of the brush in the application of colour.—The larger kinds of *brushes* are made of hog-hair. They are either round or flat, but the latter are generally preferred, though for some purposes round ones are found to be useful. Brushes are also made of sable; these should have the property of coming to a fine point when required. Brushes of badger's hair are used for "softening" or "sweetening,"—that is, blending the colours by sweeping lightly to and fro over them while freshly laid (a practice to be avoided as much as possible). Brushes should be carefully washed after use, either in spirits of turpentine or with soap and tepid water, dried, and the hairs laid smooth with the finger and thumb. A brush in which the colour has been allowed to dry is difficult to clean, and is much injured, if not rendered entirely useless, by such negligence. Not a little depends on the good condition in which the brushes are kept.—The *mahl-stick* is used to steady the hand while painting details. It is held in the left hand, and the end of the stick, properly wadded, rests on the canvas. It should be light and firm. The old painters never used the mahl-stick when working on large pictures, and many artists dispense with it altogether. Rubens mentions being obliged to have recourse to one in his old age.—The *dais* or *throne* is a platform varying from a foot to 18 inches in height. Portrait painters, and artists who generally stand while at work, find it desirable to have the sitter or model nearly on a level with the eye.—A *mirror* hung in a convenient place in the painting-room will be found of great use. It enables the artist to detect faults in drawing to which he might otherwise be blinded from too long gazing at his work. The picture is seen in the mirror reflected in reverse, and errors consequently appear greater than they really are.—The *lay-figure*, a wooden or stuffed doll, usually life-size, is very serviceable in painting elaborate dresses and draperies. The best kinds are so constructed that they can be made to assume and retain any posture. Fra Bartolommeo first brought the lay-figure into use.

Materials used in Painting.—These consist of canvases, prepared panels and mill-boards, oils, varnishes, and colours.

1. *Canvas* is the material now generally used. It is kept in rolls of various width and of three qualities—plain cloth, Roman, and ticken. It is prepared with two kinds of grounds—the hard or oil ground, and the absorbent ground. The ground is generally of a light colour; many artists prefer pure white. The grounds employed by the first oil painters were identical with those of tempera; the surface of the panel was prepared with two or three coats of size, a layer of coarse gesso was then applied, and on this at least eight layers of a finer description were spread, and the surface carefully scraped till it became smooth and white. In the Italian school of a later period, the grounds were generally composed of pipe-clay mixed with chalk. It is generally acknowledged that white grounds are in every way preferable, although it matters little whether the brightness reside in the ground or is reproduced at a subsequent stage by painting with a solid body of opaque colour over a dark ground. Velazquez and other Spanish painters used canvases prepared with a red earthy ground. The intention of priming the ground is to prevent the very rapid absorption of colours. Canvas prepared with the object of partially abstracting the oil from the first layers of colour is called "absorbent." For small cabinet pictures panels of well-seasoned mahogany are used; mill-boards, academy boards, and oil paper are serviceable for sketching from nature.

2. *Oils and Varnishes.*—The introduction of oil painting on the modern methods dates from the time of John Van Eyck. This artist introduced a varnish, probably composed of linseed or nut oil mixed with some resinous substance, which was more siccative than the oil vehicles previously in use, and possessed the property of drying without exposure to the sun or to artificial heat. The oil painting of the early Flemish masters was, strictly speaking, (oil) varnish painting: an oleo-resinous substance, such as amber varnish, was mixed with the colours, and rendered final varnishing unnecessary. The Venetian painters also adopted this vehicle. The term "vehicle" is borrowed from pharmacy. In art it is applied to the fluid used for bringing the pigments into a proper working state. Painters differ greatly as to the vehicles they employ: some use oil only; others peculiar compounds of their own, made of linseed, poppy, or walnut oils, copal or amber varnishes, drying oil and mastic, &c. Siccative, a medium specially prepared for oil painting, is now largely used; mixed with spirits of wine, it forms a beautiful transparent varnish.

3. *Colours.*—The permanent colours are the earths and ochres and those mineral colours which bear the test of fire and lime. Colours prepared from lead and animal and vegetable substances are more or less fugitive. Artist's colours were originally kept in a dry state, and afterwards in small bladders; they are now enclosed in very convenient collapsible metal tubes.

The discoveries of modern chemistry have added largely to the simple list of colours known to the old masters, but perhaps with little advantage to their successors, for their is much truth in the maxim that "the shortest way to good colouring is through a simple palette." Pliny asserts that the ancient Greek painters employed but four colours in their works.

A large proportion of colours, such as the ochres, vermilion, ultramarine, &c., is derived from minerals; indigo, madder, gamboge, &c., from vegetable, and carmine, Indian yellow, sepia, &c., from animal substances. The artificial or chemical preparations include Prussian blue, Naples yellow, zinc white, French blue, cobalt, the lakes, &c.

The natural or true pigments are prepared for use by calcining and washing, and for oil painting are ground up in poppy or linseed oils. With two or three exceptions the pigments derived from the mineral kingdom are the most permanent, especially those containing iron or copper. Those derived from animal and vegetable substances have less permanence, but they form an important acquisition to the palette, as they not unfrequently possess a purity and brilliancy of colour which makes it almost impossible to dispense with them.

Colours are opaque or transparent. The former, on account of their solidity and opacity, are employed to represent light. For shadows and glazing transparent pigments are used. Yellow, red, and blue cannot be composed, and are called primary colours. The union of two of these in the three combinations of which alone they admit produces secondary colours. White represents light; and in oil painting the only white pigment used is white lead, prepared with great care. The ochres are the most permanent yellows. Their composition is very variable, but they may be considered true chemical combinations of clay and oxide of iron. The native ochres are yellow and red. By calcination the yellow ochres become red. Other yellows are prepared from arsenic, lead, and vegetable substances. Iron is the great colouring principle of red in nature. All the three kingdoms—mineral, animal, and vegetable—contribute to the red pigments. The first supplies vermilion and the red ochres; the second carmine, obtained from the cochineal insect; the third

the madder pigments. The principal blue pigments are ultramarine (native and artificial), cobalt, smalt, Prussian blue, and indigo. Ultramarine is the only pure primary colour; the finer specimens have neither a tinge of green on the one hand nor of purple on the other. It is obtained from the mineral lazulite or lapis-lazuli, and is probably a volcanic product, as it resists the action of fire. Its scarcity, and consequent high price, have produced many artificial imitations. These are of many qualities. The inferior are used in paper staining, the finer alone being reserved for artists' use. Cobalt is now prepared in a state of great purity, but it has the objection of appearing violet in artificial light.

In "guides to oil painting" long lists of pigments are generally given; but these serve only to perplex and embarrass. About a dozen colours, judiciously chosen, will be quite sufficient to supply the palette.

Processes and Manipulations.—There are various technical distinctions in the modes of applying the colours to a picture in its successive stages. *Glazing* is the laying of thinly transparent colours, diluted with a considerable quantity of vehicle, which allows the work beneath to appear distinctly through, but tinged with the colour of the glaze. The Venetian painters, Titian especially, largely employed this process, advancing their pictures as far as possible with solid, opaque colour, and upon this ground glazing repeatedly the richest and purest colours. The process of glazing is generally effected by the application of diluted transparent colour, but semi-transparent colours are also used when rendered sufficiently transparent by the admixture of a large proportion of vehicle. When carried to excess, the result is a "horny" impure dulness of surface and a heavy and dirty tone of colour. Much practice and experience are required for its proper performance. *Scumbling* resembles glazing in that a very thin coat is spread lightly over portions of the work, but the colour used is opaque instead of transparent. A hog-hair brush sparingly charged with the tint is employed. Carried to excess, scumbling produces a "smoky" appearance. *Impasting* is the term applied to laying colours in thick masses on the lights. The shadows or dark portions of a picture are painted thinly and transparently, the lights solidly, with opaque colours. Impasting gives "texture" and "surface" to the latter, and helps to produce the appearance of roundness and relief. When carried too far it produces an appearance of coarseness and affords a lodgment for dirt and varnish in what should be the brightest and purest passages in the colouring.

Irregularities of surface in such passages of a picture as it may be desirable to repaint are removed by using an instrument especially made for the purpose; but an old razor, an ordinary pocket-knife, or a piece of window glass, properly broken, will, in skilful hands, answer the purpose equally well. This process should not be attempted till the colour to be removed has hardened, otherwise the pigment will tear off and leave the surface in a condition which it will be found difficult to remedy.

It is the practice of some artists to lay the colours at first cold and pale, gradually strengthening the light and shade, and enforcing the colour in subsequent paintings. When this practice is adopted, the colours used should be as few and as simple as possible. It sometimes happens that considerable portions of the first painting are apparent through all the subsequent processes, and this early part of the work should be done with great care and judgment.

The first principle in the application of paint is to avoid unnecessary mixing, or, as it is called, "troubling" or saddening the tints, the result of which is a waxy surface and muddiness of colour. When this is avoided the touches are clear and distinct, but when the principle is carried to

excess it degenerates into manner; or it may serve as a convenient screen for the want of accurate observation and thorough execution.

Among the masters most remarkable for precision and rapidity of handling are Velazquez, Tintoretto, Veronese, and Rubens. The execution of Leonardo da Vinci is laboured. Vanderwerf, Mengs, and Denner are also instances of laboured smoothness. The three last-named belong to a class designated "the polishers,"—"little men, who did not see the whole at a time, but only parts of a whole, and thus vainly essayed to make up the whole by a smooth union of parts."

No two artists employ the same method in painting. Some attain the result aimed at by involved and complicated, others by direct and simple methods. The difference in *technique* between the work of an English artist and artists trained in French or German ateliers may be seen at a glance, and it is of little use attempting to lay down hard and fast rules on the subject. Even among the great Italian painters a wide variety of practice existed. It has been pretty well ascertained, partly from unfinished works, that Titian's method was to work out the effect of his pictures, as far as possible, with pure white, red, and black, the shadows being left cold. To prevent the yellowing of the oil, and to harden the colour, the picture was exposed to the sun, months were sometimes allowed to elapse, and then the surface of this *dead* or first colouring was rubbed down with pumice stone and fresh colours and the glazings applied, a considerable period—during which the picture was exposed to the sun—elapsing between successive applications of colour. Titian is said to have been very partial to the use of his fingers when laying on paint, particularly on flesh and glazings.

The practice of Paul Veronese was quite opposed to that of Titian. He sought almost the full effect at once by direct means and simple mixture of tints, seldom repeating his colours, and using few glazings. When the work was well advanced in this way he covered the whole with a thin coat of varnish to bring up the colours, and then re-touched the lights and enforced the shadows with dexterous touches.

It is said of Reynolds, who spent half his life in experiments, that in order to discover their technical secrets he deliberately scraped away and destroyed Venetian pictures of value. The decay of so many of his works shows with how little success these experiments were rewarded.

Numerous "guides to oil painting" exist, but little real instruction or benefit is to be gained from their perusal. They abound in minute directions how to paint "trunks of trees, heaths, fields, roads, skies (grey, blue, and stormy), sunsets, sunrises, running streams and waterfalls, mountains, the smoke or steam of steamers, and chimneys of cottages," as well as "heads, flesh, backgrounds, draperies (blue, red, and black)," with lists of the proper colours to be employed for each. All this, it is hardly needful to say, is worse than useless. The surest and safest way for any one who intends to study painting seriously, or to make it his profession, is to place himself under the instruction of an artist of repute, either in his own country or in some foreign atelier; but, even after acquiring a sound technical knowledge of the processes employed in painting, it will be found that much remains to learn which no master can teach. It is said of Velazquez that "he discovered that nature herself is the artist's best teacher, and industry his surest guide to perfection, and he very early resolved neither to sketch nor to colour any object without having the thing itself before him."

Water-Colour Painting.—The use, in painting, of earths and minerals of different colours diluted with water, is

of great antiquity. Painting with oils or oleo-resinous vehicles is a comparatively modern invention. Tempera, encaustic, and fresco were ancient modes of water painting. Several of the early Dutch and Flemish oil painters attained to considerable technical excellence in the separate practice of water-colour painting; little more than simple washings of water colour were employed by them, the processes which have in modern times so greatly raised and extended its scope being then unknown.

Painting in water colour owes much of its development to English artists, and may be regarded as a peculiarly national school of art. The first English water-colour painter of note, Paul Sandby, used Indian ink in the earlier stages of his drawings, finishing them with a few tints of thin colour. At this period paintings in water colour were little more than flat washes, and in the early catalogues of the Royal Academy Exhibition were designated "water-tinted" or "water-washed drawings." Improvements were gradually effected, first by varying the ground-work tint with blue and sepia, over which washes of colour, commencing with a warm generalizing tint, were struck. John Cozens was the first to substitute a mixture of indigo and Indian red in place of Indian ink as a neutral tint in the early stages of his work, a practice which was long retained. The old water-colour painters used the lead pencil or the reed pen in finishing their drawings. The first to break away from this conventional method was Girtin, who painted objects at once with the tints they appeared to possess in nature. Turner, perhaps the greatest master of the art, was closely associated with Girtin in early life, and in the course of his long career he carried water-colour painting to a degree of perfection which can scarcely be surpassed. Nearly all the great improvements which have taken place of late years in water-colour painting are due more or less to him. John Lewis, De Wint, Prout, Hunt, Cox, Harding, and Copley Fielding have all contributed to the development of the art.

Materials used in Water-Colour Painting.—1. *Paper.*—A great variety of papers is used, varying in texture from the extreme of roughness to hot-pressed smoothness. In many of Turner's drawings the paper is tinted. Nothing, however, seemed to come amiss to him; papers of almost any surface or texture were used. David Cox, in many of his later works, employed a rough paper made from old sail-cloth. The paper most generally used is known as "Imperial," and is made of various degrees of texture and thickness. Whatman's papers are also much esteemed.

The proper sizing of the paper is of great importance; if it is too strongly done the colours will not float or work freely, if too little they are absorbed into the fabric and appear poor and dead. In this last case, gum-arabic dissolved in warm water will improve the effect by bringing up the colour and giving greater depth and richness of tone. The paper is prepared to receive the drawing by being well sponged and stretched upon a drawing-board.

2. *Pigments.*—The permanent earthy minerals were chiefly used in ancient works, and these, with the addition of a few transparent colours, such as sepia, indigo, and Indian ink, satisfied the early water-colour painters of England. Richer and more delicate colours were gradually added, and of late years chemistry has supplied many entirely new ones. No method of giving permanency to some of the transparent yellows, carmine, and other colours obtained from the cochineal insect has yet been discovered, but the improved methods of preparing pigments from the root of the madder plant have rendered the use of carmine not so necessary. The earths and minerals are the most permanent pigments, but when employed with water they are more unmanageable, and flow less freely than the fugitive vegetable colours. Among the earlier water-colour,

painters the use of opaque or "body" colour was generally considered illegitimate. Turner was the first to break through this restraint, and since his time the use of opaque colour has been carried perhaps to excess, many modern artists wilfully resigning much of the peculiar freshness and brilliancy of pure water colour for the sake of rivalling the richness and depth of oil painting.

3. *Brushes*.—Brown sable is the hair generally used; but brushes are also made of red sable and squirrel or "camel" hair. The brushes are made by the insertion of the hair into quills, the various sizes of brush being recognized by the names of the birds which supply them—eagle, swan, goose, crow, &c. Flat brushes in German-silver ferules are also used.

Perhaps as great a variety of practice exists among water-colour painters as among those working in oils; each arrives at his own peculiar method by the teaching of experience. As in the case of oil painting, it would serve little purpose if the attempt was made to lay down rules and methods. All men cannot be painters, and a knowledge of the nature of the materials and of the processes employed does not necessarily carry with it ability to paint. Such essentials as a knowledge of composition, drawing, light and shade, and colour are all requisite, and these can only be obtained after years of study. If possible the guidance of some good master should be sought for at first; this will shorten the way and prevent the making of some awkward mistakes. (G. RE.)

PAINTING, HOUSE. See BUILDING, vol. iv. p. 510; and MURAL DECORATION.

PAISIELLO, or PAESIELLO, GIOVANNI (1741–1815), one of the most talented precursors of Rossini in the Italian school of musical composition, was born at Tarento, May 9, 1741. The beauty of his voice attracted so much attention that, in 1754, he was removed from the Jesuit college at Tarento to the Conservatorio di S. Onofrio at Naples, where he studied under Durante, and in process of time rose to the position of assistant master. For the theatre of the Conservatorio he wrote some intermezzi, one of which attracted so much notice that he was invited to write two operas, *La Pupilla* and *Il Mondo al Rovescio*, for Bologna, and a third, *Il Marchese di Tulipano*, for Rome. His reputation being now firmly established, he settled for some years at Naples, where, notwithstanding the popularity of Piccini, Cimarosa, and Guglielmi, of whose triumphs he was bitterly jealous, he produced a series of highly successful operas, one of which, *L'Idolo Cinese*, made a deep impression upon the Neapolitan public. In 1776 Paisiello was invited by the empress Catherine II. to St Petersburg, where he remained for eight years, producing, among other charming works, his masterpiece, *Il Barbiere di Siviglia*, which soon attained a European reputation. The fate of this delightful opera marks an epoch in the history of Italian art; for with it the gentle saavity cultivated by the masters of the 18th century died out to make room for the dazzling brilliancy of a later period. When, in 1816, Rossini set the same libretto to music, under the title of *Almaviva*, it was hissed from the stage; but it made its way, nevertheless, and under its true title, *Il Barbiere*, is now acknowledged as Rossini's greatest work, while Paisiello's opera is consigned to oblivion,—a strange instance of poetical vengeance, since Paisiello himself had many years previously endeavoured to eclipse the fame of Pergolesi by resetting the libretto of his famous intermezzo, *La serva padrona*.

Paisiello quitted Russia in 1784, and, after producing *Il Re Teodoro* at Vienna, entered the service of Ferdinand IV. at Naples, where he composed many of his best operas, including *Nina* and *La Molinara*. After many vicissitudes, resulting from political and dynastic changes, he

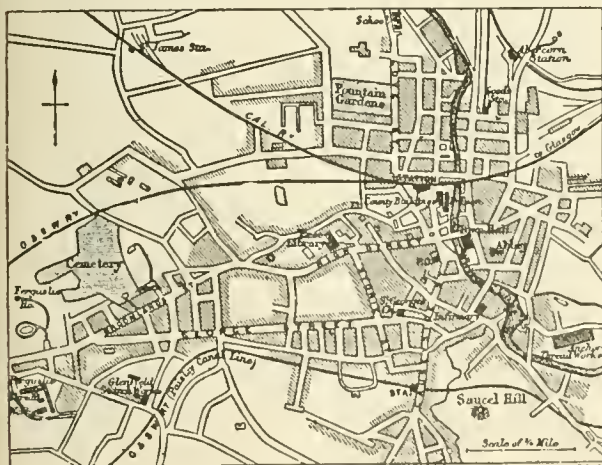

was invited to Paris (1802) by Napoleon, whose favour he had won five years previously by a march composed for the funeral of General Hoche. Napoleon treated him munificently, while cruelly neglecting two far greater composers, Cherubini and Méhul, to whom the new favourite transferred the hatred he had formerly borne to Cimarosa, Guglielmi, and Piccini. But he entirely failed to conciliate the Parisian public, who received his opera *Proserpine* so coldly that, in 1803, he requested and with some difficulty obtained permission to return to Italy, upon the plea of his wife's ill health.

On his arrival at Naples Paisiello was reinstated in his former appointments by Joseph Bonaparte and Murat, but he no longer enjoyed the brilliant reputation for the attainment of which he had so industriously laboured. He had taxed his genius beyond its strength, and was unable to meet the demands now made upon it for new ideas. His prospects, too, were precarious. The power of the Bonaparte family was tottering to its fall; and Paisiello's fortunes fell with it. The death of his wife, in 1815, tried him severely. His health failed rapidly. His constitutional jealousy of the popularity of others was a continual source of worry and vexation. And on June 5, 1815, he died, a disappointed man, notwithstanding his extraordinary successes and well-earned fame.

It is impossible to believe that even the best of Paisiello's operas would be listened to at the present moment with patience, yet they abound with melodies the graceful beauty of which is still warmly appreciated. Perhaps the best known of these charming airs is the famous *Nel cor più* from *La Molinara*, immortalized by Beethoven's delightful variations. The greatest sizers of the time spread the fame of this and other similar effusions throughout the length and breadth of Europe. The part of Nina conduced to one of Pasta's most splendid triumphs; and of the ninety-four operas which Paisiello is known to have composed not one can be said to have been unsuccessful. His church music was very voluminous, comprising one hundred and three masses, besides many smaller works; he also produced fifty-one instrumental compositions of more or less importance, and many detached pieces. MS. scores of many of his operas were presented to the library of the British Museum by the late Signor Dragonetti.

PAISLEY, a municipal and parliamentary burgh of Renfrewshire, Scotland, is situated on both sides of the White Cart, 3 miles from its junction with the Clyde, and on the Caledonian and the Glasgow and South-Western Railways, 7 miles west-south-west of Glasgow and 17 east-south-east of Greenock. In 1791 the river was at great expense made navigable to the town for sloops of about 50 tons burden. The old town, situated on rising ground on the west bank of the river, consists chiefly of long regular streets, and contains the principal warehouses and factories. The new town was begun towards the close of last century, and is built on level ground to the east, at one time forming the domains of the abbey. Surrounding the town there are extensive suburbs, occupied chiefly by villa residences. The river is crossed by a railway viaduct, and three bridges for carriage traffic, two of these being of iron and an old one of stone. The abbey of Paisley was founded in 1164, originally as a priory, by Walter, great steward of Scotland. Its lands were erected by James II. into a regality of which the abbot was lord, and the abbey formed the mausoleum of the Stuarts until their accession to the throne. The abbey was burned in 1307 by the English, and in 1561 by Lord Glencairn. In 1484 the grounds were surrounded by a lofty wall of hewn stone about one mile in circumference. In 1553 Claude Hamilton, a boy of ten, fourth son of the duke of Chatellerault, was made abbot *in commendam*, and in 1587 the lands

and abbey were made a temporal barony in his favour. His son was created earl of Abercorn. The abbey lands, after passing from the earl of Abercorn to the earl of Angus and thence to Lord Dundonald, were purchased in 1764 by the earl of Abercorn, with the view of making the abbey his residence, but changing his intention he let the grounds for building sites. The buildings inhabited by the monks have been totally demolished, but the nave of the abbey church is entire, and has been fitted up as a place of worship. It is one of the finest extant specimens of old ecclesiastical architecture in Scotland, and also contains several fine sculptures and monuments. The unroofed transept and the foundations of the choir enclose a burying ground. The chapel of St Mirin, forming part of the transept, and now used as the place of sepulture of the Abercorn family, contains a monument to Mary Bruce, mother of Robert II., which has been recently reconstructed. The principal secular buildings of the town are the county buildings and prison, erected in 1818 at a cost of £40,000, and afterwards extended; the John Neilson institution, opened in 1852, a handsome structure occupying a commanding position on the site of the old Roman camp; the George A. Clark town-hall, in the Gothic style, erected in 1882 at a cost of £50,000, and presented to

Plan of Paisley.

the town; the news-room, 1808; the grammar school, in the Gothic style, 1864; the Government school of art, 1847; and the theatre. The benevolent institutions include the infirmary, the town hospital or poorhouse, the philosophical institution and humane society, the workhouse, the lunatic asylum, and Hutcheson's charity school. The Duncan Wright educational endowment provides for natives of the town several school bursaries of the value of from £5 to £10, and several college bursaries of the value of £25. The town possesses three public recreation grounds:—the Fountain Gardens of 6 acres, presented by Mr Thomas Coats in 1868, and containing an elegant structure for a museum and library erected by Sir Peter Coats in 1870; the Brodie Park, 26 acres, laid out in 1877, and presented by the late Robert Brodie of Craigiehall; and St James's Park, formed out of the race-course, which has lately been acquired by the corporation. There are statues of Wilson the ornithologist and Tannahill the poet.

Linen was manufactured at Paisley before the Union, shortly after which coarse linen cloths were succeeded by plain and figured lawns. About the beginning of the 18th century an important manufacturing industry is said to have been originated by Christian Shaw, daughter of the laird of Bargarren. She acquired great skill in the

spinning of yarn, and, with the co-operation of a friend in Holland, originated the manufacture of fine linen thread. From 1760 till 1785 silk gauze was the principal manufacture. Muslin, cambric, and cotton thread next came into prominence. The shawl manufacture, introduced about the beginning of the present century, the specialty of which was imitation cashmere shawls—"Paisley filled plaids"—is now of minor importance. A wide range of worsted goods, mixed figured fabrics, and light figured muslins at present employ the looms. The spinning of thread and cotton is perhaps the industry for which the town is best known, although it is almost equally celebrated for its patent manufactures, including soap, starch, corn-flour, and preparations of coffee. There are also extensive bleachfields, large dye and print works, engineering works, and some shipbuilding. Since the beginning of the present century the population of the burgh (area 3520 acres) has more than trebled. In 1781 it was 11,000, which in 1791 had increased to 13,800, in 1801 to 17,026, in 1821 to 26,428, in 1831 to 31,460, in 1851 to 48,026, in 1871 to 48,257, and in 1881 to 55,642, of whom 25,832 were males and 29,810 females.

There is no doubt that on the ridge of high ground above the Cart there was a Roman fort and camp, and the supposition that Paisley was the Vanduara of the Romans is supported by the derivation of that name, which means white water. The modern village grew up round the abbey, but the origin of the name Paisley, which was first written *Paislet*, has been disputed. About the end of the 15th century its growth had excited the jealousy of the neighbouring burgh of Renfrew, to protect it from the molestations of which Abbot Schaw in 1488 obtained its erection into a free burgh of barony. According to this charter, granted by James IV., it obtained the privilege of returning a member to the Scottish parliament. By the Reform Act of 1832 it was created a parliamentary burgh with one representative. The burgh is governed by a provost, four bailies, a treasurer, and ten councillors. Among the eminent persons connected with Paisley are Patrick Adamson, archbishop of St Andrews; Tannahill the poet; Alexander Wilson the ornithologist; Watt, author of *Bibliotheca Britannica*; Motherwell the poet; and Professor John Wilson, "Christopher North."

PAJOU, AUGUSTIN (1730-1809), born at Paris on 19th September 1730, was a member of the Academy and a leading sculptor of the French school during the reigns of Louis XV. and Louis XVI. His portrait busts of Buffon and of Madame Du Barry, and his statuette of Bossuet (all in the Louvre), are amongst his best works. He died at Paris May 8, 1809.

PAKHOI, or PEIHAÏ, a city and port of China, in the west of the province of Kwang-tung, situated on a bay of the Gulf of Tong-king, formed by a peninsula running south-west from the *fu* city of Lien-chow, in 21° 30' N. lat. and 109° 10' E. long. Dating only from about 1820-30, and at first little better than a nest of pirates, Pakhoi rapidly grew into commercial importance, owing partly to the complete freedom which it enjoyed from taxation, and partly to the diversion of trade produced by the Tai-ping rebellion. The establishment of a Chinese custom-house, and the opening of the ports of Hankow and Haiphong, for a time threatened to injure its prospects; but, foreign trade being permitted in 1876-77, it began in 1879 to be regularly visited by foreign steamers. The average value of the open trade between 1880 and 1882 was £475,000 per annum, and a great deal of smuggling still takes place. Liquid indigo, sugar, aniseed and aniseed oil, cassia-lignea and cassia oil, cuttle-fish, and hides are the chief exports. With Macao especially an extensive junk trade is carried on £77,000 worth of

goods being despatched for Pakhoi in the course of a year. A large number of the inhabitants (who exceed 10,000 in all) are engaged in fishing and fish-curing.

PALACKY, FRANTIŠEK (FRANCIS) (1798-1876), the Bohemian historian, was born in the year 1798 in the village of Hodslavice, in the north-eastern corner of Moravia, where his father was a schoolmaster. His ancestors had, secretly, remained Protestants through all the persecutions of the 17th century, and only declared themselves as such on the publication of the edict of toleration by the emperor Joseph II. His mother's name was Anna Krizan; she died in the year 1822, before her son had gained his great reputation. His father, Jiri (George), died in 1836; besides Francis they had three other sons and three daughters. Concerning the early years of the future historian we are told that he was an indefatigable reader, eagerly devouring all books which came in his way. In 1812 Palacky entered the gymnasium of Pressburg; his original intention was to become a Protestant clergyman. The national movement then going on in the country aroused the enthusiasm of the youthful student, who was induced to apply himself to the study of his native tongue by the *Essay on the Bohemian Language* of Jungmann. While in Pressburg, Palacky assisted the publicist Palkovich in his journal, *Tydennik*, and first made his appearance as an author with a translation of some of the poems of Ossian (1817), then so popular throughout Europe. After this he was for some time private tutor in various families. In 1823 Palacky removed to Prague, and formed friendships with the leading Czech literati—Jungmann, Presl, Dobrovsky, Hanka, and others. Dobrovsky introduced him to Count Sternberg, and he was appointed editor of the new *Casopis Ceskeho Musea*, which is still published. In this occupation he continued till 1838. Count Caspar Sternberg and his brother were munificent patrons of the new Bohemian Museum, which had finally been founded after many efforts. The conduct of these men was the more remarkable that the Bohemian aristocracy had then become almost entirely Germanized.

In 1829 Palacky was appointed public historiographer by the Bohemian states, and made several lengthened tours to consult documents in public libraries at Munich, Berlin, Dresden, Rome, and elsewhere. He then commenced his *History of the Bohemian People*, which has earned him the undying gratitude of his countrymen. The first volume appeared in German in 1836, but the work was carried on in the Bohemian language from 1848, and was concluded with the year 1526, the period when Ferdinand I. ascended the throne and the political independence of the Czechs ceased. Besides this Palacky obtained a prize from the Bohemian Society of Arts for his work entitled *Würdigung der alten böhmischen Geschichtschreiber*. In the year 1840 he published, in conjunction with Schafarik, *Die ältesten Denkmäler der Böhmisches Sprache*. In this he appears as the champion of the early Bohemian manuscripts, the authenticity of which has been so much disputed, adopting among others the glosses in the *Mater Verborum* in the library at Prague, which have been proved to be forgeries. In the troubled year 1848 Palacky, a man of the student type, was forced into political life, but acquitted himself well. He refused to take a seat in the German parliament at Frankfort when invited to do so, on the ground that as a Czech he had nothing to do with German affairs. It was on this occasion that he uttered the memorable sentiment that so essential was Austria to the interests of Europe that, if such an empire had not existed, it would have been necessary to create one—words which were afterwards used by Jellachich as the device on his flag. Before his death, however, Palacky had changed his opinion, and despaired of any help coming from such a

source. Thus in a series of articles which he published in his old age under the title *Radhost*, he tells us—"I have thought all my life that the right would prevail, and my mistake has been in believing in the good sense and spirit of justice of the German people."

So great was the influence of Palacky at this period that he was offered a portfolio in the ministry of Pillersdorf; but in a short time the confidence placed in him by the Austrian Government was withdrawn, and he was regarded with suspicion. He soon, however, quitted politics and betook himself to his literary labours. His influence among his countrymen was now at its height. In 1860 he had the misfortune to lose his wife, whom he had married in 1827. In 1861 he was made a life member of the Austrian senate. He died in 1876, busy with literature to the end.

The great work of Palacky, his *History of the Bohemian People*, is indeed a monument of conscientious labour. His love of truth and marvellous accuracy are conspicuous on every page. To enable the Bohemians to resist the insidious attempts at their denationalization which had been steadily pursued by their enemies during the 17th and 18th centuries, it was necessary to bring before them the great past which they had been taught to forget. This Palacky has done, and his work has become a national monument. The occupation of the last years of his life was the rewriting of some of the chapters, which had seemed to him imperfectly executed, owing to the want of original documents or the censorship of the Austrian Government. In 1845 the first part of his third volume appeared, dealing with the life and religious opinions of Huss. As the work was published, it had already undergone serious mutilation at the hands of the appointed censors, but the Bohemians saw the history of Huss presented to them in its true colours; and so great was the sensation created that a Roman Catholic publicist named Helfert was commissioned to write an account of Huss and Jerome, his disciple, with the view of counteracting the effects of Palacky's work. This book duly appeared at Prague in 1857. Palacky, however, must be considered to have triumphed in the controversy. He published two other polemical works on the same subject in German: in 1868 appeared *Die Geschichte des Hussitentums und Prof. C. Höfler*, and in 1871 another work entitled *Zur Böhmisches Geschichtschreibung*. Besides the interesting portion of his work dealing with Huss and the subsequent Hussite wars, Palacky appears to great advantage when dwelling upon the most prosperous periods of Bohemian nationality, as the reigns of Charles IV. and George Poděbrad. No pains were spared by him in his researches. Dr Kalousek tells us in his interesting memoir that, when he visited Rome in 1837 to consult the library of the Vatican, he read through 45,000 documents in ten weeks and copied 400 of them with his own hand. The work is a monument of erudition; but it may perhaps be said to be written in a somewhat dry and frigid style. It has become familiar to general readers in a German translation. Palacky also founded an historical school in Bohemia, foremost among his pupils being Vaclav Tomek and Antonin Gindely.

PALADIN (Lat., *palatinus*) literally means a courtier, a member of a royal household, one connected with a palace. The *palatium* of the Roman emperors on the Palatine Hill supplied a name for all the royal and imperial residences in mediæval Europe, and a corresponding adjective and noun for royal officials and dependants. From being applied to the famous twelve peers of Charlemagne, the word paladin became a general term in romance for knights of great prowess.

PALÆICHTHYES. See ICHTHYOLOGY, vol. xii. p. 685.

PALÆOGRAPHY

PALÆOGRAPHY is the study of ancient handwriting from surviving examples. While epigraphy (see INSCRIPTIONS) is the science which deals with inscriptions engraved on stone or metal or other enduring material as memorials for future ages, palæography takes cognizance of writings of a literary, economical, or legal nature, written generally with stile, reed, or pen, on tablets, rolls, or books. The boundary, however, between the two sciences is not always to be exactly defined. The fact that an inscription occurs upon a hard material in a fixed position does not necessarily bring it under the head of epigraphy. Such specimens of writing as the graffiti or wall-scribblings of Pompeii and ancient Rome belong as much to the one science as to the other; for they neither occupy the position of inscriptions set up with special design as epigraphical monuments, nor are they the movable written documents with which we connect the idea of palæography. But such exceptions only slightly affect the broad distinction just specified.

The scope of this article is to trace the history of Greek and Latin palæography from the earliest written documents in those languages which have survived. In Greek palæography we have a subject which is self-contained. The Greek character, in its pure form, was used for one language only; but the universal study of that language throughout Europe, and the wide diffusion of its literature, have been the cause of the accumulation of Greek MSS. in every centre of learning. The field of Latin palæography is much wider, for the Roman alphabet has made its way into every country of western Europe, and the study of its various developments and changes is essential for a proper understanding of the character which we write.

Handwriting, like every other art, has its different phases of growth, perfection, and decay. A particular form of writing is gradually developed, then takes a finished or calligraphic style and becomes the hand of its period, then deteriorates, breaks up, and disappears, or only drags on an artificial existence, being meanwhile superseded by another style which, either developed from the older hand or introduced independently, runs the same course, and, in its turn, is displaced by a younger rival. Thus in the history of Greek writing we see the uncial hand passing from early forms into the calligraphic stage, and then driven out by the minuscule, which again goes through a series of important changes. In Latin, the capital and uncial hands give place to the smaller character; and this, after running its course, deteriorates and is superseded almost universally by the modern Italian hand dating from the Renaissance.

Bearing in mind these natural changes, it is evident that a style of writing, once developed, is best at the period when it is in general use, and that the oldest examples of that period are the simplest, in which vigour and naturalness of handwriting are predominant. On the other hand, the fine execution of a MS. after the best period of the style has passed cannot conceal deterioration. The imitative nature of the calligraphy is detected both by the general impression on the eye and by uncertainty and inconsistencies in the forms of letters. It is from a failure to keep in mind the natural laws of development and change that early dates, to which they have no title, have been given to imitative MSS.; and on the other hand, even very ancient examples have been post-dated in an incredible manner.

Down to the time of the introduction of printing,

writing ran in two lines—the set book-hand and the cursive. MSS. written in the set book-hand filled the place now occupied by printed books, the writing being regular, the lines kept even by ruling, and the pages provided with regular margins. Cursive writing, in which the letters employed were fundamentally the same as in the set hand, was necessary for the ordinary business of life. The set book-hand disappeared before the printing press; cursive writing necessarily remains.

Materials.—Before passing to the discussion of Greek and Latin handwriting, the materials employed and the forms which they took may be briefly noticed. The various works on palæography enumerate the different substances which have been put in requisition, to receive writing. Metals, such as gold, bronze, lead, tin, have been used; leaden plates, for example, in addition to those which have been found buried with the dead and bearing inscriptions of various kinds, were also used in the Venetian states down to the 14th or 15th century as a material on which to inscribe historical and diplomatic records. The ancient Assyrians recorded their history on sun-dried or fire-burnt bricks; and inscribed potsherds or *ostraka* have been gathered in hundreds in the sands of Egypt. Such hard materials as these, however, would have no extensive use where more pliant and convenient substances, such as animal skin or vegetable growths, could be had. We have therefore practically to confine our attention to such materials as papyrus, vellum, and paper, the use of which became so universally established. But midway between the hard and soft substances, and partaking of the nature of both, stand the waxen tablets made of wood coated with wax, on which the writing was scratched with the point of the *stilus* or *graphium*. These tablets were called by the Greeks *δέλτος*, *δελτίον* or *δελτίδιον*, *πυκτίον* or *πυκτίον*, *πίναξ*, *πινακίς*, &c., and in Latin *tabulæ* or *tabellæ*, or *ceræ*; and two or more, put together and connected with rings or other fastenings which served as hinges, formed a *caudex* or *codex*. A *codex* of two leaves was called *δίθυροι* or *δίπτυχα*, *diptycha*; of three, *τρίπτυχα*, *triptycha*; and so on. From the early specimens which have survived, and which will be examined below, the *triptycha* appear to have been most commonly used. The tablets served for the ordinary affairs of life, for accounts, letters, drafts, school exercises, &c. The various references to them by classical writers need not be here repeated; but their survival to a late time should be noted. St Augustine refers to his tablets, and St Hilary of Arles also mentions their use for the purpose of correspondence; and there remains the record of a letter written in *tabellæ* as late as 1148 A.D. (Wattenbach, *Schriftwesen*, 2d ed., p. 46). They were very commonly used through the Middle Ages in all the west of Europe. Specimens inscribed with money accounts of the 13th and 14th centuries have survived in France; and similar documents of the 14th and 15th centuries are to be found in several of the municipal archives of Germany. Reference to their use in England occurs in literature; and specimens of the 14th or 15th century have been dug up in Ireland. Similarly in Italy their use is both recorded and proved by actual examples of the 13th or 14th century. With the beginning of the 16th century their general employment seems to have come to an end; but a few survivals of this custom of writing on wax have lingered on to modern times. It is said that sales in the fish-market of Rouen are still noted down on this material.

Among the Romans ivory was sometimes substituted for wood in the waxen tablets, as appears from passages in classical authors. The large consular diptychs are examples of the custom. The rich carvings with which these were embellished have secured their preservation in several instances; and they were often kept in the churches in the Middle Ages and inscribed with lists of bishops or abbots and benefactors.

The employment of PAPYRUS (*q.v.*) as an ordinary writing material in ancient Egypt, and, exported from thence, in Greece and Italy, is well known. The most ancient examples of Greek writing which will have to engage our attention are those which are found in the papyrus rolls of Egypt of the 2d century B.C. Though superseded in course of time by vellum, this material continued to be used by Greek scribes down to the 9th century. The earliest Latin writing on papyrus is contained in some fragments recovered at Herculaneum. Dating from the 5th to the 10th century are the papyrus deeds of Ravenna; and papal documents on the same substance extend from the 8th to the 11th century. Papyrus was also used for documents in France under the Merovingian kings. It was also made up into books, for the reception of literary works, in which form it was sometimes strengthened by the addition of vellum leaves which encased the quires; and, as far as can be ascertained from extant remains, it was used thus in Italy and France down to the 10th century.

Skins of animals have doubtless served as a writing material from the very earliest period of the use of letters. Instances of the use of leather in western Asia are recorded by ancient writers; and from Herodotus we learn that the Ionians applied to the later-imported papyrus the name *διφθέραι*, by which they already designated their writing material of leather. The Jews also have retained the ancient Eastern custom, and still inscribe the law upon leathern rolls. The use of parchment (*περγαμηνή*, *charta pergamena*) may be considered a revival of the ancient use of skins, now prepared by a new method attributed to Eumenes II., king of Pergamum (197–158 B.C.), who was opposed by the jealousy of the Ptolemies in his endeavours to establish a library in his capital. They forbade the export of papyrus, and so compelled him to revert to the ancient custom. The new material was prepared in such a way as to be fit to receive writing on both sides, and could thus be conveniently made up into book-form, the *σωμάτιον*. The ancient name *διφθέραι* (Lat., *membranæ*) was also transferred to the new invention. By common consent the name of parchment has in modern times given place to that of vellum, a term properly applicable only to calf-skin, but now generally used to describe a mediæval skin-book of any kind. Parchment is a title now usually reserved for the hard sheep-skin or other skin material on which law-deeds are engrossed.

Purple-stained vellum was used by the Romans for wrappers for their papyrus rolls. In the 3d century it is recorded that entire volumes were made of this ornamental substance and written in gold or silver; and it was against luxury of this kind that St Jerome directed his often-quoted words in his preface to the book of Job. Examples of such costly MSS. of the 6th century have survived to the present day, as the Codex Argenteus of the Gothic Gospels at Upsala, the fragments of the illustrated Genesis at Vienna, the leaves of the purple Gospels in the Cottonian Library and elsewhere, the Codex Rossanensis, lately discovered, and some others. Some richly stained leaves of the 8th century remain in the Canterbury Gospels (Royal MS., 1 E. vi.) in the British Museum. On the Continent the great impetus given to the production of

splendid MSS. under the rule of Charlemagne revived the art of staining; and several fine examples of it exist in MSS. of the 8th, 9th, and 10th centuries. At a later period, when the art was forgotten, the surface only of the vellum was painted in imitation of the older staining which soaked into the substance of the skin. Other colours besides purple were sometimes employed, particularly in the period of the Renaissance, to paint or stain vellum; but MSS. so treated are rather to be regarded as curiosities produced by the caprice of the moment.

Cotton paper (*charta bombycina*) is said to have been known to the Chinese at a remote period, and to have passed into use among the Arabs early in the 8th century. It was imported into Constantinople, and was used for Greek MSS. in the 13th century. In Italy and the West it never made much way. Rag paper came into general use in Europe in the 14th century, and gradually displaced vellum. In the 15th century MSS. of vellum and paper mixed were common. See PAPER.

With regard to the forms in which writing material was made up, the waxen tablets have already been referred to, and will be more minutely described below. Ancient papyri usually appear in the form of rolls; vellum was made up into books. The roll (*κύλινδρος*, *volumen*; later, *εὐλητάριον*, *εὐλητόν*, *ἐξεὐλημα*, *rotulus*) was the ordinary form of written documents known to the ancients. When a work was contained in several rolls, a single roll was called *βιβλος*, *βιβλίον*, *volumen*, *charta*; later, *τόμος*. From the circumstance of the Bible filling many rolls it acquired such titles as *pandectes* and *bibliotheca*, the latter of which remained in use down to the 14th century. The title of the work was written at the end of the roll; and at the same place was recorded the number of columns and lines, *στίχοι*, which it contained—probably for the purpose of estimating the price. To roll and unroll was *εἰλεῖν* and *ἐξεἰλεῖν*, *plicare* and *explicare*; the work unrolled and read to the end was the *liber explicitus*. Hence comes the common *explicit* written at the end of a work; and, from the analogy of *incipit liber* in titles, the word was afterwards taken for a verb, and appears in such phrases as *explicit liber*, *explicit*, *explicet*, &c.

The book-form was adopted from the waxen tablets, and the name *caudex* or *codex* was also taken over. It has been inferred, from the terms in which Martial speaks of vellum books, that they were articles of luxury at Rome, and, although no examples have survived from classical times, and none were found in the ruins of Herculaneum, the sumptuousness of the earliest extant volumes supports this view. The shape in which they are made up during the early centuries of the Middle Ages is the broad quarto.

The quires or gatherings of which the book was formed generally consisted, in the earliest examples, of four sheets folded to make eight leaves (*τετράς* or *τετράδιον*, *quaternio*), although occasionally quinterns, or quires of five sheets (ten leaves), were adopted. Sexterns, or quires of six sheets (twelve leaves), came into use at a later period. The quire-mark, or "signature," was usually written at the foot of the last page, but in some early instances (*e.g.*, the Codex Alexandrinus) it appears at the head of the first page. The numbering of the separate leaves in a quire, in the fashion followed by early printers, came in in the 14th century. Catch-words to connect the quires date back to the 12th century.

No exact system was followed in ruling the lines and in arranging the sheets when ruled. In the case of papyri it was enough to mark with the pencil the vertical marginal lines to bound the text; the grain of the papyrus was a sufficient guide for the lines of writing. With the firmer material of vellum it became necessary to rule lines to keep the writing even. These lines were at first drawn

with a hard point, almost invariably on the hair (or outer) side of the skin, and strongly enough to be in relief on the flesh (or inner) side. Marginal lines were drawn to bound the text laterally; but the ruled lines which guided the writing were not infrequently drawn right across the sheet. Each sheet should be ruled separately; but two or more sheets were often laid and ruled together, the lines being drawn with so much force that the lower sheets also received the impressions. In rare instances lines are found ruled on both sides of the leaf, as in some parts of the Codex Alexandrinus. In this same MS. and in other early codices the ruling was not always drawn for every line of writing, but was occasionally spaced so that the writing ran between the ruled lines as well as on them. In making up the quires, care was generally taken to lay the sheets in such a way that hair-side faced hair-side, and flesh-side faced flesh-side; so that, when the book was opened, the two pages before the reader had the same appearance, either the yellow tinge of the hair-side, or the fresh whiteness of the flesh-side. In Greek MSS. the arrangement of the sheets was afterwards reduced to a system: the first sheet was laid with the flesh-side downwards, so that that side began the quire; yet in so early an example as the Codex Alexandrinus the first page of a quire is the hair-side. In Latin MSS. also the hair-side appears generally to have formed the first page. Ruling with the plummet or lead-point came into ordinary use in the 12th century; red and violet inks were used for ornamental ruling in the 15th century. The lines were evenly spaced by means of prickings in the margins; in some early MSS. these prickings run down the middle of the page.

Inks of various colours were employed from early times. Red is found in initial lines, titles, and colophons in the earliest vellum MSS. For purposes of contrast it was also used in glosses, as in the Lindisfarne Gospels and in the Durham Ritual. In the Carolingian period entire volumes were occasionally written with this ink. Other coloured inks—green, violet, and yellow—are also found at an early date. Writing in gold and silver was inscribed on purple vellum in ancient MSS., as has been noted above; under Charlemagne it again came into fashion. Gold was then applied to the writing of ordinary vellum MSS. It was also introduced into English MSS. in the 10th century.

With regard to writing implements, it will be here enough to note that for writing on waxen tablets the pointed *stilus* or *graphium* was used; that the reed (*καλαμος*, *calamus* or *canna*) was adapted for both papyrus and vellum, and that in Italy at least it appears to have been used as late as the 15th century; and that the quill pen can be traced back to the 6th century of our era.

GREEK WRITING.

The period which has to be traversed in following the history of Greek palæography begins with the 2d century B.C. and ends at the close of the 15th century. For all this long period the subject is illustrated by a fair amount of material, more or less connected in chronological sequence. Greek writing in MSS., as far as we know it from extant remains, passed through two courses,—that of the uncial or large letter, and that of the minuscule or small letter. The period of the uncial runs from the date of the earliest specimens on papyrus to the 9th century, that of the minuscule from the 9th century to the invention of printing. An established form of writing, however, cannot, any more than any other human habit, be suddenly abandoned for a new one; and we are therefore prepared to find the uncial character continue to be used after the first introduction of the smaller hand. It did in fact sur-

vive for special purposes for some three centuries after it had ceased to be the common form of book-writing. Inversely, no fully developed handwriting suddenly springs into existence; and we therefore look for the first beginnings of the minuscule hand in documents of far higher antiquity than those of the 9th century.

Uncial.—The term uncial has been borrowed from the nomenclature of Latin palæography¹ and applied to Greek writing of the larger type to distinguish it from the minuscule or smaller character. In Latin majuscule writing there exist both capitals and uncials, each class distinct. In Greek MSS. pure capital letter-writing was never employed (except occasionally for ornamental titles at a late time). As distinguished from the square capitals of inscriptions, the uncial writing has certain rounded letters as ε, Ϸ, ω, modifications in others, and some extending above or below the line.

Uncial Greek writing in early times is found in two forms,—the set and the cursive. In examining the set or, as it may be termed, the literary hand, we find that regard must be had to the material on which it was written. For the material has always had more or less influence on the character of the writing. To the substitution of a soft surface for a hard one, of the pen for the graving tool, we undoubtedly owe the rounded forms of the uncial letters. The square-formed capitals were more easily cut on stone or metal; the round letters more readily traced on skin or wax or papyrus with stile, reed, or pen. Again, the earliest specimens of Greek uncials are found on papyrus, and this delicate and brittle material naturally required a light style of penmanship. When the firmer material of vellum came into use, there followed a change in the style of writing, which assumed the calligraphic form, which will be considered in its place.

The earliest examples of Greek uncial writing are on papyrus, and have been discovered in Egypt and in the ruins of Herculaneum. When we turn to the literary remains with the view of following the course of the set hand, a difficulty arises at the outset; for in some of the most ancient specimens (and notably the Εἰδόξου τεχνῆ referred to below) there is a fluctuation between set and cursive writing which makes it no easy matter to decide how they should be classed. In the same way, when we come to consider the first examples of cursive hand, we shall find much in them which might be termed a set cast of writing. In fact, in the period when these ancient examples were produced, the formal and cursive styles were not so distinctive as they afterwards became. For our present purpose we may class the literary works in this doubtful style of writing under the book-hand, and place the documents among the specimens of cursive.

With regard to the different dates to be assigned to these early relics, those which have been recovered from Herculaneum have a limit, after which they cannot have been written, in the year of the destruction of the city, 79 A.D. But how far before that date they may be set it is hazardous to conjecture, although the greater number probably fall within the 1st century of our era. In the case of most of the Egyptian papyri there is no such limit either way. In some instances, however, literary remains have been found in company with deeds bearing an actual date, and in two of them the documents are written on the backs of the literary papyri. The work on astronomy entitled Εἰδόξου τεχνῆ, among the papyri of the Louvre. (*N. et Extr.*, pls. i.-x.),² is endorsed with deeds of 165 and

¹ St Jerome's often-quoted words, "uncialibus, ut vulgo aiunt, litteris," in his preface to the book of Job, have never been explained. If the character referred to as "uncial" there is no doubt, but the derivation of the term is unknown.

² *Notices et Extraits des Manuscrits*, vol. xviii., Paris, 1865.

164 B.C., and may consequently be at least as old as the first half of the 2d century B.C. The writing of the text of this MS., as has been already noticed, is of a rather cursive character. But the fragments of a work on dialectics in the same collection (*N. et Extr.*, pl. xi.), which is endorsed with a deed of 160 B.C., is written in set uncials of a perfectly simple style, formed with fine and even strokes. The columns of writing lean out of the perpendicular, to the right, a peculiarity which is seen again in the orations of Hyperides (below). So far as one may venture to take this specimen as a standard whereby to judge of the age of others, a simple and fine and light stroke, without exaggeration of forms in the letters, and unrestraint in the flow of the writing seem to be the chief characteristics of this class of hand in the centuries immediately preceding the Christian era. And these characteristics are generally to be observed in all documents which there is reason to assign to this period.

Not inconsiderable fragments of the *Iliad* dating from the pre-Christian period have also come down to us. First in importance stands the fragmentary papyrus of bk. xviii., found in a tomb near Monfalat in 1849-50. It may be confidently dated as early as the 1st century B.C. The text is written in slender uncials, formed with regularity and generally upright, the inclination, if any, being to the left. This tendency to incline the letters back is a mark of age which repeats itself in the earliest forms of the set minuscule hand. Breathings and accents and various corrections have been added by a later hand in this papyrus, which is now in the British Museum (*Cat. Anc. MSS.*, i. pl. 1.).¹ Another papyrus of a portion of the *Iliad*, on the back of which is a work of Tryphon, the grammarian, was found at the same time, but remains in private hands. Among the papyri of the Louvre are also some fragments of the *Iliad*, viz., of bk. xiii. (*N. et Extr.*, pl. xii.) and of bks. vi. and xviii. (pl. xlix.), all of a date previous to the Christian era. The fragment of bk. vi. is of particular interest as being written in a hand which is much more set and formal than is generally found in papyri, in rather narrowed letters, among which the normal form of capital A appears. In the other fragments are seen here and there accents and breathings which from all accounts are ancient, although not to be taken as the work of the first hand. Not being applied systematically, they are probably added by some teacher for instruction on particular points. But the Homeric papyrus which has hitherto had the widest reputation is that which bears the name of its former owner, Banks, who bought it at Elephantine in 1821. It contains the greater part of the last book of the *Iliad*. The writing, however, differs very essentially from that of the other Homeric fragments just noticed. It is less free, and wants the spirit and precision of the others, and in the form of letters it approaches more nearly to the east of those in the early MSS. on vellum. For these reasons it seems better to date this papyrus after the time of our Lord, perhaps even in the 2d century.

A fragment of papyrus containing a copy in duplicate of some lines supposed to be taken from the *Temenides* of Euripides, together with a few lines from the *Medea* and some extracts from other works, has been lately published (H. Weil, *Un Papyrus inédit de la bibl. de M. A. Firmin-Didot*, Paris, 1879). The writing is in set uncials earlier than the year 161 B.C., a document of that date having been added.

But the most important discovery hitherto made among the papyri from Egypt is that of four of the orations of the Athenian orator Hyperides, all of which are now in the British Museum. The papyrus containing the orations

for Lycophron and Euxenippus is in unusually good preservation, being 11 feet in length and having forty-nine columns of writing. Other portions of the same roll are extant, containing fragments of a third oration against Demosthenes. The writing is particularly elegant, and is evidently by a skilled penman, considerable play being exhibited in the formation of the letters, which, while still set uncials, are often linked together without raising the pen. The columns of writing incline to the right. There can be no hesitation in placing this papyrus as far back at least as the 1st century B.C. (see editions of Professor Babington, 1853; *Cat. Anc. MSS.*, pls. 2, 3; *Pal. Soc.*,² pl. 126). Of much later date, however, is the papyrus containing the funeral oration on Leosthenes, 323 B.C. The writing differs entirely from that of the other orations, being in coarsely-formed uncials, sometimes wide apart and in other places cramped together; and the forms of the letters are irregular. This irregularity is not the rough and hasty character of writing of an early age, such as that of the Εὐδόξου τεχνή, where, in spite of the want of regularity, it is evident that the scribe is writing a natural and practised hand. Here we have rather the ill-formed character bred of want of skill and familiarity with the style of writing. On the back is a horoscope, which has been shown to be that of a person born in 95 A.D. It was at one time assumed that this was an addition written after the oration had been inscribed on the other face of the papyrus. But from the evidence of the material itself the contrary appears to be the fact; and we may accordingly accept the theory that, as no work intended for sale would have been so written, the text of the oration probably represents a student's exercise,—a view which is also supported by the numerous faults in orthography. This specimen of writing, then, may be assigned to the 2d century of our era.

Lastly, among the discoveries in Egypt in Greek literature is the fragment of writings of the poet Alcman, now in the Louvre, which, however, appears to be not older than the 1st century B.C., the hand being light and rather sloping, and inclining in places to cursive forms. It is of interest as having scholia in a smaller hand, and a few accents and breathings added probably, as in the case of the fragment of Homer quoted above, by a teacher for the purpose of demonstration (*N. et Extr.*, pl. 1). It may be also added that some early documents are extant written in a set hand (e.g., *N. et Extr.*, pl. xvii., Nos. 12, 13).

Turning to the remains discovered at Herculaneum, it is to be regretted that there exist hardly any sufficiently trustworthy facsimiles. The so-called facsimiles engraved in the *Herculaneusia Volumina* are of no palaeographical value. They are mere lifeless representations, and only show us that the texts of the different papyri are usually written in neatly-formed and regularly-spaced uncials. The character is better shown in two autotypes (*Pal. Soc.*, pls. 151, 152) from the works of Philodemus and Metrodorus, although the blackening of the material by the action of the heated ashes threw great difficulty in the way of getting satisfactory reproductions by photography. In the first of these specimens the writing is very beautifully formed and evenly spaced, in the second it is rougher. But it is well to remember, when we have facsimiles from the Herculaneum papyri before us, that in many cases the material will have shrunk under the heat of the destroying shower, and that the writing, as we see it, may be much smaller than it was originally, and so have a more delicate appearance than when first written.

Very few waxen tablets inscribed with Greek uncial writing have survived. Two of them found at Memphis are preserved in the British Museum, and on one of them

¹ *Catalogue of Ancient MSS. in the British Museum—Part I., Greek*, 1881.

² *Palaeographical Society, Facsimiles*, 1873-83.

are traced some verses in large roughly-formed letters, the date of which can only be conjectured to fall in the 1st century (*Verhandl. d. Philologen-Versamml. zu Würzburg*, 1869, p. 244). Another set of five tablets is in the Cabinet des Médailles at Paris, containing scribbled alphabets, and a contractor's accounts in a later and more current hand (*Rev. Archéol.*, viii. p. 461). A tablet from which the wax has worn, and which is inscribed with ink upon the wood, in characters of the 4th century, as is thought, is described in *Trans. Roy. Soc. Lit.*, 2d ser., vol. x.

With the introduction of vellum as a writing material, the uncial characters entered on a new phase. As already observed, the firmer and smoother ground offered by the surface of the vellum to the pen of the scribe would lead to a more exact and firmer style in the writing. The light touch and delicate forms so characteristic of calligraphy on papyrus gave place to a rounder and stronger hand, in which the contrast of fine hair-lines and thickened down-strokes adds so conspicuously to the beauty of the writing of early MSS. on vellum. Of such MSS., however, none have survived which are attributed to a higher antiquity than the 4th century. And here it may be remarked, with respect to the attribution to particular periods of these early examples, that we are not altogether on firm ground. Internal evidence, such, for example, as the presence of the Eusebian Canons in a MS. of the Gospel, assists us in fixing a limit of age, but when there is no such support the dating of these early MSS. must be more or less conjectural. It is not till the beginning of the 6th century that we meet with a MS. which can be approximately dated; and, taking this as a standard of comparison, we are enabled to distinguish those which undoubtedly have the appearance of greater age and to arrange them in some sort of chronological order. But these codices are too few in number to afford material in sufficient quantity for training the eye by familiarity with a variety of hands of any one period—the only method which can give entirely trustworthy results.

The earliest examples of vellum uncial MSS. are the three famous codices of the Bible. Of these, the most ancient, the Codex Vaticanus, is probably of the 4th century. The writing must, in its original condition, have been very perfect as a specimen of penmanship; but nearly the whole of the text has been traced over by a later hand, perhaps in the 10th or 11th century, and only such words or letters as were rejected as readings have been left untouched. Written in triple columns, in letters of uniform size, without enlarged initial letters to mark even the beginnings of books, the MS. has all the simplicity of extreme antiquity (*Pal. Soc.*, pl. 104). The Codex Sinaiticus (*Pal. Soc.*, pl. 105) has also the same marks of age, and is judged by its discoverer, Tischendorf, to be even more ancient than the Vatican MS. In this, however, a comparison of the writing of the two MSS. leads to the conclusion that he was wrong. The writing of the Codex Sinaiticus is not so pure as that of the other MS., and, if that is a criterion of age, the Vatican MS. holds the first place. In one particular the Codex Sinaiticus has been thought to approach in form to its possible archetype on papyrus. It is written with four columns to a page, the open book thus presenting eight columns in sequence, and recalling the long line of columns on an unfolded roll. The Codex Alexandrinus is placed in the middle of the 5th century. Here we have an advance on the style of the other two codices. The MS. is written in double columns only, and enlarged letters stand at the beginning of paragraphs. But yet the writing is generally more elegant than that of the Codex Sinaiticus. Examining these MSS. with a view to ascer-

tain the rules which guided the scribes in their work, we find simplicity and regularity the leading features; the round letters formed in symmetrical curves; ε and C, &c., finishing off in a hair-line sometimes thickened at the end into a dot; horizontal strokes fine, those of ε, Η, and Ο being either in the middle or high in the letter; the base of Δ and the cross-stroke of Π also fine, and, as a rule, kept within the limits of the letters and not projecting beyond. Here also may be noticed the occurrence in the Codex Alexandrinus of Coptic forms of letters (*e.g.*, Δ, Ι, alpha and mu) in the titles of books, &c., confirmatory of the tradition of the Egyptian origin of the MS.

ΤΕΚΝΩΝ ΣΟΥ ΠΕΡΙΠΑΤΟΥΝ
ΤΑΣ ΕΝ ΑΛΗΘΕΙΑ ΚΑΘΩΣ ΕΥΤΟ
ΛΗΝ ΕΛΑΒΟΜΕΝ ΑΠΟ ΤΟΥ Π[ΑΤ]Ρ[ΟΣ]. — 2 John 4.)

Greek Uncial (Cod. Alex.), 5th century.

(ΤΕΚΝΩΝ ΣΟΥ ΠΕΡΙΠΑΤΟΥΝ
ΤΑΣ ΕΝ ΑΛΗΘΕΙΑ ΚΑΘΩΣ ΕΥΤΟ
ΛΗΝ ΕΛΑΒΟΜΕΝ ΑΠΟ ΤΟΥ Π[ΑΤ]Ρ[ΟΣ]. — 2 John 4.)

In the 5th century also falls the illustrated Homer of the Ambrosian Library, sadly mutilated. Some fifty fragments remain, cut out for the sake of the pictures which they contain; and all the text that is preserved is that which happened to be on the backs of these pictures. Here the writing shows differences from that of the three codices just noticed, being taller; and, to instance particular letters, the cross-stroke of ε is abnormally low down, and the shape of Α and Ρ (the latter not produced below the line) and the large bows of Β are also points of difference. It has been suggested that the MS. was written in the south of Italy by a Latin scribe (*Pal. Soc.*, pls. 39, 40, 50, 51).

To the 5th century may also belong the palimpsest MS. of the Bible, known from the upper text as the Codex Ephraemi, at Paris (ed. Tischendorf, 1845), and the Octateuch, whose extant leaves are divided between Paris, Leyden, and St Petersburg—both of which MSS. are probably of Egyptian origin. Of the end of the 5th or beginning of the 6th century is the illustrated Genesis of the Cottonian Library, now unfortunately reduced to fragments by fire, but once the finest example of its kind (*Cat. Anc. MSS.*, i. pl. 8). And to about the same time belong the Dio Cassius of the Vatican (Silvestre, pl. 60) and the Pentateuch of the Bibliothèque Nationale (Id., pl. 61).

In the writing of uncial MSS. of the 6th century there is a marked degeneration. The letters, though still round, are generally of a larger character, more heavily formed, and not so compactly written as in the preceding century. Horizontal strokes (*e.g.*, in Δ, Η, Τ) are lengthened and finished off with heavy points or finials. The earliest example of this period which has to be noticed is the Dioscorides of Vienna, which is of particular value for the study of the palæography of early vellum MSS. It is the earliest example to which an approximate date can be given. There is good evidence to show that it was written early in the 6th century for Juliana Anicia, daughter of Flavius Anicius Olybrius, emperor of the West in 472. Here we already notice the characteristics of uncial writing of the 6th century, to which reference has been made. To this century also belong the palimpsest Homer under a Syriac text, in the British Museum (*Cat. Anc. MSS.*, i. pl. 9); its companion volume, used by the same Syrian scribe, in which are fragments of St Luke's Gospel (*Ibid.*, pl. 10); the Dublin palimpsest fragments of St Matthew and Isaiah (T. K. Abbot, *Par Palimpsest. Dubl.*), written in Egypt; the fragments of the Pauline epistles from Mount Athos, some of which are at Paris and others at Moscow (Silvestre.

pls. 63, 64; Sabas, pl. A), of which, however, the writing has been disfigured by retracing at a later period; the Gospels written in silver and gold on purple vellum, whose leaves are scattered in London (Cott. MS., Titus C. xv.), Rome, Vienna, and its native home, Patmos; the fragmentary Eusebian Canons written on gilt vellum and highly ornamented, the sole remains of some sumptuous volume (*Cat. Anc. MSS.*, i. pl. 11); the Coislin Octateuch (Silvestre, pl. 65); the Genesis of Vienna, one of the very few early illustrated MSS. which have survived (*Pal. Soc.*, pl. 178). Tischendorf has given facsimiles of others, but too-insufficiently for the critical study of palæography.

Reference may here be made to certain early bilingual Græco-Latin uncial MSS., written in the 6th and 7th centuries, which, however, have rather to be studied apart, or in connexion with Latin palæography; for the Greek letters of these MSS. run more or less upon the lines of the Latin forms. The best-known of these examples are the Codex Bezae of the New Testament, at Cambridge (*Pal. Soc.*, pls. 14, 15), and the Codex Claromontanus of the Pauline epistles, at Paris (*Pal. Soc.*, pls. 63, 64), attributed to the 6th century; and the Laudian MS. of the Acts of the Apostles (*Pal. Soc.*, pl. 80) of the 7th century. To these may be added the Harleian glossary (*Cat. Anc. MSS.*, i. pl. 13), also of the 7th century.

An offshoot of early Greek uncial writing on vellum is seen in the Mæso-Gothic alphabet which Ulfilas constructed for the use of his countrymen, in the 4th century, mainly from the Greek letters. Of the few extant remains of Gothic MSS. the oldest and most perfect is the Codex Argenteus of the Gospels, at Upsala, of the 6th century (*Pal. Soc.*, pl. 118), written in characters which compare with purely written Greek MSS. of the same period. Other Gothic fragments appear in the sloping uncial hand seen in Greek MSS. of the 7th and following centuries.

About the year 600-Greek uncial writing passes into a new stage. We leave the period of the round and enter on that of the oval character. The letters Ε, Θ, Ο, Γ, instead of being symmetrically formed on the lines of a circle, are made oval; and other letters are laterally compressed into a narrow shape. In the 7th century also the writing begins to slope to the right, and accents are introduced and afterwards systematically applied. This slanting style of uncials continued in use through the 8th and 9th centuries, becoming heavier as time goes on. In this class of writing there is again the same dearth of dated MSS. as in the round uncial, to serve as standards for the assignment of dates. We have to reach the 9th century before finding a single dated MS. in this kind of writing. It is true that sloping Greek uncial writing is found in a few scattered notes and glosses in Syriac MSS. which bear actual dates in the 7th century, and they are so far useful as showing that this hand was firmly established at that time; but they do not afford sufficient material in quantity to be of really practical use for comparison (see the tables of alphabets in Gardthausen's *Griech. Palæog.*). Of more value are a few palimpsest fragments of the *Elements* of Euclid and of Gospel Lectionaries which occur also in the Syriac collection in the British Museum, and are written in the 7th and 8th centuries. There is also in the Vatican a MS. (Reg. 886) of the Theodosian code, which can be assigned with fair accuracy to the close of the 7th century (Gardth., *Gr. Pal.*, p. 158), which, however, being calligraphically written, retains some of the earlier rounder forms. This MS. may be taken as an example of transitional style. In the fragment of a mathematical treatise from Bobio, forming part of a MS. rewritten in the 8th century and assignable to the previous century, the slanting writing is fully developed. The formation

of the letters is good, and conveys the impression that the scribe was writing a hand quite natural to him.

ΠΡΩΤΗ ΠΑΝΤΟΤΕΡΕΥΧΗΛΗ
ΠΡΟΣΤΙΜΕΤΩΡΟΝ ΕΥΧΕΡΕΣΤΕΡ

Greek Uncial (Mathemat. Treatise), 7th century.

(πρωτ[ο]ν μ[ε]ν γ[α]ρ παντ[ο]ς στερεου σχη[μα]τος
προς τι μετewρον ευχερεστερ—)

It should be also noticed that in this MS.—a secular one—there are numerous abbreviations (Wattenbach, *Script. Gr. Specim.*,¹ tab. 8). An important document of this time is also the fragment of papyrus in the Imperial Library at Vienna, which bears the signatures of bishops and others to the Acts of the council of Constantinople of 680. Some of the signatures are in slanting uncials (Wattenb., *Script. Gr. Specim.*, tabb. 12, 13; Gardth., *Gr. Pal.*, tab. 1). Of the 8th century is the collection of hymns (Brit. Mus., Add. MS. 26113) written without breathings or accents (*Cat. Anc. MSS.*, i. pl. 14). To the same century belongs the Codex Marcianus, the Venetian MS. of the Old Testament, which is marked with breathings and accents. The plate reproduced from this MS. (Wattenb., *Script. Gr. Specim.*, tab. 9) contains in the second column a few lines written in round uncials, but in such a laboured style that nothing could more clearly prove the discontinuance of that form of writing as an ordinary hand. In the middle of the 9th century at length we find a MS. with a date in the Psalter of Bishop Uspensky of the year 862 (Wattenb., *Script. Gr. Specim.*, tab. 10). A little later in date is the MS. of Gregory of Nazianzus, written between 867 and 886 (Silvestre, pl. 71); and at the end of the 9th or beginning of the 10th century stands a lectionary in the Harleian collection (*Cat. Anc. MSS.*, i. pl. 17). But by this time minuscule writing was well established, and the use of the more inconvenient uncial was henceforth confined to church-service books. Owing to this limitation uncial writing now underwent a further calligraphic change. As the 10th century advances the sloping characters by degrees become more upright, and with this resumption of their old position they begin in the next century to cast off the compressed formation and again become rounder. All this is simply the result of calligraphic imitation. Service-books have always been the MSS. in particular on which finely-formed writing has been lavished; and it was but natural that, when a style of writing fell into general disuse, its continuance, where it did continue, should become more and more traditional, and a work of copying rather than of writing. In the 10th century there are a few examples bearing dates. Facsimiles from two of them, the Curzon Lectionary of 980 and the Harleian Lectionary of 995, have been printed (*Pal. Soc.*, pls. 154, 26, 27). The Bodleian commentary on the Psalter (D. 4, 1) is likewise of great palæographic value, being written partly in uncials and partly in minuscules of the middle of the 10th century (Gardth., *Gr. Pal.*, p. 159, tab. 2, col. 4). This late form of uncial writing appears to have lasted to about the middle of the 12th century. From it was formed the Slavonic writing in use at the present day.

Under the head of late uncial writing must be classed a few bilingual Græco-Latin MSS. which have survived, written in a bastard kind of uncial in the west of Europe. This writing follows, wherever the shapes of the letters permit, the formation of corresponding Latin characters,—the purely Greek forms being imitated in a clumsy fashion. Such MSS. are the Codex Augiensis of Trinity College, Cambridge, of the end of the 9th century (*Pal.*

¹ *Scriptura Græcæ Specimina*, Berlin, 1883.

Soc., pl. 127), and the Psalter of St Nicholas of Cusa (pl. 128) and the Codex Sangallensis and Boernerianus of the 10th century (pl. 179). The same imitative characters are used in quotations of Greek words in Latin MSS. of the same periods.

Cursive.—The materials for the study of early Greek cursive writing are found in papyri discovered in Egypt and now deposited in the British Museum, the Louvre, the library of Leyden, and the Vatican. The earliest of these to which an exact date can be assigned are contained in the collection of documents of a certain Ptolemy, son of Glaucias, a Macedonian Greek, who became a recluse of the Serapeum at Memphis in 173–172 B.C., and collected or wrote these documents relating to himself and others connected with the service of the temple in the middle of the 2d century B.C. A series of these and other documents can be selected so as to give a fairly continuous course of cursive handwriting from that period for several centuries. The papyri are supplemented by the ostraka or potsherds on which were written the receipts for payment of taxes, &c., in Egypt under the Roman empire, and which have been found in large quantities. Lastly there are still extant a few specimens of Greek cursive writing on waxen tablets; and in documents of the 6th and 7th centuries from Naples and Ravenna there are found subscriptions in Latin written in Greek characters (Marini, *I papiri diplom.*, 90, 92, 121; *Cod. Dipl. Cavensis*, vol. ii., No. 250).

Facsimiles of the cursively written papyri are found scattered in different works, some dealing specially with the subject. By far the most plentiful and best executed are those which reproduce the specimens preserved at Paris in the atlas accompanying *Notices et Extraits des Manuscrits*, vol. xviii.

In the earliest examples of cursive writing we find the uncial character in use, and, as has been already remarked, many of the specimens fluctuate between the more formal or set book-hand and the cursive. As time goes on the two styles diverge more widely. The uncial book-hand had, as we have seen, a disposition to become more formal; cursive writing naturally has the opposite tendency, to become more flowing and disintegrated, the more extensively it is used. But the fact that there existed in Egypt in the 2d century B.C. a cursive hand not differing very materially from a more formal contemporary hand seems to indicate that the two styles had diverged at no very long time before. It cannot, however, be supposed that a cursive form of Greek writing did not exist still earlier. The highly developed calligraphy of the earliest examples proves that Greek writing, as we there see it, was then no newly-discovered art. Judging by the analogy of later reforms, it is perhaps not going too far to conjecture that in the papyri under consideration we see the results of a calligraphic reform, in which a new model was perfected from earlier styles.

The cursive hand in its best style (*e.g.*, *N. et Extr.*, pls. xxviii., xxix.) is very graceful and exact. This elegance is indeed characteristic of most of the writings of the 2d century B.C., and if a criterion can be established for assisting in the difficult problem of dating the early papyri, this simplicity and evenness of writing appears to be the best.

Greek Cursive, 163–162 B.C.

(ὅφ' ὅμων ἡμιν χρηματίσμενα
εὐλαβεῖαν προορωμένων ἡμῶν δε)

In the course of successive centuries the cursive hand

becomes slacker and more sloping. There is more combination of letters, and a continual disintegration, so to say, of the forms of the letters themselves. Naturally the letters which undergo most change are those which lend themselves most readily to combination with others. *Alpha*, for example, a letter in constant use, and appearing in frequently recurring words (as *κατ*), quickly altered its shape. In the earliest papyri it is seen more cursively written than most of its fellows. *Epsilon*, again, is a letter which soon took a second form. It was found easier to make the cross-bar in conjunction with the upper half of the curve of the letter than by a separate stroke after the formation of the full curve *ε*. The upper half of the letter naturally linked itself with the next following letter; and the epsilon thus broken is found as early as a hundred years B.C., and runs through succeeding centuries. The *tau* was treated in the same way. In the specimen given above it may be seen how the scribe first made half the horizontal stroke and attached it to the main limb by one action of the pen *τ*, and then added the other half separately. By this device he avoided moving his hand far back. Next, to write the letter in one stroke, something like a *γ*, was a natural development. The transformation of *pi* follows on the same lines; and the *n*-shaped *nu* comes from the capital letter quickly written, just as the same shape was derived in the Roman alphabet. Such a form as the sickle-shaped *rho* *ρ* is one that would be expected; but the system of breaking-up is in no form better illustrated than in the case of *delta*. This letter, it might be thought, would, from its original shape, resist combination more than any other, yet even in the 2d century B.C. this combination is accomplished, and *delta* occasionally appears open on the right side and linked with the following letter *Δ*.

Minuscule.—The gradual disintegration of the pure forms of the early uncials by this progressive development of more cursive characters led eventually to the formation of minuscule letters. By the beginning of the 6th century most of the letters which are afterwards recognized as minuscules in form had become individually developed. For example, the three letters *B*, *H*, and *K*, which in their capital or uncial shapes are quite distinct, had, at this period, acquired alternative shapes which are not very dissimilar from one another, and which by a careless reader may be confused. The letter *B* in cursive writing lost its loops and was joined by a tag to the following letter—a process by which it became very like the Latin *u*. So the *H* readily passed through the form *η* to *h*; and *K* became *u*. The *Δ* developed at the apex an elongation of the right side of the triangle, which, for junction with the next letter, was bent over, and hence resulted the small *δ*. The transformation of *M* through *μ* to *μ*, and of *N* through *ν* to *ν*, is obvious. This development, however, of minuscules from the old uncials was a work of time. The incipient changes in individual letters can be detected in papyri of the 2d and 1st centuries B.C.; but a fully developed minuscule hand, used as an independent form of writing, had no existence for some centuries to come. Arrived, however, at the end of the 6th century, we find a document of 600 A.D. given in facsimile in the *Notices et Extraits* (pl. xxiii., No. 20), the writing of which is so full of the smaller letters that the hand is practically a minuscule one. This document and six others which are extant formed part of the business papers of one Aurelius Paelymius, a dealer in purple dye, and, ranging in date from 592 to 616 A.D., are valuable material for elucidating the history of the Greek minuscule character. After an interval of eighty years another important document presents itself, in which the two styles of writing, the old uncial and the new minuscule, are seen on the same page. This is the frag-

mentary papyrus at Viennæ, originally brought from Ravenna, which contains the subscriptions of bishops and others to the acts of the synod of Constantinople of 680 A.D. A facsimile was first printed by Lambecius (*Comm. de Bibl. Cæsar.*, ed. Kollar, lib. viii. p. 863), and is reproduced by Wattenbach (*Script. Gr. Specim.*, tabb. 12, 13), whose latest opinion, however, with regard to the document is, that the writing is too uniform to be the actual subscriptions, but that it is the work of a scribe imitating to some extent (and certainly so far that he has repeated the uncials and minuscules as he found them) the peculiarities of the original. This appears to be really the case, but the document being a nearly contemporary copy continues to have considerable paleographical value. An analysis of the alphabets of this papyrus and of the one of 600 A.D. cited above is given by Gardthausen (*Gr. Pal.*, taf. 4). The facsimile of the will of Abram, bishop of Harmonthis (*Pal. Soc.*, pl. 107), may also be referred to as showing the mixture of large and small letters in the 8th century; and in the single surviving specimen of Greek writing of the Imperial Chancery, containing portions of a letter addressed apparently to Pepin le Bref on the occasion of one of his wars against the Lombards in 753 or 756, appears a hand which approaches nearest to the set minuscule book-hand of the next century (Wattenb., *Script. Gr. Specim.*, tabb. 14, 15).

Arrived at this matured stage of development, the minuscule character was in a condition to pass into the regular calligraphic form of writing. In the documents quoted above, it appears generally in a cursive form, and in this form it was undoubtedly also used for literary works. An example of such book-writing in the 8th century has been given in facsimile by Gardthausen (*Beitr. zur griech. Pal.*, 1877, taf. 1). But in the 9th century the minuscule hand assumed a set form from which the writing of the succeeding centuries developed as from a new basis.

The establishment of this set hand is to be ascribed to the fact of the minuscule being now generally adopted as the recognized literary hand, in place of the larger and more inconvenient uncial, and its consequent introduction into vellum books. As we have already seen, uncial writing was influenced in the same way when applied to vellum. The firmer surface of the skin offered to the calligrapher a better working ground for the execution of his handiwork; and thus may be explained the almost sudden appearance of the beautiful and regular writing which presents itself in the minuscule MSS. of the 9th century.

Greek MSS. written in minuscules have been classed as follows:—(1) *codices vetustissimi*, of the 9th century and to the middle of the 10th century; (2) *vetusti*, from the middle of the 10th to the middle of the 13th century; (3) *recentiores*, from the middle of the 13th century to the fall of Constantinople, 1453; (4) *novelli*, all after that date.

Of dated minuscule MSS. there is a not inconsiderable number scattered among the different libraries of Europe. Gardthausen (*Gr. Pal.*, 344 sq.) gives a list of some thousand, ending at 1500 A.D. But, as might be expected, the majority belong to the later classes. Of the 9th century there are not ten which actually bear dates, and of these all but one belong to the latter half of the century. In the 10th century, however, the number rises to nearly fifty, in the 11th to more than a hundred.

In the period of *codices vetustissimi* the minuscule hand is distinguished by its simplicity and purity. The period has been well described as the classic age of minuscules. The letters are symmetrically formed; the writing is compact and upright, or has even a slight tendency to slope to the left. In a word, the beauty of this class of minuscule

writing is unsurpassed. But in addition to these general characteristics there are special distinctions which belong to it. The minuscule character is maintained intact, without intrusion of larger or uncial-formed letters. With its cessation as the ordinary literary hand the uncial character had not died out. We have seen that it was still used for liturgical books. It likewise continued to survive in a modified or half-uncial form for scholia, rubrics, titles, and special purposes—as, for example, in the Bodleian Euclid (*Pal. Soc.*, pl. 66)—in minuscule written MSS. of the 9th and 10th centuries. These uses of the older character sufficed to keep it in remembrance, and it is therefore not a matter for surprise that some of its forms should reappear and commingle with the simple minuscule. This afterwards actually took place. But in the period now under consideration, when the minuscule had been cast into a new mould, and was, so to say, in the full vigour of youth, extraneous forms were rigorously excluded.

Ἐπὶ τοῦ ἈΒΥ ἐπιέδου διχα τηρηθεῖται
ὈΜΝ ἐπιέδου· διὰ ταῦτα αὐτὰ δὴ κ[α]ί ἡ ἀπο

Greek Minuscule (Euclid), 888 A.D.

(ἐπὶ τοῦ ἈΒΥ ἐπιέδου διχα τηρηθεῖται
ὈΜΝ ἐπιέδου· διὰ ταῦτα αὐτὰ δὴ κ[α]ί ἡ ἀπο)

The breathings also of this class are rectangular, in unison with the careful and deliberate character of the writing; and there is but slight, if any, separation of the words. In addition, as far as has hitherto been observed, the letters run above, or stand upon, the ruled lines, and do not depend from them as at a later period. The exact time at which this latter mechanical change took place cannot be named; like other changes it would naturally establish itself by usage. But at least in the middle of the 10th century it seems to have been in use. In the Bodleian MS. of Basil's homilies of 953 A.D. (*Pal. Soc.*, pl. 82) the new method is followed; and if we are to accept the date of the 9th century ascribed to a MS. in the Ambrosian Library at Milan (Wattenb., *Script. Gr. Specim.*, tab. 17), in which the ruled lines run above the writing, the practice was yet earlier. Certain scribal peculiarities, however, about the MS. make us hesitate to place it so early. In the Laurentian Herodotus (W. and V., *Exempla*,¹ tab. 31), which belongs to the 10th century, sometimes the one, sometimes the other system is followed in different parts of the volume; and the same peculiarity happens in the MS. of Gregory of Nazianzus of 972 A.D. in the British Museum (*Pal. Soc.*, pl. 25; *Exempla*, tab. 7). The second half of the 10th century therefore appears to be a period of transition in this respect.

The earliest dated example of *codices vetustissimi* is the copy of the Gospels belonging to Bishop Uspensky, written in the year 835. A facsimile is given by Gardthausen (*Beiträge*) and repeated in the *Exempla* (tab. 1). Better specimens have been photographed from the Oxford Euclid of 888 A.D. (*Pal. Soc.*, pls. 65, 66; *Exempla*, tab. 2) and from the Oxford Plato of 895 A.D. (*Pal. Soc.*, pl. 81; *Exempla*, tab. 3). Sabas (*Specim. Palæograph*) has also given two facsimiles from MSS. of 880 and 899. To this list may be added a facsimile of the Chronicles of Nicephorus in the British Museum, which falls within the 9th century (*Cat. Anc. MSS.*, i. pl. 15), and also one of the Aristotle of Milan, which may be of the 9th or early 10th century (*Pal. Soc.*, pl. 129; Wattenb., *Script. Gr. Specim.*, tab. 16). Of the year 905 is the *Catena on Job* at Venice (*Exempla*, tab. 4); and other facsimiles of MSS. of this class are taken

¹ Wattenbach and Von Velsen, *Exempla Codicum Græcorum. lit. minusc. scriptorum*, Heidelberg, 1878.

from a MS. of the Gospels in the British Museum (*Cat. Anc. MSS.*, i. pl. 16), the Ambrosian Plutarch (Wattenb. *Script. Gr. Specim.*, tab. 20), and the Ambrosian MS. of the Prophets (tab. 17), the last having, among other peculiarities, an unusual method of distinguishing the sigma at the end of a word by an added dot. These few facsimiles are all that are at present available for the purpose of studying minuscule book-writing of the first class. They are, however, all reproduced by photography, and serve sufficiently to show the character of writing which we are to look for in other, undated, examples of the same time.

After the middle of the 10th century we enter on the period of the *codices vetusti*, in which it will be seen that the writing becomes gradually less compact. The letters, so to say, open their ranks; and, from this circumstance alone, MSS. of the second half of the century may generally be distinguished from those fifty years earlier. But alterations also take place in the shapes of the letters. Side by side with the purely minuscule forms those of the uncial begin to reappear, the cause of which innovation has already been explained. These uncial forms first show themselves at the end of the line, the point at which most changes first gained a footing, but by degrees they work back into the text, and at length become recognized members of the minuscule characters. In the 11th and 12th centuries they are well established, and become more and more prominent by the large or stilted forms which they assume. The change, however, in the general character of the writing of this class of *codices vetusti* is very gradual, uniformity and evenness being well maintained, especially in church books. Among the latter, a trilingual Psalter of the year 1153, in the British Museum (*Pal. Soc.*, pl. 132), may be noted as an example of the older style of writing being adhered to at a comparatively late time. On the other hand, a lighter and more cursive kind of minuscule is found contemporaneously in MSS. of a secular nature. In this hand many of the classical MSS. of the 10th or 11th centuries are written, as the MS. of Æschylus and Sophocles, the Odyssey and the Apollonius Rhodius of the Laurentian Library at Florence, the Anthologia Palatina of Heidelberg and Paris, the Hippocrates of Venice (*Exempla*, tabb. 32-36, 38, 40), and the Aristophanes of Ravenna (Wattenb., *Script. Gr. Specim.*, tab. 26). In a facsimile from a Plutarch at Venice (*Exempla*, tab. 44), the scribe is seen to change from the formal to the more cursive hand. This style of writing is distinguishable by its light and graceful character from the current writing into which the minuscule degenerated at a later time. The gradual rounding of the rectangular breathings takes place in this period. In the 11th century the smooth breathing, which would most readily lend itself to this modification, first appears in the new form. In the course of the 12th century both breathings have lost the old square shape; and about the same time contractions become more numerous, having been at first confined to the end of the line. Facsimiles from several MSS. of the *codices vetusti* and the following class have been published by the Palæographical Society and by Wattenbach and Von Velsen in their *Exempla*.

When the period of *codices recentiores* commences, the

ἡ ἀρχὴ τοῦ ἱεροῦ κήρυκος τοῦ ἀρχιεπισκοπικοῦ
 ὡς ἀρμόζει τῆς σφύρας ἡ ἀρχιεπισκοπικὴ
 ἀμφιδόμιον πρὸς γούνα καθέξοτο δουλικῆς

Greek Minuscule (Odyssey), 13th century.

