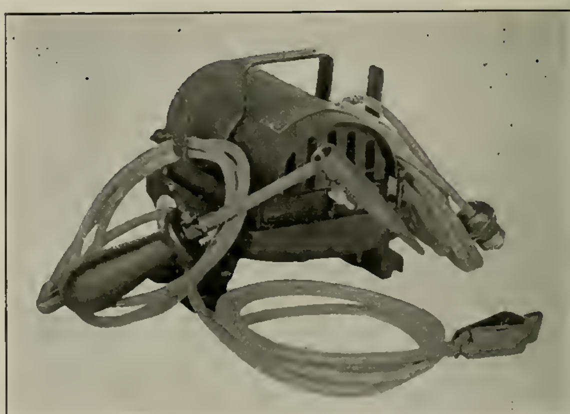
When the pointed arc welding carbon is brought into contact with the lead the pointed end of the carbon becomes intensely hot, so hot that it melts the lead over a restricted area quicker than a pointed gas flame will do it. The welding or burning operation is carried out by a sort of puddling process, the carbon terminal being manipulated to flow the lead where it is needed.

It will be noted that this is not an arc welding process, and that no arc is drawn during the burning, but the nose of the carbon is kept immersed, perhaps 1/16 in. in the lead.

Among the advantages of the electric lead burner is that repair work in hard-to-get-at corners can be done more easily



Transformer Equipped with Attachment Plug, Big-Brute Clip and Welding Tip

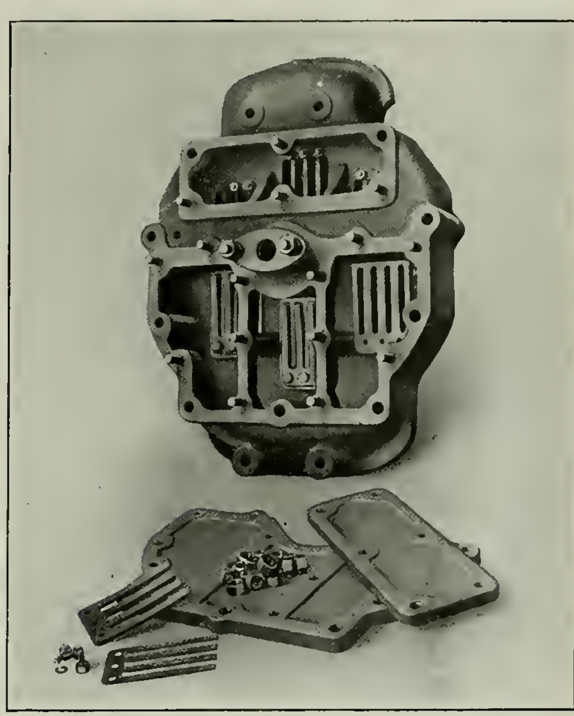
as the heat is always right at the point of the carbon, the device is readily portable weighing approximately 25 lb., joints do not have to be cleaned as the dirt and slag automatically rise to the surface of the molten lead and the surfaces are joined while cleansed; when properly used, there is no glare to injure the operator's eyes, as he looks down on the cool end of the carbon in such a way that the bright point where the carbon touches the lead is hidden from view; there is no danger from electric shock because of efficient insulation.

On the basis of 10 cents per kilowatt hour, it costs about 8 cents per hour for current when the device is operating steadily. The instant the carbon point is removed from the work, the current consumption practically ceases, as the device then takes only 4½ watts from the line.

Owners of these transformers have found an increasing field of application. The device is said to be especially valuable in reconstructing and repairing batteries; while in the shop and foundry it has been used where all kinds of odd soldering jobs must be done. The device has also been found applicable in plumbing, roofing, tank building, etc.

AIR COMPRESSOR WITH PLATE TYPE VALVES

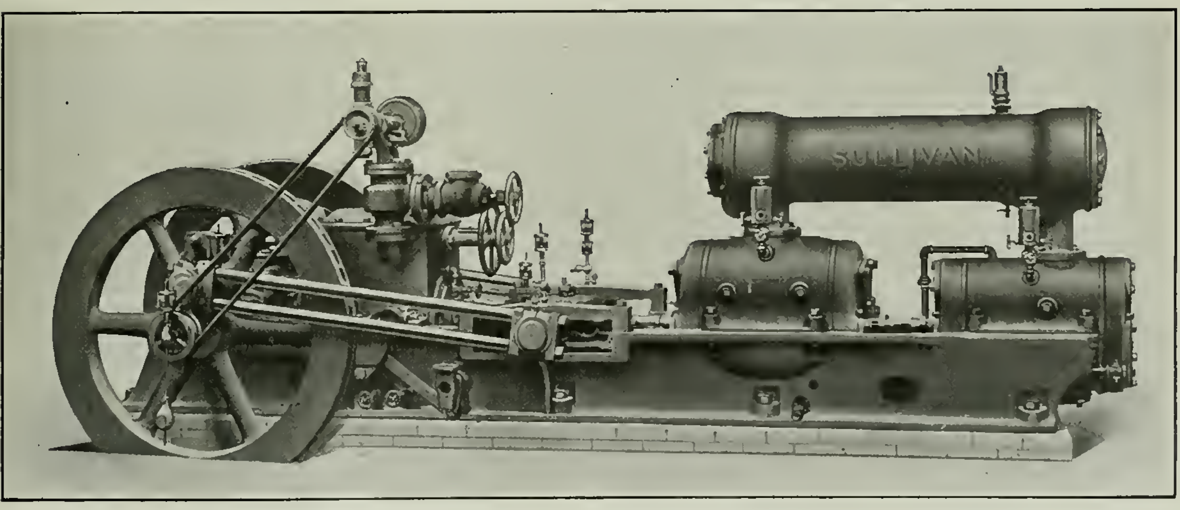
THE air compressor shown in the photograph is a redesign of an earlier straight line type of two-stage compressor with a single steam cylinder and two air cylinders, and provides from 400 to 940 cu. in. of free air per minute, compressed to a maximum pressure of 100 lb. per sq. in. One of its principal improvements consists of a speed and pressure governor admitting of three adjustments, namely, maximum and minimum speed and air pressure, each adjustment being independent of the others. The speed controlling element is entirely enclosed in a casing to protect it from dirt.



Cylinder Head with Valve Covers and Some of the Valves Removed

End rolling finger valves constitute another important new application to the air cylinder heads and are illustrated in the view which shows a cylinder head with the cover removed. These valves consist of thin flat steel sheets cut to form four finger-like blades; these are bolted at one end to the cylinder heads so that the fingers seat over long narrow ports which are opened or closed according to whether the fingers rest flat against the seat or are bent backward away from it. To protect the valves and prevent excessive lifting from the seats they are covered by steel guards having the same general shape as the valves, but made of a thicker material and given a definite curve away from the valve seat. In opening the fingers impinge against these guards with a rolling motion, hence the name "rolling finger valve." It is stated that the end rolling effect eliminates the hammering which commonly occurs in the operation of air valves and provides a rapidity of action, wide port opening with minimum wire drawing, and a reduction in the number of moving parts.

These pumps, known as the Sullivan WB-3 air compressors, are manufactured by the Sullivan Machinery Company, Chicago, in two sizes.



Class WB-3 Air Compressor, Straight Line Type with Simple Steam and Two-Stage Air Cylinders

A MACHINE FOR SHARPENING OLD FILES

THE American file sharpening machine, manufactured by the Abrasive Machine Company, Irvington, N. J., is designed for the resharpening of old files of all kinds. The resharpening of a dull file is accomplished through the grinding action of a patented abrasive combination known as Carboflynt, mixed with water, propelled at high velocity by a jet of steam through a nozzle.

A cross section of the nozzle (Fig. 1) shows a flat file in the proper resharpening position, resting on the bevelled edge of a block of metal called the "test iron" because of the fact that a properly resharpened file will gently adhere to its surface. The correct angle of the file to the jet of Carboflynt shown projected from the nozzle is about 30 deg. and the bevel on the test iron serves as a guide to the operator in handling the file.

An enlarged longitudinal section of the teeth of a new file is shown at *A* in Fig. 2; the result of the grinding action on the teeth of an old file is shown by the dotted lines in *B*, Fig. 2. It will be seen that the Carboflynt jet grinds away the back of the teeth, leaving the cutting edge clean and sharp. The operation requires about half a minute and the resharpening can be performed as often as there are any teeth left to work on.

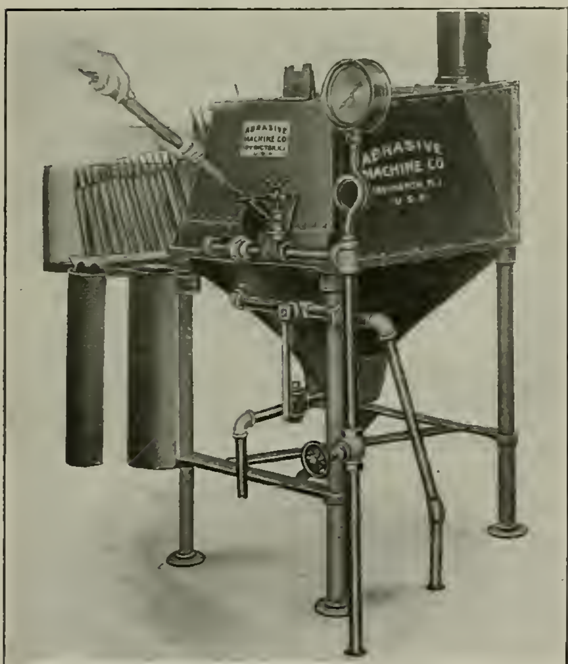


Fig. 3—Machine for Sharpening Files

It is estimated that by the use of this machine, old files can be put back into use, practically as good as new, at a cost not to exceed 10 per cent of their original value. It is further stated that ten pounds of Carboflynt at 10 cents per pound will resharpen $300 worth of files, owing to the fact that the Carboflynt is used over and over again.

The complete machine is shown in Fig. 3 and consists of a sheet metal box mounted on a stand with an opening in front for admission of the nozzle and the file. The partly open window on the left is for the purpose of replenishing the supply of Carboflynt and water when necessary; an overflow pipe controls the level of the water in the hopper.

The vertically mounted cylindrical tank at the right hand side is a water container, used for dipping files to clean them when drawn from the chamber.

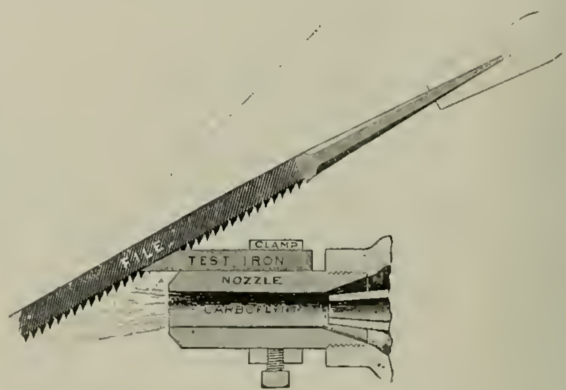

Fig. 1—Cross-section Through Nozzle Showing Flat File in Position for Resharpening

The method used in the treatment of files in the American file sharpening machine does not subject them to the danger of "losing their temper" in the slightest degree, and this fact is gradually overcoming the prejudice which has existed toward "file sharpeners."

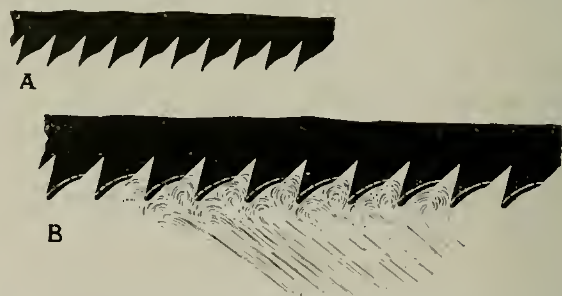

Fig. 2—(a) Shape of Teeth on New File. (b) Dotted Lines Show Recut Teeth

A typical installation is shown in Fig. 4. Steam is piped directly from the boiler to the nozzle through a ¾ in. pipe;

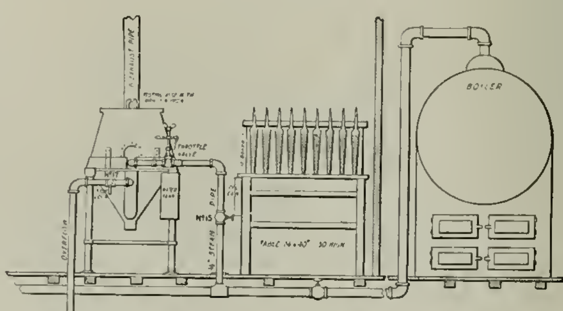

Fig. 4—Typical Arrangement of Apparatus Used for Sharpening Files

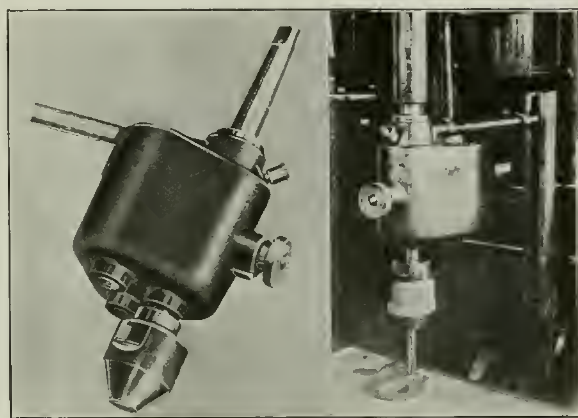
the pressure recommended for the best results is from 85 to 150 lb. of steam. Where steam is unavailable, compressed air has been used with success. Among recent installations that have been made are machines for Pennsylvania Railroad at Reading, Pa., and the Mobile & Ohio Railroad at Murphysboro, Ill.

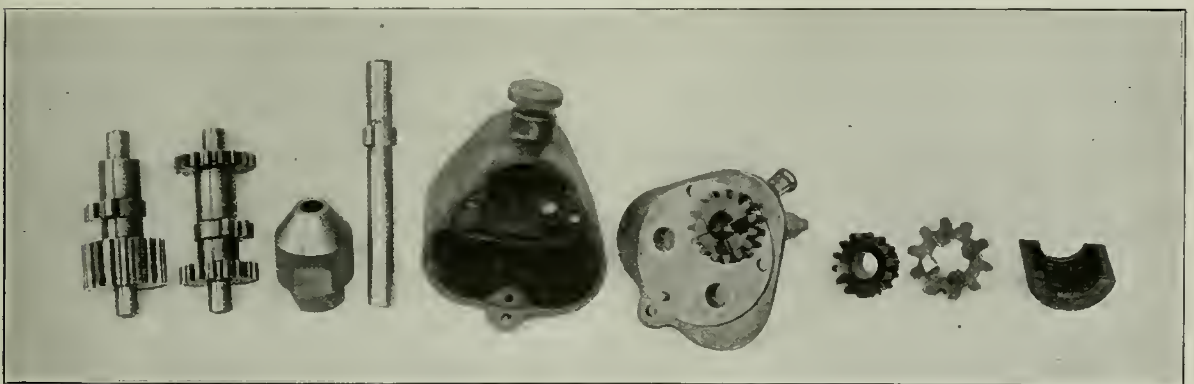
BACKING OFF THE TAP MECHANICALLY

THE mechanical tapping attachment for a drill press shown in the photographs is so constructed that in operation it imitates the motion of the human hand, advancing the tap into the work and then, reversing itself automatically, it backs out the tap sufficiently to clear itself, when it again resumes its forward direction. This is particularly necessary in tapping steel or tough material. The forward movement being greater than the backward movement advances the tap. The return movement in backing the tap out is continuous and at an increased speed. This automatic oscillating operation is considerably faster than hand tapping. By the use of this apparatus the entire tapping job may be done with the finishing tap only, thus eliminating the preliminary work of starting taps; the time saving economy of this, in addition to the speed at which the apparatus can be run, is manifest.

The device is foolproof and strongly made; no springs are used in its design and it can be instantly changed from the oscillating to a continuous drive for use in soft metals where the automatic "backing off" is not required, by the operation of the knob on the front of the machine. Turning the knob disengages a clutch, which throws a gear on the countershaft out of mesh with the tapping spindle.



(Left) Automatic Tapping Attachment Which Imitates Hand Tapping. (Right) Application of Tapping Attachment



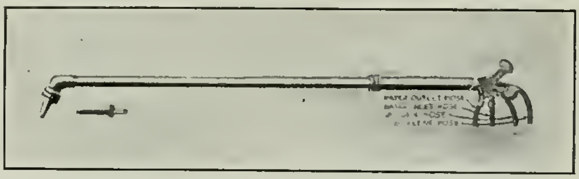
Parts of the Automatic Oscillating Tapping Attachment

These machines, carrying a No. 2 Morse taper shank, are furnished for all sizes of taps up to ⅝ in. by the Wahlstrom Tool Company of Brooklyn, N. Y.

WATER-COOLED WELDING TORCH FOR HEAVY WORK

MUCH time and gas are often wasted because of the overheating of the tip of the oxy-acetylene welding torch when the work must be done in hot corners, in holes, or in the handling of heavy and difficult work. A big saving could also be effected on some jobs if the preheating blast could be kept on the weld while the metal is being fused, or if two or more torches could be used continuously to secure and retain the proper heat. The Admiral Welding Machine Company, Kansas City, Mo., has developed a water cooled torch to meet these difficulties.

The circulation of the water keeps all parts of the torch cool and because of this the torch will work uniformly on a weld of any thickness. It is said that if the torch is suspended from the ceiling by a wire or cable and the welder



Admiral Water Cooled Torch

is protected from the heat, the torch may be kept on a weld indefinitely, and if necessary the welders can take turns in operating it. The torch may be connected to the city water pressure or even to a barrel or tank, as the amount of water required is not very great.

The torch is 34 in. in length, weighs 3 lb., and is furnished with two interchangeable tips. The connections are ground joints and the torch may be quickly taken apart in order to remove any scale or obstruction in the water line. It is finished in brass with knurled fittings.

NEW LUBRICANTS AND CUTTING OILS

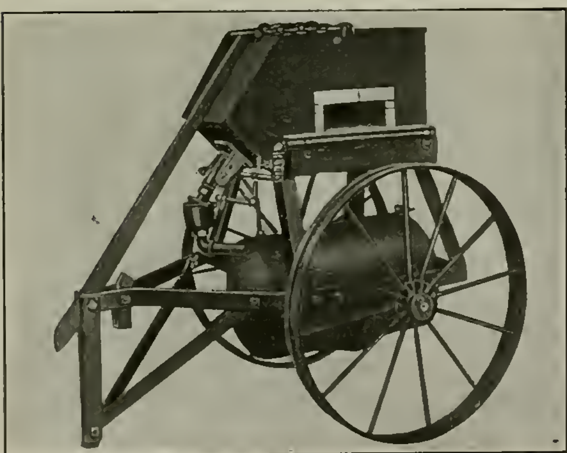
In addition to three grades of cutting oils recommended as substitutes for lard oil on account of their greater cooling qualities, a lubricant especially developed for use in portable pneumatic tools and said to have unusual consistency and lasting qualities, has been recently introduced by the Fiske Brothers Refining Company, New York.

Their No. 1040 cutting oil is light in body and is intended for light cutting operations, No. 1770 is prescribed for medium work and No. 2020 is furnished for extremely heavy work.

A product known as Ferrol Economizer, which is said to be impervious to fresh or salty water or water containing acids, and is not affected by heat or cold, is also manufactured by this company for lubricating gears, chains and ropes, or for use wherever a question of extreme temperature or high bearing pressure with low speed arises.

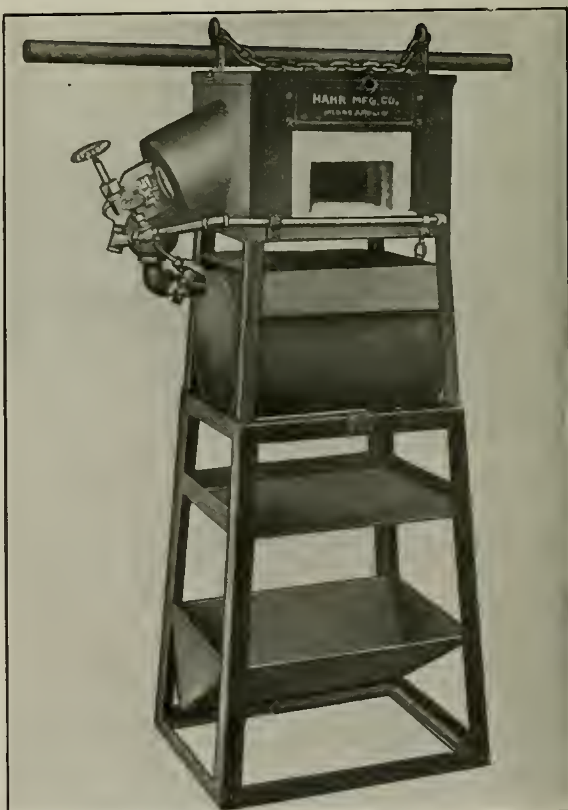
OIL FUEL RIVET FORGE FOR THE REPAIR TRACK

High wheels clear the tracks and the comparatively low center of gravity due to the fuel tank's location near the center of the axle of the wheels in the rivet forge illustrated herewith, decreases the difficulty of getting it from one section of the "rip track" to another in car repair work. The handle used in pulling it folds back against the body of the forge without interference. The operation of this forge, which will heat four hundred ¾-in. by 3-in. rivets per hour, involves the use of a special burner constructed on the vacuum principle, which makes it possible to burn any grade of fuel oil or kerosene, without pressure on the 18-gallon fuel tank. This is a "safety first" consideration of no mean value.



Oil Fuel Rivet Forge for Car Repair Work

The forge is made by the Mahr Manufacturing Company, Minneapolis, Minn., and the burner is of the standard type made by that company. A hollow chamber through which passes the air used in atomizing the oil, extends across the front of the furnace above the opening. At the entrance to this chamber a portion of the air is led down to a point below the furnace, opening into a perforated pipe. From this chamber the air passes to the atomizing valve. An oil chamber is formed in the lower end of the lead, the oil passing up through this chamber, where it is pre-heated. From there it passes to the atomizing valve, being at such a temperature that when the hot air strikes it it becomes immediately gasified, passing into the combustion chamber in that condition. A by-pass from the air pipe passes up above the combustion chamber and feeds air into the furnace, in this way insuring perfect combustion of the oil. An interesting feature in the performance of this furnace is the lack of scale formed on the work; this is accomplished by having



Rivet Forge Mounted on Convenient Stand

a neutral flame, no more air being admitted than is necessary thoroughly to consume the oil. The flow of the air through the by-pass is controlled by a valve, as is the air and oil mixture. The atomizing valve also is of a distinctive design. It is constructed on the piston valve principle and permits passing the impurities in the oil through to the combustion chamber without danger of clogging the valve.

A small portable forge is also shown, using the same principles of operation as the outfit described above. It is conveniently mounted on a strong, wrought iron stand provided with two trays; the bottom one may be used as a cold rivet bin, the upper one for tools.

MULTIPLE PUNCH FOR CAR UNDERFRAMES

BY GEORGE P. THOMAS

President, Thomas Spacing Machine Company, Pittsburgh, Pa.

The necessity of reducing manufacturing cost, with labor cost tending to stay fixed, makes standardization of design a most important consideration in plants engaged in steel construction, such as steel car shops. Only on the basis of standardized design is it possible to take advantage of the possibilities offered by special tools which will increase output and cheapen unit costs through quantity production.

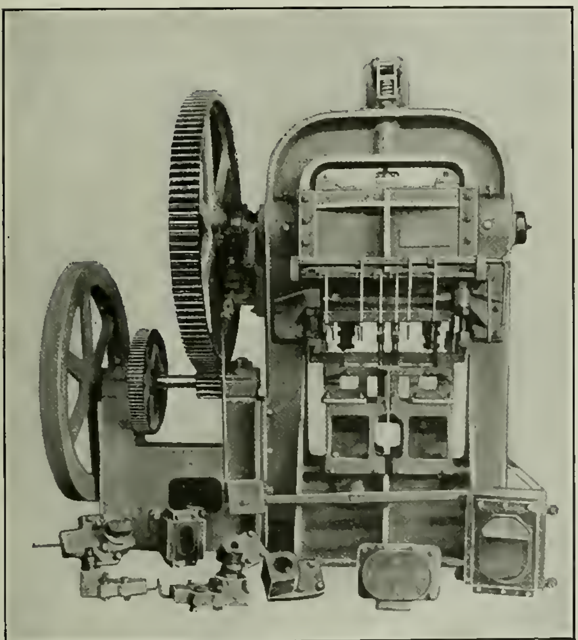


Fig. 1—Car Underframe Type Multiple Punch with Interchangeable Special Tools

The demand for a punching machine with a wide range of application, such as is found in the steel car shops, was responsible for the design, or perhaps it may better be said, the development, of the machine here described. The punch with several of the interchangeable punching and blanking-out tools and dies is shown in Fig. 1. This machine was built for one of the large tank car companies. Its utility and capacity are greatly increased when it is operated in conjunction with a spacing table, as described in subsequent paragraphs.

Steel car underframe work requires punching, shearing and sometimes coping and blanking-out of plates or structural sections. In some cases the structural sections are made by flanging flat plates, which are punched most readily before being flanged. Tool set-ups suitable for these operations are shown in Figs. 2 and 3. With other tools and spacing blocks to suit, angles up to 6 in. x 6 in. x 5/8 in. can be punched singly or in pairs, the latter method having the advantage that, with the clamping device illustrated in Fig. 1, the angles are held back to back, and the tendency to curling is overcome and the holes are uniformly spaced with reference to the heel of the angle. Likewise, I-beams up to 6-in. flange and 15-in. web and channels of corresponding dimensions can be punched on either the flanges or web, the channels for flange punching being handled in pairs as though they were an I-beam, by means of the automatic, cam-operated clamping device illustrated in Fig. 1. In punching channels, the web is always punched first. For punching the webs of beams and channels, guide rollers

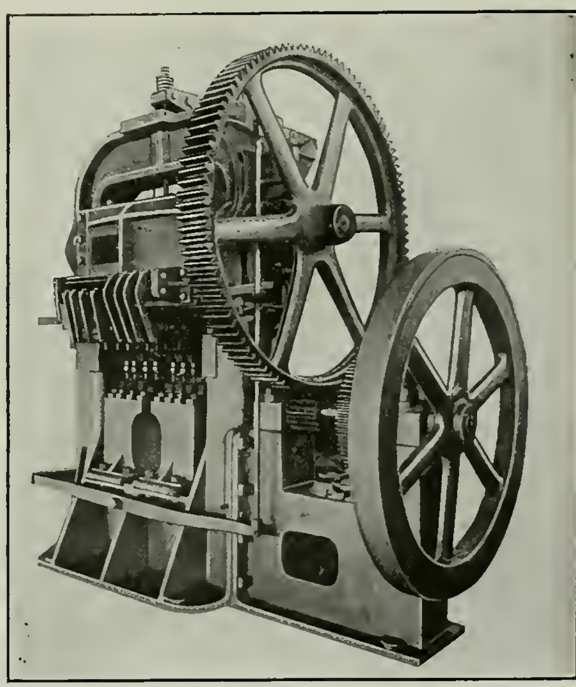

Fig. 2—Punch Equipped with Tools for Multiple Punching of Plates

are mounted on the punch blocks in the same way that the die holders are held in place, that is, by means of T-head bolts. Z-bars are also handled in pairs with a special set-up, for either web or flange punching. For this work, high and low die holders, and long and short punch spindles are required. As the clearance between housings is approximately 39 inches, plates or sills up to 36 inches in width can be punched.

The design of this tool is such that it can be fitted up very readily with coping tools, or it can be converted into a gate shear, guillotine type shear, angle and channel shear, or bar shear.

The adaptability of this multiple punch for use in connection with a spacing table is shown in Fig. 4, in which the spacing carriage (of the hand-operated type) is shown in the foreground in place on the roll table. The trailer carriage, for guiding the trailing end of the plate or other member while going through the punch is shown somewhat indistinctly on the far end of the roll table. The movement of the spacing carriage in advancing the plate through the punch can be made entirely automatic by the use of a motor mounted on the carriage and driving through a clutch arrangement and gear train to the pinions that are to be seen in the illustration adjacent to the carriage wheels. However, as the rollers of the roll table are all equipped with ball bearings, the heaviest plate can be moved by hand with remarkable ease.

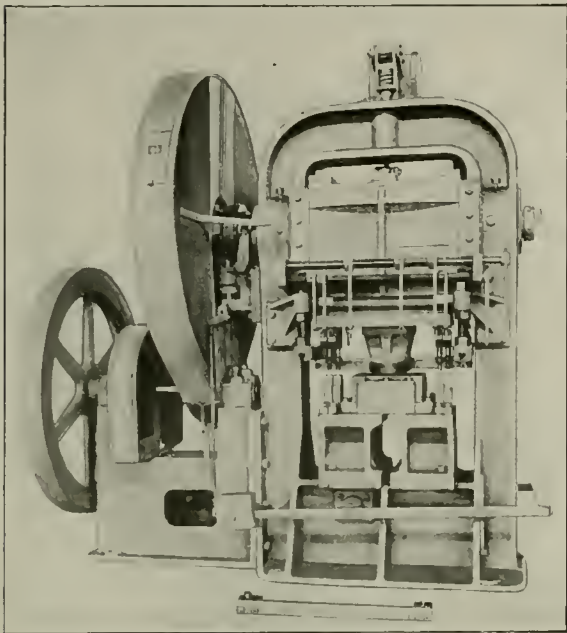

Fig. 3—Set-Up of Tools for Blanking Out Web of Channel and Punching at Each Side in Pairs

Whether motor or hand driven, the spacing between holes or rows of holes, as the case may be, lengthwise of the plate, is automatically controlled by means of a full-sized templet which is fastened to the side of the roll table by means of clamps. This templet is simply a wooden strip, which can be prepared in the pattern shop, having steel pins driven in at intervals corresponding to the pitch between holes, measured lengthwise of the plate. The drawing for the punching layout is used in making this templet which is thereafter identified by being marked with this drawing number. These steel pins on the templet simply serve to actuate the tripping mechanism on the spacing carriage, which in turn releases a set of pawls that drop by gravity into the spacing rack mounted on the framework of the table. The operation of these pawls is electrically interlocked with the operation of the ram of the punch, so that when the pawls are down in the spacing rack, locking the carriage where it is stopped, the punch can then operate, and as soon as the punching tools strip the plate a cam-operated contact on the main cam shaft of the punch closes the circuit to the solenoid shown in Fig. 4 mounted on the carriage, which operates to lift the pawls out of the spacing rack and thus allows the carriage to advance with the plate to which it is clamped until the next spacing pin on the templet again causes the carriage to stop while the punch makes another stroke.

The standard punching tools can be set to a minimum of 2-inch centers, and may be controlled singly or in groups. Thus, the number of holes punched at a time across the plate with each stroke of the punch is under the control of the operator by means of the hand levers which operate the gags in the respective punching tool holders. This is shown most plainly in Fig. 2 in which the gags for the eight punching tools are seen to be linked up to the arms mounted on the two horizontal operating bars in two groups of four each. In Fig. 3, a different grouping of gag controls is shown. The two middle arms on the upper bar are idle; the third arm operates the gag for the inner tool on the right-hand side. The other three tools are controlled by the lower gag-operating bar. With hand-operated gag control, the operator has to be on the alert to work the proper combinations of gags to give the required punching layout for each successive position of the plate as it advances through the punch.

A method of automatically controlling the operation of

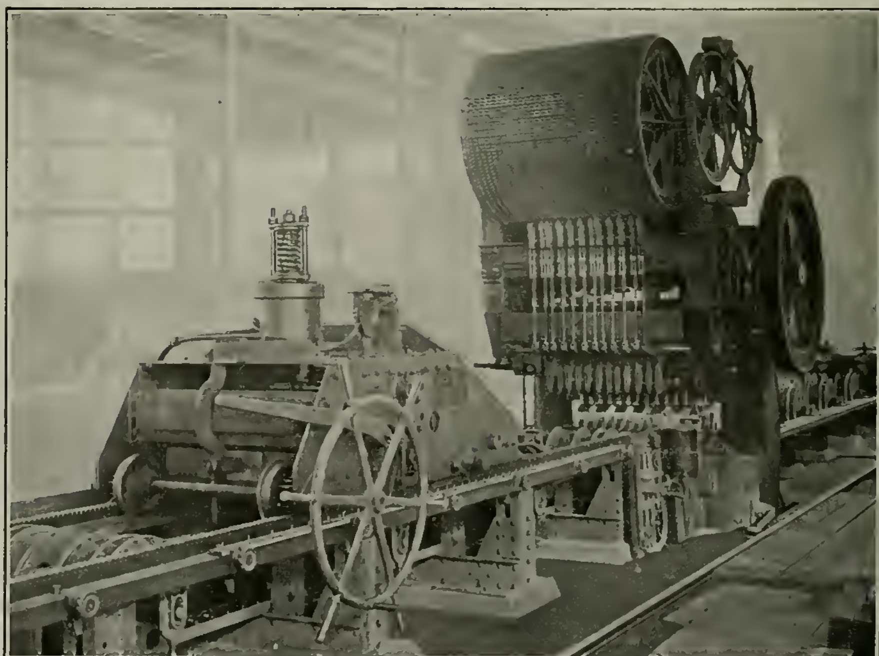

Fig. 4 30-Inch Automatic Spacing Table, and Punch Equipped with Gag Control Mechanism

the gags is shown in Fig. 4. The drum is driven through a gear train from the main cam shaft of the multiple punch. Pins properly located on the drum operate through the vertical connecting rods to throw the gags in and out of the tool holders. With this automatic gag control in operation on a multiple punch also equipped with an automatic spacing table, it is possible to put through the most complicated punching layout without the possibility of errors due to mistakes of an operator, and, moreover, with this full-automatic equipment, it is possible to tune up the equipment to the point of maximum productive capacity without danger of losses due to incorrect operation of the equipment. It will be evident, however, to even the casual observer that the use of full-automatic equipment such as this presupposes quantity production of standardized punching layouts, although it is a comparatively simple matter to change over the complete set-up of the punches and dies, gag control, and spacing templet for an entirely new punching layout, only a short time being involved in making the change.

The two side housings of this multiple punch and the top yoke are cast as a unit, the bearings for the main cam shaft being carried in the side frames without splitting the bearing housings. These babbitted bearings are carried in solid bronze shells, one of which has an outside diameter such as to allow the cam shaft, with the cam forged solid thereon, to be threaded through the housing in assembling the machine. After the cam shaft is in position the bronze bearing shell is slipped over the shaft and into place, where it is securely locked.

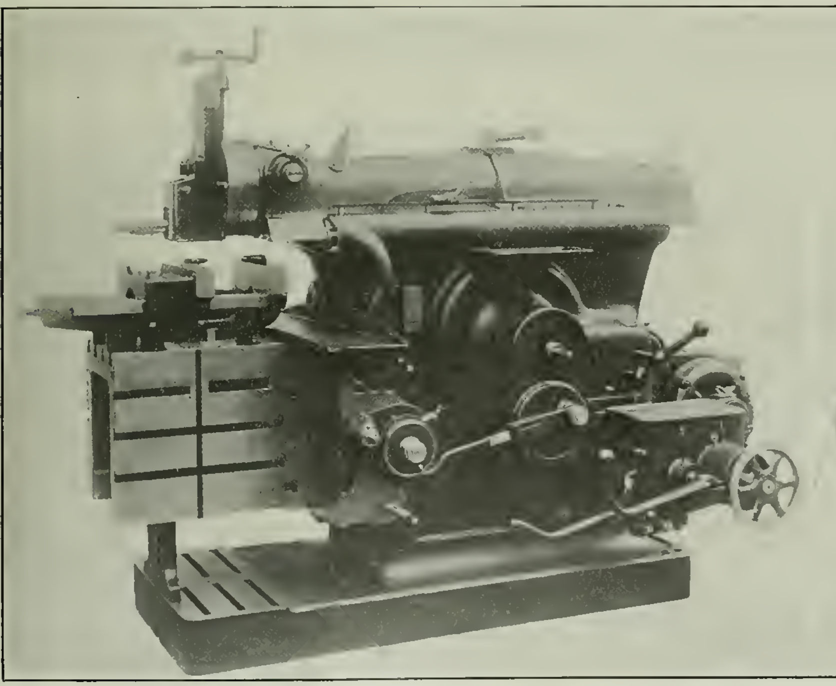
The advantages of this construction are, first, the extreme rigidity of the frame in comparison with the ordinary open throat or "C"-type punch used for the same work; second, lighter weight, which justifies the use of cast steel instead of cast iron for the frame, thus introducing a much higher factor of safety; third, much smaller floor space required for the punch; fourth, greater strength with a one-piece frame casting than with frame made in sections and bolted together; fifth, the tension strains are carried in a straight line from the shaft to the base, thereby insuring maximum strength and rigidity, which in turn results in longer service from the punching tools and dies.

The capacity of the punch here illustrated, which is designated as a No. 14 machine, is 450,000-lb. ram pressure, or in other words a capacity for punching a 2-inch hole in 1¼-in. plate, or its equivalent, and for shearing flats up to 8 in. x 1¼ in., and rounds up to 2¾ in. The ram has a travel of 2 in., and at normal speed makes 26 strokes per minute. This machine requires a 10-H. P. driving motor.

CONSTANT SPEED MOTOR DRIVE FOR SHAPER

Gould & Eberhardt, Newark, N. J., have designed what is known as a selective type gear box, with steel case-hardened gears, which may be used with a constant speed motor drive or a single pulley belt drive, giving the same changes of speed as are ordinarily obtained with the cone pulley drive. It is unnecessary to stop the machine in changing speed except when changing from single gear to back gear, or vice-versa.

A 10 h. p., 1,200 r. p. m., constant speed motor is used on the 28-in. Invincible shaper shown in the photographs. This machine, by the way, will be exhibited at the mechanical conventions at Atlantic City. Eight changes of speed may be obtained for every change in stroke. Some idea of the proportions of the gear box and the motor and of the relative location of the control levers and wheel on the operator's side of the machine may be obtained from the photographs.



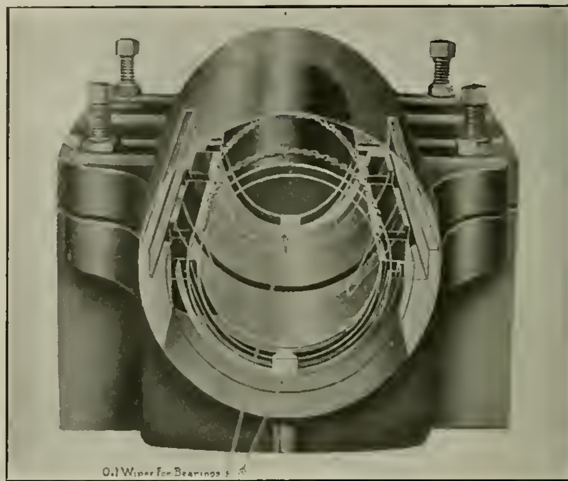
(Left) Operator's Side of Machine Showing Application of Motor and "Selective Type" Gear Box. (Right) Partial Rear View.

The shaper has a range of cutting strokes of from 9 to 115. The maximum stroke is $28\frac{3}{4}$ in. and it planes for a width of 29 in. The maximum distance from the table to the ram is $17\frac{1}{2}$ in., and the minimum distance is $4\frac{1}{4}$ in. The head has a vertical movement of 8 in., while the table has a similar movement of $13\frac{1}{2}$ in.

AN OIL CONSERVER FOR BEARINGS

An improvement in the application of oil wipers for bearings is shown in the illustration. It consists of a tempered steel spring with a triangular shaped piece of babbit metal mounted on the end. The babbitt is shaped to the shaft and wipes the shaft clean, returning the oil to the reservoir of the bearing. The spring is fastened to a convenient point in the groove at the end of the bearing or to the housing. A wiper is placed at each end, and it is stated that it will hug the shaft under all conditions even if the bearing wears or the shaft thins so as to normally pull away from the wiper. Reversing the direction of the shaft will not decrease the effectiveness of the wipers, which are furnished for all plain roller or ball self-oiling bearings.

These new oil wipers are manufactured by the Industrial Products Company, Detroit, Mich. The makers state that bearings equipped with these wipers have been in satisfactory service for over two and a half years; tests and records show that the saving in oil required for replacement has been not less than 85 per cent on line shafts 6 inches in diameter and upwards. On tests run for the last four months on 10 bearings, each transmitting 250 h. p., there has been required one gallon of oil for replacement on all 10 bearings.

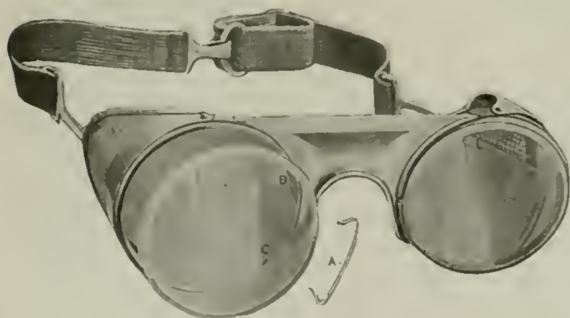


Oil Wiper for Bearings

EYE PROTECTORS FOR SHOP AND LOCOMOTIVE MEN

Protection for the eyes of enginemen and firemen, riveters, grinders, foundrymen, electric and gas welding operators and other shop men whose duties require the wearing of goggles is provided by the Insula Welda Eyetects and the Resistal Industrielle Eyetects which are shown in the illustrations.

The lenses of the Resistal Industrielle Eyetects are quickly changeable by the removal of the lock wire from the holes in the frame. The bridge is wide and is said to rest comfortably on the nose; it is provided with a lip at the top which protects the eyes at the nose. The side shields, which are of perforated sheet nickel-silver, are hinged and fold easily; they afford ventilation and prevent the entrance of dust. The goggles are held in place by an adjustable elastic strap which is light and comfortable.



Resistal Industrielle Eyetects, a Safety Goggle

The Insula Welda Eyetects are made specially for welding operators and contain removable colored Resistal lenses, for which it is claimed no harmful glare can penetrate, yet provides a perfect vision for the operator. The nose bridge is an adjustable strap. The shield has five ventilating holes behind the lens cap to admit air. There are also four compression slots on the circumference of the shield which make it possible for the lens cap to be slipped over the shield and be held in place by friction. The elastic also serves to hold the friction cap snugly in place regardless of the thickness of the lens. This construction makes it possible quickly to remove and replace the lenses while the goggles are in use.

A Goggle for Welders, Known as the Insula Welda Eyetects

Both goggles are provided with lenses of non-shatterable glass known as Resistal, a combination of double glasses with a layer of transparent celluloid between them, which has satisfied an official government test conducted by the Bureau of Standards as to its safety features. The following sentence is taken from one of the Bureau's reports: "In view of the tenacity with which celluloid holds glass and prevents it from shattering, the slightly lower light transmission of such a combination is probably compensated by the superior protection offered to the eyes in case of accident to the goggles."

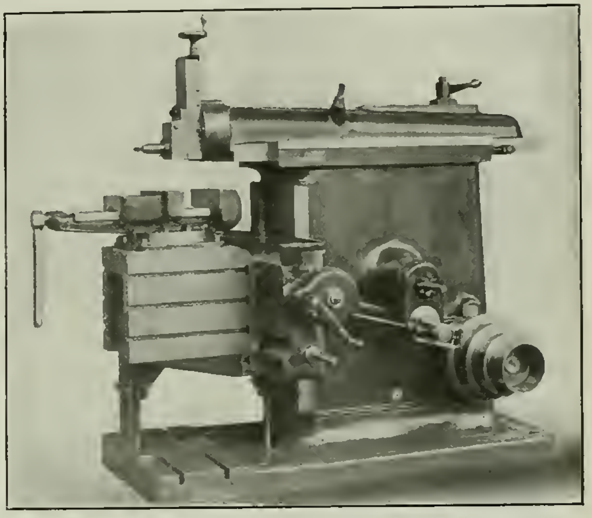
These goggles are manufactured by Strauss & Buegeleisen, New York City.

20-INCH BACK GEARED CRANK SHAPER

The Springfield Machine Tool Company, Springfield, Ohio, has added to its line of shapers a 20-in model, which is similar in all respects, except size, to its 25-in. back geared crank shaper. The column has well rounded corners and is internally ribbed; the ram is exceptionally long with ample bearing surface. The tool head has a long travel and has a down feed screw with a micrometer collar attachment. The tool block feeds 9½ in. in any direction, and the size of tools used is ¾ in. by 1½ in.

The 15¼-in. by 20-in. table has a transverse movement of 32 in. and a clearance of 17 in. from its top to the ram. The cross-rail is long and deep and is elevated by means of a telescopic screw provided with a ball bearing thrust. One gib is provided with an angular rear face, so that the cross-rail is always kept square with the column. The cross-rail is provided with automatic cross feed in either direction and the cross feed screw has a micrometer collar.

The cross slide has an extra large bearing surface on the cross-rail. The vise is clamped to the table and revolves upon a graduated index plate which is keyed to the table. By means of an index pin it can be readily locked at right angles or parallel with the ram. The vise jaws are lined with steel and provided with a tension screw. The crank gears are made with large pitches and wide faces. The stroke arm is connected to the ram by means of a link, providing ample space to allow a 4-in. shaft to pass entirely through the column for keyseating or any other similar operation. The stroke is varied from a convenient point and adjustment is possible while the machine is in motion. Eight speeds are provided and the number of strokes per minute varies from 7 to 129. The machine occupies a floor space of 56 in. by 136 in. and weighs 4,850 lb.

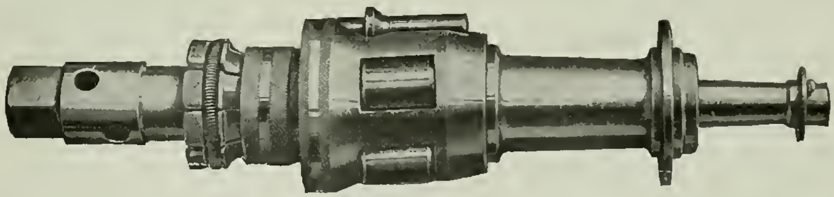


Springfield 20-in. Crank Shaper

DOUBLE UTILITY TOOL FOR BOILER TUBES

The self-feeding flue expander illustrated is designed to "finish the job" by flaring the end of the flue before the expander is withdrawn; it saves the time required for flaring with an additional tool in a different operation. When the expander has been inserted into the flue to the point of the flaring part of the flaring roller, the mandrel is turned to the right and the flue is rolled tight in the sheet. To obtain the flare the mandrel stop is placed against the cage, which prevents the mandrel from entering the expander further, and then by continuing to turn the mandrel to the right the expander is forced further into the flue and the flare is produced. To remove the expander the mandrel is turned to the left. It is stated that a perfect job of rolling flues tight in the sheet can be performed, and that any angle of flare up to 45 deg. can be made.

This tool is known as the locomotive superheater expander and is made in several sizes, for 4½-in., 4¾-in., 5-in. and 5½-in. flues, by the J. Faessler Manufacturing Company, Moberly, Mo., who also manufacture a similar tool for locomotive arch tubes and water tube boiler flues. The latter, in sizes ranging from 2½ in. to 4½ in., are provided with collars which are adjustable up to a maximum distance of 10 in. or more between the base of the collar and the center of the rollers. In operation, the adjustable collar on the cage shank is set back from the outside sheet to the distance the tube projects from the inside sheet and then the operator proceeds exactly as with the other tools, already described. These tools do not pinch or thin the tube at the bottom of the flare and the outside edge of the sheet; these parts are left the same thickness as the body of the tube.

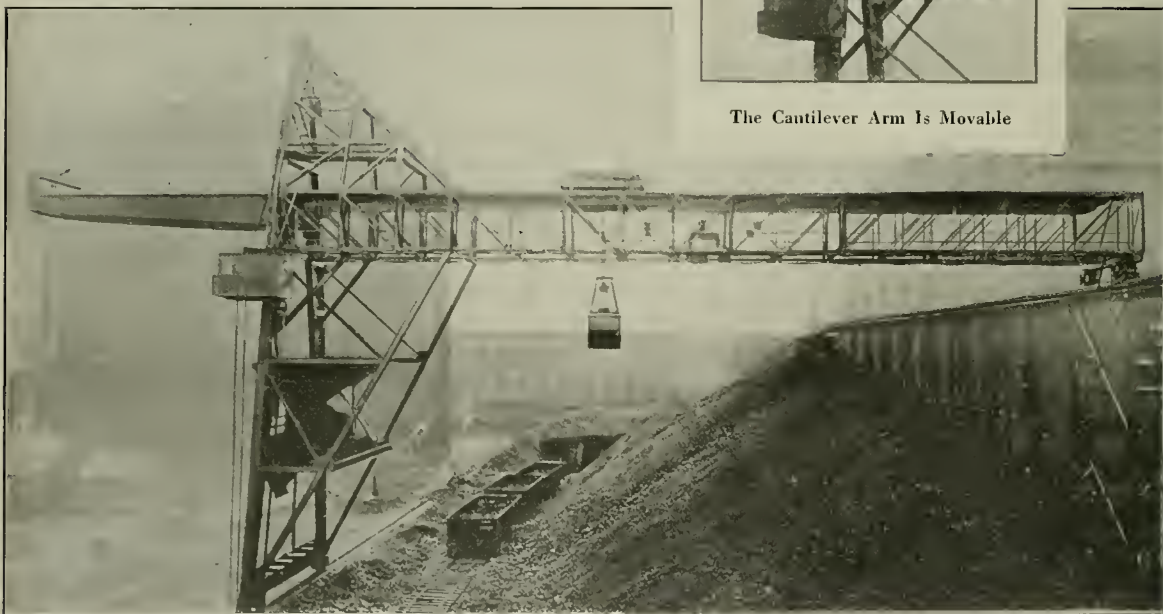


Tool for Expanding and Flaring Tubes

AN EFFICIENT COAL HANDLING APPARATUS

TWO HUNDRED AND FIFTY tons of coal per hour is shown in the illustration. It is adapted for the han- the rated capacity of the gantry type bucket crane dling of ashes, cement, clinker, crushed rock, stone, slag, sand, gravel and other loose materials. The span between the rails in the installation shown is 138 ft. 9 in. The effective cantilever is 43 ft. 9 in.; the over-all height of the gantry leg is 97 ft. 3 in., and the lifting speed of the bucket is 320 ft. per minute. Coal is crushed before it is delivered to the power house by a 250-ton capacity crusher attached to the gantry leg. The cantilever leg is movable and can be drawn up out of the way at places where there is not sufficient clearance. The installation shown was manufactured by the Whiting Foundry Equipment Company, Harvey, Ill., manufacturers of a line of industrial cranes and hoisting apparatus, including special types adapted for railway cinder pits.

The Cantilever Arm Is Movable



Whiting Bucket Crane, Gantry Type; Capacity 250 Tons Per Hour

VAPOR AND MOISTURE PROOF ELECTRICAL FITTINGS

THE Appleton Electric Company, Chicago, Ill., has added several weather-proof, and vapor and moisture proof fittings, to its line of "Unilet" conduit fittings. These fittings are particularly suitable for service in roundhouses, power plants, boiler rooms, tunnels, oil houses, and in any place where the switch or the light is exposed to weather, to locomotive gases, or to moisture. The weather-proof snap switch fitting is No. 1 in the illustration. The bridge in the fitting permits of mounting any 5 or 10 ampere snap switch. It is complete with flanged hood, rubber gasket, and all necessary fastening screws. Room is allowed around the switch handle for convenient

Moisture Proof Conduit Switch Fittings and Outlets use. When a lock switch is desired, the switch handle may be removed and replaced with lock attachment. Extension stems are furnished for use with Perkins' switches, but stems for other makes can be furnished if the make is specified.

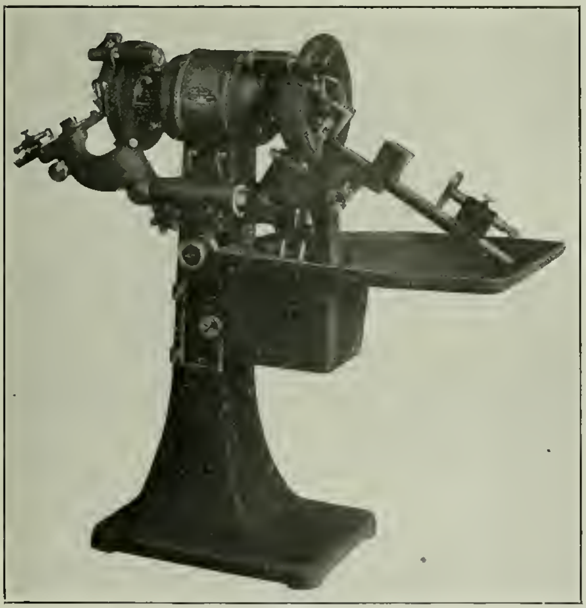
The weather-proof fitting for double push-button switches (No. 2) was designed to protect push-button switches from vapor, gas and dust. The body has four ears to which the cover is fastened. The cover is flanged, and is furnished with a mechanism which operates the push buttons and extends through the side of the dome terminating in an operating handle. That portion of the shaft to which the handle is fastened, passes through a stuffing box. The handle is marked with indicators "on" and "off."

The vapor-proof lamp outlets, Nos. 3 and 4 are fittings so designed that they remain vapor, gas or dust-proof even though the globe may be broken or removed for renewal of lamp. The guards are of the screw type, and do not require the use of a screw driver. These fittings are furnished with receptacles, sealing plates, gaskets and all necessary screws, and with or without globe and guards.

The weather-proof lamp outfit No. 5 is suitable for use in places where a small, durable fitting is required. It is furnished complete with receptacle, gasket, holder and guard. Brass guards are regularly furnished on this fitting, but steel guards can be furnished if so specified. This type is not made to take vapor-proof globes.

A REFINEMENT IN TWIST DRILL GRINDERS

THAT the agitation for "more holes for less money" has influenced the development of other factors than improved and harder steel for drills and improvement in the design and construction of the machines for driving them, is attested by the results of studies on the proper maintenance of the drills. One of the results is shown in the photograph. This is a double holder drill grinder which contains several new and time saving features, conspicuous among which is the departure from the usual practice by the furnishing of a double holder machine in which is combined a small minimum capacity convenient in handling small drills, with the necessary capacity for large drills. The smaller holder will accommodate drills from No. 52 to ¾-in., while the larger one will handle drills up to 4 in. or more. The larger holders grind the large drills wet and use a coarse wheel. The small drills are ground dry on a fine grain wheel.



Motor Driven Double Holder Drill Grinder

In grinding drills on this machine the rotation of the wheel is downward from the point of the drill, thus obviating a tendency for the drill to lift from the holder, as well as throwing all grit downward, resulting in safety for the operator's eyes.

Extra weight has been incorporated in the main frame or column to provide for rigidity. The spindle is furnished with a ring oiled bronze bearing. Radial wear and end play are provided for and the bearing is made dustproof through the use of felt washers. The wheel guards are mounted on the stand by three substantial supports. The wheels are carried between heavy flanges to lessen danger, increase rigidity and insure good grinding results.

The lip rests furnished with these machines are flat strips of hardened steel of uniform width and thickness with slotted holes, by means of which they are held in position on the front of the holder; the screws hold them not only against the front of the holder, but automatically bring the back edge against the shoulder, which is machined in a line parallel to the correct position for the front edge. The shape is so simple that it is stated that if one of the lip rests becomes lost or damaged it can be duplicated without difficulty. A comparatively long life for the lip rests is made possible by the fact that they can be reversed, the front edge being substituted for the back edge.

An important improvement is incorporated in the wheel truing mechanism. A wheel truing diamond is carried in a member attached to the hood of the wheel which is adapted to swing across the face of the grinding wheel. The carrier for the diamond and a stop are moved in unison across the wheel by the turning of the knurled nut on the end of the spindle, which is seen just in front of and near the top of the motor in the photograph. Whatever amount is dressed off by the diamond will be automatically taken care of by the new position of the stop and when the drill holder is again brought in front of the wheel a perfect setting is obtained.

The swiveling action provided for grinding the drill is accomplished by the use of a ground stud 1½ in. in diameter by 4¼ in. long on which is journaled the cast iron swivel head with a bronze bushing bearing on the full length of the ground steel stud. The top of the bearing is covered with a plate for the exclusion of dust and dirt from the bearing surfaces. A grease cup lubricates the swivel bearing.

The grinder is particularly adapted to take care of high speed steel drills which are welded or screwed into machine steel shanks, where frequently the shanks are considerably larger than the drill. A special drill holder has been designed for left hand drills.

To accommodate the differences in the amount of clearance required on different classes of work, provision is made for rocking the drill holder in the upper swivel bearing, which rocking adjustment is controlled by turning a knurled handwheel operating a differential screw.

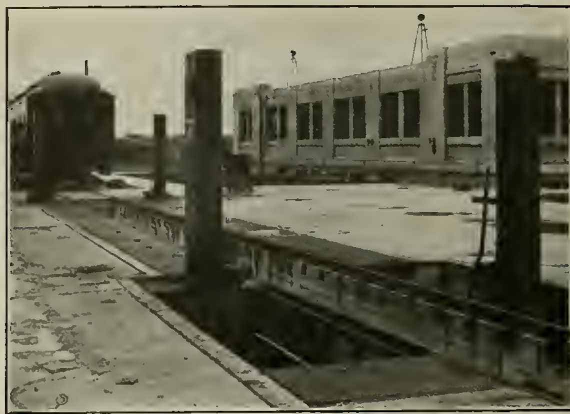
This double holder drill is characteristic of the line of grinding machines manufactured by the Grand Rapids Grinding Machine Company, Grand Rapids, Mich., who will exhibit the style C-6-A grinder mentioned, with several other models, at the June mechanical conventions at Atlantic City.

QUICK-ACTING DEVICE FOR UNWHEELING COACHES

THE successful application of the principle of raising locomotives for unwheeling by means of permanently installed, electrically operated screw jacks lifting from the floor, has been extended to the car repair tracks and the illustrations give some intimation of the speed, cleanliness and general efficiency in jacking up cars preparatory to rolling out the trucks from both ends.

The electric controller box is at the right of the first pair of jacks in Fig. 1. The upright members of the jacks are spaced a fixed distance apart laterally. The near pair have the floor boards removed to show the mounting of the jacks upon a truck, which provides for adjusting their spacing longitudinally for the different lengths for cars.

The heavy steps or knees on the jacks travel between the jaws or flanges of the cast steel column or post. Each is controlled by a revolving screw, and provision is made for raising each step to the sills of the car independently; then all four jacks can, by throwing a clutch, be controlled as a unit. The equipment is manufactured by the Whiting Foundry & Equipment Company, Harvey, Ill.

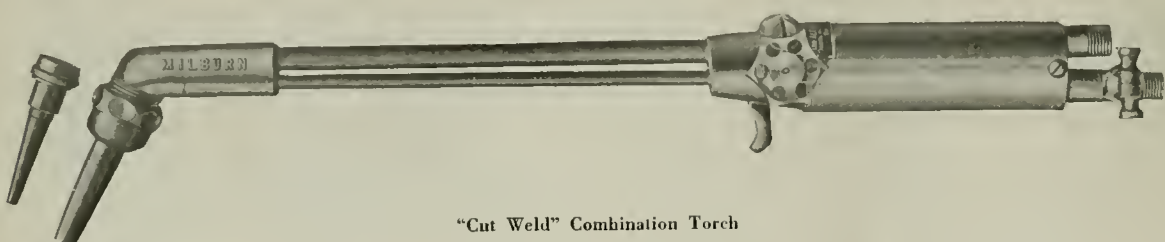


Jack for Unwheeling Coaches

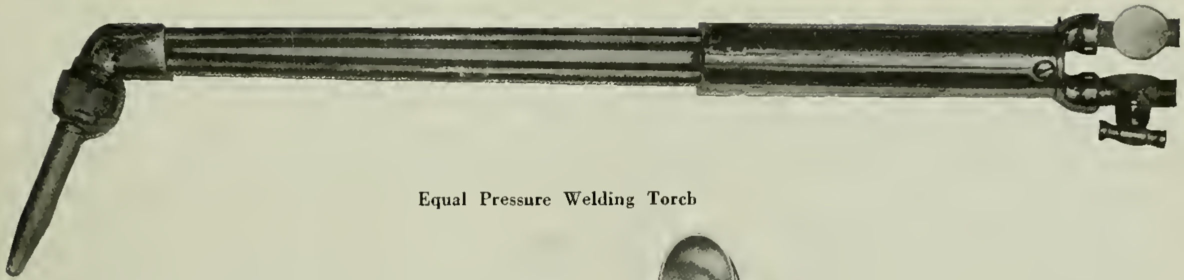
Coach Raised Sufficiently for the Trucks to Be Removed

A CARBIDE LAMP AND WELDING TORCHES

THE new 5,000 candle power carbide lamp illustrated herewith is said to be able to throw a strong light from a 12-in. white enamel reflector for 12 hours with the use of 8 lb. of carbide—a cost of approximately 3c. an hour. It is equipped with a vanadium steel burner cleaner which operates from the rear while the light is burning. The container is equipped with shelves or pockets (see A) which will accommodate the rated carbide capacity of the container and no more; it has the added advantage of facilitating the quick disposal of the used carbide which can be easily dumped by



"Cut Weld" Combination Torch



Equal Pressure Welding Torch

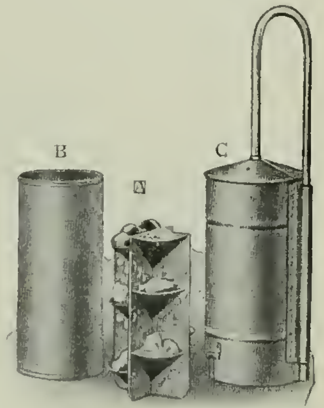
simply withdrawing the container and tapping it on the edge. The light has 10,000 candle power. It burns over 12 hours on 12 lb. of carbide, at a cost of 4 cents per hour.

The lamps are the product of the Alexander Milburn Company, Baltimore, Md., who manufacture a general line of carbide illuminating apparatus, as well as oxy-acetylene torches for welding.

The "quick-weld" torch, type J, illustrated herewith, is an equal pressure oxy-acetylene torch for welding and has only recently been produced by the same company. In this torch the gases are mixed in the tip and each size of tip has its own mixture. The torch head and tips have a flat seat which insures a perfect fit at all times, a new tip fitting the old torch without difficulty. It is provided with five different sizes of tips and is equipped with union hose couplings. This torch is known as the equal pressure welding torch because the oxygen and acetylene are used at equal pressures; this is said to make a softer flame and prevent danger of oxidation of the metal through an oversupply of oxygen; the torch is said to be non-flash-back.

The "cut-weld" torch, also illustrated, is also a new product and is an all-purpose torch with interchangeable tips which can be used for cutting or welding as the case requires.

Carbide Light



Parts of Carbide Container

OIL STORAGE AND PREVENTION OF WASTE OF OIL

THE bung stopper, shown in the illustration, is so constructed that it may be tightly fitted in the bung hole of a barrel whose contents may then be transferred to storage tanks without the loss of a drop of oil.

The threaded main stem through the center of the body of the bung stopper, is connected to the two upturned fingers which rest against the inside of the barrel. The fingers are pivoted to the stem in such a way that they can readily be slipped through the bung hole. By tightening the hand screw at the upper end of the stem, the bung stopper is clamped to the barrel at the bung hole. When the stopper has been placed directly over the fill opening the sliding gate on the outlet of the stopper is opened. The bung stopper is a standard attachment furnished by the Milwaukee Tank Works, Inc., Milwaukee, Wis., who are also manufacturers of the storage tanks illustrated.

The battery of tanks placed in series forms an ideal method of handling oils of different kinds. All the dimensions of the tanks are the same, except for the width which varies according to the capacity. Tanks of various capacities may therefore be placed in the same series without disturbing the uniformity of appearance. The pumps which are furnished with the tanks are of standard self-measuring designs. An 18 in. manhole affords easy access for cleaning or inspection.

Bung Stopper Designed to Prevent Waste of Oil

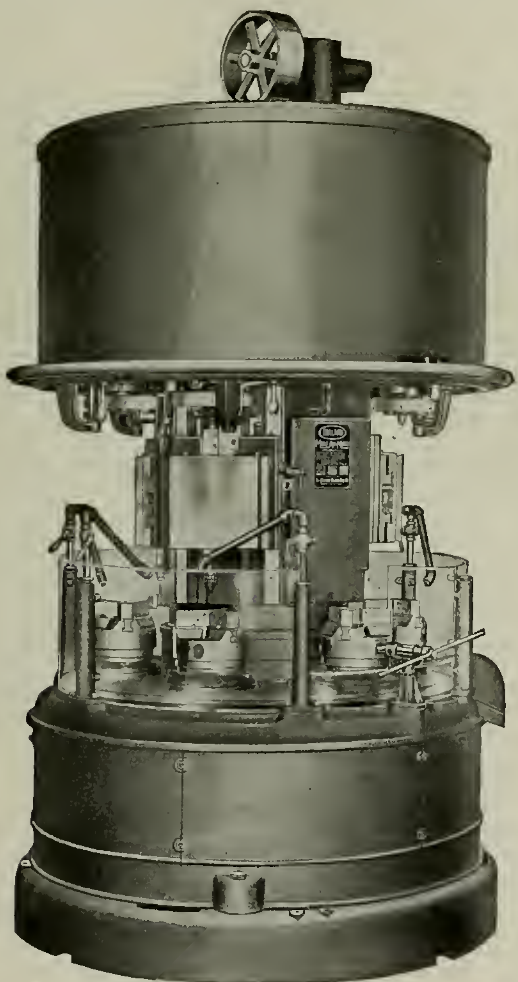
Tanks of Different Capacities But Uniform Appearance May Be Placed in Series

A BORING MILL THAT IS SIX MACHINES IN ONE

A MACHINE that is a self-contained, fully equipped factory, capable of producing the highest grade of work, correct to within a thousandth part of an inch, marks the advanced stage of multi-spindle boring mills which has been achieved in the "Mult-Au-Matic."

This machine will be exhibited in operation at the June mechanical conventions at Atlantic City with a new vertical turret lathe and the Maxi-Mill, a development of the 2-spindle boring mill, by its designers and manufacturers, the Bullard Machine Tool Company, Bridgeport, Conn.

The Mult-Au-Matic illustrated in the photographs is six engine lathes in one machine, each working in sequence and operated by one man, whose only duties consist of loading and unloading. There are five working stations, each of

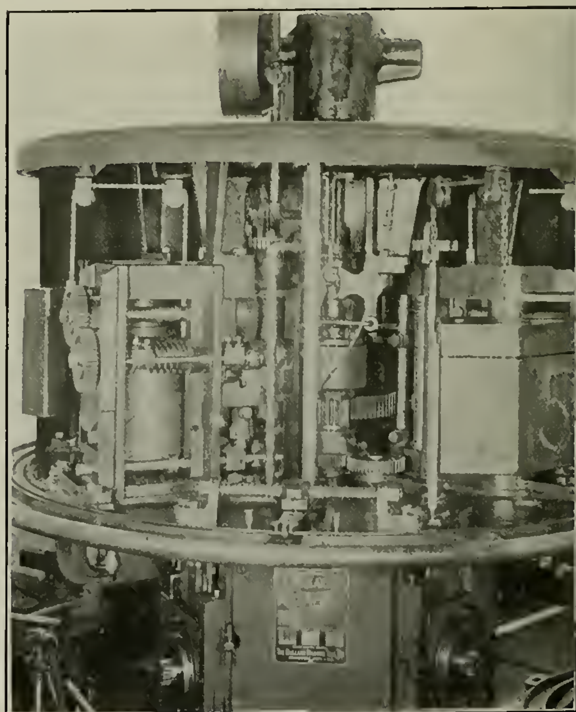


Bullard Mult-Au-Matic

which impresses the onlooker as being an engine lathe standing on its head, and working the better because of the new position, for all the humanly operated lathe motions are followed out without the mind or hand of man to guide and with slight possibility of human lapses in time and accuracy.

The field of the Mult-Au-Matic includes all classes of castings, forgings, or bar-stock sections, cut to length, coming within its capacity, and which require boring, turning, facing or threading operations, either singly or in combination. It comprises six independent vertical lathes automatically operated in combination on a series of pieces of the same form and size, all of the sequence of operations, including chucking, being performed simultaneously. Thus there is produced a completely finished piece in the time required for the largest operation of the sequence plus the few seconds needed for the indexing of the carrier and its spindles from one station to the next. The six independent work-holding spindles are mounted on a carrier, or turret, which revolves around a central column having six faces, the first of which, being the loading station, is blank. On the remaining five faces are mounted tool-carrying slides which are independently adjustable in amount, rate and direction of movement.

The cylindrical base is divided into two sections, the lower of which serves as a tank of large capacity for cutting lubricant or "Coolant" and the upper as a reservoir for the lubricating oil circulated throughout the machine. On its lower

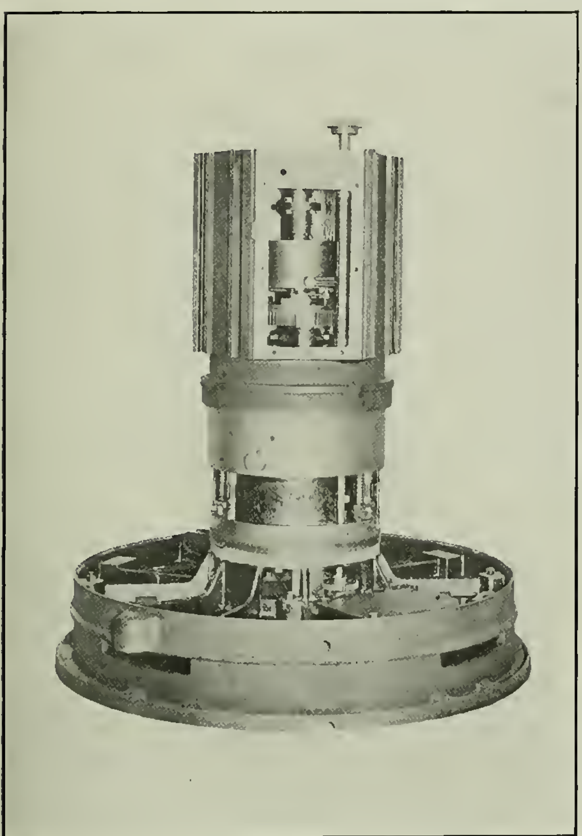


Inside View of the Upper Story of 8-Inch Mult-Au-Matic with Metal Splash Guards Removed

end is found the main, or central, bearing for the spindle carrier, or turret. This section contains the indexing or turret registry mechanism and is illustrated herewith showing an inside view of the upper section, with the sheet metal guard removed revealing the main drive shaft, the outside hand-controlled clutch ring, work spindle drive, feed change gears, quick return cam on feed head, and a view of a counterweight on one of the stations of the machine.

On its upper end are mounted the independent tool-carrying heads, and on the head of the column and firmly secured thereto is mounted a strongly ribbed base for the feed and driving mechanism.

The work spindles, in type and proportion, are somewhat like those used in the Bullard boring mills and vertical turret lathes. Means for obtaining widely variable independent selective speeds for the work-carrying spindles are provided at each station. Speed changes are made through the transformer gears, located at the head of the column.



Base and Hexagonal Column Showing Controller Drum, Locking Pin and One of the Work Spindle Driving Pinions

The carrier is rotated from station to station by power. The tool-carrying heads are mounted on the faces of the column at the five work stations. These heads are entirely independent in direction, amount and rate of movement, and consist of a main slide gibbed to the column, on which is mounted a secondary slide to which the tool combination can be secured. The secondary slide may be swiveled to 90 degrees either way of the work axis and rigidly located at any angle.

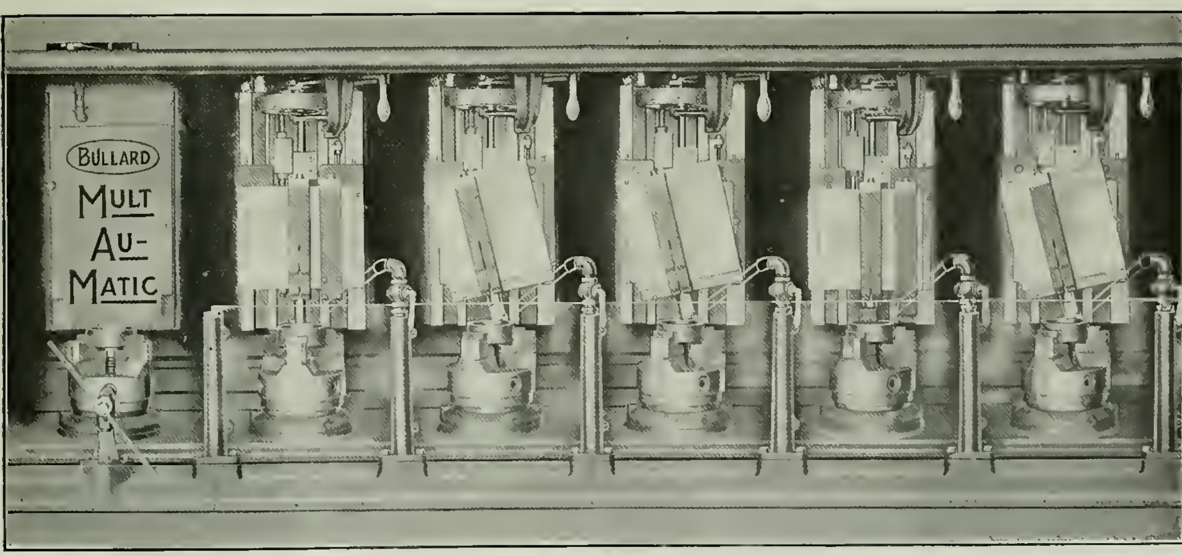
For straight boring, reaming and turning, the secondary slide is locked at zero and the entire head moves as a unit throughout the distance required to complete the operation, meets its stop and is returned.

For taper boring—an example of which is shown in one of the illustrations, a developed view of the six heads—angular turning or facing at any angle with the work axis the secondary slide, which is fed the distance required, is brought to rest by a stop and locked in position. The motion is then taken up by the secondary slide, which is fed the distance required, brought to rest by an adjustable stop and returned through its original path. The heads are rapidly advanced to the point where feed should begin, the feeds then engaged at the predtermined rate per revolution, and at the completion of the feed movement are rapidly returned. The rate of advance and return is constant regardless of feed or spindle speed, but the point of change from rapid advance to speed is adjustable.

Each tool head has also an independent manual control, saving time in the setting up of a job. The time element of all automatic motions is therefore constant and cannot be varied or adjusted by the operator.

The Mult-Au-Matic operates on a principle that makes the total time for machining a piece on it the time of the longest single operation. A feature that promotes flexibility of set-up and at the same time decreases the expense of tool equipment is the use of traverse and angular feeds. The necessity of sweep cutters for facing is done away with.

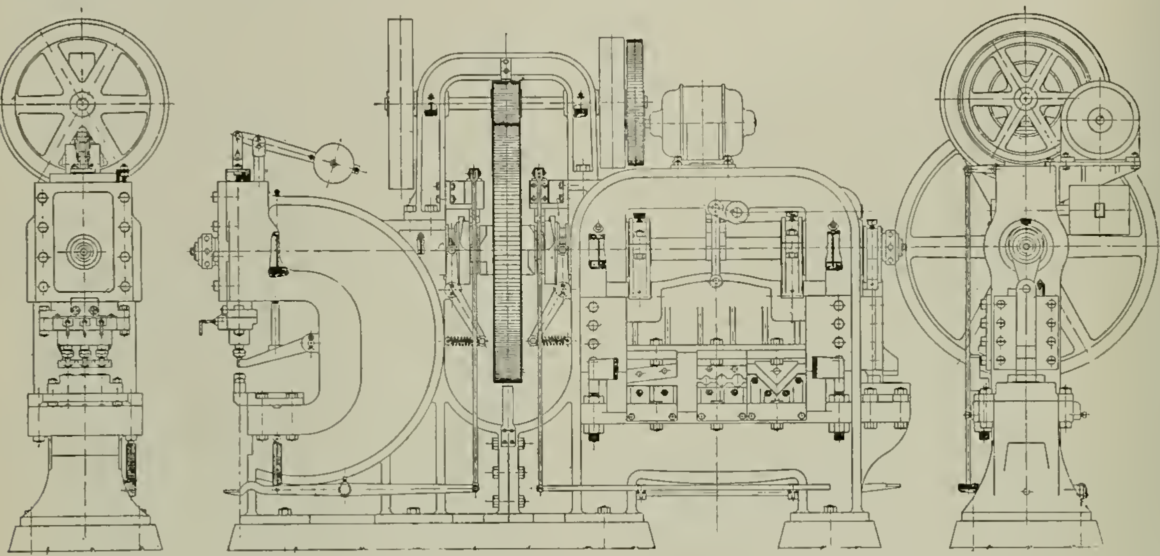
Some idea of the remarkable savings brought about by this machine may be had from the experience of a manufacturer of international renown. In his plant a Mult-Au-Matic has cut the total time for a series of different machining operations on a certain piece from 15 minutes to 2 minutes and 15 seconds. In addition to this saving in time, the work is of higher and more uniform quality.



Developed View of the Loading Station and Five Working Stations, Showing the Mult-Au-Matic Tooled for Machining a Conical Roller-Bearing Race

COMBINATION TOOL FOR THE STEEL CAR SHOP

As evidence of an increasing tendency in the construction of machine tools which, constituting one unit only, are designed to do the work of and supplant two or more independent installations, a recent addition to the motor-driven heavy punch and shear line is shown in the illustration. It was specially designed for use in car repair shops.



Combination Punch and Shear Especially Designed for Steel Car Repair Work

The left hand or punching end of the machine is equipped with a semi-steel architectural jaw for handling structural shapes; the throat depth can be furnished in any required practicable dimension. Three different sizes of punches can be set up simultaneously and each may be operated independently at the option of the operator. The right hand end of the machine comprises a semi-steel guillotine frame supporting and operating three different types of shears; one for flat work, one for different sizes of round bars and another for angle irons, while the extreme right end of the machine contains a set of coping tools. Seven sets of tools, each set ready for instant use, constitutes the working range of this interesting combination; it will be recognized that in overcoming the loss of time incident to the setting up of various tools as generally required in the operation of the simple double-ended punch and shear, a marked advantage has been gained. The frame of the machine is of semi-steel; the bearings are of phosphor bronze with ring oilers; the clutches are fitted with automatic release.

This machine, furnished in several sizes, will be exhibited at the June mechanical convention at Atlantic City by its manufacturers, the Beatty Machine & Manufacturing Company, Hammond, Ind. It is arranged for motor drive, as indicated in the drawing, all of the driving mechanism being mounted on the head.

HIGH SPEED STEEL COUNTERSINKS

New designs of high speed steel countersinks with three or four flutes are shown in the photographs and are obtainable in 15, 37, 45 and 60 deg. angles of points. One of the photographs illustrates the method of attaching the countersink to the shank. The countersink is firmly screwed and solidly brazed into the taper tool steel shank with a patented Latrobe connection. These tools are the product of the Latrobe Tool Company, Latrobe, Pa., a subsidiary of the Vanadium-Alloys Steel Company, Pittsburgh, Pa.

Latrobe Countersink with Four Flutes

Latrobe Countersink with Three Flutes

These high-speed countersinks were specially developed for use in car building, bridge building, shipbuilding and structural work. It is particularly desirable for work of this character, as well as ordinary shop use, that the tools be made of material of such toughness and hardness that they will stand up under rough usage. These countersinks are said to give maximum efficiency on the hardest material.

Showing How Countersinks Are Attached to Shanks

THE RAILWAY MECHANICAL ENGINEER is a member of the Associated Business Papers (A. B. P.) and the Audit Bureau of Circulations (A. B. C.).

War Cost of Railway Equipment

For the information of the Liquidation Commission, the office of the chief of engineers has prepared an estimate of the costs of railroad equipment shipped to the A. E. F. computed on the basis of 1914 prices. The government actually paid from two to two and a half times the pre-war costs.

UNIT COST OF STANDARD GAGE RAILWAY EQUIPMENT COMPARED WITH PRE-WAR COST

	Shipped to A. E. F.	Unit price		Actual cost in per cent of pre-war cost
		Pre-war	Actual	
Locomotives—				
Consolidation	1,306	$17,500	$42,966	245
Gasoline	10	9,350	22,000	235
Saddle tank	30	4,500	9,700	216
Total	1,346	....	....	...
Cars—				
Tank	675	$1,367	$3,397	248
Gondola, l. s.	3,429	1,090	2,340	215
Flat	1,900	982	2,107	215
Box	7,299	1,290	2,755	214
Refrigerator	950	1,649	3,489	212
Gondola, h. s.	2,650	1,155	2,430	210
Dump	500	1,026	2,108	206
Ballast	400	1,454	2,987	205
Box, with cab	500	1,366	2,770	203
Total	18,303	....	....	...

COST OF STANDARD GAGE RAILWAY EQUIPMENT COMPARED WITH PRE-WAR COST

	Pre-war cost	Actual cost	Actual cost in per cent of pre-war cost
Locomotives	$23,083,500	$56,524,870	245
Cars	22,346,745	48,822,100	214
Total	$45,430,245	$105,346,970	230

Surplus Military Railway Equipment

The War Department has given out the following statement of the amount and value of property on hand or on order available for sale. The figures are as of May 1:

	Number	Total cost
Standard gage locomotives	197*	$7,540,175
Standard gage freight cars	12,404†	27,621,536
Locomotive cranes	195††	3,924,938
Raised pier cranes	34†	652,960
Track pile drivers	18	603,000
Total	....	$40,342,609

*All on hand.
†None delivered.
††Forty-six not yet delivered.

The locomotive and raised pier cranes will be turned over to the Railroad Administration, by arrangement with the director general of railroads, for sale to the railroads. Under the arrangement with the Railroad Administration the director general will use every effort to dispose of the property to the several railroads at market prices at the time and place at which disposition is made. The incidental expenses incident to the care of the material are to be taken from the proceeds of the sale.

This arrangement also covers about 1,366 tank cars purchased by the Ordnance Department, 100 twelve-yard and 1,320 twenty-yard side dump cars, all of which are fitted to comply with Master Car Builders' and Interstate Commerce Commission standards. In the event of termination of federal control of the railroads before this material is entirely disposed of, the material remaining at the time is to revert to the War Department's possession but in all cases where the material has been sold by the Railroad Administration on the deferred payment plan the War Department will protect such arrangements after the federal control of the railroads ceases.

This entire transfer covers approximately $18,000,000 worth of material. The distribution of the property to the railroads will be handled by the director of the Division of Purchases.

The sales of surplus supplies by the department of military railways, as reported to the director of sales up to April 25, amounted to $71,104,130, of which $68,993,837 represented rolling stock. The prices received represented the actual original cost.

Record of the Engineer Corps

A resumé of the work of the Engineer Corps of the American Expeditionary Forces has been issued by the office of the chief engineer of the A. E. F. and is included in Engineering Recruiting Circular No. 2 used by army recruiting officers in their campaign for volunteers. The circular states that there were 174,000 engineer troops in the service. Part of the work done by the railway engineering units in this force consisted of the construction of 947 miles of standard gage track and a six mile cut-off at Nevers requiring a bridge across the Loire river, 2,190 ft. long.

Among the accomplishments of this force are listed many records in the construction and operation of military railroads. The light railways of the American Expeditionary Forces handled to February 1, 860,652 tons of freight, of which 166,202 tons was ammunition. In one week the ammunition moved amounted to 10,600 tons, and in five nights 23,135 soldiers were carried on these railways. The daily net tonnage handled in October, 1918, was 8,100 tons. In one week 10,700 tons of rations were handled. At the time of the signing of the armistice 2,240 kilometers (1,392 miles) of light railway were in operation, of which 1,740 kilometers had been taken from the Germans, the balance being newly constructed or rebuilt. On November 11, 165 locomotives and 1,695 cars were available for use. In five hours 135 men laid 14,200 ft. of light railway track. Among the shops erected were 10 buildings at Abainville, with a total floor area of 70,000 sq. ft. Over 2,300 cars have been erected and 140 locomotives have been repaired in these shops.

R. H. Aishton, regional director of the Northwestern region, in a telegram to Northwestern roads states that locomotive builders are urging the placing of orders for locomotives in order that they may keep their shops in operation, and also keep down the overhead cost of the locomotives that have been or will be built. The telegram asks for information as to the number and type of additional U. S. standard locomotives that will be required on lines in this region and whether or not approved by the railroad corporation. If the corporations are not willing to buy the United States standard type they are asked to give the number and the type or types that they will be willing to purchase of their own standard.

The American Railroad Association has moved its Chicago offices from the Transportation building, 608 South Dearborn street, to the Manhattan building, 431 South Dearborn street, where the entire fourteenth floor has been secured for its offices and those of the railway associations which have been merged or affiliated with it. The office of the secretary of the Master Mechanics' and Master Car Builders' associations heretofore in the Karpen building, has been moved to the same building.

The Inspection and Test Section of the Railroad Administration is considering the question of tests of locomotive specialties, such as bell ringers, firedoors and electric headlights, and would be glad to receive full information from the various manufacturers desiring to participate in the tests. Communications should be addressed to C. B. Young, manager, Room 709, 1800 Pennsylvania avenue, Washington, D. C.

MEETINGS AND CONVENTIONS

Western Railway Club.—The Western Railway Club on May 19 elected the following officers: President, G. S. Goodwin, mechanical engineer, C., R. I. & P.; first vice-president, J. Purcell, assistant to federal manager, A., T. & S. F.; second vice-president, E. J. Brennan, superintendent of motive power, C., M. & St. P.; secretary-treasurer, J. M. Byrne, chief clerk to mechanical assistant, Central Western Region; directors, E. B. Hall, assistant superintendent of motive power and car department, C. & N. W.; L. S. Kinnaird, superintendent of motive power, C. & E. I.; W. H. Flynn, superintendent of motive power, Michigan Central.

American Society for Testing Materials. — This association will hold its twenty-second annual meeting at the Hotel Traymore, Atlantic City, N. J., on June 24, 25, 26 and 27. Among the features of special interest to railway men as outlined in the tentative program are a session on preservative coatings, lubricants and containers on Tuesday afternoon; a session on steel and wrought iron on Wednesday forenoon; one on Wednesday evening on corrosion and magnetic analysis, and one on concrete and gypsum, including the report of the committee on reinforced concrete, on Friday afternoon. The convention will close with a joint session on cement and concrete with the American Concrete Institute. This will be held on Friday evening, June 27.

Air Brake Appliance Association.—An organization of manufacturers of air brakes and accessories, for supervising the exhibits in connection with conventions of air brake associations, was formed at a meeting held in the Hotel Sherman, Chicago, May 7. At this meeting a constitution and by-laws were adopted and the name, Air Brake Appliance Association, chosen. The following officers were elected: Chairman, J. J. Cizek, The Leslie Company; secretary-treasurer, F. W. Venton, Crane Company. Members of the executive committee for three years: J. F. Gettrust, Ashton Valve Company; J. C. Younglove, H. W. Johns-Manville Company; J. D. Wright, Westinghouse Air Brake Company. Members of the committee for two years: F. W. Venton, Crane Company; J. H. Dennis, New York & New Jersey Lubricant Company; L. H. Snyder, Joseph Dixon Crucible Company. Members of the executive committee for one year: J. J. Cizek, The Leslie Company; M. S. Brewster, U. S. Metallic Packing Company; D. S. Prosser, U. S. Rubber Company.

Twenty-one supply companies exhibited devices at the Air Brake Association convention this year.

Atlantic City Mechanical Convention.—The American Railroad Association has issued the calendar for the first annual convention of Section III—Mechanical, which is to be held at Atlantic City, N. J., June 18 to 25. The order of business is as follows:

Wednesday, June 18, 9:30 *A. M. to* 1:30 *P. M.*

Prayer; address of welcome by the mayor of Atlantic City; address by the chairman.

Action on minutes of annual meeting of 1918 (M. C. B.); report of secretary and treasurer (M. C. B.).

Appointment of committees on subjects, resolutions, correspondence, obituaries, etc.; unfinished business; new business.

Report of general committee, including announcement of nominations for members of nominating committee; discussion of reports on nominations; standards and recommended practice (M. C. B.); train brake and signal equipment; brake shoe and brake beam equipment.

Wednesday, 3 *P. M.*

Revision of the Rules of Interchange, including consideration of the following reports of committees: (1) Arbitration; (2) Revision of prices for labor and material; (3) Depreciation for freight cars; (4) Revision of passenger car rules of interchange.

Thursday, 9:30 *A. M. to* 1:30 *P. M.*

Discussion of reports on car wheels; standard blocking for cradles of car dumping machines; specifications and tests for materials (M. C. B.); welding truck side frames, bolsters and arch bars; couplers; draft gear.

Questions proposed by members.

Friday, 9:30 *to* 1:30.

Discussion of reports on safety appliances; loading rules; car construction; car trucks; train lighting and equipment; tank cars.

Questions proposed by members.

Saturday, 9:30 *to noon.*

Consideration of rules of order, election of officers, general committee and nominating committee, presentation of badges to retiring officers, etc.

Monday, June 23, 9:30 to 1:30.

Address of vice-chairman; action on minutes of 1918 annual meeting (M. M.); reports of secretary and treasurer (M. M.).

Discussion of reports on standards and recommended practice (M. M.); mechanical stokers.

Paper on "Standardization," by Frank McManamy.

Questions proposed by members.

Tuesday, 9:30 to 1:30.

Discussion of reports on fuel economy and smoke prevention; specifications and tests for materials (M. M.); design and maintenance of locomotive boilers; locomotive headlights; superheater locomotives.

Paper on carbonization in valve chambers and cylinders of superheated steam locomotives, by F. P. Roesch.

Amalgamation of other mechanical associations with Section III, A. R. A.

Questions proposed by members.

Wednesday, 9:30 to 1:30.

Discussion of reports on design, maintenance and operation of electric rolling stock.

Paper on "Use of bronze for valve snap rings and piston surfaces, and for bull rings in large cylinders," by C. E. Fuller.

Discussion of reports on train resistance and tonnage rating; on subjects; on resolutions, correspondence, etc.

Unfinished business; questions proposed by members and closing exercises.

Arrangements have been made for a special train to accommodate railroad men from Chicago and points west who will attend the convention. The train will leave Chicago at 3 p. m., June 16, and will arrive at Atlantic City about 5 p. m., June 17. It will have club and dining cars, 12-section drawing room sleepers and 7-compartment drawing room cars. Requests for reservations on this train should be addressed to C. L. Kimball, 175 W. Jackson boulevard, Chicago.

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations:

AIR-BRAKE ASSOCIATION.—F. M. Nellis, Room 3014, 165 Broadway, New York City.

AMERICAN RAILROAD MASTER TINNERS', COPPERSMITHS' AND PIPEFITTERS' ASSOCIATION.—O. E. Schlink, 485 W. Fifth St., Peru, Ind.

AMERICAN RAILWAY MASTER MECHANICS' ASSOCIATION.—V. R. Hawthorne, 431 South Dearborn St., Chicago. Convention, June 23-25, 1919, Atlantic City, N. J.

AMERICAN RAILWAY TOOL FOREMEN'S ASSOCIATION.—R. D. Fletcher, Belt Railway, Chicago. Convention, August 27-29, Hotel Sherman, Chicago.

AMERICAN SOCIETY FOR TESTING MATERIALS.—C. L. Warwick, University of Pennsylvania, Philadelphia, Pa.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—Calvin W. Rice, 29 W. Thirty-ninth St., New York.

ASSOCIATION OF RAILWAY ELECTRICAL ENGINEERS.—Joseph A. Andreucetti, C. & N. W., Room 411, C. & N. W. Station, Chicago.

CAR FOREMEN'S ASSOCIATION OF CHICAGO.—Aaron Kline, 841 Lawlor Ave., Chicago. Meetings second Monday in month, except June, July and August, Hotel Morrison, Chicago.

CHIEF INTERCHANGE CAR INSPECTORS' AND CAR FOREMEN'S ASSOCIATION.—W. R. McMunn, New York Central, New York, N. Y.

INTERNATIONAL RAILROAD MASTER BLACKSMITHS' ASSOCIATION.—A. L. Woodworth, C. H. & D., Lima, Ohio.

INTERNATIONAL RAILWAY FUEL ASSOCIATION.—J. G. Crawford, 542 W. Jackson Blvd., Chicago.

INTERNATIONAL RAILWAY GENERAL FOREMEN'S ASSOCIATION.—William Hall, 1061 W. Wabasha Ave., Winona, Minn. Convention September 2-3, 1919. Hotel Sherman, Chicago.

MASTER BOILERMAKERS' ASSOCIATION.—Harry D. Vought, 95 Liberty St., New York.

MASTER CAR BUILDERS' ASSOCIATION.—V. R. Hawthorne, 431 South Dearborn St., Chicago. Convention, June 18-21, Atlantic City, N. J.

MASTER CAR AND LOCOMOTIVE PAINTERS' ASSOCIATION OF U. S. AND CANADA.—A. P. Dane, B. & M., Reading, Mass.

NIAGARA FRONTIER CAR MEN'S ASSOCIATION.—George A. J. Hochgrebe, 623 Brisbane Bldg., Buffalo, N. Y.—Meetings, third Wednesday in month, Statler Hotel, Buffalo, N. Y.

RAILWAY STOREKEEPERS' ASSOCIATION.—J. P. Murphy, Box C, Collinwood, Ohio.

TRAVELING ENGINEERS' ASSOCIATION.—W. O. Thompson, N. Y. C. R. R., Cleveland, Ohio.

PERSONAL MENTION

GENERAL

S. A. CHAMBERLAIN has been appointed superintendent of motive power of the Lake Superior & Ishpeming and the Munising, Marquette & Southeastern, with headquarters at Marquette, Mich.

MAJOR C. E. LESTER of Meadville, Pa., has been appointed general superintendent of the 19th Grand Division, Transportation Corps, of the American Expeditionary Force. He entered the National Guard, 13th Pennsylvania Infantry, in August, 1916, and was commissioned first lieutenant, infantry, in October of the same year. In August, 1917, he was transferred to the engineers. He was appointed captain, engineers, in the National Army in April, 1918, and commanding officer of the 50th Engineers, with which he went abroad in July, 1918. Upon his arrival in France he was appointed general foreman at the Nevers locomotive shops, operated entirely by United States soldiers. He subsequently served as assistant superintendent of the same shops and then as acting general superintendent of the 19th Grand Division until his appointment as general superintendent of the same division. Major Lester was formerly general foreman boiler maker on the Erie at Meadville, Pa., from April, 1906, to January, 1911, and was assistant master mechanic on the Baltimore & Ohio at Pittsburgh, Pa., until March, 1912, when he returned to the Erie as foreman boiler maker at Jersey City. From July, 1912, to July, 1914, he was assistant foreman in the tank shop of the American Locomotive Company at Dunkirk, and then was inspector with the Lima Locomotive Works at Lima, Ohio, and from February, 1915, to August, 1916, was boiler maker foreman on the Lehigh Valley at Sayre, Pa.

J. W. OPLINGER, superintendent of motive power of the Second and Third divisions of the Atlantic Coast Line, with headquarters at Waycross, Ga., resigned on May 1. He entered the service of the Central of New Jersey on March 1, 1874, as a machinist apprentice and after completing his apprenticeship in 1878, served as a machinist until 1880 on the same road. He then went to the Lehigh Valley as a machinist at Wilkes-Barre, Pa., and four years later left that road to go to the Atchison, Topeka & Santa Fe, in New Mexico, remaining in the service of that road until 1887. He then returned to the Central of New Jersey as gang foreman, and later was erecting foreman on that road. In 1894 he served as general foreman on the New York, Susquehanna & Western, and in 1900 was appointed master mechanic on the Atlantic Coast Line. Four years later he was promoted to superintendent of motive power of the Second and Third divisions, with office at Savannah, Ga., and since 1910 at Waycross, Ga., from which position he resigned to retire to his farm in Pennsylvania.

H. L. WORMAN, master mechanic of the St. Louis-San Francisco, with office at Memphis, Tenn., has been appointed assistant superintendent of motive power, with headquarters at Springfield, Mo.

MASTER MECHANICS AND ROAD FOREMEN OF ENGINES

C. E. ALLEN, general master mechanic of the Northern Pacific, at Livingston, Mont., has been appointed general master mechanic of the lines east of Mandan, N. D., with headquarters at St. Paul, Minn., succeeding T. J. Cutler.

T. J. CUTLER, general master mechanic on the Northern Pacific, with headquarters at St. Paul, Minn., has been transferred to Livingston, Mont., with jurisdiction over the lines from Mandan, N. D., to Paradise, Mont., succeeding C. E. Allen.

G. R. Wilcox, assistant master mechanic of the St. Louis-San Francisco at Monett, Mo., has been appointed master mechanic of the Southern division, with headquarters at Memphis, Tenn., succeeding H. L. Worman. Mr. Willcox was born at Winfield, Kan., on September 10, 1879, and after graduating from high school attended the State Normal School at Stuttgart, Ark., for two years. In January, 1900, he entered railroad service as a machinist with the St. Louis Southwestern, and later worked in that capacity for the St. Louis, Iron Mountain & Southern at Bearring Cross, Ark., and for the Illinois Central at Memphis, Tenn. From the latter part of 1906 to the early part of 1907 he was division foreman of the St. Louis, Iron Mountain & Southern at Cotter, Ark., but in 1907 he came to the St. Louis-San Francisco as machinist and in September, 1908, was promoted to night roundhouse foreman. In July, 1909, he was appointed machine shop foreman, in 1911 general foreman and in July, 1913, was transferred to Birmingham, Ala., as general foreman. From February, 1914, to January, 1916, he acted as assistant foreman of the South roundhouse at Springfield, Mo., from January, 1916, to February, 1917, was general foreman at Ft. Scott, Kan., and from that time until April, 1919, he acted as assistant master mechanic at Neodesha, Kan., Sapulpa, Okla., and Monett, Mo. On the latter date he received his appointment as master mechanic of the Southern division, with headquarters at Memphis, Tenn.

SHOP AND ENGINEHOUSE

H. H. Maxfield, formerly superintendent of motive power of the New Jersey division of the Pennsylvania Railroad, with headquarters at New York, who was granted a furlough to enter military service, as an officer in the 9th Engineers, National Army, in July, 1917, has returned to the service of the Pennsylvania as acting works manager, with office at Altoona, Pa., in charge of the Altoona shops, comprising the Altoona machine shops, the Altoona car shops, the Juniata shops and the South Altoona foundries. This is a new position recently created on the Pennsylvania Railroad, Eastern Lines. Mr. Maxfield reports to the general superintendent of the Eastern Pennsylvania division and the superintendent of motive power of that division has been relieved of the jurisdiction over the above-named plants. While in France Mr. Maxfield was superintendent of motive power of the Transportation Corps, American Expeditionary Force.

PURCHASING AND STOREKEEPING

J. E. Anderson, purchasing agent of the Ft. Worth & Denver City; the Ft. Worth & Rio Grande; the Gulf, Colorado & Santa Fe.; the International & Great Northern; the Missouri, Kansas & Texas; the Missouri, Kansas & Texas of Texas, and the Texas Midland, with office at Dallas, Texas, has been appointed assistant purchasing agent of the St. Louis-San Francisco; the Kansas City, Clinton & Springfield; the Paris & Great Northern; the West Tulsa Belt, and the Rock Island-Frisco Terminal, with headquarters at St. Louis, Mo.

C. Z. Hughes has been appointed purchasing agent of the Ann Arbor Railroad, with office at Toledo, Ohio.

OBITUARY

Edward Lawless, master mechanic of the Illinois Central at Freeport, Ill., died at his home on March 9, at the age of 51. Mr. Lawless had been in the employ of the Illinois Central at Freeport since 1890, when he entered it as a machinist. He was promoted a number of times, and in October, 1917, was appointed master mechanic.

Supply Trade Notes

J. S. Cullinan has been elected president of the Galena Signal Oil Company, New York.

The Nathan Manufacturing Company, New York, has opened new offices in Chicago in the Great Northern building, 20 West Jackson boulevard, room 707, with R. Welsh in charge.

Joseph Douglas Gallagher, director, vice-president and general counsel of the American Brake Shoe & Foundry Company, New York, died at his home in Glen Ridge, N. J., on May 20, at the age of 65. He was educated at Princeton University and at Ohio Wesleyan University, Delaware, Ohio. He was engaged in the practice of law in Newark, entering the firm of Whitehead & Gallagher, which later became Gallagher & Richardson. Mr. Gallagher became director and vice-president of the American Brake Shoe & Foundry Company when it was organized about eighteen years ago, and during the last four years was also its general counsel. This company did much work on munitions for the United States Government during the war, and overwork in this connection probably hastened Mr. Gallagher's death, which followed an operation in the Morningside Hospital.

J. D. Gallagher

F. J. Foley, recently appointed general sales agent of the Railway Steel-Spring Company, New York, as was announced in these columns last month, was born in Chillicothe, Ohio, on May 14, 1879. He entered the service of the Baltimore & Ohio at Newark, Ohio, as a messenger in 1892, and then until 1897, was telegraph operator and despatcher on various roads in the West. He entered the manufacturing department of the Pullman Company at Pullman, Ill., in 1897, where he remained until 1900, when he became connected with the Steel Tired Wheel Company, which company was subsequently absorbed by the Railway Steel-Spring Company in 1902. Mr. Foley has been successively manager of all of its various spring plants, and while he has occupied the position of general superintendent of the company since 1912, during much of this time he was closely associated with the sales department.

F. J. Foley

George L. Fowler, consulting mechanical engineer, has moved his office from 83 Fulton street to 120 Liberty street, New York.

Ross F. Hayes has been appointed general sales manager of the Curtain Supply Company, Chicago. Mr. Hayes has been eastern manager of the company for 12 years, with headquarters at 50 Church street, New York, and will continue to act as eastern manager and retain his office in New York. Mr. Hayes was born at Lewiston, Me. He entered the service of the Boston Woven Hose & Rubber Company in 1888, remaining with that company for 16 years. He was a salesman in the rubber goods department in New England and New York state until 1893; and then served consecutively as city sales manager of the St. Louis branch for two years; New England representative of the bicycle tire department for two years; southern representative of the mechanical rubber goods department for two years, and as manager of the Philadelphia office until 1904. He then entered the service of the Curtain Supply Company, Chicago, as western representative, and since 1907 served as eastern manager of the company.

R. F. Hayes

Frank H. De Brun has been appointed mechanical engineer in charge of design and improvement for Mudge & Co., Chicago. Mr. De Brun was born in Switzerland in 1883 and received his education in the Higher Polytechnic University of Geneva. After graduation from that institution he served three years as an apprentice in mechanical and electrical laboratories in Switzerland and the following two years as a mechanical draftsman for the Coventry Motor Works, Ltd., at Coventry, England. The next seven years he was in the employ of the Royal Automobile Club of London, England, as superintendent in charge of garage and repairs, resigning from that position to come to the United States as manager of the Universal Auto Training School in New York City, where he remained for two years. In the fall of 1917 Mr. De Brun became associated with the Detroit Institute of Technology, where he had charge of the automotive engineering laboratories work, electrical equipment and battery work and special courses in the maintenance and repair of tractors.

F. H. De Brun

The Van Dorn Electric Tool Company, Cleveland, Ohio, has opened a Chicago office at 527 South Dearborn street, in charge of William Cottrell, sales manager.

The Joseph Dixon Crucible Company, of Jersey City, N. J., has moved its Philadelphia, Pa., sales office from 1020 Arch street to the Finance building, South Penn Square.

The Southern Railway Car Company has been organized at Wichita Falls, Texas, with James A. Jones, president, to make tank, railway and street cars; also to repair cars.

The Booth-Hall Company, designers and builders of electric furnaces, has removed its executive and sales offices from 2307-15 Archer avenue, Chicago, to the Hearst building, 326 West Madison street.

The Baldwin Locomotive Works has recently established a separate department for handling foreign sales in charge of F. de St. Phalle, recently elected vice-president, and Reeves K. Johnson is manager of foreign sales.

At the annual election by the board of directors of the Safety Car Heating & Lighting Company, New York, W. L. Conwell was made president of the company; J. A. Dixon, Randolph Parmly and James P. Soper, vice-presidents; C. W. Walton, secretary and treasurer, and William Stewart, assistant secretary and assistant treasurer. W. L. Conwell, president, has been connected with the company since January, 1916. He was born at Covington, Ky., on January 25, 1877. He received his education in the public schools of Philadelphia and at the University of Pennsylvania, from which he graduated in 1898 with the degree of electrical engineer. He then passed the examination for first assistant engineer for the United States Navy, but received no appointment because of the close of the war with Spain. He was employed in contracting work as a timekeeper for the Tennis Construction Company, Philadelphia, becoming later chief engineer and secretary of the company. In 1901 he resigned to become city salesman of the Westinghouse Electric & Manufacturing Company in New York. He was later placed in charge of the isolated plant department of the company, and for five years, ending in 1911, was engaged in railway work. In that year he became vice-president of the Transportation Utilities Company, and later became also treasurer of the same company. In January, 1916, he was appointed assistant to the president of the Safety Car Heating & Lighting Company, and upon the death of R. M. Dixon, former president of that company in October, 1918, Mr. Conwell was made acting president. His headquarters are in New York.

W. L. Conwell

The American Steam Conveyor Corporation, Chicago, has appointed N. B. Stewart district representative in charge of its St. Louis territory. Offices have been opened at 708 Merchants-LaClede building, St. Louis, Mo.

T. W. Holt, superintendent of shops of the Pressed Steel Car Company, Pittsburgh, Pa., who had entire charge of the munition work undertaken by that company, has resigned to become assistant general manager of the Curtain Supply Company, Chicago, succeeding the late R. S. Reynolds.

George W. Hoover, formerly in charge of the procurement of railway material in the Construction Division of the army, has been appointed manager of the St. Louis office of the Buda Company, Chicago, which office was opened on April 1 at 2025 Railway Exchange building.

The Clark Equipment Company, manufacturers of "Celfor" drills and precision tools, has just completed a modern hospital at its plant in Buchanan, Mich. The hospital is intended primarily for the use of employees, but is also open to citizens of the community at cost.

J. N. Ebling, recently returned from France, after spending 13 months with the American Expeditionary Forces, has resumed his position as president of the Railway Specialties Corporation, New York. D. A. Munro, formerly secretary, is no longer connected with the corporation.

The Duntley-Dayton Company, Chicago, has opened a branch office in the Century building, Cleveland, Ohio, under the management of J. C. Sague. This company has also opened a branch office in the Home Trust building, Pittsburgh, Pa., under the management of W. M. Hankey.

Frank H. Clark, formerly general superintendent of motive power of the Baltimore & Ohio, has opened offices at 15 Park Row, New York, and will undertake engineering investigations, report upon railway conditions and operations and prepare or co-operate in the preparation of plans and specifications for railway equipment and materials. He will also act in an advisory capacity to export firms and to foreign railway or other concerns purchasing equipment or material from manufacturers in the United States, and make such inspections as may be desired. Mr. Clark was associated for four years with David L. Barnes, consulting engineer, of Chicago, after which he entered the service of the Chicago, Burlington & Quincy, where he held successively the positions of chief draftsman, mechanical engineer, superintendent of motive power and general superintendent of motive power. He resigned his position with that company on December 30, 1910, to enter the service of the Baltimore & Ohio as general superintendent of motive power and held that position for eight years. He is a member of the American Society of Mechanical Engineers, the Franklin Institute and other technical societies. He is also a member of the American Railway Master Mechanics' Association and of the Master Car Builders' Association. He served as president of the M. M. Association for the early part of the term 1918-1919 and of the M. C. B. Association in 1910-1911.

F. H. Clark

The American Railway Equipment Company, Pittsburgh, Pa., on May 26, located its general offices in the Liberty building, Philadelphia, Pa., where G. W. Mingus, president of the company, will have his office. The company will retain an office in the Diamond Bank building, Pittsburgh, in charge of R. C. Crawford.

W. J. Cromie, who has of late years been with the Belmont Packing & Rubber Company, became associated with the Gustin-Bacon Manufacturing Company, 1021 Filbert street, Philadelphia, Pa., on May 1. Mr. Cromie was formerly connected with the B. & O. and the D. L. & W.

Lieut. Joseph P. Schneider, who for the past nine months has been on duty with the Railway Transportation Corps, U. S. A., as railway transportation officer with headquarters at Paris, France, has received his honorable release from the service and has resumed his duties as Western office assistant with the Locomotive Superheater Company at Chicago.

C. D. Barrett, who has just returned from France atter 18 months' service as an officer in the Transportation Corps of the American Expeditionary Force, has been appointed district engineer of the Locomotive Stoker Company, with headquarters at New York. He was born in Fort Wayne, Ind., and after graduation from Purdue University in 1901, he entered the service of the Pennsylvania Railroad as a special apprentice at Altoona. He remained with the Pennsylvania in the positions of motive power inspector, foreman, assistant master mechanic, assistant engineer of motive power and master mechanic until the summer of 1917. He then received a commission as major in the United States Army and went to France in command of the First Battalion of the Nineteenth Engineers. In France Major Barrett organized the St. Nazaire locomotive erecting shop, where all the locomotives used by the A. E. F. were erected. He remained in charge of this shop until July, 1918, when he was appointed assistant general superintendent of motive power in the Transportation Department.

C. D. Barrett

Oscar F. Ostby & Co., Inc., is the name of a new corporation recently organized, with Oscar F. Ostby as president. Mr. Ostby's offices, at 1044 Grand Central Terminal, New York, are the headquarters of the company, which will continue to handle the lines of railway supplies hitherto handled by Mr. Ostby, and in addition is the exclusive railway distributor for Davidson high speed steel and tools, manufactured by the Davidson Tool Manufacturing Corporation, New York. Mr. Ostby was born on March 5, 1883, and received his education in the public schools of Providence, R. I. From 1901 to November, 1904, he was engaged in publicity work, following which he was connected with the Commercial Acetylene Railway Light & Signal Company, serving as president of the International Acetylene Association during 1910-11. Later he was general manager of the Refrigerator, Heater & Ventilator Car Company. He has for some time represented the White American Locomotive Sander Company of Roanoke, Va., and since September, 1918, has served as vice-president of the

O. F. Ostby

Glazier Manufacturing Company of Rochester, N. Y. Mr. Ostby has been one of the leading members of the Railway Supply Manufacturers' Association and was its president in 1915-1916.

Stone Franklin Company

The Stone Franklin Company has been organized to market the Stone Franklin car lighting system in the United States and Canada. This system was introduced into this country by the Franklin Railway Supply Company. The new company has elected the following officers: Joel S. Coffin, chairman of the board of directors; Ralph G. Coburn, president; C. E. Walker, vice-president; H. D. Rohman, chief engineer, and W. Truelove, secretary, with offices at 18 East Forty-first street, New York.

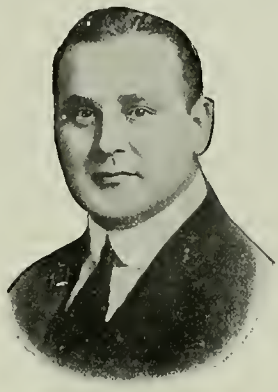
Ralph G. Coburn, president of the new company, has been identified with the Franklin Railway Supply Company. He was born at Boston in 1882, and graduated from Harvard in 1904. From 1904 to 1909 he was in the service of the American Glue Company, having charge of its western factories with his headquarters at Des Moines, Ia., and Chicago. On May 1, 1909, he opened the Chicago office of the Franklin Railway Supply Company as resident sales manager. On June 1, 1911, he was made assistant to the vice-president, in charge of eastern-southern territory, with headquarters at New York. In December, 1913, he was appointed eastern sales manager of the Franklin Railway Supply Company, which position he held until his appointment with the Stone Franklin Company.

R. G. Coburn

Charles E. Walker, vice-president of the new company, has had a broad experience in industrial manufacturing, sales and railroad work both in this country and abroad. He is a graduate of the engineering course of the University College, of Bristol, England. He served as an apprentice with the Bristol Railway Carriage Company and as junior assistant on the staff of the Newcastle Electric Supply Company. He later went to South America on the mechanical constructional staff of the Buenos Ayres & Pacific Railroad. While in South America he joined J. Stone & Co., Ltd., as technical adviser and sales manager with office in Buenos Ayres. In the latter part of 1912 he went to England to take charge of foreign sales in the main office at London. When war was declared he joined the British army and saw active service at the front for nearly three years. Receiving the order of the British Empire in February, 1917, he was returned to England to take charge of the manufacture of anti-submarine devices, which is the work he leaves to take up the position of vice-president of the Stone Franklin Company.

C. E. Walker

Harry D. Rohman, chief engineer of the Stone Franklin Company, New York, is a graduate of the technical schools of Zurich, Switzerland. Upon graduation he entered the works of the Oerlikon Electrical Construction Company, and in 1903 qualified as an electrical engineer, with experience in high and low tension and a. c. and d. c. work, especially electrical traction. Later he entered the service of J. Stone & Co., London, and in 1910 was appointed chief of the testing and experimental departments. In 1914 he was appointed chief assistant electrical engineer, and held that position until October 1, 1915, when he entered the service of the Franklin Railway Supply Company as chief electrical engineer, which position he held at the time of his recent appointment. Mr. Rohman speaks several languages and has had an extensive experience in all European countries, as well as in South Africa and the Belgian Congo. He has a broad experience in car lighting engineering, obtained by many years of active work in that field.



H. D. Rohman

E. Roy Bordon has been appointed service engineer of Mudge & Co., in which capacity he will have charge of investigating service given by the products manufactured by that firm and their successful handling, care and operation. He was born on January 17, 1893, at Galveston, Tex., and after graduation from the public schools entered Purdue University, Lafayette, Ind., where he remained for three years, at the end of which time he entered the service of the Pennsylvania at Fort Wayne, Ind., as a special apprentice in the shops of that road. The following year he returned to Purdue University, graduating from that institution as a mechanical engineer in June, 1915. In the fall of the same year he entered the employ of the Atchison, Topeka & Santa Fe in the test department where he remained until December, 1917, at which time he was commissioned a second lieutenant in the ordnance department of the United States army and sent to France. On February 13, 1919, he received his honorable release from the service and returned to the testing department of the Atchison, Topeka & Santa Fe, which position he held prior to his appointment with Mudge & Co. on May 1.

E. R. Borden

William K. Stamets, Pittsburgh, Pa., announces the opening of an office in Cleveland, Ohio, under management of William S. Dickson, formerly general manager of the Greaves Klusman Tool Company, Cincinnati, Ohio. The Stamets organization will represent exclusively most of machine tool manufacturers it now represents in Pittsburgh.

The Toledo Pipe Threading Machine Company, Toledo, Ohio, has organized a "Toledo Ten-Year Club," whose membership will be limited to owners of Toledo pipe threader machines that have been in service ten years. All applications for membership must be in by July 1, 1919, and on that date the six members owning the six oldest "Toledos" will be notified and given their choice of a Toledo ratchet threader complete or a Toledo, No. O, tool.

Colonel Douglas I. McKay has been elected president of the Pulverized Fuel Equipment Corporation, New York, to succeed John E. Muhlfeld, who has retired to return to consulting engineering practice. Since July, 1917, Colonel McKay has been engaged in war work. He was commissioned major in the Ordnance Department in charge of the raw materials branch of the gun division and purchased all raw and semi-finished materials used by the ordnance department and contractors for the ordnance department. Between August and December, 1917, these purchases amounted to $268,000,000. In January, 1918, he was promoted to lieutenant-colonel in the National Army and appointed assistant director of purchase and supply. Here he had supervision over the purchasing operations of the several supply corps of the War Department, including the ordnance department, the quartermaster department, the medical corps, the corps of engineers and the signal corps. He was subsequently promoted to colonel, and continued in this capacity until he returned to civil life after the armistice was signed. In addition to his duties as president of the Pulverized Fuel Equipment Corporation, Colonel McKay is also vice-president and director of the Chemical Foundation, Inc., director of the International Agriculture Corporation and director of the Botany Worsted Mills.

Col. D. I. McKay

Willis B. Clemmitt and George H. Ruppert have entered the employ of the Powdered Coal Engineering & Equipment Company of Chicago as advisory engineers. Mr. Clemmitt was formerly associated with the Central Iron & Steel Company at Harrisburg, Pa., and Mr. Ruppert, before his entry into the chemical branch of the government military service, had charge of the sodium-ferro-cyanide department of the Semet-Solvay Company.

The Wetmore Reamer Company is the new name of the Wetmore Mechanical Laboratory Company, of Milwaukee, Wis. This company has completed all of its contracts with various munition makers of Canada and this country to whom it supplied Wetmore expanding reamers, hobs, taps, lathe and boring bar tools. Since the completion of this work it has resumed its former tool business, specializing in a type of expanding reamer for all grades of industrial reaming operations. More floor space has been added and the offices enlarged. P. H. Door, recently released from the government service, is secretary and sales manager.

The Carborundum Company

Frank J. Tone has been elected president of the Carborundum Company, Niagara Falls, N. Y., in place of F. W. Haskell, deceased, and George W. Rayner has been elected vice-president. Mr. Tone was formerly works manager, having been in charge of manufacturing operations since the setablishment of the works at Niagara Falls in 1895. He was previously engaged in electric railway work in Pittsburgh. He is well known for his work in the electric furnace field on artificial abrasives, refractories and silicon alloys, and is past president of the American Electrochemical Society. Mr. Tone graduated from Cornell University in 1891.

F. J. Tone

George R. Rayner, the new vice-president of the Carborundum Company, was born in Springfield, Mass. He served for a period of time as a member of the sales force of the Hampden Wheel Company, and in June, 1898, he was appointed manager of the Chicago branch of the Carborundum Company. In August of the same year he was transferred to Niagara Falls, and was appointed secretary and general sales manager of the company. Mr. Rayner is a past president of the American Foundry & Supply Association and is a member of the board of directors of the Chamber of Commerce, at Niagara Falls.

G. R. Rayner

Railway Business Association

This association's committee on government purchasing policies was organized in New York City recently. The chairman of the committee is Knox Taylor, president of the Taylor-Wharton Iron & Steel Company, High Bridge, N. J.; and the other members are Samuel G. Allen, vice-chairman, Franklin Railway Supply Company, New York; G. S. Brown, president, Alpha Portland Cement Company, Easton, Pa.; Andrew Fletcher, president, American Locomotive Company, New York; Howard A. Gray, manager railroad sales, Joseph T. Ryerson & Son, Chicago; A. L. Humphrey, president, Union Switch & Signal Company, Swissvale, Pa.; A. H. Mulliken, president, Pettibone, Mulliken & Co., Chicago; L. G. Parker, assistant manager of sales Cleveland Frog & Crossing Company, Cleveland, Ohio; W. H. Woodin, president, American Car & Foundry Company, New York.

Colorado Brake Shoe and Foundry Company

The Colorado Brake Shoe & Foundry Company, Denver, Colo., was organized on January 1, 1919, by James C. Dolan, representative of a number of railway and mine equipment and supply firms at Denver, Colo. Mr. Dolan, in addition to assuming the presidency of the new company, retains his connection with the companies with whom he has been engaged for the past six years. Previous to this he was in the employ of the purchasing department of the Denver & Rio Grande for nine years.

J. C. Dolan

F. T. Dickinson, general manager of the new company was formerly superintendent of the Railway Material Company's plant at Toledo, Ohio, and later the plants at Phoenixville, Pa., and Stevens Point, Wis. Mr. Dickinson has been associated with the foundry business for the past 35 years, having received his early training in the general foundry business in Chicago. He first became interested in the manufacture of reinforced brake shoes while working for the Union Iron & Steel Company of Chicago in 1905. Soon after Mr. Dickinson was employed by the American Brake Shoe & Foundry Company, and here he was given opportunity to develop ideas on permanent iron molds for making brake shoes. After remaining with the American Brake Shoe & Foundry Company for two years he resigned to establish the Illinois Malleable Company, of Chicago, in the brake shoe business. In 1909 Mr. Dickinson resigned from this company to accept the superintendency of the Railway Material Company's plant at Toledo and later, while still in the employ of this company, started and operated its new plant at Phoenixville, and later at Stevens Point, retaining the latter position until his appointment as general manager of the Colorado Brake Shoe & Foundry Company. Mr. Dickinson is the inventor of numerous brake shoes and foundry devices pertaining to the manufacture of steel brake shoes.

F. T. Dickinson

The company has acquired a modern brake shoe foundry with a floor space of 150 ft. by 250 ft. and equipped with modern machinery. This foundry has a capacity of 50 tons a day, entirely of reinforced brake shoes.

As a war memorial to the more than 8,000 employees of the Westinghouse Electric & Manufacturing Company who have entered the service of the government in the war, the company has decided to establish four technical scholarships each year. Candidates will be limited to sons of employees of the Westinghouse Electric & Mfg. Company and its subsidiaries and to the younger employees of the company or its subsidiaries who have been in their service for a period of at least two years and who do not exceed the age of 23. The selection is to be determined by competitive examination, to be conducted annually by the company's educational department under direction of a committee composed of three vice-presidents of the company.

Vauclain Succeeds Johnson as Head of Baldwin Locomotive Works

Alba B. Johnson, president of the Baldwin Locomotive Works, has resigned from that position and has been succeeded by Samuel M. Vauclain, hitherto senior vice-president. Mr. Johnson, who had been contemplating the step for a considerable time, presented his resignation at a special meeting of the board of directors in Philadelphia, May 9. He will retain his extensive interests in the company and will remain a director. In connection with the resignation and the election of Mr. Vauclain as president, there were rumors of friction between different interests in the company, but the existence of such friction has been emphatically denied by Mr. Johnson and Mr. Vauclain alike.

A. B. Johnson

Following the meeting of the board of directors, Mr. Johnson issued a statement in which he explained that he had desired to withdraw from the presidency of the company in order to devote his time to his extensive personal and public interests and in which he expressed his wishes for the success of Mr. Vauclain.

Mr. Vauclain declined to issue any statement, but said in answer to a question that there would be no change in the policy of the company.

S. M. Vauclain

Mr. Johnson has been connected with the Baldwin Locomotive Works since 1877 and its president since 1911. He was born at Pittsburgh, Pa., February 8, 1858, and upon his graduation from the Central High School of Philadelphia entered the employ of Burnham, Parry, Williams & Co., as the present Baldwin Locomotive Works was then known, as a junior clerk in May, 1877. On the advice of John H. Converse he studied stenography and then for about 20 months was in the employ of William Sellers of the Edge-Moor Iron Works, Wilmington, Del. Upon returning to the Baldwin works he became secretary to Mr. Converse and served in that capacity for 33 years, gradually working up in the company and taking over Mr. Converse's work. In 1896 he was made a partner in the firm of Burnham, Williams & Co., as the firm had then become known, and was in charge, first of sales and later, on the withdrawal of George Burnham, Jr., of sales and finances. Upon the incorporation of the company under the name of the Baldwin Locomotive Works on July 1, 1909, he was elected vice-president and treasurer, becoming president on July 1, 1911.

In the period during which Mr. Johnson was president the company had what may truly be called a phenomenal growth, its gross sales having increased from a total of $29,000,000 in 1912, the first full year after he became the head of the company, to over $98,000,000 in the year ended December, 1918. The total undivided profits over the same period increased from $4,470,000 in 1912 to $5,752,000 in 1918, while in 1917 a total was reached of $8,306,000, excluding the return from the Standard Steel Works Company and the Southwark Foundry & Machine Company.

Mr. Johnson has extensive personal and public interests, and is one of the country's leaders in export trade. He is president of the Railway Business Association; a member of the National Foreign Trade Council, having acted as president of all the National Foreign Trade conventions with the exception of the one in Cincinnati last year, and is connected with other commercial and civic organizations.