(ἡ ἀλλοίωσις ἐστὶν ἱερὴ ἐνίκησας τὸν ἀλλόγητον
 ὡς ἀρμόζει τῆς σφύρας ἡ ἀρχιεπισκοπικὴ
 ἀμφιδόμιον πρὸς γούνα καθέξοτο δουλικῆς)

Greek minuscule hand undergoes extensive changes. The

contrast between MSS. of the 13th century and those of a hundred years earlier is very marked. In the later examples the hand is generally more straggling, there is a greater number of exaggerated forms of letters, and marks of contraction and accents are dashed on more freely. There is altogether a sense of greater activity and haste.

The increasing demand for books created a larger supply. Scholars now also copied MSS. for their own use, and hence greater freedom and more variety appear in the examples of this class, together with an increasing use of ligatures and contractions. The introduction of the coarse cotton paper into Constantinople in the middle of the 13th century likewise assisted to break up the formal minuscule hand. To this rough material a rougher style of writing was suited. Through the 14th and 15th centuries the decline of the set minuscule rapidly advances. In the MSS. on cotton paper the writing becomes even more involved and intricate, marks of contraction and accents are combined with the letters in a single action of the pen, and the general result is the production of a thoroughly cursive hand. On vellum, however, the change was not so rapid. Church books were still ordinarily written on that material, which, as it became scarcer in the market (owing to the injury done to the trade by the competition of cotton paper), was supplied from ancient codices which lay ready to hand on the shelves of libraries. The result was an increasing number of palimpsests. In these vellum liturgical MSS. the more formal style of the minuscule was still maintained, and even on paper church services are found to be in the same style. In the 14th century there even appears a partial Renaissance in the writing of church MSS., modelled to some extent on the lines of the writing of the 12th century. The resemblance, however, is only superficial; for no writer can entirely disguise the character of the writing of his own time. And lastly there was yet another check upon the absolute disintegration of the minuscule in the 15th century exercised by the professional scribes who worked in Italy. Here the rag-paper, which had never made its way in the East, was the only paper in use. Its smoother surface approximated more nearly to that of vellum; and the minuscule hand as written by the Greek scribes in Italy, whether on paper or vellum, reverted again to the older style. The influence of the Renaissance is evident in many of the productions of the Italian Greeks which were written as specimens of calligraphy and served as models for the first Greek printing types.

The Greek minuscule hand had, then, by the end of the 15th century, become a cursive hand, from which the modern current hand is directly derived. We last saw the ancient cursive in use in the documents prior to the formation of the set minuscule, and no doubt it continued in use concurrently with the book-hand. But, as the latter passed through the transformations which have been traced, and gradually assumed a more current style, it may not unreasonably be supposed that it absorbed the cursive hand of the period, and with it whatever elements of the old cursive hand may have survived.

LATIN WRITING.

In writing a history of Latin palæography, it will be first necessary, as with the Greek, to follow its development in two main divisions—the set book-hand and the cursive. Under the former head will be first ranged the capital, uncial, and half-uncial hands found in early MSS.; on the other side will be traced the course of Roman cursive writing in the waxen tablets and papyri. Next will be shown how this cursive hand was gradually reduced into forms of writing peculiar to different countries on the continent of Europe (reserving for separate examination

the development of the Irish and English schools), and finally how, in the revival of learning under Charlemagne, the reformed Caroline minuscule became the standard on which the writing of all the Western nations was finally modelled.

Capital.—The oldest form of book-writing which we find employed in Latin MSS. is in capitals; and of these there are two kinds—the square and the rustic. Square capitals may be defined as those which have their horizontal lines at right angles with the vertical strokes; rustic letters are not less accurately formed, nor, as their title would seem to imply, are they rough in character, but, being without the exact finish of the square letters, and being more readily written, they have the appearance of greater simplicity. In capital writing the letters are not all of equal height; F and L, and in the rustic sometimes others, as B and R, overtop the rest. In the rustic the forms are generally lighter and more slender, with short horizontal strokes more or less oblique and wavy. Both styles of capital writing were obviously borrowed from the lapidary alphabets employed under the empire. But it has been observed that scribes with a natural conservatism would perpetuate a style some time longer in books than it might be used in inscriptions. We should therefore be prepared to allow for this in ascribing a date to a capital-written MS., which might resemble an inscription older by a century or more. Rustic capitals, on account of their more convenient shape, came into more general use; and the greater number of the early MSS. in capitals which have survived are consequently found to be in this character.

In the *Exempla Codicum Latinorum* of Zangemeister and Wattenbach are collected specimens of capital writing, which are supplemented by other facsimiles issued by the Palæographical Society. The earliest application of the rustic hand appears in the papyrus rolls recovered from the ruins of Herculaneum (*Exempla*, tabb. 1–3), which must necessarily be earlier than 79 A.D. In some of these specimens we see the letters written with a strong dashing stroke; in others they are mixed with cursive and uncial forms. In the vellum MSS. the writing in the earliest instances is of a perfectly exact character. MSS. of this class were no doubt always regarded as choice works. The large scale of the writing and the quantity of material required to produce a volume must have raised the cost to a height which would be within reach of only the wealthy. Such are the two famous copies of Virgil in the Vatican—the Codex Romanus, adorned with paintings, and the Codex Palatinus (*Exempla*, tabb. 11, 12; *Pal. Soc.*, pls. 113–115), which may be even as early as the 3d or 4th century, for in the regularity of their letters they resemble very nearly the inscriptions of the 1st and 2d century. There are no marks of punctuation by the first hand; nor are there enlarged initial letters.

Roman Rustic Capitals (Virgil), 3d or 4th century

(Testaturque deos iterum se ad proelia cogi
Bis iam Italos hostis haec altera foedera)

*In a third and younger MS. of Virgil, the Schedæ Vaticanæ (*Exempla*, tab. 13; *Pal. Soc.*, pls. 116, 117), the imitation of the lettering of inscriptions is far less apparent, and the writing may be said to have here settled down into a good working book hand; but, like the MSS. just noticed, this volume also was, doubtless prepared for a special purpose, being adorned with well-finished paintings of classical style. In assigning dates to the earliest MSS. of capital-writing, one feels the greatest hesitation, none

of them bearing any internal evidence to assist the process. It is not indeed until the close of the 5th century that we reach firm ground,—the Medicean Virgil of Florence having in it sufficient proof of having been written before the year 494. The writing is in delicately-formed letters, rather more spaced out than in the earlier examples (*Exempla*, tab. 10; *Pal. Soc.*, pl. 86). Another ancient MS. in rustic capitals is the Codex Bezae of Terence (*Exempla*, tabb. 8, 9; *Pal. Soc.*, pl. 135), a volume which is also of particular interest on account of its marginal annotations, written in an early form of small hand. Among palimpsests the most notable is that of the Cicero *In Verrem* of the Vatican (*Exempla*, tab. 4).

Of MSS. in square capitals the examples are not so early as those in the rustic character. Portions of a MS. of Virgil in the square letter are preserved in the Vatican, and other leaves of the same are at Berlin (*Exempla*, tab. 14). Each page, however, begins with a large coloured initial, a style of ornamentation which is never found in the very earliest MSS. The date assigned to this MS. is therefore the end of the 4th century. In very similar writing, but not quite so exact, are some fragments of another MS. of Virgil in the library of St Gall, probably of a rather later time (*Exempla*, tab. 14a; *Pal. Soc.*, pl. 208).

In the 6th century capital-writing enters on its period of decadence, and the examples of it become imitative. Of this period is the Paris Prudentius (*Exempla*, tab. 15; *Pal. Soc.*, pls. 29, 30) in rustic letters modelled on the old pattern of early inscriptions, but with a very different result from that obtained by the early scribes. A comparison of this volume with such MSS. as the Codex Romanus and the Codex Palatinus, shows the later date of the Prudentius in its widespread writing and in certain inconsistencies in forms. Of the 7th century is the Turin Sedulius (*Exempla*, tab. 16), a MS. in which uncial writing also appears—the rough and misshapen letters being evidences of the cessation of capital writing as a hand in common use. The latest imitative example of an entire MS. in rustic capitals is in the Utrecht Psalter, written in triple columns and copied, to all appearance, from an ancient example, and illustrated with pen drawings. This MS. may be assigned to the beginning of the 9th century. If there were no other internal evidence of late date in the MS., the mixture of uncial letters with the capitals would decide it. In the Psalter of St Augustine's, Canterbury, in the Cottonian Library (*Pal. Soc.*, pl. 19; *Cat. Anc. MSS.*, ii. pls. 12, 13), some leaves at the beginning are written in this imitative style early in the 8th century; and again it is found in the Benedictional of Bishop Æthelwold (*Pal. Soc.*, pl. 143) of the 10th century. In the sumptuous MSS. of the Carolingian school it was continually used; and it survived for such purposes as titles and colophons, for some centuries, usually in a degenerate form of the rustic letters.

Uncial.—Uncial writing differs from the capital in adopting certain rounded forms, as Ω ð ε η ϑ, and in having some of its letters rising above or falling below the line. The origin of the round letters may be traced in some of the Roman cursive characters as seen in the wall inscriptions of Pompeii and the waxen tablets. A calligraphic development of these slighter forms resulted in the firmly-drawn letters which are seen in the early vellum MSS. The most ancient of these may without much hesitation be assigned to the 4th century, and in them the writing is so well-established that one might well believe that it had been already practised for some generations. On the other hand, a calligraphic style may be stimulated into quick development by various causes,—caprice, fashion, or even the substitution of a different writing material, as vellum for papyrus. Uncial writing lasted as an ordinary book-

hand into the 8th century, when it was supplanted by the reformed small writing of the Carolingian school; but, like the capitals, it survived for some time longer as an ornamental hand for special purposes.

The *Exempla* of Zängemeister and Wattenbach, so often quoted above, contains a series of facsimiles which illustrate the progress of uncial writing throughout the period of its career. The letter *o* has been adopted by the editors as a test letter, in the earlier forms of which the last limb is not curved or turned in. The letter *e* also in its earlier and purer form has the cross stroke placed high. But, as in every style of writing, when once developed, the earliest examples are the best, being written with a free hand and natural stroke.

The Gospels of Vereelli (*Exempla*, tab. 20), said to have been written by the hand of Eusebius himself, and which may indeed be of his time, is one of the most ancient uncial MSS. Its narrow columns and pure forms of letters have the stamp of antiquity. To the 4th century also is assigned the palimpsest Cicero *De Republica* in the Vatican (*Exempla*, tab. 17; *Pal. Soc.*, pl. 160), a MS. written in fine large characters of the best type; and a very ancient fragment of a commentary on an ante-Hieronimian text, in three columns, has also survived at Fulda (*Exempla*, tab. 21). Among the uncial MSS. of the 5th century of which good photographic facsimiles are available are the two famous codices of Livy, at Vienna and Paris (*Exempla*, tabs. 18, 19; *Pal. Soc.*, pls. 31, 32, 183), and the Gaius of Verona (*Exempla*, tab. 24). The latter MS. is also of special interest, as it contains abbreviations and has certain secondary forms amongst its letters. To distinguish between uncial MSS. of the 5th and 6th centuries is not easy, for the character of the writing changes but little, and there is no sign of weakness or wavering. It may, however, be noticed that in MSS. which are assigned to the latter century there is rather less compactness, and occasionally, as the century advances, there is a slight tendency to artificiality.

I AM TIBI ILLA QUAE IGNO
RANTIA SAECULARIS BO
NA OPINATUR OSTENDAM

Latin Uncial, 5th or 6th century.

(Iam tibi illa quae igno
rantia saecularis bo
na opinatur ostendam)

When the 7th century is reached there is every evidence that uncial writing has entered on a new stage. The letters are more roughly and carelessly formed, and the compactness of the earlier style is altogether wanting. From this time down to the age of Charlemagne there is a continual deterioration, the writing of the 8th century being altogether misshapen. A more exact but imitative hand was, however, at the same time employed, when occasion required, for the production of calligraphic MSS., such as liturgical books. Under the encouragement given by Charlemagne to such works, splendid uncial volumes were written in ornamental style, often in gold, several of which have survived to this day (*Cat. Anc. MSS.*, ii. pls. 39-41).

Half-Uncial.—A very interesting style of writing, and for the study of the development of the set minuscule hand of later periods a most important one, is that to which the name of half-uncial has been given. It lies between cursive and uncial, and partakes of the character of both. As early apparently as the 4th century, a set style of small writing, partly following in formation the characters found in the Roman cursive writing of the Ravenna and other

documents on papyrus, and in some of its letters betraying an uncial origin, is found in glosses or marginal notes of early MSS. The limited space into which the annotations had to be compressed compelled the writer to abandon the free style of the ordinary cursive hand, and at the same time a mere reduction of capital or uncial letters would have been too tedious a process to adopt. A middle course was followed, and a neat minute hand, half-set half-current, was used,—just as in the present day it is no uncommon practice to write a so-called printing hand for similar purposes. The earliest example of this hand appears to be in the marginal directions for the painter in the Quedlinburg fragment of an illustrated early Italic version of the Bible (see Schum in *Theolog. Studien u. Kritiken*, 1876). In these notes appear *b, d, m, n* as fully developed minuscules; *r* is represented by *ŕ*, half way between the uncial and the minuscule, and *s* is *r*. Again in the notes by the Arian bishop Maximin (*Exempla*, tab. 22), of the 5th century, the same style of writing appears,—with some variations, however, in individual letters, as in *g* and *r*, which come near to minuscule shapes. In the Codex Bezae of Terence (*Exempla*, tab. 8) there are many glosses giving ample opportunity for studying the hand, which is here in a small and well-formed character. From this specimen, and also from the notes in the Itala of Fulda (*Exempla*, tab. 21), a complete alphabet of set minuscule letters may be selected, as written probably early in the 6th century. Rather later and more uncial in form are the glosses in the Medicean Virgil (*Exempla*, tab. 10).

This set form of small writing, then, was, as it appears from the examples quoted above and from many others (see the enumeration in Wattenbach, *Einleitung zur Lat. Palæog.*, p. 12), in pretty general use for the purposes of annotation; and it was but natural that it should also come to be adopted in MSS. for the text itself. The introduction into the text of uncial-written MSS., at an early date, of forms of letters borrowed from cursive writing is illustrated by the Verona Gaius (*Exempla*, tab. 24) of the 5th century, in which, besides the ordinary uncial shapes, *d* is also found as a minuscule, *r* as the transitional *ŕ*, and *s* as the tall letter *r*. Again, in the Florentine Pandects of the 6th century, one of the scribes writes a hand which contains a large admixture of minuscule forms (*Exempla*, tab. 54). And some fragments of a Græco-Latin glossary on papyrus, of which facsimiles have been published (*Comment. Soc. Göttingen.*, iv., 1820, p. 156; *Rhein. Museum*, v., 1837, p. 301), likewise contain, as secondary forms of uncial *m, r*, and *s*: *ṡ, ŕ, r*. From these few instances it is seen that in uncial MSS. of a secular nature, as in works relating to law and grammar, the scribe did not feel himself restricted to a uniform use of the larger letters, as he would be in producing a church book or calligraphic MS. The adaptation then of a set small hand, very similar to, and in some particulars identical with, the annotating hand above referred to, is not surprising. The greater convenience of the small hand in comparison with the larger uncial is obvious, and the element of calligraphy which was infused into it gave it a vitality and status as a recognized book-hand. Thus we have a series of MSS., dating from the end of the 5th century, which are classed as examples of half-uncial writing, and which appear to have been written in Italy and France. The MS. of the *Fasti Consulares*, at Verona, brought down to 494 A.D. (*Exempla*, tab. 30), is in this hand, but the earliest MS. of this class to which a more approximate date can be given is the Hilary of St Peter's at Rome, which was written in or before the year 509 or 510 (*Exempla*, tab. 52, *Pal. Soc.*, pl. 136); the next is the Sulpicius Severus of Verona, of 517 A.D. (*Exempla*, tab. 32); and of the year 569 is a beautifully-written MS. at Monte Cassino containing a

Biblical commentary (*Exempla*, tab. 3). Other examples, of which good facsimiles may be consulted are the Corbie MS. of Canons, at Paris (*Exempla*, tabb. 41, 42), and the St Severianus at Milan (*Pal. Soc.*, pls. 161, 162), of the 6th century; and the Cologne MS. of Canons (*Exempla*, tab. 44), and the Josephus (*Pal. Soc.*, pl. 138) and St Ambrose (*Pal. Soc.*, pl. 137) of Milan, of the 6th or 7th century.

Latin Half-Uncial, 509-510 A.D.

(episcopi manni innocente[m]—
[in]guam non ad falsiloquium coeg[isti]—
nationem anterioris sententi[æ]—)

The influence which this style of hand had upon the minuscule book-writing of the 7th and 8th centuries may be traced in greater or less degree in the Continental MSS. of that period. It appears at a comparatively late time with much of its old form in the Berlin MS. of Gregory's *Moralia* (Arndt, *Schrifttaf.*, 5), attributed to the 8th century. After the Caroline reform an ornamental kind of half-uncial, evidently copied from this hand, was used for particular purposes in minuscule MSS. (*Pal. Soc.*, pl. 239).

Cursive.—For examples of Roman cursive writing we are able to go as far back as the 1st century of the Christian era. During the excavations at Pompeii in July 1875, there was discovered in the house of L. Cæcilius Jucundus a box containing as many as one hundred and twenty-seven *libelli* or waxen tablets consisting of *per-
scriptiones* and other deeds connected with sales by auction and receipts for payment of taxes (*Atti della R. Accademia dei Lincei*, ser. ii., vol. iii. pt. 3, 1875-76, pp. 150-230). Other waxen tablets, twenty-five in number, some bearing dates ranging from 131 to 167 A.D., were found in the ancient mining works in the neighbourhood of Alburnus Major (the modern Verespatak) in Dacia, at different times between 1786 and 1855. In 1840 Massmann published such as had at that time been discovered (*Libellus aurarius*); and the whole collection is given in the *Corpus Inscr. Lat.* of the Berlin Academy, vol. iii. pt. 2 (1873).

Although the waxen tablets prepared for the reception of legal instruments followed the system of the bronze diptychs on which were inscribed the privileges granted to veteran soldiers under the empire, in so far that they contained the deed witnessed and sealed, and also its duplicate copy open to inspection, yet they differed in being generally triptychs. Wood was a cheaper material than bronze, and the third tablet gave protection to the seals. These triptychs then were *libelli* of three tablets of wood, cleft from one piece and fastened together, like the leaves of a book, by strings passed through two holes pierced near the edge. In the case of the Pompeian *libelli* one side of each tablet was sunk within a frame, and the hollowed space was coated with wax, in such a way that, of the six sides or pages, Nos. 2, 3, 5 were waxen, while 1, 4, 6 presented a wooden surface. The first and sixth sides were not used, but served as the outside of the *libellus*; on 2 and 3 was inscribed the deed, and on 4 the names of the witnesses were written in ink and their seals were added in a groove cut down the centre, the deed being closed against inspection by means of a string of twisted threads which passed through two holes, one at the head and the other at the foot of the groove, round the two tablets and under the wax of the seals which thus secured it. An abstract or copy of the deed was written on the fifth page. The arrangement of the Dacian *libelli*

differed in this respect that page 4 was also waxen, and that the copy of the deed was commenced on that page in the space on the left of the groove, that on the right being reserved for the names of the witnesses. In one instance (*Corp. Inscr. Lat.*, iii. 2, p. 938) the seals and fastening threads still remain.

In these tablets some of the writing contains more capital letters, and is not so cursive as the rest; but here it is the cursive hand which has to be considered. This writing in both the Pompeian and Dacian tablets is very similar, differing only slightly in some of the letters; and both resemble the more cursive graffiti found on the walls of Pompeii.

Roman Cursive (Dacian Tablet), 167 A.D.

(descriptum et recognitum factum ex libello—
erat Alb[urno] maiori ad statione Resculi in quo scri-
id quod i[n]fra] s[criptum] est)

It is of particular importance to notice that, when examining the alphabet of this early Roman cursive hand, we find (as we found in the early Greek cursive) the first beginnings of minuscule writing. The slurring of the strokes, whereby the bows of the capital letters were lost and their more exact forms modified, led the way to the gradual development of the small letters, which, as will be afterwards seen, must have formed a distinct alphabet at an early time. With regard to the particular forms of letters employed in the waxen tablets, compare the tables in *Corp. Inscr. Lat.*, vols. iii., iv. The letter A is formed by a main stroke supporting an oblique cross-stroke above it; similarly P and R, having lost their bows, and F throwing away its bar, are formed by two strokes placed in relatively the same positions but varying in their curves. The main stroke of B dwindles to a slight curve, and the two bows are transformed into a long bent stroke so that the letter takes the shape of a stilted *a* or of a *d*. The D is chiefly like the uncial *o*; the E is generally represented by the old form || found in inscriptions and in the Faliscan alphabet. In the modified form of G the first outline of the flat-headed *g* of later times appears; H, by losing half its second upright limb in the haste of writing, comes near to being the small *h*. In the Pompeian tablets M has the four-stroke form ||||, as in the graffiti; in the Dacian tablets it is a rustic capital, sometimes almost an uncial *m*. The hastily written O is formed by two strokes, almost like *a*. As to the general character of the writing, it is close and compressed, and has an inclination to the left. There is also much combination or linking together of letters (*Corp. Inscr. Lat.*, iii. tab. A). These peculiarities may, in some measure, be ascribed to the material and to the confined space at the command of the writer. The same character of cursive writing has also been found on a few tiles and potsherds inscribed with

alphabets or short sentences—the exercises of children at school (*Corp. Inscr. Lat.*, iii. p. 962).

But unfortunately material for the study of this hand fails us for some time after the period of the Dacian tablets, and whole centuries have to be passed before we find examples. At length some very interesting fragments of papyri, assigned to the 5th century, disclose the official cursive hand of the Roman chancery of that time, in which are seen the same characters, with certain differences and modifications, as are employed in the waxen tablets. They contain portions of two rescripts addressed to Egyptian officials, and are said to have been found at Philæ and Elephantine. Both documents are in the same hand; and the fragments are divided between the libraries of Paris and Leyden. For a long time the writing remained undeciphered, and Champollion-Figeac, while publishing a facsimile (*Chartes et MSS. sur papyrus*, 1840, pl. 14), had to confess that he was unable to read it. Massmann, however, with the experience gained in his work upon the waxen tablets, succeeded without much difficulty in reading the fragment at Leyden (*Libellus aurarius*, p. 147), and was followed by M. de Wailly, who published the whole of the fragments (*Mém. de l'Institut*, xv., 1842, p. 399). Later, Mommsen and Jaffé have dealt with the text of the documents (*Jahrbuch des. gem. deut. Rechts*, vi., 1863, p. 398), and compared in a table the forms of the letters with those of the Dacian tablets.

Roman Cursive (Imperial Chancery), 5th century.

(portionem ipsi debitam resarcire
nec ullum precatorem ex instrumento)

The characters are large, the line of writing being about three-fourths of an inch deep, and the heads and tails of the long letters are flourished; but the even slope of the strokes imparts to the writing a certain uniform and graceful appearance. As to the actual shapes of the letters, as will be seen from the reduced facsimile here given, there may be recognized in many of them only a more current form of those which have been described above. The A and R may be distinguished by noticing the different angle at which the top strokes are applied; the B, to suit the requirements of the more current style, is no longer the closed *d*-shaped letter of the tablets, but is open at the bow and more nearly resembles a reversed *b*; the tall letters *f*, *h*, *l*, and long *s* have developed loops; O and *v*-shaped U are very small, and written high in the line. The letters which seem to differ essentially from those of the tablets are E, M, N. The first of these is probably explained correctly by Jaffé as a development of the earlier *ll* quickly written and looped. The M and N have been compared with the minuscule forms of the Greek *mu* and *nu*, as though the latter had been adopted; but they may with better reason be explained as cursive forms of the Latin capitals M and N.

That this hand should have retained so much of the older formation of the Roman cursive is no doubt to be attributed to the fact of its being an official style of writing which would conform to tradition. To find a more independent development we turn to the documents on papyrus from Ravenna, Naples, and other places in Italy which date from the 5th century and are written in a looser and more straggling hand. Examples of this hand will be found in largest numbers in Marini's work specially

treating of these documents (*I Papiri Diplomatici*), and also in the publications of Mabillon (*De Re Diplomatica*), Champollion-Figeac (*Chartes et MSS. sur papyrus*), Massmann (*Urkunden in Neapel und Arezzo*), Gloria (*Palæografia*), as well as in *Facsimiles of Ancient Charters in the British Museum*, part iv., 1878, Nos. 45, 46, and in the *Facsimiles of the Palæographical Society*. The development that is found in these papyri of minuscule forms almost complete shows how great a change must have been at work during the three centuries which intervene between the date of the Dacian tablets and that of these documents; and the variety of shape which certain of them assume in combination with other letters proves that the scribes were well practised in the hand.

Roman Cursive (Ravenna), 572 A.D.

(huius splendidissimæ urbis)

The letter *a* has now lost all trace of the capital; it is the open *u*-shaped minuscule, developed from the looped uncial (*au*); the *b*, throwing off the loop or curve on the left which gave it the appearance of *d*, has developed one on the right, and appears in the form familiar in modern writing; minuscule *m*, *n*, and *u* are fully formed (the last never joining a following letter, and thus always distinguishable from *a*); *p*, *q*, and *r* approach to the long minuscules, and *s*, having acquired an incipient tag, has taken the form *r* which it keeps long after.

This form of writing was widely used, and was not confined to legal documents. It is found in grammatical works, as in the second hand of the palimpsest MS. of Licinianus (*Cat. Anc. MSS.*, pt. ii., pls. 1, 2) of the 6th century, and in such volumes as the Josephus of the Ambrosian Library of the 7th century (*Pal. Soc.*, pl. 59), and in the St Avitus of the 6th century and other MSS. written in France and referred to below under the head of Merovingian writing. It is indeed only natural to suppose that this, the most convenient, because cursive, hand, should have been employed for ordinary books which were in daily use. That so few of such books should have survived is no doubt owing to the destruction of the greater number by the wear and tear to which they were subjected.

NATIONAL WRITING.

Roman writing—capital, uncial, half-uncial, and cursive—became known to the Western nations, and in different ways played the principal part in the formation of the national styles of writing. In Ireland and England it was adopted under certain restrictions. On the Continent it had a wider range; and from it were constructed the three kinds of writing which in many characteristics closely resembled one another, and which, practised in Italy, Spain, and Frankland, are known by the names of Lombardic, Visigothic, and Merovingian. The basis of all three was the Roman cursive, as is very evident in the national charters which have survived; and by a certain admixture of uncial and half-uncial forms with the cursive were produced the set book-hands of those countries.

Lombardic.—In Italy the cursive hand of the Ravenna documents, which have been already referred to, continued in use and became more and more intricate and difficult to read. Facsimiles have been reproduced from Milanese documents of the 8th and 9th century (Sickel, *Monumenta*

Graphica, fasc. 1), the earlier examples, down to the middle of the 9th century, being in the large straggling character of their prototypes (see also *Cod. Dipl. Cavensis*, vol. i.; and Silvestre, i., pl. 137). The illegible scrawl into which this hand finally degenerated in notarial instruments of southern Italy was at length suppressed by order of Frederick II. (1210-50 A.D.). But at La Cava and Monte Cassino was especially cultivated the Lombardic hand, properly so called. There is much resemblance between this hand in its earlier stages and that which appears in certain MSS. written in France at the same period. Both starting from the same basis, it is not surprising that a likeness should be maintained for some time. Hence there is often no small difficulty in deciding whether a particular MS. is to be classed as Lombardic or Merovingian. If all MSS. written in the Merovingian kingdom are to be styled Merovingian, there are different styles which must be included under that title. A form of Frankish writing which is marked by a certain solidity and evenness, and thus more nearly resembles the Lombardic writing of Italy, is often classed with the latter. The Lombardic book-hand as written in Italy is seen in facsimile in *Exempla Codd. Lat.* (tabb. 29, 30), Silvestre (pl. 136), *Pal. Soc.* (pl. 92). As developed in the southern monasteries referred to above, it took, in the 9th century, a very exact and uniform shape, as seen in the Bible of La Cava (Silv., pl. 141). From this date the attention which it received as a calligraphic form of writing, accompanied with accessory ornamentation of initial letters, brought it to a high state of perfection in the 11th century, when by the peculiar treatment of the letters, they assume that strong contrast of light and heavy strokes which when exaggerated, as it finally became, received the name of broken Lombardic.

sc nox est de qua scriptum est Et
nox ut dies illuminabitur.

Broken Lombardic Writing, 12th century.

((H)sc nox est de qua scriptum est Et
nox ut dies illuminabitur)

This style of hand lasted to the 13th century. The fullest collection of examples is to be found in facsimile in the *Bibliotheca Casinensis* (1873, &c.). For other specimens see Silvestre, pls. 142-146, 150; Arndt, *Schrifttaf.*, 7. 32; *Pal. Soc.*, pl. 146.

Papal Documents.—A form of writing practised in Italy, but standing apart, is that found in papal documents. It has been erroneously named *littera Beneventana*. Specimens exist dating from the latter part of the 8th century. In the earliest examples it appears on a large scale, and has rounded forms and sweeping strokes of a very bold character. Derived from the official Roman hand, it has certain letters peculiar to itself, such as the letter *a* made almost like a Greek ω , *t* in the form of a loop, and *e* as a circle with a knot at the top.

This hand may be followed in examples from 788 A.D. through the 9th century (*Facs. de Chartes et Diplomes*, 1866; Gloria, *Palæog.*, tab. 22; Ch. Figeac, *Chartes et doc. sur Papyrus*, i.-xii.; Letronne, *Diplom. Merov. Etat.*, pl. 48, Silvestre, pls. 138, 139). In a bull of Silvester II., dated in 999 (*Bibl. de l'Ec. des Chartes*, vol. xxxvii.), we find the hand becoming less round; and at the end of the next century, under Urban II., in 1097 (Mabillon, *De Re Dipl.*, suppl., p. 115) and 1098 (Sickel, *Mon. Graph.*, v. 4), it is in a curious angular style, which, however, then disappears. During the 11th and 12th centuries the imperial chancery hand was also used for papal documents,

and was in turn displaced by the exact and calligraphic papal Italian hand of the later Middle Ages. The later invention of the 16th century, the so-called *littera Sancti Petri*, which seems to have been written to baffle the uninitiated, need only be referred to.

Bull of Pope John VIII. (much reduced), 876 A.D.

(Dei genetricis mariae fili.—
haec igitur omnia quae huius praecepta.)

Visigothic.—The Visigothic writing of Spain ran a course of development not unlike that of the other national hands; and a series of photographic facsimiles lately published (*Exempla Scripturae Visigothicae*, 1883) enables us to mark the different periods of change. In the cursive hand attributed to the 7th century (*Ex.*, 2, 3), the Roman cursive has undergone little change in form; but another century developed a most distinctive character (*Ex.*, 4, 5). In the 8th century appears the set book-hand in an even and not difficult character, marked by breadth of style and a good firm stroke. This style is maintained through the 9th century with little change, except that there is a growing tendency to calligraphy. In the 10th century the writing deteriorates; the letters are not so uniform, and, when calligraphically written, are generally thinner in stroke. The same changes which are discernible in all the hand-writings of western Europe in the 11th century are also to be traced in the Visigothic hand,—particularly as regards the rather rigid character which it assumes. It continued in use down to the beginning of the 12th century. Perhaps the most characteristic letter of the book-hand is the *g*-shaped *g*. The following specimens illustrate the Visigothic as written in a large heavy hand of the 9th century (*Cat. Anc. MSS.*, ii., pl. 37), and in a calligraphic example of 1109 (*Pal. Soc.*, pl. 48).

(patrum et profetarum et sanctorum et apostolorum
que gemitibus et tormentis desiderii sui
habuit usquequo fructum ex parte sua.)

Merovingian.—The writing of the Frankish empire, to which the title of Merovingian has been applied, had a wider range than the other national hands. It had a long career both for diplomatic and literary purposes. In this writing, as it appears in documents, we see that the Roman cursive is subjected to a lateral pressure, so that the letters received a curiously cramped appearance, while the heads and tails are exaggerated to inordinate length.

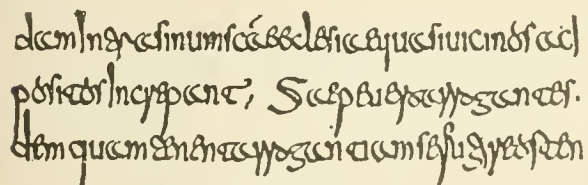

Merovingian Cursive, 679-680 A.D.

(dedit in responsis eo quod ipsa—
de annis triginta et uno inter ipso—
—ondam semper tenerant et possiderant si—,

Facsimiles of this hand, as used in the royal and imperial chanceries, are to be found scattered in various works; but a complete course of Merovingian diplomatic writing may be best studied in Letronne's *Diplomata*, and in the *Kaiserurkunden* of Profs. Sybel and Sickel now in course of publication. In the earliest documents, commencing in the 7th century and continuing to the middle of the 8th century, the character is large and at first not so intricate as it becomes later in this period. The writing then grows into a more regular form, and in the 9th century a small hand is established, which, however, still retains the exaggerated heads and tails of letters. The direct course of this chancery hand may then be followed in the imperial documents, which from the second half of the 9th century are written in a hand more set and evidently influenced by the Caroline minuscule. This form of writing, still accompanied by the lengthened strokes already referred to, continued in force, subject, however, to the varying changes which affected it in common with other hands, into the 12th century. Its influence was felt as well in France as in Germany and Italy; and certain of its characteristics also appear in the court-hand which the Normans brought with them into England.

The book-hand immediately derived from the early Merovingian diplomatic hand is seen in MSS. of the 7th and 8th centuries in a very neatly written but not very easy hand (*Cat. Anc. MSS.*, ii, pls. 29, 30; Arndt, *Schrifttaf.*, 28).

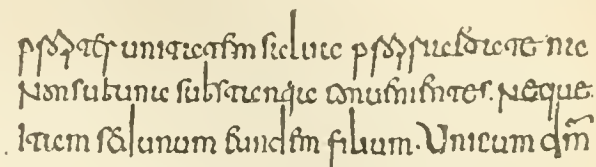

Merovingian Writing, 7th century.

(—dam intra sinum sanctae ecclesiae quasi uicinos ad-
positos increpant. Saepe uero arrogantes—
—dem quam tenent arrogantiam se fugire osten—)

But other varieties of the literary hand as written in France are seen to be more closely allied to the Roman cursive. The earliest example is found in the papyrus fragments of writings of St Avitus and St Augustine, of the 6th century (*Études paléogr. sur des Papyrus du VI^{me} Siècle*, Geneva, 1866); and other later MSS. by their

diversity of writing show a development independent of the cursive hand of the Merovingian charters. It is among these MSS. that those examples already referred to occur which more nearly resemble the Lombardic type.

Franco-Lombardic Writing, 8th century

propter unitatem salua proprietate na—
non sub una substantia conuenientes, neque—
—itam sed unum eundem filium. Unicum dñm

The uncial and half-uncial hands had also their influence in the evolution of these Merovingian book-hands; and the mixture of so many different forms accounts for the variety to be found in the examples of the 7th and 8th centuries. In the *Notice sur un MS. Mérovingien d'Égypte* (1875) and the *Notice sur un MS. Mérovingien de la Bibl. d'Épinal* (1878), Delisle has given many valuable facsimiles in illustration of the different hands in these two MSS. of the early part of the 8th century. See also *Exempla Codd. Lat.* (tab. 57), and autotypes in *Cat. Anc. MSS.* ii. There was, however, through all this period a general progress towards a settled minuscule writing which only required a master-hand to fix it in a calligraphic form.

Irish Writing.—The early history of the palæography of the British Isles stands apart from that of the Continental schools. It is evident that the civilization and learning which accompanied the establishment of an ancient church in Ireland could not exist without a written literature. The Roman missionaries would certainly in the first place have imported copies of the Gospels and other books, and it cannot be doubted that through intercourse with England the Irish would obtain Continental MSS. in sufficient numbers to serve as models for their scribes. From geographical and political conditions, however, no continuous intimacy with foreign countries was possible; and we are consequently prepared to find a form of writing borrowed in the first instance from a foreign school, but developed under an independent national system.

In Ireland we have an instance how conservative writing may become, and how it will hand on old forms of letters from one generation to another when there is no exterior influence to act upon it. After once obtaining its models, the Irish school of writing was left to work out its own ideas, and continued to follow one direct line for centuries: The English conquest had no effect upon the national handwriting. Both peoples pursued their own course. In MSS. in the Irish language the Irish character of writing was naturally employed; and the liturgical books produced in Irish monasteries by Irish monks were written in the same way. The grants and other deeds of the English settlers were, on the other hand, drawn up by English scribes in their national writing. The Irish handwriting, then, went on in its even uninterrupted course; and its consequent unchanging form makes it so difficult a matter to assign dates to Irish MSS. A stereotyped form of letters is transmitted for so long that there is more risk of giving an early date to a late Irish MS., when written with care, than to one written, under similar conditions, in the English or Continental schools. And nowhere is it more necessary to look for the changes, slight though they be, which may indicate an advance.

The early Irish handwriting is of two classes—the round and the pointed. The round hand is found in the earliest examples: the pointed hand, which also was

developed at an early period, became the general hand of the country, and survives in the native writing of the present day. Of the earliest surviving MSS. written in Ireland none are found to be in pure uncial letters. That uncial MSS. were introduced into the country by the early missionaries can hardly be doubted, if we consider that that character was so commonly employed as a book-hand, and especially for sacred texts. Nor is it impossible that Irish scribes may have practised this hand. The copy of the Gospels in uncials, found in the tomb of St Kilian, and preserved at Würzburg, has been quoted as an instance of Irish uncial. The writing, however, is the ordinary uncial, and bears no marks of Irish nationality (*Exempla*, tab. 58). The most ancient examples are in half-uncial letters, so similar in character to the half-uncial MSS. of Italy and France, noticed above, that there can be no hesitation in deriving the Irish from the Roman writing. We have only to compare the Irish MSS. of the round type with the Continental MSS. to be convinced of the identity of their styles of writing. There are unfortunately no means of ascertaining the exact period when this style of hand was first adopted in Ireland. Among the very earliest surviving examples none bears a fixed date; and it is impossible to accept the traditional ascription of certain of them to particular saints of Ireland, as St Patrick and St Columba. Such traditions are notoriously unstable ground upon which to take up a position. But an examination of certain examples will enable the palæographer to arrive at certain conclusions. In Trinity College, Dublin, is preserved a fragmentary copy of the Gospels (*Nat. MSS. Ireland*, i., pl. ii.) vaguely assigned to a period from the 5th to the 7th century, and written in a round half-uncial hand closely resembling the Continental hand, but bearing the general impress of its Irish origin. This MS. may perhaps be of the early part of the 7th century.

ad ille de in tur res pondar
 4 m i n m o l a t u r e r r e i a m o r a
 e s t & p u e r i i n c u b i c u l o m e c u m

Irish Half-uncial Writing, 7th century.

(ad ille de in tur res pondens [dicit, No] mihi molestus esse, iam ost[um clausum] est et pueri in cubiculo mecum [sunt])

Again, the Psalter (*Nat. MSS. Ireland*, i., pls. iii., iv.) traditionally ascribed to St Columba (*ob.* 597), and perhaps of the 7th century, is a calligraphic specimen of the same kind of writing. The earliest examples of the Continental half-uncial date back, as has been seen above, to the end of the 5th or beginning of the 6th century. Now the likeness between the earliest foreign and Irish MSS. forbids us to assume anything like collateral descent from a common and remote stock. Two different national hands, although derived from the same source, would not independently develop in the same way, and it may accordingly be granted that the point of contact, or the period at which the Irish scribes copied and adopted the Roman half-uncial, was not very long, comparatively, before the date of the now earliest surviving examples. This would take us back at least to the 6th century, in which period there is sufficient evidence of literary activity in Ireland. The beautiful Irish calligraphy, ornamented with designs of marvellous intricacy and brilliant colouring, which is seen in full vigour at the end of the 7th century, indicates no small amount of labour bestowed upon the cultivation of writing as an ornamental art. It is indeed surprising that such excellence was so quickly developed. The Book of Kells has been justly acknowledged as the culminating example of Irish calligraphy (*Nat. MSS. Irel.*,

i., pls. vii.-xvii.; *Pal. Soc.*, pls. 55, 56). The text is written in the large solid half-uncial hand which is again seen in the Gospels of St Chad at Lichfield (*Pal. Soc.*, pls. 20, 21, 35), and, in a smaller form, in the English-written Lindisfarne Gospels (see below). Having arrived at the calligraphic excellence just referred to, the round hand appears to have been soon afterwards superseded, for general use, by the pointed; for the character of the large half-uncial writing of the Gospels of MacRegol, of about the year 800 (*Nat. MSS. Irel.*, i., pls. xxii.-xxiv.; *Pal. Soc.*, pls. 90, 91), shows a very great deterioration from the vigorous writing of the Book of Kells, indicative of want of practice.

Traces of the existence of the pointed hand are early. It is found in a fully developed stage in the Book of Kells itself (*Pal. Soc.*, pl. 88). This form of writing, which may be termed the cursive hand of Ireland, differs in its origin from the national cursive hands of the Continent. In the latter the old Roman cursive has been shown to be the foundation. The Irish pointed hand, on the contrary, had nothing to do with the Roman cursive, but was simply a modification of the round hand, using the same forms of letters, but subjecting them to a lateral compression and drawing their limbs into points or hair-lines. As this process is found developed in the Book of Kells, its beginning may be fairly assigned to as early a time as the first half of the 7th century; but for positive date there is the same uncertainty as in regard to the first beginning of the round hand. The Book of Dimma (*Nat. MSS. Irel.*, i., pls. xviii., xix.) has been attributed to a scribe of about 650 A.D.; but it appears rather to be of the 8th century, if we may judge by the analogy of English MSS. written in a similar hand. It is not in fact until we reach the period of the Book of Armagh (*Nat. MSS. Irel.*, pls. xxv.-xxix.), a MS. containing books of the New Testament and other matter, and written by Ferdomnach, a scribe who died in the year 844, that we are on safe ground. Here is clearly a pointed hand of the early part of the 9th century, very similar to the English pointed hand of Mercian charters of the same time. The MS. of the Gospels of MacDurnan, in the Lambeth Library (*Nat. MSS. Irel.*, i., pls. xxx., xxxi.) is an example of writing of the end of the 9th or beginning of the 10th century, showing a tendency to become more narrow and cramped. But coming down to the MS. of the 11th or 12th centuries we find a change. The pointed hand by this time has become moulded into the angular and stereotyped form peculiar to Irish MSS. of the later Middle Ages. From the 12th to the 15th centuries there is a very gradual change. Indeed, a carefully written MS. of late date may very well pass for an example older by a century or more. Later forms must be detected among the fairly written characters. A book of hymns of the 11th or 12th century (*Nat. MSS. Irel.*, i., pls. xxxii.-xxxvi.) may be referred to as a good typical specimen of the Irish hand of that period; and the Gospels of Mælbrighte, of 1138 A.D. (*Nat. MSS. Irel.*, i., pls. xl.-xlii.; *Pal. Soc.*, pl. 212), as a calligraphic one.

In Irish MSS. of the later period, the ink is black, and the vellum, as a general rule, is coarse and discoloured, a defect which may be attributed to inexperience in the art of preparing the skins and to the effects of climate.

When a school of writing attained to the perfection which marked that of Ireland at an early date, so far in advance of other countries, it naturally followed that its influence should be felt beyond its own borders. How the influence of the Irish school asserted itself in England will be presently discussed. But on the Continent also Irish monks carried their civilizing power into different countries, and continued their native style of writing in the monasteries which they founded. At such centres as Luxeuil in

France, Würzburg in Germany, St Gall in Switzerland, and Bobbio in Italy, they were as busy in the production of MSS. as they had been at home. At first such MSS. were no doubt as distinctly Irish in their character as if written in Ireland itself; but, after a time, as the bonds of connexion with that country were weakened, the form of writing would become rather traditional, and lose the elasticity of a native hand. As the national styles also which were practised around them became more perfected, the writing of the Irish houses would in turn be reacted on; and it is thus that the later MSS. produced in those houses can be distinguished. Archaic forms are traditionally retained, but the spirit of the hand dies and the writing becomes merely imitative.

English Writing.—In England there were two sources whence a national hand could be derived. From St Columba's foundation in Iona the Irish monks established monasteries in the northern parts of Britain; and in the year 635 the Irish missionary Aidan founded the see of Lindisfarne or Holy Isle, where there was established a school of writing destined to become famous. In the south of England the Roman missionaries had also brought into the country their own style of writing direct from Rome, and taught it in the newly founded monasteries. But their writing never became a national hand. Such a MS. as the Canterbury Psalter in the Cottonian Library (*Pal. Soc.*, pl. 18) shows what could be done by English scribes in imitation of Roman uncials; and the existence of so few early charters in the same letters (*Facs. of Anc. Charters*, pt. i., Nos. 1, 2, 7), among the large number which have survived, goes to prove how limited was the influence of that form of writing. On the other hand, the Irish style made progress throughout England, and was adopted as the national hand, developing in course of time certain local peculiarities, and lasting as a distinct form of writing down to the time of the Norman Conquest. But, while English scribes at first copied their Irish models with faithful exactness, they soon learned to give to their writing the stamp of a national character, and imparted to it the elegance and strength which individualized the English hand for many centuries to come.

As in Ireland so here we have to follow the course of the round hand as distinct from the pointed character. The earliest and most beautiful MS. of the former class is the Lindisfarne Gospels or "Durham Book" in the Cottonian Library (*Pal. Soc.*, pls. 3-6, 22; *Cat. Anc. MSS.*, pt. ii., pls. 8-11), said to have been written by Eadfrith, bishop of Lindisfarne, about the year 700. The text is in very exactly formed half-uncials, differing but slightly from the same characters in Irish MSS., and is glossed in the Northumbrian dialect by Aldred, a writer of the 10th century.

mc heofna
regnum caelorum
Beati mites quoniam
ipsi possidebunt

Lindisfarne Gospels, circ. 700 A.D.

(regnum caelorum. Beati mites quoniam ipsi possidebunt.
ric heofna eadge bidon ða milde forðon ða agnagað.)

MSS. in the same solid half-uncial hand are still to be seen in the Chapter Library of Durham, this style of writing having been practised more especially in the north of England. But in addition to this calligraphic book-writing, there was also a lighter form of the round letters

which was used for less sumptuous MSS. or for more ordinary occasions. Specimens of this hand are found in the Durham Cassiodorus (*Pal. Soc.*, pl. 164), in the Canterbury Gospels (*Pal. Soc.*, pl. 7; *Cat. Anc. MSS.*, pt. ii., pls. 17, 18), the Epinal Glossary (*E. Eng. Text. Soc.*), and in a few charters (*Facs. Anc. Charters*, pt. i., 15; ii., 2, 3; *Pal. Soc.*, 10), one of which, of 778 A.D., written in Wessex, is interesting as showing the extension of the round hand to the southern parts of England. The examples here enumerated are of the 8th and 9th centuries,—the earlier ones being written in a free natural hand, and those of later date bearing evidence of decadence. Indeed the round hand was being rapidly displaced by the more convenient pointed hand, which was in full use in England in the middle of the 8th century. How late, however, the more calligraphic round hand could be continued under favouring circumstances is seen in the Liber Vitae or list of benefactors of Durham (*Cat. Anc. MSS.*, pt. ii., pl. 25; *Pal. Soc.*, pl. 238), the writing of which would, from its beautiful execution, be taken for that of the 8th century, did not internal evidence prove it to be of about the year 840.

The pointed hand ran its course through the 8th, 9th, and 10th centuries, until English writing came under the influence of the foreign minuscule. The leading characteristics of this hand in the 8th century are regularity and breadth in the formation of the letters and a calligraphic contrast of heavy and light strokes—the hand being then at its best. In the 9th century there is greater lateral compression, although regularity and correct formation are maintained. But in the 10th century there are signs of decadence. New forms are introduced, and there is a disposition to be imitative. A test letter of this latter century is found in the letter *a* with obliquely cut top, *a*.

The course of the progressive changes in the pointed hand may be followed in the *Facsimiles of Ancient Charters in the British Museum* and in the *Facsimiles of Anglo-Saxon MSS.* of the Rolls Series. The charters reproduced in these works have survived in sufficient numbers to enable us not only to form a fairly accurate knowledge of the criteria of their age, but also to recognize local peculiarities of writing. The Mercian scribes appear to have been very excellent penmen, writing a very graceful hand with much delicate play in the strokes. On the other hand the writing of Wessex was heavier and more straggling, and is in such strong contrast to the Mercian hand that its examples may be easily detected with a little practice. Turning to books in which the pointed hand was employed, a very beautiful specimen, of the 8th century, is a copy of Bede's *Ecclesiastical History* in the University Library at Cambridge (*Pal. Soc.*, pls. 139, 140), which has in a marked degree that breadth of style which has been referred to. Not much later is another copy of the same work in the Cottonian Library (*Pal. Soc.*, pl. 141; *Cat. Anc. MSS.*, pt. ii., pl. 19), from which the following facsimile is taken.

tus sui temporis gerebat
venerabilis oðilunald. qui multis
annis in monasterio quod dicitur Inhyr

English Pointed Minuscules, 8th century.

(tus sui tempora gerebat.
Vir venerabilis oðilunald, qui multis
annis in monasterio quod dicitur Inhyr—)

For an example of the beginning of the 9th century, a MS. of miscellanea, of 811-814 A.D., also in the Cottonian Library, may be referred to (*Pal. Soc.*, pl. 165; *Cat. Anc.*

MSS., pt. ii., pl. 24); and a very interesting MS. written in the Wessex style is the Digby MS. 63 of the middle of the century (*Pal. Soc.*, pl. 168). As seen in the charters, the pointed writing of the 10th century assumes generally a larger size, and is rather more artificial and calligraphic. A very beautiful example of the book-hand of this period is found in the volume known as the Durham Ritual (*Pal. Soc.*, pl. 240), which, owing to the care bestowed on the writing and the archaism of the style, might at first sight pass for a MS. of higher antiquity, were not the characteristics of its period evident in the angularity of certain letters.

In the latter part of the 10th century the foreign set minuscule hand began to make its way into England, consequent on increased intercourse with the Continent and political changes which followed. In the charters we find the foreign and native hands on the same page:—the body of the document, in Latin, in Caroline minuscules; the boundaries of the land conveyed, in the English hand. The same practice was followed in books. The charter (in book form) of King Eadgar to New Minster, Winchester, 966 A.D. (*Pal. Soc.*, pls. 46, 47), the Benedictional of Bishop Æthelwold of Winchester (pls. 142, 144) before 984 A.D., and the MS. of the Office of the Cross, 1012–20 A.D. (pl. 60), also written in Winchester, are all examples of the use of the foreign minuscule for Latin. The change also which the national hand underwent at this period may certainly be attributed to this foreign influence. The pointed hand, strictly so-called, is replaced by a rounder or rather square character, with lengthened strokes above and below the line.

manan heper hīr mæga. sceard freonda ge
pylled on polc fæde beþlagen æt sēge. þīr sunu
forlæt. on wælstowe wundum forgrunden.

English Minuscules, 11th century.

(manan he was his mæga. sceard freonda ge
fyllen on folcstede beþlagen æt sēge. and his sunu
forlæt. on wælstowe wundum forgrunden.)

This style of writing becomes the ordinary English hand down to the time of the Norman Conquest. That event extinguished the national hand for official purposes—it disappears from charters; and the already established use of the Caroline minuscule in Latin MSS. completed its exclusion as the handwriting of the learned. It cannot, however, be doubted that it still lingered in those parts of the country where foreign influence did not at once penetrate, and that Englishmen still continued to write their own language in their own style of writing. But that the earlier distinctive national hand was soon overpowered by foreign teaching is evident in English MSS. of the 12th century, the writing of which is of the foreign type, although the English letter thorn, þ, survived and continued in use down to the 15th century, when it was transformed to y.

The Caroline Reform.—The revival of learning under Charlemagne naturally led to a reform in handwriting. An ordinance of the year 789 required the revision of church books; and a more correct orthography and style of writing was the consequence. The abbey of St Martin of Tours was the principal centre from whence the reformation of the book-hand spread. Here, from the year 796 to 804, Alcuin of York presided as abbot; and it was under his direction that the Caroline minuscule writing took the simple and graceful form which was gradually adopted to the exclusion of all other hands. In carrying out this reformation we may well assume that Alcuin brought to

bear the results of the training which he had received in his youth in the English school of writing, which had attained to such proficiency, and that he was also beneficially influenced by the fine examples of the Lombard school which he had seen in Italy. In the new Caroline minuscule all the uncouthness of the later Merovingian hand disappears, and the simpler forms of many of the letters found in the old Roman minuscule hand are adopted. The character of Caroline writing through the 9th and early part of the 10th century is one of general uniformity, with a contrast of light and heavy strokes; the limbs of tall letters being clubbed or thickened at the head by pressure on the pen. As to characteristic letters—the *a*, following the old type, is, in the 9th century, still frequently open, in the form of *u*; the bows of *g* are open, the letter somewhat resembling the numeral 3; and there is no turning of the ends of letters, as *m* and *n*.

accipere mariam coniugem tuam quod
enim ex ea nascetur de spiritu sancto est. Pariet
autem filium et uocabis nomen eius iesum

Caroline Minuscules, 9th century.

(accipere mariam coniugem tuam quod
enim ex ea nascetur de spiritu sancto est. Pariet
autem filium et uocabis nomen eius iesum)

In the 10th century the clubbing of the tall letters becomes less pronounced, and the writing generally assumes, so to say, a thinner appearance. But a great change is noticeable in the writing of the 11th century. By this time the Caroline minuscule may be said to have put off its archaic form and to develop into the more modern character of small letter. It takes a more finished and accurate and more upright form, the individual letters being drawn with much exactness, and generally on a rather larger scale than before. This style continues to improve, and is reduced to a still more exact form of calligraphy in the 12th century, which for absolute beauty of writing is unsurpassed. In England especially, the writing of this century is particularly fine

culos cū arumulis suis adoluit super
altare. ut culū cū pelle & carnibus &
fimo cremas. extra castra. sic precepit dñs.

English Minuscules, 12th century.

(—culos cum arumulis suis adoluit super
altare nitulum cum pelle et carnibus et
fimo cremans extra castra sicut preceperat dominus.)

As, however, the demand for written works increased, the fine round hand of the 12th century could not be maintained. Economy of material became necessary, and a smaller hand with more frequent contractions was the result. The larger and more distinct writing of the 11th and 12th centuries is now replaced by a more cramped though still distinct hand, in which the letters are more linked together by connecting strokes, and are more laterally compressed. This style of writing is characteristic of the 13th century. But, while the book-hand of this period is a great advance upon that of a hundred years earlier, there is no tendency to a cursive style. Every letter is clearly formed, and generally on the old shapes. The particular letters which show weakness are those made of a succession of vertical strokes, as *m*, *n*, *u*. The new method of connecting these strokes, by turning the ends and running on, made the distinction of such letters

difficult, as, for example, in the word *minimi*. The ambiguity thus arising was partly obviated by the use of a small oblique stroke over the letter *i*, which, to mark the double letter, had been introduced as early as the 11th century. The dot on the letter came into fashion in the 14th century.

*Eligite hodie quod placeat cui servire potissimum
debeat. Utrum diis quibus seruierunt patres uestri in
mesopotamia, an diis amorcorum in quorum terra
habitatis. Ego autem et domus mea seruimus domino. Respon-
ditque populus et ait, Absit a nobis ut relinquamus dominum*

Minuscule Writing, 13th century.

(Eligite hodie quod placeat cui servire potissimum
debeat. Utrum diis quibus seruierunt patres uestri in
mesopotamia, an diis amorcorum in quorum terra
habitatis. Ego autem et domus mea seruimus domino. Respon-
ditque populus et ait, Absit a nobis ut relinquamus dominum)

In MSS. of the 14th century minuscule writing becomes slacker, and the consistency of formation of letters falters. There is a tendency to write more cursively and without raising the pen, as may be seen in the form of the letter *a*, of which the characteristic shape at this time is *a*, with both bows closed, in contrast with the earlier *a*. In this century, however, the hand still remains fairly stiff and upright. In the 15th century it becomes very angular and more and more cursive, but is at first kept within bounds. In the course of the century, however, it grows more slack and deformed, and the letters become continually more cursive and misshapen. An exception, however, to this disintegration of minuscule writing in the later centuries is to be observed in church books. In these the old set hand of the 12th and 13th centuries was imitated and continued to be the liturgical style of writing.

It is impossible to describe within limited space, and without the aid of illustrations, all the varieties of hand-writing which were developed in the different countries of western Europe, where the Caroline minuscule was finally adopted to the exclusion of the earlier national hands. In each country, however, it acquired, in a greater or less degree, an individual national stamp which can generally be recognized and which serves to distinguish MSS. written in different localities. A broad line of distinction may be drawn between the writing of northern and southern Europe from the 12th to the 15th century. In the earlier part of this period the MSS. of England, northern France, and the Netherlands are closely connected. Indeed, in the 12th and 13th centuries it is not always easy to decide as to which of the three countries a particular MS. may belong. As a rule, perhaps, English MSS. are written with more sense of gracefulness; those of the Netherlands in darker ink. From the latter part of the 13th century, however, national character begins to assert itself more distinctly. In southern Europe the influence of the Italian school of writing is manifest in the MSS. of the south of France in the 13th and 14th centuries, and also, though later, in those of Spain. That elegant roundness of letter which the Italian scribes seem to have inherited from the bold characters of the early papal chancery, and more recently from Lombardic models, was generally adopted in the book-hand of those districts. It is especially noticeable in calligraphic specimens, as in church books,—the writing of Spanish MSS. in this style being distinguishable by the blackness of the ink. The mediæval minuscule writing of Germany stands apart. It never attained to the beauty of the hands of either the north or the south which have been just noticed; and from its ruggedness and slow development German MSS. have the appearance of being older than they really are. The writing has also very commonly a certain slope in the letters which con-

pires unfavourably with the upright and elegant hands of other countries. In western Europe generally the minuscule hand thus nationalized ran its course down to the time of the invention of printing, when the so-called black letter, or set hand of the 15th century in Germany and other countries, furnished models for the types. But in Italy, with the revival of learning, a more refined taste set in in the production of MSS., and scribes went back to an earlier time in search of a better standard of writing. Hence, in the first quarter of the 15th century, MSS. written on the lines of the Italian hand of the early 12th century begin to appear, and become continually more numerous. This revived hand was brought to perfection soon after the middle of the century, just at the right moment to be adopted by the early Italian printers, and to be perpetuated by them in their types.

It must also not be forgotten that by the side of the book-hand of the later Middle Ages there was the cursive hand of every day use. This is represented in abundance in the large mass of charters and legal or domestic documents which remains. Some notice has already been taken of the development of the national cursive hands in the earliest times. From the 12th century downwards these hands settled into well-defined and distinct styles peculiar to different countries, and passed through systematic changes which can be recognized as characteristic of particular periods. But, while the cursive hand thus followed out its own course, it was still subject to the same laws of change which governed the book-hand; and the letters of the two styles did not differ at any period in their organic formation. Confining our attention to the charter hand, or court hand, practised in England, a few specimens may be taken to show the principal changes which it developed. In the 12th century the official hand which had been introduced after the Norman Conquest is characterized by exaggeration in the strokes above and below the line, a legacy of the old Roman cursive, as already noted. There is also a tendency to form the tops of tall vertical strokes, as in *b*, *h*, *l*, with a notch or cleft. The letters are well made and vigorous, though often rugged.

*z Gynffr. z Omnis fidelis suis francis z
Regine uxoris mee z Eustachii filii
mei dedi z concessi ecclesie Beate Marie*

Charter of Stephen, 1136-39 A.D.

(et ministris et omnibus fidelibus suis Francis et—
Regine uxoris mee et Eustachii filii—
mei dedi et concessi ecclesie Beate Marie)

As the century advances, the long limbs are brought into better proportion; and early in the 13th century a very delicate fine-stroked hand comes into use, the cleaving of the tops being now a regular system, and the branches formed by the cleft falling in a curve on either side. This style remains the writing of the reigns of John and Henry III.

*Omnia presentia litteras inspecturis salutem. Noueritis quod—
ford et Essexie et Constabularium Anglie et Willelmum de Fortibus
ad iurandum in animam nostram in presencia nostra de pace*

Charter of Henry III., 1259 A.D.

(univcrsis presentes litteras inspecturis salutem. Noueritis quod—
—ford et Essexie et Constabularium Anglie et Willelmum de Fortibus
—ad iurandum in animam nostram in presencia nostra de pace)

Towards the latter part of the 13th century the letters grow rounder; there is generally more contrast of light and heavy strokes; and the cleft tops begin, as it were, to shed the branch on the left.

More cum p'm in mora que vocatur Inkelesmore continet
se in longitudine per medium more illius ab uno capite
Abbas et Conuentus aliquando tenuerunt et quam prefatus Co

Charter of Edward I., 1303 A.D.

More cum pertinentiis in mora que vocatur Inkelesmore continet
—se in longitudine per medium more illius ab uno capite—
Abbas et Conuentus aliquando tenuerunt et quam prefatus Co—

In the 14th century the changes thus introduced make further progress, and the round letters and single-branched vertical strokes become normal through the first half of the century. Then, however, the regular formation begins to give way and angularity sets in. Thus in the reign of Richard II. we have a hand presenting a mixture of round and angular elements—the letters retain their breadth but lose their curves. Hence, by further decadence, results the angular hand of the 15th century, at first compact, but afterwards straggling and ill-formed.

And fully to be endid payinge yerely the seid
Successours in hand halfe yere afore that is
next sayinge xxij. s. iijij. d. by evne porcions.

English Charter, 1457 A.D.

(and fully to be endid, payinge yerely the seid—
successours in hand halfe yere afore that is—
next sayinge xxij. s. iijij. d. by evne porcions.)

Palimpsests.—A class of MSS. must be briefly noticed which, on account of the valuable texts which many of them have yielded, have a particular interest. These are the palimpsests. The custom of removing writing from the surface of the material on which it was inscribed, and thus preparing that surface for the reception of another text, has been practised from early times. The term palimpsest is used by Catullus, apparently with reference to papyrus; by Cicero, in a passage wherein he is evidently speaking of waxen tablets; and by Plutarch, when he narrates that Plato compared Dionysius to a βιβλίον παλίνηστον, in that his tyrant nature, being δυσέκπλητος, showed itself like the imperfectly erased writing of a palimpsest MS. In this passage, reference is clearly made to the washing off of writing from papyrus. The word παλίνηστος can only in its first use have been applied to MSS. which were actually scraped or rubbed, and which were, therefore, composed of a material of sufficient strength to bear the process. In the first instance, then, it might be applied to waxen tablets; secondly, to vellum books. There are still to be seen, among the surviving waxen tablets, some which contain traces of an earlier writing under a fresh layer of wax. Papyrus could not be scraped or rubbed; the writing was washed from it with the sponge. This, however, could not be so thoroughly done as to leave a perfectly clean surface, and the material was accordingly only used a second time for documents of an ephemeral or common nature. To apply, therefore, the title of palimpsest to a MS. of this substance was not strictly correct; the fact that it was so applied proves that the term was in common use.

In the early period of palimpsests, vellum MSS. were also washed. The ink of the earlier centuries was easily removed with the sponge, and at the moment when this was done it may be supposed that the pages presented a clean surface. In course of time, however, by atmospheric action or other chemical causes, the original writing would to some extent reappear; and it is thus that so many of the capital and uncial palimpsests have been successfully deciphered. In the later Middle Ages the knife was used; the surface of the vellum was scraped away and the writing with it. The reading of the later examples is therefore very difficult or altogether impossible. Besides actual rasure, various recipes for effacing the writing have been found,—such as, to soften the surface with milk and meal, and then to rub with pumice. In the case of such a process being used, total obliteration must almost inevitably have been the result. To intensify the traces of the original writing, when such exist, various chemical reagents have been tried with

more or less success. The old method of smearing the vellum with tincture of gail restored the writing, but did irreparable damage by blackening the surface, and, as the stain grew darker in course of time, by rendering the text altogether illegible. Of modern reagents the most harmless appears to be hydrosulphuric acid of ammonia; but this also must be used with caution, and should be washed off when it has done its work.

The primary cause of the destruction of MSS. by wilful obliteration was, it need hardly be said, the dearth of material. At certain periods, from political or social changes, the market was interfered with, and production or importation failed. In the case of Greek MSS., so great was the consumption of old books, for the sake of the material, that a synodal decree of the year 691 forbade the destruction of MSS. of the Scriptures or the church fathers—imperfect or injured volumes excepted. The decline of the vellum trade also on the introduction of paper, as already noticed above, caused a scarcity which was only to be made good by recourse to material already once used. Vast destruction of the broad quartos of the early centuries of our era took place in the period which followed the fall of the Roman empire. The most valuable Latin palimpsests are accordingly found in the volumes which were remade from the 7th to the 9th centuries, a period during which the large volumes referred to must have been still fairly numerous. Late Latin palimpsests rarely yield anything of value: often the first writing precedes the later one by only a century or two; and sometimes both hands are of the same age. In the earlier examples, many of the original texts were sacrificed to make room for patristic literature or grammatical works. In many instances MSS. of the classical writers have been thus destroyed; and the sacred text itself has not always been spared. On the other hand, there are instances of classical texts being written over Biblical MSS.; but these are of late date. It has been remarked that no entire work has been found in any instance in the original text of a palimpsest, but that portions of many works have been taken to make up a single volume. These facts, however, go rather to prove, not so much that only imperfect works were put under contribution, as that scribes were indiscriminate in selection of material.

An enumeration of the different palimpsests of value is not here possible (see Wattenbach, *Schriftwesen*, pp. 252–257); but a few may be mentioned of which facsimiles are accessible. The MS. known as the Codex Ephraemi, containing portions of the Old and New Testaments in Greek, attributed to the 5th century, is covered with works of Ephraem Syrus in a hand of the 12th century (ed. Tischendorf, 1843, 1845). Among the Syriac MSS. obtained from the Nitrian desert in Egypt, and now deposited in the British Museum, some important Greek texts have been recovered. A volume containing a work of Severus of Antioch of the beginning of the 9th century is written on palimpsest leaves taken from MSS. of the *Iliad* of Homer and the Gospel of St Luke, both of the 6th century (*Cat. Anc. MSS.*, i., pls. 9, 10), and the *Elements* of Euclid of the 7th or 8th century. To the same collection belongs the double palimpsest, in which a text of St John Chrysostom, in Syriac, of the 9th or 10th century, covers a Latin grammatical treatise in a cursive hand of the 6th century, which in its turn has displaced the Latin annals of the historian Granius Licinianus, of the 5th century (*Cat. Anc. MSS.*, ii., pls. 1, 2). Among Latin palimpsests also may be noticed those which have been reproduced in the *Exempla* of Zangemeister and Wattenbach. These are—the Ambrosian Plautus, in rustic capitals, of the 4th or 5th century, re-written with portions of the Bible in the 9th century (pl. 6); the Cicero *De Republica* of the Vatican, in uncials, of the 4th century, covered by St Augustine on the Psalms, of the 7th century (pl. 17; *Pal. Soc.*, pl. 160); the Codex Theodosianus of Turin, of the 5th or 6th century (pl. 25); the Fasti Consulares of Verona, of 486 A.D. (pl. 29); and the Arian fragment of the Vatican, of the 5th century (pl. 31). Most of these originally belonged to the monastery of Bobbio, a fact which gives some indication of the great literary wealth of that house. The new photographic processes are particularly well adapted for the reproduction of palimpsests, for the reason that, however faint the subject, it is nearly always intensified in the negative. By using skill and judgment, with a favouring light, photography may be often made a useful agent in the decipherment of obscure palimpsest texts.

Mechanical Arrangement of Writing in MSS.—In the papyrus rolls the text was written in columns, generally narrow, whose length was limited by the width of the material, allowing a margin at top and bottom. In books, if the text did not extend across the page, it was usually written in two columns. A few instances, however, are known of MSS. which have more than two columns of writing in a page. Among them, the Codex Sinaiticus of the Bible has four columns, and the Codex Vaticanus three columns. In the Fulda fragment of an ancient Latin Bible (*Exempla*, 21) the arrangement is one of three columns; and a late instance of the same number occurs in a Latin Bible of the end of the 9th century in the British Museum (*Cat. Anc. MSS.*, ii., pl. 45). Besides the practice of continuous writing without distinction of words, which

will be referred to more fully below, the letters towards the end of a line were, in the earliest MSS., reduced in size and cramped together, and very frequently in Latin MSS. two or more letters were linked or combined in a monogrammatic form, as UR UF (ur, ant). By these devices space was saved and words were less divided between two lines. Combinations survived partially in minuscule MSS. The opening lines of the main divisions of the text, as for example the different books of the Bible, were frequently written in red, for distinction. At first there was no enlargement whatever of letters in any part of the text, but still at an early period the first letter of each page was made larger than the rest. Rubrics and titles and colophons were at first written in the same character as the text; afterwards, when the admixture of different kinds of writing was allowed, capitals and uncials were used at discretion. In papyri it appears to have been the practice to write the name of the work at the end only. Running titles or head-lines are found in some of the earliest Latin MSS. in the same characters as the text, but of a small size. Quotations were usually indicated by ticks or arrow-heads in the margin, serving the purpose of the modern inverted commas. Sometimes the quoted words were arranged as a sub-paragraph or indented passage. In commentaries of later date, the quotations from the work commented upon were often written in a different style from the text of the commentary itself.

In MSS., both Greek and Latin, of the earlier centuries the writing runs on continuously without breaking up into distinct words. To this system there are, however, a few partial exceptions, in some of the very earliest examples. For instance, the Εὐδῶξου τεχνή, written on papyrus in the 2d century B.C., has a certain amount of separation of words, and in the fragments of the poem on the battle of Actium which were recovered at Herculaneum the words are marked off with points, monosyllabic or short prepositions and conjunctions, however, being joined to the words which immediately follow them—a system which we find in practice at a later time. In the early vellum MSS. there is no such separation; and unless there is a pause in the sense, at which a small space may be left, the line of letters has no break whatever. In Greek MSS., indeed, a system of distinct separation of words was never thoroughly worked out, even as late as the 15th century. The continuous writing of the uncial MSS. was carried on in the minuscules; and, although, in the latter, a certain degree of separation is noticeable as early as the 10th century, yet a large proportion of words remain linked together or wrongly divided.

In the case of Latin uncial MSS., when the latter part of the 7th century is reached, there is more evidence of separation, although no regular system is followed. Concurrently the same process is observed in minuscule MSS., in which a partial separation goes on in an uncertain and hesitating manner down to the time of the Caroline reform. In early Irish and English MSS., however, it may be observed that separation is more consistently followed. In MSS. of the 9th and 10th centuries the long words are separated, but short prepositions and conjunctions are joined to the next following word. It was not until the 11th century that these smaller words were finally detached and stood apart.

Punctuation.—From the use of continuous writing naturally arose in the first place the necessity for the breaking up of the text into paragraphs and sentences, and afterwards the introduction of marks of punctuation. In the Greek works on papyrus before the Christian era certain marks of division are found. In the Harris Homer (*Cat. Anc. MSS.*, i., pl. 1) a wedge-shaped sign > is inserted between the beginnings of the lines to mark a new passage. In the prose works of Hyperides a pause in the sense (unless it occurs at the end of a line) is indicated by a short blank space being left in the line and by a horizontal stroke being drawn under the first letter of the line in which the pause occurs. In a few instances, in the space left to mark the pause a full point or slight oblique stroke is added high in the line. As large letters were unknown, this system of dividing the paragraphs was calculated to sacrifice the least amount of space, as the rest of the line, after the pause, was utilized for the beginning of the next paragraph. In the early vellum MSS. the same plan is followed, with the more general use of the full point, which is placed on a level with either the top or the middle of the letters; and the marginal dividing signs are of different patterns. When large letters were introduced to mark the paragraphs, had they been invariably placed at the beginning of their respective paragraphs, the latter must of necessity have each begun a new line, unless the lines had been wide enough apart to leave room for the insertion of the large letters. This latter arrangement would, however, have entailed considerable loss of space; and the device was accordingly invented, in cases where the paragraph began in the middle of a line, to place the large letter as the first letter of the next line, even though it might there occur in the middle of a word, and, as it was placed in the margin, it did not affect the normal space between the lines. It need hardly be said that, if the paragraph commenced at the beginning of a line, the large letter took its natural place as the initial. The use of these large or initial letters led to the abolition of the paragraph

marks. As early as the 5th century there is evidence in the case of the Codex Alexandrinus that the marks were losing their meaning in the eyes of the scribes; for in that MS. they are frequently placed in anomalous positions, particularly over the initial letters of the different books, having been evidently considered as mere ornaments. The position of the initial as the leading letter of the second line of a paragraph beginning in the middle of a line was maintained in the Greek minuscule MSS. into the 15th century. The practice of continuous writing also led to the arrangement of the text of the Bible and some other works in short sentences, according to the sense, which were called *στίχοι*, as will be noticed presently; but other minor methods were followed to prevent the ambiguity which would occasionally arise. In even the earliest Greek uncial MSS. an apostrophe was often inserted above the line between two words, as a dividing mark, as, for instance, in the Codex Alexandrinus, ΟΤΝ ΟΥΚ; and it was specially used after words ending in κ, χ, ξ, ρ, and after proper names which have not a Greek termination. It was even placed, apparently from false analogy, between two consonants in the middle of a word, as ΗΝΕΤ'ΚΕΝ. Some of these uses of the apostrophe survived in minuscule MSS. A mark also, resembling an accent or short horizontal stroke, was employed to indicate words consisting of a single letter, as Η, which as a word has so many different meanings.

In the earliest surviving Latin volumes there was no punctuation by the first hand, but in the later uncial MSS. the full point, in various positions, was introduced—being placed on a level with either the bottom, middle, or top of the letters, the two latter positions being the most common. In minuscule MSS. the full point, on the line or high, was first used; then the comma and semicolon, and the inverted semicolon (?), whose power was rather stronger than that of the comma. In Irish and early English MSS. the common mark of punctuation was the full point. As a final stop one or more points with a comma . . , were frequently used.

Stichometry.—While dealing with the subject of punctuation, the system of stichometry, or division of the texts into *στίχοι*, *versus*, or lines of a certain length may be referred to.¹ It was the custom of the Greeks and Romans to estimate the length of their literary works by lines. In poetical works the number of verses was computed; in prose works a standard line had to be taken, for no two scribes would naturally write lines of the same length. This standard was a medium Homeric line, and it appears to have consisted, on an average, of 34 to 38 letters, or 15 to 16 syllables. The lines of any work, so measured, were called *στίχοι* or *ἐπη*. The practice of thus computing the length of a work can be traced back to the 4th century B.C. in the boast of Theopompus that he had written more *ἐπη* than any other writer. The number of such *στίχοι* or *ἐπη* contained in a papyrus roll was recorded at the end with the title of the work; and at the end of a large work extending to several rolls the grand total was given. The use of such a stichometrical arrangement was in the first place for literary reference. The numeration of the *στίχοι* was no doubt at an early period regularly noted in the margin, just as lines of poetical works or verses in the Bible are numbered in our printed books. In a Greek Biblical MS. at Milan they are numbered at the end of every hundred, and the verses in the Banke's Homer are counted in the same way. But the system was also of practical use in calculating the pay of the scribes and in arranging the market value of a MS. When once a standard copy of a work had been written in the normal lines, the scribes of all subsequent copies had only to record the number of *στίχοι* without keeping to the prototype. When we find therefore at the end of the different books of a Bible that they severally contain so many *στίχοι* or *versus*, it is this stichometrical arrangement which is referred to. Callimachus, when he drew up his catalogue of the Alexandrian libraries in the 3d century B.C., registered the total of the *στίχοι* in each work. Although he is generally lauded for thus carefully recording the numbers and setting an example to all who should follow him, it has been suggested that this very act was the cause of their general disappearance from MSS. For, when his *πινakes* were published, scribes evidently thought it was needless to repeat what could be found there; and thus it is that so few MSS. have descended to us which are marked in this way.

There was also in use in Biblical MSS. another arrangement. This was the division of the text into short sentences or lines, according to the sense, chiefly with a view to a better understanding of the meaning and a better delivery in public reading. The Psalms, Proverbs, and other poetical books were anciently thus written, and hence received the title of *βιβλῶν στιχηραῖς*, or *στιχηραῖ*; and it was on the same plan that St. Jerome wrote, first the books of the prophets, and subsequently all the Bible of his version, *per cola et commata* "quod in Demosthene et Tullio solet fieri." In the Greek Testament also Euthalius, in the 5th century, introduced the method of writing *στίχνηδόν*, as he termed it, into the Pauline and Catholic Epistles, and the Acts. The surviving MSS. which contain the text written in short sentences *στίχνηδόν*

¹ See the article by C. Graux in *Revue de Philologie*, 1878, vol. ii., p. 97.

the diversity of the latter that the rhythmical sentences or lines of sense were differently calculated by different writers; but the original arrangement of St Jerome is thought to be represented in the Codex Amiatinus at Florence, and that of Euthalius in the Codex Claromontanus at Paris. With regard to St Jerome's reference to the division *per cola et commata* of the rhetorical works of Demosthenes and Cicero, it should be noticed that there are still in existence MSS. of works of the latter in which the text is thus written, one of them being a volume of the *Tusculans* and the *De Senectute* in the Bibliothèque Nationale at Paris. The same arrangement of the text of the orations of Demosthenes is also mentioned by the rhetoricians of the 5th and subsequent centuries. It is a curious circumstance also that the text of the only two surviving documents of the Roman chancery addressed to Egyptian officials in the 5th century (see above) is written in lines of various lengths, apparently for rhetorical convenience.

Corrections.—For obliteration or removing pen strokes from the surface of the material the sponge was used in ancient times. While the writing was still fresh, the scribe could easily wash off the ink by this means; and for a fragile material, such as papyrus, he could well use no other. On vellum he might use sponge or knife. But after a MS. had left his hands it would undergo revision at the hands of a corrector, who had to deal with the text in a different manner. He could no longer conveniently apply the sponge. On hard material he might still use the knife to erase letters or words or sentences. But he could also use his pen for such purposes. Thus we find that a very early system of indicating erasure was the placing of dots or minute strokes above the letters to be thus "expunged." The same marks were also (and generally, at later periods) placed under the letters; in rare instances they stood inside them. It need scarcely be said that letters were also struck out with strokes of the pen or altered into others, and that letters and words were interlined. A long sentence, however, which could not be admitted between the lines, was entered in the margin, and its place in the text indicated by corresponding reference marks, such as *ad. h.* — *hic deest*, *hoc supra*, &c.

Tachygraphy.—The systems of tachygraphy which were followed by both Greeks and Romans had an effect upon the forms of contraction found in mediæval MSS. The subject of Greek tachygraphy has lately received a good deal of attention on account of recent discoveries. How far back the practice of shorthand writing existed among the Greeks there is nothing to show; for, although certain words of Diogenes Laertius have been taken to imply that Xenophon wrote shorthand notes (*ὑποσημειωσάμενος*) of the lectures of Socrates, yet a similar expression in another passage, which will not bear this meaning, renders it hardly possible that tachygraphy is referred to. The first undoubted mention of a Greek shorthand writer occurs in 195 A.D., in a letter of Flavius Philostratus. But unfortunately there appear to be no very ancient specimens of Greek tachygraphy in existence; for it is denied that certain notes and inscriptions in the papyri dating from the 2d century B.C., which have been put forward as such, are in shorthand at all. The extant examples date only from the 10th century. First stands the Paris MS. of Hermogenes, with some tachygraphic writing of that period, of which Montfaucon (*Pal. Gr.*, p. 351) gives some account, and accompanies his description with a table of forms which, as he tells us, he deciphered with incredible labour. Next, the Add. MS. 18231 in the British Museum contains some marginal notes in shorthand, of 972 A.D. (Wattenb., *Script. Græc. Specim.*, tab. 19). But the largest amount of material is found in the Vatican MS. 1809, a volume in which as many as forty-seven pages are covered with tachygraphic writing of the 11th century. Mai first published a specimen of it in his *Scriptorum Veterum Nova Collectio*, vol. vi. (1832); and in his *Novæ Patrum Bibliothecæ tom. secundus* (1844) he gave a second, which, in the form of a marginal note, contained a fragment of the book of Enoch. But he did not quote the number of the MS., and it has only lately been found again. The tachygraphic portion of it is now being made the subject of special study by Dr Gittbauer for the Vienna Academy. It contains fragments of the works of St Maximus the Confessor, the confession of St Cyprian of Antioch, and works of the pseudo-Dionysius Areopagita. The writing used in these examples is syllabic, and appears to be a younger form of tachygraphy as distinguished from an older system, the existence of which may be inferred from the occurrence of certain signs or symbols of contraction used in the minuscule MSS. For, while many of the signs thus used correspond with the tachygraphic signs of the above examples, there are others which differ and which have been derived from an earlier source. For a system of tachygraphic contractions had been developing at an earlier period; and its elements have been traced in both cursive and uncial MSS. as far back as the 5th or 6th century. If then we may suppose that the new system of tachygraphy was an invention of the 9th or 10th century, this will account for the occurrence in MSS. of that period of two forms of abbreviation for certain syllables—the one adopted from the old or ordinary system, and the other being the neo-stenographic symbol. As to the first origin of Greek tachygraphy, it has been supposed that it grew from a system

of secret writing which was developed from forms of abbreviation, and which the early Christians adopted for their own use.

Evidence of the use of tachygraphy among the Romans is to be found in the writings of authors under the empire. It appears to have been taught in schools, and, among others, the emperor Titus is said to have been skilful in this style of writing. Ennius has been named as the inventor of a large collection of shorthand symbols; but more generally Cicero's freedman M. Tullius Tiro is regarded as the author of these signs, which commonly bear the title of "Notæ Tironianæ." The shorthand writers or notaries were well trained in the use of these notes, and in the early Christian times were largely employed in taking down the words of the bishops of the church which were preached in sermons or spoken in councils, and in recording the acts and lives of martyrs. In the Frankish empire the notes were used in signatures or subscriptions of charters, and later, in the 9th and early 10th centuries, they were adopted by the revisers and annotators of the texts of MSS. Of this period also are several MSS. containing the Psalter in these characters, which it has been suggested were written for practice at a time when a fresh impulse had been given to the use of shorthand in the service of literature. The existence also of volumes containing collections of the Tironian notes, and written at this time, points to a temporary revival. The notes appear to have gone out of general use, however, almost immediately after this, although in isolated cases, such as in subscriptions to charters, they linger as late as the beginning of the 11th century. A few of the forms of the Tironian notes were adopted in mediæval MSS. as symbols of contraction for certain common words, as will be noticed presently.

Contractions.—The use of contractions or abbreviations in MSS. would arise from two causes—first, the natural desire to write as quickly and shortly as possible words of frequent occurrence which could not be misread in a contracted form, and, secondly, the necessity of saving space. The contractions satisfying the first requirement were necessarily limited in number and simple in character, and are such as are found with more or less frequency in the oldest MSS. But the regular system of contracted forms, with the view of getting as much writing as possible into a limited space, was only elaborated in course of time, and was in use in the later centuries of the Middle Ages. Different kinds of literature also were, according to their nature, more or less contracted. From early times abbreviations were used more freely in secular books, and particularly in works in which technical language was employed, such as those on law or grammar or mathematics, than in Biblical MSS. or liturgies. In the Greek fragment of a mathematical treatise of the 7th century, at Milan, there are numerous contractions; and the same is found to be the case in a Latin MS. of the 5th century, the Verona Gaius. With regard to the different systems or styles of contraction, the oldest and simplest is that in which a single letter, or at most two or three letters, represent a whole word. Among Latin classical writers we know that these contractions were common enough, and ancient inscriptions afford plentiful examples. In the waxen tablets also they are found; and they survive in the later papyri of Ravenna, &c., and in law deeds. Next is the system of dropping the final syllable or syllables of a word, or of omitting a letter or syllable or more in the middle,—such omissions being easily supplied from the general sense of the context—e.g., *σχῆμα* = *σχῆματος*, *habuef* = *habuerunt*, *p̄m* = *patrem*. And lastly, there are the arbitrary signs and contractions formed in a special manner or marked by certain figures whereby they may be regularly interpreted.

Traces of a system of contraction are found in some of the early Greek papyri. For example, in the papyrus of the oration of Hyperides for Lycophron, of at least the 1st century B.C., the *nu* of the syllable *ων*, when occurring at the end of a line, is omitted, and its omission marked by a light horizontal stroke above the line of writing; and, as marks of reference to an accidentally omitted line, abbreviated forms of *ἄνω* and *κάτω* are used. In the Banks Homer also the sign $\overline{\omega}$ for *ποινῆς* is placed in the margin to mark the narrative portion of the text. In the ancient Greek Biblical MSS. the contractions are usually confined to the sacred names and titles, and a few words of common occurrence, as $\Theta\varsigma$ = *θεός*, $\overline{\iota\varsigma}$ = *ἰησοῦς*, $\overline{\chi\varsigma}$ = *χριστός*, $\overline{\Pi\alpha}$ = *πνεῦμα*, $\overline{\chi\eta\tau\eta\rho}$ = *σωτήρ*, $\overline{\kappa\varsigma}$ = *κύριος*, $\overline{\text{CT}\rho\text{OC}}$ = *σταυρός*, $\overline{\Pi\eta\rho}$ = *πατήρ*, $\overline{\text{M}\eta\rho}$ = *μήτηρ*, $\overline{\gamma\varsigma}$ = *υἶος*, $\overline{\text{ANOC}}$ = *ἄνθρωπος*, $\overline{\text{O}\rho\text{NOC}}$ = *οὐρανός*, $\overline{\text{K}}$ = *καί*, $\overline{\text{T}}$ = *ταί*, $\overline{\text{N}}$ = *μου*, $\overline{\text{μοι}}$, &c. Final N, especially at the end of a line, was dropped, and its place occupied by the horizontal stroke, as $\overline{\text{TO}}$. This limited system of contraction was observed generally in the uncial Biblical and liturgical MSS. In the mathematical fragment at Milan abbreviations by dropping final syllables, and contracted particles and prepositions, are numerous; and in the palimpsest Homer of the 6th century in the British Museum final syllables are occasionally omitted. Such omissions were, however, indicated by strokes or curves, or by some leading letter of the omitted portion being placed above the line of writing. Certain signs also were borrowed from tachygraphy, at first sparingly, but afterwards, in the later and

more elaborate system of contraction, in sufficient numbers to represent certain common words and terminations.

In the early Greek minuscule MSS. contractions are not very frequent in the texts; but in the marginal glosses, where it was an object to save space, they are found in great numbers as early as the 10th century. The MS. of Nonnus, of 972 A.D., in the British Museum (Wattenb. and Von Vels., *Exempla*, 7) is an instance of a text contracted to a degree that almost amounts to tachygraphy. In secular MSS. contractions developed most quickly. In the 12th, 13th, and 14th centuries texts were fully contracted; and as the writing became more cursive contraction-marks were more carelessly applied, until, in the 15th century, they degenerated into mere flourishes.