Samuel M. Vauclain, the new president of the Baldwin Locomotive Works, has been connected with the company or its predecessors since 1883, and its senior vice-president since 1911. He entered the employ of the plant in 1883 as a foreman. In November, 1885, he was promoted to superintendent of equipment, and in 1886 was advanced to general superintendent. He became a member of the firm of Burnham, Williams & Co., in 1896, and in 1911 was elected a vice-president of the Baldwin Locomotive Works. It is through his work as manager of operations in the Baldwin Works that Mr. Vauclain is generally recognized as one of the leaders in shop management in the country.

Mr. Vauclain's greatest work, however, was during the war, not only in connection with the work of the Baldwin Locomotive Works in supplying locomotives for the allied armies overseas, but also in connection with the great shell making plant of the Eddystone Munitions Company at Eddystone, Pa. Mr. Vauclain was on a number of occasions called into consultation with various of the allied governments, and so well was his work regarded that he was made a chevalier of the Legion of Honor by the French government. At a banquet given in his honor at the Bellevue-Stratford Hotel in Philadelphia on May 17, he was presented by Benedict Crowell, assistant secretary of war, with the Distinguished Service Medal for the part he played in America's mobilization for war. In this connection he served with the Council of National Defense, first in an advisory capacity and later as chairman of the committee on ordnance and as chairman of the committee on cars. After the War Industries Board was organized he became chairman of that body's special committee on plants and munitions and was also the head of the committee of car and locomotive builders.

Carl H. Peterson, western representative of the Baldwin Locomotive Works, Philadelphia, Pa., and the Standard Steel Works Company, Philadelphia, with headquarters at Chicago, resigned on May 1, to become president of the Iron Mountain Company, Chicago, and vice-president of the Jackson-Park Machine Company, Chicago. Mr. Peterson will be succeeded by Arthur S. Globe, southwestern representative of the Baldwin Locomotive Works and the Standard Steel Works Company, with headquarters at St. Louis, who will have the title of manager of the Chicago office, the title of representative having been abolished. Paul G. Cheatham, assistant to the western representative, with headquarters at Chicago, will become manager of the St. Louis office.

General Miller Heads New Oil Company

General Charles Miller, of Franklin, Pa., has assumed the chairmanship of the board of directors of the Home Oil Refining Company of Texas. General Miller occupies a unique position in the history of American railroads. He was the first man to recognize the great importance of a scientific study of oil and lubrication problems in transportation, and he taught the railroads the best ways and means to efficient and economical use of lubricating oils. Prior to 1869 the railroads began using what was known as pure West Virginia oil (a mineral oil from 28 to 29 gravity with a cold test of 10 below zero and a fire test of 175).

General Charles Miller

In July, 1869, General Miller formed a partnership with three associates and began to manufacture an oil in all appearances like pure West Virginia oil and meeting the same tests. The product was, however, superior because of the addition of certain materials. The company made a specialty of supplying railways with cylinder, engine and freight car oils. General Miller studied the subject of railway lubrication in all its aspects. His company was the first to formulate a plan of furnishing railway oils under contracts guaranteeing the cost per thousand miles on locomotives and freight cars. It was the first to organize a department of lubrication experts, whose services were given to the railroads.

In 1878 the Galena Signal Oil Company was shipping 12,000 barrels per year, supplying about 15 per cent of the railroad mileage in the country. In 1918 its product was said to be standard upon approximately 98 per cent of the entire railway mileage of the United States and Canada, with a large export trade to France and South America. With the advent of electric railways the company developed special oils to meet their requirements, making contracts on the same basis which had proved so satisfactory to the steam railroads. Not only did the company furnish lubricants to the railways but also signal oil, long time burner oil, headlight oil and other illuminating oils.

General Miller severed his connection with the Galena Signal Oil Company some months ago because of differences of opinion as to policy. The Home Oil Refining Company which he heads as chairman of the board has large oil contracts covering a production of 7,500 barrels per day in the Ranger and Burkburnett (Texas) fields. It also holds leases on approximately 200,000 acres of oil lands exceptionally well located and now in process of development. The company owns a refinery at Yale, Okla., now operating at 2,500 barrels daily capacity. It is constructing a large refinery at Fort Worth which will be in operation in a few weeks. Nearly 600 men are now engaged in the construction work on the site of 165 acres located on the St. Louis-San Francisco Railway in the outskirts of Fort Worth. Recently the Home Oil Refining Company purchased a convenient site of 50 acres at Franklin, Pa., for the erection of a large plant for the production of railroad oil.

Railway Mechanical Engineer

CONTENTS

Investigate Reclamation Practices

During the last few years the railroads have carried on reclamation work more extensively than ever before. In some cases the difficulty of securing material made reclamation necessary, and this was the deciding factor, rather than the saving effected. Now that conditions are becoming more nearly normal some of the reclamation practices put into effect during the war should be investigated to see whether they are economical under present conditions. It is quite possible that in many cases the purchase of new material would be cheaper in the end. There is another phase of the problem brought up by the changes in the prices of material and in the rates of wages which is perhaps of even greater importance, namely, the advisability of adopting more extensive reclamation policies. The advance in the prices of some materials has been greater than the advance in labor costs. New tools and new methods have been introduced, and some work that was uneconomical under former conditions can now be carried on at a saving. The entire status of reclamation work has been changed and present practices must be carefully reconsidered if costly mistakes are to be avoided.

Grinding Twist Drills

The practice of grinding all twist drills on special grinding machines is quite general in railroad shops, and it might seem that any comments on the advantages of this method are superfluous. Observation in some small shops, however, indicates that grinding by hand on ordinary stand grinders is by no means obsolete. Even in shops equipped with drill grinders mechanics often grind drills by hand to avoid making a trip to the tool room to obtain a sharp drill. The desire to save time in this way is praiseworthy, but the object is seldom attained. Unless the drill is ground on a special machine one edge is invariably longer than the other, and as a result the drill uses more power than it would if properly ground, its capacity to stand up under high speeds and heavy feeds is reduced and it becomes dull more rapidly than if both edges did an equal amount of work. The influence of grinding on the endurance of drills was illustrated by comparative tests of drills used for forming telltale holes in staybolts. Drills of small sizes are considered easy to sharpen by hand, yet machine sharpened drills permitted much more rapid work and finished 80 per cent more holes before becoming dull.

Locomotive Front End Design

There is probably no other part of the modern locomotive which is designed on such an unscientific basis as the draft appliances. It is surprising but nevertheless true that no attempt has been made to establish general rules for proportioning nozzles and stacks since 1902, when a series of tests was conducted by the *American Engineer* with the co-operation of the Master Mechanics' Association. During recent years several roads have made tests to determine suitable front end proportions for certain classes of locomotives. These have added little to the general knowledge of front end design, but have emphasized the need for further information on the subject, as in practically every instance these tests were undertaken only after it had been found that front ends designed according to the usual practice would not give satisfactory results.

The large amount of power used to develop draft in a locomotive boiler is seldom realized. In a simple locomotive at ordinary running speeds the back pressure is often equal to one-fourth of the mean effective pressure, in which case the draft requires one-fourth as much power as is developed by the cylinders. In compound locomotives the loss is still greater. Even a slight reduction in back pressure will cause a considerable increase in the power developed by the locomotive. One recent test showed that by a change in the front end arrangement, the back pressure could be reduced six pounds and the power delivered by the locomotive increased 188 hp.

A general redesign of the draft appliances on many locomotives is very desirable. This work cannot be done until the best proportions for the front ends of large locomotives are definitely established. However, the comparatively low efficiency of circular nozzles as compared with nozzles of irregular form has been proved and economies that are well worth while can be obtained by applying the later form of tip to existing locomotives as a temporary expedient until the best arrangement of draft appliances for modern motive power is developed.

Condemning Limits for Steel Wheels

The relocation of the limit of wear groove for wrought steel wheels ½ in. from the inside of the rim instead of ¾ in. as at present was discussed in the report of the Committee on Car Wheels presented at the convention of the Mechanical Section of the American Railroad Association. The committee stated that other factors besides the strength of the wheel are involved and suggested that a circular of inquiry will be sent out covering these points. Elsewhere in this issue will be found an account of tests recently conducted to determine the strength of the flange on steel wheels with the treads turned to the proposed condemning limit. These tests indicate that wheels worn to within ¾ in. of the rim still have an ample factor of safety to resist lateral stresses.

The possibility of getting more mileage from rolled steel wheels is so important that it should be carefully considered. The committee mentions the maintenance of drawbar height, truck clearance and the effectiveness of brakes as factors that might prevent the change in the scrapping limit. Some slight alterations in the trucks would probably overcome these difficulties in most cases, and if it were feasible the change should prove economical as it would reduce the cost of wheel renewals throughout the life of the car. Even though all trucks cannot be changed to admit of wearing the wheels to smaller diameter, there seems no reason why roads that are able to use wheels until the rims are ¾ in. thick should not be allowed to do so.

Spontaneous Combustion in Coal Chutes

The destruction of several coaling stations by fires, due presumably to spontaneous combustion in the coal, recently led the Insurance and Fire Protection Section of the Railroad Administration to issue a warning regarding conditions in and about coal chutes. When such accidents occur they cause serious interruption to traffic and every precaution should be taken to guard against them. Spontaneous fires in coal have been carefully studied and while all the causes are not definitely known, certain conditions that increase the fire hazard have now been well established.

Coal which is freshly mined may absorb oxygen from the air and the more finely divided it is the greater the tendency to heat due to this action. Damp coal also heats more readily than dry coal. Wood, greasy waste, or other combustible matter, furnishes a starting point for fire and should be carefully removed before loading the coal into the chutes. Probably the majority of fires in coal chutes could be prevented by avoiding the accumulation of fine coal in the pockets for any considerable period. The screenings will settle to the bottom, particularly in large pockets, and if the chute is not completely emptied this lower strata may remain undisturbed long enough to absorb oxygen and finally become ignited. Coal chutes should be emptied regularly once a day to clean out the fine coal and if there are any pockets from which the coal will not flow by gravity, they should be shoveled out or remodeled to remove the chance for spontaneous combustion which otherwise will exist.

The Welder in Locomotive Repairs

The importance of having competent welders, particularly in the repair of locomotive boilers, was again emphasized at the recent convention of the Master Boiler Makers' Association. The boiler being, so to speak, the heart of the locomotive, any laxity in its construction or inspection is usually followed by disastrous results. One vital feature of boiler making and repairing is the practice now becoming quite extensive, of welding patches to the sheets when repairing cracked or otherwise defective parts of the boiler. There is no other form of repair work that may be so easily slighted through incompetent or careless workmanship and still pass the required inspection, only to fail at some critical moment in the operation of the locomotive. Many excellent papers are published from time to time in the technical journals, devoted to railroad questions and it is the duty of the men who have taken up welding to keep themselves fully informed concerning the methods and progress of the art of welding. Both the electric and the acetylene gas welding apparatus have been developed to a point where they require only careful and intelligent operation to secure satisfactory results. Anyone taking up this line of work may be assured of every assistance from the manufacturers of the welding outfits, as well as from their shop foremen and should not fail to take advantage of every channel of information available. The importance of careful welding in every repair made to a locomotive boiler cannot be too strongly impressed on those who are engaged in this work.

Labor and Scientific Research

One of the significant actions taken by the convention of the American Federation of Labor, recently held at Atlantic City, was the passing of a resolution defining the attitude of the organization toward scientific research in its relation to industrial progress. The resolution sets forth that a broad program of scientific and technical research is of major importance to the national welfare, should be fostered in every way by the Federal government and that the activities of the government itself in such research should be adequately and generously supported in order that the work may be strengthened and extended. In setting forth the reasons for this action the resolution states that the productivity of industry is greatly increased by the technical application of the results of research in the various sciences, as well as in engineering and agriculture, and that the increased productivity in industry resulting from such research is the most potent factor in the ever-increasing struggle of the workers to raise their standards of living. One of the most significant reasons given for the action taken is that the importance of such productivity must steadily increase, since there is a limit beyond which the average standards of living of the whole population cannot progress by the usual methods of readjustment, which limit can only be raised by research and the utilization of the results of research in industry. The recognition of this situation by the great national labor organization is a sign of a most hopeful condition in the possibility for a better understanding between the various agencies which make up the national industrial structure. It is a platform on which the investor and the manager, as well as the worker, have every reason to take a common stand. Much excellent work has been done by the various bureaus of the federal government which has been of great practical value, and with proper support in the way of adequate appropriations the practical value of this work could be greatly increased.

Co-operation with Other Departments

In an organization as complex as a large railroad system the proper inter-relation of the departments presents a difficult problem. With each man engrossed in his own work and carrying out the plan of his immediate superior, conflicts of authority with consequent friction and bad feeling are almost sure to occur. If, as is often the case, all business matters are handled by mail or by wire and personal contact is eliminated minor irritations sometimes produce an effect out of all proportion to their actual importance and animosity is created between the different parts of the organization that has a very harmful effect on the morale. How often the roundhouse force vilifies the back shop force, which it has never seen, or the yard employees, with whom daily battles are fought over the telephone.

No base ball team could be successful if the first baseman refused to catch the balls which the short stop threw to him and no railroad can have a high record for efficiency unless there is teamwork among the different departments. If the roundhouse foreman and the yardmaster met occasionally when there were no differences to be decided between them, the acquaintance would no doubt lead to better relations during working hours, with the result that Bill would take more interest in telling Jim what trains he expected to run and Jim would try to have the power ready in time to meet Bill's schedule. System is a wonderful thing, but some of our railroads are overburdened with it. A few hours a week devoted to common human intercourse between members of different departments is the best lubricant for any organization and one that is often sorely needed.

Retrenchment and Maintenance

The Railroad Administration has recently inaugurated a policy of retrenchment in an effort to reduce the large deficit that is being incurred. Much criticism has been directed at the railroad companies in the past because of the methods adopted when reductions in expenses seemed necessary, due to financial and traffic conditions. Beyond a doubt much of this criticism has been merited. The serious objection to any drastic retrenchment policy is that it attempts to control expenses without regard for the natural factors that influence costs and, therefore, often leads to the adoption of measures which in the end prove false economies.

Reductions in unit costs are often demanded when there is a decrease in traffic, but this is contrary to the natural tendency of unit costs to increase as the business decreases. Heavy loading of cars and locomotives is essential for economy of operation, but where there is a reduced traffic to move, it is almost impossible to haul the maximum average tonnage per train. Thus the cost of fuel and of wages for train and enginemen have a tendency to increase in proportion to the amount of traffic handled. The possibilities for economy in this direction are small and any saving must be effected almost entirely in the cost of maintenance of way and repairs to locomotives and cars. While the *total* expense for equipment maintenance will fall as the traffic declines, the *unit* expense has a tendency to increase, and an immediate substantial reduction in the unit costs can be secured in only one way, by slighting the work.

During the war equipment was not maintained to a high standard. There has been a marked improvement in the last few months, but it would be a serious mistake if the roads, in an attempt to make a show of economy, should again neglect the little things that are so important in railroad operation. The ultimate economy of a high standard of maintenance cannot be questioned and if the officers of the mechanical department could impress on their superiors the many ways in which the elimination of small items leads to much larger expenses, some of the drastic reductions in maintenance allowances might be avoided. The neglect of minor repairs causes equipment to deteriorate rapidly. Lack of attention to draft appliances, flues, fireboxes and grates results in inefficient combustion. Valves out of square, packing blowing, or auxiliaries in poor condition cause a waste of steam. These factors contribute to delays on the road and increase the expense of wages for train crews. Poor maintenance inevitably leads to waste and inefficiency. The Railroad Administration has indicated that an effort will be made to bring about a marked reduction in the cost of equipment maintenance. So far as this campaign is confined to developing improved methods, it deserves, and will surely receive, hearty support. It is to be hoped, however, that the administration officers will not resort to the short sighted policies that have been used under similar circumstances in the past to effect a reduction in expenses.

NEW BOOKS

Cambria Steel Handbook. Prepared and compiled by George E. Thackray, C.E. 603 pages, illustrated, 4½ in. by 6¾ in., flexible binding. Published by the Cambria Steel Company, Philadelphia, Pa.

This is the twelfth edition of the Cambria handbook and in addition to a thorough revision of all data pertaining to the various structural steel sections manufactured by the Cambria Steel Company, it contains a large amount of new material covering the wider range of structural steel sections now manufactured, and includes additional tables of use in calculations involved in the design of structures in which the sections are used. Among the new sections for which illustrations and properties are included in the new edition are a number of bulb angles, small channels for cars, ship channels, T-bars and three sizes of rolled steel car stakes. Among the large number of new tables which have been added are weights of flat and corrugated steel sheathing, roof truss dimensions and stresses, sizes of spikes and wood screws, square roots and cube roots of fractions, weights of circular steel plates, trigonometric formulae, etc.

Applied Mechanics, Volume II, Strength of Materials. By Charles E. Fuller, S. B., and William A. Johnson, S. B., professors of theoretical and applied mechanics, Massachusetts Institute of Technology. 556 pages, 6 in. by 9¼ in., illustrated, bound in cloth. Published by John Wiley & Sons, Inc. New York.

While this book has been prepared primarily for the students of engineering in the Massachusetts Institute of Technology, it covers the fundamentals of applied mechanics to such an extent that it will be found a valuable text book for any engineer's library. A person using this book should have a fundamental knowledge of differential and integral calculus, the principles of statics and dynamics and the methods of determining centers of gravity and moments of inertia of areas and solids. The subject has been developed logically, special care being taken to point out the limitations of the different theories, and emphasis is laid on the divergence of the conditions met in practice from ideal conditions. Graphic methods of solution have been freely employed and a number of problems involving the application of each of the theories discussed have been included and solutions given where it has appeared that these would be an aid to a clear understanding of the subject. The authors of the book have had many years' experience in teaching the subject, and this book is the result of their most careful study of the manner in which such an important subject can be more clearly and firmly fixed in the mind of the student. It covers the physical properties of materials, a study of stress and strain with their application to beams of various loading, and a discussion of the general theory of flexure, columns, shafting and springs, curved bars, arches and catenaries, cylinders and plates, and reinforced concrete beams and columns.

COMMUNICATIONS

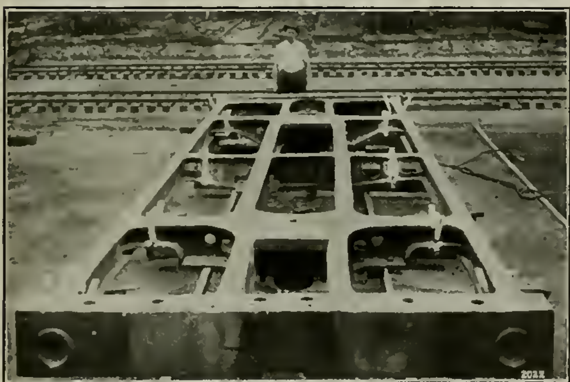
THERMIT VS. AUTOGENOUS WELDING

Clifton Forge, Va.

To the Editor:

I have read with a great deal of interest the article "Oxy-Acetylene Welding Problems," by Mr. W. L. Bean, in the February issue of the *Railway Mechanical Engineer*, and was particularly interested in the description given by him of reclaiming a damaged Commonwealth cast steel one-piece tender frame. We had an occasion to make repairs to a frame similar to this one, but used the Thermit process of uniting the members of the frame after they had been cut apart for straightening instead of using oxy-acetylene or electric processes, both of which we have in use at these shops.

The frame shown in the illustration was 28 ft. long and 9 ft. 6 in. wide, the members being of heavy I-beam sections; the weight was approximately 15,000 lb. The frame was very badly bent and in order to straighten it we found it necessary to cut the side sills. These sills were then straightened in a pneumatic press after being heated in a large furnace. The rest of the frame was then heated by the use of a blow torch and straightened, after which the side sills were clamped into position and welded with Thermit, making ten welds in all.



Cast Steel Tender Frame Reassembled by Thermit Welding Process

In making the welds 1,150 lb. of thermit was consumed. I should like to call your attention to the following comparative results as shown by the two operations, which indicate an advantage in time, cost and strength of weld by the method we used over the New Haven method:

Time—The method used by the New Haven consumed about six weeks. The time consumed in preparing the frame and welding it at the shops at this point was only 10 days.

Cost—The cost of reclaiming the frame on the New Haven was about the same as a new frame. The cost of reclaiming the frame with the Thermit process was $502.50. A new frame would have cost approximately $1,500.

Strength of Weld—The Thermit weld leaves no doubt as to the strength of the weld, owing to the thorough amalgamation of the metal due to the intense heat of the Thermit reaction. After 15 years' continuous use of the Thermit process of welding at the Clifton Forge shops we have found it to give us the best results. Especially is this true where heavy sections are to be welded.

Since November, 1908, we have made approximately 300 frame welds, and it is very gratifying to say that only six failures have occurred. The welded tender frame has been in continuous service for upwards of two years.

E. A. Murray, Master Mechanic.

INADEQUATE MAIN BOXES

Allston, Mass.

To the Editor:

The communication on inadequate main boxes from Charles F. Prescott, which appeared in the April, 1919, issue, has awakened many thoughts in the minds of persons who are interested in this subject. The wear of main driving boxes on heavy locomotives is one of the chief factors causing engines to be shopped with a small amount of mileage; that is, the main box does not give service in proportion to the other parts of the engine, and distributes the effect of its poor condition to the other parts.

This necessitates the treatment of main driving boxes at short intervals, or an engine going to the shop on small mileage, because of the wear and tear due to the bad condition of the main driving boxes. To all who are familiar with this condition, the problem is how to avoid it without the introduction of something which will require more expert attention. One of the most important features of the locomotives designed in the United States is simplicity of construction and the abuse they will stand when maintenance is neglected.

The solid crown brass is a development away from the three-piece crown brass with a wedge center. The solid key in the eccentric is a development away from the rifled key and set screw which gave us the slipping eccentrics.

Mr. Prescott says that the lengthening of bearings toward the neutral axis of the axle has not resulted in improvement. My opinion is that the reason we have found no improvement in extending the bearing toward the neutral axis is that we have not made a scientific distribution of the work on the bearing surface; that we have not made any provision for compensation of the difference in the coefficient of expansion of the various metals massed together between the frames.

The bearing surface of the crown should be bored out between the ends of the brass, allowing a bearing surface on each end to prevent the escape of grease, so as to bring the bearing down on the sides where the piston thrust is concentrated. The bearing on the shoe and wedge should be cut away for about one-third of the width of the shoe and wedge face on each side so as to concentrate the lead from the thrust of the piston in the center of the points of bearing between both ends. For example, assume that the width of wedge and shoe faces were 15 in.; after having fitted them up for the box the next operation would be to set them up on the planer and, starting on lines 2½ in. each side of the center, plane the faces to allow 1/64 in. clearance at the edges. This will permit the box to align itself to the journal bearing.

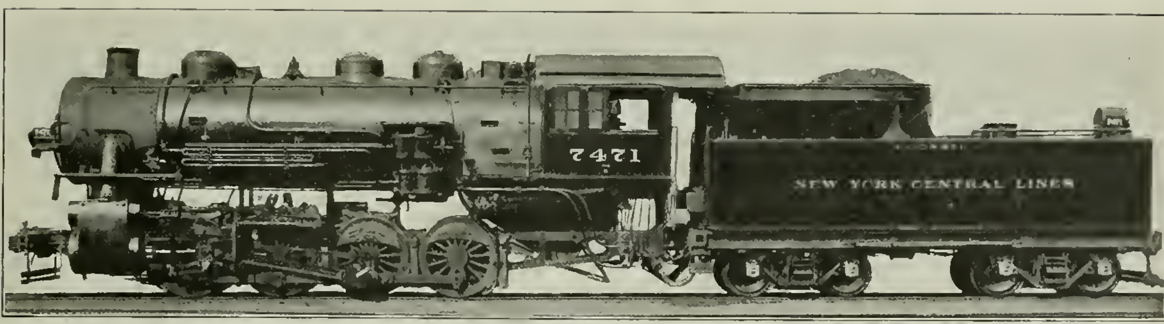
As driving boxes are now fitted, the ends of the bearing wear and cause pounding because the shoe and wedge hold the box so that it cannot adjust itself to the axle alignment.

To compensate for the coefficient of expansion I would suggest a spring under the wedge which will balance the weight of the wedge and also compensate for inertia when the engine is riding, with provision made for the wedge to unload itself by backing down when loaded by virtue of the expansion. This is not to be construed to mean a wedge with a constant spring thrust to maintain adjustment for wear.

The ¾ in. per ft. taper used in the wedge may be proved mathematically as about equal to the coefficient of friction between the wedge and bearing on the frame so that zero may be taken as the amount of work necessary to hold the wedge up against the piston thrust.

Frequently the brasses are loose at points in the box and this is caused by the inequality of expansion of the different metals, the consequent compression being exerted on the metal offering the least resistance.

John C. Murdock.



Eight wheel Switcher Converted from Consolidation Type Locomotive

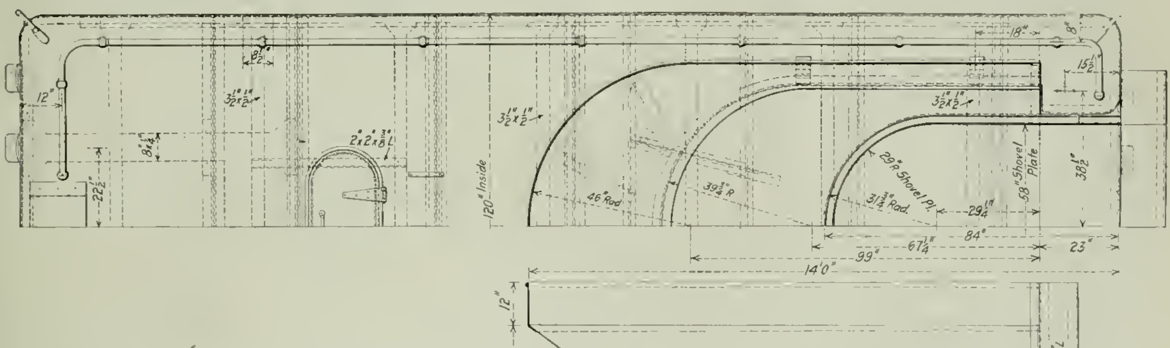
C. C. C. & St. L. 0-8-0 Switchers

Consolidation Type Converted with Special Features to Adapt Engines for Switching Service

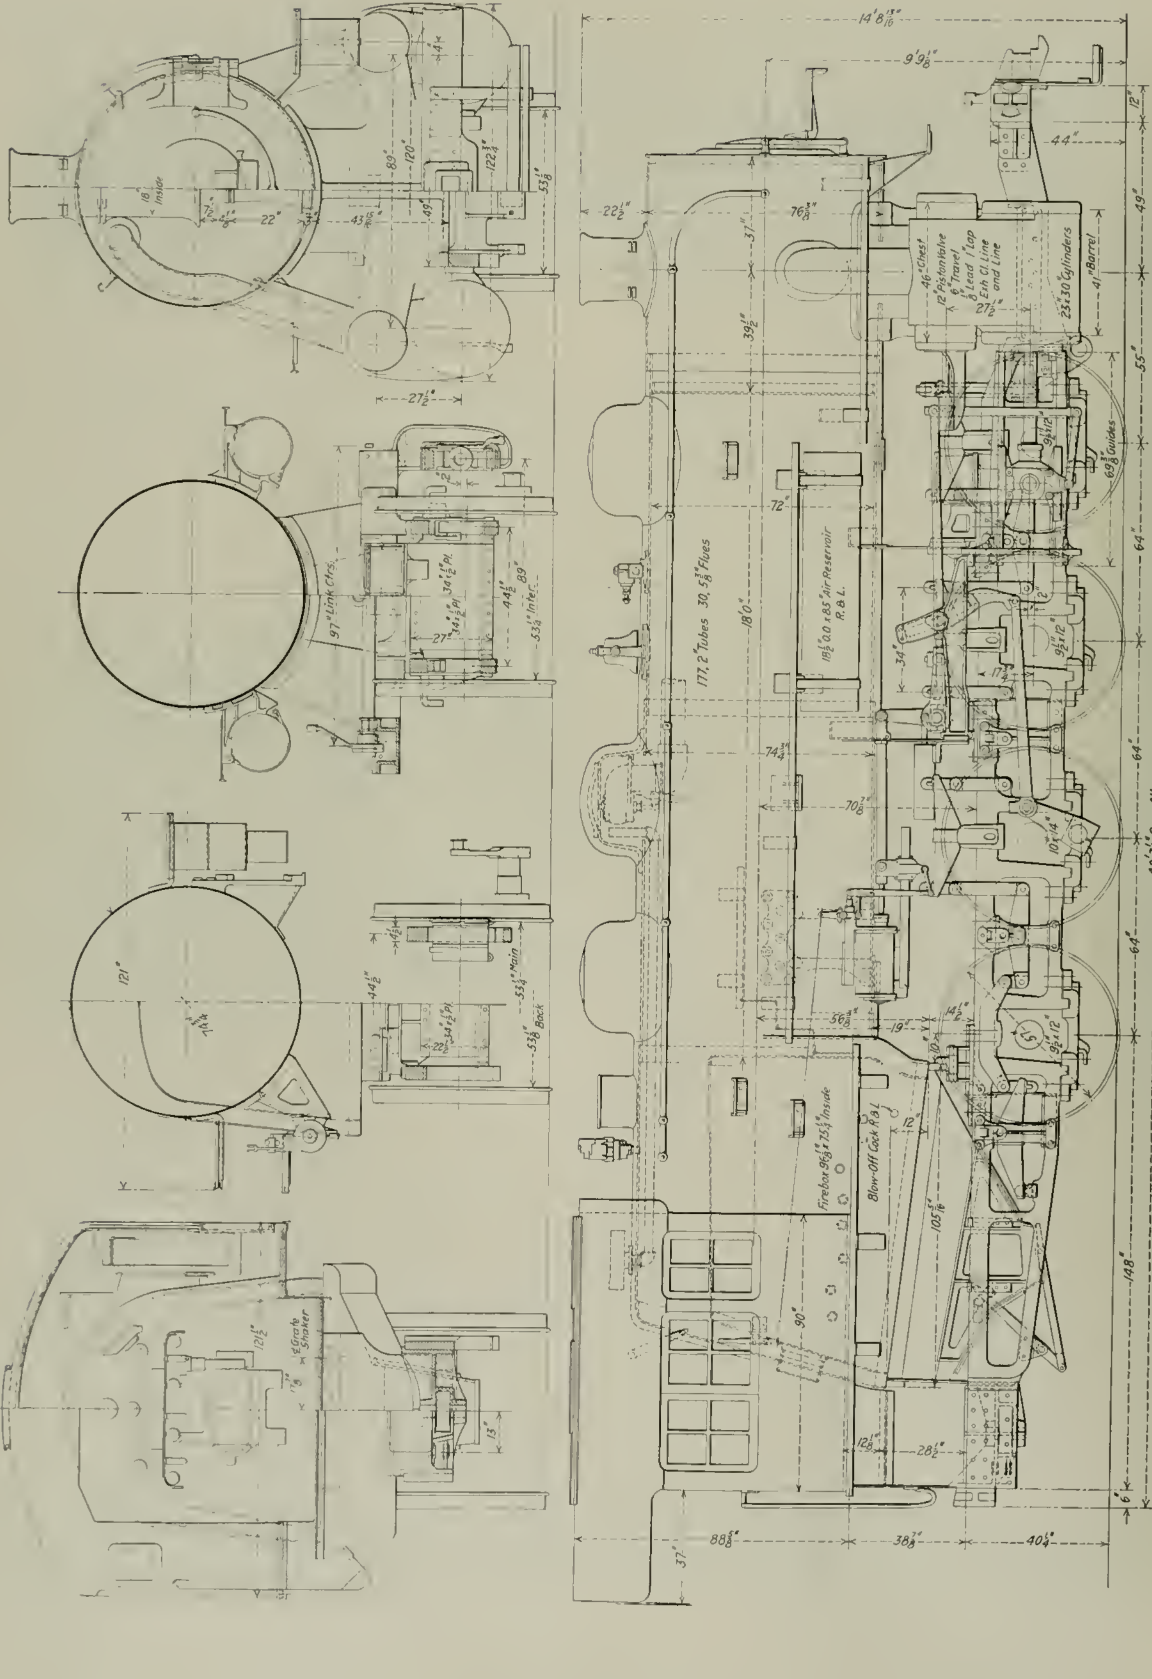
BY R. W. RETTERER
Assistant Mechanical Engineer, C. C. C. & St. L.

The constantly growing demand for increased locomotive capacity due to the heavy freight traffic and the increase in train loads has necessitated heavier and more powerful switching locomotives to handle efficiently the heavy trains brought into the terminal yards. A switching locomotive in order to meet these demands must necessarily be equal, at least, in tractive effort to the heaviest road locomotive, and must also be of such design as to insure quick operation. To accomplish this the Beech Grove shops of the Cleveland, Cincinnati, Chicago & St. Louis have completed the first of 15 eight-wheel type switching locomotives in which a number of interesting features have been incorporated.

As the prices of material entering into the construction of locomotives were much above normal, it was found a considerable saving could be made by converting Consolidation type locomotives into 0-8-0 switchers. The Consolidation locomotives selected were built in 1900, having a tractive effort of 43,000 lb., 22-in. by 30-in. cylinders, and 57-in. driving wheels. Conditions had shown that these locomotives were not sufficiently powerful to handle a train of satisfactory tonnage at scheduled speeds in freight service. In designing the new locomotive it was imperative that, to keep down operating costs, every hour of high priced labor should be made to produce the utmost. With this result in view, the



Design of Tender Tank Which Delivers 75 Per Cent of the Coal at the Coal Gates



Side Elevation and Sections of Big Four Eight-wheel Switcher design of each item that makes for economy of operation was carefully gone over, considering not only the railroad company's interest but also the convenience for the shop and enginemen.

The elimination of the front truck with the consequent increase in weight on driving wheels made it necessary to provide larger cylinders, 23-in. by 30-in. cylinders of the outside steam pipe design being applied. The relation of boiler capacity to the cylinder demand, calculated in accordance

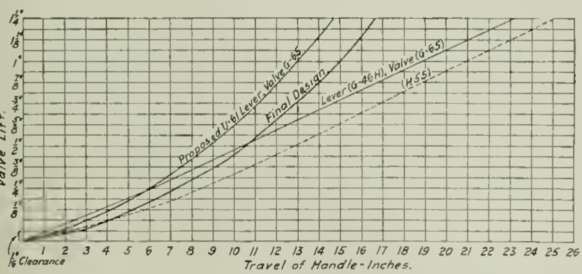


Fig. 1—Diagram Showing Relation Between Valve Lift and Travel of Handle for Various Types of Throttle Rigging

with Cole's ratios, shows ample boiler capacity both as to heating surface and grate area. The boiler is of the radial stay, straight top, wide firebox type having 177 2-in. tubes and 30 5⅜-in. flues. The Locomotive Superheater Company's type A superheater and the American brick arch are used. The total heating surface is 2,621 sq. ft. and the superheating surface 551 sq. ft., with a grate area of 50.2 sq. ft. The boiler is fitted with a one piece pressed steel dome.

The smokebox design is generally similar to that of a Mikado locomotive. The front end is mounted on the smokebox by a hinge of cast steel, amply strong to permit swinging the boiler front to one side, permitting easy access to the superheater units and other front end parts without the entire removal of the boiler front. The hinge is fitted with an eccentric cam which when turned, pushes the front end off the studs, allowing it to swing to one side. This feature eliminates the necessity of using several men when the smokebox front must be removed in the roundhouse.

Steam is supplied to the cylinders through a 7½-in. dry pipe and 7-in. branch pipes, the admission being controlled by a balanced throttle valve. The throttle rigging is of a different design than is ordinarily used. The curve shown in the throttle rigging drawing indicates the lift of the valve plotted against the movement of the throttle lever for these locomotives and for other classes having different throttle rigging. This action gives an easy opening throttle on the start, and also provides for a quick acting engine. The rigging is adjustable to permit taking up the wear, as will be noted from the general arrangement shown in Fig. 2. The Walschaert valve gear and the Ragonnet power reverse gear are used, the controlling levers being conveniently located in the cab.

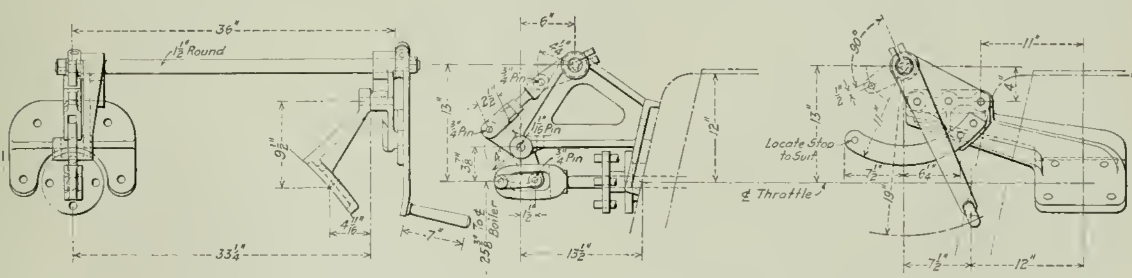

Fig. 2—Arrangement of Throttle Lever Used on Big Four Switchers

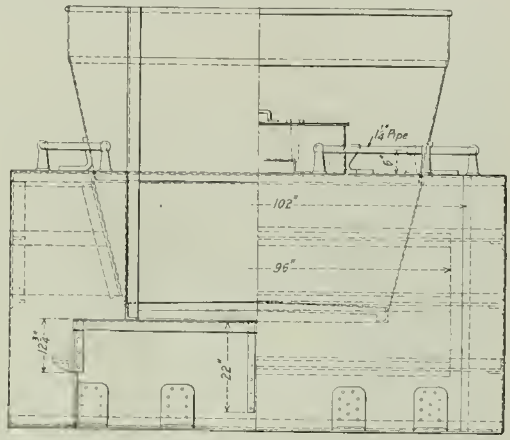
Each frame is a single steel casting 37 ft. 0 in. long. The top rail is 4½ in. wide by 5¾ in. deep, the section changing to 4½ in. wide by 6¾ in. deep over the jaws, the lower rail being 4 in. deep. The single rail to which the cylinders are bolted is 4½ in. wide by 10 in. deep. The frames are securely tied between each pair of drivers with a cast steel cross brace. The brake rigging is designed so as to eliminate the large holes through the frame for the brake hanger pins. The brake hanger supports are bolted to the frame and a short pin is used for supporting the hanger. This feature has done away with the annoying hanger pin failures where the pin is fitted into the frame. A combination brake fulcrum and cross equalizer support is used which permits using a short shaft for the brake fulcrum in place of the usual shaft



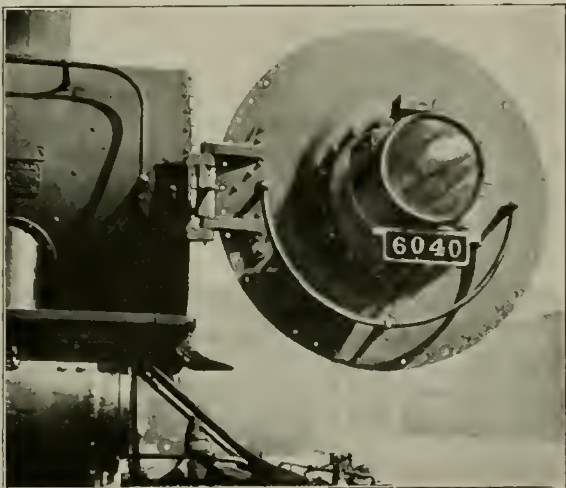
Half End Elevations of the Big Four Switch Engine Tenders

which extends from frame to frame. This permits the removal of one fulcrum independently of the other, also where the clearances are small as is usually the case, the short shaft can be readily removed.

In designing the spring rigging the center of gravity of frames, cross ties, cylinders, etc.,—that is, all parts above the springs except the boiler and attachments,—was calculated as one factor, and of the boiler and attachments as another factor. The boiler was then located so as to make the center of gravity of the whole slightly to the rear of the center line of the wheel base. From these data, the load on each spring was calculated, and the equalizers between drivers were designed so as to be in balance with the load applied. The results of this method are shown in the scale weights of the first engine out of shop, the additional weight on the main wheel being largely due to the weight of heavier rods, counterbalances and valve gear parts connected to it. The weight on each pair of drivers is as follows:

Front wheels	Intermediate wheels	Main wheels	Rear wheels	Total
54,100 lb.	53,200 lb.	57,800 lb.	54,900 lb.	220,000 lb.

The question of making available at the coal gate of the tender a greater per cent of the coal carried without shoveling down by the fireman or taking coal at frequent intervals has become more a matter of importance as the size of engines and trains has increased. To obviate the necessity for coal pushers an investigation was conducted which resulted in the final design of a tender tank with a conical space for coal, the capacity being 9,000 gal. of water and 12 tons of coal. Actual service results show that the coal works forward to the fireman without shoveling down. Some of the features of the design are as follows: Practically all coal is available to the fireman; 75 per cent without opening the gates. The tender carries the same amount of coal as other designs with additional water space of approximately 1,000 gal. The rusting of slope sheets due to the collection of old coal is eliminated. An engine can be coaled with but one spotting under the dock. The self feeding of coal and the increased



Smokebox Front Mounted on Hinge to Permit of Easy Access to the Front End

water capacity eliminate water and coal stops and there is no bad coal left as an accumulation in the tank.

The following table gives the principal dimensions and ratios of these locomotives:

General Data	
Gage	4 ft. 8½ in.
Service	Switching
Fuel	Bit. coal
Tractive effort	47,200 lb.
Weight in working order	220,000 lb.
Weight of engine and tender in working order	380,000 lb.
Wheel base, driving	16 ft. 0 in.
Wheel base, engine and tender	54 ft. 3 in.
Ratios	
Weight on drivers ÷ tractive effort	4.66
Tractive effort × diam. drivers ÷ equivalent heating surface*	780.5
Equivalent heating surface* ÷ grate area	68.7
Firebox heating surface ÷ equivalent heating surface,* per cent	5.6
Weight on drivers ÷ equivalent heating surface*	63.8
Volume both cylinders	14.42 cu. ft.
Equivalent heating surface* ÷ vol. cylinders	239.0
Grate area ÷ vol. cylinders	3.48
Cylinders	
Kind	Simple
Diameter and stroke	23 in. by 30 in.
Valves	
Kind	Piston
Diameter	12 in.
Greatest travel	6 in.
Outside lap	1 in.
Wheels	
Driving diameter over tires	57 in.
Driving, thickness of tires	3½ in.
Driving journals, main, diameter and length	10 in. by 14 in.
Driving journals, others, diameter and length	9½ in. by 12 in.
Boiler	
Style	Straight top, wide firebox
Working pressure	200 lb. per sq. in.
Outside diameter of first ring	74¾ in.
Firebox, length and width	96⅛ in. by 75¼ in.
Firebox plates, thickness	½ in.
Firebox, water space	4½ in.
Tubes, number and outside diameter	177—2 in.
Flues, number and outside diameter	30—5⅜ in.
Tubes and flues, length	18 ft. 0 in.
Heating surface, tubes and flues	2,428 sq. ft.
Heating surface, firebox and arch tubes	193 sq. ft.
Heating surface, total	2,621 sq. ft.
Superheater heating surface	551 sq. ft.
Equivalent heating surface*	3,447 sq. ft.
Grate area	502 sq. ft.
Tender	
Tank	Water bottom, conical hopper
Weight	160,000 lb.
Wheels, diameter	36 in.
Journals, diameter and length	5½ in. by 10 in.
Water capacity	9,000 gal.
Coal capacity	12 tons

*Equivalent heating surface = total evaporative heating surface + 1.5 times the superheating surface.

A LOCOMOTIVE REPAIR SHOP OUTPUT SCHEDULE

BY H. L. BURRHUS

Is it possible to rate locomotive repairs on a manufacturing basis and figure output at a regular stated amount per month? In the past the answer to this question has been that the nature of repairs varies so much that it is impossible to place any specified shop time on a locomotive when it receives general repairs.

There was a time when one shop would claim to handle 40 locomotives a month while some other shop could only boast of 30, yet the shop which turned out the 30 locomotives actually did more work, for they counted only such engines as received a general overhauling as an engine out of shop, while the shop which claimed the 40 engines as a month's output would charge every class of repairs as "general." Now that all shops are using the same unit of measure to classify repairs we can compare the output of shops with greater accuracy. As all shops are paying their workmen on a day work basis, conditions are even more comparable, and any wide variance found in shop output must be due to the shop system or facilities.

Man effort is the same in the east as in the west, hence the shop equipment and system are the deciding factors in the maintenance or the building up of shop output. If several shops have different scheduling systems, the reason why one shop exceeds in output is that their system is better in preventing loss of time and waste of man power.

There are many shop scheduling systems in use which are giving good results, but as a rule they require the services of several clerks and considerable book or card keeping. A system which can be handled by the foremen without adding to their already numerous duties would be desirable, and as we look to the initiative and judgment of the supervising forces to carry out any system, we should not burden a foreman with additional clerical duties.

As cost of repairs, shop time and working schedules are all based on hourly time, it is practicable to develop an "hourly period system."

Before going into the details of this proposed system, let us see how the "shop schedule system" compares with the "hourly period system." If the shop schedule system has been developed on the basis of a ten-hour day and the shop working period is reduced to eight hours a day, the system is entirely disorganized, and if some unlooked for holiday is granted, the schedule is upset. The hourly system period, being based on the one-hour period, is flexible and covers these conditions irrespective of the number of hours worked each day.

It may be claimed that a shop schedule system is not based on the time taken to complete operations, but to see that operations are completed in a specified order so that work in the erecting department will follow in proper sequence. Such a system is at fault in that there may be many lapses of time between the delivery of finished parts, hence any workable shop schedule is a time system, irrespective of the system adopted and the elimination of a vast amount of detail is provided for when a final date is given for an engine to leave the shop. If an engine is marked up to go out of the shop on the fifteenth of the month, that one date is the summary of every item of detail which the various departments should provide for.

With the hourly period system, if the class of repairs requires 120 shop hours and every foreman knows the number of hours he is allowed for his portion of the job, he needs no card record or follow up system to see that his particular part is delivered on time.

Shop conditions naturally affect the number of working hours required to overhaul an engine. In a shop where the stripping is handled by a special stripping gang we find it is possible for 15 men to strip an engine in one 10-hour day or 150 work hours. If, as often happens, this gang is short a few men there should be no failure to complete the stripping on time as the number of man hours necessary to strip an engine is known to be 150 hours whether it be 15 men working 10 hours or 10 men working 15 hours. It is easy to lose sight of time when an engine first comes in the shop but this is the critical period and the time to rush repairs is at first—not the last few days.

When the shop is placed on an eight-hour working day we find that the original gang of 15 men makes a total of 120 effort hours a day, or 30 hours less than the required time, thus reducing the output of this gang to one engine less every five days.

To establish such a system we must depend on the experience and support of the foremen. To say that a foreman has no idea of the time required by his department to complete certain operations, is to admit that the selection of such a supervising officer has been at fault.

The foreman of a shop handling driving wheels had no system to get out his work and he usually started the heaviest jobs first, for he prided himself on turning out heavy jobs in a short time. He would turn tires and take care of crank pins first and in the meantime the boring and facing of the driving boxes would be held up.

A time schedule of 40 hours was placed on this work as follows: 15 hours from the end of stripping time to the completion of journal truing; 20 hours to completion of crank pins and 40 hours from the end of stripping time to the time the completed set of driving wheels was delivered to the erecting gang. This arrangement allowed for driving boxes being bored and faced so that at the end of 40 hours after stripping they also were delivered to the erecting gang. The foremen soon learned to watch the stripping pit to see what they would have to do on their particular parts of the work. As the wheels were dropped shortly after stripping began, the driving box foreman could note if any new boxes were required and it was not unusual to have new boxes brought in from the storehouse and machine work started by noon on the day an engine was being stripped. By nine o'clock the wheel foreman had checked the crank pins so that orders for material were placed fully eight hours before his working time period began.

The hourly period system required a set of driving wheels to be delivered ready for application in 40 hours. The foreman of the wheel department could meet this demand by working his entire force on one set of wheels but in the meantime, the stripping gang had delivered another set of wheels which was also due to leave the department in 40 hours.

The wheel shop was tied up tight and the hourly system period showed up the faults at once as it was found that this foreman did not keep his men regularly on one job. A mechanic would start to turn journals, then go to the tire lathe and then perhaps turn a new axle, but by assigning men to regular jobs and planning to keep the work coming to them in stated quantities it was soon found that wheels could be delivered to meet the requirements.

After checking up the driving box work and placing 40 hours as the time limit to complete a set of boxes it was found that certain conditions in this department delayed the work. Because of a rough floor two men were required to a truck instead of one and the extra man did not have steady work. This condition was corrected. Depending on the busy overhead electric crane caused many delays, so an individual crane was installed. The arrangement for pressing out and pressing in brasses was very unhandy and at a slight expense a press was installed so that these time delays were eliminated. These and many other things, unnoticed before, were brought out when the foreman was required to deliver a set of finished boxes 40 hours after he received them.

Ask any erecting foreman how long it will take him to put out an engine and he will tell you so many hours after he receives the wheels and boxes and other fittings and he needs no card system to follow up his work. Keep him supplied with finished work from the various shops and he will keep his date—or as is often the case—reduce the time an hour or two.

When the engine has been delivered to the erecting pit, parts such as spring rigging, shoes and wedges and other parts handled by the erecting gang are also delivered at the same time and we now start on our hourly period system to handle these parts. Spring rigging has been scheduled for a 50-hour period, subdivided as follows: Five hours, after completion of stripping, to be inspected and parts delivered to various departments for attention; 15 hours from the end of this period all forging and blacksmith work to be completed in order to allow 20 hours for laying out and to have machinework done. This allows 10 hours to apply the parts to the engine and as several parts have already been returned, these final 10 hours are ample to complete application ready for wheeling. Seventy-five hours from the time the engine has been delivered to the erecting pit, the wheels have been applied, trammed, and are ready for the application of the motion work and for valve setting. Twenty hours from this period is allowed for the completion of valve setting. In the meantime the flues have been applied and the boiler shop forces, working on an hourly period system have carried their work along so that the boiler test can be applied 80 hours after the engine has been stripped.

Allowing 35 hours to complete the engine after the valves have been set we find that the engine has gone through the shop in a total of 140 hours. This may seem a rather long period, but these figures are given for a modern heavy locomotive and are taken from averages.

It was found that it had been taking practically two weeks to get a set of eccentrics through the machine department, but with the hourly time period this was reduced to 40 hours from the completion of the stripping period to the delivery of the eccentrics to the erecting shop ready for application. Machines which had been idle were put in commission to insure a steady flow of finished machine jobs to the fitting and erecting shops, and after all, it is the steady and regular return of such parts that governs shop output.

When regulated in this manner the shop output was increased nearly 100 per cent with less workmen, and as there were still many items to be corrected, the output could be increased over this figure. While it had been possible in some special cases to turn two engines per month off the same pit, it was found that to do so, some other engine was being neglected, and the desired regular output was obtained by adhering strictly to the hourly period system.

The wheel gang instead of finishing one set of wheels today and then skipping two or three days before delivering other finished wheels to the erecting shop, has been developed so that they give a set of finished wheels just as fast as the stripping gang strips an engine. The driving box gang can average a set of boxes in 10 hours, though we find that each workman only averages about seven hours per set. The reason for this is that much roundhouse work, for which provision must be made, is handled by this gang.

Today all locomotive repair work is heavy and a working schedule should take this important item into consideration. The day when one man could lift a driving box onto the journal is past, and shop equipment should be provided to save man power.

When the question of output requirements is considered, the benefit of this system to the higher officers is apparent, as they have the complete possibilities before them in a table showing the total work hours required for each type of engine and each class of repairs.

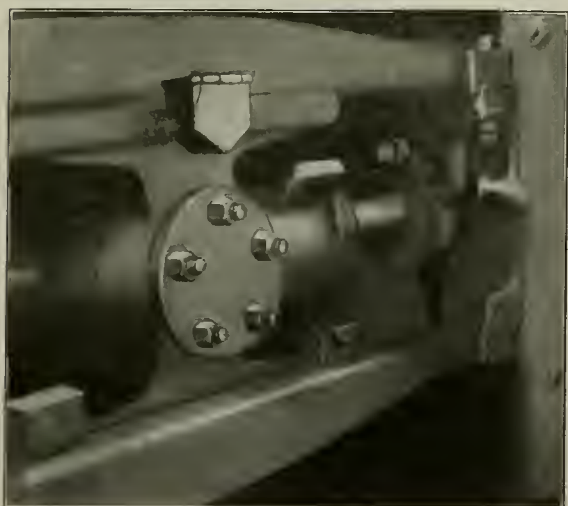
A good system without a mass of detail to follow will make the work easier for the men, simplify the duties of the foremen and practically double the output.

In making up any system, do not lose sight of what constitutes a fair day's work. Strike an average fair to the workmen and fair to the employer and the workmen will take pride in keeping their department on the honor roll. And as a word of caution, the man selected for the establishing of any system should be transferred from another shop, as a man selected to install a system in his own shop is likely to ignore certain points which might have great influence on its success.

CROSSHEAD PIN ON RUSSIAN BUILT LOCOMOTIVES

BY LIEUT. JAMES GRANT
Russian Railway Service Corps., American Expeditionary Forces in Siberia

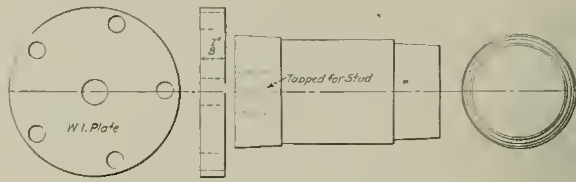
The accompanying sketch and photograph show a design of crosshead pin in general use on Russian built locomotives. This style of pin has some advantages over the one so commonly used on American locomotives, and is probably easier to make and apply. The crosshead is bored with the large



The Crosshead Pin Applied

end of the taper to the outside, so that the pin is applied from the outer side of the guides. On most American locomotives the pin is applied from the inside, and it is quite a difficult operation for a mechanic to reach behind the guide bars and apply the heavy pins that are now used on large locomotives.

Another advantage is that it is securely held in place by a neatly machined plate, with five 7/8-in. studs. On American locomotives the pin is drawn and held in place by large nuts, which necessitate enormous wrenches and consequent difficulty in drawing the pin tight.



Details of the Russian Crosshead Pin

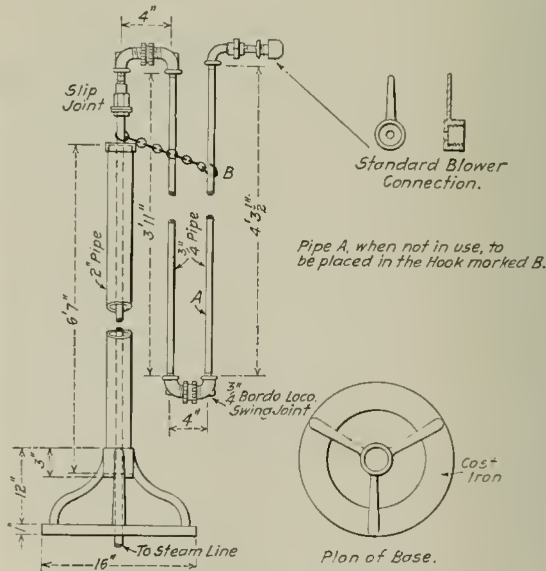
Provision is made for extracting the pin by a 1½-in. hole, tapped in its center so that it can be easily pulled with a plate and a stud.

BLOWER PIPE STAND FOR ROUNDHOUSES

BY E. A. MILLER

A blower pipe stand has been devised for use in roundhouses which has proved to be very convenient for quickly connecting up the blower to engines that have just been fired.

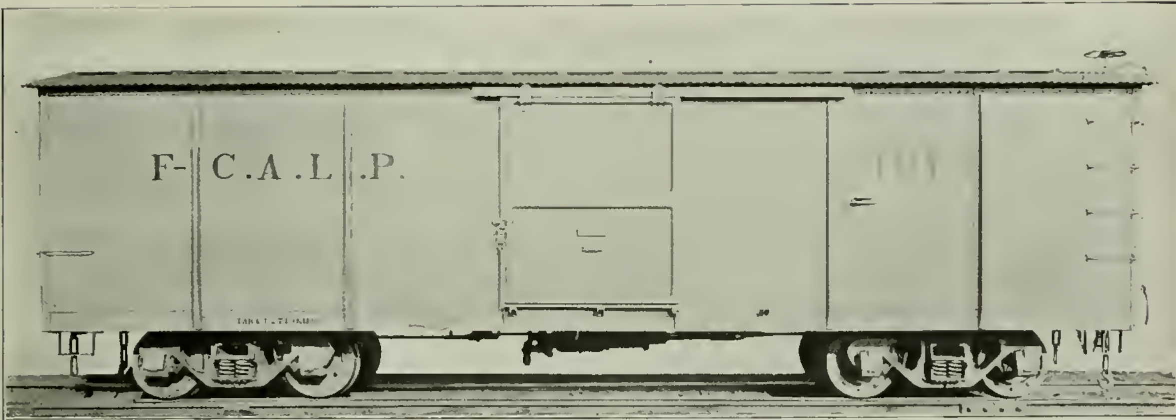
The stand consists of a cast iron base holding a 2 in. wrought iron pipe through which passes a ¾ in. pipe connected with the steam line. Other pipes with elbows, unions and swing joints are installed to give the scope necessary and a standard blower connection is attached to the outer



The Stand with Piping Held by the Chain

end. These stands are placed between the stalls in a roundhouse so that the device may be connected to the blower on either side. The 2 in. wrought iron pipe serves as a stand for the steam piping and at the same time affords protection against being burned to any one who might otherwise come in contact with the heated pipes.

When the device is not in use it can be swung back and held close to the stand by the chain, as shown in the illustration.

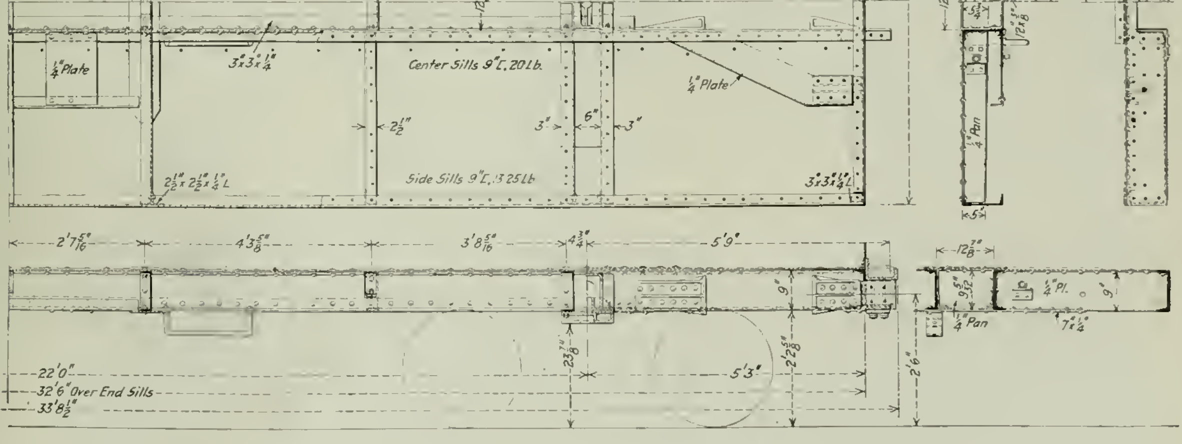


Narrow Gage Steel Box Car for Use in Chile

Box Cars For Chilean Railway

Steel Construction of American Type for Meter Gage Line, Including M. C. B. Couplers and Trucks

THE Arica-La Paz Railroad, part of the Chilean Government system, has recently received from the Pullman, Ill., works of the Pullman Company an order of 100 steel box cars for operation on a meter gage line. These cars will be found of interest to American readers because of the extent to which American standards and lb. The principal dimensions are, length inside, 32 ft. 6 in.; width inside, 7 ft. 9 in.; height, 6 ft. 2 3/16 in. from the top of the sill to the plate; height, rail to top of running board, 10 ft. 6 5/16 in.; height, rail to center of drawbar, 2 ft. 6 in., and distance center to center of trucks, 22 ft. The transverse contour of the roof is circular and the height



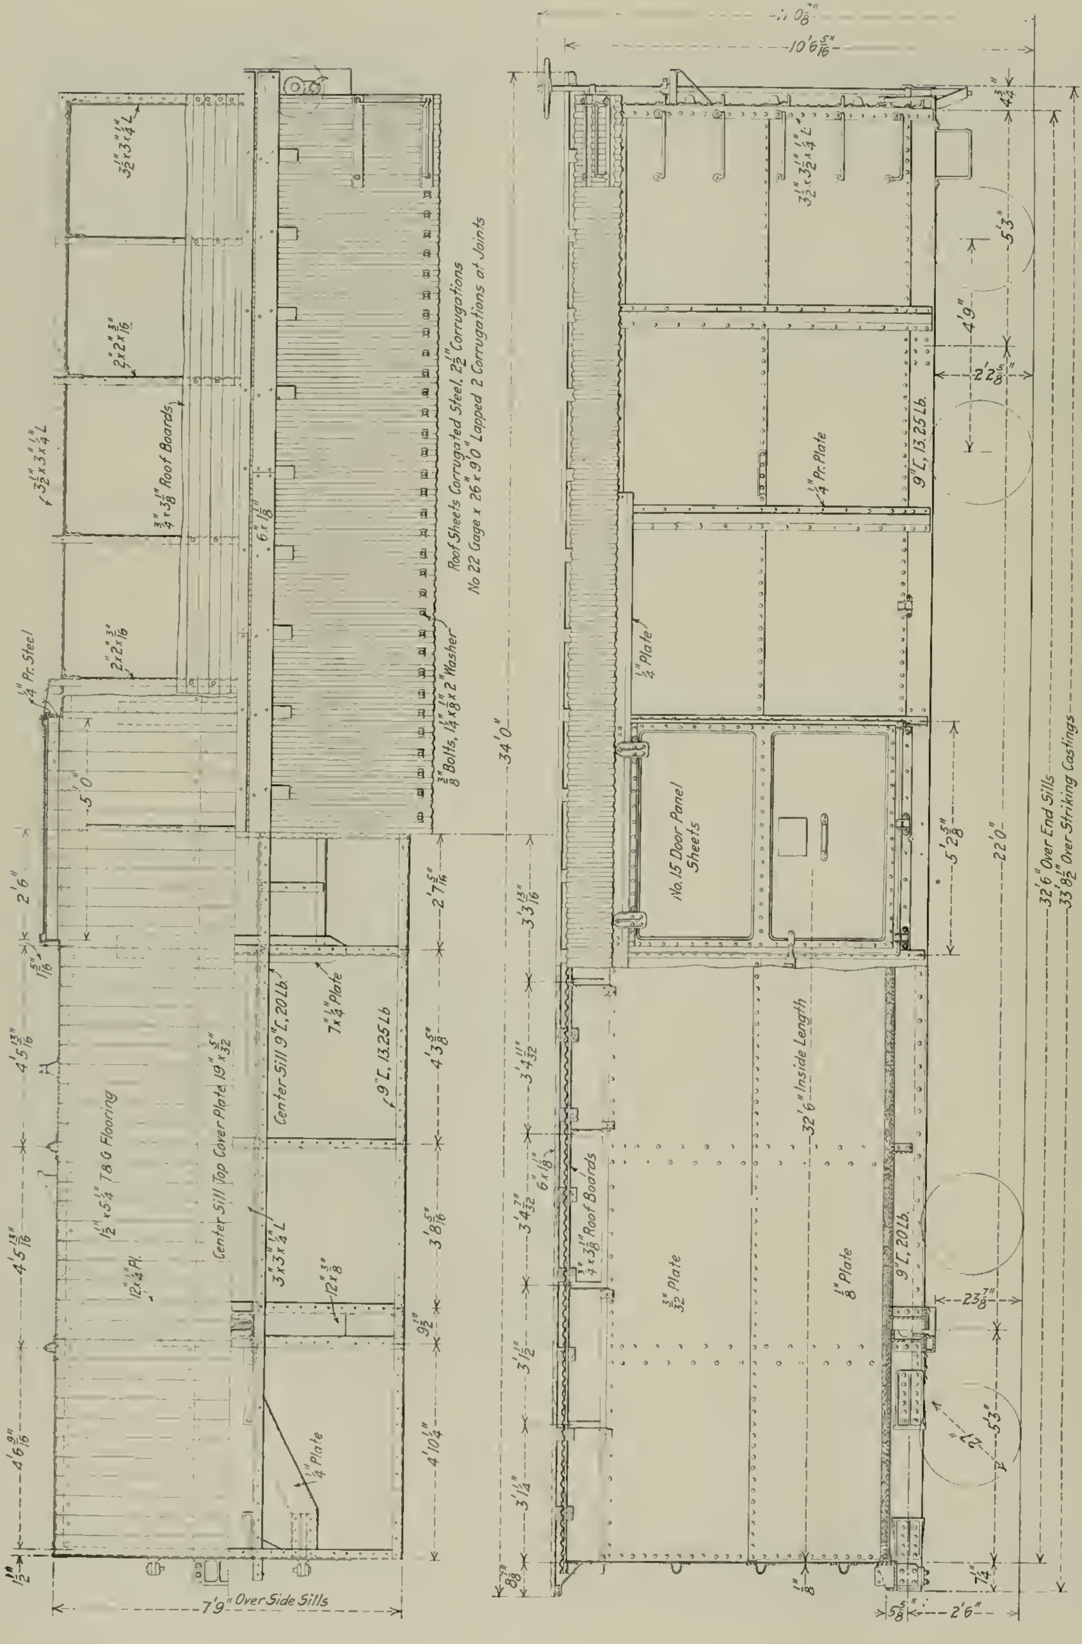
Underframe of the Narrow Gage Box Car

types of design have been embodied in them, as well as because of several interesting features not usually incorporated in the design of cars for use on this continent.

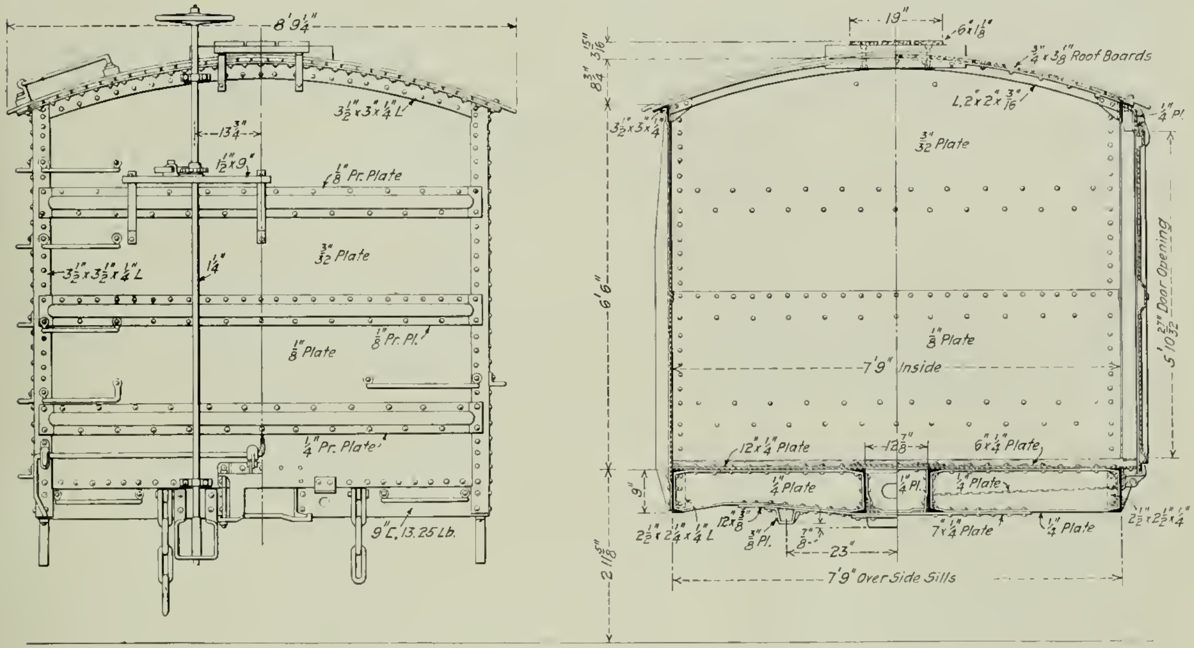
These cars have a rated capacity of 25,000 kilos, or 55,000 lb., and have a light weight of 12,719 kilos, or 28,000

under the carline at the center of the car is 6 ft. 11 3/32 in. The cars have the customary arrangement of side doors, which are about 5 ft. wide by 5 ft. 10 in. high. The cars are practically of steel construction throughout.

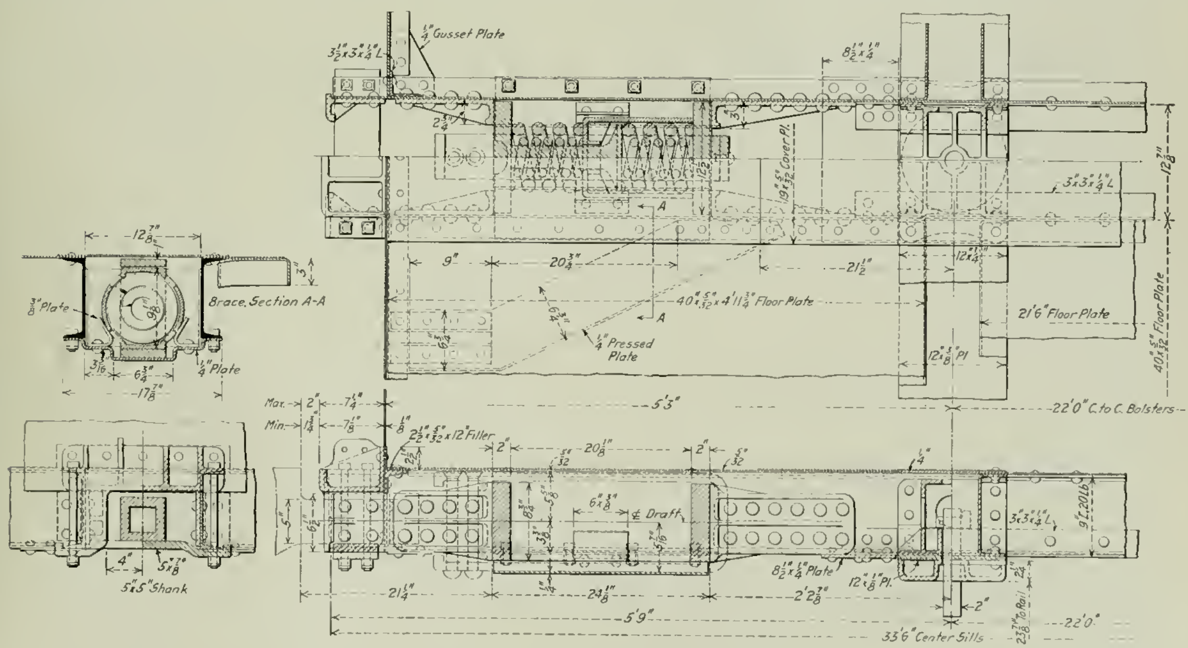
The main members of the underframe are of structural



Plan and Elevation of the Arica-La Paz Steel Box Car section with bolsters and intermediate diaphragms of pressed steel. The center sills are of 9-in., 20-lb. channel section while the side sills are 9-in., 13.25 lb. channels. The center sills are placed back to back with a spacing of 12 7/8 in. and have a top cover plate of 5/32-in. material, 19 in. wide, which extends continuously between points 21 1/2 in. toward the ends of the car from the center line of the bolsters.



End Elevation and Half Sections of the Chilean Box Car



Twin Spring Draft Gear Arranged in Tandem

The bolsters are of the double plate type and are built up of two pressed steel channel sections placed 6 in. back to back, with a filler casting between the center sills. A 1/4-in. top cover plate 12 in. wide, extending continuously across the car, is riveted to the top flanges of the web members. The bolsters are completed by a bottom cover plate 3/8 in. thick, extending across the center sills to points 13 1/4 in. from the face of the side sills. A 5/32-in. plate is riveted to the top flanges of the center sills between the bolster cover plate and the end sills.

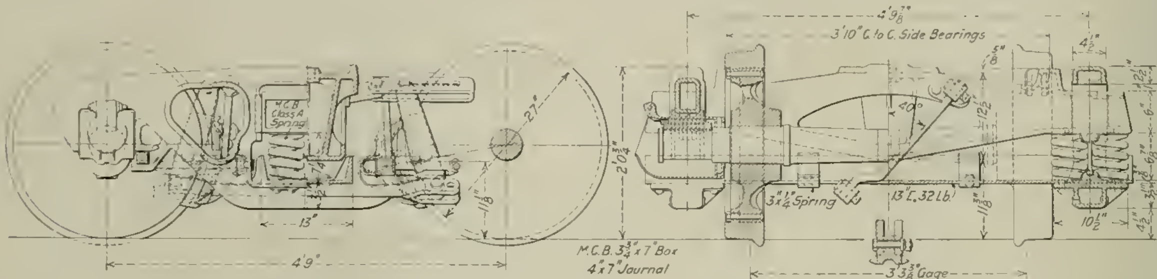
There are four intermediate diaphragms. The two center diaphragms are located in line with the side door posts and are of single plate pressed steel section with a uniform depth of nine inches. Both top and bottom flanges are reinforced with ¼-in. plates which extend only part way across the car. The top plate is six inches wide while the lower one is seven inches wide. The other two diaphragms are also of the single plate type of ¼-in. pressed channel section but have a uniform depth of only five inches. These are about five feet inside of the center of the bolsters.

One of the interesting features of this design is the draft gear, which in general is of the type ordinarily used in America, but involves an unusual arrangement of the draft springs. In principle the gear is of the twin spring type, but the springs are arranged in tandem. The direct action of the two springs is secured by an ingenious arrangement of sleeve and spool, which carries the reaction of each spring directly from one follower plate to the other. The forward spring is slipped over a spool, the rear end of which bears against the forward end of the rear spring, thus carrying the forward reaction of the rear spring directly against the forward follower plate. The backward reaction of the forward spring is similarly carried to the rear follower plate by means of a spool which encircles the rear spring.

The body is made up of 3½-in. by 3½in. by ¼-in. angle corner posts, channel section door posts of ¼-in. pressed steel and four special flanged U-section intermediate posts on each side of the car. The steel sheathing on the sides and ends of the car are laid in two courses which are joined with a lap joint. The upper course is of 3/32-in. plate while the plate in the lower course is ⅛-in. thick. The ends of the car are reinforced with three flanged U-section steel pressings, placed horizontally.

The carlines are 2-in. by 2-in. by 3/16-in. angles, the horizontal flanges of which are riveted to the tops of the 3½-in. by 3-in. by ¼-in. angle side plates. The roof is surfaced with corrugated steel sheets of No. 22 gage material, which is laid over a course of ¾-in. by 3⅛-in. longitudinal roof boards bolted to the carlines. These sheets are secured near the eaves by ⅜-in. bolts, which pass through the horizontal flange of the side plate and the outside roof boards. The entire underframe is covered with 5/32-in. steel plates on which the floor is laid. The floor is of 1½-in. tongued and grooved yellow pine material.

The truck is of the Buckeye pedestal type for 3-ft. 3⅜-in. track gage and has a wheel base of 4 ft. 9 in. The wheels are steel tired on cast iron centers and are 27 in. in diameter. They are mounted on axles with 4-in. by 7-in. journals which run in M. C. B. standard 3¾-in. by 7-in. journal boxes. The cast steel bolster is carried on M. C. B. class A springs. The truck has a height of center plate under load of 23⅞ in.



Buckeye Narrow Gage Pedestal Truck for the Arica-La Paz Box Cars

The cars are equipped with M. C. B. type automatic couplers and in addition are provided with safety chains on either side of the drawbar. The cars are fitted with ladders and grab irons, practically in accordance with American practice. Westinghouse automatic air brakes, schedule HC-812, are used on these cars, and in addition they are provided with an auxiliary train line for direct control of brake pressure from the locomotive, with the pressure retaining valve cut out.

THE LONGITUDINAL DISTURBING FORCES IN LOCOMOTIVES

BY EDWARD L COSTER
Assoc. Am. Soc. M. E.

In the American Engineer and Railroad Journal for December, 1905, there appeared an article by the present writer entitled "Comparative Magnitude of Longitudinal Disturbing Forces in a Cole Balanced Compound and a Single Expansion Express Locomotive," in which several important formulae were presented, but their derivation was not explained. It is the object of the present paper to derive these

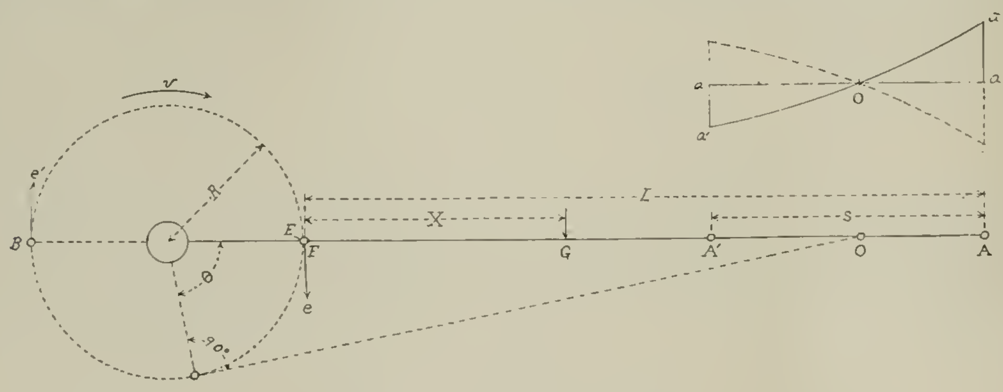


Diagram on Which Discussion Is Based.

formulae in the simplest possible manner, without the use of the higher mathematics which are usually employed for this purpose. The practical application of these formulae is illustrated in the article above referred to.

In the diagram, let *F* and *B* denote the front and back dead points, respectively.

Let s = piston stroke in inches.
D = driving wheel diameter in inches.
R, r, = crank radius in feet and inches, respectively.
L, l, = length of connecting rod in feet and inches, respectively.
X, x, = distance of center of gravity, *G*, of connecting rod from crank pin center in feet and inches, respectively.
W = weight of unbalanced revolving parts (if any) in pounds.
W' = weight of reciprocating parts in pounds.
W" = weight of connecting rod in pounds.
V = speed in miles per hour.
v = uniform crank pin velocity in feet per second.
P = horizontal inertia of unbalanced revolving parts at *F* and *B* in pounds.
P'_f = inertia of reciprocating parts at *F* in pounds.
P'_b = inertia of reciprocating parts at *B* in pounds.
P''_f = horizontal inertia of connecting rod at *F* in pounds.
P''_b = horizontal inertia of connecting rod at *B* in pounds.
C = centrifugal force of connecting rod at *F* and *B* in pounds.
g = gravitational acceleration = 32.16 ft. per sec. per sec.

Since the centripetal acceleration of the crank pin is $\frac{v^2}{R}$ ft. per sec. per sec.

$$P = \frac{Wv^2}{gR}.$$

$$\text{But } \frac{v^2}{gR} = \frac{\left\{2\pi\frac{r}{12} \times \frac{5280V \times 12}{\pi D \times 60^2}\right\}^2}{32.16\frac{r}{12}} = \frac{8.602r^2\frac{V^2}{D^2}}{2.68r} = 3.2r\frac{V^2}{D^2} = 1.6s\frac{V^2}{D^2}$$

$$\text{Therefore } P = 3.2Wr\frac{V^2}{D^2} = 1.6Ws\frac{V^2}{D^2} \quad \ldots\ldots(1)$$

At "diameter speed," V = D, hence for this case

$$P = 3.2Wr = 1.6Ws \quad \ldots\ldots(1a)$$

$$\text{For } L = \text{infinity}, \; P'_f = P'_b = \frac{W'v^2}{gR}$$

But for a finite connecting rod, as the crank pin passes *F*, the center point, *E*, of the rod's crank pin bearing, describes an infinitely small arc of a circle, *e*, about the axis of the cross-head pin *A*. The circumferential velocity of *E* is v, and if L = nR, the forward (centripetal) acceleration of *E* is $\frac{v^2}{nR}$ ft. per sec. per sec. But the backward acceleration of the crank pin is $\frac{v^2}{R}$; hence, since *E* is constrained to travel in the crank pin path, its total backward acceleration, and therefore that of *A* and the reciprocating parts, is

$$\frac{v^2}{R} + \frac{v^2}{nR} = \frac{v^2}{R}\left\{1 + \frac{1}{n}\right\} = \frac{v^2}{R}\left\{1 + \frac{R}{nR}\right\} = \frac{v^2}{R}\left\{1 + \frac{R}{L}\right\}$$

Therefore:

$$P'_f = \frac{W'v^2}{gR}\left\{1 + \frac{R}{L}\right\} = 3.2W'r\frac{V^2}{D^2}\left\{1 + \frac{r}{l}\right\} = 1.6W's\frac{V^2}{D^2}\left\{1 + \frac{r}{l}\right\} \quad ..(2)$$

and at diameter speed:

$$P'_f = 3.2W'r\left\{1 + \frac{r}{l}\right\} = 1.6W's\left\{1 + \frac{r}{l}\right\} \quad \ldots\ldots(2a)$$

As the crank pin passes *B*, the point *E* again describes an infinitely small circular arc, *e'*, about *A'*, the forward acceleration of *E* being $\frac{v^2}{nR}$ as before. But since the direction of this acceleration is now the same as that of the crank pin, the resultant forward acceleration of *E*, and therefore that of *A'* and the reciprocating parts is:

$$\frac{v^2}{R} - \frac{v^2}{nR} = \frac{v^2}{R}\left\{1 - \frac{1}{n}\right\} = \frac{v^2}{R}\left\{1 - \frac{R}{nR}\right\} = \frac{v^2}{R}\left\{1 - \frac{R}{L}\right\}$$

Therefore:

$$P'_b = \frac{W'v^2}{gR}\left\{1 - \frac{R}{L}\right\} = 3.2W'r\frac{V^2}{D^2}\left\{1 - \frac{r}{l}\right\} = 1.6W's\frac{V^2}{D^2}\left\{1 - \frac{r}{l}\right\} \quad \ldots(3)$$

and at diameter speed:

$$P'_b = 3.2W'r\left\{1 - \frac{r}{l}\right\} = 1.6W's\left\{1 - \frac{r}{l}\right\} \quad \ldots\ldots(3a)$$

As the crank pin passes *F* and *B*, the center of gravity, *G*, of the connecting rod attains its maximum circumferential velocity of $v\frac{L - X}{L}$ ft. per sec. about *A* and *A'*, respectively; hence at these points the forward (centripetal) acceleration of *G* is:

$$\frac{\left\{v\frac{L-X}{L}\right\}^2}{L-X} = \frac{v^2(L-X)^2}{(L-X)L^2} = \frac{v^2(L-X)}{L^2} \text{ ft. per sec. per sec.}$$

But at *F* the backward acceleration of *A* is $\frac{v^2}{R}\left\{1 + \frac{R}{L}\right\}$ therefore the resultant backward acceleration of *G* is:

$$\frac{v^2}{R}\left\{1 + \frac{R}{L}\right\} - \frac{v^2(L-X)}{L^2}$$

At *B* the forward acceleration of A' is $\frac{v^2}{R}\left\{1 - \frac{R}{L}\right\}$, therefore total forward acceleration of *G* is:

$$\frac{v^2}{R}\left\{1 - \frac{R}{L}\right\} + \frac{v^2(L-X)}{L^2}$$

Consequently the general expression for the maximum horizontal acceleration of *G* in feet per second per second, is:

$$\frac{v^2}{R}\left\{1 \pm \frac{R}{L}\right\} \mp \frac{v^2(L-X)}{L^2}$$

the upper and lower signs corresponding to the front and back dead points, respectively. Thus by reducing we have:

$$\frac{v^2}{R}\left\{1 \pm \frac{R}{L}\right\} \mp \frac{v^2(L-X)}{L^2} = \frac{v^2}{R} \pm \frac{v^2R}{RL} \mp \frac{v^2L}{L^2} \pm \frac{v^2X}{L^2} = \frac{v^2L^2}{RL^2} \pm \frac{v^2RL}{RL^2} \mp \frac{v^2LR}{RL^2} \pm \frac{v^2XR}{RL^2} = \frac{v^2L^2}{RL^2} \pm \frac{v^2RL}{RL^2} \mp \frac{v^2RL}{RL^2} \pm \frac{v^2XR}{RL^2} =$$

$$\frac{v^2L^2 \pm v^2XR}{RL^2} = \frac{R}{v^2}\left\{\frac{L^2 \pm XR}{L^2}\right\} = \frac{v^2}{R}\left\{1 \pm \frac{XR}{L^2}\right\}$$

Hence

$$P''_f = \frac{W''v^2}{gR}\left\{1 + \frac{XR}{L^2}\right\} = 3.2W''r\frac{V^2}{D^2}\left\{1 + \frac{xr}{l^2}\right\} = 1.6W''s\frac{V^2}{D^2}\left\{1 + \frac{xr}{l^2}\right\} \quad .(4)$$

and at diameter speed

$$P''_f = 3.2W''r\left\{1 + \frac{xr}{l^2}\right\} = 1.6W''s\left\{1 + \frac{xr}{l^2}\right\} \quad \ldots\ldots(4a)$$

$$P''_b = \frac{W''v^2}{gR}\left\{1 - \frac{XR}{L^2}\right\} = 3.2W''r\frac{V^2}{D^2}\left\{1 - \frac{xr}{l^2}\right\} = 1.6W''s\frac{V^2}{D^2}\left\{1 - \frac{xr}{l^2}\right\} \quad \ldots(5)$$

and at diameter speed

$$P''_b = 3.2W''r\left\{1 - \frac{xr}{l^2}\right\} = 1.6W''s\left\{1 - \frac{xr}{l^2}\right\} \quad \ldots\ldots(5a)$$

Equations 4 and 5 indicate that the horizontal inertia of the connecting rod is increased at *F* and diminished at *B* by a quantity $\frac{W''v^2}{gR} \times \frac{XR}{L^2}$, whose direction of action is forward in both cases, it appearing under the negative sign in equation 5 as the main force of inertia in this case is really negative, as it acts backward. Hence, since at both dead points the centrifugal force of the connecting rod, $C = \frac{W''v^2(L-X)}{gL^2}$, acts backward, it tends to neutralize this irregularity. Thus:

$$\frac{W''v^2}{gR} \times \frac{XR}{L^2} - \frac{W''v^2(L-X)}{gL^2} = \frac{W''v^2}{gR} \times \frac{XR}{L^2} - \frac{W''v^2}{gR} \times \frac{R(L-X)}{L^2} = \frac{W''v^2}{gR}$$

$$\left\{\frac{XR}{L^2} - \frac{R(L-X)}{L^2}\right\} = \frac{W''v^2}{gR}\left\{\frac{XR - RL + XR}{L^2}\right\} = \frac{W''v^2}{gR} \cdot R\frac{2X - L}{L^2}.$$

which is the difference between the two forces, or the amount that is not neutralized. Complete neutralization evidently requires that $R\frac{2X-L}{L^2} = 0$ for which condition $2X = L$, or $X = \frac{L}{2}$; i. e. *G* must be at the center of the connecting rod. If it be nearer *E*, as is always the case, 2X<L, and the result is negative, or *C* more than neutralizes the irregularity of the horizontal inertia of the rod.*

Consequently, when the effect of *C* is included,

$$P''_f = \frac{W''v^2}{gR}\left\{1 + R\frac{2X - L}{L^2}\right\} = 3.2W''r\frac{V^2}{D^2}\left\{1 + r\frac{2x - l}{l^2}\right\} = 1.6W''s\frac{V^2}{D^2}$$

$$\left\{1 + r\frac{2x - l}{l^2}\right\} \quad \ldots\ldots(6)$$

and at diameter speed:

*See Henderson's "Locomotive Operation," 2nd edition, pp. 39-41.

$$P''_f = 3.2W''r\left\{1 + r\frac{2x-1}{l^2}\right\} = 1.6W''s\left\{1 + r\frac{2x-1}{l^2}\right\}\ldots\ldots\ldots(6a)$$

$$P''_b = \frac{W''v^2}{gR}\left\{1 - R\frac{2X-L}{L^2}\right\} = 3.2W''r\frac{V^2}{D^2}\left\{1 - r\frac{2x-1}{l^2}\right\}$$

$$= 1.6W''s\frac{V^2}{D^2}\left\{1 - r\frac{2x-1}{l^2}\right\}\ldots\ldots\ldots\ldots(7)$$

and at diameter speed

$$P''_b = 3.2W''r\left\{1 - r\frac{2x-1}{l^2}\right\} = 1.6W''s\left\{1 - r\frac{2x-1}{l^2}\right\}\ldots.(7a)$$

For the values of $\frac{L}{R}$ obtaining in locomotive practice, the point *O*, of maximum horizontal velocity and consequent zero acceleration of both the reciprocating parts and the center of gravity of the connecting rod, corresponds very approximately to the position in which the axis of the rod is normal to the crank, i. e., when $AO = R + L - \sqrt{L^2 - R^2}$, and the crank angle, θ, is that whose tangent $= \frac{L}{R}$. Hence if we so locate point *O* either on the atmospheric line of a pair of superimposed indicator diagrams, or the base line of a net piston pressure diagram, which lines are represented by *aa'*; from the extremities of this line lay off to the scale of the indicator spring, the vertical distances *aa* and *a'a'*, equal respectively to $P'_f + P''_f$, and $P'_b + P''_b$, per square inch of effective piston area, and describe a circular arc through the points *aoa'*, then *aoa'* represents with quite sufficient accuracy for most practical purposes the curve of horizontal inertia of the reciprocating parts and connecting rod with which to correct the indicator, or effective pressure diagrams, when determining the force transmitted to the crank pin during the backward stroke. For the forward stroke, the inertia curve (shown dotted) is of course simply the reflection of the curve *aoa'*.

TEAMWORK OF ENGINEMEN AND FIREMEN*

BY M. A. DALY

General Fuel Supervisor, Northern Pacific

Engine crews dispose of nearly all of the coal used on the railroads of the United States. Approximately 95 per cent of all railroad coal passes through their hands. Nearly 130,000,000 tons of coal will this year be mined, hauled and placed on the tenders of locomotives. Into the fireboxes about $434,000,000 worth of coal will be shoveled.

Some of the coal mined for the locomotives will not be delivered to the tenders, some of the coal delivered to the tenders will not be thrown into the fireboxes, and some thrown into the fireboxes will not be burned. Coal will be lost from cars en route from mines to coal docks, coal will be lost off the side rails, decks and end sills of the tenders, and unburned coal will be lost through the grates and through the smokestacks. A large percentage of those losses are avoidable. Just how much, however, may always be an unknown quantity. Nevertheless, many railroads are now recognizing that such losses are enormous, and that partial prevention is easily possible.

The value of a ton of coal may be carelessly considered in railroad operation, but the cost of each ton will inevitably take its deliberate bite out of the current operating revenues. Each morning in the United States 65,000 locomotives stand ready for service. At the close of each day $1,190,000 worth of locomotive coal has been turned to ashes. Every ton of the coal contains a definite amount of potential draw-bar-pull. How much of it is actually utilized in pulling cars will depend largely on the condition of the locomotive, the manner in which it is operated, and the skill with which the coal is placed on the firebed.

When a locomotive is properly maintained, properly operated and properly fired, it will not only require the least possible amount of fuel, but it will also deliver the highest possible character of service. All three of these points are of direct concern to road foremen and traveling engineers. In fact, these points embody the chief part of the work of those officers, for most railroad executives now hold that the principal duties of road foreman and traveling engineers are to develop economy in the use of fuel. Economical fuel operation is a mark of good railroading. It may be possible, perhaps, to have economical fuel operation without good railroading, but no more is it considered to be good railroading unless there be economical fuel operation.

The locomotive is not a one-man machine. Its operation requires two men. One is occupied in converting water into steam, while the other is manipulating valves which permit the steam to do the work desired. The two men work at the same time. It may almost be said that the steam is being used at the same time that it is being made. There being a limit to the steam storing capacity of the locomotive, when the engineman stops using steam the fireman stops making it. At least such should be the fireman's aim. The fireman should have advance information of the approximate time of closing the throttle, so that he may control the fire accordingly. The engineer should know that the fireman has this information and see that he is guided by it.

Similar information should be common knowledge before starting trains. In this case coal should be placed on the fire a short interval before the locomotive is worked heavily. The successful engineer closely supervises the firing of the locomotive, especially at this time of the trip. The fire must be properly prepared and built up to meet the requirements.

This business of fire prepartion and fire control, like preventing the waste of coal that works out and drops off end sills of tenders, is the work of the fireman, but it is the engineer's responsibility to see that he does it. When you have an engineer who sympathetically and intelligently supervises the firing of a locomotive, you soon have a fireman who becomes more careful in his work. This, of course, is teamwork. Perfect teamwork is easy to recognize, but difficult to develop. First of all, it requires the proper state of mind in the engineer. The engineer must be made to feel his authority and responsibility in directing the work of the fireman. This assumes the full support of his immediate superiors, especially road foremen and master mechanics, and the full support of their superiors.

It is common knowledge that locomotives make trips on which several tons of coal more are consumed than on other locomotives of the same class, on similar runs, in the same service, over the same piece of track, by other crews. The difference in consumption is in the condition of the locomotive or in the work of the engineer or fireman. Habitually close supervision of the fireman makes it much easier for an engineman to suspect that an engine is getting a little "off" on steaming qualities, when he may proceed to locate the trouble and have it remedied.

There is nothing new about these considerations. Teamwork is universally desired. To realize it is the thing for accomplishment. We all acknowledge the existence of irregularities in practice. These should be removed. This paper was written to ask you to give your opinions and convictions as to how these irregularities may best be removed, after we go back to our respective railroads.

*Abstract of a paper presented before the Convention of the International Railway Fuel Association at Chicago, May 19-22, 1919.

Arch Tubes Equivalent to 1,200 Locomotives.—Arch tubes totaling more than one million feet are in active service today. They are capable of evaporating 48,000,000 lb. of water per hour, which is equivalent to the total evaporation of 1,200 large locomotives.—*Erie Railroad Magazine.*

Air Brake Association Meeting

Abstracts of Committee Reports and Papers Presented at the Twenty-Sixth Annual Convention

A BRIEF account of the proceedings of the twenty-sixth annual convention of the Air Brake Association, which was held at the Hotel Sherman, Chicago, May 6 to 9, inclusive, was published in the June issue of the *Railway Mechanical Engineer,* on page 301. The following are abstracts of the more important reports and papers which did not appear in the June issue.

AIR CONSUMPTION OF LOCOMOTIVE AUXILIARY DEVICES*

The committee submitted a report of progress, giving a resumé of the work which had been done. The purpose of the committee's investigation was, (1) to investigate the rate of air consumption of auxiliary devices as found in service on locomotives; (2) to investigate the relation of air consumption by auxiliary devices to compressor operation; (3) to determine if the amount of air used is sufficient to warrant a separation of auxiliary devices from the air brake system, with a separate compressor to furnish air for them; (4) to determine if it is satisfactory to have the auxiliary devices take their air supply from the air brake system, but necessary on this account to install an additional compressor;

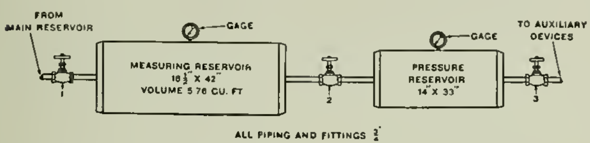

Fig. 1—Measuring Apparatus Used in Standing Tests of Air Operated Auxiliaries

(5) to investigate the cost of compressed air for operating the auxiliary devices used, and (6) to make recommendations with respect to the maintenance of auxiliary devices.

TESTS MADE AND RESULTS

While the data given here do not cover the subject completely, they will at least serve to give a conception as to what the use of air operated auxiliary devices on locomotives may mean in the ordinary practice of busy railroads. It is to be expected that this report will be regarded as a report of progress, and it is hoped that the work of the committee will be continued for the ensuing year.

The investigation covered in this report naturally divides itself into two parts, *viz.*, standing and running tests. The standing tests were made on locomotives in roundhouses, and consisted in measuring the amount of air used by the auxiliary devices operated while the locomotives were standing. The running tests were made on freight engines working over the road in service, and consisted of the continuous measurement of air used by the auxiliary devices in operation while the engine was running. The standing tests involved a total of 48 engines, and the running tests were made with six engines. A total of 489 individual tests were made, the results of which have been classified and arranged for the purposes of this report.

The locomotives used during these tests were not selected, nor were any locomotives inspected before the tests were made. It was desired to test the equipment just as it might happen to be available so that the data would be representative of average operating conditions. Furthermore, the standing tests were made at three division points and involved the equipment on four different divisions. The running tests were conducted on two road divisions.

Standing Tests—The standing tests involved measuring the amount of air used by the various auxiliary devices with the locomotive at rest. The form of apparatus for making this measurement is shown in Fig. 1. It consisted of two tanks connected as shown, the larger being designated as the measuring reservoir and the smaller as the pressure

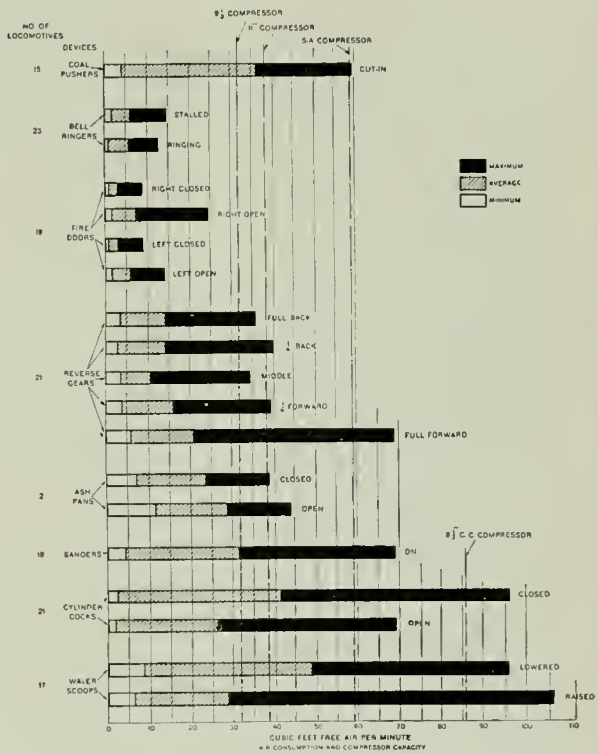

Fig. 2—Results of Standing Tests of Auxiliary Devices on All Locomotives

reservoir. The measurement of the air used by each auxiliary device was accomplished in the following manner:

The auxiliary device to be tested was disconnected from the main reservoir on the locomotive and reconnected to the measuring apparatus at globe valve No. 3. A connection was likewise made from the main reservoir on the locomotive to the measuring reservoir at globe valve No. 1. The air was measured by opening valve No. 3 and manipulating globe valves Nos. 1 and 2. The operator of valve No. 2 regulated that valve so that a constant pressure of 70 lb. was maintained in the pressure reservoir as the supply of air pressure to the auxiliary device under test. The operator of the main reservoir valve No. 1 opened this valve so as to charge the measuring reservoir up to the main reservoir pressure of the locomotive, usually 40 to 50 lb. higher than the constant pressure in the pressure reservoir. This operator

*The meaning of the term "air operated auxiliary devices on locomotives," as used in this report, can be defined as referring to all air operated devices on locomotives which are not a part of the air brake system, such as air operated fire doors, bell ringers, reverse gears, sanders etc.

then closed valve No. 1 and noted the time required for the pressure in the measuring reservoir to drop any given amount during the time it was supplying air continuously to maintain the constant pressure in the pressure reservoir.

The air consumption was calculated as follows:

$$\frac{20 \text{ (drop in measuring reservoir)}}{14.7 \text{ (atmospheric pressure)}} = 1.36 \text{ drop in measuring reservoir expressed in atmospheres.}$$

1.36 atmospheres × 5.76 (volume of measuring reservoir) = 7.83 cu. ft. of free air supplied during the test.

$$\text{Then } \frac{7.83 \times 60 \text{ (No. of sec. in one min.)}}{78 \text{ (time of test in sec.)}} = 6.03 \text{ cu. ft. per minute.}$$

The standing tests made on all auxiliary devices have been classified and arranged according to the type of locomotive upon which they were found, and the results are shown in graphic form in Fig. 2. Each figure on the chart shows the minimum, average and maximum rates of air consumption of all the auxiliary devices of the several types tested. The results for passenger locomotives are based on the standard passenger train reservoir pressure of 130 lb., although the actual tests were made at a constant pressure of 70 lb. In every case the data were converted from the 70 lb. basis to give the equivalent rate of air consumption at 130 lb. in the following manner:

$$\frac{\text{Rate of leakage, cu. ft. per min.}}{\text{Absolute press. on test (84.7 lb.)}} \times \text{Absolute press. on locomotive (144.7 lb.)} = \text{rate of leakage on engine when main reservoir pressure is 130 lb. instead of 70 lb.;}$$

that is, the leakage is taken as proportional to the absolute pressures. The data for freight engines are based on 100 lb. main reservoir pressure, standard for freight service.

It will be noted that all charts have the capacity of air compressors indicated on them for convenient comparison with the rates of air consumption given. These values for compressor capacity are based on the rate of air delivery established by the Interstate Commerce Commission's compressor condemning tests, as shown in Table 1.

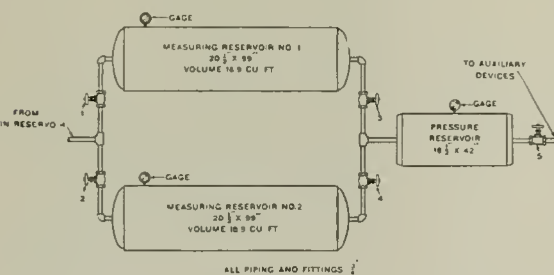

Fig. 3—Measuring Apparatus Used in Running Tests

Table 1—Compressor Capacities Based on I. C. C. Condemning Tests

Type of compressor	Delivery rate, cu. ft. free air per minute, 60-lb. pressure
9½-in.	32
11 -in.	37.5
5-A	59
8½-in. C.C.	86

Running Tests—Running tests were made with the object of determining the rate and total amount of air used by the auxiliary devices while the locomotive was working in regular service. An apparatus was devised for measuring continuously the rate and amount of air used, and is shown diagrammatically in Fig. 3. This apparatus is similar to that described above and shown in Fig. 1; the only difference being that two measuring reservoirs are used, with the object of permitting the measurement of air to go on continuously.

This apparatus was manipulated so that while the air was being measured by the dropping pressure in one reservoir, the other reservoir was allowed to charge from the main reservoir in order to be ready to start measuring the supply of air to the pressure reservoir as soon as the air pressure in the first measuring reservoir was exhausted.

The measuring apparatus was installed in a caboose which was run at the head end of the train next to the engine. The piping was so arranged that with either end of the caboose toward the engine, connections could be made to the main reservoir and the auxiliary devices on the locomotive under test.

The length of running tests covered in this report varied from 3½ to 8 hours, or the time required to make a fast freight movement over a division of 131 miles. The running tests made were six in number and can be divided into two classes, *viz.:* (a) Running tests in which the rate of air consumption was measured for the reverse gear only, and (b) running tests in which the rate of air consumption was measured for all auxiliary devices.

Fig. 4—Results of Freight Service Running Tests

Three tests of each kind were made, and each test was made during a full trip of an engine in regular service on fast freight. The running tests are, of course, of a great deal more importance than the standing tests, in that they show the rate of air consumption as it varies during the working time of the locomotive, and it is the judgment of the committee that more tests of this kind should be made.

The tests herewith presented do not provide sufficient data for basing definite conclusions, but they do show how the leakage of auxiliary devices will vary with running conditions on the road, and that cases do exist in which the air consumption is unreasonably high, if not actually dangerous, in the sense that it increases the possibilities of an engine failure as the result of overworking the air compressor.

The running test data are shown plotted in graphic form in Fig. 4. Each of the six tests is represented by a line which shows how the rate of air consumption varied throughout the trip. The three solid lines represent tests made on all auxiliary devices, and the three dotted lines represent the tests made in which the air consumption was measured for the reverse gear only. Additional lines are shown on the charts to indicate the capacity of different air compressors in order that comparisons between the compressor air capacity and the rate of air consumption can readily be made. All of the engines used in the six tests plotted on this chart were of the same class, and were equipped with two No. 5-A air compressors and the following air operated auxiliary devices: reverse gear, double fire doors, bell ringer, sander, water scoop and cylinder cocks.

The tabulation below shows the total amount of free air used and the average rate of using during each of the six running tests shown in Fig. 4.

Locomotive designations	Auxiliary devices	Total cu. ft. free air used during trip	Cu. ft. free air used per min.
A	Rev. gear only..........	5,665.2	11.84
B	Rev. gear only..........	4,939.8	10.55
C	Rev. gear only..........	1,809.62	4.50
D	All devices..............	14,750	46.93
E	All devices..............	7,761.2	23.13
F	All devices..............	1,738.4	8.17

Cost Data—Fig. 5 has been made up from the running test data to show the relative cost of maintaining auxiliary devices at the minimum, maximum and average conditions of leakage found during these tests. The first two figures of this chart show the minimum and average rates of air consumption for the three tests in which the reverse gear only was measured and the three tests in which all auxiliary devices were measured. These values were obtained from the test data by dividing the total amount of air used during the trip by the total time of the trip in minutes. The actual values used are shown in the last column of the preceding tabulation. The remaining figures in Fig. 5 give the relative

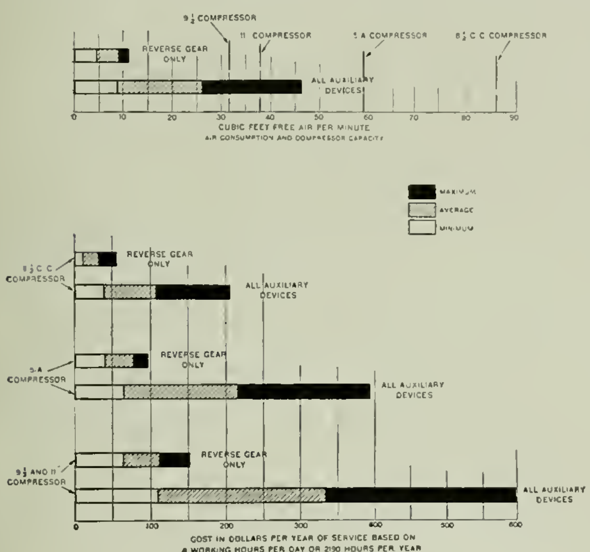

Fig. 5—Cost Data Based on Running Tests of Various Types of Air Compressors

minimum, maximum and average cost for compressed air when using various types of air compressors. There are two figures for each type of compresser, one for the tests made with reverse gears only, and the other for the tests made with all auxiliary devices. These figures show the relative cost of supplying the compressed air required under the various conditions, based on the following assumptions: (1) That the average working time for locomotives is 6 hr. per day, or 2190 hr. per year; (2) That the rate of evaporation is 7 lb. of water per pound of coal; (3) That the price of coal on the tender is $2.00 per ton, or $1.00 per 1,000 lb.; (4) That the rate of steam consumption in pounds of steam used per 100 cu. ft. of free air compressed, is in accordance with the values given in Table II. These values have been determined from a series of steam consumption tests made on each of the types of air compressors indicated.

Table II—Steam Consumption of Locomotive Air Compressors

Type of compressor	Lb. of steam, at 200 lb. pressure per 100 cu. ft. free air compressed: To 100 lb. main res. pressure	To 130 lb. main res. pressure
9½-in. and 11-in	68	76.25
5A	44.7	51
8½-in. C. C......................	24	25

The cost comparison figures are based upon the above assumptions only, no consideration being given to such factors as the cost of handling coal on engines, cost of water, depreciation of boiler plant and compressor plant, etc. These considerations have been omitted because the committee does not have sufficient data to accurately determine them. It is obvious that these factors would increase the costs shown, and the chart figures can therefore be regarded as the minimum conservative values.

A detailed account of the results of the tests of individual appliances was given in the report. The theoretical or computed air consumption did not account for even the minimum consumption that was found during the standing test, proving that the greatest part of the air used was wasted through leakage due to improper maintenance of the devices. The committee believes that it would be worth while to continue the test with a view to establishing more complete data upon which performance standard and condemning tests could be made.

Conclusions

(1) Auxiliary devices under average conditions were found to use too much air.

(2) Conditions frequently exist where compressor capacity may be exceeded by the demands of the auxiliary devices.

(3) Some of the data justify the conclusion that auxiliary devices should be operated separately from the air brake system. On the other hand, some of the data show that with proper maintenance this conclusion might not be warranted.

(4) Under some of the conditions shown by these data, it would not be satisfactory to connect the auxiliary devices to the air brake system and increase the compressor capacity accordingly, unless the air brake main reservoir is protected from the consequences of excessive air requirement by the auxiliary devices.

(5) Cost basis data show that better maintenance would be profitable.

(6) Standards of performance, including maximum permissible leakage, should be established upon which to condemn devices unfit for service.

(7) Means should be devised for checking and testing the performance of auxiliary devices.

Recommendations

The committee recommended that its work be continued and this report be regarded only as a report of progress; that the data be made more complete by investigations on individual railroads, conducted as outlined in the report, such investigations to be reported to the chairman of this committee; that steps be taken to secure better maintenance of auxiliary devices; that further experiments be made with the object of devising satisfactory means for testing, and satisfactory standards of performance which can be applied to show whether the device is fit for service; and that consideration be given to the plan of operating the auxiliary devices at a pressure lower than that carried in the air brake system main reservoir. This plan would effect a large saving in air used, but would require a separate air supply reservoir with means provided for controlling the reduced pressure.

The report was signed by C. H. Weaver (N. Y. C.), chairman; C. B. Miles (Big Four), W. W. White (M. C.), and R. E. Miller (W. A. B. Co.).

Discussion

Great interest was shown in the results of the test and numerous opinions were advanced as to the cause of excessive leakage in auxiliaries and the method that should be used to overcome it. The practice of operating power reverse gears by steam when handling locomotives around the roundhouse was condemned by several speakers, who stated that steam destroyed the packing in the cylinders and caused excessive leakage. Some roads are now equipping metal disk power reverse systems with metal packing rings. T. F. Lyons (N. Y. C.) brought out the fact that leakage in the auxiliary devices might interfere with the proper operation of the brake even though it did not result in a large waste of air. The loss due to leaks in water scoop cylinders did not cause excessive air consumption because the cylinder is operated at infrequent intervals. However, in approaching water tanks the scoop is usually dropped at the same time as the brakes are released and excessive leakage in the water-scoop cylinder might seriously interfere with the recharging of the auxiliary reservoir.

M. C. B. AIR BRAKE DEFECT CARD

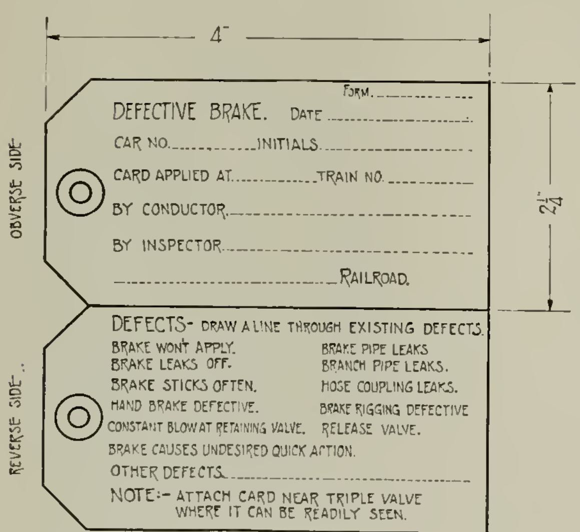
BY JAS. ELDER

General Air Brake Inspector, Chicago, Milwaukee & St. Paul

The United States Railroad Administration, Fuel Conservation Division, in Circular No. 13, of August 31, 1918, issued by Eugene McAuliffe, manager, presents 15 specific recommendations made by an Air Brake Association committee. Recommendation No. 9 is as follows: "A rule should be put into effect that trainmen must apply an M. C. B. standard air brake defect card in cases where defects develop en route or for brakes cut out by them; defect to be checked off on back of card."

The M. C. B. card shows careful thought, but the changed conditions since its last revisions demand certain alterations to meet present requirements. Some believe the brake defect card has outlived its usefulness, basing this on (a) the great difficulty in getting it applied where needed; (b) on incoming brake tests rendering it less necessary; (c) and some object because of the appearance occasional trains would present if all cars with defective brakes were carded. Assuredly the brake defect card should either be used to better advantage or discontinued.

If a defect card is yet needed and is practicable after having simplified the card, it will be very desirable to have



Suggested Revision of M. C. B. Air Brake Defect Card

mandatory instructions as to responsibility for its application. As this car is a detail of repairing, for which car men are responsible, *car men should be primarily responsible for its application;* that is, before a departing train is released from the blue signals, the inspectors should have either repaired or carded every defective brake. With this insured, it would be fair to insist that the departing train crew should card every defective brake delivered at the next terminal. However, as the incoming test should invariably be made, and as this would disclose to inspectors all defects except with cut-out brakes, it is submitted that if train men are required merely to card properly every brake brought in cut-out, all needs will be met, and the work of getting cards used by them will be lessened in a rational manner.

If one road cards all defective brakes not repaired and a connecting line does not, the former will be subjected to an unfair comparison; hence, that if real value is to be obtained from the defect card, its full and similar use must be obligatory on all roads in interchange traffic. If the defect card is to be continued the following additional means for bettering the results obtained should be adopted. The card and its use should be simplified, and then action looking toward its obligatory and uniform use by all railways in interchange service should be taken. The stub should be omitted. If it were possible to get the stubs filled out and forwarded, they would merely burden the mails and the offices. The reasons warranting omission of the stub also justify dropping from the card all matter pertaining to its use after the defect has been repaired. The size proposed is 4 in. by 2¼ in.

With all-air trains, a defect which prevents placing a certain car between other air brake cars, puts it back of the caboose. This advertises the defect on arrival at the next terminal, and as it must not go farther until repaired, there is now no use for the second card, as there was when the present M. C. B. card was designed. Where an existing defect does not require air pressure to locate it, such as one with either the hand brake or the foundation brake, it is plainly undesirable to elaborate the card by specifying the various points where such defects commonly develop. The revised card submitted is here illustrated.

DISCUSSION.

Practically all who discussed the paper agreed that the defect card gave valuable information, but that considerable difficulty was found in getting train men to use them. There was a marked difference of opinion regarding the advisability of eliminating the stubs. The association adopted a motion recommending the adoption of the air brake defect card revised as suggested in the paper, the use of this card to be confined to train men and inspectors in departure yards.

HOLDING STANDING FREIGHT TRAINS AND CARS ON GRADES

BY R. J. WATTERS

Assistant Air Brake Inspector, Northern Pacific

While many, if not most roads with steep grades have recognized the possible great dangers incident to holding standing trains and cars on grades, and have generally issued rules or instructions to guard against such dangers, yet the fact that even on such roads there is a strong tendency on the part of some officials as well as of the men in the train service to gravitate toward easier and more dangerous practices, and the further fact that many accidents from lack of the right practices occur on roads with grades too light to include them under the term mountain or steep grade roads, amply justify the Air Brake Association's careful consideration of this subject.

As before implied, probably the greater danger is due to laxness in the daily enforcement of rules and instructions on this subject. Observance of these requires more forethought and co-operation on the part of engine and trainmen to reduce the time and labor for compliance; and even then the latter will be greater than by the easier but more dangerous ways. Familiarity with steep grades, and the many deviations from safe practices that can occur so generally without an accident following, tend constantly toward habits which, unless checked regularly, will eventually result in disaster. One of the most common and dangerous of these is failure to release and recharge the train brakes promptly after stopping on a grade, which should invariably be done whether or not the engine in control is to be cut off.

A general superintendent of a large road with several long and steep grades, expressed this matter well by the statement that it was necessary about every six months to instruct each superintendent having a steep grade, to report how well safety precautions against runaways were being observed, but not to do so until he had the trainmaster and the traveling engineer make a special investigation and report. He said that without this, a serious accident invariably occurred in time.

The following definite instructions and recommendations are submitted on the subject of this paper:

As soon as a train is stopped on a grade, brakes should be released and recharged at once. If the engine from which brakes are being operated remains attached, and keeps the train charged, as it then should, it may be held with the independent brakes; that is, by keeping the independent or the straight air brake valve in application position. An exception is where the engineer is to leave the engine. In this case enough hand brakes to alone hold the train should be applied. This should be proved by having all automatic and independent brakes off and, if the compressor may be kept running, then the independent brake should be reapplied and its brake valve handle left in application position.

If the engine from which the train brakes are being operated is to be cut off, enough hand brakes to alone hold the train, should be applied, but the trainmen should not commence to apply them until the automatic brakes are released. Where retaining valves are in use, none need be turned down, but no hand brakes should be applied until one minute after train brake release is begun.

Hand brakes used to hold cars or a train on a grade should be applied at the down-grade or lower end, thereby assuring against any car starting if uncoupled. All slack should be in, against the applied hand brakes, as well as all automatic brakes off (see previous exception about retaining valves) before cutting off an engine.

If, with the engine in control of the train cut off, another engine is to be detached, as a helper or pusher, its engineer should first cut in, release and recharge the train brakes, then release the independent brake so as to be certain the train will stand after the engine is cut off. While remaining with the train the independent brake should be kept applied on each of any such other engines.

With a descending train, the final reduction to bunch the slack, as the stop is being completed, should be followed, during the wait of one minute after release is begun before commencing to apply hand brakes (at the head end), by reversing and pushing the slack in as much more as possible, then holding the train with the independent brake while the hand brakes are being applied.

With an ascending train, see that the slack is in before cutting off by allowing it to drop back gradually, with train brakes off, until the train will stand with no aid from the engine in control. It should be held by hand brakes applied at the rear, aided by the independent brake of each other engine in the train.

If a break-in-two, or burst hose occurs on a grade, immediately apply more than enough hand brakes to alone hold the train until its brakes are again recharged. If it is a descending train, and a coupling is damaged that will take some time to repair, and if the portion of the train with the engine (ahead) can be backed so as to couple the detached hose, it should be done and the train kept recharged during any necessary wait while obtaining a repair part, as a knuckle or pin, or if a delay must ensue before putting the damaged car elsewhere, as where this occurs where the car may be switched out or to the rear end.

It should be noted that the air brakes are off before applying hand brakes on cars set out on a grade, and on level track as well, sufficient to hold them. It is not necessary to bleed the air from auxiliary reservoirs of cars so set out as long as the air brakes are off when the hand brakes are applied. In addition to the foregoing any rules regarding blocking cars should be complied with. Hand brakes applied when the car air brakes are set, may result in broken chains when the air brakes leak off, especially dangerous with one or two cars. Even where this exceptional failure does not occur, they will often be so difficult to release as to necessitate the delay and waste of air required to apply the air brakes to aid in releasing them.

HOW CAN ENGINEMEN AND TRAINMEN ASSIST IN AIR BRAKE MAINTENANCE?

BY H. A. GLICK
Air Brake Inspector, Bangor & Aroostook

While locomotive engineers are not primarily responsible for air brake design and maintenance, they can, nevertheless, aid materially by making careful and specific reports about air brake conditions on their locomotives requiring attention. Many of the defects that may arise in the course of a trip, especially leakage in the numerous pipe connections that contain air pressure, due to vibration or improperly connected pipe joints, can be discovered better by the engineer while the locomotive is under steam and air pressure and in his charge. His co-operation in reporting intelligently and reliably all brake troubles is essential to good maintenance.

Whenever trouble arises with any air brake part on an engine, the man that delivers the engine should properly book on the work report the actual defect that exists, but should not book non-essential or imaginary defects; for by so doing he causes a great deal of unnecessary work on the part of the roundhouse force. The time so used is simply wasted and might be used to good advantage performing essential work on this and other engines. Before taking an engine out the engineman should know that all air brake parts perform their functions, and not take it for granted that they do.

The trainman can assist and he should be duty bound to do so, by following the general air brake instructions now existing on all railroads, by taking greater interest in them, and consequently, in his own welfare. If he does not follow the general instructions, he should be made to do so by proper measures from his superiors, and also by the urging of his fellow workmen. He should be made to recognize the right and wrong of his part in air brake maintenance. There are times when the brake is cut out for no reason. No brake should be cut out of service unless a defect exists; then whoever cuts the brake out should specify the trouble on a a proper air brake defect card and tie the card to the cross-over pipe on the car.

Trainmen should do everything possible to stop brake pipe leakage, as this leakage causes hardship on the air compressor, takes away from the engineer the ability to properly control the amount of the application, contributes to brakes sticking and prevents the maintenance of sufficient brake pipe pressure. The practice when separating cars of closing but one angle cock, allowing the brakes on cars back of the separation to apply in emergency, should be discontinued. When separating cars, both angle cocks should always be closed and hose should always be separated by hand. When opening angle cocks on the charged portion of train, they should be opened slowly to prevent brakes from applying in emergency. When switching cars they should not be allowed to strike any harder than three miles per hour. Coupling cars at a greater speed creates shocks, which in turn are absorbed by the unions in brake pipe connections, causing brake pipe leakage. The cordial co-operation of enginemen and trainmen in the matter of air brake maintenance is very necessary in order to get the best results.

DISCUSSION

The necessity for co-operation between the trainmen and enginemen and the air brake repair men in order to promote proper maintenance, was emphasized by several speakers. One road reported good results by requiring trainmen to pass an examination on the proper handling of brakes.

THE AIR BRAKE SUPERVISOR'S RESPONSIBILITIES TO THE STORE DEPARTMENT

BY W. H. CLEGG
Air Brake Supervisor, Canadian National

The air brake supervisor's interest in this question starts with his discovery that some standard practice or regulation relative to air brake maintenance is not being adhered to, or that a locomotive or car is being held out of service awaiting the arrival of certain repair parts by reason of lack of knowledge or failure of the local officers to anticipate the requirements, and this in spite of the fact that less important stations are overstocked with the very parts that are needed to release the locomotive or car in question, or permit of adherence to standard practice covering repairs. Thus it appears that the supervisor in order to help himself must of necessity assist the stores department. The following should form the basis of the air brake supervisor's assistance to the storekeeper: (1) Providing suitable places for the care and preservation of repair parts in stock. (2) Advising as to the various repair parts and quantities required to be carried in stock at general stores. (3) Approving of sub-requisitions placed with general stores. (4) Periodical inspection of divisional stores and assistance to divisional storekeepers. (5) Preventing the accumulation of a surplus stock of repair parts that are seldom used. (6) Advising the general storekeeper where a surplus of repair parts are found so that same may be transferred to other terminals or returned to general stores.

The recommended assistance as outlined above requires but a small portion of the supervisor's time and his often unsolicited efforts will eventually be fully appreciated.

RAILROAD ADMINISTRATION NEWS

The director general has accepted from the War Department the custody of 100 locomotives which were originally constructed for the Russian government, and has arranged until further notice to continue the operation of that equipment on federally operated lines.

Prior to the present arrangements, the lines using these locomotives were obligated to the War Department for a rental based upon $45 per locomotive per day. The amount payable was considerably in excess of that required under the present agreement, which is 6 per cent per annum upon a valuation of $55,000 per locomotive, or an annual rental of $3,300 per locomotive from the date it went into service, or pro rata for any fractional part of a year. The agreement for the use of these locomotives provides that they shall be fully maintained at the expense of the director general.