In Latin Biblical uncial MSS. the same restrictions on abbreviations were exercised as in the Greek. The sacred names and titles \overline{DS} = *deus*, \overline{DMS} , \overline{DNS} = *dominus*, \overline{SCS} = *sanctus*, \overline{SPS} = *spiritus*, and others appear in the oldest codices. The contracted terminations Q' = *que*, B' = *bus*, and the omission of final *m*, or (more rarely) final *n*, are common to all Latin MSS. of the earliest period. There is a peculiarity about the contracted form of our Saviour's name that it is always written by the Latin scribes in letters imitating the Greek IHC , XPC , *ihc*, *xpc*. In secular works, as already noticed, contractions were used in many forms at an early period. In minuscule MSS. of the 8th, 9th, and 10th centuries the system of dropping middle or final syllables was commonly applied. In this stage the simpler marks of contraction, such as a horizontal stroke or an apostrophe to mark the omitted termination, were generally used. Certain ordinary words also, as prepositions and conjunctions, and a few prefixes and terminations, had particular forms of contraction from an early date. Such are \bar{e} = *est*, \bar{i} = *vel*, \bar{n} = *non*, \bar{p}' = *per*, \bar{p} = *pro*, \bar{u} = *termination us*. The letter *g* with distinctive strokes applied in different positions represented the often recurring relative and other short words, as *quod*, *quia*. Conventional signs also derived from the Tironian notes were employed, particularly in Irish and English MSS., as \bar{u} = *autem*, \div = *est*, \bar{e} = *ejus*, \bar{t} = *enim*, $\bar{7}$ = *et*. From the practice of writing above the line a leading letter of an omitted syllable, as int = *intra*, t = *tur*, other conventional signs were also developed. Such growths are well illustrated in the change undergone by the semicolon, which was attached to the end of a word to indicate the omission of the termination, as \bar{b} = *bus*, \bar{q} = *que*, \bar{d} = *debet*, and which in course of time became converted into a \bar{z} , a form which survives in our ordinary abbreviation viz. (*i.e.*, *vi*; = *videlicet*). The different forms of contraction which have been noticed were common to all the nations of western Europe. The Spanish scribes, however, attached different values to certain of them. For example, in Visigothic MSS., \bar{q} , which elsewhere represented *quoniam*, may be read as *quum*; and \bar{p} , which elsewhere = *pro*, is here = *per*.

By the 11th century the system of Latin contractions had been reduced to exact rules; and from this time onwards it was universally practised. It reached its culminating point in the 13th century, the period of increasing demand for MSS., when it became more than ever necessary to economize space. After this date the exact formation of the signs of contraction was less strictly observed, and the system deteriorated together with the decline of handwriting. In conclusion, it may be noticed that in MSS. written in the vernacular tongues contractions are more rarely used than in Latin texts. A system suited to the inflexions and terminations of this language could not be readily adapted to other languages so different in grammatical structure.

Breathings and Accents.—These were not systematically applied to the texts of Greek MSS. before the 7th century. Such as are found in isolated passages in the ancient papyri do not appear to have been written by the first hand, and most of them are probably of much later date. They have been freely added to the ancient texts of Homer, as in the Harris and Bankes papyri, but palpably long after the dates of the writing. Nor were they used in the early uncial MSS. The ancient codices of the Bible are devoid of them; and, although in the Ambrosian Homer of the 5th century it is thought that some of the breathings may be by the original hand, the other marks of breathing and the accents are of later date. So likewise the few breathings and accents which are seen

in the palimpsest Homer of the 6th century in the British Museum have been, to all appearance, added afterwards. In Latin texts, and particularly in early Irish and English MSS., an accent is occasionally found over a monosyllabic word or one consisting of a single letter. But such accentuation, serving to distinguish such small words in reading, rather corresponds to the similar marking of short words in Greek MSS., as noticed above.

Numerals.—An examination of the different forms of numerals to be found in Greek and Latin MSS. is beyond the province of this article. It may, however, be pointed out that, while in Greek MSS. one system was followed, in Latin MSS. both the Roman and Arabic numerals were in use. The Roman numerals appear in all kinds of documents at all times. When occurring in the text of a MS. they were usually placed between full points, *e.g.*, .cxliii., to prevent confusion with the letters of the words. Arabic numerals were established in common use by the end of the 14th century, but their occurrence in MSS. has been traced back to the middle of the 12th century, from which date down to the time of their general adoption they were principally confined to mathematical works.

Bibliography.—GREEK PALÆOGRAPHY.—The first book which dealt with the subject in a systematic manner was the *Palæographia Græca* of the learned Benedictine, Dom Bernard de Montfaucon, published in 1708. So thoroughly well was the work done that down to our own time no other scholar attempted to improve upon it, and Montfaucon remained the undoubted authority in this branch of learning. At length, in 1879, Gardthausen published his *Griechische Palæographie*, in which is embodied fuller information that was unavailable in Montfaucon's day. In this work the development of Greek writing in its various styles is carefully and lucidly worked out and illustrated with tables, and a useful list of dated Greek MSS. is added. See also a review of Gardthausen's work by Charles Graux in the *Journal des Savants* (1881). A most useful and handy introduction is Wattenbach's *Anleitung zur Griechischen Palæographie* (2d ed., 1877), in which will be found references to all the most important MSS. With regard to facsimiles, those which are found in Montfaucon and other books of the same time are practically useless for critical purposes. The invention of photography has entirely driven into the background all handmade facsimiles, and in the future none will be admissible which are not produced by the action of light. Autotypes or photolithographs from MSS. are given in the *Facsimiles of the Palæographical Society* (1873-83); in the *Exemplar Codicum Græcorum litteris minusculis scriptorum* (1878) of Wattenbach and Von Velske; in the *Catalogue of Ancient MSS. in the British Museum*, part I, (1881); in Wattenbach's *Scripturæ Græcæ Specimina* (1883); and, in fewer numbers, in *Specimina Palæographica codd. Græc. et Slav. bibl. Mosquensis* (1863-64) by Bishop Sabas. Facsimiles made by hand, but excellently finished, are in Silvestre's *Paléographie Universelle* (1850) and in *Notices et Extraits des Manuscrits*, tom. xviii., pt. 2 (1865), where the papyri of Paris are faithfully represented.

LATIN PALÆOGRAPHY.—The bibliography of Latin palæography in its different branches is very extensive, but there are comparatively few books which deal with it as a whole. The most complete work is due to the Benedictines, who in 1750-65 produced the *Nouveau Traité de Diplomatique*, which examines the remains of Latin writing in a most exhaustive manner. The fault of the work lies indeed in its diffuseness and in the superabundance of subdivisions which tend to confuse the reader. The extensive use, however, which the authors made of the French libraries renders their work most valuable for reference. As their title shows, they did not confine themselves to the study of MS. volumes, but dealt also with that other branch of palæography, the study of documents, in which they had been preceded by Mabillon in his *De Re Diplomatica* (1709). Wattenbach's *Anleitung zur Lateinischen Palæographie*, 3d ed., 1878, is a thoroughly practical introduction, classifying the different kinds of writing, and giving full biographical references, and tracing the forms of letters and the history of contractions, &c. Works which give facsimiles in general are—Silvestre, *Paléographie Universelle*; the *Facsimiles of the Palæographical Society*; Arndt, *Schrifttafeln*, 1874, 1878; the *Catalogue of Ancient MSS. in the British Museum*, part II., 1884; and among those which deal with particular branches of Latin palæography the following may be enumerated—*Exemplar Codicum Latinorum litteris minusculis scriptorum* (1876, 1879) by Zangemeister and Wattenbach; on Roman cursive, and on Lombardic, Merovingian, and Visigothic writing, the *Corpus Inscriptionum Latinarum*, vols. III., IV.; Maassmann, *Libellus avaratus*, 1840; Marini, *Papiri Diplomatici*, 1805; the *Chartes Latines sur Papyrus* (1835-40) of Champollion-Figeac; Gloria, *Palæographa*, 1870; Sickel, *Monumenta Graphica*, 1858-69; Letronne, *Diplomata et Chartæ Merovingicæ Altiæ*, 1848; "Facsimila de Chartæ et Diplomes," in the *Archives de l'Empire*, 1866; Sybel and Sickel, *Kaiserurkunden*, 1880-84; *Bibliotheca Casinensis*, 1873, &c.; Merino, *Escuela Palæographica*, 1780; and the *Exemplar Scripturæ Visigoticæ* (1883) of Ewald and Laeue. On Irish and English writing—Astle, *Origin and Progress of Writing*, 1873; *Facsimiles of Ancient Charters in the British Museum*, 1873-78; *Facsimiles of Anglo-Saxon MSS.*, 1878, 1881, Rolls Series; *Facsimiles of National MSS. of England, Scotland, and Ireland*, in separate series. The various works on illumination, such as those of Count Bastard, Westwood, Tynms and Wyatt, and others may also be consulted. For the study of the Tironian Notes, see Carpentier, *Alphabetum Tironianum*, 1747; Kopp, *Palæographia Critica*, 1817; Jules Tardif, "Mémoire sur les Notes Tironiennes," in the *Mémoires de l'Académie des Inscriptions*, sér. 2, tom. III., 1852; and the "Nota Bernenses," &c., published in the *Panstenographikon* periodical. A useful handbook of contractions is Chassant's *Dictionnaire des Abréviations*, 1862. For particulars as to materials employed and the mechanical arrangements followed in the production of MSS., see Birt's *Antike Buchwesen* (1882) and Wattenbach's *Schriftwesen im Mittelalter* (1875). (E. M. T.)

PALÆOLOGUS, a Byzantine family name which first appears in history about the middle of the 11th century, when George Palæologus is mentioned among the prominent supporters of Nicephorus Botaniates, and afterwards as having helped to raise Alexius I. Comnenus to the throne in 1081; he is also noted for his brave defence of Durazzo against the Normans in that year. Michael Palæologus, probably his son was sent by

Manuel II. Comnenus into Italy as ambassador to the court of Frederick I. in 1154; in the following year he took part in the campaign against William of Sicily, and died at Bari in 1155. A son or brother of Michael, named George, received from the emperor Manuel the title of *Sebastos*, and was entrusted with several important missions; it is uncertain whether he ought to be identified with the George Palæologus who took part

in the conspiracy which dethroned Isaac Angelus in favour of Alexius Angelus in 1195. Andronicus Palæologus Comnenus was Great Domestic under Theodore Lascaris and John Vatatzes; his eldest son by Irene Palæologina, MICHAEL (*q.v.*), became the eighth emperor of that name in 1260, and was in turn followed by his son Andronicus II. (1282-1328). Michael, the son of Andronicus, and associated with him in the empire, died in 1320, but left a son, Andronicus III., who reigned from 1328 to 1341; John VI. (1355-1391), Manuel II. (1391-1425), and John VII. (1425-1448) then followed in lineal succession; Constantine XIII., the last emperor of Constantinople (1448-1453), was the younger brother of John VII. Other brothers were Demetrius, prince of Morea until 1460, and Thomas, prince of Achaia, who died at Rome in 1465. A daughter of Thomas, Zoe by name, married Ivan III. of Russia. A younger branch of the Palæologi held the principality of Monferrat from 1305 to 1533, when it became extinct.

PALÆONTOLOGY. See **GEOLOGY**, vol. x. pp. 319 *sq.* Further details will be found in **DISTRIBUTION** and in the articles on the various zoological groups and forms (see, *e.g.*, **BIRDS**, **ICHTHYOLOGY**, **ICHTHYOSAURUS**, **MAMMALIA**, **MAMMOTII**).

PALÆOTHERIUM. See **MAMMALIA**, vol. xv. p. 429.

PALÆPHATUS, the author of a treatise *περὶ ἀπίστων*, "On Incredible (Narratives)," which has been preserved. It consists of a series of explanations of Greek legends, without any attempt at arrangement or plan. It is obviously a mere epitome of some more complete work. The great number of MSS., containing numerous variations in text, and the frequent quotations made from the treatise by late writers, show that it was a favourite work in their time. It is probable that the original treatise, from which it was abbreviated, was the *λύσεις τῶν μυθικῶς εἰρηγμένων* of a late writer mentioned by Suidas as a grammarian of Egypt or of Athens.

PALAFIX Y MELZI, JOSÉ DE (1780-1847), duke of Saragossa, was the youngest son of an old Aragonese family. Brought up at the Spanish court, he entered the guards at an early age, and in 1808 he accompanied Ferdinand to Bayonne, but made his escape after the king's abdication. While he was living in retirement at his family seat near Saragossa, the inhabitants proclaimed him governor of that city and captain-general of the kingdom of Aragon (May 25, 1808), an honour which he owed to his rank, and, it is said, to his appearance, rather than to talent or experience in military affairs. Despite the want of money and of regular troops, he lost no time in declaring war against the French, who had already overrun the neighbouring provinces of Catalonia and Navarre, and soon afterwards the attack he had provoked began; Saragossa was bombarded on July 22, and on August 4 the French were masters of nearly the half of the town. Summoned to surrender, Palafox sent the famous reply of "War to the Knife," and on the following day his brother succeeded in forcing a passage into the city with 3000 troops. It was resolved, amid the enthusiasm of the inhabitants (whose real leaders belonged to the lower orders), to contest possession of the remaining quarters of Saragossa inch by inch, and if necessary to retire to the suburb across the Ebro, destroying the bridge. The struggle, which was prolonged for nine days longer, resulted in the withdrawal of the French (August 14) after a siege which had lasted sixty-one days in all. Operations, however, were resumed by Marshals Mortier and Moncey in November, and after more than 50,000 (it is said) of the inhabitants had perished, partly through the ravages of an epidemic by which Palafox himself was attacked, a capitulation was signed on February 21.

After his recovery Palafox was sent into France and closely confined at Vincennes, but was liberated on the restoration of Ferdinand. In June 1814 he was confirmed in the office of captain-general of Aragon, but soon afterwards withdrew from it, and, having indeed no real aptitude for them, ceased to take part in public affairs. He received the title of duke of Saragossa in 1824, and died at Madrid on February 15, 1847.

PALAMAS. See **HESYCHASTS**, vol. xi. p. 782.

PALANPUR, a native state in Guzerat, Bombay, India, lying between 23° 57' and 24° 41' N. lat., and between 71° 51' and 72° 45' E. long., with an area of 3510 square miles, and a population of 234,402. The country is mountainous, with much forest towards the north, but undulating and open in the south and east. The principal rivers are the Saraswati and Banás. The chief, an Afghán of the Loháni tribe, enjoys an estimated gross revenue of £40,000, and pays a tribute to the gáekwár of Baroda. Palanpur town, the capital of the state, contained a population in 1881 of 17,547.

PALATINATE, THE (German, *Pfalz*), included for some time (from the middle of the 17th to the latter part of the 18th century) two distinct German districts, the Upper or Bavarian Palatinate, and the Lower Palatinate or the Palatinate on the Rhine. The Upper Palatinate, a duchy, belonged to the Nordgan and Bavarian circle, and was bounded by Baireuth, Bohemia, Neuburg, Bavaria, and the territory of Nuremberg. In 1807 (with Cham and Sulzbach) it had 283,800 inhabitants. The Lower Palatinate belonged to the electoral Rhenish circle, and was bounded by Mainz, Katzenellenbogen, Würtemberg, Baden, Alsace, Lorraine, and Treves. It took in the Electoral Palatinate (with a population, in 1786, of 305,000), the principality of Simmern, the duchy of Zweibrücken, half of the county of Sponheim, and the principalities of Veldenz and Lautern.

The palsgaves of the Rhine originally had their seat in Aix-la-Chapelle. In the 11th century the country called the Palatinate belonged to them as an hereditary fief, in virtue of which they ranked among the foremost princes of the empire. In 1156, after the death of Palgrave Hermann III. without heirs, the Palatinate was granted by the emperor Frederick I. to his step-brother Duke Conrad of Swabia. Conrad was succeeded by his son-in-law, Duke Henry of Brunswick, the eldest son of Henry the Lion. In the contest for the crown between Otho IV. and Frederick II., Henry took part with Otho IV., his brother; and in 1215 Frederick II. punished him by putting him to the ban of the empire, and by granting the Palatinate to Louis, duke of Bavaria. Louis was never able to assert his claims with complete success; but his son Otho II. married Agnes, the daughter and heiress of Henry, and thus the Palatinate passed into the hands of the Bavarian family. In 1256 the whole territory of the family was divided between Louis II. and Henry, Otho's sons,—Louis II. obtaining the Palatinate and Upper Bavaria, and Henry Lower Bavaria. The possessions of Louis II. were inherited in 1294 by his two sons, Rudolph I. and Louis, the Palatinate and the electoral dignity going to the former, while the latter (who ultimately became emperor) received Upper Bavaria, to which Lower Bavaria was afterwards added. The claims of Louis to the imperial crown were contested by Frederick the Fair, duke of Austria; and, as Rudolph I. supported Frederick, his brother deprived him of his lands, which were then held in succession by Rudolph's three sons, Adolph, who died in 1327, Rudolph II., who died in 1353, and Rupert I., who died in 1390. Rudolph II. concluded a treaty with the emperor Louis, whereby the electoral vote was to be delivered alternately by Bavaria and by the Palatinate;

but the emperor Charles IV., in return for a part of the Upper Palatinate, conferred on Rupert I. and his heirs the exclusive right to the electoral dignity. Rupert I., in 1386, founded the university of Heidelberg. He was succeeded by his nephew, Adolph's son, Rupert II., whose son and successor, Rupert III., was elected emperor in 1400. After the death of Rupert III. in 1410, his hereditary territories were divided among his four sons, Louis III., John, Stephen (who became palgrave of Simmern and Zweibrücken), and Otho. The families of John and Otho soon died out, and the last representative of the line of Louis III.—Otho Henry—died in 1559. The lands of Otho Henry and the electoral dignity then passed to Frederick III., of the Simmern line; and Frederick III. marked an important epoch in the history of the electorate by definitely associating himself and his house with the Reformed or Calvinistic Church. His immediate successors were Louis VI., Frederick IV., and Frederick V. The latter, in 1619, rashly accepted the crown of Bohemia; and the result was that, after his expulsion from his new kingdom, the Palatinate was given by the emperor Ferdinand II. to Maximilian, duke of Bavaria. In virtue of the treaty of Westphalia, Charles Louis, Frederick V.'s son, who died in 1680, received back the Lower Palatinate, and in his favour an eighth electorate was created, with which was associated the office of lord high treasurer (Erzschatzmeisteramt). The house of Bavaria retained the Upper Palatinate, with the office of arch-sewer (Erztruchsessamt), and with the rank which had formerly been held in the electoral college by the counts palatine; but it was arranged that, if the male line of Bavaria died out, the lands and rights which had belonged to the rulers of the whole Palatinate should be restored to their descendants. Charles, Charles Louis's son, who died in 1685, was the last representative of the Simmern line. The electoral dignity and the lands connected with it then passed to Charles's kinsman, Philip William, of the Neuburg line, which sprang from Louis the Black, the second son of Stephen, son of Rupert III. Of Louis the Black's two grandsons, Louis and Rupert, the latter was the ancestor of the Veldenz line, which died out in 1694, while from the former sprang all other palatine lines—the Neuburg line, the Neuzweibrücken line, the Birkenfeld line, the Sulzbach line. Philip William, of the Neuburg line, died in 1690, and was succeeded by his son John William, who in 1694 inherited Veldenz, and during the war of the Spanish succession received the Upper Palatinate and all the ancient rights of his house. At the conclusion of the war, however, both rights and lands were restored to the elector of Bavaria. In 1716 John William was succeeded by his brother Charles Philip; and with Charles Philip, who died in 1642, the Neuburg line came to an end, and the Lower Palatinate was inherited by Charles Theodore, of the Sulzbach line. In 1777 the male line of Bavaria became extinct by the death of the elector Maximilian Joseph; and then, in accordance with the treaty of Westphalia, the Upper Palatinate and the Lower Palatinate were reunited, and the palgrave resumed the office of arch-sewer and the ancient place of his family in the electoral college, while the office of lord high treasurer was transferred to the elector of Brunswick. The successor of Charles Theodore, who died childless in 1799, was Maximilian Joseph, duke of Zweibrücken. By the treaty of Lunéville in 1801 his territories were divided, the part which lay on the left bank of the Rhine being taken by France, while portions on the right bank were given to the grand-duchy of Baden, to Hesse-Darmstadt, to the prince of Leiningen-Dachsburg, and to Nassau. By the treaties of Paris concluded in 1814 and in 1815, the palatine lands

on the left bank of the Rhine were restored to Germany, the larger part of them being granted to Bavaria, and the rest to Hesse-Darmstadt and Prussia. The Prussian part of the Palatinate is in the Rhine province; the Hesse-Darmstadt part is included in the province of Starkenburg and Rhine Hesse; the Bavarian part is known as Rhenish Bavaria; and the Baden part is in the Lower Rhine district, which in 1865 was divided into the districts of Mannheim, Heidelberg, and Mosbach.

See Hauser, *Geschichte der rheinischen Pfalz*, 1845; Nebenius, *Geschichte der Pfalz*, 1874.

PALAWAN. See PHILIPPINE ISLANDS.

PALAZZOLO (often *P.-Acride* to distinguish it from several other places of the same name), a city of Italy, in the province of Syracuse, Sicily, 28 miles west of Syracuse, with a population of 11,069 according to the census of 1881. It is mainly of interest on account of the remains it still preserves of the ancient city of *Acrae*, which was founded by Syracuse in 663 B.C. These consist of a temple, an aqueduct, a theatre with a fine view towards Etna, a smaller theatre or odeum, a group of thirteen cisterns, and, in the vicinity, various rows of rock-cut tombs, from which a rich harvest of vases, &c., was obtained by Baron Judica, the great explorer of the site. See Judica, *Antichità di Acrae*.

PALEARIO, AONIO (c. 1500–1570), Italian humanist and Reformer, was born about 1500 at Veroli in the Roman Campagna. Other forms of his name are Antonio Della Paglia, A. Degli Pagliaricci. In 1520 he went to Rome, where, during the years immediately following, he made lasting friendships among the scholars and men of letters whom Leo X. had gathered to his brilliant court. Driven from Rome by the troubles of 1527, he found a home first at Perugia and afterwards, from 1530 onwards, at Siena, where he married happily in 1534. In 1536 his didactic poem in Latin hexameters, *De Immortalitate Animarum*, was published at Lyons. It is divided into three books, the first containing his proofs of the divine existence, and the remaining two the theological and philosophical arguments for immortality based on that postulate. The whole concludes with a rhetorical description of the occurrences of the second advent. Meanwhile his religious views had been undergoing considerable modification, and in 1542 an Italian tract written by him and entitled *Della Pienezza, Sufficienza, et Satisfazione della Passione di Christo*, or *Libellus de Morte Christi*, was made by the Inquisition the basis of a charge of heresy, from which, however, he successfully defended himself. To the period of his stay in Siena belongs also his *Actio in Pontifices Romanos et eorum Asselas*, a vigorous indictment, in twenty "testimonia," against what he now believed to be the fundamental error of the Roman Church in subordinating Scripture to tradition, as well as against various particular doctrines, such as that of purgatory; it was not, however, printed until after his death (Leipzig, 1606). In 1546 he accepted a professorial chair at Lucca, which he exchanged in 1555 for that of Greek and Latin literature at Milan. Here about 1566 his enemies renewed their activity, and in 1567 he was formally accused of having taught the doctrine of justification by faith alone, denied that of purgatory, spoken slightly of monastic institutions, and so on. Removed to Rome to answer these charges, he was detained in prison until sentence of death was carried out in July 1570.

An edition of his works (*Ant. Palearii Verulani Opera*), including four books of *Epistolae* and twelve *Orationes* besides the *De Immortalitate*, was published at Lyons in 1552; this was followed by two others, at Basel, during his lifetime, and several after his death, the fullest being that of Amsterdam, 1696. A work entitled *Beneficio di Cristo* ("The Benefit of Christ's Death"), frequently translated, has often been attributed to Paleario, but on insufficient grounds.

PALEMBANG. See SUMATRA.

PALENCIA, an inland province of Spain, one of the eight into which Old Castile is divided, is bounded on the N. by Santander, on the E. by Burgos, on the S. by Valladolid, on the W. by Valladolid and Leon, and has an area of 3127 square miles. In shape it is an irregular parallelogram, measuring 83 miles from north to south with a maximum breadth of 48 miles, sloping from the Cantabrian chain to the Douro. The general direction of all its larger streams is from north to south; of these the principal are the Pisuega and the Carrion, which unite at Dueñas and flow into the Douro in Valladolid. The tributaries of the former within the province are the Burejo, the Cieza, and the united streams of the Buedo and Abanades; the latter is joined on the right by the Cuezsa. The northern part of the province, including the whole partido of Cervera, is mountainous, with some wood and with good pasture in the valleys; the remainder, the "Tierra de Campos," belongs to the great Castilian table-land, and is in general level and almost wholly devoid of trees. In the south occurs a considerable marsh or lake known as La Laguna de la Nava, as yet only partially drained. The mountainous district abounds in minerals, but only the coal is worked, the principal mines being those of San Feliceo de Castilleria, Orbo, and Villaverde de la Peña. The province is crossed in the south-east by the trunk railway connecting Madrid with Irun, while the line to Santander traverses it throughout from north to south; there is also railway connexion with Leon. The highways following the same routes are maintained in good order; the state of the other roads is often bad. The Canal de Castilla, begun by Ensenada in 1753, and completed in 1832, connects Alar del Rey with Valladolid. The province is essentially agricultural, wheat and other cereals, legumes, hemp, and flax being everywhere extensively grown, except in the mountainous districts. Other industries are of secondary importance, the principal being flour-milling and the manufacture of linen and woollen stuffs. The province is divided into seven partidos—Astudillo, Baltanas, Carrion, Frechilla, Palencia, Saldaña, and Cervera; the total population in 1877 was 180,785. The only ayuntamiento with a population exceeding 10,000 was that of Palencia.

PALENCIA, capital of the above province, occupies a level site on the left bank of the river Carrion, here crossed by a good stone bridge and by another called Los Puenteccillos. Palencia is the junction of the lines from Asturias and Galicia, and is 7 miles from Venta de Baños on the Madrid and Irun Railway. The distances north-north-east from Valladolid and south-east from Leon are 23 and 82 miles respectively. The height above sea-level is 2362 feet. The town is protected on the west by the river; on the other sides the old machicolated walls, 36 feet high by 9 in thickness, are in fairly good preservation, and beautified by alamedas or promenades which were laid out in 1778. The city is divided into two parts, the ciudad and the puebla, by a winding arcaded street, the Calle Mayor, which traverses it from north to south. The cathedral, which overlooks the Carrion, was begun in 1321 and finished in 1504; it is a large building in the later and somewhat poor Gothic style of Spain. The site was previously occupied by a church erected by Sancho el Mayor over the cave of St Antholin, which is still shown. The church of San Miguel is a good and fairly well-preserved example of 13th-century work; that of San Francisco, of the same date, is inferior, and has suffered more from modernization. The hospital of San Lazaro is said to date in part from the time of the Cid, who was married to Ximena here. The leading industries of Palencia are the woollen and linen manufactures, in which

a third of the inhabitants are engaged; flour-milling comes next in importance. The population of the ayuntamiento was 14,505 in 1877.

Palencia, the Pallantia of Strabo and Ptolemy, was the chief town of the Vaccei. Its history during the Gothic and Moorish periods is obscure; but it was a Castilian town of some importance in the 12th and 13th centuries. The university founded here in 1203 by Alphonso IX. was removed in 1239 to Salamanca.

PALENQUE, RUINS OF, in Chiapas, Mexico. See ARCHITECTURE, vol. ii. pp. 450–51; and H. H. Bancroft, *Native Races of the Pacific Coast of North America*, vol. iv.

PALERMO (Greek, Πάνοπος; Latin, Panhormus, Panormus), the capital of the Sicilian kingdom as long as it kept its separate being, now capital of a province of the same name in the kingdom of Italy, and the see of an archbishop. The population numbered 205,712 in 1881. The city stands in the north-west part of the island, on a small bay looking eastwards, the coast forming the chord of a semicircle of mountains which hem in the *campagna* of Palermo, called the Golden Shell (Conca d'Oro). The most striking point is the mountain of Heirkte, now called Pellegrino (from the grotto of Santa Rosalia, a favourite place of pilgrimage), which rises immediately above both the sea and the city. Palermo has been commonly thought to be an original Phœnician settlement of unknown date,

Plan of Palermo.

1. Church of S. Giuseppe.
2. Palazzo del Municipio.
3. Church of S. Salvatore.
4. Church of S. Giovanni degli Eremiti.

but lately Prof. Holm, the historian of ancient Sicily, has suggested that the settlement was originally Greek.¹ There is no record of any Greek colonies in that part of Sicily, and Panhormus certainly was Phœnician as far back as history can carry us. According to Thucydides (vi. 2), as the Greeks colonized the eastern part of the island, the Phœnicians withdrew to the north-west, and concentrated themselves at Panhormus, Motye, and Soloeis (*Solutum*, *Solunto*). Like the other Phœnician

¹ The coins bearing the name of ΠΑΝΟΝΤΗ are no longer assigned to Palermo; but it is probable that certain coins with the name ΠΑΝΟΝΤΗ are of Panhormus.

colonies in the west, Panhormus came under the power of Carthage, and became the head of the Carthaginian dominion in Sicily. As such it became the centre of that strife between Europe and Africa, between Aryan and Semitic man, in its later stages between Christendom and Islam, which forms the great interest of Sicilian history. As the Semitic head of Sicily, it stands opposed to Syracuse the Greek head. Under the Carthaginian it was the head of the Semitic part of Sicily; when, under the Saracen, all Sicily came under Semitic rule, it was the chief seat of that rule. It has been thrice won for Europe by Greek, Roman, and Norman conquerors—in 276 B.C. by the Epirot king Pyrrhus, in 254 B.C. by the Roman consuls Aulus Atilius and Gnaeus Cornelius Scipio, and in 1071 A.D. by Robert Guiscard and his brother Roger, the first count of Sicily. After the conquest by Pyrrhus, the city was soon recovered by Carthage, but this first Greek occupation was the beginning of a connexion with western Greece and its islands which was revived under various forms in later times. After the Roman conquest an attempt to recover the city for Carthage was made in 250 B.C., which led only to the great victory of Metellus just under the southern wall of the city. Later in the First Punic War, Hamilcar Barca was encamped for three years on Heirkto or Pellegrino, but the Roman possession of the city was not disturbed. Panhormus remained a Roman possession, and one of the privileged cities of Sicily, till it was taken by the Vandal Genserich in 440 A.D. It afterwards became a part of the East-Gothic dominion, and was recovered for the empire by Belisarius in 535. It again remained a Roman possession for exactly three hundred years, till it was taken by the Saracens in 835. As Syracuse remained to the empire for a much longer time, Panhormus now became the Mussulman capital. In 1063 the Pisan fleet broke through the chain of the harbour and carried off much spoil, which was spent on the building of the great church of Pisa. After the Norman conquest the city remained for a short time in the hands of the dukes of Apulia. But in 1093 half the city was ceded to Count Roger, and in 1122 the rest was ceded to the second Roger. When he took the kingly title in 1130, it became and remained the capital and crowning-place of the kingdom, "Prima sedes, corona regis, et regni caput." During the Norman reigns Palermo was the main centre of Sicilian history, especially during the disturbances in the reign of William the Bad (1154-66). The emperor Henry VI. entered Palermo in 1194, and it was the chief scene of his cruelties. In 1198 his son Frederick, afterwards emperor, was crowned there. His reign was the most brilliant time in the history of the city. After his death Palermo was for a moment a commonwealth. It passed under the dominion of Charles of Anjou in 1266, but he was never crowned there. In the next year, when the greater part of Sicily revolted on behalf of Conradin, Palermo was one of the few towns which was held for Charles; but the famous Vespers of 1282 put an end to the Angevin dominion. From that time Palermo shared in the many changes of the Sicilian kingdom. In 1535 Charles V. landed there on his return from Tunis. The last kings crowned at Palermo were Victor Amadeus of Savoy in 1713, and Charles III. of Bourbon in 1735. The loss of Naples by the Bourbons in 1798, and again in 1806, made Palermo once more the seat of a separate Sicilian kingdom. The city rose against Bourbon rule in 1820 and in 1848. In 1860 came the final deliverance at the hands of Garibaldi, but with it came also the yet fuller loss of the position of Palermo as the capital of a kingdom of Sicily.

The original city was built on a tongue of land between two inlets of the sea. There is some question as to their extent inland, and as to the extent of salt and fresh

water. But there is no doubt that the present main street, the Cassaro, Via Marmorea, or Via Toledo (in official language Via Vittorio Emmanuele), represents the line of the ancient town with water on each side of it. Another peninsula with one side to the open sea, meeting as it were the main city at right angles, formed in Polybius's time the *Neapolis* or new town, in Saracen times *Khalesa*, a name which still survives in that of *Calsa*. It was on this side that both the Romans and the Norman conquerors entered the city. But the old relations of land and water have long been changed. The two ancient harbours have been dried up; the two peninsulas have met; the long street has been extended to the present coast-line; a small inlet called the *Cala* alone represents the old haven. The city kept its ancient shape till after the time of the Norman kings. It is still easy to mark the site of the two inlets, which now form valleys on each side of the long street. The old state of things fully explains the name *Πάνορμος*.

There are not many early remains in Palermo. The Phœnician and Greek antiquities in the museum do not belong to the city itself. The earliest existing buildings date from the time of the Norman kings, whose palaces and churches were built in the Saracenic and Byzantine styles prevalent in the island (see NORMANS). Of Saracen works actually belonging to the time of Saracen occupation there are no whole buildings remaining, but many inscriptions and a good many columns, often inscribed with passages from the Koran, which have been used up again in later buildings, specially in the porch of the metropolitan church. This last was built by Archbishop Walter, a native of England, and consecrated in 1185, on the site of an ancient basilica, which on the Saracen conquest became a mosque, and on the Norman conquest became a church again, first of the Greek and then of the Latin rite. What remains of Walter's building is a rich example of the Christian-Saracen style. This church contains the tombs of the emperor Frederick the Second and his parents, as also the royal throne, higher than that of the archbishop; for the king of Sicily, as hereditary legate of the see of Rome, was the higher ecclesiastical officer of the two. But the metropolitan church has been so greatly altered in modern times that by far the best example of the style in Palermo, or indeed anywhere, is the chapel of the king's palace at the west end of the city. This is earlier than Walter's church, being the work of King Roger in 1143. Besides the wonderful display of mosaics, it is, simply as an architectural whole, beyond all praise. Of the palace itself the greater part has been rebuilt and added in Spanish times, but there are some other parts of Roger's work left, specially the hall called *Sala Normanna*.

Alongside of the churches of this Christian-Saracen type, there is another class which follow the Byzantine type. Of these the most perfect is the very small church of San Cataldo, embodied in public buildings. But the best, though much altered, is the church commonly called Martorana, the work of George of Antioch, King Roger's admiral. This is rich with mosaics, among them the portraits of the king and the founder. Both these and the royal chapel have cupolas, and there is a still greater display in that way in the church of San Giovanni degli Eremiti, which it is hard to believe never was a mosque. It is the only church in Palermo with a bell-tower, itself crowned with a cupola.

* Most of these buildings are witnesses in different ways to the peculiar position of Palermo in the 12th century as the "city of the threefold tongue," Greek, Arabic, and Latin. Elements from all three sources may be seen, and inscriptions abound in all three languages. King Roger's sun-

dial in the palace is commemorated in all three, and it is to be noticed that the three inscriptions do not translate one another. In private inscriptions a fourth tongue, the Hebrew, is also often found. For in Palermo, under the Norman kings, Christians of both rites, Mussulmans, and Jews were all allowed to flourish after their several fashions. This distinguishes Palermo from some other Sicilian cities which belonged wholly or mainly to one people—Greek, Latin, or Saracen. In many of the early churches of Palermo it is easy to see that they were first designed for the Greek rite, which was gradually supplanted by the Latin. The abiding connexion of Palermo with the races of south-eastern Europe comes out in several other shapes. In Saracen times there was a Slavonic quarter on the southern side of the city, and there is still a colony of United Greeks, or more strictly Albanians, who sought shelter from the Turks, and who keep their national religious usages.

The series of Christian-Saracen buildings is continued in the country houses of the kings which surround the city, La Favara and Miminerno, the works of Roger, and the better known Ziza and Cuba, the works severally of William the Bad and William the Good. The Saracenic architecture and Arabic inscriptions of these buildings have often caused them to be taken for works of the ancient emirs; but the inscriptions of themselves prove their date. Different as is their style, their mere shape is not very unlike that of a contemporary keep in England or Normandy.

All these buildings are the genuine work of Sicilian art, the art which had grown up in the island through the presence of the two most civilized races of the age, the Greek and the Saracen. Later in the 12th century the Cistercians brought in a type of church which, without any great change of mere style, has a very different effect, a high choir taking in some sort the place of the cupola. The greatest example of this is the neighbouring metropolitan church of Monreale; more closely connected with Palermo is the church of San Spirito, outside the city on the south side, the scene of the Vespers. Palermo is full of churches and monasteries of later date, as in Saracen times it was crowded with mosques. But only a few are of any architectural importance, and they often simply range with the houses.

Domestic and civil buildings, from the 12th century to the 15th, abound in Palermo, and they present several types of genuine national art, quite unlike anything in Italy. The later houses employ a very flat arch, the use of which goes on in some of the houses and smaller churches of the Renaissance, some of which are very pleasing. But the general aspect of the streets is later still, dating from mere Spanish times. Still many of the houses are stately in their way, with remarkable heavy balconies. The most striking point in the city is the central space at the crossing of the main streets, called the Quattro Cantoni. Here the eye catches the mountains at three ends and the sea at the fourth. But none of the chief buildings come into this view, and the intersecting streets suggest a likeness, which is wholly deceptive, to the four limbs of a Roman *chester*. Two indeed of the four are formed by the ancient Via Marmorea, but the Via Maqueda, which supplies the other two, was cut through a mass of small streets in Spanish times.

The city walls remain during the greater part of their extent, but they are of no great interest. The gates also are modern. The best is Porta Nuova, near the king's palace, built in 1584 to commemorate the return of Charles V. fifty years earlier. The design is far better than could have been looked for at that time. Outside the walls, in the immediate neighbourhood of the city, there are, besides

the royal country houses and the church of San Spirito, several buildings of the Norman reigns. Among these are the oldest church in or near Palermo, the Lepers' church, founded by the first conqueror or deliverer, Count Roger; and the bridge over the forsaken stream of the Oreto, built in King Roger's day by the admiral George. There are also some later mediæval houses and towers of some importance. These all lie on to the south of the city, towards the hill called Monte Grifone (Griffon = Greek), and the Giant's Cave, which has furnished rich stores for the palæontologist. On the other side, towards Pellegrino, the change in the ancient haven has caused a new one to grow up, but there is little of artistic or historic interest on this side.

Besides works dealing with Sicily generally, the established local work on Palermo is *Descrizione di Palermo Antico*, by Salvatore Morso, Palermo, 1827. Modern research and criticism have been applied in *Die Mittelalterliche Kunst in Palermo*, by Anton Springer, Bonn, 1869; *Historische Topographie von Panormus*, by Julius Schubring, Lübeck, 1870; *Studi di Storia Palermitana*, by Adolf Holm, Palermo, 1880. See also "The Normans in Palermo," in the third series of *Historical Essays*, by E. A. Freeman, London, 1879. The description of Palermo in the second volume of Gsell's guide-book, *Unter-Italien und Sicilien*, Leipzig, leaves nothing to wish for. (E. A. F.)

PALES, an old Italian deity, worshipped in the festival of the *Palilia* at Rome on the 21st April. Like most of the ancient Italian deities, Pales is little more than a name to us; the authorities are at variance whether the name belonged to a goddess or to a god. In this festival Pales was invoked to grant protection and increase to flocks and herds; the worshippers entreated forgiveness for any unintentional profanation of holy places of which they might have been guilty, and sprang through fires of straw as a purificatory rite. The German *Maifeuer*, which remained in use till a very recent date, was a precisely similar custom; the intention was to propitiate the wrath of the deity for any neglect of her service before the summer began, and so ensure her favour to the flocks. The foundation of Rome, *dies natalis Romæ*, was commemorated on this same day,—a custom still kept up. The name *Palilia* is often written, by dissimilation, *Parilia*.

PALESTINE. As Palestine, geographically considered, forms the southernmost third of SYRIA, its general geographical relations, as well as its geological structure, its botany, &c., will be treated under that heading. In the matter of climate, on the other hand, it holds a more or less independent position; and this is more strikingly the case with its ethnographic characteristics, at least so far as the pre-Christian period is concerned. Purely historical questions have already been discussed in the article ISRAEL.

By Palestine is to be understood in general the country seized and mainly occupied by the Hebrew people. That portion of territory is consequently excluded which they held only for a time, or according to an ideal demarcation (*cf.* Numbers xxxiv., from the older source) by which the land of the Israelites was made to extend from the "river of Egypt" to Hamath; but, on the other hand, that other ancient tradition is accepted which fixes the extreme borders at Dan (at the foot of Hermon) in the north and at Beersheba in the south, thus excluding the Lebanon district and a portion of the southern desert. In like manner, though with certain limitations to be afterwards mentioned, the country east of Jordan stretched from the foot of Hermon to the neighbourhood of the Arnon. Towards the west the natural boundary—a purely ideal one so far as occupation by the Israelites was concerned—was the Mediterranean, but towards the east it is difficult to fix on any physical feature more definite than the beginning of the true steppe region. That the territory of Israel extended as far as Salcah (east of Bosra at the foot of the Hauran Mountains) is the statement of an ideal rather

than an historical frontier (Josh. xiii. 11). Palestine thus lies between 31° and $33^{\circ} 20'$ N. lat., its south-west point is situated about $34^{\circ} 20'$ E. long., some distance south of Gaza (Ghazza), its north-west point about $35^{\circ} 15'$ E. long., at the mouth of the Litány (Kásimiye). As the country west of the Jordan stretches east as far as $35^{\circ} 35'$ it has a breadth in the north of about 23 miles and in the south of about 80 miles. Its length may be put down as 150 miles; and, according to the English engineers, whose survey included Beersheba, it has an area of 6040 square miles. For the country east of the Jordan no such precise figures are available. The direct distance from Hermon to Arnon is about 120 miles, and the area at the most may be estimated at 3800 square miles. The whole territory of Palestine is thus of very small extent, equal, in fact, to not more than a sixth of England. The classical writers ridicule its insignificant size.

General Geography.—Palestine, as thus defined, consists of very dissimilar districts, and borders on regions of the most diverse character. To the south lies a mountainous desert, to the east the elevated plateau of the Syrian steppe, to the north Lebanon and Anti-Libanus, and to the west the Mediterranean. In the general configuration of the country the most striking feature is that it does not rise uninterruptedly from the sea-coast to the eastern plateau, but is divided into two unequal portions by the deep Jordan valley, which ends in an inland lake (see JORDAN). Nor does the Jordan, like the Nile in Egypt, simply flow through the heart of the country and form its main artery; it is the line of separation between regions that may almost be considered as quite distinct, and that too (as will afterwards appear) in their ethnographic and political aspects. This is especially the case in the southern sections of the country; for even at the Lake of Tiberias the Jordan valley begins to cut so deep that crossing it from either direction involves a considerable ascent.

The country west of Jordan is thus a hilly and mountainous region which, forming as it were a southward continuation of Lebanon, slopes unsymmetrically east and west, and stretches south, partly as a plateau, beyond the limits of Palestine. The mountain range consists of a great number of individual ridges and summits, from which valleys, often rapidly growing deeper, run east and west. Towards the Mediterranean the slope is very gradual, especially in the more southern parts, where the plain along the coast is also at its broadest. About three-fourths of the cis-Jordan country lies to the west of the watershed. Towards the Dead Sea, on the other hand, the mountains end in steep cliffs; and, as the Jordan valley deepens, the country draining towards it sinks more abruptly, and becomes more and more inhospitable. The plateaus back from the coast-cliffs of the Dead Sea have been desert from ancient times, and towards the east they form gullies of appalling depth. On the other side of the Jordan the mountains have quite a different character, rising from the river gorge almost everywhere as a steep wall (steepest towards the south) which forms the edge of the great upland stretching east to the Euphrates.

Geology.—The mountains both east and west of the Jordan consist in the main of Cretaceous limestone; nummulitic limestone appears but rarely, as on Carmel, Ebal, and Gerizim. Towards the Dead Sea the rock is traversed by hornblende and flint. Formations of recent origin, such as dunes of sea-sand and the alluvium of rivers and lakes, cover the western margin of Palestine (i.e., the whole of Philistia and the plain of Sharon) and the entire valley of the Jordan. Plutonic or volcanic rocks occur occasionally in the country east of Jordan; less frequently in the country to the west, as, for example, in the mountains round the plain of Jezreel.

Physical Divisions.—The mountain system west of Jordan must be broken up into a number of separate groups, which, it may be remarked, are of political as well as physical significance. A first group, consisting of the country north of the plain of Jezreel, may be subdivided into a large northern portion with summits reaching a height of 4000 feet, and a smaller southern portion not exceeding 2000 feet. The former, the Upper Galilee of antiquity, is a mountainous region with a somewhat intricate system of valleys, stretching from the Kásimiye in the north to a line drawn from Acre ('Akka) towards the Lake of Tiberias. Of the valleys (more than thirty in number) which trend westwards to the Mediterranean, the Wádi Hubeishiyé, Wádi 'Ezziye, and Wádi el-Kurn deserve to be mentioned. Not far west of the watershed is a plateau-like upland draining northwards to the Kásimiye. The slope to the Jordan is steep. Jebel Jermak, a forest-clad eminence 3934 feet above the sea, is the highest *massif*. The whole territory is fruitful, and forms decidedly one of the most beautiful as well as best-wooded districts of Palestine. The plain along the Mediterranean is on the average hardly a mile broad; between cliff and sea there is at times barely room for a narrow road, and at some places indeed a passage has had to be cut out in the rock. South of Rás en-Nakúra, on the other hand, this plain widens considerably; as far as Acre the portion named after this town is about 4 miles broad.

The mountain structure of the second subsection, or Lower Galilee, is of a different character,—low chains running east and west in well-marked lines, and enclosing a number of elevated plains. Of these plains the most important is that of Buttauf (plain of Zebulun or Asochis), an extremely fertile (in its eastern parts marshy) depression 9 miles long and 2 broad, lying 400 to 500 feet above the sea, between hills 1700 feet high. To the south-west, about 700 feet above the sea, is the smaller but equally fertile plain of Tor'an, 5 miles long and 1 mile broad. Among the mountains the most conspicuous landmarks are Nebi Sa'in (1602) near Nazareth, Jebel es-Sih (1838), and especially, to the east of this last, Jebel et-Túr or Tabor (1843), an isolated wooded cone which rises on all sides with considerable regularity, and commands the plain of Esdraelon. Eastwards the country sinks by a succession of steps: of these the lava-strewn plateau of Sahel el-Ahma, which lies above the cliffs that look down on the Lake of Tiberias, but is 300 feet below the level of the Mediterranean, deserves mention. The principal valleys of the whole region are (1), towards the west, the great basin of Nahr Na'mán (Belus of the ancients), whose main branch is Wádi Khalzún, known in its upper course as Wádi Sha'ib or Wádi Khashab, and, farther south, the basin of the Wádi Melek (Wádi Rummáni), which flows into the Nahr el-Mukatta' (Kishon); and (2) towards the east the rapid-flowing Wádi Rubudiye, Wádi el-Hamám, and Wádi Fejjás.

A certain connexion exists between the plains already mentioned (those of Buttauf, Acre, &c.) and the great plain which, with an average height of 250 feet above the sea, stretches south from the mountains of Galilee and separates them from the spurs of the mountains of Samaria (the central portion of the cis-Jordan country). This great plain, which in ancient times was known as the plain of Megiddo, and also as the valley of Jezreel or plain of Esdraelon, and which now bears the name of Merj Ibn 'Ámir (pasture land of the son of 'Ámir), is one of the main features of the whole cis-Jordan region (Josephus called it the Great Plain *par excellence*), and presents the only easy passage from the coast districts to the Jordan valley and the country beyond. The larger portion lies west of the watershed, which at El-'Afulé is 260 feet above

the Mediterranean. In the narrower application of the name, the whole plain forms a large triangle with its southern corner near Jennín and its western near the mouth of the gorge of the Nahr el-Mukatta' (for here the hills of Nazareth shoot out towards Carmel); and connected with it are various small plains partly running up into the hills. The plain to the south of Acre, in which marshes are formed by the Kishon and Na'mán, and various other recesses towards north and east really belong to it. To the north-east stretches a valley bounded in one direction by Jebel Duhy (the Lesser Hermon, a range 15 miles long and 1690 feet high) and in the other direction by the hills of Nazareth and Mount Tabor (where lie Iksal and Dehuriye); then to the east of the watershed lies the Bfere valley, and the well-watered Wádi Jálúd from Zer'in (Jezreel) falls away towards the Jordan between the slopes of Jebel Duhy and the more southern range of Jebel Fuku'a (Mountains of Gilboa). And finally towards Jennín in the south lies the secondary plain of 'Arráne. Quite recently it has been proposed to construct in the Merj Ibn 'Amir the beginning of a railway system for Palestine, and to turn to account the wonderful fertility of its rich basaltic loam which now lies almost completely waste, though in ancient times the whole country was densely peopled and well-cultivated.

To the south of the plain of Jezreel, which belongs to the northern system of Palestine, it is much more difficult to discover natural divisions. In the neighbourhood of the watershed, which here runs almost regularly in great zigzags, lie a number of plains of very limited extent:—the plain of 'Arrábe (700 to 800 feet above the sea) connected south-east with the Merj el-Ghuruq, which having no outlet becomes a lake in the rainy season; the plain of Fendekúmiye (1200 feet); and the plain of Rújib, east of Shechem, connected with the plain of Mukbna (1600 to 1800 feet) to the south-west. The highest mountains too are generally near the watershed. In the east lies the south-westward continuation of Gilboa. In the west Mount Carmel (highest point 1810 feet, monastery 470) meets the projection of the hills of Nazareth, and sends its wooded ridge far to the north-west so as to form the southern boundary of the Bay of Acre, and render the harbour of Haifa, the little town at its foot, the best on all the coast of Palestine. The belt of land along the shore, barely 200 yards wide, is the northern end of the lowland plain, which, gradually widening, stretches south towards Egypt. At Athlút (9 miles south) it is already 2 miles broad, and it continues much the same for 21 miles to the Nahr ez-Zerka (named by the ancients after the crocodile which is still to be found in its marshes), where a small ridge El-Khashm projects from the highlands. South of Nahr ez-Zerka begins the marvellously fertile plain of Sharon, which with a breadth of 8 miles near Cæsarea and 11 to 12 miles near Yáfá (Jaffa), stretches 44 miles farther to the Nahr Rúbín, and slopes upwards towards the mountains to a height of about 200 feet above the sea. Its surface is broken by lesser eminences, and traversed by a few coast streams, notably the Nahr el-Falik.

Between the maritime plain and the mountains proper lies a multiform system of terraces, with a great number of small ridges and valleys. In this the only divisions are those formed by the basins of the larger wadis, which, though draining extensive districts, are here too for the most part dry. They all have a general east and west direction. First comes the basin of the Nahr Mejjir, bounded south by the Bayazid range, and debouching a little to the south of Cæsarea; and about 5 miles farther south is the mouth of the Iskanderúne, which is distinguished in its upper portion as the Wádi Sha'fr, running

east as far up as Nábulus (Shechem), hardly a mile west of the watershed. It is in this neighbourhood that we find the highest portions of the mountains of Samaria—Jebel Eslámiye or Ebal, 3077 feet high, to the north of Shechem, and Jebel et-Túr or GERIZIM (*q.v.*), 2849 feet high. Both are bare and rugged, and consist, like all the loftier eminences in the district, of hard limestone capped with chalk. It was generally possible, however, to carry cultivation up to the top of all these mountains, and in ancient times the highlands of Samaria are said to have been clothed with abundant forest. From the watershed eastward the important Wádi Fár'a (also known as Wádi Keráwa in its lower course) descends to the Jordan. Returning to the western slope, we find to the south of Nahr el-Falik the basin of the 'Aujá, which after it leaves the hills is fed by perennial (partly palustrine) sources, and falls into the sea 5 miles north of Jaffa. As at this place the watershed bends eastward, this extensive basin stretches proportionally far in that direction; and, the right side of the Jordan valley being also very broad, the mountains of the eastern slope soon begin to sink rapidly. On the watershed, not far from Jifna, lies Tell Asúr (3378 feet), and with this summit of hard grey limestone begin the hills of ancient Judah. South of the 'Aujá comes the Nahr Rúbín (near Jabne), perennial up to the Wádi Surár (Sorek of Scripture?), and reaching, as Wádi Bét Hanína, as far as the country north of Jerusalem; the Wádi el-Werd is one of its tributaries. Farther south begins the maritime plain of Philistia, which stretches 40 miles along the coast, and, though now but partially under cultivation, consists of a light brown loamy soil of extraordinary fertility. It is crossed by numerous ridges of hills; and to the south of Ashdod (Ezdúd) the highlands advance westwards, and form a hilly district composed of horizontal strata of limestone, sometimes considered part of the lowlands (Shephela), and separated from the more elevated region in the interior by a ridge more or less parallel with the line of the watershed. The basins to the south of the Rúbín are those of Wádi Sukereir, which runs up towards Tell-es-Sáfi in one direction and to Bét Jibrín in another, of Wádi el-Hesy, and finally of Wádi Ghazza, which forms the proper boundary of Palestine towards the south, runs past Beersheba as Wádi es-Seba, and receives the Wádi el-Khalíl (Hebron) from the north-east.

As regards the central parts of the country, the mountainous district north of Jerusalem is now known as Jebel el-Kuds, of which the loftiest point is the summit of the Nebi Samwíl (2935), rising above the plateau of El-Jib. Near Jerusalem the watershed lies at a height of about 2600 feet. Wild deep-sunk valleys descend eastwards to the Jordan; the Wádi Kelt, Wádi en-Nár (Kedron valley), Wádi ed-Dereje, and southernmost Wádi Seyál deserve to be mentioned. The country sloping to the Dead Sea falls in a triple succession of terraces,—a waterless treeless waste (in ancient times known as the desert of Judah), which has never been brought under cultivation, but in the first Christian centuries was the chosen abode of monasticism. To the north of Hebron, in the neighbourhood of Hulhúl, lie the highest elevations of this part of the central highlands (up to 3500 feet), which may be distinguished as the mountains of Hebron. Towards Yutta (Juttah) in the south is a sudden step; there begins a plateau at a height of about 2600 feet, but 500 feet below the Hebron watershed. It consists of open wolds and arable land, the soil being a white soft chalk; but there are no wells. Southward another step leads to the white marl desert of Beersheba, abounding in caves. In ancient times this southern district was called the Negeb; it extends far to the south, but is properly a part of Palestine. The country was in former times a steppe region without

definite boundaries, and consequently the abode of nomadic herdsmen.

The Jordan valley having already been described in a separate article (vol. xiii. p. 746), we may pass at once to a brief sketch of the physical character of the country east of Jordan (compare also the article GILEAD, vol. x. p. 594). This is a more difficult task for several reasons: first, no connected series of investigations and measurements has been made in this region; and, secondly, as the ideal demarcation of the book of Joshua is a hardly sufficient basis on which to build, and the information about the actual state of matters supplied by other ancient sources is insufficient, it is impossible to determine the limits of the country as far as it was occupied by the Israelites.

In the opinion of the present writer, the plain of BASHAN (*q.v.*) can hardly be assigned to Palestine. To the south of the Yarmuk (Hieromax of the Greeks and Romans, Hebrew name unknown), which falls into the Jordan below the Lake of Tiberias, begins the Cretaceous formation; only in the east of the country the basalt of the Hauran territory stretches farther south. Ascending from the Yarmuk, we first of all reach a mountainous district of moderate elevation (about 2000 feet) rising towards the south; this is Jebel 'Ajlûn, which abounds in caves, and, according to recent explorers, is extremely well watered and of great fertility—the whole surface being covered with pasture such as not even Galilee can show. Eastwards are massive ridges as much as 4000 feet in height—Jebel Kafkafa and especially Marâd—separating this territory from the waterless desert lying at no great depth below. The plateau stretches away to the south of the deep gorge of the perennial Zerka (Jabbok), and reaches a considerable height in Jebel Jil'ad (Gilead in the stricter sense). The landmark of the region is Jebel 'Osha, to the north of Es-Salt, so-called from the traditional tomb of Hosea. From the deep-sunk Jordan valley the mountains rise grandly in terraces, partly abrupt and rocky; and, while fig trees and vines flourish down in the lower levels, valonia oaks, *Laurus Pinus*, cedars, and arbutus grow on the declivities. Owing to its perennial springs, the interior terrace of the country, Mishôr, is a splendid pasture land, famous as such in ancient times; and abundance of wood and water renders this whole middle region of the trans-Jordan country one of the most luxuriant and beautiful in Palestine. Only a few individual summits, such as Jebel Nebâ (Mount Nebo), are noticeable in the ridges that descend to the Jordan valley. The country from the Zerka southward to the Mójib (Arnon) is now known as El Belka; and beyond that begins the land of Moab proper, which also consists of a steep mountain-wall through which deep gorges cut their way to the plain, and behind this of a plateau poorly watered but dotted over with ancient ruins. In this district, too, there are a few individual summits. And here also a mountain-wall separates the plain from the eastern desert; and the mountain district continues farther south along the Araba (*cf.* IDUMEA, vol. xii. p. 699).

Water.—Palestine is not exceptionally deficient in water. Perennial streams, indeed, are scarce, and were so in antiquity; but except in certain districts, as the desert of Judah, the country is not badly supplied with springs. In keeping with the structure of the rocks, these usually break out at the junction of the hard and soft strata. Thus abundant springs of good water occur on the very summit of the cis-Jordan country, as, for example, near Hebron, at Nâbulus, and in Galilee; and, though few are found in the immediate neighbourhood of Jerusalem, more than forty may be counted within a radius of 15 to 20 miles round the city. There is no water in the low hilly

country behind the coast region; and, though in its northern portion some fairly large streams take their rise, the same is true of the coast-region itself. Rising as they do at the foot of a great mountain range, the most abundant springs in Palestine are those of the Jordan, especially those near Bânias and Tell-el-Kâdi. The mountains of Gilead are rich in excellent water. A considerable number of hot springs occur throughout the country, especially in and near the Jordan valley; they were used in ancient times for curative purposes, and might still be so used. The water of the bath of El-Hammâm, about 2 miles south of Tiberias, has a temperature of 137° Fahr., and the spring near the Zerka Ma'in, formerly known as Callirrhoe, as much as 142° Fahr. Hot sulphur springs also occur on the west coast of the Dead Sea. Many of the springs in Palestine are slightly brackish. From the earliest times cisterns have naturally played a great part in the country; they are found everywhere in great numbers. Generally they consist of reservoirs of masonry widening out downwards, with a narrow opening above often covered with heavy stones. Open reservoirs were also constructed to collect rain and spring water. Such reservoirs (pools; Arab., *birka*; Hebrew, *berékha*) are especially numerous near Jerusalem and Hebron; the largest still extant are the three so-called Pools of Solomon, in Wâdi Urtâs (Artas), arranged in steps at a little distance from each other. Besides the conduits connected with this gigantic work, fine remains of aqueducts of Roman date are found near Jericho, in the ruins of many towns in the trans-Jordan country, at Sefûriye (Sepphoris) in Galilee, in ancient Caesarea, &c. Many of these aqueducts, as well as many now ruined cisterns, could be restored without much trouble, and would give a great stimulus to the fertility and cultivation of the country.

Climate and Vegetation.—Palestine may be considered part of the subtropical zone. At the summer solstice the sun stands 10 degrees south of the zenith; the shortest day is thus one of ten hours, the longest of only fourteen. In a few points, as already remarked, there is a difference between Palestine and the rest of Syria. The extensive maritime plain and the valley of the Jordan give rise to important climatic contrasts. From its vicinity to the sea the former region is naturally warmer than the highlands. The mean annual temperature is 70° Fahr., the extremes being 50° and 85°. The harvest ripens two weeks earlier than among the mountains. Citrons and oranges flourish; the palm also grows, but without fruiting; melons are largely cultivated; and pomegranate bushes are to be seen. Less rain falls than in the mountains. Another climatic zone consists of the highlands (from 500 to 3000 feet above the sea), which were the real home of the Israelites. The average temperature of Jerusalem, which may be taken as pretty much that of the upland as a whole, is 62°, but the extremes are considerable, as the thermometer may sink several degrees below the freezing point, though frost and snow never last long. The rainfall of 20 inches is distributed over about fifty days. In this climate the vine, the fig, and the olive succeed admirably. Even in the southernmost districts (of the Negeb), as well as throughout the whole country, there are traces of ancient wine-growing. A large share of the oil is consumed at home, partly in the manufacture of soap. The mountain ridges in this zone are for the most part bare, but the slopes and the valleys are green, and beauty and fertility increase as we advance northwards. In regard to the climate of the third zone, see JORDAN (vol. xiii. *ut sup.*). The barley harvest here ends with the middle of April. The thermometer rarely sinks below 77°, and goes as high as 130°. The fourth zone, the elevated plateau of the trans-Jordan region, has an extreme climate.

The thermometer may frequently fall during the night below the freezing point, and rise next day to 80°. The mountains are often covered with snow in winter. Whilst the rainfall in the Jordan valley is very slight, the precipitation in the eastern mountains is again considerable; as in western Palestine the dewfall is heavy. From this short survey it appears that Palestine is a country of strong contrasts. Of course it was the same in antiquity; climate, rainfall, fertility, and productiveness cannot have seriously altered. Even if we suppose that there was a somewhat richer clothing of wood and trees in the central districts of the country, yet on the whole the general appearance must have been much the same as at present. To the stranger from the steppes arriving at a favourable season of the year Palestine may still give the impression of a land flowing with milk and honey. The number of cisterns and reservoirs is proof enough that it was not better supplied with water in ancient times; but, on the other hand, the numerous ruins of places which were still flourishing during the Roman period show that at one time (more especially in the southern districts, which now possess but few inhabited localities) cultivation must have been carried on more extensively and thoroughly. In general the country enjoyed the greatest security, and consequently the greatest prosperity, under Western rule, which even protected the country east of Jordan (at present partly beyond the control of the Government) from the inroads of the Bedouins. The Romans also did excellent service by the construction of roads, portions of which (as well as Roman milestones and bridges) still exist in good preservation in many places. Thus it cannot be denied that the resources of the country were formerly better developed than at present. Like all the lands of the nearer East, Palestine suffers from the decay of the branches of industry which still flourished there in the Middle Ages. The harbours are not of sufficient size for large vessels; that of Haifa alone is capable of any development. The road from Yáfá to Jerusalem is the only one in the country fit for carriages. The proposal to construct a railway along this route (for which a firman was granted in 1875) is renewed from time to time; but it will be hard to carry it out, as, in spite of the pilgrims (who, besides, are restricted to one period of the year), the passenger traffic is not large enough to be remunerative, and commercial traffic there is almost none. At the same time the formation of means of communication would increase the productiveness of the country. The culture of olives and export of oil are especially capable of expansion. As regards the industrial arts, souvenirs for the pilgrims, rosaries, carved work in olive wood and mother-of-pearl, &c., are produced at Jerusalem and Bethlehem, and to some extent are exported. Wheat from the Hauran is also shipped at Acre and elsewhere, but neither exports nor imports are commercially important. The salt farming, which could easily be carried on at the Dead Sea and the deposit of salt to the south of it, is hampered by the difficulty of bringing the produce up the steep paths to the top of the mountains. In the valley of the Jordan all the products of the tropics could with little trouble be cultivated. Bee-keeping still receives attention, but might also be extended.

Political Geography.—Evidence of an early occupation of Palestine is afforded by the stone monuments (cromlechs and circles of stones), which are found more especially in the country east of Jordan, but also in the country to the west. To what period they belong in this part of the world is as doubtful as it is elsewhere; but it may be remarked that stories of a gigantic primeval population once prevailed in Palestine. To what race these people may have belonged is, however, unknown. For thousands

of years Palestine was an object of conflict between the vast monarchies of western Asia. As Egypt, whenever she sought to extend her power, was from the very position of the country naturally led to make herself mistress of the east coast of the Mediterranean, so, on the other hand, there were no physical boundaries to prevent the westward advance into Palestine of the Asiatic empires. For both Egypt and the East indeed the country formed a natural thoroughfare, in time of war for the forces of the contending powers, in time of peace for the trading caravans which carried on the interchange of African and Asiatic merchandise.

One of the oldest of the still extant historical documents in regard to the geography of Palestine is the inscription on the pylones of the temple of Karnak, on which Thothmes III. (in the beginning of the 16th century B.C.) has handed down an account of his military expedition to western Asia. Many of the topographical names of Palestine there mentioned are certainly hard to identify; a number, however, such as Iphu for Yáfá, Luden for Lydda, Magedi for Megiddo, &c., are beyond dispute. The lists show that these names are of extreme antiquity, dating from before the Hebrew immigration. There is also a hieratic papyrus of the 14th century B.C., which contains a description of a carriage journey through Syria made by an Egyptian officer, possibly for the collection of tribute. Bethshean and the Jordan, among other localities, appear to be mentioned in this narrative, but the identification of most of the names is very dubious. Another foreign source of information as to the geography of Palestine can only be alluded to—the records contained in the cuneiform inscriptions, which mention a number of the most important towns:—Akku (Akko, Acre), Du'ru (Dor), Magidu (Megiddo), Yappu (Jaffa), Asdudu (Ashdod), Iskaluna (Askalon), Hazzatu (Ghazza, Gaza), Altaku (Eltheke), Ursalimmu (Jerusalem), and Samarina (Samarina), and—of course only from the 8th century, when they came into hostile contact with Assyria—the countries of Judah, Moab, Ammon, and Edom.

The information supplied by the Old Testament enables us to form only an extremely imperfect conception of the earliest ethnographic condition of the country. The population to the east of the Jordan was already, it is clear, sharply marked off from that to the west. In the latter region dwelt an agricultural people which had already reached no inconsiderable degree of civilization. Closely related to the Phœnicians, they were distinguished as Canaanites from the name of their country, which originally applied to the maritime belt and afterwards to the whole cis-Jordan territory (vol. iv. p. 62). Though for particular reasons they are placed among the Hamitic races in Gen. x., many modern investigators are of opinion that, according to our principles of ethnographic classification, they were Semitic; their language, at any rate, was very similar to Hebrew. The separation of Canaanites from Semites may have been due, in part at least, to the fact that a deep contrast made itself felt between them and the Hebrews, though they were only, perhaps, an older result of Arabic emigration. The enumeration of the names of the various branches of the Canaanites leaves it an extremely difficult task to form a clear idea of their tribal distribution; names of separate sections, too, like that of the Amorites, are sometimes applied to the Canaanites as a whole. The Amorites were at any rate the most powerful tribe; they dwelt in the southern portion of Canaan, as well as more especially in the northern parts of the country east of Jordan. About the others nothing more can be said save that the Perizzites, Hivites, and Girgashites dwelt in the heart of Canaan and the Jebusites near Jerusalem. The Philistines occupied

the south-west of the country; all Arabian population was settled in the south and south-west. Amalekites and Midianites, and the Kenites, a branch of the latter, early entered into close relationship with the Israelites, and along with them took possession of the extreme south, where, however, they remained nomadic. Of peoples closely akin to the Israelites may be mentioned the Moabites, the Ammonites, and the Edomites. Before the arrival of the Israelites the Moabites had developed a certain degree of power. The district, bordering on Edom, which they occupied in the south of the country east of Jordan, was bounded on the south by Wádi el-Aḥsa (called in Is. xv. 7 the brook of the willows), an affluent of the southern part of the Dead Sea, and on the north stretched far beyond the Arnon (originally, indeed, to the north end of the sea, as in later times the country near Jericho was known as the steppes of Moab). Its eastern frontier must always have been matter of dispute, the relations of the nomadic tribes of the Syrian desert being the same as they are now, and contests with the Ammonites taking place from time to time. The Ammonites, a closely related people, lay to the north-east of Moab, east of the later possessions of Israel; but, as they were in the main nomadic, their frontiers were of a shifting character (see vol. i. p. 742). The Edomites (also nomadic) were situated in the south of the country east of Jordan; how far, at an earlier period, they extended their encampments to the west of Jordan and into the Negeb district cannot be with certainty decided.

It depends on the conception we form as to the general tribal relations of Israel how we represent to ourselves the method in which the settlement of the country by the tribes was accomplished as they passed from the nomadic to the fixed mode of life (*cf.* ISRAEL, JOSEPH, JUDAH). To explain this tribal relationship is not the task of a geographical sketch; it is enough for the present purpose to call attention to the fact that the account of the rise of the Israelitic tribes as it has come down to us is in great measure mythical or the product of later reflexion; even the number twelve is made out only with difficulty. Further, the settlements of the several tribes must be by no means conceived as administrative districts after the fashion of the modern canton; and, thirdly, the view that the several tribes had, after a general invasion of the country, their tribal territories allotted by Joshua (as we now read in the book of Joshua) is taken from the most modern, post-exilic, source of the Hexateuch, and stands in glaring opposition to the accounts in other books, according to which the conquest was in the main a peaceful one, and the assimilation with the native Canaanites gradually effected. The tribes which settled to the north of the great plain, especially those on the sea-coast, appear to have been much less successful in keeping free from Canaanitish influence; gradually, however, as the state and religion of Israel grew stronger, Israelitish influence made its way more and more even there. The heart of the country was the central portion later known as Samaria. The opposition between this district and the southern part of the country took shape at an early date. In the extreme south the Simeonites retained their nomadic way of life, and were by degrees mixed up with other wandering tribes. Down into the time of the early kings the dominion of the powerful Philistines stretched far into the centre of the country, and gave the first impulse to a firmer concentration of the energies of Israel. But the Israelites did not succeed in forcing their way in the southern regions down to the sea; in culture and well-established political institutions they were far surpassed by the Philistines. As regards the geography of the Philistine territory, the position of four of their chief

towns, Gaza, Askelon, Ashdod, and Ekron, is known; but it has not been ascertained where the fifth, Gath, was situated, though it must have lain not far from the present Bét Jibrín.—No definite boundaries can be assigned to the Israelitic country to north, south, or west.

Up to the conquest of Jebus the most important city of the southern region was undoubtedly Hebron (see vol. xi. p. 603). Clans belonging to Judah had there combined with others of alien origin; and the portions of this tribe which dwelt in the farthest south had become mingled with elements from the tribe of Simeon, while on the other hand the Simeonites acquired certain places in the territory of Judah. In regard to the south country in general, we obtain in the Old Testament the most detailed description of the frontiers, but the reason that we are able to follow it with so much accuracy is that the statements refer exclusively to post-exilic times, though it must be assumed that a certain recollection was still preserved of the original boundary between Judah and Benjamin. The line of the marches of the northern tribes, as indeed this whole system of demarcation, frequently follows the configuration of the ground, but occasionally becomes vague and doubtful. Especially striking is the omission of the districts of Samaria; it seems that at the time of the codification of the system this district was little known to the Judeans. A great deal of trouble has been expended—more especially since the rise of a more scientific exploration of the country—in verifying the old place-names which are known from the Bible, the writings of Eusebius, and the Talmud. The task is rendered much easier by the fact that in Palestine, as in every country where the ethnographic conditions have not been too violently revolutionized, a large number of ancient names of places have been preserved in use for thousands of years, often with only insignificant changes of form—a state of matters to which the continuous existence in the country of Semitic-speaking people has powerfully contributed. The identification of the ancient with the modern names demands none the less thorough historical and philological investigation. Through the labours of Robinson and Guérin we now possess a list of the names in use at least in the country west of Jordan. The list of six thousand names collected during the English survey by Lieuts. Conder and Kitchener is particularly rich,—though it must be borne in mind that the orthography in many cases has not been determined with sufficient accuracy, and that a revision of the collection on the spot by a trained Arabic scholar would be desirable. By the help of this abundant material many of the ancient place-names can undoubtedly be assigned to their localities, and in part at least the direction of the tribal boundaries as they were conceived by the author of the lists preserved in the book of Joshua can be followed. In regard to a large number of places, Joshua leaves us to mere conjecture; and the investigations and combinations hitherto effected are (in the opinion of the present writer) far from sufficient for the construction of such a map of ancient Palestine as the Palestine Exploration Fund has published. The difficulties of the case are further increased by the fact that the ancient localities were at an early date fixed by tradition. An undoubted example of this is furnished by the grave of Rachel between Jerusalem and Bethlehem, the localizing of which goes back to an ancient gloss on Gen. xxxv. 19. Even in the case of apparently well-established identifications such as Beitin=Bethel, the question may be raised whether in reality artificial tradition may not have been at work, and ancient Bethel have to be sought elsewhere. Too much care, therefore, cannot be brought to bear on the reconstruction of the ancient geography of Palestine.

It lies beyond the purpose of the present article to enter into the details of the ancient tribal demarcation of Palestine, especially as the tradition, as has been explained, is relatively late and artificial. As an illustration of our view of the subject we may select the boundaries of Judah itself (Josh. xv.) Here the first thing that strikes the reader is that the western frontier as there described for the earliest times is purely ideal, inasmuch as it includes the land of the Philistines. Inconsistencies of view are apparent in the ascription of certain places in Judah to Simeon and of others to Dan. A further difficulty arises from the discrepancies between the Massoretic text and that of the Septuagint in regard to the number of towns belonging to Judah. As regards the southern boundaries described in Josh. xv. 2 *sq.*, the course of the line, in our opinion, cannot be determined with certainty even if it were generally admitted that Kadesh-Barnea is to be fixed at 'Ain Kadis. The determination of the northern boundary is more explicit: it ran from the mouth of the Jordan to Beth-hogla (which is found in 'Ain el-Hajla). The position of Beth-arabah (Beth ha-Araba) is doubtful; and at least it has not been absolutely settled whether Eben Bohan ben Reuben really corresponds to Hajar el-Asbah. The identification of Debir with Thughrat-ed-Debr may be correct. Gilgal, which follows, is unknown. The ascent from Adummim may correspond with Talat-ed-Dem, which preserves at least an echo of the older name. It is a mere conjecture which places the water of Eu (Ain) Shemesh in 'Ain Handh. The Fuller's Spring, En Rogel, has in recent times been sought in St Mary's Well; but, with others, we consider Bir Eiyub a more probable identification. The position of the valley of Hinnom and the plain of Rephaim has been determined; Nephtoi corresponds perhaps to the modern Lifta. The places situated on Mount Ephron—Baalath and Kirjath-Jearim—cannot be made out any more than the mountains Seir and Jearim. It may be admitted that Chesalon is Kesla and Bethshemesh is 'Ain Shems, since the direction towards Timnah (Tibna) is imperative. The position of Ekron is ascertained; but it is hazardous to find Shicron in Khirbet Sukereir; and where Mount Baalah was situated we do not know. Finally, Jabniel corresponds to Yebna. From this example it is clear how difficult it is with the existing material to determine the ancient tribal limits, and how necessary it is in such an undertaking to distinguish provisional conjectures from well-established identification. To carry out this task lies beyond the scope of this article; to prove individual points whole treatises require to be written. Compare the articles on the several tribes and the maps.

It has already been remarked that the extension given to the tribal territories in the book of Joshua is frequently the mere reflexion of pious wishes. This holds true in general of the territories of Zebulun, Naphtali, and especially Asher; it is to be particularly remembered that down to a very late date (the time of the Maccabees) the Israelites were almost entirely shut out from the sea-coast. To the north of the land of the Philistines the maritime plain was in the hands of the Phœnicians; the plain to the south of Dor (the modern Tantura) was called Naphoth Dor (hill range of Dor). Even in the New Testament mention is made of a district of Tyro and Sidon to which we must not assign too narrow an extension inland. How matters stood in the country east of Jordan it is hard to decide. The stretch from the north of the Dead Sea to the Yarmuk (practically to the south end of the Lake of Tiberias) was the only portion securely held by the tribes of Israel; here, on the Jabbok, in the centre of the trans-Jordan region, the Gadites had settled; here there was an ancient Israelitic district in the neighbourhood of Mahanaim, Jabesh (on the present Wâdi Yâbis), Succoth, Penuel—places whose position for the most part cannot be determined. From some passages it is evident that the warlike tribe of Gad found it difficult to protect itself against its enemies. Numbers xxxii., a chapter belonging to the older class of sources, throws much light on the conditions under which the country east of Jordan was occupied, and it represents Reuben and Gad as having seized the Moabite territory to the north of the Arnon. We have in this a picture of a temporary extension of the territory of Israel, probably from the time of Omri (compare Moab).

According to the inscription of King Mesha, the Gadites were still in Ataroth; Dibon, on the contrary, was Moabitic; other towns, such as Kirjathaim, Nebo, Jahaz, had been conquered by Mesha from the Israelites. It is remarkable that the Reubenites are not once mentioned in the inscription. At the date, too, when Isaiah xv.-xvi. were written (before the time of Isaiah himself?), the Moabite dominion was widely extended. From all this it may be concluded that the Reubenites had to carry on a protracted struggle with Moab for the possession of the country,—the walled towns being now subject to the one belligerent and now to the other, and the Arnon consequently forming only an ideal boundary. No accurate knowledge of the condition of the settlements of Manasseh in the country east of Jordan has come down to us. The clan Machir had its seat in Gilead; and there, too, were the tent-villages of Jair, a clan which also possessed the district of Argob in Bashan, situated somewhere to the east of the Lake of Tiberias. The Nobah clan was settled in Kenath (the modern Kanawât) on

the western slope of the Hauran Mountains. From these facts it is evident that in the trans-Jordan region north of the Yarmuk and east of the Lake of Tiberias, there were at least a few Israelite colonies; but they occupied merely scattered points, and thus in this district also the allotment of the country in the book of Joshua must be regarded as a mere pious wish. Other peoples settled in the Hauran, and the ever-advancing Aramæans soon diminished and absorbed these Israelite possessions.

The tribes of Israel made a great step in the conquest of the country when, under the early kings, they became subject to a single central government. They were now strong enough to seize many of the walled towns which the Canaanites had hitherto occupied; and their dominion, indeed, extended far beyond the limits of Palestine. Our information in regard to the divisions of the country during the regal period is very defective. The list of Solomon's twelve "officers" (1 Kings iv.) at least is derived from ancient sources; but it must be observed that, while the boundaries of some of the districts appear to coincide with the tribal boundaries, the political division was not based on the tribal. Nor at a later date was the line of separation between the kingdoms determined simply by the tribal division; the most that is meant is that Judah and Benjamin stood on the one side; of Simeon there is no longer any word. In the account given in 1 Kings xi. mention is only made of one tribe that remained true to David, by which must naturally be understood that of Judah. The limits, in fact, so far as they related to the tribal territory of Benjamin, seem to have varied from time to time; the northern portion as far as Ramah (1 Kings xv.), or as far as the ravine of Michmash (Mukhmâs), usually belonged to the northern kingdom, and the same was the case with Jericho. It was to this kingdom of Israel, also, with its general superiority in strength and influence, that all the Israelitic districts beyond Jordan were attached. That it consisted, however, of ten tribes (1 Kings xii.) is a highly artificial computation. The small extent of the southern kingdom is evident from a list (if indeed it be trustworthy) given in 2 Chron. xi. of the towns fortified by Rehoboam. As regards the capitals of the northern kingdom, the royal court was originally at Shechem (Nâbulus), from the time of Jeroboam I. at Tirzah (not yet identified), and from the time of Omri at Samaria (Sebastiye); the house of Ahab had its seat for a season at Jezreel (Zer'in) (see vol. xiii. p. 689).

It is rather an historical than a geographical task to describe in detail the boundaries or divisions of Palestine in later times. From the lists for the post-exilic period, found in the books of Ezra and Nehemiah, and containing a series of new topographical names, it is evident that a considerable portion of the old tribal territory of Benjamin as well as of Judah was again peopled by Jews,—on the one hand the places from Jericho to Lydda, on the other a strip to the north of Bethel down to Beersheba in the south. Gradually, however, Edomites (perhaps pressed upon by Nabatæans) forced their way into the southern portion of the country, with the capital Hebron, so that it obtained the name of Idumæa.

Before proceeding to the Græco-Roman period it will be well to consider the names by which the country in general was called at different times. Gilead was the centre of the power of the Israelites on the east side of Jordan, and the whole country which they possessed there bore this name. Gilead consequently is opposed to Canaan, the "Promised Land." For the later Hebrews distinguished this western territory as more especially the country which had been promised them, and regarded it as the possession of their national God, and therefore as a holy land. After the separation the more important northern and eastern portion naturally became the land of Israel *par excellence*, while the southern portion ultimately received the name of the individual tribe of Judah (as indeed the northern kingdom was frequently called after the most powerful tribe of Ephraim). The name of the southern kingdom appears in Cuneiform inscriptions as mâ (ir) Ya-u-du (di); and it is said that mâ Sir-lai occurs once for the land of Israel, though more frequently it is called mâ Hittiri (Land of Omri). Though it has not been absolutely proved that even the Assyrians occasionally included Judah under the designation Palastav or Pilsta (Philistia), still there is nothing improbable about the supposition. But it cannot be taken for granted that the cis-Jordan country bore the name of land of the Philistines at a time when it was the scene of a great development of the Philistian power; the name was rather, as so often happens, extended by their neighbours from Philistia proper to the country beyond, and from the Egyptians it passed to the Greeks. In the Old Testament Peleshet is still always restricted to the Philistine coast-plain; the same is the case in Josephus; and in Herodotus, though the usage is not very explicit, Palestina appears usually to have no wider application. Gradually, however, the designation Palestina Syria, or simply Palæstina, got into vogue, and was made to include even the country east of Jordan, and consequently the whole territory between Lebanon and Sinai.

We now return to the divisions of Palestine. Already in the book of Kings that is, by the time of the exile) the name Shameron (Samara) is applied to the territory of the northern kingdom, for mention is made of the "towns of Samaria." In the

apocryphal books of the Old Testament, Judea and Samaria (*Sapapeitis*, *Sapapis*, *Sapapeia*) are opposed to each other; but the limits of the two divisions at the time of Christ, and for centuries previously, can hardly be laid down. Thus in Josephus the Mediterranean coast as far as Acre is assigned to Judea; towards the south this country was bounded by Idumea; in the north it extended to about 8 miles to the south of Nâbulus (Shechem). Whether Samaria extended from the Jordan to the sea is uncertain; in the north it reached the southern edge of the plain of Esdraelon, the frontier town being 'En Gannim (Jennin). Galilee (in regard to which see vol. x. p. 27) was originally the district in the neighbourhood of Kedès, afterwards distinguished as Upper Galilee. The Jewish population was there largely mixed with Phœnicians, Syrians, Greeks, and even Arabs. The whole maritime region to the north of Dor was still called Phœnicia in the time of the Romans, and thus does not strictly belong to Palestine in our sense of the word. Along the coast, as well as more especially in the north of the country, numerous Greek colonies were established; how strong the foreign influence must have been in Samaria and Galilee is evident from the preservation of so many Græco-Roman names like Neapolis (Nâbulus), Sebaste (Sebastiye), Tiberias (Tabariye). Elsewhere too, in the south for example, the old nomenclature was altered: Ælia was substituted for Jerusalem, Azotus formed from Ashdod, and so on; but the old names were always retained in the mouth of the people. The north of the country and the trans-Jordan region were much more thoroughly brought under the influence of the Greeks and Romans than the south. The Greek towns in some cases date from the time of Alexander the Great, and others were founded by the Ptolemies; but most of them owe their origin to the Seleucids. One district of the trans-Jordan region retained at that period its old name in the Greek form of Peræa. Josephus says that this district extended from the Jordan to Philadelphia (Rabbath Ammon, 'Ammân) and Gerasa (Jerash), went southward as far as Machærus (Mkaur on the Zerka Ma'in), and north as far as Pella (Fâhil opposite Beisan). Adjoining Peræa, and mainly to the east of Jordan, lay the Decapolis, which was not, however, a continuous territory, but a political group of cities occupied by Greek republics distinguished from the tetrarchies with their Jewish-Syrian-Arabic population in the midst of which they were scattered. The largest of these cities was Scythopolis (Beisan); others were Hippos, Gadara (Mkés), Philadelphia, Dion, Gerasa, &c.; but ancient authorities do not agree about the names. Little requires to be said about the division of the country in later Roman times. In the 5th century a threefold partition began to prevail:—Palestina Prima (roughly equal to Judea and Samaria), Palestina Secunda (the countries about the upper Jordan and the Lake of Gennesaret), and Palestina Tertia or Salutaria (Idumea and Moab). In the time of the crusades the same names were applied to three divisions (at once political and ecclesiastical) of the country west of Jordan,—Palestina Prima or Maritima being the coast region as far as Carmel (with Caesarea as its archbishop's see), Palestina Secunda comprising the mountains of Judah and Ephraim (with the patriarchal see of Jerusalem), and Palestina Tertia corresponding roughly to Galilee (with its bishop's see at Nazareth). The country east of Jordan was called Arabia, and was in like manner divided into three parts lying north and south of each other.

The Arabians retained the name Filistin, and they divided the country into two principal portions,—the Jordan district (chiefly the northern parts) and Filistin proper, which extended from the Lake of Gennesaret to Aila and from Lejjûn to Refah. Under the Turks Palestine was till quite recently subject to the governor of Syria; the greater part of it now forms an independent vilayet. The chief districts are (each with its town) Gaza, Hebron, Yâfa, Ludd (with Ramla), Nâbulus, Sha'rawiye, Jennin (with Beisan), Haifa, Acre, Tabariye, Nâsira, Safed; and in the country east of Jordan 'Ajlûn, Belkâ es-Salt, Kerak, and Ma'an.

Palestine is by no means so strikingly a country apart as is usually supposed. It lay, as already mentioned, near the great military highway from western Asia to Egypt and Africa. The traffic by sea was also formerly of importance; and even in the Middle Ages something was done for the protection of the harbours. At no time, however, was the country in the proper sense of the word a rich one; it hardly ever produced more than was necessary for home consumption. The great trading caravans which passed through were glad for the most part to avoid the highlands, and that region at least was thus more or less isolated. The following is a brief survey of the principal routes, partly as they formerly existed, and partly as they are still used. From Egypt a road runs by El-'Arish (Rhinocolura) or "the river of Egypt" by Rafah (Raphia) to GAZA (*q.v.*). From Gaza another runs by Umm Lâkis (Lachish?) and Bêt Jibrin (Eleutheropolis) across the mountains to Jerusalem. Northwards from Gaza the main route continues along the plain at some distance from the sea (which in this part has piled up great sand dunes) to El-Mejdel (Migdal Gad) near Askelon, and so on to Ashdod (Ezdud, Azotus). From Ashdod a road runs by 'Akir (Ekron) to Ramle, an important town in the mediæval Arabian period, and Ludd (Lôd, Lydda). From these towns, which are con-

nected with the port of Yâfa (Japho, Joppa), three routes run to Jerusalem, of which the one most used in antiquity was evidently the northern one passing by Jimzu (Gimzo) and the two Bêt Urî (Beth-horon), and not the one now followed by 'Amwâs (Nicompolis), and Wâdi 'Ali. From Yâfa a road continues along the coast by Arsuf (Apollonia) to the ruins of Kaisariye (Caesarea), then past Tantûra (ruins of Dor) and 'Athlit (Castellum Peregrinorum of the crusaders) and round the foot of the promontory of Carmel, to Haifa and Acre (a town of great importance from early times). Another route starting from Ludd runs north close to the mountains by Antipatris (now Kefr Saba or Kâs el-'Ain?) and Kakiin, and ends at Khân Lejjûn. The Great Plain offered the easiest passage from the coast inland. El-Lejjûn (a corruption of the Latin *Legio*) was certainly an important point; it is still conjecturally identified, according to Robinson's suggestion, with the ancient Megiddo, which Conder would rather place at Mejedde. In the vicinity lie the ruins of Ta'anuk (Ta'anach), and farther south-west the great centre of Jennin ('En Gannim, Ginnea). From Acre there also runs a road directly east over the mountains to Khân Jubb Yûsuf.