COST OF TRAIN AND LOCOMOTIVE SERVICE

The total cost of train service, including locomotive service, shows a steady decrease as compared with preceding months, although increases as compared with last year, according to the monthly reports compiled by the Operating Statistics Section. For the month of April it was 112.7 cents per 1,000 gross ton miles, as compared with 119.5 in March and 126.5 in February. The cost of locomotive service per locomotive mile in April was 115.2 cents, as compared with 98.5 cents in April, 1918; 119.2 cents in March, 1919, and 120.7 cents in February. The cost of train service per train mile was 162.2 cents, as compared with 141.7 in April, 1918, 167.5 cents in March, 1919, and 169.3 cents in February, 1919. The increase in the cost of locomotive service in March this year over March last year was 17 per cent, and the increase in the cost of train service was 14.5 per cent. All items of cost show increases as compared with last year. The figures are reported by roads and by regions. The combined averages for all regions are as follows:

	April, 1919	April, 1918
Cost of locomotive service per locomotive mile	115.2	98.5
Locomotive repairs	39.4	30.6
Enginehouse expenses	9.6	6.8
Train enginemen	18.9	18.1
Locomotive fuel	43.6	40.2
Other locomotive supplies	3.7	2.8
Cost of train service per train mile	162.2	141.7
Locomotive repairs, Enginehouse expenses	55.5	43.0
Locomotive fuel	49.4	46.2
Other locomotive supplies	4.2	3.3
Train enginemen	21.4	20.8
Trainmen	25.3	23.9
Train supplies and expenses	6.4	4.5

	April, 1919	March, 1919	February, 1919
Cost of train service per 1,000 gross ton miles	112.7	119.5	126.5
Locomotive repairs, Enginehouse expenses	38.6	40.8	43.1
Locomotive fuel	34.3	37.5	40.3
Other locomotive supplies	2.9	3.1	3.4
Enginemen and trainmen	32.4	33.5	34.8
Train supplies and expenses	4.4	4.6	4.8

LOCOMOTIVE FUEL PERFORMANCE

The Fuel Conservation Section has issued a bulletin on locomotive fuel performance for January, February and March, 1919, as compared with the same period of the previous year, which shows an estimated saving in coal consumption by using less coal per 1,000 gross ton miles, or per car mile, amounting to $11,263,774. This is based on incomplete returns covering 76 per cent of the total mileage. In determining the estimated total saving for all roads in a region it has been assumed that the average per cent of saving for the whole region is the same as the average per cent for the roads in that region for which complete information is available. The grand total saving for all regions has been taken as the sum of the regional totals. In freight train service the estimated saving for all roads is $7,773,170. The saving on the roads for which information is available was 12.3 per cent. In passenger service the saving is estimated at $3,530,604, or 12½ per cent. The average cost of coal per ton shows increases in the various regions, as follows: Eastern region, from $3.48 to $3.92; Allegheny region, from $2.92 to $3.00; Pocahontas region, from $2.55 to $2.67; Southern region, from $2.82 to $3.40; Northwestern region, from $3.58 to $3.91; Central Western region, from $3.07 to $3.55; Southwestern region, from $3.13 to $4.14; Grand total, all regions, from $3.16 to $3.57.

The total tons of coal consumed in the three months amounted to 26,191,000 as compared with 30,943,000 in the corresponding period of 1918, and the total cost of coal was $93,503,000 as compared with $97,541,000. In freight service the pounds of coal per 1,000 gross ton miles averaged 220 as compared with 243.7 in the corresponding period of 1918. This is a decrease of 9.7 per cent. In passenger train service the pounds of coal per passenger train car mile averaged 20 as compared with 22½ last year, 11.1 per cent less.

DIRECTOR GENERAL APPEALS FOR EFFICIENCY AND ECONOMY

Walker D. Hines, director general of railroads, has sent the following letter to all officers and employees of railroads under federal control:

"The increased payroll cost, due to improved wages and working conditions, and the increased cost of material and supplies, are now resulting, in connection with the falling off in business, in the United States Railroad Administration incurring heavy deficits in railroad operations.

"For the first four months of this year, these deficits, after deducting the rental due the railroad company, were about $250,000,000 or at the rate of $62,500,000 per month. This critical condition makes it imperative not only that costs shall not increase but also that every effort be made to help the government through every reasonable effort to economize and realize greater efficiency.

"These deficits, so far as they cannot be eliminated through greater economies and through increased business, will eventually have to be offset by increased transportation rates which all should endeavor to avoid.

"I ask every officer and every employee to redouble his efforts to do efficient work, to economize in the use of railroad materials, fuel and other supplies, and to use great care not to injure equipment, tools, office furniture or injure property being transported by the railroad and for which payment must be made if injury occurs, and further than this, to try to encourage others to do the same. Please remember that if you should fail in any of these respects to do what you reasonably could and ought to do you would impose unnecessary cost upon the government. This is true because it is the government which has to bear the loss if there is one or which will receive the profit if any is earned.

"Do not wait for the other fellow to begin this improvement, but begin yourself. Do not decline to help because some other fellow is not helping; turn in and help, and keep on setting the other fellow a good example. You are interested in the great movement for the improvement of the condition of the individual worker. You can aid in that great movement, through efficiency and saving in reducing the cost of railroad operation, because thereby you help to keep down transportation rates, and thereby you help to keep down the cost of living. An increase in rates will give occasion for an increase in prices of what the public consumes and that will mean a new cycle of increasing still further the cost of living. It is to the interest of every man, woman and child in this country that this shall be avoided just as far as possible.

"The government, during federal operation of the railroads, as a result of its nation-wide control, has been able to do much to promote justice to railroad employees through making proper increases in their wages and proper improvement in their working conditions. In the nature of things the result cannot be equally satisfactory to all, involving 2,000,000 employees, because it is not possible in this vast undertaking to satisfy equally every one or even every class of these employees. If any employee feels he has a ground for such dissatisfaction he ought to remember the remarkable strides that have been taken by the government in the last 12 months in the recognition of the just rights of railroad employees, and compare the situation today with what it was in December, 1917, before federal control began. It has been a source of satisfaction to me to aid in this great work. Will you not, in turn, do justice to the government and help sustain my work, as director general, and also justify what has been done for you, by doing all that you can reasonably do to save the government money and to increase the efficiency of your work?

"I sincerely want your assistance in demonstrating that the railroads may be operated successfully even though the wages of its employees have been materially increased."

ORDERS OF REGIONAL DIRECTORS

Cars Rented to War Department.—The regional director, Eastern Region, by circular 500-51A773 promulgates an order from the Division of Operation to the effect that where freight cars are furnished for the War Department, the rental rate is to be uniformly $3 a day, beginning with June 1.

Rental Charges on Equipment.—Order 207 of the Southwestern regional director cancels Orders 183 and 185 previously issued by the Southwestern regional director pertaining to rental charges on locomotives and other equipment and outlines new rates for locomotives, dining cars, locomotive cranes, etc., effective March 1. These rates do not abrogate those named in any contracts of prior execution.

U. S. R. A. Standard Cars; Repairs.—The regional director, Eastern Region, by circular 500-101A771 promulgates a notice from the Division of Purchases that when it becomes necessary to make repairs on standard freight cars, or standard locomotives, orders for material, before being placed, should be referred to the director of the division, H. B. Spencer, Washington, so that any surplus material accumulating at the car plants can be properly distributed.

Safety Appliances on Freight Cars; Time Limit September 1.—The regional director of the Eastern region, by Circular 500-92A767, calls the attention of federal managers to the laws of Congress, the orders of the Interstate Commerce Commission and the rules of the Master Car Builders' Association, designed to insure the complete equipment of all freight cars with the legal safety appliances by September 1, 1919. Foreign as well as owned cars should be equipped under certain regulations.

Flexible Staybolts.—Northwestern Regional Purchasing Committee Bulletin 146 states that the American Locomotive Company has completed the installation of equipment necessary for the manufacture of flexible staybolts and will prepare to furnish them upon order.

New Locomotives Moved Free.—The regional director, Eastern Region, by circular 500-1-106-A783, advises that no freight charges are to be assessed on any class of new locomotives moving from the works of the builders to the purchasing roads, whether under their own steam or dead.

Locomotive Fuel Contracts.—Supplement 17 to Northwestern Regional Purchasing Committee Circular 3 contains the following clause which will be incorporated in all contracts for locomotive fuel: "In the event the railroad is released from federal control before the expiration of this contract, it is understood that the corporate owners have the option to be exercised at their pleasure, of being substituted for the director general of railroads, as to the benefits and obligations of this contract, effective upon the date the owners assume control." This will not require the approval of the corporate companies at this time.

Superheaters.—A. T. Hardin, regional director, Eastern Region, by circular 500-1-97A728A promulgates for the information of federal managers the order of the director of the Division of Capital Expenditures relative to the application of superheaters to locomotives. The order says: "Consideration by the Mechanical Section of the Division of Operation develops that these superheaters will not pay for the cost of application, irrespective of the cost of the material, if the engine is not actually in service by October 1, 1919. It is of course expected that business judgment will be exercised in installing the superheater even after that date, but unless the corporations are willing to stand the operating charge as well as the capital charge for applying superheaters after October 1, 1919, the program should cease as of that date."

Capital Expenditures less than $1,000.—A. T. Hardin, regional director, Eastern Region, by circular 2700-A776, quotes a letter from Washington calling attention to apparent violations of the spirit of the rule which allows federal managers to make expenditures, chargeable to capital, without first consulting the corporation, provided the total expenditure is less than $1,000. Corporations have made protests that many items coming within the limit are really parts of a general program, and do not properly stand by themselves. Among such items are:

(1) Office facilities—typewriters, tabulating machines, desks, etc., spread over eight or ten months. (2) Machine tools evidently part of a general improvement of shop facilities but split up into single purchases. (3) Expenditures incident to heavier rail, divided up into monthly charges, giving no indication of the scope of the program. (4) Fencing,

divided up into short sections * * * (5) Tie plates and rail anchors, divided up into short sections. (6) Rebuilding freight cars reported under the heading of the individual car number. Federal managers are advised to refer such matters, where possible, to the corporate officer, to avoid these objections.

REDUCING EXHAUST NOZZLES TO OVERCOME FRONT END AIR LEAKS*

BY F. P. ROESCH
Supervisor, Fuel Conservation Section, Northwestern Region

The manager of the Fuel Conservation Section, United States Railroad Administration, under date of August 1, 1918, sent out Fuel Conservation Circular No. 8, addressed to all motive power officials concerned with locomotive maintenance. The circular called particular attention to the prevalence of air leaks around the outside steam pipes on superheated steam locomotives at the point where these pipes enter the smoke arch, and advised how these leaks could be detected by means of an ordinary torch test.

While in some instances the recommendations embodied in circular No. 8 were fully complied with, in other cases it was found that proper measures were not used.

The usual methods pursued in taking care of the air leaks around these steam pipes was to pack the opening between the pipe and gland with fibrous asbestos packing, either rope asbestos or plaster being used. Tests have proved that through the action of the exhaust this packing is gradually pulled into the front end, eventually leaving a combined opening around the two steam pipes in the average construction, equal to an orifice 8½ in. in diameter.

These air leaks, of course, do not occur suddenly, consequently the effect on the draft is gradual, and this in turn gradually reduces the steaming qualities of the locomotive. It is because locomotives gradually fail for steam that nozzle bushing is eventually resorted to, as did the steam failures occur suddenly the cause would be investigated and corrected.

In order to determine the exact effect of reducing nozzles and disarranging front end apparatus to overcome the effects of these leaks and to improve the gradually failing steaming qualities of the locomotive, the Fuel Conservation Section authorized a series of tests to be conducted to see what the losses amounted to in increased fuel consumption.

In conducting these tests no particular locomotive was selected, the locomotive test being one in regular chain gang freight service and assumed by all concerned to be in good condition. Draft gages were used in front and behind the diaphragm, in the firebox and in the ash pan. In addition to the draft readings, pyrometer readings were also taken at stated intervals as well as cylinder indicator cards at various speeds and cut off. A dynamometer car was employed in order to register the draw bar pull under varying conditions so that the results obtained would not be based on the tonnage alone, but equated on the train resistance. The tender was cut off, drained and weighed prior to taking coal on each trip. Only the coal consumed in actually pulling the train was taken into consideration, all coal used on sidings and at other stops being used from a separate source.

The locomotive tested was of the light Mikado type and superheated, having cylinders 26 by 30 inches, 63-inch driving wheels, 200 pounds steam pressure, with a calculated tractive effort of 54,720 lb. The tests were conducted over a double track freight division, 91 miles long, having a maximum grade of .67 per cent, the same engine crew being used throughout all tests.

The first trip was made with the locomotive as found. On the completion of this trip, the openings around the steam pipes were packed with rope asbestos, and it was found that the average draft in the front end was raised two inches, as shown by the draft gauge. As this now gave a vacuum in the front end greater than necessary to produce the desired vacuum in the firebox, it was decided to open the nozzle a sufficient amount to reduce this.

On the first trip it was found that the draft gauge in front of the diaphragm registered practically double the height of the column of water as registered by the draft gauge behind the diaphragm, indicating that the draft plate was so adjusted as to offer quite an obstruction to the flow of gases from the firebox to the atmosphere. It was, therefore, decided to raise this plate in order to better equalize the draft.

On the next trip the openings around the steam pipes were again packed with asbestos and front end cement, as inspection on arrival showed that the greater part of the packing applied on the previous trip had pulled out. The nozzle was enlarged ⅛ inch in diameter and the draft plate raised as noted in the preceding paragraph. On this trip the locomotive showed a marked decrease in the consumption of coal per 1,000 G. T. M. equated on the draw bar pull as registered by the dynamometer car. It also showed a decrease in cylinder back pressure at the same speed and cut off, due, of course, to the enlarging of the nozzle.

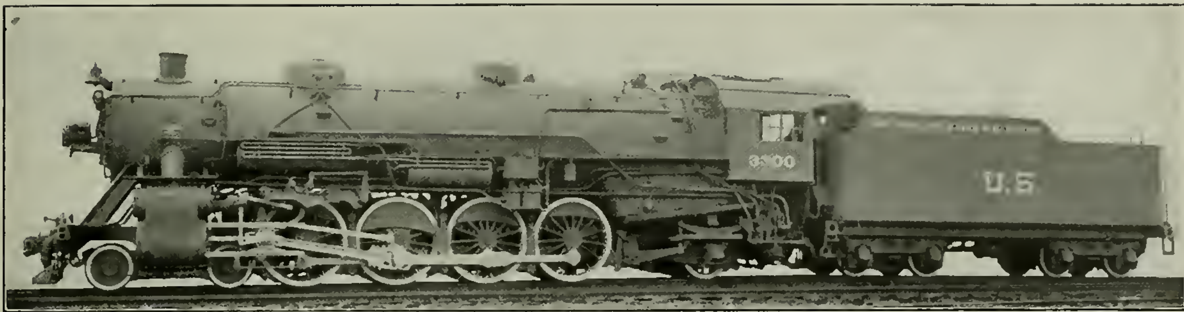
As the front end vacuum was still greater than necessary, it was decided to further increase the diameter of the nozzle on the following trip.

On the next trip the nozzle was enlarged ⅛ inch more in diameter, or a total of ¼ inch above the size originally carried. The draft sheet was left as adjusted on the previous trip. Finding, however, that the packing around the steam pipes had again partially pulled out, it was decided to seal these openings by means of plates made of No. 10 gauge steel, slightly corrugated, the outer circumference of these plates being welded to the smoke arch on the inside of the arch and the inner circumference of the plates welded to the steam pipes. An electric welder was used, thereby permanently sealing these openings. On this trip, while the locomotive did not show any decrease in fuel consumption per 1,000 G. T. M. over the previous trip, it did show an increase in locomotive efficiency, due to the further increase in the size of the exhaust nozzle, and as a point had now been reached where the fuel consumption and locomotive efficiency practically balanced, and it having been decided that any further increase in the size of the exhaust nozzle would affect the steaming of the locomotive to such an extent as to increase the coal consumption, the tests were concluded.

The final results can be briefly summarized in the following statement: Opening the nozzle ¼ inch or 4.5 per cent of the diameter, giving an increase of 9.3 per cent in area, resulted in a decrease in fuel consumption of 14.3 to 21.17 per cent, the comparisons as shown for the different trips wherein the larger nozzle was used being 14.3, 17.2, 18.2 and 21.17 per cent, the difference being due to variations in the quality of coal, weather conditions, etc. The efficiency of the locomotive was increased from 8.1 to 16.5 per cent based on the averages at various speeds and cut off, as shown by indicator cards and dynamometer records. The locomotive steamed equally as well with the larger nozzle as with the one originally used. The raising of the diaphragm resulted in a better distribution of the draft over the fire, and decreased the fuel consumption about 3 per cent.

On the whole, the tests brought out forcibly the necessity of maintaining nozzles with the largest possible diameter consistent with good steaming; of maintaining air tight front ends in order that the large nozzle can be successfully used, and of so adjusting the draft plate as to maintain an even distribution of draft over the entire grate surface, as well as to carry it at such a height as to provide ample area for the free flow of gases from the firebox to the stack.

*Abstract of a paper read at the convention of the International Railway Fuel Association, held at Chicago, May 19-22, 1919.

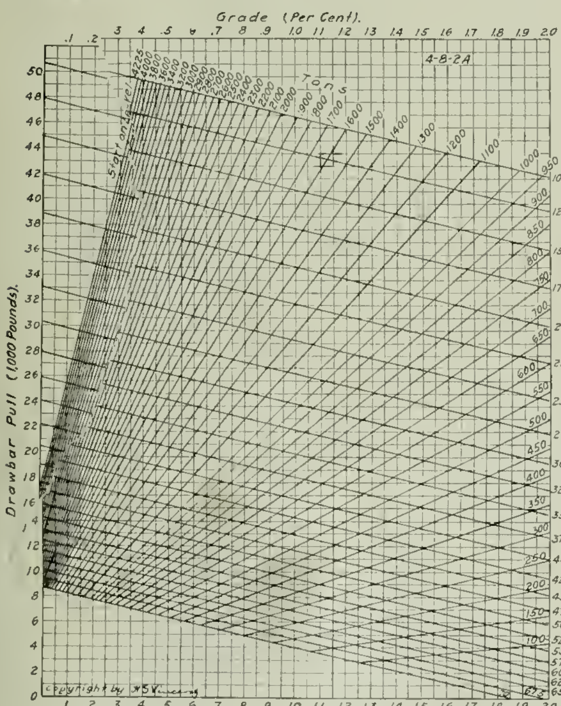


The U. S. R. A. Standard Light Mountain Type Locomotive

Standard Light Mountain Type

Last of the Administration Designs to be Built; Total Weight 327,000 lb.; Tractive Effort 53,900 lb.

THE first of the Railroad Administration standard light Mountain type locomotives has recently been turned out at the Richmond works of the American Locomotive Company and assigned for service on the New York, New Haven & Hartford. This is the last of the standard designs prepared by the Railroad Administration from which

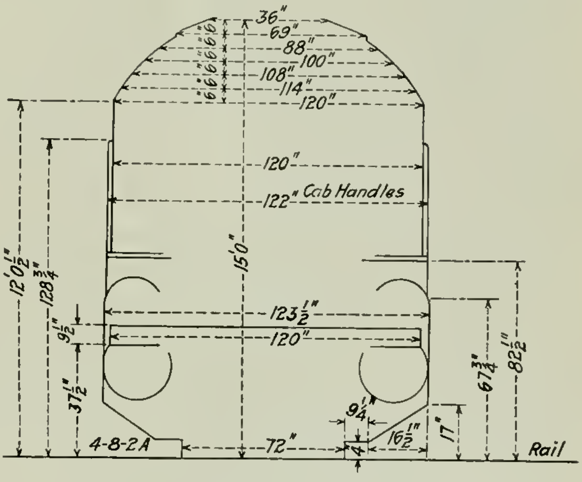


Copyright by H. S. Vincent

Standard Light Mountain Type Tonnage Rating Chart

locomotives have been built and locomotives of each of the twelve standards are, therefore, now in service.

These locomotives were designed on the basis of rail loads of 55,000 lb. on each driving axle. The actual weight in working order is 327,000 lb., of which 224,500 lb. is on the drivers. The engines produce a tractive effort of 53,900 lb., with a factor of adhesion of 4.2. In the table is presented a comparison of some of the more important dimensions and ratios of the standard light Mountain type with other moderate size locomotives of this type designed to meet conditions which would not permit of the use of maximum axle loads. With the exception of the Canadian Pacific locomotive few Mountain type locomotives designed for passenger service have been built with piston strokes greater than 28 in.

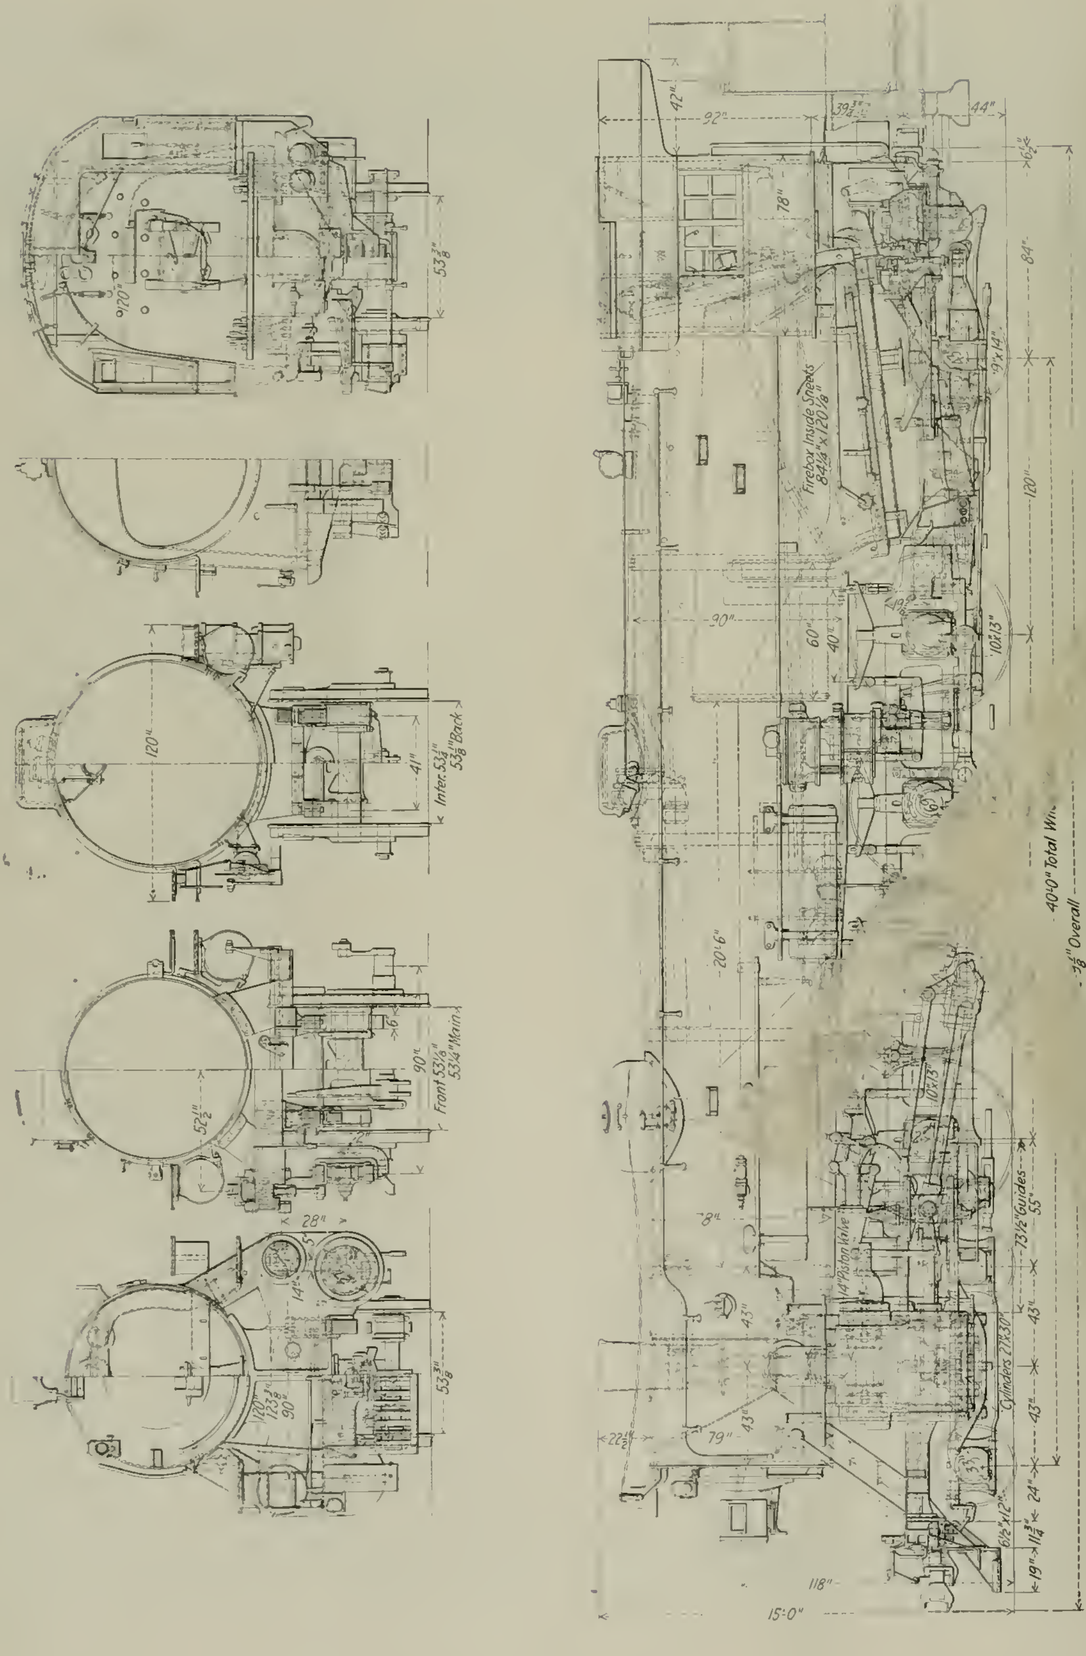


Clearance Diagram for the Light 4-8-2 Type

Comparison of the Principal Dimensions of Light Mountain Type Locomotives

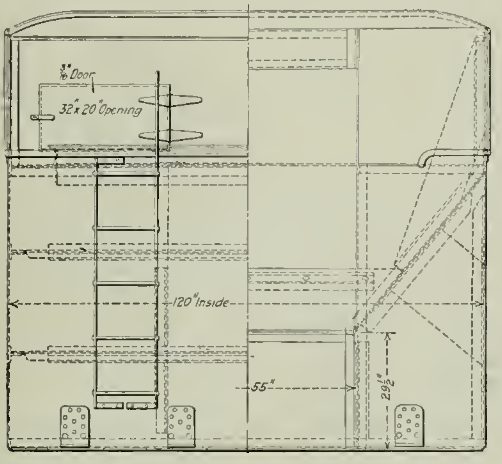
Road	U.S.R.A.	Cent. of Ga.	C.R.I. & P.	Can. Pac.
Year built	1919	1919	1913	1915
Tractive effort, lb.	53,900	47,800	50,000	42,900
Total weight, lb.	327,000	316,000	333,000	286,000
Weight on drivers, lb.	224,500	209,500	224,000	192,000
Diameter of drivers, in.	69	69	69	70
Cylinders, dia. and stroke, in.	27 x 30	27 x 28	28 x 28	23.5 x 32
Boiler pressure, lb.	200	190	185	200
Heating surface, total, sq. ft.	4,121	3,649	4,117	3,667
Superheating surface, sq. ft.	966	961	944	760
Grate area, sq. ft.	70.3	66.8	62.7	59.6
Tractive effort × dia. drivers ÷ equivalent heating surface	667.7	648.0	623.5	625.0
Equivalent heating surface ÷ grate area	79.2	76.2	88.2	80.7
Firebox heating surface ÷ equivalent heating surface	6.2	5.8	3.4	5.5

It will be seen that the light Mountain type has cylinders of 30 in. stroke, which is also the case with the standard heavy



...tion and Sections of the Standard Light ... Type ...omotive

Mountain type locomotive. Except for its greater tractive effort, partly due to the increased cylinder stroke and partly to the greater boiler pressure, the standard light Mountain type compares closely with the Chicago, Rock Island & Pacific Mountain type built in 1913. The heating surfaces



Half End Elevations of the Standard 10,000-Gal. Tender Tank

compare closely, although the standard locomotive has a considerably larger grate than the earlier built locomotive.

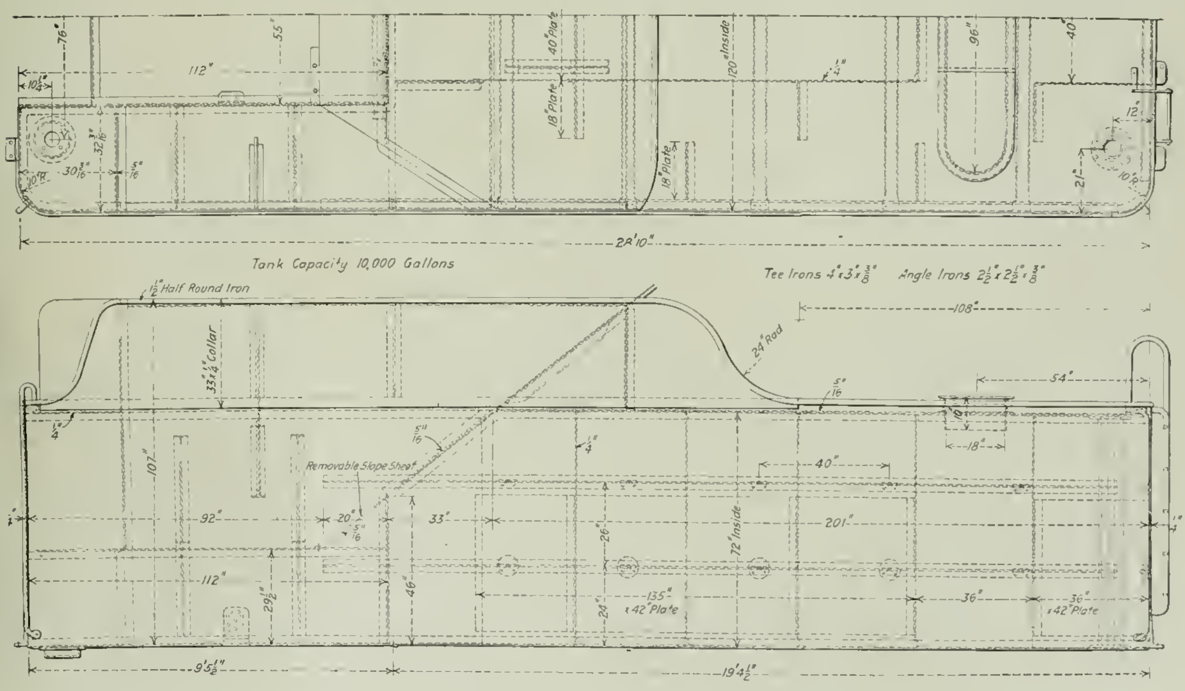
In design the light Mountain type locomotive is essentially the same as the other standard types, following closely the lines of the heavy Mountain and the two Pacific types.

The boiler is of the conical wagon top type, with the dome type A superheater. The same number of tubes and flues are also used in the boiler of the heavy Pacific type locomotive, the length of which, however, is 19 ft., with a 38-in. combustion chamber. The size of firebox at the mudring is the same for both boilers. The boiler of the light Mountain type is fitted with a Shoemaker power operated firedoor.

The frames are similar in design to those of other single unit standard types. The width is six inches and the top rail has a maximum depth of 7⅛ in. over the pedestals, with a minimum of six inches between the pedestals. The lower rail has maximum and minimum depths of 4¾ in. and 4¼ in., respectively. The cylinders are carried on a single front rail of slab section, cast integral with the main frame. This rail tapers under the cylinder fit from a depth of 10⅝ in. at the rear to a depth of 9⅝ in. at the front, the width being 6 in. under the cylinders and to a point 30 in. back from the front end of the casting. Unit steel cradle castings are spliced to the rear of the main frames, the joint being of the same type used on all of the other designs which are fitted with trailer frames.

The cylinders, pistons and valves are similar in details to those on practically all of the other locomotives, the valves being of the piston type and 14 in. in diameter. The front and back cylinder heads are interchangeable between this locomotive and others having cylinders 27 in. in diameter, including the heavy Mikado, the light Santa Fe and the heavy Pacific types. The cylinder and valve chamber bushings, valve bull rings and packing rings, piston bull ring and packing rings and crosshead shoes are all of Hunt-Spiller gun iron.

The main and side rods differ in no essential from those on any of the other locomotives. The side rods are of slab section, this being the rule the only exceptions to which are

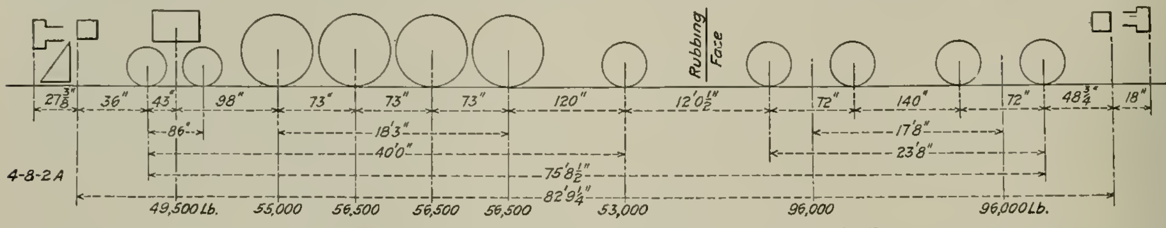


The Railroad Administration Standard 10,000-Gal. Tender Tank

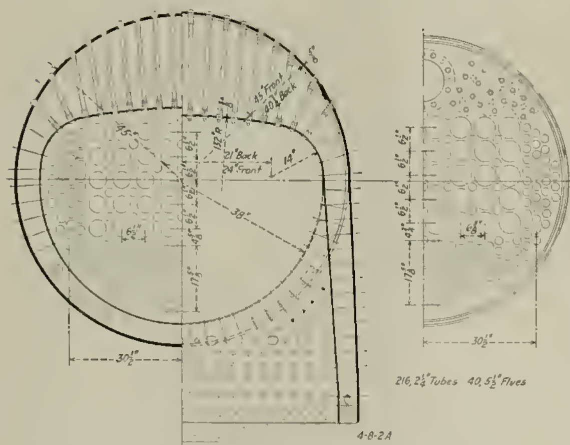
set on the third course. The firebox includes a combustion chamber extending forward 60 in. from the throat sheet, leaving for the tubes a length of 20 ft. 6 in. There are 216, 2¼-in. tubes and 40, 5½-in. flues for the elements of the in the case of the two Pacific type locomotives, which have I-section side rods. There is a considerable degree of interchangeability in the side and main rod bearings between the various classes of standard locomotives. The back end main rod brasses of the light Mountain type interchange with those of the heavy Mikado, light Santa Fe and heavy Pacific types, while the front end main rod brasses interchange with both Mikado type locomotives, the eight-wheel switcher, the light Santa Fe and both Pacific types. Similar, although not exactly the same interchangeability applies to the side rod bearings.

Driving boxes and axles are also of interchangeable design to a very considerable degree. The journal sizes on the front, intermediate and back pairs of drivers of the light Mountain type are 10 in. in diameter by 13 in. in length. With the exception of the main journals, those of the light Pacific, both Mikado types and both Santa Fe types have the same size and both axles and driving boxes interchange. The main journals of the light and heavy Mountain, heavy Mikado, heavy Pacific and light Santa Fe types are interchangeable.

The tenders have Commonwealth unit frame castings and are carried on Commonwealth equalized four-wheel trucks.



The Distribution of Wheel Loads for the Standard Light Mountain Type



Half Sections and Tube Sheet Layout of the Light Mountain Type Boiler

The tank has a capacity of 10,000 gallons, carries 16 tons of coal and is fitted with the Locomotive Stoker Company's coal pusher. The tanks are built up of ¼-in. and 5/16-in. plate with 2½-in. by 2½-in. by ⅜-in. angles at the corners, for the attachment of the splash plates and for the crossties. Two T-irons of 4-in. by 3-in. by ⅜-in. section are used as horizontal stiffeners on each side of the water space and to these the ends of the crossties are attached. The cistern opening has a length of 96 in. across the tank and a width of 18 in.

The clearance diagram and wheel loading diagrams which are included were prepared by F. P. Pfahler, chief mechanical engineer of the Division of Operation, of the Railroad Administration. Actual weights are shown on the wheel loading diagram. The tonnage rating diagram was prepared and is copyrighted by H. S. Vincent. The curves of hauling capacity are constructed for a car resistance of four pounds per ton. The chart may be used for any other car resistance or for any combination of resistances by converting them into terms of grade.

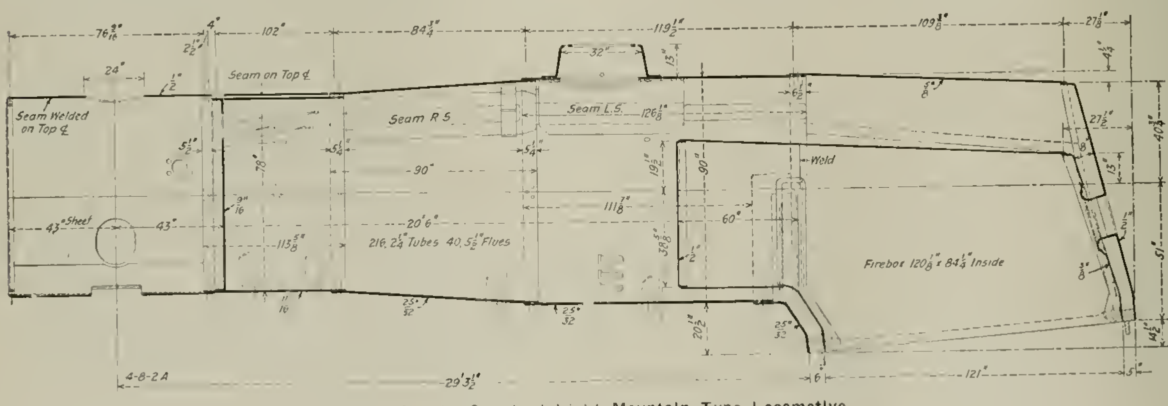
1 lb. car resistance = .05 per cent grade
1 deg. curve uncompensated = .04 per cent grade

For example, find the tonnage which can be hauled in passenger service on 0.5 per cent grade combined with a five degree uncompensated curve at 40 m. p. h. The resistance of passenger coaches at 40 m. p. h. is 6.65 lb. per ton.* The equivalent grade is then:

$$0.5 + (5 \times .04) + (2.65 \times .05) = 0.8325 \text{ per cent.}$$

At the intersection of the ordinate for 0.8325 per cent grade with the drawbar pull curve for 40 m. p. h., we find 800 tons as the capacity of the locomotive.

A list of the specialties on all of the standard locomotives



Boiler for the Standard Light Mountain Type Locomotive

*See the *Railway Mechanical Engineer* for November, 1918, page 607, for a table of passenger cars resistances for use with these charts.

was published in the March issue of the *Railway Mechanical Engineer*, p. 137. The principal dimensions and data for the light Mountain type locomotive are as follows:

General Data

Gage	4 ft. 8½ in.
Service	Passenger
Fuel	Bit. coal
Tractive effort	53,900 lb.
Weight in working order	327,000 lb.
Weight on drivers	224,500 lb.
Weight on leading truck	49,500 lb.
Weight on trailing truck	53,000 lb.
Weight of engine and tender in working order	519,000 lb.
Wheel base, driving	18 ft. 3 in.
Wheel base, total	40 ft. 0 in.
Wheel base, engine and tender	75 ft. 8½ in.

Ratios

Weight on drivers ÷ tractive effort	4.2
Total weight ÷ tractive effort	6.1
Tractive effort × diam. drivers ÷ equivalent heating surface*	667.7
Equivalent heating surface* ÷ grate area	79.2
Firebox heating surface ÷ equivalent heating surface,* per cent	6.2
Weight on drivers ÷ equivalent heating surface*	40.3
Total weight ÷ equivalent heating surface*	58.7
Volume both cylinders	19.9 cu. ft.
Equivalent heating surface* ÷ vol. cylinders	279.9
Grate area ÷ vol. cylinders	3.5

Cylinders

Kind	Simple
Diameter and stroke	27 in. by 30 in.

Valves

Kind	Piston
Diameter	14 in.
Greatest travel	7 in.
Steam	1¼ in.
Exhaust clearance	3/16 in.
Lead	¼ in.

Wheels

Driving diameter over tires	69 in.

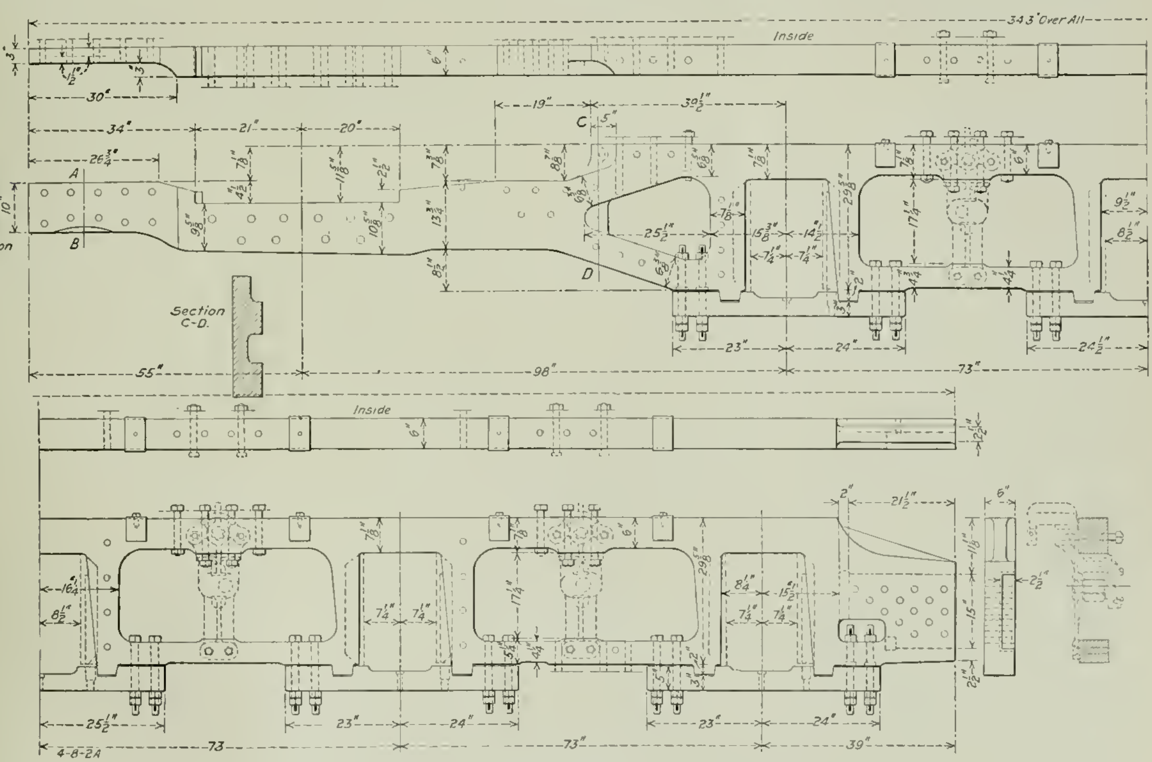
Water capacity	10,000 gal.
Coal capacity	16 tons

*Equivalent heating surface = total evaporative heating surface + 1.5 times the superheating surface.



The Frame of the U. S. R. A. Standard Light 4-6-2 Type Locomotive

STORAGE OF COAL BY RAILROADS DURING 1918*

BY H. H. STOEK

Professor of Mining Engineering, University of Illinois

About two years ago the writer sent out a questionnaire to several hundred parties storing coal in quantities varying from a few tons stored in the ordinary house-cellar to hundreds of thousands of tons as stored on the docks along the Great Lakes and by some of the large industrial concerns. The replies to this questionnaire were studied and a tentative set of conclusions drawn up, and sent to the parties who had answered the original questionnarie, with the request that they be thoroughly criticized. As a result of these criticisms, a revised set of conclusions was drawn up and published in Circular 6 of the Engineering Experiment Station of the University of Illinois.

Realizing that during the period of the war the conditions under which coal was stored were unusual, because of the pooling of coal and because the coal furnished was dirtier

*Abstract of a paper presented at the convention of the International Railway Fuel Association at Chicago, May 19-22, 1919.

and less carefully sized than under normal conditions, another questionnaire was sent out during the fall of 1918 to practically the same list of persons as the previous one, asking for the experiences of those who had stored coal during the year 1918 and for a criticism of the conclusions published in Circular 6. A similar questionnaire was sent to a large number of power plants in the state of Illinois, and a large number of fires in coal piles were studied during the summer and fall of 1918. In these several studies, railroad storage was only one of the problems included and furthermore, the study had particular reference to Illinois and Middle West coals.

On March 11 a conference was held in Chicago, at which the general subject of railroad storage was discussed and the general conclusions in Circular 6 were endorsed. Each one was asked to furnish the writer his own conclusions upon railroad storage and copies of all instructions issued by railroads in his territory to be studied and summarized by a sub-committee consisting of Messrs. McAuliffe, Roesch, Collett, Hardy and the writer, at a meeting held in Urbana, March 25. At that meeting certain general conclusions were drawn up as representing what in the opinion of the committee represents safe practice at the present time and these preliminary conclusions were issued by Mr. McAuliffe in a circular addressed to the railroads of the country as a guide to them in storing coal during 1919.

Why Should Railroads Store Coal?—The insurance feature of coal storage is so self-evident as not to need discussion, and the equalization of equipment throughout the year has been fully discussed in the reports of the several coal storage committees. (See also Railway Administration circular.)

Coal stored in summer costs less to transport than would the same amount hauled during the winter. By relieving the roads of transportation cost, general traffic is helped.

Other reasons for storing coal by the producer or by the consumer need not be considered here, as the railroad is a transporting agent only.

The railroads are also interested in the storage of coal, because they are the largest users of it, using more than 25 per cent of the total output for their own uses, and since the transportation of the coal output forms about 34 per cent of the freight carried by the railroads of the United States, the railroads should, therefore, not only protect their own interests by storing coal, but should encourage both the mine operators and consumers to store coal so as to help stabilize the coal industry in order that it can be conducted more nearly up to its full time efficiency and thus decrease the present excessive but absolutely necessary overhead charge due to the fact that the miners of the country work only about 200 days per year.

Suggestions Regarding Storage of Coal by Railroads.—The replies to the questionnaire sent out in 1918 asking for experiences in storing coal during 1918 and for a criticism of the conclusions published in Circular 6, show that the experience of the past year has confirmed these conclusions* in very great part.

Summarizing these suggestions:

Each railroad should study its own storage problem in great detail. Get ready to store before it is time to begin actual storing by outlining a definite policy far enough in advance so that every one who will have to do with the storing can receive *definite* instructions, not merely suggestions. Then when storing begins, see that the instructions are carried out to the letter. Many failures have been due not to faulty instructions from the head office but to the fact that they have not been followed.

When it is time to store, prepare a place carefully. Do not wait until the coal to be stored is on the track and then dump it anywhere to get it out of the cars. Specify the kind of coal that is to be stored and see that the specifications are carried out by having an inspector at each storage pile who is competent, not only to inspect the coal furnished and reject it if not according to specifications, but who has authority to see that the storage instructions are carried out to the letter.

Prepare definite instructions as to the sizes of piles for different coals and for the different kinds of storage appliances that may be available.

Watch the stored coal carefully for any evidence of heating and if the temperature rises sufficiently, begin to move it in time. See that adequate machinery for handling the coal is available and always in condition to be used. Do not store coal unless you are prepared to do it properly and to watch it thoroughly after it has been stored.

Attention to these details will very largely prevent heating of coal or if heating occurs will prevent loss from fires.

It should be understood that each coal storage is a distinct proposition and while it is believed that the suggestions in this paper will be helpful to any one wishing to store coal, they are suggestions and guides only. They are not absolute facts and subsequent experience may show changes to be advisable.

Effect of Storage Upon the Properties of Coal.—The heating value of coal as expressed in B. t. u. has been shown by experiments of the United States Bureau of Mines and by Professor S. W. Parr of the University of Illinois, to be very little decreased by storage. It must be admitted, however, that the opinion is very wide-spread that storage coal burns less freely than fresh coal. This opinion is by no means universal amongst railroad men, for it is distinctly stated by some that the storage coal burns better than the fresh coal.

Experiments at the University of Illinois have indicated that coal that has been in storage can be burned as readily as fresh coal if a thinner bed is kept on the grate and the draft properly regulated. This, of course, applies particularly to stationary plants.

Insurance Adjustments.—An attempt has been made to obtain information regarding the adjustment of insurance in connection with the storage of coal but very incomplete information had been received at the time of writing. It is suggested that this subject is worthy of much more careful and extended study, possibly by a subcommittee of the Fuel Association.

STORAGE SYSTEMS

Choice of a Storage System.—In the choice of a storage system, the following points should be considered:

(1) The location, size, and topography of the available storage ground.

(2) The capacity of the desired installation, that is, the amount of coal which it is desired to load and unload in a given time.

(3) The cost of the plant.

(4) The cost of maintenance.

(5) The cost of operation.

(6) The amount of breakage to be permitted in handling the coal.

(7) The way in which the coal is received, in open or box cars, or in boats.

(8) The length of time the coal must be kept in storage.

(9) Climate: A dry climate with cold nights such as is found in Colorado, for instance, may give different conditions than will be found in Illinois, where there is a great deal of moisture in the air and the summer nights are almost as hot as the days.

The requirements of an ideal plant are:

*The conclusions included detailed instructions regarding the storage of coal as regards location of piles, season when coal should be stored, kinds and sizes which may safely be stored, methods of piling, ventilation and precautions to be taken to avoid spontaneous combustion.

(1) Adequate ground area, so that different kinds of coal may be stored separately if necessary.

(2) Adequate facilities for rapidly and economically transferring coal from cars or from boats into the storage piles.

(3) Adequate facilities for rapidly and economically reclaiming the coal and for rapidly moving any part of the pile which shows evidences of taking fire.

(4) Adequate track facilities, with gravity facilities, if possible, for handling cars.

(5) Means for preventing undue breakage in handling.

(6) Adequate available water supply.

(7) Low cost of installation, maintenance, and operation per ton of capacity. A storage plant is in operation very irregularly and costs are likely to be correspondingly higher because of the heavy fixed charges.

(The paper gave detailed analyses of the advantages and disadvantages of methods of storage particularly applicable to railroad conditions. Replies to questionnaires summarizing current practice and opinion were also included.)

Limit Of Wear For Steel Wheels

Tests Show Flanges of Wheels Worn Below the Present Condemning Limit Have Adequate Strength

A TEST was recently conducted by the testing department of one of the large railroads to determine by comparison with worn cast iron wheels whether or not rolled steel wheels, worn 1/4 in. below the present scrap wearing limit, can be used with safety. To make this test

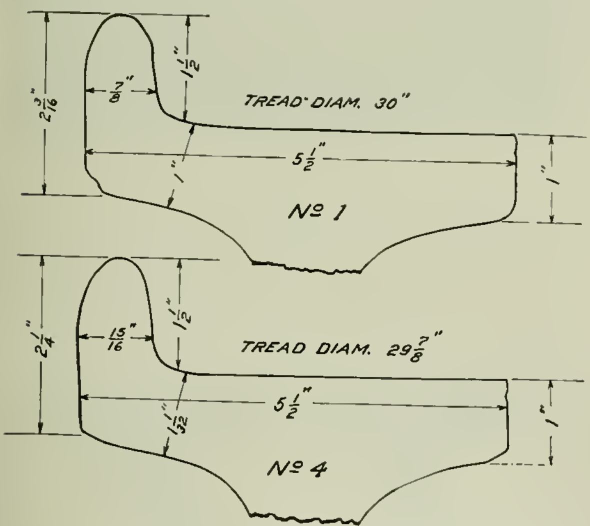


Fig 1—Cross Section and Contour of Wheels to Present Scrap Wearing Limit

four rolled steel wheels were selected from a lot of scrap wheels. The wheels had been in service under locomotive tenders and had treads worn from 2 3/8 in. to 2 1/2 in. below the new diameter, about 1/4 in. above the limit marks. They were rolled in 1917 from three different heats.

The treads of wheels numbered 1 and 4 were turned to a thickness of 1 in. or to the present scrap wearing limit. All flanges were turned to the minimum allowable thickness of 15/16 in. and with vertical surfaces and sharp fillets similar to the worn condition developed in service. Cross sections of the treads and flanges are shown in Fig. 1 and Fig. 2.

In order to make a comparison with worn cast iron wheels, three wheels were selected for test from among the scrap wheels at a large wheel foundry. These wheels were cast at three different foundries the weight and dimensions being as follows:

Wheel number	44 997	2,328	158,891
Date cast	May 27-16	Sept. 16-07	Aug. 14-14
Stenciled weight	740 lb.	700 lb.	625 lb.
Flange thickness	13/16 in.	1 in.	1 in.
Tread diameter	32 13/16 in.	32 3/4 in.	32 11/16 in.

DROP TESTS

The M. C. B. drop test machine at the wheel foundry was used for the tests. The wheels were supported in a way that caused the entire thrust to be taken by the flange. The three steel blocks on which the flange rested were rounded off so as to eliminate any cutting action against the flange, and to confine the supported area to the vertical surface above the fillet. These blocks were supported on three 5-in. anvil blocks, which are the standard equipment of the machine. An iron band surrounding the wheel and blocks

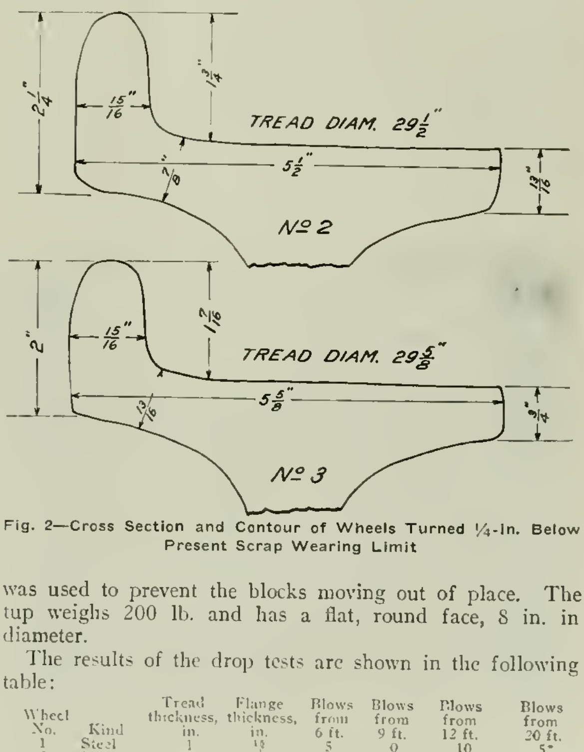

Fig. 2—Cross Section and Contour of Wheels Turned 1/4-In. Below Present Scrap Wearing Limit

was used to prevent the blocks moving out of place. The tup weighs 200 lb. and has a flat, round face, 8 in. in diameter.

The results of the drop tests are shown in the following table:

Wheel No.	Kind	Tread thickness, in.	Flange thickness, in.	Blows from 6 ft.	Blows from 9 ft.	Blows from 12 ft.	Blows from 20 ft.
1	Steel	1	15/16	5	0	10	5*
2	Steel	3/4	15/16	12	2	10	15
3	Steel	3/4	15/16	5	0	10	30
4	Steel	1	15/16	5	0	10	9†
44,997	Cast iron	..	13/16	..	..	1†	..
2,328	Cast iron	..	1	3†	..	..	..
158,891	Cast iron	..	1	1†	..	..	..

*Plate cracked after two blows. Flange not broken.
†Flange broken off.

Typical fractures developed under the drop test are shown in Fig. 3 and Fig. 4. None of the fractures showed any imperfections or irregularities in the metal structure. Wheel No. 1 developed only a slight elongation of the crack through the plate after it had received three additional blows from a height of 20 ft.

STATIC TESTS OF ONE INCH SECTIONS

Sections one inch thick were cut from each of the steel wheels and tested in a Riehle testing machine in a manner which is shown, with the plate removed, in Fig. 5. This arrangement provides a loading, which produces a thrust

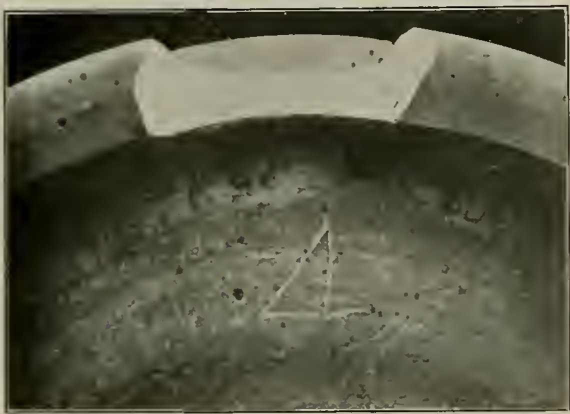

Fig. 3—Failure of Steel Wheel No. 4

in a direction parallel to the axis of the wheel similar to that which occurs in service. A clearance was cut in the lower end of the ram, causing the load to be applied the same distance from the tread in each case.

The results of these tests are as follows: Specimens from wheels numbered 1 and 4, whose treads had been turned to the present scrap wearing limit, broke under loads of 40,450 lb. and 34,720 lb. respectively. Specimens from wheels numbered 2 and 3, whose treads were turned 1/4 in. below the present scrap wearing limit, broke under loads of 22,540

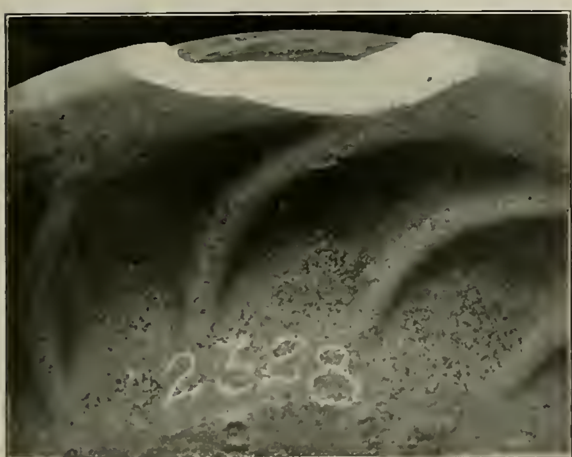

Fig. 4—Failure of Cast Iron Wheel No. 2328

lb. and 24,900 lb. respectively. The character of the failures are shown in Fig. 6.

CONCLUSIONS

The results showed a decided superiority of steel over cast iron wheels under the drop test. Of the three cast iron wheels tested, the best showing was made by the one which had the flange broken off after three blows of a 200-lb. tup from a height of 6 ft., whereas the only steel wheel whose flange was broken, failed after nine blows from 20 ft. Fifteen and thirty blows from 20 ft. caused no failure of the two steel wheels which were turned below the present limit.

These results indicate that a reduction of the thickness of the tread does not affect the strength of the flange in rolled steel wheels.

The failures of the 1-in. sections were similar, in that all broke in the same way at about the same place. In no case did the break occur at the throat of the flange or at the

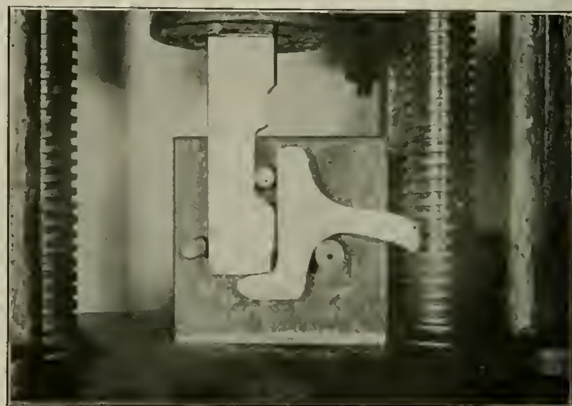

Fig. 5—Manner of Applying Load in Test of 1-in. Sections

thinnest section of the tread, but to one side of the thinnest section, toward the center of the tread.

The results of the drop tests indicate that the rolled steel wheels with treads turned 1/4 in. below the present scrap wearing limit and flanges of the minimum allowable thick-

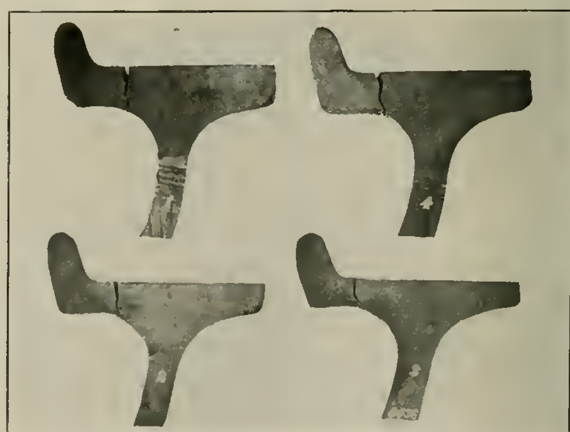

Fig. 6—Failures of 1-in. Sections Taken From Steel Wheels.

ness, have decidedly stronger flanges than cast iron wheels the flanges of which are worn to the minimum allowable thickness.

The nature and similarity of the failures of the 1-in. sections indicate that there is no weakening effect on the flange proper, caused by reducing the tread thickness. There is, however, a weakening of the tread due to its own reduced section.

Master Boiler Makers' Convention

Reports and Discussion; Brick Arches, Ash Pans, Threading of Radial Stays, and Other Subjects

A PARTIAL report of the proceedings of the convention of the Master Boiler Makers' Association, held in Chicago May 26 to 29, was given in the June issue of the *Railway Mechanical Engineer*, which also contained a list of the newly elected officers of the association. In addition to the addresses and papers given in the June issue, other reports of committees were offered to the convention and discussed by the members.

APPLICATION OF BRICK ARCHES

The minimum distance between the grates and the lower part of the arch at the throat sheet for different classes of locomotves depends upon the local conditions; that is, the grade of coal being used, whether it fills up badly or not; and whether the firemen have been taught to shake grates and keep the fire worked down. There are a great many engines which have eight inches as a minimum distance between the grates and the lower part of the arch, and the railroads are getting along very successfully with it.

The proper distance from the door sheet to the top of the brick arch and from the crown sheet to the top of the brick arch for various classes of locomotives is also a local condition. Arches have been run in a great many cases as close to the crown sheet at 11 in. with good results, but some railroads insist that the arch shall not be closer than 16 to 18 in. The distance from the door sheet to the top of the arch is a distance varying greatly, depending upon the length of the firebox. The arch should be run as long as possible in all cases and the top of the arch should be up higher than the top of the door.

The report was signed by L. M. Stewart (A. C. L.), chairman.

An individual report on this subject was submitted by E. W. Young, general boiler inspector, C. M. & St. P., an abstract of which is given below.

It is impossible to set any figure for the minimum distance between grates and the lower part of arch tubes for different classes of locomotives, as so many variables must be taken into account. The distance from the grates to the lower part of the arch tube may be less with a throat sheet that sets back at an angle from the vertical than for a throat sheet which is vertical. It may be less where the grate is flat, than where there is a steep pitch of the front end of the grate, or it may be less in a short firebox than in a long firebox.

The distance from the grates to the lower part of the arch tube may be less in a compound locomotive with its mild draft than in a simple locomotive with its sharp draft. It may be less with one grade of coal than with some other grade.

On account of the variable conditions, it is impossible to set any figure. A good rule and a simple one may be stated as follows: Locate the arch tubes as high above the grates as the design of the firebox will permit. In some cases the arch tubes have had to be located as near as 8 in. to the grate, and yet satisfactory results have been accomplished; however, better results will be obtained if the throat sheet be such that the distance of 18 in. can be obtained between the grates and the arch tubes. The proper distance from the door sheet to the brick arch in various classes of locomotives is just as difficult to determine as it is to answer the first question. One answer might be stated as follows: The brick arch should approach the door sheet as near as possible without restricting the area between the arch and the door sheet, to a figure below the gas area through the flues. It is very seldom, however, that we find a case where the arch can be run as close to the door sheet as the above rule would dictate, due to the fact that under such a condition the gas area between the arch and the crown sheet is unduly restricted. It might be stated that an arch may be built back to within 24 in. of the door sheet, provided conditions other than the relation of the arch to the door sheet will permit.

A good rule in connection with arch designs is that an arch should be as long as conditions will permit, and it is usually the case that these conditions must be studied from two or three angles before we can decide just what the length of the arch shall be, or what the distance shall be between the arch and the door sheet. It would be very much easier to get an ideal arch if the arch were first designed and then the firebox built around it. If the latter condition existed, it would be very easy to answer the two questions, and they would read about as follows: The grates should be placed 18 in. below the front end of the arch tubes. The door sheet should be placed about 24 in. from the back end of the arch. It should be understood, however, that the above two specifications can rarely be made use of for the very reason that arches are built into fireboxes instead of fireboxes built around arches.

Arch tubes must be so located in the flue sheet that there will be access to the front end of the arch tube through the waterleg. In order to get this access through the waterleg, and through a plug hole in the outside throat sheet, arch tube locations are often found to be impracticably low and in such instances a special spacer block is used to elevate the front course of arch brick, so that practical firing clearance is obtained.

The distances discussed above as found on the different types of locomotives used on the Chicago, Milwaukee & St. Paul, and also on the United States Standard locomotives, are shown in the following table:

Chicago, Milwaukee & St. Paul Railway

Type	Distance between grates and lower part of arch tube, inches	Distance from door sheet to brick arch, inches
1-5	13½	45½
G-4	18	37
A-1	16	49
A-2 Straight top	13½	53½
A-2 Slope top	14	44½
B-4 Wide firebox	14½	64½
B-4 Narrow firebox	11½	67
G-6	13	46
K-1	24	59
L-2	23½	49
U. S. Standard Locomotives		
0- 6-0	10	28
0- 8-0	10	37
4- 6-2-A	13	53
4- 6-2-B	15	47
2- 6-2-A	13½	52
2- 8-2-B	15	47
4- 8-2-A	15	46
4- 8-2-B	15	42
2-10-2-A	14½	42
2-10-2-B	15	59

The use of syphons in the place of arch tubes will, in very many cases, permit of considerably better firing clearance than can be obtained where arch tubes are used. There may be many cases of firebox construction, in which an arch on syphons will be practical, while arches on arch tubes would be impracticable. Syphons make a good foundation for a brick arch, and on account of being so substantial they make a practical device to take the place of arch tubes.

DISCUSSION

The discussion developed the fact that there was considerable difference of opinion regarding the proper location of the arch. The point was brought out, however, that it is largely governed by local conditions. It is considered necessary to have the area between the arch and the crown or door sheet from 10 to 25 per cent greater than the area through the tubes.

DESIGN OF ASH PAN AND DRAFT APPLIANCES

Your committee has failed to discover a recognized rule for designing ash pans. The result of our investigations indicates that methods are largely the result of experiments which have developed designs which seem best suited to the type of locomotive and condition of service. The objective to be attained was a self-cleaning arrangement of sufficient storage capacity to prevent the necessity of dumping the ashes except at regular ash pan cleaning points; and to prevent the cinders from burning and warping the pan. The lower parts are designed to be practically air tight, air for draft being admitted at the upper parts only. Ash pan air inlets of eight classes of locomotives averaged 14 per cent of the grate area which, from information obtainable, seems to be about the average air opening in ash pans for coal burning engines.

With the modern wide firebox, pans are made wide at the top, projecting several inches beyond the mud ring with vertical sides to prevent sparks from falling or being blown out by side winds. These upper plates are sloped toward the hopper or storage part so that cinders will slide to the hopper. There seems to be a tendency to sacrifice this slope to obtain greater draft opening, which has resulted in some instances in the cinders piling up on the wings and shutting off the draft, as well as causing stuck grates and burned grates and connecting bars. Therefore the slope from the hopper to the edge of the pan should be not less than 30 degrees and rather than lose this slope, it is better policy, if possible, to get increased opening from back or front.

When locomotives are being designed, the ash pan should be considered and provided for as an important part of the machine, and not as something to be hung on after the locomotive has been set up. The modern ash pan is expensive to construct and still more expensive to maintain, and the greatest possibility of improvement seems to be in the designers who may find it practicable to change the frame lines or other parts sufficiently to give relief where it is greatly needed.

MAINTENANCE OF ASH PAN

Slides, hoppers and dumps should be maintained in an operative condition. Grates should be maintained in first-class condition. Broken, burned or warped grates should not be allowed in service. One bad grate often causes damage to a whole section and also causes waste of fuel and damage to the ash pan.

No air openings should be allowed in the ash pans except those provided for in the design. This is particularly important in the case of oil burning locomotive draft pans, for the reason that air leaks permitted at other points than those designed usually result in brick work troubles as well as interfering with the proper steaming of the locomotive.

Air leaks at the lower parts of coal burning locomotive ash pans are extremely undesirable and annoying, not only on account of burning and warping the plates of the ash pan, but particularly on account of sparks dropping and causing fires along the right of way. It is a mooted point whether fires set from locomotives are not more frequently from the pans rather than from the stack.

FRONT END DRAFT APPLIANCES

The method of determining the design of front end draft appliances has, no doubt, as its basic principle, what was known as the Master Mechanics' front end, and like other parts, constant experiments and experience develop a type of front or setting to suit the conditions.

All parts of ash pan and front end appliances should be carefully fitted and securely bolted in place so that there is no reasonable probability of any part becoming displaced, and should be maintained at all times in first-class condition, each part performing its full function strictly in accordance with the design, particularly draft openings and passages which govern the flow of air and gases through the firebox flues and smoke arch. Dampers which are designed to be operated should be maintained in an operative condition and air admitted only at such points as the drawings provide for. Draft passages should be maintained so that all the draft will pass through those channels, which is not the case if loose or poor fitting plates are allowed. Draft appliances, which include deflecting plates, nozzle, petticoat pipe and stack, may be designed and adjusted to thoroughly clean cinders from front ends, and because plates were not well fitted, leaks direct to the stack may be sufficient to defeat the object of the design, causing cinders to accumulate in the front end, sometimes resulting in burning and warping front end rings and doors and overheating the lower joints of exhaust and steam pipes and developing leaks at those parts.

FRONT END LEAKS

The committee is of the opinion that positively no air leaks should be permitted and that where front ends show indications of burning on account of the combustion of cinders, it is just as often the result of poor fitting plates and air leaks as it is of faulty design or of wrong adjustment of draft appliances. We also incline to the opinion that we should make use of the autogenous welding process to secure permanently to the smoke arch and flue sheet a suitable sheet iron border to which to bolt deflecting plates. This border may be spot welded when being applied or welded in solid. At any rate, it can be an absolutely tight fit, in fact, air tight, if desired. An arrangement of this kind will expedite the work of applying or removing deflecting plates and simplify front end inspection. Petticoat pipes should be maintained to practically a true circle free from holes or indentations, and be securely held in central position between nozzle and stack.

As an item of interest to this association, and to give an idea of the general dimensions of draft openings, the following is given. We find in eight different classes of coal burning locomotives the following comparative dimensions of draft passages:

Eight Coal Burning Locomotives.—Ash pan air inlets equal 14 per cent of grate area, or 39.5 per cent of grate opening, and is 4 per cent more than flue opening area. From this it would appear that pan opening and flue opening are practically the same, while stack area is about 10 per cent of flue opening area.

Seven Oil Burning Locomotives.—These have the same stack opening, flue opening and grate area. They have no grates, but the air inlets through the fire or brick pan, also called the draft pan, are 28 per cent less than the flue opening area, and are 69 per cent, or a little more than twice the stack opening. The comparatively small air openings to the fire in oil burning engines compared to coal may raise the question of whether or not we are allowing too much air to the coal burner, especially with a clean fire. We are of the opinion that the size and location of these openings have been worked out principally by experimental process and, while perfection may not have been attained, when we observe a good steaming oil burner at work one is pretty apt to conclude that there is not much room for improvement.

The effect of proper upkeep of ash pan and front end appliances is to save fuel and maintaining a high standard of condition of those parts saves labor, and effects an economy. Like many other economies not reducible to plain figures, we must accept the above statement because we know that well maintained draft appliances and ash pans do fully perform their functions of furnishing the necessary drafts for economical combustion of the fuel and prevent fires being set out and the destruction and loss of property, which is an important economical consideration. Well fitted and well secured parts of the draft appliances reduce the liability of displacement and failure on account of not steaming and loss of fuel due to poor steaming, and also reduce the necessity of constant changing of front end draft appliances, which is another considerable economy. Finally, well maintained draft applainces may well be considered the difference between a satisfactory, efficient locomotive, which everyone appreciates, and a poor steaming inefficient machine that no engineer wants to run.

The report was signed by Geo. Austin (A. T. & S. F.), chairman; E. J. Nicholson (C. & N. W.), F. Beyer (Penn. Lines), H. F. Weldin (Penn..) and H. B. Nelson (Mo. Pac.)

DISCUSSION

Methods of eliminating the leaks around the steam pipe holes in the front ends were discussed at length. The best results were said to be secured by welding a plate around the opening.

One member told of results which had been secured by the use of cast steel ashpans. He submitted an estimate of cost showing the expense of applying and maintaining sheet steel pans for 15 years to be $915, while the corresponding cost of cast steel pans was $214.

BRACING LOCOMOTIVE TENDERS

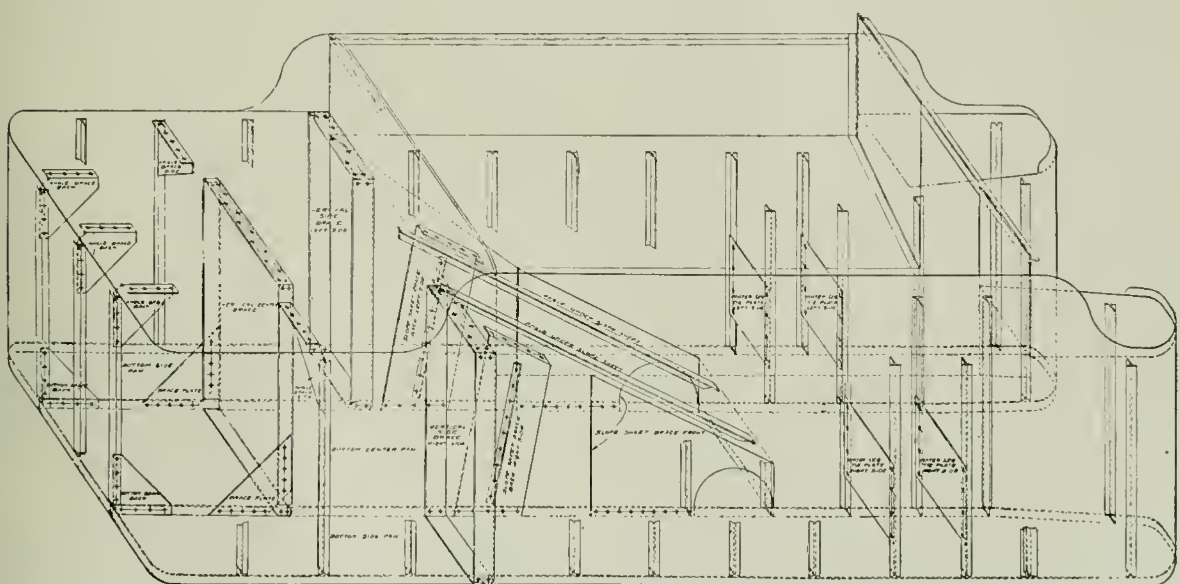
The object of bracing locomotive tenders is to make them sufficiently strong to stand the stresses that take place when the engine is in motion and to prevent the sides and back of the tank from bulging outward. To do this braces are applied on the interior of the tank, and anchor lugs are provided to stop the tank from moving on the tender frame.

What then is the best method of doing this work? Our opinion is the application of T-bars 3 in. by 3 in. by 3/8 in. on sides and back spaced about 24 in. apart in a vertical position, the length of the bars to be equal to the height of the tank from bottom to top, these bars to be riveted with not less than 5/8 in. diameter rivets spaced about six inches apart, zigzag.

The top of the tank at the rear end is braced by the application of T bars riveted to the under side with gusset plates rivetted on the ends. The slope sheet in the coal space is braced by the application of two T bars riveted to the under side, also supported by stay plates placed vertically and riveted to slope sheet and the tank bottom reinforced by angle bars. Dasher or splash plates of 1/4 in. or 5/16 in. thickness are used for the purpose of frustrating the rush of water in the tank; they also form a brace for the top and bottom of the tank. One plate is placed in the center between the coal slope sheet and the back of the tank. Two plates are placed on each side, these are riveted to the top and bottom of the tank. The center dasher plate is flanged on the sides and riveted to the top of the tank, also gusset plates are applied at the bottom and riveted, which gives the dasher plate added strength. In order to make a permanent job all braces used in the construction should be riveted and not bolted.

This method of bracing is recommended for all rectangular tanks made from steel plates of 5/16 in. thickness or less, because it gives better service than the old method of applying longitudinal angle iron bars with cross stays. Also it has the tendency to eliminate leaky rivets in anchor lugs. We are of the opinion that when *weight* is not taken in account when designing locomotive tenders if the tanks were made from heavier material, say steel sheets 3/8 in. thick, it would greatly simplify the matter of bracing as heavier material could be used which no doubt would be more satisfactory. However, with 1/4 in. plates for tank sides and top, and 5/16 in. plates for the bottom of the tank this is the best method of bracing, as it braces the tank in all its principal parts, and still leaves plenty of space on the interior so that the inspector can move around easily to make his inspection or repairs when necessary.

The report was signed by Thomas Lewis (L. V.), chairman; E. J. Sweeney (N. Y. C.), J. J. Orr (D. L. & W.), J. P. Malley (St. L. & S. F.) and J. T. Johnson (A. T. & S. F.).



Recommended Method of Bracing Rectangular Tenders

DISCUSSION

The superiority of vertical over horizontal braces was generally conceded. One of the principal sources of trouble reported was the loosening of the transverse braces. This can only be overcome by good workmanship and by substituting rivets for bolts in these parts.

ACETYLENE WELDING

The committee in presenting this paper realized that this topic has been before the convention for several years and has been thoroughly threshed out by the members. We find it at this time very difficult to write up any new facts on this subject. However, we believe the following information will be beneficial.

APPARATUS

Many shops a few years back were equipped with portable generators, using what is termed "high pressure." Later, new apparatus was installed and shops were piped throughout for the acetylene and oxygen, using low pressure, which at this time is in pretty general use throughout the United States. A number of shops still use the oxygen and acetylene gas furnished in holders with the oxygen holders containing 1,800 to 2,000 lb., and the acetylene holders from 200 to 250 lb. pressure. With this method it is necessary to have different regulators for the oxygen as well as the gas for each wolder. But where the low pressure system is used, it is only necessary to have the regulators where the gas is generated and the oxygen manifolded. It is the opinion of the committee that the low pressure system piped throughout the different departments will give the best results.

WELDING TORCHES .

There are several different makes of welding torches on the market, and while they will all do good work with an experienced operator, some torches are more quickly regulated and do not back-fire as readily as some other makes. In most all cases the welding tips are made of copper and give much better results than the brass.

CUTTING TORCHES

Many different styles of cutting torches are on the market. Some will back-fire readily, where with others it is almost impossible to make them back-fire, and in some cases both with the welding and cutting torches where they do back-fire, can be ignited quickly from the heated iron without readjusting; while, with other makes, it is necessary to shut off and start all over. This causes a loss of time as well as a waste of material.

Different methods are seemingly getting good results. The Chicago, Milwaukee & St. Paul are welding in all side sheets, bolting up securely, and applying stay bolts and rivets before welding. Cross-seams are welded by removing rivets, scarfing down, and welding up all holes and not removing any stay bolts. Door collars, inside and out; three-quarter door sheets, one-half flue sheets, top or bottom; full flue sheets; front sections of crown sheet; bottom patches of front flue sheet, 12 in. to 20 in. high, are all welded and all stay bolts and radial stays are cut off with the torch. In fact, we are doing everything in the line of welding we may find to do, and the sheets we are welding are standing up well and giving us no trouble. The only trouble at times is welding in patches in old side sheets, or where side sheets go to pieces rapidly due to poor water conditions. Where engines are in bad water territory, sheets do bulge between the bolts and at times the weld is pulled in two.

In the different railroad shops on such work as applying fireboxes, side sheets and door sheets, the welding in most cases is being done with the acetylene torch. Shops visited had both the acetylene and electric welding outfits, but were using the electric outfit mostly for welding flues, mud ring corners and roundhouse work, where the portable electric welding outfit will give good results.

Electric welding outfits have been installed for welding in all flues, mud ring corners, side sheets, cutting out the center and welding in new without removing mud ring rivets. It is also planned to do considerable firebox and boiler work with the electric welder, where flanges on front or back flue sheet are still good, cutting out the center and welding in new.

The report was signed by Henry J. Wandberg (C., M. & St. P), chairman; L. M. Stewart (A. C. L.), J. J. Davey (Nor. Pac.), John Harthill (N. Y. C.), P. F. Gallagher (B. & O.), and T. F. Powers (C. & N. W.).

DISCUSSION

The discussion brought out a great diversity of opinion regarding the advisability of welding firebox seams. Some condemned the practice as unsafe, while others contended that with proper care welded seams could be made stronger than riveted seams.

Some roads reported good results from welded tubes, others that the use of this practice had been a failure because of cracks in the bridges of tube sheets. All agreed that experience was essential for the production of satisfactory work. Some roads check the ability of welders by requiring weld specimens regularly each month; these specimens are then broken in a testing machine.

PROPER METHODS OF THREADING RADIAL STAYS AND TAPPING THE HOLES

The theoretical way to thread a radial stay is to make its thread align with the tap with which the holes in the crown and roof sheets are tapped. Experiments have proved that no better results are obtained from this method than where no attention was paid to the alinement. This is due to a slight variation in taps and threading machines and the tendency of the tap when tapping the roof sheet to assume a radial position in relation to roof sheet.

A practical method of tapping the holes is to use a double ended tap. However, good results are obtained with single ended spindle taps. It is very necessary that the tapping and applying of radial stays should have the same consideration as stay bolts in side sheets. The holes should be tapped with a suitable length tap so as to make a continuous thread. Radial bolts should be threaded in a machine equipped with a lead screw. If this is done there will be no trouble with entering bolts in crown sheet, on account of stripped threads.

The report was signed by H. J. Raps (I. C.) chairman and J. J. Keogh (C. R. I. & P.).

DISCUSSION

The threading of holes for radial stays from the outside was considered advisable due to the fact that the hole in the sheet next to the motor was slightly enlarged, and, if on the inside of the fire box it was difficult to make a tight joint. Practically all the members were of the opinion that it was a waste of time to try to get the same lead on the tap and on the stay as the variation in lead could not exceed half a thread or 1/24 in., which was easily compensated by the spring of the sheet.

CUTTING OFF STAYBOLT ENDS

In a shop that is equipped with crane facilities, where boilers are removed from frames and can be turned in any position, nippers can be used to good advantage. However, complaints have frequently been heard that the nippers do not make a good even end to drive, and it is very often necessary to go over the bolts and trim them with a chisel before driving The use of the chisel in cutting off stay ends can hardly be considered, as it will damage the thread on the bolt and in the sheet; it also elongates the holes.

We believe the acetylene is so far superior to this method that there is hardly any room for discussion. In using the oxy-acetylene process the bolts can be cut to a uniform length, with the boiler in any position. It leaves the bolt annealed for driving. In shops that are not provided with crane facilities, for boilers with narrow fireboxes, for cutting off scattered bolts, bolts applied in patches and radial stays, or where the boiler is on the frames and in an upright position and the bolts are applied from the inside, we believe the acetylene has no equal. The difference in cost will depend a great deal on the operator.

The report was signed by W. S. Larason (H. V.) and J. B. Tynan (W. & L. E.).

CO-OPERATIVE RESEARCH AND THE FUEL PROBLEM*

BY CAPTAIN O. S. BEYER, JR., U. S. A.

The influence of such fundamental items of railway operating expense as the cost of fuel and labor on the direction of developments, both mechanical and economical, in the industry has always struck me as a most important subject for consideration. When practices of locomotive and car construction or train operation of America are compared with those of Europe, striking differences are revealed. Intensive studies of the effect of basic cost items indicate more clearly than anything else the reasons why, for instance, the superheater, the mechanical stoker, the brick arch, the feed water heater, as well as the composite modern types of American locomotives themselves, assume tendencies in this country differing quite markedly from analogous tendencies in other countries. In fact, I do not think it an exaggeration to say that the whole course of American railway development is greatly influenced by the cost of fuel and labor. The problems created by the railway labor and fuel situation have a large economic background, which is very fundamental in its relation to the whole transportation industry. An analysis of this phase of the problem is a big subject in itself and cannot be elaborated here. Certain elements of the problem, however, are amenable to certain forms of solution which are becoming more and more important. Briefly, these particular solutions may be characterized as possible methods for increasing the productivity of the agencies creating the operating cost in question. To increase, at it were, the yield of fuel, to get more out of every pound, to utilize it more efficiently, is of more importance today than it ever was, and will become more and more so as each increment added to its cost places an additional premium on its efficient use.

The time has come, in my estimation, to survey the railway fuel situation, its problems and possibilities, with a thoroughness never attempted before. This association has succeeded, after several years of strenuous effort, in effecting a co-operation between many interests, whereby a piece of fuel research was accomplished which undoubtedly some day will be considered the inception of a movement contributing most extensively to the solution of the present-day railway fuel problem.

Since the committee on Fuel Tests handed in its report on the Test of Six Grades of Coal from a Franklin County, Illinois, Mine, at the 1917 convention, much has transpired. We have come to realize, as never before, the true significance of the scientific method in the solution of the problems in our industries, as compared with the slow, dull, expensive practices of cut and dry, rule-of-thumb, or by whatever other term the awkwardness of much of the industrial progress of the past might be characterized. Perhaps no other event of international importance than the war for democracy has served to emphasize this so well. A new realization has developed among scientists, engineers, administrators, statesmen, concerning the value of the *scientific method* in the solution of industrial problems.

It is my intention to point out as far as this association is concerned that its greatest opportunity lies in the direction of continuing and developing as rapidly as possible the lead it took when, through its Committee on Fuel Tests, it brought together the many interests and secured the necessary funds which eventually made possible the report already mentioned. This was but a beginning and a beginning under most adverse circumstances. As all this is indicative of what co-operation in research really means, the question which arises is, what can be done in this direction on behalf of contributing to the solution of the railway fuel problem? The Fuel Conservation Section of the United States Railroad Administration thoroughly appreciates the activities of this association. The extensive fuel and locomotive test facilities, but so meagerly used, at the Illinois, Iowa and Purdue experiment stations need but to be referred to. It seems, therefore, that the whole question reduces itself to one of initiative with the International Railway Fuel Association.

All these remarks would perhaps have little appeal were there not many important railway fuel problems pressing for solution. Consequently, in support of the remarks I have made above, the following fuel investigations, which can only be carried on in a sufficiently comprehensive way by co-operative research, are submitted for consideration by way of conclusion:

(a) *The Chemistry of Combustion.*—The theory of combustion as it exists today, applied to the burning of locomotive fuel, is incomplete, and fails to explain the occurrence of some very important phenomena, especially with reference to fires of varying thicknesses, clinkering, coking, the nature of the higher hydrocarbon products of combustion, etc.

(b) *Firing Practices.*—The purpose of this should be to determine the most economical combination of practice, devices and kinds of fuel in different territories possible. Maximum boiler capacities resulting from these combinations as well as relative smoke production should be determined.

(c) *Heat Absorption.*—A detailed experimental, as well as mathematical study of the process of heat transfer in the locomotive boiler should be made, especially with reference to the distribution of the heating surfaces between tubes, flues, combustion chamber and firebox.

(d) *Chemical and Physical Nature of Exhaust Gases.*—A splendid opportunity exists to investigate the products of combustion as they appear in the locomotive front end after they have done their work. The results might go a long way towards explaining the mysterious "unaccounted for" losses in the heat balance.

(e) *Accurate Smoke Measuring and Indicating Devices.*—Jointly with the foregoing investigation, attempts should be made to develop accurate smoke measuring and indicating devices.

(f) *The Drafting System.*—An investigation of the entire drafting system of the modern locomotive cannot be made too soon. The proportioning of ash pan opening, grate opening, gas areas between the end of the arch and the door sheet, of flues, tubes, and superheater damper, the space under the smoke box diaphragm, and the smokestack should all be carefully determined and general values for them expressed in empirical formulae having a wide range of application. This is far from accomplished today.

(g) *The Law of Resistance to Flow of Gases.*—Detailed study of the flow of gases through the locomotive boiler reveals possibilities for reducing their resistance to flow and perhaps at the same time suggests ways for effecting greater interchange of heat between these gases and the heating surfaces.

(h) *Radiation Losses.*—Very little is known about this important item, and in consequence losses resulting there-

*Abstract of a paper presented before the convention of the International Railway Fuel Association at Chicago, May 19-22, 1919.

from are thrown in with those considered as "unaccounted for." It is entirely possible to develop data on this point, especially with the perfected methods of pyrometry now in existence.

(i) *Locomotive Feed Water Heating.*—After a long period of development, the locomotive feed water heater is at last becoming available. As it stands today, it is perhaps one of the finest examples of the results of scientific experimentation applied to the solution of locomotive problems. The good work, however, should not stop. As long as feed water can be heated to still higher temperatures, as long as there are heat units still going up the stack which might be saved, the feed water heater investigation should continue.

(j) *Locomotive Boiler Performance.*—The whole general subject of locomotive boiler performance needs more study. Unfortunately the available reliable test data covering a sufficient range of performance is entirely too limited for this purpose. Consequently little opportunity exists for developing an extensive and well founded theory for locomotive boiler design.

(k) *Further Study of the Superheater.*—The superheater deserves further investigation. The work done at Purdue and especially at Altoona with varying lengths and diameters of superheater units has certainly contributed most valuable knowledge on this subject. As a continuation of this work the correlation between degree of superheat and boiler pressure as reflected in the steam economy of the engine should be worked out over wider ranges and mathematical determinations verified. Another very important question coming within this field is the effect of varying degrees of moisture in the steam entering the superheater.

(l) *Fuel.*—Investigation concerning fuel should primarily contemplate securing data on the relative steaming values of the fuel used in the railway service as determined from a complete series of boiler performances as well as maximum evaporative capacity tests. The data should also include information on the spark and smoke production of the various coals and their clinkering and honeycombing qualities, in order, if possible, to tie up practical performances of coals with the characteristics indicated by proximate and ultimate analysis and other laboratory tests of selected samples. The fuels which should thus be investigated are: (1), Typical coals from all important mining districts; (2), various commercial sized and some specially sized coals; (3), land stored, water stored and freshly mined coals; (4), powdered bituminous, anthracite, lignite and peat, together with combinations thereof; (5), oil, lignite, anthracite and bituminous coals, coke, peat, briquets and possible mixtures of these fuels.

Complete information as outlined would enable the railroads more clearly to specify desirable and necessary characteristics of fuel and to select fuels with far more intelligence than can now be done. It would enable them to determine with much greater accuracy the actual value of the various fuels available instead of solving this vital question by the unscientific methods now employed of "collective bargaining" between coal salesmen and fuel or purchasing agents. Some tests have been made to determine the relative steaming value of and the maximum capacity obtainable from certain typical locomotive coals and a limited number of different sized coals. One railroad, which has developed this data for coal used on its lines, has effected economies which have paid in one year over tenfold the cost of making the experiments.

It is entirely possible mechanically to prepare fuel in a highly pulverized form and burn it in a locomotive furnace. The machinery for doing this has been devolped and used with success. The next logical step is to determine accurately just what is the complete economic value of the utilization of pulverized fuel. The many general advantages which are bound to follow its use are, of course, recognized, but it is not known how much, for instance, the evaporation per pound of coal is increased at different rates of combustion. The heat balances over the complete range of boiler capacities of a few typical boilers fired with pulverized fuel have yet to be compared with the balances of these same boilers fired with ordinary fuel. And lastly, values as exactly as possible of the increase in capacity of the pulverized fuel fired boiler should be established. It is not yet possible completely and finally to judge the wisdom either of attempting to perfect or of widely introducing this system of combustion.

GAS WELDING SPRING BANDS

The cost per piece is a most important factor in determining the best process of welding when a large number of similar parts are required. For welding spring bands the oxy-acetylene process has given good results at the Rocky Mount shops of the Atlantic Coast Line.

The bands are formed to the required shape with a V-joint at one of the small sides and the welding done as shown in

Welding Spring Bands At Rocky Mount

the illustration. One operator welds five bands per hour at an average cost of 30 cents each for labor and material. Before the oxy-acetylene process was used these bands were welded at the forge, a blacksmith and helper welding two bands per hour at a cost of 57 cents each. A saving of 27 cents per band is thus effected.

Five Years Wandering in the Wilderness.—Pacific Electric box car 2586, which left the builders, American Car & Foundry Company, St. Louis, Mo., December, 1913, arrived on home rails (first appearance) May 18, 1919. It had made seventeen trips between the Middle West and Eastern States, three between Atlantic and Pacific ports, one trip between Colorado and Eastern states and two trips between Eastern states and Texas. On one road it stayed 108 days; another it visited nine times in one month. This is the last to arrive of ninety box cars bought in 1913.—*Pacific Electric Magazine.*

NEW DEVICES

A DEVICE FOR BREAKING IN LOCOMOTIVES

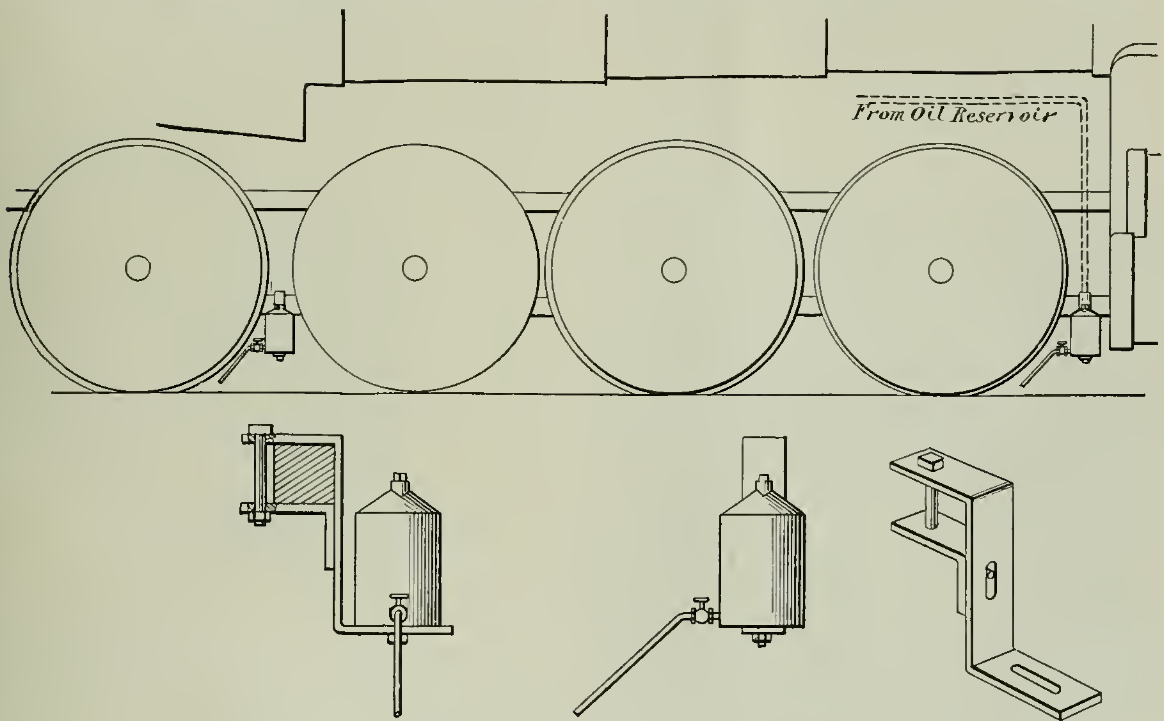
A device designed to permit the breaking in of a new or repaired locomotive on a short length of track near the shop is described in a patent granted to A. C. Hinckley, superintendent of motive power and machinery, of the Oregon Short Line at Pocatello, Idaho. It consists of a bracket attached to the locomotive frame and supporting a small oil reservoir having a discharge pipe extending down close to the rail directly in front of the wheel. The reservoir is filled through a hole in the top, and a valve located in the discharge pipe controls the flow of oil to the rail. When the device is used on oil-burning locomotives it may be connected to the oil tank, thus insuring a constant supply of oil without the necessity of refilling the reservoir.

This device is attached at several or all of the driving wheels and by means of the discharge of oil on the rail, under the wheel tread, causes them to slip and rotate rapidly but, because of the lack of adhesion of the wheel and the rail, the locomotive is moved along the track at a very slow speed.

By its use the driving wheels may be revolved at a speed equivalent to forty miles per hour while the locomotive itself does not move along the rack at more than three or four miles per hour.

This gives the same effect as a break-in trip in service and being near the shop at all times permits immediate adjustment as the operation of the locomotive indicates it may be necessary.

Breaking in and making adjustments at the terminal reduces the probability of engine failure on the road with the consequent delays to traffic.



The Breaking-in Device Attached at the Front and Rear Driving Wheels

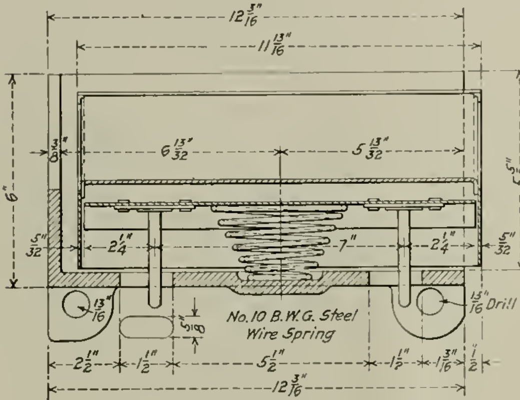
This method of breaking in locomotives is being used at the Pocatello shops of the Oregon Short Line with execelent results.

UTILITY STEAM OR COMPRESSED AIR HAMMER

In an article under this title, which appeared on page 372 of the June issue of the *Railway Mechanical Engineer,* the hammer was incorrectly described as a 30-in. Cincinnati special forge, operated either with compressed air or steam. The hammer should have been described as a general utility forge hammer which uses either compressed air or steam. This hammer is the product of the Sullivan Machinery Company, Chicago, Ill.

GREASE LUBRICATION OF LOCOMOTIVE DRIVING WHEEL HUBS

Excessive lateral motion between driving wheel hubs and driving boxes is a very serious defect as it is costly to repair and necessitates taking the locomotive out of service for a considerable period. The report of the chief inspector of locomotives for 1918 shows that 1,432 locomotives were taken out of service by federal inspectors for this defect alone.



Cross Section of Journal and Hub Lubricator

Despite the expense caused by excessive lateral motion and the fact that heating of the hubs is regarded as a frequent cause of overheated journals, the lubrication of driving wheel hubs is usually left to take care of itself. In order to overcome the objectionable conditions mentioned, a grease lubricator which feeds the lubricant to the hub face as well

Sheet Steel Cellar for Locomotive Driving Box

as the journals has been developed by I. Scranton, Decatur, Ill.

The device consists of two perforated plates, one to fit the journal and the other to bear against the hub liner. The grease rests on a solid plate inside the perforated plates and is supported by a coil spring which sets in a recess in the cellar and holds the plate against the journal and the hub, as shown in the drawing.

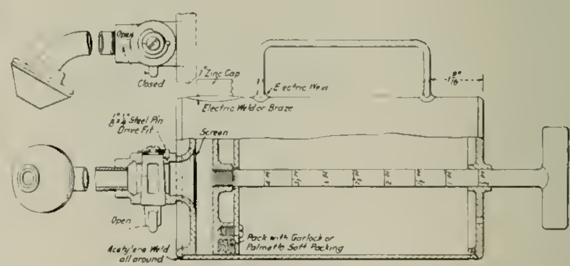
A recent improvement in the construction of the Scranton hub lubricating device consists in the elimination of the cast cellar. Two spreaders are used to form a base for the grease cellar to rest on, these being held in place by the usual cellar bolts. Fastened to the spreaders is a sheet which has a recess in which the supporting spring rests. Doing away with the cast cellar allows the perforated plate to come up higher on the journal, increasing its width 3 in. on a journal 10 in. in diameter and also increases the area of the sheet which lubricates the hub. The use of the spreader eliminates the trouble due to the box closing in on the cellar and facilitates the removal of the cellar. The Scranton hub lubricating device has been applied to several types of locomotives on the Wabash and service tests have shown that it reduces the lateral wear on driving boxes and hubs from 25 to 40 per cent.

A CYLINDER LUBRICATOR FILLER

A practicable lubricator of simple construction is the invention of G. W. Sturmer, a locomotive engineer, of Baltimore, Maryland, to whom a patent covering it has been granted. It consists of a cylindrical container having its interior surface finished to receive a piston which is attached to a rod passing through the cylinder head at one end and having a handle on its outer end. A packing held in place by a follower bolted to the piston gives a close contact to the cylinder walls. A handle is welded to the container body.

The central delivery passage, formed integral with one of the heads, is fitted with a delivery cock having an operating handle. A flexible filling pipe is attached to the outer end of the delivery passage and is provided with a nozzle fitted with a conical washer of compressible material. The supply opening is located in the body wall at the delivery end and can be tightly closed by a removable screw cap.

To operate the filler the piston rod is drawn out, (an atmospheric relief opening in the cylinder head permits this to be done easily), so that the graduations on the rod indicate that the volume of the space between the piston and the delivery cock is sufficient to contain the quantity



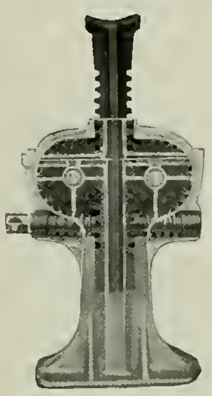
Lubricator Filler With the Delivery Cock Closed

of oil desired. The oil is then poured in through the supply opening, the screw cap replaced and tightened and the nozzle inserted in the filling hole of the lubricator. The piston is then pushed in, thus forcing the oil into the lubricator. A strainer of fine wire gauze placed over the inlet to the delivery passage prevents any foreign matter from entering the lubricator.

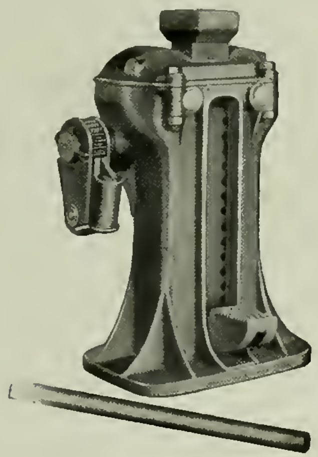
This filler provides an accurate, economical and safe means of filling a lubricator, as the graduations on the piston rod indicate the exact amount of oil delivered. The pressure on the piston, with the close contact of the conical washer at the lubricator, insures a constant flow of oil with a reduction of the waste experienced when filling a lubricator from a can and at the same time protects the operator from steam leakage through the lubricator throttle.

DOUBLE WORM DRIVE LIFTING JACK

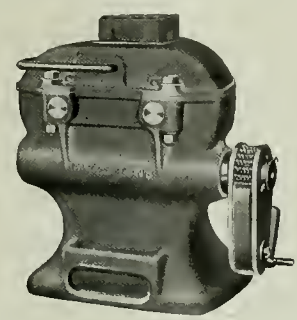
A new type of lifting jack is being manufactured by the Iron City Products Company, Pittsburgh, Pa., which is known as the Rees Double Worm Drive Lifting Jack. Instead of a single worm gear pinioned to a lifting bar the double worm principle is employed. In this design right and left hand worms are cut on the worm shaft, which mesh with right and left hand worm gears carrying heavy pinions. The lifting bar, which has a set of teeth on either side, is located between the pinions and is raised or lowered by the double action of the two gears with extremely small effort and without the loss of power due to the friction that is caused by an unbalanced thrust on the worm shaft and lifting bar.



Cross Section of Rees No. 1 Jack



General Purpose Jack



Car Journal Jack

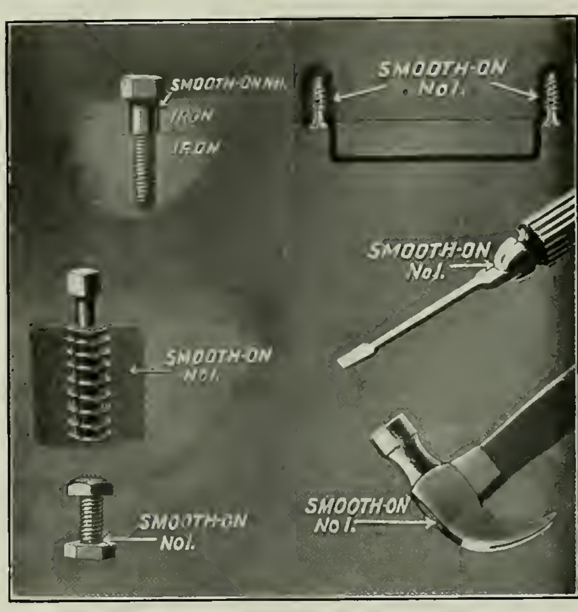
A number of different sizes and capacities of jacks designed with the double worm drive are being made. The car and general purpose jacks are made in a number of different heights and capacities, rating from 10 to 25 tons, while the jack shown in the sectional view is made in three heights, 9 in., 10 in. and 11 in., all having a rated capacity of 25 tons.

The simplicity and strength of construction of these jacks and the small number of working parts adapt them to rough usage, as there are only four working parts and no small parts to get out of order.

HANDY KINKS WITH IRON CEMENT

Some unique uses to which Smooth-On iron cement has been put are described by the Smooth-On Manufacturing Company, of Jersey City, N. J., and are shown in the illustration. This cement expands as it hardens and it is this property which makes it effective for the following applications.

The handles of hammers, which have become cracked and loosened may be strengthened and securely fastened in the tool by the use of Smooth-On. The cement is mixed with water to the consistency of putty and the handle dipped in it until that portion of the handle which enters the tool is covered and all the irregularities and cracks completely filled with cement. The inside surface of the hammer head is then thoroughly covered with cement and the handle pressed in. After wiping off any surplus cement and allowing the cement to harden, the hammer is ready for use. The handles of chisels, files, screw drivers and other tools may be treated in a similar manner.



A Number of Convenient Uses for Iron Cement

A method of securing expansion bolts or screws in concrete or a brick wall is also shown. A hole considerably larger than the bolt or screw is drilled and filled with cement. The bolt or screw is then inserted, twisting it as it is pushed in, and the cement allowed to harden before placing any weight upon it.

As a substitute for a lock nut or a lock washer this cement may be applied as shown in the top and bottom left hand illustrations. The cement must always be allowed to harden before any use is made of the parts so treated.

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

Subscriptions, including the eight daily editions of the Railway Age, published in June, in connection with the annual convention of the American Railroad Association, Section III—Mechanical, payable in advance and postage free: United States, Canada and Mexico, $2.00 a year; Foreign Countries, $3.00 a year; Single Copy, 20 cents.

WE GUARANTEE, that of this issue 10,000 copies were printed; that of the 10,000 copies 9,000 were mailed to regular paid subscribers, 80 were provided for counter and news company sales, 206 were mailed to advertisers, 27 were mailed to employees and correspondents, and 687 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 62,610, an average of 8,659 copies a month.

THE RAILWAY MECHANICAL ENGINEER is a member of the Associated Business Papers (A. B. P.) and the Audit Bureau of Circulations (A. B. C.).

The new shops of the Pullman Company at Ludlow, Ky., were destroyed by fire on the night of May 20, together with six sleeping cars; estimated loss, $225,000.

The new shops of the Canadian National at Leaside, near Toronto, Ont., were opened for business a few weeks ago. The plant consists of a roundhouse, powerhouse, administration building, locomotive repair shop and car repair shop.

The use of heavy guns on railroad cars is engaging the attention of officers of the War Department at Washington in connection with their studies of the defenses of the Chesapeake bay district. Coast artillery officers are now conferring with railroad officers regarding the practicability of constructing permanent spurs from the main lines to the coast around Chesapeake bay. The vicinity of Roanoke, Va., is also being studied in connection with its importance to the defense of the national capitol. Several heavy howitzers and rifles mounted on cars already are available, other units are under construction and still others will be brought back from France.

The Federal Board of Vocational Education has issued a 35-page pamphlet, for the benefit of disabled soldiers, sailors and marines, telling what kinds of work they may be able to find in the field of transportation, including steam railroads, street railways, wagons, automobiles and ocean steamships and harbor craft. The government stands ready to educate and re-educate disabled men, and the educational department in the military and naval hospitals will give inquirers all needed information. This pamphlet is designed to aid individuals in choosing a vocation. It tells what kind of work must be done, and what qualifications are required, in the case of telegraphers, train despatchers, station agents and other station workers, yardmasters, clerks, ticket examiners and traffic department employees; shop work, boiler making, blacksmithing, electrical work and car repairs; track work and train work. The work on electric railways and on ocean and harbor vessels is described in the same way. The Federal Board of Vocational Education, which is ready to give all possible aid to disabled soldiers, has offices in Boston, New York, Philadelphia, Pittsburgh, Baltimore, Washington, Atlanta, New Orleans, Dallas, St. Louis, Cincinnati, Chicago, Detroit, Kansas City, Minneapolis, Denver, San Francisco and Seattle.

MEETINGS AND CONVENTIONS

New York Electrical Society.—Edwin B. Katte, chief engineer of electric traction of the New York Central, has been elected president of the New York Electrical Society. Mr. Katte was graduated from Sibley College, Cornell University, with the degree of M.E. in 1893, and with the degree of M.M.E. in 1894. He began railroad work on the New York Central & Hudson River in 1896. In 1903 he was appointed electrical engineer, which carries with it the secretaryship of the electric traction commission. In 1906 he was appointed chief engineer of electric traction of the New York Central & Hudson River. Mr. Katte is a past vice-president of the American Society of Mechanical Engineers.

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations:

Air-Brake Association.—F. M. Nellis, Room 3014, 165 Broadway, New York City.

American Railroad Association, Section III—Mechanical.—V. R. Hawthorne, 431 South Dearborn St., Chicago.

American Railroad Master Tinners', Coppersmiths' and Pipefitters' Association.—O. E. Schlink, 485 W. Fifth St., Peru, Ind.

American Railway Tool Foremen's Association.—R. D. Fletcher, Belt Railway, Chicago. Convention, August 27-29, Hotel Sherman, Chicago.

American Society for Testing Materials.—C. L. Warwick, University of Pennsylvania, Philadelphia, Pa.

American Society of Mechanical Engineers.—Calvin W. Rice, 29 W. Thirty-ninth St., New York.

Association of Railway Electrical Engineers.—Joseph A. Andreucetti, C. & N. W., Room 411, C. & N. W. Station, Chicago.

Car Foremen's Association of Chicago.—Aaron Kline, 841 Lawlor Ave., Chicago. Meetings second Monday in month, except June, July and August, Hotel Morrison, Chicago.

Chief Interchange Car Inspectors' and Car Foremen's Association.—H. J. Smith, D. L. & W., Scranton, Pa.

International Railroad Master Blacksmiths' Association.—A. L. Woodworth, C. H. & D., Lima, Ohio.

International Railway Fuel Association.—J. G. Crawford, 542 W. Jackson Blvd., Chicago.

International Railway General Foremen's Association.—William Hall, 1061 W. Wabasha Ave., Winona, Minn. Convention September 2-5, 1919. Hotel Sherman, Chicago.

Master Boilermakers' Association.—Harry D. Vought, 95 Liberty St., New York.

Master Car and Locomotive Painters' Association of U. S. and Canada.—A. P. Dane, B. & M., Reading, Mass.

Niagara Frontier Car Men's Association.—George A. J. Hochgrebe, 623 Brisbane Bldg., Buffalo, N. Y. Meetings, third Wednesday in month, Statler Hotel, Buffalo, N. Y.

Railway Storekeepers' Association.—J. P. Murphy, Box C, Collinwood, Ohio.

Traveling Engineers' Association.—W. O. Thompson, N. Y. C. R. R., Cleveland, Ohio. Convention, September 16-19, Hotel Sherman, Chicago.

PERSONAL MENTION

GENERAL

C. I. Evans, chief fuel supervisor of the Missouri, Kansas & Texas of Texas, has been appointed chief assistant mechanical superintendent of the Missouri, Kansas & Texas and associate roads, with office at Denison, Texas, in charge of maintenance of equipment.

H. P. Anderson, mechanical superintendent of the Missouri, Kansas & Texas and the Missouri, Kansas & Texas of Texas, with office at Denison, Texas, has been transferred to the staff of the federal manager at St. Louis, Mo., in charge of executive and administrative matters of the mechanical department on the roads under the jurisdiction of C. N. Whitehead, federal manager, at St. Louis.

MASTER MECHANICS AND ROAD FOREMEN OF ENGINES

F. S. Kelly, master mechanic of the Louisiana division of the Texas and Pacific, with headquarters at Gouldsboro, La., has been transferred to Marshall, Texas, succeeding R. E. Roe, resigned.

W. L. Robinson, superintendent of fuel and locomotive performance of the Baltimore & Ohio, with headquarters at Cincinnati, Ohio, has been promoted to division master mechanic of the Illinois division, at Washington, Ind.

CAR DEPARTMENT

J. McWood has been appointed master car builder of the Grand Trunk, Eastern Lines, with headquarters at Montreal, Que., succeeding J. Hendry, assigned to other duties.

SHOP AND ENGINEHOUSE

Joseph Chidley, assistant superintendent of motive power of the New York Central, Lines West of Buffalo, at Cleveland, Ohio, has been appointed superintendent of motive power of the Lines West, succeeding D. R. MacBain.

D. R. MacBain, superintendent of motive power of the New York Central, Lines West of Buffalo, has been appointed assistant general manager of the Lines West, with headquarters at Cleveland, Ohio.

Herman F. Noyes, traveling engineer of the Maine Central, has been appointed superintendent of fuel economy of that road and the Portland Terminal, with office at Portland, Maine.

Charles J. Scudder has been appointed superintendent of shops of the Delaware, Lackawanna & Western, with headquarters at Scranton, Pa., succeeding Joseph Grieser assigned to other duties.

PURCHASING AND STOREKEEPING

W. C. Bower, purchasing agent of the New York Central, with headquarters at New York, has had his jurisdiction extended over the Lines West of Buffalo, succeeding G. R. Ingersoll, who has resigned to engage in other business.

Dwight C. Curtis, inspector of stores on the Chicago, Burlington & Quincy, with headquarters at Chicago, has been promoted to supervisor of stores of the Northwestern region, with the same headquarters, succeeding J. E. Mahaney, resigned to accept service elsewhere.

Horacio V. Garza has been appointed assistant purchasing agent of the National Railways of Mexico, with office at New York, succeeding F. P. de Hoyos, who was local purchasing agent. Mr. de Hoyos remains as general agent of the National Railways of Mexico as well as purchasing and general agent of the Southeastern Lines of Mexico.

SUPPLY TRADE NOTES

R. P. Lamont, president of the American Steel Foundries, Chicago, has authorized the announcement that a contract for the purchase of the Griffin Wheel Company has been signed.

Edward Walters, sales engineer for the American Steel Foundries, Chicago, has resigned to enter the employ of the Keyoke Railway Equipment Company, Chicago, as salesman, with headquarters at Chicago.

H. M. Davison, for the past 14 years connected with the sales organization of the Hayward Company, has left that company to become sales manager of the Ohio Locomotive Crane Company, Bucyrus, Ohio.

George W. Jones, assistant manager of the New York office of the Pittsburgh Steel Company, of Pittsburgh, Pa., has been appointed manager of the Chicago office, with headquarters in the McCormick building.

W. R. Gillies has resigned as mechanical engineer of the Oregon Short Line, with headquarters at Pocatello, Idaho, to enter the employ of the Union Asbestos & Rubber Company, Chicago, as assistant to the president.

The Bordon Company, Warren, Ohio, manufacturers of the Beaver die stocks and die cutters, has opened a downtown Chicago office at 549 West Washington street, in charge of Charles A. Green, Chicago representative.

The Duntley-Dayton Company, Chicago, has taken over the sales agency for the Red Devil rivet cutting guns, made by the Rice Manufacturing Company, Indianapolis, Ind., for all territory east of the Rocky mountains.

F. W. McIntyre, who for the past 16 years has been connected with the Niles-Bement-Pond Company in Boston and Chicago, has been appointed sales manager of the Becker Milling Machine Company, Hyde Park, Mass.

F. G. Echols, for many years general manager of the small tools department of Pratt & Whitney Company of Hartford, Conn., has accepted a position as vice-president of the Greenfield Tap & Die Corporation, of Greenfield, Mass.

The General Tool & Supply Company, Saginaw, Mich., has been appointed to represent the Cleveland Milling Machine Company in the Saginaw district, and will carry a stock of milling machines and a large supply of cutters.

The Niles-Bement-Pond Company, Pittsburgh, Pa., has removed its office from the Frick building to 425 Seventh avenue. The company has also opened a new office and store at 116 South avenue, Rochester, N. Y., and will keep a stock of Pratt & Whitney small tools at both places.

Edwin T. Jackman, formerly of E. S. Jackman & Co., Chicago, has returned from Sheffield, England, where he has been investigating methods in connection with tool and alloy steels. On July 1 he became manager of the Boston, Mass., office of the Firth-Sterling Steel Company, McKeesport, Pa.

The North American Car Company, Chicago, has purchased a 23-acre tract at 135th street on a joint right of way of the Indiana Harbor Belt, the Baltimore & Ohio Chicago Terminal and the Chicago, Rock Island & Pacific, on which a car construction and car repair plant will be built in the neart future.

W. E. Millar has been appointed Pittsburgh district manager of the Cleveland Milling Machine Company and L. H. Mesker, vice-president of the company, has turned over the duties of sales manager to H. I. Miner. The company also announces that the J. Horstmann Company has been appointed French agent, under the personal direction of Henri Nourry.

George Shields, who was purchasing agent of the American Car Company, St. Louis, for ten years, and later served with the National Safety Car & Equipment Company since its organization, has become associated with The Dayton Manufacturing Company as sales representative, with headquarters at Dayton, Ohio.

The Allied Steel Castings Company, Harvey, Ill., which is controlled by the Chicago Malleable Castings Company and the Universal Draft Gear Attachment Company, Chicago, will install a 10-ton open hearth furnace to supplement the present Wellman-Seaver-Morgan 5-ton tilting furnace, which will be enlarged.

John T. Mahoney, purchasing agent of the Buda Company, Chicago, with headquarters at Harvey, Ill., has been promoted to sales manager of the truck and tractor engine department, to succeed Lon R. Smith, who has resigned to become general sales manager of the Midwest Engine Company, Indianapolis, Ind.

Joseph Robinson, formerly president of the Robinson Connector Company, Inc., announces that he is no longer connected with that company in any managerial capacity and has no supervision over the mechanical details of construction of the automatic hose connector, of which he is the inventor and which bears his name.

W. M. Carty, assistant superintendent of the American Brake Shoe & Foundry Company, Chicago, has been appointed superintendent of the Pine Bluff, Ark., plant of the Standard Brake Shoe & Foundry Company. The latter company recently purchased equipment to increase its capacity from 350 to 800 tons a month.

Major Charles E. Sholes has been elected vice-president, director and general sales manager of the Edison Storage Battery Company to succeed Harrison G. Thompson, who has resigned to organize and conduct the Transportation Engineering Corporation of New York. Major Sholes has heretofore been identified with the construction, operation and management of chemical industries. He was the active member of the Creditors' Committee of the Aetna Explosives, Inc., during the receivership. During the war he served as major in ordnance, first as chief of the chemical branch, which attended procurements of platinum, cotton linters, alcohol, acids, etc., and as army representative before the War Industries Board, and numerous other committees and boards. He was subsequently made contracting officer for the United States on the staff of Colonel Lamont, and retains his rank in the Officers' Reserve Corps. He is also chairman of the Society of Chemical Industry.

Major C. E. Sholes

Paul H. Schatzmann, foreign representative of the Joseph T. Ryerson & Son Company, is temporarily in charge of the company's interests in Brazil, Argentina and Peru. In August Mr. Schatzmann will sail for Europe, thence to India, China and Japan. A. L. G. Gentles will take care of the interests of this firm in Great Britain and Scandinavia, with headquarters in London.

Samuel F. Joor, consulting engineer of Chicago, has joined the American Steam Conveyor Corporation, Chicago, in the capacity of sales engineer. Mr. Joor has had wide experience in the conveyor field, at one time being western manager and sales engineer of the Jeffrey Manufacturing Company, previously being with the Link Belt Company.

The McMyler Interstate Company, Cleveland, Ohio, makers of car dumpers, locomotive cranes, ore and coal handling machinery, scraper and railroad equipment, with works at Bedford and Warren, Ohio, has opened a branch office in the Merchants Exchange building, San Francisco, Cal., with L. A. Somers as district representative.

W. L. Garland, manager of the Philadelphia, Pa., office of the Safety Car Heating & Lighting Company, has been elected a vice-president, with headquarters at Philadelphia, Pa. Mr. Garland was born in Blair county, Pennsylvania. He completed his apprenticeship at the Altoona shops of the Pennsylvania Railroad in 1892; he then served in various departments of the shops for five years, and later took up locomotive and car design. In 1901 he was appointed chief car inspector on the Pennsylvania Railroad. In 1907 he was appointed general agent of the Safety Car Heating & Lighting Company, and in 1909, was promoted to manager. Mr. Garland was commissioned a major in the Corps of Engineers and was assigned to the 87th Battalion, Military Railroads. He was released from active service on the signing of the armistice.

W. L. Garland

J. Stanley McCormack, formerly sales manager of the Bell Locomotive Works, Inc., New York City, will return to resume his old position on his discharge from the Naval Aviation Corps. Mr. McCormack enlisted at the outbreak of the war, training as a naval aviator, received his commission and was detailed to special experimental aviation development.

E. E. Maher has organized the Maher Engineering Company, with office in the Michigan Boulevard building, Chicago, to handle the sales and installation of Erie Engine Works high speed engines, Sims feedwater heaters, Dayton-Dowd centrifugal pumps, Wagner steam pumps and Pratt Engineering & Machine Company fertilizer and sulphuric acid machinery.

The Betson Plastic Fire Brick Company has been incorporated under the name of the Betson Plastic Fire Brick Company, Inc., with headquarters at Rome, N. Y. Frank J. Jewell is president and secretary, and Nelson Adams vice-president and treasurer. The company manufactures plastic fire brick for boiler furnace linings and baffle walls and "Hi-Heat" cement for use in boiler rooms.

Col. E. J. Hall, first vice-president of the Hall-Scott Motor Car Company, San Francisco, Cal., recently received the distinguished service medal from the government in recognition for designing the major portion of the liberty motor and also having an excellent record as chief of the Technical Section, Air Service, in charge of aviation engineering, inspection, and acceptance of airplane parts and equipment with the A. E. F. in France, England and Italy.

The International Oxygen Company, Newark, N. J., has appointed Preston Belvin district sales engineer, in charge of the Pittsburgh district sales work, with office at 1310 First National Bank building, Pittsburgh, Pa. The Chicago office, in charge of Philip G. Wesley, has been removed from 223 Railway Exchange building to 817-820 Chicago Stock Exchange building, 30 North La Salle street.

The manufacturing facilities of the U. S. Light & Heat Corporation, Niagara Falls, N. Y., are to be increased by the addition of several buildings. The plant space now covers about nine acres and consists of 22 buildings. Recently two structures of brick and concrete were added. Contracts have been let and construction is already under way on the new buildings which will be of reinforced concrete and brick.

Marcel E. Cartier, sales engineer of the Joseph T. Ryerson & Son Company, Chicago, with headquarters at Paris, France, has returned to France after a few weeks' visit in this country. He will be joined in Paris by John H. Romann, sales engineer of the same firm. Messrs. Cartier and Romann will have charge of the company's business in France, Belgium, Holland, Switzerland, Italy, Spain and Portugal.

J. G. Carruthers, manager of sales of the Carnegie Steel Company, the Illinois Steel Company, and the Tennessee Coal, Iron & Railroad Company, with headquarters at Cincinnati, Ohio, has been appointed manager of sales for the Chicago district of the Illinois Steel Company at Chicago. He has been succeeded at Cincinnati by George H. Vant, who has been transferred from the Pittsburgh office of the Carnegie Steel Company.

The National Railway Appliance Company, New York, announce that by arrangement with Holden & White, Inc., Chicago, general agents, they are now prepared to offer in eastern and southern states a line of car heaters of all types. These include the Jewel hot blast forced ventilation stove, the hot water coal burning coil type, and a complete line of electric heaters, including cross seat, panel, truss plank and vestibule types.

Donald M. Ryerson, who for the past two years has been in the United States Navy, has received his discharge from the service and has returned to his duties as vice-president in charge of purchases and sales of the Joseph T. Ryerson & Son Company, Chicago. E. L. Ryerson, Jr., has also received his honorable discharge from the army, and has returned to the company as vice-president and works manager after nearly two years of absence.

E. A. Hitchcock has been elected vice-president of the Bailey Meter Company, Cleveland, Ohio. He will supervise the training of technical graduates for the company's service and sales departments. During the past six years he has been connected with the E. W. Clark & Co. Management Corporation as advisory, consulting and power sales engineer. Previous to that time he was professor of experimental engineering at Ohio State University.

J. W. McCabe, until recently district manager of sales at Buffalo, N. Y., for the Chicago Pneumatic Tool Company, Chicago, has been appointed special representative for the company's foreign trade department and will make an extended trip throughout the Orient, the Philippine Islands and Australia. W. H. White has been appointed acting district manager of sales at Buffalo to take charge of that territory during Mr. McCabe's absence.

Colonel R. P. Lamont, president of the American Steel Foundries, Chicago, has been awarded the distinguished service medal for "exceptionally meritorious service as assistant to the chief of the procurement division, later as chief of the procurement division and as a member of the claims board of the ordnance department," and for "rendering material assistance to the nation's industry in adjusting equitably outstanding contracts in full justice to employers and employees alike."

The Standard Car Construction Company and the Standard Car Equipment Company were merged on June 4, under the name of the Standard Tank Car Company, with head office and works at Sharon, Pa., and branch offices at New York, St. Louis and Chicago. John Stevenson, Jr., is president and G. F. Wood-Smith is vice-president of the new company, which will continue all the functions of the two companies, both as to the building and leasing of tank cars and all forms of steel plate construction.

The Buffalo Forge Company, Buffalo, N. Y., announces that Lieut. C. C. Cheyney has returned from service in the United States Navy, and is now in charge of its Chicago office and store. Lieut. Cheyney had charge of the mechanical repair shops at the naval aviation station, Pensacola, Fla., where from 500 to 1,200 men were employed during the war. Captain H. H. Downes, 12th U. S. Engineers (Railway), has returned from France, and after receiving his discharge expects to take charge of the Buffalo Forge Company's interests in the St. Louis territory.

The Bay City Foundry & Machine Company, Bay City, Mich., manufacturer of coal conveyors, saw mill machinery and hoists, has purchased the business of the Howlett Construction Company, Moline, Ill., manufacturer and builder of the Williams, White & Co., coaling stations. W. E. Howlett, manager and engineer of the Howlett Construction Company, will be manager of the railroad coaling station department of the consolidated company. This consolidation will unite the engineering facilities of the two companies and enable them to manufacture their own machinery.

The Central Steel Company, Massillon, Ohio, has opened new offices in Detroit, in the Book building, 35-37 Washington boulevard. Arthur Schaeffer, former assistant director of sales at the home office, Massillon, has been appointed district manager of sales, with Frank Gibbons as his assistant. Mr. Gibbons, who has just joined the organization, has been associated with the Carbon Steel Company for five or six years. He spent a great part of this time in the Carbon Company's Pittsburgh plant, and for the last several months has been district sales manager, with office at Detroit.

Tentative plans for a large increase in the capacity of the Pollak Steel Company, both at the Cincinnati and Chicago works, have been laid and are rapidly being worked out. D. E. Sawyer has been appointed general manager of sales, with headquarters at 120 Broadway, New York. Mr. Sawyer was formerly connected with the Illinois Steel Company, and was assistant steel director of purchases of the War Industries Board. The B. M. Parsons Company, 1001 Pioneer building, St. Paul, Minn., has been appointed northwestern sales representative in St. Paul, Minneapolis, Duluth and the Iron Range district.

The S. F. Bowser Company, Ltd., Toronto, Ont., which has for a number of years been manufacturing and selling Bowser gasoline and oil pumps, tanks and storage systems under the control of the parent company, S. F. Bowser & Co., Inc., Fort Wayne, Ind., has been re-organiezd under the Canadian laws to operate as a strictly Canadian firm. H. C. Christie, who has been for some time past connected with the Canadian factory of the S. F. Bowser Company, recently as sales manager, has been elected manager, with E. E. Cummings as factory manager. For a number of years, nearly the entire Canadian trade of the S. F. Bowser Company has been supplied from the Toronto factory, but this company has been under the direction of the home office at Fort Wayne. Through the present re-organization, the Canadian factory is to be operated and controlled as a separate institution. The officers are S. F. Bowser, president; S. V. Bechtel, vice-president; H. J. Grosvenor, secretary, and W. G. Zahrt, treasurer.

American Brake Shoe & Foundry Changes

William G. Pearce has retired as president of the American Brake Shoe & Foundry Company to become chairman of the executive committee, and Joseph B. Terbell, vice-president, has been elected president to succeed Mr. Pearce. Randolph Ortman, who has been president for one of the company's subsidiaries, has been elected a director, succeeding the late Joseph D. Gallagher.

W. G. Pearce

William G. Pearce, chairman of the executive committee of the American Brake Shoe & Foundry Company, was born at Marietta, Ohio, on June 11, 1859. He entered railway service in August, 1877, as a clerk in the office of the controller of the Missouri, Kansas & Texas, at Sedalia, Mo. He was later promoted to bookkeeper and chief clerk in the same office, and in August, 1879, left that road to take a clerical position in the auditing department of the Northern Pacific. He was successively promoted to assistant express auditor, assistant auditor of disbursements and auditor of disbursements in the same department, and in February, 1890, was appointed general purchasing agent. From May, 1892, to September, 1896, he was assistant general manager of the same road, and when the Northern Pacific was reorganized on the latter date, he was transferred to Tacoma, Wash., as assistant general superintendent. From August, 1900, to July 1, 1901, he was assistant to the president of the Northern Pacific, the Seattle & International, and the Washington & Columbia River, at the same time being general manager of the Seattle & International. From July, 1901, to March, 1902, he was general manager of the Northern Pacific, leaving railway service at the end of that time to become second vice-president of the Griffin Wheel Company. On June 5, 1905, he was also made general manager of this company, with headquarters at Chicago. He left the Griffin Wheel Company on November 22, 1910, to become vice-president of the American Brake Shoe & Foundry Company, and in May, 1916, was elected president, with headquarters at New York.

J. B. Terbell

J. B. Terbell, the new president, was born at Corning, N. Y., in February, 1863, and was educated at Hamilton College, graduating in the class of 1884 with the degree of A. B. After leaving college he served with the Fall Brook Railway, now the Pennsylvania division of the New York Central, with headquarters at Corning, N. Y., and later was vice-president of the Corning Iron Works. In 1897, he became president of the Corning Brake Shoe Company, and in 1902, was elected vice-president of the American Brake Shoe & Foundry Company, with headquarters at Chicago, in charge of the company's western business. In 1915, Mr. Terbell came to the New York office in connection with munition contracts for the British government.

Transportation Engineering Corporation Organized

Harrison G. Thompson resigned from his position as vice-president and general sales manager of the Edison Storage Battery Company on June 1, 1919, and has incorporated the Transportation Engineering Corporation, with offices at 200 Fifth avenue, New York. The officers are as follows: H. G. Thompson, president; F. V. McGinness, vice-president, and Harold H. Smith, secretary-treasurer. The new corporation will act as railway distributors for the Edison Storage Battery Company and for the Automatic Transportation Company, of Buffalo, N. Y. It will handle the Edison storage battery for train lights, railway signaling, multiple unit control, and for other purposes to which storage batteries may be applied. It will also handle the complete line of industrial trucks, tractors, and industrial engines manufactured by the Automatic Transportation Company, with such apparatus as charging equipment and other supplies incident to the above lines.

H. G. Thompson

Mr. Thompson became associated with the Edison Storage Battery Company in 1910, and was elected a vice-president in 1913. He was born at Weston, Mass., in 1875. In 1896 he entered the service of the Pullman Company, and after two years was made foreman of electricians. In 1900 he resigned to become foreman of the battery department of the Riker Motor Vehicle Company, but left the latter at the time of its absorption by the General Vehicle Company, of Hartford, Conn., to become associated with W. L. Bliss, one of the pioneers in electric car lighting development. In 1905 he entered the service of the Pennsylvania Railroad and was placed in charge of electric car lighting, with headquarters at Jersey City, N. J. About one year later he became electrical superintendent of the Safety Car

F. V. McGinness

Heating & Lighting Company, New York, and was in charge of that company's electrical laboratories during the development of its first electric car lighting system. In December, 1909, he was appointed manager of the railroad department of the Westinghouse Storage Battery Company and later, for a short time, was in the employ of the United States Light & Heat Company, New York. In July, 1910, he became manager of the railway department of the Edison Storage Battery Company; in July, 1915, he was appointed general sales manager, and became also vice-president of the company in July, 1918.

Frances V. McGinness, who recently resigned as railway sales manager of the Edison Storage Battery Company, is vice-president of the new corporation. He graduated from Columbia University, School of Engineering, with the degree of electrical engineer in 1910, and then spent a short time in the engineering departments of the New York Telephone Company and the New York & Queens Light & Power Company. He became connected with the Edison forces in 1911, being then engaged in experimental work in Mr. Edison's laboratory. At this time he also received a thorough training in the manufacture of the Edison battery. He was later appointed assistant manager of the railway department of the Edison Storage Battery Company, and in March, 1916, he was promoted to manager of the same department.

Harold H. Smith, electrical engineer of the Edison Storage Battery Company, becomes secretary-treasurer of the newly formed Transportation Engineering Corporation. Mr. Smith graduated from the Polytechnic Institute, Brooklyn, N. Y., in 1909, with the degree of E.E. For one year thereafter he was employed by the Pennsylvania Tunnel & Terminal Railroad, in the office of the chief engineer of electric traction, in connection with the New York electrification of the Pennsylvania Railroad. He then joined the staff of the laboratory of Thomas A. Edison, at Orange, and for several years was engaged in research work in connection with the Edison storage battery. Later he became connected with the selling department of the Edison Storage Battery Company in the capacity of engineer, and retained that position up to the time of his recent resignation.

H. H. Smith

The Stark Rolling Mill Company, Canton, Ohio, has appointed George W. Scott district manager for the Chicago territory, with headquarters at 1119 Marquette building. Mr. Scott was formerly Chicago representative of the Pittsburgh Steel Company. Thomas F. Murphy has been appointed district manager for the Canton territory. He was formerly connected with the American Sheet & Tin Plate Company.

The Metallo Gasket Company has recently been incorporated to manufacture gaskets and other packings, at New Brunswick, N. J., with the following officers: Zeno Schultes, president and treasurer; George Geipel, vice-president, and Stanley S. Geipel, secretary. Mr. Schultes was manager of the Goetze Gasket & Packing Company for about 14 years. George Geipel has been an erecting engineer for 35 years, specializing in refrigerating and steam power plants, and Stanley S. Geipel has had ten years' experience in mechanical engineering. The company will concentrate for a time on its metallo corrugated copper gasket with asbestos cord inlaid in the copper grooves or corrugations.

The Chicago Pneumatic Tool Company announces the election of Allan E. Goodhue as managing director of its English subsidiary, the Consolidated Pneumatic Tool Company, Ltd., whose offices are at 170 Piccadilly, London, and whose plant is in Fraserburg, Scotland. Mr. Goodhue will also have charge of European sales for the Chicago Pneumatic Tool Company. He was for a number of years connected with the sales department of the Midvale Steel Company and Midvale Steel & Ordnance Company in Philadelphia, Chicago and Boston, leaving that company in March, 1918, to enter the service of the government. From that time until January 1, 1919, when he became connected with the Chicago Pneumatic Tool Company, he was assistant manager of the steel and Raw Material Section, Production Division, of the Emergency Fleet Corporation.

Railway & Industrial Engineers, Inc.

The Railway & Industrial Engineers, Inc., with offices at 25 Broad street, New York, recently organized by J. E. Muhlfeld and V. Z. Caracristi announces that it has associated with it an experienced, competent and reliable staff of experts thoroughly familiar with domestic and foreign methods and practices, and offers to bankers, corporations and others its services in a representative, advisory, consulting or administrative capacity as follows:

J. E. Muhlfield

Organization, management and operation of railroad, public utility, industrial and manufacturing enterprises.

Examination of proposed capital and consequential expenditures for facilities or equipment to ascertain whether they are justified and will improve conditions, increase revenues or reduce costs of operation and maintenance.

Assistance in connection with plans for financing projected improvements and extensions.

Review or preparation of plans, specifications and estimates of costs of contemplated new construction work, or enlargements of existing facilities.

Rehabilitation and modernization of unprofitable undertakings, including, if desired, their temporary management and operation until satisfactory results are obtained.

Advisory or consulting engineers to insure that expenditures are made in a manner that will produce maximum economic results and reflect the greatest return to the properties, and provide the best security to the owners.

Advisors and conferees in labor problems and in the preparation of rules and regulations governing compensation and working conditions.

Preparing, passing upon or approving inventories, valuations and appraisals of properties and equipment.

Consulting engineers for exporters and importers and their foreign representatives, to co-ordinate specifications, prices and purchases for the best interest of each.

Reporting on inventions, new methods and processes, and assistance in the development of those having practical merit and commercial value.

J. E. Muhlfeld, who has been in transportation work for about 25 years, has, during the past ten years, been engaged in rehabilitation of roadway, terminals, shops and equipment on various railways, and more particularly in the design and development of the Mallet and other types of large steam locomotives in combination with the utilization of low-grade fuels for the purpose of increasing the average train load and reducing the costs of operation and maintenance on railroads in the United States, Canada and Brazil. He was born at Peru, Ind., on September 18, 1872, and studied mechanical engineering at Purdue University; he served as machinist, and then as locomotive fireman and engineer on the Wabash Railroad and later successively as engine house foreman and general foreman on the same road; master mechanic at Port Huron and Montreal, on the Grand Trunk; superintendent of machinery and rolling stock on the Canadian Government Railways; superintendent of motive power on the Baltimore & Ohio, and vice-president and general manager of the Kansas City Southern. During the past five years he has been located in New York and has specialized in railway and other valuation and improvement work and in the development of methods and appliances for the modernization of locomotives and central power stations for the purpose of reducing investment and fuel costs, utilizing waste heat, eliminating arduous labor, and increasing capacity.

V. Z. Caracristi has been engaged in railway and industrial work for the past 20 years, having specialized in locomotive, car and shop design and construction. He served as shop engineer and maintenance supervisor for the Richmond plant of the American Locomotive Company, and in the inauguration and installation of a uniform system of maintenance and shop betterment he was general maintenance supervisor for all of the plants of the same company. He assisted in the design and construction of the Washington, D. C., terminal and station, and later served as assistant to general superintendent of motive power of the Baltimore & Ohio, in charge of shop additions, construction and equipment, and general betterment of the design and construction of locomotives and cars, which included the design and construction of the first Mallet type locomotive. He was then engaged in carrying out improvements in the Brewster shops of the Wheeling & Lake Erie, and the Watervliet shops, and Carbondale mechanical terminal of the Delaware & Hudson Company; in charge of the layout, design and equipment of extensions to the Lima Locomotive Works, and various additions to plants and power houses of the American Locomotive Company. For the past six years he has been engaged in consulting work for various bankers on financial reports and suggesting improvements in industrial operating methods for controlled corporations. During this time he was engaged in development and commercial work on means and methods of burning coal in suspension. He will continue this same work in his new connection.

V. Z. Caracristi

CATALOGUES

Ash Disposal.—The American Steam Conveyor Corporation, Chicago, has issued another booklet on the question of ash handling facilities, entitled "Reducing Ash Disposal Costs." Of special interest is a diagram and description of a steam ash conveyor installed by this company, that saved over three dollars a day in ash handling costs. The experiences of a number of other users in securing ash disposal economies are described, and the text is illustrated with a number of diagrams and photographs of actual installations.

Chain Drives.—The Morse Chain Company, Ithaca, N. Y., in a 12-page pamphlet has reprinted from the 1919 Year Book of the National Association of Cotton Manufacturers an article by J. S. White, entitled "Chain Drives," which explains the advantages which may be secured in the textile industry from the use of chain drives in general power transmission work. This is a short synopsis of the general subject of chain driving and does not exploit any particular make or type of power chain, and includes engineering data useful in designing silent chain drives.

Electric Headlights.—The second edition of an instruction book covering the installation, care and operation of Sunbeam turbo-generators and headlights has been published by the Schroeder Headlight & Generator Company, Evansville, Ind. The information given in this book is quite extensive and not only deals with the Sunbeam turbo-generators and headlights, but contains considerable information pertaining to incandescent headlights in general, as well as many useful tables and formulae. It also contains many drawings and photographs showing detail parts and wiring arrangements.

Locomotive Coaling Plants.—A comprehensive book on locomotive coaling facilities, Rand gravity sand plan s and cinder handling equipment for railroads, describing a large number of representative installations, has been published by the Roberts & Schaefer Company, Chicago. The catalogue contains 68 pages, 9 in. by 11½ in., is well illustrated and includes erection drawings of several of the plants. It also describes and illustrates some of the special features of Roberts & Schaefer equipment, including the Schraeder automatic measuring feeder and a patented elevating bucket. Some interesting data is also given showing in detail the cost of handling coal, taken from carefully compiled records of a large railway system which employs 10 different methods of handling coal, comparing the cost of operating plants designed by the Roberts & Schaefer Company with the others.

Stoker Fired Locomotives.—The Locomotive Stoker Company, Pittsburgh, Pa., has published an attractive booklet of 96 pages, bound in heavy cardboard covers, illustrating some of the principal types of locomotives that have been equipped with mechanical stokers by the Locomotive Stoker Company, which include the largest and most powerful locomotives constructed, as well as the standard locomotives of the United States Railroad Administration. The various types of locomotives considered to be in the stoker class are grouped in sections, each page containing an illustration of a representative locomotive of different railroads, with a table of the principal dimensions. After each section is a tabulation which permits of a direct comparison of the like dimensions of all locomotives of that class. These tables should be of special interest to mechanical engineers designing new locomotives, as well as to those contemplating installing stokers on old locomotives.

Railway Mechanical Engineer

CONTENTS

Supporting the Sides of Wooden Gondolas

During the period when the shortage of cars for the coal traffic was acute, many roads put back into service open top wooden cars that would ordinarily have been retired and replaced with modern equipment. Since the price of cars has increased so greatly there seems to be a disposition to keep these cars in service. As a result it is a common thing to find wooden gondola cars under load with the sides bulging out so far that they are a menace to trainmen riding on the sides of other cars. In extreme cases, the side posts sometimes interfere with the safety appliances on cars on adjoining tracks.

There are several causes that lead to the excessive bulging of the sides of wooden cars. In many cases, the construction is such that the torsional strength of the side sills alone keeps the sides from spreading. If the underframe sags under the load, the distortion has a tendency to force the posts out still further. During recent years the increased difficulty of obtaining siding to extend the full length of the car has led to the use of short pieces, which further weakens the side.

Of the methods used to overcome spreading of the car sides the most common is the use of tie rods fastened to the tops of opposite posts. While this is a cheap and effective means of overcoming the trouble it should be used only as a temporary expedient, as the rods make the loading and unloading of long material very difficult. It is doubtful whether the bulging of sides can be entirely overcome on cars with weak underframes. Probably the most effective reinforcing for the sides on the majority of wooden cars is secured by adding diagonal tie straps to make the side act as a truss and by placing gusset sheets transversely in the center of the car to give lateral stiffness. If wooden gondolas are to be retained in service some effective method of strengthening the sides should be used.

Accidents Due to Locomotive Failures

Graphic comparisons of personal injury accidents resulting from failure of various locomotive details, classified by details and by years, included in an article appearing elsewhere in this issue, form a valuable summary of the work which has been done by the Division of Locomotive Inspection of the Interstate Commerce Commission during the seven years for which reports have been rendered, and throw into relief the points on which much improvement must still be made before a satisfactory situation can be said to have been reached.

One of the most striking comparisons brought out by the charts is the consistent and rapid decrease in the number of accidents due to boiler explosions from 1912 to 1915, followed by an almost equally rapid increase in the numbers of similar accidents in the years following, until a total of 90 was reached in 1918, only 7 less than the number reported in the fiscal year 1912. Considering the two principal classifications of causes of boiler explosions; that is, crown sheet failures due to low water, with and without contributing causes, it is significant that while the latter was reduced from a total of 69 accidents reported during the fiscal year 1912 to a minimum of 14 in 1913, and again increased to 38 in 1917 and 34 in 1918, the former had jumped from a minimum of 9 in 1915 to 51 in 1918, as compared with the largest number previously reported of 28 in 1913. The conditions reflected in these figures no doubt are due to the war, with the extraordinary demands for motive power which it created, and the unsatisfactory labor situation both as to quantity and quality which the railroads had to contend with during the year 1918.

Post mortems, however, are of little value unless some lesson may be drawn from them for future guidance. In this case the lesson seems to be obvious. It is that any neglect of firebox maintenance, particularly of the inspection and maintenance of boiler appliances such as water gage glasses, gage cocks, injectors, steam gages, safety valves, etc., results in grave and immediate danger. Whatever slighting of work the exigencies of such a situation as that created by the war may seem to require, safety demands that this requirement be met elsewhere than in connection with the parts just mentioned.

While perhaps not among the leading causes of personal injury accidents, boiler studs are a persistent cause of a sufficient number of accidents to give weight to the author's suggestion that their use be eliminated in every way possible. Aside from the element of danger accompanying the use of the studs themselves the practice of hanging air pumps, sometimes two of the large 8½-in. cross compound compressors, on the shell of the boiler, with the vibrations set up by the pumps in operation, subjects the boiler shell to stresses in addition to those due to the working pressure the magnitude of which it is practically impossible to evaluate. While past experience offers nothing to occasion alarm on this point, the uncertainty as to the future results of the tendency toward increasing the severity of these secondary stresses, together with the trouble and occasional accidents due to the studs themselves, clearly justifies an effort on the part of the designer to relocate the various appliances and details now secured to the boiler with studs.

The suggestion of the author that the annual reports of the Division of Locomotive Inspection of the Interstate Commerce Commission be studied by all mechanical department foremen having to do with locomotive repairs, if followed, should have very beneficial results. A careful analysis not only of the countrywide results, but of the conditions on their own lines would result inevitably in a tightening up of maintenance at the weak points. A decrease in the number of accidents would follow, and fewer locomotives would be taken out of service by the Commerce Commission inspectors for needed repairs.

Modern High-Speed Steel

In a paper discussing the subject of high speed steel, appearing elsewhere in this issue, John A. Matthews makes the interesting statement that "it is still a constant source of surprise to see tests conducted in which a steel that may appear of inferior analysis proves successful, whereas some of the other type of analysis judged from this viewpoint only would naturally be expected to prove the better steel," and he draws the conclusion that "it, therefore, seems that steel-making rather than chemical analysis is the first consideration, and so far we are not able to define or to specify all the elements which enter in from the melting to the finishing of the bar to produce first-class material." These statements coming from a present day authority in steel making are the results of long experience in the manufacture and study of tool steels and the conclusions drawn should be given careful consideration by every one engaged in the production or use of high speed steels. It has generally been thought that the chemical analysis of steel bears a direct relation to its utility and efficiency and this is usually true, but it has been demonstrated, in exhaustive tests, that the chemical analysis of a high speed steel may be ideal, but if the tool making process is not properly conducted, the resulting tool will not be of a satisfactory quality. The heat treatment of high speed steel by the tool makers has a most important bearing on the quality of the cutting tool and must be carefully done. Very often too much reliance is placed on the chemical analysis and generally known good qualities of some particular brand of high speed steel with the result that a superior grade of steel often produces a very inferior tool because of the failure of the tool maker to realize the importance of his treatment of the metal. Conscientious work by the tool maker will add greatly to the serviceability of cutting tools and effect a substantial economy in tool costs.

The Ultimate Locomotive Stoker

One of the most difficult and vital operating mechanical problems which the railroad world must solve is that of the further development of the mechanical stoker for locomotives. What is the ultimate locomotive stoker to be? The urgent need of efficient and economical locomotive firing is clearly apparent when it is realized that from 80 to 90 per cent of the millions of tons of coal burned annually by the railroads of the United States is burned on the locomotive. This immense amount of fuel not only represents a vast money value as a commodity, but it is directly related to the problems of labor and transportation. Each ton of coal used needlessly or wastefully means the economic loss of the labor necessary to produce it, and is also an added burden to the already overtaxed transportation facilities of the nation. The physical limits of hand firing have been reached because of the great increase in the size of fireboxes on modern locomotives, and it has become necessary to devise mechanical means of conveying and distributing the fuel to the grate. Several types of mechanical stokers have been built and developed to a remarkable degree of efficiency, so far as supplying the fuel to the fire is concerned, but it is quite generally conceded by the stoker manufacturers that in the use of stokers fuel economy is largely sacrificed for increased capacity and that in fireboxes within the physical limitations of the fireman the stoker is not as economical as hand firing. The use of the stoker results in the production of more ton-miles per locomotive mile, which increases the efficiency and economy of operation, but it does not produce that result with as small a use of coal as is manifestly desirable.

The methods now in use for mechanically feeding fuel to the locomotive firebox may be divided into three classes: the class by which the fuel, after being crushed in comparatively small pieces, is conveyed to the door of the firebox and then blown on and distributed over the grates by means of steam jets; second, the class by which the fuel is crushed and conveyed to the firebox in a similar manner, but is distributed over the grates by purely mechanical means, and third, the class by which the fuel is pulverized before being placed on the locomotive tender and is blown into the firebox and burned in suspension.

While all of these methods have great advantages over hand-firing on large locomotives at present, and each of them has great possibilities of future development and may prove to be the much sought solution of the problem, it is at the same time quite conceivable that a method differing radically from those now in use will be devised and will solve better than any of them the problem of feeding into the locomotive sufficient quantities of fuel in such a manner as to secure as efficient or more efficient use of the fuel than can be obtained by hand-firing. That the manufacturers of mechanical stokers are alive to the situation is evidenced by their constant efforts toward improvement in their devices. The more extensively stokers of the present types are used on the railroads, and the more study railroad mechanical men as well as manufacturers give to the improvement of their design and operation, the more rapidly the results theoretically possible will be obtained in actual practice.

Advantages of Large Water Capacity for Tenders

One large western railroad has recently adopted the practice of equipping locomotives with tenders having a very large water capacity. The results secured have been so favorable that an analysis of the advantages and disadvantages of high water capacity will be of interest. The most evident benefit is the reduction of the number of water stops, which saves fuel and wear on the brake apparatus and reduces the running time, thus often effecting a saving in the wages of the train crew. Incidentally, the larger water capacity may permit of passing water tanks where the water is of inferior quality, or where the location makes starting difficult, which under certain conditions may be very important. Against these advantages must be balanced the increased tonnage hauled and the additional maintenance cost.

The amount by which the capacity must be increased to permit a reduction in the number of water stops varies under different conditions. With the usual spacing of water tanks an increase of 50 per cent will in most cases make it possible to run past one more tank between stops. In order to bring out the economies resulting from the elimination of the stop, assume a locomotive having a tender with a capacity of 8,000 gal. of water operating over a division 100 miles long on a run that necessitates taking water at five intermediate stops and coal at one point on the division. By increasing the water capacity to 12,000 gal. the number of water stops might be reduced from five to three and since a conservative estimate of the average cost of a stop is 60 cents, the saving per trip would be $1.20. As the extra weight of water would not increase the number of trains, the cost of hauling the increased weight would be limited to the cost of the additional fuel burned. The gross ton miles would be increased 833 ton-miles. Figuring the coal consumption at 250 lb. per 1,000 ton-miles and the cost at $3.50 a ton the extra fuel would cost 36 cents. Even though there is considerable increase in the cost of maintenance of the larger tender, there should be a substantial economy effected by its use.

Operating conditions will determine the extent to which the increase in water capacity can profitably be carried. In passenger service there would be no economy in providing capacity in excess of that required by the train between station stops where water tanks are located. For freight engines, however, the capacity could profitably be increased to the amount consumed between coaling stations where stops are necessary. This would require about twice the water capacity now usually provided.

The Shop Craft Strike

The scattering strikes of railway shop men, variously estimated at the time of going to press as involving from 100,000 to 250,000 of the approximately 450,000 men thus employed, and which will, if the threats of some of the leaders of the shop crafts unions are carried out, paralyze the transportation system of the country, seem to mark the breakdown of the policy followed by the Railroad Administration in dealing with the labor situation in the shops.

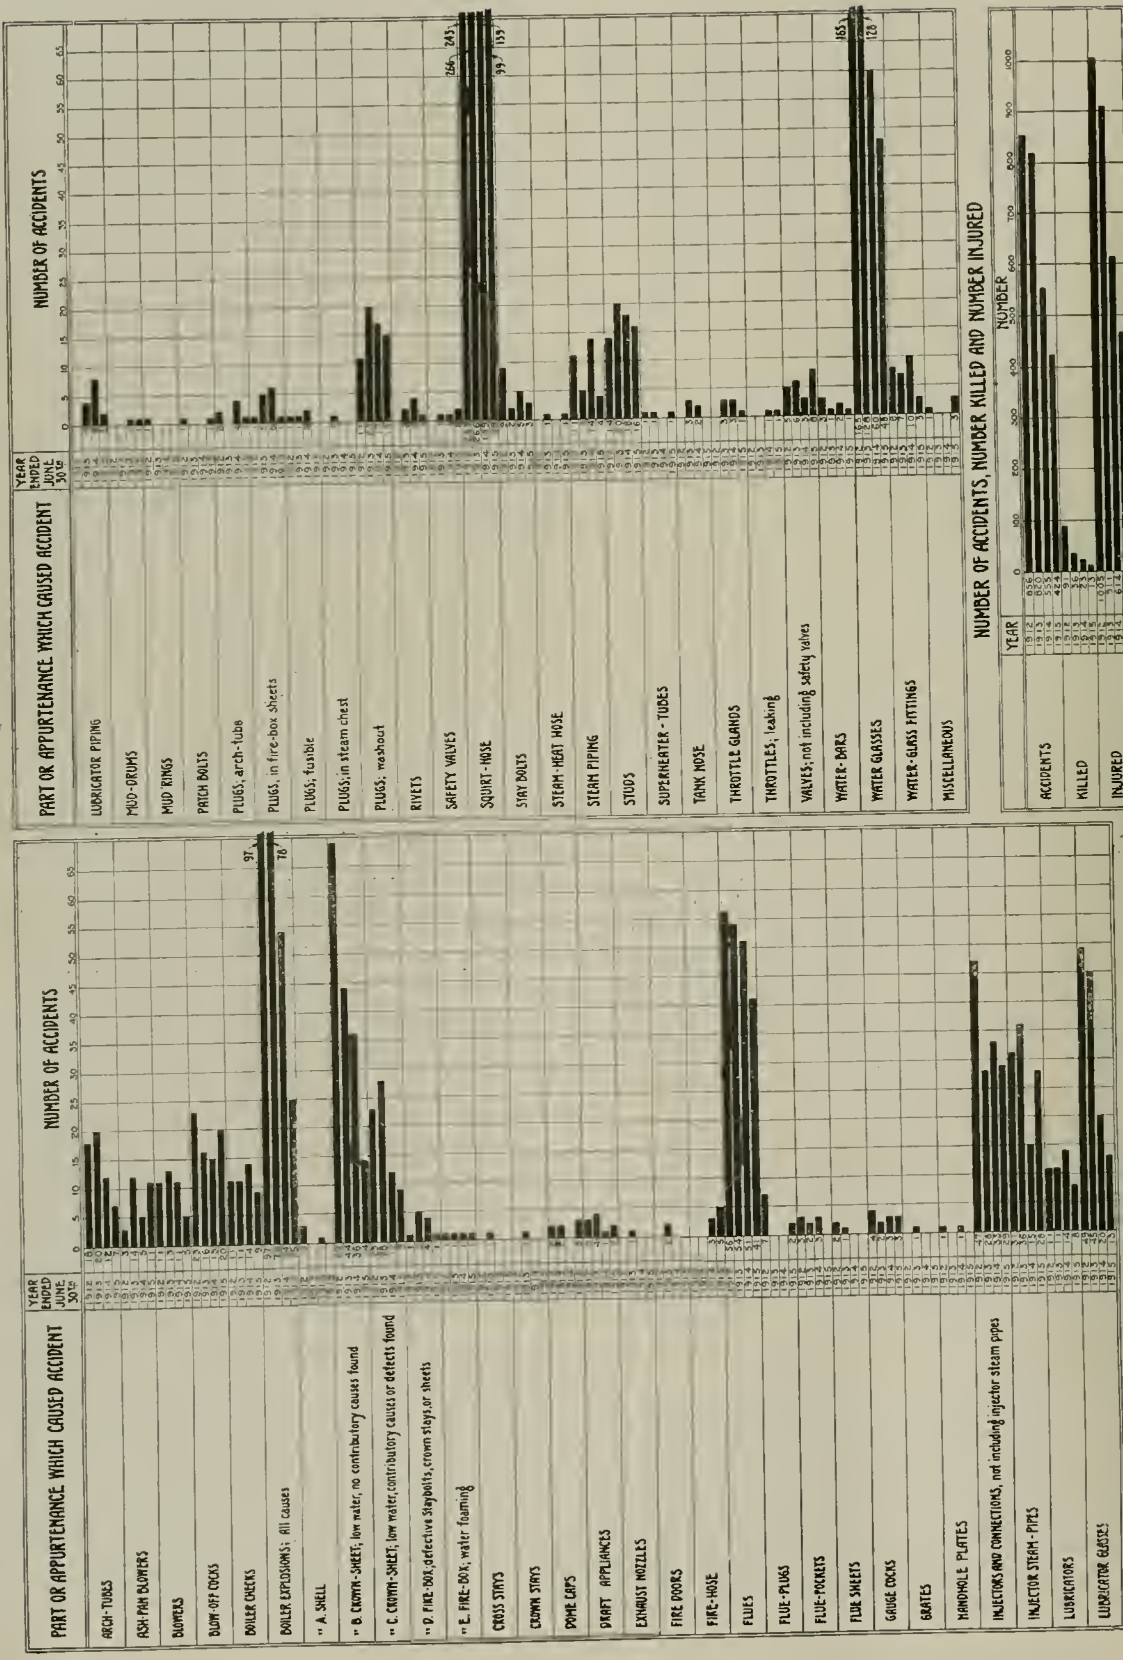
One of the early acts in the administration of Director General McAdoo was the creation of a railroad wage commission to investigate and recommend adjustments and increases required to meet the special conditions created by the war. During the latter part of 1915 and early in 1916, conditions at which time were assumed by the wage commission as the basis of its work, railway mechanics were receiving from 34 to 38 cents an hour, with earnings ranging approximately from $75 to $90 a month. During the intervening two years, however, increases had been given by the railroad companies, so that the average monthly earnings of mechanics for 1916 had ranged from $90 to over $100, and for 1917, from $105 to about $120. The award proposed by the wage commission, based as it was on conditions as of December, 1915, was modified by the Director General in General Order No. 27 in order that the shop men might receive some increase and a minimum of 55 cents an hour was established for mechanics. This, however, met with immediate expressions of dissatisfaction, accompanied by a number of local strikes, and was followed by a request for an increase in the mechanics' rate to 75 cents an hour. In July, Supplement No. 4 to General Order No. 27 was issued, raising the mechanics' rates to 68 cents an hour, which rate was to be retroactive to January 1, 1918. It also authorized the eight-hour day after August 1, with time and a half for overtime. Incidentally, Supplement No. 4 resulted in the destruction of piece work.

According to the wage commission the cost of living had increased by from 37 to 40 per cent from January 1, 1916, to January 1, 1918. The Bureau of Labor Statistics of the Department of Labor quotes average prices of a wide range of food products, the average increase in price of which was 16 per cent from January, 1918, to January, 1919. As food is the largest single item entering into the cost of living, it hardly seems possible that the cost of living in January, 1919, or about the time the present demands were presented, had advanced more than 60 per cent since the beginning of 1916, although the labor leaders base their present wage demands on an alleged increase of some 80 per cent. Judging from the month to month increases in food prices since that time, it is impossible to conceive that a 100 per cent increase has taken place up to date. But the wage rates of the shop men have increased approximately 100 per cent over those in effect late in 1915. The increase in the cost of living, therefore, seems clearly to be a specious and fallacious argument in connection with the present wage demands.

The source of dissatisfaction is not merely the increase in living costs. The spread of labor union policies, which it was supposed would cause satisfaction, probably is responsible for much of the dissatisfaction. Take the piece-work situation: Men who had been averaging good earnings on a piece-work basis before the issuance of Supplement No. 4, found themselves under the provisions of this order, earning practically as much as before without any effort on their part, and what was worse, with their hands tied so far as their ability to further increase their earnings by their own efforts was concerned. A source of dissatisfaction and unrest among piece workers was thus created. Another provision of Supplement No. 4 was the institution of the eight-hour day with time and a half for overtime after August 1, 1918. This resulted in a temporary increase in earnings, a reduction in which soon followed when overtime work was discontinued. A reduction of earnings is never a source of satisfaction and good feeling.

The failure of the liberal policy of the Railroad Administration in its dealings with labor to meet with a response in the way of stimulated effort or co-operation is generally conceded and has been commented on in some of its phases in these columns. The following case is typical in kind, if not strictly in degree, of a general condition: A certain engine terminal in eastern territory, which in 1916 despatched 100 engines daily in addition to taking care of some heavy Mallet repairs, employed about 200 men in two shifts. Since the first of this year the same terminal has employed over 500 men in three shifts. From $15,000 to $16,000, the payroll has increased to $130,000 a month in the same period.

Just what will be the outcome of the present situation no one can predict. It is, however, quite evident that no satisfactory and stable working arrangement can be effected until the worker and the manager in their relations with one another are free to and do give expression in what they say and what they do to their own inherent sense of justice.



Compiled from the Annual Reports of the Chief Inspector of Locomotive Boilers to the Interstate Commerce Commission

Fig. 1—Personal Injury Accidents Resulting from Failures of Locomotive Boilers and Their Appurtenances—1912 to 1915 Inclusive

Injuries from Locomotive Failures

Suggestions for Their Reduction Based on a Digest of the I. C. C. Locomotive Inspection Reports

BY JOHN L. MOHUN
Assistant to Consulting Engineer, Union Pacific System

By presenting the personal injury accidents, as listed in the several annual reports of the Chief Inspector of Locomotive Boilers to the Interstate Commerce Commission in a comparative graphic form, with an analysis of the cause of the principal locomotive failures which caused these accidents, it seems possible that means may be devised whereby accidents due to such failures may further be reduced.

As these reports emanate from a source independent of the railroads and are national in scope, tendencies toward faulty construction or improper maintenance are naturally more forcibly brought out than in the case of the usual railroad mechanical department reports covering locomotive failures, which are confined to a single or a system of roads. Therefore, serious attention should be given these reports and the recommendations as to improvements made by the Chief Inspector.

The Federal Locomotive Boiler Inspection Law enacted February 17, 1911, made it unlawful to operate a locomotive with its boiler in an unsafe condition and prescribed rules and regulations for the inspection and test of the boiler. The law further requires the railroads to report to the Interstate Commerce Commission all accidents resulting from locomotive boiler failures or their appurtenances causing serious personal injury or death. The Commission considers a serious injury as one causing the person involved to be incapacitated for more than three days in the aggregate within ten days immediately following the accident. The law also requires the facts concerning such accidents to be investigated by the Chief Inspector of Locomotive Boilers or one of his assistants.

The Congress on March 4, 1915, amended the original Locomotive Boiler Inspection Law by making its provisions apply to the entire locomotive and its tender and all their appurtenances. The features as to reporting and investigating accidents remain the same.

Attention is invited to the charts, which present the personal injury accidents in a comparative graphic form for the years 1912 to 1918 inclusive. As the law at first related solely to the locomotive boiler, Fig. 1 lists the personal injury accidents chargeable to the failure of locomotive boilers and their appurtenances only, for the years 1912 to 1915. As the law was later amended to cover the locomotive and its tender, Fig. 2 covers all personal injury accidents chargeable to the entire locomotive and tender, and their appurtenances, for the years 1916 to 1918 inclusive.

It is obvious that certain tendencies indicated by these charts must be interpreted with reservations, as there are a number of conditions varying from time to time which should be given consideration before drawing definite conclusions, such as the amount of traffic, number of locomotives in service, weather and labor conditions, and the very abnormal state of affairs brought about by the world war in the past few years. However, these charts and the information given in detail, covering individual accidents in the annual reports of the Chief Inspector, bring out certain features in such a pronounced manner that quite definite conclusions can be drawn notwithstanding the effect of these variable conditions.

The predominating feature in Fig. 1 is the consistent reduction each year in the total number of accidents, number killed, and number injured. In the majority of cases this is also true of the number of accidents chargeable to the failure of individual parts of the boiler or its appurtenances. Evidently the material falling off in traffic during the years 1912 to 1915 had considerable to do with reducing the number of accidents, but undoubtedly a large amount of this improvement was directly attributable to the rules and regulations governing the inspection and testing of locomotive boilers and their appurtenances, put into effect in 1911 and 1912 by the Division of Locomotive Boiler Inspection of the Interstate Commerce Commission, and the general co-operation of the railroads, locomotive builders and the railway supply companies.

Fig. 2 shows a reverse state of affairs, with the exception of the number killed, in this respect 1918 showing an improvement over 1917.

The increased number of accidents between the years 1915 and 1916 was primarily due to the extension of the law to include the entire locomotive and tender; and the increase each year from 1916 to 1918 no doubt was principally caused by the abnormal condition the railroads were working under during these years, resulting from the war and the severe winter of 1917-1918. It is obvious that even if conditions had been normal during these years, the same ratio of reduction in accidents which occurred in the first few years after the Locomotive Boiler Inspection Act went into effect, could hardly have been expected.

The principal accidents causing personal injuries shown by these charts were due to the failure of the following locomotive parts or their appurtenances: Boilers, flues, grate shakers, injector and connections, injector steam pipes, reverse levers, squirt hose, lubricator glasses, water glasses.

BOILERS AND THEIR APPURTENANCES

Of these items, boiler failures are, of course, the most serious, both in the loss of life and damage to property. Fig. 1 shows a large reduction in the number of boiler explosions from all causes, there being 97 in 1912 as compared with 25 in 1915. Fig. 2 shows just the reverse, there being an increase in the number of boiler explosions from all causes from 41 in 1916 to 90 in 1918.

As will be seen by these charts, boiler explosions due to low water, no contributory cause, fell off fairly constantly from 69 in 1912 to 34 in 1918; but explosions due to low water, contributory causes or defects found, increased during the same period from 23 to 51.

The following cases of contributory causes to boiler explosions are taken from the Chief Inspector's reports for the years 1912 to 1918, and a considerable percentage of all boiler explosions disclose similar self-evident defects.

"A bad leak was found in packing nut of top water glass cock; no packing in nut at all, and valve handle was wired to prevent it from being blown out. Union nut in steam pipe to water glass was very loose and had been leaking badly. Such leaks cause water to raise in the glass and show an incorrect water level. These leaks had been reported four times previous to accident."

"Improperly located water glass and gage cocks; lowest reading of water glass one-eighth inch above highest point of crown sheet; bottom gage cock 1⅝ inches above highest point of crown sheet; locomotive received new fire box nine months before accident and had evidently been operating in this dangerous condition for that length of time."

"Obstruction in bottom water glass fitting; bottom gage cock stopped up with solid scale and inoperative and water glass cocks and three gage cocks not extending through reinforcing plates."

Compiled from the Annual Reports of the Chief Inspector of Locomotive Boilers to the Interstate Commerce Commission

Fig. 2—Personal Injury Accidents Resulting from Failures of Locomotives and Tenders and their Appurtenances—1916 to 1918 Inclusive

"Both injectors defective; injectors reported 14 times previous to accident."

"The failure occurred along the edge of the longitudinal seam where a crack had formed completely through the plate in several places and more than halfway through for the entire length of the course. The engineer had reported a leak under the jacket at this point three times immediately prior to the accident."

"Crown bolt beads defective and excessively calked, due to having been overheated some time previous."

"Crown sheet failure, overheated; water foaming badly; reported six times by different engineers prior to accident, but boiler not washed."

"Twelve crown bar braces were defective on account of seven pins missing; four pins broken and one brace broken. Scale was found in the crowfoot holes, where pins should have been, showing that pins had been out for some time."

"Mud ring cracked and leaking badly; reported 18 times, and crown bolts reported leaking badly 16 times within 30 days prior to the accident."

"Opening in fusible plug filled with sediment or slag, rendering it inoperative; report of inspection made three days before accident occurred, shows fusible plug removed and cleaned, yet it was found in this condition and had to be cut out of the sheet."

It is realized that quite often locomotive running repairs have to be made from day to day, under the most trying circumstances as to constant demand for and shortage of power, lack of proper facilities, and other unfavorable conditions. These facts should not, however, be considered valid reasons for placing locomotives in service without knowing that such serious defects as those listed above do not exist.

BOILER STUDS

The charts show a yearly average of about fourteen personal injury accidents chargeable to the failure of boiler studs, but the Chief Inspector's reports disclose many times this number found by the district inspectors in a leaky or defective condition. A large number of accidents are shown to be due to studs blowing out on account of improper application, in some cases not more than two or three threads having entered the sheet. A number of accidents were also caused by studs failing, while being tightened, under pressure. The Chief Inspector in his sixth annual report states that studs should not be repaired by calking and under no circumstances should an attempt be made to tighten them while there is steam pressure on the boiler.

An effort should be made to reduce as much as possible the large number of studs now being placed in the boiler for attaching various parts and auxiliary devices, especially when the device produces vibrations or shocks on the studs, such as is the case with air compressors and reverse lever quadrants.

In connection with large Mallet locomotives, several railroads and the Railroad Administration have placed the air compressors on the front of the locomotive and it is believed that this should be followed generally with respect to all large locomotives for the reasons that all boiler studs are dispensed with, the compressors can more readily be looked after by the engine crew when running and as two compressors are usually used on large locomotives, by placing one on each side of the center line an equal weight distribution is obtained. By placing the compressors on the front, instead of on one side of the locomotive, more free air would be passed over the air cylinders when running, thus securing a better cooling effect.

The reports show a number of failures of studs which attach the reverse lever quadrant, undoubtedly due to vibration set up in the reach rod. The use of a power reverse gear wherein the shocks or vibrations are cushioned by the air in the cylinder, would seem to offer means for avoiding this trouble.

There are also a number of minor parts fastened to the boiler by studs which by a little study on the part of the designer, could be avoided; for example, usually two steps are provided in connection with the sand box, requiring altogether four boiler studs. A light ladder could readily be substituted; secured at the top to the base of the sand box, and at the bottom to the running board.

On all of the locomotives recently ordered by the Railroad Administration, with the exception of the switchers, the bell stand is attached to the front end. This is good practice, as it is not only the logical place for the bell, but all boiler studs for attaching the stand are dispensed with. Such matters as the fastening of sand box steps and bell bases may seem of little moment, but there are many such parts which may be similarly treated to eliminate boiler studs, which taken in the aggregate assume considerable importance.

When a new firebox, back end or an entire boiler is applied to an old locomotive it is generally renewed in kind, with the possible exception of the application of a superheater and a brick arch, and certain improved features of construction developed in the past few years are not usually employed, although such improvements may cost little or nothing. In renewals of this kind where boilers have originally been attached to the frame by means of pads and clamps in connection with which a large number of studs are placed in the firebox sheets, it would seem advisable to substitute furnace bearers or furnace expansion plates attached to the mud ring of the firebox, thus dispensing with the troublesome boiler studs. If the side grate bearers had originally been supported by studs placed in the side sheets of the furnace, it would also seem desirable when renewing a firebox or back end to substitute the more modern method of supporting the grate bearers; that is, by brackets fastened by studs placed in the mud ring, thus further dispensing with boiler studs.

When a firebox, back end or a new boiler is installed, the steam turret and possibly the injectors could be placed outside the cab; thereby reducing the possibility of accidents due to the failure of their steam connections.

BOILER WASHOUT PLUGS

These reports show that quite a number of accidents are caused by boiler washout plugs being tightened while under pressure. After a boiler has been washed, filled with water and fired up, if a washout plug should be found leaking it is a very natural temptation, in order to save time and labor, to attempt to tighten the plug while under pressure. But the very fact that the plug is leaking indicates that the fine threads may have been crossed and it should in no case be touched with a wrench while the boiler is under pressure.

ARCH TUBES

The charts indicate a yearly average of about 11 accidents caused by the failure of arch tubes. The reports show the major number of failures due either to an accumulation of mud within the tubes or faulty setting. In 1912 there were 18, and in 1918 only 9 accidents chargeable to arch tubes. Considering the fact that the number of arch tubes in service increased in this period from approximately 40,000 to 100,000, the showing may be considered a very satisfactory one and indicates that those concerned realize the importance of keeping arch tubes free from obstructions in order to obtain proper circulation through the tubes and thereby prevent them from being burnt.

TUBES

By referring to the charts it will be noted that personal injury accidents due to the failure of tubes fell off quite consistently from 56 in 1912 to 40 in 1918, most of the failures being due to poor welds; but the reports show a much greater improvement in the number of defective or leaky tubes found by the district inspectors, the decrease being about from 2,270 in 1912 to 565 in 1918. Unquestionably this improvement was largely due to better methods of setting tubes, electric welding of beads, and the rule of the Commission limiting the use of tube plugs and specifying, when they are used, they must be tied together with a rod through the tubes.

SUPERHEATER FLUES

Only nine accidents are shown by the charts for the years 1912 to 1918 due to the failure of superheater flues, which indicates that these flues are being well maintained, especially when it is considered that the total number of superheater tubes in service increased from about 125,000 in 1912 to 980,000 in 1918.

AUTOMATIC FIRE DOORS

In order to reduce as much as possible the serious consequences of firebox, flue, and arch tube failures, the Chief Inspector in his annual report for the year ended June 30, 1917, recommends that all new and all locomotives then in service, when receiving general repairs, be provided with a mechanically operated fire door, so constructed that it is only open when the operator places his foot on the pedal. He further states that with the ordinary swing door, such boiler failures invariably result in blowing the fire door open and discharging steam and boiling water, together with the contents of the firebox, into the cab of the locomotive, seriously or fatally burning persons therein. He also directs attention to the fact that with the automatic fire door, the door will remain closed if the failure occurs while it is closed; and if the failure takes place while it is open, it will automatically close the instant the fireman's foot is removed from the operating device, thus preventing the direct discharge of steam and scalding water into the cab of the locomotive.

From the above it would appear that the automatic fire door is a most important safety device, and its use is well warranted solely for this reason and regardless of its coal saving features, which are generally recognized.

GRATE SHAKERS

As disclosed by Fig. 2, personal injury accidents chargeable to grate shakers amounted to 23 in 1916; 51 in 1917 and 39 in 1918. Reports show these accidents principally due to improper maintenance of the grate shaker mechanism, such as worn or missing pins and hand shaker bars slipping off staff, due to wear in the socket and the lever stub. The use of steam operated grate shakers should preclude the possibility of such accidents.

As a large number of grate bars on old locomotives are connected by single rods placed on one side of the lug on the grate bars and employ rather small pins, lost motion is soon set up and the whole grate shaker mechanism becomes loose and wobbly and when in this condition is liable to cause an accident.

It would appear advisable in such cases to substitute a more modern method consisting of double connecting rods, one placed on each side of the grate bar lugs with large, substantial pins. This change could be made at a relatively small cost. If it should require a change in, or relocating of, the lugs on the grate bars, this could readily be taken care of at practically no increase in cost, as grate bars have to be renewed constantly. At the same time it might be found expedient to redesign the grates in order to conform to more modern practice, especially as to providing maximum air openings obtainable without the loss of coal, thereby increasing the coal burning efficiency of the grates. This can be done at small cost due as stated before, to the fact that grates have to be replaced repeatedly.

As coal dust frequently accumulates on the top of the grate lever stubs, the socket of the detachable hand bar should be so arranged that there would be at least one inch clear space between the bottom of the socket and the top of the stub lever when the socket is placed home on the stub. Further, a hole should be drilled through the sides and at the bottom of the socket in order to allow any coal which may have lodged on the top of the lever to fall out.

INJECTOR AND CONNECTIONS

The charts show that personal injury accidents chargeable to the failure of injectors and connections (not including injector steam pipes) decreased almost constantly from 47 in 1912 to 23 in 1918, and accidents chargeable to injector steam pipes fell off in the same period from 31 to 16. The reports indicate that practically all of these accidents were due to the union nuts or brazed on collars. Failure of union nuts were due in most cases to threads stripping, nuts too large or broken by the use of improper tools, such as hammer and chisel. A large number of accidents are shown to be due to the failure of union nuts while being tightened under pressure. This is, needless to say, a dangerous undertaking and should be avoided. Failure of the brazed collars and sleeves is generally due to poor brazing. The district inspectors' reports disclose the fact that there were 26,342 injectors and connections found defective in 1913 and that there was practically a consistent reduction to 5,803 in 1918. Even the latter figure seems to indicate a rather bad state of affairs as to the proper maintaining of so important a piece of apparatus, especially in view of the Commission rule requiring the injectors to be tested before each trip.

Undoubtedly the use of non-lift injectors placed outside of the cab, and the so-called "mechanical" pipe joints in place of brazed collars, both of which are now coming into general use, will materially improve conditions in this respect.

REVERSE LEVERS

Fig. 2 shows that there were 38 accidents in 1916, 29 in 1917 and 40 in 1918 chargeable to the failure of reverse levers.

District inspectors' reports disclose that there were 60 defective levers found in 1916, 178 in 1917 and 244 in 1918. Practically all of these accidents are shown to be due to the reverse lever slipping out of the quadrant, caused by the worn condition of teeth of the quadrant or lever latch, defective latch springs or dirt in quadrant. On account of the incessant vibrations which the valve motion sets up in the reach rod it is very difficult to keep lost motion out of the teeth of the quadrant and reverse lever latch. The writer believes that the most practical way to reduce accidents of this kind is by the use of a power reverse gear in which the vibrations in the reach rod are cushioned and absorbed by the compressed air within the reversing cylinder.

SQUIRT HOSE

There were 266 personal injury accidents in 1913 due to squirt hose. The number has quite consistently been reduced to 47 in 1918. District inspectors' reports show 3,711 squirt hose or applications found defective in 1913, which was consistently reduced to 511 in 1918. Practically all of these accidents are shown to be due to the squirt hose blowing off, parting at splice or bursting caused by defective hose or clamps. These accidents usually resulted in scalding the fireman, as until recently the water for the squirt was generally taken from the delivery pipe of the injector. Undoubtedly the very satisfactory improvement made in the number of accidents chargeable to this device is due to the fact that the attention of all concerned was focused on the large number of accidents caused by such an insignificant piece of apparatus, with the result that a one piece hose of better quality, sometimes armored, was used and more substantial clamps and attachments generally provided. A considerable amount of credit for this improvement is also due the several injector manufacturers who have developed squirt hose attachments which deliver water cool enough to be handled without danger.

One of the large eastern railway systems uses a cold water sprinkler or squirt arrangement, consisting of a small reservoir of about ten gallons capacity, placed inside and at the bottom of the tender tank. The reservoir is provided with a strainer and check valve through which water is admitted from the tank of the tender, the sprinkler hose connection being taken from the bottom of the reservoir. Air from the main reservoir is admitted to the top of the small water reservoir through a hand operated valve located at a convenient place on the tender. When the air pressure is turned on the check valve closes and cold water is forced from the reservoir through the sprinkler hose. When the air pressure is released the reservoir is automatically recharged with water through the check valve.

LUBRICATOR AND WATER GAGE GLASSES

Accidents chargeable to the failure or breaking of lubricator glasses fell off quite consistently from 49 in 1912 to 12 in 1918, and those due to the failure of water gage glasses from 165 in 1912 to 20 in 1918. The decided improvement between the years 1912 and 1918 must be largely attributed to the Commission's rule requiring all tubular water and lubricator glasses to be provided with a suitable shield, although the reports indicate that there are still occurring a number of accidents chargeable to inefficient shields. The more general use of the "bulls-eye" type of lubricators and the "reflex" type of water gage also probably contributed to this improvement; however, the reports show that the glasses in these two devices are also failing and causing accidents.

AIR RESERVOIRS

Fig. 2 indicates that there were from four to six accidents each year chargeable to the failure of air reservoirs generally caused by corrosion through the underside of reservoir. In at least one case the material had wasted away until only 1/64 in. remained at the time of bursting. Possibly these reservoirs were old and had not been enameled and baked inside and out, as has been the practice of the air brake companies for the past several years. However, it would seem that if these reservoirs had received the proper hydrostatic and hammer tests, as prescribed by the rules, the thin sheets would have been detected and the accidents avoided.

BLOW-OFF COCKS

The number of accidents chargeable to the failure of blow-off cocks is shown to have been from 15 to 20 each year since 1912 and to have been due to defective threads, cocks, or their operating mechanism. This would seem to indicate that these parts are not being maintained as well as their importance requires. As the cocks which are now generally being used are of an improved type and of more substantial construction than those formerly used, an improvement in this respect may be looked for in the future.

DRAW GEARS

Personal injury accidents due to the failure of draw gears fell off from 22 in 1916 to 11 in 1918—probably the result of the rigid rules of the Commission governing the proper maintenance of draw gears. These accidents are generally shown to have been due to the pins or holes in the bar being worn, or to flaws or defects in the materials of which they are made. A number of these accidents are also reported as due to excessive lost motion between locomotive and tender and in several cases the safety chains are stated as having been too long. When one of the pins or the drawbar breaks, the entire shock due to the momentum of the locomotive is taken by the safety chains or safety bars, and on account of the slack which it is necessary to provide in these parts, they generally fail to hold the locomotive and tender together. Naturally the results of such accidents are usually of a serious nature. The type of gear whereby a single heavy safety bar is placed directly under the drawbar and on the center line of the locomotive, thus requiring a very small amount of slack, would seem to offer means whereby accidents of this kind could practically be avoided.

GENERAL CONCLUSIONS

The writer is unable to say to what extent the annual reports of the Chief Inspector are in the hands of mechanical department employees, but all such employees as general foremen of locomotive department, roundhouse foremen, foremen boilermakers and their subforemen should be supplied with them as issued, for the reason that they not only list and classify all accidents, but the cause and circumstances under which they occur are clearly stated. They should also be of considerable value to the several locomotive builders and to all companies furnishing locomotive appliances.

The intelligent interpretation of the causes of these accidents should not only reduce their number, but it should also tend to improve the efficiency of the men and equipment, which is of the utmost importance at the present time on account of the prevailing high cost of labor and material.

The Chief Inspector's reports reveal the fact that personal injury accidents, due to the failure of certain locomotive parts, are occurring to a much greater extent on some roads than on others in proportion to the number of locomotives operated by each road and allowing for other varying conditions. This prompts the suggestion that the mechanical department of each railroad check the design, material and maintenance methods of all parts which are shown by these reports to be causing them an excessive number of failures, with the design and maintenance practice of similar parts showing the best performance on locomotives of other roads operating under approximately the same conditions.

When the Congress passed the original Boiler Inspection Law in 1911 it was thought unnecessary by a number of railroad men, and resented by some as an unwarranted interference with their prerogatives, but largely due to the practical manner in which the provisions of the law have been administered by the Division of Locomotive Boiler Inspection under the Interstate Commerce Commission, its beneficial results are now fully recognized and railroad men generally are heartily co-operating with the Commission.

The writer, having had actual roundhouse experience, fully realizes that it is a very simple matter to analyze locomotive accidents and to offer suggestions for their avoidance in the future, in comparison with the very difficult problem of actually maintaining running repairs in a thoroughly practical manner under the quite common conditions of shortage of power and inadequate facilities. He therefore trusts that any criticisms made in this article will be understood in this light, and as having been offered solely as constructive criticism for the possible betterment of the future service.

STANDARDIZATION IN FRANCE AND BELGIUM

BY ROBERT E. THAYER

European Editor

Equipment standardization in France and Belgium is being considered principally for the reason that large quantities of new equipment must be built eventually and vast quantities must be repaired because of the great amount of damage done to the cars and locomotives in both countries by the Germans during the war, and also because of the fact that the maintenance of equipment in both these countries had to be seriously neglected.

Four of the important French railways, namely, the Paris-Lyons-Mediterranean, the Paris-Orleans, the Midi, and the State railways, have formed a committee for the consideration of standard equipment. Two designs of locomotives are being considered, one of the Pacific type for passenger service, which will have driving wheels of about 78 in. in diameter, and a Mikado locomotive for fast freight and heavy grade passenger service, having driving wheels of about 65 in. in diameter. It is very interesting to note that these locomotives will be of the two cylinder, simple, superheater type. With the improvements in the design of this type of locomotive, it is now generally conceded in France that the economies obtained from the compound locomotives as compared with a good design of two cylinder, simple locomotive using superheated steam, do not warrant the increased first cost, the increase in the cost of maintenance and the added complication of the compound locomotives. Furthermore these standard engines will have a lower factor of adhesion than is customarily used in America. The design will probably not give a factor any higher than 3.5.

The traffic conditions in France are such that a high speed locomotive is needed both in passenger and freight service. The Pacifics will be designed to operate at a speed of about 74 m.p.h. and to work on grades of 0.5 and 0.6 per cent. The Mikado locomotives are to be built for speeds of about 56 m.p.h. and for grades of from one to 1.2 per cent. The axle load of these locomotives will be limited to about 41,000 lb. as that is the limit required by the Minister of Public Works and Transports of France. This limit is set on account of the fact that many of the bridges in France are too weak to carry a higher wheel load, and as a general rule there are two less ties used per rail than is the practice in America.

The adoption of the two standard types of locomotives does not mean, however, that other locomotives will not be built, and it is expected that other locomotives will be designed and built by any of the four roads to meet any special conditions they may have. However, as many details as possible will be the same as those used on locomotives built to the standard designs.

There are five standard designs of cars to be built; two types of box cars, with and without screw brakes; two types of coal cars, with and without screw brakes, and flat cars with no screw brakes. The question of power brakes is under consideration. It is the desire of progressive engineers in France to have continuously braked freight trains, but whether this will be permitted with the excessive amount of slack between the cars of the present day French freight train with the type of coupling in use at present, remains to be seen.

Several engineers have expressed a strong desire to use automatic couplers, but with the present screw type of coupler generally used in France, the introduction of the automatic coupler would entail numerous difficulties, and until some design of automatic coupler is made which will readily interchange with the screw type of coupling now used, but little will be done in this respect.

The work on standard passenger cars has not progressed to the same extent as in the freight cars. They will, however, be of all-steel construction. This type of construction is not new to French railways. The Paris-Orleans has built nothing but steel passenger equipment for years, and, in fact, some of our first steel equipment was patterned after the Paris-Orleans designs.

The work in Belgium has not developed to the extent that it has in France, but the conditions in Belgium are such that until the disposition of the German equipment running on Belgian rails under the terms of the Armistice is known, no definite plans will be formulated. The Belgians, in addition to their varied stock of power, have had to cope with the added inconvenience of some 40 to 45 designs of German locomotives and innumerable designs of German cars. This has accentuated the need of equipment of more uniform design. It is the desire of the State railways there eventually to return the German equipment and receive indemnities with which to buy new equipment. If this is granted—it is doubtful if it will be—some plan of standardization will be formulated as a vast amount of equipment will have to be built to replace the equipment which has been destroyed during the war.

EQUATED TONNAGE AND FUEL CONSUMPTION *

BY R. N. BEGIEN
Federal Manager, Baltimore & Ohio, Western Lines

Equated tonnage has a certain relation to fuel consumption. However, this relation is established through the medium of the trainload. The fuel consumption per gross ton mile decreases as the trainload increases, provided the speed of the movement does not suffer to such an extent as to increase the time on the road materially. The purpose of equated tonnage is to secure uniform loading of power, regardless of the kind of equipment or number of cars involved. It is a well known fact that an empty car has a much higher resistance per ton of weight than a loaded car. For example, a 20-ton empty will show a resistance in the neighborhood of eight pounds per ton of weight, or 160 lb. total resistance to traction on a level. On the other hand a 70-ton car shows a resistance of approximately four pounds per ton of weight, or 280 lb. of resistance to traction on a level. These figures are approximate, but for practical use are correct. Of course many other features enter into the question, such as temperature, wind, rate of grade, curvature, type of car, etc.

In order to make practical standards which can be placed in the hands of yardmasters, it is necessary to use certain adjustments in building up trains, and to modify them as is necessary in the judgment of the chief train despatcher to suit conditions under which the operation is conducted. If a locomotive is able to produce 30,000 lb. of effective tractive effort behind the tender at rating speed, the train should have a combined resistance of 30,000 lb., irrespective of the character of the cars, and in order to accomplish this a certain arbitrary adjustment is added to the weight of each car, and the effect of this arbitrary adjustment is to automatically compensate the different weights of cars. This adjustment varies with the rate of grade, being about 15 tons per car on a 0.3 per cent grade, and about two tons per car on a 2½ per cent grade.

Building up a train tonnage, composed of the dead weights of cars, plus an adjustment, so that the combined resistance of the cars is equal to the effective tractive power behind the tender, gives a tonnage which is known as an equated tonnage. The object is to secure uniformity of rating in order that the trains will always have a rated tonnage, irrespective of the kind of cars. There are a number of different ways of applying this principle, but unless some kind of equated tonnage is used it is not possible to rate trains with any degree of accuracy.

It is safe to say that any road which has not used the equated tonnage system, and which has through freight to haul, has not built up its trainload to the best possible advantage. Full trainload at uniform speed spells efficiency in fuel consumption, and the relation of equated tonnage to fuel consumption is very clearly evidenced through the trainload.

Proper train loading contemplates each locomotive handling the maximum trainload which it can move on the ruling grade at the economic speed. At such speed the locomotive is working most efficiently. An increased speed, which may be brought about by reduced trainload, will result in inefficient locomotive performance, while a reduced speed, brought about by overloading, will produce the same result. With all trains moving at the economic speed, the locomotives operating at maximum effort and hauling the uniform trains under these conditions, the fuel consumption, when measured on the ton-mileage basis, will be the minimum obtainable.

*Abstract of paper presented before the International Railway Fuel Association convention at Chicago, May 19-22, 1819.

Mechanical Stoking of Locomotives*

Factors Determining Necessity of Applying Stokers; Operating Results Secured by Stoker Firing

BY W. S. BARTHOLOMEW
President, Locomotive Stoker Company

THE FIRING OF MODERN LOCOMOTIVES by mechanical means could properly be separated into four distinct subjects: First, the stokers themselves; second, the locomotives to which they are applied; third, the particular reasons which lead up to any given application, and fourth, the results which were achieved by such application. I assume that you are familiar with all of the stokers which are now being applied to locomotives and shall begin with the second subject.

All locomotives do not require stokers. Locomotives that can be hand-fired to maximum capacity through sustained periods do not require stokers. Locomotives which are of such size as to come within the specifications of those which are regularly being equipped with stokers, but which are not operated beyond the limits of hand-firing, do not need stokers. These statements must lead to the conclusion that only locomotives which are of such size as to bring them regularly beyond the limits of hand-firing, or locomotives of smaller size but which are regularly operated beyond the limits of hand-firing, require stokers. This must mean that we do not need stokers to do a hand-firing job and that the stoker job cannot be done by hand. This means also that stoker-firing and hand-firing are not directly comparable. Up to the present time, no locomotives have been equipped with stokers which do not need them.

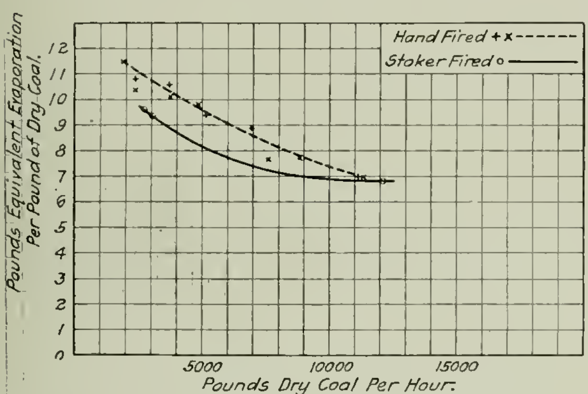


Fig. 1—Comparative Evaporation, Hand and Stoker Firing

LOCOMOTIVES WHICH REQUIRE STOKERS

These statements must bring up immediately the question as to whether such a definite line can be drawn between locomotives which do not need stokers and those to which they could be applied to advantage. To show you that a definite line can be drawn as to locomotives which can be hand-fired through sustained periods and those which cannot, my own convictions are that no locomotive really requires a stoker that does not weigh approximately 200,000 lb. on drivers, have a calculated tractive power of 50,000 lb. or over, a grate area of 60 sq. ft. or over, and a coal consumption through sustained periods of 4,000 lb. or more per hour.

The commercial application of Mechanical Stokers to locomotives really began in 1910. One of the first important stoker applications was made to five very large locomotives which were designed and built originally to be equipped with stokers. This is especially significant in that, in the main practically all stoker applications have been made to date to locomotives without requiring any general modification in the conventional locomotive design. This application was made on a Chicago, Burlington & Quincy M-2 Santa Fe type locomotive which included in its original specifications such details of design as would permit the application of the Barnum under-feed stoker.

The particular point of interest about this locomotive is that in designing such a locomotive it was realized that to put it in service with a tractive effort of about 72,500 lb., a weight on drivers of over 300,000 lb., and with a grate area of 88 sq. ft. would call for a coal consumption beyond the possibilities of hand-firing.

Five of these locomotives were built in the year 1911 and equipped with stokers, which later proved inadequate in capacity for the requirements and were removed, and the locomotives were put in service in such districts as would permit them to be hand-fired. It was found, however, that they could be hand-fired only by reducing the grate area

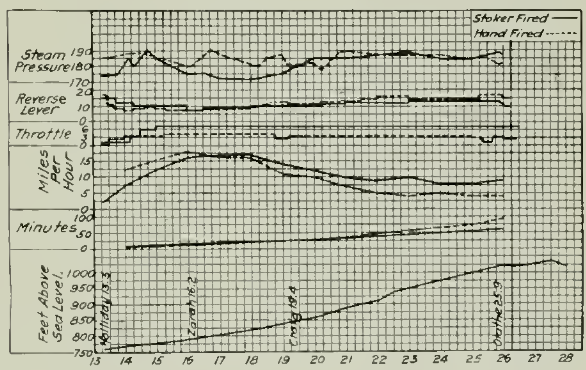

Fig. 2—Hand and Stoker-Fired Tests on 13-Mile Grade

about 25 per cent by blocking off with fire-brick. These circumstances plainly indicate that on such a locomotive a differential is immediately established between hand-firing, and stoker-firing of at least 25 per cent in capacity. A very gratifying development of this particular situation has been that other stokers were later applied to these locomotives with such success that 60 more have been purchased.

The decision reached by the Burlington as to necessity for a stoker on a Santa Fe type locomotive of this size has practically set the pattern for all such locomotives of this type built. During the past five years over 95 per cent of all Santa Fe type locomotives built for coal-burning service have been equipped with mechanical stokers.

STOKERS INCREASE CAPACITY OF LOCOMOTIVES

Another very early important stoker installation beginning in 1912 was made by the Norfolk & Western on a large number of Mallet locomotives. This installation probably rep-

*Abstract of a paper presented before the Western Railway Club.

resents the most marked increase in revenue tons per train that has been accomplished by any stoker installation made so far. To make a concrete illustration the tonnage rating for the 12-wheel locomotives in service on the Norfolk & Western between Portsmouth, Ohio, and Columbus, which were standard for that division before the advent of the Mallet locomotives was 3,000 tons per train for one Class M-2 12-wheel locomotive, or 6,000 tons for a double-header, whereas when the Mallets were tried out and rated on that division it was found that one of these locomotives could haul 6,000 tons between those two points in practically the same time that one of the smaller locomotives could haul 3,000 tons or two of them could haul 6,000 tons.

It was also discovered that the coal consumption of one of the Mallets was approximately one and one-half times one of the 12-wheelers, which, with twice the tonnage, would make an immediate saving of 25 per cent in coal consumption for any given number of total gross tons per mile.

There is current gossip to the effect that the application of stokers to locomotives means more coal consumption, which, of course, it does from one point of view, as one of the main purposes of the stoker is to make it possible to burn more coal per locomotive mile or per locomotive hour than would be possible by hand-firing. The benefits, however, from such increased coal consumption are such as to make the proposition attractive from every point of view as "movement of tons per day" over any given piece of track is the most important consideration in railroad operation. You only need to refer to the annual reports of the Norfolk & Western for the past five or six years to see what has been accomplished in this direction through the use of larger locomotives equipped with stokers.

The stoker fired H-2 and H-4 Mallet locomotives on the Chesapeake & Ohio have accomplished very similar results

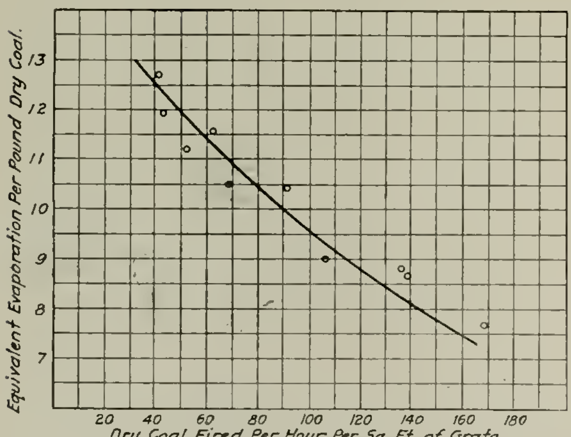

Fig. 3—Effect of Rate of Firing on Equivalent Evaporation

in increased tons per train and the use of over 300 such Mallets in freight service is a further tribute to the value of the mechanical stoker in the assistance it renders in putting into service such locomotives which regularly are operated with a coal consumption beyond the limits of hand-firing.

It is not a question of the pounds of water evaporated per pound of coal altogether, although these particular locomotives show an evaporation, stoker-fired, that comes well within the limits of anything that is regularly accomplished on smaller hand-fired locomotives which are operated anywhere near maximum capacity.

EARLY INSTALLATION OF STOKERS

About the time these Mallets were put in service on the Chesapeake & Ohio 50 heavy Mikados with a tractive effort of approximately 60,000 lbs. were purchased and have now been successfully stoker-fired for over six years. There has been established a differential of 25 per cent between hand-fired and stoker fired tonnage rating on the division where these locomotives are operated. The rating between Russell, Kentucky, and Silver Grove, is 6,000 tons stoker-fired and 4,800 tons hand-fired.

Another very early and important stoker installation was made by the Virginian on somewhat larger Mallet locomotives. These early stoker installations had to do with coal traffic, which, of course, is a low-grade commodity from a freight revenue point of view and the earnings are in more direct relation to the tons per train than is the case with other traffic. The operation of these locomotives in the coal traffic

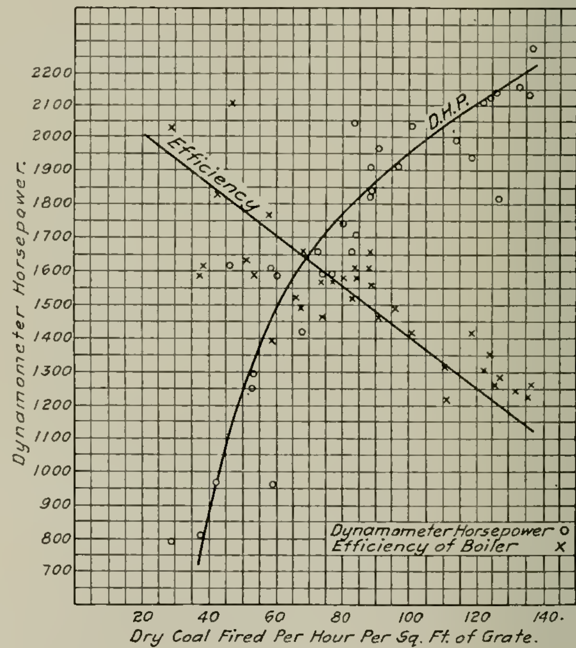

Fig. 4—Boiler Efficiency as Related to Horsepower Chart

on the Virginian has been so successful that special track, special cars, special coal-handling devices at the docks and still larger locomotives have been built to make it possible to increase the gross tons per train still further.

The specifications for the stokers for the Virginian 2-10-10-2 Mallets called for an ultimate coal-delivering capacity of 15,000 lb. per hour as a possibility, and in actual service it is not unusual to have a coal consumption of five tons every 60 min.

The locomotives referred to thus far have all had a calculated tractive effort of more than 60,000 lb. However, a Baltimore & Ohio Mikado which has a calculated tractive effort of only 54,000 lb. represents the largest installation of mechanical stokers to any one type of locomotives up to the present time. The Baltimore & Ohio has over 400 of one design stoker-fired and this locomotive really established the point where the Railroad Administration began the application of stokers to the standard locomotives.

This locomotive not only represents a very important early stoker application as to number of locomotives equipped, there having been 50 of these locomotives equipped as early as 1911, but it also represents definitely the point at which we believe the application of stokers should begin to both new and old locomotives.

STOKERS PROVE ADVANTAGEOUS ON SMALL LOCOMOTIVES

The reason which led the Baltimore & Ohio to apply stokers to such a large number of these locomotives as early as 1911 had largely to do with the fact that the bridges, track, and sidings on the Baltimore & Ohio were such that a locomotive with a heavier axle load than 55,000 lb. could not be operated at many points on the Baltimore & Ohio system. The traffic conditions, however, especially between Cumberland, Md., and Martinsburg, W. Va., which is the throat of the system between the Lines East and Lines West, were such as to require a maximum tonnage movement for long periods of the year to avoid congestion.

At the time the first 50 of these locomotives were put in service on the Cumberland Division 48 maximum tonnage eastbound drag freight trains were operated daily. It will be immediately appreciated that both time and maximum tonnage per train were of immense importance under such stress of traffic conditions. Immediately upon putting into service the stoker-fired Mikados referred to on this division, where a large number of duplicate locomotives were already in operation hand fired, the operating department began to load down the stoker-fired locomotives with heavier tonnage than the hand-fired until within six months after they were put in operation more than 500 tons per train were regularly added to the stoker-fired locomotives over and above the tonnage given to the same locomotives hand-fired.

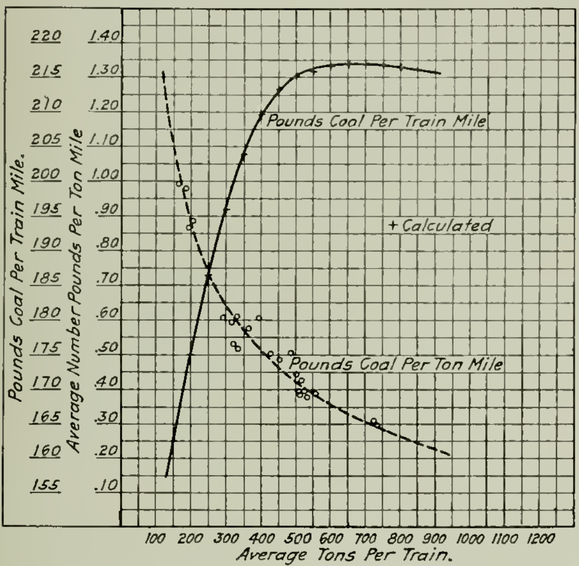

Fig. 5—Relation Between Coal per Train-Mile and Tons per Train

The Baltimore & Ohio at this time owned 160 of these locomotives without stokers and 50 stoker-fired. Since then they have purchased over 300 of these locomotives equipped with stokers which are now in daily service over all parts of the system.

To haul the traffic under the conditions just outlined between Cumberland, Maryland, and Martinsburg, W. Va., an average coal consumption per hour of 6,500 lb. was not unusual for the entire running time between division points, which will readily explain why the stokers have been so successful on the Baltimore & Ohio even on this comparatively small power. When the United States Railroad Administration came to place orders for a large number of locomotives, which included over 600 of this particular type and size, they were also equipped with mechanical stokers which made it possible to use them in such service as I have just described.

The Pennsylvania has a Decapod type locomotive which weighs over 300,000 lb. on drivers; carries 250 lb. steam pressure and has a calculated tractive effort of nearly 90,000 lb. It is of special interest to know that this locomotive was originally designed to be hand-fired and the first one constructed was put in service without a stoker for the reason that it was intended to operate these locomotives only within the limits of coal consumption which could be fired by hand through sustained periods. Over 100 of these locomotives have been built to date and not only the first one which was originally put into service hand-fired, but all of the others have been equipped with mechanical stokers.

COMPARATIVE FUEL ECONOMY OF HAND AND STOKER FIRING

The reason which led up to this application was entirely one of capacity rather than what is ordinarily referred to as economy. The first locomotive originally hand-fired was equipped with a mechanical stoker, and extensive comparative tests made to determine the relative economy of stoker-firing and hand-firing. The chart shown in Fig. 1 indicates the result secured, and confirms the statement that a stoker is not needed to do a job which can be done by hand, nor can the stoker job be done by hand-firing.

It will be noted that within the limits of hand-firing, namely, below 5,000 lb. of coal consumption per hour, there was a slight difference in economy shown in favor of hand-firing. It will be further noted, however, that when the rate of firing in the different tests was increased to where the stoker became a necessity that no difference in economy in favor of hand-firing occurred, and, as a matter of fact, while the hand-firing was of the most expert nature, the capacity was not reached by hand that was easily obtained with the stoker.

A most interesting situation was developed in connection with putting these locomotives into service under actual operating conditions, which was fully to be expected from the results shown in this graphic chart. One of these locomotives was put in service with its rated tonnage on a certain division and hand-fired, the coal consumption noted, and other records made of the performance. Very shortly thereafter another test was made with the same locomotive over the same division with similar tonnage, all conditions being duplicated as far as possible except that the locomotive was stoker-fired instead of hand-fired. The coal consumption, the water evaporated and the horse-power hours developed over the division were almost identical in each instance.

FUEL ECONOMY SACRIFICED FOR INCREASED CAPACITY

There has been much discussion in connection with the application of mechanical stokers to locomotives as to the comparative economy between stoker-firing and hand-firing, and I wish to refer again to my earlier statement that stoker-firing and hand-firing are not directly comparable. The reason for this has really nothing to do with the stokers themselves, but is due to the different points at which the locomotive is worked with hand-firing as compared with stoker-firing.

The significant fact in connection with the comparative tests, however, is that it required 11 hrs. to develop the necessary horsepower-hours to take the train over the division hand-fired, whereas, practically the same horsepower-hours were developed and the train taken over the division in 7 hrs. when stoker-fired. In other words, taking a maximum hand-firing capacity of approximately 5,000 lb. per hr. as a gage of the limit of hand-firing, this would mean that by firing 8,000 lb. per hr. into the fire-box of the same locomotive with the stoker the same number of horsepower-hours could be developed in 7 hrs. that it took 11 hrs. to do by hand.

From the traffic point of view I believe there would be no argument if there were no other considerations than this marked difference in time saved by developing more horsepower with the stoker on this very large locomotive than was possible to do by hand even with the same measure of economy. One of our engineers estimated the difference in results, however, from another point of view; namely, reducing the tonnage to a point where the train could be handled over the division by hand-firing in seven hours to compare with the heavier train stoker-fired over the same division in seven hours. A very conservative estimate would indicate that on the basis of seven mills per revenue ton income per mile the locomotive would pay for itself in less than 100 trips by being stoker-fired and hauling the heavier tonnage. There has not come to my attention in all of our stoker experience a better example of the real purpose of the stoker than its application to this large lot of locomotives.

SPECIAL SERVICE CONDITIONS MAKE STOKERS NECESSARY

In marked contrast to these large locomotives is a small Consolidation locomotive in service on the El Paso & Southwestern to 21 of which stokers have been applied and which are the smallest locomotives to receive stokers to date so far as I know. They have a tractive effort of but 47,000 lb. The considerations, however, leading up to the stoker application had nothing to do with capacity or economy. The climatic conditions in the desert country during a large part of the year which made it almost impossible to secure firemen to operate such locomotives at all was the main factor so that it was not in any sense inconsistent to apply stokers even to these small locomotives in order to operate them, although I understand the hauling capacity has been actually increased by the stoker application, which it would be very natural to expect under the circumstances.

We come now to a consideration of some of the results which have been achieved by the stoker applications that have been made in different parts of the country and on different locomotives up to this time.

The data shown in Table I. were obtained by the Atchison, Topeka & Santa Fe in tests of a Mikado locomotive having approximately 60,000 lb. tractive effort. This tabulation will serve to bring out some points with regard to coal consumption per hour as related to the hauling capacity of a locomotive of this kind when it is desired to increase the revenue tons per train. The significant points about this tabulation are that the coal consumption per hour is fairly representative of the difference between the maximum possibilities of hand-firing and the ordinary range of operation when stoker-fired.

Table I—Comparative Test Data, Hand and Stoker Firing

Test No.	Tonnage	Cars	Loads	Empties	Running time Hr. Min.	Coal used, lbs.	Evaporation Per lb. coal	1,000-ton miles	Coal per 1,000 T. M.	Coal per hour	Coal per sq. ft. gr. per hour	Average steam pressure	Hand or stoker
7	2,579	65	63	2	6:42	35,000	5.62	281.9	124.2	5,224	78.2	184.3	H
9	2,713	69	60	9	5:48	35,500	5.58	296.6	119.8	6,121	91.3	178.8	S
11	2,849	71	67	4	6:34	46,600	4.75	311.4	149.7	7,096	106.2	175.7	S
13	2,835	74	58	16	5:40	38,083	5.39	306.8	124.3	6,721	100.6	177.0	S
15	2,848	75	73	2	5:38	41,076	4.91	300.1	136.8	7,403	110.8	185.9	S
17	2,896	56	56	0	5:53	43,300	4.73	312.8	138.4	7,360	110.7	185.8	S
19	2,872	71	66	5	6:31	44,890	4.55	310.2	144.7	6,888	103.1	167.5	S
21	2,869	65	65	0	5:28	35,600	4.76	313.6	113.5	6,512	97.7	183.6	S
23	3,059	73	72	1	6:04	37,350	5.03	334.3	111.7	6,156	92.0	179.4	S
25	3,061	65	56	9	6:16	38,250	5.57	334.6	114.3	6,203	92.9	181.2	S
27	2,887	61	57	4	5:27	32,300	5.62	314.6	102.7	5,927	88.7	187.7	S

It will be noted that the coal consumption per hour on hand-fired run No. 7 was 5,224 lb. per hr. or 78.2 lb. of coal per square foot of grate area per hour. This brought a coal consumption per thousand ton miles of 124.2 lb. and I believe represents maximum hand-firing possibilities. All of the ten other trips shown on this tabulation show a coal consumption of from 6,000 lb. to 7,400 lb. per hour, and taking the high and low coal consumption per thousand ton miles, the average happens to be for the ten trips almost to a fraction the same as the coal consumption per thousand ton miles for the hand-fired trip, the larger percentage of the stoker-fired trips being below the hand-fired trips in coal per one thousand ton miles. A maximum increase of nearly 500 tons per train was secured on some of the stoker-fired trips, and it will also be noted that on no stoker-fired trip was the actual running time as long as on the hand-fired trip.

SPEED ON GRADES INCREASED BY STOKERS

At the end of one of the runs I took occasion to go into the train despatcher's office, look over his operating sheet, and make inquiries as to the time required by all of the freight

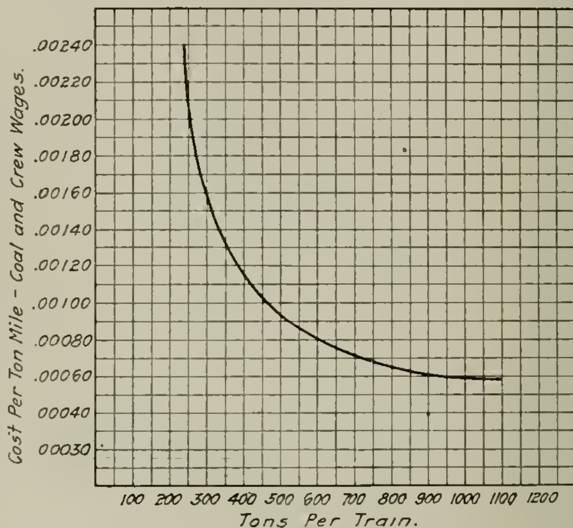

Fig. 6—Cost of Coal and Crew Wages as Related to Tons per Train

trains westbound on that day to cover a 13-mile and an 8-mile 6/10 per cent grade, which grades are the limiting factor on that particular division. The result of that inquiry is shown in Table II.

The 2,900 tons taken up the 13-mile grade in 50½ min. has illustrated better than any description that could otherwise be given the real purpose of the application of a stoker to a locomotive like the Mikado which hauled this train as compared with other similar locomotives hauling from 500 to 1,000 less tons in longer time up the same grade hand-fired. It is true that more coal was consumed in the 50½ min. hauling 2,900 tons in that time up the 13-mile grade than would have been the case if the locomotive had been operated at a less cut-off, less throttle and consequently less speed, but the fact remains that to get maximum tonnage over the division in the minimum amount of time requires this kind of locomotive performance. In addition to illustrating the main purpose of the stoker it also shows why it is quite often stated that from the point of view of water evaporated per pound of coal the coal consumed per locomotive mile is more when stoker-fired than might be the case when such a locomotive was hand-fired under less strenuous conditions.

Table II—Time on Ruling Grades

Engine No.	Gross tons	13-Mile grade 31.68 feet. Per mile	8-Mile grade 31.68 feet. Per mile
3211	1,800	61 min.	30 min.
3202	2,180	48 min.	27 min.
3207	1,950	63 min.	25 min.
3209	2,900	50½ min.	31 min.
3206	2,120	75 min.	32 min.
3200	1,945	46 min.	31 min.
3121	2,000	58 min.	....
3192	2,285	82 min.	....
3193	1,850	54 min.	....

In order to get a more direct comparison of the possibility of hand-firing and stoker-firing with the tonnage rating such as shown on the stoker-fired trips of the tabulation, and also to compare the performance on the 13-mile grade with the 2,900-ton train, a hand-fired trip was made over the division with what might be called stoker tonnage. Fig. 2 is a graphic chart showing the comparative performance between a hand-fired and a stoker-fired trip. It will be noted that the locomotive was worked at a point stoker-fired which was not possible on the hand-fired trip, the result being that 31 min. more time was required to take the train with stoker tonnage up the 13-mile grade with hand-firing than with stoker-firing.

There are additional points of interest which cannot be plotted by curves namely, that on the particular day on which the hand-fired run was made, the traffic was exceptionally heavy and one manifest and one drag freight train were immediately behind the hand-fired train on the 13-mile grade which would not have been the case had that particular trip been stoker-fired and the 31 min. less time on the hill.

The diagram shown in Fig. 3 illustrates the rate of evaporation as related to the rate at which dry coal is fired per square foot of grate area per hour. The tests indicated on this diagram were all hand-fired so that this drop in the evaporation rate had nothing whatever to do with hand-firing as compared with stoker-firing, but must be definitely borne in mind as usually being related to the price we must pay when we stoker-fire a locomotive to its maximum capacity; in other words, get a coal consumption rate up to the point shown on some of the tabulations.

The next diagram, Fig. 4, illustrates the point even better. The many tests plotted on this diagram were practically all hand-fired, but no better illustration could be prepared to illustrate the price we must pay for operating the modern locomotive to its maximum capacity.

There are many locomotives being operated at the point where less horsepower output is being secured in order to keep the evaporation of water per pound of coal up to a point shown in the left-hand section of this diagram, but on the other hand there are very many more locomotives being operated under the conditions shown on the right-hand section of this diagram and, of course, from the stoker manufacturers' point of view, this is really where we expect a large locomotive to be operated if equipped with a stoker.

The reason that more locomotives are operated at their highest possible horsepower output, notwithstanding the fact that this brings a decrease in so-called boiler efficiency, is, of course, because a very satisfactory return is secured on the price paid for such operation. This price is represented in the cost of coal per locomotive mile, and the returns on the investment are represented in the reduced cost of coal per ton mile brought about by the increase in revenue tons per train hauled by the locomotive when operated at its maximum horsepower output. The curves in Fig. 5 illustrate the relation between the increased cost of coal per locomotive mile and the decreased cost of coal per ton in the heavier train.

This decrease in cost per ton mile is not altogether confined to coal alone as the increased revenue tons per train made possible by the maximum horsepower output of the locomotive is directly related to crew wages as well. Fig. 6 illustrates the decrease in the cost per ton mile of both coal and crew wages combined, and further illustrates why it is desirable to operate freight locomotives to maximum capacity even at an increased cost of coal per locomotive mile.

I have said nothing so far in this paper about the stoker doing the manual work of the fireman or relieving him from the suffering incident to the heat of the fire-box due to opening the fire door when hand-firing, as it has been my endeavor to illustrate the returns which are being secured on the large investment which has been made in mechanical stokers for locomotives during the past six or eight years. It goes without saying, however, that there are many other advantages in the application of stokers to locomotives. One of these is, of course, the relief of the firemen, making the position of locomotive fireman more attractive and, therefore, making it possible not only more readily to secure men for this work, but also to select those men who are particularly qualified later to become locomotive engineers rather than to consider only their physical stamina.

I have tried to be very frank in my statements and have in no sense endeavored to have you reach a conclusion that it is not necessary to pay a certain price for the use of the stokers on locomotives such as have been equipped with them. On the other hand, it is very plain that whatever the price that it is necessary to pay it brings a most satisfactory return from every point of view. Objection can be raised against the stokers, of course, just as objections can be raised to many of the other modern labor-saving and capacity-increasing devices and features which have been added to locomotives in recent years to enable us to travel the avenues of economy which have brought such large returns in present-day railroad operation. The mark which we are aiming at in the application of mechanical stokers to locomotives is mainly one of capacity; and in the sense that the word economy is ordinarily used, we must conclude that the kind of locomotive capacity which I have pointed out must take precedence over economy for large modern locomotives.

It is significant that the cost of coal is after all a comparatively small part of the total operating expenses, and as the economies that occur from any increase in revenue tons per train mile have a much larger influence upon the net annual earnings of any given railroad company than does any variation either up or down of the cost of total coal used per annum by that railroad. It follows that what must be accomplished first and above all other things is to increase the revenue tons per train mile.

LOCOMOTIVE CONDITIONS IN ENGLAND

The condition of the locomotives of the London, Brighton & South Coast Railway, which is considered indicative of the general conditions throughout the country, was made a matter of comment in the London Post of July 1.

It is reported that out of about 600 locomotives there are 166 awaiting repairs. At the same time the traffic condition of this road has increased from 80,000,000 passengers a year before the war to 100,000,000 passengers a year at the present time, or an increase of 25 per cent. This is being handled with a 25 per cent reduction in service and a 20 per cent reduction in force. This company released 5,263 men or nearly 33 per cent of its total force for war service, out of which 2,279 have returned. A large number of those who have not as yet come back are men of technical skill, and this is largely responsible for the retarded repairs. Also many of the skilled workmen have left the railroad to go to the ship yards. This is particularly the case with the boilermakers. At the repair shops at Brighton in July, 1914, there were 70 locomotives under repair with only seven awaiting shop. In May of this year there were 107 locomotives under repair with 59 awaiting shop. The situation is so bad that this company has found it necessary to have locomotives repaired in contract shops. One shop promised to repair two engines a month, beginning with January of this year, but as yet none have been delivered. In addition to the shortage of men, a reduction of working hours has accentuated the difficulty. With the present situation the company does not expect to get back to pre-war conditions for at least another twelve months.

Considerable pressure has been brought to bear for a reduction in fares, but if this were done, traffic would increase beyond the capacity of the company to handle it. The increase in the cost of wages and materials is more than 50 per cent of pre-war conditions.

Railroad Administration News

Shop Men's Wage Negotiations Reach Critical Stage; Standard Freight Cars Being Put in Service

The railroad Administration has revised the instructions issued early last year that new locomotives being delivered by the builders be sent under steam and hauling tonnage and the regional directors have been given discretion to decide whether new locomotives shall be sent dead in trains or under steam with a load, upon notifying the mechanical department. The question will depend on whether it will be practically useful to use the new locomotives for hauling tonnage that is going in the direction of the locomotives. The use of such locomotives when moving under steam will be accepted as full payment for transportation charges.

Shopmen to Take Strike Vote

The 1919 cycle of demands on the Railroad Administration for increased wages has reached a critical stage. Committees representing the various shop craft unions federated under the organization of the Railway Employees' Department of the American Federation of Labor, that presented demands to the director general in January for a wage increase from 68 to 85 cents an hour for the principal classes of craftsmen, as well as increases for helpers and differentials for various classes of special work, were in Washington all of the last week in July conferring with the Railroad Administration officials and threatening strikes unless a favorable decision was forthcoming soon. The unions also demanded the issuance of an order prescribing uniform rules and working conditions. Both propositions have been under investigation for several months by the Board of Wages and Working Conditions, which submitted its recommendations on both to Director General Hines.

On August 1, President Wilson, on the representations of Director General Hines, urged upon Congress the necessity of passing speedy legislation providing for the creation of a tribunal to investigate and determine all questions concerning the wages of railroad employees, but excluding rules and working conditions, and also making its decisions mandatory upon the Interstate Commerce Commission to provide any increase in rates necessary to cover any recommended increases in wages. In his letter to the President, the director general further recommended that Congress be asked to provide in any such legislation that any increases in railroad wages which may be made by the tribunal constituted for that purpose, be made effective as of August 1, 1919, so that the delay incident to the creation of such a tribunal will not be prejudicial to the employees. In his letters to Senator Cummins and Representative Esch, the President expressed his approval of this recommendation.

Prior to this apparent attempt on the part of the Railroad Administration to shift the responsibility of meeting the wage increase demands of the various classes of employees, the shopmen had already been displaying a great deal of impatience because of the delay in passing on their demands and several local strikes had been called.

The labor organizations, generally, apparently did not take kindly to Mr. Hines' proposal and the shop organizations particularly were aroused by the suggestion that any increases be made effective as of August 1 because they had demanded that their increase be made retroactive to January 1, 1919. B. M. Jewell, acting president of the Railway Employees' Department of the American Federation of Labor, announced on August 2 that it had been decided to call for a strike vote, returnable by August 24, of the approximately 500,000 shop employees involved.

Acting on behalf of the six shop crafts a committee of 100, of which Mr. Jewell as chairman presented to the director general on January 7 a request for a minimum of 85 cents an hour for mechanics, an increase of 17 cents; a minimum of 60 cents for helpers, an increase of 15 cents; an increase of 10 cents per hour for apprentices and various differentials for special classes of work. On February 8 the question was referred to the Board of Wages and Working Conditions, during March and April hearings were held by the board, and on July 16 the board made its divided report to the director general. During this period the board was also giving consideration to a demand by the shop crafts for a national agreement covering rules and working conditions, to be effective on all roads under federal control regardless of whether they had previously had contracts with the unions.

These were considered by committees representing the employees and the regional directors, which submitted a report to the board and the board made its recommendation to the director general on July 16.

During June and July several local shop strikes were called by way of protest against the delay in passing on these two matters, but they were settled. Beginning on July 28 the committee of 100 began a series of conferences with the director general demanding a decision by August 1. The unions on the southeastern roads had definitely decided to strike on that date unless their demands were granted. On July 30 Mr. Hines advised the committee he would be glad to enter into the agreement covering rules and working conditions, and promised to give a decision on the wage question later. Mr. Jewell then wired the various local organizations that they had gained one point sought and instructing them that there must be no stoppages of work pending the conclusion of the negotiations. This was not sufficient to hold the men in check, however, and the shop men walked out in various parts of the country on August 1, the number increasing on the following days. The dissatisfaction was increased on that date, when in lieu of a decision on the wage question Mr. Hines read to the committee his letter to the President proposing a special wage tribunal. Meanwhile the negotiations as to the rules and working conditions have been temporarily set aside.

"We shall continue to endeavor to settle the demands by negotiation with the Railroad Administration pending receipt of the strike vote," said Mr. Jewell. "That will, when taken, simply center the power for calling a strike in the hands of the committee. The first effect will probably be the ending of the present strike, which has taken out a considerable number of men over various sections of the country who have been impatient of the long delay. Their walkouts have been unauthorized, but we expect they will return when they see that the organizations intend action in a united fashion."

Approximately 30,000 shopmen in Chicago and 100,000 men in the Chicago district were reported to have left their work at 10 a. m. on August 1 and approximately 35,000 men on 16 railways in the Southeast took similar action. This strike came at a particularly unfortunate time because the Railroad Administration has been bending every effort to put its equipment in condition to meet the demands of the heavy grain traffic. Shopmen in Boston, Philadelphia and

Denver were also reported to have gone out, and the strike spread somewhat on the following day. By August 4 leaders of the shopmen in Chicago declared that 50,000 men were out throughout the country. The shop employees of the Southern Railway at Alexandria, Va., a stragetic location for making an impression on Congress, were among the first to walk out and they were followed on Saturday by the employees at Potomac yard, and on Monday by those at the Washington terminal.

On August 4, B. M. Jewell and other members of the shopmen's committee called on the President at the White House.

STANDARD FREIGHT CARS BEING PUT IN SERVICE

Because of the favorable progress being made in working out the plan for financing the standard equipment ordered by the Railroad Administration through a national equipment corporation, and because of the growing demand for cars, the Railroad Administration has arranged to put into service at once all of the standard freight cars that have been built and that have been kept in storage on railroad tracks near the plants of the builders because of the failure of many of the railroads to accept the allocation of the cars as made by the Railroad Administration. This will put into service several thousand cars, including a large proportion of coal cars, as fast as the cars can be stencilled with the initials of the roads to which they have been allocated. The cars that have been built but not accepted have been paid for by the Railroad Administration as they have been completed, with a deduction representing the cost of stencilling and marking, and the storage has been at the expense of the Railroad Administratoin. It is understood that the cars are being placed in service without opposition on the part of the railroad companies, many of whom formerly protested against the allocations, largely on the ground of their inability to finance them, because the Association of Railway Executives has received assurances from roads representing 70 per cent of the equipment that they will participate in the new equipment trust plan.

Reports of scattering local car shortages are coming from various parts of the country, but while there is understood to be a very large number of surplus cars in the country as a whole the Railroad Administration is unwilling to give out the figures. On June 1 there was a surplus of about 300,000 cars, and it is believed this was considerably reduced by July 1 and still more reduced during July, but the number of freight cars reported as unserviceable for the month of June was nearly 200,000, or 8.1 per cent, although a large number were so reported merely because they were not grain tight and would require little work to put them in shape. Orders were issued late in June to increase the car repair forces that had been reduced earlier in the year in an effort to put the equipment in condition for the summer and fall traffic.

NUMBER OF WOMEN EMPLOYEES REDUCED

The total number of women employed under the United States Railroad Administration reached the highwater mark on October 1, 1918. At that time there were on the rolls 101,785 female employees. The number of women employed on April 1, 1919, shows a decrease of 14.3 per cent as compared with January 1, 1919.

Statistics compiled by the Women's Service Section, giving the number of women employed and the character of their employment since the roads came under federal control have been made public by the director general.

On January 1 of the present year there were on the rolls of the railroads 99,694 women employees, while on April 1 the number had dropped to 85,393. This was due chiefly to the reduction of labor force which occurred in February and March. It was also partly due to the return of men from military service who were reinstated by the railroads.

The statistics show that more than 5,000 women were employed in railroad shops and more than 1,000 in roundhouse work. The latter included, among others, turntable operators and engine wipers. On October 1, 1918, there were 6 women employed as blacksmiths, helpers and apprentices, while a large number of others worked as boilermakers, coppersmiths, electricians and machinists.

The report shows that, considered from the point of view of occupation, the greatest reduction of women employees has taken place in round-houses and shops. Their work in these places was in many cases found unsatisfactory, there being too much heavy physical labor involved.

COST OF FREIGHT TRAIN AND LOCOMOTIVE SERVICE DECREASING

The total cost of freight train service, including locomotive service, continues to show a steady decrease each month as compared with preceding months, although increases as compared with last year, according to the monthly report compiled by the Operating Statistics Section. The combined averages for all regions and the comparative figures for last year and for April, March and February, this year are as follows:

	May, 1919	May, 1918
Cost of locomotive service per locomotive mile	110.3	97.8
Locomotive repairs	37.9	31.3
Enginehouse expenses	9.0	6.6
Train enginemen	19.1	18.1
Locomotive fuel	40.7	38.9
Other locomotive supplies	3.5	2.8
Cost of train service per train mile	156.8	141.0
Locomotive repairs / Enginehouse expenses	53.4	43.7
Locomotive fuel	46.3	44.9
Other locomotive supplies	3.9	3.3
Train enginemen	21.8	20.9
Trainmen	25.1	23.7
Train supplies and expenses	6.4	4.6

	May, 1919	April, 1919	March, 1919	Feb'y, 1919
Cost of train service per 1,000 gross ton miles	103.9	112.7	119.5	126.5
Locomotive repairs / Enginehouse expenses	35.4	38.6	40.8	43.1
Locomotive fuel	30.6	34.3	37.5	40.3
Other locomotive supplies	2.6	2.9	3.1	3.4
Enginemen and trainmen	31.1	32.4	33.5	34.8
Train supplies and expenses	4.2	4.4	4.6	4.8

MAINTENANCE INSRRUCTIONS FOR LAST SIX MONTHS OF 1919

New instructions outlining a working basis for maintenance of way expenditures for the last six months of 1919 have been issued to the regional directors by W. T. Tyler, director of the Division of Operation. While the new instructions are tentative and temporary, in order to control maintenance of way expenditures month by month during the remainder of 1919 to the end that the contract obligations of the Railroad Administration to the railroad companies may be fully complied with but not exceeded, they provide a definite basis on which maintenance officers may proceed as well as prescribing the character of the information which is to be used as the final standard.

While the Railroad Administration takes the position that an excess of expenditures for maintenance of equipment on any road may fairly be considered together with, and as an offset against, any deficiency that may result in maintenance of way expenditures on that road, it is stated that it is not the purpose deliberately to curtail maintenance of way in any respect with this in view and the new instructions treat maintenance of way expenditures on their own footing. Director General Hines has stated that, taking roadway and structures and equipment together, the average condition of the property as a whole is as well off as it was on January 1, 1918. This is because on some roads the equipment had got into a very run down condition at the end of 1917, as the result of the great pressure that had been put upon railroad facilities, and it was therefore necessary to make very heavy expenditures in 1918 in order to put it in condition for handling the war traffic, at a time when no one then knew how long it would last. Since the armistice traffic has fallen off and there was a mild winter, with the result that a large amount of equipment put in readiness for the winter is now being stored. A reserve of over 4,000 locomotives has been put in storage and every effort has been made to put the cars in good condition to handle the grain crops. Instructions were recently issued that car repair forces be put on full time at all points where a reduction in hours has been made and special attention is to be given to grain, coal and refrigerator cars in the sections where such cars are most needed.

In connection with figures showing the number of unserviceable locomotives and cars, Railroad Administration officials point to the fact that many locomotives are now reported as unserviceable, which merely require a few hours' work and could be used if necessary and would formerly not have been classified as unserviceable; also that cars which are in storage or are transferred from one region to another to be put in storage for the grain traffic may automatically be transferred to the bad order class because while good for most commodities they require some recoopering to fit them for grain.

The maintenance of way and maintenance of equipment programs are not being treated alike because they represent somewhat different situations. The equipment is being prepared for a possible car shortage this fall, but instructions have also been issued to the regional directors to concentrate repairs on locomotives and cars which by reason of their size can render the most efficient and economical service, to discontinue expenditures on small locomotives and cars not necessary for current use, and for the prospective traffic for the balance of the year, and to confine expenditures on small capacity freight cars to those authorized by Circular No. 20.

ORDERS OF REGIONAL DIRECTORS

Locomotive Maintenance Material.—Northwestern Regional Purchasing Committee Circular 68 states that many locomotives heretofore used on roads other than those to which they belong are now being returned to the owning road and that these locomotives were provided a supply of material for their maintenance peculiar to the individual engine by the using road. It is directed that this material be utilized in lieu of the purchase or manufacture of new material wherever possible.

Traveling Engineers' Association.—The Northwestern regional director, file 77-I-100; suggests that where it is deemed advisable, traveling engineers attend the convention of the Traveling Engineers' Association at Chicago commencing Thursday, September 9. Transportation should be furnished to the men attending and reasonable expenses allowed.

Freight Cars Damaged.—Supplement 1 to Circular 39 of the Southwestern regional director states that 12,183 cars were damaged in yards and trains on Federal controlled railroads during the week ending May 24, 1919, the cost of repairs for which is estimated at $310,764. While this is a substantial reduction compared with one year ago, and is also below the average for the entire year, still further improvements should be made, by closer supervision.

Leaky Western Pacific Cars.—Order 219 of the Southwestern regional director calls attention to claims for loss of grain by leakage from new Western Pacific cars, series 16,801 to 18,300. These cars should be repaired by seeing that there are no short floor boards, that the floors are well fitted around the posts and braces, and that the beveled grain strips are well fitted between the posts and braces and securely fastened to the floor. The side sheathing boards should be well secured by nails to the side-sill nailing timber.

Floor Racks for Refrigerator Cars.—The Northwestern regional director, file 16-1-65, states that Division of Operation, Circular CS43, has been withdrawn insofar as it applies to floor racks for refrigerator cars, and that authority should be received from the Division of Capital Expenditures before ordering material or beginning the application of floor racks in refrigerator cars which are not now equipped with them.

Application of Floor Racks to Refrigerator Cars.—Circular 225 of the Southwestern regional director states that the Division of Capital Expenditures will approve forms for the application of standard floor racks to refrigerator cars not now equipped with such floor racks and which are used for the transportation of perishable freight requiring floor racks for their proper refrigeration, provided such forms are approved by the corporation, with a commitment that it will take care of the finances. This is not to be construed, however, to require application of standard floor racks to cars now equipped with floor racks, except as renewals are required.

Charges for Application of Grip Nut Locks.—Circular 226 of the Southwestern regional director quotes a letter from Frank McManamy, assistant director, of the Division of Operation, relative to an interpretation made by Section 3, Mechanical, of the American Railroad Association that grip unit nuts, which take the place of a commercial nut and a nut lock, but which, under the rule as at present interpreted must be billed either as a common nut at $.035 per lb. or as a nut lock at $.03, are patented manufactured articles and may be charged as such at the net store department cost in accordance with Rule 105.

Repair of Box and Refrigerator Cars.—Supplement 15 to Circular 70 of the Northwestern regional director contains instructions for the repairing of box and refrigerator cars. Car repairing forces are to be at once put on a 48-hour basis at all points where reduction has been made below that figure. Repairers who have been furloughed are to be returned to service and, where necessary, forces will be increased. After the completion of the cars now in the shops, the rebuilding of box cars of 60,000 lb. capacity or less will be discontinued until the bad order cars on hand have been repaired. The Southwestern regional director has issued similar instructions in Order 215.

Safety Appliances on 80,000 Freight Cars.—The regional director, eastern region, by circular 500-92, promulgates a letter from Frank McManamy, assistant director of operation, calling attention to the importance of having all freight cars equipped with United States standard safety appliances by September 1. About 80,000 freight cars now in service need the equipment. These safety appliances are all of standard dimensions, therefore all cars, both home and foreign, should be equipped; there is no loss either of time or material in equipping foreign cars. These appliances constitute a betterment in the interest of safety which can properly be billed against the owners of the cars. Federal managers are called upon to report what progress they are making.

(Orders similar to the above have been issued by other regional directors.)

Pitch and Creosote as Fuel.—The performance of a heating furnace utilizing a fuel composed of pitch and creosote is reported in the engineering supplement of the *London Times.* Two tons of steel billets were heated in 55 to 60 minutes to 2,000 deg. F., using about 16 gallons of the fuel per hour. The internal size of the furnace is 10 ft. by 5 ft. by 3.5 ft. Equal weights of creosote and pitch form the mixture, which is kept at a temperature of 180 deg. F., and, strained through a wire gauze strainer of 40 meshes to the inch, is pumped through an injector type of burner.

CAR DEPARTMENT

THE OPERATION OF THE STANDARD "D" COUPLER

After a number of years of the most painstaking work on the part of the Coupler Committee of the Master Car Builders' Association, with the co-operation of the coupler manufacturers, a coupler design has been evolved which was questions as to its operation and construction are of growing concern to car department employees. The following description of the operation of the Standard Coupler is taken from an illustrated booklet published jointly by the several coupler manufacturers.

The coupler is shown in Figs. 1 to 5, arranged for top operation, and in Figs. 6 to 8 arranged for botton operation.

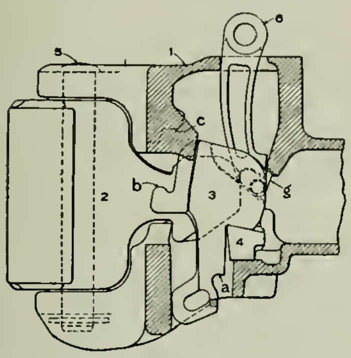

Fig. 1

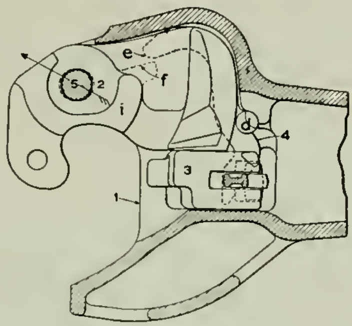

Fig. 2

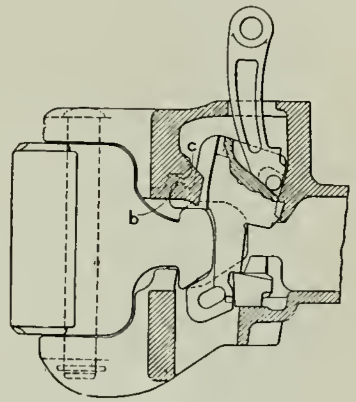

Fig. 3

adopted as standard by letter ballot of the association in July, 1916.

The coupler, known as the Standard "D" coupler, weighs about 400 lb., an increase of about one-third over the types previously in general use. The distribution of this metal, The essential parts of the coupler are the body 1, knuckle 2, lock 3, knuckle thrower 4, and knuckle pin 5, each of which, except the body, remains unchanged for either type of operation. When equipped for top operation the lifter 6 is used and when the coupler is intended for bottom operation the

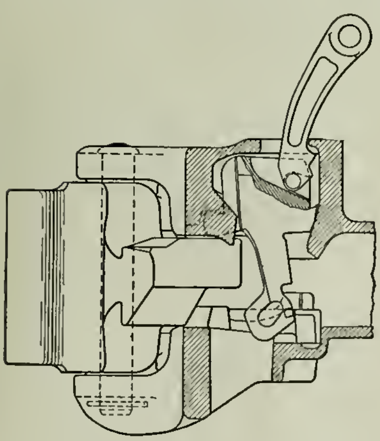

Fig. 4

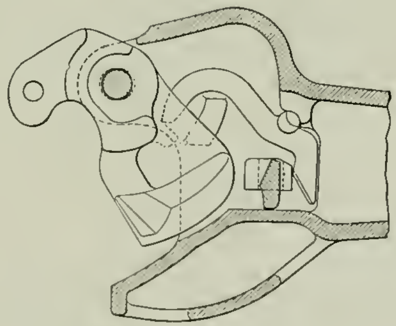

Fig. 5

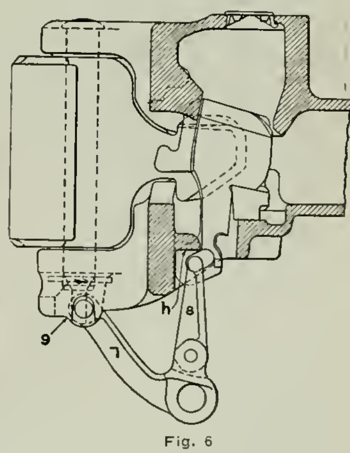

Fig. 6

however, has been such that tests indicate an increase of about 100 per cent in the ultimate strength and an estimated service life three times as long as that of the preceding types. This coupler is now rapidly coming into general use and bottom lock lifter 7 and toggle 8 are used, a cap covering the hole for the lifter 6 and lugs 9 providing a bearing for the lifter 7.

When in locked position (Fig. 1) the lock rests upon the top of one end of the knuckle thrower 4, and its head is located between the knuckle tail and inner guard arm wall as shown in Fig. 2. To lockset the lock, it is lifted either by the top lifter 6, or by the toggle 8, until the lockset seat *a* on the leg of the lock becomes level with the top surface of the knuckle thrower, whereupon the leg of the lock tips rearwardly and seats upon the knuckle thrower as is shown in Fig. 3.

In either top or bottom operating forms the lock is lifted at a point to the rear of its center of gravity so that there is always a tendency for the leg of the lock to swing rearwardly as soon as the lock is lifted. To throw the knuckle the lock is lifted above its lockset position until the fulcrum *b* upon its forward side strikes the shoulder *c* within the coupler head. The vertical movement of the lock is stopped by this contact, and the lock is thereafter forced to rotate about its fulcrum, which gives the lock leg a positive rearward movement, which in turn rotates the knuckle thrower about its trunnions *d*. The tip *e* of the thrower contacts the shoulder *f* on the underside of the knuckle and throws the knuckle open.

The lock-to-the-lock or anti-creep function is obtained in the top operated form by the co-operation of the lock lifter with the rear wall of the coupler head as shown in Fig. 1. When the parts are locked the lifter slides rearwardly in the lock until its projection *g* underlies the lower edge of the rear wall of the coupler head. Any upward movement of the lock merely binds this projection between the lock and the rear wall. As soon as the lifter itself is raised, however, it slides forward and upward in the lock and frees its anti-creep engagement. In the bottom operated arrangement the upper end of the toggle 8 (Fig. 6) normally underlies the projection *h* upon the lower wall of the coupler cavity, and thus performs the lock-to-the-lock function. When the lifter 7 and toggle 8 are raised to lift the lock the end of the toggle 8 slides rearwardly and up in the inclined slot of the lock leg and frees the anti-creep engagement.

In order to obtain the strongest possible anchorage for the knuckle within the coupler head and at the same time to allow the knuckle to swing freely when unlocked, the knuckle is provided upon its tail with the pulling lugs *m* and *n*, Fig. 9, which engage the corresponding lugs *o* and *p* upon the upper and lower walls of the coupler head, and serve to relieve the knuckle pivot pin of the greater part of the pulling stress. Above and below the lugs *o* and *p* are the buffing shoulders *q* and *r* against which corresponding shoulders on the knuckle bear in buff.

The forward pull upon the knuckle in draft not only pulls the knuckle directly forward against the pulling lugs, but also tends to force the knuckle laterally in the direction of the arrow in Fig. 2. To resist this lateral pressure the knuckle is provided upon top and bottom with the outwardly extending "pin protector lugs" *i* which enter correspondingly shaped recesses in the upper and lower walls of the coupler head. In order to relieve the knuckle pin of the greater part of pulling and buffing stresses the knuckle pinholes in the pivot lugs of the coupler are elongated slightly, as shown in Figs. 2 and 5, allowing the knuckle to take a firm bearing within the head in pull or buff without stressing the knuckle pin.

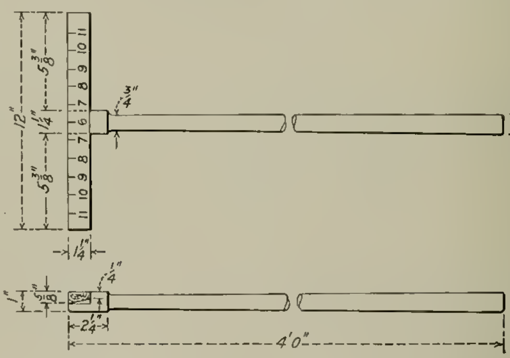
THE MEASUREMENT OF PISTON TRAVEL IN YARDS

BY T. BIRCH

Air Brake Foreman, C. M. & St. P.

When making the incoming brake test it is necessary for the inspector to go over the train quite rapidly to inspect all the cars before the brakes leak off. Most men are unable to judge the distance the piston travels without going under the car, and for that reason rarely mark a car for brake adjustment unless it has very long travel. In order to overcome this trouble, car inspectors on the Chicago, Milwaukee & St. Paul have been furnished with a device for measuring the travel, which is shown in the drawing herewith. It consists of a scale 12 in. long mounted on a handle 4 ft. long. Both parts are made of seasoned pine material.



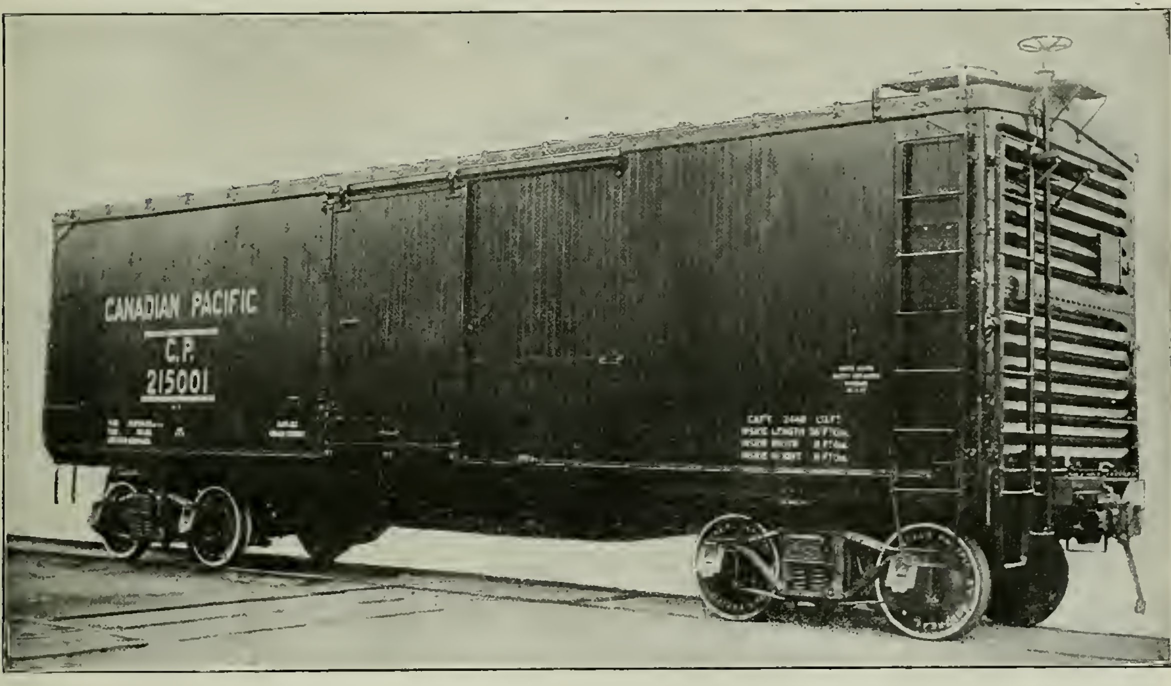
A Convenient Scale for Measuring Brake Cylinder Piston Travel

The scale is painted black and stenciled with white figures once inch apart, the numbers running from the center both ways. By holding the scale against the piston rod the travel can be checked accurately and rapidly without getting under the car.