The coast road from Acre northwards passes through Zib (Akhezib, Edippa) and the two promontories of Râs en-Nâkûra and Ras-el-Abyad (Scala Tyriorum), and so continues to the maritime plain of Tyre.—To return to the south, from Egypt (Suez, Arsinoe) the desert was crossed to Kuleibe (Rechoboth), Khulasa (Elusa), and Bir-es-seba (Beersheba), and from this place the route went northward to Ed-Dhoheriye and El-Khalil (Hebron). In like manner a road from Aila up the Araba valley crossed the Es-Sufâh pass to Hebron.—One of the most frequented highways traverses the central mountain chain northwards, and, though somewhat difficult in various parts, connects a number of the most important places of central Palestine. Starting from Hebron, it runs past Rama and Hulhûl through the Wâdi el-Biyâr, and leaving Bethlehem on the right holds on to Jerusalem, where a branch strikes east by Khân Hadrîr (probably there was once another route) to Jericho. From Jerusalem northwards it naturally continues by Sha'fat past Er-Râm (Rama) to El-Bire (Beeroth), and then onwards by 'Ain el-Haramiye, Sinjil, and Khân Lubban through the Mukhna plain to Nâbulus (Shechem). From this point a route runs down to the Jordan and Es-Salt (Ramoth Gilead?); another passes by Tubâs (Thebez) north-eastward in the line of the Jordan valley to Beisan (Bethshean, Scythopolis). The road across the highlands passes a little to the east of Sebastîye (Samaria, Sebaste), running along the west side of the Merj el-Ghuruk and past Tell Dothan (Dothan) to Jennin. Thence the road northward to Nazareth skirts the east side of the plain of Esdraelon, and from Nazareth a path strikes to Acre. The caravan route proper passes from 'Afulê north-eastwards past Jebel et-Tûr (Tabor) to Khân et-Tujjâr (where several roads cross), and reaches the Lake of Tiberias near Mejdal (Magdala). It keeps by the shore only for a short distance. Having traversed the small plain of Gennesar, it begins again to climb the mountains where they approach the lake at Khân Minye (which, however, for many reasons cannot be Capernaum), and then it goes on to Khân Jubb Yûsuf, strikes down again into the valley of the Jordan, and crossing the river at Jisr Benât Ya'kûb holds on across Jebel Hîsh to Damascus. The mountain district of Samaria is crossed by a great number of small roads, but none of them are true caravan routes or worth particular mention. An old caravan route once ran northwards up the Jordan valley from Jericho to Beisan; and from Beisan an important, now less frequented, road crossing the river at the bridge El-Mejâm'a struck north-east to Fik Tseil and Nawa in the Haurân, and finally to Damascus.—In the country east of Jordan a great highway of traffic ran from Petra (or really from the Elanitic Gulf) by Kerak (Kir Moab) to Rabba (Rabbath Moab, Arcopolis); in front of Arer (Ar'âr) it crosses the Môjib (Arnon) and runs northwards through the highlands to Hesban (Heshbon) and thence to Amman (Rabbath Ammon, Philadelphia). A route also led from Jericho to Es-Salt (which could also be reached from Hesban) and thence northwards to the Jabbok and Jerash (GERASA, see vol. x. p. 441); and then from Jerash one stretched north-west by Tibne to Mkés (Gadara) and the valley of the Jordan, and another north-east to the Zumle and the Hauran or more precisely to Bosra (Bostra), and so on to Damascus. It must also be mentioned that the great pilgrim's track direct from Damascus to Medina and Mecca skirts the eastern frontier of the country. A great many roads await more detailed investigation; what has been said may suffice to show what lines of communication existed and still exist between the more important places of Palestine.

Population.—There are no trustworthy estimates of the number of inhabitants in the country at any period of its history. Certain districts, such as Galilee, have, there is no doubt, from early times been much more populous than certain other districts; the desert of Judah and some portions of the country east of Jordan must all along have been very sparsely peopled. The figures given in the book of Numbers indicate that the whole country contained about 2½ million souls,—it being assumed that the statistics do not refer to the time of the wandering in the wilderness, and that the details

may be suspected of being artificially adjusted. The number 2½ to 3 millions may indeed be taken as a maximum; the population can hardly ever have been more than four times its present strength, which is estimated at 650,000 souls. Thus, in the most flourishing period, about 250 to 300 inhabitants would go to the square mile, while at present there may be about 65, a number which is rather above than below the mark. Lists based on information collected by the Turkish Government give much lower figures, viz., for the sanjak of Jerusalem (with the districts Jerusalem, Yâfa, Hebron), 276 places with about 24,000 houses (families); for the sanjak Belka (with the districts of Nâbulus, Jennin, Ajlûn, and Es-Salt), 317 places and 18,984 houses; for the sanjak 'Akka (Acre) (with the districts 'Akke, Haifa, and Safed), 160 places with 11,023 houses, —making a total of 753 places with 54,237 houses. Reckoning five persons per house, this gives a population of 271,185, exclusive of the small number of Bedouins. Detailed statistics there are none as regards the relative strength of the Bedouin element and the peasantry, the numerical representation of the different religions, or any matter of this sort.

The ethnographic-geographical sketch given above has shown how the population of Palestine even at an early date was a very mingled one; for even when they arrived in the country foreign elements were present among the Israelites, and later on they absorbed or were absorbed by the Canaanites. The Philistines, Moabites, and others in course of time were merged in the new nationality. From the period of the exile colonies from the east settled in the country, and so powerful did the Aramaean contingent gradually grow that Aramaean became the popular tongue. Next were added Greek and Roman colonies. The Arabic element exerted considerable influence even before the days of Islam; with the Mohammedan conquest it became the dominant power, though it was only by slow degrees that it obtained numerical superiority. The Arab tribes transplanted to Palestine their old distinctions, especially that between Northern and Southern Arabs (Kais and Yemen; cf. ARABIA). The Arab peasantry is still divided into clans; for example, the districts of the Beni Hasan and Beni Malik to the west of Jerusalem, those of the Beni Hârith, Beni Zeid, and Beni Murra to the north, and that of Beni Sâlim to the east. Till recently the relations of the separate clans of fellahin was one of mutual hostility, and, unhindered by the Turkish Government, they engaged in sanguinary conflicts. In manners and in language (though Arabic is universally in vogue) the Palestine peasants retain much that is ancient. It is extravagant, however, to maintain from the traditions they preserve that primeval Canaanite elements still exist among them. The prevalent type, in fact, is Syro-Arabic, or in many districts pure Arabic; and their superstitious customs are partly remains of Syrian beliefs, partly modern Arabic reproductions, under similar external conditions, of ancient superstitions. These remarks are applicable to the saint worship at present spread through the whole Oriental world. The fellahin are on the whole a diligent frugal race, not destitute of intelligence. If well treated by a just Government which would protect them from the extortions of the nomadic tribes, they would be the means, with the assistance of the capitalist, of greatly improving the cultivation of the country, especially in the various lowland districts. They choose their own village sheikhs, who derive most of their authority from the reputation of their virtues, their bravery, and their liberality. The Bedouins, i.e., wandering tribes of pure Arab origin, also play an important part in the country. Till quite recently they used to visit certain settled districts and exact black mail from the peasants; and they find their undisputed domain in those districts which are incapable of cultivation, and fit only for cattle rearing, and in other fertile portions which for various reasons are not occupied by the husbandman. To the first class belong the belt of desert to the west of the Dead Sea, the southernmost parts of the country west of Jordan and the south country beyond the river (Moab); to the second belong the greater portion of the maritime plain, the depression of the Jordan valley, and part of the country to the east. The divisions of the Arab tribes will be discussed in the article SYRIA. In Palestine east of Jordan the Beni Sakhr (Moab) are of most importance; Jebel 'Ajlûn is the seat of the 'Adwân. The Ghawârîne (the inhabitants of the Ghor or Jordan depression) form a peculiar race which, as they are partly agricultural, have been a long time settled in the district. In type, as well as by their degeneracy, they are distinguished from the other Bedouins. The true Bedouin style of life can be studied only beyond the Jordan or to the south of Palestine, —the tribes west of the river, such as the Ta'âmire and Jehalin in the south being all more or less deteriorated. As the Turkish race does not fall to be treated in connexion with Palestine, it simply remains to mention the Frankish (European) elements. During the Middle Ages these were not unimportant, especially along the coast; numerous ruined churches are still to be seen as the last and only memorials of crusaders' colonies (see Vogüé, *Les églises de la Terre Sainte*, Paris, 1860, and the article SYRIA). Nor must the missionary efforts be forgotten which in our own times have been again specially directed to Palestine. As regards the Roman Catholic Church, the Francis-

cans have maintained their position in the Holy Land even in troublous times, and have not only established schools and printing presses but protected the Christian sanctuaries and taken care of pilgrims and travellers. On the whole it may be said that, in comparison with that of the Roman and Greek Churches, the influence of Protestants is outwardly small. A German sect called the Templars settled in Palestine some years ago, and has now colonies at Yâfa, Sarona, Jerusalem, and Haifa. The colonists, about 1000 in number, have to contend with many and grievous difficulties, and are deficient in capital. Wine-growing is the most lucrative branch of their activity. As long as the Turks hold rule over the country successful colonization is hardly possible.

Literature.—The literature in regard to Palestine is extremely abundant. As bibliographical guides of the first class may be mentioned—Tobler, *Bibliographia geographica Palestine*, Lepsic, 1869 (a supplement to this appeared in *Petzhold's Neuer Anzeiger für Bibliogr. und Bibliothekwissenschaft*, Dresden, 1875). The works published between 1867–77 (with additions to Tobler) will be found in Röhricht and Meisner's *Deutsche Pilgerreisen nach dem Heiligen Lande*, Berlin, 1880 (pp. 647–648). Socin has given an annual survey of current literature from 1877 in the *Zeitschr. des Deutschen Palästina-Vereins*. Compare also *Archives de l'Orient Latin*, I., Paris, 1881. The series of old pilgrimages published by the Société de l'Orient Latin deserves special mention:—*Itinera Latina belis sacris anteriora*, Geneva, 1879; *Itinéraires à Jérusalem et descriptions de la Terre Sainte red. en français aux XI–XIII siècles*, Geneva, 1882. Older studies on the geography of Palestine are Eusebius, *Onomasticon urbium et locorum Sancte Scripturæ* (edited by Larsow and Parthey, 1862, and De Lagarde, 1870); Neubauer, *La géographie du Talmud*, Paris, 1858; Hadz. Reland, *Palestina monumentis veteribus illustrata*, 2 vols., 1714; Ritter, *Vergleichende Erdkunde*, vol. xx., xviii., Berlin, 1850–55; K. Raumer, *Palestina* (4th ed., 1860; now to be completely remodelled by Furrer). Strictly scientific accounts of travel begin only in the present century; the credit of having led the way belongs to E. Robinson (*Biblical Researches in Palestine*, 1841; *Later Biblical Researches*, 1856; *Physical Geography*, 1865). Of importance is the voluminous work of V. Guérin, *Description géographique, historique, et archéologique de la Palestine*, 1868, sq. Splendid service has been rendered by the Palestine Exploration Fund, which has published *Quarterly Statements* since 1869.—the labours of Wilson, Warren, and Conder being particularly noteworthy. In 1880 appeared Conder and Kitchen's *Map of Western Palestine* (26 sheets), the result of surveys extending over many years; an edition in six sheets was published in London in 1881. Trelawney Saunders's *Special Edition illustrating the Divisions and the Mountain Ranges*, 1882, is to be recommended (compare his valuable *Introduction to the Survey of Western Palestine—its Waterways, Plains, and Highlands*, 1881); but the same cannot be said about the *Special Edition* of the map illustrating the Old Testament and that illustrating the New Testament, London, 1882 (each six sheets), many of the identifications resting on mere provisional conjecture. As companions to the great maps we have *Memoirs of the Topography, Orography, Hydrography, and Archaeology* (3 vols.), a *Name-List* (1 vol.), *Special Papers* (reprinted from the *Statements*, 1 vol.), *Jerusalem* (1 vol.), *Flora and Fauna* (1 vol.). The Exploration Fund is preparing to accomplish a similar work for the country east of Jordan, since the American Society, which was to have undertaken the survey of that region, has relinquished the undertaking (compare also Selah Merrill, *East of the Jordan*, New York, 1881). The German Palästina-Verein has published its *Zeitschrift* since 1878, a yearly volume of topographical and historical investigations on definite points. Guide-books which may partly serve as works of reference are—Baedeker's *Palestine and Syria* (written by Socin, 1876), Murray's *Handbook for Travellers in Syria and Palestine* (by Porter, 1875), and Joanne's *Guide* (new edition, 1882). The best illustrated work is *Picturesque Palestine, Syria, and Egypt* (edited by Colonel Wilson, &c., London, 1881), to which may be added D. Roberts, *The Holy Land*, and Lortet, *La Syrie d'aujourd'hui*, 1884. W. M. Thomson's *The Land and the Book*, London, 1881–83, is of particular value for manners and customs. For natural history, see Tristram, *The Land of Israel* (London, 1861) and *Natural History of the Bible* (London, 1873). Lortet's geological investigations will be found in De Laynes, *Voy. d'exploration à la Mer Morte*, &c., Paris, 1876. For matter of geographical detail consult especially Tobler's works (*Bethlehem; Nazareth; Dritte Wanderung*, &c.). Wilson, *The Lands of the Bible*, Edinburgh, 1847; Conder, *Tent Work in Palestine*, 1878; and Flinn, *Byways in Palestine*, London, 1868, may conclude the list. Meisner's *Historischer Atlas* (Gotha, 1868) is still the best. (A. SO.)

PALESTRINA. See PRÆNESTE.

PALESTRINA, GIOVANNI PIERLUIGI DA (c. 1524–1594), now universally distinguished by the honourable title *Princeps Musicæ*, occupies a more important position in the history of art than any other composer, ancient or modern; for it is to his transcendent genius that music is indebted for its emancipation from pedantic trammels, which, ignoring beauty as its most necessary element, were fast tending to reduce it to the level of an arithmetical problem.

The exact date of Palestrina's birth is unrecorded. It most probably took place in 1524, and certainly at Palestrina (the Præneste of Roman geographers,—whence the style accorded to him in Latin¹). Some early writers call him Gianetto da Palestrina, or simply Gianetto; and this early custom—which has led some modern critics to mistake his identity—combined with the general use of his Christian names only, has induced the belief that he was of peasant origin; but Signor Cicerchia is said to have discovered at Palestrina documents proving that his father bore the family name of Sante, and his mother that of Gismondi,—in which case he must have been of gentle birth. The statement, however, needs confirmation.

¹ Joannes Petrus Aloysius (or Petralloysius) Prænestinus.

In early youth Palestrina studied at Rome in company with Animuccia, and, perhaps also, Giovanni Maria Nanini, in a music-school founded by Goudimel (*q.v.*). After this, we hear no more of him until 1551, when, by favour of Pope Julius III., he was elected Magister Cappellæ and Magister Puerorum at the Cappella Giulia, S. Pietro in Vaticano, with a salary of six scudi per month, and a house. Three years later he published his *First Book of Masses*, dedicated to Pope Julius III., and beginning with the Missa "Ecce Sacerdos magnus," concerning which we shall have to speak more particularly hereafter.¹ On January 13, 1555, Palestrina was enrolled, by command of Pope Julius III., among the singers of the Cappella Sistina. This honour involved the resignation of his office at the Cappella Giulia, which was accordingly bestowed upon his friend Animuccia. But the legality of the new appointment was disputed on the ground that Palestrina was married, and the father of four children, his wife, Lucrezia, being still alive; and, though, for the moment, the pope's will was law, the case assumed a different complexion after his death, which took place only five weeks afterwards. The next pope, Marcellus II., was succeeded, after a reign of twenty-three days, by Paul IV.; and within less than a year that stern reformer dismissed Palestrina, together with two other married singers, Ferrabosco and Bari, with a consolatory pension of six scudi per month to each. This cruel disappointment caused Palestrina a dangerous illness; but better fortune was in store. In October 1555 he was appointed Maestro di Cappella at the Lateran, without forfeiting his pension; and in February 1561 he exchanged this preferment for a similar one, with an allowance of sixteen scudi per month, at Santa Maria Maggiore.

Palestrina remained in office at this celebrated basilica for ten years; and it was during this period that the most critical event in his life took place—an event of such grave importance that its results have never ceased to furnish matter for discussion to the musical historian from the time of its occurrence to the present day.

In 1562 the council of Trent censured the prevalent style of ecclesiastical music with extreme severity. In 1564 Pope Pius IV. commissioned eight cardinals to investigate the causes of complaint; and these proved to be so well founded that it was seriously proposed to forbid the use of all music in the services of the church, except unisonous and unaccompanied plain-chant—a proceeding which, so far as the church was concerned, would have rendered the "art of music," properly so called, a dead letter, not only for the time being, but in perpetuity, for the decree, once promulgated, could only have been repealed by another general council.

It is evident that very gross abuses must have been needed to justify so stringent a measure as this in the eyes of men accustomed to regard art as the obedient handmaid of religion; yet, strange to say, the nature of these abuses has never yet been clearly established by any musical historian, either English or foreign. Baini devotes several chapters of his great work² to their discussion, but without arriving at any definite conclusion. Burney and Hawkins seem to have regarded the question as one involving no deeper significance than a more or less exalted standard of artistic purity. Ambros, generally so reasonable a critic, denies the existence of any just ground of complaint at all, even in the limited sense claimed by Burney and Hawkins, and condemns the severer censures of Baini and his followers as attempts to substantiate a groundless myth. Bernsdorf speaks little less strongly, simply because a certain tradition, which represented the circumstances as having taken place in 1555, during the short reign of Pope Marcellus II., has been proved to be certainly false. That more than one groundless myth have been substituted for the real

account of the occurrence is true enough—one, at least, involving an anachronism of no less than twelve centuries. But no sober historian has ever credited these absurd stories; and it is not to them that Baini gives currency or that Ambros objects. The misfortune is that each successive narrator has perpetuated the vague statements of his predecessor, instead of seeking for information at original sources; and this mistaken course has resulted in an infinity of oracular utterances, no two of which agree. To conflicting opinions like these, one only form of answer is possible—that furnished by contemporary documents. Fortunately, an immense amount of church music, written in the style universally cultivated at the period of which we are treating, has been preserved to us both in MS. and in print; and, though the forms of notation employed by its transcribers are no longer in common use, students of mediæval music are able to decipher them with absolute certainty. Objections like those raised by Ambros can therefore be met by reference to examples of the music actually sung at the time the council of Trent condemned the then prevailing style.

The first impression derived from the study of these venerable records tends to confirm a statement already made, to the effect that the art of music was rapidly degenerating into a mere system of figures. There is evidence enough to prove the existence, from the 14th century downwards, of a growing tendency to cultivate, at the expense of ideal beauty, certain forms of technical ingenuity worthy only of association with a clever conundrum. A canon which could be sung upside down, as well as backwards and forwards, was more highly esteemed than one that could be sung backwards and forwards only. The amount of skill and learning wasted on the construction of such canons was almost incredible; and equally so was the puerility of the conceits with which men known to have been profound scholars endeavoured to give an additional zest to their strange inventions. When the construction of a canon, often written in the form of a cross or a rainbow, was so complicated that it was almost impossible to find out how to sing it, they hinted at the secret by means of a motto as obscure as the music itself. In one instance, *Respicce me, ostende mihi faciem tuam*, indicates that two singers are to hold the music between them, each reading it upside down from the other's point of view. In another, *Justitia et Pax osculatur sunt* intimates that two singers are to begin simultaneously at opposite ends of the music, singing all the notes in correct time until they meet in the middle. In a third case, *Βάρανος ἐκ Σερφίφου* means that a certain voice is to be silent—in allusion to Ælian's assertion that the frogs on the island of Seriphus do not croak. We do not say that all the music of the period was of this character; but a multitude of such examples, written by the most celebrated musicians of the Middle Ages, have been preserved to us, and most of them are adapted to the words of the Mass. Surely the council had just right to complain of this.

Another still more serious abuse consisted in the introduction, among the words of the Mass, of foreign passages having no connexion whatever with the original text,—one voice being made to sing "Alleluia" or "Ave Maria," while others were singing the words of the "Credo" or the "Sanctus."

In order to justly appreciate the true bearing of this very prevalent abuse, it will be necessary for the English Church composer to divest himself of certain not very unnatural prejudices,—and, first of all, of the idea that the custom implied intentional irreverence on the part of those who introduced it, which, in spite of appearances, it certainly did not. In England the music sung forms an essential part of the service. This is not the case with the Mass. In reciting the prescribed form of words with the prescribed ceremonies, the officiating priest fulfils unaided all the necessary conditions of the service, while the congregation looks on and worships, and the choir endeavours to excite its devotion by singing appropriate music. As a matter of fact, the words to which this music is set are identical with a portion of those recited by the priest; but they represent no essential element of the service, nor are they for the most part sung at the same time that the priest recites them. Except in the delivery of a few responses, the action of the choir is entirely independent of that of the priest; and the action of the congregation is independent of both. Each member of it may use any book of devotions he pleases, and he will generally be careful to use prayers and meditations suitable to the festival in which he is taking part. For instance, at Christmas he will meditate on the nativity, "our Lord, at Easter on His resurrection,—continuing his meditations on these subjects, without reference, during the greater part of the mass, to the words the priest is reciting. It is only by bearing these facts carefully in mind that we can rightly understand what is to follow.

The mediæval composer very rarely constructed his Mass upon an original subject. His favourite plan was to select as his principal theme a fragment of some well-known plain-chant hymn or antiphon, and from the words proper to this melody—technically called the *canto fermo*—the Mass was named. We

¹ The first edition of this was printed in 1554; the second—with a title-page representing Palestrina offering his music to the Pope—in 1572.

² *Memorie storico-critiche della vita e delle opere di Giovanni Pierluigi da Palestrina*, Rome, 1828.

still possess countless examples of the Missa "Æterna Christi munera," the Missa "Vidi turbam inagmam," "Repleatur os meum," "Dum compleretur," "Iste Confessor," and others of like character, all named after the *canti fermi* on which they are based, though, except in a few comparatively rare cases to be presently mentioned, the words proper to the *canti fermi* do not appear in the work, the selected melody being adapted to the actual words of the Mass. And thus far the custom was not only an unobjectionable but a thoroughly commendable one; for the melodies employed were familiar to every educated member of the congregation, and to these the sound of the well-known tune must necessarily have suggested the sacred words belonging to it, and that so powerfully that the performance on Christmas Day of a Mass founded on the melody of "Hodie Christus natus est," or on Whitsunday of one based on that of "Veni, Creator Spiritus," could scarcely have failed to induce in the minds of the assembled worshippers the exact train of meditation most desirable on these great festivals.

Had composers been contented with this, all would have been well. But unhappily they were tempted to add the extraneous words; and their intention, in doing so, has been grossly misrepresented. They have been accused of wilfully sacrificing sense to sound, with the unworthy object of displaying their technical skill to greater advantage. At the first blush there may seem some truth in this; but here again the strictures will not bear examination in presence of the actual records.

Nearly a century before the birth of Palestrina, Joannes de Tinctoris—the compiler of the earliest known *Dictionary of Musical Terms*—wrote a Mass in which one voice interpolated the words here printed in italics, while the others sang the authorized text, exactly as it appears in the Missal:—

Cherubim ac seraphim ceterique spiritus angelici Deo in altissimis incessabili voce proclamant, "Sanctus, Sanctus, Sanctus, Dominus Deus Sabaoth." "Pueri Hebræorum sternerunt vestimenta ramos palmarum Jesu filio David clamabant Osanna in excelsis." "Benedictus semper sit filius Altissimi, qui de caelis huc venit in nomine Domini."

Clearly this is nothing more than an amplification of the received version—a reverent commentary upon the words actually recited by the priest. In what way can the addition of these extraneous sentences conduce to the display of the composer's musical learning? He might just as easily have set the same notes to the unaltered text.

Again, Palestrina himself begins his *Liber primus Missarum*, already mentioned, with a Mass for which he has chosen, as a *canto fermo*, the entire melody of the gradual, "Ecce Sacerdos magnus," sung on the festivals of certain great doctors of the church, such as Ambrose and Athanasius,—one voice being constantly employed in the reiteration of this in long, slow notes, sung to its own proper words, while three others sing the authorized text in the usual way. What object could possibly have tempted the composer to arrange his music thus, other than that of using the familiar words and tune as a means of reminding his hearers of the great work wrought by the saints whose festival they are commemorating? Palestrina was the last man in the world to have paraded his learning; and, had he wished to call attention to it, he might have done so in a hundred easier ways. Indeed, if the Mass were to be sung to-morrow, nothing would be easier than to fit the words of the Mass to the notes of the *canto fermo* throughout. Still, notwithstanding the innocence of the composer's intention, there can be no doubt that the custom was a highly reprehensible one; and it led to something very much worse.

The troubadours and minnesingers of the Middle Ages produced a host of beautiful secular melodies, many of which still live among us in the guise of "national airs," though the names of their authors have been forgotten for ages. The beauty of many of these melodies tempted composers to select them as *canti fermi* for their Masses; and not a few such works were actually named after them, as the Missa "L'Homme armé" (a very common example), the Missa "Mon cuer se recommande à vous," and many others. And in this the mediæval musician had no more thought of intentional irreverence than had the Flemish painter when he represented the Nativity as taking place in a little roadside hostelry like that to which he was accustomed to resort for his evening meal. But he committed a grave error of judgment. For, just as the sound of the sacred *canto fermo* brought to remembrance the words with which it was connected, so, we may be sure, did that of the secular one; and the greater its beauty the more surely would it do its evil work. It was by its beauty alone that it attracted the composer; yet his treatment of it proves beyond all doubt that he meant no evil. This, however, is the last stage of our history at which we can acquit him of it; and perhaps even here we may have strained the point a little too far.

As might naturally have been expected, the introduction of the secular *canto fermo* was followed by exactly the same results as that of the sacred one. It took a longer time to bring about the evil, but it came at last. The familiar words were sung to the familiar notes, not by the will of the composer, who would never have dared to insert them, even had he wished to do so, but by that of profane singers, who surreptitiously trolled them forth for the

gratification of a prurient taste, while the great body of the choir adhered to the sacred text. And, in the face of these undeniable facts, Hawkins calmly speaks of the reform as one of style only, while Ambros, intoxicated by the beauty of so much of the music preserved to us, and especially by the compositions of Claude Goudimel, for whom he entertained a well-founded admiration, tells us, in so many words, that no reform of church music was ever needed or demanded, and that no such reform as that popularly attributed to the influence of Palestrina ever took place.

Two of the commissioners, however,—Cardinals Borromeo and Vitellozzi,—while admitting the urgent need of reform, pleaded for a compromise, and happily the commission agreed to postpone its final decision until Palestrina—already recognized as the greatest composer then living—had been permitted to prove, if he could, the possibility of producing a Mass which should not only be free from the abuses complained of, but should also conduce to the excitation of true devotional feeling by bringing the plain sense of the words into the strongest possible relief, and that so manifestly that it might be presented to all future composers as the pattern of what true ecclesiastical music ought evermore to be.

A careful comparison of Palestrina's works with those of the best of his contemporaries conclusively proves that in him alone were united all the qualifications necessary for the success of this difficult attempt, which demanded the earnestness of a deeply religious mind, the science of a profoundly learned musician, and the refined taste of an artist whose sense of beauty was strong enough to overcome all desire for the display of technical power at the expense of that delicacy of expression without which the required solemnity of style would have been unattainable. Animuccia lived as holy a life as Palestrina. The elder Nanini, if not so learned a musician as he, was at any rate more learned than by far the greater number of his contemporaries. But the world had yet to learn how far refinement of taste could be carried in the composition of sacred music; and upon Palestrina devolved the duty of teaching it its lesson. Ockenheim had already astonished it by the ingenuity with which he evolved from the contrapuntal materials at his command a form so symmetrically proportioned that it seemed as if no future artificer could add to its perfection¹; but the materials were dry bones, and the resulting form no more than a wonderfully articulated skeleton. To the erudition of Ockenheim Josquin Depres united the fire of true genius. To him we are indebted for many, if not most, of the finest works produced before the age of Palestrina.² Yet even he could do no more than clothe Ockenheim's bare skeleton with flesh. It remained for Palestrina to breathe into the perfect body the breath of that artistic life which alone could enable it to give thanks to the Creator of all things in tones which betokened the presence of the soul within it. He first taught the world that music was not a mere lifeless collection of notes,—that, as the gift of speech enabled man to express his thoughts to his fellow-man, so the gift of harmony enabled him to express his feelings, whether of devotion, or praise, or prayer, and this so intelligibly that he might "sing praises with understanding" in the truest sense of the words. And it was to the decree of the council of Trent that he was indebted for the opportunity of showing how great a work it was possible to accomplish in this direction, as well as for the means of accomplishing it with such good effect that to this day the results are apparent in every church in which true ecclesiastical music is sung.

Dreading to trust the issue of so severe a trial to a single work, Palestrina, with characteristic modesty, submitted

¹ For examples, consult the *Dodecachordon* of Glareanus, and Petrucci's *Odhecaton* and *Canti C. No. cento cinquanta*.

² See two extremely rare volumes of his Masses in the library of the British Museum.

three Masses to Cardinal Carlo Borromeo for approval. These were privately rehearsed, in presence of the commissioners, at the palace of Cardinal Vitellozzi; and, while warmly admiring them all, the judges were unanimous in deciding that the third mass fulfilled, in the highest possible degree, all the conditions demanded. The private trial took place in June 1565; and, on the 19th of that month, the Mass was publicly sung at the Sistine Chapel, in presence of Pope Pius IV., who compared its music to that heard by St John in his vision of the New Jerusalem. Thenceforth it was formally accepted as the type of all true ecclesiastical music. Parvi transcribed it, for the library of the choir, in characters of extraordinary size and beauty; and, in acknowledgment of his services to art, Palestrina was appointed by the pope composer to the Sistine Chapel, an office created expressly in his honour, and confirmed to him by seven later pontiffs, though with the very insufficient honorarium of three scudi per month, in addition to the six which formed his pension.

In 1567 this Mass was printed in Palestrina's *Liber secundus Missarum*. The volume was dedicated to Philip II. of Spain, but the Mass was called the "Missa Papæ Marcelli." This title, clearly given in honour of the short-lived pope Marcellus II., has given rise to an absurd story, told by Pellegrini and others, to the effect that the Mass was composed by Pope Marcellus I., martyred early in the 4th century, and was only discovered by Palestrina. Of course, in the 4th century the composition of such music was impossible; but this is only a specimen of the innumerable fables which have brought the true history into disrepute. The Missa Papæ Marcelli is undoubtedly Palestrina's greatest work. Its ineffable beauty has often been described in glowing terms by those who have heard it in the Sistine Chapel, but it was never heard in England until 1882, when the Bach choir, consisting of two hundred unaccompanied voices, sang it at St James's Hall, under the direction of Mr Otto Goldschmidt; and the effect produced on that occasion more than justified all that had ever been said of the music, which is certainly the most beautiful, the most solemn, and the most truly devotional that has ever been dedicated to the service of the church.

We have dwelt at some length on these circumstances, because they left a more indelible impression upon the history of art than any other events in Palestrina's life, which was not what the world would call a prosperous one, though he himself was quite satisfied with his condition.

Upon the death of Animuccia in 1571 Palestrina was re-elected to his appointment at the Cappella Giulia. He also succeeded Animuccia as Maestro di Cappella at the Oratory of Philip Neri; but these appointments were far from lucrative, and he still remained a very poor man. In 1580 he was much distressed by the death of his wife; and the loss of three promising sons, Angelo, Ridolfo, and Silla, left him with one child only—Igino—a very unworthy descendant. In 1586 a new trouble befel him: Pope Sixtus V. wished to appoint him maestro to the pontifical choir, as successor to Antonio Boccapadule, then about to resign, and commissioned Boccapadule to prepare the choir for the change. Boccapadule, however, managed so clumsily that Palestrina was accused of having meanly plotted for his own advancement. The pope was very angry, and punished the calumniators very severely; but Palestrina lost the appointment. These troubles, however, did not hinder his work, which he continued, without intermission, until February 2, 1594, when he breathed his last in the arms of his friend, Filippo Neri.

The printed works of Palestrina include twelve volumes of Masses; seven volumes of Motets for from four to twelve voices; two volumes of Offertoria, and one of Hymns, for the whole year; one

volume of Lamentations, three of Litanies, and one of Magnificats; two of Madrigals, the loveliest in existence; and two of Madrigali spirituali; besides an immense number of compositions still remaining in MS. The whole of these are now in course of publication by Breitkopf and Härtel, of Leipsic. (W. S. R.)

PALEY, WILLIAM (1743–1805), was born in 1743 at Peterborough, where his father was one of the minor canons of the cathedral. The Paley family belonged to the West Riding of Yorkshire, and in 1745 Paley's father was appointed head master of the grammar school of Giggleswick, his native parish. Here Paley received his early education under his father's care. In 1759 he proceeded to Cambridge, where his first undergraduate years were given up, according to his own account, more to society than to study. But, being roused by a reproof from one of his companions, he used the remainder of his time to such advantage that he came out senior wrangler at the end of his course. After taking his degree in 1763, Paley was for about three years assistant in a school at Greenwich; but on his election to a fellowship he returned to Cambridge, and became, in 1768, one of the junior tutors of his college. His colleague in this office was John Law, son of Dr Edmund Law, then master of Peterhouse, and afterwards bishop of Carlisle. To the connexion thus formed Paley was afterwards indebted for his first preferments in the church. As tutor at Christ's, Paley lectured on Locke, Clarke, and Butler, and also delivered a systematic course on moral philosophy, which formed the basis, more than ten years later, of his well-known treatise. The subscription controversy was then agitating the university, and Paley published an anonymous *Defence* of a pamphlet in which Bishop Law had advocated the retrenchment and simplification of the thirty-nine articles. But, though Paley was all for "worshipping God in that generality of expression in which He himself has left some points," he did not see his way to join the petitioners for a relaxation of the terms of subscription. His own view of the articles, as simply "articles of peace," probably led him to consider their action as a piece of overstrained conscientiousness. In 1776 Paley vacated his fellowship by marriage, and retired to the rectory of Musgrave in Westmoreland, which had been conferred on him the year before by the bishop of Carlisle. This very modest living was soon supplemented by the vicarage of Dalston, and presently exchanged for that of Appleby. In 1782 he became archdeacon of Carlisle on the appointment of the younger Law to an Irish bishopric. His first important work, *The Principles of Moral and Political Philosophy*, was published (as *Principles of Morality and Politics*) in 1785, and Paley received the unusually large sum of £1000 for the copyright. The book at once became the ethical text-book of the university of Cambridge, and passed through fifteen editions in the author's lifetime. It was followed in 1790 by his first essay in the field of Christian apologetics, *Horæ Paulinæ, or the Truth of the Scripture History of St Paul evinced by a comparison of the Epistles which bear his name with the Acts of the Apostles and with one another*. Though the original idea of the book was derived from Doddridge, this is probably the most original of its author's works. It was followed in 1794 by a more general work in the same field, the celebrated *View of the Evidences of Christianity*. Paley's latitudinarian views, combined with a certain homely outspokenness in the *Moral and Political Philosophy* regarding the foundations of civil authority ("the divine right of kings is like the divine right of constables"), are said to have debarred him from the highest positions in the church. But his able defence of the faith brought him substantial acknowledgments from the episcopal bench. The bishop of London gave him a stall in St Paul's; the bishop of Lincoln made him subdean of that

cathedral; and the bishop of Durham conferred upon him the rectory of Bishop-Wearmouth, worth £1200 a year. Paley transferred his household to Bishop-Wearmouth in 1795. His wife, the mother of eight children, had died four years before, and in the end of 1795 Paley married a second time. During the remainder of his life his time was divided between Bishop-Wearmouth and Lincoln. In 1800 he was attacked by the disease of the kidneys which ultimately carried him off. It was in the intervals of comparative health and ease that remained to him that his last, and in some respects his most remarkable, work was produced, *Natural Theology, or Evidences of the Existence and Attributes of the Deity collected from the Appearances of Nature* (1802). He endeavoured, as he says in dedicating the book to the bishop of Durham, to repair in the study his deficiencies in the church. He died on the 25th May 1805.

In the dedication just referred to, Paley claims a systematic unity for his works. It is true that "they have been written in an order the very reverse of that in which they ought to be read"; nevertheless the *Natural Theology* forms "the completion of a regular and comprehensive design." The truth of this will be apparent if it is considered that the *Moral and Political Philosophy* admittedly embodies two presuppositions—(1) that "God Almighty wills and wishes the happiness of His creatures," and (2) that adequate motives must be supplied to virtue by a system of future rewards and punishments. Now the second presupposition depends, according to Paley, on the credibility of the Christian religion (which he treats almost exclusively as the revelation of these "new sanctions" of morality). The *Evidences* and the *Horæ Paulinæ* were intended as a demonstration of this credibility. The argument of these books, however, depends in turn upon the assumption of a benevolent Creator desirous of communicating with His creatures for their good; and the *Natural Theology*, by applying the argument from design to prove the existence of such a Deity, becomes the foundation of the argumentative edifice. The sense of unity in the structure is increased to a reader of the present day by the uniformity of the point of view from which the world is regarded throughout. Paley has popularized for 19th-century use the Deistic conception of the universe and the divine economy which was common ground last century both to the assailants and the defenders of orthodox Christianity.

In his *Natural Theology* Paley has adapted with consummate skill the argument which Ray (1691) and Derham (1711) and Nieuwentyt¹ (1730) had already made familiar to Englishmen. "For my part," he says, "I take my stand in human anatomy"; and what he everywhere insists upon is "the necessity, in each particular case, of an intelligent designing mind for the contriving and determining of the forms which organized bodies bear." This is the whole argument, and the book consists of a mass of well-chosen instances marshalled in support of it. But by placing Paley's facts in a new light, the theory of evolution has deprived his argument of its force, so far as it applies the idea of special contrivance to individual organs or to species. Paley's idea of contrivance is only applicable if we suppose a highly developed organism to be dropped suddenly into foreign surroundings. But the relation of an organism to its environment is not of this external nature, and the adaptation of the one to the other must be regarded as the result of a long process of interaction in the past history of the species. In thus substituting the operation of general laws for Paley's continual invocation of a supernatural cause, evolution passes no judgment on the question of the ultimate dependence of these laws upon intelligence; but it evidently alters profoundly our general conception of the relation of that intelligence to the world.

The *Evidences of Christianity* is mainly a condensation of Bishop Douglas's *Criterion* and Lardner's *Credibility of the Gospel History*. But the task is so judiciously performed that it would probably be difficult to get a more effective statement of the external evidences of Christianity than Paley has here presented. The general position, however, that the action of the first preachers of Christianity was due "solely" to their belief in the occurrence of

certain miraculous events is on the same level as the view that "the proper business of a revelation" is to certify future rewards and punishments. It betrays a defective analysis of the religious consciousness. For the rest, his idea of revelation depends upon the same mechanical conception of the relation of God to the world which dominates his *Natural Theology*; and he seeks to prove the divine origin of Christianity by isolating it from the general history of mankind, whereas later writers find their chief argument in the continuity of the process of revelation.

For the place of Paley's theological utilitarianism in the history of ethical speculation in England, see *ETHICS*.

The face of the world has changed so greatly since Paley's day that we are apt to do less than justice to his undoubted merits. He is nowhere original, and nowhere profound, but he justly claims to be "something more than a mere compiler." His strong reasoning power, his faculty of clear arrangement and forcible statement, place him in the first rank of expositors and advocates. He masses his arguments, it has been said, with a general's eye. His style is perfectly perspicuous, and its "strong home-touch" compensates for what is lacking in elasticity and grace. Paley's avoidance of ultimate speculative questions commended him to his own generation, and enabled him to give full scope to the shrewd practical understanding in which his strength lay. He displays little or no spirituality of feeling; but this is a matter in which one age is apt to misjudge another, and Paley was at least practically benevolent and conscientiously attentive to his parish duties. The active part he took in advocating the abolition of the slave-trade is evidence of a wider power of sympathy. His unconquerable cheerfulness becomes itself almost religious in the last chapters of the *Natural Theology*, when we consider the circumstances in which they were composed. The chapter on the goodness of the Deity is more touched with feeling than any other part of his writings, and impresses the reader with respect for his essential goodness of heart. (A. SE.)

PĀLGHĀT, a town in Malabar district, Madras, India, situated in the gap or pass of the same name in the Western Ghāts, in 10° 45' 49" N. lat. and 76° 41' 48" E. long., 74 miles south-east of Beypur, with a population in 1881 of 36,339. Being the key to Travancore and Malabar from the east, it was formerly of considerable strategic importance. The fort fell for the first time into British hands in 1768, and subsequently formed the basis of many of the operations against Tippoo, which terminated in the storming of Seringapatam. It still stands, but is no longer garrisoned. Pālgāt is a busy entrepôt for the exchange of produce between Malabar and the upland country, and is a station on the Madras railway. The easy ascent by the Pālgāt Pass, formerly covered with teak forests, supplies the great route from the south-west coast of India to the interior.

PALGRAVE, SIR FRANCIS (1788–1861), historian, was born in London in July 1788, the son of Meyer Cohen, a Jew, and a wealthy member of the stock exchange. He was privately educated, and such was his capacity for languages that at the age of eight he translated the Latin version of the *Frogs and Mice* into French, which his father published in 1797 with a short preface. On account of the failure of his father's fortunes in 1803 he was articled as clerk to a firm of solicitors, with whom he remained till 1822, acting for some years as their managing clerk, after which he took chambers in King's Bench Walk, Temple, and was employed under the record commission. On his marriage in 1823 he obtained the royal permission to change his name from Cohen to Palgrave, the maiden name of his wife's mother. He was called to the bar at the Middle Temple in 1827, and soon acquired a good practice in pedigree cases in the House of Lords. From an early period of his life he had devoted much attention to literary and antiquarian studies. In 1818 he edited a collection of Anglo-Norman chansons, and previous to his call to the bar contributed largely to the *Edinburgh* and *Quarterly Reviews*. In 1831 he published the *History of England*, in the Family Library series, and in 1832 he brought out *The Rise and Progress of the English Commonwealth*, and *Observations on the Principles of New Municipal Corporations*. The same year he received the honour of knight-

¹ Nieuwentyt (1654–1718) was a Dutch disciple of Descartes, whose work, *Regt gebruik der weereld beschavinge*, published in 1716, was translated into English in 1730 under the title of *The Religious Philosopher*. A charge of wholesale plagiarism from this book was brought against Paley in the *Athenæum* for 1848. Paley refers several times to Nieuwentyt, who uses the famous illustration of the watch. But the illustration is not peculiar to Nieuwentyt, and had been appropriated by many others before Paley. In the case of a writer whose chief merit is the way in which he has worked up existing material, a general charge of plagiarism is almost irrelevant.

flood. In 1837 he published *Merchant and Friar*, an imaginary history of Marco Polo and Friar Bacon. On the reconstruction of the record commission service in 1838, he was appointed to the post of deputy-keeper. Under the sanction of Government he edited *Rotuli Curie Regis* (2 vols., 1835) and *Calendars and Inventories of the Exchequer* (3 vols., 1836). He was the author of *Detached Thoughts on the Polity and Ecclesiastical History of the Middle Ages*, printed for private circulation, and a learned and elaborate *History of Normandy and England* (4 vols., 1851-64). He died at Hampstead, 6th July 1861.

PĀLI (pronounced *Bali* by the Siamese) is the name of the literary language of the Buddhists in Ceylon, Burmah, Siam, and Cambodia. Laloubère (*Rel. de Siam*) is the first European writer who mentions the name, towards the end of the 17th century. Various opinions have been advanced as to the etymology—from *path*, to read (Mason, Minayeff), or *pāli* = *pra* + *āli* (J. D'Alwis, E. Kuhn)—and original meaning of the word. The latter, given as "row," "range," "line," is applied by Trenckner (*Pāli Misc.*, i. 69) to the "series" of teachers by whom the text of the sacred tradition was handed down, and, according to the Burmese conception of the word (see Forchhammer's *Report* for 1879-80, p. 6), to the sacred texts simply, irrespectively of the language or dialect in which they are written; whereas Pāli scholars generally use the word less in the sense of sacred canon than in that of the language in which the canon is written (Childers, D'Alwis, Fausböll, Oldenberg). The same applies to the synonymous term *Tanti*. When and where that language was formed is still a matter of controversy. We quote here only the opinions of the two principal writers on the subject, Professors E. Kuhn and H. Oldenberg. The former, following Westergaard, holds that Pāli was the Sanskrit vernacular spoken at Ujjain, the capital of Mālava, at the time when Mahendra, the son and successor of the great Asoka, took the sacred canon with him to Ceylon in the form in which it had two years previously received the sanction of the third general council (*Beitr. zur Pāli-Gramm.*, Berlin, 1875). On the other hand, Professor Oldenberg, rejecting that tradition, considers the naturalization of the Pāli language in Ceylon to have been the fruit of a period of long and continued intercourse between that island and the adjacent parts of India, more especially the Kalinga country. Though he does not state within what limits of time that gradual naturalization took place, he records his opinion that at least one portion of the Buddhist canon, the *Vinaya*, in its present form existed in the Pāli language about a hundred and fifty years before Mahendra, that is, about 400 B.C. This is in all probability the earliest period that may be assigned to Pāli as a literary language (*The Vinayapitakam*, edited by Oldenberg, vol. i., 1879, Introduction). Both scholars have discussed the question as to the Pāli being identical with the Māgadhi dialect, and have satisfactorily disposed of it. There can be no doubt that some considerable time must have elapsed before the Pāli recension of the canon was completed, and that, as regards the locality of the language, through the contiguity of cognate vernaculars a palpable number of words and word-forms found their way into Pāli, enriching alike its vocabulary and its grammatical resources; or how else could we account for the occurrence of such doublets and triplets as *adda*, *alla* (Sanskrit, *ādra*), *āvaṭa*, *āvuta* (S. *āvṛita*), *isa*, *issa*, *ikka*, *acca* (S. *riksha*), *kiccha*, *kasira* (S. *kricchra*), *gaddha*, *giddha*, *gijjha* (S. *gridhra*), *kilā*, *khelā*, *khiddā* (S. *Kṛidā*), *taṇhā*, *tasinā* (trishnā), *tikkhina*, *tikkha*, *tiṇha* (S. *tikshṇa*), *dosinā*, *junhā* (S. *jyotsnā*), *rukkha*, *vaccha* (S. *vṛiksha*), *sita*, *miḥita* (S. *smṛita*), *sināna*, *nahāna* (S. *snāna*), *sunisā*,

sunhā, *husā* (S. *snushā*), and for the many alternative forms in the declensions, some of which will presently be specified? It is also certain that the very belief in the sacred character of the canon must have tended to preserve the text unchanged in form and substance from the time that it was received in Ceylon till the present day. There is, however, a voluminous literature which has grown around and out of the sacred texts, such as Buddhaghosa's great commentary on them (beginning of the 5th century), and several historical works and their commentaries. In this secondary stage many new words and hybrid grammatical forms, due to what Childers appropriately calls false analogy, have found admission into the language (see Fausböll's *Dhammapada*, Introduction); and the grammarians who at this period appear to have treated of language after the Sanskrit models enrol them in their scheme as correct and legitimate.

Though tradition (*Mahāvansa*, xii. 6; *Buddhāvansa*, xxii.) makes the introduction of Buddhism into Burmah contemporaneous with the conversion of Ceylon, there is every probability that the event took place at a much later period. It must, however, have taken firm root in Burmah at the time that in consequence of religious persecutions Buddhist priests from Ceylon went to Burmah to obtain a copy of the sacred canon and Buddhaghosa's commentary thereon (5th century of our era). Thence an uninterrupted religious intercourse has been kept up between the two countries up to the present, notwithstanding which certain discrepancies between the Pāli texts of Burmah and those of Ceylon point to the fact that the latter retain older forms and expressions, whereas the former replace these by more modern, more common, or more regular ones (Fausböll, *Ten Jātakas*, Introd.). This fact, however, can only be established on a scientific basis when good old copies of grammatical works, both in the Sinhalese and Burmese character, shall have been carefully examined and compared *ad hoc*. It is certainly true that in Ceylon, where the study of Sanskrit flourishes, and where the people have spoken for upwards of two thousand years an Indo-Aryan idiom, Pāli learning has obtained a far firmer and more favourable footing than in Burmah, where the nature of the vernacular places considerable difficulties in the path of the student of the sacred language.

As regards the status of Pāli in Siam, no trustworthy information is available. It would appear, however, that Pāli MSS. from that country—invariably written in the Cambodian character—are more remarkable for caligraphy than for correctness. Both in Burmah and Ceylon Pāli is written in the character of the vernacular. The well-known *Manual* used at the admission of a novice into the monastic order is almost the only book in which the so-called square character is customary (see Burnouf and Lassen, *Essai sur le Pāli*, Paris, 1826).

Since the days of Prinsep the name of Pāli has also been given to the various local dialects, and the name of Pāli character to the monumental alphabet, or rather alphabets, in which the so-called Asoka inscriptions are written. The language of these records, it is true, comes nearer to the Pāli than to any other early Sanskrit idiom; still it is sufficiently distinct from the language of Buddhist literature to be treated by itself (see E. Senart, *Les Inscriptions de Piyadasi*, vol. i., Paris, 1881; and G. Bühler, in *Z. D. M. G.*, vol. xxxvii.).

Pāli has aptly been said to stand phonetically in the same position to Sanskrit as Italian does to Latin. There is the same tendency to smooth down all sounds difficult of utterance, to assimilate or otherwise simplify compound consonants, and to substitute vocalic or nasal for consonantal word-terminations. More especially, Pāli lacks the *ri* and *li* vowels and the diphthongs *ai* and *au*. The Sanskrit vowel *ri* generally passes in Pāli into *a*.

sometimes also into *i* or *u*; as *isi* (S. *rishi*), *daḥa* (S. *dr̥idha*), *puṭha* (S. *pr̥ithag*). *E* and *o*, representing S. *ai* and *au* respectively, can before double consonants be further shortened into *i* and *u*, just as other long vowels may be shortened under the same circumstances; thus *ussukka* (S. *autsukya*), *raḥṭha* (S. *rāṣṭra*). Some anomalous vowel changes are exhibited in the following examples:—*koṇḍañña* (S. *kaundinya*), *pana* (S. *punar*), *purisa* (S. *purusha*), *usu* (S. *ishu*), *viññā* (S. *viññā*), *heṭṭhā* (S. *adhaṣṭāt*). As regards consonants, Pāli has only the dental sibilant, and replaces by anusvāra most final consonants of Sanskrit words; as *manam* (S. *manāk*), *saṇim* (S. *sanaṣ*), *khattum* (S. *kṛitvas*). Two or more consonants meeting in the middle of a word are mostly assimilated, as *unmagga* (S. *unmārga*), *pabbhāra* (S. *prāgbhāra*). Other changes are *paṇha* (S. *praṇa*), *pallanka* (S. *pariyāṇka*), *dāḥā* (S. *damṣṭra*), and of initial consonants *laṭṭhi* (S. *yaṣṭhi*), *luḍḍa* (S. *rudra*), *naṅgala* (S. *lāṅgala*), *kipillika* (S. *pipillika*), *khāṇu* (S. *sthānu*). Contraction is very frequent, as well as metathesis, as the following examples will show:—*kho* (S. *khalu*), *acceka* (S. *atṛayika*), *ācāra* (S. *ācārya*), *cuddasa* (S. *caturdaśan*), *iṣṣera* (S. *aiṣvarya*), *abboḥāra* (S. *avyavahāra*). In the Scenic Prakṛits and in the Māgadhī of the Jains the consonantal decay has reached a much higher stage than it has in Pāli, showing that the latter holds its place between the former and the Sanskrit. This applies also to *Sandhi*, which in Pāli is indeed sporadically and irregularly attended to, but shows a tendency to being altogether neglected.

There is no dual in the declension any more than in the conjugation; the only remnants of it appear to be *to* (S. *tau*) and *ubho* (S. *ubhau*). The old dative case is rarely used, and the genitive takes its place. The declension of nouns has in some cases been encroached upon by the pronominal declension. According to the nature of Pāli phonology, there cannot be any real consonantal stems, and therefore no regular consonantal declension. Final consonants are either dropped or have an *a* added to them. In the former case the final consonants reappear before the vowel terminations, in the latter the declension follows the false analogy of the *a*-declension. Thus, *dhamā* (S. *dhamat*) is declined as follows:—*Sing.*—nom. *dhamā*, *dhamanto*; voc. *dhamam*, *dhamā*, *dhamā*; acc. *dhamantaṃ*, *dhamam*; instr. *dhamatā*, *dhamantaṃ*; dat. gen. *dhamato*, *dhamantaṃ*, *dhamassa*; abl. *dhamatā*; loc. *dhamatī*, *dhamante*, *dhamantaṃ*, *dhamantaṃ*; *Plur.*—nom. voc. *dhamanto*, *dhamantaṃ*; acc. *dhamante*; instr. abl. *dhamantehi*, *dhamantehi*; dat. gen. *dhamantaṃ*, *dhamantaṃ*; loc. *dhamanteṣu*. Examples of multifarious cases are the loc. sing. of *nadi*, which exhibits the forms *nadiyā*, *nadiyam*, *najjam*; the voc. plur. of the honorific pronoun *bhavam* (S. *bhavat*), which has *bhavanto*, *bhonto*, *bhanto*; the gen. dat. sing. of *pitā*, which has *pitū*, *pituno*, *pitussa*, and in the plur. *pitūnam*, *pitunnam*, *pitārānam*, *pitānam*; the loc. sing. of *mano*, *manam* (S. *manas*), which has *manasi*, *mane*, *manasmiṃ*, *manasmi*. The personal pronouns also show a variety of forms, some of which are still traceable in the modern Prakṛits. Thus *ahaṃ* has in the plural—nom. *vayam*, *mayam*, *amhe*; acc. *asme*, *amhe*, *amhākam*; instr. abl. *amhehi*, *amhehi*; dat. gen. *amhākam*, *amhānam*, *amham*; loc. *amhesu*. Similarly, the gen. dat. sing. fem. of the demonstrative pronoun has the forms *imissā*, *imissāya*, *imāya*, *assā*, *assāya*.

The Pāli verb shows even more than does the noun a tendency to break with the analogy of the Sanskrit. Though native grammarians arrange the conjugations on a plan similar to that of the Sanskrit, the disorganizing process which pervades the whole of Pāli grammar is in no part so advanced as in this particular. Thus, the present tense of the verb *thā* (S. *sthā*) is *thāti* as well as *tiṭṭhati*; of *dā* it is *dadhāti*, *dahati*, and *dhāti*; of *dā* *dadāti*, *deti*, *dāti*, and (by false analogy from the optative *dajjem*) *dajjati*; of *jī* *jayati*, *jeti*, and *jināti*; of *bhī* *bhāyati*; of *rudh* *rundhati*, *rundhiti*, and *rundheti*; of *mar* (S. *mṛi*) *marati* and *miyati*; and of *kar* (S. *kṛi*) the plural has *karoma*, *karotha*, *karonti*, and also regularly *kubbanti*, from which form again by false analogy a 3d person singular *kubbati* has been derived. The termination *re* of the 3d person plural perfect *ānāpāda* has been transferred to the present tense, where it is used along with *-ante*. But there is a general predilection for the *parasmaipada* terminations, even in the passive. While the perfect sensibly recedes before the other tenses, and is of rare occurrence, the use of the aorist largely encroaches on that of the imperfect, the conjugation of which is in many verbs influenced by the former, as, e.g., in the verb *as*, in which the imperfect is:—1st sing., *āsim* or *āsi*; 2d and 3d, *āsi*; 1st plur., *āsimha*; 2d, *āsitha*; 3d, *āsimu*. In the imperative par. the 1st sing. and 2d plur. do not differ from the corresponding forms of the present. The affixes of the future (*-ssa*) and passive (*-ya*) may also be added to the special base; thus we have the forms *dakkhati* and *passissati*, “he will see,” and *gamiyati* and *gacchiyati*, “he is gone to.” In the causative verb the form with *p* greatly preponderates, and may even be added to the special base, as, e.g., *sunāpeti* (S. *grāyayati*), “he informs”; *gaṇhāpeti* (S. *grāhāyati*). Lastly, the gerund in *-vā* is not only used in compound verbs in preference to the one in *-ya*, but may also

occasionally be superadded to the latter for the sake of greater precision. Thus, *sajjivā*=*sad*+*ya*+*i*+*tvā*; and *abhiruyhitvā*=*abhiruh*+*ya*+*i*+*tvā*. Instead of *tvā* the forms *tvāna* and *tāna* often occur. There are two forms of the infinitive, there being besides the usual form in *-tum* one in *-tave*, which appears to have lingered in the vernacular long after it was disused in Sanskrit literature.

Literature.—The study of Pāli by Europeans is of comparatively recent date; in fact, our knowledge of the very existence of an extensive Pāli literature dates scarcely half a century back. It is true that in 1826 Professors Burnouf and Lassen were enabled, from an examination of certain Pāli MSS. which had fallen under their notice, to give a general account of the language; but it was reserved for the late Mr G. Turnour, colonial secretary of Ceylon, to collect the first trustworthy information concerning the sacred books of the island, and to edit and translate the first Pāli text of any extent. His choice of the *Mahāvamsa*, one of the oldest chronicles, was all the more fortunate, as, in the almost total absence of historical works in Sanskrit literature, these annals were calculated to yield a vast amount of information regarding the origin and earlier history of the Buddhist religion in India. The book had been ready for the press many years, but was not published till 1837, while a series of articles by the same author, embodying the results of his examination of the *Mahāvamsa* and its commentary and of the contemporaneous *Dīpavamsa* (*Jour. Bengal As. Soc.*, vols. v. and vi.), had been received by Oriental scholars with the utmost interest. The thirty-eight chapters published by him bring the history of Ceylon down to 477 A.D.; they comprise the original work of *Mahānāma*. Six more chapters, ready for the press in text and translation, were found among Turnour's papers at his early death in 1842, and are now in the India office library. The whole *Mahāvamsa*, in Pāli and Sinhalese, has since been printed at the Government press, Colombo, 1877–83, and an English translation is in progress. However, a critical edition of the earlier part, and more especially of the commentary upon it, is still a desideratum. There is an excellent edition and translation of the *Dīpavamsa* by Professor Oldenberg (London, 1879), according to whom the work was written between the beginning of the 4th and the first third of the 5th century. Among the historical works may also be classed the *Dāṭṭhāvamsa*, a poetical history of the tooth-relic of Buddha, composed by Dhammakitti early in the 13th century. The work was printed at Colombo in 1882, and an English translation by M. Kumāraswāmi appeared in London in 1874. Further, the *Attanagaluvasa*, the history of a temple, likewise of the 13th century, edited and translated by J. D'Alwis at Colombo in 1866. Other historical works are described in the catalogues of Pāli MSS. Lastly, there exist many mediæval Pāli inscriptions, some of considerable extent, as, e.g., those of Kalyāṇi in Burmah, which are now in course of publication, and are likely to yield valuable historical results. Many of them are accompanied by a translation in Burmese or Talaing,—a language now all but extinct. It is worth noting that neither in Ceylon nor in Cambodia have any old Pāli inscriptions been found; in the island the old inscriptions are in Sinhalese, in Cambodia they are in Sanskrit, frequently with a translation in Khmer.

Though there is an old ninefold division (*navanga*, see Dr R. Morris's “Report on Pāli Literature,” in *Philological Society's Proceedings*, 1880) of the canonical scriptures, it is the general practice of Pāli scholars to abide by the division into three “baskets” (*tipitaka*, *piṭakattaya*), first specified by G. Turnour, and then more correctly in Ch.lers's Dictionary, p. 507, viz., the *Vinayapiṭaka*, the *Suttapiṭaka*, and the *Abhidhammapiṭaka*, or the baskets of discipline, of discourses, and of metaphysics. Only the

first of these, and at the same time the earliest, has been published in a critical edition in five volumes by Professor Oldenberg, London, 1879-83, while a translation by the same and Mr Rhys Davids is in progress in the *Sacred Books of the East*. One of its constituent parts, the *Pāṭimokkha*, mentioned already by Laloubère, was edited and translated into Russian by Minayeff (1869); an English translation by Gogerly had appeared thirty years previously in vol. iii. of the *Ceylon Friend*, and the *Journal of the Royal Asiatic Society* for 1875 brought out a new translation, accompanied by the Pāli text, by J. F. Dickson. Editions of the text have also appeared in Ceylon and Burmah. A ritualistic manual, the *Kammavācā*, the first chapter of which was edited by Spiegel with a Latin translation in 1841, was the first Pāli text published in Europe. The first of the numerous works composing the *Suttapīṭaka* that was made accessible to Pāli scholars in Europe was the *Dhammapada*, or Path to Virtue, a critical edition of which, with a Latin translation and copious extracts from Buddhaghosa's commentary, was brought out by Professor Fausbøll, of Copenhagen, in 1855. So popular has this work proved as a type of Buddhist sentiment that no less than two English translations (by Professor F. Max Müller in 1870 and 1881, and by Professor J. Gray, of Rangoon, in 1881), one in German (by Professor A. Weber, 1860), and one in French (by M. F. Hù, 1878) have appeared; besides various editions printed at Colombo and Rangoon, with translations into the respective vernaculars. Other collections of moral maxims also, such as *Lokanīti* and *Dhammanīti*, appear to be favourite books in Burmah. Of the other works of the *Suttapīṭaka*, the *Jātakā* Book, an account of the five hundred and fifty previous births of Buddha, has till quite recently absorbed the lion's share of attention on account of its being the oldest extant collection of fables and popular stories, many of which have at an early date found their way to the West, and are still current amongst us. Three volumes of the text of this extensive work, edited by Professor Fausbøll, and one volume of the translation, by Professor Rhys Davids, have up to the present appeared, while many of the most interesting tales, in groups of from two to twelve, were separately published by the same editor between the years 1858 and 1872. Other works belonging to the same division which have been published are *Khuddakapāṭha* (by Professor Childers, 1869), *Buddhavaṇsa* and *Cariyāpīṭaka* (by Dr Morris, 1882), *Anguttaranikāya* (by the same, 1884), and *Majjhimanikāya* (by Trenckner, 1884); and a number of others, such as *Itivuttaka*, *Theragāthā*, *Therīgāthā*, and *Apaddana*, are, thanks to the active zeal of the working members of the newly founded Pāli Text Society, either in progress or in preparation. An edition of *Suttanipāṭa*, by Professor Fausbøll, whose translation of the work appeared in 1881, is also passing through the press. Seven suttas from the *Dighanikāya*, prepared for publication by the late P. Grimblot, appeared in Paris in 1876; and a number of others, from various collections, edited and translated by L. Feer, are to be found in the *Journal Asiatique*. An edition, by Professor Childers, of the *Mahāparinibbānasutta*, from the *Dighanikāya*, was published in 1876, and a translation of the same and other suttas, by Professor Rhys Davids, forms vol. xi. of the *Sacred Books of the East*. Lastly, Dr Morris has in the press an edition and translation of "the Six Jewels of the Law," one of which is the *Mahāsatipatthānasutta*, a favourite text-book in Burmah and Ceylon. The *Milindapañha*, a work of the middle of the 2d century B.C., a scholarly edition of which we owe to Trenckner (1880), though obviously not a canonical book, may well be classed with this second division. The *Abhidhammapīṭaka* has so little in it to attract the European student of Pāli that an

edition of any of its components parts is not likely to be forthcoming for some time. A compendium of its tenets, the *Abhidhammatthasangaha*, has been frequently printed in the Burmese and in the Sinhalese character.

While in Siam and Ceylon the law-books are in the vernacular, they are in Burmah in the original Pāli, which is generally accompanied by a Burmese gloss. San Germano translated one of them (see his work on *Burmah*, p. 173 sq.) in the end of last century. Several of them have in recent years been brought out at Rangoon by Colonel H. Browne, and the oldest of them, by King Wagaru, is passing through the press. The editor, Professor Forchhammer, has also supplied valuable translations to the series of Mr Jardine's *Notes on Buddhist Law*, which are appearing at Rangoon. A critical edition of the *Laws of Manurāja*, by Dr Führer, is in the press at Bombay.

The age of the oldest Pāli grammarian, Kaccāyana, is still under dispute; it is far more likely, however, that it has to be placed towards the end of the 11th century A.D. (see Colonel Fryer's paper in *Jour. Beng. As. Soc.* for 1882) than with J. D'Alwis in the 6th century B.C. While his system is the one which has long been current in Burmah, the grammar by Moggallāna (second half of the 12th century) represents the leading grammatical school of Ceylon. Round both a large number of grammatical works have grown up, more than sixty of which are specified and fully described by Subhuti in the introduction to his book on the Pāli declensions (*Nāma-mālā*, Colombo, 1876). M. E. Senart has given an excellent edition and exposition of Kaccāyana's grammar (Paris, 1871), some chapters of which had previously been made the subject of separate treatises by J. D'Alwis and Professor E. Kuhn. The first five chapters of the *Bālāvatāra* were edited and translated by L. F. Lee (*Ceylon As. Soc. Jour.* for 1870-71), and the sixth chapter of the *Rāpasiddhi*, another old grammar, was recently published by Dr Grünwedel (Berlin, 1883). The oldest Pāli vocabulary, called *Abhidhānappadīpikā*, and compiled by the above-mentioned Moggallāna on the model of the *Amara-kosha*, was first printed at Colombo in 1824 as an appendix to Clough's grammar. A better edition, by Subhuti, with English and Sinhalese interpretations, notes, and appendices, appeared in 1865, of which a much improved reissue has just appeared at Colombo, to be followed in a second volume by full alphabetical indices. The *Dhātumanjāsā*, a dictionary of Pāli radicals, by Silavansa, was edited with English and Sinhalese translation at Colombo in 1872. *Vuttodaya*, a work on metre by Sangharakkhita, who is identified with Moggallāna, was first edited and translated by Professor Minayeff of St Petersburg in 1869, and in 1877, as No. II. of his *Pāli Studies*, by Colonel G. E. Fryer, who had previously, in the first essay (1875), given the text with a full analysis of a work on rhetoric, called *Subodhāntakāra*, by the same author.

There are great facilities in Europe for the study of Pāli and its extensive literature. The British Museum, the University Library of Cambridge, and the library of the India Office are rich in Pāli MSS., and a catalogue raisonné of the last-mentioned collection, by Professor Oldenberg, is accessible to students. The Royal Library of Copenhagen contains the MSS. which the late Professor E. Bask had brought from India, probably the finest collection in Europe, a catalogue of which was published in 1846. The National Library of Paris is the only one in Europe that possesses, in addition to a large number of MSS. in the Sinhalese and Burmese characters, a fine assemblage of MSS. in Cambodian letters. There are also Pāli MSS. in the museums of learned societies and in private hands, and it would be well if means could be devised for bringing these hidden treasures to light and utilizing them for literary purposes, for the study of the Pāli language and literature has been making rapid strides within the last ten years. Lectures on Pāli are delivered at Cambridge, in Paris, and in most of the German universities, and the number of publications of Pāli texts increases year by year. It is already admitted that Childers's *Dictionary*, the publication of which in 1875 formed an epoch in the study of Pāli, no longer suffices to supply the want, and that a more comprehensive work, or at least a supplementary dictionary, is urgently needed. Clough's *Pāli Grammar*, which appeared at Colombo in 1824, found its way to Europe so tardily that it was still unknown to the authors of the *Essai sur le Pāli* when they published their supplement to it in 1827, and it has always been a scarce book. In 1872 Professor Minayeff brought out at St Petersburg a Pāli grammar, written in Russian, which was translated into French by M. S. Guyard five years later. An English translation made from that French version, by C. G. Adams, appeared at Maulmain in 1882. Meantime Professor F. Kuhn of Munich published his valuable *Beiträge zur Pāli-Grammatik* (Berlin, 1875), a mine of wealth for all students of the language. It is from this book and from Dr Ed. Müller's grammar, to be named presently, that most of the examples in the above grammatical sketch have been culled. In 1881 there appeared at Christiania *Die Flexion des Pāli in ihrem Verhältniss zum Sanskrit*, by Alf Torp, and last year in London Dr Frankfurter's *Handbook of Pāli, being an Elementary Grammar, a Chrestomathy, and a Glossary*, at the same time that at Rangoon Professor J. Gray's *Elements of Pāli Grammar* left the press. The grammar by Dr Ed. Müller, just published, deserves to be called a pattern of critical scholarship. Much valuable information on grammatical and etymological questions may also be gained from Professor Fr. Müller's *Beiträge zur Kenntnis der Pāli-Sprache*, Vienna, 1867-68; Dr Morris's "Report on Pāli Literature," in *Proc. Philol. Soc.*, 1880; and last, not least, V. Trenckner's *Pāli Miscellany*, part I., Copenhagen, 1879. (R. R.)

PALIMPEST, a term applied to any material from which writing has been removed to make room for another text, and which has thus been prepared or scraped a second time (*παλίμψητος*). Such an object therefore as an inscribed monumental stone or brass may be made palimpsest.

But the term is most commonly applied to ancient MSS. which have undergone this treatment. See *PALEOGRAPHY*.

PALINDROME (παλιν, again, and δρόμος, a course), a verse or sentence which runs the same when read either backwards or forwards. Such is the verse—

Roma tibi subito motibus ibit amor ;

or

Signa to, signa, temere me tangis et angis ;

or

νύψ ν ἀνομήματα μὴ μόνον ὀψιν¹

Some have refined upon the palindrome, and composed verses each word of which is the same read backwards as forwards,—for instance, that of Camden—

Odo tenet mulum, madidam mappam tenet Anna,
Anna tenet mappam madidam, mulum tenet Odo.

The following is still more complicated, as reading in four ways—upwards and downwards as well as backwards and forwards :—

S A G O R
A R E P C
T E N E T
O P E R A
R O T A S

PALISSY, BERNARD (1510–1589), was born in 1510 at La Chapelle Biron, a village in the province of Périgord, France. His parents were poor, and at an early age he was thrown upon his own resources for even the most elementary education. With indomitable energy he read all the books within his reach, and, aided by naturally keen powers of observation, gained a knowledge, remarkable for that time, of chemistry, geology, botany, and other branches of natural history. Bernard Palissy's father was a painter of stained glass, and taught his son the practice of this important craft ; he thus became a skilful draughtsman, learned the manipulation of colours, and gained that training of the eye which in after years helped to bring him success and reward as a potter. After a period of travelling apprenticeship, Palissy married and settled in Saintes. At first he practised his craft of glass-painter, varied by portrait-painting and land-surveying. The search for subjects for his window-paintings led Palissy to extend his already wide course of study to history and classical mythology. He had not long been married when the whole course of his life was changed by a new ambition. He happened to see a fine piece of enamelled pottery, probably majolica ware from Italy, and thereupon resolved to spend any time and labour to discover for himself the secret of the beautiful enamelled surface that he admired so much in that piece of pottery. His trade as a glass-painter had taught him something of the methods of painting and firing enamel colours, and at the neighbouring village of La Chapelle des Pots he learned the rudiments of the potter's art in its simplest form ; but this was all the help he had. He knew nothing whatever of the manufacture of the finer sorts of faience, or of the composition of the white enamel which was to form the covering of his clay vessels and the ground for his coloured ornament.

Year after year, through a succession of utter failures, and almost without a gleam of hope, he laboured on, working often blindly and at random in search for the secret of the white enamel. Almost starving for want of food, his wife in rags bitterly and not unreasonably reproaching him for his cruelty, his furniture broken up to feed his kilns, and without a hand to help, Palissy struggled on for nearly sixteen years before success came. A truly tragic story is this, for after all it was no new discovery that Palissy ever reached or even aimed at.

¹ This last is from the *καρκίνου* of the emperor Leo VI., the Philosopher, and occurs in a palindrome piece of twenty-seven lines, which can be seen in the *Excerpta Variorum* of Leo Allatius (1641). See also *N. and Q.*, 5th ser., vii. 372, viii. 77.

The secret of the white enamel was known to every potter of northern Italy, and there, if he had but known, he might have learned that process on the rediscovery of which he wasted so many of the best years of his life. All those struggles and failures are most vividly told by Palissy himself in one of the most thrilling pieces of autobiography ever written. The nearest parallel to it is perhaps (widely different as the two men are) that of his contemporary the Florentine Cellini.

For a few years Palissy enjoyed untroubled reward for his years of toil and unflinching constancy of purpose. His works were bought and appreciated by the queen, Catherine de' Medici, and many of the great nobles of her court, who were eager for specimens of his skill. But before long Palissy, who had always been something of a theologian and a constant Bible student, became irresistibly enthralled by the new doctrines of the Reformation, and enrolled himself an enthusiastic member of the Huguenot party. He could do nothing by halves ; he devoted himself heart and soul to the cause, and, in 1558, while engaged in making plaques, tiles, and rustic figures in faience to decorate the Constable de Montmorency's Château d'Ecouen, Palissy was arrested and imprisoned at Bordeaux, while his kilns and the materials of his trade were destroyed by command of the magistrates.

Through the intervention of the French court Palissy was, after a time, liberated, and about 1563, under the protection of the king, set up his pottery-works in Paris, on a plot of ground afterwards occupied by part of the gardens of the Tuileries. Here Palissy lived and worked in comparative peace and prosperity till 1588, when a fresh outburst of religious zeal against the Huguenots proved too strong even for the royal patronage, which for so long had sheltered him. He was thrown into the Bastille, and, though Henry III., who was then king, offered him rewards and freedom if he would recant, Palissy preferred death to falsehood. Henry III., though not unmindful of the forty-five years during which Palissy had faithfully served the court of France, was too timid or too weak to save his old servant, then nearly eighty years of age. Palissy was condemned to death, but died shortly after, in one of the dungeons of the Bastille, in the year 1589. This martyr's death was a not unfitting end for one whose whole life had been a sacrifice to noble aims, and who, years before, had suffered a protracted martyrdom in the to him sacred cause of art.

Palissy's Pottery.—Though very varied in design, Palissy's pottery is for the most part executed after one technical process. Hard well-burnt earthenware, sometimes fired at so high a temperature as to have almost a metallic ring, was covered with a white enamel, formed of the usual ingredients of glass, to which opacity and creamy whiteness were given by the addition of an oxide of tin. On this white ground various colours were applied in enamel-pigments, and the whole finally covered with a thin plumbeo-vitreous glaze. The potter's wheel was but little, if at all, used by Palissy, who, in his pieces, aimed less at purity and beauty of outline than at elaborate surface-decoration in high relief, formed by pressing the clay into a mould.

Palissy's best-known productions are large plates, ewers, vases, and other forms, decorated in alto-relief, with very realistic figures of reptiles, fish, insects, shells, plants, and other objects, executed with wonderful truth and accuracy from moulds formed by taking casts of the objects themselves (see woodcut). Thus we see reproduced every scale on a snake's or fish's back, and the minutest peculiarities of the fossil shells and living plants which Palissy saw around him and delighted in copying with the scientific accuracy of a student of natural history and geology. Casts from these objects were fixed on to a metal dish or vase of the shape required, and a fresh cast from the whole formed a mould from which Palissy could reproduce many articles of the same kind. After being covered with the long-sought-for white enamel, the various parts of the piece were painted in realistic colours, or as near truth as could be reached by the pigments Palissy was able to discover and prepare. These colours were mostly various shades of blue from indigo to ultramarine, some rather crude greens, several tints of brown &

and greys, and, more rarely, yellow. Other pieces, such as dishes and plaques, were ornamented by figure subjects treated after the same fashion, generally Scriptural scenes or subjects from classical mythology. These were in many cases copied from works in sculpture by contemporary artists.

Another class of designs used by Palissy were plates, tazze and the like, with geometrical patterns moulded in relief and pierced through, forming a sort of open network. Perhaps the most successful as works of art were those plates and ewers which Palissy moulded in exact facsimile of the rich and delicate works in pewter for which Francois Briot and other Swiss metal-workers were so

Rustic Plate by Palissy.

celebrated. These are in very slight relief, and are executed with a cameo-like finish, mostly of good design, after the style of the Italian silversmiths of the 16th century. Palissy's ceramic reproductions of these metal plates are not improved by the colours with which he picked out the designs.

Some enamelled and painted earthenware statuettes, full of life and expression, have been attributed to Palissy; but it is doubtful whether he ever worked in the round. On the whole his productions cannot be assigned a very high rank as works of art, though they are certainly remarkable as objects of curiosity and marvels of ingenious skill. They have always been highly valued, and in the 17th century attempts were made both at Delft and Lambeth to copy his "rustic" plates with the reliefs of animals and human figures. These imitations are very blunt in modelling, and coarsely painted. They are generally marked on the back in blue with initials and a date—showing them to be honest copies, not attempts at forgery, such as have been produced in the present century.

The best collections of Palissy ware are those in the museums of the Louvre, the Hôtel Cluny, and Sévres; and in England that at Narford Hall, with a few specimens in the South Kensington and British Museums.

As an author Palissy was perhaps even more successful than as a potter. A very high position among French writers is assigned to him by Lamartine (*B. Palissy*, 8vo, Paris, 1852). He wrote on a great variety of subjects, such as agriculture, natural philosophy, religion, and especially his *L'Art de terre*, in which he gives an account of his processes and how he discovered them. A complete edition of his works was published by P. Antoine Cap, *L'Œuvres Complètes de B. Palissy*, Paris, 1844.

See Morley, *Life of Palissy*, 1855; Merryat, *Pottery*, 1850, pp. 31 sq.; Dumesnil, *B. Palissy, le potier de terre*, 1851; Talinurier, *Terres Émaillées de Palissy*, 1863; Delécluze, *B. Palissy*, 1838; Enjubault, *L'Art céramique de B. Palissy*, 1858; Audiat, *Étude sur la vie . . . de B. Palissy*, 1868; Delange, *Monographie de l'œuvre de B. Palissy*, 1862. For Palissy as a Huguenot see Roeselgnol, *Les Protestants illustres*, No. iv., 1861. (J. H. M.)

PĀLITĀNĀ, a "second class" native state of India, in KĀTHIĀWĀR (q.v.), Bombay presidency, lying between 21° 23' 30" and 21° 42' 30" N. lat., and between 71° 31' and 72° 0' 30" E. long., with an area of 305 square miles, and a population (1881) of 49,271. The chief pays a tribute jointly to the gāekwār of Baroda and the nawāb of Junagarh. The capital of the state is Pālītānā (population, 7659). Above the town, to the west, rises the sacred hill of Satrunjaya, which is covered with temples dedicated to Adināth, one of the deified saints of the Jains, and is the resort of innumerable pilgrims from all parts of India.

PALLADIO, ANDREA (1518–1580), a native of Vicenza in the north of Italy, one of the chief architects of his century. Palladio's early student life was spent in Rome, where he learned the practical part of his profession, and

spent several years in making drawings of the buildings of ancient Rome. In 1547 he returned to his native city Vicenza, where he designed a very large number of fine buildings—among the chief being the Barbarano, Porti, and Chiericati palaces, as well as many others for various nobles of Vicenza and the neighbourhood. Perhaps his finest work in Vicenza itself was the Palazzo della Ragione, with two stories of open arcades of the Tuscan and Ionic orders. Most of these buildings, however, look better on paper than in reality, as they are mainly built of brick, covered with stucco, now in a very dilapidated condition. This does not affect the merit of their design, as Palladio intended them to have been executed in stone. His fame extended widely throughout Italy, and Pope Paul III. sent for him to Rome to report upon the state of St Peter's. In Venice, too, Palladio built many stately churches and palaces, such as S. Giorgio Maggiore, the Capuehin church, and some large palaces on the Grand Canal. His last great work was the Teatro Olimpico at Vicenza, designed after a classical model; he died before its completion, and it was finished, though not altogether after the original design, by his pupil and fellow-citizen Scamozzi.

In addition to his town buildings, Palladio designed many country villas in various parts of northern Italy. The villa of Capra is perhaps the finest of these, and has frequently been imitated. Palladio was a great student of classical literature, and was much influenced by Vitruvius's great work on architecture. He also published in 1575 an edition with notes of Cæsar's *Commentaries*.

His great literary work was *I quattro libri dell' Architettura*, first published at Venice in 1570, which has passed into countless editions, and been translated into every European language. The original edition is a small folio, richly illustrated with well-executed full-page woodcuts of plans, elevations, and details of buildings,—chiefly either ancient Roman temples or else palaces designed and built by himself. The influence of this book on the architecture of Europe has been enormous. Among many others, an edition with notes was published in England by Inigo Jones, most of whose works, and especially the palace of Whitehall, of which only the banqueting room remains, owed much to Palladio's inspiration. Though other Italian architects in the 16th century worked out and developed the same style, yet, in England at least, the term Palladian has been used to include all the results of this revival of classicism. Vignola, Scamozzi, and Serlio were among the chief of Palladio's contemporaries. The style adopted and partially invented by Palladio expressed a kind of revolt against the extreme licence both of composition and ornament into which the architecture of his time had fallen. Though often noble, dignified, and full of the most harmonious proportions, Palladio's style is dull and lifeless, dominated by scholasticism, and regardless of considerations of utility and convenience.

He was fascinated by the stateliness and beauty of proportion which are the chief charms of the buildings of ancient Rome, and did not stop to reflect that reproductions of these, however great their archaeological accuracy, could not but be lifeless and unsuited to the wants of the 16th century. Palladio's carefully measured drawings of ancient buildings are now of great value, as in many cases the buildings have altogether or in part ceased to exist.

The following is a short abstract of the contents of Palladio's great work on architecture:—

Book I. Materials; construction; the five orders (Tuscan, Doric, Ionic, Corinthian, and Composite); the proportions of various parts of buildings; construction of stairs.

Book II. Plans and elevations of city and country houses designed by Palladio; restoration of Greek and Roman houses; sites; Palladio's designs for palaces for certain Venetian and other noblemen, in Venice, Vicenza, Verona, and elsewhere.

Book III. Roads; bridges; piazze; piazza of Greeks and Romans; ancient basilica; modern basilica at Vicenza; baths and xysti of the Greeks.

Book IV. Temples of ancient Rome; Brauante's "Tempietto" (S. Pietro in Montorio); Roman temples in Italy, outside Rome; Roman temples (such as those at Nîmes) outside Italy.

See Montanari, *Vita di Andrea Palladio*, 1749; Rigato, *Osservazioni sopra Andrea Palladio*, 1811; Magrini, *Memorie intorno la vita di Andrea Palladio*, 1845; Milizia, *Memorie degli Architetti*, 1781, II. pp. 35-64; Symonds, *Renaissance in Italy—Fine Arts*, pp. 94-99.

PALLADIUM, an archaic wooden image (ξόανον) of Pallas, preserved in the citadel of Troy as a pledge of the safety of the city. It represented the goddess, standing in the stiff archaic style, holding the spear in her right hand. According to one story, Zeus had thrown it down from heaven when Ilus was founding the city of Ilium. Odysseus and Diomedes carried it off from the temple of Pallas, and thus made the capture of Troy possible. Many different cities boasted that this ancient image had passed into their possession—Athens, Argos, Rome, Lavinium, &c. It is probable that the Palladium is an image of the warlike goddess Pallas, who must in origin be distinguished from Athena. The theft of the Palladium is a frequent subject in Greek art, especially of the earlier time.

PALLADIUS, **RUTILIUS TAURUS ÆMILIANUS**, a writer of the 4th century after Christ, author of a poem on agriculture (*De Re Rustica*) in fourteen books. It is not certain whether he can be identified with any known historical person of the time. His work consists of an introductory book of general directions on agriculture, twelve books describing the operations suitable for the twelve months of the year, and a final book on the cultivation of trees. The material is derived from Columella and other earlier writers. The work was popular in the Middle Ages; it is conveniently arranged, but far inferior in every other respect to that of Columella.

PAL LAHÁRA, a tributary state of **ORISSA** (q.v.).

PALLAS. See **ATHENA**, vol. ii. 830.

PALLAS, **PETER SIMON** (1741-1811), naturalist and traveller, was born in Berlin, September 22, 1741, the son of Simon Pallas, surgeon in the Prussian army, and professor of surgery in Berlin. Pallas was carefully educated by his father, being accustomed from boyhood to the use of several languages, among them English and French. He was intended for the medical profession, and his progress was such that in 1758 he lectured publicly on anatomy. Pallas studied at the universities of Berlin, Halle, Göttingen, and Leyden. He early displayed a strong leaning towards natural history investigations, which by the time he reached manhood almost monopolized his attention. In 1761 he came to England, where he spent a year, devoting himself to a thorough study of the collections he found there, and to a geological investigation of part of the English coast; and at the age of twenty-three he was elected a foreign member of the Royal Society. Pallas spent some time in Holland, where he found ample scope for investigation in his special subjects, the results of which appeared at the Hague in 1766 in his *Elenchus Zoophytorum* and *Miscellanea Zoologica*, and in 1767-1804 in his well-known *Spicilegium Zoologicum* (Berlin). In 1768 he gladly accepted the invitation of the empress Catherine to fill the professorship of natural history in the Imperial Academy of Science, St Petersburg, and from that time until within a year of his death his home was in Russia. The great event of his life, and that by which he will be permanently remembered, was the expedition through Russia and Siberia in 1768-74, in which he acted as naturalist, in company with Falk, Lepechen, and Gildenstadt, the immediate object being the observation of the transit of Venus in 1769. In this leisurely journey Pallas went by Kasan to the Caspian,

spent some time among the Calmucks, crossed the Urals to Tobolsk, visited the Altai Mountains, traced the Irtysh to Kolyvan, went on to Tomsk and the Yenissei, crossed Lake Baikal, and extended his journey to the frontiers of China. Few explorations have been so fruitful as this six years' journey. Pallas's collections included all departments of natural history, and his observations extended to every point of interest in the region traversed and its inhabitants. The leading results were given in his *Reisen durch verschiedene Provinzen des Russischen Reichs* (3 vols. 4to, St Petersburg, 1771-76), richly illustrated with coloured plates. A French translation in 1788-93, in 8 vols., with 9 vols. of plates, contained, in addition to the narrative, the natural history results of the expedition; and an English translation in three volumes appeared in 1812. As special results of this great journey may be mentioned *Sammlungen historischer Nachrichten über die Mongolischen Völkerschaften* (2 vols. 4to, St Petersburg, 1776-1802); *Novæ Species Quadrupedum*, 1778-79; Pallas's contributions to the dictionary of languages of the Russian empire, 1786-89; *Icones Insectorum, præsertim Rossicæ Sibericæque peculiarium*, 1781-1806; *Zoographia Rosso-Asiatica* (3 vols., 1831); besides many special papers in the *Transactions* of the academies of St Petersburg and Berlin. The empress bought Pallas's natural history collections for 20,000 roubles, 5000 more than he asked for them, and allowed him to keep them for life. He spent a considerable time in 1793-94 in visiting the southern provinces of Russia, and was so greatly taken with the Crimea that he determined to take up his residence there. The empress gave him a large estate at Simpheropol, and 10,000 roubles to assist in equipping a house. Though disappointed with the Crimea as a place of residence, Pallas continued to live there, devoted to constant research, especially in botany, till the death of his second wife in 1810, when he removed to Berlin, where he died September 8, 1811. The results of his journey in southern Russia were given in his *Bemerkungen auf einer Reise durch die südlichen Statthalterschaften des Russischen Reichs* (Leipsic, 1799-1801; English translation by Blagdon, vols. 5-8 of *Modern Discoveries*, 1802, and another in 2 vols., 1812). Pallas also edited and contributed to *Neue Nordische Beiträge zur physikalischen Erd- und Völkerbeschreibung, Naturgeschichte, und Oekonomie* (1781-96), published *Illustrationes Plantarum imperfecte vel nondum cognitarum* (Leipsic, 1803), and contributed to Buffon's *Natural History* a paper on the formation of mountains, and to the *Transactions* of various learned societies a great number of special papers.

The solid value and great extent of Pallas's contributions to natural science have been long admitted; his name is inseparably associated with the geography (in its varied branches) of Siberia and a large part of European Russia. That he had a marked influence on the progress of zoology there is no doubt, some authorities even hold that he changed the face of the science; while his geological investigations and speculations, if they did not revolutionize the young science (as has been maintained), greatly helped its progress. Though not in any sense brilliant either as an investigator or as a writer, Pallas is certainly one of the most important figures in the science of the latter half of the 18th century.

See the Essay of Rudolph in the *Transactions* of the Berlin Academy for 1812; Cuvier's Eloge in his *Recueil des Éloges Historiques*, vol. II.; and the Life in Jardine's *Naturalists' Library*, vol. IV., Edin., 1843.

PALLAVICINO, **FERRANTE** (1618-1644), a writer of pasquinades, who is now known chiefly for his early and tragical end, was a member of the old and widely ramified Italian family of the Pallavicini, and was born at Piacenza in 1618. He received a good education at Padua and elsewhere, and early in life entered the Augustinian order, residing chiefly in Venice. For a year he accompanied Ottavio Piccolomini, duke of Amalfi, in his German campaigns as field chaplain, and shortly after his return

he published a number of clever but exceedingly scurrilous satires on the Roman curia and on the powerful house of the Barberini, which were so keenly resented at Rome that a price was set on his head. A Frenchman of the name of Charles de Breche decoyed him from Venice, where he was comparatively safe, to the neighbourhood of Avignon, and there betrayed him into his enemies' hands. After fourteen months' imprisonment and some observance of the formalities of a trial he was beheaded at Avignon on March 6, 1644.

His *Opere Permesse* was published at Venice in 1655, but being, as may be imagined, inferior in scurrility and grossness (Pallavicino's specialities), are much less prized by the curious than the *Opere Scelte* (Geneva, 1660), which were more than once reprinted in Holland, and were translated into German in 1663.

PALLAVICINO, or PALLAVICINI, SFORZA (1607–1667), cardinal, representative of another branch of the same family, was born at Rome in 1607. Having taken holy orders in 1630, and joined the Society of Jesus in 1638, he successively taught philosophy and theology in the Collegio Romano; as professor of theology he was a member of the congregation appointed by Innocent X. to investigate the Jansenist heresy. In 1659 he was made a cardinal by Alexander VII. His death occurred in 1667.

Pallavicino is chiefly known by his history of the council of Trent, written in Italian, and published at Rome in two folio volumes in 1656–57 (2d edition, considerably modified, in 1666). His avowed object was to correct and supersede the very damaging work of Sarpi on the same subject, and he certainly, by virtue of his position, had access to many important sources from the use of which his predecessor had been precluded; the contending parties, however, are far from agreed as to the completeness of his success. The work was translated into Latin by a Jesuit named Giattinus (Antwerp, 1670). There is a good edition of the original by Zaccharia (6 vols. 4to, 1792–99). It was translated into German by Klitsche in 1835–37.

PALLIUM, PALLA. These articles of Roman dress, corresponding to the Greek *himation*, are described in the article *COSTUME* (vol. vi. pp. 453, 456–57), where also the pallium, as an ecclesiastical vestment peculiar to archbishops in the Roman Church, has been spoken of (pp. 461, 463). In the East the pallium is worn by all bishops, and one or two instances have occurred in the Western Church also in which it has been conferred by the pope on prelates of less than archiepiscopal rank. The canon law forbids archbishops to wear this vestment until it has been solemnly asked for (either personally or by deputy) and obtained from the holy see; even then it is only to be worn on certain specified occasions, such as at high pontifical mass or at an episcopal consecration. Every archbishop must apply for it within three months after his consecration, and it is buried with him at his death. The pallium is never granted until after payment of considerable dues. The pallia are prepared by nuns from white wool obtained from lambs which have been consecrated on St Agnes's eve in the church of that saint in Rome; the vestments are blessed on the festival of Saints Peter and Paul, and deposited for a night on the altar over St Peter's tomb; they are afterwards taken charge of by the sub-deacon, and given out as required. The growth of the occasional practice of bestowing the pallium into an invariable custom, and of the custom into a law, will be traced in the article *POPEDOM*.

PALM. From their noble aspect, and perhaps from the surpassing utility of several of the members of the group, the Palms (*Palmaceæ*) have been termed the princes of the vegetable kingdom. Neither the anatomy of their stems nor the conformation of their flowers, however, entitles them to any such high position in the vegetable hierarchy. Their stems are not more complicated in structure than those of the common butcher's broom (*Ruscus*); their flowers are for the most part as simple as those of a rush (*Juncus*). For all that, palms have

always had great interest, not only for botanists, but also for the general public, in the latter case by reason of the historical and legendary interest connected with them no less than from their beauty and economic value. The order *Palmaceæ* is characterized among monocotyledonous plants by the presence of a stem very frequently unbranched, and bearing a tuft of leaves at the extremity only, or with the leaves scattered, these leaves, often gigantic in size, being usually firm in texture and branching in a pinnate or palmate fashion. The flowers are borne on simple or branching spikes, very generally protected by a spathe or spathes, and each consists typically of a perianth of six greenish, somewhat inconspicuous segments in two rows, with six stamens, a pistil of 1–3 carpels, each with a single ovule and a succulent or dry fruit never dehiscent (figs. 1, 2). The seed consists almost exclusively of perisperm or albumen in a cavity in which is lodged the relatively very minute embryo (fig. 3). These are the general charac-

teristics by which this very well-known order may be discriminated, but, in a group containing considerably more than a thousand species, dispersed widely and at different elevations throughout the tropics of both hemispheres, with stragglers in subtropical and even in warm temperate regions, it may well be imagined that deviations from the general plan of structure occur with some frequency. As the characteristic appearances of palms depend to a large extent upon these modifications, some of the more important among them may briefly be noticed.

Taking the stem first, we may mention that it is in very many palms relatively tall, erect, unbranched, regularly cylindrical, or dilated below so as to form an elongated cone, either smooth, or covered with the projecting remnants of the former leaves, or marked with circular scars indicating the position of those leaves which have now fallen away. In other cases the stem is very slender, short, erect, prostrate, or scandent by means of formidable hooked prickles which, by enabling the plant to support itself on the branches of neighbouring trees, also permit the stem to grow to a very great length and so to expose the foliage to the light and air above the tree-tops of the dense forests these palms grow in, as in the genus *Calamus*. In some few instances the trunk, or that portion of it which is above ground, is so short that the plant is in a loose way called "stemless" or "acaulescent," as in *Geonoma*, and as happens sometimes in the solitary species found in a wild state in Europe, *Chamærops humilis*. In many species the trunk is covered over with a dense network of stiff fibres, often compacted together at the free ends into spines. This fibrous material, which is so valuable for cordage, consists of the fibrous tissue of the leaf-stalk, which in these cases persists after the decay of the softer portions. It is very characteristic of some palms to produce from the base of the stem a series of adventitious roots which gradually thrust themselves into the soil and serve to steady the tree and prevent

its overthrow by the wind. The underground stem of some species, *e.g.*, of *Calamus*, is a rhizome, or root-stock, lengthening in a more or less horizontal manner by the development of the terminal bud, and sending up lateral branches like suckers from the root-stock, which form dense thickets of cane-like stems. The branching of the stem above ground is unusual, except in the case of the Doum Palm of Egypt (*Hyphene*), and, when present, is probably the result of some injury to the terminal bud at the top of the stem, in consequence of which buds sprout out from below the apex.

The internal structure of the stem does not differ fundamentally from that of a typical monocotyledonous stem, the taller, harder trunks owing their hardness not only to the fibrous or woody skeleton but also to the fact that, as growth goes on, the originally soft cellular tissue through which the fibres run becomes hardened by the deposit of woody matter within the cells, so that ultimately the cellular portions become as hard as the woody fibrous matters proper.

The leaves of palms are either arranged at more or less distant intervals along the stem, as in the canes (*Calamus*, &c.), or are approximated in tufts at the end of the stem, thus forming those noble crowns of foliage which are so closely associated with the general idea of a palm. In the young condition, while still unfolded, these leaves, with the succulent end of the stem from which they arise, form "the cabbage," which in some species is highly esteemed as an article of food.

The adult leaf very generally presents a sheathing base tapering upwards into the stalk or petiole, and this again bearing the lamina or blade. The sheath and the petiole are very often provided with stout spines; and when, in course of time, the upper parts of the leaf decay and fall off the base of the leaf-stalk and sheath often remain, either entirely or in their fibrous portions only, which latter constitute the investment to the stem already mentioned. In size the leaves vary within very wide limits, some being only a few inches in extent, while those of the noble *Caryota* may be measured in tens of feet. In form the leaves of palms are very rarely simple; usually they are more or less divided, sometimes, as in *Caryota*, extremely so. In *Geonoma Verschaffeltia*, and some others, the leaf splits into two divisions at the apex and not elsewhere; but more usually the leaves branch regularly in a palmate fashion as in the fan-palms *Latania*, *Chamærops*, *Sabal*, &c., or in a pinnate fashion as in *Areca*, *Kentia*, *Calamus*, &c. The form of the segments is generally more or less linear, but a very distinct appearance is given by the broad wedge-shaped leaflets of such palms as *Caryota*, *Martinezia*, or *Mauritia*. These forms run one into another by transitional gradations; and even in the same palm the form of the leaf is often very different at different stages of its growth, so that it is a difficult matter to name correctly seedling or juvenile palms in the condition in which we generally meet with them in the nurseries, or even to foresee what the future development of the plant is likely to be. Like the other parts of the plant, the leaves are sometimes invested with hairs or spines; and, in some instances, as in the magnificent *Cerozylon andicola*, the under surface is of a glaucous white or bluish colour.

The inflorescence of palms consists generally of a fleshy spike like that of an *Arum*, either simple or much branched, studded with numerous, sometimes extremely numerous, flowers, and enveloped by one or more sheathing bracts called "spathes." These parts may be small, or they may attain relatively enormous dimensions, hanging down from amid the crown of foliage like huge tresses, and adding greatly to the noble effect of the leaves.

As to the individual flowers, they are usually small, greenish, and insignificant; their general structure has been mentioned already. Modifications from the typical structure arise from differences of texture, and specially from suppression of parts, in consequence of which the flowers are very generally unisexual (figs. 1, 2), though the flowers of the two sexes are generally produced on the same tree (monoecious), not indeed always in the same season, for a tree in one year may produce all male flowers and in the next all female flowers. Sometimes the flowers are modified by an increase in the number of parts; thus the usually six stamens may be represented by 12 to 24 or even by hundreds. The carpels are usually three in number, and more or less combined; but they may be free, and their number may be reduced to two or even one. In any case each carpel contains but a single ovule.

Owing to the sexual arrangements before mentioned, the pollen has to be transported by the agency of the wind or of insects to the female flowers. This is facilitated sometimes by the elastic movements of the stamens and anthers, which liberate the pollen so freely at certain times that travellers speak of the date-palms of Egypt (*Phoenix dactylifera*) being at daybreak hidden in a mist of pollen grains. In other cases fertilization is effected by the agency of man, who removes the male flowers and scatters the pollen over the fruit-bearing trees. This practice has been followed from time immemorial; and it afforded one of the earliest and most irrefragable proofs by means of which the sexuality of plants was finally established. The fruit which results from this process of fertilization is various: sometimes, as in the common date, it is a berry with a fleshy rind enclosing a hard stony kernel, the true seed; sometimes it is a kind of drupe as in the cocoa-nut, *Cocos nucifera*, where the fibrous central portion investing the hard shell corresponds to the fleshy portion of a plum or cherry, while the shell or nut corresponds to the stone of stone-fruits, the seed being the kernel. Sometimes, as in the species of *Sagus*, *Ruphia*, &c., the fruit is covered with hard, pointed, reflexed shining scales, which give it a very remarkable appearance.

The seed varies in size, but always consists of a mass of perisperm, in which is imbedded a relatively very minute embryo (fig. 3). The hard stone of the date is the perisperm, the white flesh of the cocoa-nut is the same substance in a softer condition; the so-called "vegetable ivory" is derived from the perisperm of *Phytelphas*.

Hooker, who in his recent revision of the genera follows the work of his predecessors Martius, Wendland, and Drude, enumerates about one hundred and thirty-two genera of the order ranged under five tribes, distinguished by the nature of the foliage, the sexual conditions of the flower, the seed umbilicate or not, the position of the raphe, &c. Other characters serving to distinguish the minor groups are afforded by the habit, the position of the spathes, the "æstivation" of the flower, the nature of the stigma, the ovary, fruit, &c.

It is impossible to overestimate the utility of palms. They furnish food, shelter, clothing, timber, fuel, building materials, sticks, fibre, paper, starch, sugar, oil, wax, wine, tannin, dyeing materials, resin, and a host of minor products, which render them most valuable to the natives and to tropical agriculturists. The Cocoa-nut Palm, *Cocos nucifera*, and the Date Palm, *Phoenix dactylifera*, have been treated under separate headings. Sugar and liquids capable of becoming fermented are produced by *Caryota urens*, *Cocos nucifera*, *Borassus flabelliformis*, *Rhapis vinifera*, *Arenga saccharifera*, *Phoenix silvestris*, *Mauritia vinifera*, &c. Starch is procured in abundance from the stem of the Sago Palm, *Sagus Rumphii*, and other species. The seeds of *Elais guineensis* of western tropical Africa yield, when

crushed and boiled, "palm oil." Cocoa-nut oil is extracted from the cocoa-nut. Wax is exuded from the stem of *Ceroxylon andicola* and *Copernicia cerifera*. A variety of "dragon's blood," a resin, is procured from *Calamus Draco* and other species. Edible fruits are yielded by the date, the staple food of some districts of northern Africa. The cocoa-nut is a source of wealth to its possessors, and many of the species are valued for their "cabbage"; but, as this is the terminal bud whose removal causes the destruction of the tree, this is a wasteful article of diet unless care be taken by judicious planting to avert the annihilation of the supplies. The famous "coco de mer," or double cocoa-nut, whose floating nuts might have suggested the twin steamboats, and are the objects of so many legends and superstitions, is known to science as *Lodoicea Sechellarum*. The tree is peculiar to the Seychelles, where it is used for many useful purposes. Its fruit is like a huge plum, containing a stone or nut like two cocoa-nuts (in their husks) united together. These illustrations must suffice to indicate the numerous economic uses of palms.

The only species that can be cultivated in the open air in England, and then only under exceptionally favourable circumstances, are the European Fan-Palm, *Chamærops humilis*, the Chusan Palm, *C. Fortunei*, of which specimens may be seen out of doors at Kew, Heckfield, Osborne, &c., and the Chilean *Jubæa spectabilis*. The date-palm now so commonly planted along the Mediterranean coast is the common Date-Palm; but this does not ripen its fruit north of the African coast. There are several low growing palms, such as *Rhapis flabelliformis*, *Chamærops humilis*, &c., which are suited for ordinary green-house culture, and many of which, from the thick texture of their leaves, are enabled to resist the dry and often gas-laden atmosphere of living rooms. Many species are now cultivated for the special purpose of the decoration of apartments, particularly the very beautiful *Cocos Weddelliana*. But, to gain anything like an idea of the magnitude and majestic character of palms, a visit to such establishments as the palm stoves at Kew, Edinburgh, or Chatsworth is necessary. In some instances, as in the famous Talipot Palm, *Borassus flabelliformis*, the tree does not flower till it has arrived at an advanced age and acquired a large stature, and, having produced its flowers, it dies like an annual weed. (M. T. M.)

PALMA, the chief town of the Spanish province of Baleares, the residence of a captain-general, a bishop's see, and a flourishing seaport, is situated 135 miles from Barcelona, on the south-west coast of Majorca, at the head of the fine Bay of Palma, which stretches inland for about 10 miles between Capes Cala Figuera and Regana. It is the meeting place of all the highways in the island, and the terminus of the railway which (opened in 1875) runs to Inca and (1879) Manacor, and will be extended to Alcudia. The ramparts, which enclose the city on all sides except towards the port (where they were thrown down in 1872), have a circuit of a little more than 4 miles. Though begun in 1562, after the plans of Giorgio Fretin, they were not finished till 1836. Palma has undergone considerable change since 1860; streets have been widened and houses built in the ordinary modern style, and the fine old-world Moorish character of the place has suffered accordingly. The more conspicuous buildings are the cathedral, the exchange, the palace, now occupied by the captain-general and the law courts, the general hospital (1456), the town-house (end of the 16th century), the picture gallery, and the college. At the time of the partial suppression in 1835 there were twenty-five monastic buildings in Palma; none of those still extant are of much note. The church of San Francisco is interesting for the tomb of Raymond Lully, a native of Palma. The cathedral, a fine

Gothic building with massive buttresses, crowns the summit of the hill on which the city stands. It was erected and dedicated to the Virgin in terms of a vow made by King Jayme as he sailed to the conquest of Majorca, but, though commenced in 1230, it was not finished till 1601. The older and more interesting portions are the royal chapel (1232), with the tomb (1779) of Jayme II., and the south front with the doorway known as *del mirador* (1389). The principal dimensions of the edifice are—length from the door to the high altar, 347 feet; width, including the chapels, 190 feet; height of the central nave, 147 feet; height of the side naves, 78 feet; and height of the belfry tower, 166. Of the architecture of the exchange (*lonja*), a Gothic building begun in 1426, the people of Palma are particularly proud, as it excited the admiration of the emperor Charles V. The columns of the windows, in black and grey marble, are of almost unexampled slinness. The harbour (formed by a mole constructed to a length of 387 yards in the 14th century and afterwards extended to more than 650 yards), has been greatly improved and enlarged since 1875 by dredging operations and a further addition to the mole of 136 yards. Previously it was not accessible to vessels drawing more than 18 feet, and men-of-war and large merchant steamers were obliged to anchor in the bay, which is sometimes rendered dangerous by violent storms. Porto Pi, about 2 miles from the city, was once a good harbour, but is now fit only for small craft. Shoemaking, tanning, and rope-spinning are prosecuted on a very extensive scale; and direct commerce is carried on with Valencia, Barcelona, Algeria, Marseilles, Cuba, Porto Rico, &c. Many of the Majorcan vessels used to be Palma-built, but the increase of steam navigation has changed the character of the trade. The population of the ayuntamiento, 53,019 in 1860, was 58,224 in 1877. There is a considerable number of Christian Jews (*Chuetas*) who were formerly confined to their own quarter.

Palma probably owes, if not its existence, at least its name (symbolized on the Roman coins by a palm branch), to Metellus Balearicus, who in 123 B.C. settled three thousand Roman and Spanish colonists on the island. The bishopric dates only from the 14th century, its foundation having been strongly opposed by the bishop of Barcelona. About a mile south-west of Palma is the castle of Bellver, where Jovellanos and Arago were imprisoned.

PALMA, distinguished since 1861 as Palma Campanià, a city of Italy, in the province of Caserta, 4½ miles south of Nola. The population was 5658 in 1881.

PALMA, distinguished since 1861 as Palma di Montechiaro, a city of Italy, in the province of Girgenti, Sicily, 13 miles S.E. of Girgenti. Though situated some distance inland, it has a port of considerable value to the coasting trade. The exports are wine, dried fruits, soda, and sulphur. Hodierna, the mathematician (1597–1660), was a priest at Palma patronized by the duke of Palma. The population, 13,458 in 1871, was 11,702 in 1881.

PALMA, one of the CANARY ISLANDS (*q.v.*).

PALMA, JACOPO, a painter of the Venetian school, was born at Scrinalta near Bergamo, towards 1480, and is said to have died at the age of forty-eight, or towards 1528. He is currently named Palma Vecchio (Old Palma) to distinguish him from Palma Giovane, his grand-nephew, a much inferior painter. About the facts of his life little is known. He is reputed to have been a companion and competitor of Lorenzo Lotto, and to some extent a pupil of Titian, after arriving in Venice early in the 16th century; he may also have been the master of Bonifazio. His earlier works are in the older manner, and betray the influence of the Bellini; but, modifying his style from the study of Giorgione and Titian, Palma took high rank among those painters of the distinctively Venetian type who remain a little below the leading masters. For rich-

ness and suffusion of colour he is hardly to be surpassed; but neither in invention, strength of character, nor vigorous draughtsmanship does he attain any peculiar excellence. His finish is great, his draperies ample, his flesh golden-hued. He painted many fine portraits. A face frequently seen in his pictures is that of his daughter Violante, of whom Titian was more or less enamoured. Two works by Palma are more particularly celebrated. The first is a composition of six paintings in the Venetian church of S. Maria Formosa, with St Barbara in the centre, under the dead Christ, and to right and left Sts Dominic, Sebastian, John Baptist, and Anthony. The second work is in the Dresden Gallery, representing three sisters seated in the open air (presumably the painter's daughters); it is frequently named *The Three Graces*. Other leading examples are—*The Last Supper*, in S. Maria Mater Domini; a *Madonna*, in the church of S. Stefano in Vicenza; the *Epiphany*, in the Brera of Milan; the *Holy Family*, with a young shepherd adoring, in the Louvre; St Stephen and other Saints, Christ and the Widow of Nain, and the *Assumption of the Virgin*, in the Accademia of Venice; and *Christ at Emmaus*, in the Pitti Gallery. Palma's grand-nephew, Palma Giovane, was also named Jacopo (1544 to about 1626). His works, which are extremely numerous in Venice, and many of them on a vast scale, belong to the decline of Venetian art.

PALMAS, LAS. See CANARY ISLANDS, vol. iv. p. 799.

PALMER, EDWARD HENRY (1840–1882), Orientalist, was born at Cambridge, August 7, 1840. He lost his parents when he was a mere child, and was then brought up by an aunt. As a schoolboy he showed the characteristic bent of his mind by picking up the Romany tongue and a great familiarity with the inner life of the Gipsies. He was not, however, remarkably bookish, and from school was sent to London as a clerk in the City. Palmer disliked this life, and varied it by learning French and Italian, mainly by frequenting the society of foreigners wherever he could find it. He had a peculiar gift for making himself at home with all manner of strange people, which served him throughout life, and was as effective with Orientals as with Europeans. His linguistic faculty was in fact only one side of a great power of sympathetic imitation. He learned always from men rather than from books, and by throwing his whole flexible personality into unison with those from whom he was learning. In 1859 Palmer returned to Cambridge, apparently dying of consumption. He had an almost miraculous recovery, and in 1860, while he was thinking of a new start in life, fell in at Cambridge with a certain Sayyid Abdullah, a teacher of Eastern languages. Under his influence he resolved to give himself to Oriental studies, in which he made very rapid progress. He now attracted the notice of two fellows of St John's College, became an undergraduate there, and in 1867 was elected a fellow on the ground of his attainments, especially in Persian and Hindustani. He was soon engaged to join the survey of Sinai, and followed up this work in 1870 by exploring the Wilderness of the Wandering along with Drake. After a visit to Palestine and the Lebanon he returned to England in 1870, and next year published his *Desert of the Exodus*. In the close of the year 1871 he became Lord Almoner's Professor of Arabic at Cambridge, married, and settled down to teaching work. Unhappily his affairs were somewhat straitened, mainly through the long illness of his wife, whom he lost in 1878; he was obliged to use his pen for Oriental and other work in a way that did not do full justice to his talents, and at length he became absorbed in journalism. In 1881, two years after his second marriage, he finally left Cambridge and ceased to teach. In the following year he

was asked by the Government to go to the East and assist the Egyptian expedition by his knowledge and his great influence over the Arabs of the desert Al-Tih. It was a hazardous task, but Palmer rightly judged that he could not refuse his country a service which no one else was able to render. He went to Gaza, and without an escort made his way safely through the desert to Suez—an exploit of singular boldness, which gave the highest proof of his capacity for dealing with the Bedouins. From Suez he was again sent into the desert with Captain Gill, to procure camels and do other service of a very dangerous kind, and on this journey he and his companion were attacked and murdered (August 1882). Their remains were recovered after the war, and now lie in St Paul's Cathedral.

Palmer's highest qualities appeared in his travels, especially in the heroic adventures of his last journeys. His brilliant scholarship is also seen to advantage in what he wrote in Persian and other Eastern languages, but not so much so in his English books, which were generally written under pressure. His scholarship was wholly Eastern in character, and lacked the critical qualities of the modern school of Oriental learning in Europe. All his works show a great linguistic range and very versatile talent; but he was cut off before he was able to leave any permanent literary monument worthy of his powers. His chief writings are *The Desert of the Exodus*, 1871; *Poems of Behá ed Din* (Ar. and Eng., 2 vols.), 1876–77; *Arabic Grammar*, 1877; *History of Jerusalem*, 1871 (by Besant and Palmer—the latter wrote the part taken from Arabic sources); *Persian Dictionary*, 1876, and *English and Persian Dictionary* (posthumous, 1883); translation of the *Qur'an* (unsatisfactory), 1880. He also did good service in editing the *Name Lists of the Palestine Exploration*.

PALMER, SAMUEL (1805–1881), landscape painter and etcher, was born in London on the 27th January 1805. He was delicate as a child, and received his education, in which a study of the classics—English as well as Greek and Latin—played a notable part, at home under the wise and genial care of his father. In 1819 we find him exhibiting both at the Royal Academy and the British Institution; and shortly afterwards he became intimate with John Linnell, who gave him excellent counsel and assistance, advising drawing from the figure and from the antique in the British Museum, and introducing him to Varley, Mulready, and, above all, to William Blake, whose strange and mystic genius had the most powerful effect in impressing on Palmer's art its solemn and poetic character. Before very long the studies of this period were interrupted by an illness which led to a residence of seven years at Shoreham in Kent. Here the artist sought a closer acquaintance with nature, and the characteristics of the scenery of the district are constantly recurrent in his works. Among the more important productions of this time are the *Bright Cloud* and the *Skylark*, paintings in oil, which was Palmer's usual medium in earlier life, but one with which he is now hardly at all associated in the popular mind. In 1839 he married a daughter of Linnell's. The wedding tour was to Italy, where he spent over two years in study. Returning to London, he was in 1843 elected an associate and in 1854 a full member of the Society of Painters in Water Colours, a method to which he afterwards adhered in his painted work. His productions are distinguished by an excellent command over the forms of landscape, and by mastery of rich, glowing, and potent colouring. He delighted in the more exceptional and striking moments of nature, and especially in her splendours of sunrise and sunset. His paintings are less literal transcripts than poetic and imaginative renderings. They are admirably composed and well-considered pastorals, which find a singularly accurate literary parallel in the landscape work of Milton in his minor poems; indeed among the best and most important paintings executed by Palmer during his later years was a noble series of illustrations to *L'Allegro* and *Il Penseroso*, now in the possession of Mr L. R. Valpy.

In 1853 the artist was elected a member of the English Etching Club; and his work with the needle is no less individual and poetic than his work with the brush. Mr Hamerton has pronounced him "one of the few really great English etchers," "one of the most accomplished etchers who ever lived." Considering his reputation and success in this department of art, his plates are few in number. They are executed with care and elaboration. Their virtues are not those of a rapid and vivid sketch, depending on force and selection of line, and adopting a frankly interpretative treatment; they aim rather at truth and completeness of tonality, and embody many of the characteristics of other modes of engraving—of mezzotint, of line, and of woodcut. Readily accessible and sufficiently representative plates may be studied in the *Early Ploughman*, in *Etching and Etchers* (1st ed.), and the *Herdsman's Cottage*, in the third edition of the same work. In 1861 Palmer removed to Reigate, where he spent an honoured and productive old age, till his death on the 24th of May 1881. One of his latest efforts was the production of a series of etchings to illustrate his English metrical version of Virgil's *Eclogues*, which was published in 1883, illustrated with reproductions of the artist's water-colours and with etchings, of which most were left unfinished at his death, and completed by his son, A. H. Palmer. A collection of Palmer's works was brought together by the Fine Arts Society in the year of his death. The descriptive and critical catalogue of this exhibition, and the memoir by his son, may be consulted for particulars of the painter's life and art.

PALMERSTON, HENRY JOHN TEMPLE, VISCOUNT, (1784–1865), statesman, minister of foreign affairs, and twice prime minister of England, was born at Broadlands, near Romsey, Hants, on the 20th October 1784. The Irish branch of the Temple family, from which Lord Palmerston descended, was very distantly related to the great English house of the same name, which played so conspicuous a part in the politics of the 18th century; but these Irish Temples were not without distinction. In the reign of Elizabeth they had furnished a secretary to Sir Philip Sidney and to Essex. In the reign of William and Mary Sir William Temple figured as one of the ablest diplomatists of the age. From his younger brother, who was speaker of the Irish House of Commons, Lord Palmerston descended; the son of the speaker was created a peer of Ireland, March 12, 1722, and was succeeded by his grandson, the second viscount, who married a Miss Mee, a lady celebrated for her beauty, who became the mother of the subject of this notice. Lord and Lady Palmerston were persons of great taste and fashion, who travelled several times in Italy with their children. Their eldest son, Henry John, is mentioned by Lady Elliot in her correspondence as a boy of singular vivacity and energy. These qualities adhered to him through life, and he had scarcely left Harrow, at the age of eighteen, when the death of his father (April 17, 1802) raised him to the Irish peerage, and placed him at the head of his family. It was no doubt owing to his birth and connexions, but still more to his own talents and character, that Lord Palmerston was thrown at a very early age into the full stream of political and official life. Before he was four-and-twenty he had stood two contested elections for the university of Cambridge, at which he was defeated, and he entered parliament for a pocket-borough, Newtown, Isle of Wight, in June 1807. Through the interest of his guardians Lord Malmesbury and Lord Chichester, the duke of Portland made him one of the junior lords of the Admiralty on the formation of his administration in 1807. A few months later he delivered his maiden speech in the House of Commons in defence of the expedition against

Copenhagen, which he conceived to be justified by the known designs of Napoleon on the Danish court. This speech was so successful that it marked him out as one of the rising statesmen of the day, in so much that, when Perceval formed his Government in 1809, he proposed to this young man of five-and-twenty to take the chancellorship of the exchequer, following apparently the examples of Pitt and Lord Henry Petty, who had filled that office at about the same age. Lord Palmerston, however, though extremely surprised and flattered by the proposal, had the wisdom to refuse it, on the ground that he was totally ignorant of finance, and had only once addressed the House of Commons. Nor did he allow the offer of a seat in the cabinet to break his modest resolution. He contented himself with the far less important office of secretary at war, charged exclusively with the financial business of the army, without a seat in the cabinet, and in this position he remained, singularly enough, without any signs of an ambitious temperament or of great political abilities, for twenty years (1809–1828). His administrative talents were confined within the limits of the War Office, which he kept in perfect order, and his parliamentary speeches to the annual statements in which he moved the army estimates of those eventful years. During the whole of that period Lord Palmerston was chiefly known as a man of fashion, and a subordinate minister without influence on the general policy of the cabinets he served. Some of the most humorous poetical pieces in the *New Whig Guide* were from his pen, and he was entirely devoted, like his friends Peel and Croker, to the Tory party of that day.

The political opinions of Lord Palmerston at that time, and perhaps through life, were those of the school of Pitt—not the effete Toryism of the Pitt clubs, which he always treated with disdain, but the enlarged Conservative views of the great minister himself, as represented after Pitt's death by Canning. Lord Palmerston never was a Whig, still less a Radical; he was a statesman of the old English aristocratic type, liberal in his sentiments, favourable to the cause of justice and the march of progress, but entirely opposed to the claims of democratic government. Thus he supported from the first the cause of Catholic emancipation, and he sympathized warmly with the constitutional party throughout the world, but he was opposed to the extension of the franchise in England, and he regarded the impulse of popular power as a force to be directed and controlled rather than obeyed. So successfully did he practise the art of governing a free people that he lived to be regarded as a popular minister, though he had been for twenty years a member of a Tory Government, and never materially altered his own opinions.

In the later years of Lord Liverpool's administration, after the death of Lord Londonderry in 1822, strong dissensions existed in the cabinet. The Liberal section of the Government was gaining ground. Canning became foreign minister and leader of the House of Commons. Huskisson began to advocate and apply the doctrines of free trade. Catholic emancipation was made an open question. Although Lord Palmerston was not in the cabinet, he cordially supported the measures of Canning and his friends. Upon the death of Lord Liverpool, Canning was called to the head of affairs; the Tories, including Peel, withdrew their support, and an alliance was formed between the Liberal members of the late ministry and the Whigs. In this combination the chancellorship of the exchequer was first offered to Lord Palmerston, who accepted it, but this appointment was frustrated by the king's intrigue with Herries, and Palmerston was content to remain secretary at war with a seat in the cabinet, which he now entered for the first time. The Canning administration ended in four months by the death of its

illustrious chief, and was succeeded by the feeble ministry of Lord Goderich, which barely survived the year. But the "Canningites," as they were termed, remained, and the duke of Wellington hastened to include Palmerston, Huskisson, Charles Grant, Lamb, and Dudley in his Government. A dispute between the duke and Huskisson soon led to the resignation of that minister, and his friends felt bound to share his fate. In the spring of 1828 Palmerston found himself, for the first time in his life, in opposition. From that moment he appears to have directed his attention closely to foreign affairs; indeed he had already urged on the duke of Wellington a more active interference in the affairs of Greece; he had made several visits to Paris, where he foresaw with great accuracy the impending revolution; and on the 1st June 1829 he made a speech on foreign affairs of such excellence that never but once in his long career did he surpass it. For it may here be remarked that Lord Palmerston was no orator; his language was unstudied, and his delivery somewhat embarrassed; but he generally found words to say the right thing at the right time, and to address the House of Commons in the language best adapted to the capacity and the temper of his audience. An attempt was made by the duke of Wellington in September 1830 to induce Palmerston to re-enter the cabinet, which he refused to do without Lord Lansdowne and Lord Grey, and from that time forward he may be said to have associated his political fortunes with those of the Whig party. It was therefore natural that Lord Grey should place the department of foreign affairs in his hands upon the formation of the great ministry of 1830, and Palmerston entered with zeal on the duties of an office over which he continued to exert his powerful influence, both in and out of office, for twenty years.

The revolution of July 1830 had just given a strong shock to the existing settlement of Europe. The kingdom of the Netherlands was rent asunder by the Belgian revolution; Portugal was the scene of civil war; the Spanish succession was about to open and place an infant princess on the throne. Poland was in arms against Russia, and the Northern powers formed a closer alliance, threatening to the peace and the liberties of Europe. In presence of these varied dangers, Lord Palmerston was prepared to act with spirit and resolution. The king of the Netherlands had appealed to the powers who had placed him on the throne to maintain his rights; and a conference assembled accordingly in London to settle the question, which involved the independence of Belgium and the security of England. On the one hand, the Northern powers were anxious to defend the king of Holland; on the other hand a party in France aspired to annex the Belgian provinces. The policy of the British Government was a close alliance with France, but an alliance based on the principle that no interests were to be promoted at variance with the just rights of others, or which could give to any other nation well-founded cause of jealousy. If the Northern powers supported the king of Holland by force, they would encounter the resistance of France and England united in arms; if France sought to annex Belgium she would forfeit the alliance of England, and find herself opposed by the whole continent of Europe. In the end the policy of England prevailed; numerous difficulties, both great and small, were overcome by the conference; although on the verge of war, peace was maintained; and Prince Leopold of Saxe-Coburg was placed upon the throne of Belgium, which enjoyed for half a century the benefits of his enlightened rule, followed with equal success by that of his son and successor. Upon the whole this transaction may be regarded as the most important and most successful of Lord Palmerston's public life.

In 1833 and 1834 the youthful queens Donna Maria of Portugal and Isabella of Spain were the representatives and the hope of the constitutional party in those countries, —assailed and hard pressed by their absolutist kinsmen Don Miguel and Don Carlos, who were the representatives of the male line of succession. Lord Palmerston conceived and executed the plan of a quadruple alliance of the constitutional states of the West to serve as a counterpoise to the Northern alliance. A treaty for the pacification of the Peninsula was signed in London on the 22d April 1834; and, although the struggle was somewhat prolonged in Spain, it accomplished its object. France, however, had been a reluctant party to this treaty. She never executed her share in it with zeal or fidelity. Louis Philippe was accused of favouring the Carlists underhand, and he positively refused to be a party to direct interference in Spain. It is probable that the hesitation of the French court on this question was one of the causes of the extreme personal hostility Lord Palmerston never ceased to show towards the king of the French down to the end of his life, if indeed that sentiment had not taken its origin at a much earlier period. Nevertheless, at this same time (June 1834) Lord Palmerston wrote that "Paris is the pivot of my foreign policy." M. Thiers was at that time in office. Unfortunately these differences, growing out of the opposite policies of the two countries at the court of Madrid, increased in each succeeding year; and a constant but sterile rivalry was kept up, which ended in results more or less humiliating and injurious to both nations.

The affairs of the East interested Lord Palmerston in the highest degree. During the Greek War of Independence he had strenuously supported the claims of the Hellenes against the Turks and the execution of the treaty of London. But from 1830 the defence of the Ottoman empire became one of the cardinal objects of his policy. He believed in the regeneration of Turkey. "All that we hear," he wrote to Mr Bulwer, "about the decay of the Turkish empire, and its being a dead body or a sapless trunk, and so forth, is pure unadulterated nonsense." The two great aims he had in view were to prevent the establishment of Russia on the Bosphorus and the establishment of France on the Nile, and he regarded the maintenance of the authority of the Porte as the chief barrier against both these aggressions. Against Russia he had long maintained a suspicious and hostile attitude. He was a party to the publication of the "Portfolio" in 1834, and to the mission of the "Vixen" to force the blockade of Circassia about the same time. He regarded the treaty of Unkiar Skelessi which Russia extorted from the Porte in 1832, when she came to the relief of the sultan after the battle of Konieh, with great jealousy; and, when the power of Mohammed Ali in Egypt appeared to threaten the existence of the Ottoman dynasty, he succeeded in effecting a combination of all the powers, who signed the celebrated collective note of 27th July 1839, pledging them to maintain the independence and integrity of the Turkish empire as a security for the peace of Europe. On two former occasions, in 1833 and in 1835, the policy of Lord Palmerston, who proposed to afford material aid to the Porte against the pasha of Egypt, was overruled by the cabinet; and again, in 1839, when Baron Brunnow first proposed the active interference of Russia and England, the offer was rejected. But in 1840 Lord Palmerston returned to the charge and prevailed. The moment was critical, for Mohammed Ali had occupied Syria and won the battle of Nezib against the Turkish forces, and on the 1st July 1839 the sultan Mohammed expired. The Egyptian forces occupied Syria, and threatened Turkey; and Lord Ponsonby, then British ambassador at Constantinople, vehemently urged the necessity of crushing so

formidable a rebellion against the Ottoman power. But France, though her ambassador had signed the collective note in the previous year, declined to be a party to measures of coercion against the pasha of Egypt. Palmerston, irritated at her Egyptian policy, flung himself into the arms of the Northern powers, and the treaty of the 15th July 1840 was signed in London without the knowledge or concurrence of France. This measure was not taken without great hesitation, and strong opposition on the part of several members of the British cabinet. Lord Holland and Lord Clarendon and some other ministers thought that, whatever might be the merits of the quarrel between the sultan and the pasha, our interference was not worth the price we were paying for it—an alliance with Russia and the rupture of our alliance with France; and the Government was more than once on the point of dissolution. Lord Palmerston himself declared in a letter to Lord Melbourne that he should quit the ministry if his policy was not adopted; and he carried his point. His consummate knowledge of details, his administrative ability, his impetuous will, and his conviction that France could not declare war against the four great powers of Europe prevailed over the resistance of an indolent premier and hesitating colleagues. The operations were conducted with extraordinary promptitude, good fortune, and success. The bombardment of Beirut, the fall of Acre, and the total collapse of the boasted power of Mohammed Ali followed in rapid succession, and before the close of the year Lord Palmerston's policy, which had convulsed and terrified Europe, was triumphant, and the author of it was regarded as one of the most powerful statesmen of the age. At the same time, though acting with Russia in the Levant, the British Government engaged in the affairs of Afghanistan to defeat her intrigues in Central Asia, and a contest with China was terminated by the conquest of Chusan, afterwards exchanged for the island of Hong Kong. Seldom has Great Britain occupied a prouder position abroad, although by a singular contrast the cabinet was in the last stage of decrepitude at home. Within a few months Lord Melbourne's administration came to an end, and Lord Palmerston remained for five years out of office. The crisis was past, but the change which took place by the substitution of M. Guizot for M. Thiers in France, and of Lord Aberdeen for Lord Palmerston in England, was a fortunate event for the peace of the world. Lord Palmerston had adopted the opinion that peace with France was not to be relied on, and indeed that war between the two countries was sooner or later inevitable. France was in his eyes a power likely to become an enemy; and he encouraged the formation of an English party to thwart her influence all over the world. Had he remained in office, the exasperation caused by his Syrian policy and his harsh refusal to make the slightest conciliatory concession to France, in spite of the efforts of his colleagues, would probably have led to fresh quarrels, and the emperor Nicholas would have achieved his main object, which was the complete rupture of the Anglo-French alliance. Lord Aberdeen and M. Guizot inaugurated a different policy; by mutual confidence and friendly offices they entirely succeeded in restoring the most cordial understanding between the two Governments, and the irritation which Lord Palmerston had inflamed gradually subsided. During the administration of Sir Robert Peel, Lord Palmerston led a retired life, but he attacked with characteristic bitterness the Ashburton treaty with the United States, which closed successfully some other questions he had long kept open. In all these transactions, whilst full justice must be done to the force and patriotic vigour which Lord Palmerston brought to bear on the questions he took in hand, it was but too apparent that he imported into them

an amount of passion, of personal animosity, and imperious language which rendered him in the eyes of the queen and of his colleagues a dangerous minister. On this ground, when Lord John Russell attempted, in December 1845, to form a ministry, the combination failed because Lord Grey refused to join a Government in which Lord Palmerston should resume the direction of foreign affairs. A few months later, however, this difficulty was surmounted; the Whigs returned to power, and Palmerston to the foreign office, with a strong assurance that Lord John Russell should exercise a strict control over his proceedings. A few days sufficed to show how vain was this expectation. The French Government regarded the appointment of Palmerston as a certain sign of renewed hostilities, and they availed themselves of a despatch in which Palmerston had put forward the name of a Coburg prince as a candidate for the hand of the young queen of Spain, as a justification for a departure from the engagements entered into between M. Guizot and Lord Aberdeen. However little the conduct of the French Government in this transaction of the Spanish marriages can be vindicated, it is certain that it originated in the belief that in Palmerston France had a restless and subtle enemy. The efforts of the British minister to defeat the French marriages of the Spanish princesses, by an appeal to the treaty of Utrecht and the other powers of Europe, were wholly unsuccessful; France won the game, though with no small loss of honourable reputation. Not long afterwards Sir Henry Bulwer was expelled from the Peninsula for an attempt to lecture General Narvaez on his duties, and for his notorious intrigues with the opposition; and in Paris the British embassy became the centre of every species of attack on the king's Government, so that friendly diplomatic relations were temporarily interrupted with both countries. No doubt the rupture of the Anglo-French alliance and the tension existing between the two Governments contributed in some degree to the catastrophe of 1848, which drove Louis Philippe from the throne, and overthrew the constitutional monarchy in France; but Palmerston did not regret the occurrence or foresee all its consequences.

The revolution of 1848 spread like a conflagration through Europe, and shook every throne on the Continent except those of Russia and Spain and Belgium. Palmerston sympathized, or was supposed to sympathize, openly with the revolutionary party abroad. No state was regarded by him with more aversion than Austria. Prince Metternich he abhorred; and, with some inconsistency, after the fall of Metternich he still pursued a policy of unrelenting hostility to his successors. Yet his opposition to Austria was chiefly based upon her occupation of great part of Italy and her Italian policy, for Palmerston maintained that the existence of Austria as a great power north of the Alps was an essential element in the system of Europe. Antipathies and sympathies had a large share in the political views of Lord Palmerston, and his sympathies had ever been passionately awakened by the cause of Italian independence. He knew the country; he knew the language; and in London some of his closest friends were Italians, actively engaged in the national cause. Hence he threw all the moral support he could give into the Italian revolution. He supported the Sicilians against the king of Naples, and even allowed arms to be sent them from the arsenal at Woolwich; and, although he had endeavoured to restrain the king of Sardinia from his rash attack on the superior forces of Austria, he obtained for him a reduction of the penalty of defeat. Austria, weakened by the revolution, sent an envoy to London to request the mediation of England, based on a large cession of Italian territory; Lord Palmerston rejected the terms

he might have obtained for Piedmont. Ere long the reaction came; this straw-fire of revolution burnt itself out in a couple of years. In Hungary the civil war, which had thundered at the gates of Vienna, was brought to a close by Russian intervention. Prince Schwarzenberg assumed the government of the empire with dictatorial power; and, in spite of what Palmerston termed his "judicious bottle-holding," the movement he had encouraged and applauded, but to which he could give no material aid, was everywhere subdued. The British Government, or at least Palmerston as its representative, was regarded with suspicion and resentment by every power in Europe, except the French republic; and even that was shortly afterwards to be alienated by his attack on Greece.

This state of things was regarded with the utmost annoyance by the British court and by most of the British ministers. Palmerston had on many occasions taken important steps, without their knowledge, which they disapproved. Over the foreign office he asserted and exercised an arbitrary dominion, which the feeble efforts of the premier could not control. The queen and the prince consort did not conceal their indignation at the position in which he had placed them with all the other courts of Europe. When Kossuth, the Hungarian leader, landed in England, after having been rescued by Palmerston from the demands made for his surrender, he proposed to receive this personage at Broadlands, a design which was only prevented by a peremptory vote of the cabinet; and in 1850 he took advantage of some very questionable claims on the Hellenic Government to organize an attack on the little kingdom of Greece. Greece being a state under the joint protection of three powers, Russia and France protested against this outrage, and the French ambassador temporarily left London, which promptly led to the termination of the affair. But it was taken up in parliament with great warmth. After one of the most memorable debates of this century, Palmerston's policy was condemned by a deliberate vote of the House of Lords. The House of Commons was moved by Roebuck to reverse the sentence, which it did by a majority of forty-six, after having heard from Palmerston the most eloquent and powerful speech ever delivered by him, in which he sought to vindicate, not only his claims on the Greek Government for Don Pacifico, but his entire administration of foreign affairs. It was in this speech, which lasted five hours, that Palmerston made the well-known declaration that a British subject—"Civis Romanus sum"—ought everywhere to be protected by the strong arm of the British Government against injustice and wrong. The entire Liberal party, from motives of party allegiance and patriotism, supported the minister who uttered these words. Even Sir Robert Peel, who opposed the resolution, said that the country was proud of him. Yet notwithstanding this parliamentary triumph, there were not a few of his own colleagues and supporters who condemned the spirit in which the foreign relations of the crown were carried on; and in that same year the queen addressed a minute to the prime minister in which Her Majesty recorded her dissatisfaction at the manner in which Lord Palmerston evaded the obligation to submit his measures for the royal sanction, as failing in sincerity to the crown. This minute was communicated to Palmerston, who did not resign upon it. These various circumstances, and many more, had given rise to distrust and uneasiness in the cabinet, and these feelings reached their climax when Palmerston, on the occurrence of the *coup d'état* by which Louis Napoleon made himself master of France, expressed to the French ambassador in London, without the concurrence of his colleagues, his personal approval of that act of lawless violence. Upon this, Lord John Russell advised his dismissal from office (December

1851). Palmerston speedily avenged himself by turning out the Government on a Militia Bill; but, although he survived for many years, and twice filled the highest office in the state, his career as foreign minister ended for ever, and he returned to the foreign office no more. Indeed he assured Lord Aberdeen, in 1853, that he did not wish to resume the seals of that department. Notwithstanding the zeal and ability which he had invariably displayed as foreign minister, it had long been felt by his colleagues that his eager and frequent interference in the affairs of foreign countries, his imperious temper, the extreme acerbity of his language abroad, of which there are ample proofs in his published correspondence, and the evasions and artifices he employed to carry his points at home rendered him a dangerous representative of the foreign interests of the country. He accused every foreign statesman who differed from him of "bully and swagger"; foreign statesmen in more polite language imputed the same defects to him. The lesson of his dismissal from office was not altogether lost upon him; and, although his great reputation was chiefly earned as a foreign minister, it may be said that the last ten years of his life, in which he filled other offices, were not the least useful or dignified portion of his career.

Upon the formation of the cabinet of 1853, which was composed by the junction of the surviving followers of Sir Robert Peel with the Whigs, under the earl of Aberdeen, Lord Palmerston accepted with the best possible grace the office of secretary of state for the Home Office. He speedily overcame the slight hesitation or reluctance he had expressed when the offer was first made to him, on the ground that the views of Lord Aberdeen and Lord Clarendon on foreign affairs had differed widely from his own; nor was he ever chargeable with the slightest attempt to undermine that Government. At one moment he withdrew from it, because Lord John Russell persisted in presenting a project of reform, which appeared to him entirely out of season; and he advocated, with reason, measures of greater energy on the approach of war, which might possibly, if they had been adopted, have averted the contest with Russia. As the difficulties of the Crimean campaign increased, it was not Lord Palmerston but Lord John Russell who broke up the Government by refusing to meet Roebuck's motion of inquiry. Palmerston remained faithful and loyal to his colleagues in the hour of danger. Upon the resignation of Lord Aberdeen and the duke of Newcastle, the general sentiment of the House of Commons and the country called Palmerston to the head of affairs, and he entered, on the 5th of February 1855, upon the high office which he retained, with one short interval, to the day of his death. Palmerston was in the seventy-first year of his life when he became prime minister of England.

A series of fortunate events followed his accession to power. In March 1855 the death of the emperor Nicholas removed his chief antagonist. In September Sebastopol was taken. The administration of the British army was reformed by a consolidation of offices. In the following spring peace was signed in Paris. Never since Pitt had a minister enjoyed a greater share of popularity and power, and, unlike Pitt, Palmerston had the prestige of victory in war. He was assailed in parliament by the eloquence of Gladstone, the sarcasms of Disraeli, and the animosity of the Manchester Radicals, but the country was with him. The Liberals applauded his spirit and his sympathy with the cause of liberty abroad; the Conservatives knew that he would never lend himself to rash reforms and democratic agitation at home. Defeated by a hostile combination of parties in the House of Commons on the question of the Chinese War in 1857, he dissolved the parliament and

appealed to the nation. The result was the utter defeat of the extreme Radical party, and the return of a more compact Liberal majority. The great events of the succeeding years, the Indian revolt and the invasion of Italy by Napoleon III., belong rather to the general history of the times than to the life of Palmerston; but it was fortunate that a strong and able Government was at the head of affairs. Lord Derby's second administration of 1858 lasted but a single year, Palmerston having casually been defeated on a measure for removing conspiracies to murder abroad from the class of misdemeanour to that of felony, which was introduced in consequence of Orsini's attempt on the life of the emperor of the French. But in June 1859 Palmerston returned to power, and it was on this occasion that he proposed to Cobden, one of his most constant opponents, to take office; and, on the refusal of that gentleman, Milner Gibson was appointed to the Board of Trade, although he had been the prime mover of the defeat of the Government on the Conspiracy Bill. Palmerston had learnt by experience that it was wiser to conciliate an opponent than to attempt to crush him, and that the imperious tone he had sometimes adopted in the House of Commons, and his supposed obsequiousness to the emperor of the French, were the causes of the temporary reverse he had sustained. Although Palmerston approved the objects of the French invasion of Italy, in so far as they went to establish Italian independence, the annexation of Savoy and Nice to France was an incident which revived his old suspicions of the good faith of the French emperor. A proposal was made to him to cede to Switzerland a small portion of territory covering the canton of Geneva, but he rejected the offer, saying, "We shall shame them out of it"; in this he was mistaken, and his remonstrances found no support in Europe. About this time he expressed to the duke of Somerset his conviction that Napoleon III. "had at the bottom of his heart a deep and unextinguishable desire to humble and punish England," and that war with France was a contingency to be provided against. The unprotected condition of the principal British fortresses and arsenals had long attracted his attention, and he succeeded in inducing the House of Commons to vote nine millions for the fortification of those important points.

In 1856 the projects for cutting a navigable canal through the Isthmus of Suez was brought forward by M. de Lesseps, and resisted by Palmerston with all the weight he could bring to bear against it. He did not foresee the advantages to be derived by British commerce from this great work, and he was strongly opposed to the establishment of a powerful French company on the soil of Egypt. The concession of land to the company was reduced by his intervention, but in other respects the work proceeded and was accomplished. It may here be mentioned, as a remarkable instance of his foresight, that Palmerston told Lord Malmesbury, on his accession to the Foreign Office in 1858, that the chief reason of his opposition to the canal was this:—he believed that, if the canal was made and proved successful, Great Britain, as the first mercantile state, and that most closely connected with the East, would be the power most interested in it; that this country would therefore be drawn irresistibly into a more direct interference in Egypt, which it was desirable to avoid, because England has already enough upon her hands, and because our intervention might lead to a rupture with France. He therefore preferred that no such line of communication should be opened. Recent events have shown that there was much to be said for this remarkable forecast, and that the mercantile advantages of the canal are to some extent counterbalanced by the political difficulties to which it may give rise.

Upon the outbreak of the American civil war in 1861, Lord Palmerston acknowledged that it was the duty of the British Government to stand aloof from the fray, but his own opinion led him rather to desire than to avert the rupture of the Union, which might have been the result of a refusal on the part of England and France to recognize a blockade of the Southern ports, which was notoriously imperfect, and extremely prejudicial to the interests of Europe. The cabinet was not of this opinion, and, although the belligerent rights of the South were promptly recognized, the neutrality of the Government was strictly observed. When, however, the Southern envoys were taken by force from the "Trent," a British packet, Palmerston did not hesitate a moment to exact a full and complete reparation for this gross infraction of international law, which President Lincoln was wise enough to make. But the attitude and language of some members of the British Government at that crisis, and the active operations of Southern cruisers, some of which had been fitted out by private firms in British ports, aroused a feeling of resentment amongst the American people which it took many years to efface, and which was at last removed by an award extremely onerous to England. The last transaction in which Palmerston engaged arose out of the attack by the Germanic confederation, and its leading states Austria and Prussia, on the kingdom of Denmark and the duchies of Schleswig and Holstein. There was but one feeling in the British public and the nation as to the dishonest character of that unprovoked aggression, and it was foreseen that Austria would ere long have reason to repent her share in it. Palmerston endeavoured to induce France and Russia to concur with England in maintaining the treaty of London, which had guaranteed the integrity of the Danish dominions. But those powers, for reasons of their own, stood aloof, and the conference held in London in 1864 was without effect. A proposal to send the British fleet into the Baltic was overruled, and the result was that Denmark was left to her own resources against her formidable opponents. It may be interesting to quote, as a specimen of Lord Palmerston's clear and vigorous style and insight, one of the last letters he ever wrote, for, though it relates to the affair of Schleswig-Holstein, it embraces at a glance the politics of the world.

"September 13, 1865.

"MY DEAR RUSSELL,—It was dishonest and unjust to deprive Denmark of Schleswig and Holstein. It is another question how those two duchies, when separated from Denmark, can be disposed of best for the interest of Europe. I should say that, with that view, it is better that they should go to increase the power of Prussia than that they should form another little state to be added to the cluster of small bodies politic which encumber Germany, and render it of less force than it ought to be in the general balance of power in the world. Prussia is too weak as she now is ever to be honest or independent in her action; and, with a view to the future, it is desirable that Germany, in the aggregate, should be strong, in order to control those two ambitious and aggressive powers, France and Russia, that press upon her west and east. As to France, we know how restless and aggressive she is, and how ready to break loose for Belgium, for the Rhine, for anything she would be likely to get without too great an exertion. As to Russia, she will, in due time, become a power almost as great as the old Roman empire. She can become mistress of all Asia, except British India, whenever she chooses to take it; and, when enlightened arrangements shall have made her revenue proportioned to her territory, and railways shall have abridged distances, her command of men will become enormous, her pecuniary means gigantic, and her power of transporting armies over great distances most formidable. Germany ought to be strong in order to resist Russian aggression, and a strong Prussia is essential to German strength. Therefore, though I heartily condemn the whole of the proceedings of Austria and Prussia about the duchies, I own that I should rather see them incorporated with Prussia than converted into an additional asteroid in the system of Europe. Yours sincerely,

PALMERSTON."

In little more than a month from the date of this letter, on the 18th October 1865, he expired at Brockton

Hall, after a short illness, in the eighty-first year of his age. His remains were laid in Westminster Abbey.

Although there was much in the official life of Lord Palmerston which inspired distrust and alarm to men of a less ardent and contentious temperament, it is certain that his ambition was not selfish but patriotic, that he had a lofty conception of the strength and the duties of England, that he was the irreconcilable enemy of slavery, injustice, and oppression, and that he laboured with inexhaustible energy for the dignity and security of the empire. In private life his gaiety, his buoyancy, his high-breeding, made even his political opponents forget their differences; and even the warmest altercations on public affairs were merged in his large hospitality and cordial social relations. In this respect he was aided with consummate ability by the tact and grace of Lady Palmerston, the widow of Earl Cowper, whom he married at the close of 1839. She devoted herself with enthusiasm to all her husband's interests and pursuits, and she made his house the most attractive centre of society in London, if not in Europe.

A *Life of Lord Palmerston*, by the late Lord Dalling, was published in three volumes in 1870, which owes its chief merit to the selections from the minister's autobiographical diaries and private correspondence. The work, however, ends at the year 1840, when more than half his ministerial career remained untold. This biography was resumed and continued by Mr Evelyn Ashley in 1876, after the death of Lord Dalling; but the whole period from 1846 to 1865 is compressed into two volumes, and no doubt materials are in existence, though still unpublished, which will eventually supply a fuller account of the important part played by this eminent statesman for sixty years in the affairs of the British empire and of Europe.

PALM SUNDAY (*Dominica in Palmis*), the Sunday immediately before Easter (see **HOLY WEEK**), in the Roman Catholic communion is characterized by a striking ceremonial which takes place in church at the beginning of the high mass of the day. Branches of palms and olives or other trees having previously been laid in sufficient quantity in front of the high altar, the anthem Hosanna is sung by the choir, the collect is said by the celebrant, and lessons from Exodus. xv. and xvi. and Matt. xxi. are sung by the subdeacon and deacon respectively. The branches of palm and olive (held to symbolize "victory over the prince of death" and "the coming of a spiritual unction") are then blessed with prayer and aspersion, whereupon the principal person of the clergy present approaches the altar, and gives a palm to the celebrant, who afterwards gives one to him, then to the rest of the clergy in the order of their rank, and finally to the laity, who receive kneeling. During the distribution appropriate antiphons are sung, and when it is over a procession begins for which there is another series of antiphons. At the return of the procession two or four singers go into the church, and, shutting the door, with their faces towards the procession, sing two lines of the hymn "Gloria, laus, et honor," which are repeated by the celebrant and others outside; this continues till the end of the hymn. The subdeacon next knocks at the door with the end of the cross he carries; the door is opened, and the procession re-enters the church. Then follows mass, when all hold the palms in their hands during the singing of the Passion and the Gospel. There is evidence that the feast of palms (*βαῶν ἑορτή*) was observed, in the East at least, as early as the 5th century, but the earliest mention of a procession similar to that which now takes place on Palm Sunday both in the Greek and in the Latin communion occurs in an *Ordo Officii* probably not earlier than the 10th century.

PALMYRA is the Greek and Latin name of a famous city of the East, now sunk to a mere hamlet, but still an object of interest for its wonderful ruins, which its

Semitic inhabitants and neighbours called Tadmor. The latter name, which is found in the Bible (2 Chron. viii. 5), and is written תדמור and תדמיר in Palmyrene inscriptions, has survived to the present day, and is now locally pronounced Tûdmir or Tidmir. The site of Palmyra¹ is an oasis in the desert that separates Syria from 'Irâk, about 50 hours' ride or 150 miles north-east from Damascus, 32 hours from Emesa, and five days' camel journey from the Euphrates.² The hills which fringe the oasis mark the northern limit of the Hammâd, the springless and stony central region of the great Syrian desert. The direct route between the Phœnician ports and the cities of 'Irâk and the Persian Gulf would be from Damascus eastward through the Hammâd, but this region is so inhospitable that for at least two thousand years caravans have preferred to make a detour to the north and pass through the oasis of Tadmor. At this point also the great line between the Persian Gulf and the Mediterranean is intersected by other routes connecting Palmyra with northern Syria on the one hand and with Bostra, Petra, and central Arabia on the other—routes now deserted or little traversed, but which in ancient times were of very considerable consequence, especially in connexion with the overland incense trade.³ The oasis was thus naturally marked out as a trading post of some importance, but the commanding position which Palmyra held in the 2d and 3d centuries of our era was due to special causes. The rise and fall of Palmyra form one of the most interesting chapters in ancient history, and must be studied not only from ancient writers but from the numerous inscriptions that have been collected from the ruins of the city and the tombs that surround it.

The oldest notice of Palmyra is in 2 Chron. viii. 5, when Tadmor in the wilderness is said to have been built by Solomon. But the source of this statement is 1 Kings ix. 18, and here the name is TMR, which cannot be read Tadmor, and from the context—in which Judæan towns are spoken of—is almost certainly the Tamar of Ezek. xlvii. 19, xlviii. 28. It is indeed extremely improbable that Solomon, whose policy was to enrich Judah by developing the Red Sea traffic, and so carrying the trade of the East to the Mediterranean ports through his own country, would have encouraged the rival route by Tadmor, which lies quite outside the Israelite settlements, and passes through districts over which Solomon was unable to maintain even the recognition of suzerainty which David had extorted by his Syrian wars. After the time of Solomon the Red Sea trade was interrupted, and an overland caravan trade from Phœnicia to Yemen and the Persian Gulf took its place. But neither on the cuneiform inscriptions nor in the Old Testament writings prior to Chronicles, not even in Ezekiel's account of the trading connexions of Tyre, is there any mention of Tadmor; up to the 6th century B.C. the caravans seem to have been organized by merchants of southern or central Arabia, and they probably reached Damascus by way of Dûma (Jauf Benî 'Amir) and the W. Sirhân, without coming near the oasis of Palmyra (see especially Isa. xxi. 11 sq.; Ezek. xxvii.). On the other hand Tadmor cannot have been a new place when the Biblical Chronicler ascribed its foundation to Solomon, and thus we shall hardly be wrong in connecting its origin with the gradual forward movement of the nomâdic Arabs which followed on the overthrow of the ancient nationalities of Syria by the Chaldæan empire. Arabian tribes then took possession of the partly cultivated lands east of Canaan, and, as has been explained in the article **NABATÆANS**, became masters of the Eastern

¹ According to the Duc de Luynes, the great temple is in 34° 32' 30" N. lat. and 35° 54' 35" E. long.

² Pliny (viii. 89) gives the distances as 176 Roman miles from Damascus and 337 from Seleucia.

trade, gradually acquired settled habits, and learned civilization and the use of writing from the Aramaeans, whose language was in current official and commercial use in the Persian empire west of the Euphrates. The Nabataeans of Petra naturally appear in Western literature before the remote Palmyrenes, who are not even mentioned by Strabo. But we learn from Appian (*Bell. Civ.*, v. 9) that in 42-41 B.C. the city was rich enough to excite the cupidity of Mark Antony, and that the population was still small and mobile enough to evade that cupidity by timely flight. The series of Semitic inscriptions of Palmyra begins a few years later. The oldest (De Vogüé, 30) bears the date 304 of the Seleucid era (9 B.C.), and was placed upon one of the characteristic tower-shaped tombs which overlooked the city from the surrounding hillsides. The dialect and the writing (a form of the "square" character) are western Aramaic; the era, as we have just seen, is Greek,¹ the calendar Macedonian; and these influences, to which that of Rome was soon added, were the determining factors in Palmyrene civilization. The proper names and the names of deities are also partly Syriac, but in part they are unmistakably Arabic. The Arabic element appears in the names of members of the chief families, and these retain some distinctive grammatical forms which suggest that, though Aramaic was the written language, Arabic may have not been quite obsolete in common life. That the town was originally an Arabic settlement is further rendered probable by the use of a purely Arabic term (فهدى "fahdh") for the septs into which the townsmen were divided. And thus we can best explain how, when the oasis was occupied by a settlement of Arabs, it gradually rose from a mere halting-place for caravans to a city of the first rank. The true Arab despises agriculture; but the pursuit of commerce, the organization and conduct of trading caravans, is an honourable business which gives full scope to all the personal qualities which the Bedouin values, and cannot be successfully conducted without widespread connexions of blood and hospitality between the merchant and the leading sheikhs on the caravan route. An Arabian merchant city is thus necessarily aristocratic, and its chiefs can hardly be other than pure Arabs of good blood. The position of Palmyra in this respect may be best illustrated by the analogy of Mecca. In both cities the aristocracy was commercial, and the ruling motive of all policy lay in the maintenance of the caravan trade, which involved a constant exercise of tact and personal influence, since a blood feud or petty tribal war might close the trade routes at any moment. To keep the interests of commerce free from these embarrassments, it was further indispensable to place them under the sanctions of religion, and, though we cannot prove that this policy was carried out at Palmyra with the same consistency and success as at Mecca, we can trace significant analogies which point in this direction. Mecca became the religious centre of Arabia in virtue of the cosmopolitan worship of the Ka'ba, in which all tribes could join without surrendering their own local gods. So at Palmyra, side by side with the worship of minor deities, we find a central cultus of Baal (Bel or Malachbel) identified with "the most holy sun." To him belonged the great temple in the south-east of the city with its vast fortress-like courtyard 256 yards square, lined with colonnades in the style of Herod's temple; and the presidency of the banquets of his priests, an office coveted by the first citizens of Palmyra (W., 2606, a), may be compared with the Meccan *ri'āda*, or right of entertaining

the pilgrims.² And, just as in Mecca the central worship ultimately became the worship of the supreme and nameless god (Allāh), so in Palmyra a large proportion of the numerous votive altars are simply dedicated to "the good and merciful one, blessed be his name for ever." In Palmyra as at Mecca the name Rahmān (merciful) may be due to the influence of the Jewish colony, which settled in the town after the destruction of Jerusalem; but the tendency to a universal religion, of which the dropping of the local proper name of God is so decided a mark, and which nevertheless is accompanied by no such rejection of polytheism as made Jehovah and Elohim synonymous in the religion of the Hebrew prophets, appears too early to be due to Jewish teaching (Mordtmann, 1), and seems as at Mecca to be rather connected with the cosmopolitanism of a merchant city. A secondary parallelism with Mecca is found in the sacred fountain of Ephka. Its tepid and sulphureous waters perhaps acquired their reputation from their medicinal use to cure the rheumatism which has always prevailed in Palmyra.³ This spring, like Zemzem at Mecca, had a guardian, appointed by the "moon-lord" Yarhibōl (W., 2571, c; De V., 30), whose oracle is alluded to in another inscription, and who may therefore be compared with the Meccan Hobal.

The wars between Rome and Parthia favoured the growth of Palmyra, which astutely used its secluded position midway between the two powers, and by a trimming policy secured a great measure of practical independence and continuous commercial relations with both (Appian, *ut sup.*; Pliny, v. 89). These wars, too, must have given it a share in the trade with north Syria, which in more peaceful times would not have chosen the desert route. To some extent, however, the oasis soon came under Roman control, for decrees regulating the custom-dues were issued for it by Germanicus and Corbulo. The splendid period of Palmyra, to which the greater part of the inscribed monuments belong, began with the overthrow of the Nabataean kingdom of Petra (105 A.D.), which left it without a commercial rival. Hadrian took Palmyra into his special favour, and gave it on the occasion of his visit to the town (*circa* 130 A.D.) the name of Adrianopolis.⁴ Under the same emperor (8th April 137) the customs and dues of Palmyra were regulated by a law which has recently been copied from the stone on which it was engraved, and gives the fullest picture of the life and commerce of the city. At this time the supreme legislative authority lay in the hands of a senate (*βουλή*), with a president, a scribe, two archons, and a fiscal council of ten. At a later date, probably under Septimius Severus or Caracalla, Palmyra received the *ius italicum* and became a Roman colony,⁵ and according to usage the legislative power came into the hands of the senate and people under the administration of officers called *strategi*. The Romans had soon other

² The sacrifices were partly maintained by endowments given by rich citizens (De V., 3; W. 2588). The dates of the inscriptions show that much the commonest time for the erection of honorific statues—often in a connexion partly religious—was in spring (Adar, or more often Nisan), and this seems to point to a great spring festival, corresponding to the Arabic sanctity of Rajab. Palmyra had an important trade with the Bedouins in skins and grease (fiscal inser., xvi. sq., xxx.); the herds of the desert are in condition for slaughter in spring, and this also points to a spring feast and fair. A trace of the hospitality so necessary to keep the Bedouins in humour may perhaps be found in De V., 16; W., 2585.

³ See Mordtmann, 18, and his notes; the oasis lies 1300 feet above the sea, is constantly swept by cutting winds, and is liable to sudden and extreme variations of temperature.

⁴ See Uranius, *apud* Steph. Byz., now confirmed by the great fiscal inscription.

⁵ See Ulpian, *Dig.*, l. 15, 1, and Waddington, p. 596. Palmyrenes who became Roman citizens took Roman names in addition to their native ones, and these in almost every case are either Septimius or Julius Aurelius.

¹ The oldest Greek inscription (bilingual) is of 10 A.D., for a statue erected jointly by the Palmyrenes and the Greeks of Seleucia, *Jour. As.*, ser. 8, i. 243.

than commercial reasons to favour Palmyra, which became an important military post, and turned its commercial organization to good account in aiding the movements of the legions marching against the Persians (De V., 15). It was the Persian wars that raised Palmyra to brief political importance, and made it for a few years the mistress of the Roman East; but before we pass to this last epoch of its greatness we must attempt to describe the aspect and life of the city during the century and a half of its chief commercial prosperity.

The chief luxuries of the ancient world—silks, jewels, pearls, perfumes, and the like—were drawn from India, China, and southern Arabia; and Pliny computes the yearly import of these wares into Rome at not less than three quarters of a million of English money. The trade followed two routes, one by the Red Sea, Egypt, and Alexandria, the other from the Persian Gulf through the Syro-Arabian desert. The latter, after the fall of Petra, was in the hands of the Palmyrene merchants. West of Palmyra there were Roman roads, and the bales could be conveyed in waggons, but east of the oasis there was no road, and the caravans of Palmyra traversed the desert either to Vologesias (near the ancient Babylon and the later Cufa), where water carriage was available, or to Forath on the Pasitigris and Charax at the head of the Persian Gulf. The trade was enormously profitable not only to the merchants but to the town, which levied a rigorous duty on all exports and imports, and even farmed out the water of the two wells; but the dangers of the desert and the risks of Parthian or Persian hostility were also formidable, and successfully to plan or conduct a great caravan was a distinguished service to the state, often recognized by public monuments erected by the "senate and people," or by the merchants of the caravan. These monuments, which form a conspicuous feature in Palmyrene architecture, took the form of statues placed on pedestals projecting from the upper part of the long rows of pillars which lined the chief streets; for every great merchant was eager to see his name handed down to posterity by an enduring memorial, and to add to the colonnades a series of pillars "with all their ornaments, with their brazen capitals (?) and painted ceilings," was the received way of honouring others or winning honour for oneself. Thus arose, besides minor streets, the great central avenue which, starting from a triumphal arch near the great Temple of the Sun, formed the main axis of the city from south-east to north-west for a length of 1240 yards, and at one time consisted of not less than 750 columns of rosy-white limestone each 55 feet high. We must suppose that this and the other pillared streets were shaded from the fierce heat of the sun like a modern bazaar; and in some parts the pillars seem to have served to support a raised footway, from which loungers could look down at their ease on the creaking waggons piled with bales of silk or purple wool or heavy with Grecian bronzes designed to adorn some Eastern palace, the long strings of asses laden with skins or *alabastra* of precious unguents, the swinging camels charged with olive oil from Palestine or with grease and hides from the Arabian deserts, and the motley crew of divers nationalities which crowded the street beneath—the slave merchant with his human wares from Egypt or Asia Minor, the Roman legionary and the half-naked Saracen, the Jewish, Persian, and Armenian merchants, the street hawkers of old clothes, the petty hucksters at the corners offering roasted pine cones, salt fish, and other cheap dainties, the tawdry slave-girls, whose shameful trade went to swell the coffers of the state, the noisy salt auction, presided over by an officer of the customs. The production of "pure salt" from the deposits of the desert was apparently one of the chief local industries, and another

which could not be lacking on the confines of Arabia was the manufacture of leather. We read too, on the inscriptions, of a guild of workers in gold and silver; but Palmyra was not a great industrial town, and the exacting fiscal system, which reached the most essential industries, and drew profit from the barest necessities of life, must have weighed heavily on the artizan classes. Though all quarters of the town still show traces of splendid buildings, wealth was probably confined to a comparatively small number of great families, and we must picture Palmyra in its best days as displaying a truly Oriental compound of magnificence and squalor, where the mud or straw-built huts of the poor stood hard by the palaces of the merchant princes.

The life of the mass of the population was the unchanging life of the Eastern poor; the great families too remained essentially Oriental under the varnish of their Greek culture and Roman citizenship. The life of a prominent townsman included an active share in the organization and even the personal conduct of caravans, the discharge of civic offices, perhaps the superintendence of the market and the victualling of a Roman expedition. The capable discharge of these functions, which sometimes involved considerable pecuniary sacrifices, ensured public esteem, laudatory inscriptions, and statues, and to these honours the head of a great house was careful to add the glory of a splendid family tomb, consecrated as the "long home" (מִן עַלְמָא—the same phrase as in Eccles. xii. 5) of himself, his sons, and his sons' sons "for ever." These tombs, which lie outside the city, are perhaps the most interesting monuments of Palmyra. Some are lofty square towers, with as many as five sepulchral chambers occupying successive stories, and overlooking the town and its approaches—a feature characteristically Arabic—from the slopes of the surrounding hills. Others are house-like buildings of one story, a richly decorated portico opening into a hall whose walls are adorned with the names and sculptured portraits of the dead. The scale of these monuments corresponds to the wide conception of an Eastern family, from which dependants and slaves were not excluded; and on one inscription, in striking contrast with Western usage, a slave is named with the sons of the house (De V., 33, a). The tombs are the only buildings of Palmyra that have any architectural individuality; the style of all the ruins is late classic, highly ornate, but without refinement.

The frequent Eastern expeditions of Rome in the 3d century brought Palmyra into close connexion with several emperors, and opened a new career of ambition to her citizens in the Roman honours that rewarded services to the imperial armies. One house which was thus distinguished was to play no small part in the world's history. Its members, as we learn from the inscriptions, prefixed to their Semitic names the Roman *gentilicium* of Septimius, which shows that they received the citizenship under Septimius Severus, presumably on the occasion of his Parthian expedition. In the next generation Septimius Odenathus¹ (Odhainat), son of Hairan, son of Wabballath, son of Nassor, had attained the rank of a Roman senator, conferred no doubt when Alexander Severus visited Palmyra (comp. De V., 15). The East was then stirred by the progress of the new Sásanian empire, and the Palmyrene aristocracy, in spite of its Roman honours, had probably never cordially fallen in with the changes which had made Palmyra a colony and a military station. Indeed the Romanizing process had only changed the surface life of the place; it lay in the nature of things that the

¹ Ὀδαίναθος, not Ὀδέρναθος, is the form of the name on the inscriptions

greatest merchant prince, with the openest hand, and the widest circle of connexions along the trade routes, was the real head of the community, and could do what he pleased with *boule* and *demos* except when a Roman commander interfered. Odaenathus appears to have been the head of a party which secretly meditated revolt, but the outbreak was prevented by a Roman officer Rufinus, who procured his assassination.¹ He left two sons; the elder named Hairan appears in an inscription of 251 A.D. as "head man" (ὡρ, ἑταρχος) of the Palmyrenes, but it was the younger brother Odaenathus who sought revenge for his father's death and inherited his ambition. In him the old Bedouin blood reasserted itself; an Esau among the Jacobs of Tadmor, he spent his youth in the mountains and deserts, where the hardships of the chase prepared him for the fatigues of war, and where no doubt he acquired the absolute influence over the nomad tribes which was one of the chief secrets of his future success. In 258, the year of Valerian's ill-fated march against Sapor, Odaenathus is called *hypatikos* or *consular*, the highest honorary title of the empire, in an inscription erected to him by the gold and silver smiths of Palmyra. The title no doubt had just been conferred by the emperor on his way eastward, and the munificent patron of the guild of workers in precious metals had, we may judge, liberally scattered their wares among the wives and daughters of the Bedouin sheikhs. He meant to have a strength and party of his own, whatever the issue of the war. If we may trust the circumstantial account of Petrus Patricius, the captivity of Valerian and the victorious advance of Sapor induced Odaenathus to send gifts and letters to Sapor; and it was only when these were rejected that he threw himself heart and soul into the Roman cause. Sapor was offended that Odaenathus did not appear before him in person; the Palmyrene chief in fact did not mean to be the mere subject either of Persian or Roman, though he was ready to follow whichever power would leave him practically sovereign at the price of occasional acts of homage. Rome in her day of disaster could not afford to be so proud as the Persian; the weak Gallienus was the very suzerain whom Odaenathus desired; and, joining his own considerable forces with the shattered fragments of the Roman armies, the Palmyrene commenced a successful war with Persia, in which he amply revenged himself on the arrogance of Sapor, and not only saved the Roman East but reduced Nisibis, twice laid siege to Ctesiphon itself, and furnished Gallienus with the captives and trophies for the empty pomp of a triumph. From the confused mass of undigested and contradictory anecdotes which form all the history we possess of this period it is impossible to extract a satisfactory picture of the career of Odaenathus; but we can see that he steadily aimed at concentrating in his own person the whole sovereignty of Syria and the neighbouring lands, and as the organization of the empire had entirely broken down, and almost every Roman general who had a substantial force at his command sooner or later advanced a claim to the purple, the Palmyrene prince, always acting in the name of Gallienus, gradually disembarassed himself of every rival representative of Western authority throughout the greater part of Roman Asia. In the year 264 he was officially named supreme commander in the East,² and, though to

the Romans he was a subject of the empire, among his own people he was an independent sovereign, supreme over all the lands from Armenia to Arabia, and able to count on the assistance of both these nations. Odaenathus himself seems to have been engaged in almost constant warfare in the east and north against the Persians and perhaps the Scythians, but in his absence the reins of government were firmly held by his wife Zenobia, the most famous heroine of antiquity, to whom indeed Aurelian, in a letter preserved by Trebellius Pollio, ascribes the chief merit of all her husband's success. Septimia Zenobia was by birth a Palmyrene; her native name was Bath Zabbai (De V., 29);³ and Pollio's description of her dark beauty, black flashing eyes, and pearly teeth, together with her unusual physical endurance and the frank commanding manners which secured her authority in the camp and the desert, point emphatically to an Arabic rather than a Syrian descent.⁴ To the union of firmness and clemency, which is the most necessary quality of an Eastern sovereign, Zenobia added the rarer gifts of economy and organization, and an unusual range of intellectual culture. She spoke Coptic as well as Syriac, knew something of Latin, and had learned Greek from the famous Longinus, who remained at her court to the last, and paid the penalty of his life for his share in her counsels. She was also a diligent student of Eastern and Western history, and the statement that she enjoined her sons to speak Latin so that they had difficulty in using Greek implies a consistent and early adoption of the policy which made the success of Odaenathus, and, taken in connexion with Aurelian's testimony, in a letter preserved by Pollio, that she had the chief merit of her husband's exploits, seems to justify the conclusion that it was her educated political insight that created the fortunes of the short-lived dynasty. In the zenith of his fame Odaenathus was cut off by assassination along with his eldest son Herod, and it is generally assumed that the murder took place under Gallienus. The authority for this view is Pollio, who says that on receiving the news Gallienus sent an army against the Persians, which was destroyed to a

Persian victories in 265 (reading *consulatu* for *consulta* in *Gall.* c. 12 with Klein in *Rhein. Mus.* 1880, p. 49 sq.). With this agrees Jerome's date of 265 for the campaign against Sapor; and it is also possible to make out from the series of Palmyrene inscriptions referring to a certain Septimius Word that in 263-264 the military organization of Palmyra ceased to be Roman. On the other hand up to 262-263 Syria was held by Macrianus and his son Quietus. Odaenathus took Emesa and destroyed Quietus probably in 263. Up to this time his sphere of action was limited by the desert, but the overthrow of Quietus left him the only real power between Rome and Persia. There is really no evidence that he was at war with Sapor before 265, and before 263 he was hardly in a position to send an embassy to him. It is most likely that his final decision in favour of Rome was not made till the fall of Emesa. Pollio is certainly wrong in saying that in 265 Odaenathus was named Augustus. He seems to have been misled by a medal in which the Augustus represented dragging Persians captive was really Gallienus, whom we know to have triumphed for Odaenathus's victories. But after his Persian successes Odaenathus strengthened his position, as we learn from coins, by having his son associated in his imperium. The first year of Wahballath is 266-267, when his father, as will be presently shown, was still alive. The title of "king" was perhaps not conferred on Wahballath till the reign of Aurelian (Sallet, *Num. Zeit.*, 1870).

³ The original reading of De Vogüé and Waddington, Bath Zebina, is now known to be incorrect. Zabbai is a genuine Palmyrene name, borne also at this period by Septimius Zabbai, the general of the forces of the city.

⁴ We need not attach any weight to the fact that Zenobia, when she was mistress of Egypt, boasted of descent from Cleopatra and the Ptolemies. Athanasius, in speaking of the support she gave to Paul of Samosata, calls her a Jewess; this is certainly false, for her coins bear pagan symbols. Athanasius probably drew a hasty conclusion, not so much from her sympathy with the Monarchian Paul as from her patronage of the Jews in Alexandria, for which the evidence of an inscription from a synagogue still exists (see Monmsen in *Zeitsch. f. Numismatik*, v. 229 sq., 1873).

¹ See the anonymous continuator of Dio (*Fr. Hist. Gr.* iv. 135). The elder Odaenathus is also alluded to in Pollio's life of Cyriades, from which one may infer that he plotted with a Persian party in Syria.

² This date is given by Pollio (*Gallienus*, c. 20) and is confirmed by other notices. The order of events is very obscure, and Pollio is self-contradictory in several places. But the two events which he dates by consulates, and which therefore are probably most trustworthy, are the appointment of Odaenathus in 264 and the rejoicings in Rome over his

man by Zenobia—a statement quite incredible, since we know from coins of her son Wabballath or Athenodorus, struck at Alexandria, that the suzerainship of Rome was acknowledged in the Palmyrene kingdom till the second year of Aurelian. That Odaenathus fell under Gallienus seems, however, at first sight to be confirmed by the coins, which give 266–7 as the first year of Wabballath. On the other hand the inscriptions on two statues of Odaenathus and Zenobia which stand side by side at Palmyra bear the date August 271, and, though De Vogüé, mistaking an essential word, supposed the former to be posthumous, the inscription really implies that Odaenathus was then alive.¹ Now Pollio himself says that his wife and sons were associated in the kingship of Odaenathus, and therefore the years of Wabballath do not necessarily begin with his father's death. The fact seems to be that, while Odaenathus was busy at the other end of his kingdom, Zenobia administered the government at Palmyra and directed the conquest of Egypt, still nominally acting under the emperor at Rome, whose authority on the Nile was disputed by one or more pretenders.² It still seems strange that Wabballath should strike money in his father's lifetime—and he did so both at Antioch and Alexandria—when there are no genuine coins of Odaenathus; but it is equally strange and yet an undoubted fact that Zenobia, who not only enjoyed the real authority behind her beardless son, but placed her name before his on public inscriptions,³ struck no coins till the second year of Aurelian, when the breach with Rome took place, and she suddenly appears as an empress (Σεβαστή, Augusta) of five years' standing. Up to that date the royal pair probably did not venture to coin in open defiance to Rome, and yet were unwilling to circulate an acknowledgment of vassalship in all the bazaars of the East.