C. P. R. Double Sheathed Box Cars

Length is 36 ft.; Weight 39,500 lbs.; Have Steel Underframe, Wood Superstructure and Metal Roof

The Canadian Pacific has built an order of box cars of the steel underframe, double sheathed type, the design of which in a general way is similar to the 40-ton double sheathed box cars designed by the United States Railroad Administration. The Railroad Administration cars, however, have an inside length of 40 ft. 6 in. and a height of 9 ft., with an actual weight of about 46,000 lb. Owing to the very high average box car load in 36 ft. by 8 ft. cars on the Canadian Pacific, the building of cars of these dimensions on trucks with 5-in. by 9-in. journals, with the additional weight which would thus be required, did not seem to be justified. The Canadian Pacific cars, therefore, have an inside length of 36 ft. and a height of 8 ft., the width in both cases being 8 ft. 6 in. An average tare weight of 39,500 lb. has thus been obtained, which represents a saving of over three ton-miles for each car-mile in the movement of loaded or empty equipment, as compared with the Railroad Administration standard car of similar type. The cars have been designed for a limit load capacity of 92,000 lb.



Double Sheathed, Steel Underframe Box Car Built by the Canadian Pacific

UNDERFRAME

Like the Railroad Administration cars the Canadian Pacific box cars have steel underframes built up on center sills of the fishbelly type. The center sills are built up of plates and angles, the web plates having a thickness of 1/4 in., with a maximum width at the center of 25 in. Each plate is flanged at the bottom with two 3 1/2-in. by 3 1/2-in. by 5/16-in. angles and at the top with a single 3 1/2-in. by 3 1/2-in. by 3/8-in. angle riveted on the outside of the plate. The top of the sills is completed with a 3/8-in. cover plate 26 1/2 in. wide, which extends continuously from end to end of the car. Bottom cover plates are also applied at each end, extending from the rear draft gear stop through the bolster construction to a point about halfway down the slope of the deepening section of the sills. These bottom cover plates are replaced for the remainder of the length of the car by the inside flange angles, the ends of which overlap the ends of the plates far enough to provide against weakening the section at the point of transfer.

The side sills are 6-in. by 4-in. by 3/8-in. angles with the horizontal flange at the top and extending outward. The end members of the underframe are 5-in. by 3-in. by 5/16-in. angles with the long flange placed horizontally, resting on the center sill cover plate and on the top flanges of the side sills.

The bolster is of the double diaphragm type. The pressed steel diaphragms are of 1/4-in. material spaced 9 1/2 in. apart, tapering with a slope of 2 1/16 in 12 from a maximum depth at the center of 13 1/2 in. A continuous top cover plate 15 in. wide is riveted at the ends to the side sills and at the center through the center sill cover plate to the top flanges of the sills. Filler diaphragms of 1/4-in. material are placed between the center sills and to these is riveted the center plate support casting. A bottom cover plate extends across the under side of the center sills, terminating just beyond the side bearings. The ends of the bolster diaphragms are secured to the vertical flange of the side sills by means of a filler casting to which all three members are riveted. Intermediate crossties of single diaphragm section are located at points 4 ft. 3 in. from the transverse center line of the car. The diaphragms of these members are of 1/4-in. plate with a depth at the center of 13 1/2 in., which decreases towards the sides of the car with a slope of 2 1/16 in 12. The flanges of these diaphragms are reinforced with a ½-in. top cover plate 7¾ in. wide, extending across the car above the center sill cover plate, and a short, tapering ½-in. bottom cover plate.

The intermediate floor beams are 4-in. Z-bars, attached at the center and side sills with angle connections and carrying the intermediate longitudinal floor support of 3-in., 6.7-lb. Z-bars, the web of which is placed 2 ft. 8⅛ in. from either side of the longitudinal center line of the car.

THE CAR BODY

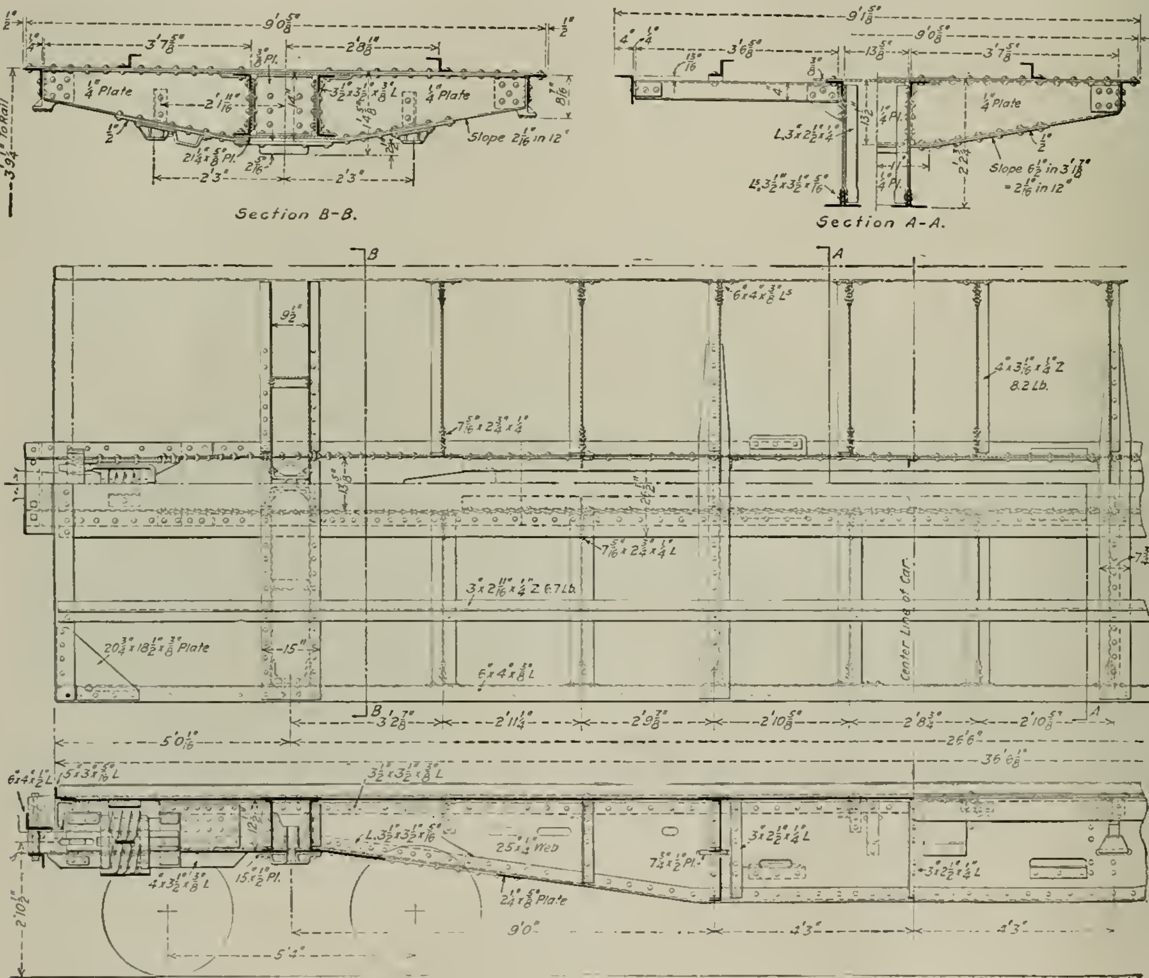
The design of the car body differs from the Railroad Administration cars in that the body frame members are not secured directly to the steel underframe. Above the side and end sills are placed 3⅝-in. wood stringers, to which the post and brace pockets are attached with bolts extending through the steel members. The floor is thus raised above the underframe structure, allowing the use of the intermediate Z-bar supports which have been previously referred to.

The side frame members are three inches thick, wood being used for the posts and braces with the exception of the intermediate posts. The wood posts and braces are of 3-in. by 4½-in. section.

The intermediate posts are 3-in. steel I-beams, these being used for the purpose of providing ample stiffening against bulging when the car is loaded high with grain. The C. P. R. cars also differ from the Railroad Administration cars in that diagonal brace rods are used at each channel section to provide against endwise racking of the car superstructure. The side plates are of 7-in. by 3½-in. section, while the end plate is formed integral with the corrugated steel end of the car.

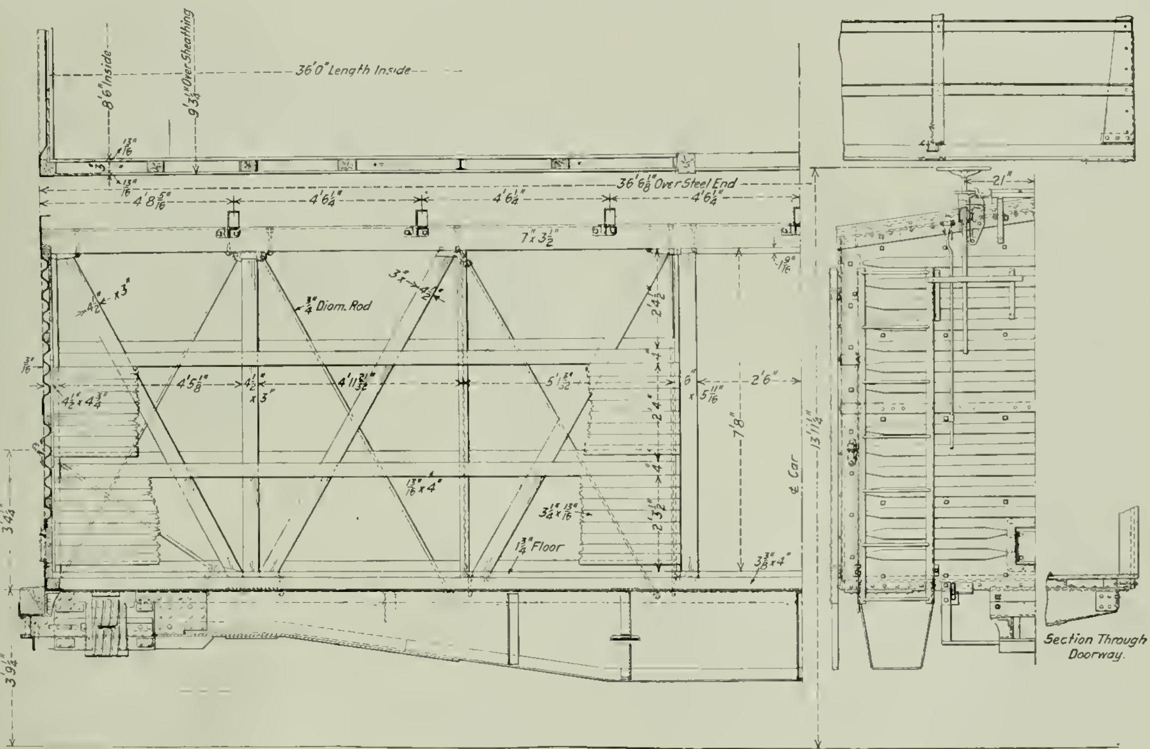
The outside sheathing is standard 13/16-in. tongued and grooved material nailed in the usual way, and in addition to nailing, it is further secured at the side sill by a steel angle bolted at frequent intervals. There are two girths on each side of the car and the inside lining is carried up to the second girth, 5 ft. 3½ in. above the floor. The ends are lined full height with tongued and grooved lumber 13/16 in. thick, which is placed vertically and nailed to strips secured in the bottoms of the steel end corrugations by means of bolts, the outer ends of which are riveted to the steel end sheet.

The side door openings are five feet wide. The doors are of wood, bound with metal on all of the edges. The band at the back edge of the door is arranged to engage with the strip on the back door post, forming an effective weather and spark strip and further securing the door from



The Underframe of the Canadian Pacific Box Cars bulging outward. The front stops are of wood, braced with malleable brackets. The locking arrangement is of the combined lock and stop type equipped with a door starting lever. Two handles are provided on each door, one on the bottom for track level operation and the other near the center girth for platform operation.

Two types of roof are applied to these cars, one an outside metal roof and the other an inside metal roof. The carlines for both roofs are of 4-in. angles, which are attached to the side plates by means of malleable brackets.



Sectional Views Showing the Body Construction and Half End Elevation

These brackets are secured to the plate by two horizontal bolts, with the nuts on the inside of the car and the head secured from turning by a flanged double washer plate located back of the facia board.

TRUCKS

The cars are fitted with trucks of the arch bar type with a wheel base of 5 ft. 4 in. and 5-in. by 9-in. journals. The bolsters are the Simplex type with long column guides to provide the maximum area between the bolster and the cast steel truck columns. The trucks are fitted with roller type side bearings.

Value of the Railroads.—According to a series of graphic illustrations showing the value represented by the railways of the United States, as compared with that of all manufacturing industries generally, compiled by E. B. Leigh, president of the Chicago Railway Equipment Company, the value of railway cars and locomotives is $4,137,318,000 and that of manufacturing machinery, tools and implements of all other trades $6,091,451,274. A comparison of the locomotives and cars with all farm implements and machinery indicates that the value of the railroad equipment is nearly three times that of the farming machinery and implements of the country.

SPECIFICATIONS FOR PLATES FOR FORGE-WELDING IN TANK CAR CONSTRUCTION*

The chairman of the Tank Car Committee of the Master Car Builders' Association, A. W. Gibbs, requested Committee A-1 of the American Society for Testing Materials to issue a specification for forge-welding plates suitable especially for tank cars. This matter was referred to Sub-Committee II and initial work taken up with particular reference to the M.C.B. specifications for the Class V tank car.†

In a note appended to the tank specifications it is stated that because of the character of the commodities to be shipped in these cars, it is so important that the tank shall be absolutely tight, that riveted tanks will not be permitted, and all seams shall be welded. The specifications are as follows:

1. *Bursting Pressure.*—The calculated bursting pressure, based on the lowest tensile strength of the plate, shall be not less than 960 lb. per sq. in.

2. *Material.*—(*a*) All plates for tank, and for dome if dome is made of plate, shall be of steel complying with the American Society for Testing Materials Specifications for Boiler Plate Steel, Flange Quality. For the purpose of welding, the lowest carbon content consistent with the strength prescribed for this quality is desired.

The requirements of the A.S.T.M. specifications for boiler steel, flange quality, are:

Chemical Composition

Carbon, per cent		....
Manganese, per cent		0.30-0.60
Phosphorus, per cent	Acid	not over 0.05
	Basic	not over 0.04
Sulphur, per cent		not over 0.05

No increase allowed for check analysis.

*Abstract of the report of Sub-committee II of Committee A-1, on steel, presented at the annual meeting of the American Society for Testing Materials, held at Atlantic City, June 24-27, 1919.

†See M. C. B. Proceedings, 1918, page 903, for the Class V tank car specifications. This car is intended for the transportation of liquid products, whose properties are such as to involve danger of loss of life in the event of any leakage or rupture of the tank.

PHYSICAL PROPERTIES

Tensile strength, lb. per sq. in.	55,000-65,000
Yield point, lb. per sq. in.	0.5 tens. str.
Elongation in 8 in., per cent	$\frac{1,500,000}{\text{Tensile strength}}$

Reduction in elongation allowed for increased thickness.

There apparently was some objection on the part of the fabricators to using steel of such high tensile strength for welding; hence a softer grade was proposed. The following specifications were recommended to be adopted as tentative:

CHEMICAL PROPERTIES

Carbon	not over 0.18 per cent
Manganese	0.30-0.60 per cent
Phosphurus	not over 0.04 per cent
Sulphur	not over 0.05 per cent

PHYSICAL PROPERTIES

Tensile strength, lb. per sq. in.	plates 3/4 in. or under in thickness	48,000
	plates over 3/4 in. in thickness	45,000
Yield point, lb. per sq. in.		0.5 tens. str.
Elongation in 8 in., per cent		$\frac{1,500,000}{\text{Tensile strength}}$

All parties at interest seem to be agreed that carbon becomes a deterrent to good welding when in excess of 0.18 per cent. To encourage the narrowing of the working limits at the mills, it was determined to fix the chemical limits as "check analysis limits," without the 25 per cent excess allowance in the Specifications for Structural Steel for Cars. The sulphur limit was then placed at 0.05 per cent, which is somewhat closer than 0.045 per cent with 25 per cent excess on check analysis allowed in the revisions presented last year. The consensus of opinion is that copper should be left out of the specifications. Limits for silicon, nickel and chromium have been set at 0.05 per cent for each element.

The sub-committee was advised by Mr. Gibbs that "the question of tensile strength is subordinate to that of the welding qualities, for if the chemistry required involves low tensile strength, the specified bursting strength can be obtained by increasing the thickness of the plate." The opinion seems to be unanimous that a soft steel is necessary, the general aim being for a carbon content of from 0.08 to 0.12 per cent for satisfactory welding properties. Having fixed the maximum carbon at 0.18 per cent, and bearing in mind the lower values which are worked to, it was seen that the tensile strength of thick plates would surely drop below 48,000 lb. per sq. in., but that the lowest carbons in the thinner plates would probably not run the tensile strength below 48,000 lb. Therefore, in order to permit designers of welded tanks when plates 3/4 in. or under in thickness are used, to have the benefit of this figure, the tensile strengths have been specified at 48,000 lb. for plates 3/4 in. or under and 45,000 lb. for plates over 3/4 in. in thickness.

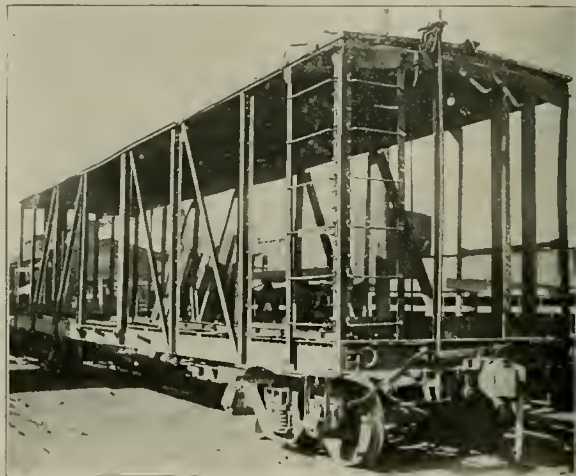
Requirements for elongation, including modifications for thick and thin plates have been made substantially the same as for structural steel for cars. Bend test requirements, however, are somewhat more severe, the bend specimen being required to bend flat on itself through 180 deg. irrespective of the thickness of the plate.

It is believed that the specifications will meet with general approval. Two of the leading consumers of this material, who are manufacturers of tanks for cars by the forge-welding process, are members of the sub-committee and voted favorably. Two manufacturers who are not members of the society were consulted and expressed themselves as favorable.

TECHNICAL MEN UNIONIZING.—Extensive unionization of engineers is predicted in the Chicago Daily News by A. J. Oliver, president of the International Federation of Technical Engineers, Architects and Draftsmen. He says the membership now amounts to 5,000 and before the end of a second year they expect to have three times that number. The organization is affiliated with the American Federation of Labor.

DURABILITY OF STEEL ENDS AND STEEL ROOFS

The ultimate economy of substantial construction of freight cars is shown in a striking manner by some interesting reclamation work which the Illinois Central recently performed. Several months ago a box car belonging to a foreign line was almost entirely destroyed in an accident. The steel



Steel Roofed Car After Passing Through Fire

ends were the only part of the car that could be salvaged and, although so badly bent, were sent to the Burnside shops where they were received in a condition shown in the first illustration. These ends were straightened under a press at a total cost of $13.06 and were later applied to an Illinois Central box car. The condition of the ends after straightening was such as to make them practically as serviceable as when new.

Steel Ends Removed from Destroyed Box Car

A similar instance in which a badly damaged steel roof was reclaimed is shown in the second photograph which gives a view of the framework of a 40-ft. box car that passed through a fire which completely destroyed the woodwork. This car was equipped with a heavy gage, all steel roof, which as will be noted, sagged badly at the center and also between the side posts. The roof was removed and after being straightened was found to be in such good condition that it was reapplied without the addition of any new material.

What is Modern Malleable Iron?*

A Brief Sketch of Present Day Methods of Manufacture and Characteristics of the Material

BY H. A. SCHWARTZ
Chief Metallurgist, National Malleable Castings Company, Indianapolis, Ind.

During the last twenty years there has been a fairly continuous tendency to substitute for malleable cast iron car parts details made of steel. In view of the fact that the organization with which the writer is connected manufactures both malleable cast iron and steel, this change of policy on the part of car builders is of relatively little commercial importance to the company. Nevertheless, it is a source of gratification to have an opportunity of presenting to a railway organization some pertinent facts concerning the manufacture and properties of malleable cast iron for the information of its members when dealing with promlems of new construction and repair.

Neither steel nor malleable cast iron is best for all purposes. There are many cases throughout all industries where steel is used ill-advisedly in preference to malleable cast iron, and some in which the reverse is true.

All malleable iron made in the United States is produced along the same general lines of manufacture, though there are very considerable differences of quality between the products of various firms according to the degree of skill which each producer possesses in the execution of generally similar operations. It is for the purpose of wiping out as far as may be possible such dissimilarities of quality that the American Malleable Association was formed some three years ago. This organization, maintaining as it does a research committee and a consulting engineer, has been of extreme value to the consuming interests in standardizing and improving the product of its members. At present the association maintains what is practically equivalent to an inspection bureau, which assures the consumer that the product purchased from those of its members in good standing will be of a uniformly good quality, at least equal to the requirements of the American Society for Testing Materials, which requirements are also standard with the United States Railroad Administration and similar organizations.

Up to about 1900 the progress in the production of malleable iron was not well systematized, but there had been evolved methods of procedure which, when carefully followed, yielded results generally satisfactory to the consumers of the period. Prior to this time there had been educated a rather limited number of very highly skilled foremen, who, by extremely close application and extraordinary force of memory, were able to interpret very well what they saw going on in the foundries and annealing departments, and to maintain, one might also say by inspiration, a sufficiently accurate control over manufacturing conditions to cope with the requirements of the time.

At approximately this time there developed a much greater general interest among engineers in metallurgical problems, considerable advance was made in the theoretical side of metallurgy and a number of producers began to attempt the introduction of better methods in their process of manufacture. The writer has been informed that as early as 1893 certain producers of malleable cast iron attempted the operation of a laboratory. Report seems to differ as to just how successful the operation of these early laboratories was and what bearing they had on control of the product which they were supposed to supervise. At any rate, in 1903 the National Company built at its Indianapolis Works a chemical laboratory for the study and control of its product. When beginning this work we found the knowledge of the subject in a rather chaotic condition. Little by little, however, order grew out of confusion, some of the company's other plants began similar work, and the problems of the industry attracted the attention of university men and others doing research work, until at present at least the broad fundamentals of the industry are firmly established, and the reason for all the operations undertaken and the circumstances under which these operations may be expected to be successful, are clearly understood.

Process of Manufacture

It may not be without interest to know just what steps are taken in well operated plants to maintain the product up to the desired standard, and to safeguard the consumers' interest against inferior material. The pig iron, which is the raw material of the malleable manufacturer, is all bought under chemical specifications and it is required that all deliveries be accompanied by analyses made by the blast furnace chemists to determine the composition of each individual carload or other unit. These analyses are checked on each carload of iron in the consumer's laboratory, and the metal is finally used on the basis of our own analyses rather than the seller's. If, however, by any chance the foundry's analysis differs from the blast furnace's by more than what is believed to be the manipulative error of analytical methods employed, it is customary to take from the carload of pig iron a second sample and to reanalyze this sample for comparison with the first. In this way it is possible to guard very thoroughly against unknown variations in the composition of metal used as our raw material.

Malleable iron is in general made in heats varying in size between 6 and 30 tons in different plants. The usual size is, perhaps, 10 or 12 tons. The chemical composition of the iron as cast is of extreme importance as fixing the quality of the product. Accordingly the combination of pig iron, scrap, etc., entering the furnace is carefully computed to give an average composition such that after the unavoidable change in chemical composition occurring in melting has taken place, the product will be of the quality desired.

As a check upon the melters, each heat is analyzed before the next heat made under the same conditions is put into the furnace, and from such information the melter is enabled to make any necessary changes in the charges entering his furnaces. In some special cases, notably in the electric furnace operation developed by our company, the heat

*From a paper read before the Car Foremen's Association of Chicago.

is analyzed before it is poured into molds, and an adjustment of chemical composition made when necessary to bring it in line with the desired practice.

The product of the foundry in a malleable plant is not, as is frequently supposed, gray iron. Gray iron is not annealable in any commercial sense, and when an attempt is made to apply this heat treatment to gray iron, a totally valueless commercial product results. The castings as they come from the mold in a malleable foundry are entirely white in fracture, are exceedingly brittle, and also extremely hard—so hard that they can not be worked with any other cutting tools than abrasive wheels. These castings are then packed in containers, sometimes surrounded by chemically active packing materials, and sometimes not, and heat treated over an extended period. In general commercial practice this entire heat treatment occupies about one week.

Within recent years most well conducted malleable foundries have adopted the practice of supervising this heat treatment by means of various types of pyrometers. The most successful of these are the recorder type which maintain a continuous record day and night of the changes of temperature. In this way those in charge of the anneal are enabled to check up the work of the night foreman, and the plant executives are enabled to check the methods of the men responsible for the operation of the annealing departments.

Furthermore, there are cast from each heat a number of test bars of the form and dimensions prescribed by the American Society for Testing Materials, and these bars are annealed with the castings. They are then broken as provided by the A. S. T. M. specifications to insure the fact that all the operations have indeed been so conducted as to produce the desired physical properties.

PROPERTIES OF MALLEABLE IRON

The American Malleable Association maintains a testing department under the supervision of Mr. Enrique Touceda, of Albany, N. Y. This laboratory tests every day bars from the plants of the firms which are members of the association. The writer has not taken the trouble to average these results recently, but from general inspection it is quite obvious that the tensile strength of malleable iron as made today approximates 50,000 lb. per sq. in., and the elongation is about 10 to 12 per cent as compared with the A. S. T. M. specifications of 45,000 lb. per sq. in., combined with an elongation of 7½ per cent.

The tensile properties of a material are the most easily determined engineering constants, and are, therefore, generally used as a measure of the quality of a product. In general, however, relatively few structural details are subjected to purely tensile stresses. Rather more common loadings are those causing cross bending, that is, where the structural detail acts as a beam loaded either at the end or at the center, or bearing a distributed load over a greater or less portion of its entire length. It has been determined that the modulus of rupture of malleable iron in loadings of this character is approximately 100,000 lb. per sq. in., and that the deflections before breaking are very great, so great indeed as to prohibitively distort the member before it actually ceases to carry any load. The material can be loaded to approximately half this intensity without passing its elastic limit.

In pure compression malleable iron possesses properties rather closely akin to those of soft steel, since both these materials in the form of short, thick details will carry almost any amount of load in comparison without breaking, though both of them will be much shortened and flattened under the influence of loads of this character. In the form of washers and similar details there is no doubt that the ultimate strength approaches 100,000 lb. per sq. in. Columns and struts made of any material, while, of course, they are primarily intended to bear compression loads, are always considerably weaker than the compression strength of the material would indicate, inasmuch as they fail, not by crushing, but by springing out of line and then bending. Their behavior under loads depends primarily upon the ratio and length to diameter of the column, and malleable iron, of course, is not usually used for columns of any considerable length.

Tests of details supposed to be representative of rather unfavorable design have shown an untimate strength of 25,000 or 30,000 lb. per sq. in. in loadings of this character. In shear, for example, when used as pins, malleable iron has a strength approximately equal to its tensile strength, or perhaps slightly less.

COMPARISON OF MALLEABLE IRON, CAST IRON AND STEEL

By way of a brief summary, it may not be uninteresting to sum up in the form of general statements a comparison of malleable iron with its two competitors, gray iron and cast steel. The tensile strength of malleable iron is approximately three-quarters that of soft steel, its elongation is a little less than that of steel, while in comparison with cast iron, the tensile strength is, perhaps, twice as great as the best cast iron, and the latter material has no permanent elongation in any measurable degree.

In cross bending, gray iron is slightly stronger than either malleable or steel, and steel is slightly stronger than malleable. Malleable iron and steel deflect to the same degree under loads of this character, and both of them distort so much before failure that there is no particular choice between the two materials from this point of view. Gray iron has no deflection under loads of this kind and is inclined occasionally to break without warning.

In compression malleable iron flows out perhaps a little less rapidly than steel, and not quite to the same degree. Gray iron deflects less rapidly than either of the other products, but crushes into fragments at loads which have not deformed malleable or steel to any material extent. Gray iron is valueless under shearing loads, whereas malleable iron has about the same properties as wrought iron, and nearly the same properties as soft steel under loads of this character.

Within the elastic limit the behavior of soft steel and malleable iron, when subjected to twisting, is very much the same. Steel, however, will take a greater twist than malleable iron without completely tearing off, though up to the point where the member is distorted permanently there is no choice between the two materials. Gray iron is too brittle to stand stresses of this character.

Gray iron serves its most useful purpose in the form of columns, where its stiffness prevents the distortion which finally leads to failure by bending. In such cases as, for instance, the queen posts of car construction, this is not as great an advantage as it seems, for the detail may be broken by an accidental blow and, therefore, be rendered inoperative for the stress which is normally applied to it.

Malleable iron will bend sufficiently to permit of its being fitted against adjoining structural details just as readily as steel. When subjected to such tests as bending double, cold, it is not as malleable as soft steel. Such tests, however, are of course not incurred in actual commercial use. It resists shock better and more continuously than either one of its competitors. The most convincing evidence of this fact to a railroad man should probably be its extended use in draft gears, in which the duty of this character is extremely severe. Its microscopic structure is such as to prevent the formation and growth of cracks which cause the failure of a good many structural details of steel under repeated stresses, particularly if these stresses are in different directions.

Malleable iron resists rusting and corrosion to a greater extent than steel; it equals, and sometimes surpasses, cast iron in this respect, more particularly if the cast iron has been carefully cleaned of sand burned to the surface. In the nature of the case, malleable cast iron is entirely free from any internal strains, due to manufacturing operations, since the long continued anneal to which it has been subjected has of necessity relieved any strains of this character. It furthermore has an advantage in structural details, in that it can be cast of lighter sections than steel, and consequently there are a great many illustrations of railway equipment in which the steel casting is much heavier than would be required to sustain the load because of the relatively greater sluggishness of the metal of which it is poured. The gray iron has to be heavy in order to resist the service strains.

Very usually there exists in the minds of consumers of malleable iron an idea that the strength of malleable iron is all in the skin; that the anneal penetrates only a limited amount, or that malleable is useless in heavy sections—the thought in each case being that there is a limit to the thickness in which malleable iron can be manufactured. Whatever form this idea takes, the conclusion is entirely erroneous. The extreme surface of a test bar of malleable iron is somewhat stronger than the exact center. It is not, however, very materially stronger, possibly 10 per cent, and it is quite possible to make malleable castings several inches thick in which the central portion possesses all the physical properties required by official specifications.

The annealing of malleable iron is not primarily a process involving the removal of carbon from the surface. Such a removal does unavoidably occur, and occurs also in the annealing of cast steel. The actual change brought about by annealing is the destruction of the combined carbon in the original white iron casting by converting it into a special form of free carbon known as temper carbon. This reaction does not start at any one place in a mass of metal any sooner than in some other place, but goes on uniformly throughout the section. Indeed under most commercial conditions combined carbon persists in the surface a little longer than it does at the center.

A much more important point in the design of malleable castings than a question of producing sections which are fairly thin, is to so design the casting as to permit the foundry an opportunity of eliminating shrinks, cracks, etc. Malleable iron is less subject to this difficulty than steel, but considerably more subjected to it than gray cast iron. There are an indefinite number of instances in which draftsmen and designers have decided upon shapes and sections not particularly essential to the use of the detail being designed, which present almost insurmountable difficulties in the foundry. Illustrations of this character are, for instance, wheels having light rims, very heavy hubs and an even number of perfectly straight spokes. It is quite easy to produce a design of a wheel of this character in which the foundry problem ceases to be a commercial one and amounts to the working of a miracle on the part of the molding department to keep the spokes from cracking or from pulling loose from the hubs. Another difficulty frequently encountered is a part so designed as to have in general very heavy sections, and then at a remote and inaccessible point, an important detail of very small cross section. Without going deeply into the metallurgy of the process, it may be said that special efforts have to be made in cases of this kind to make it possible to run the small, thin portion at all satisfactorily, unless this small portion is located so that it can be brought close to the gate through which the metal is poured into the mold. These and similar items are in addition to the usual problems of the design of cast details such as producing a design which does not require the use of cores to produce unnecessary pockets, designs which can be made in a two part flask and other similar self-evident matters.

MODERN REFRIGERATOR EQUIPMENT*

BY L. L. YATES

General Superintendent Car Department, Pacific Fruit Express

The refrigerator car was primarily designed for the transportation of fresh meats for a comparatively short distance, little thought being given to the dimensions or general design. The success which was met with its advent for this purpose, was such as to warrant extending its use for the transportation of other perishable commodities and longer hauls. This necessarily developed the fact that refrigerator cars as originally designed would not meet all requirements.

In the latter part of the nineteenth century, because of the length of the hauls, which increased as more distant markets demanded perishable commodities, and to eliminate as far as possible losses from decay in transit, more thought was given to the design of refrigerator cars as to dimensions, insulation and capacity of ice bunkers. Since that time there has been very rapid development in the design and construction of these cars, which, when properly loaded and handled, will insure the delivery of perishables at distant markets in practically as good condition as when loaded into the car, this being the result of complete co-operation between shippers, the United States Department of Agriculture, rail lines and car lines, which enabled the carriers to determine the proper dimensions, quantity of insulation and type and size of ice bunkers to use.

CONSTRUCTION

The lumber must be well seasoned to prevent shrinkage when framed and assembled. The efficiency, quantity and application of the insulation is of the utmost importance, and has been given more thought than any other feature in the construction of the refrigerator car. It will readily be seen, on account of the belt rails, sills and carlines, that difficulty is encountered in maintaining the continuity of the insulation, which is highly desirable. Particular care is taken in the application of the insulation to the car, to see that it is not only securely applied, but all parts protected, and vertical dead air spaces frequently blocked to prevent circulation within the walls, which, if not prevented, would assist in the absorption or radiation of heat. The insulation in the floor of the car, which is highly important, is more susceptible to damage or deterioration due to the misuse of equipment, such as driving nails or spikes into the floor to brace the load, loading ice or commodities requiring ice in packages, and other commodities which later require the washing of floors, with the result that moisture will penetrate the insulation, affecting not only its efficiency as an insulator, but also the floor timbers, causing rapid decay or deterioration.

The floor insulation itself should be as nearly waterproof as practicable, without impairing its efficiency as an insulator, and when applied should be well coated with an odorless waterproofing compound, with a melting point of not less than 175 deg. F., which must be pliable at zero, highly adhesive when hot and not sticky when cold. This requirement is necessary to meet the extremes of temperatures, both hot and cold, to which these cars are subjected. This waterproofing compound should be liberally used around the side walls at the floor line to prevent capillary attraction in the side-wall insulation.

The side and end sills should be thoroughly coated after framing with red lead and oil, or some other preservative of equal merit. It is also necessary to minimize, if not entirely eliminate, the use of bolts through the insulation, as they afford direct channels for the heat transmission.

The main floor should be of select vertical grain lumber, with the edges laid in white lead and oil and coated with raw linseed oil. Other parts of the interior of the car should re-

*Abstract of a paper presented before the Pacific Railway Club.

ceive one coat of raw linseed oil and two coats of waterproof varnish. The floor, side and end lining around the ice bunkers should receive a coat of mineral paint carrying a high percentage of raw linseed oil to prevent decay from condensation.

There are approximately 140,000 refrigerator cars in the United States, the majority of which have been constructed in recent years, and are built in accordance with recognized designs, suitable for the business for which the cars are intended. There are, however, many older cars that are being made to conform to modern methods of construction.

MAINTENANCE

The Pacific Fruit Express Company owns and operates 15,600 refrigerator cars of the most modern type. To maintain them in a high state of efficiency, each car as it returns to California after a trip East, before being placed for loading, as a rule passes through one of our shops, whether or not it is in need of repairs, where it receives the most careful inspection by specially trained men. Any defects discovered are plainly marked with chalk and written up on an inspection card, which is placed on the car door. Following these inspectors, are repair men, who are trained and skilled in their respective crafts, carpenters making any repairs necessary to superstructures, truckmen on underframes, trucks and brake rigging, tinners making ice tank repairs, upholsterers, side-door and hatch-plug padding, air brake men testing all air brakes and cleaning and repairing all that may require such attention. Car cleaners thoroughly clean the ice bunkers and the body of the car, and if the car contains oil spots or other foreign matter requiring washing, this work is done by another class of workmen. The interior walls and ceiling, if in need of revarnishing, are attended to by painters.

After all this work has been performed, inspectors make an after-inspection to see that the repairs have been properly made and the car is in safe and serviceable condition, particular care being given to the side doors to see that they are perfectly tight. The side doors are then closed and sealed with a heavy wire, and the ventilators set in an open position, permitting thorough ventilation. The car is then ready for service and is marked under the side door with the date on which it is OK'd and reported on the yard report to the general or district agent for forwarding to the loading station.

This work is all performed in the light repair yard. Any cars requiring extensive repairs are switched to the heavy repair yard, or reconstruction shed, where men specially skilled in the art of rebuilding refrigerator cars are employed. Here any wood part or insulation showing decay is removed and replaced with new material, special care being given to the renewing of insulation in a workmanlike manner to see that the vulnerable parts are protected. This work is under the supervision of foremen who have had years of experience in refrigerator car maintenance, and are cognizant of the functions of the refrigerator car.

The location and volume of perishables shipped from Pacific coast points render it impossible at all times to pass cars through our main shops, and in this event, we have inspectors and repair men at the principal loading centers to thoroughly clean and make minor repairs, and cars requiring heavy or general repairs are forwarded to one of the main shops.

In view of the fact that over 100,000 carloads of perishables are hauled annually from Pacific coast points in Pacific Fruit Express equipment, it necessarily follows that each of its 15,600 cars receives inspection and repairs on an average of seven times per year.

Railroad companies realize the importance and necessity of the proper maintenance of refrigerator cars and when they find them in damaged or bad-order condition, requiring extensive repairs to superstructure, as a rule, endeavor to return them to the car owner for repairs, as the owner has the material and trained mechanics to repair them properly.

No doubt many little realize the work and the attention given to the cars that are handling perishables. Any of you who have not been to a well organized refrigerator repair shop would be surprised to see the inspection and attention given to refrigerator cars, minor repairs that you would not consider making on any other equipment. We are fully alive to the highly perishable commodities handled by this equipment and appreciate the necessity of keeping them in a safe, serviceable and sanitary condition. Go into a refrigerator car and inspect the construction and you will find that all parts that would collect any foreign matter and be injurious to the load have been eliminated.

The United States Department of Agriculture has been of very great assistance to the car designers in improving the equipment. Last year the Railroad Administration appointed a committee to design a standard car for the government. That committee was composed of four representatives of the car lines and two from the Department of Agriculture. The car designed for the government was not the car that any of us would want individually. It was the result of take and give on the part of each of us, but I am sure that none of the committee regrets the design finally proposed and accepted by the government. The Railroad Administration has the acme of perfection in the refrigerator car today.

Out of the 140,000 refrigerator cars in the country the majority are good for the purpose for which they are intended. All refrigerator cars are not intended to handle perishables from California. Many of them are for meats and dairy products and short haul runs. Cars that were considered efficient twelve or fifteen years ago are obsolete today for long hauls.

DISCUSSION

L. W. Collins (Refrigeration Technologist, U. S. Department of Agriculture).—For the past year I have been connected with the Pacific Fruit Express Company in carrying on a series of investigations for the committee appointed by the Railroad Administration, to outline and devise a certain method of heating cars to prevent so much damage in transit from cold weather. A plant has been constructed at Roseville where there was developed a type of heating system that was put in the P. F. E. cars last winter. We loaded trains to go through to New York, a fourteen-day trip, and on these trains we had the government system of heating and all the present types of cars on the market. There were six types of heaters. It was found that the fruit temperatures were increased very materially on the top part of the load and freezing at the bottom with the average difference in temperature of 30 degrees F. and in some of the systems there was only 12 degrees between the top and bottom of the load. In the government car during the high winds in Wisconsin there was a difference of 4 degrees. The car companies and car lines have not been able to get the shipments through except on the short lines. In the winter there has been no provision made other than the temporary method for heating the cars and in the years 1917 and 1918 there was an estimated loss in New York City of $1,000,000 worth of food products on account of being frozen in transit. With everyone working along the lines of development in getting the best type of heater, we all hope to be able to very materially reduce the tremendous losses in the winter time that the railroads and the car lines have suffered in the past.

On the car developed at Roseville we have insulated air space and put stringers one and three-quarters inches on top. These were formed to furnish hot and cold air ducts in the center of the car, where the door was so arranged as to carry the heated air from the top to the bottom of the bunker and the cold air was drawn down. There were three different types of heaters, using steam, alcohol and kerosene. Each one had some advantages and it is not yet definitely decided which type is more desirable.

SHOP PRACTICE

ELECTRIC ARC WELDING APPARATUS

BY H. L. UNLAND

Power and Mining Engineering Department, General Electric Company

There are several simple precautions to be observed in the use of electric arc welding equipment whatever the nature of the apparatus may be. Many of the accidents which occur are generally the result of a misconception of the nature of the equipment and its proper use. This applies more particularly to the auxiliary apparatus.

The eyes should be thoroughly protected by a mask from the light of the arc or serious burns to the interior of the eye will certainly result. No chinks or holes in the mask should be permitted since only a brief exposure of the eyes is required to bring on painful results. The inside of the mask should be kept painted dull black to prevent reflection of the light from behind.

The mask consists of a thin sheet of aluminum formed to the proper shape and provided with an adjustable band for supporting it from the operator's head. An opening in the front of the mask is provided for a window of glass, which may be either a number of individual sheets of different colors or a single compound sheet of glass.

The colored protective glass should be sufficiently dense to reduce the light intensity to a value not objectionable to the eye and at the same time the area immediately around the arc should be sufficiently clear to enable the operator to properly follow the work. Different color combinations are used but the most general seems to be a combination of red and green glass.

The glass is held in a recess in the front of the mask by means of a clamping frame so that the light from the arc cannot pass through joints or cracks around the edge of the glass, as a small amount of light coming through one of these openings would in a short time affect the eyes of the operator.

It is advisable to keep a piece of clear glass on the outside, since, in welding, this outside surface will be struck by particles of molten metal, and will become roughened to such an extent that it becomes useless and must be replaced.

A hand shield is principally used in doing metallic electrode welding. It consists of a light wooden frame with provision for a protective glass window similar to that used in the mask. The shield is also used by inspectors and others who require the protection only for short periods and at infrequent intervals. A light box frame surrounding the window is fitted to the operator's face, preventing light from the side or rear reaching the operator's eyes, thus eliminating any interference of a number of operators due to the light from the arcs. The protective glass of the hand shield is supported in guides on the front of the shield and is clamped in place by a wooden wedge driven through openings in the guides.

ELECTRODE HOLDERS

The function of the electrode holder is to electrically connect the electrode to the cable connected to the welding equipment. The requirements of this service are: It must securely grip the electrode so that the welder can operate it without play in the mechanism or without the electrode becoming loose in the holder while in use; the clamping arrangement should be such as to facilitate changing electrodes; it should be so constructed that the minimum heat reaches the operators' hand; the weight should be as low as possible and the balance such as to facilitate manipulation by the operator; the construction should be such that the operating parts are protected from accidental contact to avoid injury by burning or by being struck, and the general construction should be substantial to avoid bending or jamming.

ELECTRODES

Carbon electrodes should be rods of hard, homogeneous uncored and uncoated carbon. The diameter used will vary with the current to be used and this information is given elsewhere. The length depends on the particular class of work to be done. Long carbons reduce the percentage of short ends thrown away, but are more liable to breakage. The average lengths range from 9 to 12 in.

For welding iron and steel the metallic electrode should be a high grade of low carbon steel wire. A large number of tests were made by the Emergency Fleet Corporation to determine the best chemical analysis of wire for this purpose, and the wire now made by a number of manufacturers meets these requirements. This material can be purchased either direct from the makers or through jobbers and can be obtained either in rolls, or in short lengths cut and straightened. In ordering, "electric welding wire" should be specified, since wire for acetylene welding is often treated in such a way as to render it unsuitatble for electric welding.

The electrode wire should be cut into pieces convenient for the operation. A length of 18 in. is satisfactory since it is about the greatest length an operator can handle, and at the same time it reduces to a minimum the number of times the electrode is changed, and consequently the wastage.

CABLES

On account of the intermittent nature of the work it is possible to use smaller cable for the welding circuits than is standard for the current capacities. In this way, there is also a gain in flexibility which permits better control of the welding arc, by facilitating the manipulation of the electrode holder.

In metallic electrode welding a length of at least 15 ft. of extra flexible cable should be connected to the electrode holder to allow the operator to fully control the arc through manipulation of the holder. For the ground or return cable the standard extra flexible apparatus or dynamo cable insulated with varnished cambric for low voltage circuit and covered with double weatherproof braid has been found suitable.

The carbon electrode welding arc is not as unstable as the metallic arc and therefore the manipulation of the electrode is not so important. For this reason the standard extra flexible dynamo cable referred to above may be used for connection to the electrode holder, as well as for the return circuit.

It is difficult to give universally applicable figures covering amperes, speed, etc., for electric arc welding, due to the effect of conditions under which the work is done, the character of the work, and to a very large extent the skill of the operator.

The following figures are based on favorable working conditions and a skilled operator. However, they are approximations only and are given here merely as a general guide.

Current Required for Metallic Electrode Welding

Light work	25 to 125 Amperes
Heavy work	up to 225 Amperes

Electrode diameter, in.	Amperes	Plate thickness, in.
1/16	25-50	up to 1/16
3/32	50-90	up to ¼
⅛	80-150	⅛ to ⅜
5/32	125-200	¼ up
3/16	175-225	⅜ up

The same size electrode may be used with various thicknesses of plate, but the heavier plate will require the use of the heavier currents.

Approximate speeds of welding sheet metal with the metallic electrode are given in the following table:

Thickness of plate	Speed, ft. per hour	Cost per ft.	Comparative cost per ft., acetylene
1/16	20	2.12	1.78
⅛	16	3.12	4.66
¼	10	7.13	13.1
⅜	6.5	12.3	36.1
½	4.3	19.8	much higher
¾	2.0	41.7	much higher
1	1.4	61.3	much higher

The above figures are based on average figures for materials and labor. They will probably vary considerably for different localities, and will vary slightly with the type of equipment, but the relative costs of gas and electric welding will in general hold true.

CARBON ELECTRIC WELDING

The carbon electrode can be used for welding and for building up metal in a large number of cases where the metal is not subjected to high strains or where it is under compression only. This process can also be used to a very large extent in rough cutting of plates and in cutting away parts of structures.

The average current ranges for different types of work are as follows:

Light welding	150 to 250 amperes
Medium welding	250 to 350 amperes
Heavy welding and medium cutting	400 to 600 amperes
Very heavy welding and heavy cutting	600 to 1,000 amperes

The maximum values of current permissible for the carbon electrodes are as follows:

Diameter of electrode	Maximum amperes
¼ in.	100
½ in.	300
¾ in.	500
1 in.	1,000

Graphite electrodes permit the use of somewhat higher current densities but the higher cost of graphite electrodes is a serious handicap to their use. Lower currents than those given may be used, but higher values will result in undue burning of the electrode.

For depositing or building up metal, by means of the carbon arc, or flat surfaces where the work is accessible and all conditions favorable, the following figures may be used:

Current, amperes,	Lb. per hour	Cu. in. per hour
200	1½	5.4
300	3	10.8
400	4½	16.2
500	6	21.6

For continuous work the above figures may be used, but for short jobs of ten minues or less the rate will be double the amounts given.

DEPTH OF CUT FOR WHEEL LATHE

BY J. E. OSMER

A convenient method of determining the depth of cut for a wheel lathe is in use at the Owosso shops of the Ann Arbor Railroad.

The wheel or tire is placed in the lathe and the nose of the tool forced against the tread at the lowest point of the contour. The side of the crosshead and carriage is then

Flange	Thick	Depth of Cut
3/4"	"	20/32
13/16"	"	18/32
7/8"	"	16/32
15/16"	"	14/32
1"	"	12/32
1 1/16"	"	10/32
1 1/8"	"	8/32
1 3/16"	"	6/32
1 1/4"	"	4/32
1 5/16"	"	2/32
1 3/8"	"	0

Measure Thickness of Flange 1/4" Above Tread.

Turn Tire Having Thinnest Flange First. And Tire from Left Main Second, as this Last Mentioned Tire is the One that Develapes a Flat Spot, Due to the Slip of Wheel, When Piston is in Extreme Foreword Position on Left Side

Table Showing Depths of Cuts for the Wheel Lathe

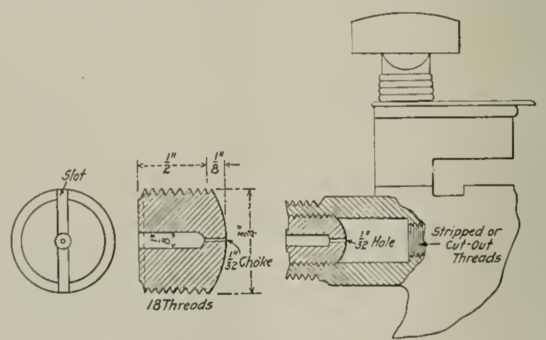
chalked and the position marked with a sharp lead pencil. The tool is then withdrawn, moved to the edge of the tire and the cross slide extended forward to the pencil mark. To this is added the depth of cut as indicated in the appended table, thus giving the total depth of roughing cut required.

REPAIRING LUBRICATOR CHOKE PLUGS

BY F. W. B.

The threads in the body of a bull's eye lubricator which take the choke end of the reducing plug, when stripped or cut out by steam are sometimes very difficult to repair. A practical improvised method of making such repairs is shown in the sketch.

The inside of the plug recess will take an 18-thread, ¾-in. tap and clean up with a satisfactory thread; it is necessary to tap it back for only about ⅝ in. The plug, which is also



Method of Repairing Bull's Eye Lubricators with Stripped Choke Plug Threads

shown in the sketch, is made and screwed firmly into this threaded recess. A slot can be sawed in the outer end of the plug to permit the use of a screw driver to put it into place or remove it for cleaning. The plug hole in most cases will be found sufficiently large for the tap, yet small enough to make no difference in the size of the oil pipe tail piece joint. This method of making repairs has been used in a number of cases by the writer with very satisfactory results.

Jacobs-Shupert Firebox Repairs

The Methods and Tools Used to Repair the Stay Sheets and Cracked and Distorted Sections

BY H. LOUIS HAHN

THE most common defects which first develop in Jacobs-Shupert fireboxes, are cracks in the inside firebox sections. They generally develop where the most heat is concentrated and are from one to six inches in length. On some engines in certain territories as many as 100 cracks have developed during the periods between shoppings. In other territories there are boxes of this type which have given seven years' service without developing any cracks of this kind.

A method of repairing these cracks, as shown in Fig 1, has been used very successfully and is now the standard method of repairing cracked firebox inside sections. A piece of the section large enough to include all of the cracks in that particular part of the section, is cut out as shown at *A*.

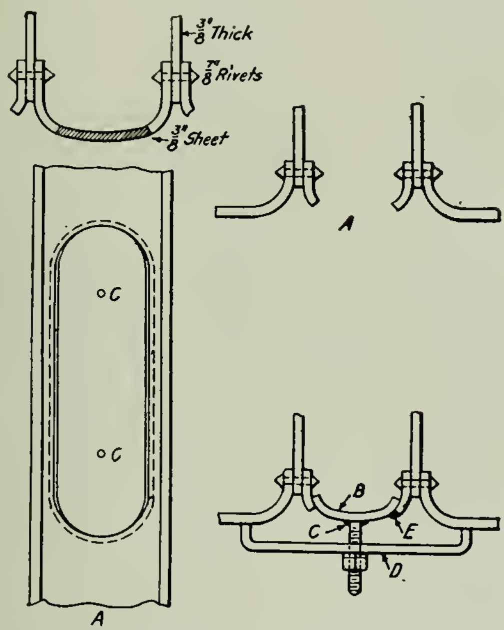


Fig. 1—Method of Patching Firebox Sheets

A patch of 5/16-in. firebox steel is then formed to fit on the inside of the section, as shown at *B*, lapping over the inside ¼ in. all around. To facilitate the handling necessary to make a good fit of the patch, one or two ¾-in. bolts six inches long, having had the heads sheared off, are welded to the patch as shown at *C*. Only one bolt is necessary for a short patch, but on long patches they should be spaced about 12 in. apart.

After the patch is properly fitted, the clamp or clamps *D* are applied to hold the patch in the proper position while it is welded in by either the gas or electric process. The edge of the old sheet is welded to the new patch as shown at *E*. The ends should be welded first and the sides last, as the curved surface of the sides will compensate the strains due to contraction of the cooling welds more easily than the ends. As much of the welding as possible is done with the clamps *D* in position. The writer has applied patches up to 48 in. in length, welded with the gas torch, which have been running two years without any leaks developing. The same method is used for cracked sections on the curve of the crown sheet side roll. In the center of the crown sections defects arising from low water, such as stretching of the sections, are repaired in the same manner. These patches meet the requirements and approval of the Interstate Commerce Commission Division of Locomotive Inspection.

The first solid stay adjacent to and on each side of the center sling stays will develop cracks under the top outside sections, as shown at *A* in Fig. 2, after the firebox have been in service. The method of repairing such cracks consists of flanging ⅜-in. brackets *B* and riveting them to the outside sections as shown, using bolts to fasten the brackets to the stay sheet.

A very common defect is the cracking of outside top sections through the center line of the rivet holes, between the holes. Cracks develop first in the section adjacent to the throat sheet connection sheet and in succeeding sections back to and including the fifth section, in some cases, as shown in Fig. 3. A number of years ago when these cracks first developed it was thought that they were the result of anchoring the backhead braces on lugs riveted to these sections. After the cracked outside sections were renewed braces were anchored ahead on the throat sheet connection sheet as shown in Fig 3 and flexible flue sheets applied. These same renewed sections are developing cracks in the same places as the original sections and necessitate the renewal of the part sections previously applied.

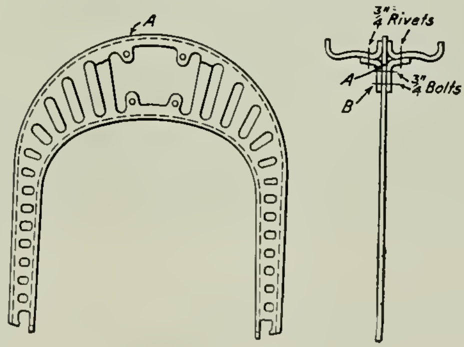

Fig 2—Stay Sheet Repairs

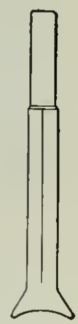

Fig. 5—Scale Tool

The defective parts of the sections are removed, the new part sections are fitted and the joints are butt welded to the old portion of the sections with the gas torch.

When any part of the inside sections become defective and cannot be repaired as shown in Fig. 1, the method shown in Fig. 4 is used. A portion of the outside section opposite the defect in the inside section is cut out and the edges chipped bevel. The cutting torch is used to remove the piece, but where this is not available it may be cut out with an air hammer and chisels.

After the cracks in the inside section, or whatever other defects there may be, are repaired, the piece of the outside section which was removed is fitted in place, beveled, welded and riveted and caulked. This method may be used for any part of the outside sections. The object of the diagonal cut is that, during the operating of welding the piece in again, there will be no strains resulting from cooling welds, the line of contraction being horizontal instead of vertical. The same method of the diagonal cut is now followed in applying new top sections as shown in Fig. 3.

A defect which often develops soon after these fireboxes go into service is the cracking of door sheet and flue sheet stay sheets in the right and left water legs, adjacent to the outside sections. These cracks start in the corners of water circulation cut-outs and gradually run upward and downward at an angle of about 15 deg. until they meet and form one continuous crack. They can readily be discovered by holding a flash light in the corner washout plug holes just above the mudring.

A method of repairing the door sheet stay sheet is to cut the backhead sheet between the first two vertical rows of staybolts high enough to remove a piece of the side roll of the backhead from the mudring up, so that the defective portion of the door sheet may be uncovered. Then either chip out the cracks in the door sheet and weld them, or apply a

Fig 3—Defective Outside Top Sections Removed

new piece of door sheet and weld it in. After the repairs to the door sheet are made, replace the piece cut out of the backhead sheet, first applying it with temporary bolts, then weld the butt joint and then rivet and caulk the sheet at the mudring.

For flue sheet stay sheet cracks in the side water legs the method of repair where a new sheet is not necessary is shown in Fig. 4. Cut out a piece of the outside section and weld the cracks in the stay sheet. When it is necessary to apply a new flue sheet stay sheet, the firebox back end is disconnected at the throat sheet connection rivets and the back end loaded on a car to facilitate handling. The flue sheet, including the defective portion in the side water legs is removed and the new sheet laid out, punched and applied When a flue sheet stay sheet only is applied to the back end, it is not necessary to remove the outside section to drive rivets in the inside section; a holding on bar is used instead. This bar is bent on the end and made small enough to go through the water circulation cut-outs. Rivets are then applied from the rear side of the flue sheet and driven from the front side. After the flue sheet is riveted to the firebox section, the firebox back end is raised and reapplied to the boiler at the throat sheet connection and riveted and caulked. An alligator hydraulic riveter is used to apply rivets in the outside section, but it is possible to countersink the holes and drive the rivets with an air hammer. One firebox had three new outside top sections, a new flexible flue sheet and a new portion of staybolt section of flue sheet stay sheet applied at the same shopping.

To renew a complete inside section, start at the flue sheet end and remove stay sheets and both outside and inside sections, one at a time, until the defective section is reached. Remove one more outside section than the number of inside sections, so that the riveting machine can be brought to the work to rivet the new inside section after it has been fitted. Then fit up the old inside sections and stay sheets, applying them in the same order as removed, so that the stay sheets

Fig. 4—A Method of Repairing Inside Sections

and sections will be in the same relative position as before. Next apply rivets to all of the inside sections, using an alligator riveter. Then fit up and reapply all outside sections in their proper place and rivet and caulk. The completed back end can then be reapplied to the boiler and the throat sheet connection riveted and caulked.

In laying out and punching any water circulation cut-outs in stay sheets, care must be exercised to have round corners, as square corners will crack out much sooner.

The Jacobs-Shupert firebox will accommodate itself to longitudinal strains due to the inequalities of the firebox and outside casing sheet expansion, but will not accommodate itself to transverse strains from the same cause. Each section being of a semi-circular shape will take care of accumulated longitudinal expansion, but the transverse rigid stay sheets will permit of no equalization of the vertical or transverse stresses which occur, especially during the operation of firing up cold boilers. These strains and stresses first cause the inside sections of fireboxes to crack and as they develop further the strains are communicated to the transverse stay sheets, causing the cracks as shown in Fig. 2 where the stay sheets come in contact with the outside sections. These same stresses also cause cracks at the door sheet and flue sheet in the side water legs.

This style of firebox tends to travel upward in service, this being proved by the fact that it is necessary periodically to inspect the two center rows of sling stay straps in the crown section. On removal of these straps after the firebox has been in service it will be noted that it is a very difficult matter to remove the supporting bolts, due to compressive strain on the sling stay straps. Often, when replacing the same straps in the same position it is noted that they are from 1/32 in. to 5/64 in. too long, thereby necessitating the making of new straps.. This compression, on the solid stays next to the center sling stays at the front end of the firebox at the flue sheet is enormous and being communicated to the outside sections is the cause of cracks in the outside sections, necessitating their removal, as shown in Fig. 3. In the writer's opinion the only way to prevent the cracking, and the resultant necessity of renewal of outside top sections, is to design the Jacobs-Shupert fireboxes with at least an 18 in. combustion chamber in front between the firebox and the tube sheet.

Scale will not accumulate to any great extent in the center of the firebox sections, due to their constant expansion and contraction. A heavy scale will collect on and adjacent to the rivet heads of the connection of the firebox sections to the stay sheets and this needs attention and should be frequently removed.

The tool shown in Fig. 5 used in connection with a small air hammer has proved very effective in removing this scale. This tool is passed rapidly over the fire side of the section along the stay sheet caulking edge, thus jarring loose the scale on the water side of the section. The cleaner the firebox sections are kept, the better the results will be and the cracking of the inside sections can be reduced somewhat by keeping the scale formation at a minimum.

The water and fuel conditions enter more largely into the question of sustained service of Jacobs-Shupert fireboxes than in the standard staybolt types. With good water, and coal as fuel, the Jacobs-Shupert firebox will give from two to three times the service of the standard staybolt type, but with oil as fuel and when operated in bad water districts, it will give only one-fourth the service of a firebox of the staybolt type.

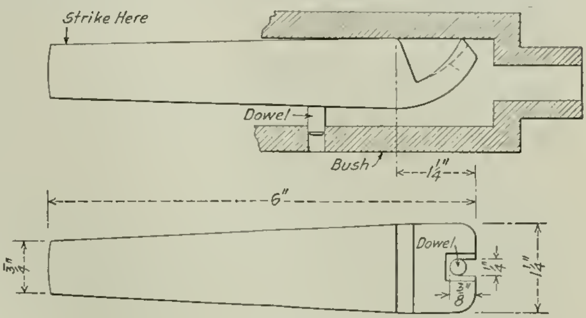
From a safety standpoint, the Jacobs-Shupert firebox is, at the present time, the most perfect form of locomotive firebox. Because of its sectional construction it is impossible to explode one of these boxes. The worst that has happened, in a number of instances, is the overheating and consequent stretching and the ultimate bursting of one of the crown sections.

Due to the fact that it is practically impossible to explode one of these fireboxes, enginemen handling them will sometimes run long distances with no water in sight in the glass. This practice causes crown sections to overheat and pressure stretches them to a semi-circular shape. In removing the flues at shoppings it is often found that in the second row from the top the flues are distorted and sometimes are collapsed from this cause. Particular care should be used in setting water glass and gage cocks on this type of firebox so that the maximum amount of steam space without the sacrifice of safety may be obtained.

REMOVING DOWEL FROM AIR PUMP REVERSING VALVE BUSHINGS

BY J. A. JESSON

In the article describing a method of repairing worn reversing valve bushings of 9½-in. air pumps, which appeared on page 210 of the April issue of the *Railway Mechanical Engineer*, no method for removing the dowel was shown. The accompanying sketch shows a single tool that will both extract and replace the dowel in a very simple manner. It consists practically of an elongated claw hammer without the handle hole. The claw is driven over the dowel, its



A Tool for Removing and Reapplying Dowels in Reversing Valve Bushings

sharp edges forming a grip in the soft metal; tapping the end of the tool pulls out the dowel in the same manner as pulling a nail.

To replace the dowel, start it in the hole, then place tool in position, as shown, and force the dowel in by striking the end of the tool. By this method all work is done from the inside of the bushing. The plug in the body need not be disturbed.

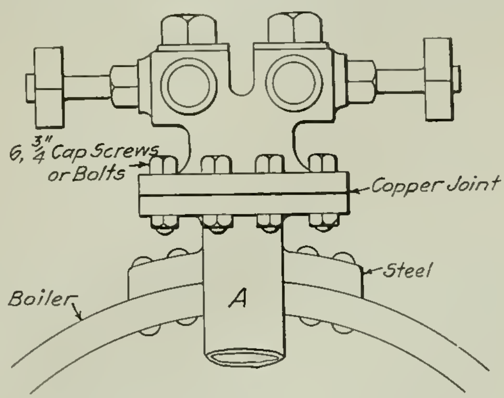
An old drill shank will make a good tool, care being taken to round off that part that bears against the bush while replacing the dowel.

A BOILER CHECK CASING WITH GASKET JOINT

BY J. H. HAHN

Night Machine Shop Foreman, Norfolk & Western Railway, Bluefield, W. Va.

The sketch shows an improved boiler check casing which was designed by the writer to overcome the trouble caused by the ordinary type of boiler check casing leaking at the



Boiler Check Casing With Special Fitting

joint where it is bolted to the boiler, as was the case with the older designs. Considerable trouble is often experienced with the check casings that bolt to the boiler direct and use a ball joint ring, but with the type of check casing shown in the sketch there is little or no possibility of the casing leaking.

This boiler check casing is provided with a flanged joint and bolts on the special fitting *A*, which is riveted to the boiler shell. A gasket is placed between the flange and the fitting *A*, thus insuring a tight joint.

Any check casing of the ball joint ring type can be converted into the gasket type by simply adding one of the special fittings and bolting the check casing to it as shown. A slight change in the branch pipes may be necessary because the fitting *A* raises the check casing slightly higher than is necessary when it is connected to the boiler in the usual manner.

AUTOMATIC SELF-DRAINING GLOBE VALVE

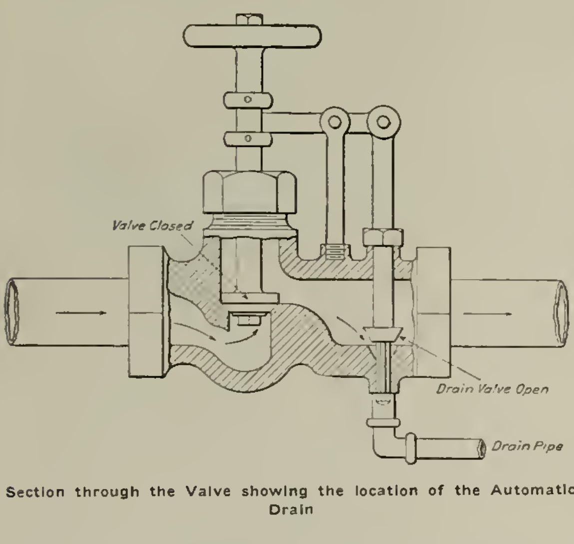
BY J. H. HAHN
Night Machine Shop Foreman, Norfolk & Western Bluefield, W. Va.

The globe valve shown in the sketch was designed to eliminate the liability of damage to air pumps, stokers, electric turbines and generators, etc., due to freezing in the winter time. It prevents the accumulation of condensation in pipes where it is not desirable.

The valve is of the usual globe valve design with an automatic or self-operating drain valve attached. When the globe valve is closed the drain valve is opened, the collars on the globe valve stem engaging the lever as shown, which in turn operates the drain valve which is contained in the valve body. When the globe valve is opened the drain valve is closed in the same manner.

This self-draining valve will save much of the additional piping necessary in putting in tees and drain valves of various kinds that depend upon the human element for their operation. With one of these self-draining valves applied in the steam line to a cross-compound air pump, all the drain cocks that are now used to drain off the condensation could be dispensed with.

On cold nights in the winter when the locomotive is in the roundhouse dead the probability of the drain valve being left closed is great, but with this self-draining device danger of freezing is eliminated.



Section through the Valve showing the location of the Automatic Drain

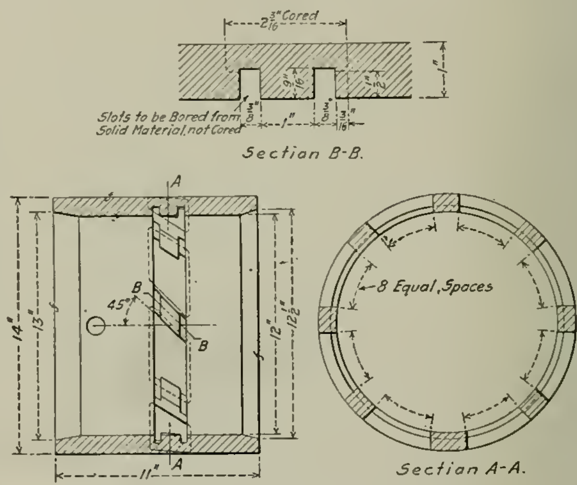
A SPECIAL VALVE BUSHING DESIGN

BY L. P. MICHAEL
Chief Draftsman, Chicago & North Western, Chicago

A valve bushing which the writer has had designed and which has been adopted as standard on the Chicago & North Western is shown in the drawing.

The special feature of this valve bushing is the method used in coring the steam port openings. These cored openings are made of such shape that the edges of the steam port can be finished in the boring mill or lathe at the same setting used for boring out the bushing.

This saves considerable time and labor, as the port edges are usually finished on either a milling machine or draw-cut shaper. The finishing of the port edges can be done in the lathe or boring mill by cutting a groove for each port edge. The groove is 3/8 in. wide and the packing ring is of tee shape, 7/8 in. wide over the head of the tee, which gives a bearing of 1/2 in. when the ring is over the finished port groove.



Method of Coring and Finishing the Ports

A bushing of this design not only can be finished with less time and expense than the ordinary bushing, but it also gives the advantage of a considerably larger port opening, especially at short cut-offs.

Heat Value of Fuels.—Tests of the heating values of fuels have become of great commercial importance, as practically all coal sold on large contracts is paid for on the basis of the heating value found in the tests conducted by or for the purchaser. The instrument used for carrying out this test is the bomb calorimeter, which comprises a strong, steel cartridge or capsule with a removable cover, adapted to contain a small charge (about 1/30 ounce) of coal. The bomb is tightly closed and oxygen is introduced under high pressure. It is then put into a calorimeter, the coal ignited electrically, the heat generated being absorbed by the water. The quantity of heat liberated in the combustion of the fuel is then calculated from the rise in temperature of the water. Important aid has been given in the standardization of the testing of coal for calorific power by the issuance by the Bureau of Standards samples of materials of accurately known heat values which afford a simple, precise, and convenient means by which the user of the calorimeter may check up the accuracy of his own determinations.—*Technical News Bulletin, Bureau of Standards.*

Modern High Speed Tool Steel*

The Origin and Development of Modern High Speed Steel; The Hardening and Tempering Qualities

BY JOHN A. MATHEWS

After accepting the invitation of the Committee on Papers and Publications to present a paper on the announced subject, the writer began to wonder just what the Committee meant by "Modern" High Speed Steel. A product that is of less than twenty years' standing is certainly modern when compared with crucible tool steel which has been manufactured for about 170 years, and even the air-hardening steels which preceded high speed steel resulted from the investigations of R. F. Mushet about fifty years ago.

I have been deeply interested in everything pertaining to the history of the iron and steel business, but this latest product, high speed steel, seems to have sprung fairly fully developed from a variety of sources and at almost the same time, and I have been unable to show just when the change from the old type of air-hardening steels to the modern type of high speed steels took place. Obviously the change is associated with the announcement of the Taylor-White process; that is, the high heat treatment given these grades of steels as compared with the ordinary treatment of carbon tool steels. This process was announced at the close of the nineteenth century, and the results of the Taylor-White process were demonstrated on a large scale at the Paris Exposition in 1900.

Notwithstanding the fact that the originators of this process took special trouble to disclaim the invention of a steel, but only a process for treating steel, a large number of workers in steel still seem to feel that they were the inventors of the product known as "High Speed Steel." Mr. Taylor, in his epoch-making paper on the "Art of Cutting Metals," very plainly states that this was not the case, and most users of steel have forgotten that the type of steel to which this treatment was first applied was the high-carbon air-hardening steel used prior to 1900.

The change from air-hardening to high speed steels was rather a matter of evolution than a distinct invention, and I have not been able to ascertain that the change was the result of any one man's discovery or invention. Chemically the change consisted in a very radical lowering of the carbon content and a great increase in the tungsten or molybdenum content. The chromium percentages have not been materially altered as compared with previously existing air-hardening steels; but high manganese, which was an important constituent of the original Mushet steel, is not now an important constituent in high speed steel; in fact, chromium replaced manganese in most of the air-hardening steels during the later years of their use in the nineties.

In 1901 the writer collected a number of the typical analyses of air or self-hardening steels from large users of these products. In 1902 our analyses showed that the change had already taken place in America, England and Germany, and the contrast is illustrated in Tables I and II. Each table contains products of the three countries mentioned, but the exact maker is not designated.

The high carbon content and the low tungsten or molybdenum content in Table I indicates the character of air-hardening steels in use prior to 1901.

In Table II, although these analyses were made only one year later, it is seen that a change in character has come about, and relatively low carbon, with high tungsten or molybdenum, is the characteristic feature of the new steels.

It will be noted that two of the steels in Table II, one a molybdenum and the other a tungsten steel, contain no chromium.

It should be borne in mind that during the later days of air-hardening steels and the earlier days of high speed steels, it was a difficult matter to produce low carbons with the available ferro-alloys. The introduction of electric furnace and alumino-thermic alloys had much to do with the success of manufacturers in keeping their carbons down, but the idea that they should be reduced and that the alloys might be increased in conjunction with the application of a high heat treatment seems to have been almost spontaneous with the makers of tool steel in every country. In my search for the definite origin of this idea I learned of a user of steel who in the early days of the Taylor-White process obtained some extraordinary results with a particular bar of the old Sanderson self-hardening steel. Upon analysis it developed that this particular bar was considerably lower in carbon than usual, and instead of reporting this fact to the maker, he gave a sample of the steel to the representative of a foreign mill.

Table I—Self-Hardening Steels, 1901

29	0.60	0.30	....	....	9.25

My former associate at the Sanderson Works, Dr. E. L. French, is on record, however, as having predicted prior to 1900 that the tendency would be to rely for hardening upon tungsten and chromium rather than upon carbon in order to secure the kind of hardness which resists tempering—in other words, the peculiar red hardness upon which high speed steels depend.

It is probable that we shall never know who took the radical step and made the first low-carbon, high-tungsten high speed steel, but immediately following the announcement of the Taylor-White process there was great activity on the part of all tool steel makers in every country to produce a product which would yield maximum results when treated by this process. The courts decided that Messrs. Taylor and White did not make a patentable invention or discovery. A world jury, however, seemed to differ with this decision and every scientific honor was awarded them for their epoch-making announcement which revolutionized machine-shop operation and machine-tool building.

With the development of high speed steels there has been much study devoted to them from many angles. The engineer, the machinist, the chemist and the metallurgist have all been interested, and much has been said and written in regard to

* A paper presented at the Twenty-second Annual Meeting of the American Society for Testing Materials, held at Atlantic City, N. J., June 24-27, 1919.

this remarkable product. The question to be answered by all investigators of high speed steels has been: What constitutes the most efficient cutting tool and why? In Mr. Taylor's work "The Art of Cutting Metals," the point of view of the machine-shop economist is most ably presented. His work records the development of a high speed tool in regard to its composition, its heat treatment and the method used to secure the most economical removal of metal. The peculiar property of these steels in resisting softening in use Mr. Taylor has called the "quality of red hardness," and he makes no attempt to connect red hardness with any of the previously known physical properties of metal. The only method of measuring this quality of red hardness known to Mr. Taylor was the very expensive and time-consuming resort to cutting tests. The necessity for shorter and more easily applied tests was appreciated by Mr. Taylor, for he says, referring to cutting tests: "This test requires so much expensive apparatus, consumes so much time and is so slow, that a simpler index or guide which will indicate correctly the quality of high speed tools is much needed. Moreover, we firmly believe that in time some simpler index to the property of red hardness in tools will be found."

Accepting this suggestion, many able scientists have conducted investigations upon the hardening and tempering qualities of high speed steels of many compositions, and also in connection with the study of the specific functions of the various elements entering into their composition. I might mention specifically the work of Dr. H. C. H. Carpenter upon the types of steel and critical ranges of heating and cooling of high speed steels under varying thermal treatment, and also upon the tempering and cutting tests of high speed steels. The writer took a special interest in these investigations because of the fact that he had the pleasure of furnishing Dr. Carpenter many of the alloys used by him, taken from materials used in his early investigations in this country.

It may be taken for granted that any one interested in the scientific study of high speed steel will study Mr. Frederick W. Taylor's work upon the art of cutting metals. Dr. C. A. Edwards has studied the function of chromium and tungsten in high speed steels, and in conjunction with Mr. H. Kikkawa, published a later paper upon the effect of chronium and tungsten upon the hardening and tempering of high speed tool steel. Particular attention should also be given to the papers by Prof. J. O. Arnold and A. A. Read upon the chemical and mechanical relations of iron and carbon when associated with tungsten, molybdenum, chronium and vanadium. Each of these elements has been taken up one at a time in its relation with iron and carbon.

Dr. Carpenter, in studying the heating and cooling curves of tungsten and molybdenum products, finds the effect of these elements to be, first, the widening, splitting and lowering of the critical ranges by the special alloy elements; second, the complete suppression of the widened, split and lowered range by rapid quenching. He found also that these steels so hardened were in the austenitic condition and showed no signs of tempering when reheated below 500° C. and in some cases to even higher temperatures. Carbon steels show the effects of tempering as low as 200° C. Dr. Carpenter later supplemented this investigation with another one in which he studied the effect of etching reagents upon hardened and tempered high speed steels as prepared for microscopic examination. In general he found that the higher the steel had been heated for hardening, the less slowly it was attacked by the etching reagent. Also that when fully hardened and later subjected to tempering operations, the converse was true, namely that the more fully the temper had been drawn the more easily it was attacked by the etching material.

Dr. Edwards, in his earlier paper, finds that hardness assists the efficiency of the cutting tool, referring to purely mineralogical hardness as distinguished from red hardness. He also states that chromium forms a double carbide with the tungsten and a new brittle constituent appears at about 700° C. in tempering which caused the failure of high speed tools. In his later statement, published jointly with Mr. Kikkawa, he abandons these last two positions but states that chromium in these steels in conjunction with carbon is the cause of the great hardness of high speed steels and that it produces a marked lowering in the temperature at which hardness can be effected. He differs with the earlier conclusions of Dr. Carpenter that chromium does not confer the quality of air hardening in the absence of tungsten or molybdenum, but that chromium steel so hardened in air develops a comparatively slight degree of secondary hardening or "red hardness," as Taylor designated it.

In regard to high tungsten steel in the absence of chromium, he finds that a large proportion of the tungsten remains undissolved even when the temperature is raised to the melting point, and agrees with Arnold and Read that this tungsten is probably in the form of a tungsten iron compound, Fe_2W. Very rapid quenching from high temperatures results in much less hardening than is obtained from a high chromium steel similarly treated; but the tungsten steel, on tempering, undergoes a very pronounced secondary hardening—in other words, it is the tungsten which confers the quality of red hardness. While Dr. Edwards, in his investigation, did not cover a study of molybdenum, we can say that molybdenum in its effects is very closely analogous to tungsten and about twice as efficient; that is, an amount of molybdenum confers a degree of red hardness similar to or greater than twice its weight of tungsten. The difference between these two metals seems to be one of degree rather than of kind. When chromium and tungsten are present together the presence of the chromium increases the solubility of the tungsten when raised to high temperatures. Dr. Edwards states that the maximum of resistance to tempering and the greatest degree of secondary or red hardness is obtained by getting the tungsten into complete solution, and in modern high speed steels he places this temperature at about 1350° C. (2462° F.). In our experience this temperature is too high for practical results and is apt to result in brittleness, and also, as will be shown later, the hardness seems to decrease rather than increase upon extreme over-heating to such a temperature, and at this temperature there is formed a so-called "brittle constituent," to which Dr. Edwards refers in his first paper. This constituent is due solely to over-heating and is not produced when tempering at 700° C. (1392° F.) in properly hardened high speed steel.

Dr. Edwards also points out very clearly, and shows by his results, that this secondary hardness by drawing the temper may be and usually is actually greater than the initial hardness of the hardened high speed before the temper has been drawn at all, but that at intermediate drawing temperatures there is some lowering of the hardness, which later increases as we approach the temperature at which full annealing begins. The temperature at which he finds the maximum secondary red hardness coincides almost exactly with the temperature given by Taylor as that recommended for the second heat treatment required in the Taylor-White process, for, as described by Mr. Taylor himself, the second heating of the hardened tool consists of heating the tools "(*a*) to a temperature below 671° C. (1240° F.), preferably to 621° C. (1150° F.) for about five minutes; (*b*) cooling to the temperature of the air either rapidly or slowly."

As previously reported to this Society, in a paper entitled "Magnetic Habits of Alloy Steels," the writer began some fifteen years ago to study systematically, and as a matter of routine, the magnetic properties of practically all the alloy steels manufactured in our regular line of business. That paper did not touch upon any magnetic work in conjunction with air-hardening or high speed steels, but such work was commenced in the earliest days of the modern high speed steel, and renewed attention was given to this matter after the suggestion of Mr. Taylor that a simpler index or guide to the quality of high speed steels would be of great use and importance. A paper on the subject of the physical characteristics of high speed steel was promised for presentation at the last meeting of the International Association for Testing Materials held in New York in 1912. At that time the work was not sufficiently advanced to permit of presenting the results, and, in fact, even yet the results are not what we had hoped to obtain from this long continued study. It was thought that there might be found some critical temperatures in connection with the magnetic or electrical resistance of high speed steel which would furnish a definite indication of its properties at those temperatures most suitable for commercial hardening. In addition to magnetic and resistance tests of various high speed steels hardened and tempered in a wide variety of ways, we have supplemented the work with microscopic examinations, and to some extent by cutting tests.

While in the aggregate a great variety of high speed steel compositions have been tested, not only of our own regular and experimental steels, but also commercial steels of a great many brands foreign and domestic, the greater part of the systematic investigation was confined to four steels, the analyses of which are given in Table III. These steels cover quite a range as regards their chromium, tungsten and vanadium content. Steel No. 31 represents a type which was fairly generally used about ten years ago; in fact, various writers as the result of practical tests, have contended that tungsten above 13 or 14 per cent is of no advantage. Practical experience, however, has led for the most part to higher tungsten percentages.

Steel No. 34 is introduced because it corresponds quite nearly with the analysis of steel to which Mr. Taylor referred as giving the best results obtained with any steel at the time he was actively engaged in this work. In fact, because of Mr. Taylor's recommendation, steel of this character was once adopted as the standard material desired by the Navy. Their specification, however, calling for high tungsten and high chromium, was abandoned after one year because it was found that steel of the type represented by No. 33 gave materially better results.

Steel No. 32 is intermediate in quality as compared with Nos. 31 and 33. As the result of a very exhaustive series of cutting tests made as nearly as possible in accordance with the methods outlined and recommended by Mr. Taylor, these four steels will rank about as follows, starting with No. 33 as 100 per cent efficient: Steel No. 34 would be represented by 70 per cent, No. 32 by 66 per cent and No. 31 by 45 per cent.

Table III—Analyses of Four Steels Used in Tests

Steel No.	Carbon, per cent	Silicon, per cent	Manganese, per cent	Chromium, per cent	Tungsten, per cent	Vanadium, per cent
31	0.63	0.19	0.26	4.21	13.10	0.25

It is apparent, therefore, not only from the analyses but from the figures above, that the steels are typical of well-known commercial types of steels, and it therefore might be thought that their behavior electrically and magnetically, also as to hardness, would show marked differences, with possibly some differences in critical temperatures both in hardening and in drawing. However, this does not appear to be the case, but the following general conclusions can be stated in regard to all of them.

Starting with hardening temperatures at 982° C. (1800° F.) and carrying them up to 1315° C. (2400° F.), it would be noted that the electrical resistance, the scleroscope hardness and the coercive force increase fairly uniformly with the hardening temperature up to about 1260° C. (2300° F.). There is a slight tendency to show a reversal of these properties beyond this temperature. In other words, it would indicate that overheating had commenced. Magnetic induction and residual density, as the hardening temperature increases, are lowered.

If these steels hardened at proper temperatures to develop full austenitic structure are subjected to the tempering operation varying from room temperature up to 649° C. (1200° F.), it is noted that there is a general falling off in the hardness, resistance and coercive force as the drawing temperature is increased. This is not quite in accord with statements that have been made that there is no effect in drawing the temper of high speed steel until the temperature of 500° C. (932° F.) has been reached. It is true, however, that the effect upon these properties is only slightly influenced below this temperature, while the rate of change increases fairly rapidly at temperatures above 482° C. (900° F.). There is no indication, as regards magnetic properties, of anything corresponding to the secondary hardening referred to by Edwards, nor have we found it in connection with hardness tests made by the scleroscope. In cases where the Brinell method is used we found it very difficult to get constant results with materials so extremely hard, but with that method we have found an indication of re-hardening, or secondary hardening at high drawing temperatures, the maximum usually being at about 593° C. (1100° F.). The lower the temperature at which the initial hardening is done the lower will be the temperature at which the re-hardening occurs on tempering, and presumably the sooner a tool so treated would fail in severe cutting where the frictional temperature was high. When the temperature in cutting is not extremely high we cannot conclude that the steel would fail sooner than one with a higher re-hardening temperature. In such cases, in my opinion, physical or mineralogical hardness plays an important part as distinguished from red hardness, but where the cutting conditions are severe it would appear logical that the higher the temperature of red hardening the longer the endurance of the tools.

The tests that we have made were for the most part made upon hot rolled 1-in. by 5/8-in. bars in just the condition that might have been used for cutting tests or for supplying to users. After all heat treatments, however, the surface was examined by file testing to see that no unreasonable decarbonization had taken place. There was, however, some slight decarbonization of surface in all cases, undoubtedly due to scale and oxidation. However, we wished to operate under conditions as nearly as possible those that would obtain in practical work in case it were found possible to make use of physical tests rather than cutting tests as a means of judging the relative merits of high speed steels. Of course for determining hardness it is necessary to remove, by grinding, sufficient material to get below any possible decarbonized or oxidized zone.

We are convinced that to make these tests with scientific accuracy would require conditions of heating and temperature control much more refined than are usually found in industrial plants and that it would be desirable to operate on round pieces which could readily be rough turned prior to any treatment and ground on centers after each treatment to insure making the test on perfectly sound material. This, in my judgment, removes such methods from the kind of tests that Mr. Taylor had in mind, as they introduce the same element of expense and require the expenditure of considerable time.

For purely scientific reasons it might be worth while to conduct such a series of tests on different types of high speed steel; the intervals of temperature should preferably be not over 10° C. (50° F.) both in the tests made on hardened bars and also on the tempering ranges, particularly from, say, 482° C. (900° F.) up to the point of softening. This is entirely too complicated and extensive a program to consider as a convenient substitute for the cutting tests.

To refer again to the title of the paper and what is meant by "Modern," we might call attention to the difference in analyses displayed in Tables II and III. The most noteworthy change is in the introduction of vanadium, which is now used in practically every high speed steel; in fact, it is the only general addition that has been made to the earlier types which seems to afford universal improvement in quality. The writer began experimenting with the use of vanadium in 1903, and it is well to bear in mind that at that time vanadium was almost a chemical curiosity. It was worth about $15.00 a pound, and this was some time prior to the formation of the American Vanadium Co. which manufactured and sold vanadium in large quantities. So far as the writer is aware, the entire stock of ferro-vanadium in the country when these experiments were begun consisted of not over 100 lb. in the hands of two different dealers in New York. We purchased one-half of the entire stock of each dealer. As the result of these experiments carried on at the old Sanderson Works, a patent was granted the writer, issued on January 3, 1905. Other experimenters were doubtless working with the same thing, and, in fact Mr. Gledhill referred to its use in 1904, as did also Mr. Taylor. In fact, the composition of tool steel previously referred to as giving Mr. Taylor his best results, showed 0.3 per cent of vanadium. During the year 1905 the Rex AA steel was put upon the market, and other vanadium steels followed shortly, but it was not until three years later that certain foreign makers copied this original steel exactly and made great claims as to originality in regard to their product.

As has been stated, vanadium seems to have conferred general benefit upon all tungsten-chrome or molybdenum-chrome high speed steels. In this particular it differs from other additions that have been introduced since. The use of cobalt received considerable attention a few years ago, but it was noted that it was always present as an addition to types of steels that would have given remarkably good results if the cobalt had been omitted. I have never seen anything to indicate that it could be used as a substitute for any of the other elements regularly present, and its use is not now as extensive as it was a few years ago. As an element of increased cost it has not shown sufficient improvement in the long run to warrant its general use. So far as our observations are concerned it seems to lead to some uncertainty in the manufacture and treatment of the steel, and steels containing it seem to be more difficult to re-forge or re-dress than steels in which it is absent. These comments are made notwithstanding the fact that one of the most carefully conducted competitive tests on high speed steel ever made in an industrial plant was won by a steel containing cobalt, and it might be added that there is every probability that the same steel without the introduction of cobalt would have been equally as successful.

The use of uranium has been advocated during the past few years, but it seems to be very difficult to handle owing to the ease with which it is oxidized, and so far as our experience goes we have been unable to see that it confers any specific benefit. Such steel as we have examined has been more apt to show seams and surface defects than steel in which it is absent, and the microstructure of the steel itself usually indicates the presence of considerable amounts of material that are suspected of being oxides of uranium. It should be noted that when oxide of uranium is formed in melting it has small chance of being eliminated in the slag owing to its great weight. It may be that with more experience means will be found of introducing this material into the bath without such great loss of expensive metal and without the formation of these impurities in the steel which cannot but prove detrimental.

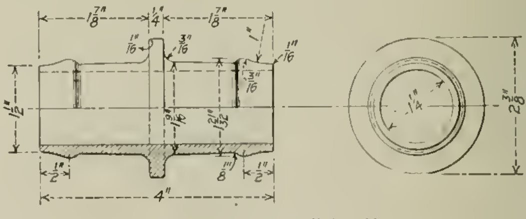
Other elements have been tried, including cerium and zirconium, but no conclusions are available as yet.

The term "Modern" High Speed Steel therefore may be considered as referring to the product since the introduction of vanadium, as no generally accepted improvement has been made in high speed steel since that time. Improvements have resulted in the general quality of the material available, due to greater skill in manufacture, and to the availability of superior raw materials in the form of metals and ferro-alloys than were obtainable in the early days of the industry. It is still a constant source of surprise to see tests conducted in which a steel that may appear of inferior analysis proves successful, whereas some other type of analysis, judged from this viewpoint only, would naturally be expected to prove the better steel. In a very elaborate series of tests, including over 50 analyses, it was noted that in those steels included in the first group as to merit the compositions vary from 12.70 to 18.59 per cent of tungsten, from 1.70 to 5.58 per cent of chromium, from 0.40 to 1.73 per cent of vanadium, and from 0.52 to 0.81 per cent of carbon. The steels rated as second and third class in general covered almost identical ranges. It therefore seems that steel making rather than chemical analysis is the first consideration, and so far we are not able to define or to specify all the elements which enter in, from the melting to the finishing of a bar, to produce first-class material in a very wide range of analyses, and no physical or chemical test has as yet been developed which helps very much in determining the matter of quality.

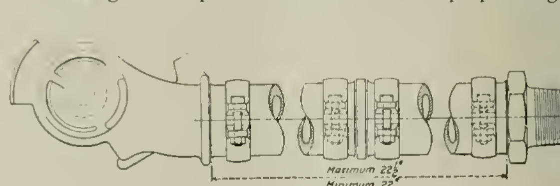
RECLAIMING AIR BRAKE HOSE

BY E. A. M.

A method of reclaiming air brake hose which is efficient and economical is illustrated in the drawings. Hose which has been cut, chafed, burst or otherwise damaged but in good condition for at least one-half its length can be reclaimed by splicing the undamaged portions as shown in the drawing. Two pieces of hose cut to the proper length are clamped to a nipple and the fittings applied at the ends of the spliced hose in the usual manner.



Special Nipple for Splicing Hose



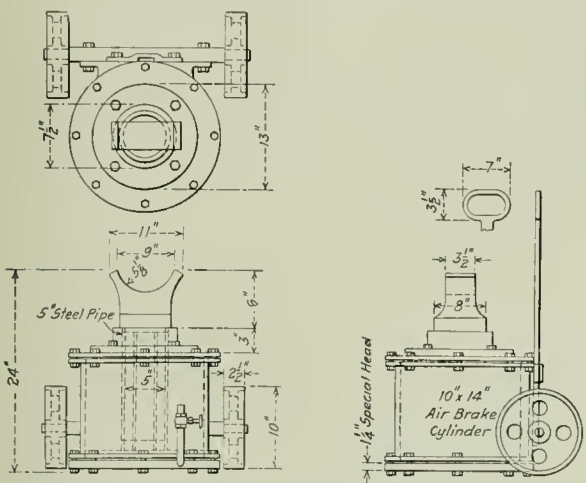
Spliced Hose with Fittings Applied

The reclaimed hose may be applied to the front end of road engines, both ends of yard engines, caboose, camp and maintenance of way cars.

AIR JACK FOR LIFTING WHEELS

BY C. W. SCHANE

The air jack shown in the drawing provides a convenient means of transferring driving wheels about the shop. The jack consists of a standard 10-in. by 14-in. air cylinder with a special head applied at the bottom so that an air pipe can be connected to the jack. The top is machined off and a guide bolted on. The standard is of five-inch steel pipe with a holder so designed that the pipe and cylinder plunger or piston rod are always in line and act as a pivot. Small wheels, similar to those used on hand trucks, are applied to



A Portable Jack for Transferring Driving Wheels

one side of the jack and a socket is provided for a removable handle by means of which the jack may be moved from place to place.

To transfer a pair of wheels from one track to another the jack is placed underneath the axle with the holder at the center and air from the shop line admitted into the cylinder at the bottom. This raises the plunger, thus lifting the wheels clear of the rails. They are then turned in the desired direction on the pivoted holder, the air pressure in the cylinder relieved, the wheels lowered to the floor, and the jack removed. The wheels may then be rolled to another track, the handle inserted in the socket and the jack moved in position to again raise and turn the wheels as may be desired.

BENDING STIRRUP BRAKE HANGERS IN A BULLDOZER

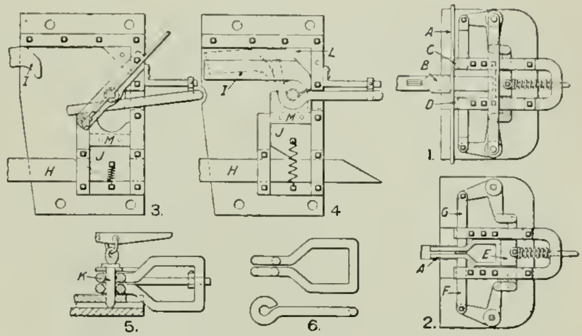
BY B. S. LYON

Blacksmith Foreman, C. B. & Q., Galesburg, Ill.

An attachment to a bulldozer for bending two eyes simultaneously has given very satisfactory results.

A piece *A* of 1-in. round stock of the required length is heated and placed in the position shown, Fig. 1, where *B*, advancing, binds *A* between *C* and *D*. As *B* continues to advance, the piece comes in contact with *E*, the movement of which compresses the spring and by the movement of two bell cranks operating *F* and *G* bends *A* as shown in Fig. 2. This completes the first operation.

The partly formed brake hanger is now reheated and inserted in a form for bending the eyes, as shown in Fig. 3. The two plungers, *H* and *I*, advance simultaneously, *H* pushing *J* and *M* forward, bending *A* as shown by dotted lines in Fig. 4. *I* then engages *A* and bends it around the pin *K* with a lateral motion imparted by *L*. This forms the eyes and completes the hanger as shown in Fig. 6. Fig. 5 shows the method of withdrawing the pin *K* from the eyes by the use of a lever and clevis.



The Attachment In Place on the Bulldozer

The two pieces *L* and *M* are removable so that other parts may be bent by substituting forms of the desired shape in place of those shown in the drawing.

ESSENTIAL FACTORS IN PROMOTING SHOP OUTPUT

BY GEORGE W. ARMSTRONG

The past eight months have witnessed a radical change in the operation of many large railroad shops through the elimination of piece work. However drastic the transition may seem to many, it should not present an insurmountable barrier to retaining a high degree of shop efficiency and in some instances of improving the quality of the output. The essential factors for the most successful shop operation, as stated by the writer in a previous article,* are not inherently different for the day-work system than for the piece-work system. The stressing of latent or neglected factors is, however, required adequately to meet the changed conditions. A brief exposition of some of these essential factors was embodied in the recommendations of a committee which recently investigated shop record and management conditions in the Eastern Region.†

First and foremost, the results attained are dependent upon the supervision, the existing degree of co-operation, attentive interest and responsiveness; in other words, an effective organization. Without co-operation and harmonious efforts of supervision and working force, the efforts of the best organization conceivable are nullified.

By sheer force and driving work may be put through a shop, but unless good feeling exists between the helper, mechanic, foreman, and shop superintendent the maximum output can never be attained. Harmony is the oil that overcomes friction—and yet harmony must not be secured at the expense of discipline, or abandoning the shop to the men in order to avoid possible labor complications. Firmness tempered with justice must be the prevailing sentiment.

The one question of justice has been the rock upon which many an organization has split. What is your idea of justice? What is the workman's idea of justice? How close does yours coincide with his? Do you make any effort to conform your ideas of management, discipline, etc., to the workman's views? Too often the actuating motive of organized labor effort has been the rankling idea that the workman was not receiving justice. Why not obviate possibility of distrust and implications of injustice by according labor a reasonable voice in local management?

Industry embodies two factors, capital and labor. Capital

*See the *Railway Mechanical Engineer* for June, 1918, page 341.
†See the *Railway Mechanical Engineer* for May, 1919, page 263.

has its representation in the business in expression through its directorate, staff officers and local supervision. Labor is restricted to its voice in collective bargaining.

Is it too much to accord labor a limited voice in the consideration of local management? Why not organize a workmen's shop committee as a portion of the shop superintendent's cabinet? The shop committee keeps the local supervisory head apprised of individual or collective grievances. But a shop committee dominated by the head of the shop is no good either to the working personnel or the employer. The manifestation of a sincere desire to insure justice, it is not unreasonable to suppose, may meet with a like response.

Unquestionably, for effective results, most shops have exhibited a dearth of supervision. The Eastern Regional committee's recommendation of one supervisor to 30 men is a maximum limit, especially for erecting or boiler shop work.

A shop scheduling system is absolutely necessary to secure expedited and co-ordinated movement of parts requiring replacement or repairs and prompt overhauling of equipment. Aside from its wholesome effect in this respect, it is an excellent indicator of the essential degree of co-operation existing in the organization and will do much to bring the laggard into line. Scheduling and routing material relieves the individual foreman of chasing material, thus affording greater opportunity for effective supervision of work.

The Eastern Regional committee report says:

"Experience shows that any system of despatching or scheduling of work through the shop must be predicated upon (1) a predetermined route; (2) a predetermined time."

The predetermined route or path over which the locomotive parts must travel is a fixed element depending upon the relation of various shop departments, sources of raw material storage, and location of machine tools within department bounds. While fixed, many improvements are not necessarily precluded. As far as possible changes should be made which will insure (1) straight line movement, and (2) balanced material trucking. Inasmuch as fixed routes which do not embody these requirements can exert a very retarding effect on scheduling, every effort should be made to study the routing thoroughly and effect all possible improvements before finally establishing a scheduling system.

Scheduling of necessity implies a despatching or scheduling supervisor. It requires a knowledge as to repair demands and a time limit. Knowledge of repair demands to be effective of the greatest good should not be confined to inspection upon arrival at the shop but supplemented by thorough advance information as to repairs required. Especially important is the knowledge as to whether new cylinders, wheel centers, driving boxes, fire boxes, extensive boiler repairs or heavy machine details are required. Properly used this information will enable the shop to prepare a greater portion of this material, or at least insure its availability in stock, so that when the engine is finally received it will involve removing defective portions and replacing these with new parts, while repairs are being made to minor details of construction, thus involving a minimum of idle time for repairs.

A predetermined time limit, to be a stimulus for bettered shop operation should be an attainable one, but yet one not reached without diligent effort. Nothing will be more detrimental to the successful use of a scheduling system than a repeated failure to meet the schedule.

In establishing suitable forms for a scheduling system too much detail is to be avoided, but essential information should not be sacrificed to secure brevity or conciseness. While it may be true that forms or reports never effect results, it is also true that the absence of proper reports permits the formation of many unguarded loop-holes and delays occur which are difficult of discovery. Forms convey standards, standards measure results and failures to secure results indicate points for investigation. How long would the business man dodge the sheriff if he did not keep a set of books? His books consolidate and provide control of the details of his business and the results lie in the details.

Scheduling requires inspection as the preliminary basis. Why not, then, enlarge the scope of inspection? A chief inspector reporting to the shop superintendent, with one or more assistants as may be necessary, can become one of the most powerful factors possible in insuring of quality workmanship. Such an inspection force can become thoroughly familiar with the standard maintenance practices, improvements ordered, etc., being charged solely with inspection duties. The subordinate supervision is thus relieved of these matters, leaving them free to devote themselves to departmental output, executive direction and discipline.

Unusual removals of material in stripping an engine should require the authorization of the inspection force and the decision as to repair or renewal of parts should be delegated to it. Miscellaneous small material could be inspected near the lye vat before delivery to respective departments for repair. If possible, material needed for replacement or repairs should be delivered with the dismantled material to the department overhauling it.

Material handling offers one of the greatest opportunities for improvement. Common labor is scarce, expensive and in the main always more or less inefficient. Mechanical facilities should be employed to the fullest extent. While in a good many shops overhead cranes assist in handling material from machine to machine or department to department, still considerable hand trucking is necessary. A reduction could be effected not only in cost of handling, but in size of force required by providing floors and walks smooth enough to operate electric trucks, preferably those embodying an elevating feature so that work is delivered to machine on a portable platform, removed from it to the machine, replaced by the machine operator and requiring simply to be lifted by the motor truck and readily transported to any point in the shop.

Why not employ an automobile truck with wide-rimmed wheels, for intershop material handling, providing wide doors in shops and roundhouses through which this truck could be run with its load of material and unloaded directly in the shop? This would eliminate much secondary handling.

Another feature of the material question which should be investigated is the possibility of securing material from the storehouse for use at various points in the shop without the necessity of men leaving their work to go to the storehouse. This can be secured by reasonable anticipation of wants and the installation of a messenger system which can be developed in connection with motor truck operation.

Orders for material may be left at different points in the shop, collected hourly and material delivered by motor despatch to the place required. This would eliminate a large loss in connection with the average shop operation in waste through loafing to and from shop and storehouse.

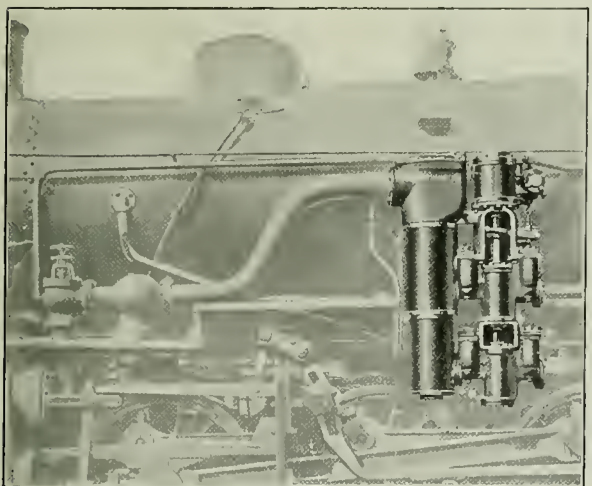
Miscellaneous small materials as bolts, nuts, washers, cotters, etc., could be placed in one or more accessible points in the shop and charged out in bulk through shop expense when delivered by the storehouse. This would reduce often needless delay and it is believed would be productive of ultimate economy in the use of materials.

An intercommunicating telephone, with a call system, placed through the shop so as to provide a phone every 100 or 150 feet would prove a large time saver and be productive of a great intangible economy. It could be effectively employed in conjunction with a material messenger delivery. Material could be ordered by the inspector or foreman, charged out by the storehouse office on a material blotter and delivered by the messenger. This would eliminate the written order and place the responsibility with the Stores Department for charging out material as well as delivery.

New Devices

AN OPEN TYPE LOCOMOTIVE FEED-WATER HEATER

The Worthington Pump & Machinery Corporation, New York, has developed and has in service on several Mikado type locomotives a combined feed pump and feedwater heater, which follows closely their marine practice. This heater is of the open type, which is now generally used in stationary power plants and is capable of handling 6,000 lb. of feed-water per hour. The full pressure of the exhaust steam is maintained in the heater, so that feedwater temperatures above 212 deg. F. are obtained when there is sufficient exhaust steam pressure available. It is designed for convenient attachment to the side of the locomotive boiler in a manner similar to that used for the attachment of air compressors.

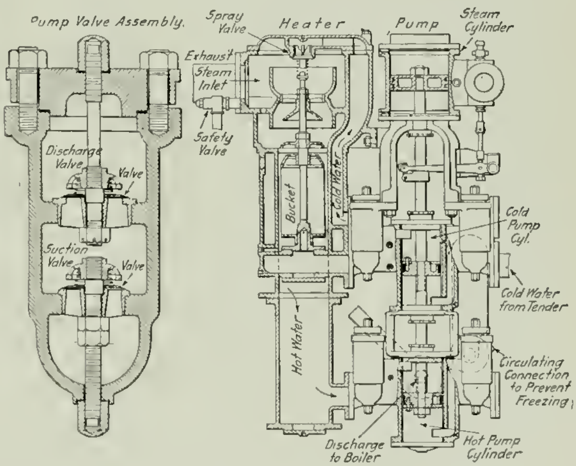


Pump and Heater Applied to Mikado Locomotive

The pump is of the vertical type with the steam cylinder at the top. It has two water cylinders, the upper or cold water cylinder taking cold water from the tender and delivering it to the heater, and the lower or hot water cylinder taking the heated water from the heater and delivering it to the boiler. The cold pump cylinder has a 6½-in. bore and the hot pump cylinder a 6 11/16-in. bore. Each of the pistons has four packing rings composed of ⅜-in. square (rock hard) piston packing. The drawing shows the pump valve assembly for both pump cylinders. The pump valves consist of three sheets of thin bronze, assembled with the smaller sheet on top and the largest on the valve seat. The valve seats, bolts, guards and springs are assembled before being placed in the pump. The suction valve seats are assembled with the long valve bolt projecting through the bottom of the pump chamber when the valves are in position. These valve seats make their joint on the pump chamber casting on the flat and not on the taper. The suction valves are held to their seat by the cap nuts on the lower end of the valve bolt, which are drawn up tight against two thin copper gaskets. The discharge valve seats are larger than the suction valve seats and also make their joint on the flat.

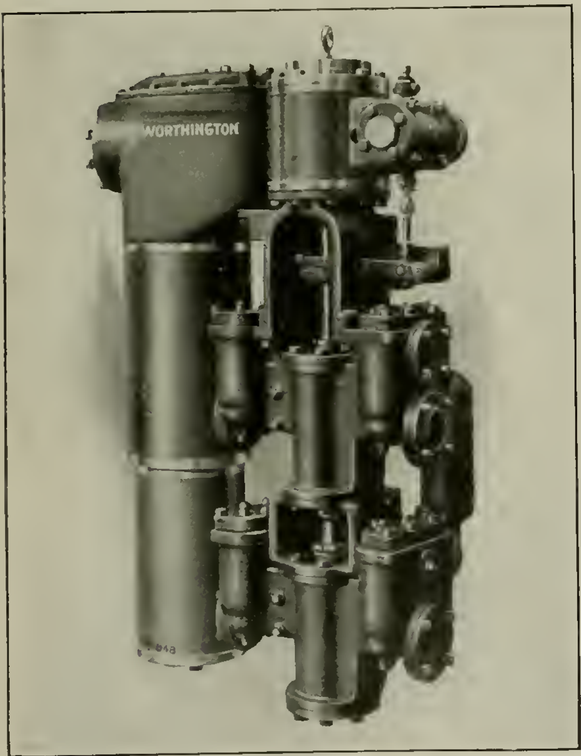
The heater is a cast iron box attached to the side of the pump by suitable pipe connections. The cold water, taken from the tender by the upper water cylinder, is delivered through a port in the side of the heater at the top, where it is sprayed into the upper part of the heater. Exhaust steam from the exhaust ports of the locomotive is led into this part of the heater through a six-inch opening in one side near the top. The cold water sprayed into this space condenses as much of this exhaust steam as is required to heat the water, and mixed with the condensate, drops to the bottom of the heater, where it is taken by the lower cylinder of the pump and delivered to the boiler. A ½-in. air vent is provided to prevent the accumulation in the heater of the air carried into it by the cold water and by the exhaust steam. A pipe from this air vent is led to a point where the air can conveniently be discharged between the rails.

The varying amount of exhaust steam condensed in heating the water necessitates some means of regulating the water level in the heater, and this is accomplished by proportioning the pistons of the two pump cylinders so that there will be a tendency for a slight excess of water to accumulate in the heater. This excess of water will return to the upper pump cylinder where it mixes with the cold water from the tender passing through that cylinder, and is again delivered to the heater. The water level in the heater is regulated by a bucket which is free to move vertically on the central stem, and having holes in its top through which it is flooded when there is too much water in the heater, causing it to sink. In sinking it uncovers holes in the central stem on which it slides, permit-



Section of the Heater and Pump Valve Assembly ting this excess of water to pass through a port to one of the suction valves of the cold water pump cylinder, from which it is returned to the heater with the water that is being taken from the tender. When the water level in the heater falls the bucket is partly emptied and rises, thus covering these holes and causing the cold pump cylinder to take all its water from the tender. The height of water in the boiler is regulated by the feed pump throttle, which consists of a 1¼-in. globe valve located in the cab. The valve connections between the heater and the locomotive are shown in the illustrations.

Exhaust steam is taken from the locomotive cylinders through holes cut in the back of the cylinder saddle casting and led through an angle stop check valve, thence through an oil separator having a continuous drip for the oil and water, and from this through the curved pipe to the top of the heater. The pump is driven by steam supplied through a pipe, which has a throttle valve conveniently located in the



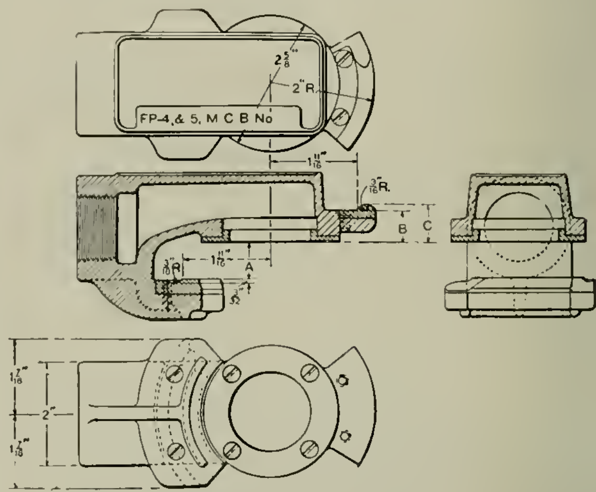
The Feed Pump and Heater

cab so that the pump can be operated at such speeds as conditions may require. The exhaust steam from the pump is led into the stop check valve, passes through the oil separator and thence to the heater with the exhaust steam from the locomotive. The pipe which conducts the cold water from the tender is shown passing behind the air compressor and entering the side of the upper or cold water pump cylinder. The heated feedwater leaves the lower or hot water pump cylinder by an opening in the rear and passes through a feed line to the boiler check valve.

So far as practicable the feed pump should be run continuously while the locomotive is in operation with the throttle open, but as the heater cannot recover any heat when there is no exhaust steam coming to it from the locomotive cylinders the injectors should be used when the locomotive throttle is not open.

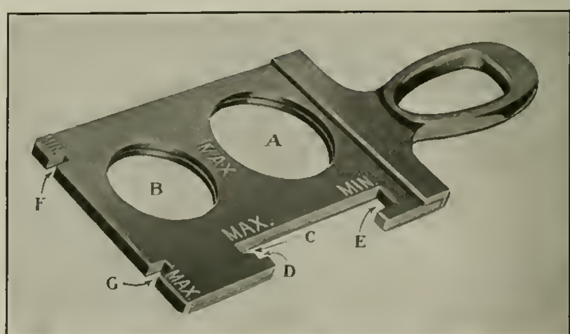
M. C. B. STANDARD HOSE COUPLING AND PACKING RING GAGES

The illustrations below show two gages adopted by the Mechanical Section of the American Railroad Association as recommended practice and now manufactured by the Westinghouse Air Brake Company, Wilmerding, Pa. The purpose of the hose coupling gage is to establish the amount of variation permissible in the guard arms of air brake hose couplings, which have become distorted or bent out of their normal position; and to determine whether the couplings are satisfactory for further use and interchange. The gages are



Gage for Testing Hose Couplings

intended for testing used couplings. Two gages are required for a set and, in practice, a coupling should enter gage No. 1 but should not enter gage No. 2. Couplings should be condemned when the guard arm is bent inward or outward from normal position; when bent inward the coupling will not enter gage No. 1 and when bent outward it will enter gage No. 2. The coupling may be used again by restoring the



Hose Coupling Packing Ring Gage

guard arm to its normal position. The Westinghouse Air Brake Company furnishes gages of the form shown for the standard FP-4 and FP-5 couplings.

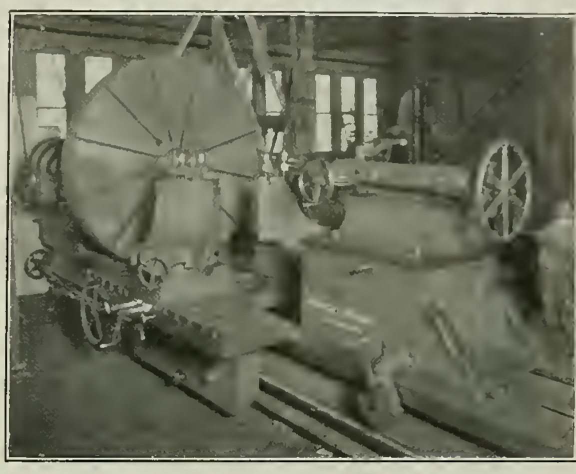
Variations in the dimensions of hose coupling packing rings are a prolific source of air brake leakage. In order to overcome this condition the Master Car Builders' Association has adopted as recommended practice a limit gage shown on sheet Q1 of the 1917 Proceedings. This gage provides a means for properly checking the maximum and minimum variations permissible in the dimensions of hose coupling packing rings, and further establishes a recognized standard for this item over the physical test specification. Opening *A* is for gaging the maximum and minimum external diameter of the packing ring flange. Opening *B* is for gaging the maximum and minimum external diameter of the projecting wall or face portion of the ring. Slots *C*, *D* and *E* are for gaging the height of the ring and the contour of the flange. Slots *F* and *G* are for gaging the maximum and minimum thickness of the projecting wall or face portion of the ring. Rings must enter all sections of the gage marked, *Max*, and must not enter any section of the gage marked *Min*.

A 96-IN. ENGINE LATHE

One of the largest lathes in the world, a 96-in. swing, triple geared Fifield engine lathe, has been produced by the Wright Works, Chicago. The machine is cone driven with the cone mounted on a back-shaft, this being necessary to obtain sufficient power to take the heavy cuts which would be required of a machine of this size. An eight-inch belt from a countershaft running at 200 r.p.m. transmits 40 hp. to the spindle of the lathe. The spindle is made of cast iron, on the theory that cast iron is less elastic than steel, and therefore will not spring when making heavy cuts, and for this reason reduces chattering. To compensate for the strength of a steel spindle the cast iron spindle is of generous proportions, the front bearing being 16 in. in diameter by 24 in. long, and the rear bearing 14 in. in diameter by 20 in. long.

The lathe is triple back geared and all changes in speed are obtained by moving the handwheel which is conveniently placed in front of the cone pulley within easy reach of the operator. The handwheel is geared to a lever shaft which materially reduces the effort required to shift the back gears into their desired positions. Only one change is made through sliding gears, the others being made by means of massive tooth clutches. The gearing and cone pulley is designed so that all speeds are in geometrical progression, the slowest speed being 0.75 r.p.m. and the fastest speed 76 r.p.m. Twelve speeds are obtainable through the four-step cone pulley and triple gearing with a ratio of 1.52 between each speed.

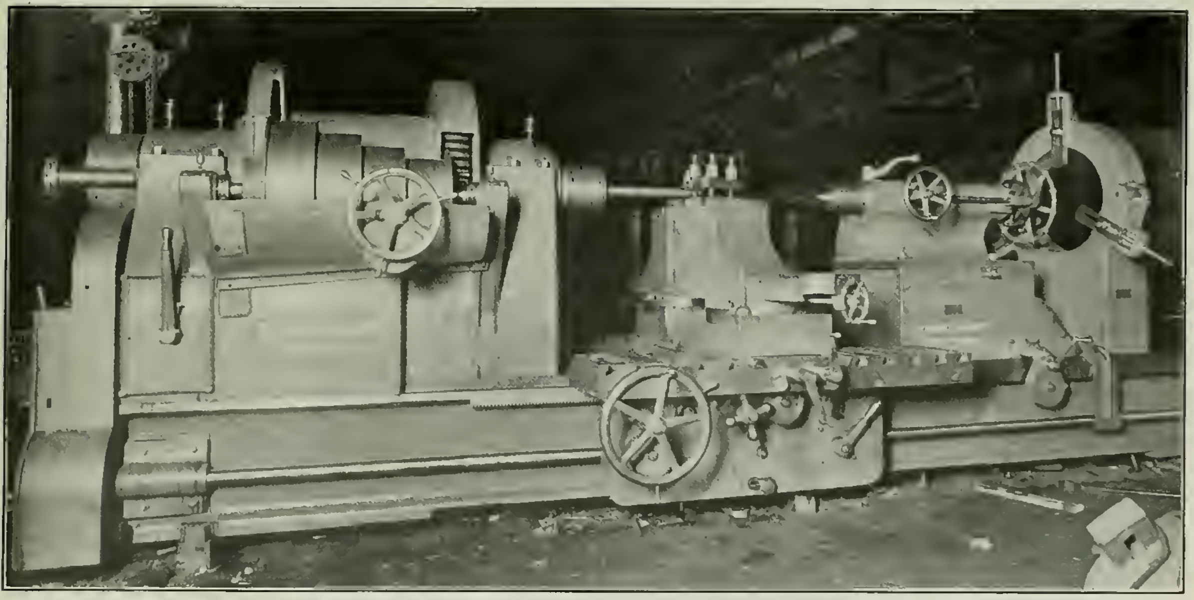
All of the gearing in the headstock, as well as throughout the machine, is made of steel and the pitch and width of face of the gears increase in proportion to the load which the teeth are required to withstand in turning the faceplate at the slow speeds required for work of large diameter. The triple gear which engages the faceplate internal gear has a diametral pitch of one and a face width of six inches.



Front View Showing the Massive Face Plate

Every shaft in the headstock runs in phosphor bronze bearings and is well lubricated by means of sight feed oilers which are in view of the operator at all times.

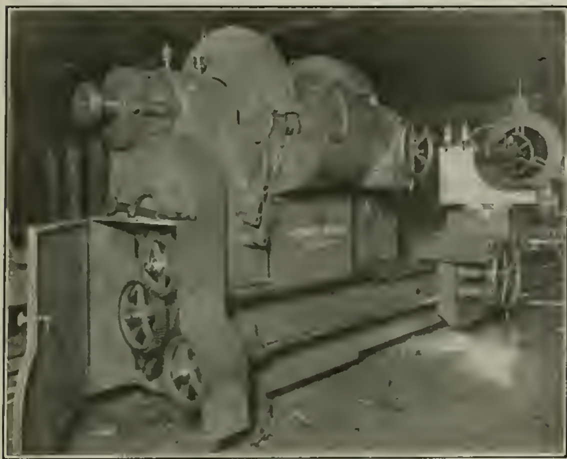
The feeds are also in geometrical progression and are obtained from a quick change gear box which is integral with the headstock. They are manipulated by the two levers shown in the illustrations, which move in either direction, giving four feeds of 0.025, 0.050, 0.100 and 0.200 in. for



The Lathe with the Face Plate Removed

each revolution of the face plate. More feeds may be had by changing the regular feed gears with the thread cutting gears. Twenty-four different threads may be cut by means of changing gears. All of the gears are guarded by covers or guards which are made conveniently removable where necessary while the gear change guard is provided with a door.

The carriage bears upon the ways for a length of 90 in.



End Showing the Change Gear

and is equipped with two compound cross slides which may be fitted with power angular feed if desired. The apron is fitted with steel gears and bronzed bushings throughout.

Buckling of the lead screw is prevented by means of supports which are adjustable and placed about 10 ft. apart.

The tailstock like the headstock is of box construction and is easily moved by hand by means of a geared device which engages the teeth in the rack on the bed. The tailstock spindle is moved by a handwheel which is placed convenient to the carriage. A massive steady rest is provided with each machine.

The bed is ribbed throughout with box sections and is fitted with a rack down a center rib which engages a pawl on the tailstock, thus removing the thrust of a cut from the clamps of the tailstock direct to the bed of the lathe. The total weight of the machine is 150,000 lb.

A LOCOMOTIVE PULVERIZED FUEL EQUIPMENT

A pulverized fuel equipment for locomotives has been developed by the Fuller Engineering Company, Allentown, Pa., and has been applied to a Lehigh Valley locomotive. This equipment consists of a fuel tank on the tender, the fuel feeding apparatus, a special arrangement of combustion chamber, slag or ash pans and smoke box. The device is mounted on the tender deck and is operated by a reciprocating steam engine and a steam turbine driven fan.

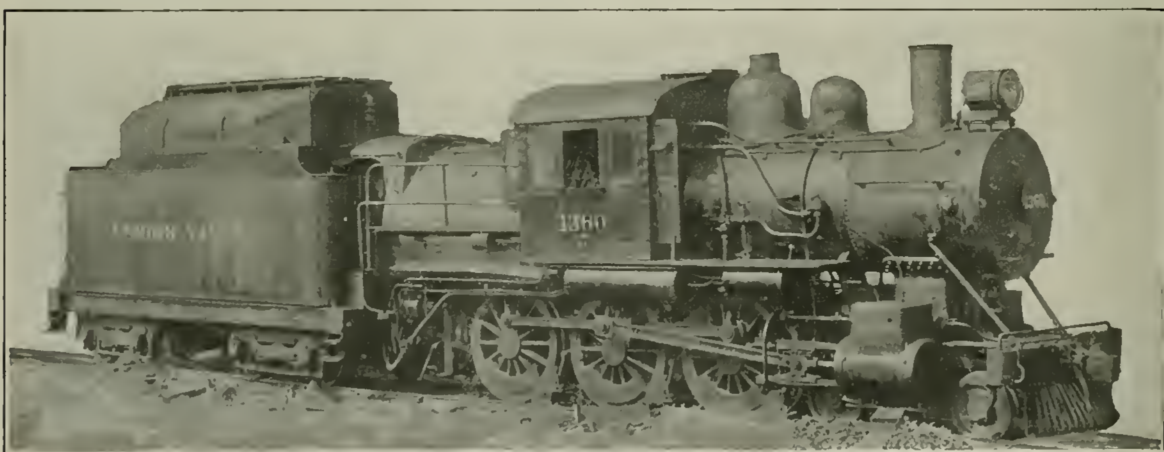
The standard brick arch supported on four 3½-in. arch tubes is applied in this locomotive as in hand fired practice, except that the arch is run within two feet of the back sheet and within about 12 in. of the crown sheet in the center, while the side bricks are not carried up so far.

The exhaust nozzles in this locomotive, of which there were two, were removed thus giving a free exhaust and eliminating all back pressure in the cylinders due to this cause. A sleeve has been secured to the end of the open exhaust stand and extended several inches up into the petticoat pipe. The petticoat pipe itself has been lowered 18 in. so that its lower end is now practically on a line with the center line of the boiler proper. This was done to reduce the draft in the front end, and thereby in the firebox, in order that the air and coal may enter the firebox at a velocity low enough to permit the coal to be completely consumed before being drawn over the arch, thus preventing the accumulation of slag on the flue sheet.

The pulverized coal tank is divided so that pulverized anthracite sludge may be carried in one side and bituminous coal in the other side. Very poor grades of coal can be burned in combination with soft coal by so manipulating the feed screws as to supply the proper proportions of soft coal and anthracite sludge necessary to maintain a proper temperature.

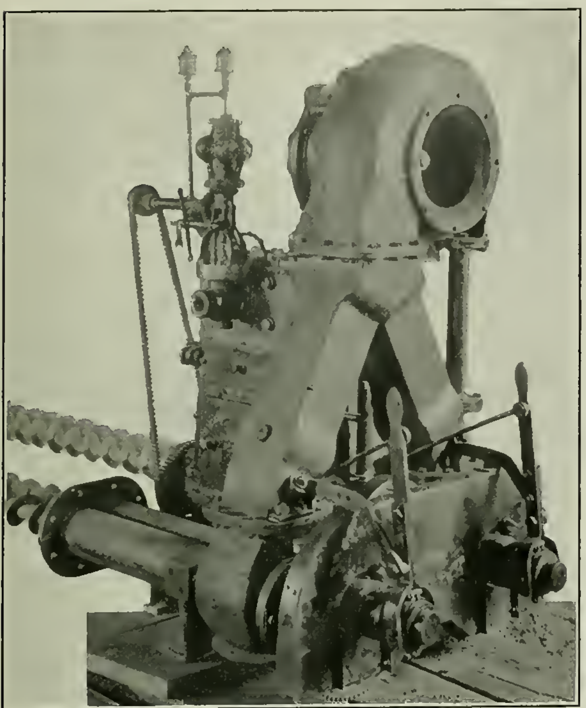
The apparatus for conveying coal from the tender to the locomotive consists of four 4-in. feed screws working in pairs and driven by a variable speed inclosed marine type two-cylinder double acting reciprocating engine. The fan for blowing the coal into the locomotive firebox is driven by a steam turbine. The turbine fan supplies approximately 15 to 20 per cent of the air required for combustion, the rest being drawn in by the action of the exhaust through the openings in the firebox and in the burner proper.

The four feeders operating in pairs prevent the fuel from arching over and feeding unevenly due to the tendency of



Lehigh Valley Locomotive Equipped with Pulverized Fuel Burning Apparatus the coal to become tightly packed in the tender by the constant vibration while the engine is running.

The reciprocating engine, which drives the feeders by means of a steel pinion and gears, is controlled by a wide range variable speed governor connected to the crank shaft by a Morse chain drive. A flexible shaft, controlling this governor, enables the fireman to obtain a variation of 346 per cent in the speed of the reciprocating engine, and thereby of the coal which is fed to the locomotive, without leaving his seat in the cab.



The Apparatus as Installed on the Tender

As it is carried forward from the tank the coal is pushed over two small shelves in the enlarged end of the feeding casing, where it is spilled off in two cascades, which are in turn caught between three currents of air from the turbine fan mounted directly above. This arrangement causes the coal to thoroughly mix with the air before it is blown to the burner, where it is further diffused and more air added to it.

The turbine fan is driven at constant speed while in operation, the determining factor being that the pressure through the hose and in the burner shall distribute the flame evenly beneath the arch without causing it to impinge on the flash wall and thereby cause undue deterioration of the fire brick.

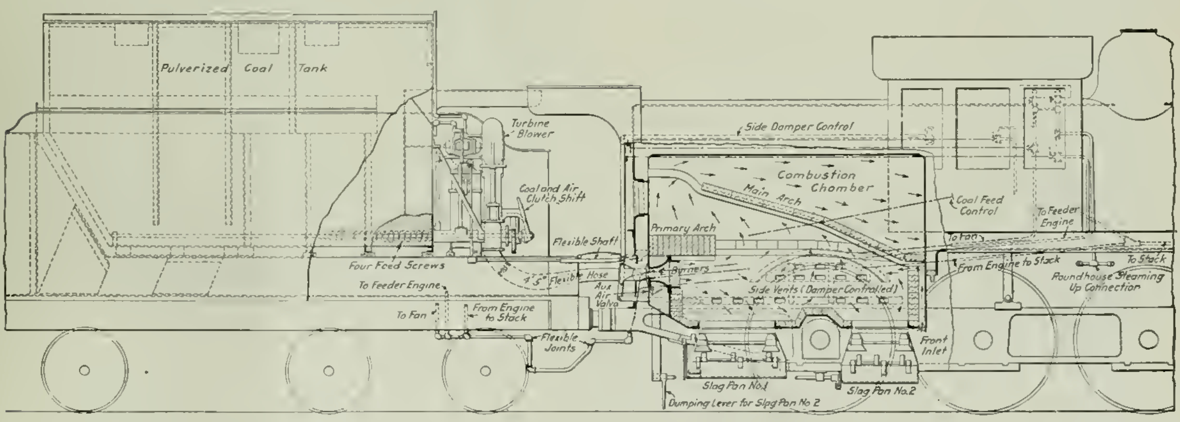
With the governor control and the two clutches a variation in coal feed of about 800 per cent between the minimum and maximum is obtainable with this apparatus, and the minimum can be reduced still further by throttling the steam in addition to the action of governor control.

Should either pair of the feeders become inoperative through some foreign matter being caught in them, the governor can be thrown out of operation and a single pair of screws can be driven at double the speed and thus supply sufficient fuel to operate the locomotive without failure. This wide range of speed is permissible as the ordinary maximum speed at which the reciprocating engine is run is less than half the speed of which it is capable, and this variation is also obtainable with the turbine fan without exceeding its rated capacity.

The maximum direct draft air pressure carried on the Fuller equipment is approximately three inches to four inches in the manifold beneath the fan or about 1¾ oz. to 2 oz., and this pressure is immediately reduced in the burner. A feature of the burner is that the flame spreads out and evenly fills the firebox beneath the arch no matter whether one pair or two pairs of feeders are in operation. The two pairs of feeders are thrown in or out as desired by the clutch shifters shown in the illustration and at the same time that either one of these is thrown out the air supply is also cut off from this side, thus preventing excess air from entering the burner.

A notable feature is that practically all of the air which enters the firebox, either through the burner or otherwise, is under the control of the fireman at all times, thus eliminating an excess of air and enabling the locomotive to be worked at maximum capacity without drawing in any more air than is necessary for complete combustion. At the same time this permits the velocity of the air entering the firebox through the different openings to be kept at a minimum. This is a desirable feature as it is chiefly the high velocity, accompanied by the abrasive action of the pulverized coal flame, and the high temperatures attendant thereto, which causes a rapid deterioration of the brick arch and the refractories in the firebox, while if these are properly controlled the life of the fire brick will be greatly prolonged.

To aid in preventing and controlling excessive and destructive temperatures a pyrometer is supplied with all pul-



Sectional View Showing the Application of the Pulverized Fuel Equipment verized fuel equipment furnished by the Fuller Engineering Company. The thermo-couple of this unit projects into the firebox beneath the brick arch about midway between the front and back sheets, and an indicating unit registering directly in deg. F., in plain view of the fireman, so that by manipulating the dampers and coal feeding mechanism the temperature can be kept at the desired point.

As this is a double cab engine with a Wootten type firebox dual control is provided so that the fireman can control the apparatus either from the tender deck or from his seat in the cab. A pyrometer indicating unit, a revolution counter showing the rate of coal feed and steam gages, indicating the pressure on the turbine fan and the boiler pressure, are located in the cab.

This apparatus as installed on the Lehigh Valley locomotive is designed to feed a maximum of approximately 4,600 lb. to 4,800 lb. of coal per hour, but this amount can be varied within considerable limits by simply changing the sprocket ratio between the governor and the feeder engine, or can still further be varied by changing the ratio between the pinion and gears driving the screws. This is a highly desirable feature as in this manner the same standard equipment can be used to feed a quantity of coal as low as 1,000 lb. or as high as 10,000 lb. an hour if desired, the only change necessary on the locomotive end being that different size burners and hose be employed for conducting the coal and air from the feeder to the burner.

The entire apparatus is assembled in one unit and can be secured to the pulverized coal tank with 18 bolts. It can be removed at any time without in any way disturbing the alinement of the gears, pinions, feed screws or any other part of the apparatus. As will be seen in the illustrations the whole apparatus is above the deck of the tender, where it is in plain view and easily accessible should any repairs or adjustments be necessary, and this feature also enables it to be applied to existing locomotives without cutting into the front water legs of the tender or without cutting below the tender deck to install it.

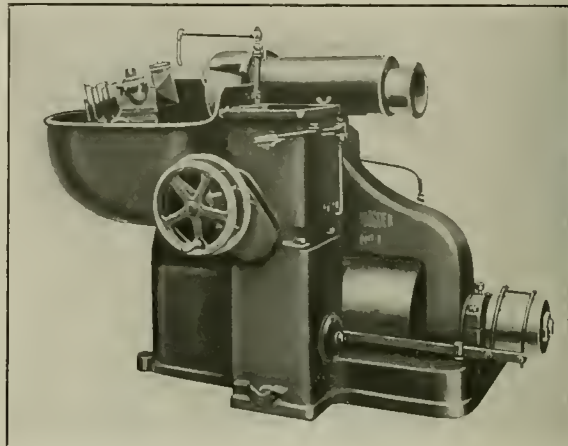
The apparatus as installed on the Lehigh Valley locomotive is said to have made a very creditable performance in a trip from the shops of the Fuller-Lehigh Company at Fullerton, Pa., to Atlantic City, during the recent convention of the mechanical section of the American Railroad Association, and also on its return trip to Fullerton.

THE LUMSDEN OSCILLATING TOOL GRINDER

A tool grinding machine designed to eliminate a large amount of tool forging and to increase production is being placed on the American market by Alfred Herbert, Ltd., 54 Dey street, New York. This is a British concern who developed this grinding machine during the recent war and are now introducing it in American shops. This machine is entirely self contained and may be driven by belt direct from the line shaft or motor.

Curved Top Face Tools

The grinding wheel is mounted on an inverted pendulum frame resting in large trunnion bearings in the base of the machine and oscillated by power. A variable eccentric motion controlled by a single lever or handwheel regulates the amount of oscillation. This eccentric arrangement is coupled to the swinging frame by a connecting rod adjustably connected to the frame by a swiveling joint. This adjustable connecting rod is controlled by a large handwheel on the front of the gear box and provides means of bringing the grinding wheel into correct relation to the tool. The grinding wheel is also adjustable in the operating frame the adjustment being controlled by another handwheel on the gear box. This provides for the feed of the grinding wheel to and from the work. By means of these two handwheels, easily reached by the operator, the grinding wheel may be moved sidewise and towards or away from the work without stopping the oscillating movement.



Front View Lumsden Grinder No. 1

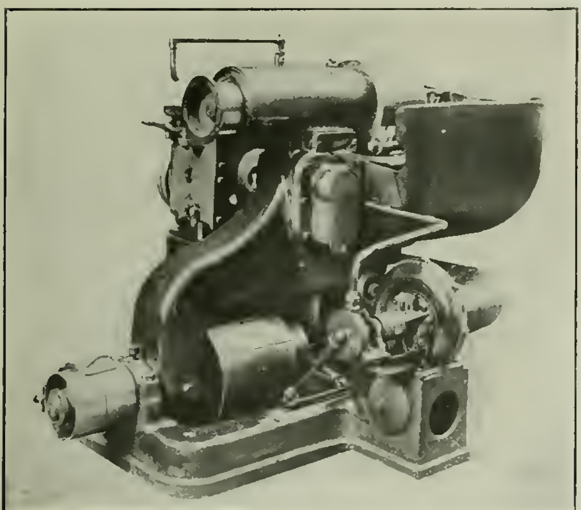
Tool Holder and Grinding Wheel

The lever controlling the oscillation is also located close to the operator's hand and the pedal for starting and stopping the machine is conveniently placed. This permits the operator to control the machine while standing in the best position to view the work being done.

The tool holder is universally adjustable for all tools other than those cranked to a right angle. A fixture for holding the latter and also for holding tools while being ground on the base is the only loose part used. The tool to be shaped is gripped in a simple chuck, which can be rotated through a complete circle on its own axis. The barrel which contains the chuck is carried in two trunnion bearings, so that the tool can be swung through an arc of about 10 degrees up or down. The trunnions have endwise adjustment in their bearings for use when grinding radius tools in which the center of the radius does not coincide with the center of the spindle. The whole tool holder can rotate on a vertical axis, enabling any side or the end of the tool to be presented to the wheel at any pre-determined angle. The tool holder is adjustable sideways on both sides of the center to allow the round nose of offset tools to be brought over the center of the vertical swinging movement.

The swivelling movement of the turntable on its vertical axis is extremely useful for grinding radius and round-nosed tools. To do this the tool is set so that the center of the desired radius is exactly over the axis of the turntable; then with the wheel stationary or oscillating but slightly the turntable is rotated back and forth until the desired curve merges into the sides and end of the tool.

Any shape or form of tool can be ground quickly without the use of a former, template or fixture other than the one specified, with the exception of tools which have a concave top face. Such tools may be ground by means of the curved face attachment, which is supplied for use on all Lumsden oscillating tool grinders. It consists of a swivelling tool holder fitted to a lever-operated slide and is arranged to fit in the tool holder of the machine. In using this device, the profile of a number of tools—the shape seen from the top—is first ground without the use of the attachment. They are then finished with curved top faces by means of the curved face attachment furnished with each machine in very little more time than would be required if they were ground with flat top faces. The degree of curvature given to the tool can be varied by commencing the grinding nearer to or farther from the cutting edge.



Rear View Showing Dust Exhauster Fan and Pump

Duplicate tools can be shaped very rapidly by making use of the adjustable stops provided for each movement of the tool holder. Each movement also has its own secure clamping arrangements, holding the tool rigid while being ground.

The grinding of new tools is done without the use of water, but when resharpening hardened tools water is necessary and the grinders are fitted with a pump and a tank for supplying water when required.

A powerful fan connected to a duct in the base of the tool holder draws all dust and chips away from the work and the operator and provision must be made when installing these machines to carry this away from the delivery pot of the fan.

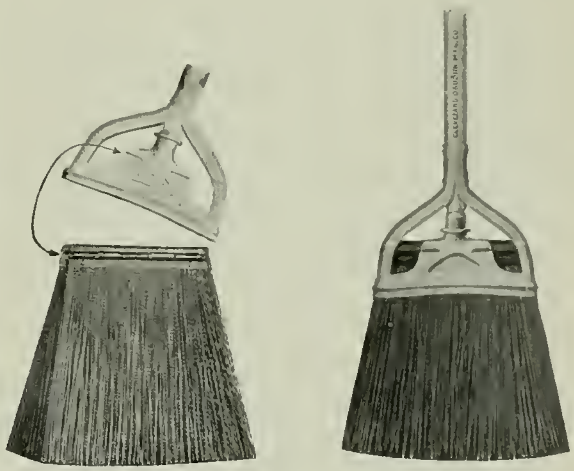
With this machine only a small amount of rough forging is required for any tool within the range of the grinder and many tools may be ground from pieces of straight bar without any forging work except to bend the end of the tool when the desired shape requires it to be done.

THE EDLUND DETACHABLE BROOM HEAD

A broom having a detachable head and known as the "Edlund" is being manufactured by the Cleveland-Osborne Manufacturing Company, Cleveland, Ohio. The broom consists of a metal holder with a clamping device and a detachable filler or broom.

The holder and clamping device is of pressed sheet steel secured to a wooden handle and is arranged with a rectangular socket, into which the filler or broom is inserted and secured by the clamp. The device is constructed so that the filler can be inserted in the holder by slipping a ring off the broom clamp and so placing the filler that the bead on the filler fits into a groove in the holder. The ring is then pushed over the clamp, thus securing the broom firmly in place.

These brooms are made of bass, bassine or bahia fibre and are furnished in grades suitable for the service in which they are to be used. They have given most satisfactory and economical service in factories, railway shops and storehouses, and tests have shown that the Edlund broom will outwear from four to six of the ordinary corn brooms. These brooms can be worn to a very short length because of the manner in which the fibres are bound together and the percentage of waste is very low. The holder is so constructed that with ordinary use it will last indefinitely and it is only necessary to purchase additional fillers, which, because of their simple construction and durable material, reduce the broom cost to a minimum.



The Edlund Broom

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

Subscriptions, including the eight daily editions of the Railway Age, published in June, in connection with the annual convention of the American Railroad Association, Section III—Mechanical, payable in advance and postage free: United States, Canada and Mexico, $2.00 a year; Foreign Countries, $3.00 a year; Single Copy, 20 cents.

WE GUARANTEE, that of this issue 10,600 copies were printed; that of these 10,600 copies 9,582 were mailed to regular paid subscribers, 20 were provided for counter and news company sales, 210 were mailed to advertisers, 28 were mailed to employees and correspondents, and 610 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 73,210, an average of 9,151 copies a month.

THE RAILWAY MECHANICAL ENGINEER is a member of the Associated Business Papers (A. B. P.) and the Audit Bureau of Circulations (A. B. C.).

During the month of June 169 locomotives were built, 12 in company shops, 45 by the builders on orders prior to federal control and 112 U. S. R. A. standard locomotives.

The shops of the New York, New Haven & Hartford at Valley Falls, R. I., were destroyed by fire on the night of July 26; estimated loss $130,000. The fire was started by lightning.

It is reported from Petrograd that the number of discarded Russian locomotives which can no longer be used amounts to nearly 60 per cent of the total stock. About one-fourth of the railway carriages are in the same state.

The National Screw Thread Commission sailed for Brest from Hoboken, N. J., on July 13, to meet French engineers in Paris and then proceed to London, for the purpose of making a tentative agreement on pipe thread standards with the British Engineering Standards Association.

The Pennsylvania System federation of employees, composed of six crafts employed in the shops of the railroad, held their first annual convention at Columbus, Ohio, on July 14. The federation represents more than 40,000 men employed in various shops of the Pennsylvania System.

It is reported that the Texas & Pacific Railroad will have more than 200 of its engines equipped for using oil as fuel in a short time, for service on the entire line between New Orleans and El Paso. The Texas & Pacific has had a few oil burning locomotives in use for several years.

Locomotives which were pooled to meet the exigencies of war conditions have now been practically all returned to the roads on which they were originally operated. All are said to have been repaired and placed in good condition before being returned. The total number under lease to various roads was about 800.

The Pennsylvania Lines West of Pittsburgh will build a group of repair shops at Stark, Ohio, to consist of a locomotive erecting shop, heavy and light machine shops, tank shop, flue shop, wheel and pipe shop, blacksmith shop, firing up shed, storehouse, office building, rest house and shed for the storage of miscellaneous material.

According to an Associated Press despatch the work of recovering stolen Belgian machinery from Germany is proceeding with full swing. Approximately 3,000 tons of machinery are being shipped back weekly to the original owners by German industrial firms, who had set them up in their own factories. The total tonnage returned to July 1 was 18,000.

It has been demonstrated that it is possible to make pig iron and iron castings direct from steel scrap in an electric furnace, and it is claimed that such iron, cast in the form of castings, is far superior to the same castings made from ordinary pig iron melted and cast. Tests recently made at Columbia University show its tensile strength to be 40,730 to 45,030 lb. per sq. in., considerably higher than of ordinary cast iron.

The shops of the Pullman Company at Ludlow, Ky., recently destroyed by fire, will probably not be rebuilt, according to a letter from Director General Hines to the Chamber of Commerce. The letter states that the shops were obsolete and that their usefulness was limited. Mr. Hines also asserts that many of the men formerly employed in the Ludlow shops have secured other positions and therefore were not greatly discommoded by the nonexistence of the plant.

Three hundred shop employees of the Southern Railways at Alexandria, Va., went out on strike on June 17 by way of protest against what they term the delay in passing on the proposed uniform rules and working conditions and also the general demand of the shop employees for an advance in wages which have both been before the Board of Wages and Working Conditions for some time. The strike was unauthorized and the men returned to work later in the day.

Enginemen on the Southern Railroad went on strike because they were required to run large new engines of the Santa Fe type through the numerous tunnels between Danville, Ky., and Oakdale, Tenn. With these engines the clearance at the sides and top is so small that the flow of fresh air is seriously checked; so much so that in hot weather the enginemen have reported temperatures in cabs of 140 deg. F. Fans to ventilate the cabs, by air drawn from below the pilot, are being fitted to the engines.

Losses of gasoline during transit are estimated by one prominent producer and shipper of gasoline to amount to eight per cent, considering only that shipped in tank cars. During 1918, about 3,500,000,000 gallons of gasoline were produced in the United States and much of it was shipped more than once. A loss of one per cent, at 20 cents a gallon, means a loss to the shippers and to the nation of $7,000,000. The railroad loss and damage figures recently published, are large, but the shippers' probable wastage through leakage and evaporation during transit is larger.

Railroad Administration reports show that 101,785 women were employed in railroad service in September, 1918, while in April, 1919, there was a reduction of 14.3 per cent, or a total still employed of 85,393. This was partly due to the general reduction in the labor forces and also to the return of the soldiers from army service. The largest percentage of decrease was from among the clerical force. In the mechanical section the largest number of reductions among the women employees took place in the roundhouses and shops. Their work in these departments was in many cases found to be unsatisfactory, the work being generally considered too heavy.

Representatives of the coal operators, as part of their propaganda to induce the early buying of coal, are already complaining of an impending car shortage and are urging the Railroad Administration to take more active steps to put cars in repair. The directors of the National Coal Association in resolutions recently adopted, declare serious car shortages exist, and that there is an abnormally large number of cars out of service awaiting repairs. George H. Cushing, managing director of the American Wholesale Coal Association, testified at Washington on July 18 before a House committee that there are many idle coal cars in all parts of the country which should be repaired.

The *Monthly Labor Review,* published by the United States Department of Labor, contains an article on the employment of women in acetylene welding, in which it is stated that they have demonstrated that they are better suited to the lightest sorts of welding than men. In England short welding courses were instituted early in the war with decided success and welding courses in many of the technical schools are now open to women. English women have done all types of welding with marked success, but in the United States they have not been given as many or as difficult types of work. It is the consensus of opinion that they have been most successful in the lighter grades of work, such as are centered in the airplane manufacturing around Detroit and it is agreed that work from which very heavy lifting cannot be eliminated is unsuitable for them. The estimates of welding authorities place the number of women welders in this country at from 1,000 to 1,500 or more, but very few of these are sufficiently skilled to do general high class welding repair work.

Bureau of Standards Studying Paint Standards

The Bureau of Standards of the United States Department of Commerce is engaged in a study of paint and paint materials in connection with a committee of scientific representatives of the government departments, including the Railroad Administration, with a view of making acceptable standard specifications to be promulgated by the bureau for the information of the public which, when issued, it is stated, will make available to the railroads a fund of information regarding paint which they have not had heretofore. Percy H. Walker of the Bureau of Standards is chairman.

Railroad Men Wanted in Russia

A request has been received at the office of the chief of engineers, War Department, Washington, from the Russian Railway Service Corps for additional men to serve on Russian railroads. At the present time there is need for first class accountants, store and material men, stenographers, shop superintendents, trainmasters, traveling engineers, round-house foremen, car foremen and foundry superintendents. These men will not be in the United States Army, but will wear a uniform and be members of the Russian Railway Service Corps, a separate service formed for the specific purpose of handling railway matters in Russia. Accountants and store material men will receive from $2,000 to $2,500 a year, shop superintendents approximately $5,000 a year, trainmasters and traveling engineers $2,500, roundhouse foremen and car foremen $2,000, and foundry superintendents $3,000. Col. L. M. Wright, Director General of Military Railways, Office of Chief of Engineers, Washington, D. C., is handling inquiries concerning the service.

Machine Tool Builders Withdraw Opposition to Government Sales Abroad

As the result of an explanation by Secretary of War Newton D. Baker of sales and machine tools abroad by the United States army, Cincinnati machine tool builders are said to have withdrawn their objections to such sales. The State Department inquired of the War Department for information regarding the sale of machine tools in Belgium and France and Secretary Baker's reply is in part as follows:

"The policy of this department is to dispose of surplus material both at home and abroad as rapidly as possible and with as little disturbance of the trade as is practical under the circumstances.

"In the United States each bureau is, thus far, making its own sales through its district offices under the policy set forth by the director of sales. A representative of the director of sales has been negotiating the sales abroad.

"Sales to date in this country have totaled $3,200,411.10 for machinery, machine tools and engineering equipment which cost the government $3,898,833.85. We have therefore disposed of this material for 82 per cent of the cost to the government, which, I think you will agree, is a very creditable showing and does not indicate any disposition on the part of the War Department to disturb the home market.

"The sale which is being negotiated with the Belgians by our representatives abroad is for slightly used machines in good condition on the basis of August 1, 1914, prices, plus 55 per cent c.i.f. Antwerp.

"The average advance reported by 133 manufacturers of this line from 1914 to 1918 was approximately 93 per cent. Since the armistice the average drop on new machinery has been about 20 per cent.

"One of the largest houses reconditioning used machinery states that in normal times their sales of entirely made-over machinery average around 75 per cent of new. For this machinery, sold as it stands, you will readily see that we are not offering it at improperly low prices, as stated by your correspondent, but at very fair prices which ought not materially disturb the trade for new machinery."

MEETINGS AND CONVENTIONS

Traveling Engineers Association.—The annual meeting of the Traveling Engineers' Association, to be held at Hotel Sherman in Chicago in September, will begin on the 16th instead of the 9th; and will hold through Tuesday, Wednesday, Thursday and Friday, ending on the 19th.

International Railway General Foremen's Association.—General car foremen are invited to attend the convention of the International Railway General Foremen's Association, which will be held at the Hotel Sherman, Chicago, on September 2 to 5, inclusive. One of the topics under discussion will be draft gears.

Master Car and Locomotive Painters' Association.—The forty-eighth annual convention of the Master Car and Locomotive Painters' Association will be held at the Hotel La-Salle, Chicago, commencing September 9. The association has held no meetings during the past two years, and the program for this year's convention is practically the same as that selected for 1917. The following papers will be presented: The Advantage of Using Pure Paints and More Time in the Painting of Steel Equipment, by Warner Bailey (B. & M.); What Quality and Size of Sand Pebble Are the Best for Blasting Paint or Corrosion From Steel or Iron, Preparatory to Painting, by J. W. Gibbons (A. T. & S. F.), S. E. Breese (N. Y. C.) and George M. Oates (Pressed Steel Car Company); The Record of Our Association, by Charles E. Copp (B. & M.); What Standardization of Painting Railway Equipment Is Necessary, Based Upon the Experience of This Association? by W. A. Buchanan (D. L. & W.), H. M. Butts (N. Y. C.) and W. O. Quest (P. & L. E.); Is the Demand for Linseed Oil as a Paint-Making Oil in Excess of the Supply; If So, What Other Oils Are Most Acceptable Substitutes for the Railway Paint Shop? by A. H. F. Phillips (N. Y. O. & W.), P. J. Hoffman (Hocking Valley) and F. B. Davenport (Penn. Lines).

Master Blacksmiths' Association.—The International Railroad Master Blacksmiths' Association has announced the following papers which are to be presented at the convention to be held at the Hotel Sherman, Chicago, August 19-21: Repairs to Locomotive Frames, P. Lavender (N. & W.), chairman; Drop Forging and Its Possibilities, J. D. Boyle (Anderson Drop Forge Company), chairman; Heat Treatment of Iron and Steel, Purposes and Results, G. Hutton (N. Y. C.), chairman; Why Railroads Should Adopt Specific Standard Safety Appliances to Comply with U. S. Standards, J. E. Dugan (U. P.), chairman; Making and Repairing Springs, John W. Russell (Pa.), chairman; Up-to-Date Smith Shop, G. Fraser (A. T. & S. F.), chairman; Scrap Reclaiming by use of the Oxy-acetylene and Electric Cutting and Welding Process and Other Methods, Walter Constance (St. L. & S. F.), chairman; The Treatment and Results of Carbon, High Speed and Other Alloy Tool and Tool Steels for Tools, J. H. DeArment (Pa.), chairman; A Modern Hammer and Hydraulic Forge Shop, R. F. Scott (P. & R.), chairman. The officers of the association are: President, W. C. Scofield (I. C.); chairman executive committee, W. J. Mayer (M. C.); first vice-president, J. Carruthers (D. M. & N.); second vice-president, G. P. White (M. K. & T.); secretary, A. L. Woodworth (B. & O.); assistant secretary, C. W. Shafer (C. of Ga.).

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations:

Air-Brake Association.—F. M. Nellis, Room 3014, 165 Broadway, New York City.

American Railroad Association, Section III—Mechanical.—V. R. Hawthorne, 431 South Dearborn St., Chicago.

American Railroad Master Tinners', Coppersmiths' and Pipefitters' Association.—O. E. Schlink, 485 W. Fifth St., Peru, Ind.

American Railway Tool Foremen's Association.—R. D. Fletcher, Belt Railway, Chicago. Convention, August 27-29, Hotel Sherman, Chicago.

American Society for Testing Materials.—C. L. Warwick, University of Pennsylvania, Philadelphia, Pa.

American Society of Mechanical Engineers.—Calvin W. Rice, 29 W. Thirty-ninth St., New York.

Association of Railway Electrical Engineers.—Joseph A. Andreucetti, C. & N. W., Room 411, C. & N. W. Station, Chicago.

Car Foremen's Association of Chicago.—Aaron Kline, 841 Lawlor Ave., Chicago. Meetings second Monday in month, except June, July and August, Hotel Morrison, Chicago.

Chief Interchange Car Inspectors' and Car Foremen's Association.—H. J. Smith, D. L. & W., Scranton, Pa.

International Railroad Master Blacksmiths' Association.—A. L. Woodworth, C. H. & D., Lima, Ohio. Convention Aug. 19-21, Hotel Sherman, Chicago.

International Railway Fuel Association.—J. G. Crawford, 542 W. Jackson Blvd., Chicago.

International Railway General Foremen's Association.—William Hall, 1061 W. Wabasha Ave., Winona, Minn. Convention September 2-5, 1919. Hotel Sherman, Chicago.

Master Boilermakers' Association.—Harry D. Vought, 95 Liberty St., New York.

Master Car and Locomotive Painters' Association of U. S. and Canada.—A. P. Dane, B. & M., Reading, Mass. Convention, September 9, Hotel La Salle, Chicago.

Niagara Frontier Car Men's Association.—George A. J. Hochgrebe, 623 Brisbane Bldg., Buffalo, N. Y. Meetings, third Wednesday in month, Statler Hotel, Buffalo, N. Y.

Railway Storekeepers' Association.—J. P. Murphy, Box C, Collinwood, Ohio.

Traveling Engineers' Association.—W. O. Thompson, N. Y. C. R. R., Cleveland, Ohio. Convention, September 16-19, Hotel Sherman, Chicago.

PERSONAL MENTION

It is our desire to make these columns cover as completely as possible all the changes that take place in the mechanical departments of the railways of this country, and we shall greatly appreciate any assistance that our readers may give us in helping to bring this about.

GENERAL

J. B. Carothers, assistant to the federal manager of the Baltimore & Ohio, Western Lines, with headquarters at Cincinnati, Ohio, has had his jurisdiction extended over the departments of fuel and locomotive operation.

H. P. Dougherty has been appointed assistant director of the Division of Labor, United States Railroad Administration.

C. I. Evans, whose appointment as chief assistant mechanical superintendent of the Missouri, Kansas & Texas and associated railroads, with office at Denison, Texas, was announced in these columns last month, was born in Bedford, Iowa, and was educated in the high schools. Before entering the service of the Missouri, Kansas & Texas he had been for six years employed as a fireman and engineman on other roads. He has been with the Missouri, Kansas & Texas for 25 years, having started as a locomotive engineman, later being promoted to road foreman of engines. Subsequently he served as trainmaster, then as lubricating expert, and at the time of his recent appointment he was chief fuel supervisor. In his present position he has direct charge of shops and all matters connected with the maintenance of locomotives and cars and reports to the general manager.

D. R. MacBain, whose appointment as assistant general manager of the New York Central, Lines West, with headquarters at Cleveland, Ohio, was announced in these columns last month, was born on October 23, 1865, at Queenstown Heights, Ont., and was educated in the common schools. He entered railway service in October, 1876, as a machinist apprentice on the Canadian Southern, and was later locomotive fireman and then locomotive engineman on the same road. From 1890 to July, 1900, he was a traveling engineer on the Michigan Central, and then until June 23, 1906, was master mechanic, latterly at Jackson, Mich.

D. R. Mac Bain

On the latter date he was appointed assistant superintendent motive power at Detroit, Mich. From April 1, 1908, to May, 1910, he was assistant superintendent of motive power of the New York Central & Hudson River at Albany, N. Y. On May 15, 1910, he was appointed superintendent motive power of the Lake Shore & Michigan Southern, the Lake Erie & Western, the Lake Erie, Alliance & Wheeling, the Dunkirk, Allegheny Valley & Pittsburgh, the Cleveland Short Line, the Chicago, Indiana & Southern and the Indiana Harbor Belt. Later he was appointed superintendent of motive power of the New York Central Lines West, with headquarters at Cleveland, Ohio, which position he held until he was recently appointed assistant general manager of the same lines.

MASTER MECHANICS AND ROAD FOREMEN OF ENGINES

F. D. Barnes, road foreman of engines of the Central of Georgia, with headquarters at Macon, Ga., has been appointed trainmaster of the Macon division, with headquarters at Macon, succeeding H. R. Frierson.

L. E. Fletcher, master mechanic of the Atchison, Topeka & Santa Fee at Raton, N. M., has been transferred to the Arkansas River and Colorado divisions, with headquarters at La Junta, Colo., succeeding I. H. Drake, assigned to other duties.

Frank Lafond has been appointed road foreman of engines of the Los Angeles division of the Southern Pacific (lines south of Ashland), with headquarters at Los Angeles, Cal., succeeding R. N. Richardson, assigned to other duties.

T. T. Ryan, general foreman of the Atchison, Topeka & Santa Fe at Las Vegas, N. M., has been appointed master mechanic of the New Mexico division, with headquarters at Raton, N. M., succeeding L. E. Fletcher.

CAR DEPARTMENT

M. C. Devine has resumed his duties as general car foreman of the Missouri, Kansas & Texas at Sedalia, Mo., having been engaged in government inspection work in Hammond, Ind.

SHOP AND ENGINEHOUSE

J. Skelton has been appointed day roundhouse foreman of the Denison (Texas) locomotive shops of the Missouri, Kansas & Texas, succeeding J. T. Smith, who is now night foreman.

PURCHASING AND STOREKEEPING

T. S. Edgell has been appointed division storekeeper of the Mobile & Ohio at Murphysboro, Ill., succeeding E. H. Landers, resigned to accept service with another company.

R. R. Jackson has been appointed division storekeeper of the Pittsburgh division of the Baltimore & Ohio, Eastern Lines, with headquarters at Glenwood, Pa., succeeding T. C. Hopkins, assigned to other duties.

H. P. McQuilkin, assistant general storekeeper of the Baltimore & Ohio, Eastern Lines, has been appointed general storekeeper of the Baltimore & Ohio, the Cumberland Valley, the Western Maryland and the Cumberland & Pennsylvania, with headquarters at Baltimore, Md. Mr. McQuilkin was born on February 6, 1887, at Martinsburg, W. Va., and was educated in the public and high schools of his native town. He began railway work on April 1, 1905, as distributor in the stores department of the Baltimore & Ohio at Cumberland, Md., and the following year served as clerk in the motive power department. He was out of railway work from October, 1906, to September, 1910, and then became storekeeper on the Baltimore & Ohio, at Connellsville, Pa. He was later storekeeper at Washington, Ind., and from April, 1914, to December, 1916, was district storekeeper for the Baltimore & Ohio and the Cincinnati, Hamilton & Dayton at Cincinnati. He was then, to April, 1918, chief clerk to the general storekeeper on the Baltimore & Ohio at Baltimore, and subsequently served consecutively as chief clerk to the purchasing agent until June, 1918, and assistant general storekeeper, until his promotion to general storekeeper on the same road.

P. H. Shay has been appointed storekeeper of the Lehigh Valley, with headquarters at Caxton, Pa.

Gordon Thomas has been appointed storekeeper of the Lehigh Valley, with headquarters at Hazleton, Pa.

R. E. Walker has been appointed storekeeper of the Lehigh Valley, with headquarters at Auburn, N. Y.

OBITUARY

Joshua A. Leach, founder of the Brotherhood of Locomotive Firemen & Enginemen, died on June 27, at Denver, Colo., where he was attending the organization's triennial convention. Mr. Leach organized the Brotherhood of Locomotive Firemen & Enginemen at Port Jervis, N. Y., in 1873. He was 76 years old.

Oscar Otto, general superintendent of the South Philadelphia Machine Works of the Westinghouse Electric & Manufacturing Company, died on June 30, as a result of injuries received in an automobile accident near Westgrove, Pa. He was born in Manitowoc, Wis., on January 2, 1859, and after finishing his apprenticeship course as a machinist in the Manitowoc shops of the Chicago & North Western, served during several years at various places in Wisconsin. He then entered the service of the Northern Pacific, at Tacoma, Wash., going from there to the Oregon Short Line, at Salt Lake City, Utah. In 1898 he returned to the service of the Chicago & North Western as superintendent at the Chicago shops. Prior to accepting a position as general superintendent of the Westinghouse Machine Works, at East Pittsburgh, Pa., in June, 1909, he was connected with the Chicago & North Western as general superintendent of its Chicago shops. When the Westinghouse Company opened its new plant at Essington, Pa., Mr. Otto supervised the installation of the machinery, and later in February, 1918, he was transferred to the new works, where he remained until his death.

Matthew J. McCarthy, superintendent of maintenance of equipment of the Baltimore & Ohio, Lines West, with headquarters at Cincinnati, Ohio, died at his home in that city on July 12. He was born at Susquehanna, Pa., in 1868, and began railway work in 1889 as an apprentice on the Erie, and subsequently worked in a number of railroad shops in the west and southwest as machinist and foreman. He was for ten years in the service of the Chicago, Burlington & Quincy, at Burlington, Iowa, as machinist inspector and general foreman, then was with the Michigan Central, as division master mechanic at St. Thomas, Ont., for four years, and during the next two years served as division master mechanic on the Lake Shore & Michigan Southern. Mr. McCarthy then went to the Cleveland, Cincinnati, Chicago & St. Louis, as superintendent of shops at Beech Grove, Ind., and later was assistant superintendent of motive power at Indianapolis, on the same road. In January, 1913, he was appointed superintendent of motive power of the Baltimore & Ohio Southwestern and the Cincinnati, Hamilton & Dayton, at Cincinnati, Ohio, later his title was changed to superintendent of maintenance of equipment of the Baltimore & Ohio, Lines West.

M. J. McCarthy

SUPPLY TRADE NOTES

The Edison Storage Battery Company announces the removal of its district office in Pittsburgh, Pa., to room 431 Union Arcade building.

The Camden Forge Company, Camden, N. J., has opened a district sales office at 2 Rector street, New York, with Samuel W. Hilt as manager.

J. E. Slimp has been appointed general manager of the Unit Railway Car Company, Boston, Mass., manufacturers of interurban and short line railway cars.

Harold E. Wade has been appointed president of the Fairmont Gas Engine & Railway Motor Car Company, Fairmont, Minn., succeeding Frank E. Wade, deceased.

The Walter A. Zelnicker Supply Company, St. Louis, Mo., has added 2,000 sq. ft. to its present office space at 325 Locust street, St. Louis, an increase of 33 1/3 per cent.

The Chicago Pneumatic Tool Company, Chicago, has removed its Minneapolis (Minn.) office from the Metropolitan Bank building to Fifth avenue and Fifth street south.

H. A. Wolcott has been appointed district manager of the Ohio Locomotive Crane Company, Bucyrus, Ohio, for the Chicago territory, with office in the Lytton building, Chicago.

E. H. Roelofs, assistant engineer of motive power on the Philadelphia & Reading, with headquarters at Reading, Pa., has resigned to enter the service of the Baldwin Locomotive Works.

J. L. Dahl has been appointed manager of the New York office of the Gregg Company, Ltd., Hackensack, N. J. He succeeded C. R. Gier, who is no longer in the employ of the company.

D. C. Schultz, Sr., who has had a wide experience in the design and sale of Morgan & Northern cranes, has been appointed sales manager of the Pittsburgh Crane & Equipment Co., with headquarters at Sharpsburg, Pa.

Frank O. Leitzell, assistant to the general manager of the H. K. Porter Company, Pittsburgh, Pa., has been appointed an engineer-salesman in the sheet and tin mill specialties department of the Blaw-Knox Company, Pittsburgh, Pa.

John McConnell, who had charge of alloy steel production for the Interstate Iron & Steel Company, Chicago, as assistant to the vice-president with headquarters at Canton, Ohio, has been promoted to vice-president with headquarters at Chicago.

Major John L. Wood, formerly connected with the Buckeye Steel Castings Company, Chicago, and interested in several railway supply companies, including Edwin S. Woods & Co., Chicago, died on June 13 at Pasadena, Cal., after a protracted illness.

Robert S. Hammond, formerly sales agent of the American Steel Foundries, Chicago, has been appointed Pittsburgh (Pa.) representative of the Whiting Foundry Equipment Company, Harvey, Ill., with office in the Fulton building, succeeding F. J. Page.

The Ulster Iron Works, Dover, N. J., has completed a new puddling mill at Dover, with the main building 390 ft. by 77 ft. and an adjoining wing 90 ft. by 60 ft. Eleven double puddling furnaces are now being operated and 11 additional furnaces of the same type will be installed. The entire output of the mill is distributed by Joseph T. Ryerson & Son, Chicago.

The Liberty Car Wheel Company, Hammond, Ind., has been incorporated with $500,000 capital stock and the following officers have been elected: President, Patrick H. Joyce; vice-president, F. O. Bunnell; treasurer, John E. Fitzgerald; secretary, Charles Aaron.

Lieut.-Col. Elmer K. Hiles, Engineers, A. E. F., who went over as captain in the Fifteenth Engineers, has returned after nearly two years' service in France, and has joined the Pittsburgh Testing Laboratory as manager of laboratories, with headquarters at Pittsburgh.

Elliot Reid, assistant to general manager of the Westinghouse Lamp Company, 165 Broadway, New York, has been appointed sales manager, and will have charge of the commercial activities of the company in both large and miniature classes of lamps in domestic territory.

Arthur Osmore Norton, president of A. O. Norton, Inc., Boston, Mass., died while writing a letter, on June 8, in his home at Coaticook, Que. He was born on February 17, 1845, on a farm in Barnston township, about ten miles from Coaticook. The family moved to a farm in Coaticook when he was a small boy, and he began his business career as a clerk in the country store. When he was about 30 years old, he started a jewelry business in Coaticook, later doing a wholesale business, and subsequently was in the wholesale jewelry business in Boston under the firm name of Norton Brothers & Butters. In 1888, he started the manufacture of the Norton ball-bearing lifting jacks, produced in two factories, one in Boston and the other in Coaticook. Mr. Norton was the first to make non-fluid self-lowering jacks; he was also the pioneer in the making of ball-bearing screw jacks.

A. O. Norton

Corporal William A. Nugent, who served during the war in Company 1, 21st Engineers, has returned from France, and resumed his duties with the Independent Pneumatic Tool Company, Chicago, as traveling representative. He has been assigned to his former territory in Indiana.

G. E. Scott, who for the past year and a half has been in the service of the American Red Cross at Washington, D. C., and from September, 1918, as general manager, has received his honorable discharge and resumed his duties as first vice-president of the American Steel Foundries, Chicago.

Albert Brunt, who for the past four years has been engineer in charge of the direct-current machine design section of the industrial engineering department of the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., has resigned to return to Holland, his native country.

Samuel O. Dunn has been elected a vice-president of the Simmons-Boardman Publishing Company, publishers of the *Railway Mechanical Engineer* and other publications, including the *Railway Age*, of which Mr. Dunn is editor-in-chief. His headquarters continue to be in Chicago.

Arthur S. Lewis, formerly with the Chicago, Cleveland Car Roofing Company and more recently with Flint & Chester, New York, has become associated with the Barco Manufacturing Company, Chicago, and will for the present be located at New York City, and cover Southern territory.

J. H. Redhead has been appointed assistant to the vice-president in charge of miscellaneous sales of the National Malleable Castings Company, Cleveland, Ohio. C. C. Gibbs, until recently associated with the sales department of the Indianapolis plant, has been appointed sales agent of the Cleveland plant, succeeding Mr. Redhead.

W. H. Woody, until April 17, 1919, supervisor of the shipfitters and allied trades at the government navy yard, Portsmouth, Va., and before enlistment in government work affiliated with the Chicago Pneumatic Tool Company, Chicago, as special representative, has been placed in charge of the Washington, D. C., office of the Keller Pneumatic Tool Company, Chicago.

F. P. Hoeck, superintendent of materials and stores of the International Railways of Central America, writes that the material department and commissary stores of his railroad requires new catalogues to replace those destroyed during the recent earthquake. Those desiring to furnish such catalogues are requested to send them to the purchasing department of the International Railways of Central America, 17 Battery place, New York, for enclosure.

Theodore L. Dodd & Company, 80 East Jackson boulevard, Chicago, have been appointed western sales representatives for the Worth Steel Company of Claymont, Del., manufacturers of high grade steel for railroad uses in connection with fireboxes and boilers. This company has a 160-in. mill with four 100-ton open hearth furnaces. It was formed by former members of the Worth Brothers Company of Coatesville, Pa., which concern was sold to the Midvale Steel Company several years ago.

George C. Isbester, district sales manager of the Rail Joint Company, with headquarters at Chicago, has resigned to become district sales manager of welded and weldless products for the American Chain Company, Inc., with headquarters at Chicago. Mr. Isbester was connected with the mechanical department of the Great Northern Railway at St. Paul, Minn., from 1897 to 1899, leaving the Great Northern at this time to go to the Sargent Steel Company, with headquarters at Chicago. He remained with this company until about 1902, when he went with the Q & C Company, with headquarters at Chicago, afterwards becoming vice-president of that company. In 1912 he left the Q & C Company to go with the Rail Joint Company as district sales manager, which position he held until his change as noted above. Mr. Isbester has been a director of the National Railway Applicances Association for several years until his resignation recently. During the war Mr. Isbester served in the United States Naval Reserve Forces as Lieutenant Commander, having been on active duty from April, 1917, until he was placed on the inactive list during May, 1919. He was recalled to active duty on July 28, 1919, to be sworn in as commander in the supply corps. He was selected for promotion from lieutenant commander to commander by the Board of Selection, and after receiving his promotion he was again detached from active duty. Commander Isbester has also served with the Illinois Naval Militia for ten years.

G. C. Isbester

The Chicago Pneumatic Tool Company announces the following changes: H. B. Barbee has been appointed manager of eastern railroad sales and Nelson B. Gatch district manager of sales, with headquarters at 52 Vanderbilt avenue, New York, to succeed L. C. Sprague, who is now manager of western railroad sales, with headquarters in Chicago. N. S. Thulin has been appointed a special railroad representative on Mr. Sprague's staff. T. J. Hudson, Jr., district manager at Chicago, is now manager of the pneumatic tool sales division.

Kenneth R. Hare has been appointed district manager for the Transportation Engineering Corporation, New York, with headquarters at Chicago, in charge of the territory in the middle west, including Chicago, St. Louis and other important railroad centers. Mr. Hare was graduated from the University of Wisconsin in 1911 with the degree of electrical engineer, having previously spent his vacations on railroad location and construction in Northern Minnesota, as concrete inspector and later in connection with transit and level work, estimates, etc. He also did considerable work in connection with the electrical construction, installation of dynamo electric machinery, transformers and switchboards for the Duluth Edison Company, and the General Electric Company. After graduation he took the test and shop course at the Schenectady works of the General Electric Company, following this, in 1912, with construction and meter work for the Great Northern Power Company, Duluth, Minn. Later, in the same year, he was appointed chief electrician for the Northern Pacific Railway, in charge of all electrical work from St. Paul to the Pacific Coast. In 1915 he was appointed associate editor, and later became managing editor of the Railway Electrical Engineer, published by the Simmons-Boardman Publishing Company, New York. He left this position in 1917 to enter military service as first lieutenant in the Ordnance Department. In 1918 he was appointed, on behalf of the government, assistant superintendent of the munition plant of the American Can Company, Kenilworth, N. J., in direct charge of the high explosive plant, remaining in that position until the work of the plant was about finished. He now becomes district manager of the Transportation Engineering Corporation, which is the authorized representative of the Edison Storage Battery Company in the sale of storage batteries to railroads, and of the Automatic Transportation Company in the sale of industrial trucks and tractors to railroads.

K. R. Hare

The American Steam Conveyor Corporation, Chicago, has established an office in the North American building, Philadelphia. H. S. Valentine has been appointed sales engineer in charge of the Philadelphia territory. He was formerly associated with the Link Belt Company, Philadelphia, for five and a half years, and with the Brown Hoisting Machinery Company and the Yale & Towne Manufacturing

Company for six years. Thomas O. Morgan, until recently head of the service department of the New York office of the company, has been promoted to the position of sales engineer and will cover Long Island and Connecticut territory.

The Q & C Company, with general offices at 90 West street, New York, announces the formation of The Q & C Packing & Lubricator Company, with general offices at the same address and a factory at 70 Pearl street, Jersey City, N. J. Charles F. Quincy is president of the new company; W. W. Hoit is vice-president, and F. F. Kister, treasurer, all of the present Q & C Company organization; S. S. Whitehurst, vice-president, and J. G. Smaltz, secretary, are now officials of Steele & Condict, Inc., Jersey City, N. J., where increased manufacturing facilities are being provided to care for the Q & C piston rod packing and lubricator.

Pratt & Lambert, Inc., Buffalo, N. Y., announces that its New York office at 185 Madison avenue, will be moved about November 1 to a new site in Long Island City, where a modern warehouse of brick construction, 200 ft. by 100 ft., consisting of two stories and basement, is now being built, not far from the Bridge Plaza. Donald L. Clement, former railway representative, who has recently returned from overseas service, will be assistant resident manager of the New York office. In order to increase the production at the main factory, Buffalo, a four-story brick building, 95 ft. by 45 ft., to be devoted to grinding, is to be put in service on October 1. At Bridgeburg, Ont., a four-story brick building, 85 ft. by 45 ft., is being erected in addition to new chimneys, double the size of the old, thinning buildings, filter buildings and other equipment which will triple the manufacturing capacity of the present factory.

Bertram Smith, assistant general sales manager of the Edison Storage Battery Company, Orange, N. J., has resigned to become president and general manager of the Automatic Electrical Devices Company, Cincinnati, Ohio. Mr. Smith has had more than 20 years' experience in the storage battery industry. He formerly served as secretary and treasurer of the old National Battery Company, which sold the Sperry plate, and after the absorption of this company by the United States Light & Heating Company, he was for a number of years manager of the western territory, with headquarters at Chicago. In 1913 he resigned to become assistant manager of the Edison Storage Battery Supply Company, with headquarters at San Francisco, and in 1915 was appointed manager of the Detroit sales district for the Edison Storage Battery Company. In September, 1918, Mr. Smith was made assistant general sales manager of that company, with headquarters at Orange.

The Norton Grinding Company and the Norton Company, both of Worcester, Mass., have been consolidated under the latter name. George I. Alden, who has been president of the Norton Company for some years, is chairman of the board of directors of the reorganized company; Charles L. Allen is president and general manager, Aldus C. Higgins, treasurer and general counsel and George N. Jeppson, secretary and works manager. Two new vice-presidencies have been created, one to be filled by W. LaCoste Neilson, vice-president and foreign manager, and the other by Carl F. Dietz, vice-president and general sales manager. A factory for the manufacture of abrasive products has been established in Japan and the company has acquired control of the Hiroshima Grinding Wheel Company, located at Hiroshima, near Kobe, Japan, which was established some years ago by the company's agents. Sales agencies have been established with native houses in several foreign countries, including England, France, Italy, Belgium, Denmark, Holland and like connections will be formed in Norway and Sweden. A new store at Detroit, Mich., has also been opened under the management of C. W. Jinnette.

CATALOGUES

Ventilators.—A six-page folder has been issued by the Garland Ventilator Company, Chicago, briefly describing and illustrating by means of drawings some of the best known and most widely used types of Garland railway car ventilators.

Electric Traveling Cranes.—A new catalogue of Chesapeake cranes has been compiled by the Chesapeake Iron Works, Baltimore, Md. The book contains 28 pages, 9 in. by 11½ in. The first half is devoted to descriptions and illustrations of the various parts of the cranes, while the last half contains full page illustrations of installations.

Curtain Roller.—The Curtain Supply Company, New York, is revising its catalogue, which will hereafter be issued in the form of bulletins describing and illustrating their various products. The first of these, R-2, covers the Rex all-metal curtain roller and consists of eight pages, describing the construction of the roller and illustrating the detail parts.

Flange Lubrication.—A flange oiler which is simple in construction, having two working parts, said to be easily applied, to eliminate slipping and to require no attention, is being placed on the market by J. H. Miner of Lumberton, Miss. This he describes in a booklet of eight pages.

Storage Battery Cars.—Typical installations of Edison equipped railway storage battery cars are shown in Bulletin 106, consisting of 16 pages and issued by the Edison Storage Battery Car Company, New York. Illustrations show cars in service in various parts of the United States, Central and South America, Mexico and Alaska. A short analysis is included of the relative costs of storage battery and steam operation on the Long Island Railroad and the Edison nickel-iron-alkaline storage battery is described.

Vulcan Soot Cleaner.—Bulletin 541, issued by the Vulcan Soot Cleaner Company, Du Bois, Pa., contains a discussion of the merits of the Vulcan patented diagonal method for cleaning soot from the tubes of horizontal water tube boilers, covering such features as maintenance cost and first cost, accessibility for inspection and repairs and ease of installation and cleaning. Illustrations in two colors show typical designs as applied to horizontal water tube boilers with vertical baffling. The bulletin also contains an analysis of the cost of Vulcan cleaners and their value as investments.

Whiting Railroad Equipment.—The Whiting Foundry Equipment Company, Harvey, Ill., has prepared Catalogue 145, containing 36 pages, to show the advantages and labor saving features of the various railroad specialties manufactured by this company. The equipment described in this catalogue consists of screw jack locomotive and coach hoists, transfer tables for locomotives and coaches, cranes and turntable tractors. For those contemplating new shops a drawing of a modern shop layout, showing the most practical and economical arrangement of the equipment, is included.

Hydraulic Machinery.—A catalogue of 63 pages, embracing all kinds of hydraulic machinery, has been prepared by William H. Wood, hydraulic engineer, Media, Pa. These machines include flanging, riveting, punching and shearing machines, cranes, hammers, valves, pumps, accumulators, etc. Several drawings are also shown of the Wood's flexible corrugated locomotive firebox and a summary of the results of comparative tests, made some years ago on the New York Central, of a Wood's firebox with arch tubes and a standard firebox without arch tubes.

Railway Mechanical Engineer

Volume 93 September, 1919 No. 9

CONTENTS

The Labor Turn-Over

A discussion of the labor turn-over problem, which is of more than ordinary interest, will be found on another page of this number. It is not written by either an efficiency engineer, an expert employment officer, or an executive. There is nothing theoretical about it. The writer who had had considerable experience as a mechanic on a railroad, had gone into industrial work and then returned again to the railroad shop. His viewpoint is that of a mechanic. We hope that all of those foremen and other officers who control shop conditions will read it closely. Doubtless your shop is much better equipped than the one in which "Newt" had his experience. Fortunately, most railroads long ago awakened to the necessity for improving these conditions. On the other hand, even the best equipped shops may fall far short of the ideal in many respects. Good work cannot be done with a dull or inefficient tool. To get the best results from the workmen, conditions must be such as to emphasize the fact that the management is interested in their comfort and convenience, and is willing to do its full share in helping to make the conditions most favorable for good work.

The Valve Setter

There is no portion of the work incident to turning a locomotive out of shop that is of greater importance than the proper setting of the valves. A locomotive may have correctly proportioned grate area and draft appliances and be otherwise in first-class condition, yet will not give economical service if the valves are not so adjusted as to secure the maximum value of the steam supplied to the cylinders. The loss of efficiency, even with the increased fuel consumption that always occurs with poorly set valves, is of such proportions that the utmost care should be taken in doing this work. The valve setter, through incompetence or indifference, can destroy the possibility of securing the benefits that should be derived from a well designed and carefully constructed machine. Observations taken on a number of locomotives known to have improperly adjusted valves have shown an increase of from 15 to 20 per cent in fuel consumption. At the same time these locomotives have decreased in efficiency from 9 to 15 per cent. The setting of valves should be conducted with the utmost care and the instructions of the designers closely followed. The men doing this work should be selected not only for their general intelligence, but should be of the type who are exacting as to detail, as this is a matter of minute adjustment and a very slight deviation in setting the valve will cause wasteful results in the operation of the locomotive.

A Bright Spot in the Industrial World

Against the background of industrial unrest, suspicion and strife with which the conduct of the economic processes of the nation and the world is being beset, the resolutions adopted by the representatives of some 30,000 employees of the Midvale Steel & Ordnance Company, the Cambria Steel Company and their subsidiaries, in session at Atlantic City on August 22 and 23, stand out in strong relief. The opinion of these employees, expressed in the resolutions, is that "the persistent and unceasing demands of workingmen employed in all classes and kinds of industries for a shorter day's work and an increased rate in order to meet the present high cost of living is uneconomic and unwise and should not be encouraged." That these men have a keen appreciation of the real situation is evident from the reasons given for this opinion, namely, that "the price of commodities is regulated by the day's labor of a man and the real unit of value or the unit of compensation is not a dollar, but the purchasing power of a dollar, and that the average price of commodities varies with the average compensation received for an hour's work by every man and every woman," and that the only sure remedy for the high cost of living is increased production and stabilization of prices in conformity with wages now being paid. It is significant that the employees of the Midvale and Cambria Companies are organized under one of the so-called industrial democracy plans to which reference has previously been made in these columns. While these resolutions are hardly sufficient evidence on which to claim the complete success of such plans, they are indicative of the sane attitude which may be expected from any group of workers when their relations with the employer are organized on a basis of open dealings and mutual freedom from suspicion.

Front End Inspection

The careful inspection of front ends of locomotives bears a very close and important relation to fuel consumption and should be given constant attention in roundhouse work. A frequent source of trouble and a serious cause of loss in steaming efficiency is leakage around the tubes in the front sheet. This was clearly demonstrated in the case of a locomotive selected for a series of tests of front-end arrangements. After a few trial trips with repeated failure of the locomotive to steam properly, even with the most careful firing by the best fireman on the division, an inspection of the front tube sheet disclosed numerous leaks, notwithstanding that a supposedly competent man had inspected the locomotive before the tests were begun. After these leaks were stopped a conservative estimate placed the saving in coal burned at approximately 1,000 lb. per hundred miles. At the price of fuel prevailing, this effected a considerable economy in fuel cost, as well as adding greatly to the efficiency, and consequently the earning power, of the locomotive. Other apparently trivial matters, such as poorly made joints between the exhaust stand and nozzle were found to have a very appreciable effect on the performance of the locomotive. The need of economy in these times of high prices of fuel and the necessity that the earning power of equipment be kept at the highest possible point warrant the most exacting inspection whenever possible between the regular inspection periods. This can readily be accomplished in the roundhouse, provided the men are each instructed that it is not only their job to make repairs as directed by their foremen, but also to report any defect that may come to their notice. Consistent co-operation of the mechanics and inspectors in the roundhouse will insure worth while results.

Car Department Problems

Changes in the application of the M. C. B. rules of interchange which take effect October 1, are such as to put the rules almost on a pre-war basis. The task of reorganizing the car department's forces and practices will not be an easy one, particularly in view of the changes in the personnel of the forces which have taken place during the past year or two.

The meeting of the Chief Interchange Car Inspectors & Car Foremen's Association at St. Louis, September 23-25, promises to be largely attended, and will, of course, be of more than ordinary interest because of these changing conditions. Like the Traveling Engineers' Association, the members of this organization concern themselves with an important and very highly specialized work. They are in daily touch with the practical application of the rules of interchange and with the detail problems of car operation and maintenance. Because of the radical changes which have taken place in the car department under wartime conditions, this organization or some other must also give early and thorough attention to the problem of recruiting the car department forces and of improving supervision in such a way as to insure that the workmen will be fully coached and educated as to how best to do their work.

The condition of the freight car equipment generally is very bad. During the war, material and labor conditions made it necessary to repair the cars only to such an extent as to keep them in service for the time being. The result of this policy, which, of course, was necessary, is now beginning to be felt, and the situation promises shortly to become acute. It demands immediate attention in a big way. Some car department officers are of the opinion that it will be necessary to have the deferred work done in outside repair shops. Others feel that with determination and support from above, the car department forces can be organized to do the work. Necessarily it will require heavy expenditures both for labor and material. When we consider what a breakdown in railroad operation may mean at this time in restricting national production and in preventing an earlier return to normal conditions, it would seem that those in authority would not long hesitate in taking the necessary steps to remedy this condition, no matter how high the cost may be.

The Traveling Engineers

Special importance attaches to the annual meeting of the Traveling Engineers' Association which will be held in Chicago, September 16-19. This organization has consistently confined its energies to the problem of improving locomotive operation, and from a purely practical standpoint alone has accomplished really remarkable results. Now it is faced with the question of deciding its future relationship to the American Railroad Association and particularly to Section III—Mechanical thereof. It is of vital importance—and this is not an exaggerated expression—in the interests of increased efficiency of operation for the railroads at large, that the action which is taken be such as to encourage and further intensify the good work which has been done so well by the Traveling Engineers' Association.

Efficient and economical locomotive operation is one of the keynotes to greater efficiency of railroad operation. The members of the Traveling Engineers' Association are largely men who are on the actual "firing line" on the road; a fact which is readily apparent to anyone who has attended the meetings of the association. These men know what they are talking about because of intimate contact with operating conditions. Because of this and because the nature of their work is such as to force them to express themselves clearly and concisely, and because they are educators and leaders in locomotive operation, their composite opinions and conclusions, as reached in conference, must carry real force and special weight.

Next in importance to deciding wisely upon the necessary changes in organization is the advisability of taking steps to insure making the personality and efforts of the traveling engineer, or whatever his title may be, more effective. It is, unfortunately, only too true on many roads that these men are handicapped and burdened with detail duties that largely prevent their being on the road as much as is desirable, or indeed necessary, for the best interests of the railroad. Men who are fitted by experience, ability and personality to educate and influence the enginemen to secure better results are being forced to give entirely too much of their time to clerical and other duties which could just as well be handled by men of less experience and not so well fitted for road work. They should not be required to assign power, despatch engines, keep up the force, assign crews and other work of this sort. Or if they are, then it should be clearly understood that they are not expected to do much road work, and steps should be taken to build up a special staff to do this work. No one will dispute the fact that it is necessary to have a competent staff on the road to supervise locomotive operation; the trouble lies in the fact that many roads are fooling themselves into the belief that they have such a staff, while, in reality, although the men are carrying titles which indicate that they are responsible for the road work, they are actually spending little or no time on the road. This situation should be remedied.

Heat Treatment of Locomotive Forgings

The heat treatment of locomotive forgings was regarded as an important advance in locomotive construction when first introduced, but at the present time the practice seems to have fallen into disuse on many roads where it has been tried. Nevertheless the Master Blacksmiths' Association at its recent convention advocated the use of heat treatment wherever possible.

The statement has been made that heat treated parts have proved unreliable in service, and certainly during the period when heat treating was first used there were many failures that for the time being remained unexplained. These troubles from heat treated material were probably due to the effort to secure extremely high tensile strength by qurnching at a high temperature and drawing at a low temperature, making the steel liable to fracture. Furthermore, some manufacturers attempted to meet the demand for heat treated material by doing the work with inadequate equipment and inexperienced men. Considerable progress in the heat treatment of large forgings has been made during the war, and at present the manufacturers can furnish a much better product than formerly.

The successful use of heat treatment on automobile forgings has been pointed out as demonstrating the feasibility of improving the properties of locomotive forgings by heat treatment. The fact must not be overlooked, however, that large pieces cannot be cooled as rapidly as small pieces, and in driving axles or similar parts there is certain to be a considerable difference in temperature between the interior and exterior of the forgings. Experiments have demonstrated that large forgings subjected to the same heat treatment as smaller pieces of the same chemical composition show a lower elastic limit and lower tensile strength, usually accompanied by a slight reduction in the elongation and reduction of area. This effect is particularly noticeable in alloy steel. For example, a test piece of nickel chrome steel in the form of a five-inch cube quenched and drawn, showed an elastic limit of 125,000 lb. per sq. in., tensile strength of 134,000 lb. per sq. in., with elongation and reduction of area of 18, and 58 per cent respectively. A forging from the same ingot 12 in. in diameter, treated at the same temperature, showed an elastic limit of 74,500 lb., or approximately 60 per cent of the elastic limit shown by the test piece. The tensile strength of the forging was 109,000 lb. per sq. in., the elongation 15 per cent and the reduction of area 42 per cent. This shows conclusively that it is unreasonable to expect the same properties in locomotive forgings that are secured in the smaller parts used for automobiles.

To call attention to the benefit to be derived from the use of heat treated material would be superfluous. Heat treated material has proved satisfactory in all respects except uniformity of results and concerted action by the railroads, co-operating with the manufacturers, should eliminate the difficulties which have prevented the railroads from using it more extensively. Where forgings are to be made by the railroads it might be well to pay more attention to the heat treatment of carbon steel, with which the railroads' blacksmiths are more familiar. On the other hand, alloy steel should not be neglected. If more importance were attached to securing a high elastic limit with moderate reduction of area and elongation, it would no doubt be possible to obtain steel which would show uniform properties and yet be very satisfactory for use for locomotive parts.

The Issue Before the Shop Crafts

President Wilson and Director General Hines cannot be too strongly commended for the unequivocal stand they have taken on the question of wage increases in denying increases ranging from 17 to 27 cents an hour to railway shop men. The labor situation, complicated by the question of the relationship of an increase to the shopmen to the rates of other classes of railway employees and by the apparent difficulty with which the national leaders of the shopmen's unions were maintaining a reasonable degree of discipline in the ranks of their organizations, has thereby been greatly clarified. The issue is now clearly drawn. Are the shopmen's unions to pursue a course of selfishness which will defeat their own ends or will they display an enlightened self-interest which does not overlook the rights of the public and the national welfare?

Vigorous action has been taken by the Administration to arrest the upward trend of prices and to reduce the cost of living and it is probable that nothing is being left undone to accomplish everything in this direction which can be accomplished by corrective legal measures and concerted action of the administrative forces of the government. At the outset, however, results must be slow in appearing and until time has demonstrated what measure of success may be expected from the experiment, the least that each citizen or group of citizens can do is carefully to refrain from injecting any new disturbing elements into the situation. A lack of steadiness on the part of any group of the public will seriously jeopardize all efforts to bring the cost of living under control.

The fundamentals of this situation have evidently been clearly visualized by some of the organized railroad men themselves. The efforts to reduce living costs now being made by the federal government were strongly advised both by Warren S. Stone, president of the Brotherhood of Locomotive Engineers, and W. G. Lee, president of the Brotherhood of Railway Trainmen, who stated frankly that this was the real remedy rather than further increases in wages.

What then will be the position of the shopmen's unions if they vote to strike in an effort to enforce their demands for a general wage increase? First, they will have caused a serious interruption of transportation and distribution of the necessities of life. An irreparable economic loss will result. Prices of necessities will increase and there will be general suffering, in which the shopmen will participate. Second, this loss and suffering will be brought about to enforce demands which, should they be granted, will ultimately result in adding $800,000,000 a year to the country's transportation bill, starting a new cycle of increased wages and increased production costs, leading straight toward national disaster

And this will all be undertaken in direct opposition to the program advised by the leaders of other organizations of railroad men and will undoubtedly meet with the condemnation of these great bodies of the shopmen's fellow-workers.

These facts have all been placed before the men and will be considered by them in making their decision. They have also been clearly presented to the public and whether it be assumed that the President's statement was an appeal to public opinion, or merely voiced public opinion, it is reasonably clear what attitude the public will now take should the shopmen strike. Under such conditions, accompanied by the same firmness and unequivocal stand in dealing with the strike as that shown in dealing with the demands for a general wage increase, the prospects for success are practically hopeless.

The issue is clearly drawn. Will the men aid the nation in obtaining economic stability, in the benefits of which they will themselves participate, retaining thereby the honor and respect of the public? Or will they attempt to bring on chaos, thereby making themselves the enemies of society, with loss of influence and dishonor to themselves and their organizations? The country awaits the answer.

COMMUNICATIONS

INADEQUATE MAIN DRIVING BOXES

BROOKLYN, N. Y.

TO THE EDITOR:

Mr. Murdock's communication on inadequate main di ving boxes which appeared in your issue of July, 1919, is inteiesting in that it draws attention to practices, at least a part of which have long been standard for long main boxes. His aversion to a constant spring thrust to maintain adjustment of wedges is not warranted or justified by the results obtained in service, as the automatic spring adjusted wedge has repeatedly demonstrated itself to be a most excellent device. It automatically takes care of expansion of the metals in driving boxes and maintains adjustment to compensate for wear of the faces of the shoe, wedge and box. That this is desirable with present box equipment there can be no doubt.

Mr. Murdock's reference to the taper of wedges is erroneous, the standard taper used by the American, Baldwin and Lima locomotive companies being one inch per foot. The angle of this taper is 4 deg., 47 min. According to good authorities, the angle of repose of smooth surfaces occasionally greased lies between 4 and 4½ deg. That is to say, the surfaces will slip at the angle mentioned. Therefore, somewhat more than sufficient spring thrust to sustain the weight of the wedge is necessary to take care of the piston thrust. In fact, the usual spring thrust, with the automatic wedge, varies between 1,600 lb. and 2,100 lb. The taper of the automatic wedge is 1 5/16 in. per foot.

When the pistons of a locomotive are moving in opposite directions, because the centers of the cylinders and the centers of the driving box bearings do not lie in the same transverse plane, the forces acting on the driving box bearings exceed the piston thrust in a ratio which is directly proportional to the ratio of the distances apart of these centers.

Assume that the distance between centers of driving boxes, in the four engines of the writer's tabulation, on page 174 of the April, 1919, issue is 42 in., and that the distance between the centers of the cylinders is 74 in. in the four coupled, 86 in. in the six coupled, 91 in. in the eight coupled and 95 in. in the ten coupled. The ratio, by which the piston thrust must be multiplied to obtain the pressure on the bearings of the main boxes is 74/42 in the four coupled, 86/42 in the six coupled, 91/42 in the eight coupled and 95/42 in the ten coupled.

Using the foregoing ratios and the piston thrusts given in the tabulation referred to above, lines 15 and 16 should read differently and a new line should be added as follows:

	Four-coupled	Six-coupled	Eight-coupled	Ten-coupled
Line 15—Box pressure, total, lb.	101,234	179,377	250,333	330,532
Line 16—Horizontal bearing pressure, lb. per sq. in.	1,349	2,174	2,782	3,390
Line 17—Ratio, horizontal to vertical bearing pressures	7.731	13.175	18.671	24.926

These figures are based upon full boiler pressure. It is fair to assume that the average M. E. P. of a freight engine in going over a division will be close to one-half boiler pressure, so we will divide the figures in line 17 by 2 and get the ratio of probable horizontal wear to probable vertical wear, which for the four-coupled engine is 3.865; for the six-coupled, 6.587: for the eight-coupled, 9.335; and for the ten-coupled, 12.463.

Now, the question arises: How can any one expect to maintain driving boxes, which wear in the horizontal direction, nearly 12½ times as fast as they do in the vertical direction? One should find no great difficulty, in arriving at the conclusion that this is a well nigh impossible proposition, even with crown bored brasses, as it has proved to be in practice.

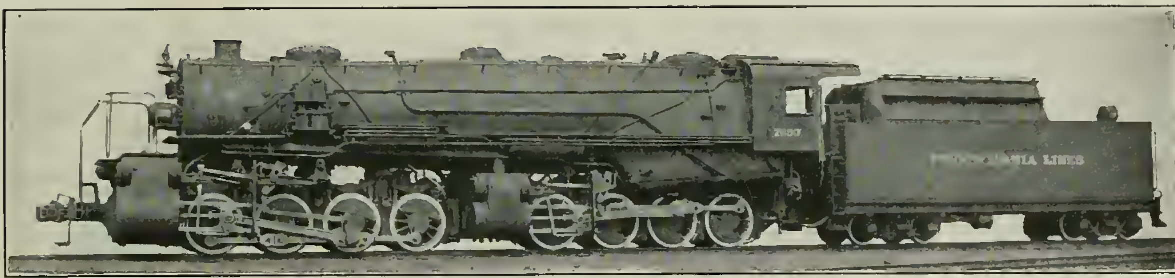
Now, let us see just what the practice of crown boring referred to by Mr. Murdock would do for the ten-coupled engine. A safe figure for bearing pressure per square inch is 200 lb. in driving boxes of freight engines.

The live load on the main journal is 26,650 lb., and on the basis of 200 lb. per sq. in. we find that we may safely reduce the vertically projected area of the bearing to 133¼ sq. in. This calls for a crown bore 5 in. wide by 12¼ in. long, and in boring the crown we have reduced the bearing area in the horizontal direction, owing to the fact that the crown bore extends downward ½ in. If ½ in. full bearing is left on each end of the brass to prevent the escape of grease the projected bearing area in the horizontal direction is 91⅜ sq. in. Dividing 330,532 lb. by 91⅜, the bearing pressure per sq. in. is found to be 3,617 lb., and the ratio of probable horizontal wear to probable vertical wear becomes 9.042. This is a betterment of 27½ per cent at the start, but it must be remembered that as wear progresses the projected area of the crown bearing will be increased in area. At any rate, the improvement thus effected has been so entirely negligible that several roads have abandoned the practice.

The writer had no idea that the rearrangement of the bearing surfaces which he suggested in his former letter would go, as it has, practically unchallenged. The most obvious difficulty with the arrangement shown lies in the fact that a very slight vertical wear would throw the lower portion of the thrust brasses out of contact with the journal and render them useless, after which the box would wear open just as fast as the half-shell type. The writer believes, however, that there is no good reason why the box should not be made sectional, say in three pieces, one to embrace a crown brass and carry the weight, while cheek plates embracing thrust brasses would be arranged at the front and back of the journal in such manner as to take care of the thrust and pull from the piston. With a box of this description it would be necessary to interlock the pieces, so that they would be incapable of any movement relatively to each other, except that necessary to close and open the bearings. To take up slack and stop a pound, set up the wedge on the engine frame. When a pre-determined limit of take-up has been reached, put shims behind the brasses to restore the original box dimension, then set up the wedge as before. The writer can see no reason why an engine should ever be taken off its wheels except to true up the tires and journals, as the brasses could be slip fits in their recesses and could be renewed whenever necessary. The box could be removed from the frame without dropping the wheels or removing the rods. This should be convenient when taking up lateral motion.

Inadequate main boxes is a most important subject, relative to the maintenance of locomotives and the mere mention of it should provoke the liveliest of discussions. The writer sincerely hopes to see more of it in future issues of your valued paper. CHARLES F. PRESCOTT.

NEW METAL ALLOY.—Trade Commissioner H. C. MacLean, at Rome, has sent a report to the Department of Commerce of a new alloy of zinc and copper which has been given the name of Biakametal. This alloy quickly demonstrated its usefulness in Italian industry, and by reason of its special qualities promises to attain similar success throughout the world. Metallurgists have made every effort to determine its exact composition, but without success. It is stronger than steel and less corrosive than copper. The most important characteristics are said to be the highest known breaking point, the highest limit of elasticity, perfect homogeneity, high resistance to thermic action and high resistance to chemical action.



Pusher Mallet Locomotive for the Pennsylvania Lines

Penn. Lines Mallet Locomotive

For Pusher and Hump Yard Service; 51-in. Wheels and 28-in. Stroke; 100,000 lb. Tractive Effort

The Pennsylvania Lines West of Pittsburgh has recently received from the Baldwin Locomotive Works 10 Mallet locomotives of the 0-8-8-0 type, which are designated by the railroad as Class CC-2-s. These locomotives are designed for heavy pusher and hump yard service and some idea of the severe conditions which they are required to meet is conveyed by the fact that they develop a tractive effort of 100,000 lb. The maximum grade in the hump yards on the Pennsylvania Lines is 3½ per cent, but the new Mallets are designed for operation on grades as steep as five per cent and on curves of 18 deg.

In the design of these locomotives there are a number of departures from well established Pennsylvania standards and in many respects the practice of the builders has been followed. The locomotives have conical wagon top boilers with radial stayed fireboxes instead of the Bellpaire type generally used on Pennsylvania power. The boiler has an outside diameter at the first ring of 88½ in., increased by the conical second course to an outside diameter of 100 in. at the throat sheet course. The firebox has an inside length of 144⅛ in. and is 96¼ in. wide. A barrel combustion chamber extends forward into the boiler 38½ in. from the vertical flange of the inside throat sheet. The tubes and flues have a length of 22 ft. and are 2¼ in. and 5½ in. in diameter, respectively. The boiler is also equipped with a 52-element Type A superheater.

Three rows of Baldwin expansion staybolts support the front end of the crown sheet. The arch is supported on five tubes and the locomotive is fired by a Duplex stoker. The throttle is of the inside connected type with the operating rod extending through the back head on the vertical center line; the throttle is equipped with an auxiliary drifting valve.

The wheels are of comparatively small diameter, measuring 51 in. over the tires and the low pressure cylinders are placed on an inclination of 1 in 35 in order to provide sufficient clearance above the rail. The high pressure cylinders are 26 in. in diameter and the low pressure 40 in. in diameter. A 28-in. stroke was made necessary by the small diameter of the drivers. Steam distribution is controlled by 14-in. piston valves for both the high and low pressure cylinders and the engines are fitted with the Simplex type of intercepting valve with auxiliary high pressure exhaust to the stack. The Walschaert valve motion is used throughout and the motion is controlled by the Ragonnet type *B* reverse gear.

The main driving axles have 10½-in. journals, while the journals of the other axles are 10 in. in diameter. All journals are 14 in. in length. The driving axles are of heat treated steel and are hollow bored. Heat treated steel is also used for the crank pins and the connecting and coupling rods. All driving tires are flanged.

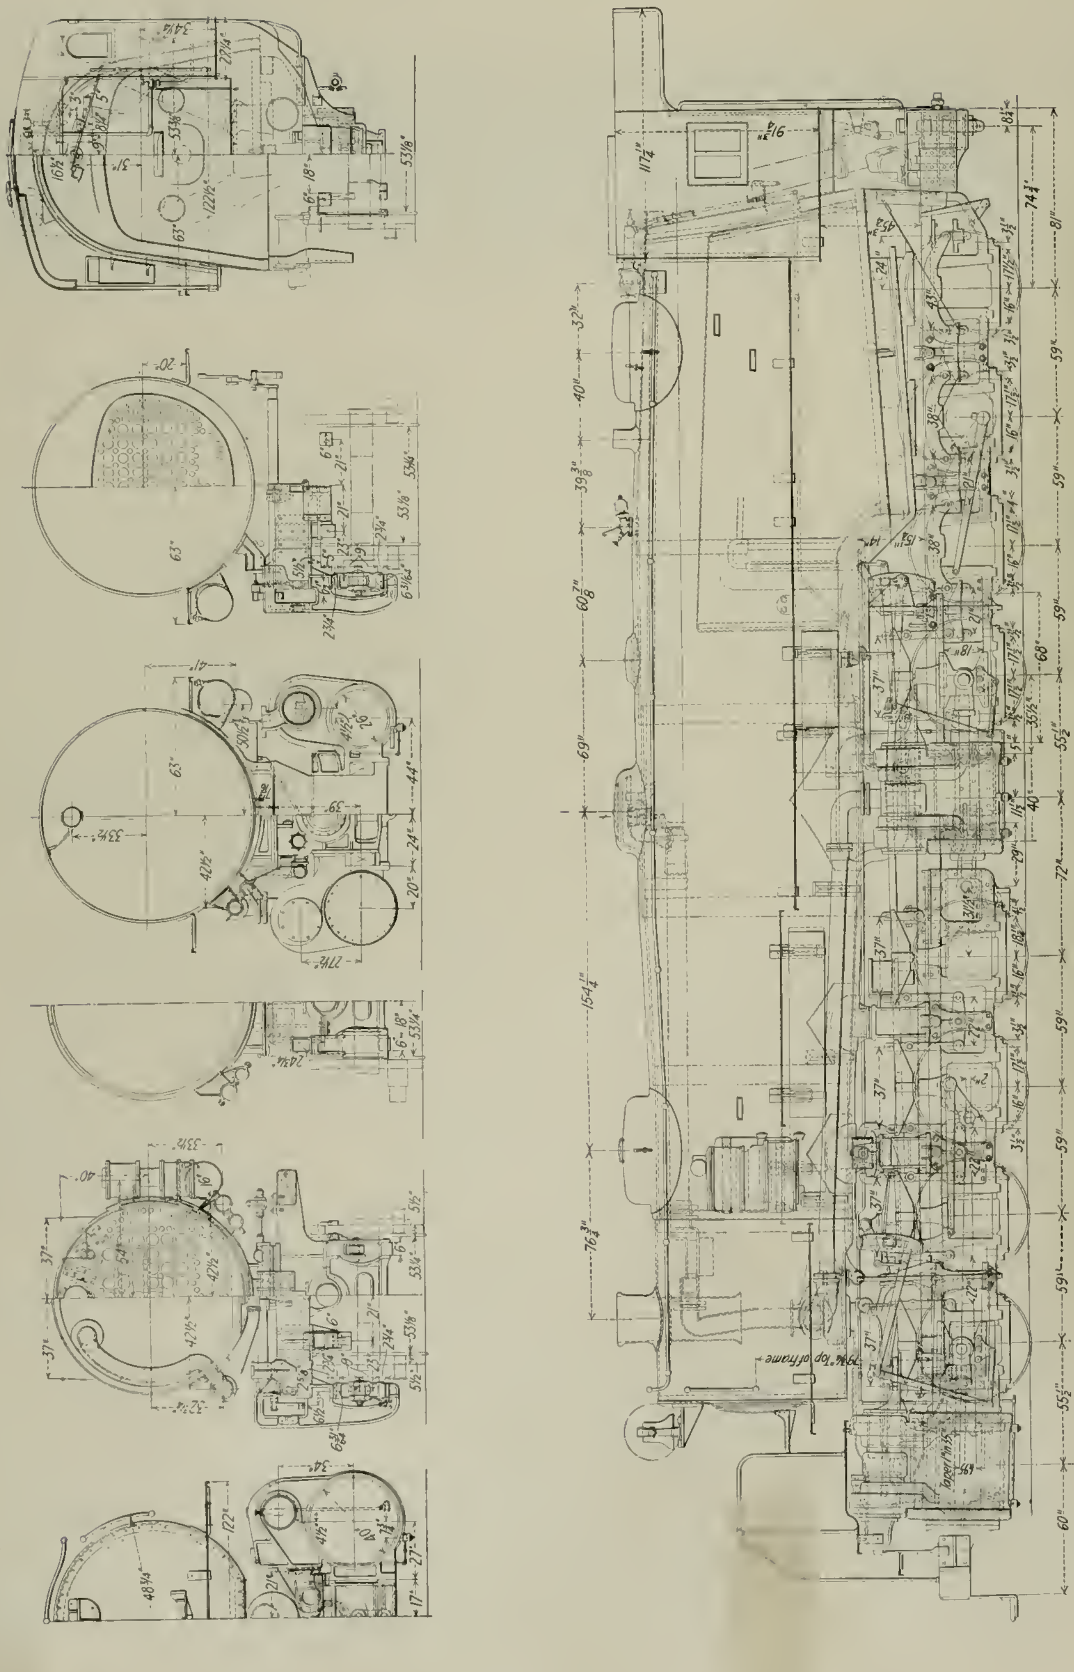
The equalization of the rear group of wheels is continuous on each side of the locomotive. In the case of the front group the springs of the leading wheels are cross equalized at the forward ends and attached to the frames at the rear ends. Those of the remaining three pairs of wheels are equalized together on each side.

Although the cab deck is roomy, the cab itself, in accordance with recent Pennsylvania practice, is comparatively short and the steam turret is placed outside and immediately in front of the cab. Two sand boxes are provided, one mounted over the first barrel course and the other above the firebox wrapper sheet just ahead of the cab. These are arranged to deliver sand to the rails at either the front or rear of each group of driving wheels.

The tender is built up with a one-piece cast steel frame and the tank is so designed that a water scoop subsequently can be applied if desired.

The following table presents the principal dimensions and data for these locomotives:

General Data	
Gage	4 ft. 8½ in.
Service	Pusher
Fuel	Bit. Coal
Tractive effort	100,000 lb.
Weight in working order	458,140 lb.
Weight on drivers	458,140 lb.
Weight of engine and tender in working order (est.)	650,000 lb.
Wheel base, driving	40 ft. 1½ in.
Wheel base, rigid	14 ft. 9 in.
Wheel base, total	40 ft. 1½ in.
Wheel base, engine and tender	78 ft. 8½ in.
Ratios	
Weight on drivers ÷ tractive effort	4.6
Total weight ÷ tractive effort	4.6
Tractive effort × diam. drivers ÷ equivalent heating surface*	714.4
Equivalent heating surface* ÷ grate area	74.1
Firebox heating surface ÷ equivalent heating surface,* per cent	5.5
Weight on drivers ÷ equivalent heating surface*	64.2
Total weight ÷ equivalent heating surface*	64.2
Volume equivalent simple cylinders	24.2 cu. ft.
Equivalent heating surface* ÷ vol. cylinders	294.5
Grate area ÷ vol. cylinders	4.0
Cylinders	
Kind	Compound
Diameter and stroke	26 in. and 40 in. by 28 in.
Valves	
Kind	Piston
Diameter	14 in.
Wheels	
Driving, diameter over tires	51 in.
Driving, thickness of tires	3½ in.
Driving journals, main diameter and length	10½ in. by 14 in.
Driving journals, others, diameter and length	10 in. by 14 in.
Boiler	
Style	Conical
Working pressure	225 lb. per sq. in.
Outside diameter of first ring	88½ in.
Firebox, length and width	144⅛ in. by 96¼ in.
Firebox plates, thickness	Sides, back and crown, ⅜ in., tube, ⅝ in.



Elevation and Cross Sections of Pennsylvania Lines 0-8-8-0 Mallet Type Locomotive

Firebox, water space	Front, 6 in.; sides and back, 4½ in.
Tubes, number and outside diameter	209—2¼ in.
Flues, number and outside diameter	52—5½ in.
Tubes and flues, length	22 ft.
Heating surface, tubes and flues	4,639 sq. ft.
Heating surface, firebox, including arch tubes	391 sq. ft.
Heating surface, total	5,030 sq. ft.
Superheater heating surface	1,406 sq. ft.
Equivalent heating surface*	7,139 sq. ft.
Grate area	96.3 sq. ft.
Tender	
Tank	Water bottom
Frame	cast steel
Weight (estimated)	192,000 lb.
Wheels, diameter	33 in.
Journals, diameter and length	6 in. by 11 in.
Water capacity	10,000 gal.
Coal capacity	20 ton

*Equivalent heating surface = total evaporative surface + 1.5 times the superheating surface.

LAME ENGINES AND THEIR EFFECT ON FUEL CONSUMPTION*

BY J. W. HARDY
Fuel Supervisor, United States Railroad Administration

The purpose of this paper is to show in a practical way how fuel is wasted by lame engines (engines with valves out of adjustment). With this end in view tests were made on the Southern Pacific between Houston and Galveston.

The engines used were of the following dimensions:

Engine 267 was of the 4-4-0 type having a total weight of 137,425 lb., weight on drivers 91,675 lb. and tractive effort of 21,240 lb. The cylinders were 20 by 24 in. The valves 12 in. diameter inside admission piston type. The valve motion was the Stephenson link, set as follows: valve travel 6 in., 1⅛-in. lap, 3/32-in. exhaust clearance, line and line in front motion and ⅛ in. lead in back motion.

The engines were equipped with superheaters and burned fuel oil.

Engine 265 was of practically the same design and dimensions with the exception that the cylinders were formerly equipped with slide valves which were replaced with piston valves, simplified steam chests with 10 in. diameter valve outside admission having 1-in. lap, 1/32-in. lead in forward motion, 1/32-in. back, and 1/16 in. exhaust clearance.

The engines in these tests were run eight trips in each case with one exception, test No. 2. The test was conducted with Engine 267, which had considerable lost motion in its valve gear, and had made 16,700 miles since last shopping. Engine 265 was in the best of condition, having been turned out of the shops after being generally overhauled and superheated. The same engineer and fireman were used throughout the entire test.

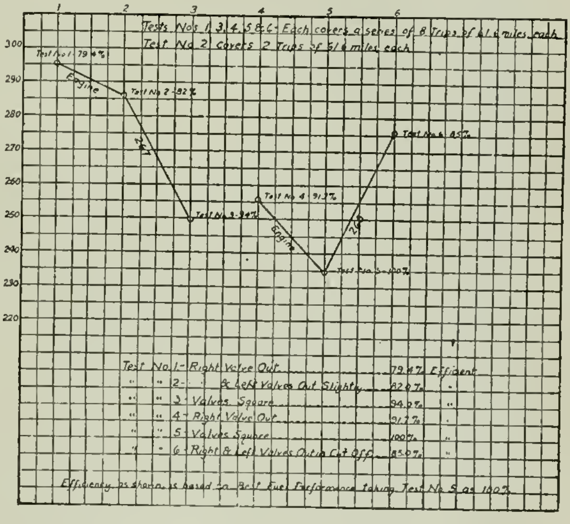
The tests made numbered from 1 to 6 inclusive—test Nos. 1 to 3 with engine 267 and 4 to 6 with engine 265. There were many places where we could get the lame engine, but we could not get the other conditions necessary to prove waste due to improper valve adjustment. We thought it was easier, better and more reliable to make changes on the engine than to attempt to work out the other conditions, many of which we had no control over.

The objects of the tests were to determine the fuel wasted by locomotives with valves out of adjustment, and to see how lame a locomotive could be without loss of time or complaint on its condition. Where an engine is so lame it cannot make time or handle its tonnage, it immediately attracts the attention of the transportation department and is taken in and repaired. It is only in rare cases that engines go lame all at once. When this occurs there is usually something lost, slipped or broken. This is noticed at once and is taken care of at the earliest possible moment; but, where the change takes place slowly and gradually, as it does by age and wear, we become more and more accustomed to it, and it is allowed to go on day after day and week after week wasting fuel all the time.

An oil burner was selected because a more accurate check could be made of the fuel used than with the coal burner. Measurements were taken just before starting, and on arrival, so that oil and water used represents what was actually used in pulling the train and making station stops. All conditions of engines and service were kept as near the same as possible, except the valve adjustment, which is shown at the heading of each test made.

There was a total of 5/16 in. lost motion in the valve gear of engine 267, but this was pretty well distributed, the engine not lame enough in any case to affect the schedule of the train. There was a noticeable kick in the engine when lame that was not there when squared.

With the slight change in valve adjustment shown between tests 1 and 3, there was a difference of 18.33 per cent in the fuel consumed; no other charge can be made of this loss of fuel than to the condition of valves. The waste would undoubtedly increase with heavier service or more distorted valve condition; this is proved by test No. 6 with engine 265. Test No. 2 is not recorded for the purpose of comparison, but to show the condition of valves after the engine was squared up by the travel at full stroke and pronounced O. K.



Relation of Fuel Consumption to Valve Setting

More throttle had to be used with the engine in this condition than when the valves were as in test No. 3.

The valves govern the application of the power of steam to the locomotive and are of great importance to fuel consumption. It takes fuel to generate power, and it means a waste of fuel if this power is improperly used in the cylinders of our locomotives. The exhaust action is different when the engine is lame, causing a pulsating draft instead of a regular and constant pull on the fire. This wastes fuel in addition to the improper application of the power to the machine. Square engines steam better than lame ones, although these engines steamed well in both cases.

Valves out of square in a measure take the economical operation of the locomotive out of the hands of the crew. Their hands are practically tied because they are robbed of the control of the power applied to the locomotive in their charge. With an indifferent crew this loss will increase.

There is no way that we know of where we can get as good returns, and get them as quickly and at as little cost, as by squaring valves. It only costs a few dollars more to do

*Abstract of a paper read before the International Railway Fuel Association at the convention in Chicago, May 19-22, 1919.

this work well; it only costs a few dollars to do it at a time when it is needed and should be done, and it will often begin to pay dividends the first trip after it is done. Transportation people should want it done because the engine will pull more and pull out less draw bars when square than when lame, because the power is more evenly distributed in the cylinders and helps to prevent lunging and jerking when starting. The mechanical department people should do it because it cuts down fuel waste and the cost of locomotive maintenance. The crew should want it done because it makes their work easier and more pleasant.

There is liable to be less complaint on a lame oil burner, especially if she steams, than on a coal burner on account of less manual labor to fire the oil burner. Why spend money for brick arches, superheaters, etc., and then waste as much with valves out as we can save with both of them? Why spend money to generate steam and then not control its use? You can go to any union station or large freight yard and hear engines pulling out every day on long, hard and heavy runs that sound worse than either of these engines did. The question of proper valve adjustment is so important that it should be specialized on.

The cut-off and steam distribution on test No. 2 with engine 267 merits careful study. This engine was run over at full stroke; in fact, was more carefully gone over than this work is usually done; pronounced O. K., and, no doubt, under ordinary circumstances, would have run possibly for months in this condition. Note how much better this engine did in test No. 3 with valves properly adjusted and a little of the lost motion taken up.

The difference in the performance of engine 267 with valves lame and square was so much we decided to make a test with an engine having as little lost motion in the valve gear as possible. We therefore arranged for a test with engine 265. This engine was new, and when broken in the right go ahead blade was changed so the cut-off was as shown in test No. 4. This engine was quite lame only on one side, and this low down in the quadrant, and, as the lever was hooked up, it got better. As the engine did most of its work at close cut-off, this change only made a difference of about 9¼ per cent in the fuel used, but the engine had a very disagreeable kick on the right side when run at high speed and short cut-off.

Certain kinds of lameness are more wasteful than other kinds. The engine that is lame where it uses the most of its steam is the most wasteful. This is clearly brought out by test No. 6 with engine 265. By changing the back motion blades so that the engine cut-off in the forward motion, this engine was made lame in the cut-off where most of its work was done.

In all tests where the engines were lame, the lameness was aggravated by its being more difficult to keep the valves lubricated, and both engines rode much harder while lame than when squared. An engine can sound square and still have valves improperly set. A condition of this kind can only be discovered by careful measurements.

My conclusions from these tests are that a waste of as much as 25 per cent of the fuel could be made by further distortion of valves before the engines would begin to lose time or affect the train service.

Conditions Surrounding Tests Nos. 1 to 6, Inclusive, with Cut-off at 6-In. Piston Travel.

Test No. 1, Engine No. 267. Right valve out—cut-off—right side, front 5 1/16 in., back 10 7/16 in. Left side, front 7¼ in., back 7¾ in.

Test No. 2, Engine No. 267. Both valves out—cut-off—right side, front 7 1/16 in., back 5 1/16 in. Left side, front 7 1/16 in., back 5 7/16 in.

Test No. 3, Engine No. 267. Both valves square.

Test No. 4, Engine No. 265. Right valve out—cut-off—right side, front 8½ in., back 3½ in. Left side, front 6½ in., back 6 13/16 in.

Test No. 5, Engine No. 265. Both valves square.

Test No. 6, Engine No. 265. Both valves out—cut-off—right side, front 3 11/16 in., hack 8 7/16 in. Left side, front 4⅛ in., back 7 13/16 ni.

Per cent increase in fuel consumption Test No. 1—18.33 per cent.

Per cent increase in fuel consumption Test No. 2—14.63 per cent.

Per cent efficiency of engine in Test No. 1, considering engine in Test No. 3 as 100 per cent—84.5 per cent.

Per cent efficiency of engine in Test No. 2, considering engine in Test No. 3 as 100 per cent—84.5 per cent.

Per cent increase in fuel consumption Test No. 4—9.12 per cent.

Per cent increase in fuel consumption Test No. 6—17.70 per cent.

Per cent efficiency of engine in Test No. 4, considering engine in Test No. 5 as 100 per cent—91.6 per cent.

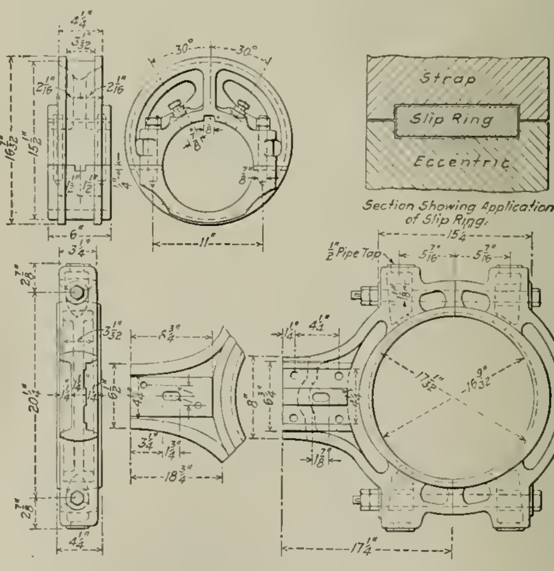
Per cent efficiency of engine in Test No. 6, considering engine in Test No. 6 as 100 per cent—84.9 per cent.

ECCENTRIC WITH FLOATING LINER

BY J. A. PULLAR

A simple and economical method of utilizing old eccentric cams is illustrated in the drawing. A 17-in. eccentric cam is turned down to 15½ in. diameter leaving a ⅜-in. flange on each side, thus forming a groove to hold a floating liner or slip ring as shown in section. The outside of the ring fits in the eccentric strap just as the old eccentric cam did.

Four rings are turned at one time from a brass bushing 14 in. long, which allows for clamping and cutting the rings. Each ring has three oil holes equally spaced and is



Eccentric Cam With Slip Ring in Place

cut in three parts on a milling machine by cutting through the center of the oil holes.

The eccentric cam can be turned down to fit the rings in the same length of time it would take to fit a new cam on the journal and considerable machine work and labor is avoided by using the old cam.

Eccentric cams converted as described have proved very successful and wear longer than when applied in the old way. The use of the ring has eliminated the usual trouble of closing the eccentric strap after every few trips and when worn the ring may be renewed in a very short time, while it would take several hours to fit a new eccentric cam and key.

Car Department Forces to be Increased.—On account of the fact that the number of bad order cars has increased considerably at the Nashville shops of the Nashville, Chattanooga & St. Louis, the forces in the car department are to be materially increased. It is understood that the additional men needed to put these cars in good condition for shipping will be drawn from the ranks of those recently laid off.

Shopmen's Wage Increase Refused

President Agrees with Director General that Demands Are Unjustified Under Present Conditions

THAT there shall be no new cycle of wage increases for railroad employees under present conditions is the decision of President Wilson and Director General Hines on the demands presented by the committee of the shopmen's unions. This conclusion was reached on the ground that the increases already granted by the Railroad Administration and by the railroad companies during the two years preceding federal control have kept pace with or exceeded the increase in the cost of living up to date, and that further advances in railroad wages are not warranted by comparison with other wages, and would merely result in a further increase in the cost of living, which the government is now bending every effort to reduce.

Whether this decision will be accepted by the labor organizations, however, will not be known until the counting of the new strike vote called for by the leaders following their formal rejection of the small increase granted the men by way of readjustment.

Following the submission to Congress by President Wilson on August 1, of his recommendation for legislation creating a tribunal for the investigation and determination of all questions concerning the wages of railway employees, the responsibility for settlement of the questions arising from the shop crafts' demands was placed squarely on the shoulders of the President and Director General by the unanimous decision of the Senate committee on interstate commerce that the President already possessed "complete and plenary authority" in the premises.

Therefore, on assurances that the 40,000 men estimated by union officials in Washington to have walked out in the unauthorized local strikes following the reference of the wage question to Congress, had returned to work, conferences were resumed on August 20 between the shop employees' representatives, headed by B. M. Jewell, and the Railroad Administration. On August 23 Director General Hines gave the President a complete report of his recommendations for a settlement and on August 25 the shopmen's committee, which had just completed the count of a vote authorizing the calling of a strike unless their demands were granted, was called to the White House to receive the final decision from the President. The shop employees were awarded an increase of 4 cents an hour, retroactive to May 1, more as an adjustment than as a direct wage increase.

At this conference a copy of Mr. Hines' report, and two statements by the President, one to the shopmen and one to the public, were given out.

THE PRESIDENT'S STATEMENT TO THE PUBLIC

In his statement to the public, President Wilson briefly reviewed the steps by which the settlement had finally been placed in his hands, then taking up the grounds on which the men had justified their demands. In discussing the high cost of living in this connection he made a strong plea for sober second thought on the part of all wage earners to the end that adjustments to meet living costs be postponed until normal conditions are restored and adjustments can be made on a more certain basis.

"Demands unwisely made and passionately insisted upon at this time," the President said, "menace the peace and prosperity of the country as nothing else could, and thus contribute to bring about the very results which such demands are intended to remedy."

THE PRESIDENT'S STATEMENT TO THE SHOPMEN'S COMMITTEE

In addressing the Committee of the shopmen's unions the President said:

I request that you lay this critical matter before the men in a new light. The vote they have taken was upon the question whether they should insist upon the wage increase they were asking or consent to the submission of their claims to a new tribunal, to be constituted by new legislation. That question no longer has any life in it. Such legislation is not now in contemplation. I request that you ask the men to reconsider the whole matter in view of the following considerations, to which I ask their thoughtful attention as Americans, and which I hope that you will lay before them as I here state them.

We are face to face with a situation which is more likely to affect the happiness and prosperity, and even the life, of our people than the war itself. We have now got to do nothing less than bring our industries and our labor of every kind back to a normal basis after the greatest upheaval known to history, and the winter just ahead of us may bring suffering infinitely greater than the war brought upon us if we blunder or fail in the process. An admirable spirit of self-sacrifice, of patriotic devotion, and of community action guided and inspired us while the fighting was on. We shall need all these now, and need them in a heightened degree, if we are to accomplish the first tasks of peace. They are more difficult than the tasks of war—more complex, less easily understood—and require more intelligence, patience and sobriety. We mobilized our man power for the fighting, let us now mobilize our brain power and our consciences for the reconstruction. If we fail, it will mean national disaster. The primary first step is to increase production and facilitate transportation, so as to make up for the destruction wrought by the war, the terrible scarcities it created, and so as soon as possible relieve our people of the cruel burden of high prices. The railways are at the center of this whole process.

The government has taken up with all its energy the task of bringing the profiteer to book, making the stocks of necessaries in the country available at lowered prices, stimulating production, and facilitating distribution, and very favorable results are already beginning to appear. There is reason to entertain the confident hope that substantial relief will result, and result in increasing measure. A general increase in the levels of wages would check and might defeat all this at its very beginning. Such increases would inevitably raise, not lower, the cost of living. Manufacturers and producers of every sort would have innumerable additional pretexts for increasing profits and all efforts to discover and defeat profiteering would be hopelessly confused. I believe that the present efforts to reduce the cost of living will be successful, if no new elements of difficulty are thrown in the way, and I confidently count upon the men engaged in the service of the railways to assist, not obstruct. It is much more in their interest to do this than to insist upon wage increases which will undo everything the government attempts. They are good Americans, along with the rest of us, and may, I am sure, be counted on to see the point.

It goes without saying that if our efforts to bring the cost of living down should fail, after we have had time enough to establish either success or failure, it will of course be necessary to accept the higher cost of living as a permanent basis of adjustment, and railway wages should be readjusted along with the rest. All that I am now urging is, that we should not be guilty of the inexcusable inconsistency of making general increases in wages on the assumption that the present cost of living will be permanent at the very time we are trying with great confidence to reduce the cost of living and are able to say that it is actually beginning to fall.

I am aware that railway employees have a sense of insecurity as to the future of the railroads and have many misgivings as to whether their interests will be properly safeguarded when the present form of federal control has come to an end. No doubt it is in part this sense of uncertainty that prompts them to insist that their wage interests be adjusted now rather than under conditions which they cannot certainly foresee. But I do not think that their uneasiness is well grounded. I anticipate that legislation dealing with the future of the railroads will in explicit terms afford adequate protection for the interests of the employees of the roads; but, quite apart from that, it is clear that no legislation can make the railways other than what they are, a great public interest, and it is not likely that the President of the United States, whether in possession and control of the railroads or not, will lack opportunity or persuasive force to influence the decision of questions arising between the managers of the railroads and the railway employees. The employees may rest assured that, during my term of office, whether I am in actual possession of the railroads or not, I shall not fail to exert the full influence of the Executive to see that justice is done them.

I believe, therefore, that they may be justified in the confidence that hearty co-operation with the government now in its efforts to reduce the cost of living will by no means be prejudicial to their own interests, but will, on the contrary, prepare the way for more favorable and satisfactory relations in the future.

I confidently count on their co-operation in this time of national test and crisis.

DIRECTOR GENERAL HINES' REPORT

Mr. Hines' report to the President, dated August 23, is as follows:

In view of the importance both to the railroad employees and to the public of the wage demands of the shop employees, and in view of the intimate relationship between that subject and the all-important subject of the cost of living, I feel it my duty to make this report to you for action by you if you wish to take personal action in regard to it.

The responsibility rests upon me to decide upon its merits the claim of the railroad shopmen for the following increases in wages:

	Now receiving Cents	Requested Cents	Increase Cents
Machinists	68	85	17
Toolmakers	68	90	22
Boilermakers	68	85	17
Riveters	68	85	17
Blacksmiths	68	85	17
Sheet metal workers	68	85	17
Electricians	68	85	17
Car inspectors	58	85	27
Car repairers	58	85	27
Car repairers, steel	63	85	22
Helpers	45	60	15

Note.—These figures represent only the principal classes.

This demand was considered by the Board of Railroad Wages and Working Conditions, a board constituted last year by the Railroad Administration to consider wage matters, and consisting of three representatives of labor and three representatives of the railroad managements. On the question of any general increase to the shopmen, the board divided equally, the three labor members favoring an increase to a basis of 80 cents and the three management members opposing any general increase whatever, although expressing the opinion that unless the cost of living could be controlled, there would need to be a further general increase in wages. This is the first time when this board has thus divided on the question of a general wage increase presented to it. In every other case the board has been in agreement upon the proposition that there ought to be a general increase, although in some cases its members have been slightly apart as to the extent of the general increase. In this case three members of the board, who in all other cases have been in favor of a general increase, have thus opposed any increase whatever for the entire class of employees.

I believed it would be more satisfactory both to the employees and to the public to have this grave problem considered and disposed of by a commission created by new legislation. Recommendation to that effect was submitted to the appropriate committees of the Senate and the House, but the unanimous adverse action of the Senate committee made it clear that such a course would not be pursued.

It is also true that the employees themselves vigorously objected to my suggestion and insisted that the matter should be decided by me.

Since the subject must be dealt with, and no other method has been or is to be provided, it follows that it must be dealt with by the director general under the powers conferred upon the President by the Federal control act, and this must be done without the aid of any action by the wage board.

I approach this matter with the clearest conviction that the railroads must be conducted now and for all time in the future in such a way as to give to railroad employees an adequate compensation and a liberal share in the returns from railroad operation. This is not only justly due to the employees who make possible the rendition of the service but it is obviously in the interest of good service. It is true now, and will be true to a continually increasing extent in the future, that a state of contentment on the part of railroad labor will be indispensable to efficient railroad service and this contentment cannot exist unless the evidence of fair treatment is so clear that it will carry conviction to the railroad employees themselves.

I have, after the most careful possible study, and after considering everything presented on behalf of the railroad shop employees, reached the following conclusions:

The main contention of the shop employees is that their demands are just because of the rates paid in the ship yards, navy yards and arsenals. The basic rate in the ship yards was 80 cents at the time the shopmen presented their demands, and an increase effective October 1 next has just been made in an agreement (to which the government was in no way a party) between the employees and the ship builders on the Pacific coast. After the most careful consideration, I can see no escape from the conclusion that the rates paid in the shipyards cannot be adopted as a measure for the rates to be paid in the railroad shops. The conditions are fundamentally different. The work performed by employees classed as railroad shop employees is performed in every city and in every railroad town of considerable size in the United States. The principal railroad shops are not in the largest cities and many of the principal shops are in towns or cities of relatively small size. At the urgent instance of the employees, the rates for all these shopmen throughout the United States, whether in large cities, small cities or towns or virtually rural communities, have been standardized on uniform bases. It cannot be, therefore, that these standardized rates can be put so high as to reflect the conditions prevailing in the relatively few industrial centers where shipbuilding was developed under high pressure during the war. Not only are the shipyards practically without exception in densely populated centers but employees had to be attracted to those yards in time of war in competition with munition plants and others paying exceptionally high wages, and the employees who were attracted to those yards had to establish themselves in these densely populated centers with particularly costly living conditions. In order to meet the keen competition of other war industries and to build up the forces of men in the shipyards exceptional rates had to be provided.

The work in the railroad shops not only offers year in and year out (despite the fluctuations incident to changes in the volume of business) reasonably steady employment, but also offers a practically permanent career. On the other hand shipbuilding represents to a large extent a temporary employment. This is brought out clearly by the following showing which is actual up to August 15, 1919, and estimated beyond that date, as to the employees who have been and will be employed in the shipyards so far as the present governmental program is concerned.

Date	Number of shipbuilders	Date	Number of shipbuilders
January, 1914	48,700	June, 1919	354,625
January, 1916	78,100	Dec. 31, 1919	250,894
January, 1918	144,600	June 30, 1920	230,000
November, 1918	373,622	Dec. 31, 1920	153,000
January, 1919	361,211	June 30, 1921	0

Note.—These figures do not include, as I understand it, members of office forces, but only include the men engaged in ship construction and men employed in fabricating shops and all other shops actually a part of the shipyard plant.

It is perfectly clear to me that the people of the United States cannot be committed to the policy that the wages of railroad shopmen in every city, town and village in the United States must be brought up to a basis created in an emergency and in a largely temporary war undertaking, concentrated in a comparatively few densely populated industrial centers where living conditions are exceptionally expensive and difficult, so that I conclude that the principal contention of the shop employees cannot be adopted.

Of course if the employees themselves were willing to accede to a plan whereby the wages of railroad shopmen in each community should be made with reference to the average wages in that community, other considerations would have weight. But the employees are insistent that the same wage scale shall be paid in every place in the United States, regardless of its size or of local living conditions, and as this principle has been adopted it necessarily follows that exceptional conditions in exceptional communities cannot be taken as the standard for the wages of railroad shopmen.

The conditions in the navy yards and arsenals cannot, largely for the reasons already stated, be taken as controlling; moreover, it has generally been recognized that the rates therein should reflect local conditions in the particular communities and they have not been standardized at all except for a temporary standardization for the war to correspond with the shipyard rates.

It is further urged by the employees that the rates they receive are below those paid in private industries for similar labor. The employees cite various instances of rates in excess of 80 cents for work of this character, but these citations merely refer to conditions in specific communities. It must also be remembered that to a large extent private industries themselves were influenced to an exceptional degree by the war conditions, enjoying the most exceptional profits and paying unusually high wages to meet emergency requirements. But no convincing evidence has been presented that the average of the wages paid in private industries generally, or in those paying union scales of wages, throughout the United States for similar labor was or is substantially higher than the rates paid by the Railroad Administration.

I myself have collected the available information from the Department of Labor and that indicates that the average rate paid the principal metal trades in private industries, having union scale of wages, was at May 15, 1919, probably not more than 3 cents in excess of the 68 cent rate paid to the railroad shop employees. It is a question whether even as to private industries the advantages of work in railroad shops, including the advantage of substantial amounts of free transportation, do not make it reasonable for the railroad shops to have a differential under the rates paid in other private industries. This question, however, need not be decided because the decision made below will make the rates for the railroad shop employees in excess, if anything, of average rates shown in the evidence thus obtainable from the Department of Labor for private industries.

In making comparisons for work of similar character between wages in the railroad industry and wages in private industries, due consideration must always be given to the fact that private industries are frequently able to increase their prices to the public without difficulty to offset, and more than offset, increases in wages, so that to a very considerable extent the wages fixed in private industries are fixed without any representation, either direct or indirect, of the general public which eventually must pay the bill. On the contrary the railroads whether under public or private control cannot increase the prices they charge, i.e., their transportation rates, except with the sanction of public authority. So the question must be viewed from the public standpoint as well as from the standpoint of the employees. This necessitates the most careful scrutiny of rates of pay which have been fixed by industries enjoying tremendous profits which are not subject to public control. Of course the wages paid railroad employees must be not only reasonable in themselves but reasonably satisfactory to the employees, and necessarily the general average rates normally paid elsewhere in permanent private industries for similar services, are an important factor for consideration. But the distinguishing conditions must never be ignored.

The further claim is made that the cost of living has increased. In a letter of August 5, 1919, signed by the executives of the six railroad shopmen's organizations, and also by the executives of the eight other organizations of railroad employees, including the various organizations of train and engine men, of telegraphers, maintenance of way men, and clerks, the proposition is laid down that railroad employees are entitled to compensation which will, at least, re-establish the pre-war purchasing power of their wage.

The way to re-establish the pre-war purchasing power of wages is to reduce the cost of production and not to increase it.

The government is now taking vigorous steps to reduce the cost of living and is meeting with gratifying progress. This great work would be arrested if not defeated through the present adoption of the policy of moving up wages so as to reflect fully what is probably the very top-notch of the high cost of living. Such a movement would tend to increase still further the cost of living and injure every working man as well as every other person in this country.

In a statement presented to the President on July 30, W. S. Stone, president of the Brotherhood of Locomotive Engineers, said:

"We believe the true remedy for the situation, and one that will result in lifting the burden under which the whole people are struggling is for the government to take some adequate measures to reduce the cost of the necessaries of life to a figure that the present wages and income of the people will meet. Should this not be considered feasible, we will be forced to urge that those whom we represent be granted an increase in wages to meet the deterioration of the purchasing power of the dollar, be that what it may, which can be easily determined by competent authority."

W. G. Lee, president of the Brotherhood of Railroad Trainmen, in a summary of a statement made by him before the Board of Railroad Wages and Working Conditions and given to the press by him on July 31, stated that an increase in wages was not the proper solution of the present economic stress under which working men are laboring because they will be followed by new increases of cost of everything which would more than absorb the additional pay.

I therefore believe it would be unfair for the general public, subversive of the efforts which the government is making to reduce the cost of living, and injurious to railroad employees themselves, for the Railroad Administration at this time to adopt the principle of moving up wages of all railroad employees so as to reflect the highest point yet reached in the high cost of living. Such action would mean inevitably an increase in freight rates which would stimulate an increase in the cost of everything consumed by the public and would give innumerable pretexts for covering up additional unwarranted increases in prices on the claim that such increases will be necessitated by the increased cost of railroad transportation. As a matter of fact the rates of pay and also the earnings of many subdivisions of classes of railroad employees have already been so advanced as to be ahead of the highest point yet reached in the general average increase in the cost of living in the country. Any effort to adopt that high point as the minimum level for all railroad wages will be highly detrimental to the public interest.

I have consistently urged throughout this calendar year that the greatest problem before the country is a reduction in the cost of living and one of the greatest obstacles in the way of such reduction would be substantial increases in transportation rates. I am convinced that it is not reasonable from the standpoint of the public and would not be beneficial from the standpoint of railroad employees to make an increase in wages in the effort to overtake the high cost of living, since the increase would thereby result in putting cost of living further out of reach and seriously obstruct the efforts now being made to bring down the cost of living.

In this connection it is proper to say that if railroad shop employees be viewed as a class it appears from the best data available that, comparing the total earnings of those employees now with their total earnings in the year ending June 30, 1915, the average increase in their earnings is somewhat in excess of the total increase in the cost of living from July 1, 1915, to August 1, 1919. This comes about by the fact that in carrying out the policy of standardization so strongly urged by the railroad employees great numbers of men employed in railroad shops were given the benefit of a higher classification which entitled them to wages much in excess of the increases indicated by the mere difference between the old rates of pay and the new rates of pay. While it is true that those railroad shop employees who enjoyed the highest scale of wages prior to the war may not have received an increase fully commensurate with the increase in the cost of living it is also true that great numbers of those employees have received increases substantially in excess of the increase in the cost of living. This condition however should afford no basis for the claim that the total increase already given to railroad shop employees is excessive, because I do not believe that such is the case. On the contrary, I believe the railroad shop employees were fairly entitled as a whole to the increases in wages provided and are also fairly entitled to the additional increase next below mentioned.

There has been insistent contention that while all other classes of railroad employees have had their wages adjusted in such manner that they receive an increase wage in addition to receiving 10 hours' pay (in the pre-war period) for eight hours' work, this same treatment was not accorded to the shopmen. While it has been urged with equal insistence that the shopmen got offsetting advantages, it seems to me it is true that in this specific matter the shopmen did not receive the benefit of equal treatment. On that account it seems to me fair in all the circumstances to recognize this condition by giving the shop employees a rate of 72 cents instead of 68 cents for the classes now receiving 68 cents.

Under Supplement 4 to General Order 27 and an addendum to that supplement, two different rates have been provided for car repairers, one a rate of 63 cents for steel freight car repairmen and another rate of 58 cents for wooden freight car repairmen. This distinction has been difficult to maintain and has been the source of dissatisfaction and there is general agreement among the members of the wage board that the condition ought to be remedied (although the labor representatives think it ought to be remedied by increasing the rates for all car repairers to the highest rates).

I therefore conclude, that, except as stated below, the rate for all freight car repairmen who by Supplement 4 to General Order 27 and the addendum thereto were intended to receive either 58 cents or 63 cents shall receive 67 cents per hour. There has been great dissatisfaction because car inspectors generally have received only the rate of 58 cents notwithstanding the fact that steel freight car repairmen have received the rate of 63 cents. My conclusion is that, except as below stated, car inspectors should receive the same rate as above indicated for freight car repairmen and therefore should receive 67 cents per hour.

The exceptions above referred to as to freight car repairmen and as to car inspectors are as to such employees at outlying points other than shops and main line terminals at which points the work, generally speaking, is not continuous. The increase for freight car repairmen and car inspectors at such outlying points will be 4 cents per hour. The determination as to the points where the freight car repairmen and car inspectors who according to this principle get only the 4 cents increase will be taken up in conference with the representatives of the shopmen with a view to arriving at a reasonable and definite working rule.

As to all other classes covered by Supplement No. 4 and not above specifically dealt with, the rate of increase shall be 4 cents per hour.

Ever since last September it has been the settled principle of the Railroad Administration to make wage orders retroactive to a date approximating the date upon which the Board of Railroad Wages and Working Conditions made its report and in this instance that report was made on July 16. The conditions here, however, are peculiar in that the action of the wage board has been delayed for an exceptional length of time, the presentation to the wage board having been made last February. In these circumstances it seems to me that, as a part of a negotiation of a national agreement, the changes above indicated could properly be made effective as of May 1, 1919, and the Railroad Administration is willing to make these changes in rates of pay effective as of that date for all employees who do not leave the service pending the completion and adoption of a national agreement with the shopmen's organizations.

SHOP EMPLOYEES TAKE NEW STRIKE VOTE

After ascertaining that this decision was final, the committee representing the shopmen, formally advised Mr. Hines on August 26 that they could not accept the offer, and an order was issued for a new strike vote. With the order were sent copies of the President's statement, at his urgent request, and also of Mr. Hines' proposition with the request that they be given most careful consideration at a summoned or called meeting of each craft. The letter to the officers and members of the unions calling for the vote stated that the director general had declared that the proposition was final and that there would be no wage increase granted to any other class of railroad employees as a class, but that in the event of unjust inequalities, as between individuals, adjustments involving increases to equalize rates of pay would be made where justified, except under the conditions stated in the fourth paragraph of the President's statement. The letter cautioned the men to consider their position very carefully and not overlook the following important facts:

In any general wage increase which may be granted the shop crafts will receive the same consideration as other classes of employees.

If a strike is authorized the shopmen will be striking alone to force an increase for all of the 2,000,000 railway employees.

Owing to the large number of members involved, the international organizations will not be obligated to pay strike benefits beyond the limits of the funds available for that purpose.

FUNCTIONS OF THE WAGE BOARD NOW LIMITED TO ADJUSTMENTS

Director General Hines has addressed a letter to A. O. Wharton, chairman of the Board of Railroad Wages and Working Conditions, to define the functions which it is appropriate for it to perform in view of the decision announced by the President. For the present these are confined to the consideration of claims of any class or subdivision of a class of railroad employees to the effect that readjustments ought to be made in order to bring about equality of treatment on the basis of the general principles of wage adjustment which the Railroad Administration has already established. The board is expected to report a statement of facts, its conclusions upon the facts and its recommendations.

MODERN TENDENCIES IN ROUNDHOUSE DESIGN*

BY EXUM M. HAAS
Railroad Specialist. The Austin Company, Cleveland, Ohio

An engine terminal is a clearing house for motive power, hence anything done to obviate delays tends to increase the traffic-carrying capacity of the road without increasing the fixed charges. The tremendous increases in traffic, operating charges, and hauling capacity of locomotives and their cost have proportionately increased the demand for full utilization of a locomotive's earning power. Mere minutes saved on each locomotive handled, when multiplied by the total number of locomotives of a given road, and reduced to money, will finance unbelievable improvements.

I refer to this phase of the engine terminal problem to indicate that a road can afford to pay for the most efficient facilities. As a matter of fact, a 100-engine terminal can be built at present day prices, and fully equipped, for $660,-000. This would result in annual fixed charges of about $69,300, at 10½ per cent for interest and depreciation, or at about $2 per engine per day. For a terminal of this size, a 20 to 25-stall roundhouse would be required. Assuming 24 stalls, the house would cost about $220,000, or about one-third of the terminal cost. This amount would provide a roundhouse, equipped with all the modern labor-saving facilities, and it could be sc constructed as to reduce depreciation to a minimum. For instance, a reinforced concrete structure would carry a rate of about 2½ per cent for depreciation, whereas a brick wall, wooden frame and roof structure would carry at least a rate of 5 per cent.

While the weight of locomotives has increased about 100 per cent, the cost has doubled. This also emphasizes the need for better facilities for the protection of the motive power. A locomotive is not a fire risk in itself, but when it is placed in a wooden roof roundhouse it certainly becomes one.

Some roundhouses are quite important running repair shops; hence anything incorporated in the design that will reduce the time to clear a locomotive should be adopted. Of course, there is an economical limit to the amount that can be spent, but that need not worry most of us, because there is so much room for improvement at most terminals that we would find it difficult to reach the limit of cost. For instance, engine terminal costs varied in 1918, so far as my knowledge goes, from $25,000 to $50,000 per stall of house capacity. The roundhouse proper has varied in cost from $6,000 per stall, with lighting, heating and plumbing, to $22,000 per stall. Both of these figures are high for the types of construction used, because of the abnormal labor and material market conditions prevailing in 1918, but the cost relation would hold even in normal times. On the other hand, from what I know of the labor-saving facilities provided in the higher-priced terminal and the permanence of its construction, I believe the mechanical department will have no difficulty in justifying the greater investment.

RELATION OF ROUNDHOUSE DESIGN TO LABOR

Another of the broader questions affecting roundhouse design at present is labor. This concerns the quantity and class of help available, and the working conditions and wages. Under prevailing industrial conditions intelligent labor has obtained employment at higher wages and with more satisfactory working conditions than are commonly found in and about a roundhouse. The roundhouse design must meet this form of competition or the quality of labor will fall below its present standard, and roundhouse labor is none too intelligent now.