When, however, Aurelian had restored the unity of the West, and stood at the head of a powerful army flushed by victory in Gaul, Palmyra had to choose between real subjection and war with Rome. Some time in the year ending August 28, 271, Wabballath assumed the title of Augustus, and drops Aurelian from his coins, and just at the same time Zabdai, generalissimo of the forces, and Zabbai, commander of the army of Tadmor, erected the statues already mentioned, where Odaenathus is styled "king of kings and restorer of the state." This was an open challenge, and the assassination of Odaenathus, which took place at Emesa, a town in which the Roman party was strong, must have followed immediately afterwards, and on political grounds.⁴ Zenobia, supported by her two generals, kinsmen of her husband, was now face to face with a Roman invasion. She held Egypt, Syria, Mesopotamia, and Asia Minor as far as Ancyra; and Bithynia was ready to join her party had not the army of Aurelian appeared just in time from Byzantium. She could count too on the Armenians and the Arabs, but the loyalty of Syria was doubtful: the towns disliked a rule which was essentially "barbarian," and in Antioch at least the patroness of the Monarchian bishop Paul of Samosata could not be popular with the large Christian party by whom he was bitterly hated. There were many Romans

in Zenobia's force, and it was they who bore the brunt of the two great battles at Antioch and Emesa, which followed Aurelian's rapid advance through Asia Minor. But Zenobia made light of these defeats,—“I have suffered no great loss” was her message to Aurelian, “for almost all who have fallen are Romans” (*Fr. H. Gr.*, iv. 197). It was now plain that the war was one of races, and the fact that the fellâhîn of Palestine fought with enthusiasm on the side of Aurelian is the clearest proof that the empire of Palmyra was really an empire of Arabs over the peasants of the settled Semitic lands, whom the true Bedouin always despises, and who return his contempt with burning hatred. Thus the analogy already traced between the early history of Tadmor and Mecca is completed by an equally striking parallel between the empire of the Septimians at Palmyra and that of the Omayyads at Damascus. In each case it was a family of Arabian merchant princes, strong in its influence over the sons of the desert, which rose to sovereignty and governed the old lands of the Semites from a city which had the desert behind it. But the empire of Palmyra came four centuries too soon. Rome was not yet exhausted, and Zenobia had neither the religious discipline of Islâm to hold the Arabs together nor the spoil of the treasures of Persia to keep their enthusiasm always fresh. Aurelian's military skill was strained to the uttermost by the prudence and energy of Zenobia, but he succeeded in forming and maintaining the siege of Palmyra in spite of its bulwark of desert, and his gold corrupted the Arab and Armenian auxiliaries. Zenobia attempted to flee and throw herself on the Persians, but she was pursued and taken, and then the Palmyrenes lost heart and capitulated. Aurelian seized the wealth of the city, but spared the inhabitants, and to Zenobia he granted her life while he put her advisers to death. She figured in his splendid triumph, and by the most probable account accepted her fall with dignity, and closed her days at Tibur, where she lived with her sons the life of a Roman matron. The fall of Zenobia may be placed in the spring of 272. Soon after, probably within a year, Palmyra was again in revolt, but on the approach of Aurelian it yielded without a battle; the town was destroyed and the population put to the sword.

An obscure and distorted tradition of Zenobia as an Arab queen survived in the Arabian tradition of Zabbâ, daughter of 'Amr b. Zarib, whose name is associated with Tadmor and with a town on the right bank of the Euphrates, which is no doubt the Zenobia of which Procopius speaks as founded by the famous queen. See C. de Perceval, ii. 23 sq., 197 sq.; Tabari, i. 757 sq. But the ruins of Palmyra, which excited the lively admiration of the Bedouins, were not associated by them with the great queen; they are referred to by Nâbigha as proofs of the might of Solomon and his sovereignty over their builders the Jinn. This legend must have come from the Jews, who either clung to the ruins or returned when Palmyra partially revived as a military station founded by Diocletian. Under the Christian empire Palmyra was a bishopric; about 400 A.D. it was the station of the first Illyrian legion (*Not. Dig.*). Justinian furnished it with an aqueduct, and built the wall of which the ruins are still visible: it was deemed important, as we gather from Procopius, to have a strong post on the disputed marches of the Arabs of Hira and Ghassân. At the Moslem conquest of Syria Palmyra capitulated to Khâlid without embracing Islâm (Belâdhori, p. 111 sq.; Yâkût, i. 531). The town became a Moslem fortress and received a considerable Arab colony; for in the reign of Merwân II. it sent a thousand Kalbite horsemen to aid the revolt of Emesa, to the district of which it is reckoned by the Arabic geographers.⁵ The rebellion was sternly suppressed and the walls of the city destroyed.⁶ References to Palmyra in later

¹ That Odaenathus lived to begin the war with Aurelian seems to have been known to Vopiscus (*Probus*, c. 9).

² That the Probus of Pollio, *Claudius*, c. 11 (the Probus of Zosimus), must have been a pretender was first seen by Mommsen, *apud* Sallet, *Fürsten von Palmyra*, p. 44.

³ This is shown for Syria by an inscription near Byblus (*C. I. G.*, 4503 b; Waddington, p. 604), and for Egypt by the inscription from the Jewish synagogue already quoted, where indeed the names are not given but the order is βασιλίσσης καὶ βασιλέως—in the Latin *Regina et rex jusserunt*.

⁴ See, for the attitude of Emesa, Zosimus, i. 54, *Frag. Hist. Græc.*, iv. 195. The assassin was a relative of Odaenathus named Mæonius, that is M'annai (*Pollio Trig. Tyr.*; Zonaras, xii. 24).

⁵ Ibn Athir (127 A.H.); compare *Frag. Hist. Ar.*, 139 (where it is said to have been held by the Beni 'Amir); Ibn Wâdih, ii. 230; Mokaddasi, p. 156.

⁶ In this connexion Yâkût tells a curious story of the opening of one of the tombs by the caliph, which in spite of fabulous incidents, recalling the legend of Roderic the Goth, shows some traces of local knowledge. The sculptures of Palmyra greatly interested the Arabs, and are commemorated in several poems quoted by Yâkût and others.

times have been collected by Quatremère, *Sultans Mcmlouks*, ii. 1, p. 255. Once all but annihilated by earthquake (434 A.D.), and passing through many political vicissitudes, Tadmor was still a wealthy place, with considerable trade, as late as the 14th century; but in the general decline of the East, and the change of the great trade routes, it at length sunk to a poor group of hovels gathered in the courtyard of the great Temple of Sun. The ruins first became known to Europe in 1678 through W. Halifax, an Aleppo merchant. The architecture was carefully studied in 1751 by Wood and Dawkins, whose splendid folio (*The Ruins of Palmyra*, Lond., 1753) also gave copies of inscriptions.¹ But, though the site was often visited and some stones with Semitic as well as Greek writing reached Europe, the great epigraphic wealth of Palmyra was first thoroughly opened to study by the collections of Waddington and De Vogüé, made in 1861-62. Subsequent discoveries have been of minor importance, with the notable exception of the great fiscal inscription spoken of above, discovered by Prince Abamelek Lazarew.

Sources.—To the writers already used by Tillement and Gibbon, of whom Zosimus appears on the whole the best informed, must be added the fragments of the anonymous continuator of Dio (Petrus Patricius?) first published by Mai. For the coins, Sallet's *Fürsten von Palmyra* (1866) must be read with his later essay, *Nun Zeitach.* ii. 31 sq. (Vienna, 1870). For the Greek inscriptions, see the *Cor. Insc. G.* but especially the work of La Bas and Waddington, vol. iii. To the great collection of Aramaic inscriptions in De Vogüé, *Syrie Centrale*, must be added the gleanings of other travellers (Nordmann, *Sitzungsb.* of the Munich Ac., 1875; Sachau, in *Z. D. M. G.*, xxxv 728 sq.), with some stones brought to Europe at an earlier date, and the monuments of natives of Palmyra in Africa and Britain (see Levy, *Z. D. M. G.*, xli. xv., xviii.; W. Wright, "The Palmyrene Inscr. of S. Shields," *Tr. Soc. Bib. Arch.*, vi.). The great fiscal inscription was published by De Vogüé, *Jour. As.*, ser. 8, vols. 1, ii.; comp. Sachau, in *Z. D. M. G.*, xxvii. 562 sq., and R. Cagnat in *Rev. de Philol.*, viii 135 sq. The dialect has been thoroughly discussed by Nöldeke in *Z. D. M. G.*, xxiv 85 sq. Its nearest affinities are with Biblical Aramaic (W. R. S.)

PALOMINO DE CASTRO Y VELASCO, ACISCLO ANTONIO (1653-1726), Spanish painter and writer on art, was born of good family at Bujalance, near Cordoba, in 1653, and studied philosophy, theology, and law at that capital, receiving also lessons in painting from Valdes Leal, who visited Cordoba in 1672, and afterwards from Alfaro (1675). After taking minor orders he removed to Madrid in 1678, where he associated with Alfaro, Coello, and Careño, and executed some indifferent frescos. He soon afterwards married a lady of rank, and, having been appointed alcalde of the mesta, was himself ennobled; and in 1688 he was appointed painter to the king. He visited Valencia in 1697, and remained there three or four years, again devoting himself with but poor success to fresco painting. Between 1705 and 1715 he resided for considerable periods at Salamanca, Granada, and Cordoba; in the latter year the first volume of his work on art appeared in Madrid. After the death of his wife in 1725 Palomino took priest's orders. He died on August 13, 1726.

His work, in three vols. folio (1715-24), entitled *El Museo Pictórico y Escala Óptica*, consists of three parts, of which the first two, on the theory and practice of the art of painting, are without interest or value; the third, with the subtitle *El Parnaso Español Pintoresco Laureado*, is a mine of important biographical material relating to Spanish artists, which, notwithstanding its faulty style, has procured for the author the not altogether undeserved honour of being called the "Spanish Vasari." It was partially translated into English in 1739; an abridgment of the original (*Las Vidas de los Pintores y Estatuarios Españoles*) was published in London in 1742, and afterwards appeared in a French translation in 1749. A German version was published at Dresden in 1781, and a reprint of the entire work at Madrid in 1797.

PALUDAN-MÜLLER, FREDERIK (1809-1876), the leading poet of Denmark during the middle of the present century, was born at Kjerteminde on the 7th February 1809. His father was Jens Paludan-Müller, a distinguished bishop of Aarhus. He was educated at the cathedral school of Odense from 1820 to 1828; in the latter year he passed to the university of Copenhagen. In 1832 he opened his career as a poet with *Four Romances*, and a romantic comedy entitled *Kjærlighed ved Høftet* ("Love at Court"). This enjoyed a great success, and was succeeded in 1833 by *Dandserinden* ("The Dancer"), and

in 1834 by the lyrical drama of *Amor og Psyche*. There was now no doubt about Paludan-Müller's genius. In 1835 he came under the influence of Byron, and published an Oriental tale, *Zuleimas Flugt* ("Zuleima's Flight"), which was less successful than the preceding books. But he regained all that he had lost by his two volumes of *Poems* in 1836 and 1838. Paludan-Müller now left his native country for the first time, and spent two years (1838-40) in Germany, Italy, and France. The next dates in his career are those of the publication of his principal masterpieces—his lyrical dramas, *Venus*, 1841; *Dryadens Bryllup* ("The Dryad's Wedding"), 1844; *Tithon* ("Tithonus"), 1844; and his famous didactico-humorous epic *Adam Homo*, in three volumes, 1841-48. His later works include *Abels Død* ("The Death of Abel"), 1854; *Kalanus*, an Indian tragedy; *Paradiset* ("Paradise"), a lyrical drama, 1861; *Benedikt fra Nurcia*, 1861. *Tiderne Skifte* ("The Times are Changing"), a comedy, 1874; and *Adonis*, an exquisite romance in verse, 1874. Besides these works, all of which are poetical, Paludan-Müller published a story, *Ungdomskilden* ("The Fountain of Youth"), in 1865, and an historical novel in three volumes, *Ivar Lykke's Historie* ("The Story of Ivar Lykke"), 1866-73. The poet lived a very retired life, first in Copenhagen, then for many years in a cottage on the outskirts of the royal park of Fredensborg. He died in his house in Ny Adelgade, Copenhagen, on the 27th December 1876.

Paludan-Müller's genius has been made the subject of one of the most brilliant of George Brandes's monographs. His work was varied, but of remarkably high and level merit. His lyrical dramas form a group of pure poems, of an elevated class, which would distinguish him above most of the European poets of his time, even if he had not shown himself, in *Adam Homo*, to be a great satirist as well. His artistic form was singularly fine. He might have been a more finished thinker if his imagination had not been disturbed by Byron. The reader who desires to study Paludan-Müller at his best must read the first book of *Adam Homo*, and the whole of *Kalanus* and of *Adonis*. His poetical works were collected in eight volumes in 1878-79.

PALWÁL, in Gurgáon district, Punjab, India, with a population in 1881 of 10,635, is a town of great antiquity, supposed to figure in the earliest Aryan traditions under the name of Apelava, part of the Pándava kingdom of Indraprástha. Its importance is purely historical, and the place is now a mere agricultural centre.

PAMIERS, capital of an arrondissement, an episcopal see, and the most populous town (10,478 inhabitants) of the department of Ariège, France, lies on the right bank of that river, 40 miles south of Toulouse, in the middle of a fertile and well-watered valley. Its wines were at one time in high repute. Its industrial establishments at present comprise flour mills, spinning-mills, serge factories, and some large forges, and there is also a gold-washing company (the Ariège derives its name from its auriferous character). The cathedral of Pamiers, with an octagonal Gothic tower, is a bizarre mixture of the Græco-Roman and Gothic styles, the church of Notre Dame du Camp is noticeable for its crenellated and machicolated façade. From the site of the old castle, which still retains the name of Castellat, there is a fine view of the Pic de St Barthélemy and the valley of the Ariège.

Pamiers was originally a castle built in the beginning of the 12th century by Roger II., count of Foix, on lands belonging to the abbey of St Antonin de Frédelas. The abbots of St Antonin, and afterwards the bishops, shared the superiority of the town with the counts. This gave rise to numerous disputes between monks, counts, sovereigns, bishops, and the consuls of the town. Pamiers was sacked by Jean de Foix in 1486, again during the religious wars, and, finally, in 1628 by Conde.

PAMIR. See *ASIA*, vol. ii. p. 686, and *Oxus*, p. 103, *supra*.

PAMPAS. See *ARGENTINE REPUBLIC*, vol. ii. p. 487.

PAMPHILUS, an eminent promoter of learning in the early church, is said to have been born of good family,

¹ For the site and the present aspect of the ruins, which are less perfect than at Wood's visit, see especially papers by W. Wright (of Damascus) in *Leisure Hour*, 1876; Socin-Baedeker's *Handbook*; and the recent *Reise* of Sachau (Berlin, 1883), which gives a general photograph, and one of the most perfect ruin, the small Sun-Temple.

at Berytus, in the latter half of the 3d century. After studying at Alexandria under Pierius, the disciple of Origen, he was ordained presbyter at Cæsarea in Palestine, where the remainder of his life was spent. There he established a theological school, and warmly encouraged students; he also founded, or at least largely extended, the great library to which Eusebius and Jerome were afterwards so much indebted. He was very zealous in the transcription and distribution of copies of Scripture and of the works of various Christian writers, especially of Origen; the copy of the complete works of the last-named in the library of Cæsarea was chiefly in the handwriting of Pamphilus himself. At the outbreak of the persecution under Maximin, Pamphilus was thrown into prison, and there, along with his attached friend and pupil Eusebius (sometimes distinguished as Eusebius Pamphili), he composed an *Apology for Origen* in five books, to which a sixth was afterwards added by Eusebius. He was put to death in 309.

Only the first book of the *Apology* of Pamphilus is extant, and that but in an imperfect Latin translation by Rufinus. It has been reprinted in De la Rue's edition of *Origen*, and also by Routh and by Galland. Eusebius wrote a memoir of his master which also has unfortunately disappeared.

PAMPHLETS: The earliest appearance of the word is in the *Philobiblon* (1344) of Richard de Bury, who speaks of "panfletos exiguos" (chap. viii.). In English we have Chaucer's "this leud pamflet" (*Test. of Love*, bk. iii.), Occleve's "go litil pamflet" (Mason's ed., 1796, p. 77), and Caxton's "paunflettis and bookys" (*Book of Eneydos*, 1490, Prologue). In all these examples pamphlet is used to indicate the extent of the production, and in contradistinction to book. In the 16th century it became almost exclusively devoted in English literature to short poetical effusions, and not till the 18th century did pamphlet begin to assume its modern meaning of a prose political tract. "Pamphlet" and "pamphletaire" are of comparatively recent introduction into French from the English, and generally indicate fugitive criticism of a more severe, not to say libellous, character than with us. The derivation of the word is a subject of contention among etymologists. The experts are also undecided as to what is actually understood by a pamphlet. Some bibliographers apply the term to everything, except periodicals, of quarto size and under, if not more than fifty pages, while others would limit its application to two or three sheets of printed matter which have first appeared in an unbound condition. These are merely physical peculiarities, and include academical dissertations, chap-books, and broadsides, which from their special subjects belong to a separate class from the pamphlet proper. As regards its literary characteristics, the chief notes of a pamphlet are brevity and spontaneity. It has a distinct aim, and relates to some matter of current interest, whether religious, political, or literary. Usually intended to support a particular line of argument, it may be descriptive, controversial, didactic, or satirical. It is not so much a class as a form of literature, and from its ephemeral character represents the changeful currents of public opinion more closely than the bulky volume published after the formation of that opinion. The history of pamphlets being the entire record of popular feeling, all that is necessary here is to briefly indicate the chief families of political and religious pamphlets which have exercised marked influence, and more particularly in those countries—England and France—where pamphlets have made so large a figure in influencing thought and events.

It is difficult to point out much in ancient literature which precisely answers to our modern view of the pamphlet. The *libelli famosi* of the Romans were simply abusive pasquinades. Some of the small treatises of Lucian, the lost *Anti-Cato* of Cæsar, Seneca's *Apocolocyntosis*

written against Claudius, Julian's *Καίσαρες ἢ Συμπόσιον* and *Ἀντιοχικὸς ἢ Μισοπύγων*, from their general application, just escape the charge of being mere satires, and may therefore claim to rank as early specimens of the pamphlet.

At the end of the 14th century the Lollard doctrines were widely circulated by means of the tracts and leaflets of Wickliffe and his followers. *The Ploughman's Prayer* and *Lanthorne of Light*, which appeared about the time of Oldcastle's martyrdom, were extremely popular, and similar brief vernacular pieces became so common that it was thought necessary in 1408 to enact that persons in authority should search out and apprehend all persons owning English books. The printers of the 15th century produced many controversial tractates, and Caxton and Wynkin de Worde printed in the lesser form. It was in France that the printing press first began to supply reading for the common people. During the last twenty years of the 15th century there arose an extensive popular literature of farces, tales in verse and prose, satires, almanacs, &c., extending to a few leaves apiece, and circulated by the itinerant booksellers still known as *colporteurs*. These folk-books soon spread from France to Italy and Spain, and were introduced into England at the beginning of the 16th century, doubtless from the same quarter, as most of our early chap-books are translations or adaptations from the French. Another form of literature even more transient was the broadside, or single sheet printed on one side only, which appears to have flourished principally in England, but which had been in use from the first invention of printing for papal indulgences, royal proclamations, and similar documents. Throughout western Europe, about the middle of the 16th century, the broadside made a considerable figure in times of political agitation. In England it was chiefly used for ballads, which soon became so extremely popular that during the first ten years of the reign of Elizabeth the names of no less than forty ballad-printers appear in the Stationers' Registers. The humanist movement of the beginning of the 16th century produced the famous *Epistolæ Obscurorum Virorum*, and the leading spirits of the Reformation period—Erasmus, Hutten, Luther, Melancthon, Francowitz, Vergerio, Curio, and Calvin—found in tracts a ready method of widely circulating their opinions.

The course of ecclesiastical events was precipitated in England by the *Supplicacyon for the Beggars* (1523) of Simon Fish, answered by Sir Thomas More's *Supplicacyon of Soules*. In the time of Edward VI. brief tracts were largely used as a propagandist instrument in favour of the Reformed religion; political tracts were represented by the address of the rebels in Devonshire (1549). The licensing of the press by Mary greatly hindered the production of this kind of literature. From about 1570 there came an unceasing flow of Puritan pamphlets, of which more than forty were reprinted under the title of *A parte of a register* (London, Waldegrave, 4to). To this publication Dr John Bridges replied by a ponderous quarto, *A defence of the government established in the church of England* (1587), which gave rise to *Oh read over D. John Bridges . . . by the reverend and worthie Martin Marprelate gentleman* (1588), the first of the famous Martin Marprelate tracts, whose titles sufficiently indicate their opposition to priestly orders and episcopacy. Bishop Cooper's *Admonition to the People of England* (1589) came next, followed on the other side by *Hay any worke for Cooper . . . by Martin the Metropolitane*, and by others from both parties to the number of about twenty-three. The controversy lasted about a year, and ended in the discomfiture of the Puritans and the seizure of their secret press. The writers on the Marprelate side are generally

supposed to have been Penry, Throgmorton, Udal, and Fenner, and their opponents Bishop Cooper, John Lilly, and Nash.

As early as the middle of the 16th century we find ballads of news; and in the reigns of Elizabeth and James I. small pamphlets, translated from the German and French, and known as "news-books," were circulated by the so-called "Mercury-women." These were the immediate predecessors of weekly newspapers, and continued to the end of the 17th century. A proclamation was issued by Charles II., May 12, 1680, "for suppressing the printing and publishing of unlicensed news-books and pamphlets of news."

In the 17th century pamphlets began to contribute more than ever to the formation of public opinion. Nearly one hundred were written by or about the restless John Lilburne, but still more numerous were those of the undaunted Prynne, who himself published above one hundred and sixty, besides many weighty folios and quartos. Charles I. found energetic supporters in Peter Heylin and Sir Roger L'Estrange, the latter noted for the coarseness of his pen. The most distinguished pamphleteer of the period was John Milton, who began his career in this direction by five anti-episcopal tracts (1641-42) during the Smectymnuus quarrel. In 1643 his wife's desertion caused him to publish anonymously *Doctrine and discipline of divorce*, followed by several others on the same subject. He printed the *Tract on Education* in 1644, and, unlicensed and unregistered, his famous *Areopagitica*—a speech for the liberty of unlicensed printing. He defended the trial and execution of the king in *Tenure of kings and magistrates* (1648). The *Eikon Basilike* dispute was conducted with more ponderous weapons than the kind we are now discussing. When Monk held supreme power Milton addressed to him *The present means of a free commonwealth and Readie and easie way* (1660), both pleading for a commonwealth in preference to a monarchy. John Goodwin, the author of *Obstructors of Justice* (1649), John Philipps, the nephew of Milton, and Abiezer Coppe were violent and prolific partisan writers, the last-named specially known for his extreme Presbyterian principles. The tract *Killing no murder* (1657), aimed at Cromwell, and attributed to Colonel Titus or Colonel Sexby, excited more attention than any other political effusion of the time. The history of the civil war period is told day by day in the well-known collection made by Thomason the bookseller, now preserved in the British Museum. It numbers 30,000 separate books, pamphlets, and broadsides, ranging from 1640 to 1662, and is bound in 2000 volumes. Each article was dated by Thomason at the time of acquisition. William Miller was another bookseller famous for his collection of pamphlets, which were catalogued by Tooker in 1693. Wm. Laycock printed a *Proposal for raising a fund* for buying them up for the nation.

The Catholic controversy during the reign of James II. gave rise to a multitude of books and pamphlets, which have been described by Peck (*Catalogue*, 1735) and by Jones (*Catalogue*, Chatham Society, 1859-65, 2 vols.). Politics were naturally the chief feature of the floating literature connected with the Revolution of 1688. The political tracts of Lord Halifax are interesting both in matter and manner. He is supposed to have written *The character of a political trimmer* (1689), sometimes ascribed to Sir W. Coventry. About the middle of the reign Defoe was introduced to William III., and produced the first of his pamphlets on occasional conformity. He issued in 1697 his two defences of standing armies in support of the Government, and published sets of tracts on the partition treaty, the union with Scotland, and many other subjects.

His *Shortest way with the Dissenters* (1702) placed him in the pillory.

Under Queen Anne pamphlets arrived at a remarkable degree of importance. Never before or since has this method of publication been used by such masters of thought and language. Political writing of any degree of authority was almost entirely confined to pamphlets. If the Whigs were able to command the services of Addison and Steele, the Tories fought with the terrible pen of Swift. Second in power if not in literary ability were Bolingbroke, Somers, Atterbury, Prior, and Pulteney. The Government viewed with a jealous eye the free use of this powerful instrument, and St John seized upon fourteen booksellers and publishers in one day for "libels" upon the administration (see *Annals of Queen Anne*, October 23, 1711). In 1712 a duty was laid upon newspapers and pamphlets, displeasing all parties, and soon falling into disuse. Bishop Hoadly's sermon on the kingdom of Christ (1717), holding that the clergy could claim no temporal jurisdiction, occasioned the Bangorian controversy, which produced seventy or eighty pamphlets. Soon after this period party-writing declined from its comparatively high standard and fell into meaner and venal hands. Under George III. Bute took Dr Shebbeare from Newgate in order to employ his pen. The court party received the support of a few able pamphlets, among which may be mentioned *The consideration of the German War* against the policy of Pitt, and *The prerogative droit de Roy* (1764) vindicating the prerogative. We must not forget that although Samuel Johnson was a pensioned scribe he has for an excuse that his political tracts are his worst performances. Edmund Burke, on the other hand, has produced in this form some of his most valued writings. The troubles in America and the union between Ireland and Great Britain are subjects which are abundantly illustrated in pamphlet literature.

Early in the present century the rise of the quarterly reviews threw open a new channel of publicity to those who had previously used pamphlets to spread their opinions, and later on the rapid growth of monthly magazines and weekly reviews afforded controversialists a much more certain and extensive circulation than they could ensure by an isolated publication. Although pamphlets are no longer the sole or most important factor of public opinion, the minor literature of great events is never likely to be entirely confined to periodicals. The following topics, which might be largely increased in number, have each been discussed by a multitude of pamphlets, most of which, however, are likely to have been hopeless aspirants for a more certain means of preservation:—the Bullion Question (1810), the Poor Laws (1828-34), *Tracts for the Times* and the ensuing controversy (1833-45), Dr Hampden (1836), the Canadian Revolt (1837-38), the Corn Laws (1841-48), Gorham Controversy (1849-50), Crimean War and Indian Mutiny (1854-59), Schleswig-Holstein (1863-64), Ireland (1868-69), the Franco-German War, with *Dame Europa's School* and its imitators (1870-71), Vaticanism, occasioned by Mr Gladstone's *Vatican Decrees* (1874), the Eastern Question (1877-80), and the Irish Land Laws (1880-82).

France.—The activity of the French press in putting forth small tracts in favour of the Reformed religion caused the Sorbonne in 1523 to petition the king to abolish the diabolical art of printing. Even one or two sheets of printed matter were found too cumbersome, and single leaves or placards were issued in such numbers that they were the subject of a special edict, September 23, 1553. An ordinance of February 1566 was specially directed against libellous pamphlets, and those who wrote, printed, or even possessed them. The rivalry between Francis I. and Charles V. gave rise to many political pamphlets, and under Francis II. the Guises were attacked by similar means. Fr. Hotman directed his *Epistre civile au tygre de France* against the Cardinal de Lorraine. The V. lois and

Henry III. in particular were severely handled in *Les Hermaphrodites* (c. 1605), which was followed by a long series of imitations. Between Francis I. and Charles IX. the general tone of the pamphlet-literature was grave, pedantic, and dogmatic, with few songs and an occasional political satire. From the latter period to the death of Henry IV. it became audacious, cruel, and dangerous, attended, however, with a considerable increase of political songs.

The *Satyre Ménippée* (1594), one of the most perfect models of the pamphlet in the language, did more harm to the League than all the victories of Henry IV. The pamphlets against the Jesuits were many and violent. Père Richeome defended the order in *Chasse du renard Pasquier* (1603), the latter person being their vigorous opponent Étienne Pasquier. On the death of the king the country was filled with appeals for revenge against the Jesuits for his murder; the best known of them was the *Anti-Colon* (1610), generally attributed to César de Plaix. During the regency of Mary de' Medici the pamphlet changed its severer form to a more facetious type. In spite of the danger of such proceeding under the uncompromising ministry of Richelieu, there was no lack of libels upon him, which were even in most instances printed in France. These largely increased during the Fronde, but it was Mazarin who was the subject of more of this literature than any other historical personage. It has been calculated that from the Parisian press alone there came sufficient *Mazarinades* to fill 150 quarto volumes each of 500 pages. Eight hundred were published during the siege of Paris (February 8 to March 11, 1649). A collection of satirical pieces, entitled *Tableau du gouvernement de Richelieu, Mazarin, Fouquet, et Colbert* (1693) extends to 432 pages. Pamphlets dealing with the amours of the king and his courtiers were in vogue in the time of Louis XIV., the most caustic of them being the *Carle Géographique de la Cour* (1668) of Bussy-Rabutin. The presses of Holland and the Low Countries teemed with tracts against Colbert, Le Tellier, Louvois, and Père Lachaise. The first of the ever-memorable *Provinciales* appeared on January 23, 1656, under the title of *Lettre de Louis de Montalte à un provincial de ses amis*, and the remaining eighteen came out at irregular intervals during the next fifteen months. They excited extraordinary attention throughout Europe. The Jesuit replies were feeble and ineffectual. John Law and the schemes of the bubble period caused much popular railery. During the long reign of Louis XV. the distinguished names of Voltaire, Rousseau, Montesquieu, Diderot, D'Alembert, D'Holbach, Helvétius, and Beaumarchais must be added to the list of writers in this class.

The preliminary struggle between the parliament and the crown gave rise to hundreds of pamphlets, which grew still more numerous as the Revolution approached. Linguet and Mirabeau began their appeals to the people. Camille Desmoulins came into notice as a publicist during the elections for the states-general; but perhaps the piece which caused the most sensation was the *Qu'est ce que le Tiers État* (1789) of the Abbé Sieyès. The *Domine salvum fac Regem* and *Pange lingua* (1789) were two royalist brochures of unsavory memory. The financial disorders of 1790 occasioned the *Effets des assignats sur le prix du pain* of Dupont de Nemours; Necker was attacked in the *Criminelle Neckerologie* of Marat; and the *Vrai miroir de la noblesse* dragged the titled names of France through the mire. The massacre of the Champ de Mars, the death of Mirabeau, and the flight of the king in 1791, the noyades of Lyons and the crime of Charlotte Corday in 1793, and the terrible winter of 1794 have each their respective pamphlet literature, more or less violent in tone. Under the consulate and the empire the only writers of note who ventured to seek this method of appealing to the world were Madame de Staël, B. Constant, and Chateaubriand. The royalist reaction in 1816 was the cause of the *Pétition* of Paul Louis Courier, the first of those brilliant productions of a master of the art. He gained the distinction of judicial procedure with his *Simple Discours* in 1821, and published in 1824 his last political work *Le pamphlet des pamphlets*, the most eloquent justification of the pamphlet ever penned. The *Mémoire à consulter* of Montlosier attacked the growing power of the Congrégation. The year 1827 saw an augmentation of severity in the press laws and the establishment of the censure. The opposition also increased in power and activity, but found its greatest support in the songs of Béranger and the journalism of Mignet, Thiers, and Carrel. M. de Comenin was the chief pamphleteer of the reign of Louis-Philippe. His *Oui et non* (1845), *Feu, feu* (1846), and *Livre des orateurs, par Timon*, were extremely successful. The events of 1848 gave birth to a number of pamphlets, chiefly pale copies of the more virile writings of the first revolution. Among the few men of power Louis Veuillot was the Père Duchesne of the clericals and Victor Hugo the Camille Desmoulins or Marat of the republicans. After 1852 there was no lack of venal apologies of the coup d'état. Within more recent times the second empire suffered from many bitter attacks, among which may be mentioned the *Lettre sur l'histoire de France* (1861) of the Duc d'Aumale, *Propos de Labiénus* (1865) of Rogeard, *Dialogue aux enfers* (1864) of Maurice Joly and Ferry's *Comptes fantastiques d'Haussmann* (1868).

Literature.—In the article *LITERATURES* will be found references to collections of pamphlets in public libraries. An excellent catalogue by W. Oldys of those in the Harleian Library is added to the 10th volume of the edition of the *Miscellany* by T. Park; and in the *Biblioteca volante di G. Cinelli*, 2d ed., 1734-47, 4 vols. 4to, may be seen a bibliography of pamphlet-literature, chiefly Italian and Latin, with notes. It is of course impossible to supply an account of all the volumes of collected pamphlets, but a few of the more representative in English may be mentioned. These are—*The Phenix*, 1707, 2 vols. 8vo; Morgan's *Phœnix Britannicus*, 1732, 4to; Bishop Edmund-Gibson's *Preservative against Popery*, 1738, 3 vols. folio, new ed., 1848-49, 18 vols. sm. 8vo, consisting chiefly of the anti-Catholic discourses of James II.'s time; *The Harleian Miscellany*, 1744-53, 8 vols. 4to, new ed. by T. Park, 1808-13, 10 vols. 4to, containing 600 to 700 pieces illustrative of English history, from the library of Edward Harley, earl of Oxford; *Collection of scarce and valuable tracts* [known as *Lord Somers' Tracts*], 1748-52, 16 parts 4to, 2d ed. by Sir W. Scott, 1809-15, 13 vols. 4to, also full of matter for English history; and *The Pamphleteer*, 1813-23, 29 vols. 8vo, containing the best pamphlets of the day.

For the derivation of the word pamphlet consult Skeat's *Etymologiae Dict.*; Pegge's *Anonymiana*; *Notes and Queries*, 3d series, iv. 315, 379, 462, 482, v. 167, 290; 6th series, ii. 156. The general history of the subject may be traced in M. Davies, *Icon libellorum*, 1715; W. Oldys, "History of the Origin of Pamphlets," in Morgan's *Phœnix Brit.*; and Nichols's *Lit. Anecdotes*; Dr Johnson's Introduction to the *Harleian Miscellany*; D'Israeli, *Aménities of Literature*; *Revue des Deux Mondes*, April 1, 1846; *Irish Q. Review*, vii. 267; *Edinb. Rev.*, Oct. 1855; Huth's *Ancient Ballads and Broad-sides* (Philobiblion Soc.); Maskell, *Martin-Margaretta Controversy*; T. Jones, *Cat. of collection of tracts for and against Popery—the whole of Peck's lists and his references* (Chetham Soc., 1855-65); Blakey's *Hist. of Political Literature*; Andrews, *Hist. of British Journalism*; Larousse, *Grand Dict. Universel*; Nodder, *Sur la liberté de la presse*; Leber, *De l'état réel de la presse*; Moreau, *Bibliographie des Mazarinades*; *Bulletin du Bibliophile Beige*, 1859-62; Nisard, *Hist. des livres populaires*. (H. R. T.)

PAMPHYLIA, in ancient geography, was the name given to a region in the south of Asia Minor, between Lycia and Cilicia, extending from the Mediterranean to Mount Taurus. It was bounded on the N. by Pisidia, a rugged mountain tract, while Pamphylia occupied only the district between this and the sea. It was therefore a country of small extent, having a coast-line of only about 75 miles with a breadth of about 30. There can be little doubt that the Pamphylians and Pisidians were really the same people, though the former had received colonies from Greece and other lands, and from this cause, combined with the greater fertility of their territory, had attained a higher degree of civilization and more refinement than their neighbours of the interior. But the distinction between the two seems to have been established at an early period. Herodotus, who does not mention the Pisidians at all, enumerates the Pamphylians among the nations of Asia Minor, while Ephorus mentions them both, correctly including the one among the nations on the coast, the other among those of the interior. Strabo distinctly describes the position of Pamphylia as given above, and assigns as its limits the pass of Mount Climax on the west, and the fortress of Coracesium, which belonged to Cilicia, on the east. Under the Roman administration the term Pamphylia was extended so as to include Pisidia and the whole tract up to the frontiers of Phrygia and Lycaonia, and in this wider sense it is employed by Ptolemy.

Pamphylia is in one respect a country of peculiar character: although it consists almost entirely of a plain extending from the slopes of Mount Taurus to the sea, this plain, though presenting an unbroken level to the eye, does not consist, as in most similar cases, of alluvial deposits, but is formed almost wholly of travertine. "The rivers pouring out of the caverns at the base of the Lycian and Pisidian ranges of the Taurus come forth from their subterranean courses charged with carbonate of lime, and are continually adding to the Pamphylian plain. They build up natural aqueducts of limestone, and after flowing for a time on these elevated beds burst their walls and take a new course. Consequently it is very difficult to reconcile the accounts of this district, as transmitted by ancient authors, with its present aspect, and the distribution of the streams which water it. By the sea-side the travertine forms cliffs from 20 to 80 feet high" (Forbes's *Lycia*, vol. ii. p. 188). Strabo describes a river which he terms Catarractes as a large stream falling with a great noise over a lofty cliff, but for the reason above given it cannot now be identified with certainty. He places it between Olbia and Attalia, where there is now no river of

any importance. East of the latter city is the Cestrus, and beyond that again the Eurymedon, both of which are considerable streams, navigable for some distance from the sea. Near the mouth of the latter is a lake called Caprias, mentioned by Strabo, but it is a mere salt marsh.

The chief towns on the coast are—Olbia, the first town in Pamphylia, near the Lycian frontier; Attalia, founded by Attalus II., king of Pergamus, which still retains the name of Adalia, and is the principal port in this part of Asia Minor, and Side, about 15 miles east of the Eurymedon. On a hill above that river, some distance inland, stood Aspendus, and in a similar position above the river Cestrus was Perga, celebrated for its temple of Artemis. Between the two rivers, but somewhat farther inland, stood Sylleum, a strong fortress, which even ventured to defy the arms of Alexander. None of these towns are historically known to have been Greek colonies, but the foundation of Aspendus was traditionally ascribed to the Argives, and Side was said to be a colony from Cyme in Æolis. But it is certain that the inhabitants, even of these towns, retained little of a Hellenic character and spoke a semi-barbarous dialect. The legend related by Herodotus and Strabo, which ascribed the origin of the Pamphylians to a colony led into their country by Amphiloehus and Calchas after the Trojan War, is merely one of those mythical fictions current among the Greeks with regard to so many non-Hellenic races. The coins of Aspendus, though of Greek character, present us with legends in a barbarous dialect.

The Pamphylians never appear in history as an independent people. They are first mentioned among the nations subdued by the kings of Lydia, and afterwards passed in succession under the dominion of the Persian and Macedonian monarchs. After the defeat of Antiochus III. in 190 B.C., they were included among the provinces annexed by the Romans to the dominions of Eumenes, king of Pergamum; but at a somewhat later period they joined with their neighbours the Pisidians and Cilicians in their piratical ravages, and their port of Side became the chief centre of the naval power of these freebooters, and the place where the captives were sold as slaves. Pamphylia was for a short time included in the dominions of Amyntas, king of Galatia, but after the death of that monarch lapsed into the ordinary condition of a Roman province, and its name is not again mentioned in history.

PAMPLONA (Pampeluna, Fr. Pampelune), a city of Spain, capital of the province of Navarre, and an episcopal see, is situated 1378 feet above sea-level, on the left bank of the Agra, a tributary of the Ebro, on a height commanding a wide view of the hill-encircled plain known as the "cuenca" or "bowl" of Pamplona. It is a station on the Ebro railway connecting Alsasua with Saragossa. The climate in general is cold and moist, but owing to the purity of the air and the excellence of its drainage the town is not unhealthy. From its position Pamplona has always been the principal fortress of Navarre. The fortifications form a rectangle of which the north-east and north-west sides face the river (here crossed by several bridges), while on the south-west side stands the citadel, which owes its present construction to Philip II., who modelled it on that of Antwerp. It is a pentagon, separated from the city by an esplanade, and is calculated to accommodate 7500 men. The streets of the town are regular and broad; there are three "plazas," the principal of which, containing the Casa de la Diputación and the theatre, is sometimes on festive occasions turned into a bull-ring. The cathedral is a late Gothic structure begun in 1397 by Charles III. (El Noble) of Navarre, who is buried within its walls; of the previous structure raised by Don Sancho about 1123 only a small

portion of the cloisters remains. The interior, which is fine, is remarkable for the peculiar structure of its apse; the wood carvings of the choir, in English oak, by Miguel Ancheta, a native artist, are excellent. The principal façade is Corinthian, from designs of Ventura Rodríguez (1783). The same architect designed the superb aqueduct by which the city is supplied with water from Monte Francoa, some nine miles off. The beautiful cloisters on the south side of the cathedral, and the chapter-house beyond them, as well as the old churches of San Saturnino (Gothic) and San Nicolas (Romanesque), are also of interest to the student of architecture. Among other places of public resort in Pamplona may be mentioned the bull-ring, capable of accommodating 8000 spectators, and the tennis court (El Trinquete). The town has a well-equipped secondary school, two normal and numerous primary schools, as well as an academy of design; and there are three hospitals. Of the public gardens and walks the finest is La Taconera. The surrounding district is fertile, producing wine as well as grain and other seeds; the manufactures are comparatively unimportant, the chief being that of linen. The yearly fair in connexion with the feast of San Fermin (July 7), the patron saint of the city, attracts a large concourse from all parts of the country. Population of ayuntamiento in 1877, 25,630.

Originally a town of the Vascones, Pamplona was rebuilt in 68 A.D. by Pompey the Great, whence the name Pampelo or Pompele (Strabo). It was captured by Euric the Goth in 466 and by the Franks under Childebert in 542; it was dismantled by Charlemagne in 778, but repulsed the emir of Saragossa in 907. In the 14th century it was greatly strengthened and beautified by Charles III., who built a citadel on the site now occupied by the Plaza de Toros and by the Basilica de S. Ignacio, the church marking the spot where Ignatius Loyola received his wound in defending the place against André de Foix in 1521. From 1808 it was occupied by the French until taken by Wellington in 1813. In the Carlist war of 1836-40 it was held by the Cristinos, and in 1875-76 it was more than once attacked, but never taken, by the Carlists.

PAN, a Greek god worshipped chiefly in Arcadia, among whose mountains he had numerous sanctuaries and holy caves. While he is a very common figure in poetry and art, it is exceedingly difficult to gain any clear idea of his actual worship in his Arcadian home. He appears to have been worshipped on the mountain tops as well as in caves; he was the herdsman's god, and the giver of fertility to flocks; he was a god of prophetic inspiration and of dreams, in which he sometimes revealed the cure of diseases; he was himself a huntsman and the god of hunters, and Arcadian sportsmen beat his image if they returned empty-handed from the chase; even fishermen invoked him for aid in their occupation; he guided travellers (as ἐνόςδιος and πομπᾶτος) on the pathless mountains, and even smoothed the rough sea by the sound of his flute; he was the god of music, of dance, and of song, Echo and Syrinx were the objects of his love, and he sported and danced with the mountain Nymphs. The nineteenth Homeric Hymn gives a most poetic account of his birth from the union of Hermes and the daughter of Dryops, and of his life among the Arcadian mountains and springs. His power of inspiration and prophecy shows that there was an orgiastic, enthusiastic side of his worship, which made it easy for Pindar to connect him with the worship of Cybele, and for others to identify him with Marsyas. His voice inspires terror, and he produced sudden panics among men. The Athenian herald Phidippides heard his voice by the way promising victory at Marathon; the Athenians attributed their triumph to his aid, and to the panic he inspired among the Persians, and consecrated to him a cave in the north side of the Acropolis. He had a temple and oracle near Acacesium, in which a fire burned continually. The analogy of his nature with Dionysus led to his assimilation with the Satyrs, and he is

often pictured among the Bacchic Thiasus. It was only a step further to speak of many Pans, male and female, and of infant Panisci. In the mystic eclecticism of Orphic religion, Pan was conceived as the universal god in a pantheistic fashion. His mother is variously called Cœnoe, or Callisto, or Penelope; his father is Zeus, or Hermes, or Apollo, or Odysseus, or the suitors generally. He was represented as a half-human half-brute figure, with the legs and horns of a goat and a face whose features resembled those of an animal. According to the Homeric Hymn, his mother was terrified when he was born with his hideous figure and long goat's beard. The story, alluded to by Milton, Mrs Browning, and the modern poets, of the pilot Thamus, who, sailing near Paxos in the time of Iphigeneia, was commanded by a mighty voice to proclaim that "Pan is dead" is first found in Plutarch (*De Orac. Defectu*, 699).

PANÆTIUS, a Stoic philosopher, lived about 185–112 B.C. He belonged to a Rhodian family, but was probably educated partly in Pergamum and afterwards in Athens. About 156 B.C. he came from Athens to Rome, where he became a friend of Lælius and of Scipio the younger. He lived as a guest in the house of Scipio, and accompanied him in his final campaign against Carthage and in his expedition to Egypt and Asia, 143 B.C. He had an important influence in the introduction of Greek philosophy into Rome, and taught a number of distinguished Romans. He returned to Athens, probably after the murder of Scipio in 129 B.C., and succeeded Antipater as head of the Stoic school. The right of citizenship was offered him by the Athenians, but not accepted. In his teaching he laid most stress on ethics; and his most important works, of which only insignificant fragments are preserved, were on this subject. He wrote (apparently during his Roman visit) a treatise on virtue, *περὶ τοῦ καθῆκοντος*, in three books, upon which Cicero has chiefly founded his work *De Officiis*. Works *περὶ προνοίας*, *περὶ εὐθυμίας*, &c., were also composed by Panætius.

PANAMÁ, a state and city of Colombia, in the extreme north of South America. The city, which is the capital of the state and the seat of a bishop, is situated on the coast of the Pacific at the head of the Gulf of Panamá, a few miles east of the mouth of the Rio Grande, occupying partly a tongue of coral and basaltic rock and partly a gentle rise towards Mount Ancon, an eminence 560 feet in height. The cathedral stands in 8° 57' 16" N. lat. and 79° 30' 50" W. long. In the 16th and 17th centuries Panamá was, next to Cartagena, the strongest fortress in South America; but its massive granite ramparts, constructed by Alfonso Mercado de Villacorta (1673), in some places 40 feet high and 60 feet broad, have been razed on the land side (where they separated the city proper from the suburbs of Santa Ana, Pueblo Nuevo, and Arrabal) and allowed to fall into a ruinous condition towards the sea. Of the old Spanish houses constructed in the Moorish fashion comparatively few remain; but three-story buildings, in which the two upper stories project, are sufficiently common to give a distinctive character to the city, which thus differs from the other towns of Central America. Ruins of churches and convents occupy a large area, those of the Jesuit college being the most imposing, and those of the Franciscan monastery (on the north-west sea wall) the most extensive. The cathedral, built in 1760, is a spacious edifice in the so-called Jesuit style, and its two lateral towers are the loftiest in Central America. It was restored in 1873–76, but the façade was destroyed and columns thrown down by the earthquake of September 7, 1882. The church of Santa Ana, in the suburb of that name, is of interest as the rallying point of the insurgents in the local revolutions: the high ground on which it

stands commands the city, and was long kept carefully free of all buildings. The president's residence, the governor's office, the state assembly house, the hospital in the old convent of the Conception, and the grand hotel (now the head offices of the canal company) in the principal square are the buildings now of most note. Besides the episcopal seminary there exist a sisters-of-charity school and a ladies' college, with teachers from the United States and Canada. In the rainy season streams of water flow down the streets, but in the dry season the city is dependent on water brought in carts from the Matasnillo, a distance of several miles, the only perennial wells which it possessed having been dried up by the earthquake of 8th March 1883. By 1885, however, water-works introducing the

Railway and Canal from Panamá to Colon.

water of the Rio Grande at a cost of £50,000 are to be completed. Rents are high, and living is expensive. As Panamá, like Colon, is a free port, statistics of trade are not collected. The local exports are india-rubber (growing scarcer), gold-dust, hides, ivory nuts, manganese, shells, tobacco, cocobolo (a cabinet wood), tortoise-shell, vanilla, whale oil, sarsaparilla, and cocoa-nuts. The Panamá pearl fishery is still prosecuted with success. The passengers across the isthmus were 35,076 in 1868, 22,941 in 1876, 52,113 in 1881, and 75,703 in 1882. In 1870 the population of Panamá (of very varied origin) was 18,378; by 1880 it was 25,000, of whom about 5000 were strangers.

Panamá (an Indian word meaning abounding in fish) was founded in 1518 by Pedro Arias Davila, and is thus the oldest European city in America, the older settlement at Santa Maria el Antigua near the Atrato having been abandoned and leaving no trace. Originally it was situated six or seven miles farther north on the left side of the Rio Algarrobo; but the former city, which was the great emporium for the gold and silver from Peru, and "had eight monasteries, a cathedral, and two churches, a fine hospital, 200 richly furnished houses, nearly 5000 houses of a humbler sort, a Genoese chamber of commerce, and 200 warehouses, was after three weeks of rapine and murder burned, February 24, 1671, by Morgan's buccaneers, who carried off 175 laden mules and more than 600 prisoners" (see *Travels of Pedro de Cieza de Leon*, Hakluyt Soc., 1864). A new city was founded on the present site by Villacorta in 1673.

The Isthmus and State.—By the Isthmus of Panamá is sometimes understood the whole neck of land between the continents of North and South America; more generally the name is restricted to the narrow crossing from Panamá to Colon, the two other narrowest crossings being distinguished as the Isthmus of San Blas (31 miles) and the Isthmus of Darien (46 miles). Nearly the whole isthmus, in the wider sense of the word, constitutes (since 1855) a state of the Confederation of Colombia, extending from the frontiers of Costa Rica to those of the state of Cauca. Besides Panamá the capital and Colon (Aspinwall), it contains Santiago, formerly chief town of a province and an apanage of the family of Columbus, Penonomé (about 15,000 inhabitants), Los Santos, formerly chief town of a province, Nata, and David. It is divided into six departments—Coclé, Colon, Chiriqui, Los Santos, Panamá, Veragua. The total population in 1870 was 221,052.

Railway and Canal.—It is the Isthmus of Panamá in the narrower sense which is crossed both by the interoceanic railway and by the line of the interoceanic ship-canal at present in course of construction. It affords a much shorter route than that of Darien, and while the central Cordillera does not sink lower than 980 feet in the Isthmus of San Blas, at the Culebra Col it is rather less than 290 feet high. As the watershed runs much nearer the south than the north side of the isthmus, the streams flowing to the Pacific are of comparatively little importance, while the Chagres on the Atlantic slope, with its tributary the Rio Obispo, forms a navigable river whose volume attains formidable dimensions at certain seasons. The railway (a single line) starting from Colon (on the swamp-island of Manzanillo on Limon Bay) reaches the valley of the Chagres at Gatun, runs along its northern flanks to Barbacoas, crosses the river by a large bridge, continues along the southern flank and up the tributary Obispo to the Culebra Col, from which it descends straight to Panamá. The ship-canal is to follow very much the same route; only it will keep closer to the bed of the Chagres, which it is to cross again and again, and on the Pacific slope it will descend the valley of the Rio Grande and be continued seaward to the island of Perico. The total length is 54 miles. Throughout the whole distance the bottom is to lie 8½ metres (nearly 28 feet) below the mean level of the oceans, and the width is to be 22 metres (72 feet) at bottom and 50 metres (160 feet) at top, except in the section through the Culebra ridge, where the depth is to be 9 metres, the bottom width 24, and the top width 28. The two great difficulties connected with the undertaking are those caused by the mountain and the river. As the idea of tunnelling the col has been abandoned, it will be necessary to cut down through the solid strata for a depth of 300 to 350 feet over a considerable distance; the rock happily is of a comparatively soft schistous character, disposed almost horizontally. The Chagres has an average discharge at Matachin of 100 cubic metres per second, which at low water may sink to 15 or 20 cubic metres, and during flood rise to 500 or 600. At Gamboa, which lies just above the influx of the Rio Obispo, it is proposed to construct an enormous reservoir by throwing a dam across the valley. From Cerro Obispo on the one side to Cerro Santa Cruz on the other this dam will be 960 metres long at the base and 1960 metres at the top, with a width at the bottom of 1000 metres and a height of 45 metres. It will thus be the largest dyke yet constructed in the world. Altogether it is calculated that the excavation of the canal involves the removal of 3531 millions of cubic feet of earth; by January 31, 1884, the actual quantity removed was 118,448,595 cubic feet, or only about one-thirtieth of the whole. All along the route, however, at Buhio Soldado, Tabernilla, San Pablo,

Mamei, &c., workshops and settlements have been formed, and by 1883 11,000 men were at work. At certain states of the tide the levels of the two oceans differ materially: while at Colon the difference between high and low water is not more than 23 inches, at Panamá it is generally 13 feet, and at times even upwards of 19½ feet. The current thus produced in the canal would be sufficient to stop navigation for a number of hours at each tide; and to obviate this difficulty it will be necessary either to construct locks at the Panamá extremity or to slope the canal from Colon to Panamá.

A proposal to pierce the Isthmus of Darien was made as early as 1520 by Angel Saavedra; Cortez caused the Isthmus of Tehuantepec to be surveyed for the construction of a canal; and in 1550 Antonio Galvão suggested four different routes for such a scheme, one of them being across the Isthmus of Panamá. In 1814 the Spanish cortes ordered the viceroy of New Spain to undertake the piercing of the Isthmus of Tehuantepec; but the War of Independence intervened, and, though a survey was made by General Obegoso in 1821, and José de Garmy obtained a concession for a canal in 1842, nothing was accomplished. Bolívar, president of Colombia, caused Messrs Lloyd and Palmare to study the Isthmus of Panamá. Lloyd, whose paper was published in the *Philosophical Transactions*, London, 1830, proposed to make only a railway from Panamá or Chorrera to the Rio Trinidad (tributary of the Chagres), and to establish a port on the Bay of Limon. M. Napoleon Garella, sent out by the French Government in 1843, advocated the construction of a sluiced canal. An American company, stimulated by the sudden increase of traffic across the isthmus caused by the discovery of gold in California, commenced in 1849 to construct a railway, and their engineers, Totten and Trautwine, already known in connexion with the canal from Cartagena to the Magdalena, managed, in spite of the extreme difficulty of procuring labour, to complete the works in January 1855. Meanwhile the question of an interoceanic canal was not lost sight of; and in 1875 it came up for discussion in the *Congrès des Sciences Géographiques* at Paris. A society under General Turr was formed for prosecuting the necessary explorations; and Lieutenant Wyse, assisted by Celler, A. Reclus, Bixio, &c., was sent out to the isthmus in 1876. In 1878 the Colombian Government granted the society known as the Civil International Interoceanic Canal Society the exclusive privilege of constructing a canal between the two oceans through the Colombian territory; and at the same time the ports and canal were neutralized. In 1879 M. de Lesseps took the matter up, and the first meeting of his company was held in 1881. The capital necessary for the "Company of the Interoceanic Canal of Panamá," as it is called, was stated at 600,000,000 francs,—the estimated cost of excavation being 430,000,000, that of weirs and trenches to take fresh water to the sea 46,000,000, and that of a dock and tide-gates on the Pacific side 36,000,000. The Panamá canal was bought for \$20,000,000. The contractors, Couvreur & Hersent, began operations in October of the same year. Meanwhile the United States Government proposed to make a treaty with Colombia by which it would be free to establish forts, arsenals, and naval stations on the Isthmus of Panamá, though no forces were to be maintained during peace; but the British Government objected to any such arrangement.

Details in regard to engineering and finance will be found in the *Bulletin du Canal Océanique*, issued since 1879, and in *Engineering*, 1883 and 1884. See also Reclus's "Explorations" in *Tour du Monde*, 1880, for an interesting series of views.

PANATHENÆA, the most splendid and brilliant of all the Athenian festivals, with perhaps the exception of the Great Dionysia. The mythic foundation is ascribed to Erechtheus; and Pausanias declares that the Olympia, the Lycea, and the Panathenæa were the three oldest feasts in Greece. It was originally a religious celebration in honour of the patron goddess of the city, celebrated by her own worshippers. It is said that when Theseus united the whole land under one government he made this festival of the city-goddess common to the entire country, and the older name Athenæa was then changed to Panathenæa. In addition to the religious rites there is said to have been a chariot race from the earliest time; Erechtheus himself won the prize in the race. The Panathenæa were modified and rendered far more magnificent by Pisistratus and his sons. It is probable that the distinction of Greater and Lesser Panathenæa dates from this period. Every fourth year the festival was celebrated with peculiar magnificence; gymnastic sports were added to the horse races; and there is little doubt that Pisistratus aimed at

making the penteteric Panathenæa the great Ionian festival in rivalry to the Dorian Olympia. The penteteric festival was celebrated in the third year of each Olympiad. The annual festival consisted solely of the sacrifices and rites proper to this season in the cultus of the goddess. One of these rites originally consisted in carrying a new peplos to the temple to serve as the clothing of the image, a ceremonial known in other cities and represented by the writer of the *Iliad* (vi.) as being in use at Troy; but it is probable that this rite was afterwards restricted to the great penteteric festival. Even the religious rites were celebrated with much greater splendour at the Greater Panathenæa. The whole empire shared in the great sacrifice; every colony and every subject state sent a deputation and sacrificial animals. On the great day of the feast there was a procession of the priests, the sacrificial assistants of every kind, the representatives of every part of the empire with their victims, the cavalry, in short of the population of Attica and great part of its dependencies. The peplos was borne in the procession and presented to the goddess, and the hecatomb was sacrificed. At least as early as the 3d century before Christ the custom was introduced of spreading the peplos like a sail on the mast of a ship, which was rolled on a machine in the procession. The subject of the frieze of the Parthenon is an idealized treatment of this great procession.

The festival which had been beautified by Pisistratus was made still more imposing, under the rule of Pericles. He introduced a regular musical contest in place of the old recitations of the rhapsodes, which were an old standing accompaniment of the festival. The order of the *agones* from this time onwards was—first the musical, then the gymnastic, then the equestrian contest. Many kinds of contest, such as the chariot race of the *apobatai*, which were not in use at Olympia, were practised in Athens. The season of the festival was the last days of Hecatombeon, and the great day was the 28th, third from the end of the month (*τρίτη φθίνοντος*, called by Euripides *φθινὰς ἀμέρα*). The prize in the games was an amphora full of olive oil produced from the holy olives, the property and gift of the goddess herself. Only one Panathenæic amphora has been found in Attica itself; and, though many have been discovered outside of Attica, especially in Cyrene, it has been maintained that the latter are not really prizes in the games, but imitations made in the export trade as a sort of mark that the oil sold in them was of the very finest quality.

PANAY. See PHILIPPINE ISLANDS.

PANCH MAHÁLS, a district in the east of Guzerat, Bombay presidency, India, lying between 22° 30' and 23° 10' N. lat., and between 73° 35' and 74° 10' E. long., with an area of 1613 square miles. The south-western portion is for the most part a level plain of rich soil; while the northern, although it comprises some fertile valleys, is generally rugged, undulating, and barren, with but little cultivation. The mineral products comprise limestone, sandstone, trap, quartz, basalt, granite, and other varieties of building stone. Only recently has any attempt been made to conserve the extensive forest tracts, and consequently but little timber of any size is now to be found.

The census of 1881 returned the population at 255,479 (131,162 males and 124,317 females); the Hindus numbered 159,624; Mohammedans, 16,060; Parsis, 30; and Christians, 44. Of the total population 30 per cent. belong to aboriginal tribes, the majority being Bhils. Of 350,996 acres—the total area of Government cultivable land—202,493 acres were taken up for cultivation in 1881–82. Of 153,262 acres under actual cultivation (41,823 acres being twice cropped), grain crops occupied 127,032 acres; pulses, 42,444; and oil-seeds, 22,238.

PANC SOVA, a town of Hungary, near the Servian frontier, is situated on the river Temes, just above its

junction with the Danube, which it reaches 9 miles above Belgrade. The town contains Roman Catholic, Protestant, and Greek churches, a convent, and manufactories of starch and beetroot sugar. Cotton and mulberries (for feeding silkworms) are cultivated, and a brisk trade in live stock and grain is carried on with Turkey. The hog fairs are largely attended. In 1880 Pancsova contained 17,127 inhabitants, partly Serbs and partly Germans. It was burned by the retreating Austrians in 1788, and was again occupied by Austrian troops in 1849, after they had defeated the Hungarians in the vicinity.

PANDARUS, son of Lycaon, led the people of Zeleia in the Troad as allies of the Trojans against the Greeks. In other passages his country is named Lycia. It is frequently said that the Lycians of the *Iliad* are a tribe of the Troad, different from the people of the country Lycia; but it is more probable that the conflicting accounts belong to different strata in the Homeric poetry. Pandarus was worshipped as a hero at Pinara in Lycia. Lycaon, the name of Pandarus's father, is merely an epithet of Apollo, the great god of Lycia. Pandarus is not an important figure in the *Iliad*. He breaks the truce between the Trojans and the Greeks by treacherously wounding Menelaus with an arrow, and finally he is slain by Diomedes. In mediæval romance he became a prominent figure in the tale of Troilus and Cressida. He encouraged the amour between the Trojan prince and his niece Cressida; and his name has passed into modern language as the common title of a lovers' go-between in the worst sense.

PANDECTS. See JUSTINIAN and ROMAN LAW.

PANDERPUR, or PANDHARPUR, a town in Sholapur district, Bombay, India, situated on the right bank of the Bhima river, in 17° 40' 40" N. lat. and 75° 22' 40" E. long., with a population in 1881 of 16,910. It is held in great reverence by the Bráhmans for its celebrated temple dedicated to Vithoba, an incarnation of Vishnu. Three large annual religious fairs are held.

PANDORA. See PROMETHEUS.

PANDUA, or PARRUAH. See GAUR, vol. x. p. 115.

PANGOLIN. In Africa, India, and Malaya are found certain curious Mammals known to the Malays as Pangolins, to the English as Scaly Anteaters, and to naturalists by the scientific name of *Manis*. These animals, which, by a superficial observer, might be taken for reptiles rather than mammals, belong to the order *Edentata*, otherwise almost wholly confined to the New World, and containing, besides the Pangolins, the Sloths, Anteaters, Armadillos, and Aard Varks.

In size pangolins range from 1 to 3 feet in length, exclusive of the tail, which varies from much shorter than to nearly twice the length of the rest of the animal; their legs are short, so that the body is only a few inches off the ground; their ears are very small; and their tongue is long and worm-like, and is used to catch ants with. Their most striking character, however, is their wonderful external coat of mail, composed of numerous broad overlapping horny scales, which cover the whole animal, with the exception of the under surface of the body, and, in most species, of the lower part of the tip of the tail. Besides the scales there are generally, especially in the Indian species, a certain number of isolated hairs, which grow up between the scales, and are also scattered over the soft and flexible skin of the belly. There are five toes on each foot, the claws on the pollex and hallux rudimentary, but the others, especially the third of the fore-foot, long, curved, and laterally compressed. In walking the fore claws are turned backwards and inwards, so that the weight of the animal rests on their back and outer surfaces, and their points are thus kept from becoming blunted.

Their skulls are long, smooth, and rounded, with imperfect zygomatic arches, no teeth of any sort, and, as in other ant-eating mammals, with the bony palate extending unusually far backwards towards the throat. The lower jaw consists of a pair of thin styli-form bones ankylosed to each other at the chin, and rather loosely attached to the skull by a joint which, instead of being horizontal, is tilted up at an angle of 45°, the outwardly-twisted condyles articulating with the inner surfaces of the long glenoid processes, an arrangement quite unique among mammals, the sloths alone showing a slight tendency towards it. The other skeletal and anatomical characters have already been sufficiently described under MAMMALIA (vol. xv. p. 388).

The single genus *Manis*, which contains all the pangolins, may be conveniently divided into two groups, distinguished both by their geographical distribution and by certain convenient, though not highly important, external characters. (1) The Asiatic pangolins are characterized by having the central series of body-scales continued quite to the extreme end of the tail, by having many isolated hairs growing up between the scales of the back, and by their small external ears. They all have a

White-bellied Pangolin (*Manis tricuspis*).

small naked spot beneath the tip of the tail, which is said to be of service as an organ of touch. There are three species, viz., *Manis javanica*, ranging from Burmah, through Malacca and Java, to Borneo; *M. aurita*, found in China, Formosa, and Nepal; and the common Indian Pangolin, *M. pentadactyla*, distributed over the whole of India and Ceylon. (2) The African species have the central series of scales suddenly interrupted and breaking into two at a point about 2 or 3 inches from the tip of the tail; they have no hair between the scales, and no external ear-conch. The following are the four species belonging to this group:—the Long-tailed Pangolin (*M. macrura*), which has a tail nearly twice as long as its body, and containing as many as forty-six caudal vertebrae, nearly the largest number known among Mammals; the White-bellied Pangolin (*M. tricuspis*), closely allied to the last, but with longer and tricuspid scales, and white belly hairs (these two, like the Indian species, have a naked spot beneath the tail tip, a character probably correlated with the power of climbing, and they are, moreover, peculiar in having the outer sides of their fore legs clothed with hair, all the other species being scaly there as elsewhere); and the Short-tailed and the Giant Pangolins (*M. temminckii* and

gigantea), both of which have their tails covered entirely with scales, and evidently never take to arboreal habits. All the four species of the second group are found in the West African region, one only, *M. temminckii*, extending besides into south and eastern equatorial Africa. The following account of the habits of *Manis tricuspis* is taken from Mr Louis Fraser's *Zoologia Typica*:—

"During my short residence at Fernando Po I succeeded in procuring two living specimens of this animal. The individuals, judging from the bones, were evidently not adult; the largest measured 30 inches in length, of which the head and body were 12 inches and the tail 18 inches. I kept them alive for about a week at Fernando Po, and allowed them the range of a room, where they fed upon a small black ant, which is very abundant and troublesome in the houses and elsewhere. Even when first procured they displayed little or no fear, but continued to climb about the room without noticing my occasional entrance. They would climb up the somewhat roughly-hewn square posts which supported the building with great facility, and upon reaching the ceiling would return head foremost; sometimes they would roll themselves up into a ball and throw themselves down, and apparently without experiencing any inconvenience from the fall, which was in a measure broken upon reaching the ground by the semi-yielding scales, which were thrown into an erect position by the curve of the body of the animal. In climbing, the tail, with its strongly-pointed scales beneath, was used to assist the feet; and the grasp of the hind feet, assisted by the tail, was so powerful that the animal would throw the body back (when on the post) into a horizontal position, and sway itself to and fro, apparently taking pleasure in this kind of exercise. It always slept with the body rolled up; and when in this position in a corner of the building, owing to the position and strength of the scales, and the power of the limbs combined, I found it impossible to remove the animal against its will, the points of the scales being inserted into every little notch and hollow of the surrounding objects. The eyes are very dark hazel, and very prominent. The colonial name for this species of *Manis* is 'Attadillo,' and it is called by the Boobies, the natives of the island, 'Gahlah.' The flesh is said to be exceedingly good eating, and is in great request among the natives." (O. T.)

PANIPAT, a decayed historical town in Karnál district, Punjab, India, situated on the Grand Trunk Road, 53 miles north of Delhi, in 29° 23' N. lat. and 77° 1' 10" E. long. The town is of great antiquity, dating back to the great war of the *Mahábhārata* between the Pándavas and Kaurava brethren, when it formed one of the tracts demanded by Yudishthira from Duryodhana as the price of peace. In modern times, the plains of Panipat are celebrated as having thrice formed the scene of decisive battles which sealed the fate of upper India,—in 1526, when Bábar on his invasion of India with his small but veteran army completely defeated the imperial forces; in 1556, when his grandson, Akbar, on the same battlefield, conquered Hemu, the Hindu general of the Afghán Sher Sháh, thus a second time establishing the Mughal power; and finally, on 7th January 1761, when Ahmad Sháh Duráni decisively shattered the unity of the Mahratta power. The modern town stands near the old bank of the Junna, upon high ground composed of the debris of earlier buildings. The population in 1881 numbered 25,022, including 16,917 Mohammedans. Although there are many brick-built houses and some well-paved streets in the centre of the town, the outskirts are low and squalid, and the general aspect of the whole town miserable and poverty-stricken.

PANIZZl. SIR ANTHONY (1797–1879), principal librarian of the British Museum, was born at Brescello in the duchy of Modena, September 16, 1797. After taking his degree at the university of Parma, he became an advocate, and speedily obtained considerable practice. Always a fervent patriot, he was almost of necessity implicated in the movement set on foot in 1821 to overturn the miserable Government of his native duchy, and in October of that year barely escaped arrest by a precipitate flight. He first established himself at Lugano, where he published an anonymous and now excessively rare pamphlet

generally known as *I Processi di Rubiera*, an exposure of the monstrous injustice and illegalities of the Modenese Government's proceedings against suspected persons. Expelled from Switzerland at the joint instance of Austria, France, and Sardinia, he repaired to England, where he arrived in May 1823, in a state bordering upon destitution. His countryman Foscolo provided him with introductions to Roscoe and Dr Shepherd, and by their aid he was enabled to earn a subsistence in Liverpool by giving Italian lessons, while diligently instructing himself in English. Roscoe further introduced him to Brougham, by whose influence he was called to London to assume the professorship of Italian in University College, upon the foundation of that institution in 1828. His chair was almost a sinecure; but his manners, his culture, and his abilities rapidly ingratiated him with the best London society; and in 1831 Brougham, having become lord chancellor, used his *ex officio* position as a principal trustee of the British Museum to obtain for Panizzi the post of an extra assistant librarian of the printed book department. At the same time he was actively prosecuting the most important of his purely-literary labours, his edition of Boiardo's *Orlando Innamorato*. Boiardo's fame had been eclipsed for three centuries by the adaptation of Berni; and it is highly to the honour of Panizzi's taste to have redeemed him from oblivion, and restored to Italy one of the very best of her narrative poets. His edition of the *Orlando Innamorato* and the *Orlando Furioso* was published between 1830 and 1834, prefaced by a valuable essay on the influence of Celtic legends on mediæval romance, and dedicated to his benefactor Roscoe. In 1835 he edited Boiardo's minor poems, and was about the same time engaged in preparing a catalogue of the library of the Royal Society, which led to a warm controversy. Panizzi was shortly to find library work of a much more important and agreeable description in the institution with which he was officially connected. The unsatisfactory condition and illiberal management of the British Museum had long excited discontent, and at length a trivial circumstance led to the appointment of a parliamentary committee, which sat throughout the sessions of 1835-36, and probed the condition of the institution very thoroughly. Panizzi's principal contributions to its inquiries as respected the library were an enormous mass of statistics respecting foreign libraries collected by him upon the Continent, and some admirable evidence on the catalogue of printed books then in contemplation. In 1837 he became keeper of printed books upon the retirement of Mr Baber, and immediately set himself to grapple with the special tasks imposed upon him by the peculiar circumstances in which he found the library. The entire collection, except the King's Library, had to be removed from Montague House to the new building; the reading-room service had to be reorganized; rules for the new printed catalogue had to be prepared, and the catalogue itself undertaken. All these tasks were successfully accomplished; but, although the rules of cataloguing devised by Panizzi and his assistants have become the basis of whatever has since been attempted in this department, the progress of the catalogue itself was slow. The first volume, comprising letter A, was published in 1841, and from that time, although the catalogue was continued and completed in MS., no attempt was made to print any more until, in 1881, the task was resumed under the direction of the present principal librarian. The chief cause of this comparative failure was injudicious interference with Panizzi, occasioned by the impatience of the trustees and the public. Panizzi's appointment, as that of a foreigner, had from the first been highly unpopular. He gradually broke down opposition, partly by his social influence, but far more by the sterling merits of his

administration, and his constant efforts to improve the library. The most remarkable of these was his great report, printed in 1845, upon the Museum's extraordinary deficiencies in general literature, which ultimately procured the increase of the annual grant for the purchase of books to £10,000. In 1847 his friendship with the Right Hon. Thomas Grenville led to the nation's being enriched by the bequest of that gentleman's unique library, valued even then at £50,000. In 1847-49 a royal commission sat to inquire into the general state of the Museum, and Panizzi was the centre of the proceedings. His administration, fiercely attacked from a multitude of quarters, was triumphantly vindicated in every point; and the inquiry had the excellent effect, not merely of establishing his reputation, but of abolishing the main source of maladministration, the anomalous position and illegitimate influence of the secretary. Panizzi immediately became by far the most influential official in the Museum, though he did not actually succeed to the principal librarianship until 1856.

It was thus as merely keeper of printed books that he conceived and carried out the achievement by which he is probably best remembered, the erection of the new library and reading-room. The want of space had become so crying an evil that purchases were actually discouraged from lack of room in which to deposit the books. Panizzi cast his eye on the empty quadrangle enclosed by the Museum buildings, and conceived the daring idea of occupying it with a central cupola too distant, and adjacent galleries too low, to obstruct the inner windows of the original edifice. The cupola was to cover three hundred readers, the galleries to provide storage for a million of books. The original design, sketched by Panizzi's own hand on April 18, 1852, was submitted to the trustees on May 5; in May 1854 the necessary expenditure was sanctioned by parliament, and the building was opened in May 1857. Its construction had involved a multitude of ingenious arrangements, all of which had been contrived or inspected by Panizzi with the genius for minute detail which he shared with so many men equally remarkable for the general breadth of their conceptions, and with the mechanical inventiveness of which he was continually giving proof. There is probably no building in the world better adapted to the purpose which it is intended to serve; and it is no discredit to the designer if, imposing as it is, neither the space nor the funds at his disposal allowed him to plan it on the colossal scale which its utility would have warranted.

Panizzi succeeded Sir Henry Ellis as principal librarian in March 1856. The most remarkable incidents of his administration were the great improvement effected in the condition of the Museum staff by the recognition of the institution as a branch of the civil service, and the decision, not carried out for long afterwards, to remove the natural history collections to Kensington. Of this questionable measure Panizzi was a warm advocate; he was heartily glad to be rid of the naturalists. He had small love for science and its professors, and, as his friend Macaulay said, "would at any time have given three elephants for one Aldus." Many important additions to the collections were made during his administration, especially the Temple bequest of antiquities, and the Halicarnassæan sculptures discovered at Budrun by Mr C. T. Newton. Feeling the effects of age and excessive labour, he expressed a wish to retire in 1865, but remained some time longer in office at the instance of the trustees. He ultimately retired in July 1866, receiving as a special mark of distinction a pension equal to the full amount of his salary. He took a house in the immediate neighbourhood of his cherished institution, and continued to interest himself actively in its

affairs until his death, which took place on April 8, 1879. He had been created a K.C.B. in 1869.

Along with Panizzi's visible and palpable activity as the centre of energy at the British Museum was another systematic activity no less engrossing and important, but unacknowledged by himself and little suspected by the world. His devotion to the Museum was rivalled by his devotion to his country, and his personal influence with English Liberal statesmen enabled him to promote her cause by judicious representations at critical periods. Throughout the revolutionary movements of 1848-49, and again during the campaign of 1859 and the subsequent transactions due to the union of Naples to the kingdom of Upper Italy, Panizzi was in constant communication with the Italian patriots, and their confidential representative with the English ministers. He laboured, according to circumstances, now to excite now to mitigate the latter's jealousy of France; now to moderate their apprehensions of revolutionary excesses, now to secure encouragement or connivance for Garibaldi. The letters addressed to him by patriotic Italians, edited by his literary executor and biographer, Mr L. Fagan, alone compose a thick volume. His own have not as yet been collected; but the internal evidence of the correspondence published attests the priceless value of his services, and the boundless confidence reposed in his sagacity, disinterestedness, and discretion. He was charitable to his exiled countrymen in England, and, chiefly at his own expense, equipped a steamer, which was lost at sea, to rescue the Neapolitan prisoners of state on the island of Santo Stefano. His services were recognized by the offer of a senatorship and of the direction of public instruction in Italy; but England, where he had been legally naturalized, had become his adopted country, though in his latter years he frequently visited the land of his birth.

Panizzi's merits and defects were those of a potent nature. He was a man born to rule, and in a free country would probably have devoted himself to public life and become one of the leading statesmen of his age. His administrative faculty was extraordinary: to the widest grasp he united the minutest attention to matters of detail. His will and perseverance were indomitable, but the vehemence of his temper was mitigated by an ample endowment of tact and circumspection. He was a powerful writer, a persuasive speaker, and an accomplished diplomatist. He was undoubtedly arbitrary and despotic; in some few points upon which he had hastily taken up wrong views, incurably prejudiced; in others, such as the claims of science, somewhat perversely narrow-minded. But on the whole he was a very great man, who, by introducing great ideas into the management of the Museum, not only redeemed that institution from being a mere show-place, but raised the standard of library administration all over England. His successors may equal or surpass his achievements, but only on condition of labouring in his spirit, a spirit which did not exist before him. His moral character was the counterpart of his intellectual: he was warm hearted and magnanimous, extreme in love and hate, a formidable enemy, but a devoted friend. The list of his intimate friends is a long and brilliant one, including Lord Palmerston, Mr Gladstone, Roscoe, Grenville, Macaulay, Lord Langdale and his family, Rutherford (Lord Advocate), and above all, perhaps, Haywood, the translator of Kant. His most celebrated friendship, however, is that with Prosper Mérimée, who, having begun by seeking to enlist his influence with the English Government on behalf of Napoleon III., discovered a congeniality of tastes which produced a delightful correspondence. Mérimée's part has been published by Mr Fagan; Panizzi's perished in the conflagration kindled by the Paris commune. The loss is to be regretted rather on account of the autobiographical than the literary value of Panizzi's share of the correspondence, although he was an accomplished man of letters of the 18th century pattern. But no man of ability has more completely exemplified the apophthegm of another distinguished person, that success is won less by ability than by character.

See L. Fagan, *Life of Sir Anthony Panizzi*, 2 vols., London, 1880. (R. G.)

PANNA, or PUNNAH, a native state in Bundelkhand, India, situated for the most part on the table-lands above the Vindhyan Ghâts, and containing much hill and jungle land, with an area of 2568 square miles, and a population in 1881 of 227,306. The state was formerly celebrated for its diamond mines in the neighbourhood of Panna town, but these appear to have become almost exhausted, and only a small and fluctuating revenue is now derived from them.

PANNONIA, in ancient geography, is the country bounded N. and E. by the Danube from a point 9 or 10 miles north of Vindobona (Vienna) to Singidunum (Belgrade) in Mœsia, and continuous westward with Noricum and Italy and southward with Dalmatia and

Mœsia Superior. It thus corresponds to the south-west of Hungary with portions of Lower Austria, Styria, Carniola, and Croatia and Slavonia. Partially conquered in 33 B.C. (when the town of Siscia was taken), Pannonia (but probably only what was afterwards known as Lower Pannonia) was made a Roman province by Tiberius in 8 A.D. The three legions stationed in the country at the death of Augustus (14 A.D.) rose in rebellion and were quelled by Drusus. Somewhere between 102 and 107 Trajan divided the province into Pannonia Superior and Pannonia Inferior. These, according to Ptolemy, were separated by a line from Arrabona (Raab) in the north to Servitium (Gradisca) in the south, but at a later date the boundary lay farther east, to the diminution of Pannonia Inferior. The erection of two new provinces, Valeria and Savia, in the time of Diocletian gave rise to a fourfold division; and Constantine placed Pannonia Prima, Valeria, and Savia under the prætorian prefect of Italy, and Pannonia Secunda under the prætorian prefect of Illyricum. Pannonia Prima was the north part of the old Pannonia Superior and Savia the south part; Pannonia Secunda lay round about Sirmium, at the meeting of the valleys of the Save, the Drave, and the Danube; and Valeria (so called by Galerius after Valeria his wife and Diocletian's daughter) extended along the Danube from Altinum (Mohacs) to Brigetio (Ó-Szöny). Theodosius II. had to cede Pannonia to the Huns, and they were followed in turn by the Ostrogoths, the Longobards, and the Avars.

During the four hundred years of Roman occupation Pannonia reached a considerable pitch of civilization, and a number of the native tribes were largely Latinized. Upper Pannonia contained Vindobona (Vienna), a municipium; Carnuntum (Petronell), which became probably about 70 A.D. the winter quarters of the Pannonian legions, was made a municipium by Hadrian or Antoninus Pius, appears in the 3d century as a colonia, and has left important epigraphic remains; Arrabona (Raab or Győr), a considerable military station; Brigetio (Ó-Szöny), founded probably in the 2d century as the seat of Legio Prima Adjutrix, and afterwards designated municipium and colonia; Scarabantia or Scarbantia (Oedenburg or Soprony), a municipium of Julian origin according to Pliny, but of Ælian according to the inscriptions; Savaria or Sabaria (Stein am Anger or Szombathely), a purely civil municipium founded by Claudius, and a frequent residence of the later emperors; Poetovio (Ptoumion of Ptolemy, Patavio of *Itin. Anton.*; modern Pettau), first mentioned by Tacitus (69 A.D.) as the seat of Legio XIII. Gemina, and made a colonia by Trajan; Siscia (Sziszek), formerly known as Segesteca or Segeste, a place of great importance down to the close of the empire, made a colonia probably by Vespasian, and restored by Severus (colonia Flavia Septimia); Nevidunum (Dernovo), designated municipium Flavianum; municipium Latobicorum (Treffen); Emona or Hemona, *Huāva* (Laibach); and Nauportus (Ober-Laibach). Lower Pannonia contained Sirmium (Mitrovic), first mentioned in 6 A.D., made a colonia by Vespasian or his successor, and a frequent residence of the later emperors; Bassianæ (near Petrovce), Cusum (Peterwardein), Malata or Bononia (Banostor), Cibale (Vinkovce), a municipium; Mursa (Eszek), made a colonia by Hadrian 133 A.D.; Sopianæ (Fünfkirchen or Peca), seat of the præses of Valeria, and an important place at the meeting of five roads; Aquincum (Alt Ofen), made a colonia by Hadrian, and the seat of Legio II. Adjutrix; and Cirpi (near Bogdány). See *Corp. Inscr. Lat.*, vol. iii. 1.

PANORAMA is the name given originally to a pictorial representation of the whole view which is visible from one point by an observer who in turning round looks successively to all points of the horizon. In an ordinary picture only a small part of the objects visible from one point is included, far less being generally given than the eye of the observer can take in whilst stationary. The drawing is in this case made by projecting the objects to be represented from the point occupied by the eye on a plane. If a greater part of a landscape has to be represented, it becomes more convenient for the artist to suppose himself surrounded by a cylindrical surface in whose centre he stands, and to project the

¹ In the 4th century it became a town of Noricum, not of Pannonia.

landscape from this position on the cylinder. In a panorama such a cylinder, originally of about 60 feet, but now extending to upwards of 130 feet diameter, is covered with an accurate representation in colours of a landscape, so that an observer standing in the centre of the cylinder sees the picture like an actual landscape in nature completely surround him in all directions. This gives an effect of great reality to the picture, which is skilfully aided in various ways. The observer stands on a platform representing, say, the flat roof of a house, and the space between this platform and the picture is covered with real objects which gradually blend into the picture itself. The picture is lighted from above, but a roof is spread over the central platform so that no light but that reflected from the picture reaches the eye. In order to make this light appear the more brilliant, the passages and staircase which lead the spectator to the platform are kept nearly dark. These panoramas were invented by Robert Barker, an Edinburgh artist, who exhibited the first in Edinburgh in 1788, representing a view of that city. A view of London and views of sea fights and battles of the Napoleonic wars followed. Panoramas gained less favour on the Continent, until after the Franco-German war a panorama of the siege of Paris was exhibited in Paris.

The name panorama, or panoramic view, is also given to drawings of views from mountain peaks or other points of view, such as are found in many hotels in the Alps, or, on a smaller scale, in guide-books to Switzerland and other mountainous districts. These too are drawn as if projected on a cylinder afterwards cut open and unrolled. The geometrical laws which guide the drawing of panoramas follow easily from the general rules for PROJECTION (*q.v.*).

PANSY (*Viola* sp.). This flower has been so long cultivated that its source is a matter of uncertainty. As we now see it, it is a purely artificial production, differing considerably from any wild plant known. By some it is supposed to be merely a cultivated form of *Viola tricolor*, a corn-field weed, while others assert it to be the result of hybridization between *V. tricolor* and other species such as *V. altaica*, *V. grandiflora*, &c. As florists and gardeners conducted, and still too often conduct, their operations without scientific method, it is unfortunately not possible to arrive at any definite conclusion on this point. Some experiments of M. Carrière, however, go to show that seeds of the wild *V. tricolor* will produce forms so like those of the cultivated pansy that it is reasonable to assume that that flower has originated from the wild plant by continuous selection. Mr Darwin confesses himself to have been foiled in the attempt to unravel the parentage of the pansy, "and gave up the attempt as too difficult for any one except a professed botanist." The changes that have been effected from the wild type are, however, more striking to the eye than really fundamental. Increase in size, an alteration in form by virtue of which the narrow oblong petals are converted into circular ones, and variations in the intensity and distribution of the colour—these are the changes that have been wrought by continued selection, while the more essential parts of the flower have been relatively unaffected. The stamens and pistil, in fact, present the characteristics of the genus *Viola*. In that genus the construction of the stamens and pistil is such as to favour cross-fertilization, and that circumstance alone would account for much of the variation that is observed. In practice it is customary to propagate by means of cuttings the varieties it is desired to perpetuate, while, if additional varieties are desired, reproduction by seed, and careful selection of seedlings, according to the desire or fancy of the cultivator, are had recourse to. Self-fertilizing

(cleistogamic) flowers, such as occur in various species of violet, and in which the petals are absent or inconspicuous, not being required for the purpose of attracting insects, have not as yet been observed in pansies.

PANTÆNUS, head of the catechetical school at Alexandria at the close of the 2d Christian century, is known chiefly as having been the master of Clement, who succeeded him. Eusebius and Jerome speak of him as having been, originally at least, a Stoic, and as having been sent, on account of his zeal and learning, as a missionary to "India"—Yemen perhaps being meant. He was the author of commentaries on various books of Scripture, all of which have been lost with the exception of a few insignificant fragments. His teaching work in Alexandria seems to have begun before 180 A.D., and it was brought to an end by the persecution of Septimius Severus in 202.

PANTELLARIA, **PANTALARIA**, or officially **PANTELLERIA** (the ancient Cossyra or Cosyra), an island in the Mediterranean, which, though only 45 miles from the African coast to the south of Cape Bon, and 75 miles from the coast of Sicily, is included in the Italian province and circondario of Trapani. It is of volcanic origin, and its area is estimated at 58 square miles. Its principal summit reaches a height of 2440 feet. Hot sulphur springs occur in various places, and there is a small salt-lake of somewhat high temperature; but there is a lack of fresh water. The principal town, Oppidolo or Pantellaria, on the north-west, lies round a port protected by two redoubts and a citadel now used as a prison. Trade is carried on with Algeria, Tunis, and Malta. From 131 vessels (12,917 tons) in 1863 the movement of the port had by 1880 increased to 923 vessels (83,524 tons). In 1881 the population of the town was 3167, that of the island 7315.

The Phœnician name **𐤏𐤍𐤕𐤏**, *Iranim*, on coins has led Renan to identify the island with the Iarime of the Latin poets. The capture of Cosyra by M. Æmilius and Servius Fulvius in the First Punic War was thought worth mentioning in the triumphal fasti, though the Carthaginians recovered possession in the following year. In modern times the island has formed a principality in the hands of the Regnesens family. The bastard Italian spoken by the inhabitants shows Arabic influence.

PANTHEISM. See **THEISM**.

PANTHER. See **LEOPARD**.

PANTOGRAPH is an instrument for making a reduced, an enlarged, or an exact copy of a plane figure. One of the simplest forms is represented in fig. 1. Four links of wood or metal are jointed together so as to form a parallelogram ABCS. On two sides BA and BC produced points P and P' are taken in a line with S, so that the triangles PSA and SP'C are similar, as the sides of the

Fig. 1.

Fig. 2.

one are parallel to those of the other. Hence $SA/AP = P'C/CS$. Now the parallelogram ABCS is movable, its angles changing whilst its sides remain unaltered. The above ratio will therefore remain constant, and therefore again the points PSP' will always remain in a line. At the same time the ratio PS/SP' does not change, as it equals the ratio PA/AB . If then the point S be kept

fixed in a plane, and if P be made to describe any given figure, the point P' will describe another figure which is similar and similarly situated to the given one with S as centre of similitude, the ratio of similitude being PS : SP'. Thus if the point S be fixed at S fig. 2, and if P be made to describe the figure ABCD, then P' will describe the similar figure A'B'C'D'. For the geometry of figures which are similar and similarly situated, compare "Similar Figures" under PROJECTION.