Conditions in the average roundhouse built 20 years ago were not conducive to efficiency or economy. Poor day and night illumination and a lack of proper handling and machine tool equipment not only reduced the capacity of the house for clearing locomotives, but resulted in serious delays. On the other hand, the shortage of desirable help and the correspondingly higher prices that must be paid to obtain good men, make it important that all the facilities necessary and consistent with economy be provided to increase the production per man. The increased use of bridge and jib cranes in roundhouses is evidence of an appreciation of this fact. The substitution of the electric hoist for the truck and driver drop pits is another example. Improved daylighting in the working areas, and better heating and ventilation are also examples of the tendency to improve roundhouse conditions. Paved floors and walks, attention to good drainage, all add to engine terminal efficiency, and do not materially increase the fixed charges.

MODERN TYPES OF CONSTRUCTION

Modern roundhouses divide themselves into three classes—the brick wall, wood frame and roof; reinforced concrete frame and roof, and a combination of steel frame and reinforced concrete structure. In one or two instances, concrete frames with wooden roofs have been built to reduce first cost, and in others reinforced concrete unit construction was adopted. The brick wall, wooden frame and roof construction has been most generally used because of its cheapness.

A roundhouse located at an unimportant terminal, housing engines that are comparatively small, is usually of simple design. The present tendency, however, is to increase the height to improve daylighting and ventilation. Houses of this type should be built of slow burning construction throughout—nothing less than 2-in. sheathing, preferably 3-in., on 6 in. by 12 in. rafters and heavily coated with a fire-resisting paint.

On many roads the frequent post spacing has been found objectionable. This was the case with the New York Central Lines, and a 64-ft. truss has been substituted in the working area for the columns and beams. These trusses were formerly of heavy timber construction, but are now built up of bolted planks. The reason for this change was to cheapen the construction without reducing the quality of the lumber.

*Abstracted from a paper presented before the Western Society of Engineers, Chicago, May 12, 1919.

This house has a one-bay portal way, with a lean-to at the back of the house. The lean-to in the rear not only provides a working aisle, but also permits the locomotives to be shifted over the driver and truck drop pits. There is some difference of opinion regarding the advantages of the lean-to style of construction but it is undoubtedly a cheaper construction than if the trusses had been carried the full width of the house.

In but comparatively few instances have the reinforced concrete houses, which are now being quite generally used, followed the same section as the wooden frame roundhouses. Generally speaking, however, they have been of the monitor-type construction, varying principally in the number and spacing of the columns. For instance, Philadelphia & Reading has built a house of three-bay construction, two low bays on each side of a monitor section. The interior columns are all structural steel encased in concrete. The reason for adopting this type of column was to permit the installation of a jib crane. The roof is a combination floor tile, T-beam construction to form an insulating medium against temperature changes and condensation. All sashes are of steel with pivoted ventilating sections. As an aid in ventilation, five permanent slot openings were provided at the ceiling line between each set of columns in both sides of the monitor and through the back wall. In addition, of course, there is the smoke jack and the opening around it.

I believe the first instance where a bridge crane was installed in a roundhouse was that in one built by the Baldwin Locomotive Company at Philadelphia. This was built for repairing locomotives, and is equipped with two cranes, the larger of which is of 50 tons capacity. Among the first of the bridge crane types of houses built by a railroad was that of the Pennsylvania Railroad at Altoona, Pa. It was constructed in 1902 and consists of 52 stalls, handling an average of between 250 and 350 locomotives daily. The head room in the crane section is about 30 ft. and the crane capacity is 12½ tons It is interesting to note that an analysis of roundhouse crane requirements on the Pennsylvania Railroad made recently developed the fact that the maximum load that a crane would be required to handle was about 8½ tons. This meant that a 10-ton crane would be adequate for all purposes.

Another house along similar lines, and one which has been described quite frequently in technical journals, and railroad engineers' hand-books is that of the Western Maryland at Hagerstown, Md. This house is a steel frame construction, encased in concrete. Woven wire mesh was wrapped about the steel, and the concrete put in place by the Gunite system. The roof slab is 3-in. concrete with Hyrib reinforcing. It is of double monitor construction, permitting daylight to enter at three points in addition to the back wall. In connection with steel frame houses, I would call your attention to the fact that built-up columns, girders of heavy section, are being used as the frame in the new houses recently built by the Pittsburgh & Lake Erie. This company believes that if proper attention is given to the painting of these steel frames an unusually long life may be obtained from them.

The type of house recommended where repairs are light has a reinforced concrete frame with a column spacing that results in economical concrete beam construction. The roof slab is flat on the under side, and is formed with 8 in. by 24 in. floor tile, and 4 in. concrete T-beams. This provides an insulated roof and one which is just as cheap to construct as the plain slab. The location of the monitor windows is such that it will throw daylight into the working area. In addition, the sash area in the lean-to at the back of the house is large. Provision has been made for omitting one set of columns in the drop pit section. This is done to provide a clear floor area between the pits for removing wheels from the drop pits to the back of the house. Permanent openings 4 in. by 18 in. in section at the front and rear of the monitor and just below the roof slab will take off the gases which collect at those points.

So far as we can learn, the life of steel sash in a roundhouse is somewhat longer than of wooden sash in the same location, and it is just about as cheap. If it is kept well painted, steel sash has the additional advantage of not swelling under excessive moisture, and therefore the ventilators can be just as readily operated in the winter months as in the summer.

In houses where heavy repairs are made a crane of approximately 50 ft. span should be provided which, with a slight shifting of the locomotive, will reach any of the heavy repair parts which have to be handled. The height of the crane rail should be 26 ft. 6 in. above the floor line, which is sufficient to permit of the crane removing the cab without striking other parts of the locomotive. This height also greatly facilitates all crane movements. In a house with a craneway the objection may be raised that the crane installation does not permit the installation of the usual smoke jack. It has been found in houses of this section that the high monitor and the installation of a large ventilator or jack in the roof over each stall does not result in an objectionable accumulation of gases and smoke. In the winter time, and even in the summer, the fan in the hot blast heating system can be kept running to force out the gases.

I also want to call attention to the growing tendency to substitute the electric hoist for the truck and driver drop pit. In addition to reducing liability of accidents it removes wheels more quickly and cheaply. While this hoist is sometimes installed in the roundhouse, its proper location is in the back shop.

Serious objection to the drop pit has developed in recent years, owing to the extremely heavy locomotives and to the declining quality of roundhouse help. While accidents due to jacking up the locomotives for the removal of wheels do not occur frequently, there is always the liability, and it has greatly increased because of the failure to obtain intelligent labor.

Two types of roundhouse doors are quite generally used—a two-leaf steel-frame, wooden swinging door, and a rolling wood slat door. The former is the most popular because repairs are more readily made. The question is frequently raised whether or not it is desirable to provide sash in the door or in a transom over the door. Sash in the door permits lowering the roof level, but to some it is objectionable because the rough usage results in frequently broken glass. Daylight at the front of the house is not so essential, and all that is really needed may be had through small transom sash. On the other hand, it has been found that most of the blows which would break the glass in the door would break a wooden panel, and the glass is more readily replaced than the wood. For that reason, the glass area in the doors is made quite liberal in the roundhouses built by a number of roads.

Another tendency in roundhouse design and construction which has come into more general use in the past few years is the substitution of the hot blast heating system for the pipe coils or other forms of direct radiation. A hot blast heating system installation costs very little more than a direct system, and it has the additional advantage of providing forced ventilation in the house, which is often very necessary. At first the selection of too low fan and radiation capacity resulted in the indirect system being unsatisfactory. This has been corrected, and the fan may be speeded up in extremely cold weather to raise the temperature for thawing out frozen locomotives quickly.

TYPES OF VALVE GEAR ON FRENCH LOCOMOTIVES

BY W. G. LANDON

Various complicated arrangements of the Walschaert valve gear, all of which are in regular use on many French locomotives, are shown in the sketches. They are a further illustration of the difference between the French and American points of view and consequently the difficulty of making American equipment popular in France.

Fig. 1 shows a gear fitted to a large number of 4-4-0

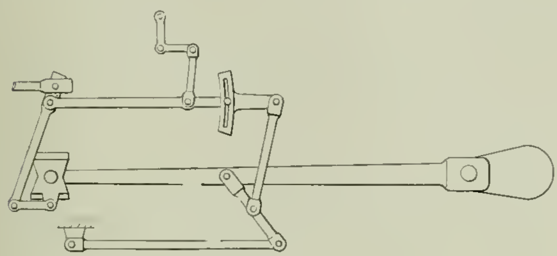


Fig. 1—Valve Gear as Applied to Etat 4-4-0 Type

engines built over twenty years ago for the Ouest (now Etat). It will be seen that a projecting arm from the link is actuated by a portion of the Joy gear. This gives a rapid valve travel at the beginning of the stroke, and the valve movement is perhaps more nearly theoretically correct

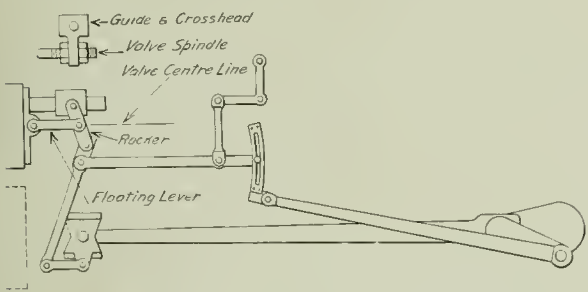

Fig. 2—Valve Gear as Applied to Etat 4-6-0 Type

than if the link were actuated by an eccentric. It would seem, however, that there are the disadvantages of the Joy gear (distortion from vertical movement of axle) plus a lot of extra parts. The driving wheels on this class of engine

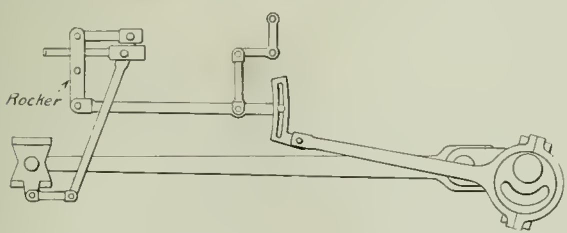

Fig. 3—Valve Gear as Applied to P. L. M. 4-6-0 Type

are equalized, but no trouble is experienced by valves getting out of square once they have been set for normal axle position.

Fig. 2 shows the evils of standardization. When a 4-6-0 superheater class engine was brought out on the Etat, the valve gear was made standard with that on the saturated engines, which have outside admission valves. The superheater engines have inside admission valves so a rocker arm was put in to make the gear distribute properly for inside admission. It will be seen that the thrust from the rocker is not in line with the valve center, and it is difficult to see anything but disadvantages either from a theoretical or practical standpoint. This arrangement is also used on the Nord.

Fig. 3 shows the valve gear on l.p. (inside) cylinders of

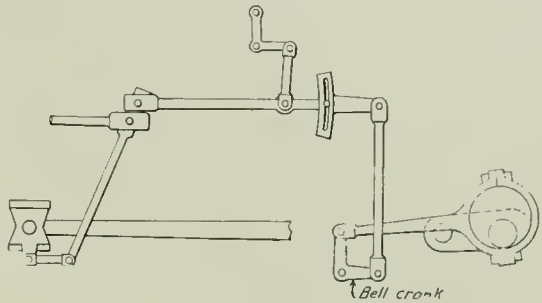

Fig. 4—Valve Gear as Applied to P. L. M. 4-8-0 Type

4-6-0 class on the Paris, Lyons & Meriterranean. The reason for the arrangement apparently was the fact that the links would not clear the bottom of the boiler. Other and simpler solutions of the problem would not, however, be hard to find.

Fig. 4 shows the gear on l.p. (inside) cylinders on 4-8-0 class, Paris, Lyons & Mediterranean. The object of this detour from eccentric to link the writer could not fathom.

PULVERIZED FUEL

At the annual convention of the International Railway Fuel Association held in Chicago, May 19-22, 1919, the Committee on Pulverized Fuel presented a progress report which consisted of the summary of some of the results obtained with pulverized coal with comments and suggestions. An abstract of the report follows:

Results obtained from tests brought out the following points: (a) A saving of 23 per cent in fuel could be made by burning pulverized coal. The main difficulties were the slagging over of the flue sheet and burning out of the brick arch. The slagging was largely overcome by an air jet to blow off the slag accumulations, but it was found impossible to overcome the rapid burning out of the brick arch. The cost of replacing the arch brick largely overcame the saving in fuel. The delay to locomotive was also a decided drawback.

"A comparison of costs of hand firing versus pulverized coal showed the hand firing to be most economical. It is thought possible to design a firebox that will eliminate such troubles as burning out of the brick arch and show an advantage in favor of the pulverized coal."

(b) "Burning 60 per cent anthracite and 40 per cent bituminous pulverized fuel gave all the steam that was wanted with splendid control.

(c) "The burning of pulverized coal in a locomotive was quite easy and satisfactory. The difficulties were with drying, pulverizing and handling the coal, and also the danger in connection with it. Locomotives equipped to burn pulverized coal would be tied up were the pulverizing plant to be burned or otherwise made inoperative."

One foreign railroad, the "Central Railway of Brazil," has made marked progress in burning pulverized coal. (See *Railway Age*, Oct. 26, 1917, page 767.)

Many pulverized fuel installations in stationary plants are reported as successfully burning various coals in pulverized form. A southwestern railroad reports: "Our stationary boiler plant that used pulverized fuel has been compelled to use a considerable amount of oil on acocunt of breakdowns and other troubles. We have had very little service on two boilers because of overhauling and remodeling of the fuel equipment. We kept the plant going on pulverized coal most of the time, but it has been a forced proposition."

The following conclusions may be deduced: The art of burning pulverized coal has shown marked progress; the experimental work has demonstrated the soundness of the principle of burning coal in a finely divided form in suspension, and that complete commercial success depends upon the careful working out of such details as proper fineness of the various grades of coals and economical and efficient methods and apparatus for preparing, storing and transporting the pulverized coal to the stationary plant or locomotive furnace. The tendency of explosion and spontaneous combustion should be eliminated entirely if possible to do so. The reabsorption of moisture will always be a problem in climates having extreme variations of temperature and humidity. It seems advisable to give more careful consideration to the steam locomotive as it exists today. A pulverizing and stoking device might be arranged that would prepare any grade of coal on the tender and deliver it to the firebox in the pulverized form, thus eliminating the expense of repairing and transporting pulverized coal from a central plant. Many of the universities have very thoroughly equipped laboratories that we are not using to a sufficient extent. It is suggested that in view of the immense supply of bituminous, lignite and other grades of coals adapted to the pulverized method of burning, the railroads, with the assistance of manufacturers and universities, make conclusive and exhaustive tests to develop the methods and apparatus necessary to meet the very urgent demands for more economical burning of coal.

The report was signed by W. J. Bohan (N. P.), chairman; H. T. Bentley (C. & N. W.), H. B. Brown (L. V.), R. R. Hibben (M., K. & T.), D. R. MacBain (N. Y. C.), J. H. Manning (D. & H.), H. C. Oviatt (N. Y., N. H. & H.), John Purcell (A., T. & S. F.), and L. R. Pyle (U. S. R. A.).

DISCUSSION

J. E. Muhlfeld (Pulverized Fuel Equipment Corporation) in a written discussion took issue with some of the statements in the committee's report. He asserted that the practicability of burning powdered coal had been established, and that it was necessary to develop it in order to increase the efficiency and capacity of the locomotive, to decrease the cost of fuel, to permit of using coal of poor quality and to eliminate smoke and soot. A. G. Kinyon (Fuller Engineering Company) submitted records of installations and reports of tests showing the high efficiency of boilers fired in this manner. Several speakers called attention to the fact that troubles similar to those experienced with pulverized fuel had been encountered in the period of development of practically all the accessories used on locomotives. M. C. M. Hatch (Pulverized Fuel Equipment Corporation) expressed the opinion that the crux of the matter lay in the design of a locomotive furnace. Large furnace volume is needed for burning pulverized fuel and no locomotive has yet been built with the proper design of furnace for this fuel. Where proper care is taken in designing the furnace, stationary installations are uniformly successful.

The association decided to ask the co-operation of Purdue University, the University of Illinois and the Bureau of Mines to solve the problem of burning pulverized coal.

LOCOMOTIVE FUEL LOSSES AT TERMINALS*

BY J. M. NICHOLSON
Fuel Supervisor, Atchison, Topeka & Santa Fe

The fuel consumed by locomotives while in terminals is an incident of operation which requires a variable amount of fuel and has been given too little consideration for the quantity involved. The engineer and fireman, who are with the locomotive while from 75 to 90 per cent of the fuel is burned, have been charged with being very wasteful. The remaining 10 to 25 per cent is burned at the terminal in getting the locomotive ready for service and taking it to the enginehouse, much of which is the result of wasteful methods and practices.

Locomotives must be moved from yards to cinder pits, have the fires knocked, and be put in the house in order that necessary repairs can be made. They must be fired up and tests of locomotive auxiliary appliances properly made, after which they must be moved from the roundhouse to the train. These essential activities of operation require the use of fuel, but the fuel used in addition to that required for these purposes must be considered as waste.

When a locomotive is brought to a terminal the fire should be burned down to such a point that it will not be necessary to rebuild the fire in order to get the water level in the boiler to the proper height before knocking the fire. The dampers on oil burning locomotives and also coal burning locomotives, so equipped, should be closed as soon as the work at the cinder pit is completed and the blower shut off to reduce circulation of air through the boiler.

The roundhouse capacity should be such that no delay will be caused in getting the locomotive into the house. When a locomotive reaches the house a competent inspector should enter the firebox and see that the flues are clean and free from leaks. The arches must be clean and in repair. The grates must be thoroughly cleaned, and grates having broken fingers or excessive openings repaired or removed. The ash pans must be thoroughly cleaned and special attention given to see that the air opening under the mudring is cleaned. The front end should be inspected to see that it is self-cleaning and that it is free from air leaks.

As soon as the boiler and grate work is completed the grates should be bedded down with from three to four inches of coal evenly distributed over the entire grate area. The coal which falls through while bedding down the grates should be reclaimed. Tests show the coal reclaimed will vary from 80 to 200 lb. per locomotive, depending on the size of coal used and the amount of surface moisture on the coal. The coal can be reclaimed by collecting it in a bag fastened to the ash pan slide and removing the bag as soon as the grates are bedded down, or at larger terminals a pit on the outgoing track can be used for dumping this coal and conveying it into the car. A terminal handling 50 locomotives per day will conserve from 50 to 100 tons per month by reclaiming this coal.

In case the boiler is to be washed, the heat in the boiler is entirely wasted unless the roundhouse is equipped with a hot water boiler wash-out system. A plant of sufficient capacity, if properly maintained and operated, will reduce the time consumed in the operations of washing the boiler from 25 to 50 per cent and reduce the amount of fuel used in firing up from 25 to 30 per cent. The saving of from two to three hours' time in getting the locomotive back in service

*Abstract of a paper presented before the International Railway Fuel Association convention at Chicago, May 19-22, 1919.

is an important factor under present operating conditions, as is also the saving of from 600 to 700 lb. of coal per locomotive.

In many cases where boilers are not due to be washed out engines are allowed to stand in the roundhouse twelve to fifteen hours before the time set for the locomotive to leave the roundhouse. During this time the heat in the boiler has been passed out through the stack unless a stack cover is used or the dampers closed to prevent circulation of air through the boiler. This heat waste can be found in practically every roundhouse, and results in several tons of coal per locomotive being wasted each month. The time required to furnish a locomotive is greatly influenced by the pressure maintained in the roundhouse blower steam line. Insufficient pressure results in the use of more coal in firing up a locomotive and decreases operating efficiency. The use of old ties, old car material, shavings, etc., will reduce the amount of coal consumed and should be used where practical.

The chief despatcher should furnish the roundhouse foreman with a list of trains that he expects to run and the roundhouse foreman should furnish the despatcher with a list of locomotives he expects to have ready. The exchange of these lists three times in twenty-four hours is advisable, after which the locomotives should be ordered for a scheduled leaving time, giving the roundhouse the necessary time to fire up the locomotive and call the engine crew. This will avoid holding locomotives under steam in cases where trains are set back or cannot be run according to the line-up. In cases where locomotives are fired up as soon as the work is completed and allowed to stand under steam for seven hours, the fuel wasted is equal to the amount of fuel that is necessary to furnish the locomotive for service. This is not an uncommon occurrence where despatching schedules are not in effect and where they are not given close supervision.

The wages paid for one hour's terminal delay on a freight train is a loss equivalent to the cost of one ton of coal, also eight locomotive hours under steam in addition to the time actually necessary to get the locomotive ready for service is a loss equal to the value of a ton of coal. Every locomotive on a division is burning some fuel at the terminals that is unnecessary, and many locomotives are burning before each trip fuel of greater value than the loss of wages paid for one hour's terminal delay. If this loss were given as close supervision as is given the wages paid for terminal delay, the cost of transportation would be reduced. Superintendents should know personally that locomotives are not being held under steam unnecessarily on their division and also that co-operation in the despatching of locomotives does exist.

The fuel that is consumed as a result of lack of facilities for handling is a costly proposition, and adequate roundhouse and shop facilities should be provided. Repairs to turntables, roundhouses, coal chutes and tracks at the terminal should be made before cold weather sets in, as it may result in congested single track movement at coal chutes and cinder pits or tie up the entire roundhouse, all of which wastes fuel. Proper care of a fire in the roundhouse contributes to economic locomotive performance on the road and also reduces the amount of fuel used at the terminal. The locomotive appliances should be tested out before leaving the roundhouse for the train to see that they are in the best possible condition to do their work, which means a saving of fuel on the road that, in most cases, cannot be accomplished after leaving the terminal. The train line leakage should be determined and the leaks repaired at the terminal. Train line air leaks cost a railroad company much more than it costs to repair them.

Locomotives should be maintained to prevent serious steam, air and water leaks. Throttles leaking, pops leaking and air pumps running in the house are to be avoided. All of the operations at a roundhouse contribute to fuel economy, and men should be impressed with the fact that neglect on their part often results in a waste of fuel greater than their day's wages before the locomotive reaches the next terminal where proper repairs can be made.

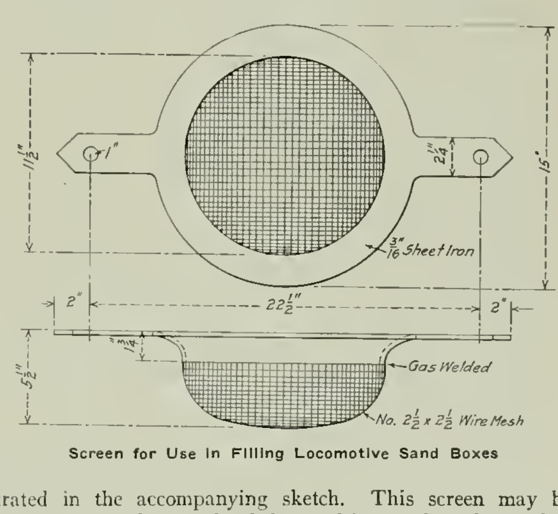
The amount of coal required for the period of firing up a locomotive and getting it ready for service under careful handling should be determined. The actual consumption against the required consumption is the fuel efficiency of the despatchers and the roundhouse organization. This efficiency is not a maximum, even on the best managed and best equipped roads. The magnitude of the amount of fuel involved in these losses should provide a strong incentive to renewed effort in fuel conservation as these conditions of fuel waste are decreasing operating efficiency and increasing the cost of transportation.

A LOCOMOTIVE SAND BOX SCREEN

BY A. P. JANDER
General Foreman, A. T. & S. F., Hutchinson, Kans.

A source of great annoyance in the roundhouse and on the road is the stoppage of the pipes and traps of the locomotive sanding apparatus. A properly working sanding apparatus is especially to be desired in bad weather as great harm is often done to an engine through the failure of the sanding equipment to work properly at a critical time, and in addition the delays occasioned by the failure of this apparatus frequently have serious results.

In drying and screening sand at the sand house all foreign matter is not always removed and this getting into the sand box eventually chokes the sand pipe so that the apparatus will not operate in a satisfactory manner. To overcome this trouble the writer has designed a sand box screen as illustrated in the accompanying sketch. This screen may be adjusted over the mouth of the sand box and as the sand is poured in, the screen is turned slightly, thus permitting the clean, fine sand to enter the box, but excluding all stones and foreign matter. Two of these screens kept in a convenient place, one on each side of the sandhouse, so that they may be used when filling the sand boxes of locomotives, will eliminate a great deal of the trouble experienced on the road. The expense of making the screens and the time required for their operation is so small that it need not be considered. An engine can be as easily and as quickly sanded with these screens as without them and if made of proper material, they are practically indestructible.



Screen for Use in Filling Locomotive Sand Boxes

RAILROAD ADMINISTRATION NEWS

Enlargement of the Board of Railroad Wages and Working Conditions from six to twelve members is under consideration. Such an enlargement has been proposed by the labor board. It is proposed to add a representative of the engineers, clerks and maintenance of way employees and three more officials.

A NATIONAL "DRIVE" FOR SAFETY

Walker D. Hines, director general of railroads, announces that a "National Railroad Accident Prevention Drive" will be started on October 18 at 12:01 a. m. and will be continued until October 31 at midnight, to be conducted under the supervision of the Safety Section. A circular, sent to the regional directors, calls for their co-operation. All officers and employees are expected to give their hearty support.

This drive follows the very satisfactory results of certain "no accident campaigns" already carried out. The results of these campaigns are summarized as follows:

Region	Total No. of employees	Casualties, 1919	Casualties, 1918
Southern, January 19-25	230,000	77	466
Southwestern. May 1-31	174,884	646	1,475
Central Western, June 22-29	327,000	100	456
Northwestern June 22-29	274,224	119	481

In the Southern region 28 out of 45 railroads reported no accidents; in the Southwestern region 12 roads were in this class, in the Central Western 47 out of 67 and in the Northwestern 50 out of 63, showed clear records.

FIREMEN DEMAND MECHANICAL STOKERS AND WAGE INCREASE

In order to meet the high cost of living the Brotherhood of Locomotive Firemen and Enginemen has decided that its members must have not only a large increase in wages, estimated at 35 to 65 per cent, but also the assistance of mechanical stokers on engines weighing over 200,000 lb., mechanical coal passers on locomotives of less weight, and power grate shakers and fire door openers on all locomotives.

The demands are as follows: Firemen and helpers in passenger service, $6.50 a day of 5 hours or less, 100 miles or less (Mallet locomotives, $7.20); through freight service on locomotives weighing less than 200,000 lb., $6.50 a day for 8 hours or less, 100 miles or less, on locomotives weighing over 200,000 lb., $6.80; local or way freight service, mixed trains, mine runs, etc., minimum of 50 cents per 100 miles or less in addition to through freight rates; helper, pusher, transfer, work, wreck, construction, snow plow, circus, milk and unclassified service, through freight rates; yard service, $6.50 (Mallet $6.80), on Mallet locomotives in all except yard service, $7.20 a day; inside hostlers, $6.80 a day; outside hostlers, $7.20; hostler's helpers, $6.50, eight hours or less; all coal burning locomotives to be equipped with power grate shakers and automatic fire door openers. All coal-burning locomotives in road service weighing over 200,000 lb., to be equipped with mechanical stokers and two firemen to be employed on each engine until so equipped. All locomotives weighing less than 200,000 lb. to be equipped with coal passers. Firemen to be relieved of cleaning locomotives, removing tools or supplies, loading coal, filling lubricators, etc.

ROADS CO-OPERATE WITH VOCATIONAL EDUCATION BOARD

W. T. Tyler, director of the Division of Operation, and W. S. Carter, director of the Division of Labor, have issued the following joint circular authorizing co-operation by the railroads in the establishment of part-time schools for railroad apprentices and others:

"The Federal Government has created under the provisions of an act of Congress, approved February 23, 1917, a Federal Board for Vocational Education.

"The purpose of this act is to provide for the promotion of vocational education in the trades and industries and in agriculture in co-operation with the various states, and an appropriation by the Federal Government is available for such work.

"The value of vocational training for mechanics and apprentices in railroad shops has been recognized by many railroads which have established schools for the training of such men. It is the desire of the Railroad Administration not only to assist and encourage such training where established, but also to extend the system to roads which have not established such schools, and it is believed that this can be best accomplished by co-operation between the United States Railroad Administration and the Federal Board for Vocational Education in extending this work.

"It is therefore desired that the different railroads under control of the United States Railroad Administration co-operate with the Federal Board for Vocational Education in the establishment of part-time schools for railroad shop apprentices and others who come within the scope of the act. Where it is found necessary in order to facilitate this work, railroads will be authorized on request, to fit up suitable study or class rooms at the different shops where such schools may be held. Where such schools are established, railroads will be authorized to pay apprentices at their usual rate for the time spent in attending such schools.

"Apprentices on roads where such schools are established will be required to attend not less than 208 hours per year.

"Complete information concerning the establishment of these schools in co-operation with the Federal Board for Vocational Education may be obtained either from the board direct or from the assistant director, Division of Operation, in charge of the Mechanical Department.

"In the preparation of a course of study, due attention must be given to meet the needs of railway shop employees, and such subjects as shop practice involving the manipulation of machines used in general repair and construction work and to related science, mathematics and drawings should be fully provided for.

"To provide uniformity as far as practicable in these courses of study, the subjects embraced therein should be submitted to the assistant director, Division of Operation, in charge of the Mechanical Department, for approval."

ORDERS OF REGIONAL DIRECTORS

Safety Chains on End Doors.—Order 227 of the Southwestern regional director promulgates a note from the Safety Section of the Railroad Administration recommending that chains or some other suitable device be applied on automobile cars with end doors to prevent these doors from opening further outward than the line of the side of the car; and gives instructions to have cars in this region so equipped as rapidly as possible.

Freight Car Distribution—Circular 27.—The Southwestern regional director in Circular 234 states that the provisions of Division of Operation Circular 27 with respect to returning cars to owners for repairs appear to have been more broadly construed than was intended. Cars have been sent long distances home for comparatively light repairs. The purpose of this circular was to put into effect former M. C. B. requirements for the return of cars to owning lines for repairs and in addition the circular was intended to provide a means for the owners to get their cars home when desired for rebuilding or for the application of betterments. It was not desired that the cars should be sent home involving an intermediate line haul except for "rebuilding or for the application of betterments" as provided in paragraph C of the circular, in which case arrangements should be made for this movement in accordance with paragraph 6.

STEAM HOSE FOR CAR HEATING*

BY H. J. FORCE

The object of this paper is to describe briefly a process of manufacture of steam hose for car heating which will neither contract nor expand when in service.

TABLE I—DESCRIPTION OF MANUFACTURE OF FOUR KINDS OF STEAM HOSE

Serial	Tube	Thickness, in.	Duck	Friction	First ply of gum to anchor braiding	First ply braiding	Second ply of gum to anchor braiding	Second ply braiding	Outside cover
P......	Special steam resisting hose.	1/8	2 ply, not under 23 oz. per sq. yd.	Heavy coated special steam resisting.	1/16 in. thick, special steam resisting.	No. 8/3 yarn in 5 by 5 strands.	1/32 in. thick, special steam resisting.	No. 8/3 yarn in 5 by 5 strands.	1/32 in. special steam resisting.
Q......	Regular specification steam hose.	1/8	Same as P.	Heavy coated regular specification steam resisting.	1/16 in. thick, regular specification steam resisting.	Same as P.	1/32 in. thick, regular specification steam resisting.	Same as P.	1/32 in. regular specification steam resisting.
R......	Regular specification steam hose.	5/32	Same as P.	Same as Q.	Same as Q.	Same as P.	Same as Q.	Same as P.	Same as Q.
S......	Regular specification steam hose.	5/32	3 ply, not under 23 oz. per sq. yd.	Same as Q.	Same as Q.	Same as P.	Same as Q.	Same as P.	Same as Q.

When made from duck alone, steam hose has been found to contract to such an extent in service that in some cases it becomes uncoupled when passing around a short curve.

	After steaming...	70	65
Time required to burst under 60 lb., hours	Before steaming..	...	...
	After steaming...	525	840

Again, the failure of steam hose in many cases has been traced directly to the excessive expansion which takes place after the hose has been in service for some time. This expansion frequently results in the hose blowing off from the coupling, requiring the use of a special clamp to hold the hose on the coupling.

After making a series of tests, it was decided to build a hose of duck with a heavy friction, and then one or more layers of braiding. If made from duck alone, hose will expand excessively. It is impracticable to make it from braiding alone, but with a combination of duck and braiding a very satisfactory grade of steam hose can be produced which will show no contraction in length and no expansion in diameter under the most severe service conditions.

Table I gives a general description of the process of manufacture of four hose designated as Serials P, Q, R and S.

In Table II are given results of tests to destruction of two samples of steam hose of Serial P. In this hose a special steam-resisting compound was used for the inner tube which was not looked upon favorably by the manufacturer.

In Table III are given the results of tests on ten samples of hose of Serial Q. This hose is similar to that of Serial P except that the regular specification tube was used which had been found to give fairly satisfactory results in service. Aside from this Serials P and Q are of the same composition. The samples of Serial Q, after steaming, withstood a pressure of 60 lb. for about 700 hours, on the average, before bursting.

In the hose of Serial R, the manufacturer endeavored to

*A paper presented before the convention of the American Society for Testing Materials at Atlantic City, June 24-27, 1919.

increase the thickness of the inner tube. Results of tests of this hose are given in Table IV. In some of the lengths of hose tested after steaming, there was an apparent increase in thickness over that of the measured sample, as compared with Serials P and Q, although these too vary considerably showing that the tubes in many cases were undoubtedly not uniform in thickness, at least at various places in the tube. The results of tests on steaming were practically the same as those in Serials P and Q.

In the hose of Serial S the number of plies of duck was increased from two to three, and this apparently had the effect of nearly doubling the life of the hose. It will be noted from Table V that samples Nos. 5 and 6 of this hose burst under 60 lb. pressure, after steaming, in 770 and 800 hours respectively, and that samples Nos. 8 and 10 withstood this pressure about the same number of hours; while samples Nos. 4 and 9 stood up for approximately 1500 hours. A careful investigation of the inner tube revealed the fact that several of these samples were defective. Pieces of wood were found embedded in the inner tube which measured ¼ in. wide, ⅛ in. thick by ½ in. long. The addition of this foreign matter to the rubber compound without a question of doubt caused the failure of samples Nos. 5, 6, 8 and 10, and this is primarily due to the use of machine-made tubes.

It is recommended that in all steam hose or in any hose that is subjected to considerable temperature, a calendered-made tube composed of three distinct layers should be used. This will very materially reduce the chances of dirt or foreign matter getting mixed with the rubber compound, and should a small amount be present the other two calenders will undoubtedly preserve the life of the hose.

This investigation shows:

1. That steam hose should be made of a composition of duck and braid.

2. That machine-made tubes should not be used, and that tubing of three-ply calender should in every case be used in hose which is to be subjected to any considerable degree of temperature.

COLOR OF LOCOMOTIVES.—"Speaking of Chinese railroads reminds me of the failure of an American manufacturer to obtain a contract for locomotives because his European competitors made a more careful study of Chinese peculiarities," writes Lynn W. Meekins in the Scientific American. "One locomotive was ordered from each of the competing companies. In every respect save one the American product was unmistakably superior. However, it had been painted black before shipment from the works, and on the way across the Pacific it became more or less rusted. Its appearance, therefore, was far less attractive than that of the European locomotives, which were painted in accordance with Chinese preference, and had been touched up by the manufacturers' agents after arriving in China. Don't get your colors mixed if you want to sell goods to the Chinese."

PRICES AND PRODUCTION.—"Far more wealth is probably lost through restricted output than is claimed in increased wages," say the Times, London. "It is not certain at present how far the industries concerned can pay the advances of wages that are or will shortly be asked, but what is very certain is that these advances, if they are paid, will have to come mainly from increased production, the promotion of which is therefore of more use to workers than even the immediate grant of increased pay. What all parties to industry will be compelled by inevitable circumstances to realize is that no source exists to pay advanced wages or even to maintain employment except actual production."

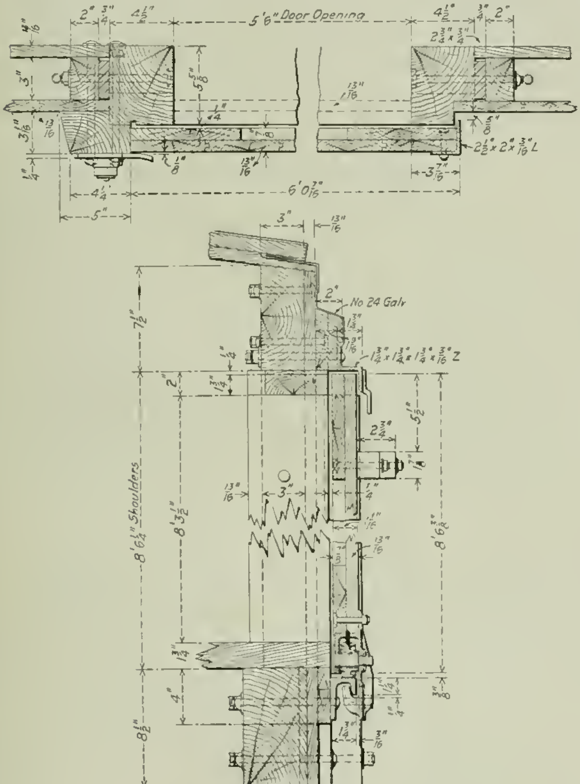
Box Cars Built by C. M. & St. P.

Underframe Has Steel Center Sill and Wooden Side Sills; Wooden Frame Body with Steel Ends

A 40-TON box car in which many interesting features have been incorporated has been designed by the Chicago, Milwaukee & St. Paul, and a lot of 1,000 is now being built in the company's shops at Milwaukee. The general outside dimensions of the car are as follows: length 42 ft. 1½ in.; height at eaves 13 ft. 2 in. and width at eaves 9 ft. 11 in. The inside of the body is 41 ft. 5½ in. long, 8 ft. 10⅜ in. wide, 9 ft. 1⅞ in. high at the center and 8 ft. 8⅝ in. high at the sides with a door opening 8 ft. 2¼ in. high. The cubical capacity of the car is 3,267 cu. ft.

UNDERFRAME

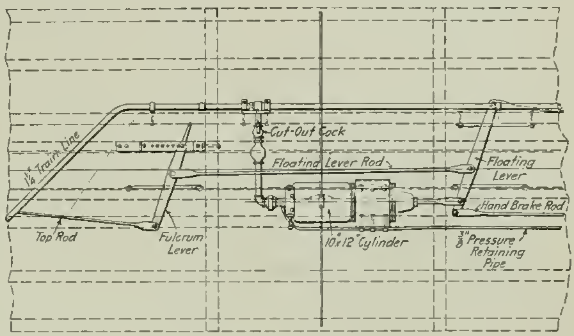
The underframe is made up of a steel center sill with three wooden sills and three truss rods on each side. The center



Details of the Door Construction

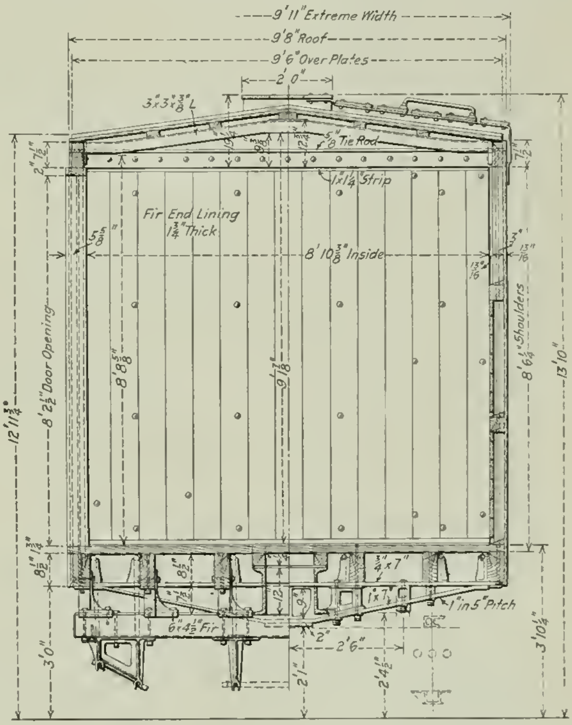
sill consists of two 12-in. 40-lb. channels 43 ft. long with a ¼-in. by 20-in. cover plate extending practically the full length on top of the sill. A double body bolster of the built-up type is used. The top chord members are ¾ in. by 7 in. and pass through the center sill channels near the neutral axis and over a combined filler and center plate casting. The bottom bolster members are 1 in. by 7 in. and pass under the center casting. Malleable iron fillers are bolted between the two members at each intermediate sill and also at the side bearings.

The end sill is of wood, 6½ in. wide by 8½ in. high. It is cut out to a height of 3¾ in. where it passes over the center sill. Two nailing strips 3¾ in. high are bolted along each side of the center sill. With the four intermediate and two side sills, there are eight points of support for the floor boards.



Foundation Brake Arrangement of the C. M. & St. P. Box Car

The sills are all 8½ in. high, the width of the intermediate sills being 4 in. and of the side sills 4½ in. The truss rods are 1¼ in. in diameter, with ends upset to 1½ in. The needle

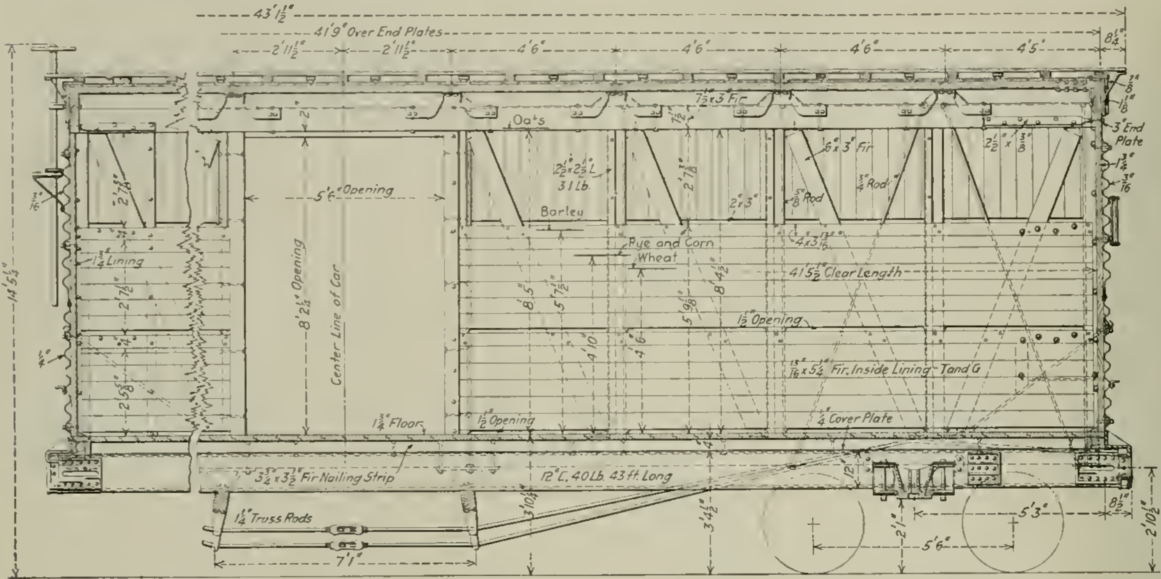


Half Sections of the C. M. & St. P. Double Sheathed Box Car

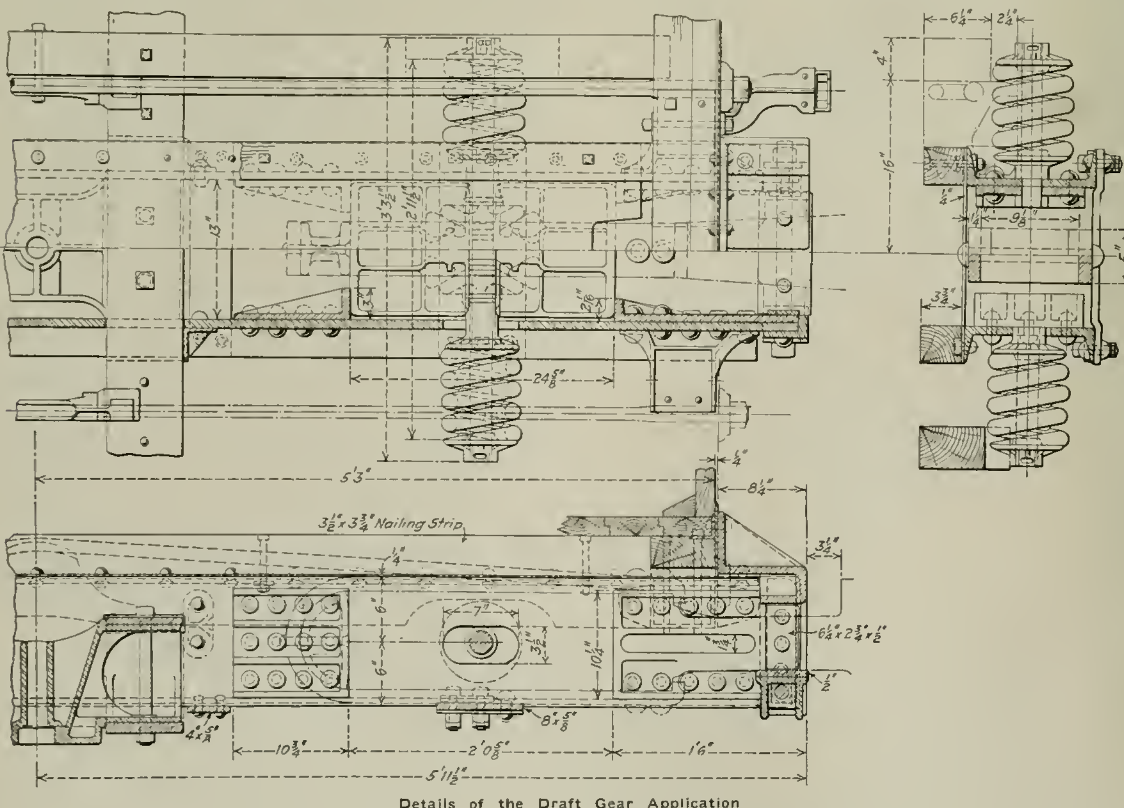
beams are secured to substantial spacing castings attached to the bottom of the sills.

The draft gear is of the Cardwell friction type. One of the illustrations shows the details of the application. A coupler with a 5-in. by 7-in. shank is used, but slots for a coupler key are provided in the sills.

The side trusses are made up of 6-in. by 3-in. posts and braces, each vertical post being reinforced by a 2½-in. by 2½-in. angle iron, weighing 3.1 lb. per ft. The door posts are made up of a 4½-in. by 5⅝-in. and a 2-in. by 3-in. post with a 2¾-in. by ¾-in. wrought iron strip between. These parts are bolted together and the front door post is further reinforced by the door stop. The side plate is 7½-in. by 3-in. There are two belt rails 4 in. by 3 13/16 in. located 2 ft. 5⅝ in. and 5 ft. 5⅛ in. from the floor. The flooring is 1¾ in. thick, the inner and outer sheathing are 13/16 in.



Longitudinal Section Showing the Arrangement of the Body Framing



Details of the Draft Gear Application

The ends are of the Murphy two-piece type, ¼-in. plates being used for the lower section and 3/16-in. plates for the upper. The lower plate extends down behind the striking casting and over the end sill and a 2½-in. by 2½-in. angle iron riveted to the plate sets into the upper face of the sill. This construction is clearly shown in the drawing of the draft rigging. Diagonal braces extend from the post pocket casting over the bolster to the top of the lower end section on each side. The end plate, to which the upper section is joined, is 3 in. thick and is fastened to the side plate with strap bolts. The end is lined with 1¾-in. matched boards placed vertically.

The roof is supported on Ideal carlines formed of two 3-in. by 3-in. by ⅜-in. angles, to which are bolted the wooden purlines and ridge pole. The roof is the Murphy type XLA flexible. The doors are of the bottom supported type with Camel door fixtures. Details of the construction at the doors are shown in one of the illustrations.

BRAKE SLACK ADJUSTER

An interesting detail of the brake rigging is the method employed for taking up the slack. No adjustment is provided in the bottom or top rods. Instead, the fulcrum lever is attached to a bracket which has several holes for adjusting the piston travel. The lever is provided with a handle and lettering on the side of the car calls attention to the fact that excessive travel is to be taken up at the fulcrum lever and not at the trucks. The convenience of this arrangement has proved of great assistance in eliminating excessive piston travel.

Maintenance of Freight Brakes

Summary of the Instructions to be Published for Distribution by the Air Brake Association

At the convention of the Air Brake Association held in Chicago May 6 to 9, 1919, a comprehensive set of instructions was presented to the association by Mark Purcell as a part of his paper on that subject. In the abstract of Mr. Purcell's paper, published in the *Railway Mechanical Engineer* for June, 1919, page 301, these instructions were not referred to in detail, and a summary of those of the greatest importance is here given.

The instructions outline the practice to be followed in cleaning and repairing air brake equipment on freight cars, and the association finally adopted them as recommended practice, to be published in pamphlet form for sale by the association, with the intention that they be distributed generally to air brake repairmen, foremen and others interested. Before final action to this effect was taken a spirited discussion took place on a number of the author's recommendations, which led to the appointment of a committee, including Mr. Purcell, to agree upon the proper instructions on the points in controversy, which were presented to the association for adoption.

GENERAL INSTRUCTIONS

The instructions specify that freight car brakes are to be cleaned on all repair and shop tracks that are equipped with air pressure for brake testing, and that they will not be cleaned at points where air pressure is not available. All cars marked for bad order triple valves or brake cylinders, or where brakes either will not apply or leak off, are to receive the same treatment as that required for brakes which are out of date. Repairs are to be made, whether their brakes are in date or out of date, on all cars with loose or missing pipe clamps, angle cocks or hose turned out of standard position, loose brake cylinders, auxiliary reservoirs and their supporting brackets, brake rods worn by contact with wheels or axles, and angle cocks which are non-standard in position.

Cars with brakes in date, that is, with a cleaning date less than nine months old, are first subjected to the brake pipe cleaning test, including the branch pipe, the triple valve and release valve. After brake pipe leaks have been remedied the piston travel is adjusted and the brake cylinder tested for leakage. The foundation brake gear is next tested and repairs made to insure that moving parts have ample clearance, that the parts are properly secured and that the levers are standard to the car. The retaining valve is also tested for leakage. If either the triple valve is changed or the cylinder cleaned, the car is considered the same as one with a brake out of date.

Out of date cars, that is, cars having cleaning dates nine months or more old, are treated as authorized for foreign cars by interchange rule No. 60.

PROCEDURE FOR VARIOUS OPERATIONS

The procedure to be followed in carrying out these general instructions is covered by detail instructions for the handling of each part. Only the more important items are referred to here.

Brake Pipe Leakage Test.—Close the branch pipe cut-out cock (except with in-date brakes), and having seen that the opposite angle cock is shut, couple the yard hose, preferably to the retaining valve end of the car, open the adjacent angle cock and charge the brake to 70 lb. Test for and repair leakage from the brake pipe and fittings up to the branch pipe cut-out cock. This includes hose coupling gaskets, leakage under the hose clamp, hose porosity, leakage around the angle cock key under the handle and also the threaded and gasket joints, including the main brake pipe union. With in-date brakes it also includes all of the branch pipe, the triple valve and the release valve. Open and close the angle cock and thereby blow out the brake pipe and the free hose. Listen at the coupler to detect angle cock leakage into the hose, and replace if defective. Then connect the dummy coupling to the hose, open the angle cock and complete the leakage test here. When inspecting for leakage use soap suds where temperature will permit. If connecting with the yard hose or the dummy coupling discloses bent hose couplings, or if hose couplings have broken stop pins, or are otherwise not fit for service, replace the hose.

Piston and Packing Cleaning.—Make certain that the rivets securing the piston to the rod are tight. Remove the packing expander. Turn the flange of the piston packing outward no more than just sufficient to clean the inside of the packing and inspect for cracks, cuts or thin spots that would warrant replacement. Avoid bending any packing more than necessary and clean both sides by dry wiping. If any scraping is necessary use only the dull round corner of the scraper. Kerosene, gasolene and other like mineral oils must not be applied to packing leather, because they remove the filler with which the leather packing is made air-tight, harden and crack the leather, and thus destroy its usefulness. Carefully inspect the piston packing, and if found cracked, cut or worn thin at any point or otherwise defective to cause leakage, replace it with a good one. Note the depression on the packing caused by the expander, as this will indicate any uneven bearing or an expander partly out of place.

Examine the follower for cracks, then measure its diameter, and if it is ¾ in. or more smaller than the rated diameter of the brake cylinder, replace it with one of standard size. If the packing appears good, tighten the follower plate nuts. These nuts sometimes loosen in service and this causes leakage. Clean the joint and flanged portion of the non-pressure head which bolts to the brake cylinder.

Where facilities or conditions will permit, the brake cylinder piston should be removed and taken to a suitable room and cleaned, then tested in a cylinder especially provided for the purpose, this to be followed by the specified test after the piston has been reapplied to the car.

Cylinder Lubrication.—Using the grease brush provided, apply a very thin, uniform coating of standard brake cylinder lubricant to the entire inner surface of the barrel of the brake cylinder, but do not apply any to the piston packing.

Brake Cylinder Reservoirs Loose on Their Supports.—If the brake cylinder moves during application or release, or if any of the cylinder or reservoir bolts are loose or gone, or lock nuts missing, needed repairs must be made by the brake cleaners unless this work has been assigned to other workmen. In this case brake cleaners will not report the brake in good order until any necessary repairs have been completed. One man can observe for movement of the brake cylinder and reservoir and brackets by bleeding off the brakes.

Brake Cylinder Leakage Test.—Use the air gage to test for brake cylinder leakage. With brakes that have just been cleaned, connect the gage to the retaining valve if the latter is the improved type, having the exhaust port threaded for this purpose. On high cars use the ¼-in. hose for making this connection. If the retaining valve is of the weight type, attach the gage to the triple valve exhaust port. In testing in-date brakes, the gage may be attached to the triple valve exhaust port in all cases. Always insure that the plug in the unused exhaust port is tight.

With the brake charged to 70 lb., see that the test gage cock is closed. Apply with a service reduction of 20 lb. and release the triple valve so that the test gage will thereby be connected with the brake cylinder and show the pressure in it. A cylinder pressure of 50 lb. must be obtained before noting the leakage, if any. Try to avoid getting over 60 lb. With the pressure at 50 lb., note the loss of pressure during one minute. If the leakage exceeds 5 lb. per minute with a brake that has just been cleaned, the cause must be found and leakage reduced to not over 5 lb. If it exceeds 10 lb. with an in-date brake treat as an out of date brake—that is, thoroughly clean, repair and test—unless correcting leakage found in the cylinder pipe, cylinder head joint of detached equipment or cylinder head joint of combined equipment reduces the leakage to within the specified amount. The most common sources of brake cylinder leakage are the piston packing, the brake cylinder pressure head gasket, the bottom of the triple valve gasket and, with detached equipment, the pipe connecting the auxiliary reservoir and brake cylinder. With the test gage attached to the retaining valve the leakage may be in the retaining valve pipe.

If temperature will permit, apply soap suds around the piston rod next to the cylinder head. Leaking packing will usually be indicated by bubbles around the rod.

If the pressure rises during the brake cylinder leakage test there is leakage into the brake cylinder past the emergency valve, the check valve case gasket, the triple valve slide valve, the triple valve gasket or an end of the tube in the auxiliary reservoir. If the rise in brake cylinder pressure is three pounds or less per minute, repairs may be omitted, but if it exceeds three pounds, locate the cause and repair before continuing the test for brake cylinder leakage.

Retaining Valve and Pipe Tests.—Test the retaining valve pipe on cars which are fitted with retaining valves not provided with test gage connection or on all in-date brake cars. Turn up the retaining valve handle, charge the brake to 70 lb. and make a service application of 20 lb. Open the by-pass in the test hose attachment and, as soon as the triple valve moves to release position, start at the triple valve and quickly apply soap suds to all of the joints of the retaining valve pipe to determine whether they are tight. Repair any defects found and re-set, repeating until the pipe is tight.

To test the retaining valve pipe of cars just cleaned which are fitted with the improved retaining valves, the test gage will be connected to the retaining valve, and the retaining valve pipe may be tested simultaneously with the brake cylinder. Carefully inspect the retaining valve pipe and correct all leakage before condemning the cylinder packing.

After it has been determined that the retaining valve vent port is open, the retaining valve, when turned up, must hold enough pressure to prevent moving the brake shoes on the wheels with the foot within three minutes after the triple valve moves to release position on the brakes which have just been cleaned, and within 1½ minutes on brakes which have been tested only. It is permissible to jar the vertical section of the retaining valve pipe to aid the retaining valve in seating accurately. A special connection equipped with an air gage may be attached to the unused exhaust port of the triple and the retaining valve pipe pressure shown on the gage, in which case the leakage should not reduce the pressure below six pounds at the end of three minutes after releasing the brake for brakes just cleaned, or at the end of 1½ minutes for in-date brakes.

DISCUSSION

The provision in the cylinder test that newly cleaned cylinders do not exceed a leakage of five pounds per minute and, as recommended by the paper's author, but afterward modified, that on in-date cars the leakage does not exceed 10 lb. per minute for cars less than three months old and 15 lb. per minute for cars over three months old, led to considerable controversy and was quite generally discussed. Some of the members considered this test too severe, which the author of the paper admitted to be the case if the average condition of brake cylinders today were to be used as the basis of judgment. The consensus of opinion, however, was that the test was conservative, and a number of members objected to so liberal a leakage allowance for cars with the older cleaning date. Experience of railroads in various parts of the country indicated that a newly cleaned cylinder which meets the five-pound leakage requirement should be able to keep well within 10-lb. leakage throughout the period between cleaning dates. To accomplish this, however, the work must be properly done when the cylinder is cleaned, a defective leather must not be placed back in service, lubricants must be used very carefully in order to avoid the destruction of the leather filler, and attention must be given to insure against leakage around the follower studs. The necessity for the use of good leather and suitable lubricants was particularly emphasized by several members. The difficulty of getting work done of a quality which would reasonably insure the cylinders keeping within the 10-lb. leakage limit between cleanings as brought out in the discussion was from two causes: first, the difficulty of securing competent labor and of properly training men for this work, and, second, the lack of facilities in many places for properly testing packing leathers and pistons for leakage before replacing them in the cylinders under the cars. The printing in pamphlet form of the instructions in Mr. Purcell's paper for distribution among the foremen and workmen concerned, was suggested as a remedy for the first difficulty and action to that effect was finally taken by the association after several revisions had been made. The remedy for the second difficulty is the provision of facilities inside the shop for cleaning and testing brake cylinder piston and packing leathers. Proper cleaning and inspection of packing leathers and pistons is difficult in the yard in all kinds of weather.

The Safe Movement of Explosives*

Duties of Car Inspectors and Repairers in Respect to Shipments of Explosives and Inflammables

BY D. J. O'DEA
Inspector, Bureau of Explosives

THE safe transportation of explosives and other dangerous articles is a subject that has required the attention of various classes of railroad employees throughout the United States and Canada during the past ten years. It is a subject that will require constant attention just as long as such articles are transported, for the dangerous nature of these articles remains the same and they must be treated in the manner prescribed by the regulations if we are to guard against injuries to persons and the destruction of life and property.

Literature consisting of the regulations for the safe transportation of explosives and other dangerous articles, bulletin notices giving the details of accidents that have occurred from time to time through the violation of such regulations and pamphlets showing pictures and sketches of the proper and improper methods of loading and bracing explosives and other dangerous shipments, have been circulated for the use and guidance of railroad employees and shippers throughout the United States and Canada, at various times during the past ten years. This distribution of literature, also our lectures and inspections, has been for the purpose of educating all railroad employees who have anything to do with the transportation of explosives and other dangerous articles, and was occasioned by the numerous serious explosions, fires and casualties that occurred on railroads due primarily to the haphazard manner in which these life and property destroying shipments were handled by railroad men and others who had no suspicions of their dangerous nature. Such deplorable single accidents as that which cut off 23 lives, injured 80 persons and caused a financial loss of over one million dollars, naturally caused public consternation and consequent alarm for the future, as similar explosions were bound to continue with the constant increase in the shipping of such dangerous articles, if uniform and stringent measures for their prevention were not promulgated and enforced throughout the country.

Therefore the American Railway Association, representing all of the railroads of the country, inaugurated the Bureau of Explosives for the purpose of carrying on this work. The regulations governing have been adopted by the Interstate Commerce Commission, which was given authority to act on the subject by a special act of Congress in which is stipulated penalties for violations to the extent of $2,000 fine, eighteen months imprisonment, or both, and if death or bodily injury is inflicted the unfortunate party responsible is liable to receive a penalty of ten years imprisonment.

The regulations for the safe transportation of explosives and other dangerous articles is one of many subjects of railroad literature requiring daily observance by the men on the ground, those men whose individual daily actions mean the operation of our great systems of railroads, and whose individual neglect, blunder, or lack of knowledge could stop operations for a time with questionable results, possible disaster, yes wipe out their own existence as well as others.

The regulations on the whole are voluminous, and would confuse a car inspector or car man who would try to memorize them all when only a small part pertains to his branch of the work, but if each of you will study and observe his own little part of the regulations, you will find them brief and simple, and instead of being a hardship they will give you confidence and satisfaction in knowing your duty and that your action was right.

These regulations have been printed and distributed at great work and expense, and it is a pity that many railroad employees have permitted them to remain within their reach without acquiring the good advice they offer, especially when it pertains to some part of their assigned duties.

It must be remembered that the regulations involve many men and duties both in and out of the railroad service, and the neglect or blunder of any one of the many having to do with the handling of a single shipment would be sufficient to render the work of all the others of no avail. It could be the actual or contributory cause not only of destructive fires, but of disastrous explosions, since large quantities of explosives must be transported, frequently through thickly populated districts and in trains containing cars loaded with other dangerous articles.

The specific duties applicable to car inspectors and car men generally are of the most importance. The essential part of any line of business is a complete knowledge of it; it is folly to expect men to do right by these shipments of explosives and other dangerous articles if they have not been properly instructed and furnished the necessary information on the subject. Unfortunately the car inspectors and car men have been the most neglected class of railroad employees in this respect in not receiving instructions pertaining to their part of the work involved in the regulations for the transportation of explosives and other dangerous articles.

EXPLOSIVES

There are three distinct classes of the explosives and other dangerous articles for especial attention by car inspectors under the regulations, namely: Explosives for which a certified car is required, the inflammables and the acids. These are the placards required on cars containing them, four placards to the car, one placard applied to each end and each door or side. The principal warning on the "Explosives" placard for car men is that portion in large letters: "EXPLOSIVES, KEEP FIRE AWAY." The condensed rules printed thereon for the handling of the car are also well for car inspectors to note and aid in having any violations of them corrected when observed, but this placard must always be accompanied by the car certificate, one on each door.

As the law requires that cars for explosives shall be in exceptionally good condition, so also it requires that they shall be inspected by men who know how and certified to so it will be known that the proper precautions were taken at the originating point. This certificate is to be executed in triplicate, two for the car doors and one to be kept on file at the originating point. There are two portions to the certificate, number one to be signed by the railway employee inspecting the car, which reads:

No. 1.

I hereby certify that I bave this day personally examined.................car No..............and that the roof and sides have no loose boards, holes, or cracks, or unprotected decayed spots liable to hold sparks and start a fire; that the kingbolts or draft bolts are properly protected, and that there are no uncovered irons or nails projecting from the floor or sides of the car which might injure packages of explosives; also, that the floor is in good condition and has this day been cleanly swept before the car was loaded; that I have examined all the axle boxes, and that they

*Abstract of a paper read before the Niagara Frontier Car Men's Association.

are properly covered, packed, and oiled, and that the air brakes and hand brakes are in condition for service.

This is practically a legal document, and when a man signs it he is holding himself responsible under the law for the proper condition of the car and should be sure that he knows that the car complies with the requirements of the regulations before he applies his signature.

It seems incredible that a man would sign his name to a document without knowing its reading, but I have found instances where these car certificates have been signed by car inspectors in such a perfunctory manner. A short time ago after a car inspector had completed his inspection of four cars for explosive shipments at a transfer station, I questioned him about the inspection work while he was signing the certificates. He paid no attention to the car numbers nor the number of certificates he was signing, and admitted that he never received a copy of the regulations nor read the car certificate and was signing for something he knew nothing about.

Practically all the car inspectors' duties pertaining to shipments of explosives are covered by one regulation, No. 1662. Considerable wrong has occurred by this class of employees doing their part of the work with their own judgment or ideas as a basis, instead of using regulation 1662 for their guide. Many inspectors considered the roof of an explosive car perfect because it was metal on the inside, whereas the regulations clearly show that the outside needs careful inspection to guard against fires from sparks holding in open or decayed spots. One fire from such a cause exploded a car of 500 cases of dynamite. The outside roof was bad, permitting a spark from a passing train to lodge and set it afire. The placard warning and consequent fear of an explosion kept people away, so there was only a property loss of $7,000. Another fire from the same cause exploded a car load of dynamite, killing two persons and causing a property loss of $8,300. The roof of another car which contained black powder caught fire from a spark of an engine and the fire spread to three other cars on a siding loaded with dynamite. All four cars exploded with a property loss of $10,891.

These heavy losses could have been avoided by the car inspector at the originating point completing his work with the proper inspection of the outside of the roof, or by an inspector at one of the interchange points through which the cars passed detecting the defective roofs. This part that pertains to interchange inspections and many other defects existing during transit with cars containing explosives, emphasizes the necessity of a careful inspection at interchange points as required by regulation 1654 *a* and *b*. In addition to the possibility of defects being overlooked at the originating point, defects are liable to develop during transit.

From the fact that the car inspector at the originating point is called upon especially to inspect a car intended for explosives and is required to sign the car certificate covering such inspection, he knows positively that the car is for explosives and the nature of the special inspection required, but it has been the common practice to assume that during transit the car inspectors would know the explosive car by the placards. In many instances this has proved unreliable, as usually the car inspector is rarely looking up for placards and on account of the infrequency of such placards in some districts, to some inspectors it would be like looking for a needle in a haystack to be looking for cars placarded "Explosives." The most practical way of having a car inspector at an interchange point know the car that contains explosives, in order to make certain that he actually inspects it as such, is to inform him of the presence of such a car.

Part of regulation 1662 reads as follows:

Holes in the floor or lining must be repaired and special care taken to have no projecting nails or bolts or exposed pieces of metal which may work loose or produce holes in packages of explosives during transit.

When packages of explosives are to be loaded over exposed draft bolts or kingbolts, these bolts must have short pieces of solid, sound wood with beveled ends (2-inch plank) spiked to the floor over them (or empty packages of the same character may be used for this purpose) to prevent possibility of their wearing into the packages of explosives.

It will be noted that this only applies to metal so located that it would injure the packages. To condemn a car for use of explosives because it has a metal band across the door sill, or exposed metal in other parts where the shipment would not be placed, is wrong. The regulations are clear on these points, and inspectors must stop adding risks by causing delay to shipments at transfer and other stations through their neglect to follow the printed regulation. Delays of two to four days have occurred at some stations on account of inspectors reporting cars unfit for explosives when as a matter of fact they were condemning cars improperly in this manner.

Of course there is quite a difference in the inspection required by these regulations for a car intended for explosives as compared with the inspection given the ordinary run of cars for merchandise and other shipments. I recall that at one large freight station an agent's faith in the thoroughness with which inspectors examined cars at all times was very much exaggerated, as he felt certain that all his cars were examined as thoroughly as any intended for explosives. The foreman of car repairs at that point expressed his opinion of the difference between such inspections thus: If his inspector spent two minutes looking over a car for the ordinary run of merchandise freight he would discharge him as too slow for the pob, but if he did not spend about three to six minutes inspecting a car intended for explosives he would consider him as not careful and thorough enough for such inspections, for he would expect as careful inspection of such a car as would be given a passenger car. Some cars of course can be inspected faster than others, a metal roof on the outside being easier to inspect than and old wooden roof; rust coated trucks and wheels fairly well worn require a slower inspection than a new or comparatively new car.

While the dangerous nature of explosives and other dangerous articles and the alarming consequences they are liable to cause in their transportation, emphasizes the great importance of particularly caring for such shipments in the manner prescribed by the regulations, it also emphasizes the importance of the car man's duties being thorough with all cars regardless of the nature of the lading. Many train accidents in which explosives and other dangerous articles were involved and through their presence added exceedingly heavily to the injuries to persons and the destruction of life and property, were the result of defective equipment other than that which contained the explosives and other dangerous articles. While the regulations provide that "at points where trains stop and time permits, cars containing explosives and adjacent cars must be examined to see that they are in good condition and free from hot boxes or other defects liable to cause damage," the importance of the car man's duties being thoroughly performed at all times should be constantly remembered.

All explosives are required to be well packed in specified containers when offered for shipment and properly loaded and braced in the cars for forwarding. However, the shocks cars receive incident to yard and road movement sometimes have the effect of breaking the bracing or the packages, permitting the contents to leak or become exposed. The records of our Bureau show many such instances. Therefore, essential requirements are to keep fires away and when inspection or other work at such a car is necessary after daylight hours, naked lights must not be used. Extreme caution must be exercised to prevent the striking of sparks or permitting the friction of tools, bolts, rods or other metal parts of the car to come in contact with loose explosives, or for such metal parts to wear through and damage the packages. A draft bolt was found broken in a car containing fifty cases of dynamite. The car repairer while replacing a draft bolt in the car struck some of the loose dynamite that settled around the bolt, burning his face and injuring both eyes. A serious accident was narrowly averted. The broken draft bolt may have been due to poor inspection at the loading point.

Many other simple acts have resulted in serious accidents with shipments of explosives. Nitroglycerine, the liquid ingredient of dynamite, leaking from containers through to the wheels and rail, caused it to detonate when the car was moved, exploding all in the car with the loss of several lives any many thousands of dollars' worth of property. One of the kegs in a shipment of black powder was found in a damaged condition with powder strewn over the car floor. After putting back in the keg what could be readily picked up from the floor of the car, the remainder was swept out on the ground. A bystander thoughtlessly threw a lighted match on the ground among the sweepings. There was an immediate flash which communicated to the kegs of powder in the car, with the result that fourteen persons were killed and eight injured. In a similar instance, a way-freight conductor instead of disposing of loose powder in the manner prescribed by the regulations and complying with the warning given on the placard, knew just enough about the characteristic of black powder, as he thought, to have some fun with it. Some powder was loose on the car floor from defective packages, and after picking up most of it he swept the remainder out on the ground. It was on a Southern road where colored men were employed as trainmen, and knowing that the loosely scattered powder would merely flash when lighted, it was thought a fine joke to get a colored man in the center of the scattered powder and then light it. The conductor and some of his men accomplished this and were enjoying a hearty laugh, when suddenly all the powder in the car exploded, killing them and some children who were playing nearby, a total of eight lives sacrificed. In the excitement of the joke, it was not considered that a small spark of the ignited powder would flash up into the car and explode all with such a disastrous result.

Loose or scattered black powder is exceedingly dangerous, and it is very odd how far a trail of it will carry fire when it catches a spark. In the city of Wilmington, a wagon loaded with powder was being driven along the street. One of the kegs had a hole from which powder escaped in small quantities, and a man driving a fast trotting horse two blocks away, crossing the street at right angles, through a spark produced by the shoe of the horse striking a cobble stone, ignited this trail of powder. The fire followed that wagon two blocks, caught up with it and exploded the entire load.

Such instances show the care that should be taken with any trail of powder from leaking packages around freight cars.

HAZARDS OF INFLAMMABLE AND ACID SHIPMENTS

While a mishap with explosives is capable of great destruction, accidents with the inflammable and acid shipments have been the most numerous, and when measured by loss of life, number of personal injuries and extent of damage to property, one of the most disastrous accidents that can be traced to the transportation of dangerous articles, occurred in September, 1915, with a tank car load of gasoline. Forty-seven persons were killed and 524 persons were injured. The property loss was over one million dollars. The greatest hazard with inflammable shipments has been with the movement of inflammable liquids.

Cars containing fireworks, smokeless powder, inflammable solids such as matches, chlorate of potash and various other articles liable to catch fire through friction or by being dropped or crushed or by spontaneous combustion; inflammable liquids like gasoline, liquified petroleum gas, bisulfide of carbon, naptha, benzol, alcohol, and some paints and varnishes; compressed gases such as acetylene, hydrogen, blaugas, hydrocarbon, must be protected by four "Inflammable" placards, one applied to each end and each side.

The three notes on the bottom of these cards are also important. They read:

1. This car must not be next to a car containing explosives.
2. Do not enter with exposed flame, nor with lighted lantern, until car has been ventilated and vapors allowed to escape.
3. When lading requiring this placard is unloaded from box or stock cars, Agents, Yardmasters and Conductors must remove the placards. Tank cars must retain placards until cleaned.

Accidents have happened frequently due to men not obeying these warnings, by car inspectors and others poking a torch, lighted lantern or match around a leaking car or in the dome of an empty tank car. The ordinary trainman's hand lantern is responsible for a large number of these accidents, and car inspectors and others are in the habit of utilizing their torches or hand lanterns for the purpose of making inspections of such cars. It is probably due to lack of knowledge that some fatalities have resulted from the use of such lights in connection with work at night, and employees should be impressed with the importance of observing the caution to keep lights and fires away. A leaking container of any inflammable is a hazard, and the best time to examine it or to do any repair work on a car protected by "inflammable" placards is during the daylight hours.

The inflammable solids or oxidizing materials when combined with combustible or organic matter may cause fires spontaneously. For example, permanganate of potash if it gets out of its package and becomes mixed with organic matter, such as may be found in the ordinary dirt of a freight car, may ignite of its own accord, or when an attempt is made to pick it up with a shovel a spark may be created which may cause ignition of the entire mass.

Inflammable compressed gases if leaking from their cylinders are readily ignited by the presence of an open flame or lighted lantern, and the ignition of these gases may result in a serious explosion and fire that may be far-reaching, for the reason that when the gases mix with the air they form an explosive mixture.

In the treatment of tank cars which are protected by the inflammable placard, or by the acid placard, according to whether the contents are inflammable liquids or acids, their handling deserves careful attention on the part of car men. The regulations require such cars to comply with the Master Car Builders' rules and when they do not their transportation is forbidden. When such cars are set out for M. C. B. defects and in addition may exhibit leaks at the seams, rivets or outlet valves, there is danger of ignition of the vapors escaping from inflammable liquids, or if the leaking liquid is acid, danger of serious burns to railroad employees. It is customary for well instructed men to stop leaks through the seams or rivets of tank cars by caulking the metal, and this can be done with reasonable safety even when the tank is loaded with gasoline. The question of whether bronze rather than steel tools should be used for the caulking has been considered, and our investigation justifies the conclusion that there is no case on record of any serious fire caused by the use of steel tools. Steel tools are more efficient for this purpose. In some instances it would be quite difficult if not impossible to caulk a seam by the use of a bronze tool. Such work on an empty tank car is dangerous, and the best method is not to permit the caulking of an empty tank car until the tank has been steam cleaned, unless it is known that it previously contained a substance that would not cause gas to remain in the tank. If the leak from a tank car is very bad, attempts should not be made to repair it, but the contents should be transferred as quickly as possible to a suitable car.

The presence on the inflammable placard of "Keep Lights and Fires Away" is not always sufficient to act as a warning, and a guard is a more reliable means of preventing the possibility of a serious accident. In a recent case when it was impossible to stop a leak at an outlet valve, every person in the railroad yard was notified of the presence and location of the tank car. Some employees owning automobiles saw an opportunity of getting gasoline without expense. This operation was performed safely during daylight hours, but when a night yardman came on duty he proceeded to steal some of the gasoline, using his lighted lantern for the purpose of seeing when his container became filled. A very serious fire followed and the employee was badly burned. The presence of an active guard could have prevented this. The Bureau's records show many instances of personal injuries and serious fires caused by employees attempting to pilfer gasoline and alcohol from tank cars.

One of the most dangerous substances handled by railroads in tank cars is casinghead gasoline. The regulations require that tank cars containing this material should bear on the top of the dome cap and on each side of the dome, a special placard reading:

CAUTION

Avoid Accidents

Do Not Remove This Dome Cover While Gas Pressure Exists in Tank. Keep Lighted Lanterns Away

The regulations also require that tank cars containing this liquid shall be equipped with a mechanical arrangement for closing of dome covers as called for in the M. C. B. specifications, and this arrangement must either be such as to make it practically impossible to remove the dome cover while the interior of the car is subjected to pressure; or suitable vents that will be opened automatically by starting the operation of removing the dome cover must be provided. One of the most serious accidents in the history of the railroads occurred in September, 1915, due to the opening of a dome cover of a tank car containing casinghead gasoline, although it was known at the time that interior pressure existed.

The regulations require that safety valves on tank cars containing any of the inflammable liquids that give off volatile vapors at or below a temperature of 20 deg. F. shall be set to operate at a pressure of 25 lb. per sq. in., as a safety precaution to prevent the frequent unnecessary escape of the vapor. The Master Car Builders' Specifications for tank cars, with which your duties require you to be familiar, covers in detail the essentials in this respect applicable to the various volatile and acid products.

The regulations require that empty tank cars that previously contained gasoline or any of the other liquids requiring the inflammable placard must retain such placards until the cars are known to have been properly cleaned with steam or reloaded with a substance that does not require the placard. Many fatal accidents have resulted from using lanterns or lighted matches to repair unsteamed tank cars, which may contain inflammable vapors even when the previous lading was not of a flash point below 80 deg. F. Only incandescent electric lights should be used for this examination.

An empty tank car, which had previously contained fuel oil, was being repaired. While a shopman with a lighted lantern stood over the open manhole of the dome an explosion occurred which threw him to the rafters of the repair shop shed and dropping back on the car he was fatally burned, dying a few hours later. A number of other employees were burned by the fire that followed, which destroyed the repair shop and all the cars in the vicinity with a heavy property loss.

While repairing an empty tank car which had previously contained naphtha, a red-hot rivet was passed to one of the employees inside of the tank, which ignited the gases, killing the employee in the tank and seriously burning the other. This car had been empty for seventeen days, but had not been cleaned by steam.

A repairman arranged to rivet a grab iron on the end of an empty tank car which had previously contained gasoline. His helper entered the tank but came out saying the vapors were too strong for him. The repairman then enterd the tank and instructed his helper to hand him a hot rivet. When the rivet entered the manhole an explosion occurred, severely burning the repairman who died two hours later.

Inspection by a car inspector and repairer was being made of an empty tank car which previously contained gasoline. They removed the dome cover to ascertain whether the car contained any liquids and the inspector thoughtlessly struck a match. The vapors were ignited and an explosion followed, severely burning the inspector.

These are only a few of the many similar accidents that have occurred to car men on empty tank cars.

Leaking packages of inflammable or corrosive liquids when observed should be immediately taken care of. If in doubt a call should be made for some authorized and competent railroad employee to supervise the removal of the leaking packages from the car.

PRECAUTIONS IN CASE OF FIRE

The best manner of extinguishing firse depends upon the immediate existing local conditions. Fires caused by nitric acid or mixed nitric and sulphuric acids can be controlled by the use of water. In applying the water care must be exercised as slight explosions may occur, accompanied by the projection of hot acid, which may cause dangerous burns. Therefore, the water should be applied from a safe distance. Sand may also be used to stop a fire started by acid. But if the fire has thus been stopped the early use of water is desirable to prevent the fire breaking out again. Thoroughly flush away any remaining acid and remove leaking and damaged containers. Acid fires give off nitrous fumes which are extremely irritating and are poisonous. Employees should not enter a car or other confined space where such fumes are present.

Fire in a car of friction matches frequently involves ignition of the match heads in only one or a few of the inside cartons. If the outside box is not broken open and the smoke dies away after a moment or two, no further action is necesary as the fire has already been extinguished for want of oxygen, and nothing will be gained by opening the box. If the fire has gained some headway, the burning box or boxes should be removed from the car if this is possible, or water should be freely used. Boxes should not be broken open as the fire will be increased by such action.

Fires in ground charcoal or in charcoal screenings are best handled by removing the burning packages (usually bags). If removal is not possible, water may be used sparingly to extinguish the visible fire; then remove all the charcoal and separate the wet from the dry. The dry charcoal should be stored under cover and under observation for several days before permitting it to be forwarded as it is probable that fire may burst out again. The wet charcoal should be destroyed as it is unsafe to transport. Fires in lump charcoal should be extinguished with as little water as possible and the wet charcoal removed from the balance of the lading. The same precautions as to observation for several days should be followed to see that fire does not occur again.

Fires which involve only a small amount of gasoline can often be extinguished by the liberal use of water, but if there is a large amount of gasoline already ignited, water will only spread the fire. Sand or earth should be used to control the flames of the burning gasoline, and could possibly be used in sufficient quantity to smother the fire.

Fires involving tank cars may occur through ignition of the vapors escaping from the safety valve. The burning of these vapors and even the liquid itself at a safety valve is not a serious matter except as a source of trouble to surrounding property. An effort should be made to promptly extinguish such fires by the use of wet bagging thrown over the safety valve, throwing sand in quantity on top, or if the means are available, by the use of a heavy jet of steam. If this cannot be done, isolation is the proper course to pursue, and the fire will eventually burn itself out.

If in repairing cars containing dangerous lading it is necessary to disturb the lading, care must be exercised to properly load and brace it before the repaired car is permitted to go forward.

The Interstate Commerce Commission regulations require that carrier's employees shall report all violations of the regulations observed, and car defects constitute serious violations of the regulations which should be reported to the proper railroad official. These reports are our best means of guarding against a repetition of violations before they result in more serious consequences.

As the regulations place upon the carriers a duty to make the regulations effective and to thoroughly instruct their employees in relation thereto, in turn the carriers necessarily hold trainmasters, yardmasters, station agents and those who have men under their jurisdiction, responsible respectively for the proper instruction of the employees under them and for their compliance with the regulations. Therefore, it is essential that chief car inspectors and foremen protect themselves with a suitable means of instructing employees under their jurisdiction and insuring compliance by them with the regulations. The monthly or periodical business meetings of car men that are in practice on some roads affords an excellent opportunity to include subjects pertaining to the regulations for discussion and instruction of the car men, who should be furnished literature pertaining to their part of the duties involved. The use of the accident bulletin issued quarterly by our Bureau also serve as an excellent means of imparting knowledge on the subject.

After proper provision is made for the instruction of employees, it is still incumbent to know that the regulations are actually complied with by them when the occasion arises. Such a knowledge can be obtained by a periodical check of the work of the various employees.

Before any work is commenced on any cars containing explosives or other dangerous articles, it should be the rule that some specially posted employee will inspect the car and supervise the work. By having some system for the handling of these subjects, a chief car inspector or foreman can then have some assurance that he has guarded against trouble or disaster with the employees and property under his jurisdiction.

ALL-METAL PASSENGER CARS FOR BRITISH RAILWAYS*

Before the war the supplies of lumber for rolling stock in Great Britain were adequate at comparatively low prices, but at the present time, the conditions have changed entirely. The United Kingdom has in the past imported about 90 per cent of its requirements but with the decrease in the available vessels since the war the problem of getting the lumber into England has been a difficult one. At the present time the British imports of timber are two years in arrears and on account of the present demand for this material on all sides, it is estimated that it will not be less than five years before the demands for lumber for railway rolling stock can be met as in pre-war days. On the other hand, the metal output of Great Britain has greatly increased during the war and there would be no difficulty in supplying the 20,000 tons of metal per year necessary for the construction of passenger car bodies required by the railway companies. Furthermore, the prices of iron and steel have increased but about 124 per cent since 1914, whereas the price of lumber has increased about 218 per cent. Thus the development of the all-metal passenger car appears to be a natural evolution.

*Taken from a paper presented by F. E. Gobey, assistant carriage and wagon superintendent, Lancashire & Yorkshire, England, before the Institution of Civil Engineers, London.

There are in Great Britain 52,250 railway passenger cars. They are mainly of wooden superstructure. A large number, however, have all-metal or composite, lumber and metal, underframes. Table I indicates, in brief, the general construction of passenger cars on fourteen railways in Great Britain:

TABLE I—SUMMARY OF PASSENGER CARS OWNED BY FOURTEEN RAILWAY COMPANIES, JULY 31, 1918, SHOWING THE AMOUNT OF TIMBER AND METAL CONSTRUCTION

BODIES

Built of	Number of cars	Percentage of total
Timber	46,133	95.9
Timber with metal outside panels	1,761	3.7
Composite, timber and metal	158	0.3
Metal entirely	46	0.1
Total	48,098	100.0

UNDERFRAMES

Built of	Number of cars	Percentage of total
Timber	592	1.2
Timber, with metal plate on solebars	19,750	41.1
Timber, with metal angle or channel on solebars	6,469	13.4
Composite, timber and metal	4,569	9.5
Metal entirely	16,718	34.8
Total	48,098	100.0

The number of cars given in this table represent 92 per cent of total number of passenger cars in Great Britain.

Most of the six-wheel passenger cars have iron or steel plates ½-in. thick on the outside of wooden side sills and the four-wheel truck cars use either the steel plates or angles or channels. In some cases they have composite underframes with rolled steel side sills and bolsters. However, the all-metal underframe and truck has been the standard practice since 1900. The average weight of metal in a modern passenger car, 56 feet long, with a steel underframe and wooden body is 41,500 lb. or 66 per cent of the total weight of the car.

The design of British cars with numerous side doors which break the continuity of the body as a girder, has made it necessary for the superstructure and load to be carried by the underframe. The bodies of this type are designed to keep free from distortion. The underframe is calculated to sustain, in addition to the weight placed upon it, strains due to buffing and drawgear, oscillation, and vibration. The British standard underframe for passenger cars with wooden superstructure is composed of four longitudinal members with bolsters and cross-bars all in the same plane suitably trussed.

TABLE II—COMPARISON OF GENERAL DIMENSIONS OF BRITISH AND AMERICAN MULTIPLE-UNIT ELECTRIC CARS

	Long Island		Lancashire & Yorkshire	
	Ft.	In.	Ft.	In.
Length over body corner posts	54	9¾	..	..
Length over buffers	64	5¾	65	3
Width over body	9	9¾	9	4
Width inside body	9	4½	8	11½
Width over cornices	9	11½	9	2
Width over belt rail	9	10¾	9	3⅛
Height from rail to top of roof	13	0	12	4½
Height from rail to top of ventilators	13	8¼	12	8⅞
Height from rail to top of floor	4	4⅝	4	1¼
Height from rail to center of buffers	2	10½	3	6
Center to center of trucks	39	9	45	0
Wheelbase of trucks				
Number of passenger seats	80		95	
Weight of car unloaded	63,100 lb.		64,960 lb.	
Weight of car without trucks	45,100 lb.		42,504 lb.	
Weight of one truck	9,000 lb.		11,228 lb.	
Weight per seat	788 lb.		683.7 lb.	

The only railway passenger cars constructed entirely of metal in Great Britain are those used in the electric service of the Lancashire & Yorkshire, between Lancashire and Bury, which uses the multiple-unit control system. These cars are like the American type of passenger car in that they have the center aisle with the doors opening onto platforms at the ends. However the Lancashire & Yorkshire cars have seating space for five passengers across the car, three on one side of the aisle and two on the other, the aisle being much narrower than in American cars. The general dimensions of these cars are shown in Table II together with those of similar cars used on the Long Island in its electric service in the United States.

In order to show the small amount of difference in weight between the all-metal, as designed by the Lancashire & Yorkshire for its electric service between Manchester and Bury, and the composite type of construction used between Liverpool and Southport, the dimensions in Table III are given. It should be stated, however, that the cars with timber bodies have an underframe of a heavier type of construction than the all-metal car, the latter being of more recent construction. The elliptical type of roof of the all-metal cars is also lighter than the clerestory type on the wooden cars and, further, there are more seats in the all-metal car which reduces the total weight per passenger seat.

Table III—Comparative Weights of Electric Motor Cars

Description	Liverpool and Southport wood cars				Manchester and Bury all-metal cars	
	Third class D.C. motor car		Third class M.U.C. motor car		Third class M.U.C. motor car	
	Ft.	In.	Ft.	In.	Ft.	In.
Length over body	60	0	60	0	63	7
Width over body	10	0	10	0	9	4
Height of car inside, floor to roof	8	0½	8	0½	8	3¼
Height of car from rail level to floor	4	4¼	4	4¼	4	1¼
Height of car from rail level to top of roof	12	7⅞	12	7⅞	12	4½
Center to center of trucks	40	6	40	6	45	0
Wheelbase of trucks	8	0	8	0	9	0
Type of roof	Clerestory		Clerestory		Elliptical	
Number of seats	69		68		74	
Weight of body and underframe, with draft and brake gear	47,110 lb.		51,188 lb.		39 592 lb.	
Weight per passenger seat, body and underframe only	682.7 lb.		752.7 lb		535 lb.	
Weight of two trucks complete	53.150 lb.		53,150 lb.		62,719 lb.	
Weight of other electrical equipment, including cables, per car	6,760 lb.		9,902 lb.		18,649 lb.	
Total weight unloaded	106.960 lb.		114,240 lb.		120,960 lb.	
Weight per passenger seat of total weight unloaded	1,550 lb.		1,680 lb.		1,634 lb.	

The difference in the cost of the two cars mentioned above is slight, the all-metal car costing about 4.8 per cent more than the wooden car with an all-metal underframe.

During the three years the all-metal cars have been in service they have averaged 250,000 miles a year. There has been no weakening of the underframe or superstructure. It was found that where aluminum, which is used for the side panels and roof sheets, comes in contact with Flexolith it will oxidize, and the aluminum in such cases has been replaced with brass. While the cars have not been in service long enough to make any direct maintenance comparison with wooden cars it is believed that slightly less material and labor will be required on the all-metal cars.

As will be noted above these cars are built with aluminum side panels and roof sheets, and it is claimed that a return of 20 per cent a year saving will be made, based on the reduction in weight, and considering the interest on the increased initial outlay. The saving amounts to 1,623 lb. per car.

An aluminum with a tensile breaking load of 24,600 lb. per sq. in. is not suitable to replace steel having a breaking load of over 62,800 to 71,600 lb. per sq. in. for framing purposes but with alloys, of both aluminum and steel, metals of sufficient strength may be used with a reduction in weight.

As regards standardization, aside from the uniformity of width and length, there is little or no advantage in the standardization of the superstructure of a passenger car, for it will last the life of the car. Commercial advantages will be obtained by the use of standard rolled sections, pressings, doors and mouldings, however, in the construction of the car. It is believed that if metal construction is adopted, the old compartment carriage should give place to the car with the center aisle such as is used in America. This type of car for main and suburban electric services in England should have a minimum inside width of 8 ft. 11½ in. This will give more seating space per passenger than the present four-a-side compartment in a side corridor car, as it will allow three passengers on one side of the aisle and two on the other.

From a study of the designs of the center aisle cars, it has been found that the weight of the car per seat diminishes as a length of 65 ft. is approached, due to the excessive girder constructions required for the underframe on cars of such length. A study of the conditions in England discloses the fact that the economic car for a suburban electric service would have a length of 63 ft. 7 in. Such a car with a center aisle with three passengers on one side and two on the other would have a seating capacity of 103 and the weight per passenger seat would be 560 lb. For long distance main line cars additional comfort to the passengers will be obtained by having seats for two passengers only on each side of the aisle.

The all-metal open car has the following advantages over ordinary compartment cars of timber construction:—

(a) Increased inside width due to the framing being thinner.

(b) A body which may be built to the full limit of the load-gage for the paying load.

(c) The deletion of the side corridor and cross partitions, saving 1120 lb. in weight.

(d) Seats will be better occupied, making each car more remunerative, and reducing the weight of trains.

(e) An open aisle, which allows the circulation of passengers, and may be passed along comfortably, even if of less width than an enclosed side corridor.

(f) Few outside doors, reducing initial cost, maintenance, and traffic-staff duties.

(g) Greater strength of car side, which, if desired, may be used as a girder.

(h) Saving of interest by gradual reduction in the present stocks of timber.

(k) Simplification of parts.

(l) Greater safety in case of accident.

There is no comfort provided by the existing main-line small passenger compartment cars which cannot be secured in an open aisle all-metal car. In suburban cars where frequent stops are made, the weight should be reduced to a minimum consistent with safety and proper maintenance. Main-line cars must be built to resist greater stresses and must provide protection for passengers in case of accident.

Automatic center couplings without side buffers have been very successful in the electric service of the Lancashire & Yorkshire during the last 15 years for train speeds up to 60 m. p. h. and the development of the coupler will be to automatically engage also the brake and electric connections. In England practically all the station platforms are elevated a certain amount above the rail to accommodate the side door compartment cars. Thus the conditions are such that on main-line cars steps from the vestibules will be necessary on account of the varying height of the station platforms above the rail level.

While much has been said about the adoption of the open aisle car in contrast with the side door compartment car, it might be said that it is not necessary that the open aisle car be used with the change from a timber to metal construction.

Throughout the discussion of this subject the author frequently referred to the practices followed by the railroads of the United States in all-metal car construction.

Plight of Russian Railways.—The Russian railway system threatens to collapse, owing to the fact that no repairs have been effected since the revolution, says an article in the Reconstruction Supplement of the Review of the Foreign Press issued by the British War Office. The station buildings are for the most part deserted, the warehouses falling in, and the central switches and signaling apparatus no longer work, owing to the lack of spares with which to replace the wornout parts.

SHOP PRACTICE

FURNACE FOR BRAZING COPPER PIPE

BY E. A. M.

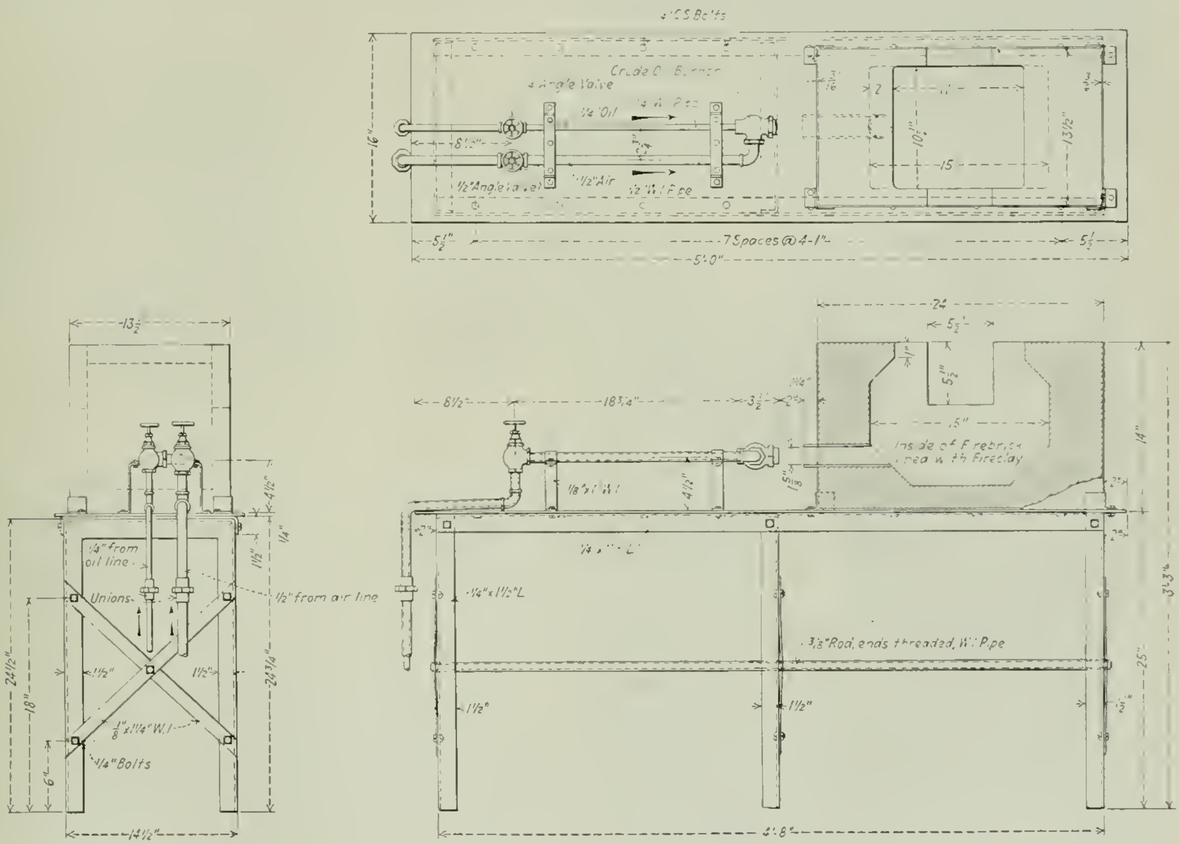
The furnace shown in the drawing is a shop made device which should prove very convenient for use in brazing copper pipe.

The furnace itself occupies a space measuring 24 in. by 13½ in. and stands 14 in. high. It is mounted on a rigid table, built up of angles, flat sections and tie rods in wrought iron pipe sleeves, and is covered with a top of ¼-in. steel or iron plate. The table is 4 ft. 8 in. long and just wide enough to conveniently hold the furnace at one end. The remainder of the top holds the burner and the air and oil supply pipes and control valves.

The furnace box is built of ⅛-in. or 3/16-in. sheet metal, with angles on the outside of the corners. It is lined with firebrick and the combustion chamber is finished with fire clay applied to the brick. Openings 5½ in. wide by 5½ in. deep are cut through the sides of the furnace to permit the pipe to be passed through the combustion chamber. The top of the box is left open, but a piece of plate may be provided which will serve as a cover when desired.

Through one side of the furnace, near the bottom of the combustion chamber, is a 1⅝-in. pipe. This forms an opening in front of the burner, which is held in position by 1-in. by ⅛-in. iron supports from the top of the table. The burner is fed by a ¼-in. oil supply pipe and a 1½-in. air pipe, controlled by angle valves. The valves are located above the top of the table about two feet from the end of the furnace. As shown in the drawing, the device is intended to use crude oil.

This furnace has been used very successfully to handle up to 4-in. copper pipes and no doubt could handle even larger sizes if occasion required.



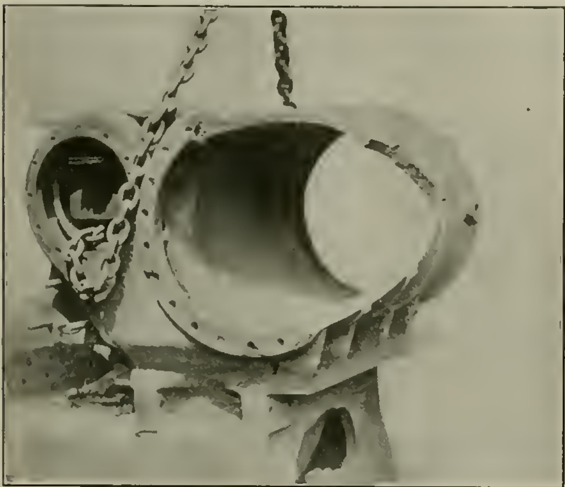
A Conveniently Arranged Furnace for Pipe Brazing

WELDING LOCOMOTIVE CYLINDERS

BY J. B. TYNAN
Superintendent Shops, Wheeling & Lake Erie, Brewster, Ohio

The possibilities of reclamation by welding are forcibly illustrated by the repairs made to a locomotive cylinder casting in the Wheeling & Lake Erie shops at Brewster, Ohio. A cylinder casting having a large section of the barrel broken off, was successfully repaired by gas welding.

In making repairs to this cylinder a pattern of the missing



The Broken Casting as Received in the Shop

part was first made and a patch casting, weighing 505 lb., cast from iron scrap. The rough edges of the cylinder were chipped to an angle of 45 deg. and the patch fitted and

The Cylinder Casting After Welding and Boring

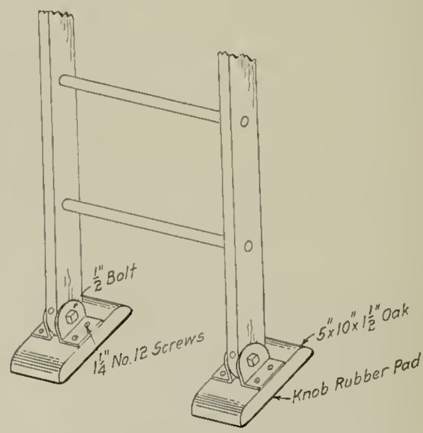
bolted into place. A furnace of brick was then built around the cylinder, with an opening at one end large enough to admit an oil torch, and the entire casting was brought to a red heat before the welding was begun. The patch was then welded to the cylinder and the old stud holes also welded shut. An oil burner was kept burning inside of the cylinder until the welding was completed.

After the welding was completed the furnace was filled with pine wood and the cylinder kept at a cherry red heat for seven hours. The furnace was then closed as tightly as possible and the cylinder allowed to cool slowly. After being thoroughly cooled, the cylinder was bored and the face finished ready for new stud holes. This method of repairing gave satisfactory results and eliminated a long wait for a new cylinder casting, thus enabling the shop to turn this locomotive out for service in a comparatively short time.

SAFETY NON-SLIP SHOE FOR LADDERS

BY A. G. JOHNSON
Mechanical Engineer, Duluth & Iron Range, Two Harbors, Minn.

A safety non-slip shoe for use on ladders is shown in the illustration. This shoe is made of hardwood blocks with two clips of No. 10 gage steel plate, formed and drilled, and attached to the ladder as shown. These plates may be selected from boiler shop scrap. A pad of rubber is glued and then nailed to the underside of the hardwood blocks, which



Application of the Non-Slip Ladder Shoe

prevents the ladder from slipping while being used on a hard or smooth surface. These shoes have been in use in the shops, roundhouse and power plant of the Duluth & Iron Range for a number of years and have given very satisfactory service when used on concrete or other hard floors, preventing slipping of the ladder and possible injury to the person using it.

Rustless Steel.—A new Sheffield invention is a rustless steel having a bright surface and able to resist the corroding effect of air, water and acids without staining. It was chanced upon largely by accident, just prior to the outbreak of the war and was immediately commandeered by the British government for use in airplane construction and for purposes where strength and durability, combined with rust resisting qualities were invaluable. A local metallurgist, Harry Brearly, author of numerous standard works, was experimenting in the armament shop to find a means of preventing erosion in gun tubes. After some of his experiments he noticed that certain pieces of chrome steel had not suffered from corrosive influences under conditions which would have rusted ordinary steel. He followed up this clue, and what is known as stainless steel was eventually worked out and added to Sheffield's metallurgical triumphs.—*Scientific American.*

Master Blacksmiths' Convention

Papers on Heat Treatment of Steel, Autogenous Welding, Spring Making and Shop Equipment

Methods of securing increased production in the shops and increasing the service secured from forgings were the principal topics discussed at the twenty-fifth convention of the International Railroad Master Blacksmiths' Association, held at the Hotel Sherman, Chicago, on August 19-21. The convention was opened with prayer and an address of welcome, following which the president, W. C. Scofield, delivered an address which reviewed briefly the developments since the last meeting in 1916.

PRESIDENT'S ADDRESS

Mr. Scofield said in part: In reviewing the great world conflict, our craft can with reasonable pride, look at the many monster guns, munitions and engines of war, and know that their ingenuity and brawn helped in making these mighty implements. In the present upheaval let us forget the fallacies of socialism, the ignorance of bolshevism, and the utter nonsense of the soviet, and return to the principles of our fathers and realize that the safety of our institutions, the success of country, and the happines of our home, depend not so much upon how much we can get, but upon how much we can do.

W. C. Scofield (Ill. Cent.)
President

J. Carruthers (D. M. & N.)
First Vice-President

G. P. White (M. K. & T.)
Second Vice-President

COST ACCOUNTING IN BLACKSMITH SHOPS

BY G. F. HINKINS
Westinghouse Air Brake Company

A paper touching on the history of the association and the duties and responsibilities of its members was submitted by G. F. Hinkins. In concluding his paper Mr. Hinkins made a plea for more thorough methods of computing the cost of work, which is given in part below:

As a rule, the foremen blacksmiths have every qualification for handling shop work. By that I mean that they possess executive and mechanical ability, but how many understand the fundamental principles on which their business is conducted? Of course, they can tell the flat labor cost of their product, but do they know the overhead expenses? This is a very complex proposition. The overhead for making a flat chisel is much less than the overhead for making an intricate drop-forging, by reason of the high first cost and upkeep of the dies. The overhead expense of producing different forgings varies in accordance with the nature and shape of the forging, as the shape of the forging will determine the cost of both the drop forging and trimming dies. Drop forgings on account of their shape and refinement will influence the life of the die. The maximum output from a set of dies will vary from 10,000 to 50,000. In order to get the cost of the product, it is necessary to get the first or original cost of the dies and also the number of times the dies are dressed before they are worn out and the number of forgings made from these dies. It will be perceived from the foregoing that everything that is necessary to produce a forging must enter into the cost of that forging.

There must be business methods for ascertaining the true cost of doing work, especially if manufacturing is being done for the market. If a furnace needs repairing and the brick mason helps himself to a load of fire brick to repair it and does not charge the brick against that furnace, then some part is not charged for something it did get and some other part is paying for something it did not get. The upkeep of the various types of equipment such as steam hammers, drop hammers and forging machines will differ and the expense for repairs must be kept separate which is done by charging such items against the individual machine. Every machine and furnace is designated with a shop or machine number so that all repairs and renewals are charged against the equipment. In this way, the cost of maintenance of every machine and furnace is known. This is a necessary feature of a cost accounting system which gives the cost of any manufactured article. You may manipulate your charges as you please, but you cannot get away from the cost. Your firm pays the bill.

DROP FORGING AND ITS POSSIBILITIES

BY J. D. BOYLE

The following is an abstract of the paper on this subject: Steel is not a simple substance like pure iron, gold or copper, but a complex artificial substance. It is composed of groupings of elements which enter into its makeup. These elements are only visible with the aid of a microscope. The term micro-structure has been given to what is thus brought to view. Upon polishing and etching a piece of steel the structure is apparent through the action of the etching medium, (acid or other corrosive materials) which affect the elements variously, causing each to assume a color or structure peculiar to itself.

When steel is heated above its critical point for the forging operation and submitted to blows under the hammer the molecules of the metal are forced apart. To bring the steel to its greatest maximum strength a proper scientific heat-treatment is needed. This is accomplished with proper furnaces, heat measuring instruments and trained workmen. With all the above-mentioned facilities, automatic signal pyrometers, well-designed cooling systems and semi-muffle furnaces designed for this purpose should be used. Heat-treating departments of this type are built to insure quality and progressive production. The materials going into the vital parts of a locomotive should be subjected to a chemical analysis and a heat-treatment applied. After heat-treatment, test specimens should be taken to determine the physical characteristics.

Discussion

H. E. Gamble (Penn.) told of the wide variety of work made under drop hammers. At the Juniata shops hammers ranging from 1,500 to 12,000 lb. are in use and the capacity of the largest size has been overtaxed. All reciprocating parts for locomotives are heat treated after they are drop forged. G. Fraser (A. T. & S. F.) stated that a steam hammer could be used for drop forge work by making dies similar to those used in the drop hammer. The dies are held in a box tool secured by a band and hung in the frame. Several members stated that this method was being used with satisfactory results. O. Schutze (C., M. & S. P.) told how drop forge dies had been adapted to use in a Bradley hammer for making spring hanger gibs. Ample clearance must be allowed to dispose of surplus material, otherwise the dies will have a short life. Attempts to make drop forgings under a hydraulic press had proved unsuccessful. There was some discussion regarding the best material for piston keys, and it was agreed that tire steel was the most satisfactory for this purpose.

REPAIRS TO LOCOMOTIVES FRAMES

BY P. T. LAVINDER
Norfolk & Western

Cast steel now having practically taken the place of wrought iron frames brings into the question of frame repairs a great many new features. The subject of repairs to an engine frame should be carefully considered from all sides. We should be governed by the results obtained by the most successful methods in repairing frames. The shops must be prepared to do this work in a quick, easy manner, keeping in mind at all times the safety of the employees. All the skilled help that is required to do this work must also be provided and the man in direct charge of, or the man doing this work, must be personally interested in it.

At the Roanoke shops of the Norfolk & Western, the following method of repairing frames is being used with great success: It was formerly the practice to use electric welding exclusively in repairing locomotive frames with the exception of welds made in the smith shop forge. In making electric welds the procedure was as follows: The frame was cut from both sides at angles of approximately 45 degrees. The frame was expanded from 3/32 in. to 5/32 in. depending on the size of the frame; using a portable grinder on the scarf where the weld was to be made, cleaning it to secure good bright metal. Welding was begun at the bottom of the scarf, one operator working on each side of the frame. Care was taken to keep the weld free from oxidization and scale as much as possible, by the use of a wire brush, and when the weld was completed it was annealed.

The Roanoke shop has made 19 oxy-acetylene welds on locomotive frames in the past 60 days. This is the first frame welding done at this shop by this process. No failures have been reported up to this time, and it is believed this method will prove very satisfactory. In making welds by the oxy-acetylene process on locomotive frames the following method is used: First, the frame is trammed over the break with a long tram, care being taken to use a tram long enough to keep clear of the heat. Second, the frame is cut from both sides in a V-shape at angles of 45 degrees. Third, the portable grinder is used on the scarf, where the weld is to be made, cleaning it to good bright metal. Fourth, the frame is spread for expansion allowing 1/4 in. to 9/32 in. according to the size of the frame. Some acetylene welders allow far less expansion than others, but we believe that a frame welded a little too long is much better than one too short. More expansion should be allowed when a furnace is used around the frame for preheating purposes. Fifth, the expansion blocks are covered with asbestos in case they are liable to get hot. Sixth, a piece of boiler plate is cut and placed under the frame at the location of the weld. Seventh, the frame is heated with a welding blow pipe or preheated with an oil burner. Eighth, welding is started at the bottom of the scarf, the operator on each side of the frame bringing the metal out to the desired thickness and proceeding up the scarf. This is necessary as a welder should never go back over a weld to apply more metal. When the weld is practically completed the spreader block is removed. This is necessary as the weld is getting shorter just as soon as welding stops. If a lower rail is to be contended with, it should be heated to a good cherry heat, thus allowing the top and bottom rails to contract evenly, removing all strains. Expansion and contraction must be governed by the welders, as some welders are faster workers than others. Frame welding, whether by the electric or oxy-acetylene process, should be done by the most competent operator available as the success of the work depends entirely upon the operator.

In conclusion I would recommend that when an engine comes into the shop for heavy repairs and the frames have been welded four or five times, the frame not having been taken from under the engine at the time the welds were made that the frame should be taken down and put in the smith shop. All welds previously made while the frame was under the engine should then be cut out and worked over and the frame made to proper dimensions. One leg of every brace should then be heated midway between the top and bottom of the rail to a red heat. By this method all strains in the frame that have been caused by welding or otherwise will be released.

Discussion

There was a prolonged controversy regarding the best methods for expanding frames preparatory to welding. Some stated that the bottom rail should never be heated to secure expansion in the top rail, as it was unnecessary and caused the rail to shorten. G. W. Grady (C. & N. W.) criticized the practice of welding from the bottom of rail due to the uneven heating of the section. He advocated welding out from the center to keep the same heat at the top and bottom of the rail. Good results have been secured by this method without annealing after the weld is completed.

PURPOSES AND RESULTS OF THE HEAT-TREATMENT OF IRON AND STEEL

BY GEORGE HUTTON
New York Central

Heat treatment as pertaining to railroad work in railroad shops seems to have gone backward during the past three or four years. When first introduced on locomotive work it was thought this method was going to create a great improvement in the quality of forgings over the hit or miss method. The method in vogue today is for the forge shop to construct the different forgings and send them to the various departments to be machined to size and then applied to the locomotive without any record or any means of knowing if these forgings are of equal strength or of uniform quality.

These are the existing conditions today. In forging side rods, piston rods, rod straps or any piece of work that may be important, you endeavor to have these forgings made up by the best workmen you may have, and to exercise great care in heating and hammering them. You may also be cautioned, and caution your men to have them carefully annealed and laid on the floor stacked in such a way as to cool off equally, so that machining may be best accomplished. When you have carefully looked after this you have forgings that will only stand up to a strain equal to the strength of annealed material. Remember, annealing weakens forgings.

You will remember when vanadium steel was introduced in railroad work about the time when heat-treatment was also introduced or brought into shop practice. Why was heat-treatment confined to the alloy steel only? The steel makers furnished a steel which, if no heat-treatment was applied, would not be any better or any different from the annealed open-hearth steel, generally in use before the time of alloys or the open hearth in use today.

You have, no doubt, noted the breakage of alloy steel forgings that may have come to your shop off the road that had been heat-treated, and I am positive in my opinion that your verdict was, "Too hard; brittle; too hot when quenched; not drawn back enough," and this is exactly what has set back or almost killed the wonderful results of heat-treatment especially on alloy steel. The average result of this method has been a sacrifice of elasticity for tensile strength. I am of the opinion that when the alloy steel was introduced it was never meant that forgings should be treated to such an extent that breakage was the natural result, but certainly this has been the case.

During the 1915 convention in the discussion on heat-treatment, one member remarked that if we make our forgings, get the proper heat and proper hammering we would have much better forgings than any of the heat-treated ones. If we could only attain efficiency of that kind the whole problem would be solved. But who are the craftsmen who could do it and put it in effect in all our smith shops? There is too much left to guesswork when that method is compared to heat-treatment. When heat-treatment was introduced the main object was to get strength, durability and uniformity, and also to reduce the weight of forgings and castings, and to a great extent this has been accomplished with the exception of securing uniformity, and that is what we are trying to attain with this method.

Heat-treatment of locomotive forgings is a very different practice in comparison with heat-treatment on automobiles or trucks or any light forgings in other industries. We must all admit that the automobile builders have been successful. It has been proved that we can get the desired strength and also the endurance test on some forgings, and several shops have been very successful on all forgings they have heat-treated, but failure has been the result in the majority of shops. I believe it has come about through the fact that all the experiments were on alloy steel only. The greatest trouble is to attain uniformity in heavy forgings. Aside from all the discouraging features of heat-treatment that are found in the average railroad shop, I believe it is a method we should all endeavor to learn more about.

There are many obstacles which are detrimental to successful heat-treatment of locomotive forgings in railroad shops. There is the cumbersome equipment and space which is essential to success. There are very few shops that could readily be prepared to treat even the lightest of forgings. Then there is the output to be considered and the extra help required. But considering all the obstacles and expensive equipment I believe it would prove a good investment when the method was thoroughly understood.

If heat-treatment was introduced in your shop, what would your opinion be, for or against it? If heat-treatment was introduced in your shop, what effect would it have on your output? What extra help would you require? What extra time would you require (if any) to complete a set of rod straps complete, heat-treated? These are questions that we should be interested in and may be asked any time regarding this method. I would like to hear the opinion of different members on this subject. I am sure there are a number of shops that have tried it out to some extent.

Discussion

There was considerable difference of opinion regarding the advantages secured by heat-treatment. H. E. Gamble (Penn.) stated that in addition to improving the quality of the steel, heat-treatment brought out defects. G. Fraser (A., T. & S. F.) stated that he considered annealing preferable to heat-treatment. While heat-treated parts showed high tensile strength they seemed to break down under the vibration to which they are subjected in actual service. W. C. Scofield (I. C.) attributed much of the trouble experienced in using heat-treated parts to the unequal rate of cooling in light and heavy sections. Large forgings are heated above the critical temperature, to treat the material in the interior of the section, and are then quenched again at a lower temperature to take care of the outer layer. Mr. Scofield thought that the high temperature might do more harm than good, and suggested that this explained why small parts have given splendid service after heat-treatment, while larger parts have often failed. George Hutton (N. Y. C.) stated that the New York Central has heat-treated material for three years, and he had still to hear of a single failure. A motion was adopted stating that it was the sense of the convention that wherever heat-treatment can be done it is a success.

SPRING MAKING AND REPAIRING

BY J. W. RUSSELL
Pennsylvania

The question of springs for locomotives in any up-to-date repair shop is one of the most important items that we have to consider because if the proper methods are not used the making and repairing of springs becomes a very expensive proposition. There are so many different ways in which the spring plant may be utilized for economy or waste, that it is incumbent upon the man in charge to put forth every effort in order to obtain the most desirable method. In the first place, we should use all the machinery possible in this class of work, because of the resultant speed and accuracy. The use, also, of all scrap steel that has not deteriorated to any great extent from re-working is economy. The plates should be annealed and cut to desired length; the long plates cut for short ones, and they in turn formed into spring clips, etc. Care must be exercised in examining and selecting this scrap steel in order to avoid reclaiming into service plates that are checked or cracked.

At Renova shop we have followed the method as outlined above and have obtained very good results. We do the spring work for the entire grand division, which requires an output of approximately 400 springs per month. Our new steel is purchased under Pennsylvania Railroad specifications of .90 to 1.15 carbon. We shear the plates to length and cut off the corners cold on a No. 7 Hilles and Jones shear, located in the smith shop, after which the material is delivered to the spring plant where the nibbing, cambering, hardening, drawing, banding and testing are done. We use oil for fuel in all operations except drawing, which operation is done by the use of sodium nitrate. We find that sodium nitrate will stand a heat up to 1,000 deg. F., at which point we draw all our heavy plates for one hour. The lighter plates are drawn at 900 deg. F. for 45 minutes. Incidentally, I might mention that we found it necessary (when using the sodium nitrate treatment for drawing these plates) to plunge the hot plate into a bath of water to remove the sodium nitrate that adheres to it.

The following table is used by us in heat treating springs,

Temperature of Bath and Time Required to Heat Treat Springs

Size of plates	Deg. F.	Time in bath, minutes
4½ in. by ⅜ in.	925	45
4½ in. by 7/16 in.	925	60
4½ in. by ½ in.	990	60
3½ in. by 7/16 in.	900	45
5 in. by ½ in.	950	60
5 in. by ⅝ in.	1,000	60
6 in. by ½ in.	950	60
4 in. by ⅜ in.	925	45
6 in. by 7/16 in.	950	60
3½ in. by ⅜ in.	925	45
3½ in. by ¼ in.	900	30
5 in. by ⅜ in.	925	45
3 in. by ½ in.	950	60
3 in. by 7/16 in.	950	45

after which is given a tabulated statement showing the transverse test of individual plates, giving the deflection and breaking angles.

In order to make the transverse test, one plate is taken from each heat and submitted to the test, using the span and deflection shown on table for that particular thickness

Specifications for Transverse Test of Spring Leaves.

Thickness of steel	Transverse span to be used	Deflection test in 100ths of an in.	Breakage test minimum angle of breakage, deg.
¼ in.	18 in.	104	63
5/16 in.	18 in.	83	50
⅜ in.	18 in.	69	42
7/16 in.	24 in.	114	36
½ in.	24 in.	93	31
9/16 in.	24 in.	82	28
⅝ in.	24 in.	74	25

of leaf, and if the leaf does not take a permanent set of more than .02 in., it has an elastice limit of not less than 120,000 lb. per sq. in. and is then broken. If it breaks at an angle not less than that shown on the table for that thickness of leaf, it is accepted.

The next operation is assembling and banding. We use a hydraulic assembling machine in connection with the hydraulic banding machine, having a pressure of 1,500 lb. per sq. in. After the band is applied, the spring is placed in such a position that a stream of water cools off the band. The spring is then tested, and if found all right is dipped into the paint vat and placed in storage. Our furnaces are equipped with the Stupokoff pyrometers, using the platinum, platinum-rhodium couples. These pyrometers are checked once each month against a standard test pyrometer, which instrument is checked against a laboratory pyrometer.

DISCUSSION

Several members expressed the opinion that spring making was carelessly handled in many shops. The part of the work which is most often neglected is drawing the temper, although uneven heating and cooling when hardening is not uncommon. J. W. Russell (Penn.) stated that the use of strong bands on trailer springs had been found advisable. The application of rollers between the band and the spring seat also added to the life of springs. Good fitting is essential and wide openings between the leaves were condemned as detrimental to strength.

AN UP-TO-DATE RAILROAD BLACKSMITH SHOP

BY GEORGE FRASER
A. T. & S. F.

The location of the blacksmith shop is an essential feature not only as it influences the design and arrangement of the building and the layout of the tools, hammers, forges, etc., but also as affecting the output of the shop. The nature of the work and the conditions surrounding it require the building to be in an isolated location in order to provide light and air on all sides. In repair work much material travels from the erecting and assembling shop to the blacksmith shop and back again, especially in locomotive work. A large proportion of the material passing between the locomotive and blacksmith shop is heavy and bulky. For this reason the blacksmith shop should be so situated in relation to the locomotive department as to provide for movement over the shortest and most direct route. Such material is usually transported on push cars and trucks so that distances are important in economizing time and increasing output.

From the standpoint of shop production, the blacksmith shop is looked upon as a feeder for other shops of prime importance. Sometimes this is overlooked in preparing the original plans, and the average blacksmith foreman is never consulted with regard to them, so when the shop is completed he is invited into it, and it is up to him from then on to make the best of it.

The blacksmith shops at the principal shop plants of the large railway systems turn out the forgings entering into the construction of new cars, and the bulk of the car forgings required in keeping up the repairs of both freight and passenger car equipment on the line, as well as the forgings for locomotive repairs. As there is a difference in the nature of the work for the two departments, each should occupy a section common to itself, and the machines, forges and equipment should be arranged accordingly. Naturally the equipment for each department is situated in that portion of the blacksmith shop building nearest to the principal shop which it serves. A ground plan in the shape of the letter L is a convenient arrangement for the blacksmith shop, accessible to both the locomotive and car departments. The many conditions affecting the demands upon the blacksmith shop and the differences in the dimensions of the shops on the various railway systems render it impractical to attempt to give a definite proportion based upon any given unit.

The introduction of cast steel in many details for which forgings were formerly used almost entirely has affected the necessary size of the blacksmith shop so far as the locomotive department is concerned. The increased scope of forging machines assisted by the extended use of formers and dies for rapidly duplicating standard parts of cars has increased the possible output of car forgings without enlarging the area required by the shop building.

A general practice has been to span the entire floor without providing intermediate supports for the roof trusses, and in a number of cases this distance equals 100 ft. The trusses are usually supported by the side walls which carry the weight of the roof structure and roof. At Topeka the steel skeleton is entirely independent and the roof structure is carried by built-up columns to which the walls are secured to provide stability. The roof trusses span a distance of 100 ft. The elimination of supporting columns and the long span of roofed trusses without intermediate support allow free scope in the distribution of equipment on the floor. The method of handling heavy work in the blacksmith shop by means of swinging jib cranes requires freedom of action for the crane arms and the absence of obstructions facilitates the arrangement of these cranes. The long span of roof trusses, together with the requirement of a stiff frame construction to withstand the additional load imposed by supporting the upper ends of the crane column, calls for heavy parts and careful design of the roof structure. The horizontal loads imposed by the swinging shop cranes requires stiff lateral bracing. While the distance from the floor to roof trusses at some of the older shops is about 20 ft., the height of the more modern shop has been increased to 30 ft.

Almost without exception, the floor of the blacksmith shop is of earth of some kind. This is frequently covered with a coating of cinders well tamped, and by all means it should be raised 6 in. higher than the level of the ground surrounding the shops.

The ventilation necessary in a blacksmith shop and the amount of natural light needed require a high free space not only to allow the smoke and gas to rise away from the floors and forges, but to permit the diffusion of light from long windows. It is a very noticeable fact that the cleanest, brightest, most airy blacksmith shops are those with high walls. The roof of the blacksmith shop is usually surmounted by a wide monitor extending nearly the entire length of the roof. This is provided for the sake of ventilation rather than to distribute light. The windows in the walls are depended upon principally for natural light, and it is generally considered that the window area should equal at least 60 per cent of the wall area. In order to offer the least obstruction to the free circulation of air throughout the shop in warm weather and in warm climates the windows should be hung on pivots to provide a greater opening than raising and lowering of sashes.