For practical working there is at P a steel tracer having a fine but not sharp point, and at P' a tracing pencil for drawing the copy, or sometimes a sharp steel point for at once engraving the copy on a plate of metal. To obtain the smooth and steady motion of the instrument required for delicate work, a variety of different constructions are in use under various names, but all rest on the above principle that three points are kept in a line with their distances in a constant ratio. It will be noticed if any three points T, Q, Q' in a line be taken, as in fig. 1, these fulfil the conditions required, so that, for instance, T might be taken as the fixed point, and Q, Q' as the tracer and pencil.

PANTOMIME is a term which has been employed in different senses at different times in the history of the drama. Of the Roman *pantomimus*, a spectacular kind of play in which the functions of the actor were confined to gesticulation and dancing, while occasional music was sung by a chorus or behind the scenes, some account has been given elsewhere (vol. vii. p. 412). To speak of the Western drama only, there is no intrinsic difference between the Roman *pantomimus* and the modern "ballet of action," except that the latter is accompanied by instrumental music only, and that the personages appearing in it are not usually masked. The English "dumb-show," though fulfilling a special purpose of its own, was likewise in the true sense of the word pantomimic. On the other hand, the modern pantomime, as the word is still used, more especially in connexion with the English stage, signifies a dramatic entertainment in which the action is carried on with the help of spectacle, music, and dancing, and in which the performance is partly carried on by certain conventional characters, originally derived from Italian "masked comedy," itself an adaptation of the *fabulæ Atellanæ* of ancient Italy. Were it not for this addition, it would be difficult to define modern pantomime so as to distinguish it from the mask, and the least rational of English dramatic species would have to be regarded as essentially identical with another to which in its later development our dramatic literature owes some of its choicest fruit (see DRAMA, vol. vii.).

As a matter of course, no fixed date can be assigned to the birth of modern pantomime. The contributory elements which it contains had very soon in varying proportions and manifold combinations introduced themselves into the modern drama as it had been called into life by the Renaissance. In Italy the transition was almost imperceptible from the pastoral drama to the opera; on the Spanish stage ballets with allegorical figures and military spectacles were known already towards the close of the 16th century; in France ballets were introduced in the days of Mary de' Medici, and the popularity of the opera was fully established in the earlier part of the reign of Louis XIV. Meanwhile, in the previous century the improvised Italian comedy (*commedia dell' arte*) had crossed the Alps with its merry company of characters, partly borrowed from masked comedy, though also largely corresponding to the favourite types of regular comedy both ancient and modern, and including Pantaloon, with Arlecchino, among other varieties of *zanni*.¹ Readers of Molière are aware of the influence of the Italian

players upon the progress of French comedy, and upon the works of its incomparable master. In other countries, where the favourite types of Italian popular comedy had been less generally seen or were unknown, popular comic figures such as the English fools and clowns, the German *Hanswurst*, or the Dutch *Pickelhering*, were ready to renew themselves in any and every fashion which preserved to them the gross salt favoured by their patrons. Indeed in Germany, where the term pantomime was not used, a rude form of dramatic buffoonery, corresponding to the coarser sides of the modern English species so-called, long flourished, and threw back for centuries the progress of the regular drama. After being at last suppressed, it found a commendable substitute in the modern *Zauberposse*, the more genial Vienna counterpart of the Paris *féerie*.

In England, where the mask was only quite exceptionally revived after the Restoration, the love of spectacle and other frivolous allurements was at first mainly met by the various forms of dramatic entertainment which went by the name of "opera." In the preface to *Albion and Albanus* (1685), Dryden gives a definition of opera which would fairly apply to modern extravaganza, or to modern pantomime with the harlequinade left out. Character-dancing was, however, at the same time largely introduced into regular comedy; and, as the theatres vied with one another in seeking *quocunque modo* to gain the favour of the public, the English stage was fully prepared for the innovation which awaited it. Curiously enough, the long-lived but cumbrous growth called pantomime in England owes its immediate origin to the beginnings of a dramatic species which has artistically furnished congenial delight to nearly two centuries of Frenchmen. Of the early history of *vaudeville* it must here suffice to say that the unprivileged actors at the fairs, who had borrowed some of the favourite character-types of Italian popular comedy, after eluding prohibitions against the use by them of dialogue and song, were at last allowed to set up a comic opera of their own. About the second quarter of the 18th century, before these performers were incorporated with the Italians, the light kind of dramatic entertainment combining pantomime proper with dialogue and song enjoyed high favour with the French and their visitors during this period of peace. The *vaudeville* was cultivated by Le Sage and other writers of mark, though it did not conquer an enduring place in dramatic literature till rather later, when it had, moreover, been completely nationalized by the extension of the Italian types.

It was this popular species of entertainment which, under the name of pantomime, was transplanted to England before in France it had attained to any fixed form, or could claim for its productions any place in dramatic literature. Colley Cibber mentions as the first example, followed by "that Succession of monstrous Medlies," a piece on the story of Mars and Venus, which was still in dumb-show; for he describes it as "form'd into a connected Presentation of Dances in Character, wherein the Passions were so happily expressed, and the whole Story so intelligibly told, by a mute Narration of Gesture only, that even thinking Spectators allow'd it both a pleasing and a rational Entertainment." There is nothing to show that Harlequin and his companions figured in this piece. Geneste, who has no record of it, dates the period when such entertainments first came into vogue in England about 1723. In that year the pantomime of *Harlequin Dr Faustus* had been produced at Drury Lane,—its author being John Thurmond, a dancing master, who afterwards (in 1727) published a grotesque entertainment called *The Miser, or Wagner and Abericock* (a copy of this is in the Dyce Library). Hereupon, in December 1723, John Rich (1692-1761), then lessee of the theatre in Lincoln's Inn

¹ Whether the traditional costume of the ancient Roman *mimi*—the *cen-tunculus* or variegated harlequin's jockey, the shaven head, the sooty face, and the unshod feet—had before this been known among the provincials, may be left undecided.

Fields, produced there as a rival pantomime *The Necromancer, or History of Dr Faustus*, no doubt, says Geneste, "gotten up with superior splendour." He had as early as 1717 been connected with the production of a piece called *Harlequin Executed*, and there seem traces of similar entertainments as far back as the year 1700. But it was the inspiring influence of French example, and the keen rivalry between the London houses, which in 1723 really established pantomime on the English stage. Rich was at the time fighting a difficult battle against Drury Lane, and his pantomimes at Lincoln's Inn Fields, and afterwards at Covent Garden, were extraordinarily successful. He was himself an inimitable harlequin, and from Garrick's lines in his honour it appears that his acting consisted of "frolic gestures" without words. The favourite Drury Lane harlequin was Pinkethman (Pope's "poor Pinky"); readers of *The Tatler* (No. 188) will remember the ironical nicety with which his merits are weighed against those of his competitor Bullock at the other house. Colley Cibber, when described by Pope as "mounting the wind on grinning dragons," briskly denied having in his own person or otherwise encouraged such fooleries; in his *Apology*, however, he enters into an elaborate defence of himself for having allowed himself to be forced into countenancing the "gin-shops of the stage," pleading that he was justified by necessity, as Henry IV. was in changing his religion. Another butt of Pope's, Lewis Theobald, was himself the author of more than one pantomime; their titles already run in the familiar fashion, e.g., *A Dramatick Entertainment, call'd Harlequin a Sorcerer, with the loves of Pluto and Proserpine* (1725; the "book of the words," as it may be called, is in the Dyce Library). In another early pantomime (also in the Dyce Library) called *Perseus and Andromeda, with the Rape of Colombine, or The Flying Lovers*, there are five "interludes, three serious and two comic." This is precisely in the manner of Fielding's dramatic squib against pantomimes, *Tumble-down Dick, or Phaeton in the Suds*, first acted in 1744, and ironically dedicated to "Mr John Lun," the name that Rich chose to assume as harlequin. It is a capital bit of burlesque, which seems to have been directly suggested by Pritchard's *Fall of Phaeton*, produced in 1736.

There seems no need to pursue further the history of English pantomime. "Things of this nature are above criticism," as Mr Machine the "composer" of *Phaeton* says in Fielding's piece. The attempt was made more than once to free the stage from the incubus of entertainments to which the public persisted in flocking; in vain Colley Cibber at first laid down the rule of never giving a pantomime together with a good play; in vain his son Theophilus after him advised the return of part of the entrance money to those who would leave the house before the pantomime began. "It may be questioned," says the chronicler, "if there was a demand for the return of £20 in ten years." Pantomime carried everything before it when there were several theatres in London, and a dearth of high dramatic talent prevailed in all; and, allowing for occasional counter-attractions of a not very dissimilar nature, pantomime continued to flourish after the Licensing Act of 1737 had restricted the number of London play-houses, and after Garrick's star had risen on the theatrical horizon. He was himself obliged to satisfy the public appetite, and to disoblige the admirers of his art, in deference to the drama's most imperious patrons—the public at large.

It should be noted that in France an attempt was made by NOVERRE (q.v.) to restore pantomime proper to the stage as an independent species, by treating mythological subjects seriously in artificial ballets. This attempt, which of

course could not prove permanently successful, met in England also with great applause. In an anonymous tract of the year 1789 in the Dyce Library, attributed by Dyce to Archdeacon Nares (the author of the *Glossary*), Noverre's pantomime or ballet *Cupid and Psyche* is commended as of very extraordinary merit in the choice and execution of the subject. It seems to have been without words. The writer of the tract states that "very lately the serious pantomime has made a new advance in this country, and has gained establishment in an English theatre;" but he leaves it an open question whether the grand ballet of *Medea and Jason* (apparently produced a few years earlier, for a burlesque on the subject came out in 1781) was the first complete performance of the kind produced in England. He also notes *The Death of Captain Cook*, adapted from the Parisian stage, as possessing considerable dramatic merit, and exhibiting "a pleasing picture of savage customs and manners." To conclude, the chief difference between the earlier and later forms of English pantomime seems to lie in the fact that in the earlier Harlequin pervaded the action, appearing in the comic scenes which alternated throughout the piece with the serious which formed the backbone of the story. Columbine (originally in Italian comedy Harlequin's daughter) was generally a village maiden courted by her adventurous lover, whom village constables pursued, thus performing the laborious part of the policeman of the modern harlequinade. The brilliant scenic effects were of course accumulated, instead of upon the transformation scene, upon the last scene of all, which in modern pantomime follows upon the shadowy chase of the characters called the *rally*. The commanding influence of the clown, to whom pantaloons is attached as friend, flatterer, and foil, seems to be of comparatively modern growth; the most famous of his craft was undoubtedly Joseph Grimaldi (1779–1837), of whom Charles Dickens in his youth edited a biography. His memory is above all connected with the famous pantomime of *Mother Goose*, produced at Covent Garden in 1806. It boots not to enumerate favourites of later days; the type of Christmas pantomime cherished by a generation now passing away has been preserved from oblivion in Thackeray's *Sketches and Travels in London*. The species still maintains its hold over sections of the grown-up public, and, though now only cultivated in a few of the leading London theatres, appears at Christmas 1883–84, according to professional statistics, to have multiplied itself in the capital alone by thirteen examples.

See Geneste, *Account of the English Stage*, especially vol. iii.; Dibdin, *Complete History of the Stage*, especially vols. ii., iv., and v.; *Apology for the Life of Colley Cibber*; Fitzgerald, *Life of Garrick*; Prölss, *Dramaturgie*. (A. W. W.)

PANYASIS, of Halicarnassus, a poet of the early half of the 5th century B.C. He was a near relation of the historian Herodotus. According to some his father Polyarchus was brother of Herodotus's father Lyxes; according to others, Rhæo or Dryo, the mother of Herodotus, was a sister of Panyasis. He led a revival of the old Ionian epic poetry, and his younger contemporary Antimachus continued the movement. Only insignificant fragments of his works are preserved. He wrote a *Hercleas*, in which the whole of the Heracles-myths were embraced in 14 books (9000 lines), and another poem in elegiacs, 7000 lines long, called *Ἰωνικά*, in which he related the story of the Ionic settlements in Asia Minor and the exploits of Codrus and Nelens. Though not much thought of in his own time, he is praised by later critics. He was slain by Lygdamis, tyrant of Halicarnassus.

PAOLI, PASQUALE DE (1725–1807), generalissimo of Corsica, was the son of Giacinto Paoli, a Corsican patriot, and his mother was descended from the old family of the

Caporali. He was born in the village of La Stretta in the district of Rostino, 25th April 1725. After the hopes of the Corsicans were overthrown by the French in 1738, he accompanied his father to Naples, where he entered the military college. In an expedition against Calabrian bandits he greatly distinguished himself, and when in 1755 he returned to Corsica he had acquired so high a reputation that he was chosen generalissimo in a full assembly of the people. His refusal to accept Matra for a colleague, led the latter to take advantage of the dissatisfaction of some influential Corsicans to stir up an insurrection. With the aid of the Genoese, Matra for a time made a formidable stand, but after his death in battle Paoli turned his arms against the Genoese with such success that in 1761 they proposed terms of peace. As Paoli would consent to nothing less than the complete independence of Corsica, the Genoese, despairing of their ability to establish a hold on the island, sold it in 1768 to France. The French effected a landing in 1769 with 22,000 men under Count Vaux, and after a stubborn and prolonged resistance Paoli was totally defeated, and, barely succeeding in cutting his way through the enemy, escaped on board an English frigate and went to England. His rule in Corsica, notwithstanding the distraction of the continual struggle to maintain its independence, had been marked by the introduction of many important reforms, such as the remodelling of the laws, the establishment of permanent courts, the regulation of the coinage, and the furtherance of various measures for the encouragement of agriculture, manufactures, and commerce. At the instance of the duke of Grafton, prime minister of England, Paoli received from the English Government a pension of £1200 a year. He came to be on intimate terms with Dr Samuel Johnson, to whom he was introduced by Boswell. When, after the French Revolu-

tion, Corsica was numbered among the departments of France, Paoli agreed to return to Corsica as lieutenant-general and governor of the department; but, the excesses of the Convention having alienated his sympathies, he, with the help of Great Britain, organized a revolt, and in 1793 was elected generalissimo and president of the council of government at Corte. Despairing, however, of maintaining the independence of the island, he in 1795 agreed to its union with Great Britain, and on George III. being declared king returned to England. He died near London in February 1807. Clemente, elder brother of Pasquale Paoli, also distinguished himself in the struggles of Corsica against the Genoese. Subsequently he retired to a convent at Vallambrosa, but at the end of twenty years returned to Corsica, and died there in 1793.

See Boswell's *Life of Johnson* and his *Account of Corsica*, 1768, *Review of the Conduct of Pascal Paoli*, 1770, *Lives of Paoli*, by Arrighi (Paris, 1843), Klose (Brunswick, 1853), Bartoli (Ajaccio, 1867), and Oria (Genoa, 1869).

PÁPA, a large country-town of Hungary, in the district of Veszprim, lies on the Raab and Steinamanger Railway, 75 miles to the west of Pesth. It is the seat of a fine chateau and park of the Eszterházy family, by whom the handsome Roman Catholic church, lined with red marble, was built in 1778. It also contains a Protestant church, a good Protestant school established about 1530, a Roman Catholic gymnasium, and three convents. A quaint one-storied edifice is shown as the house of Matthew Corvinus. The chief industries are weaving, wine-growing, and the manufacture of paper and stoneware. The population in 1880 was 14,654.

P A P E R

THE origin and early history of paper as a writing material are involved in much obscurity. The art of making it from fibrous matter, and, among other substances, from the wool of the cotton plant, reduced to a pulp, appears to have been practised by the Chinese at a very distant period. Different writers have traced it back to the 2d century B.C. But however remote its age may have been in eastern Asia, cotton paper first became available for the rest of the world at the beginning of the 8th century, when the Arabs captured Samarkand (704 A.D.), and there learnt its use. The manufacture was taken up by them in that city, and rapidly spread through all parts of their empire. From the large quantities which were produced at Damascus, it obtained one of the titles, *charta Damascena*, by which it was known in the Middle Ages. The extent to which it was adopted for literary purposes is proved by the comparatively large number of early Arabic MSS. on paper which have come down to us, dating from the 9th century.¹

¹ A few of the earliest dated examples may be instanced. The *Gharibu 'l-Hadith*, a treatise on the rare and curious words in the sayings of Mohammed and his companions, written in the year 866, is probably one of the oldest paper MSS. in existence (*Pal. Soc.*, Orient. Ser., pl. 6). It is preserved in the University Library of Leyden. A treatise by an Arabian physician on the nourishment of the different members of the body, of the year 960, is the oldest dated Arabic MS. on paper in the British Museum (Or. MS. 2600; *Pal. Soc.*, pl. 96). The Bodleian Library possesses a MS. of the *Divānu 'l-Adab*, a grammatical work of 974 A.D., of particular interest as having been written at Samarkand on paper presumably made at that seat of the first Arab manufacture (*Pal. Soc.*, pl. 60). Other early examples are a volume of poems written at Baghdad, 990 A.D., now at Leipsic and the Gospel of St Luke, 993 A.D., in the Vatican Library (*Pal.*

With regard to the introduction of paper into Europe, it naturally first made its appearance in those countries more immediately in contact with the Oriental world. Besides receiving the names of *charta* and *papyrus*, transferred to it from the Egyptian writing material manufactured from the papyrus plant (see PAPHYRUS), cotton paper was known in the Middle Ages as *charta bombycina*, *gossypina*, *cultunea*, *zylina*, *Damascena*, and *serica*. The last title seems to have been derived from its glossy and silken appearance. It was probably first brought into Greece through trade with Asia, and from thence transmitted to neighbouring countries. Theophilus presbyter, writing in the 12th century (*Schedula diversarum artium*, i. 23), refers to it under the name of Greek parchment—"tolle pergamenam Græcam, quæ fit ex lana ligni." In the 10th century *bambacium* was used at Rome. There is also a record of the use of paper by the empress Irene at the end of the 11th or beginning of the 12th century, in her rules for the nuns of Constantinople. It does not appear, however, to have been very extensively used in Greece before the middle of the 13th century, for, with one doubtful exception, there are no extant Greek MSS. on paper which bear date prior to that period.

The manufacture of paper in Europe was first established by the Moors in Spain, the headquarters of the industry being Xativa, Valencia, and Toledo. But on the fall of

Soc., pls. 7, 21). In the great collection of Syrian MSS. which were obtained from the Nitrian desert in Egypt, and are now in the British Museum, there are many volumes written on cotton paper of the 10th century. The two oldest dated examples, however, are not earlier than 1075 and 1084 A.D.

the Moorish power the manufacture, passing into the hands of the less skilled Christians, declined in the quality of its production. In Italy also the art of paper-making was no doubt in the first place established through the Arab occupation of Sicily. But the paper which was made both there and in Spain, it must be remembered, was in the first instance cotton paper. In the laws of Alphonso of 1263 it is referred to as cloth parchment, a term which well describes the thick material made from cotton. As, however, the industry was pushed north, into districts where cotton was not to be found as a natural growth or was not imported, other substances had to be pressed into the service. Hence by degrees arose the practice of mixing rags in the first instance no doubt of woollen fabrics, with the raw material. The gradual substitution of linen, in countries where it was more abundant or where it was the only suitable material at hand, was a natural step in the progress of the manufacture.

The first mention of rag paper occurs in the tract of Peter, abbot of Cluny (1122-50 A.D.), *adversus Judæos*, cap. 5, where, among the various kinds of books, he refers to such as are written on material made "ex rasuris veterum pannorum." At this early period woollen cloth is probably intended. Linen paper was first made in the 14th century; but in the first half of that century it is probable that woollen fabrics still entered largely into the component parts of the pulp—a fact which, however, can only be proved in individual instances by aid of the microscope. This being the case, it is of less practical advantage to try to ascertain an exact date for the first use of linen in paper-making than to define the line of demarcation between the two classes of paper, viz., that made in the Oriental fashion without water-marks, and that in which these marks are seen. The period when this latter kind of paper came into existence lies in the first years of the 14th century, when paper-making at length became a veritable European industry. Cotton paper of the Oriental pattern, it is true, is still found here and there in use some time after the manufacture of the water-marked material had begun, but the instances which have survived are few and are mostly confined to the south of Europe.

A few words may here be said respecting the extant examples of cotton paper MSS. written in European countries. Several which have been quoted by former writers as early instances have proved, on more recent examination, to be nothing but vellum. The ancient fragments of the Gospel of St Mark, preserved at Venice, which were stated by Maffei to be of cotton paper, by Montfaucon of papyrus, and by the Benedictines of bark, are in fact written on skin. The oldest document on cotton paper is a deed of King Roger of Sicily, of the year 1102; and there are others of Sicilian kings, of the 12th century. The oldest known imperial deed on the same material is a charter of Frederick II. to the nuns of Goess in Styria, of the year 1228, now at Vienna. In 1231, however, the same emperor forbade further use of paper for official documents, which were in future to be inscribed on vellum. In Venice the *Liber plegiorum*, the entries in which begin with the year 1228, is made of rough cotton paper; and similarly the registers of the Council of Ten, beginning in 1325, and the register of the emperor Henry VII. (1308-13) preserved at Turin, are also written on a like substance. In the British Museum there is an older example in a MS. (Arundel 268) which contains some astronomical treatises written on an excellent paper in an Italian hand of the first half of the 13th century. The letters addressed from Castile to the English king, Edward I., in 1279 and following years (Pauli in *Bericht. Berl. Akad.*, 1854) are instances of Spanish-made paper; and other specimens in existence prove that in this latter country a rough kind of

charta bombycina was manufactured to a comparatively late date.

In Italy the first place which appears to have become a great centre of the paper-making industry was Fabriano in the marquisate of Ancona, which rose into importance on the decline of the manufacture in Spain. The jurist Bartolo, in his treatise *De insignis et armis*, refers to the excellent paper made there in the middle of the 14th century, an encomium which will be supported by those who have had occasion to examine the extant MSS. of Italian paper of that period, which even now excites admiration for its good quality. In 1340 a factory was established at Padua; another arose later at Treviso; and others followed in the territories of Florence, Bologna, Parma, Milan, Venice, and other districts. From the line of factories of northern Italy the wants of southern Germany were supplied as late as the 15th century. As an instance the case of Görlitz has been cited, which drew its paper from Milan and Venice for the half century between 1376 and 1426. But in Germany also factories were rapidly founded. The earliest are said to have been set up between Cologne and Mainz, and in Mainz itself about the year 1320. At Nuremberg Ulm Stromer established a mill in 1390, with the aid of Italian workmen. Other places of early manufacture were Ratisbon and Augsburg. Western Germany, as well as the Netherlands and England, is said to have obtained paper at first from France and Burgundy through the markets of Bruges, Antwerp, and Cologne. France owed the establishment of her first paper-mills to Spain, whence we are told the art of paper-making was introduced, as early as the year 1189, into the district of Hérault. The French paper of this early date was of course of cotton. At a later period, in 1406, among the accounts of the church of Troyes, such mills appear as *molins à toile*. The development of the trade in France must have been very rapid, for, as we have already noticed, that country was soon in a position to supply her neighbours as well as to provide for her own wants. And with the progress of manufacture in France that of the Netherlands also grew.

A study of the various water-marks has yielded some results in tracing the different channels in which the paper trade of different countries flowed; but a thorough and systematic collection and classification of them has yet to be accomplished. Experience also of the different kinds of paper, and a knowledge of the water-marks, aid the student in fixing nearly exact periods to undated documents. Rag paper of the 14th century may generally be recognized by its firm texture, its stoutness, and the large size of its wires. The water-marks are usually simple in design; and, being the result of the impress of thick wires, they are therefore strongly marked. In the course of the 15th century the texture gradually becomes finer and the water-marks more elaborate. While the old subjects of the latter are still continued in use, they are more neatly outlined, and, particularly in Italian paper, they are frequently enclosed in circles. The practice of inserting the full name of the maker in the water-mark came into fashion in the course of the 16th century. The variety of subjects of water-marks is most extensive. Animals, birds, fishes, heads, flowers, domestic and warlike implements, armorial bearings, &c., are found from the earliest times. Some of these, such as armorial bearings, and national, provincial, or personal cognizances, as the imperial crown, the crossed keys, or the cardinal's hat, can be attributed to particular countries or districts; and the wide dissemination of the paper bearing these marks in different countries serves to prove how large and international was the paper trade in the 14th and 15th centuries.

In the second half of the 14th century the use of paper for all literary purposes had become well established in all western Europe; and in the course of the 15th century it gradually superseded vellum. In MSS. of this latter period it is not unusual to find a mixture of vellum and paper, a vellum sheet forming the outside leaves of a quire while the rest are of paper.

With regard to the early use of paper in England, there is evidence that quite at the beginning of the 14th century it was a not uncommon material, particularly for registers and accounts. Under the year 1310, the records of Merton College, Oxford, show that paper was purchased "pro registro," which Prof. Rogers (*Hist. Agricul. and Prices*, i. p. 644) is of opinion was probably cotton paper of the same character as that of the Bordeaux customs register in the Public Record Office, which date from the first year of Edward II. The college register referred to, which was probably used for entering the books that the fellows borrowed from the library, has perished. There is, however, in the British Museum a paper MS. (Add. 31,223), written in England, of even earlier date than the one recorded in the Merton archives. This is a register of the hustings court of Lyme Regis, the entries in which commence in the year 1309. The material is cotton paper, with apparently an admixture of rag, the threads of which are visible, imbedded in the pulp—similar to the kind which was used in Spain. It may indeed have been imported direct from that country or from Bordeaux; and a seaport town on the south coast of England is exactly the place where such early relics might be looked for. Professor Rogers also mentions an early specimen of paper made from rag in the archives of Merton College, on which is written a bill of the year 1332; and some leaves of water-marked paper of 1333 exist in the Harleian collection. Of a date only a few years later is the first of the registers of the King's Hall at Cambridge, a series of which, on paper, are preserved in the library of Trinity College. Of the middle of the 14th century also are many of the municipal books and records still to be found among the archives of ancient cities and towns. The knowledge, however, which we have of the history of paper-making in England is extremely scanty. The first maker whose name is known is one Tato, who is said to have set up a mill in Hertford early in the 16th century; and a German named Spielman had works at Dartford in 1588. But it is incredible that no paper was made in the country before the time of the Tudors. No doubt at first it was imported. But the comparatively cheap rates at which it was sold in the 15th century in inland towns, as well as in those nearer the coast, seem to afford ground for assuming that there was at that time a native industry in this commodity, and that it was not altogether imported.

As far as the prices have been observed at which different kinds of paper were sold in England in the early period of its introduction, it has been found that in 1355-56 the price of a quire of small folio paper was 5d., both in Oxford and London. In the 15th century the average price seems to have ranged from 3d. to 4d. for the quire, and from 3s. 4d. to 4s. for the ream. At the beginning of the 16th century the price fell to 2d. or 3d. the quire, and to 3s. or 3s. 6d. the ream; but in the second half of the century, owing to the debasement of the coinage, it rose, in common with all other commodities, to nearly 4d. the quire, and to rather more than 5s. the ream. The relatively higher price of the ream in this last period, as compared with that of the quire, seems to imply a more extensive use of the material which enabled the trader to dispose of broken bulk more quickly than formerly, and so to sell by the quire at a comparatively cheap rate.

Brown paper appears in entries of 1570-71, and was

sold in bundles at 2s. to 2s. 4d. Blotting paper is apparently of even earlier date, being mentioned under the year 1465. It was a coarse, grey, unsized paper, fragments of which have been found among the leaves of 15th century accounts, where it had been left after being used for blotting.

See *Gerardi Meerman et doctorum virorum ad eum Epistolæ atque Observationes de Chartæ vulgaris seu lineæ origine*, Hague, 1767; G. F. Wehrs, *Vom Papier*, Halle, 1789; M. Koops, *Historical Account of the substances used to describe events and to convey ideas, from the earliest date to the Invention of Paper* (London, 1801), in great part repeating Wehrs—the book is printed on paper manufactured from straw; Ersch and Gruber, *Allgem. Encyclopædie*, art. "Papier," Leipzig, 1838; Sotzmann, "Ueber die ältere Papierfabrikation," in *Serapeum*, Leipzig, 1846; W. MANUFACTURE OF PAPER.

Paper is a thin tissue composed of vegetable fibres (rarely of woollen fibres), resulting from their deposition on wire-cloth while suspended in water. At first it was entirely made by hand, but the invention in 1798 of the paper machine by Louis Robert, a clerk in the employment of Messrs Didot, of the celebrated Essonnes paper-mills, near Paris, gave a new impetus to the industry. The invention was introduced into England through the agency of Messrs Fouldrinier, who employed Bryan Donkin, the engineer, to assist in working it out; but, although they expended a large fortune in developing the invention, their enterprise resulted only in bankruptcy. Their first paper machine was erected in 1804 at Frogmoor Mill, near Boxmoor, Herts. In the United States it was not till 1820 that such a machine was started for the first time by Messrs T. Gilpin & Co., on the Brandywine. Since that period, machine-made paper has gradually supplanted that made by hand for all except special purposes, and has been brought to a high state of perfection by subsequent improvements in the machinery.

Paper may be divided into three main classes:—writing paper, printing paper, and wrapping paper. The staple of which writing and printing paper is made is, in Britain, rags and esparto; in America a considerable quantity of wood pulp is used. The staple of wrapping papers is old ropes and in some cases jute. The best writing and printing papers are still made, whether by hand or by machine, from rags.

Manufacture of Paper from Rags.—The first process is the cutting and sorting of the rags, which is invariably done by women. The rag-cutter stands behind a knife about 14 inches long set in an oblique position in a table before her; the rags are cut into pieces about the size of the hand, and the linen pieces separated from the cotton, the various qualities being put into different receptacles. After being cut they are subjected to the action of the willow and duster, which knocks the loose dust off. The willow is composed of two conical cylinders, inside of which iron spikes project. In the interior of these cylinders an iron drum, also provided with spikes, revolves at about 300 revolutions per minute. The rags are fed into the first cylinder by a travelling felt, and dashed through from the one to the other by the action of the revolving drum, and from the second cylinder thrown forward into the duster. This consists of a large rectangular wooden case, in the interior of which an iron cage, covered with coarse wire-cloth, revolves slowly at right angles to the willow. This cage is set at a slight incline, so that the rags which are thrown into it by the willow at one end slowly pass to the other, while the dust, &c., which has been disengaged by the action of the willow, falls through the wire-cloth, and the dusted rags pass out at the other end, now ready for the boiler. The boiler is of different

forms, revolving or stationary. The most usual is stationary. It consists of an upright cylinder of cast or malleable iron (fig. 1), about 8 feet in diameter by 6 feet deep, and fitted with a perforated false bottom, on which the rags rest. The boiler is further fitted with a filling door A at the top, and an emptying door B below. After being

FIG. 1.—Section of Rag-Boiler.

charged with rags, it is filled to about half its height with water; a sufficient quantity of caustic soda, varying according to the nature of the rags, is introduced; the door is then shut, and steam is admitted by a small pipe C which is contained in, and communicates at the foot with, a larger pipe D and causes a constant circulation of hot liquid, which is dispersed all over the boiler by striking against a hood E at the top. This is technically known as the "vomit." The rags are boiled in this solution of caustic soda for ten to twelve hours, when the steam is turned off and the liquid is discharged by the pipe G. After a subsequent washing with cold water in the boiler the lower door is opened and the boiled rags withdrawn into small trucks, and picked by women to remove impurities, such as india-rubber, &c.

The rags are now submitted to the action of the breaking engine (figs. 2 and 3). This is an oblong trough with

FIG. 2.—Breaking Engine—Vertical Section.

rounded ends, and may be about 6 feet wide and 12 feet long by about 2 feet in depth, but the size varies greatly. It is partially divided in the centre by the midfeather A, and provided with a heavy iron roll B, fitted with knives technically called bars, which revolves at a high speed on the plate C, also furnished with knives. The engine is half filled with water and packed with the boiled rags.

Water is introduced by the valve D, and is withdrawn by the washer E. The washer consists of a drum about 3 feet in diameter and 18 inches broad, covered with fine wire-cloth, and fitted inside with buckets shown by the dotted lines G. It is partially immersed in the pulp, and as it revolves discharges the water by the centre down the

FIG. 3.—Breaking Engine—Horizontal Section.

shoot H. The rags are allowed to remain in this washer, according to their cleanness, from one to two hours, and then the solution of chloride of lime by which they are bleached is introduced. After running mixed with this in the engine from one to two hours, the pulp is run down into large stone chests, where it is allowed to lie for twenty-four hours till it becomes perfectly white; it is then drained and pressed to remove the remaining bleaching solution as far as possible.

The bleached pulp is now removed to the beating engine, which differs but little from the washing engine except that in the roll of the beater there are three bars to the bunch, while in the washer there are only two to the bunch. Here the pulp is furnished in the engine with water as before, and washed till it is free from chloride of lime, or this may be neutralized by the use of a sulphite or hyposulphite of soda. The pulp is then submitted to the action of the beater roll for from four to six hours, the circular knives being allowed to revolve very near the plate, so as to draw out the fibres into a very fine state, while preserving their strength as far as possible. While the operation of "beating" is being proceeded with, the loading material, consisting of china clay or pearl white, is added. This is by no means to be viewed entirely as an adulteration, as it too generally is. No doubt to a certain extent it weakens the paper, but it is not added in hand-made papers, in which great strength is required. In writing papers for ordinary purposes, however, and in printing papers, the addition of mineral matter in moderation is of positive advantage, as it closes up the pores of the fibres and enables the paper to take a much better finish than it would otherwise do.

The next process is the sizing, to which all papers for writing and most of those for printing purposes are subjected. Sizing consists in the deposition on the fibres of a substance which is comparatively waterproof, and for engine sizing a mixture of resin soap treated with alum is employed. The resin soap is formed by dissolving resin in carbonate or caustic soda, allowing the mixture to cool, when the soap floats on the surface, and the mother-liquor, containing the excess of alkali, is run off. It is of considerable importance to get rid of this mother-liquor before using the soap, as it is of no use, and takes alum to neutralize it. The soap is now dissolved in water, and, in many mills where starch is used for stiffening purposes,

mixed with the starch. This mixture is put into the beating engine in which the pulp is circulating, and when it is thoroughly incorporated with the pulp the solution of alum or sulphate of alumina is added. This forms a finely divided precipitate of resinate of alumina on the fibres. The pulp, after the sizing material is thoroughly incorporated with it, is now ready for colouring. Even to produce a pure white, colour must be added to the pulp. In general, for white papers, either cochineal and ultramarine blue are employed, or magenta and aniline blue. In all cases where permanence of colour is of importance, the former are to be preferred. For blue papers, ultramarine is generally used. Tinted papers are, as a rule, produced by the use of aniline colours. Coloured papers are produced by the use of various pigments.

The operation of beating the pulp is of the greatest importance, and too much care cannot be devoted to it. In America, where the mills are generally driven by water-power, the pulp is kept for a much longer time in the engine than in Great Britain, and this accounts to

a considerable extent for the superiority of the American papers.¹

After the pulp is prepared in the beating engine it is run into the chests of the paper machine (figs. 4 and 5). These chests A are fitted with agitators, and from them the pulp is pumped into the supply-box B, which communicates with the sand-traps C by means of a regulating cock. Along with the pulp a certain amount of water is allowed to flow into the sand-trap, so as to thin it down sufficiently; in most cases the save-all water (see below) is employed for this purpose. The pulp flows backward and forward here in a shallow stream, so as to deposit any heavy impurities which it may contain. After issuing from the sand-traps it is delivered on to the strainers, which are made in many varieties, the most common being the revolving strainer D, shown on the plan. This is a rectangular trough into which the pulp flows. In the centre of this the strainer, rectangular in form, composed of four sets of brass plates bolted to a frame in which very fine slits are cut, revolves slowly. The size of this is about 7 feet by 2 feet. The pulp is made to flow from the

FIG. 4.—Paper Machine—Vertical Section.

outside through the slits to the inside of the strainer by means of suction produced by bellows or disks in the interior of the plates, and is discharged by the pipe E into a box from which it flows on to the apron F, which is placed on the top of the breast roll. The apron is made of a piece of moleskin or india-rubber cloth the full width of the wire, and prevents the pulp from running away down the back of the wire. It covers the wire for 12 to 18 inches at the beginning. The wire consists of an endless sheet of fine wirecloth (about 66 wires per square inch) which stretches from the breast roll G to the couch roll H, returning underneath by the leading rolls I. Underneath the first portion of the wire are the tube rolls K, and farther along are the vacuum boxes L, L. These communicate by pipes with the vacuum pumps M. As the wire revolves in the direction shown in fig. 4 the pulp is allowed to flow from the strainer and spreads itself out in a thin film, covering the surface of the wirecloth. It is prevented from flowing over the sides of the wire by the deckle straps, endless india-rubber straps N. Part of

the water runs off through the meshes of the wire by gravitation, and the rest is removed through the suction boxes L by the vacuum pumps M. Stretching along under the wire from the breast roll to the first suction box is the save-all, a shallow trough into which the water which passes through the wire falls. The contents of this box flow into a cistern at the back of the machine into which the vacuum pumps also discharge their water; and from this cistern the water is pumped into a service box and used instead of fresh water for mixing with the pulp, as it flows on to the sand-trap. There is a considerable saving in this, as the fine fibre, size, &c., contained by the water passing through the wire is all in this way

¹ Another form of beating engine which is finding great favour is the Umpherston engine, which differs little from the ordinary beater, except in having, instead of a midfeather, a passage under the roll by which the pulp circulates. It is claimed for it that one capable of preparing 10 cwt. of paper does not occupy more floor area than an ordinary beater for 3 cwt. The pulp is also said to travel more freely, and does not lodge about the corners as in the ordinary engine.

recovered. Between the first and second suction box the dandy roll, a skeleton roll covered with wirecloth, revolves on the top of the pulp. By means of raised wires on it in the form desired the paper is rendered thinner at these parts and a water-mark is produced. In order to secure regularity in the layer of pulp, as also to increase the strength of the paper, a lateral motion is communicated to the wire by the shake O. The half-dried pulp now passes between the couch rolls, where it receives the first pressure. The under couch roll generally consists of a brass shell fixed by iron rings to a spindle; the top roll may be either similar to the lower one or made of mahogany, and is always covered with a felt jacket. Pressure is applied to the ends of the top roll by means of levers and weights. From these the sheet of partially

dried pulp is carried by endless felts through the first and second press rolls R and S. The press rolls are either made of solid iron, or may with advantage have a brass shell shrunk on. Having been freed by these from a great part of its water, the web of paper is carried over the steam-heated cylinders T, T. The first two cylinders are generally bare, and the heat applied to these is gentle, in the case of the others, the paper is kept close to the cylinder by means of endless felts. The web then passes through the intermediate rolls U in a half-dried state, over three more cylinders and the calenders V. These are heavy iron rollers heated by steam internally and polished externally. Their object is to communicate a gloss to the web of paper. It is then wound up on the reel W, and these reels when filled with paper are removed as required

FIG. 5.—Paper Machine—Horizontal Section.

to the paper cutter. In cases where the paper is to be sized with gelatin after leaving the machine, it is wound up rough.

A modification of the Fourdrinier machine, suitable for the manufacture of thin papers and those which only require to be smooth on one side, is shown in fig. 6. It consists of an ordinary paper machine as far as the couch rolls A, A. From these the paper is carried backwards on the top of the endless felt B till it comes in contact with the large steam-heated cylinder C at d. Here it adheres to the cylinder, being pressed against it at the same time by the press roll E. The paper then continues round the surface of the cylinder, and is wound up dry on reels at G. The felt washer H is a box filled with water through which the felt passes as it travels. After this the paper is cut or glazed in the usual way

At this stage papers which require to be hard-sized, principally the better sorts of writing papers, are sized with gelatin or "tub-sized." This is done occasionally by passing the sheets separately through a trough containing a strong solution of gelatin, and afterwards hanging them up to dry in the same way as hand-made papers, but in general the paper is sized and dried in the web after leaving the paper machine. For this purpose a sizing and drying machine is used (fig. 7). The web of paper to be sized is shown at A. From this it is passed through a trough B containing a strong solution of gelatin into which a certain amount of alum is introduced, after passing through this by means of the size rolls C, C, it is passed through the press rolls D, which squeeze out the superfluous size from it, and rewound on a reel at E to allow

the size time to set. The web is then transferred to the drying machine at G, and passed over a series of spar drums H, H at a slow speed. These drums are fitted round their circumference with wooden spars I on which the

paper rests, while a current of heated air from pipes underneath ascends through them and is driven against the inner surface of the paper by the fanners K, K, which revolve at a high speed. The great thing to be studied in this

FIG. 6.—Single-Cylinder Machine.

operation is to keep as low a temperature as possible, not above 80° Fahr. There may be any number of these drums; the larger the number the lower the temperature at which the paper can be dried. In some mills as many

as two hundred of them go to a drier. After being wound up at the end of the drier the paper is ready for cutting in the ordinary way.

The ordinary paper cutter (fig. 8) cuts from six to eight

FIG. 7.—Sizing and Drying Machine.

webs at once. The webs to be cut may be seen on the drawing at *a, a*. The webs of paper from these are led between the leading rolls *b, b* through the feeding rolls *c, c*. These, by means of the change pulley *d*, are driven at such a speed that they feed the paper to the revolving knife at the exact speed necessary to give the length of sheet required. After passing the feeding rolls the paper passes on to the slitting knives *e*. These are circular revolving knives which slit the paper into the width required. From these the webs pass through the drawing rolls *f, f* to the revolving knife *g*, which, coming down with a sheer against the dead knife *g'*, cuts them crosswise into the required length of sheet. The size of the sheet may be made longer or shorter, by altering the size of the expanding pulley *h* and the change pulley *d*. After being cut, the sheets of paper are caught by the endless felt *i* and carried forward to the table *k*, where they are arranged by boys.

Another form of paper cutter which is employed for water-marked papers (see paper machine) is the single-sheet cutter, fig 9. In this cutter only one web of paper is cut at a time, but it can be adjusted to a much

FIG. 8.—Reel Paper Cutter.

greater degree of nicety than the revolving cutter. After passing through the slitting knives *A*, which are in all

respects similar to those in the revolving cutter, the paper is carried over the measuring drum C, which, by a crank arrangement DE receives an oscillating motion and can be adjusted to draw the exact quantity of paper forward for the length of sheet required. The paper is kept fast on the drum by the gripper rolls F, F, arranged so as to rise and fall

FIG. 9.—Single-Sheet Paper Cutter.

as the drum oscillates, while the dancing roll B keeps the web at a uniform tension. The paper is cut into sheets by the knife I, connected with cranks and links G, and supported by the link rods H, H working horizontally with a swinging motion against the dead knife K. At the same time the clamp L holds the web in position. The sheet to be cut may be seen hanging down at the dotted line M. The sheets are then caught by girls and dressed up in the usual way. This cutter requires a great deal of attention, and is only used when extreme accuracy is required.

Calenders.—If it is desired to give the paper a higher gloss than can be done on the calenders of the paper machine, or where, as in the case of papers sized with gelatin, these must be glazed after leaving the paper machine, it is done by the use either of the plate or roll

FIG. 10.—Plate Calender.

calender. (1) The plate calender (fig. 10) is composed of a framework A, in which are set two highly polished rolls of solid iron B, B, with a space of about $\frac{3}{4}$ inch intervening. By means of levers and weights pressure can be applied to the top roll. The paper to be glazed is placed sheet by sheet between copper or zinc plates, till a bundle considerably thicker than the space between the rolls is made. This bundle is then passed backward and forward between the rollers, under considerable pressure, and the polished surface of the plates communicates a gloss to the paper.

(2) In America a calender of different construction is employed (fig. 11). In it a perpendicular series of highly polished iron and compressed cotton or paper rolls are placed alternately between frames, and revolve at a high speed. The sheets of paper are one by one introduced by an attendant, who sits in a convenient position near the

FIG. 11.—Sheet Glazing Calender.

top of the calender, under the tapes a, which, running against the roll A, convey the sheet to the next roll B. After passing under the roll A, the paper has a tendency to adhere to the metal surface; this is overcome by a sharp-pointed knife b placed against it, so that the sheet is again caught by the next set of tapes, and so on till it completes its course, and comes out at the foot of the calender. If a still higher glaze is required, the sheets are passed through a second time. A much larger quantity of paper can be glazed in the same time by one of these calenders than by the so-called plate calender, and at a greatly smaller outlay for wages, but the surface acquired by the paper wants the peculiar gloss communicated to it by the latter, and for the higher grades of paper this still retains its position in Great Britain.

After being cut, and, if necessary, calendered, the paper is sorted, that is to say, it is examined sheet by sheet, and all torn or soiled sheets are taken out. It is then counted into quires and reams, each quire containing twenty-four sheets, and each ream twenty quires.

Hand-Made Paper.—So far the preparation of pulp, whether for paper making by hand or by machine, is identical, the chief difference being that only the most expensive drawing and writing papers are now manufactured by hand, and for this purpose only the finest qualities of rags are used. The process will be best understood by reference to the drawing (fig. 12). The pulp, after being prepared in the beating engine as above described, is run into large chests from which the vat is supplied. Before reaching this it is strained as on the paper machine. Hand-made paper is made by means of a mould (fig. 13). This consists of framework of fine wirecloth with a "deckle" or movable frame of wood all round it, to keep the pulp from running off. Nearly all hand-made papers have also a water-mark (W. King in this instance), which is produced by wires representing these letters being raised above the rest of the mould. Hence the paper in these parts is thinner, and the letters can be read on holding the sheet up to the light.

The sheet of paper is formed in the following way. The vatman, fig. 12, takes up enough pulp on the mould to fill the deckle. He runs the stuff evenly over the mould from the foreside to the back, throwing back any pulp

Fig. 12.

which may be superfluous, and then gives the mould the "shake," a gentle shake both along and across the mould, causing the water to run through the wirecloth while the pulp which forms the sheet of paper stays on the top. The vatman then brings the mould to the stay; it is placed by the coucher on an inclined elbow, where some more water drains away, and he afterwards turns it over on the felt, leaving the sheet of paper on the felt. When the

FIG. 13.—Mould.

proper number of sheets of paper, with a felt between each, has been placed in the pile called a "post," it is taken to the press, and a great quantity of the water is pressed out, leaving the sheets of paper sufficiently dry to be handled by the "layer," who places them in packs, one sheet above the other, and after being parted sheet from sheet they are re-pressed. After this the paper is hung in a drying loft on cow-hair ropes in spurs of three to five sheets thick until dry. It is then sized by passing the spurs through a strong solution of gelatin contained in a long trough. The paper passes along on an endless felt, and is freed from superfluous size by press rolls at the end of the trough. It is then parted again to prevent the sheets from sticking together, and is again dried at a temperature of 70° to 80° Fahr. After being picked and then glazed between plates, it is sorted and finished in the same way as other paper, but with much greater care.

It will readily be understood that the expense of manufacturing paper in this way is very much greater than by machinery; but the gain in strength, partly owing to the time allowed to the fibres to knit together, and partly to the free expansion permitted them in drying, still maintains a steady demand for this class of paper, and probably 60 to 70 tons per week are made in Great Britain at present.

In America, papers of great strength are manufactured by machinery, and not much hand-made paper is made.

Manufacture from other Substances than Rags.—Although the better varieties of both writing and printing paper are still manufactured from rags, the supply of these has been found altogether insufficient to supply the increasing demand for paper, and other fibres have to a great extent been substituted for the cheaper classes of paper. First among these is ESPARTO (*q.v.*).¹ The treatment of esparto does not greatly vary from that of rags. On arrival at the mill the grass is sorted; that is to say, it is spread out in bunches on a table with a wire gauze cover, and these are shaken to remove the dust, while the roots and weeds are removed by picking. This is technically known as dry picking. In some mills this process is done mechanically by aid of a duster, which removes dust and other heavy impurities from the esparto, but it must then be picked in the wet state after boiling. The boiling is done in the same way as rags, but with a larger proportion of caustic soda. Mr Thomas Routledge, the introducer of esparto, specifies 10 per cent. real caustic soda, but with improved forms of boilers such as Roeckner's or Sinclair's, operating at 40 to 50 lb pressure, a considerable saving on this amount of alkali may be effected. The subsequent treatment of esparto is similar to that for rags; it is again "wet-picked" after boiling, then washed and bleached, a much larger quantity of chloride of lime being required than in the case of rags. It can be treated either alone or mixed with rags, and forms a very mellow bulky paper admirably adapted for printing purposes.

A considerable quantity of straw is used both in Britain and in America for paper-making. In general it is mixed either with rags or with esparto, being of too brittle a nature when bleached to make into paper alone. It is generally dusted after arrival at the mill, in many cases cut into chaff before the boiling operation, so as to allow the soda freer access to the fibres, and boiled under high pressure with considerable quantities of caustic soda up to 15 per cent. of real caustic. It is then washed either separately or along with esparto, and bleached in the ordinary way. As at present treated, the yield averaging only 33 to 40 per cent., straw will not come into general use, except in cases where the raw material can be bought on unusually advantageous terms. There is no doubt that, in this case especially, a more rational method of extracting the cellulose than by boiling under high pressure with a large amount of caustic soda is most desirable, for, many of the fibres of the straw being extremely fine, these are to a considerable extent actually dissolved by the soda, and, whereas theoretically straw with 15 per cent. moisture ought to produce 45 per cent. cellulose, by the soda treatment not more than 33 per cent. are obtained, where a good white colour is desired.

The only other fibre which has seriously threatened to compete with rags or esparto is wood. From the fact that the supply of this raw material is apparently inexhaustible, a great deal of attention has been paid to methods for reducing it to a fibre capable of being made into paper. These divide themselves into two—(1) mechanical and (2) chemical treatment. (1) The wood generally selected for this purpose is white pine or poplar. It is cut into slabs of convenient size, which are then pressed against the face of a mill-stone revolving at a high speed, while a flow of water conveys the fibres of wood away as they are separated. They are then sieved according to fineness, collected, and pressed into pulp or half stuff, which is used for admixture in inferior papers, or even, in some cases, for making paper. By

¹ The imports, which in 1863 amounted to 18,000 tons, had risen to 100,000 tons in 1870, and in 1883 reached 206,000 tons.

this means of treatment, however, the wood is not split up into its ultimate fibres, but is left with all the incrusting matter attached, and the pulp and paper so obtained are only fitted for the commonest purposes. (2) Many efforts have been made with the view of preparing wood chemically, so that the resulting fibre might be introduced into fine papers, and latterly with considerable success. In the earlier processes, patented by Houghton and Sinclair, wood was boiled with about 20 per cent. real caustic soda under a pressure of from 10 to 14 atmospheres. By this means, with certain improvements in detail, dictated by experience, so-called chemical wood pulp is prepared in large quantities on the Continent, and is imported as pulp into England to a considerable extent. In America this process has been extensively adopted. While pulp of very fair quality is prepared in this way suitable for papers where a perfectly white colour is not required, there is no room for doubt that the action of the caustic soda solution at the extreme temperature which a pressure of upwards of 10 atmospheres involves, leads to a certain extent to a degradation and consequent weakening and browning of the fibres, and a great deal of work has been directed to the surmounting of this difficulty. The result has been a series of patents, all containing the same principle, namely, the treating the wood with a chemical agent which should prevent oxidation and subsequent degradation of the fibres from taking place. Such patents are those of Mitscherlich and Francke (bisulphite of lime), Ekman and Graham (bisulphite of magnesia). While these all contain a common principle, they differ in detail, as to pressure, blowing off of the sulphurous acid gas, &c., but they all present a very marked resemblance

to Tilghmann's expired patent, 1866, No. 2924. The pulp produced by all those processes is of excellent quality; and, according to the statements of the patentees, it can be prepared at a cost greatly lower than by the soda process. The strength of the fibre is maintained unimpaired even after bleaching, and white paper made solely from such pulp is in every respect superior to that manufactured solely from pulp prepared by boiling with caustic soda.

Dr Mitscherlich's process has been extensively adopted in Germany, and there seems little doubt that these processes will in time supplant the use of soda in the case of wood. The great objection to them all is that, as they all depend on the use of bisulphite, which, being an acid salt, cannot be worked in an iron boiler, the boiler must be lined with lead; and great difficulty has been encountered in keeping the lead lining of the boiler in repair. This is a difficulty, however, which will probably be overcome with further experience. The objection to cellulose

prepared from wood by all the acid processes is that it is not pure, but a considerable quantity of incrusting matter is left in the fibre, and hence the paper manufactured from it solely is harsh in character and very transparent; to procure a pure cellulose, it must be exhausted in an alkaline solution subsequent to the treatment with acid.

The waste of *jute* is largely used in the manufacture of coloured papers, but it has not hitherto been found possible to thoroughly bleach this fibre without at the same time destroying its strength.

A long series of experiments, with a view to the introduction of *bamboo* fibre for paper making, has been undertaken by Mr Thomas Routledge, the well-known introducer of esparto, who recommends the employment of the young shoots. It may well be doubted whether the bamboo has any chance as a competitor against the new processes for preparing wood.

A host of other fibres have been tried from time to time, such as dis grass from the north coast of Africa, the leaves of the dwarf palm, sugar-cane refuse, the stalks of the hop plant, nettles, peat, *Phormium tenax* from New Zealand, with many others (see Dr Hugo Müller's *Pflanzenfaser*), but none with such success as to call for notice here.

Soda Recovery.—In the preparation of esparto, wood, and other raw material for manufacture into

FIG. 14.—Porion Evaporator.

paper, large quantities of caustic soda are employed, and, as the resulting liquid after boiling the fibre in caustic soda solution is strongly alkaline and dark-coloured, it is very desirable to keep it out of the rivers. In order to effect this it is in many mills evaporated, and the soda it contains recovered, and, after causticizing, re-used. Many forms of evaporator have been proposed, and of late years great improvement has been made in their construction. Probably the best form is the Porion evaporator (fig. 14). This consists of an evaporating chamber A, on the floor of which a few inches of the liquid to be evaporated rest. By the action of fanners B, B revolving at a high speed and dipping into the liquid, it is thrown up in a fine spray through which the heated gases pass to the chimney. After being concentrated in the evaporating chamber the liquid flows into the incinerating furnaces C, C, where the remaining water is driven off by the heat of the fire D, and the mass afterwards ignited to drive off the carbonaceous matter. A considerable feature in this evaporator is Menzies and Davis's patent smell chamber E, a chamber filled with masonry in which the strongly-smelling gases from the incinerating furnace are allowed to remain at a red heat for a short time. After being recovered, the soda, in the form of crude carbonate, is lixiviated and re-causticized by boiling with milk of lime.

Sizes of Paper.—The following are the ordinary sizes:—

| Writing Papers. | | Book and Drawing Papers. | | Printing Papers. | | Cartridge Papers. | |
|-------------------------|-----------|--------------------------|-----------|----------------------|-----------|-------------------|-----------|
| | Ins. | | Ins. | | Ins. | | Ins. |
| Pott..... | 12½ × 15 | Foolscap..... | 14 × 18½ | Crown..... | 16½ × 21 | Foolscap..... | 14 × 18½ |
| Double pott..... | 15 × 25 | Demy..... | 15½ × 20 | Demy..... | 17½ × 22½ | Demy..... | 17½ × 22½ |
| Foolscap..... | 13½ × 16½ | Medium..... | 17½ × 22½ | Medium..... | 18½ × 23 | Royal..... | 19 × 24 |
| Double foolscap..... | 16½ × 26½ | Royal..... | 19 × 24 | Royal..... | 20 × 25 | Super royal..... | 19½ × 27½ |
| Foolscap and third..... | 13½ × 22 | Super royal..... | 19½ × 27 | Super royal..... | 21 × 27 | Imperial..... | 21 × 26 |

American Paper Trade.—At the end of 1882 there were in the United States 1051 paper mills (1004 the previous year). Of this number 1018 are in active operation. These mills are owned and worked by 823 firms or establishments, an increase of 23 over the previous year. Twenty-three mills were abandoned during 1882, while 17 were destroyed by fire; 36 were in course of construction, and 68 new mills went into full work during 1882. This number is composed of a few mills reconstructed after fire, and 39 new establishments erected during 1882. The mills represent almost every variety of paper and pulp, and have an estimated daily capacity of 300 tons. Altogether there were in 1883 44 more mills in operation than in 1882. At the beginning of 1884 36 new mills

were being constructed and may be expected to be at work during the year. Every variety of paper is extensively manufactured in the United States with the exception of hand-made, but of late years attention has been devoted to this also, English plant and labour having been imported for the purpose, and hand-made papers are now regularly produced in small quantities.

PAPER HANGINGS. See MURAL DECORATION, vol. xvii. p. 38.

PAPHLAGONIA, in ancient geography, was the name given to a province of Asia Minor, situated on the Euxine Sea, and adjoining Bithynia on the west and Pontus on the east, while towards the south it was separated from Galatia by a range of mountains which may be considered as a prolongation to the east of the Bithynian Olympus. According to Strabo, whose authority is generally followed upon this point, the river Parthenius formed the western limit of the region so-called, and it was bounded on the east by the much more important river Halys. Although the Paphlagonians play scarcely any part in history, they were one of the most ancient nations of Asia Minor, as their name appears in the Homeric catalogue of the allies of Priam during the Trojan War (*Il.*, ii. 851). They are afterwards mentioned by Herodotus among the races reduced to subjection by Croesus, and they sent an important contingent to the army of Xerxes in 480 B.C. They seem, however, to have enjoyed a state of at least semi-independence, as Xenophon speaks of them as being governed by a prince of their own, without any reference to the satraps of the neighbouring parts of Asia. The rugged and difficult nature of their country, which is described by Xenophon as containing fertile and beautiful plains, but traversed by lofty ranges of mountains, which could only be crossed by narrow and difficult passes, doubtless contributed to this result. At a later period Paphlagonia passed under the yoke of the Macedonian kings, and we find it after the death of Alexander the Great assigned, together with Cappadocia, to Eumenes. It continued, however, to be governed by native princes until it was absorbed by the encroaching power of the neighbouring kingdom of Pontus. The rulers of that dynasty became masters of the greater part of Paphlagonia as early as the reign of Mithradates III. (302–266 B.C.), but it was not till that of Pharnaces I. that the important city of Sinope fell into their hands (183 B.C.). From this time the whole province was incorporated with the kingdom of Pontus until the fall of the great Mithradates (65 B.C.). In the settlement of Asia

which followed that event, Pompey united the coast districts of Paphlagonia with the province of Bithynia, but left the interior of the country under one of the native princes, two or three of whom followed in succession until the dynasty became extinct and the whole country was incorporated in the Roman empire. All these petty native rulers appear to have borne the name or surname of Pylæmenes, as a token that they claimed descent from the chieftain of that name who figures in the *Iliad* as the leader of the Paphlagonians. Under the Roman empire Paphlagonia, with the greater part of Pontus, was united into one province with Bithynia, as we find to have been the case in the time of the younger Pliny; but the name was still retained by geographers, though its boundaries are not distinctly defined by Ptolemy. It reappears as a separate province in the 5th century (Hierocles, *Synecd.* c. 33).

The ethnic relations of the Paphlagonians are very uncertain. It seems perhaps most probable that they belonged to the same race with the Cappadocians, who held the adjoining province of Pontus, and who were undoubtedly a Semitic race. Their language, however, would appear from the testimony of Strabo to have been distinct from that of their neighbours. Equally obscure is the relation between the Paphlagonians and the Eneti, or Heneti, who are mentioned in connexion with them in the Homeric catalogue, and who were supposed in the mythical fictions of antiquity to be the ancestors of the Veneti, who dwelt at the head of the Adriatic. But no trace is found in historical times of any tribe of that name in Asia Minor.

The greater part of Paphlagonia is a rugged and mountainous country, but it contains fertile valleys, and produces great abundance of fruit. The mountains also are clothed with dense forests, which are conspicuous for the quantity of boxwood which they furnish. Hence its coasts were from an early period occupied by Greek colonies, among which the flourishing city of Sinope, a colony from Miletus, founded about 630 B.C., stood prominent. Amastris, a few miles east of the Parthenius,

became an important town under the Macedonian monarchs; while Amisus, a colony of Sinope, which was situated a short distance east of the Halys, and therefore did not fall strictly within the limits of Paphlagonia as defined by Strabo, though often considered as belonging to that province, rose to be almost a rival of its parent city. The other towns along the coast of the Euxine were of little consequence, and none of those in the interior ever rose to any importance. The most considerable were Gangra, in ancient times the capital of the Paphlagonian kings, afterwards called Germanicopolis, and situated near the frontier of Galatia, and Pompeiopolis, in the valley of the Amnias (a tributary of the Halys), near which were extensive mines of the mineral called by Strabo sandarake (red arsenic), which was largely exported from Sinope. (E. H. R.)

PAPHOS, the name of two cities near the west coast of Cyprus. Old Paphos was on the river Bocarus, about 10 stadia from the coast, near the promontory Zephyrium; it had a harbour at the mouth of the river. The city was distinguished by a temple of Aphrodite, to which an oracle was attached; the priest exercised a sort of hieratic supremacy over the whole island. Paphos was the favourite city of Aphrodite, who is often styled the Paphian goddess. The grave of Aphrodite was shown in the city, and her image in the temple was a conical stone. There is no doubt that both the city and the cultus were of Phœnician origin. Apollodorus says that the Syrian king Cinyras was the founder. The place was subject to earthquakes; it was totally destroyed by a shock in the time of Augustus, and, being restored by that emperor, took the name Augusta or Σεβαστή, which, however, did not displace the old name. New Paphos was situated in a fertile plain, about 10 miles inland from Old Paphos. There was a great festal procession from it every year to the temple of Aphrodite in the old city. It was a flourishing commercial place in the time of Strabo.

PAPIAS, bishop of the Phrygian Hierapolis in the first half of the 2d century, is mentioned by Irenæus as "an ancient man," "the hearer of John and the companion of Polycarp." According to the *Chronicon Pascale*, Papias suffered martyrdom at Pergamum in the year of that of Polycarp at Smyrna (163 A.D., or, according to other reckonings, 156). His name figures largely in Biblical criticism in connexion with his work entitled *λογίων κυριακῶν ἐξηγήσεις*, of which only a few small fragments have been preserved in the form of citations in the writings of Irenæus, Eusebius, and later authors. See GOSPELS, vol. x. p. 815 sq.

The fragments are collected in Routh's *Reliq. Sacr.* (vol. i., 1846), and in Gebhard and Harnack's *Patr. Apost. Opera*.

PAPIER MÂCHÉ (mashed or pulped paper) is a term embracing numerous manufactures in which paper pulp is employed, pressed and moulded into various forms other than uniform sheets, such as ordinary paper and millboards. In the East the art has long been practised, especially in Kashmir, where, under the name of *kar-i-kalamdani*, or pen-tray work, the manufacture of small painted boxes, trays, and cases of papier mâché is a characteristic industry. About the middle of the 18th century papier mâché work came into prominence in Europe in the form of trays, boxes, and other small domestic articles, japanned and ornamented in imitation of Oriental manufactures of the same class; and contemporaneously papier mâché snuff boxes ornamented in vernis Martin came into favour. In 1772 Henry Clay of Birmingham secured a patent for a method of preparing this material, which he used for coach-building, for door and other panels, and for many furniture and structural purposes. In 1845 the application of the material to internal architectural decoration was patented by C. F. Bielefeld

of London, and for this purpose it has come into extensive use. Under the name of carton pierre, a substance which is essentially papier mâché is also largely employed as a substitute for plaster in the moulded ornaments of roofs and walls, and the ordinary roofing felts, too, are very closely allied in their composition to papier mâché. Under the name of ceramic papier mâché, architectural enrichments are also made of a composition patented by Mr Martin, the constituents of which are paper pulp, resin, glue, a drying oil, and acetate of lead. Among the other articles for which the substance is used may be enumerated masks, dolls' heads and other toys, anatomical and botanical models, artists' lay figures, milliners' and clothiers' blocks, mirror and picture frames, tubes, &c.

The materials for the commoner classes of work are old waste and scrap paper, repulped, and mixed with a strong size of glue and paste. To this very often are added large quantities of ground chalk, clay, and fine sand, so that the preparation is little more than a plaster held together by the fibrous pulp. For the finest class of work Clay's original method is retained. It consists of soaking several sheets of a specially made paper in a strong size of paste and glue, pasting these together, and pressing them in the mould of the article to be made. The moulded mass is dried in a stove, and, if necessary, further similar layers of paper are added, till the required thickness is attained. The dried object is hardened by dipping in oil, after which it is variously trimmed and prepared for japanning and ornamentation. For very delicate relief ornaments, a pulp of scrap paper is prepared, which after drying is ground to powder mixed with paste and a proportion of potash, all of which are thoroughly incorporated into a fine smooth stiff paste. The numerous processes by which surface decoration is applied to papier mâché differ in no way from the application of like ornamentation to other surfaces. Papier mâché for its weight is an exceedingly tough, strong, durable substance, possessed of some elasticity, little subject to warp or fracture, and unaffected by damp.

PAPIN, DENIS (1647–c.1712), French physicist, and one of the inventors of the steam-engine, was a native of Blois, where he was born in 1647. In 1661 or 1662 he entered upon the study of medicine at the university of Angers, where he graduated in 1669, with the intention apparently of settling as a practising physician in that city. Some time prior to 1674 he removed to Paris and assisted Huygens in his experiments with the air-pump, the results of which (*Expériences du Vuide*) were published at Paris in that year, and also in the form of five papers by Huygens and Papin jointly, in the *Philosophical Transactions* for 1675. Shortly after the publication of the *Expériences*, Papin, who had crossed to London hoping to find some congenial employment, was hospitably received by Boyle, and gave him some assistance in his laboratory and with his writings; about this time also he introduced into the air-pump the improvement of making it with double barrels, and replacing by the two valves the turn-cock hitherto used. He is said, moreover, to have been the first to use the plate and receiver, which are organs of capital importance in the modern form of the instrument. Subsequently he invented the condensing-pump, and in 1680 he was admitted, on Boyle's nomination, to the Royal Society. In the following year he communicated to the Society an account of his famous steam "digester, or engine for softening bones," afterwards described in a tract published at Paris, and entitled *La manière d'an illir les os et de faire cuire toutes sortes de viandes en fort peu de tems et à peu de frais, avec une description de la machine, ses propriétés et ses usages*. In this instrument the principle of the safety-valve was applied for the first time. After some further experiments with the digester he accepted an invitation to Venice to take part in the work of the recently founded Academy of the Philosophical and Mathematical Sciences; here he remained until 1684, when he returned to London and received from the Royal Society an appointment as "temporary curator of experiments," with a small salary. In this capacity he carried

on numerous and varied investigations, in the course of which he discovered a siphon acting in the same manner as the "Sipho Wirtembergicus" (*Phil. Tr.*, 1685), and also constructed a model of an engine for raising water from a river by means of pumps worked by a water-wheel driven by the current. In November 1687 he was appointed to the chair of mathematics in the university of Marburg, and here he remained until 1696, when he removed to Cassel. From the time of his settlement in Germany he carried on an active correspondence with Huygens and Leibnitz, which is still preserved, and in one of his letters to Leibnitz, in 1698, he mentions that he is engaged on a machine for raising water to a great height by the force of fire; in a later communication he speaks also of a little carriage he had constructed to be propelled by this force. Again in 1702 he wrote about a steam "ballista," which he anticipated would "promptly compel France to make an enduring peace." In 1705 Leibnitz sent Papin a sketch of Savery's engine for raising water, and this stimulated him to further exertions, which resulted two years afterwards in the publication of the *Ars nova ad aquam ignis adminiculo efficacissime elevandam* (Cassel, 1707), in which his high-pressure boiler and its applications are described (see STEAM-ENGINE). In 1707 he resolved to quit Cassel for London, and on September 24th of that year he sailed with his family from Cassel in an ingeniously constructed boat, propelled by paddle-wheels, to be worked by the crew, with which he apparently expected to reach the mouth of the Weser. The expedition, however, came to an ignominious end at Münden, where the vessel was confiscated at the instance of the boatmen, who objected to the invasion of their exclusive privileges in the Weser navigation. Papin, on his subsequent arrival in London, found himself without resources and almost without friends; various applications through Sleane to the Royal Society for grants of money were made in vain, and he died in total obscurity, probably about the beginning of 1712.

¹ The published writings of Papin, besides those already referred to, consist for the most part of a large number of papers, principally on hydraulics and pneumatics, contributed to the *Journal des Savans*, the *Nouvelles de la Republique des Lettres*, the *Philosophical Transactions*, and the *Acta Eruditorum*; many of them were collected by himself into a *Fasciculus dissertationum* (Marburg, 1695), of which he published also a translation into French (*Recueil de diverses piéces touchant quelques nouvelles machines* (Cassel, 1695)). His correspondence with Leibnitz and Huygens, along with a biography, has been published by Dr Ernst Gerland (*Leibniz's und Huygens' Briefwechsel mit Papin, nebst der Biographie Papin's*, Berlin, 1881).

PAPINIAN, the most celebrated of Roman jurists, was *magister libellorum* and afterwards prætorian prefect under Septimius Severus. He was an intimate friend of the emperor, whom he accompanied to Britain, and before his death Severus specially commended his two sons to his charge. Papinian was faithful to his trust, and tried to keep peace between the brothers, but with no better result than to excite the hatred of Caracalla, to which he fell a victim in the general slaughter of Geta's friends which followed the fratricide of 212 A.D. The details are variously related, and have undergone legendary embellishment, but it is certain that the murder of Papinian, which took place under Caracalla's own eyes, was one of the most disgraceful crimes of that hideous tyrant. Little more is known about Papinian. He was perhaps a Syrian by birth, for he is said to have been a kinsman of Severus's second wife, Julia Domna; that he studied law along with Severus under Scaevola is asserted in an interpolated passage in Spartian (*Caracal.*, c. 8). Papinian's place and work as a jurist will fall to be discussed under ROMAN LAW (*q.v.*).

PAPPENHEIM, GOTTFRIED HEINRICH, GRAF ZU

(1524-1632), imperialist general in the Thirty Years War, was born on the 29th May 1594. He attended the high schools of Altdorf and Tübingen, but did not seem to profit much by the instruction he received at either institution. In his twentieth year he joined the Roman Catholic Church; and zeal for his new faith induced him to enter the military service of King Sigismund in Poland and afterwards that of Maximilian, duke of Bavaria, head of the Catholic League. In 1620, as a colonel in the army of the League, he distinguished himself in the battle near Prague which decided the fate of Frederick, king of Bohemia. In this battle, after fighting with extraordinary energy, he was severely wounded, and for many hours lay unnoticed under his horse. He received, in 1623, the command of a regiment of cuirassiers who became famous as the Pappenheimer, and with them he fought from 1623 to 1625 at the head of the Spaniards in Lombardy. In 1626, having been recalled to Germany by Duke Maximilian, he crushed an insurrection of peasants in Upper Austria, obtaining in the course of a month a series of victories in which 40,000 peasants are said to have been killed. He then went to the help of Tilly against Christian IV. of Denmark, and took a prominent part in the storming of Magdeburg, the inhabitants of which were treated by him and by his soldiers with savage cruelty. After the battle of Breitenfeld, which was fought at an unsuitable time, contrary to the wish of Tilly, in consequence of Pappenheim's impetuosity, he covered the retreat of the imperialists; and in Westphalia and the country of the lower Rhine he stimulated the enthusiasm of his party by several successful engagements. When Tilly died, Pappenheim aided Wallenstein in subduing Saxony. On his way to the lower Rhine, where he proposed to support the Spaniards, he was summoned by Wallenstein to Lützen, where battle was about to be given to Gustavus Adolphus; and at the moment of his arrival fortune seemed already to have declared for the Swedes. Pappenheim threw himself into the conflict, and his attack was so furious that the enemy began to give way; but two musket balls penetrated his breast, and he had to be carried from the field. He died on the 17th November 1632, the day after the battle. He left behind him the reputation of one of the bravest warriors and most ardent Catholics of his day. Notwithstanding the sternness of his discipline, he was idolized by his troops.

See Hess, *Gottfried Heinrich, Graf zu Pappenheim*, 1855.

PAPPUS, OF ALEXANDRIA, a geometer of a very high order, belongs to a time when already the Greek mathematicians of great original genius had been succeeded and replaced by a race of learned compilers and commentators, who confined their investigations within the limits previously attained, without adding anything to the development of mathematics. To the general mediocrity Pappus must be considered to be a remarkable exception; for, although much even of his work is of the nature of compilation (which is, however, itself of great historical value), there is yet much the discovery of which cannot well be attributed to any one else. According to Proclus, he was at the head of a school; but how far he was above his contemporaries, how little appreciated or understood by them, is shown by the absence of references to him in other Greek writers, and by the fact that his work had no effect in arresting the decay of mathematical science. In this respect the fate of Pappus strikingly resembles that of Diophantus, another living power amid general stagnation. In reading the *Collection* of Pappus, we meet with no indication of the date of the authors whose treatises he makes use of, or of the time at which he himself wrote. If we had no other information than can be derived from a perusal of his work, we should

only know that he was later than Claudius Ptolemy, whom he quotes often and with respect. Suidas states that he was of the same age as Theon of Alexandria, who wrote commentaries on Ptolemy's great work, the *Almagest*, and flourished in the reign of Theodosius I. (379–395 A.D.). Suidas asserts also that Pappus wrote a commentary upon the same work of Ptolemy. But it would seem incredible that two contemporaries should have at the same time and in the same style composed commentaries upon one and the same work, and yet neither should have been mentioned by the other, whether as friend or opponent. We have apparently no reason to question the statement of Suidas that Pappus wrote such a commentary. But the similarity of two such commentaries as those of Pappus and Theon may easily have led Suidas to confuse the two, and so suppose the two authors to have been contemporary. There is, then, reason to believe that Suidas may have been mistaken; we have, however, another authority, whose statement, on the supposition that it is false, is completely incomprehensible. This is the author of certain historical glosses, which are found in the margin of a MS. belonging to the beginning of the 10th century. Here it is stated, in connexion with the reign of Diocletian (284–305 A.D.), that Pappus wrote during that period. Except the two distinctly contradictory statements of Suidas and the scholiast, we have no evidence of the date of Pappus; and it seems accordingly best to accept the date indicated by the scholiast.

The work of Pappus which has come down to us bore the title *συναγωγή* or *Collection*, as we gather from references in the work itself, and from the scholia appended to the Vatican MS. 218 of the 12th century. This collection, which consisted of eight books, we possess only in an incomplete form, there being no part remaining of the first book, and the rest also having suffered considerably. It is curious that no ancient writer, with the exception of the author of the appendix to book iii., quotes the work under its proper title, though Eutocius's reference (Archimedes, p. 139 sq., ed. Torelli), ὡς Πάππος ἐν μηχανικαῖς εἰσαγωγαῖς, is no doubt to book viii. of the *Collection*.

Suidas enumerates other works of Pappus as follows:—*χωρογραφία οἰκουμένης, εἰς τὰ τέσσαρα βιβλία τῆς Πτολεμαίου μεγάλης συντάξεως ὑπόμνημα, ποταμούς τοὺς ἐν Λιβύῃ, ὄνειροκριτικά*. The question of Pappus's commentary on Ptolemy's work is discussed by Hultsch, *Pappi Collectio* (Berlin, 1878), vol. iii. p. xiii. sq. Pappus himself refers to another commentary of his own on the *ἀνάλημμα* of Diodorus, of whom nothing is known. There are, moreover, indications that he commented on Euclid's *Elements*, and on Ptolemy's *ἁρμονικά*. Further, there is a doubtful work entitled *Opusculum de multiplicatione et divisione sexagesimalibus Diophanto vel Pappo tribuendum*, which has been edited by C. Henry (Halle, 1879); and, lastly, a tract, *Anonymi commentarius de figuris planis iso-perimetris*, has been inserted by Hultsch in vol. iii. of his edition of Pappus.

The characteristics of Pappus's *Collection* are that it contains an account, systematically arranged, of the most important results obtained by his predecessors, and, secondly, notes explanatory of, or extending, previous discoveries. These discoveries form, in fact, a text upon which Pappus enlarges discursively, many of his additions having no very decided points of connexion with the direct subject under discussion. Very valuable are the systematic introductions to the various books which set forth clearly in outline the contents and the general scope of the subjects to be treated. From these introductions we are able to judge of the style of Pappus's writing, which is excellent and even elegant the moment he is free from the shackles of

mathematical formulæ and expressions. At the same time, his characteristic exactness makes his collection a most admirable substitute for the texts of the many valuable treatises of earlier mathematicians of which time has deprived us.

We proceed to summarize briefly the contents of that portion of the *Collection* which has survived, mentioning separately certain propositions which seem, in the light of modern developments of mathematics, to be among the most important.

Of book i. the whole has been lost. We can only conjecture that it, as well as book ii., was concerned with arithmetic, book iii. being clearly introduced as beginning a new subject.

The whole of book ii. (the former part of which is lost, the existing fragment beginning in the middle of the 14th proposition) related to a system of multiplication due to Apollonius of Perga. On this subject see Nesselmann, *Algebra der Griechen*, Berlin, 1842, pp. 125–134; and Friedlein, *Die Zahlzeichen und das elementare Rechnen der Griechen und Römer*, Erlangen, 1869.

Book iii. contains geometrical problems, plane and solid. It may be divided into five sections. (1) On the famous problem of finding two mean proportionals between two given lines, which arose from that of doubling the cube, reduced by Hippocrates to the former. Pappus gives the solutions of this problem by Eratosthenes, Nicomedes, and Heron, and finally his own solution of the more general problem of finding geometrically the side of a cube whose content is in any given ratio to that of a given one. (2) On the three different means between two straight lines, the arithmetic, the geometric, and the harmonic, and the problem of representing all three in one and the same geometrical figure. This serves as an introduction to a general theory of means, of which Pappus distinguishes ten kinds, and gives a table representing examples of each in whole numbers. (3) On a curious problem of the same type as Eucl. i. 21. (4) On the inscribing of each of the five regular polyhedra in a sphere. (5) An addition by a later writer on another solution of the first problem of the book.

Of book iv. the title and preface have been lost, so that the programme has to be gathered from the book itself. At the beginning are various theorems on the circle, leading up to the problem of the construction of a circle which shall circumscribe three given circles touching each other two and two. This and several other problems of contact form the first division of the book. Pappus turns then to a consideration of certain properties of Archimedes's spiral, the conchoid of Nicomedes (already mentioned in book i. as supplying a method of doubling the cube), and the curve discovered most probably by Hippias of Elis about 420 B.C., and known by the name *ἡ τετραγωνίζουσα*, or quadratrix, from the property that, if it could be practically constructed, it would enable us to square the circle. Having described the ordinary—the mechanical, as Pappus calls it—definition of this curve, he proceeds to show how it might be constructed by projecting orthogonally suitable plane sections of certain surfaces which he calls *plectoids* described by means of (a) the helix described on a cylinder, (b) the plane helix, or Archimedes's spiral. From these propositions it would seem that *plectoid* was the Greek general term for surfaces described by the motion of a straight line always passing through a fixed straight line and a curve, and remaining parallel to a fixed plane. Proposition 30 describes the construction of a curve of double curvature called by Pappus the helix on a sphere; it is described by a point moving uniformly along the arc of a great circle, which itself turns about its diameter uniformly, the point describing a quadrant and the great circle a complete revolution in the same time. The area of the surface included between this curve and its base is found—the first instance of quadrature of a curved surface. The rest of the book treats of the trisection of an angle, and the solution of certain problems by means of the quadratrix and spiral.

In book v., after an interesting preface concerning regular polygons, and containing some remarks upon the hexagonal form of the cells of honeycombs, Pappus addresses himself to the comparison of the areas of different plane figures which have all the same perimeter (following Zenodorus's treatise on this subject), and of the volumes of different solid figures which have all the same superficial area, and, lastly, a comparison of the five regular solids of Plato.

According to the preface, book vi. is intended to resolve difficulties occurring in the so called *μικρὰ ἀστρονομία*. It accordingly comments on the *Sphærica* of Theodosius, a treatise of Autolycus, Theodosius's book on *Day and Night*, the treatise of Aristarchus *On the Size and Distances of the Sun and Moon*, and Euclid's *Optics* and *Phænomena*.

The preface of book vii. explains the terms analysis and synthesis, and the distinction between theorem and problem. Pappus then enumerates works of Euclid, Apollonius, Aristæus,

and Eratosthenes, thirty-three books in all, the substance of which he intends to give, with the lemmas necessary for their elucidation. With the mention of the *Porisms* of Euclid we have an account of the relation of porism to theorem and problem. In the same preface we have enunciated (a) the famous problem known by Pappus's name—*Having given a number of straight lines, to find the geometric locus of a point such that the lengths of the perpendiculars upon, or (more generally) the lines drawn from it obliquely at given inclinations to, the given lines satisfy the condition that the product of certain of them may bear a constant ratio to the product of the remaining ones*; (b) the theorems which since the 17th century have been called by the name of Guldin, but appear to have been discovered by Pappus himself. Book vii. contains also (1) under the head of the *de determinata sectione* of Apollonius, lemmas which, closely examined, are seen to be cases of the involution of six points; (2) important lemmas on the *Porisms* of Euclid (see *Porism*); (3) a lemma upon the *Conics* of Apollonius, which is the first statement of the constant relation between the distances of any point on a conic from the focus and directrix.

Lastly, book viii. treats principally of mechanics, the properties of the centre of gravity, and some mechanical powers. Interspersed are some questions of pure geometry. Proposition 14 gives a simple construction for the axes of an ellipse, when a pair of conjugate diameters are given.

Of the whole work of Pappus the best edition is that of Hultsch, bearing the title *Pappi Alexandrini Collectionis quæ supersunt a libris manuscriptis editæ Latina interpretatione et commentariis instruxit Fridericus Hultsch*, Berlin, 1876-78. Previously the entire collection had been published only in a Latin translation, *Pappi Alexandrini mathematicæ collectiones a Federico Commandino Urbinate in latinum conversæ et commentariis illustratæ*, Pesaro, 1559 (reprinted at Venice, 1599, and Pesaro, 1602). A second edition of this work was published by Carolus Manchesius, entitled *Pappi Alexandrini mathematicæ collectiones a Federico Commandino Urbinate in latinum conversæ et commentariis illustratæ*, in hac nostra editione innumeris quibus scatebant mendis et præcipue in Græco contextu diligenter vindicatæ, Bolognæ, 1660. The merits of these two works are discussed by Hultsch, who remarks that the editor of the second edition, so far from making good the title and his boastful preface, has actually much marred the original book.

Of books which contain parts of Pappus's work, or treat incidentally of it, we may mention the following titles:—(1) *Pappi Alexandrini collectiones mathematicæ nunc primum Græce editæ* Herm. Jos. Eisenmann, *Libri quinti pars altera*, Pörlsle, 1824. (2) *Pappi Alexandrini Secundi Libri Mathematicæ Collectionis Fragmentum e codice MS. editum Latine fecit Notisque illustravit Johannes Walits*, Oxoniæ, 1688. (3) *Apollonii Pergæi de sectione rationis libri duo ex Arabico MS. latine versi, Accedunt eiusdem de sectione spatii libri duo restituti, Præmittitur Pappi Alexandrini præfatio ad VII. collectionis mathematicæ, nunc primum Græce editæ: cum lemmatibus eiusdem Pappi ad hos Apollonii libros, Opera et studio Edmundi Halley*, Oxoniæ, 1706. (4) *Apollonii Pergæi conicorum libri IV. priores cum Pappi Alexandrini lemmatibus ex codic. MSS. Græcis editis Edmundus Halleus*, Oxoniæ, 1710. (5) *Der Sammlung des Pappus von Alexandrien siebentes und achttes Buch griechisch und deutsch herausgegeben von C. I. Gerhardt*, Halle, 1871. (C. L. II.)

PAPUAN LANGUAGES. The languages spoken in NEW GUINEA (*q.v.*) and other islands peopled by Papuas differ more widely from the Malayo-Polynesian languages than those of the Negritos in the Philippine Islands do from the dialects of the contiguous Malayan tribes. In fact, they form as separate a class by themselves as the Melanesian languages do as contradistinguished from the Polynesian group. From the meagre grammatical sketch of the Mafor (or Nufor) language—the only one to which the Dutch missionaries have paid some attention, but which may be taken as a type of the class—we gather that the verb has the subject pronoun prefixed in the singular, dual, and plural; past time is expressed by the word *kwār*, “already,” prefixed, and futurity by *nerri*, “still,” added to the verb; certain modifications of the sense are effected by *i* being prefixed, and others by *i* being affixed, to the radical vowels *a*, *o*, or *u*, and others again by the substantive affix *ia* (plur. *sia*). Much uncertainty, however, still prevails as to the precise import of those grammatical forms. See J. L. van Hasselt's *Woordenboek and Beknopte Spraakkunst der Noefoorsche taal*, both of which appeared at Utrecht in 1876; Fr. Müller's *Grundriss der Sprachwissenschaft*, i., ii. p. 30 *sq.*; and more especially G. von der Gabelentz and A. B. Meyer, *Beiträge zur Kenntnis der Melanesischen, Mikronesischen, und Papuanischen Sprachen*, Leipsic, 1882, and their essay, “Einiges über das Verhältniss des Mafoor zum Malayischen,” in *Bijdragen tot de taal-, land-, en volkenkunde van Nederlandsch-Indië*, for 1883. The former of these publications contains also a survey of the literature on the subject. Vocabularies of the languages spoken by the various coast tribes with whom Europeans have come in contact have been collected by S. Müller, Von Rosenberg, Miklucho

Maclay, and others. An intercomparison of those vocabularies not only shows great phonetical divergencies, especially in the liquids *r* and *l*, but also in many cases the same absence of word affinity in consequence of which neighbouring Melanesian tribes are known to be unable to understand one another.

PAPYRUS, the paper reed, the *Cyperus Papyrus* of Linnæus, was in ancient times widely cultivated in the Delta of Egypt, where it was used for various purposes, and especially as a writing material. As, however, the plant is now extinct in Lower Egypt, it is believed that it was not indigenous there, but was probably introduced from Nubia, where it is found at the present time, as well as in Abyssinia. Theophrastus (*Hist. Plant.*, iv. 10) adds that it likewise grew in Syria; and, according to Pliny, it was also a native plant of the Niger and Euphrates. From one of its ancient Egyptian names, *Papu*, was derived its Greek title *πάπυρος*, Lat. *papyrus*. By Herodotus it is always called *βύβλος*, a word which was apparently also of Egyptian origin. The first accurate description of the plant is given by Theophrastus, from whom we learn that it grew in shallows of 2 cubits (about 3 feet) or less, its main root being of the thickness of a man's wrist, and 10 cubits in length. From this root, which lay horizontally, smaller roots pushed down into the mud, and the stem of the plant sprang up to the height of 4 cubits, being triangular and tapering in form. The tufted head or umbel is likened by Pliny to a thyrus.

The various uses to which the papyrus plant was applied are also enumerated by Theophrastus. Of the head nothing could be made but garlands for the shrines of the gods; but the wood of the root was employed in the manufacture of different utensils as well as for fuel. Of the stem of the plant were made boats, sails, mats, cloth, cords, and, above all, writing material (*τὰ βύβλια*). The pith was also a common article of food, and was eaten both cooked and in its natural state. Herodotus too notices its consumption as food (ii. 92), and incidentally mentions that it provided the material of which the priests' sandals were made (ii. 37). He likewise refers to the use of byblus as tow for caulking the seams of ships; and the statement of Theophrastus that King Antigonus made the rigging of his fleet of the same material is illustrated by the ship's cable, *ἔπλον βύβλανον*, wherewith the doors were fastened when Ulysses slow the suitors in his hall (*Odyss.*, xxi. 390). That the plant was itself used also as the principal material in the construction of light skiffs suitable for the navigation of the pools and shallows of the Nile, and even of the river itself, is shown by sculptures of the period of the fourth dynasty, in which men are represented in the act of building a boat with stems cut from a neighbouring plantation of papyrus (Lepsius, *Denkm.*, ii. 12). It is to boats of this description that Isaiah probably refers in the “vessels of bulrushes upon the waters” (xviii. 2). If the Hebrew *gōmē* (גֹּמֶה) also is to be identified with the Egyptian papyrus, something may be said in favour of the tradition that the bulrushes

Papyrus.

of which the ark was composed in which the infant Moses was laid, in the flags by the river's brink, were in fact the latter plant. Ancient authors have likewise referred to the adaptation of the papyrus to other domestic purposes, both culinary and medicinal. But it seems hardly credible that the *Cyperus Papyrus* could alone have sufficed for the many uses to which it is said to have been applied. Wilkinson has pointed out (*Anc Egyptians*, ii. 121) that, the cultivation of this variety being limited to certain districts, where, moreover, it was a monopoly of the Government, it cannot have been employed for so many purposes and we may therefore conclude that several plants of the genus *Cyperus* were comprehended under the head of byblus or papyrus—an opinion which is supported by the words of Strabo, who mentions both inferior and superior qualities. The *Cyperus dives* is still grown in Egypt, and is used to this day for many of the purposes named by ancient writers.

The widespread use of papyrus as a writing material throughout the ancient world is attested by early writers, and by documents and sculptures. In addition to the names of the plant, which were also applied to the material, the latter was also known as *χάρτης*, *charta*. Papyrus rolls are represented in ancient Egyptian wall-paintings; and extant examples of the rolls themselves are sufficiently numerous. The most ancient of these, known, from the name of its former owner, as the Prisse papyrus, and now preserved at Paris, contains a work composed in the reign of a king of the fifth dynasty, and is computed to be itself of the age of upwards of 2000 years B.C. The papyri discovered in Egypt have generally been found in tombs, and in the hands, or swathed with the bodies, of mummies. The ritual of the dead, which in its entirety or in an abridged form was buried with every person of consequence from the eighteenth dynasty to the Roman period, is most frequently the subject. And, besides the ritual and religious rolls, there are the hieratic, civil and literary, documents, and the demotic and enchorial papyri, relating generally to sales of property. Coptic papyri usually contain Biblical or religious tracts or monastic deeds.

The early use of papyrus among the Greeks is proved by the reference of Herodotus (v. 58) to its introduction among the Ionians. An inscription of 407 B.C. records the sale of two sheets (*χάρται δύο*) at Athens, for two drachmas and four obols. Greek papyri have been found in Egypt of great importance both for their palæographical and literary worth. The first instalment which came to light, as late as the year 1778, consisted of some fifty rolls, which were discovered in the neighbourhood of Memphis; but all, with one single exception, were carelessly destroyed. More fortunate were the documents found near the Serapeum of Memphis, and connected with that temple; and further discoveries of valuable texts of Homer, Hyperides, and other classical writers have rewarded later searches (see PALEOGRAPHY). The numerous rolls found in the ruins of Herculaneum generally contain the less interesting works of writers of the Epicurean school.

Papyrus also made its way into Italy, but at how early a period there is nothing to show. Under the empire its use must have been extensive, for not only was it required for the production of books, but it was also universally employed for domestic purposes, correspondence, and legal documents. So indispensable did it become that it is reported that in the reign of Tiberius the scarcity and dearth of the material, caused by a failure of the papyrus crop, nearly brought on a riot (Pliny, *N. H.*, xiii. 13).

The account which Pliny (*N. H.*, xiii. 11–13) has transmitted to us of the manufacture of the writing material from the papyrus plant should be taken strictly to refer to the process followed in his own time: but, with some

differences in details, the same general method of treatment had doubtlessly been practised from time immemorial. His text, however, is so confused, both from obscurity of style and from corruptions in the MSS., that there is much difference of opinion as to the meaning of many words and phrases employed in his narrative, and their application in particular points of detail. In one important particular, however, affecting the primary construction of the material, there can no longer be any doubt. The old idea that it was made from layers or pellicules growing between the rind and a central stalk has been abandoned, as it has been proved that the plant, like other reeds, contains only a cellular pith within the rind. The stem was in fact cut into longitudinal strips for the purpose of being converted into the writing material, those from the centre of the plant being the broadest and most valuable. The strips (*philyræ*), which were cut with a sharp knife or some such instrument, were laid on a board side by side to the required width, thus forming a layer (*scheda*), across which another layer of shorter strips was laid at right angles. The two layers thus "woven"—Pliny uses the word *texere* in describing this part of the process—formed a sheet (*plagula*, or net), which was then soaked in water of the Nile. The mention of a particular water has caused trouble to the commentators. Some have supposed that certain chemical properties of which the Nile water was possessed acted as a glue or cement to cause the two layers to adhere; others, with more reason, that glutinous matter contained in the material itself was solved by the action of water, whether from the Nile or any other source; and others again read in Pliny's words an implication that a paste was actually used. Be this as it may, the sheet was finally pressed and dried in the sun. Any roughness was levelled by polishing with ivory or a smooth shell. But the material was also subject to other defects, such as moisture lurking between the layers, which might be detected by strokes of the mallet; spots or stains; and spongy strips (*tæniæ*), in which the ink would run and spoil the sheet. When such faults occurred, the papyrus must be re-made. To form a roll the sheets were joined together with paste (glue being too hard), but not more than twenty sheets in a roll (*scapus*). As, however, there are still extant rolls consisting of more than the prescribed number of sheets, either the reading of *vicenæ* is corrupt, or the number was not constant in all times. The best sheet formed the first or outside sheet of the roll, and the others were joined on in order of quality, so that the worst sheets were in the centre of the roll. This arrangement was adopted, not for the purpose of fraudulently selling bad material under cover of the better exterior, but in order that the outside of the roll should be composed of that which would best stand wear and tear. Besides, in case of the entire roll not being filled with the text, the unused and inferior sheets at the end could be better spared, and so might be cut off.

The different kinds of papyrus writing material and their dimensions are also enumerated by Pliny. The best quality, formed from the middle and broadest strips of the plant, was originally named *hieratica*, but afterwards, in flattery of the emperor Augustus, it was called, after him, *Augusta*; and the *charta Livia*, or second quality, was so named in honour of his wife. The *hieratica* thus descended to the third rank. The first two were 13 digiti, or about 9½ inches in width; the *hieratica*, 11 digiti or 8 inches. Next came the *charta amphitheatreica*, named after the principal place of its manufacture, the amphitheatre of Alexandria, of 9 digiti or 6½ inches wide. The *charta Fanniana* appears to have been a kind of papyrus worked up from the *amphitheatreica*, which by flattening and other methods was increased in width by an inch, in the factory of a certain Fannius at Rome. The *Sritica*, which took its name from the city of Sais, and was probably of 8 digiti or 5½ inches, was of a common description. The *Tantiotica*, named apparently from the place of its manufacture, a tongue of land (*ταύρια*) near Alexandria, was sold by weight, and was of

uncertain width, perhaps from 4½ to 5 inches. And lastly there was the common packing-paper, the *charta emporctica*, of 6 digiti or 4½ inches. Isidore (*Etymol.*, vi. 10) mentions yet another kind, the *Cornelianiana*, first made under C. Cornelius Gallus, prefect of Egypt, which, however, may have been the same as the *amphitheatrica* or *Fanniana*. The name of the man who had incurred the anger of Augustus may have been suppressed by the same influence that expunged the episode of Gallus from the Fourth Georgic (Birt, *Antik. Buchwesen*, p. 250). In the reign of the emperor Claudius also another kind was introduced and entitled *Claudia*. It had been found by experience that the *charta Augusta* was, from its fineness and porous nature, ill suited for literary use; it was accordingly reserved for correspondence only, and for other purposes was replaced by the new paper. The *charta Claudia* was made from a composition of the first and second qualities, the *Augusta* and the *Livia*, a layer of the former being backed with one of the latter; and the sheet was increased to nearly a foot in width. The largest of all, however, was the *macrocollon*, probably of good quality and equal to the hieratic, and a cubit or nearly 18 inches wide. It was used by Cicero (*Epp. ad Attic.*, xiii. 25; xvi. 3). The width, however, proved inconvenient, and the broad sheet was liable to injury by tearing.

An interesting question arises as to the accuracy of the different measurements given by Pliny. His figures regarding the width of the different kinds of papyrus have generally been understood to concern the width (or height) of the rolls, as distinguished from their length. It has, however, been observed that in practice the width of extant rolls does not tally in any satisfactory degree with Pliny's measurements; and a more plausible explanation has been lately offered (Birt, *Antik. Buchwesen*, pp. 251 sq.) that the breadth (not height) of the individual sheets of which the rolls are composed is referred to.

The first sheet of a roll was named *πρωτόκολλον*; the last, *ἔσχατοκόλλων*. Under the Romans, the former bore the name of the *comes largitionum*, who had control of the manufacture, with the date and name of place. It was the practice to cut away the portion thus marked; but in case of legal documents this mutilation was forbidden by the laws of Justinian. On the Arab conquest of Egypt in the 7th century, the manufacture was continued, with the substitution of Arabic in marking the protocol. An instance of one of these Arab signatures is preserved in a bull of Pope John VIII. of the year 876.

Varro's statement, repeated by Pliny, that papyrus was first made in Alexander's time, should probably be taken to mean that its manufacture, which till then had been a Government monopoly, was relieved from all restrictions. It is not probable, however, that it was ever manufactured from the native plant anywhere but in Egypt. At Rome there was certainly some kind of industry in papyrus, the *charta Fanniana*, already referred to, being an instance in illustration. But it seems probable that this industry was confined to the re-making of material imported into Italy, as in the case of the *charta Claudia*. This second manufacture, however, is thought to have been detrimental to the papyrus, as it would then have been in a dried condition requiring artificial aids, such as a more liberal use of gum or paste, in the process. The more brittle condition of the Latin papyrus found at Herculaneum has been instanced as the evil result of this re-making of the material.

According to Strabo the Romans obtained the papyrus plant from Lake Trasimene and other lakes of Etruria, but this statement is unsupported by any other authority and appears to have been made in error. At a later period, however, a papyrus was cultivated in Sicily, which has been identified by Parlatores with the Syrian variety (*Cyperus syriacus*), far exceeding in height the Egyptian plant, and having a more drooping head. It grew in the east and south of the island, where it was probably introduced during the Arab occupation. It was seen in the 10th century, by the Arab traveller Ibn-Haukal, in the neighbourhood of Palermo, where it thrived luxuriantly in the pools of the Papireto, a stream to which it lent its name. From it paper was made for the sultan's use. But in the 13th century it began to fail, and in 1591 the drying up of the Papireto caused the extinction of the plant in that district. It is still to be seen at Syracuse, but it was probably transplanted thither at a later time, and reared only as a curiosity, as there is no notice of it to be found previous to 1674. It is with this Syracusan plant that some attempts have been made in recent years to manufacture a writing material similar to ancient papyrus.

Even after the introduction of vellum, papyrus still continued in use among the Romans, and was not entirely superseded until a late date. It ceased, however, to be used for books sooner than for documents. In the 5th century St Augustine apologizes for sending a letter written on vellum instead of the more usual substance, papyrus (*Ep. xv.*); and Cassiodorus (*Varr.*, xi. 38), writing in the 6th century, indulges in a high-flown panegyric on the plant and its value, and refers to the abolition of the tax on paper by the emperor Theodoric. Of medieval Greek papyri a very few remains containing Biblical or patriotic matter have survived, and one or two fragments of Græco-Latin glossaries have been published. Of

Greek documents, apart from monastic deeds discovered in Egypt, there are two which are well known, viz., the fragmentary epistle of Constantine V. to Pepin le Bref, of 753 or 756, now preserved at Paris, and the papyrus containing the subscriptions to the council of Constantinople of 680, at Vienna. Mediæval Latin MSS. on papyrus in book form are still extant in different libraries of Europe, viz.:—the Homilies of St Avitus, of the 6th century, at Paris; Sermons and Epistles of St Augustine, of the 6th or 7th century, at Paris and Geneva; works of Hilary, of the 6th century, at Vienna; fragments of the Digests, of the 6th century, at Pommersfeld; the Antiquities of Josephus, of the 7th century, at Milan; Isidore, *De Contemptu Mundi*, of the 7th century, at St Gall; and the Register of the Church of Ravenna, of the 10th century, at Munich. Of Latin documents on papyrus (*tomus* was the technical word of the Middle Ages to designate such a document), the first to be mentioned are the fragments of two imperial rescripts addressed to an official in Egypt in the 5th century. The employment of this material in Italy for legal purposes is sufficiently illustrated by the large number of documents which were preserved at Ravenna, and date from the 5th to the 10th century. In the papal chancery too it was used at an early date, evidence of its presence there being found in the biography of Gregory I. But of the extant papal deeds the earliest to which an authentic date can be attached is a bull of Stephen III. of the year 757, while the latest appears to be one of 1004. There is evidence to show that in the 10th century papyrus was used, to the exclusion of other materials, in papal deeds. In France it was a common writing substance in the 6th century (Gregory of Tours, *Hist. Franc.*, v. 5). Of the Merovingian period there are still extant several papyrus deeds, the earliest of the year 625, the latest of 692. Under Charlemagne and his successors it was not used. By the 12th century the manufacture of papyrus had entirely ceased, as appears from a note by Eustathius in his commentary on the *Odyssey*, xxi. 390.

PARÁ, or SANTA MARIA DE BELEM DO GRÃO PARÁ, one of the most flourishing cities of Brazil, capital of the province of Pará or Grão Pará, lies on a point of land with sandy porous soil at the junction of the Guamá with the Rio Pará or eastern arm of the Amazons, about 75 miles from the sea. The main river is about 20 miles wide opposite the town, but is broken by numerous islands. Pará is regularly built, well-paved, and well-lighted. The houses, which seldom exceed two or three stories in height, are usually substantial structures of stone; and a general brightness of aspect is produced by red-tiled roofs and white, yellow, or even pink and blue coloured walls relieved by dense tropical foliage. The Estrada das Mongubeiras, running about a mile from the river to Largo da Polvora in the east end of the city, has long been famous for its magnificent cotton trees (*Bombax Monguba*, *B. Ceiba*); but the grand old trees are dying out, and the finest avenue in Pará is now the Estrada de São José, with its colonnade of tall "royal palms" (*Oreodoxa regia*). In the outskirts of the city the wealthy merchants have villas with very extensive grounds, and a little way beyond these begins the dense swamp-forest. Pará has a wonderfully pleasant and healthy climate, with a temperature extremely equable throughout the year. "The mornings are cool. From 10 till 2 the heat increases rapidly, commonly reaching 90° or 91°. A little later great black clouds appear in the east and spread quickly over the sky; the temperature falls suddenly, the wind blows in varying gusts, the rain pours down, and ere one is aware the sun leaps out. Sometimes the first shower is followed by a second or even a third. By sunset the ground is dry." This is the rule all the year round; only in the height of the dry season a week may pass without any showers. The Brazilians have a proverb, "Who came to Pará was glad to stay; who drank assai went never away." The

assaí referred to is a beverage made by squeezing the black grape-like berries of the assaí palm (*Euterpe edulis*); it is largely drunk by all classes in Pará. The importance of the city is due to its being the great emporium of the rapidly-developing trade of the Amazons. The trade is carried on by several steamboat companies; the most important, the Amazonian Steamboat Company, receives a subsidy from the Brazilian Government. Two lines of steamers run between Liverpool and Pará; there are also a French line and a German line. A large trade is transacted with the United States, but mainly through English, French, German, and Portuguese houses. The principal exports are cocoa, Brazil nuts, hides, deer-skins, isinglass, balsam of copaiba, tonka beans, and Peruvian bark. In 1863 the total value of the imports was about £500,000 and of the exports about £525,000; by 1882 the duties paid to the custom-house amounted to £864,396.

Population has been growing faster than the supply of houses. In 1819 the inhabitants were estimated at 24,500, but by 1850 they had declined to 15,000; in 1866 they were 35,000 (about 5000 slaves); and they are now (1884) nearly 40,000. Besides a vast cathedral (1720) and the president's palace, usually considered one of the best buildings of its kind in Brazil, Pará contains an episcopal palace (formerly the Jesuit college), a handsome theatre, a large market building, a custom house (formerly a convent, with two great towers), naval and military arsenals (the first of some size, with shipbuilding yards and a gridiron), a botanical garden, &c. About a mile from the city is the chapel of Our Lady of Nazareth, the most celebrated shrine in northern Brazil.

In 1615 Francisco Caldeira de Castello Branco, sent out by the Portuguese at Maranhão, built the fort of Santo Christo and founded the settlement of Nossa Senhora de Belem. By 1641 it was a place of 400 inhabitants, with four monasteries. A premature declaration of independence was made at Pará in 1823, and soon after Captain Grenfell, sent by Lord Cochrane, brought the city over to the Brazilian party; but for many years it was subject to political disturbance. In 1835 "every respectable white was obliged to leave the city" by the anarchical proceedings of the so-called "Liberals" Gomes, Vinagre, and Rodriguez.

PARACELSUS (c. 1490–1541). It seems now to be established that Paracelsus was born near Einsiedeln, in the canton Schwyz, in 1490 or 1491 according to some, or 1493 according to others. His father, the natural son of a grand-master of the Teutonic order, was Wilhelm Bombast von Hohenheim, who had a hard struggle to make a subsistence as a physician. His mother was superintendent of the hospital at Einsiedeln, a post she relinquished upon her marriage. Paracelsus's name was Theophrastus Bombast von Hohenheim; for the names Philippus and Aureolus good authority is wanting, and the epithet Paracelsus, like some similar compounds, was probably one of his own making, and was meant to denote his superiority to Celsus. In 1502–3 his father, taking his family with him, removed to Villach in Carinthia; and he resided there in the practice of the medical art till his death in 1534. In one of his works, dedicated to the magistracy of the town, Paracelsus refers to the esteem in which his father was held, and expresses his own gratitude for it.

Of the early years of Paracelsus's life there is hardly anything known. His father was his first teacher, and took pains to instruct him in all the learning of the time, especially in medicine. Doubtless Paracelsus learned rapidly what was put before him, but he seems at a comparatively early age to have questioned the value of what he was expected to acquire, and to have soon struck out ways for himself. As he grew older he was taken in hand by several distinguished churchmen, although it has been objected that dates will not warrant the idea of actual

personal instruction. This, however, is not correct, for all the men Paracelsus mentions were alive in his lifetime, though he was so young that he could hardly have profited by their lessons, unless on the supposition that he was a quick and precocious boy, which it is very likely he was. At the age of sixteen he entered the university of Basel, but probably soon abandoned the studies therein pursued. He next went to Trithemius, the bishop of Sponheim and Würzburg, under whom he prosecuted chemical researches. Trithemius is the reputed author of some obscure tracts on the great elixir, and as there was no other chemistry going Paracelsus would have to devote himself to the reiterated operations so characteristic of the notions of that time. But the confection of the stone of the philosophers was too remote a possibility to gratify the fiery spirit of a youth like Paracelsus, eager to make what he knew, or could learn, at once available for practical medicine. So he left school chemistry as he had forsaken university culture, and started for the mines in Tyrol owned by the wealthy family of the Fuggers. The sort of knowledge he got there pleased him much more. There at least he was in contact with reality. The struggle with nature before the precious metals could be made of use impressed upon him more and more the importance of actual personal observation. He saw all the mechanical difficulties that had to be overcome in mining; he learned the nature and succession of rocks, the physical properties of minerals, ores, and metals; he got a notion of mineral waters; he was an eyewitness of the accidents which befel the miners, and studied the diseases which attacked them; he had proof that positive knowledge of nature was not to be got in schools and universities, but only by going to Nature herself, and to those who were constantly engaged with her. Hence came Paracelsus's peculiar mode of study. He attached no value to mere scholarship; scholastic disputations he utterly ignored and despised,—and especially the discussions on medical topics, which turned more upon theories and definitions than upon actual practice. He therefore went wandering over a great part of Europe to learn all that he could. In so doing he was one of the first physicians of modern times to profit by a mode of study which is now reckoned indispensable. In the 16th century the difficulty of moving about was much greater than it is now; still Paracelsus faced it, and on principle. The book of nature, he affirmed, is that which the physician must read, and to do so he must walk over the leaves. The humours and passions and diseases of different nations are different, and the physician must go among the nations if he will be master of his art; the more he knows of other nations, the better he will understand his own. For the physician it is ten times more necessary and useful to know the powers of the heavens and the earth, the virtues of plants and minerals, than to spend his time on Greek and Latin grammar. And the commentary of his own and succeeding centuries upon these very extreme views is that Paracelsus was no scholar, but an ignorant vagabond. He himself, however, valued his method and his knowledge very differently, and argued that he knew what his predecessors were ignorant of, because he had been taught in no human school. "Whence have I all my secrets, out of what writers and authors? Ask rather how the beasts have learned their arts. If nature can instruct irrational animals, can it not much more men?" In this new school discovered by Paracelsus, and since attended with the happiest results by many others, he remained for about ten years. He had acquired great stores of facts, which it was impossible for him to have reduced to order, but which gave him an unquestionable superiority to his contemporaries. So in 1526 or 1527, on his return to Basel, he was appointed town physician.

and shortly afterwards he gave a course of lectures on medicine in the university. Unfortunately for him, the lectures broke away from tradition. They were in German, not in Latin; they were expositions of his own experience, of his own views, of his own methods of curing, adapted to the diseases that afflicted the Germans in the year 1527, and they were not commentaries on the text of Galen or Avicenna. Unfortunately they attacked, not only these great authorities, but the German graduates who followed them and disputed about them in 1527. They criticized in no measured terms the current medicine of the time, and exposed the practical ignorance, the pomposity, and the greed of those who practised it.

The truth of Paracelsus's doctrines was apparently confirmed by his success in curing or mitigating diseases for which the regular physicians could do nothing. For about a couple of years his reputation and practice increased to a surprising extent. But at the end of that time people began to recover themselves. Paracelsus had burst upon the schools with such novel views and methods, with such irresistible criticism, that all opposition was at first crushed flat. Gradually the sea began to rise. His enemies watched for slips and failures; the physicians maintained that he had no degree, and insisted that he should give proof of his qualifications. His manner of life was brought up against him. It was insinuated that he was a profane person, that he was a conjurer, a necromancer, that, in fact, he was to be got rid of at any cost as a troubler of the peace and of the time-honoured traditions of the medical corporations. Moreover, he had a pharmaceutical system of his own which did not harmonize with the commercial arrangements of the apothecaries, and he not only did not use up their drugs like the Galenists, but, in the exercise of his functions as town physician, urged the authorities to keep a sharp eye on the purity of their wares, upon their knowledge of their art, and upon their transactions with their friends the physicians. The growing jealousy and enmity culminated in the Lichtenfels dispute; and, as the judges sided with the canon, to their everlasting discredit, Paracelsus had no alternative but to tell them his opinion of the whole case and of their notions of justice. So little doubt left he on the subject that his friends judged it prudent for him to leave Basel at once, as it had been resolved to punish him for the attack on the authorities of which he had been guilty. He departed from Basel in such haste that he carried nothing with him, and some chemical apparatus and other property were taken charge of by Oporinus, his pupil and amanuensis. He went first to Esslingen, where he remained for a brief period, but had soon to leave from absolute want. Then began his wandering life, the course of which can be traced by the dates of his various writings. He thus visited in succession Colmar, Nuremberg, Appenzell, Zurich, Pfäfers, Augsburg, Villach, Meran, Middelheim, and other places, seldom staying a twelvemonth in any of them. In this way he spent some dozen years, till 1541, when he was invited by Archbishop Ernst to settle at Salzburg, under his protection. After his endless tossing about, this seemed a promise and place of repose. It proved, however, to be the complete and final rest that he found, for after a few months he died on the 24th of September. The cause of his death, like most other details in his history, is uncertain. His enemies asserted that he died in a low tavern in consequence of a drunken debauch of some days' duration. Others maintain that he was thrown down a steep place by some emissaries either of the physicians or of the apothecaries, both of whom he had during his life most grievously harassed. In proof of this surgeons have pointed out in Paracelsus's skull a flaw or fracture, which could have been produced only during life. Authorities,

however, are not agreed on this point, and it may be simplest to suspend belief until more evidence is got. He was buried in the churchyard of St Sebastian, but in 1752 his bones were removed to the porch of the church, and a monument of reddish-white marble was erected to his memory.

In making the attempt to ascertain what was Paracelsus's character, and what were his philosophical and medical opinions, a very considerable difficulty presents itself at the outset. "Of the voluminous writings which pass under his name, what are really his work, and what, if not actually composed by him, express his ideas? To this question no complete critical reply has as yet been given, though many opinions have been expressed. Dr Marx, for example, will admit only ten treatises as genuine. Dr Haeser allows seventeen for certain, a considerable number—some twenty-four—as doubtful, and the rest—he enumerates eleven—as spurious. Dr Mook does not accept these estimates, or the criteria by which the genuineness of a treatise is ascertained. But neither does he give altogether convincing criteria of his own, and, what is still less satisfactory, he does not apply them—such as they are—to decide the numerous doubtful cases. The only thing Mook has done is to draw up a list of the different editions of Paracelsus's so-called works. This list is not complete in the enumeration of editions, and it is quite imperfect in bibliographical description, but with these and other serious defects it is the fullest at present extant. The first book by Paracelsus was printed at Augsburg in 1529. It is entitled *Practica D. Theophrasti Paracelsi, gemacht auff Europen*, and forms a small quarto pamphlet of five leaves. Prior to this, in 1526-27, appeared a programme of the lectures he intended to deliver at Basel, but this can hardly be reckoned a specific work. During his lifetime fourteen works and editions were published, and thereafter, between 1542 and 1845, there were at least two hundred and thirty-four separate publications according to Mook's enumeration. The first collected edition was made by Johann Huser in German. It was printed at Basel in 1589-91, in eleven volumes quarto, and is the best of all the editions. Huser did not employ the early printed copies only, but collected all the manuscripts which he could procure, and used them also in forming his text. The only drawback is that rather than omit anything which Paracelsus may have composed, he has gone to the opposite extreme and included writings with which it is pretty certain Paracelsus had nothing to do. The second collected German edition is in four volumes folio, 1603-5. Parallel with it in 1603 the first collected Latin edition was made by Palthenius. It is in eleven volumes quarto, and was completed in 1605. Again, in 1616-18 appeared a reissue of the folio German edition of 1603, and finally in 1658 came the Geneva Latin version, in three volumes folio, edited by Bitiskius.

The works were originally composed in Swiss-German, a vigorous speech which Paracelsus wielded with unmistakable power. The Latin versions were made or edited by Adam von Bodenstein, Gerard Dorn, Michael Toxites, and Oporinus, about the middle of the 16th century. A few translations into other languages exist, as of the *Chirurgia Magna* and some other works into French, and of one or two into Dutch, Italian, and even Arabic. The translations into English amount to about a dozen, dating mostly from the middle of the 17th century. The original editions of Paracelsus's works are getting less and less common; even the English versions are among the rarest of their class. Over and above the numerous editions, there is a bulky literature of an explanatory and controversial character, for which the world is indebted to Paracelsus's followers and enemies. A good deal of it is taken up with a defence of chemical, or, as they were called, "spagyric," medicines against the attacks of the supporters of the Galenic pharmacopoeia.

The aim of all Paracelsus's writing is to promote the progress of medicine, and he endeavours to put before physicians a grand ideal of their profession. In his attempts he takes the widest view of medicine. He bases it on the general relationship which man bears to nature as a whole; he cannot divorce the life of man from that of the universe; he cannot think of disease otherwise than as a phase of life. He is compelled therefore to rest his medical practice upon general theories of the present state of things; his medical system—if there is such a thing—is an adaptation of his cosmogony. It is this latter which has been the stumbling-block to many past critics of Paracelsus, and unless his character is remembered it will be the same to others in the future. Dissatisfied with the Aristotelianism of his time, Paracelsus turned with greater expectation to the Neoplatonism which was reviving. His eagerness to understand the relationship of man to the universe led him to the Kabbala, where these mysteries seemed to be explained, and from these unsubstantial materials he constructed, so far as it can be understood, his visionary philosophy. Intertwoven with it, however, were the results of his own personal experience and work in natural history and chemical pharmacy and practical medicine,

unfettered by any speculative generalizations, and so shrewd an observer as Paracelsus was must have often felt that his philosophy and his experience did not agree with one another. It was doubtless a very great ideal of medicine which Paracelsus raised; but when it came to realizing it in every-day life he could hardly do else than fail. During the three hundred years which have elapsed since his time knowledge both of the macrocosm and of the microcosm has increased far beyond what Paracelsus could have understood, even had it been all foretold him; the healing art has advanced also, though perhaps scarcely at the same rate, but it would be as hard for us as for him to apply any cosmogony, however rational, to curing disease. We are not one whit nearer the solution of the problems which puzzled Paracelsus than he was; the mystery of the origin, continuance, and stoppage of life is, perhaps through the abundance of light shed on other phenomena, even darker than it may have seemed to Paracelsus. If this be so it is no matter for surprise, or blame, or ridicule that he missed constructing a theory of the universe which at the same time would be a never-failing guide to him in the practical work of alleviating the evils which a residence in this universe seems to entail.

Some of his doctrines have been already alluded to in the article *MEDICINE* (*q.v.*), and it would serve no purpose to give even a brief sketch of his views, seeing that their influence has passed entirely away, and that they are of interest only in their place in a general history of medicine and philosophy. Defective, however, as they may have been, and unfounded in fact, his kabbalistic doctrines led him to trace the dependence of the human body upon outer nature for its sustenance and cure. The doctrine of signatures, the supposed connexion of every part of the little world of man with a corresponding part of the great world of nature, was a fanciful and false exaggeration of this doctrine, but the idea carried in its train that of specifics. This led to the search for these, which were not to be found in the bewildering and notested mixtures of the Galenic prescriptions. Paracelsus had seen how bodies were purified and intensified by chemical operations, and he thought if plants and minerals could be made to yield their active principles it would surely be better to employ these than the crude and unprepared originals. He had besides arrived by some kind of intuition at the conclusion that the operations in the body were of a chemical character, and that when disordered they were to be put right by counter operations of the same kind. It may be claimed for Paracelsus that he embraced within the idea of chemical action something more than the alchemists did. Whether or not he believed in the philosopher's elixir is of very little consequence. If he did, he was like the rest of his age; but he troubled himself very little, if at all, about it. He did believe in the immediate use for therapeutics of the salts and other preparations which his practical skill enabled him to make. Technically he was not a chemist; he did not concern himself either with the composition of his compounds or with an explanation of what occurred in their making. If he could get potent drugs to cure disease he was content, and he worked very hard in an empirical way to make them. That he found out some new compounds is certain; but not one great and marked discovery can be ascribed to him. Probably therefore his positive services are to be summed up in this wide application of chemical ideas to pharmacy and therapeutics; his indirect and possibly greater services are to be found in the stimulus, the revolutionary stimulus, of his ideas about method and general theory. It is not difficult, however, to criticize Paracelsus and to represent him as so far below the level of his time as to be utterly contemptible. It is difficult, but perhaps not impossible, to raise Paracelsus to a place among the great spirits of mankind. It is most difficult of all to ascertain what his true character really was, to appreciate aright this man of fervid imagination, of powerful and persistent convictions, of unabated honesty and love of truth, of keen insight into the errors (as he thought them) of his time, of a merciless will to lay bare these errors and to reform the abuses to which they gave rise, who in an instant offends us by his boasting, his grossness, his want of self-respect. It is a problem how to reconcile his ignorance, his weakness, his superstition, his crude notions, his erroneous observations, his ridiculous inferences and theories, with his grasp of method, his lofty views of the true scope of medicine, his lucid statements, his incisive and epigrammatic criticisms of men and motives.

A character full of contradictory elements cannot but have had contradictory judgments passed on it; and after three hundred years the animus is as strong and the judgments are as diverse as ever. (J. F.)

PARADISE is an old Persian word (*Pairidaēza* in the *Vendidad*) meaning an enclosure, a park. The Greeks use the word in the form Παράδεισος of the parks of the Persian kings, and it was borrowed also by the Hebrews in the form פֶּרֶדִּים (Cant. iv. 13; Eccles. ii. 5; Neh. ii. 8; A. V., "orchard," "forest"). The Septuagint chose the Greek form to translate the "garden" of Genesis ii.; other

Greek and Latin versions followed them, and thus "paradise" became the usual ecclesiastical name for the garden of Eden, which has been spoken of under EDEN. Now, as Paradise in this sense was the residence of man before he sinned, it was natural enough that theological speculation as to the dwelling-place of the righteous, after death, or in the future glory, should attach itself to the account given in Genesis of the original habitation of righteous Adam, and borrow not only the name but in some measure also the conception of paradise as there described. This took place in more than one way, as we see from the Jewish apocalyptic literature, and especially from the book of Enoch. Thus we find (1) the idea that the old Paradise still exists in a secret part of the earth, and that Enoch, Elijah, and other elect and righteous persons dwell there. This is the foundation of the doctrine of the earthly paradise, which passed into Christianity—being supposed to find confirmation in the New Testament, especially in Luke xxiii. 43. The *earthly* paradise, as developed by Christian fancy, is the old garden of Eden, which lay in the far East beyond the stream of Ocean, raised so high on a triple terrace of mountain that the deluge did not touch it. It is the residence of certain departed saints, and the pictures drawn of it are coloured with classical reminiscences of Elysium and the Islands of the Blest. How these outlines were filled up at different periods may be learned from Ephraem Syrus's poem on Paradise (4th century), from Cosmas Indicopleustes (6th century), from the *Divina Commedia* of Dante, and other mediæval sources. A more ideal conception is (2) that of the *heavenly* paradise. To the Hebrews ideal things represent themselves as the heavenly counterparts of earthly things; ideals which God's people are to realize in the future are already existent in heaven; or even things which have once been lost, but which are necessary to man's true happiness, are preserved in heaven. Thus the heavenly paradise was either a mere figure for the good things, corresponding to those which Adam lost, which are reserved in heaven for the righteous, or it was the heavenly archetype of which the earthly paradise was a copy, or on a crasser way of thinking it was held that the paradise which Adam lost had been actually transported to heaven. The commonest form of the idea was perhaps that expressed in 4 Ezra and the Talmud, by saying that paradise was created before the earth. This paradise is not conceived as the place of the souls of all the righteous after death, but it is inhabited by certain select persons—Enoch, Elijah, Moses, Ezra—who enjoy in it the fellowship of the coming Messiah. After the last judgment, when the enemies of Israel are cast into Gehenna, the righteous are raised to paradise, and there behold the glory of God. Associated with such views as these, we find farther the idea (3) that in the future glory paradise, or the heavenly Jerusalem, which stood in paradise before the fall and was removed to heaven with it (Apoc. Baruch), will be brought down from heaven to earth, that the tree of life will be planted on Zion (Bk. Enoch, 4 Ezra). All these apocalyptic crudities, which it is not necessary to follow into details, are really mechanical developments of a legitimate, one may even say an inevitable, inference from the position that the garden of Gen. ii. represents a state of ideal human felicity lost through sin. For, if this be so, the future bliss of the redeemed must be conceived as somehow analogous to the life of Eden, and a literal unimaginative conception of this analogy, making no allowance for the difference between the happiness of childhood, prior to experience of the everyday world, and the happiness of a life which has conquered the world, must end in regarding the future home of the blest as a mere reproduction of Eden. But the use of the word paradise for the home of

the blessed does not necessarily imply so mechanical a conception as we find in the Jewish apocalypses; to speak of the future bliss at all, without the use of metaphysics, is possible only in the form of poetical description, and for such description the story of the garden of Eden supplied the necessary concrete elements, which the apocalyptists took literally, while higher thinkers used them as symbols—and ordinary language, perhaps, as mere conventional equivalents—for ineffable things. Thus the images borrowed from Edea in such a prophecy as Isa. xi. are certainly not meant literally, any more than the figure of the tree of life in the book of Proverbs. So in the New Testament even Rev. ii. 7 is plainly figurative, and in Luke xxiii. 43 paradise is simply the place of bliss. In 2 Cor. xii. 4 paradise is a heavenly place where ineffable words were heard by Paul; but he himself does not know whether he visited it in the body or out of the body.

See Dillmann's *Buch Enoch*, and his articles "Eden" and "Paradies" in Schenkel's *Bibel-Lexicon*; Weber, *Altynagogale Theologie*; and the books on Biblical theology. The Mohammedan paradise (al-Janna) is borrowed from the Jews, as appears from the name *Jannatu 'Adnin*, that is, Garden of Eden. It is described in the Koran and by later theologians as a place of all sensuous delights, where the righteous recline on couches in a fair garden drinking the delicious beverage supplied by the fountain Tasmim and waited on by damsels with great bright eyes ("Hür," Kor. lv. 72, hence our "houris," which is properly a Persian form). The expression "gardens of Firdaus" (the Persian form of the word Paradise) occurs in Kor. xviii. 107, and is interpreted as meaning the highest region of the Janna (Beidawi in l.).

PARADISE, BIRDS OF. See vol. iii. p. 778.

PARAFFIN. In the course of his classical investigation on the tar produced in the dry distillation of wood, Reichenbach in 1830 discovered in it, amongst many other things, a colourless wax-like solid which he called paraffin (*parum affinis*) because he found it to be endowed with an extraordinary indifference towards all reagents. A few years later he isolated from the same material a liquid oil chemically similar to paraffin, to which he gave the name of *eupion* (εὐπίων, very fat). For many years both these bodies were known only as chemical curiosities, and even scientific men looked upon them as things entirely *sui generis*; this was natural enough as far as paraffin is concerned, but it is rather singular that it took so long before it was realized that eupion or something very much like it forms the body of PETROLEUM (*q.v.*), which had been known, since the time of Herodotus at least, to well up abundantly from the bowels of the earth in certain places. Though extensively known, it was used only as an external medicinal agent, until the late Mr James Young conceived the idea of industrially working a comparatively scanty oil-spring in Derbyshire, and subsequently found that an oil similar to petroleum is obtained by the dry distillation of cannel coal and similar materials at low temperatures. This discovery developed into a grand industry, which may be said to have led to the utilization of those immense natural stores of petroleum in America. Scientific chemists naturally directed their attention to the products of these new industries, and it was soon ascertained that solid paraffin and eupion, as well as natural and artificial petroleum, are substantially more or less impure mixtures of saturated hydrocarbons; and so it comes that, on the proposal of H. Watts, the word paraffin in scientific chemistry has been adopted as a generic term for this class of compounds of carbon and hydrogen.

When the electric light is generated within an atmosphere of hydrogen, then, at the immense temperature of the electric arc, part of the carbon of the charcoal terminals unites with the hydrogen into acet, lene gas, C_2H_2 . Apart from this isolated fact, which was discovered by Borthelot in 1862, it might be said that the two elements are not capable of uniting directly, although an innumerable

variety of hydrocarbons exist in nature, and can be produced artificially from organic substances. Individual hydrocarbons may differ very much in their properties. At ordinary temperature and pressure a few are gases; the majority present themselves as liquids; not a few are solids. But the solids are fusible; and all liquid or liquefied hydrocarbons, at a high enough temperature, volatilize, as a rule without decomposition. To the latter circumstance to a great extent we owe our precise knowledge of their chemical constitution.

In all the numerous series of hydrocarbons the percentages of carbon vary from 75 (in marsh gas) to 94.7 (in chrysene). Within this narrow range of some 20 per cent. several dozens of elementary compositions have to be accommodated; and many of these, to be represented in formulae C_xH_y , with an adequate degree of precision, require formulae in which the coefficients x and y are so large that, by means of integers less than these, any fancy composition (within our limits) may be expressed with a degree of exactitude which is quite on a par with the analyses. But these hydrocarbons, in general, can be volatilized into gases, and in regard to these Avogadro's law tells us that quantities proportional to the molecular weights (i.e., the weights represented by the true chemical formulae) occupy the same volume. Hence, to find the true value, $M = C_2H_2$, of the formula as a whole, we need only determine the vapour density, and from it calculate the weight of the respective hydrocarbon which, as a gas at t° and P millimetres pressure, occupies the same volume as, for instance, H_2O parts of steam. This is M . The elementary analysis enables us to calculate the weight $x \times C$ of carbon contained in M parts, and the analysis must be very poor to leave us in doubt as to whether it is for instance 6×12 parts of carbon or 7×12 parts that we have to deal with. The reader will now understand how it has been possible to ascertain the elementary composition of all pure hydrocarbons with a degree of precision which goes beyond that of the analysis, and to prove what analysis could never have done by itself, namely, that there are numerous groups of hydrocarbons which have absolutely identical elementary compositions,—cases of isomerism, as they are called. We speak of "isomerism in the narrower sense" when the atomic formulae are identical (there are, for instance, two hydrides of butyl, C_4H_{10}), while we speak of "polymeric" bodies when the several formulae are integer multiples of the same primitive group (e.g., ethylene, $2 \times CH_2$, and butylene, $4 \times CH_2$, are polymers to one another).

The following table gives an idea of the several classes of hydrocarbons which for us come more particularly into consideration.

| n | Paraffins. | Olefines. | Acetylenes. | | Benzols. |
|-----|---------------|-------------|-------------|--|---------------|
| 1 | CH_4 | Vacat. | Vacat. | Intermediate bodies, many non-existent; all omitted. | Vacat. |
| 2 | C_2H_6 | C_2H_4 | C_2H_2 | | Vacat. |
| 3 | C_3H_8 | C_3H_6 | C_3H_4 | | Vacat. |
| 4 | C_4H_{10} | C_4H_8 | .. | | Vacat. |
| 5 | C_5H_{12} | C_5H_{10} | .. | | Vacat. |
| 6 | C_6H_{14} | C_6H_{12} | .. | | C_6H_6 |
| 7 | C_7H_{16} | C_7H_{14} | .. | | C_7H_8 |
| 8 | C_8H_{18} | C_8H_{16} | .. | | C_8H_{10} |
| ... | ... | ... | ... | | C_9H_{12} |
| n | C_nH_{2n+2} | C_nH_{2n} | ... | | C_nH_{2n-6} |

The first column, under "n," gives the number of carbon atoms per molecule in the compounds whose formulae stand in that horizontal line,—these latter being arranged in a descending series according to the number of hydrogen atoms united with n atoms of carbon. Instead of pointing out those regularities, in regard to the atomic proportions in which carbon and hydrogen can unite into compounds, which the table illustrates so forcibly, let us rather state that the "benzols," in opposition to all that stands to their left in the table are things of their own kind. In them six atoms of the carbon are most firmly united (into a "ring," as a certain theory says), and the rest are, so to say, hooked on to the ring in a less intimate fashion. Thus benzol is (C_6H_6) , each one of the six H's being tied to one of the six C's; toluol is $(C_6H_5) - CH_3$; it is a benzol from which one of the six hydrogen atoms has been removed, and in which the gap left has been filled by a "methyl," CH_3 :—

But similarly two dehydrogenated benzols, C_8H_6 , can unite into one double ring of diphenyl: $2C_8H_6 - 2H = (C_8H_5)(C_8H_5)$; and two benzol rings may unite more firmly in such a manner that two carbon atoms of the one ring do service for the two rings, and a double ring is formed firmly united by these two common carbons, the four hydrogens of the original two benzols being away. This gives naphthalene. —

In a similar manner three benzols may unite into one anthracene:—

Generally speaking, a hydrocarbon is the more volatile the less the number of carbon atoms and the greater the number of hydrogen atoms in the molecule. Thus, in the series of "paraffins," CH_4 (marsh gas) and C_2H_6 (ethane) are gases, C_3H_8 (propane) and C_4H_{10} (butane) are very volatile liquids, and C_5H_{12} , &c., are liquids,—with higher and higher boiling points as we ascend the series. From a certain value of n upwards we find ourselves amongst the paraffins proper, which are solids, more or less easily fusible, but not, in general, volatile without decomposition. Benzol, C_6H_6 , and its neighbouring homologues are volatile liquids. Naphthalene and anthracene are crystalline solids, fusible at 79°C and 180°C , and boiling at 217° and above 300°C respectively without decomposition.

All hydrocarbons agree in this, that they are practically insoluble in water, but more or less readily soluble (in general) in alcohol and in ether. They are all combustible; the more readily volatile ones are inflammable. Any complete combustion, of course, leads to the formation of only carbonic acid and water, with evolution of a large amount of heat; but the mechanism of the process is more or less complex. Naphthalene and anthracene remain undecomposed at a red heat; only at the very high temperature of their flames, and by the co-operation of the oxygen of the air, they are decomposed with large elimination of charcoal; a similar, though less, stability is exhibited by the benzols. The paraffins, on the other hand, are relatively unstable. Marsh gas, it is true, stands a red heat; but, to pass to the other end of the series, the paraffins proper, and also the higher liquid paraffins to some extent, even when being distilled, and especially when distilled "under pressure," *i.e.*, at higher temperatures than their natural boiling points, break up into olefines and lower paraffins (Thorpe and John Young). Similar changes take place when the vapours of paraffins are passed through red-hot tubes; only the products formed then suffer deeper-going decomposition with formation of hydrogen, marsh-gas, acetylene, ethylene, and charcoal, and, last not least, benzols and naphthalene. To this latter fact the paraffins owe their pre-eminent fitness as illuminating agents.

When organoid minerals, such as cannel coal, shale, &c., are subjected to dry distillation, all the several classes of hydrocarbons are in general produced at the same time; but, from what we have said it will be understood that, even with the same material, the quantitative composition of the complex vapour which comes out of the retort depends on the way in which the distillation is being conducted. If we operate at the lowest practicable temperature, comparatively little gas is produced, and in the condensable part of the vapour the paraffins predominate largely; at a bright red heat, such as is used in making coal gas, and especially if the vapours have to pass along red-hot surfaces before they get into the condenser pipes, more gas is produced, and the place of the liquid paraffins is taken by benzols. These latter, however, are always accompanied by naphthalene, often also by anthracene, and invariably by certain ternary benzol-derivatives, namely, by "phenols," feebly acid bodies containing hydroxyl groups, OH 's, where the corresponding hydrocarbon bore plain hydrogens (ordinary phenol, $\text{C}_6\text{H}_5(\text{OH})$, derived from benzol, C_6H_6 , is a representative example), and, secondly, basic compounds of carbon, hydrogen, and nitrogen. Of the latter aniline and picoline—both $\text{C}_6\text{H}_7\text{N}$, but widely different in their properties—may be quoted as examples. The gas produced in this case through the presence in it of the vapour of higher hydrides, but especially of acetylene, C_2H_2 , and

benzol is highly luminous. Supposing now, as a third instance, the distillation to be conducted at a white heat, and so that the primary vapour has to wind its way through a spiral pipe kept at a bright red heat, the proportion of gas increases largely, and there is an increased yield of retort charcoal; but the liquid hydrocarbons of all classes almost vanish; the gas consists mainly of hydrogen, marsh gas, carbonic oxide, and carbonic acid, and gives little light when kindled.

The aim of the paraffin oil manufacturer is to produce the best possible approximation to a mixture of paraffins, wherefore he conducts his distillation at the lowest working temperature. Of course his paraffin mixture contains more or less of the other classes of bodies referred to, whose removal, however, offers no great difficulty. In the laboratory we should commence by shaking the crude oil with caustic alkali ley, which withdraws the phenols and other acid bodies, as part of a lower layer, the upper being purified oil. By shaking the latter with dilute sulphuric acid the bases are removed as a solution of their sulphates, and a still purer oil results. Application of concentrated sulphuric acid to the latter removes part at least of the benzols and olefines as sulpho-acids, and also of the phenols and all the bases, should the two preceding operations have been omitted. But the most thorough mode of getting quit of the benzols and their derivatives is—after having exhausted the milder agents—to shake the oil with first aqueous and then stronger and stronger nitric acid, which reagent converts the benzol-bodies into nitro-products, soluble in the acid, or removable, after separation of the acid layer, by aqueous alkali. By all these tortures the paraffins—being what the name implies—are not much affected, so that what ultimately survives all belongs to their family. The separation of the individual paraffins from one another is a very difficult problem which has not yet found a satisfactory solution. What we know of individual paraffins is derived chiefly from the investigation of decompositions of pure chemical substances leading to the formation of that one paraffin principally if not solely. To split up a mixture of paraffins approximately the only known method is fractional distillation (see DISTILLATION, vol. vii. p. 260), preferably by means of an apparatus so constructed that the vapour, before reaching the condenser, ascends through an intermediate inverted condenser or still-head, and there suffers partial condensation at some suitable temperature (enforced in the most perfect form of the apparatus by an oil-bath surrounding the still-head). In this latter case, singularly—not as a matter of course by any means—what goes over boils very nearly at the temperature of the still-head. This particular form of the method therefore lends itself chiefly for the final purification of an unitary substance of known boiling point already purified by preceding distillations. With mixtures of unknown composition the process is very tedious, and may assume something like this form.

We distil the substance (slowly and with ample chance of partial condensation) and collect as separate fractions what came over at, for instance, 100° to 105° , 105° to 110° , 110° to 115° , &c., as I., II., III., IV., &c. Each of these when redistilled yields I. and II. and III. and IV., &c., which parts are poured into the respective receptacles, and on this principle we continue working. If the substance happens to be of comparatively simple composition, it usually turns out, after a while, that (say) the two fractions II. and VI. increase while the rest get less and less; and by working on we may be able to isolate two bodies of the constant boiling points t_2 and t_6 respectively, with formation of "tails" of other boiling points. Unfortunately, even a constant boiling point is no proof of chemical purity; and, if a constant-boiling substance is a

mixture, only chemical methods can help us out of the difficulty.

The following table (extracted from Roscoe and Schorlemmer's *Handbook of Chemistry*, German edition) gives the names, specific gravities, and boiling points of the more important paraffins. The first column, "n," gives the number of carbon-atoms in the molecule, and consequently the molecular weight M and the vapour density S. In the case of "pentan," for instance, we have $n = 5$; hence $M = C_5H_{12} = 72$; and, as $H_2 = 2$, the gas-density, referred to hydrogen = $S = 36$, while, as air is 14.45 times as heavy as hydrogen, for the gas-density referred to air the value

$$\frac{1}{2}M \div 14.45 = 36 \div 14.45 = 2.491.$$

| n | Name. | Boiling Point in Degrees. | | Sp. Gr. of Liq. at t° C. | |
|----|---|---|--------------|--------------------------|-------|
| | | Fahr. | Cent. | | t |
| 1 | *Methan or marsh gas..... | Liquid at -11° C. and 180 atmospheres' pressure (Cailliet). | | | |

| 25 | *Dimethyl-heptylmetan..... | 320° | about 160° | (?) | ... |
| 26 | *Tetramethyl-hexan or "diamyl"..... | 320° | 160° | 0.7413 | 0° |
| 27 | *Hendekan..... | Not yet isolated. | | ... | ... |
| 28 | *Dodekan, normal..... | 396° | 202° | (?) | ... |
| 29 | Not isolated yet. | | ... | ... | ... |
| 30 | Hekdeka-dekan, normal, fuses at +21° C..... | | 532° | 275° | ... |

Probably all the paraffins enumerated in the table are present in paraffin oil and in petroleum; those marked * have been actually found in the one or the other. The solid paraffins are not known as unitary chemical substances; no chemist as yet has succeeded in splitting up solid paraffin into its proximate components. The manufacturer, in regard to the liquid paraffins even, does not trouble himself with the isolation of chemical species; he contents himself with splitting up his oil into fractions corresponding to certain ranges of boiling point, and consequently adapted to certain practical applications. But even the boiling point is not much heeded industrially; the several kinds of oil are defined by their specific gravity at 60° F., which, as experience shows, increases as the boiling point rises. But it is as well here to point out that the same (initial) boiling point even, and in a much higher degree the same specific gravity, may be exhibited by oils of widely different proximate composition. Hence a relatively (and in a sense sufficiently) high specific gravity is no guarantee against dangerous inflammability; the degree of inflammability in an oil must be—and in practice always is being—determined by direct experiment. For this purpose it is not sufficient to heat a sample oil in an open vessel gradually to higher and higher temperatures, and to note the temperature at which the atmosphere over the oil proves inflammable when a lighted taper is brought in contact with it. By this method (which formerly was the universally recognized test) the most varying results may be obtained with the same oil. Far

more trustworthy is the close test first proposed by Keates about 1870, the principle of which is to heat the oil within a close vessel which is opened only from time to time to apply a light to its atmosphere. For the execution of this test many varieties of apparatus have been proposed. That adopted by Abel, and now (1884) legally recognized in Great Britain, is made of sheet copper, the exact thickness of which is prescribed for every part. The oil is placed in a close cup, suspended in an air-bath, which latter is heated by immersion in a warm-water bath, provided with an air-jacket. The top of the oil cup is pierced with three circular orifices, one in the centre for trying the best flame, and two smaller lateral holes for admitting air at the close of each trial. The holes are covered by a slide so contrived that when the central hole has become almost uncovered the lateral ones are also open. The slide carries a small colza-oil lamp suspended on trunnions, having a flame of a prescribed size. A pendulum two feet in length vibrates in front of the observer, who, in testing, withdraws the slide slowly during three vibrations, tilts the lamp to bring its flame in contact with the atmosphere of the vessel, and quickly shuts the slide during the fourth vibration. To execute a test the oil at about 60° F. is placed in the cup, which is immersed in the water-bath having water of 130° F. A thermometer plunged into the oil and another in the water-bath indicate their temperatures. When the oil has approached its presumable flashing point, trials are made at each rise of 1° F. in the temperature of the oil. The lowest temperature at which the atmosphere of the cup inflames is the flashing point of the oil tested. The legal minimum flashing point of burning oil by the close test is 75° F., corresponding to about 100° F. by the obsolete open test.

The variety of mixed paraffins which the oil-distiller produces may be arranged under the following heads:—(1) oils too volatile to be available for domestic illumination, serving chiefly as solvents; (2) burning oils, as required for house lamps; (3) oils of very high boiling point, available, and used chiefly, for lubricating purposes; (4) solid paraffin.

The products of the second class have long come to practically supersede the colza oil which used to be the illuminating oil *par excellence*. Over it they offer the advantages of greater cheapness and of giving, weight for weight, more light. But their drawbacks are that, however carefully refined they may be, they have, when allowed to leak out, or in lamps of inferior construction, a somewhat disagreeable pungent odour, and that there is always a lurking danger in the possible presence of highly volatile inflammable hydrocarbons. Colza oil will never burn without a wick; paraffin oil or petroleum may do so.

Products of the second and third classes, separately or combinedly, are of course available as fuels proper, i.e., for the production of heat. At the time when mineral oil was first produced in great quantity in America, the advantages it would offer as a fuel for marine boilers especially were very emphatically insisted on. Of course mineral oil can be more economically stored than coal, and its combustion-heat is susceptible of more exhaustive utilization. The latter fact forms the *raison d'être* of those beautiful petroleum kitchen-stoves and culinary lamps which are very much used on the Continent where gas is not at hand. But to talk of mineral oil as a cheap fuel for wholesale heating is nonsense. H. St Claire Deville, about 1870, made an extensive investigation on the calorific value of American petroleum which, as we know, is pretty much the same thing as paraffin oil. He used a large apparatus, enabling him to burn several hundred litres of oil in one experiment; in fact he realized

more fully than other experimenters had ever done the conditions prevailing in the working of steam-boilers; the only difference was that he took care to collect all the heat produced in a large mass of water of known weight, and measured the heat by the increase of temperature produced in this heat receptacle. He found that even heavy Virginia lubricating oil gave not more than 10,180 units of heat (Centigrade) per unit-weight of fuel burned. But, on the other hand, in direct experiments made by Scheurer-Kestner, a coal containing 88.4 per cent. of carbon, 4.4 of hydrogen, and 7.2 per cent. of oxygen, nitrogen, and ash gave 9628 units of heat, while another coal of the same elementary composition gave 9117 units. Gas retort coke (though a far closer approximation to pure carbon) yields only 8050 units. Supposing coal yielded just that in opposition to the 10,000 units from petroleum, it is clear that the latter must not cost more than 1.25 times as much as coal weight for weight, or else it is the more expensive fuel. Take one ton of coal at 10s.; eight-tenths of a ton of petroleum is its calorific equivalent; but this weight of the oil (taking the specific gravity at 0.8) measures 224 gallons. Hence petroleum, to be as cheap as coal, must not cost more than about a halfpenny a gallon. Cheap as mineral oil is nowadays, it has not yet come down to this level.

To pass to the lubricating oil (third class), it, like the burning oil, competes with the fats and fatty oils which until lately were exclusively employed. In opposition to these it offers other and very substantial advantages besides its lower price. Good mineral lubricating oil may have such very high flashing point that it may be positively less inflammable than fatty oils or tallow; and, as a lubricant for high-pressure steam cylinders, it offers the great advantage that it is not, like fatty oils, decomposed by hot steam into glycerin and fatty acids, which latter cannot but attack the metal of the machinery to some extent. A still more important feature in mineral lubricating oil is that, even when diffused throughout a mass of cotton (or other textile) waste, it shows no tendency towards spontaneous combustion. In exhaustive experiments by Galletly and by Coleman, it was found that mineral lubricating oils diffused through textile waste do not take fire at temperatures at which even colza oil ignites, and also that fatty lubricants to which from 20 to 50 per cent. of mineral oil was added were thereby prevented from igniting.

Solid paraffin, industrially and commercially, is a substitute for the more expensive stearin as a material for candles. To this latter it is more than equivalent in light-giving power; but it offers the drawback of greater softness and lower fusing point. In practice paraffin is always alloyed with stearin to produce candles possessing the necessary degree of hardness and stability of form.

The Paraffin Oil Industry of Scotland.

In December 1847 Lyon Playfair drew the attention of the late Mr James Young, F.R.S., a Glasgow chemist, to a spring or exudation of petroleum at Alfreton in Derbyshire, and induced him to lease the spring, with the view of turning the material to commercial advantage. In 1848 Mr Young commenced the purification and preparation from this petroleum of two varieties of oil—one, thick, for lubricating, the other, thin and limpid, for burning in lamps. It was found that this crude petroleum contained paraffin in notable proportion; but the solid paraffin was not separated for trade purposes, and that body continued still a simple chemical curiosity. Within two years the quantity of petroleum yielded by the spring began to decrease, and in the beginning of 1851 it was practically exhausted, and the business there ceased. Meantime it had occurred to Mr Young that the petroleum he was working might have been produced by the action of heat on the underlying coal; and, under the impression that it might be possible by artificial means to produce a similar substance, he began an extensive series of experiments on the destructive distillation of coal. As the result of a long-con-

tinued investigation in this direction, with many varieties of coal, Mr Young in October 1850 secured a patent for the manufacture of paraffin and paraffin oil from bituminous coal, which patent became the basis of the new industry. "The coals," the patentee says, "which I deem to be best fitted for the purpose are such as are usually called parrot coal, cannel coal, and gas coal, and which are much used in the manufacture of gas for the purpose of illumination." Early in 1850 Mr Young's attention was called to the Boghead mineral, which he found to be of all the substances experimented upon the most promising for his purpose. That circumstance determined Mr Young and his original partners to set up their works at Bathgate in the region of the Boghead mineral, where consequently, in 1850, the necessary buildings and plant were erected, and manufacturing operations were begun in 1851. In 1853 a lawsuit of great importance, which turned on the scientific question "What is coal?" took place between the proprietor of a portion of the Boghead mineral and his mineral tenant, who was entitled to work coal only. The proprietor averred that the mineral in question was not coal; but, after a great amount of scientific evidence on both sides had been heard, the decision was that the substance came, so far as regarded the purposes of the lease, within the definition of coal. Had the issue of the case been in favour of the proprietor of the mineral, Mr Young's patent would have been practically valueless, for he claimed only the distillation of bituminous coal. The distillation of mineral schists or shale at a low red heat had, moreover, been previously patented by Du Buisson; and the only raw materials which have been used to any extent in the Scottish industry are the Boghead mineral and subsequently bituminous shale.

The essential feature of Young's invention was the distillation of bituminous substances at the lowest temperature at which they could be volatilized to a practically sufficient extent. In practice it was found that a temperature of 800° F. is the point about which the best results are obtained.

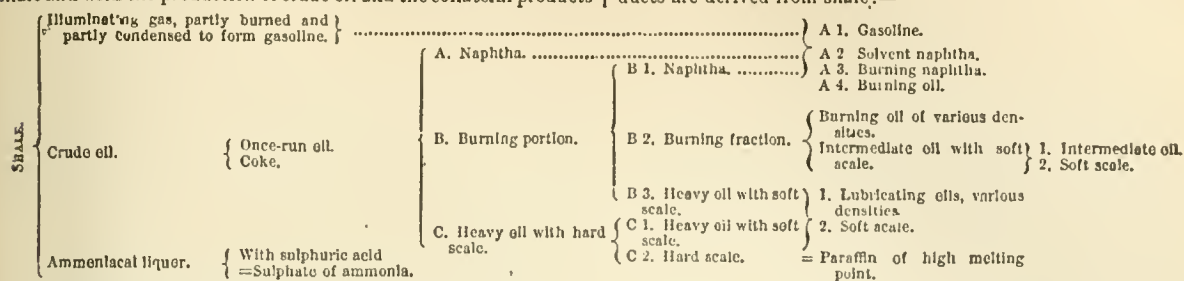

The material exclusively distilled in the early years of the industry in Scotland was the Boghead cannel or Torbanehill mineral. The supply of this mineral was limited, and, as its value for gas-making as well as for oil-distilling was very great, it rapidly advanced in price from 13s. 6d. per ton, at which it was contracted for when the Bathgate works began operations, till it rose to 90s. per ton before its final disappearance from the market about 1866. As early as 1859 the bituminous shales which are found in the Scottish Carboniferous formation began to attract attention as a possible source of raw material for the industry, and in that year a seam was experimentally opened up at Broxburn, Linlithgowshire. In 1861 a shale oil work was established at Gavieside, West Calder, and by the period of the expiry of Young's patent in 1864 several works distilling shale were in operation. But, while from the Boghead mineral from 120 to 130 gallons of crude oil were obtainable for every ton distilled, the ordinary bituminous shales yield at most only 35 gallons per ton; and even with the improved methods of working in use at the present day the average yield of crude oil from shales is not more than 32 gallons per ton.

The bituminous shales of Scotland are found in a wide belt of the Carboniferous formation, extending from Ayrshire in a north-easterly direction to the Fife coast. In Ayr and Renfrew they are found to some extent in the true Coal-measures; but, generally, and especially in the east, they are obtained in the Lower Carboniferous series. These oil shales consist of fissile argillaceous bands, highly impregnated with bituminous matter. As a rule the shale of the west country yields a high percentage of crude oil, but the Linlithgow, Midlothian, and Fife shales produce oils comparatively rich in lubricating oil and solid paraffin, the most valuable product of the industry. The ordinary Broxburn shale contains 17 per cent. of bituminous volatile matter, and leaves 76 per cent. of spent shale (char) on distillation. In contrast with this is the composition of the Boghead mineral, which contained not less than 65 per cent. of volatile bituminous matter and only 22 per cent. of ash.

In the early years of the industry at Bathgate, the two classes of oil—heavy (lubricant) and light (illuminating)—were the products to which attention was principally directed. Paraffin was separated from the heavy oils; but the demand for it was at first small, and many difficulties had to be overcome before candles consisting principally of that body could be favourably brought into the market. With the increased knowledge, improved methods, and eager competition of the present day, the range of products has largely extended, and almost everything obtainable from the shale, except the incombustible ash, is turned to profitable account. The commercial products embrace sulphate of ammonia, illuminating and heating gas, gasoline and naphtha, highly volatile oils, several grades of burning oil and of lubricating oil, heavy green oil used for making oil gas, and solid paraffin. The sequence of manufacturing operations has not changed in any essential particular since first established by Young; but at every stage and in all the appliances numerous and important modifications have been, and continue to be, actively introduced, all tending to greater economy of work, increase of production, and improvement of the quality and variety of commercial products.

Manufacturing Operations.

The manufacture divides itself into two distinct sections:—(1) the crude works, dealing with the preparation and distillation of the shale and with the production of crude oil and the collateral products

Crude Works.—Bituminous shale as brought from the pits is passed through powerful toothed cylinder machinery, reducing it to fragments not larger than a man's fist. In this state it is conveyed in hutches to the retorts, in which it undergoes destructive distillation—the distinctive operation under Mr Young's patent. The retorts used have undergone many and important modifications. Originally, as was natural, horizontal retorts arranged in benches, in all respects like gas retorts, were employed, but these in the Scottish trade very quickly gave way to the vertical retort. The form of vertical retort originally in general use consisted of a cast-iron cylinder, circular or oval in cross section, 8 or 10 feet in height and about 2 feet in diameter, or equivalent thereto. It tapered at the top, where it was provided with a hopper for charging the material to be distilled and a valve for closing the retort mouth. The bottom end dipped into a trough of water, forming an efficient lute, and effectually preventing the escape downwards of any of the gaseous products of distillation. These retorts were arranged in linear benches of six, three on each side of a furnace fed with coal, the heat from which passed to each side into the chamber or oven in which the retort stood. The distilled vapours passed away by a pipe at the upper end of the retort, their emission being aided by a jet of superheated steam injected at the bottom. The distillation in these retorts was continuous, a portion of spent shale being withdrawn through the water in the trough every hour or thereby, and a corresponding amount of fresh shale being added by the hopper.

As competition with American petroleum increased, the efforts of manufacturers were directed to cheapening the distilling process, by utilizing the spent shale from the retorts in its hot condition as fuel for distilling the succeeding charge. The difficulties in the way of accomplishing this were very great, chiefly on account of the large proportion of ash in the coked residue, amounting to from 85 to 90 per cent. of the whole. To use spent shale so poor in carbon it was essential that it should be dropped into the furnace direct from the retort without exposure to the air, and this was first successfully accomplished by the improved retorts and furnace patented by Mr Norman M. Henderson in 1873. According to the Henderson system, which has been adopted in the more important Scottish oil works—a series of four vertical retorts are arranged in quadrangular order over a common fire-chamber or furnace; the bottom ends of the retorts are provided with doors capable of being closed gas-tight; and immediately below each door there is a valve which, in one position, and while the charge is being distilled, entirely cuts off the retort bottom from the furnace or fire-chamber, leaving the retort bottom exposed to the external air, but when the retort charge has been exhausted of oil, and is about to be passed into the furnace as fuel, the valve can be turned over outwards, in which position it forms an inclined shoot contiguous to the bottom of the retort and the fire-chamber. The door-closing at the bottom of the retort having been first withdrawn, and the valve drawn back, the contents of the retort pass freely into the furnace, where their combustion is at first assisted by a jet of the incondensable inflammable gas given off by the retorts themselves.

Each Henderson retort can contain about 18 cwt. of shale. The four retorts forming a set are being cleared in rotation at intervals of five hours, so that each charge suffers distillation for twenty hours. The temperature is kept at about 800° F., this giving the best results. The vapour produced in the retort is led off by a pipe issuing from near the bottom, and, in order to avoid unnecessarily prolonged sojourn of the vapour in the hot vessel, a jet of superheated steam is constantly made to stream in above and guide the vapour downwards. The vapour, which amounts to about 3000 cubic feet per ton of shale distilled, is passed through a system of condensing pipes, communicating below through a properly divided horizontal chest, like that used in gas works for the condensation of the tar. From the last compartment of the condenser the still uncondensed gas is drawn away by a fan or other "exhaust" through a set of "acumbbers." In the first of these the

—illuminating gas, gasoline, and ammonia; and (2) the refinery, in which the crude oil is purified and separated or split up into the considerable range of commercial products obtainable from it. The following table shows the stages through which the various products are derived from shale:—

gas is washed with water and thus stripped of what it still contains of ammonia; in the succeeding ones it is washed with heavy oil, which withdraws a considerable portion of the vapours of the more highly volatile hydrocarbons which are diffused throughout it. From this heavy-oil solution the absorbed hydrocarbons are extracted by distillation as "naphtha." The gas, after having thus been freed from its more readily condensable parts, is either led away into gas-holders to be utilized as illuminating gas or used directly as a fuel (see above). The product which collects in the condenser chests consists of crude oil (about one-fourth of it) and a weak aqueous solution of ammonia and volatile ammonia salts, containing from 2 to 5 per cent. of real ammonia, NH_3 , which, however, in all cases represents only a small percentage of the potential ammonia which was contained in the original shale in the form of nitrogenous carbon compounds. In the golden days of paraffin oil making this ammonia liquor was simply allowed to go to waste; but when the American petroleum began to depress the prices of the oils the manufacturer saw the propriety of working up the liquors for sulphate of ammonia by the same methods as are employed in connexion with the coal-gas industry (see NITROGEN, vol. xvii. p. 519). And as, during the last decade or two, the demand for ammonia has been steadily increasing, the ammonia in the shale industry by and by rose from the rank of a minor collateral to that of one of the principal products, and a number of attempts have been made to recover that part of the nitrogen which, in the ordinary process, is lost as a component of the coke. Dr H. Grouven proved (1875-77) that all nitrogenous organic or organoid matter when exposed to a current of steam at about 1000° C. burns into carbon oxides, hydrogen, and ammonia, the last-named including all the nitrogen. Messrs G. T. Beilby and William Young have worked out and patented a process for discounting this fact in the shale industry for a more exhaustive extraction of the ammonia. In one of the later forms of the process the shale is being distilled in retorts standing over a fire-brick chamber surrounded by flues and kept at a far higher temperature than the retorts themselves. The coke from the retorts is discharged straight into this chamber, and therein exposed to a mixed current of steam and air, which burns away the carbonaceous part into carbonic acid, carbonic oxide, hydrogen, and ammonia. The large mass of hot gas thus produced passes next through the retorts above to aid in the distillation, and conjointly with the retort vapour is subjected to systematic successive condensation. The incondensable gas which is ultimately obtained includes all that the gas from the ordinary process contains, and also a large proportion of hydrogen and carbonic oxide from the hot-chamber process. It serves as a fuel for heating the chamber and the retorts; but, as it does not furnish quite enough of heat for all this, a combined retort and gas-producer is built into the bench with the shale retorts. This supplementary apparatus is charged with coal, which, in it, is first distilled, then converted partially into gas by steam and at last completely by a regulated current of air. The gas from the first and second stages is scrubbed to strip it of its ammonia and tar, and then, conjointly with the gas from the third, used as a fuel for the retorts. In this way the advantages of gas-firing are secured at little expense, as the condensed products are nearly equivalent in money value to the coal consumed. In the Young-Beilby process, which is extensively used in Scottish works, the yield of ammonia is on the average double, and in special cases five times, that obtained in the ordinary process of distillation.

The Working of the Oil.—The composition of the crude oil is very variable (see above). It generally forms a very dark green, almost black, liquid, somewhat tarry in appearance, and endowed with a highly unpleasant empyreumatic odour. The specific gravity ranges from 0.862 to 0.895. Each ton of shale distilled yields on an average 30 gallons of crude oil (about 260 lb), 700 lb of coke, gas, and loss, and 1270 lb of cinders. The crude oil on refining yields 38 to 44 per cent. of oils available as "spirit" or for burning, 15 to 20 per cent. of lubricating oil, and 9 to 12 per cent. of solid paraffin.

Refinery.—The first operation in oil refining consists in submitting the crude oil to distillation in large pot-shaped stills capable of holding 1200 or 1400 gallons. The distillation is continued till only a pure vesicular coke remains in the still, and the vapours (condensed by the ordinary worm-pipe arrangement) constitute "once-run oil," which from its bright green colour is also known as green oil. The once-run oil is the material from which, by a repeated series of washings with sulphuric acid and caustic soda and fractional distillations, the graduated series of purified products is finally obtained.

Washing.—Once-run oil contains a series of basic and acid components. To separate these the oil is first repeatedly treated with sulphuric acid of different degrees of strength, which is thoroughly intermixed and brought in contact with the oil by mechanical means in an agitating tank or washer. The acid first used is a weak tarry acid which has been already used in a subsequent stage of the manufacture. This produces a copious tarry deposit, which is removed; the process is repeated with a similar result; and thereafter the oil is further treated with two successive washings of strong vitriol. After settling and removal of the precipitated tars, a similar series of washings with caustic soda solutions of increasing strength, and corresponding precipitation and removal of tars which combine with the alkali, are carried out. During both the acid and the soda treatments the oil is maintained at a temperature of about 100° F. by the circulation of steam through the tanks in coiled pipes. The sulphuric acid tars are to some extent used as fuel in the fractionating stills.

Fractional Distillation.—The purified once-run oil is a very mixed substance, giving off vapours within a wide range of temperatures, which condense into products of varied specific gravity. By the series of fractional distillations to which it is submitted a series of products are ultimately obtained comparatively homogeneous in constitution, which distil within relatively narrow limits of temperature. The ordinary method of fractionating once-run oil consists in running it into large cylindrical boiler stills heated by furnaces in which the acid tar already spoken of is consumed. The stills have led into them steam-pipes, through which steam is injected into the oil in process of distillation as required. When the heat is first raised, superheated steam is injected to aid in carrying off the lighter vapours, which are condensed as naphtha or "spirit." As the distillation proceeds, and the gravity of the condensed product increases, it is run into separate receivers, and thus a series of fractionated intermediate products is produced, the first portion up to 0.750 specific gravity being naphtha, while from 0.750 to 0.850 is the burning oil portion, and the subsequent portion separated is heavy oil containing paraffin. The portion remaining in the still is removed to the residue stills, in which it is distilled till the still contains only coke. The oil driven off from the residue stills is called "heavy oil and paraffin," and passes to the paraffin house for treatment there.

Improved Fractionating Stills.—Many attempts have been made to adapt the fractionating still to a system of continuous working by keeping the contents at a constant level as the distillation proceeds. For a long period continuous distillation was only imperfectly applicable, and yielded unsatisfactory results. The lighter fractions alone were driven off, and as the distillation progressed the density of the contents of the still gradually increased, making the difference between the oil added to the still and that within it increasingly great. In the end the contents of the still had to be removed and completely distilled as one charge in a separate still. In 1883 Mr Norman M. Henderson, the patentee of the Henderson retort, patented a continuous process of distillation which completely obviates all difficulties, and largely reduces the time, labour, and cost of fractionation as compared with the ordinary intermittent method. According to Henderson's system, purified once-run oil is fractionated continuously in a connected series of three cylindrical stills. Each still is fitted with inlet and outlet pipes, the mouths of which opening upwards are placed at opposite extremities of the still. The outlet pipe of No. 1 passes as inlet into No. 2, and similarly outlet of No. 2 is connected as inlet with No. 3, while the outlet of No. 3 passes into one or more common residue stills. The inlet or feed pipe of No. 1 traverses the long horizontal condensing pipes of the whole three, and thus the once-run oil, while absorbing heat before entering No. 1 still, also aids the condensation of the vapours. In working there is a constant feeding of heated once-run oil into No. 1 still, a like steady flow from No. 1 to No. 2, from No. 2 to No. 3, and from No. 3 to a residue still. The oil of course increases in density as it passes onwards; but the specific gravity in each still is practically constant, and, as the heat applied is increased in proportion to the gravity, the oil vaporized in each separate still is of uniform quality and specific gravity. In No. 3 still, where, in consequence of the high gravity and temperature, there is a tendency to deposit carbonaceous matter, circulating plates or dishes hinged to each side of the still, and concentric with the bottom shell, are placed. The circulation of the oil from the bottom up the sides in the space between the shell and the circulating plates is directed and assisted by jets of steam from a pipe laid

along the bottom of the still. In this way the oil is kept in steady circulation up the sides and down the centre, and any deposit of coke which may take place forms on the inner surface of the circulating plates, from which there is provision for its easy removal when required.

The manufacturer has now his material split up into three products—naphtha, burning oil, and heavy oil with paraffin. By renewed treatments with acid and alkali and fractional distillations, these products are further purified and differentiated. We cannot go into technical details, and in regard to the principles upon which the processes are founded reference may be made to what has been said above in connexion with corresponding laboratory methods. As a final result the following products (or a similar series of other products) are produced and sent out into the market:—

1. Gasoline: a mixture of paraffins, so volatile that a current of air by being passed through it at ordinary temperatures is converted into combustible (non-explosive) gas.
2. Naphtha: a mixture of hydrocarbons which in volatility and otherwise are equivalent to the crude benzol of the coal-gas industry.
3. Burning oil: a mixture of oils sufficiently volatile and light to be suitable for combustion in domestic lamps with wicks, and yet practically free of dangerously volatile inflammable components.
4. Heavy oil, corresponding to a range of very high boiling points; too heavy or viscid to be raised by the wick of a lamp, but well adapted for lubricating purposes. This part contains the solid paraffin which the manufacturer takes care to extract as completely as possible before the oil is sold as "lubricating oil." The several kinds of crude paraffin extracted are classed as "hard scale" or "soft scale," according to their fusing points and consequent degrees of hardness at ordinary temperatures.

Separation of Hard Scale.—The heavy oil forming the last of the three portions into which once-run oil is fractionated; at ordinary atmospheric temperatures, becomes thick and pasty by the abundant formation of crystals of solid paraffin. This mixture of oil and paraffin is separated by draining through canvas bags, or, as is now the almost universal practice, by passing the magma into a filter press. This apparatus contains a series of thirty or forty perforated plates about 2 feet square, the faces of which are covered with filtering canvas. They are screwed up together in an oblong horizontal frame, so that a space or chamber about an inch wide is left between each pair of plates. Into these chambers the pasty mixture is forced under high pressure, the material passing into and filling each chamber through an orifice in the centre of the plates till the whole of the chambers are filled. The pressure being kept up, the fluid oil exudes through the canvas and perforations in the plates, leaving solid paraffin, which continues to accumulate till the chambers are filled with it in a comparatively dry condition. The soft cake from the filter press is further squeezed in canvas in an hydraulic press giving off more fluid oil, and the cake from this pressure consists of commercial hard scale or crude paraffin.

Soft Scale.—The heavy oils separated in the second and third fractionation of burning oils, and the oil from which the above hard scale is separated, hold dissolved in them paraffin of low melting point, which can only be crystallized out by bringing the oil to a very low temperature. For this purpose the oils are reduced to from 18° to 20° F. by artificial refrigeration. The method now employed consists in sufficiently cooling a continuous current of brine or of chloride of calcium solution by passing it through an ether refrigerating machine. This cold current of brine circulates through the interior of a large cylinder or drum, which revolves slowly, dipping into a trough containing the oil to be cooled. The cold surface of the drum in contact with the oil takes on a deposit of solid paraffin crystallized out of the mixture. It is removed by scrapers and made to fall into a separate receptacle, whence it goes to the filter press and the hydraulic press in the same way as the hard scale.

Lubricating Oil.—The oil from which hard and soft paraffin are separated as above stated exhibits a blue fluorescence, and is hence called blue oil. It receives an acid and soda series of washings, after which it is submitted to fractionation. The first portion given off, up to about 0.850 specific gravity, is transferred to the burning-oil series, with which it is mixed for further treatment. The remainder is received as various grades of lubricating oil, with specific gravity ranging from 0.860 to 0.890. These heavy oils are again refrigerated, yielding a further crop of soft scale, after which they get a final acid and alkali treatment, and are finished for use by having steam blown through them for a prolonged period, the effect of which is to reduce greatly their objectionable smell. Finally they are kept in warm settling tanks at a temperature of not less than 90° F. for eight or ten days, when they are ready for the market.

Occasion has already been taken to name the advantages which this kind of mineral oil offers as a lubricating agent. Let us now add that it cannot quite take the place of fatty lubricants, lacking the degree and kind of viscosity which fits these for certain purposes. A mixture of fatty and mineral oil in proper proportions is often found to work better than either component would by itself. As mineral oil is far cheaper than all the fatty oils, it is largely used as adulterant of these. Such adulteration can

often be detected without the aid of chemical tests; all heavy mineral oils exhibit a characteristically strong blue fluorescence, which becomes rather more prominent by the presence of fatty oil. Manufacturers, however, have learned to remove the fluorescence by the addition of certain chemical substances, and large quantities of such "bloodless" oil are being sold and used as colza or other fatty oil.

Paraffin Refining.—The crude paraffin which remains to be dealt with consists of soft scale, melting point between 90° and 105° F., and hard scale melting between 115° and 120° F. The greater part of the soft scale is disposed of in the crude state for impregnating match splints in lucifer-match making. The remainder, hard and soft, is purified by an acid and soda treatment, and decolorized by repeated washings with solvent naphtha. To this end the scale is melted, mixed with 25 per cent. of naphtha, cooled down, and thus caused to crystallize, and subjected to hydraulic pressure. The solvent naphtha is thus squeezed out, and this series of operations is repeated two or three times. Each of the mother-liquors produced is utilized as a purifying agent for the paraffin of a preceding stage of purity, so that it at last arrives at and serves for the original crude scale.

In its progress through these washings the naphtha takes up much heavy oil and solid paraffin, which are extracted by systematic fractionation and crystallization. The paraffin, after its last squeezing, is a dull chalky-looking white mass strongly impregnated with naphtha, to drive off which it is melted and has a current of steam blown through it, till no trace of naphtha odour comes away with the steam. The ultimate decolorization is effected by mixing the heated paraffin with animal charcoal, allowing the charcoal to settle, and drawing off the paraffin through filters. The molten paraffin flows into oblong tins which mould it into the beautiful translucent blocks used for candle making and the several other purposes to which paraffin is applied.

The soda-tar obtained in the various processes is to some extent collected and treated for the recovery of a soda sufficiently pure to be used in the first stages of purification of the crude oil. It is also employed to neutralize the acid tar, after which both are distilled, yielding as a bye-product an oil known as "green oil," largely used for the manufacture of oil gas under Pintsch's patent.

Commerce.—The development of the paraffin industry under Young's patents, and the rapid increase of demand for the products, led directly to the rise of the great petroleum industry in America. The United States acting commissioner of patents, Mr John L. Hayes, in reporting on Mr Young's claim for an extension of his patent rights, states that "the manufactures of coal oil in this country had their origin in Mr Young's discovery. The use of petroleum followed so directly and obviously from the use of coal oils that it can hardly be denied that the one originated from the other." The petroleum industry once started, however, grew with so startling rapidity, and attained such gigantic proportions, that it threatened the entire extinction of the parent manufacture. In the early days of the trade a considerable development of manufacturing activity took place in Wales, where an inferior kind of cannel coal was distilled; and at many localities in Germany brown coal and sometimes peat were utilized as the raw materials of a considerable industry. The pressure of the competition with American oil was felt severely by all, and it was only with much difficulty that the great Scottish companies succeeded in holding their own, and in carrying on a constantly extending production. The Welsh industry was practically extinguished, and the production in Germany, notwithstanding the imposition of high protective duties, was greatly circumscribed. The chief seats of the manufacture in Germany are now in Saxony, near Weissenfels, where a peculiar variety of lignite called "pyropissite" forms the raw material for distillation.

In the Scottish industry there was in the middle of 1884 about £2,000,000 of capital invested, the working capacity of works in operation being equal to the distillation of 4170 tons of shale a day, while plant is being provided to increase that capacity to 5920 tons. The following table represents the present output of a year of 312 working days.

| | Actual. | In View. | Total. |
|---|------------|------------|------------|
| Shale distilled per day, tons..... | 4,170 | 1,750 | 5,920 |
| Shale distilled, tons.....per annum | 1,301,910 | 546,000 | 1,847,910 |
| Crude oil produced, gallons..... | 39,051,200 | 16,380,000 | 55,431,200 |
| Burning oil and spirit, in barrels of 40 gallons..... | 400,070 | 167,895 | 567,965 |
| Lubricating oil, tons (of about 256 gallons)..... | 24,490 | 10,277 | 34,767 |
| Paraffin scale, tons..... | 15,331 | 6,435 | 21,766 |
| Sulphate of ammonia, tons..... | 10,454 | 4,388 | 14,842 |

(W. D.—J. F.A.)

PARAGUAY, a South American republic situated in the basin of the Parana-Paraguay system, between 22° and 27° 35' S. lat. and 54° 35' and 61° 40' W. long. It is conterminous with Brazil, Bolivia, and the Argentine

Republic, and its boundaries were long under dispute. The Argentine Republic especially laid claim to a portion of the Gran Chaco to the north-east of the Pilcomayo; but in 1878 the president of the United States (to whose arbitration the matter had been submitted) decided in favour of Paraguay.¹ The town of Villa Occidental, on the Gran Chaco side of the Paraguay river, opposite Asuncion, has since been called Villa Hayes. The whole area of the country is estimated at 91,980 square miles, of which 35,280 are in the Gran Chaco portion.

Paraguay proper, or the country between the Paraguay and the Paraná, is traversed from north to south by a broad irregular belt of highlands which are known as the Cordillera Amanbaya, Cordillera Urucury, &c., but partake rather of the character of plateaus, and form in fact a continuation and outwork of the great interior plateau of Brazil (Keith Johnston, jun.²). The elevation nowhere much exceeds 2200 feet. On the western side these highlands terminate with a more or less sharply-defined edge, the country sloping gradually up to their bases in gentle undulations with open ill-defined valleys; on the eastern side they send out broad spurs enclosing deep-cut valleys, and the whole country retains more of an upland character. The tributaries that flow westward to the Paraguay are consequently to some extent navigable, while those that run eastward to the Paraná are interrupted by rapids and falls often of a formidable description.³ Apart from the central highlands there are several plateaus and knots of hills in the west between 25° and 26° 20' S. lat. The plateau on the edge of which Asuncion is built has a relative height of about 200 feet, and skirts the Paraguay for about 25 miles with red sandstone cliffs; to the north of this is the Altos Cordillera, with a relative height of 600 feet. From the Asuncion plateau southwards, near the confluence of the Paraguay and Paraná, there is a vast stretch of marshy country draining partly into the Ypoa lagoon; and smaller tracts of the same character are found in other parts of the lowlands, especially in the valley of the Paraguay. The country sloping to the Paraná is nearly covered with dense and well-nigh impenetrable forest, and has been left in possession of the sparsely-scattered native tribes. On the other hand the country sloping to the Paraguay, and comprising the whole of the properly settled districts, is, in keeping with its proximity to the vast plains of the Argentine Republic, grassy and open, though the hills are usually covered with forest, and clumps of trees are frequent in the lowlands. Except in the marshy regions already mentioned and along the rivers the soil is dry, porous, and sandy, produced by the weathering of the red sandstone, which is the prevailing formation throughout the country.

The year in Paraguay is divided into two seasons,— "summer" lasting from October to March, and "winter" from April to September. December, January, and February are generally the hottest months, and May, June, July, and August the coldest. The most temperate month is April. The mean temperature for the year seems to be about 75° or 76°; for summer 81°, for winter 71°. The rainfall, amounting to 58 inches at Asuncion, is distributed