In addition, the shops should be provided with rolling doors and the lay of the shop should be east and west with an open space clear from other buildings on the south side so that all alike will share the south breeze in hot weather. An arrangement frequently followed in the construction of the monitor is to alternate the windows along the sides with space having wooden slats built in on an angle, thus permitting the free circulation of air while excluding rain and snow.

The removal of smoke and gases from the forges is provided for by different methods. Experience in some shops where great care was used in their design to provide for efficient ventilation is said to have proved that smoke hoods in high shops are unnecessary and that the interior of the building is clear and free from smoke and gas at all times.

Hand forges are usually arranged in a row along the wall conveniently placed according to the class of work which they serve. The distance between centers of forges varies from 16 to 20 ft. and 5 ft. from the wall. Forges are arranged at a uniform height of about 24 in. and should be of uniform shape and size.

Careful provisions for tool racks is a necessary detail not to be overlooked, for the care and maintenance of tools and equipment is the duty of the energetic foreman. Tool racks are generally arranged along the wall of the shop and in the center of the shop. For hammer tools, etc., a revolving cone shape tool rack may be provided.

Oil is the most common fuel used in blacksmith shop furnaces. In latter years it has rapidly displaced coal and coke, not only proving more satisfactory and economical as fuel, but also improving the appearance of the shop by removing the necessity of the unsightly coal and coke boxes about the shop. It has been demonstrated by practice that with oil as fuel it is possible to obtain a larger output, a better grade of work by the greater intensity of heat as well as more even heat, the elimination of the necessity of attending the fires, the shortening of the time required to bring the furnace to the desired working temperature and improvements in the conditions under which furnace men work. It is a noticeable fact that in a majority of the new shops particular attention has been paid to the furnace equipment, the design of the furnaces for the various machines and their location in relation to the machine and the movement of the material.

The location of large scrap furnaces should be on the outside of the shop with the working side of the furnace flush with the inside of the main wall. To avoid any possible shortage of steam, boilers should be installed over all large scrap and forging furnaces. By this plan no fuel expense is chargeable to producing steam as the flame and gas from the furnaces do the work.

In arranging the fire and furnaces, they should be so placed that the men are not too near a furnace or fire when working on the metal. Efficiency engineers will figure on the number of steps that can be saved in handling from the fire or furnace to the hammer, or anvil, overlooking entirely the comfort of the men whose vitality is sapped by having the fires too close to the anvil or hammer. The arrangement of furnaces, anvils, hammers and machines should be left to the judgment of a practical man, one who is acquainted with shop practice and who is in charge of smith shops.

No part of the general railroad repair plant has undergone a greater change during the past 10 or 15 years than the blacksmith shop. A few years ago the majority of work passing through that shop was done on open fires and a large quantity of the new material was purchased from manufacturing concerns; today, due to the introduction of forging machines, the majority of work in the modern shop is, or should be, machine work.

Modern machines without proper die equipment are of little value. The main blacksmith shop should be provided with its own tool room where the die work could be carried along independent of the locomotive department, thus avoiding delays. Little attention is given by other departments in assisting foremen blacksmiths along these lines. The following equipment is sufficient for the average shop: one each, planer, shaper, lathe, drill press and face plate. This equipment is installed in the blacksmith shop tool room at Topeka, and greatly facilitates tbe work of getting out dies for the blacksmith shop.

In connection with furnace equipment and open fires, particular attention should be paid to the layout of blast piping. Efficient blast is a very important consideration to the blacksmith shop as it practically governs the heating capacity not only of furnaces but of the open fires. The blast line should be overhead and the safety valves should be provided in the up and down line leading to the forges to take care of any gas that may possibly enter the blast line.

The main blast line should be reduced in area in proportion to the distance covered so as to maintain a good pressure at the end of the line. When compressed air is used in addition to the blast to atomize fuel oil an eight ounce blast is sufficient. When fan blast alone is used nothing short of ten ounces will give satisfactory results. The exhaust pipes on steam hammers should pass downward through an independent pipe suitable to carry the exhaust beyond the shop into a catch basin.

The modern shop may have all the facilities it is possible to provide and still not get results. The foreman in charge must have the good will and hearty co-operation of each and every man under him to reach the maximum of efficiency.

DISCUSSION

The ideas presented in Mr. Fraser's paper were endorsed by the members who agreed that the arrangement outlined was practically ideal. W. J. Mayer (M. C.) questioned the advisability of restricting the exhaust from the steam hammers, and asked whether any plants used the exhaust for heating. Several plans for using the steam were described. In some cases a butterfly valve is used in the exhaust steam line to limit the pressure. At the West Albany shop of the New York Central the exhaust from the hammers is piped to the heating system and no heat is required in any part of the plant other than that furnished by the exhaust steam. A similar arrangement is used on the St. Louis-San Francisco at Springfield, Mo. The advantage of piping the exhaust down to prevent condensation injuring the packing and dripping on the dies was brought out by several who spoke.

RECLAIMING SCRAP IN THE RAILROAD SHOP

BY WALTER CONSTANCE
St. L. & S. F.

Although the subject of the paper I am to present includes scrap reclaiming by the use of oxy-acetylene and electric cutting and welding process, electric welding is not in use at our reclamation plant, and I will have to leave the discussion of electric welding in relation to reclamation to others.

We use the oxy-acetylene torch in stripping frogs, switches, etc. We save good filler blocks, reinforcement and similar parts to use again. We furnish over 50 per cent of all switch material used on the system. Switch frogs, switch stands, switch rods and plates are reclaimed or repaired. Brace or slide plates are made from old Weber joints and scrap boiler steel, also transit clips for switch points from scrap steel.

We have also made up quite a number of oil tanks from tank cars which have been burned. These are cut up by the torch and the best of the steel is sent to the boiler shops for use. The rest is cut up under shears to make switch material and repair parts for steel frame cars. Old cisterns for locomotive tenders are cut up and used to make loading platform running boards, and coal car corner bands. Good parts of scrap steel cars are used for the same purpose. Some of our brake beam stripping is done by the oxy-acetylene torch.

We formerly welded quite a number of bolsters and baggage wagons and warehouse trucks. Oxy-acetylene welding comes in handy on these things, especially for repairing steel warehouse trucks, the frames of which are broken, as it does not pay to repair them in the blacksmith shop when they have to be stripped, but by oxy-acetylene welding they can be made serviceable again at small cost without stripping them.

We formerly welded quite a number of bolsters and truck frames as well as broken couplers at this plant, but of course we have discontinued doing so now. However, we are changing a large number of good couplers with 5 in. by 5 in. shank, 6½ in. butt, to 5 in. by 7 in. shank and 9⅛ in. butt. This is done by welding tapered slabs of steel on the shanks and blocks upon the butts. These then conform to M. C. B. dimensions.

We also reclaim a number of derailing frogs, which are for smaller rails than our standard 90-lb. by splitting them and inserting a piece in the side and welding up with oxy-acetylene so as to bring them to the proper height for the larger rail.

There are no rolls at our plant, but all second-hand bolts are used by cutting off and re-threading, and nuts by re-tapping. Also all flat iron and round bars are saved for use. Bottom rods are made with solid jaws from old 1½-in. A. C. rods, dump rods, and so on. Truss rods 1¼ in. in diameter are made into brake stuff. The short pieces left over are made into brake beam truss rods, bolts and coupler rivets. Other sizes of rounds are used for handholds, bolts, etc. Rusty ¾ in. and ⅞ in. steel is rolled into brake shoe keys on an abandoned spring roll. Rusty and pitted rounds 1⅛ in., 1¼ in. and 1⅜ in. are made into grade stakes for the engineering department. All lined iron is rattled and made into frog bolts and switch chain links. We make standard 1 3/32-in. brake pins by upsetting one-inch iron on the forging machine.

All brake beam repairing on the system is done at this plant. We use an air bulldozer for straightening. All beams are stripped by laborers, and are re-assembled by blacksmiths and helpers.

All round iron and bolts are straightened under air hammers at the scrap docks. The bolts are sheared to length and sent to the threader and the iron is sheared for heading in the blacksmith shop. All serviceable track spikes are also straightened at the yard shop.

Coil springs that are standard are reset. Scrap springs are uncoiled on a special machine and made into lining bars, jack bars, rock drills and drift pins.

All track tools on the system are sent here for repairs. Worn claw bars are made into engine pinch bars and lining bars. Picks are welded if they have one end long enough to sharpen. Where both ends are to be welded it does not pay to repair them. Short picks are heated and cut off to obtain steel for welding out others. We also make new claw bars, lining bars and tamping bars from scrap tire steel. All blacksmith's tools are made from tire steel and we also use tire steel for the manufacture of bolt dies and hammer tools.

Crooked angle bars for small sized rails are straightened in tools under the steam hammer. This tool spreads the bars slightly and makes them serviceable for siding and commercial tracks.

All coupler yokes are stripped at this plant under a power shear. Yokes are repaired when possible and scrap yokes are used to obtain iron for the forging furnace.

Brake levers that are not standard are re-punched, cold plugged and returned to service. Old sill steps are used to make running board brackets, pipe clamps, etc. All car material, such as brake rods, brake hangers, brake staffs and fulcrums which are repairable are sorted at the scrap docks and repaired in the blacksmith shop.

A very close check is kept on the costs, and if a good margin of profit is not shown we do not attempt to repair and reclaim. The welding and cutting apparatus is here to stay because we make a specialty of repairing or reclaiming, whereas that is only a side line in ordinary shops and naturally not so successful.

DISCUSSION

C. E. Stone (D., L. & W.) told of the good results secured by re-rolling scrap bars. G. Fraser (A., T. & S. F.) brought out the advantages of reclaiming as much material as possible at the shop where it originates. He also called attention to the necessity for careful consideration of the work done in order to avoid reclaiming where it is more expensive than the purchase of new material.

HEAT-TREATING

BY H. E. GAMBLE
Pennsylvania

Of late years there has been a marked advancement in the art of heat-treating parts incidental to locomotive and car construction and maintenance. In making the forgings, the billets are cold throughout before being heated to the forging temperature. The finishing temperature, the rate of heat advancement and the capacity of the hammer used are of great importance in forging the different parts. After forging, the parts are first thoroughly annealed to relieve the strains set up in forging. They are then heated and quenched in oil or water. From there they are placed in the drawing back furnace, where they are tempered. The steel used in making these forgings is covered by specifications which call for a carbon content of from .40 per cent to .55 per cent. The quenching and drawing back temperatures are governed by the per cent of carbon contained in the steel. The physical requirements of the heat-treated forgings are determined by the specified diameter or thickness which governs the size of the prolongation from which the test specimen is secured. It should be taken at a point midway between the center and outside of the forging in the direction in which the metal is most drawn out in the forging process.

Each forging must have the manufacturer's mark, melt number and year in which made stamped on as a means of following up the treatment in case of failure in service. It is most important to give all forgings a thorough annealing to relieve the strains set up during the forging operations to insure a good treatment. Furnaces properly charged and forgings heated thoroughly will give the best results. We are reclaiming all main and side rods that are free from fractures, that have been bent, twisted, upset and stretched while in service, thus doing our bit to help the repairing of locomotives along by saving steel, time and labor. These rods are made correct to a template by the blacksmith, allowing for the proper shrinkage. They are then taken to our heat-treating plant, giving them the proper annealing, quench heating, quenching and drawing back. They are then returned to the blacksmith for final inspection and are then ready for service. In reclaiming rods for service, it is necessary to have blacksmiths who are interested and careful in their heating and workmanship. The reclamation, reforming and subsequent heat-treating of many parts which heretofore were scrapped, is one item that will pay the entire cost of heat-treatment alone, not to mention the saving effected along other lines.

POWDERED COAL FOR FURNACE HEATING IN SMITH SHOP

BY H. E. GAMBLE

In handling producer gas and oil furnaces for forging heavy locomotive parts, drop forging, heat-treating and bolt making, the question arises whether a change to powdered coal would be warranted on account of the low cost in operating. In connection with experiments on mixing crude oil with powdered coal, this might help to use up heavy grades of fuel oil coming into the markets for heating purposes. Coal in a finely divided or powdered state represents the most advanced method for producing perfect combustion, making it possible to more nearly obtain the full heat value of the fuel than by any other known means. The generally recognized waste, unstaple or otherwise low-value coal mine products are suitable for converting into the powdered form. To give the best results as regards complete combustion and the least trouble as regards ash and slag, it is very necessary to have powdered fuel dry and keep approximately 48 hours' supply on hand to prevent the possibility of the coal absorbing too much moisture. The statement has been made that it is not necessary to build new furnaces, as by a slight change present equipment can be made to handle powdered coal. Coal rich in volatile matter is preferred, slack or screenings in preference to run of mine. To successfully burn powdered coal, it should be uniformly fine. The maintenance of a correct ratio of air to coal is absolutely necessary, as on this depends the ability to hold an unwavering and uniform temperature in the furnace, which ranges up to 2,200 deg. F.

We have unquestionably passed through one of the greatest fuel conservation periods known, and the members of this association should do all in their power to secure the best equipment and use their good judgment in conserving all fuel possible in running the blacksmith shops.

OTHER BUSINESS

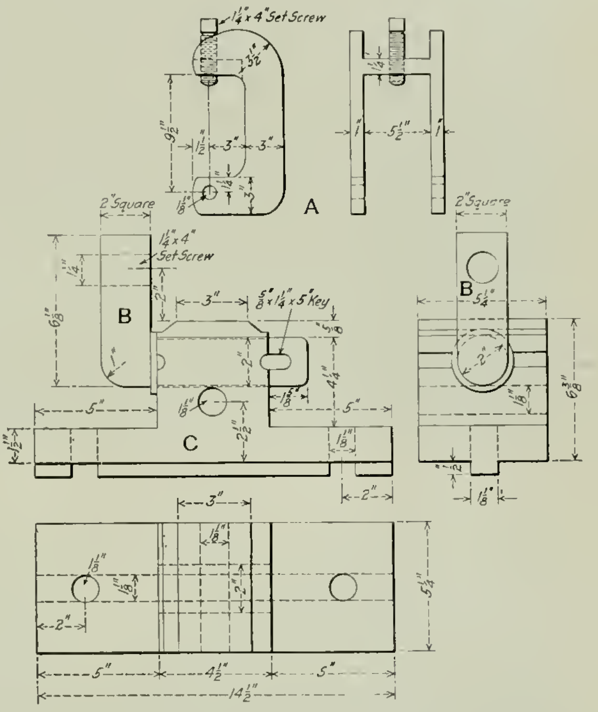
The report of the secretary-treasurer showed a total membership of 375 and a balance of $741 in the treasury. A committee was appointed to confer with the officers of the American Railroad Association regarding amalgamation with Section III, Mechanical.

The following officers were elected: President, J. Carruthers (D., M. & N.); first vice-president, W. J. Mayer (M. C.); second vice-president, Joseph Grine (N. Y. C.); secretary-treasurer, A. L. Woodworth (B. & O.). In the balloting for the location of the next convention Birmingham, Ala., received the largest number of votes.

A TIRE CLAMP FOR BORING MILLS

BY H. L. LINGO

A clamp for a boring mill, so designed as to permit the boring and turning of a tire at one setting, is shown in the drawing. A complete set consists of four of these clamps; all of the parts shown and the necessary keys and set screws are made of steel. To set up a tire on the mill ready for boring, the blocks *C* are secured to the table at the proper points for the diameter of the tire to be bored. The tire is placed on the blocks and the clamps *B* inserted through the block, on the outside of the tire, and then keyed in position through the slot shown in the drawing. A 1¼-in. set screw in the square portion of each of the clamps *B* provides a



Details of the Block and Clamps

means of securing the tire firmly and accurately in place. When the boring is finished the clamps *A* are placed over the blocks *C* so that the 1⅛-in. holes in the clamp coincide with cross-wise holes in the block, and a pin or key is inserted. The upper portion of the clamps *A* are directly over the tire and the 1¼-in. set screws are tightened against the tire, holding it firmly to the block. The clamps *B* are then removed and the tire being secured by the clamps *A*, may be turned without resetting.

This method is very useful in a shop turning out extra tires of varying diameters and tread thicknesses for replacement of worn tires at other points on the road, and can also be used with equally good results in turning new tires.

THE LUMBER FREIGHT BILL.—The annual freight bill of the lumber industry is estimated at about $215,000,000. Lumber and forest products furnish about 11 per cent of the total tonnage of the American railroads or about 215,000,000 tons yearly, according to Interstate Commerce Commission statistics. This is greater than the movement of all agricultural products and is exceeded only by the tonnage of general manufacturers and mine products.

British Army Locomotive Repairs

Story of the Military Shops Near Rouen, France, Equipped and Operated by the Royal Engineers

BY H. L. COLE
Lieutenant Colonel, R. E.

THE shops shown herewith in various stages of their construction and equipment were used by the British Transportation Service for locomotive repairs during the last two years of the war.

The project is located near Rouen and was commenced by the French State Railway in 1912, but only partially erected when, in 1914, war broke out and interrupted the work. By arrangement with the French, the British Royal Engineers, Transportation Branch, took over the uncompleted shops in February, 1917, finished and equipped them, and continued to use them for the repair of the British, American, Canadian and Belgian standard gage locomotives in use by the British Expeditionary Force, until after the armistice was signed.

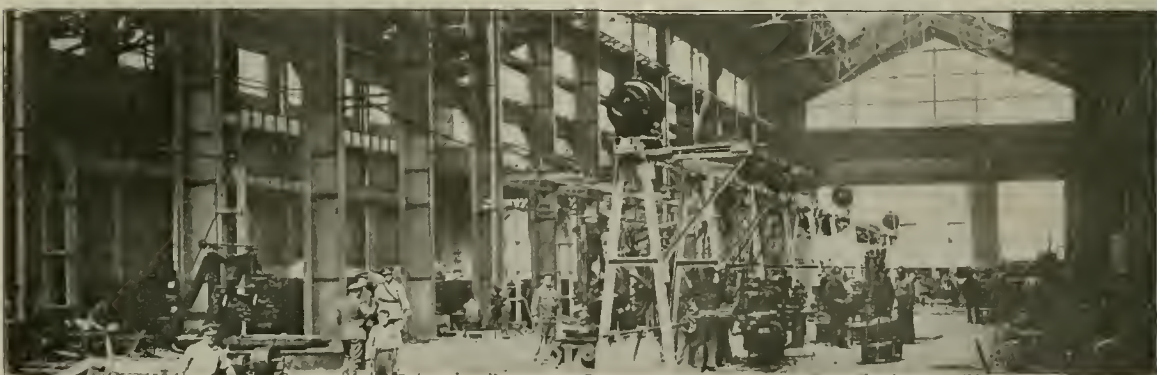
Within half a mile of the shops the sappers built their standing camp, the living huts being 16-ft. by 66-ft. demountable structures, to a standard and very economical design. A large proportion of the camp was built of packing-case timber, stripped off imported locomotive parts and run through an improvised saw mill on the site.

Near the main shops, but outside the main shop yard, the Royal Engineers built and equipped a pattern shop and brass and iron foundries, which turned out castings as large as locomotive cylinders on occasions, but normally supplied all common renewals requisite for locomotive casualties and fair repairs.

The corrugated cupola shown in one of the photographs was improvised out of a collapsed Fox corrugated furnace, bought as scrap-iron from a French junk-shop and rushed up to increase much needed output at a time of stress. Another was added later. Each gave approximately two (British) tons an hour, with a coke consumption between 4 and 5 cwts. per ton of fettled castings.

To appreciate the actual output of erected and repaired locomotives, it should perhaps be mentioned that the scheme was only mooted in December, 1916. On December 18 the first officer was appointed, on the 19th the site was inspected; on Christmas Day, the machine tool and equipment estimates were put up for approval and detailed lay-out plans were in

British Expeditionary Force Base Locomotive Repair Shops Near Rouen, France, As They Appeared in March, 1917; the Erection of the Outside Bay on the Left Was Started in February, 1917



Erecting Shop, Partly Completed, in August, 1917, With Canadian Built Locomotives in Course of Erection; Cranes of Eight Tons Capacity are Shown on the Lower Runway, Heavy Cranes Not Being Installed On the Upper Runway till February, 1918 hand. However, it was not till February, 1917, that the first small draft could commence work on the site, and the machinery and equipment arrived but slowly.

Both camp and works were built and fitted up by the men who had to use them. These were skilled men of all the necessary locomotive workshop trades. Half of the officers and men had fought in the front line, over a hundred had been through the Mons retreat or later operations entitling them to the 1914 Star and very many carried wound stripes.

The power plant, ordered in March, 1917, was placed in operation on October 4, 1917; but prior to that several machines were got going with temporary drives from small internal combustion engines. Over 30 (British) tons of iron castings were produced in a small emergency foundry before the power-house was working. The fan was driven at one time by a jacked-up Ford car, but mostly by a venerable portable steam engine, salvaged from a scrap-heap.

By the end of 1917, however, the establishment was up to

Machine Shop During Installation of Machine Tools, September, 1917

There were officers and men from India, China, South Africa, South America and Australia; and numbers of others who had never been outside the Old Country before the war. There was nothing of trades union restriction about these men. Machinists, blacksmiths, boilermakers, pattern-makers or moulders, dug and mixed concrete for foundations, built

strength and the shops almost in full swing. There had been 135 locomotives erected and a start had been made with heavy —some very heavy—repairs.

Up to the end of December, 1918, 232 new locomotives were erected and 370 engines were repaired, 2,073 pairs of wheels were turned up and 275 wheels re-tired, 737 tons of

The Foundry as it Appeared in December, 1917; Note the Cupola Built Out of a Corrugated Furnace

huts, erected shops, rigged derricks or did the next job that had to be done, whatever it might be.

The erection of engines imported from Canada and the United States was commenced almost as soon as the machine tool equipment began to arrive and months before the cranes were up, and proceeded simultaneously with the building and internal preparation of the shops. The first two engines were turned out together early in July, 1917.

forgings were turned out, 2,186 tons of iron castings and 168 tons of brass. The average output for 1918 is shown in the table.

Throughout the operation of the shops the work was gravely handicapped by the extraordinary variety of engines to be dealt with, the exceptionally bad condition of many that had worked for years without a good repair, the paucity of working drawings and the impossibility of either obtaining or maintaining good stocks of spares, or of getting them rapidly from England or America. Not the least of the handicaps were the natural corollaries to war conditions; an abnormally high proportion of serious defects due to rough track, rough handling and rough working conditions. For example, of the first 300 engines repaired, 15 had burnt fireboxes. One engine, a six-coupled inside cylinder type, arrived with her boiler-barrel pierced clean through and her motions wrecked by an aerial bomb. Cracked cylinders, bent and cracked frames, and chewed-up front or trailing ends due to collisions or other roadside adventures flowed in erratically, at times, especially during the great German effort in March-April, 1918, in abnormally high proportions.

The spirit and discipline of the men were well shown when, instead of being told that the strain could be eased off after the armistice, they were called upon to slam into their work again for all they were worth, in order to cope with the increased strain necessarily thrown on the transportation services due to the general advance of the Allied armies. Their average out-turn of repaired engines per week from the date of the signing of the armistice till December 31, 1918, was 8.8.

The average time the engines were detained in the shops during 1918 was 30 days per engine, including trial. The average man-hours expended per engine, excluding spares

Average Output of British Army Locomotive Repair Shops Near Rouen in 1918

	Number per week
Engines repaired	7
Wheels turned up, pairs	38.4
Wheels re-tired	5.4
Forgings, tons	12.8
Iron castings, tons	37.9
Brass castings, tons	2.8

drawn from stock, amounted to 3,418 for engine and boiler (including 655 for boilermakers) and 643 for the tender; total, 4,061 man-hours per engine complete for the road. The figures cover direct charges only and do not include time required for patterns and castings.

A planning department was maintained and the work was scheduled and routed through the shops. Several forms were used for routing, to suit the different types of locomotives handled and the different classes of repairs. A typical form, for heavy repairs to a locomotive with outside cylinders and valve chests, including renewal of boiler and cylinders, is shown in one of the cuts.

ROUTING SCHEDULE

ENGINE NO. CLASS REPAIR CLASSIFICATION

OPERATION (ERECTING SHOP)	Date routed	Actl date
Engine in shop, stripping begun		
Off wheels, wheels to wheel shop		
All parts delivered to Bosh.		
Boxes back to engine for gages		
Final inspection and orders		
Boiler out		
Cylinders off, S		
Stripping completed		

EX STORES AND BLACK SHOPS	Date routed	Actl date
Cylinders (from stock) to E.S.		
Hornblocks, clips, wedges		
Slidebars

Trial trip		

Type of Locomotive Repair Schedule Used in British Military Shops Near Rouen, France, for Heavy Repairs, Including Renewal of Cylinders and Boiler for Outside Cylinder Type Locomotive

Reasons for Excessive Labor Turnover

Experiences of a Former Railroad Mechanic on Going Back Into That Work in a Western City

BY "NEWT"

It is a well established fact that there are two great wastes in industry today; one the lack of efficiency in management and the other the labor turnover.

After being away from railroad shop work for almost eight years, circumstances recently compelled me to seek work in this field. Being in a certain western city where my acquaintances were few, it was necessary for me to apply for work as machinist in a railroad shop. In view of the wonderful strides made along efficiency lines in many other classes of work, I naturally expected to find many new and better methods, especially for running repair work on locomotives. If the roundhouse I worked in is typical of the methods more generally used, then there has been little change for the better and certainly there is room for great improvement.

THE QUESTION OF PHYSICAL EXAMINATIONS

The first thing that struck me was the objection on the part of the employees to the physical examination, and yet I could see that this is a small but rather important matter as concerns labor turnover. Very few men give good excuses for objecting to it, except that it interferes to a certain extent with their personal liberty. One criticism is that the company requires it and yet compels the men to pay for it. The general opinion advanced by the employees is that if the corporation wants this examination it should pay for it, as it is really no concern of the employee. Another and vital criticism is that after taking the examination, no precautions are taken by the corporation to protect the men in a sanitary way. My own experiences will bear this out, as far as this particular shop is concerned, and to my knowledge many others are just as bad. It is a fact that few men are turned down for shop work on their physical examination.

Is "Newt" Right?

"Newt," in his discussion of the labor turnover problem, scores the railroad in question for miserably inefficient methods and practices.

Is this case an isolated or unusual one? It reads almost like a chapter from the Dark Ages. Certainly the conditions are below the standards which exist on most roads.

Cities have been greatly beautified and improved by the publication of photographs showing examples of filth and untidiness. We shall welcome "pen pictures" from our readers of inefficient and unsanitary conditions which come under their observation on railroads with which they are familiar.

What is the underlying cause of the condition described by "Newt?" In the final analysis who is really responsible for it?

SANITARY CONDITIONS DISGUSTING

After taking a somewhat severe examination I naturally expected that sanitary conditions would be about right in the shop. What was my surprise after the first day's work was completed, to be compelled to wash in a hog trough—a real community trough—which is filled with water and steam heat applied; then as many as 50 men wash in the same water. After three days my face broke out in sores and kept getting worse each day until I finally came to my senses and found a boiler wash lead pipe, where I could wash in cold water with the added pleasure of having my feet get a bath. Should not the doctor in addition to making the physical examination go far enough to see that sanitary conditions are good? Evidently he does nothing of the kind and his work ends just where it really should begin. The general opinion around that "trough" was, "what a farce the physical examination was when such a condition was allowed to exist."

I learned that the matter had been up to the local manager several times and many promises had been made, but the abuse still remained. Is it any wonder men combine to take such matters up with the management? Good men will not stay long in such a place. At a small cost the corporation could install a sanitary washing system which would do away with this cause of dissatisfaction and the resulting improvement in the labor turnover would soon pay for the investment. The engineers and firemen at this particular point were provided with good washing facilities within plain sight of the "hog trough," but the shop men were denied its use. This was rank discrimination and the other workmen did not fail to express themselves concerning it. I am sure a great many objections to the physical examination would be removed if some thought were given to the question of sanitation.

There were 20,000 deaths in this community from influenza; while this wash trough was not the cause of all this trouble, who can deny that it must have been a wonderful agency in helping spread the disease? Who would have gained most if sanitary washing places had been provided for the shopmen?

TOOLS ARE REQUIRED FOR GOOD WORK

Another very strong factor in the labor turnover is the reception a new man usually gets. After reporting for work the first morning I was turned over to an old man, who was supposed to equip me with the necessary tools to work with. It was soon apparent that his only interest was to give out just such tools as he had on hand; he could give no idea as to when the remaining tools, if there were to be any, would be forthcoming. The tools I was furnished with were a monkey wrench, two chisels and a hammer; except for files, this was my entire equipment during the whole time I remained.

No attempt was made on the part of the foreman to acquaint a new man as to how the tools or supplies could be reached. He had no time to attend to such details. As no specialty men were allowed in the shop, mechanics had to do all sorts of work. A man had to hunt a new set of tools for each new kind of work, and he might have a dozen different kinds of work in the day's run. There were two tool rooms or two places where tools were kept; just why I could not understand and the result was that a new man often found himself at the wrong tool room and was compelled to retrace his steps to the other. The result was that a new man was of very little use for the first two or three weeks because of this fact.

One of the tool rooms was presided over by the old man who provided the new man with his tools, as mentioned above; I have seen three and four men stand for 30 minutes waiting for his return from some (very important in his imagination) errand. The only reason I could see for the two tool rooms was to provide this old employee with work. It seems to me he could have been placed where he would have done less harm or else have been pensioned as was suggested by many who had to contend with this vexation.

MATERIAL MIGHTY SCARCE

Another thing that has a very direct bearing on labor turnover, and one that is not given a great deal of thought in many places, is the method of material deliveries to the men who have the real work to do. To make this more clear I will outline some of my experiences. The first thing that was necessary when wanting materials from the storehouse was to go to the office and get an order. This was placed in a box, where it was picked up by the stores department and the materials were then delivered to a box located in the roundhouse. I was given a couple of front end main rod brasses to reduce; before starting the work I ordered a half-round file with which to do the work, thinking it would surely be delivered by the time it should be needed. When ready for the file, I went to the delivery box and it was not there, this being about one and one-half hours after starting the work. After going to two or three machinists in an endeavor to borrow one, I finally managed to find an old worn out file and to get the work done in time to prevent any delay in the movement of the engine to the train. The new half round file was delivered 24 hours later. Good fortune played into my hands in this respect, for I happened to be going by the delivery box at the time the file was delivered; otherwise it would have found its way into some other man's equipment. Why was the stores department so long in making this delivery, or if it was short on this item why was there no advice as to non-delivery, in view of the fact that the order had been O.K.'d by the proper party?

Some may say this was an isolated case, but to show what a farce this delivery actually was I will recite some other experiences. A few hours later it was necessary for me to order some small bolts for a drop pit engine and being in no hurry I thought I would see how long it would take to get the material. After placing the order in the usual manner I waited until the next morning before going to delivery box. Not finding the bolts I had another order placed and again waited. After going to the box the third morning I went to the clerk and explained the circumstances and after phoning the stores department the third order was placed and then came the delivery. Before I had time to reach the box more than half the bolts had been taken. You can readily see how much time was wasted on such a small matter. Upon asking some of the older men what they did when they wanted materials in a hurry I was told there were some scrap cars about 1000 feet from the house and that they usually went there and after searching managed to find something for a makeshift.

My contention is that the materials should be delivered promptly or the mechanical department notified at once so that provision may be made for some method of getting the material without a high priced mechanic spending his time hunting in the scrap pile. There seemed to be no co-operation between the mechanical and stores department as far as efficient delivery of materials was concerned.

INADEQUATE SUPERVISION

Another feature that has a very direct bearing on the labor turnover is the manner in which the work was supervised. The organization at this particular place consisted of one assistant master mechanic, general roundhouse foreman, roundhouse foreman and assistant roundhouse foreman. The assistant roundhouse foreman, as far as I could see, did most of the work, his duties consisting of taking all the work off the engineers' reports, distributing this work, as well as all the inside and outside inspectors gave him, handling the engines on the drop pit, and handling the machine shop where the roundhouse work was mostly done; this shop was one hundred feet from the house and on the opposite side from the office. He also kept 48 machinists busy. The general roundhouse foreman made a trip or two a day through the house and the roundhouse foreman spent most of his time at the turntable; indeed I have often seen him taking a turn at running the table.

Much has been written about keeping the number of men handled by any one man down to 30, but here was a man handling at least 75 men in addition to all the other duties mentioned. If that man had been burdened with less duties he could have given more time to seeing that the men were properly supplied with tools and have given more direct supervision to their work.

KEEPING DOWN THE LABOR TURNOVER

I would suggest some of the following things to help keep down the labor turnover:

Matters Causing Dissatisfaction.—Intelligent consideration should be given to the complaints from individuals rather than to let them reach a stage where some labor organization can make them a grievance. After the medical examination is given see that proper sanitary measures are taken to safeguard the employees, especially in providing suitable places for washing and for the men to hang their clothes. It was three weeks after I went to work before I was provided with a place to hang my clothes. When I spoke to the general foreman about it I was informed that there would be more cupboards next day, but they had not arrived when I left the service. This is a matter entirely up to the local manager and proper thought and consideration on his part would easily have removed this cause for dissatisfaction.

Lack of Proper and Sufficient Tools.—Every man should be equipped with a full complement of small tools to keep the trips to the tool room down to the minimum. Proper checking of the tools a man has when he begins and leaves the service would go a long ways in keeping down the loss of them and more than pay for the money invested. Many railroads think that giving a man small tools that should be carried (in their estimation) in the tool room is a distinct loss, but after being around a shipyard and seeing the methods used there in this respect, I am sure much time would be saved, and money too, if all mechanics were properly equipped with small tools. In the shipyards it takes about one and one-half hours to get a clearance and most of this time is spent in "squaring up" with the tool room. If the railroad shop spent half this time checking a man in and out what a saving it would be.

Proper Supervision.—This question is rather a hard one to solve, but its relation to the labor turnover is very intimate. The man who is kept reasonably busy by a foreman who knows how to get the work out of his men is a much better contented and a more reasonable man. Indifferent care in this respect forces good men to move. Wages have reached such a high level that a reasonable amount of attention to the above details will go a long way in stopping the turnover, which is a big factor in helping to make railroad shop costs soar skyward.

Car Shortage Likely in Fall.—A statement has been authorized by the Southern regional director's office to the effect that only the most careful handling of cars by the railroads with consistent and wholehearted co-operation from the shipping public can prevent another shortage of freight cars during the coming fall and winter. It is stated that every piece of equipment is now in use on many lines.

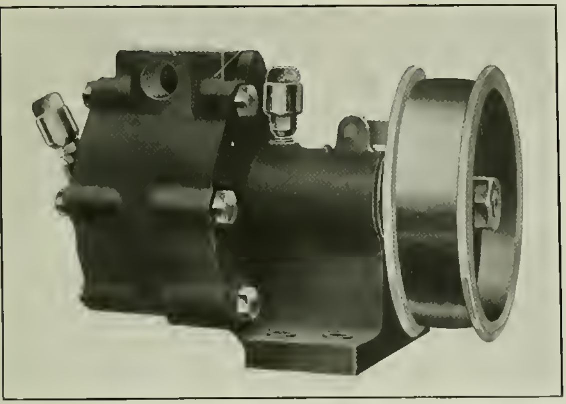
NEW DEVICES

THE ROLLWAY PUMP

A new departure in pump design has been developed and placed on the market by the Michigan Machine Company, Detroit, Mich. This pump, known as the Rollway, is especially designed for pumping cutting tool lubricants.

The end sought in designing this pump was the elimination of such trouble as loss of prime, clogging, inadequate suction and short life. These pumps have now been in use for more than a year and have been found to possess these qualities and are said to have shown many other advantages as well.

The illustrations show the simplicity of the pump construction. The principal working parts consist of two rollers which rotate eccentrically in the pump chamber. The entire motion is rolling, thus eliminating all wear which is caused by the scraping of working parts against the pump chamber.



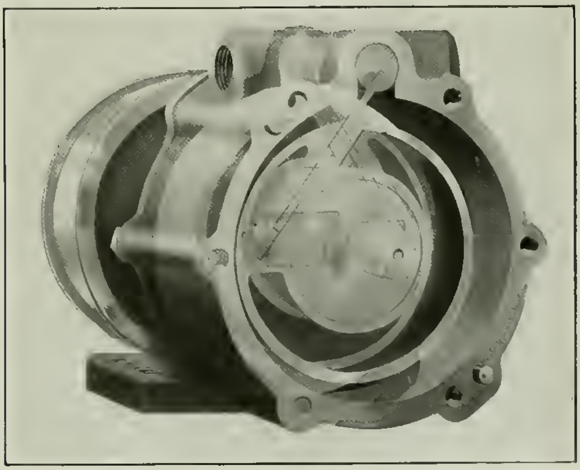
The Rollway Self Priming Pump

The pump is self-priming, may be used anywhere within 10 ft. above the level of the liquid and will prime itself, requiring no valves. This positive suction is not affected by aeration, as is the case with many other pumps. The tank from which the liquid is being pumped may be entirely emptied and the pump allowed to suck air, and when the tank is refilled it will immediately prime and start pumping again. No relief valves or overflow piping are required. The outlet in the discharge piping may be closed and the pump allowed to run without damage to itself or the piping. This result is obtained by the use of a spring placed in the rectangular slot in the inner roller, which bears against the squared shaft. This spring operates only when the pressure on the pump is as great as the pressure required to compress the spring. When this pressure is reached the compression of the spring allows the rollers to come to the center of the pump, where they continue to revolve in the liquid without exerting further pressure on it.

The pump is not affected by foreign matter in the liquid, and will not clog. Any particles, such as cast iron and steel chips, paper, rags, waste, etc., which can pass through the intake pipe will pass through the pump without clogging or damaging it in any way. The action of the pump is to roll the liquid in front of the pump rotor, so that should anything stick, the spring will compress, allowing the roller to pass over the obstacle without damage. The foreign matter will be washed out on the next revolution of the motor.

The pump is universal and may be used with either side up and at any point on a machine where its application is most convenient. Either side of the pump may be used as intake or outlet. Plain pumps may be used on a reversing machine where no liquid is required when the machine is reversing. The pump can be reversed without harming it, and it will deliver liquid again immediately its proper direction of rotation is resumed. A pump equipped with reverse valves is furnished where it is necessary to maintain a constant flow in a given direction regardless of the direction of the rotation of the pulley.

Speed is not a factor in the efficient operation of the Rollway pump. It may be operated at speeds ranging from 100 to 600 r. p. m. or more, making it applicable to all types of machines without the extra expense of making special provision for either high or low speeds in order to secure maximum efficiency. The fact that it may be operated at very low speeds insures long life where low speed can be obtained.



Interior of the Rollway Pump

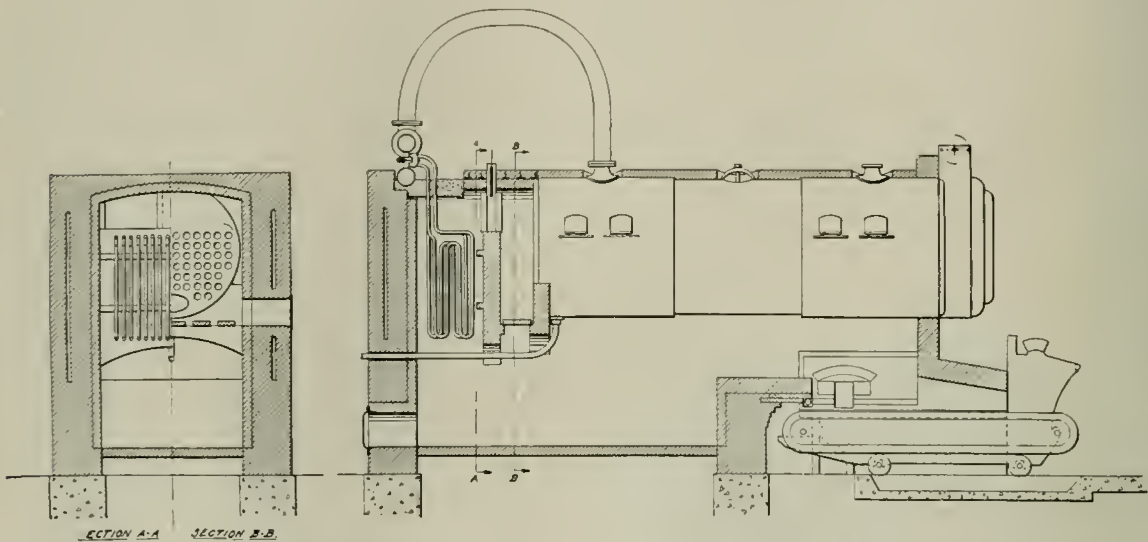
The Rollway eliminates the necessity of using numerous sizes and types of pumps in order to obtain maximum efficiency on various types of machines and the necessity of carrying repair parts for different types of pumps. It operates with equal efficiency in pumping either water or oil, and the low horsepower required per gallon of liquid pumped permits a considerable economy in cost of operation.

These pumps are furnished with controlling springs to develop 25 lb. pressure at 200 r. p. m., or for higher or lower pressures as may be required.

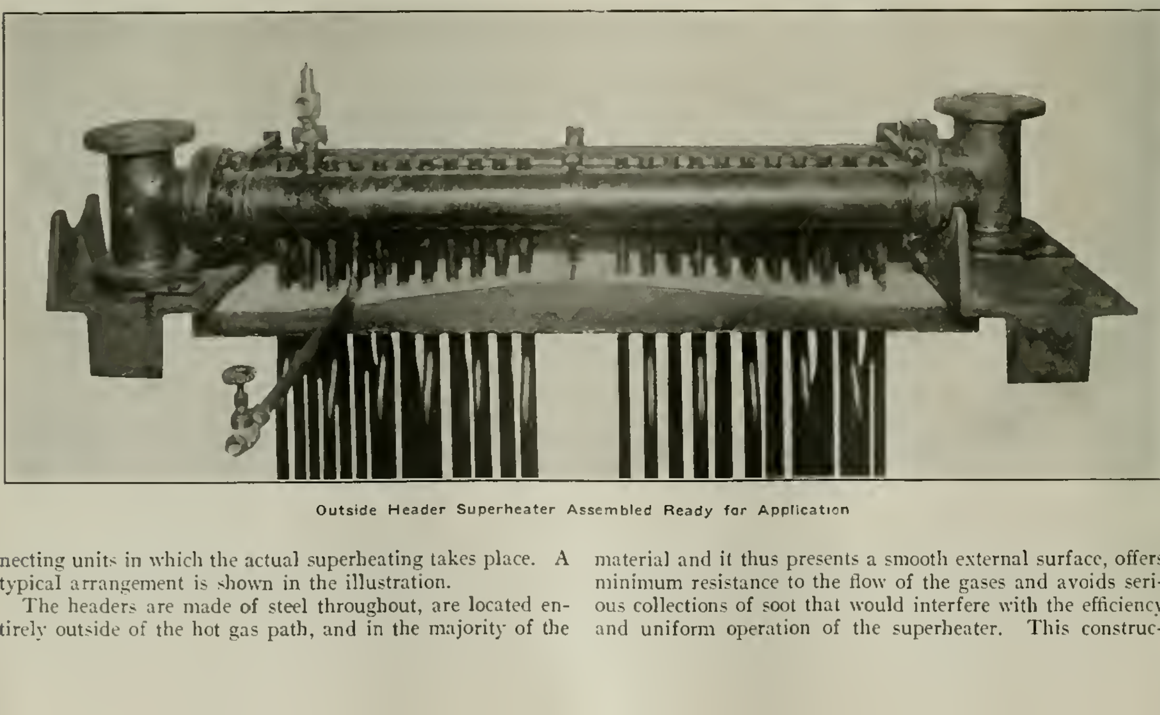
SUPERHEATER FOR STATIONARY BOILERS

An adaptation of the locomotive type of superheater to stationary boilers is being introduced by the Locomotive Superheater Company, New York. This superheater is known as the Elesco.

The superheater consists of two headers, one acting as the distributor for the saturated steam coming from the boiler and the other a superheated header for the collection of the steam after it has been superheated, and the necessary connecting units in which the actual superheating takes place. A typical arrangement is shown in the illustration.



Elesco Superheater Adapted to a Horizontal Return Tubular Type Boiler



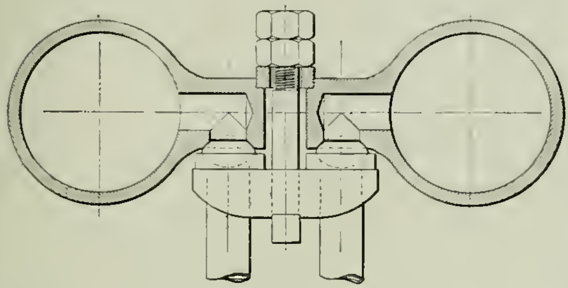
Outside Header Superheater Assembled Ready for Application

The headers are made of steel throughout, are located entirely outside of the hot gas path, and in the majority of the designs, outside of the boiler setting proper, so that the headers as well as the unit joints are accessible for inspection and repairs without entering the boiler setting. The advantage of such an arrangement will readily be appreciated. Safety valves conforming to the A. S. M. E. Boiler Code are provided and are located near the outlet. Provision is also made for drainage and connections for thermometer cups.

In most cases the headers are made with the outlet on the superheated header in an opposite location to the inlet on the saturated header, assuring an even distribution of the steam flow through all units. Where conditions are such as to require it, the saturated header is provided with several inlets.

The superheater units are made of heavy, cold drawn seamless steel tubing of the proper diameter to give correct steam areas. The tubing is not covered with any other material and it thus presents a smooth external surface, offers minimum resistance to the flow of the gases and avoids serious collections of soot that would interfere with the efficiency and uniform operation of the superheater. This construction also brings the steam into intimate contact with the gas-touched heating surface, and gives a low resistance to the flow of heat from the gases to the steam.

The form of the unit is such as to permit free expansion and contraction of all parts. The tubes are bent on specially designed machines that do not weaken them or reduce the steam areas. Ample provision is made to prevent the pipes from warping. In cases where severe moisture and scale conditions are prevalent, the units can be made so that they may be satisfactorily cleaned on the inside. Due to the fact that the units are made of small diameter tubing, it is possible to obtain correct relations between steam areas and heating surface and so distribute the cross sectional area through the superheat as to obtain the most desirable steam velocity without the use of cores. The use of cores in super-



Ball Joint Connection Between Units and Header

heater tubes causes a considerable drop in pressure through the superheater, because of the added frictional resistance of the steam and where bad water and foaming occurs, the small space between the cores and the inside of the tubes is quickly stopped by scale-forming material.

The connection between the units and headers is a metal to metal joint. This joint is made so as to permit the easy removal of the units without special tools, and its use also avoids two holes in the header which would be necessary with rolled joints. Any unit in the superheater can be disconnected without interference with the other units, and the work of disconnecting a unit, which consists merely of loosening a bolt, can readily be done by the ordinary power plant attendant.

The ball end, as shown in the illustration, is formed integral with the tube by a special forging process. The ball is then faced and ground, and fits into a ground seat in the header, which is made at an angle of 45 degrees. The clamps and washers are made of forged steel, and the header bolts are made of heat-treated alloy steel, with an elastic limit of not less than 75,000 lbs., per square inch. This joint, while a new departure in stationary superheater design, has been used in a great number of locomotive superheater units and has withstood the extremely hard service of locomotive operation.

This superheater is suitable for application to all types of vertical or horizontal fire tube or water tube boilers and the possible fuel economy and increase in boiler efficiency make its use very desirable.

AN OPEN TYPE LOCOMOTIVE FEED-WATER HEATER

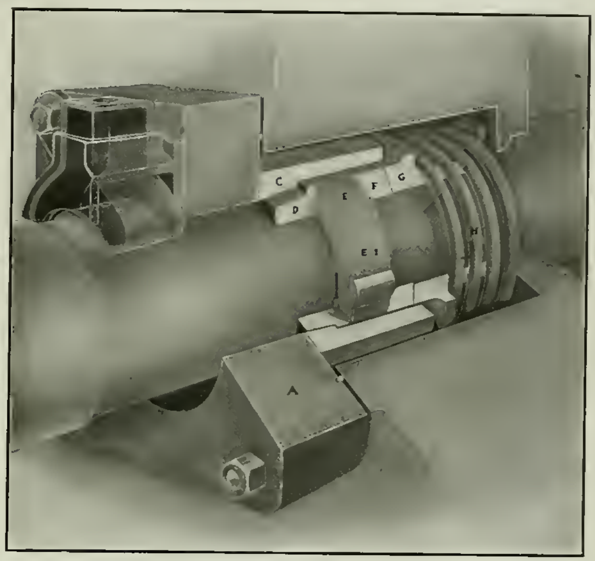
A typographical error in the description of the Worthington feedwater heater, which appeared on page 495 of the August issue, erroneously gave the capacity of the heater as 6,000 lb. of water per hour. This should have read 60,000 lb. of feedwater per hour.

Q & C PISTON ROD PACKING AND LUBRICATOR

The Q & C Packing & Lubricator Company, New York, is marketing a piston rod packing and lubricator.

THE Q & C PACKING

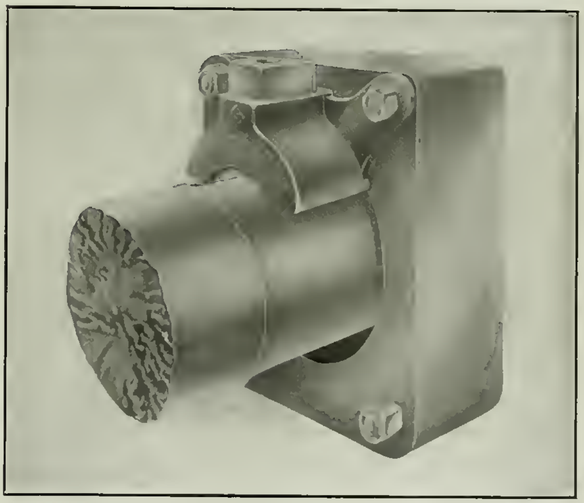
The packing is so designed that it is held tight against the rod by steam pressure, and the spring shown at the back serves only to hold the parts in place. By this means the wear



Piston Rod with the Packing and Lubricator Applied

of parts is practically limited to the time in which steam is actually used, thus greatly prolonging the life of the packing.

The cylinder head is bored out to sufficient depth and diameter to receive the packing. All of the parts of the



Application of the Piston Rod Lubricator

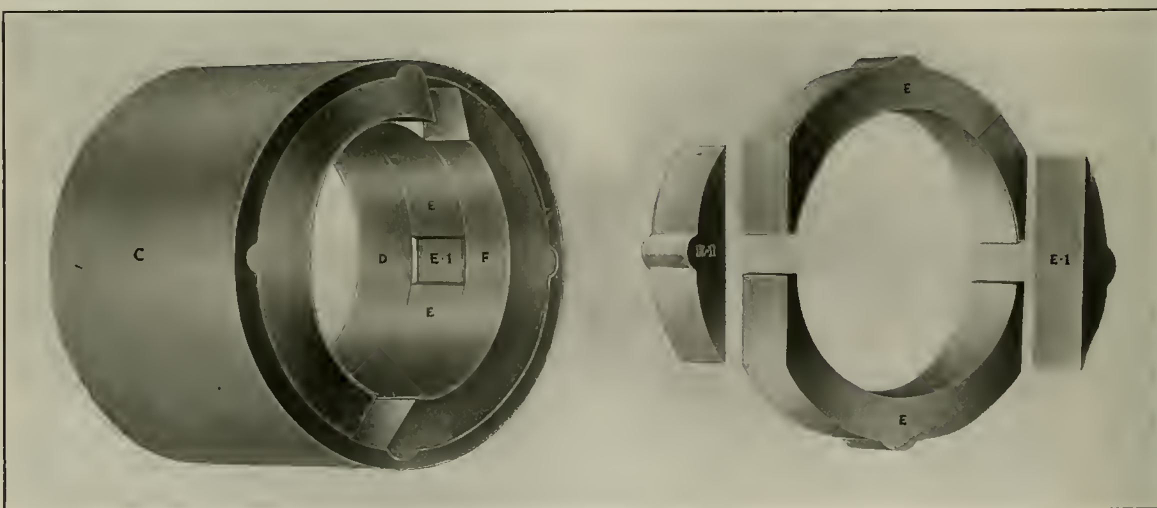
packing are made in two pieces with the exception of the retaining sleeve *C*. This is made in one piece and, in order to put it in place, the piston rod must be taken out of the crosshead. It is turned to slip easily into the cylinder head and bored out to take the retaining sleeve bushing *D*, the packing ring *E*, the packing shoe *E*-1 and the packing ring *F*.

These three sets of rings are made in sections. The parts *D* and *F* are made in two pieces each, and when the parts are brought together they can be entered in the sleeve and fit loosely on the rod. The parts *E* and *E*-1 are in two pieces each, so that four pieces are used to form the complete ring. The joints of the three sets of rings are made to break so that there is no longitudinal leakage of the steam.

The spring stop *G* has a bevel face bearing against *F* so that the latter is prevented from lifting the rod. The spring *H* has a tension only sufficient to hold the parts in place and prevent longitudinal movement under the action of the piston rod. The outward thrust of the spring passes through the rings to *D*, which is held by its lip bearing against the shoulder turned on the inner face of *C*, and *C* has a bearing against the gland *A*.

Steam enters the packing chamber from the cylinder and circulates freely over the rings, bushing and sleeve. The steam has the same access to the space between these parts and the piston rod, but as the outer surfaces of the rings are greater than the inner, the excess of pressure on those surfaces forces the parts against the rods and makes a tight joint. The instant the steam throttle is closed the pressure is relieved and the engine drifts without any pressure being exerted on the rod, so that the packing is purely steam actuated without the spring having any influence on the actual tightening of the parts.

Leakage of steam past the gland is prevented by a copper wire that is inserted between the gland and the cylinder head.



Details of the Piston Rod Packing Rings

THE Q & C LUBRICATOR

The lubricator shown in the illustration was designed to overcome the difficulties experienced with the ordinary cotton swab. This device consists of a brass shoe or cup held loosely within a retainer and free to adjust itself to the diameter and position of the piston rod, without appreciable wear on the rod. The hollow shoe is filled with lubricant and attached to the cylinder head as shown in the illustration. The use of this lubricator eliminates such trouble as glazing of the lubricating material or strands of the swabbing being drawn into the packing rings, thus causing steam leaks. The easy self-adjustment of the shoe insures long service and low cost of piston rod lubrication.

REGO WELDING AND CUTTING TORCHES

The Bastian-Blessing Company, Chicago, has developed torches for welding and cutting in which an original departure from existing apparatus has been made in the principle of mixing the gases. In these devices, which are known as the Rego torches, the acetylene is delivered at the mixing chamber under a pressure slightly greater than the pressure of the oxygen. With this arrangement the acetylene holds back any excess of oxygen under all conditions, thus eliminating the flashback which is a source of continual annoyance in most welding and cutting torches.

In the construction of the torch several innovations are introduced; no high pressures are used, the acetylene pressure even on tips larger than ⅛ in. being only 9 lb. In order to secure the correct volume of the gases, the mixing is accomplished in the tip so that the mixing chamber is changed each time that a different tip is applied. This form of construction facilitates repairs and reduces the volume of the mixed gases. The tip is of an alloy high in copper and is made without a thread and with a cone seat having a broad angle to prevent the tip sticking in the head.

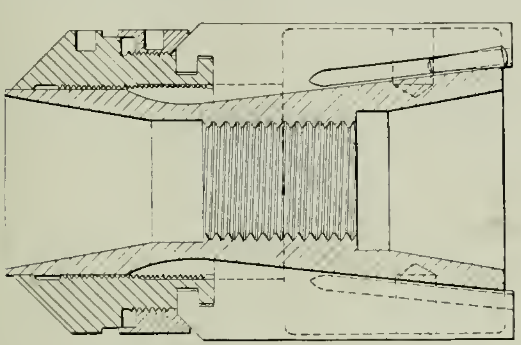
The cross section of the oxygen passage leading to the mixing chamber is of substantially the same cross section as the mixing chamber itself, while the acetylene passages have a cross section equal to approximately one-half the area of the mixing chamber. Both gases are delivered to the point where they mingle at a velocity higher than the rate of flame propagation in the mixture which will produce the neutral flame. The arrangement of the passages normally produces the neutral flame, and any obstruction of the tip will result in excess of combustible gas in the mixing chamber which reduces the rate of flame propagation at the point of mixing. Thus, if a condition is present which tends to cause a flashback the acetylene immediately shuts off the oxygen, automatically thus producing a rich mixture which will not backfire.

It is claimed that this torch positively prevents the flashback, thus eliminating the time wasted in relighting the torch. It is also claimed that it effects a marked saving in the gas consumption, insures a better quality weld and permits of employing less skilled labor than can be used with torches which do not employ the same principles of mixing the gases.

DAVIS EXPANSION REAMER

The old style of solid shell reamers have been in use for a long time, but with the constant improvement of other machine shop equipment, the necessity for a reamer whose blades could be expanded, to compensate for wear, has been keenly felt. To meet this situation the Davis Boring Tool Company, St. Louis, Mo., has developed the Davis expansion reamer. It is claimed that the design possesses all the advantages and eliminates all the disadvantages of the solid reamer.

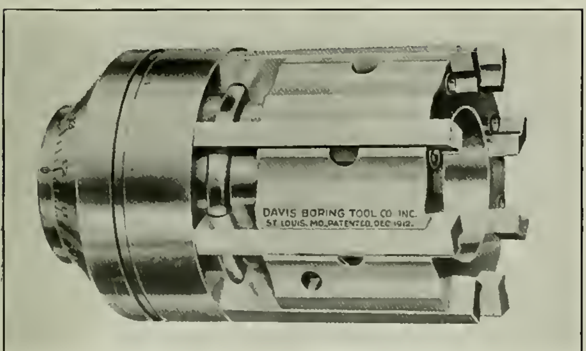
The distinguishing features of the Davis expansion reamer are simplicity and practical construction, with the minimum number of parts. The blades are positively controlled by an



Cross Section of Davis Expansion Reamer

accurate micrometer adjusting dial, graduated in quarter thousandths, which acts for both expanding and receding of blades. The blades are slotted and fit over the ring on the adjustable dial which prevents their movement either way, without turning the dial. When the reamer is set to the size required the blades are individually and doubly locked to the reamer body by a locking principle which positively locks the blades without the use of screws, virtually making a solid reamer.

The elimination of screws for holding the blades in a



Expansion Reamer Which Indicates Several New Features

reamer body is a distinct advantage. The blades are held with a special taper hardened and ground pin, which is fitted to the reamer body and to a groove in the blade resulting in a constant downward and lateral thrust that firmly holds the blades under all conditions. They are then clamped to the reamer body with the locking ring threaded on the adjusting dial, making it impossible to expand or recede the blades either by accident or carelessness without releasing the locking ring, which must be done before the expanding dial can be turned in either direction.

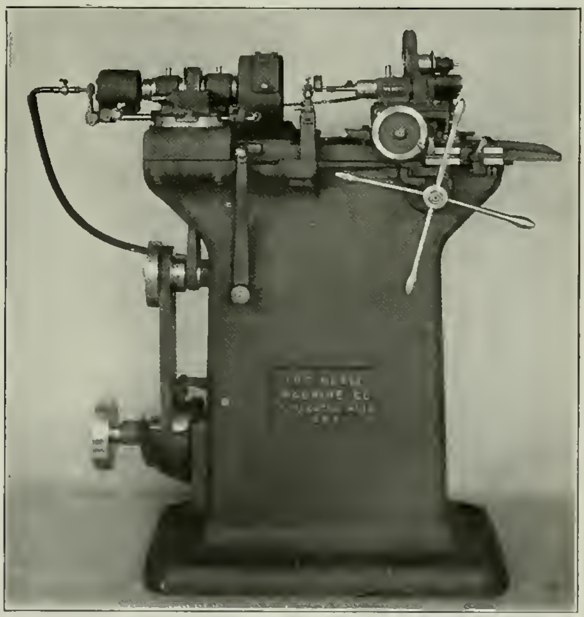
This reamer represents the first application of the forward movement of blades, for the purpose of expansion in a tool of this type. This feature always keeps the blades cutting in advance of the tool body, consequently the blades never lose their bottoming feature. The movement of the blades is positively controlled by the adjusting dial, which expands or recedes them. The blades have liberal expansion, with one-quarter thousandth adjustment and the locking of the blades is absolute and positive. Among the distinctive features of Davis expansion reamers is simplicity of driving which eliminates the necessity of making costly arbors. Any size can readily be applied without interfering with the driving shank. True alinement is assured when assembled in multiple form, virtually making a solid line reaming bar.

Blade efficiency and the cost of blades is an important factor which should be considered in connection with adjustable reamers. Davis expansion reamers require but three groups of blades to cover a range of sizes from 1⅝ in. to 6 in. inclusive. When the blades for a 6-in. reamer are worn under size they can be used in a number of smaller sizes down to and including 4 1/16 in. Blades for a 4-in. reamer can be used in smaller sizes down to 2½ in. Blades in a 2 7/16-in. reamer can be used in smaller sizes down to 1⅝ in. This wide range of adjustment permits of reaming the maximum number of holes per set of blades.

These tools are made either in the shell type or with a solid shank, straight or taper, to which a floating holder can be applied. All wearing parts are hardened and all threaded parts are protected from dust, chips or possible injury, which might result from careless usage or accident.

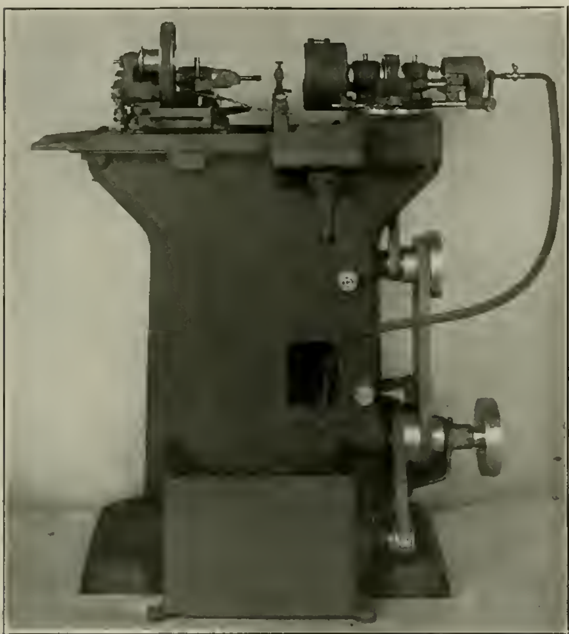
HEALD NO. 85 INTERNAL GRINDING MACHINE

An internal grinding machine designed especially for small, short work is being made by the Heald Machine Company, Worcester, Mass. This machine is of simple design and is very strongly built. A conveniently located pilot



Front View of the Heald No. 85 Grinder

wheel furnishes hand feed movement to the table and a quick acting collet operated by a lever with an automatic brake to the working head, which also shuts off the water, reduces the chucking time to a minimum. The wheel heads are of an entirely new design and have proved very successful. The working head is driven by a cross belt through the base from a four-step cone, giving three speeds of 161, 292 and 528 r. p. m. It is arranged to swivel and is graduated to permit 4-in. taper to the foot. The rotation of the working head is automatically stopped and the water shut off when the grinding wheel is withdrawn from the work. This is accomplished by means of a friction clutch in the base, operated by a lever on the front of the machine. As the table moves to the right a small dog attached to it engages the lever and throws the clutch out. To resume work the operator simply pushes the lever back into its vertical position, starting the working head and the water. The working head is bolted directly to the base of the machine and is fitted with adjustable dustproof bronze bearings. The working spindle is made of high grade steel, ground and lapped, the front bearing being 1⅝ in. in diameter and the rear bearing 1⅜ in. in diameter.



Rear View of the Grinding Machine

The holding fixture furnished with this machine consists of a quick-acting collet chuck with a capacity of ⅜ in. diameter up to 3 in. This is operated by a lever with an adjustable compensating device, which prevents distortion of the work. The feed to the cross slide is calibrated to one-quarter thousandths of an inch. The feed lever is at the left side of the cross slide, enabling the operator to keep his right hand on the pilot wheel while using his left hand to feed the slide. The main table has flat and "V" ways, and is extremely rugged for a machine of this size. It is provided with a positive stop accurately governing the travel, thus enabling the operator to grind up to a shoulder or any given point without danger of overrunning.

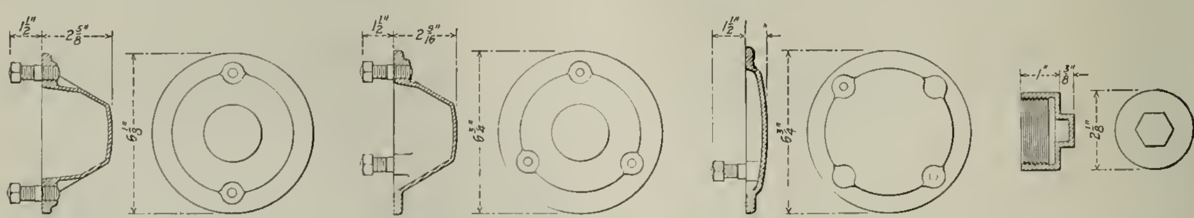
To reduce vibration to a minimum an overhead countershaft has been used. This shaft is of simple construction, having two steel hangers equipped with self-alining ball bearings, a driving pulley, a drum for the flexible idler and tight and loose pulleys to receive power from the main line, and it has a speed of 600 to 620 r. p. m. A wheel guard automatically covers the wheel as it is withdrawn from the work. This prevents injury to the operator's hand while plugging the work. The idler pulley is fitted with ball bearings and keeps an even tension on the spindle and countershaft belts at all times.

The water equipment includes a pump, tank, water guard and connections. The water tank and pump fit into the back of the base of the machine, requiring only a few more inches of floor space than the machine itself. This machine was designed for work ranging from ¼ in. to 2 in. in diameter by 4 in. long, and is especially adapted for use on holes smaller than ¾ in. in diameter by 1½ in. long. The actual swing inside the water guard is 6 in., while without the guard it is 10 in.

The machine is equipped with a wheel head having solid, adjustable taper bearings at the wheel end, with ball bearings at the pulley end. Another style of head is designed so that different sized quills may be inserted in the nose of the spindle. These quills are tapered which, when put in with a slight tap on the end of the quill, gives it a firm grip and practically makes it a part of the spindle. These heads are complete units in themselves, each having its own pulley, thereby securing correct spindle speeds.

SHIPPING CAPS FOR WESTINGHOUSE TYPE OF TRIPLE VALVES

Among the devices recently developed by the Westinghouse Air Brake Company, Wilmerding, Pa., are shipping caps for various types of triple valves. The illustrations show these caps which are designed to protect the cylinder flange end and the threaded check case connection of the valves during shipment. The caps were devised to meet an urgent demand for a protective device to be used in shipping triple valves from point to point on the railways and when returning them for repairs. Three caps constitute a set which takes care of all existing standard triple valves manufactured by the Westinghouse Air Brake Company. In the case of the type *H* and type *P* triple valve, two caps are required, one for the brake pipe connection in the check valve case after the union nut and swivel have been removed.



Caps for Protecting Triple Valves During Shipment

The caps are made of cast iron and are substantially proportioned to retain their shape and permit of being used an indefinite number of times. Studs as shown in the illustration are made an integral part of the casting, thus insuring that they will always accompany the caps. The bell portion is of proper size to provide clearance for the retarding device and the chucking threads on the *K* type triple valves.

WE GUARANTEE, that of this issue 11,400 copies were printed; that 10,174 of these 11,400 copies were mailed to regular paid subscribers, 20 were provided for counter and news company sales, 211 were mailed to advertisers, 28 were mailed to employees and correspondents, and 967 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 84,610, an average of 9,401 copies a month.

THE RAILWAY MECHANICAL ENGINEER is a member of the Associated Business Papers (A. B. P.) and the Audit Bureau of Circulations (A. B. C.).

A company has been formed, says the Times (London) Trade Supplement, for the manufacture of special rolling stock for India which contains no wood.

Memberships in French labor unions have increased five-fold since the beginning of the war. At that time the French Labor Confederation had about 300,000 members. At the present time their membership has increased to about 1,500,000.

The Traveling Engineers' Association has announced that the question of the amalgamation of this association with Section III, Mechanical, of the American Railroad Association has been considered by a committee. Its findings will be presented at the convention which opens on September 16, at which time it is expected that the association will take definite action on the matter.

A pamphlet entitled Treatment of Industrial Problems by Constructive Methods is being sent to employers by the office of the director general, U. S. Department of Labor, with a chart showing the various subdivisions of the Department of Labor and the details handled by them. The working conditions service of the department is intended to offer a constructive plan for reducing industrial accidents and sickness and to render assistance in making better working conditions.

The contention that it is not always the inexperienced apprentice or helper who, through ignorance, adopts unsafe practices in his work, is made by George Bradshaw, supervisor of safety on roads under the jurisdiction of Federal Manager Frank H. Alfred in Educational Letter No. 18. Two instances are cited in support of this contention, one a case where a machinist who was reaming out holes with a hardened steel reamer struck the hardened end of the reamer with a hammer to make it go into the hole before putting the wrench on it. A piece of steel flew off and struck him in the eye, but fortunately the injury was slight. The second case was that of the workman who was about to cut off a file in a shear when one of his fellow workers stopped him.

A controversy among machinists arose on the St. Louis-San Francisco because of the appointment of W. J. Foley as general roundhouse foreman at North Springfield, Mo., and strike ballots were sent out. The contract between the company and the machinists states that a machinist shall be placed over machine men, and it is this clause of the contract that the men claimed had been violated in the appointment of Mr. Foley, who was formerly a locomotive engineer. He was later promoted to road foreman of engines and then was acting assistant superintendent in the operating department until the return of the assistant superintendent from government service. In defense of the appointment of Mr. Foley, officers of the road say that no portion of the contract between the machinists and the company has been violated, because the duties of the general foreman cover not only machinists but boilermakers, pipefitters, electricians, tank men and miscellaneous repairmen as well as engineers and firemen. Mr. Foley has been a member of the Brotherhood of Locomotive Engineers.

Steam vs. Electrical Working of Locomotives

An abstract by the Technical Supplement of the Review of the Foreign Press from an article in the Zeitschrift des Oesterreichischen Ingenieure und Architekten-Vereines, states that the railways of German-Austria only use about one-tenth of the entire coal consumption of the country. Details of the coal consumption are given, pointing out that with the modern superheaters the locomotive has become much more efficient than formerly. Steam locomotives are stated to work more efficiently than electric locomotives especially where goods trains are concerned; and even in Switzerland the cost per ton-kilometer on the electric railways is often higher than on the railways worked by steam. The whole argument is to the effect that only under certain conditions will electrical working prove cheaper than steam working.

Classification of Technical Employees in the Northwestern Region

A definite step toward the classification of technical employees of the engineering, mechanical, land and valuation departments was recently made in the Northwestern region through the issuance of a communication by R. H. Aishton, regional director, to the federal managers of railways in the Northwestern region for their information and guidance. This schedule is of particular interest because of the detail in which the duties, responsibilities, degree of technical training and extent of experience are treated in defining each classification. The statement covers positions in the engineering, mechanical, land and valuation departments below the grades of assistant engineer and chief draftsman, and the definition of each grade includes a salary rating giving the maximum and minimum limits of salary comparable to the character of services rendered in each grade.

Authority is given to apply this classification as effective July 1, 1919. No overtime is to be allowed men covered in this classification.

The schedule for the five classes of particular interest to the mechanical department is as follows:

DRAFTSMEN, CLASS 1, $200-225

On general or special duty, requiring special knowledge, training and experience, and a special degree of initiative and originality, thoroughly competent, engaged regularly in the design and general direction of the design of large and difficult work on yards and terminals, track details, etc., or steel, concrete and timber bridges and structures, or special buildings, etc., or locomotives, cars, special machinery, mechanial and electrical power plants, etc.

DRAFTSMEN, CLASS 2, $175-190

On general or special duty, requiring special knowledge or training and experience and the use of initiative and originality. Engaged in the general designing and the direction of detailing of plans of yards and terminals, track details, etc., or steel, concrete, or timber bridges and structures, or special buildings, power plants, etc., or locomotives, cars, special machinery, or signals and signal apparatus, or land, right-of-way and valuation maps and profiles from field notes and records.

DRAFTSMEN, CLASS 3, $150-165

On general or subordinate duty, requiring special knowledge or training, experience and initiative, generally engaged in the designing and detailing of work in accordance with standard practices, and the direction of work of a minor character on right-of-way maps, mileage records, or steel, concrete and timber bridges and structures, or locomotives, cars, special machinery, mechanical and electrical power plants, or signals and signal apparatus, or land, right-of-way and valuation maps and profiles from field notes and reords.

DRAFTSMEN, CLASS 4, $125-140

On subordinate duty requiring a certain amount of knowledge, training or experience, and engaged generally in detailing, compiling and recording general engineering plans, land and right-of-way maps, or valuation maps and profiles, or records of bridges, buildings, locomotives, cars or signals.

TRACERS, $100-120

On subordinate duty requiring a certain amount of experience or knowledge of drafting. Capable of doing neat, accurate and rapid work.

MEETINGS AND CONVENTIONS

Chief Interchange Car Inspectors' and Car Foremen's Association.—The nineteenth annual convention of this organization will be held on September 23, 24 and 25, 1919, at the Planters Hotel, St. Louis, Mo.

The Traveling Engineers' Convention.—The Railway Equipment Manufacturers' Association announces that 65 firms have already arranged for space at the exhibit which will be held in connection with the convention of the Traveling Engineers' Association at the Hotel Sherman, Chicago, on September 16, 17, 18 and 19.

Foundrymen's Association Convention.—The annual convention of the American Foundrymen's Association will be held at the Commercial Museum, Philadelphia, September 29 to October 3. In connection with this convention there will be one of the most extensive exhibits of machine tools and shop devices ever displayed. Over 200 companies will be represented, among them a large number whose products are widely used in railroad shops.

Steel Treaters Society.—The first convention of the American Steel Treaters Society will be held in the Seventh Regiment Armory, Chicago, September 23 to 27, inclusive. The sessions will be held in the morning, afternoon and evening. An extensive exhibit is planned in connection with the meeting. Among the subjects covered by the papers will be the selection of steel, the design of tools, the heat treatment of steel for various purposes, case hardening, and equipment for heat treating. The papers are intended to cover the latest practice in every branch of the art of heat treating and are prepared by recognized experts. Non-members as well as members of the society may attend the meetings and join in the discussions.

The following list gives names of secretaries, dates of next or regular meeting, and places of meeting of mechanical associations:

AIR-BRAKE ASSOCIATION.—F. M. Neilis, Room 3014, 165 Broadway, New York City.

AMERICAN RAILROAD ASSOCIATION, SECTION III—MECHANICAL.—V. R. HAWTHORNE, 431 South Dearborn St., Chicago.

AMERICAN RAILROAD MASTER TINNERS', COPPERSMITHS' AND PIPEFITTERS' ASSOCIATION.—O. E. Schlink, 485 W. Fifth St., Peru, Ind.

AMERICAN RAILWAY TOOL FOREMEN'S ASSOCIATION.—R. D. Fletcher, Belt Railway, Chicago.

AMERICAN SOCIETY FOR TESTING MATERIALS.—C. L. Warwick, University of Pennsylvania, Philadelphia, Pa.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—Calvin W. Rice, 29 W. Thirty-ninth St., New York.

ASSOCIATION OF RAILWAY ELECTRICAL ENGINEERS.—Joseph A. Andreucetti, C. & N. W., Room 411, C. & N. W. Station, Chicago.

CAR FOREMEN'S ASSOCIATION OF CHICAGO.—Aaron Kline, 841 Lawler Ave., Chicago. Meetings second Monday in month, except June, July and August, Hotel Morrison, Chicago.

CAR FOREMEN'S ASSOCIATION OF ST. LOUIS.—Thomas B. Koeneke, secretary, Federal Reserve Bank Bldg., St. Louis, Mo. Meetings first Tuesday in month at the American Hotel Annex, St. Louis.

CHIEF INTERCHANGE CAR INSPECTORS' AND CAR FOREMEN'S ASSOCIATION — H. J. Smith, D. L. & W., Scranton, Pa. Convention September 23-25, Planters Hotel, St. Louis, Mo.

INTERNATIONAL RAILROAD MASTER BLACKSMITHS' ASSOCIATION.—A. L. Woodworth, C. H. & D., Lima, Ohio.

INTERNATIONAL RAILWAY FUEL ASSOCIATION.—J. G. Crawford, 542 W Jackson Blvd., Chicago.

INTERNATIONAL RAILWAY GENERAL FOREMEN'S ASSOCIATION.—William Hall, 1061 W. Wabasha Ave., Winona, Minn. Convention September 2-5, 1919. Hotel Sherman, Chicago.

MASTER BOILERMAKERS' ASSOCIATION.—Harry D. Vought, 95 Liberty St., New York.

MASTER CAR AND LOCOMOTIVE PAINTERS' ASSOCIATION OF U. S. AND CANADA. —A. P. Dane, B. & M., Reading, Mass.

NIAGARA FRONTIER CAR MEN'S ASSOCIATION.—George A. J. Hochgrebe, 623 Brisbane Bldg., Buffalo, N. Y. Meetings, third Wednesday in month, Statler Hotel, Buffalo, N. Y.

RAILWAY STOREKEEPERS' ASSOCIATION.—J. P. Murphy, Box C, Collinwood, Ohio.

TRAVELING ENGINEERS' ASSOCIATION.—W. O. Thompson, N. Y. C. R. R., Cleveland, Ohio. Convention, September 16-19, Hotel Sherman, Chicago.

RAILROAD CLUB MEETINGS

Club	Next Meeting	Title of Paper	Author	Secretary	Address
Canadian	....	....	....	James Powell	P. O. Box 7, St. Lambert, Que.
Central	....	....	....	H. D. Vought	95 Liberty St., New York.

St. Louis	Sept. 12	The Railroad Question of Today	Dr. Wm. G. Raymond	B. W. Frauenthal	Union Station, St. Louis, Mo.
Western	Sept. 15	Electric Car Lighting	E. Wanamaker	J. M. Byrne	547 West Jackson Blvd., Chicago.

PERSONAL MENTION

GENERAL

Lieut. Leigh Budwell has resumed his duties as mechanical engineer of the Richmond, Fredericksburg & Potomac and the Washington Southern, with headquarters at Richmond, Va., having just returned from 12 months' service in the Transportation Corps in France, where he served as master mechanic in the 16th Grand Division. B. J. Coffman, who has been acting mechanical engineer during the absence of Lieutenant Budwell, has been assigned to other duties in the mechanical department.

S. D. Dimond has been appointed chief electrician on the Minneapolis, St. Paul & Sault Ste. Marie, with headquarters at St. Paul, Minn., succeeding J. R. Smith, who has been appointed signal supervisor.

B. F. Kuhn, master mechanic on the New York Central lines west of Buffalo, with office at Ashtabula, Ohio, has been appointed assistant superintendent of motive power, with headquarters at Cleveland, Ohio.

Herman F. Noyes, whose appointment as superintendent of fuel economy of the Maine Central and the Portland Terminal with office at Portland, Me., was announced in the July issue of the *Railway Mechanical Engineer*, was born on August 1, 1877, at Freeport, Me., and was graduated from the University of Maine in 1899. He began railroad work on March 4, 1902, as a fireman on the Maine Central, being promoted in August, 1906, to the position of assistant air brake inspector and in February, 1907, air brake inspector. He was appointed motive power inspector on August 4, 1913, his title being changed in June, 1918, to traveling engineer, and served in that capacity until his appointment recently as superintendent of fuel economy.

H. F. Noyes

MASTER MECHANICS AND ROAD FOREMEN OF ENGINES

F. M. Crandall, assistant master mechanic on the New York Central lines west of Buffalo, at Collinwood, Ohio, has been appointed master mechanic, with headquarters at Ashtabula, Ohio, and has jurisdiction over the Franklin division, including the Oil City branch, the Franklin & Clearfield branch, Ashtabula and Youngstown yards, and the Alliance division.

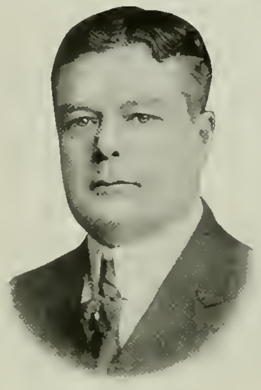
PURCHASING AND STOREKEEPING

J. D. East has been appointed division storekeeper of the Baltimore & Ohio Eastern Lines, with headquarters at Keyser, W. Va., succeeding C. S. Filler, resigned.

G. H. Greer, storekeeper on the Yazoo & Mississippi Valley, with headquarters at Vicksburg, Miss., has been appointed storekeeper for the Gulf, Mobile & Northern, at Mobile, Ala., succeeding R. C. Brown, resigned.

SHOP AND ENGINEHOUSE

H. H. Maxfield, whose appointment as acting works manager of the Pennsylvania Railroad, Eastern Lines, with office at Altoona, Pa., was announced in the June issue of the Railway Mechanical Engineer, has been appointed works manager. He has charge of the Altoona shops, comprising the Altoona machine shops, the Altoona car shops, the Juniata shops and the South Altoona foundries, and reports to the general superintendent of the Eastern Pennsylvania division. Mr. Maxfield was born in 1873 and was educated at Stevens Institute. He entered the service of the Pennsylvania Railroad on September 5, 1885, as an apprentice in the Meadow shops. On August 1, 1899, he became machinist and in March, 1900, inspector and gang leader. He was promoted in December, 1902, to assistant master mechanic at the Pavonia shops of the Trenton division and in April, 1903, was appointed assistant engineer of motive power of the New Jersey division at Jersey City. On April 1, 1905, he was appointed master mechanic of the Trenton division and in July, 1911, was transferred to the Pittsburgh division in the same capacity. On May 1, 1916, he was promoted to superintendent of motive power of the Western Pennsylvania division and about June, 1917, was transferred to the New Jersey division, with office at New York. In July, 1917, he was granted a furlough to enter military service as an officer in the Ninth Engineers, and while in France he was superintendent of motive power of the Transportation Corps, American Expeditionary Force.



H. H. Maxfield

OBITUARY

George J. Duffey, superintendent of motive power of the Lake Erie & Western, with headquarters at Lima, Ohio, died at his home in that city on August 16. He was born at Clinton, Ont., Canada, on May 24, 1863, and began railway work as an apprentice on the Michigan Central at St. Thomas, Ont., and served later as roundhouse foreman and general foreman on that road. In 1907 he left the service of the Michigan Central to go to the Chicago, Indiana & Southern as general foreman at Gibson, Ind. On June 1, 1908, he was appointed superintendent of shops of the Lake Erie & Western at Lima, Ohio; on November 1, 1908, was promoted to assistant master mechanic and in March, 1911, was again promoted to master mechanic. Since January 1, 1916, he served as superintendent of motive power on the same road.

Harry H. Hilberry, master mechanic of the Eastern division of the Pennsylvania Lines West of Pittsburgh, with headquarters at Pittsburgh, Pa., died in that city on August 5, aged 50 years.

W. H. Watkins, master mechanic on the Illinois Central at Memphis, Tenn., who was granted a leave of absence in the early part of this year, died at his home in Memphis on August 22. at the age of 50.

SUPPLY TRADE NOTES

George J. Lynch has been appointed sales manager for the Youngstown Steel Car Company, with headquarters at Youngstown, Ohio.

The Page Steel & Wire Company, New York, has opened a branch office at 29 South LaSalle street, Chicago, and another in the Book building, Detroit.

The Falls Rivet Company, Kent, Ohio, is preparing plans for the construction of a new building at Kent. It is probable that work on the new structure will not begin before early spring.

The Schroeder Headlight & Generator Company, Evansville, Ind., has appointed S. Herbert Lanyon as its representative on the Pacific coast, with office at 507 New Call building, San Francisco, Cal.

The Chicago Railway Equipment Company, Chicago, is completing plans for the reconstruction of that part of its plant which was damaged by fire on August 2. About $25,000 will be expended on the work.

J. L. Canby has been appointed district manager of sales of the Chicago Pneumatic Tool Company, Chicago, with offices at Chicago, succeeding Nelson B. Gatch, who has been transferred to the New York office.

A. E. Braun, president of the Farmers Deposit National Bank, Pittsburgh, Pa., has been elected a director of the Pressed Steel Car Company, New York, to fill the vacancy caused by the death of T. H. Given.

Earle W. Vinnedge has received his discharge from the military service and has been appointed sales engineer for the Worthington Pump & Machinery Corporation, New York, with headquarters at Cincinnati, Ohio.

T. L. Dodd & Co., Railway Exchange building, Chicago, have been appointed western sales representatives of the Worth Steel Company, Claymont, Del., manufacturers of fire box steel plates, boiler and tank plates.

L. H. Elliott has been elected vice-president and secretary of the Upson Nut Company, Cleveland, Ohio, succeeding Norris J. Clarke, who has resigned. Mr. Elliott will retain his former position as secretary and treasurer of the Bourne-Fuller Company, Cleveland.

The Anglo-Saxon Trading Corporation, 114-A Pitt street, Sydney, Australia, advises through its New York office that it desires to receive catalogues and full particulars from manufacturers of all kinds of devices relating to the mechanical side of railway transportation.

James M. Monroe has resigned as representative of the Southeastern territory of the Hunt-Spiller Manufacturing Corporation, Boston, Mass., to become vice-president of the Harry Vissering Company, Chicago, and vice-president of the Charles R. Long, Jr., Company, Louisville, Ky.

Herbert Duckworth has been appointed sales manager of the grinding wheel division of the Norton Company, Worcester, Mass.; Howard W. Dunbar has been appointed sales manager of the grinding machine division; John C. Spence, superintendent, and Charles H. Norton chief engineer.

W. Terry Field, constructing engineer for the American Car & Foundry Company, New York, with office at Detroit, Mich., has resigned to form a partnership with John R. Fordyce, formerly Major and Construction Quartermaster at Camp Pike, Ark. The new firm will be known as Fordyce & Field, consulting and construction engineers, Little Rock, Ark.

The Railway Motor Car Company of America, Chicago, plan to construct a manufacturing plant at Hammond, Ind., at an approximate cost of $80,000. The building will be 300 ft. long by 100 ft. wide, 50 ft. of which will be two stories high. The superstructure will be of brick construction.

E. T. Sawyer has been appointed a representative of the railway sales department of the U. S. Light & Heat Corporation, Niagara Falls, N. Y. Mr. Sawyer will specialize on car lighting equipment and electric car welders and will have his headquarters at 30 East Forty-second street, New York City.

The Rickert-Shafer Company, Erie, Pa., is making plans for the erection of another wing to the factory building, 33 ft. by 150 ft., two stories high, of steel and brick construction, in order to take care of the increased demand for Boehm automatic die heads and R & S tapping machines. The company is also about to place several new tools on the market.

F. O. Slutz has been appointed manager of the railway sales department of the B. F. Goodrich Rubber Company, Akron, Ohio, succeeding C. M. Woodruff, who has resigned to accept a position with the Akron Board of Education. Mr. Slutz was born on April 29, 1883, and received a high school education. He entered the service of the B. F. Goodrich Rubber Company, on October 24, 1901. In 1909, he served as a clerk in the pneumatic tire sales department and the following year was transferred to the railway sales department, where he served in various positions, giving most of his attention in recent years to railway sales work exclusively, until his appointment as manager of the same department. Mr. Slutz will have his headquarters at Akron, Ohio.

F. O. Slutz

Captain Thomas O'Leary, Jr., of the Fifty-First Engineers, has returned to the service of the New York Air Brake Company, New York, as western representative on lines west of the Missouri river. Captain O'Leary was adjutant of the Touraine division of the Fourteenth Grand division, Camp De Grasse, France, operating the French railroad out of that place.

The Ryan Car Company, Chicago, is constructing an all-steel, steel car plant 90 ft. by 600 ft., upon a recently acquired 50-acre tract one-half mile east of its old plant at Hegewisch, Ill. In addition to the main plant three smaller buildings are being constructed. It is expected that operation will begin in the fall. The approximate cost of the new buildings with new equipment will be $350,000.

F. B. Hartman has been appointed representative of the Hunt-Spiller Manufacturing Corporation, Boston, Mass. He is to cover the southeastern district, succeeding J. M. Monroe, who has resigned to become vice-president of the Charles

H. Long Company. Previous to 1906 Mr. Hartman was in the service of the Union Pacific and later was with the Southern Railway, part of the time as general equipment inspector.

The Onondaga Steel Company, Inc., Syracuse, N. Y., is making plans for building several new additions to the plant at James street and Thompson road, Syracuse, in 1920. To carry out this program the capitalization of the company has been increased from $150,000, to $1,000,000. The new building program calls for an annealing plant 160 ft. by 40 ft., an 80-ft. extension to the present mill building and several other buildings.

American Car & Foundry Company

The directors of the American Car & Foundry Company, New York, having recently abolished the office of general manager, James M. Buick, formerly vice-president and general manager, has assumed the direction of the sales division of the company and will be known as vice-president in charge of sales.

W. C. Dickerman

The production division will be directed by William C. Dickerman, who will be known as vice-president in charge of operations. He will be assisted by Frederick A. Stevenson, as assistant vice-president in charge of operations, who will be head of the manufacturing section and have charge of production in the car plants, rolling mills and foundries, also supervision over the engineering improvement and research, patent and industrial relations sections. The headquarters of both divisions will be at the general offices, 165 Broadway, New York. Mr. Dickerman, as head of the war division, and Mr. Stevenson, as his assistant, directed the company's recent program in the manufacture of munitions for the government of the United States and its allies.

F. S. Stevenson

William C. Dickerman was born on December 12, 1874, at Bethlehem, Pa. After a preparatory course at William Penn Charter School, Philadelphia, he was graduated from Lehigh University in 1896, with the degree of mechanical engineer. Mr. Dickerman entered the employ of the Milton Car Works, Milton, Pa., in 1897, and when the American Car & Foundry Company was organized he was made assistant district manager for the Milton district. In 1900 he became sales agent of the company and in 1905 was elected to the vice-presidency.

Frederick A. Stevenson was born on April 6, 1880, at Detroit, Mich. After completing the high school course, he entered the employ of the American Car & Foundry Company in 1899, as an apprentice in the machine shop at the Detroit plant. In 1902 he was transferred to the Berwick plant and served as master mechanic in charge of all mechanical work in the steel car department, and in 1907 he returned to Detroit to assume a similar position in the company's plant. In 1909 he entered the assistant general manager's department at Chicago and carried on the development of new ideas and methods until October, 1910, when he became assistant general superintendent of the Detroit plant. In 1912 Mr. Stevenson was made general superintendent at Detroit and held this position until January, 1916, when he was appointed assistant general manager.

J. Leonard Replogle, president of the American Vanadium Company, New York, also president of the Wharton & Northern Railroad and chairman of the board of directors of the Wharton Steel Company, who, during the period of the war was director of steel supplies for the War Industries Board, has had conferred upon him by the French government the decoration of Chevalier of the Legion of Honor, in recognition of services rendered by him in the Allied cause during the war.

The Schroeder Headlight & Generator Co., Evansville, Indiana, announce the opening of two new offices. One of these offices, in charge of Harlow A. Varney, district sales manager for the company, is located at 1051 McCormick building, Chicago. The second office, at 507 New Call building, San Francisco, will be the headquarters of S. Herbert Lanyon, district sales manager for the Pacific coast territory. Both Mr. Varney and Mr. Lanyon have had a number of years experience in the railway supply business.

Roland S. Lebarre, assistant manager of sales for the Cleveland, Ohio, district of the Carnegie Steel Company, Pittsburgh, Pa., has resigned to become general sales manager of the alloy steel department of the Interstate Iron & Steel Company, Chicago. He began his business career 20 years ago with the United States Steel Corporation and in 1902 entered the sales department of the Illinois Steel Company. During the past 14 years he has been assistant district manager of sales for the Carnegie Steel Company, at Cleveland.

The Duff Manufacturing Company, Pittsburgh, Pa., is constructing an addition of 160 ft. by 80 ft., to its works at Pittsburgh. The new building is of brick and steel and is designed to accommodate the forge shop and heat treating department. Provision has been made for installing 16 steam hammers, with an equal number of trimming presses. The heat treating department will be equipped with furnaces of the latest type, burning either oil or gas. The completion of the new forge shop, about October 1, will make possible a large increase in the production of Duff jacks.

At the annual meeting of the U. S. Light & Heat Corporation, Niagara Falls, N. Y., on August 13, the following directors were elected: R. C. Caples, E. H. Gold, J. E. Kepperley, C. L. Lane, C. O. Miniger, J. O. Moore, B. J. O'Reilly, J. A. Roberts, G. G. Shepard, J. Allan Smith and J. N. Willys; and the following officers were elected for the ensuing year: John N. Willys, chairman of the board of directors; E. H. Gold, vice-chairman of the board of directors; J. Allan Smith, president; C. L. Lane, vice-president and general manager; R. C. Caples, vice-president; B. J. O'Reilly, treasurer; R. H. Van Nest, secretary, and T. G. Swannie, assistant secretary and assistant treasurer.

The Chicago Pneumatic Tool Company, Chicago, is now erecting a 10-story office building at 6-8 East Forty-fourth street, New York, in which will be housed its general offices now at Chicago. The new building will be completed early in 1920. The structure will be of steel, brick and limestone construction and will be occupied solely by the offices of the company. The ground floor will contain a permanent exhibition room and display of its pneumatic and electric drills and other tools, gas engines, air compressors, etc. A completely equipped service station will also be maintained. The six American plants and 26 sales and service branches will be directed from New York. A sales and service organization will be maintained in Chicago on a more extensive scale than formerly.

George H. Richie, sales engineer in New England and Eastern Canada for the Sullivan Machinery Company, Chicago, has been promoted to New England sales manager, succeeding George Elmer Wolcott, deceased. R. S. Weiner has been appointed district manager with headquarters at El Paso, Tex., in place of Don M. Sutor, who has been transferred to the St. Louis, Mo., office as sales manager for Missouri, Arkansas, eastern Texas, Oklahoma, Kansas (except the oil territory), western Kentucky and western Tennessee. Phillips S. Jarvis has resigned as sales manager for the territory controlled from the St. Louis office and Marion C. Mitchell has been appointed sales manager for the territory in Indiana and Illinois previously controlled from the St. Louis office, with temporary headquarters at St. Louis. Daniel H. Hunter has been appointed sales manager for Louisiana, Texas (except the southwestern section), and the oil fields of Oklahoma and Kansas with headquarters at Dallas, Tex.

The housing facilities of the Westinghouse Air Brake Company, Wilmerding, Pa., are to be extended at once by the erection of a number of new dwellings, for the families of employees. The Westinghouse Air Brake Home Building Company has been organized with a capital of $1,000,000 to transact all business relative to the real estate and dwellings, which have been transferred by deed to this company by the Westinghouse Air Brake Company. It includes over 400 houses and considerable vacant property in the borough of Wilmerding and adjacent territory. The officers of the new organization are A. L. Humphrey, chairman of the board of directors; C. A. Rowan, president; W. S. Bartholomew, vice-president, and H. C. Tener, secretary. In addition to the first three mentioned above J. F. Miller and G. W. Wildin are included in the board of directors. S. R. Gittens has been appointed manager. Since the Westinghouse Air Brake Company built its first houses for employees in 1890 there has never been an increase in rents and the new company will carry out the same policy.

The Detroit Seamless Steel Tubes Company has begun construction of a $3,000,000 plant on a 60-acre tract at Detroit, Mich. The first unit of the plant will cost $1,000,000 and will be completed by January 1, 1920. The building plans call for a structure of steel and glass with brick and concrete facing. The plant proper will occupy a space of 350 ft. by 700 ft. It will consist of three bays for manufacturing units, a separate heating plant and a two-story administration building. The three manufacturing units will be each 90 ft. wide, by 700 ft. and 550 ft. long and 45 ft. high, to permit the use of traveling cranes and other labor saving machinery. The interior layout and special tube mill machinery was designed under the direction of C. A. Ross, consulting mechanical engineer, and C. L. Stafford, mill superintendent. The plant will be equipped with the latest types of modern labor saving devices and machines, and a powdered coal system will be used for all the heating and annealing processes used in manufacturing operations. The total capacity of the first unit of the new plant will be 2,500 tons of seamless steel tubing a month, the range of sizes being from one-half inch to six inches outside diameter, and No. 13 gage and heavier.

CATALOGUES

Window Fixtures.—Catalogue W-19 of the O. M. Edwards Company, Inc., Syracuse, N. Y., contains 64 pages and should prove of practical value to car designers. It contains considerable detailed information about the fixtures and the service for which the various designs are best adapted and by means of drawings clearly shows their application to single and double sash windows. All of the detail parts, such as sash balances and brackets, sash locks, racks and lifts, compression devices and weather stripping, are shown in numerous sketches and photographs.

Welding Rods and Wire.—A small booklet of 60 pages has been published by the Page Steel & Wire Company, New York, which contains a large amount of useful information on welding and welding materials and describes the method of manufacturing Armco iron rods and wire for oxy-acetylene and electric welding, illustrated with microphotographs showing the structure of the material used. The booklet contains a large number of other illustrations and data in tabular form, including a table showing the diameter of rods to be used on various thicknesses of metals to be welded, temperature and metric conversion tables and data regarding the properties of elements and metal compositions, etc.

Texaco Lubricants.—The series of advertisements of the Texas Company, New York, entitled "How Texas Jones Convinced the Railways," which has appeared in the *Railway Mechanical Engineer*, has been reprinted in a booklet of 39 pages, 9 in. by 12 in., issued by the Texas Company. Thirty pages each contain a record in dialogue form, with illustrations, of imaginary meetings of a railroad purchasing board, showing the evidence brought by "Texas Jones" and others to convince the railways of the value of using Texaco lubricants. In addition the book contains a list covering four pages of railroad products made by the Texas Company.

Steel Tanks and Boilers.—A cloth bound book of 96 pages, 6 in. by 9¼ in., has been published by the Coatesville Boiler Works of Coatesville, Pa., manufacturers of steel tanks for a large variety of uses, A. S. M. E. boilers, stacks, open hearth furnaces, blast furnaces, cement kilns, regenerators, etc., to show the vast scope of the business and the great variety of heavy steel plate work manufactured in the shops of this company. This is indicated in over 100 illustrations. Included in the book are the specifications for steam boilers formulated by a committee appointed by the American Society of Mechanical Engineers, in accordance with which Coatesville boilers are made. The book is designated as General Catalogue No. 24.

Steam Pumps.—Several bulletins have been issued by the A. S. Cameron Steam Pump Works, New York, describing their pumps, which are bound together in a heavy manila folder. Included among these are Bulletin 7204, which explains the general characteristics and operation of Cameron steam piston and plunger pumps; bulletin 7152, showing the construction of a single suction volute centrifugal pump, with tables of capacities, speeds and horsepowers; bulletin No. 7251, covering two-stage motor driven and three-stage turbine driven centrifugal pumps and giving complete information regarding their operation, specifications and detail parts; and bulletin 7150, describing and illustrating the general design of a double suction volute centrifugal pump, including the results of tests made with this pump and useful information regarding the friction and pressure of water.

CONTENTS

An Educational Campaign Necessary

Railroads generally have made the same mistake as other industries in not giving critical attention to the Americanization of aliens in their employ. A study made by employment experts indicates that a large percentage of the misunderstandings with labor in industrial organizations is due to the fact that foreigners do not appreciate the conditions under which they are working and the ideals which dominate American industrial establishments. A comparatively small amount of educational work along these lines in some establishments has been very helpful in promoting harmony and in eliminating possible sources of trouble. The seriousness of the alien problem is no more clearly indicated than by the steel strike. The American born workers are apparently against the strike and are loyal to their employers, while the foreign born, or aliens, are supporting the strike and are apparently entirely in the hands of the radical element. It is time that every railroad and every department on the railroad took careful steps to study its labor conditions and wherever necessary to introduce intensive educational work tending to completely Americanize all of its employees. Work along this line will certainly result in a more effective organization.

Limitations of Welding

The oxy-acetylene and electric welding processes have been found suitable for such a wide variety of work that some have gained the impression that autogenous welding can be used satisfactorily under practically any conditions. One large railroad recently had two wrecks due to the failure of welded parts, which illustrates the disastrous results that may follow if welding is not confined to its proper sphere. These wrecks occurred in an interval of a few weeks and in both cases the cause was traced to a welded car axle. Appearances indicated that at some time brake rods or other parts had borne on the axle and had worn a groove around it. This depression had been filled by welding and the axle had been reapplied. Instead of strengthening the axle, the heat of the welding operation probably affected the structure of the metal, weakening it and resulting in failure under load. The damage caused by these two wrecks amounted to several thousand dollars and it is hardly necessary to point out that this would have been sufficeint to pay for a considerable number of new axles.

The American Railroad Association Committee on Welding Truck Side Frames, Bolsters and Arch Bars has recommended that welding cracks or fractures should not be permitted on axles, arch bars, car wheels or tires, truck equalizers, spring or bolster hangers, brake wheels, coupler bodies or knuckles, knuckle pins, locks, lifters or throwers, or on parts made of alloy steel or heat treated carbon steel. Although the welding of these parts has not been officially prohibited by the association, the committee's report will almost certainly be adopted. At any rate, it would seem that roads that have made a practice of welding the parts named above might do well to follow the recommendations of the committee.

Injustice to Stores Department

The stores departments of the railroads have faced a most difficult situation during the past year or so. The men in this department have not been organized and for some reason the Railroad Administration has left the readjustment of wages and salaries to the regional authorities. The matter was finally attended to in some regions, but the employees in other regions have up to this time had little, if any, consideration. Not only have the storekeepers themselves been discouraged because of lack of recognition in the revision of salaries, but they have bad to struggle along as best they could with the payment of very low wages to their employees, as compared to the other departments alongside of which they have been working. This was quite forcefully brought out in the discussion of the paper which was presented at the September meeting of the New York Railroad Club by Director of Purchases Henry B. Spencer. Complaint was also made of the large amount of red tape which the storekeeping departments are having to observe in connection with the preparation of reports preliminary to the turning back of the railroads to their owners.

In the words of one of the speakers, the stores department could make good under the present conditions if it was required to provide only those things which were essential and could cut out the frills. In reply to this criticism, Frank McManamy, assistant director of operation, claimed that the ball of red tape was small as compared to that used on some of the railroads under former conditions. George G. Yeomans, the assistant director of purchases, stated that the requirements of the Railroad Administration were burdensome only to those roads which did not keep accurate records as to the amount of material on hand and where it was located. Regardless of these statements, however, the testimony of storekeepers generally is that the conditions under which they are now working are extremely difficult and burdensome and that some relief should be afforded, both in making suitable allowances for the wages and salaries of men in this department, as well as the elimination of all reports that are not absolutely essential.

Is the Five Coupled Engine a Success?

The progressive increase in the size of road engines has in recent years led to the adoption of the Santa Fe and Decapod types to replace the Consolidation and Mikado. Railroad officers have considered it axiomatic that as the tractive effort of locomotives increases the cost of wages for train and engine men and of locomotive repairs would decrease (on a ton-mile basis). So long as this holds good the adoption of heavy motive power would prove economical as the other two large items of expense, locomotive fuel and maintenance of way and structures, were only slightly affected by the size of the locomotives. Some statistics of the cost of maintenance of locomotives with five pairs of drivers which have recently been compiled indicate that there is some room for doubt as to whether the introduction of these locomotives has reduced the cost of transportation.

The cost of maintaining the machinery on Santa Fe and Decapod locomotives has been found to be disproportionately high. The wear on side rod bushings, back end main rod brasses and driving boxes is excessive. Tire wear in some cases amounts to as much as 1-16 in. per month, necessitating turning the tires every 20,000 miles. In some designs the boiler tubes have been placed too close together in the attempt to secure adequate heating surface, and this has made frequent tube renewals necessary. Where the roadbed has many curves, locomotives with five pairs of drivers have proved extremely hard on the track.

Against these disadvantages must be weighed the advantage of the heavier train load to be secured due to higher tractive effort. In this connection it is well to note that each successive increase of 10,000 lb. in the tractive effort causes a smaller reduction in the cost of wages for the train crew per gross ton mile. Furthermore, the cost of locomotive repairs and enginehouse expenses on a ton-mile basis is greater than the cost of wages for enginemen and trainmen, therefore a decrease in the cost of wages may be more than offset by an increase in the cost of locomotive maintenance.

The Santa Fe and Decapod types have probably not been in service long enough to determine definitely under what conditions they can be operated more economically than the Mikado type. The data given above indicates that careful consideration is necessary to avoid costly mistakes in the selection of heavy motive power.

Bad Order Car Situation

With the approach of the winter season and its attending difficulties of transportation the freight car situation is a matter of concern not only to railroad men but to the people of the entire country. The condition of freight cars in general is of great moment, but the most vital question is whether or not we are to have efficient service in the distribution of fuel. In recent statements made before the Senate committee investigating the coal situation we find a wide divergence of opinion as to the probability of a coal shortage and the necessity of immediate attention being given to the repair of bad order cars, of which there are undoubtedly a great number—far too many. The coal producers insist that they are not supplied with coal cars in sufficient numbers to warrant the constant operation of the mines; that at many of the mines it has been necessary to suspend operations entirely for extended periods (285 mines were reported idle during the week of July 26) because of the car shortage.

The Railroad Administration, however, contends that there is no serious car shortage and that car repairs are being made as rapidly as conditions require. Recent statements by Railroad Administration officials indicate that for the purpose of keeping down expenditures the car repair program has been much curtailed in recent months and that this accounts in part for the increase in the number of bad order cars. The Railroad Administration claims to have the situation under control and that any coal shortage will not be due to lack of cars.

Whatever may be the merits of either side of this controversy it is a fact that the general condition of freight cars throughout the country is bad. Evidence of this may be seen at any terminal. The aspect of the bad order car situation is not very bright in view of the conditions existing during the last half of 1918 and the fact that the working hours of the shopmen have been very considerably reduced during 1919 the result of which can not have been other than to reduce the output of repairs.

The reports of the railroads to the Division of Operation of the Railroad Administration covering a period of 10 weeks from July 20 to September 21, 1918, show that while the number of cars requiring heavy repairs increased from 49 per cent to 59 per cent of the total number listed as in bad order, only about 10 per cent of the cars reported as turned out of shop during that time were given heavy repairs. This indicates that many cars requiring heavy repairs were given only sufficient attention to put them in such condition as would permit their use—in other words, they had been turned in for heavy repairs and were given only light repairs. This practice of putting off the evil day can not be too strongly condemned, as it inevitably leads to a generally poor condition of equipment and merely adds to the difficulty of eventually putting the cars in proper condition.

The steady increase in the percentage of cars requiring heavy repairs and the reduced output of the repair shops makes it highly improbable that the car repair situation is under control or in a very encouraging condition at the present time. For the purpose of keeping down expenditures the needed repairs have been neglected during the present year and it is quite probable that since the opportunity to remedy the poor condition during a favorable season has passed, we can look for no great improvement now that the demands for cars will become greater, unless immediate and adequate steps are taken to remedy the bad order car situation.

It is the plain duty of those entrusted with the production and distribution of a necessity such as coal to leave nothing undone that might cause disruption of the service to which the consumer, who, of course, must pay the bills, is entitled. While the doctors disagree on the diagnosis the patient frequently dies of the disease. Have done with quibbling over the cause and apply the remedy.

Wage Systems and Shop Efficiency

At the present time there is a great deal of discussion concerning the relative cost of doing work on an hourly wage basis of payment and under special wage systems, such as piecework or bonus plans. Some contend that the abolition of piecework has reduced the shop output very greatly; others claim that operations can be performed quite as economically under the day work system if the supervisory force is properly organized. Whatever the ultimate effect may be, there is no question that some shops that have changed from piecework to day work are finding the readjustment to meet the new conditions very difficult.

Special wage systems have been likened to patent medicines that often proved remedies for many of the diseases of the shop system. They supplied an individual incentive for high production which counteracted the effects of inadequate supervision, lack of facilities and poor shop arrangement. The piecework system caused the men to plan their work to avoid delays as much as possible while the fixing of rates for various operations necessitated close attention to the details of the work, which disclosed wastes and led to their correction. In order to secure as good results from day work as were secured when piecework was in operation, some other agency must be supplied to effect the performance of these functions.

One of the handicaps which have often been overcome by piecework is a poor shop layout. When each man is interested in having work brought to his machine promptly the foreman is not called on to give much attention to the delivery of material, regardless of the defects in the arrangement of tools in the shop. Under a daywork system there is more need for a scientific layout and for co-operation with the workmen to eliminate wasted time. With the incentive for following up work removed, adequate crane or trucking service and means for furnishing the necessary tools and drawings without delay are essential.

Of even greater importance than the routing and distribution of work is the detailed study of shop operations and the establishment of definite standards to gage results. This could be followed out as well under day work as with piecework, but there is some question as to the feasibility of establishing such systems under present conditions. The labor organizations which are now the recognized representatives of the shop craftsmen have in the past opposed any detailed time studies of machine operations in any of the union shops.

The unions have maintained that time studies were only a means of exploiting the workers, while the railroad officers have interpreted the opposition as an attempt to decrease production and to shield inefficient workmen. Time studies, if rationally employed, would be of great benefit in improving shop operation and there is no inherent reason for opposition on the part of labor organizations. There seems to be developing among the officers of the American Federation of Labor a tendency to recognize the fact that high production is the only guarantee of prosperity for the workers. The position which this organization has assumed in the past may be considerably modified and the objections to detailed studies of shop operations may be abandoned. The matter has such an important bearing on shop costs that the future attitude of the federation will be watched with a great deal of interest.

Some Neglected Recommendations

During the past two months conventions were held by several of the mechanical associations which had not met since 1916. Among the most important action taken at these conventions was the renewal of recommendations made in previous years but not yet adopted by the railroads.

The Master Blacksmiths' Association brought out the benefits that could be derived by a standardization of certain details of safety appliances. At the present time brake staffs are made with drums of various diameters and lengths. The Safety Appliance Act forbids the welding of brake staffs, therefore, in case a broken brake staff cannot be duplicated from stock it must be forged by hand, which is an expensive process. A standard brake staff could readily be designed which would vary only as to length and a limited number of lengths could be adopted to meet the requirements of all ordinary types and sizes of freight cars now in service.

A like situation exists with regard to grab irons. The safety appliance standards mention four different lengths, namely 14 in., 16 in., 18 in. and 24 in. The roads, however, have not adhered to these dimensions and as the welding of grab irons is not permitted under the M. C. B. rules, it is often a difficult matter to replace one that is broken. If standard designs of each of the lengths given above were adopted, one type for application to the car body and another for use with wooden or metal stiles, these eight different sizes could be made to meet practically all of the requirements.

Definite action intended to bring about a standardization of small tools was taken at the convention of the Tool Foremen's Association. Many of the hand tools which are now made in railroad shops could be purchased at a saving if the manufacturers were able to meet the demands of all the railroads with a single design. Due to minor differences in the sizes of squares, or lengths and diameter of shanks, these tools are now classed as special material. Not only is the price considerably higher than for standard types but the time required to fill an order is also much longer. The makers of small tools would willingly co-operate with the railroads in establishing standards and it is to be hoped that the work begun in 1915 will now be carried to a successful conclusion.

Another matter which has awakened renewed interest is the purchase of paint and varnish on specifications, which was brought up at the convention of the Master Car and Locomotive Painters' Association. The immediate cause of the protest against specifications for these materials was the inferior quality of the paint furnished under the Administration's requirements. The shortage of linseed oil makes it almost necessary to accept substitutes, but this will not necessarily result in lowering the quality of the material as many of these substitute oils have been thoroughly tested and found superior to linseed oil for certain purposes. Apparently, the specifications have led to the use of inferior grades of linseed oil and have sustained the contention of the master painters, that practical tests, backed by the guarantee of a reputable manufacturer form the best basis for buying paint and varnish.

COMMUNICATIONS

INADEQUATE MAIN DRIVING BOXES

Philadelphia, Pa.

To the Editor:

Your article in a recent issue in regard to the main driving boxes for large locomotives calls to mind some experience with driving boxes that were hard to get running nicely, and what I thought then and still do should be a satisfactory solution of the difficulty. The ordinary form of driving box has a bearing on only one side of the shaft, and while this has worked well in the past with small locomotives, there does not always seem to be bearing in the proper place, and it is not the best form for lubrication.

My attention was first called to this matter a few years ago, when in the mechanical department of an Eastern road. This road had some three-cylinder locomotives in high-speed passenger service which were built about 10 years ago. They were fine machines, ran fast and well, and were in general very reliable. But they had one defect—they were very hard to break in service—and even after they were running well it was always possible that they would suddenly develop hot boxes. Designed originally for grease lubrication, the first one refused to run until oil, with a force feed lubricator, had been substituted. This gave results, but after any shopping at which work was done on the driving journals or brasses there was always the same difficulty. The development of hot boxes seemed to be a matter of the attention paid to the lubrication; sometimes a locomotive working out of our roundhouse would go a surprisingly long time without any trouble, out of another it would develop a hot box in a very short time. After any general overhauling the work of breaking in the locomotive would be about as follows. The locomotive would be run leisurely up the line and back again, and on its return be looked over. But unlike the ordinary locomotive one or all of the driving boxes would be pretty warm. The waste in the cellars would then be shaken up, the lubricator filled, and they would try again. About thirty miles up the line a stop would be made, the boxes looked over and the warmest ones repacked. By this time some of them would be getting pretty hot, and these would be given additional treatment in the form of a generous amount of tallow on top of the waste. And so it would go up and down the line, always watching the driving boxes, repacking the warmest, and putting on tallow when one got real hot, the boxes cooling off one by one until finally all would run cool. Sometimes it seemed hopeless for one or more of the boxes ever to run right, and the locomotive had to go into the shop and have more work done on them. After several days or a week of running light and now and then pushing a coal train, the locomotive would be fit to start in passenger service.

The reason usually given for this trouble in breaking in the bearings is that the more uniform turning moment of the three-cylinder locomotive causes the axles to ride more steadily in the boxes and the lubricant does not get the chance to spread that it does in the case of the two-cylinder locomotive. A brief analysis of the stresses in such a three-cylinder locomotive shows that the stresses on the main boxes for a single axle locomotive alternate twice in each revolution, the same as a two-cylinder locomotive, but that this maximum is much less, and the build up more slow, so that the theory is probably correct. It seemed to me at the time, and I still believe that a different form of box with a different lubricating system would have enabled these locomotives to get into service as readily as any others. What is needed is a box where the oil does not have a chance to get off the bearing, as it does in a box with an open cellar, and fitted so that the lubricant is applied at the point of greatest pressure.

About this time some locomotives were built, designed, as I recall, for a 104,000-lb. piston thrust and a load per pair of driving wheels of 74,000 lb. Although having two cylinders, they developed the same trouble as the three-cylinder engines—they would not run on grease. Force feed oil lubrication was substituted with satisfactory results. These locomotives had hollow main shafts which, of course, contributed to their running hot, but a little thought reveals a strange condition in the driving boxes. The piston thrust is abnormally large, compared to the weight on drivers; the spread of the cylinders is more than twice the distance between frame centers so that at certain parts of the revolution the stress on the frames due to piston thrust will be about double the piston load, about 200,000 lb. in each frame; to this must be added the proportionate share of the tractive effort, making a maximum total of 220,000 lb. for one side of this locomotive. At the beginning of the stroke the side rods cannot be counted on to carry any of the load, and this full load will be thrown on the main driving box. The vertical load on this box probably is not over 32,000 lb. The ordinary form of driving box with which the locomotive was fitted has a bearing on the top side of the shaft only, and it is cut away for a half inch or so from the center line to help lubrication. Now notice what happens in this particular case. There is a horizontal thrust on the bearing of possibly 200,000 lb. at certain parts of the revolution. There is a vertical load of only 32,000 lb. The resultant of these two will be pretty nearly horizontal, and will hit the bearing only about an inch above the center line, or about ½ in. above the actual bottom of the bearing, and the whole load is being carried on a narrow strip at the bottom. The bearing instead of being the nominal 11-in. by 14-in. or thereabouts, is only 1-in. by 14-in., and the load, instead of 32,000 lb., is actually 200,000 lb. An adequate remedy would take the form of extending the bearing further around the axle, so that there would be bearing surface at the center line of the axle where the great frame load is applied.

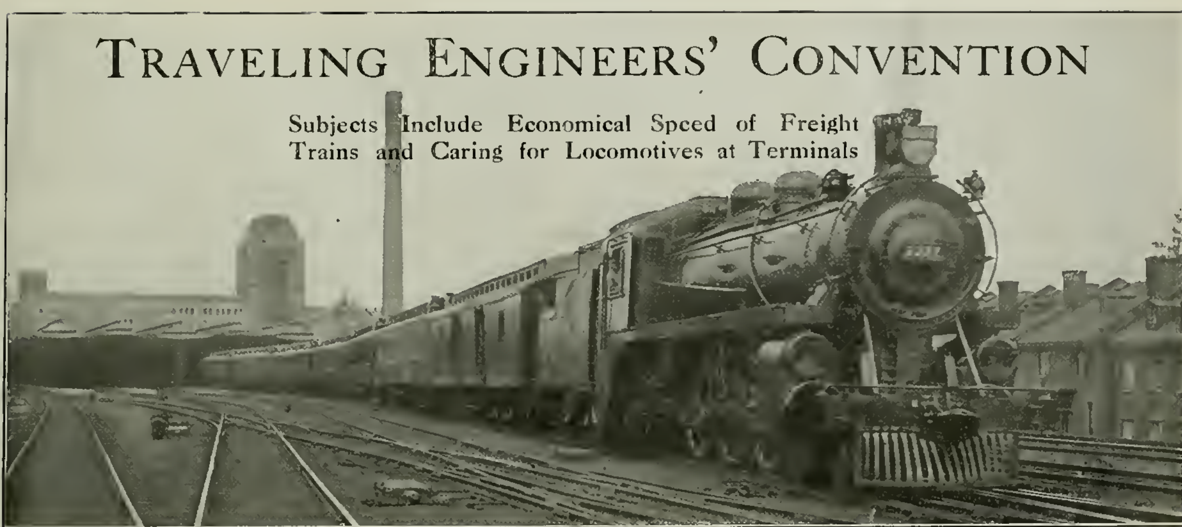
Such an axle box would have the bearing covering more than half of the shaft, which would mean that it would be made in more than one piece in order to get it off. There is no insurmountable difficulty in this and probably several solutions could be found. It would mean more machine work on the new box, but the maintenance should be less. Increasing the length of the journal to give more bearing surface will not give the same results, as there is very little bearing surface to increase, and increasing the length throws the frame centers nearer together, increasing the load on the bearing. For an engine with oil—and oil lubrication is more efficient than grease—a bearing of but two pieces, completely encircling the shaft would be the thing. This could be bored to a nice running fit and should last a long time. With oil lubricant a force feed lubricator, leading the oil to the proper point on the bearing, would seem most suitable. For grease lubrication the bearing might be made in three nearly equal pieces, or made in two pieces, one large and strong enough to have a cavity to hold the grease pad.

The conditions I have mentioned are, of course, excessive for a locomotive with only two pairs of drivers, but with a powerful locomotive having five pairs the condition must be much worse. With the ordinary form of locomotive full piston load is thrown on the main crank pin at the time it crosses the dead center, but the side rods do not carry any load until it is quite a way past, and for that time the main driving box must carry all the horizontal load on its side of the engine, which is more than it can do, as it is now constructed.

George L. Clouser.

Traveling Engineers' Convention

Subjects Include Economical Speed of Freight Trains and Caring for Locomotives at Terminals



C. P. R. Passenger Train Leaving Windsor Street Station, Montreal, Que.

THE Traveling Engineers' Association held its twenty-seventh convention at the Hotel Sherman, Chicago, beginning September 16 and closing September 19. Following the formal opening exercises the president, H. F. Henson, road foreman of engines of the Norfolk & Western, addressed the convention.

PRESIDENT'S ADDRESS

Mr. Henson spoke in part as follows: Our last convention met during the great world struggle and at that time all our attention was devoted to bringing the conflict to a successful conclusion. We have met the challenge of war. Now let us meet the challenge of peace and securely re-establish justice, loyalty and freedom. In these trying times labor cannot afford to put itself in the position of obstructing the wheels of progress. The workers must see that not only loyalty to their country but also loyalty to its industries is essential. The conservatism and loyalty of the traveling engineers has never been questioned and they can help to influence opinion among the many employees with whom they come in contact.

After referring to the present industrial unrest, Mr. Henson made a plea for rigid economy in the use of fuel and supplies on the railroads. In discussing the affairs of the association he mentioned that the American Railroad Association has invited the Traveling Engineers to amalgamate with it and asked the members to give this consideration.

COMMITTEE REPORT ON PASSENGER TRAIN BRAKING

The following is a summary of the report of the Committee on Handling Air Brakes on Passenger Trains.

Before coupling to the train the compressor steam valve should be opened wide, the steam end lubricator feed increased to about two drops per minute for each compressor having two steam cylinders, or one drop per minute for each compressor having one steam cylinder. To assist in charging the train quickly the brake valve should be placed on lap, the maximum main reservoir pressure accumulating. To charge the train quickly release position should be used until five pounds less than standard brake pipe pressure is shown on moving the valve to running position.

BRAKE TESTS

The report outlined the procedure for making the standing brake test and also contained instructions for a brake pipe test to be made if for any reason an angle cock or double heading cock had been closed at any time, to insure that all such cocks have been reopened. A running test to insure that the brakes can be operated from the brake valve must be made when the engines have been changed or at other times after the hose has been uncoupled or parted, also at a sufficient distance from drawbridges, railroad crossings or before going down heavy grades, so that the train can be stopped by hand brakes. The train should be left with a reduction of 20 lb. on the completion of a stop at terminals for the incoming brake inspection.

STARTING AND SLACKING

To avoid shocks, which are disagreeable to passengers and damaging to equipment, the committee recommends that where starting requires the taking of slack the throttle should be closed, the independent brake applied, the locomotive reversed and the engine brake then graduated off. Steam should be used if necessary to close in all train slack and if the train must be backed to a more favorable place for starting, the engineman should continue to work steam moderately until the stop is completed in order to have all slack closed in. The engine should then be reversed, the release of the brakes started and steam then used as carefully as consistent with starting the train, at the time when experience indicates that the holding power of the rear brakes is ending.

The independent brake should not be used in making passenger train stops.

SLACK CONTROL

Smooth handling of passenger trains requires that slack must never be changed suddenly and any heavy reduction should be avoided when speed is low; the split reduction should be used when commencing other than light applications. While applying brakes on trains of more than eight cars the use of steam should be continued, to hold the slack while the brakes are being applied where conditions will permit.

COMPLETE RELEASE

Sand should not be used while braking on good rails, except in an emergency. To completely release passenger train brakes the automatic brake valve handle should be moved to release position, back to running position and then, after waiting about seven seconds, "kick-off" should be made. The proper time in release position is indicated when the brake pipe hand shows five or six pounds more after returning to running position than before moving from lap to release, varying from a second with a very short train to more than 15 seconds with the longest train. A release should not be attempted unless the pressure has been reduced at least seven pounds below the standard carried if the train has less than eight cars, and ten pounds for longer trains.

STOPPING TRAINS WITHOUT GRADUATED RELEASE

Stopping without graduated release from usual speeds requires the two application stop. The application should be made while working steam and using the split reduction; a reduction of about 15 to 18 lb. should be made, depending upon speed and grade. Steam should then gradually be shut off. This application having been made at a point that will reduce the speed to 12 or 15 miles an hour when about 500 ft. from the stopping point, should be released and followed by a second application of about seven pounds reduction, avoiding a total of over 10 lb. if possible.

In stopping with the one-application method from slow speeds, sufficient time should be allowed between shutting off steam and starting the brake application to permit drawbar springs to react and start the slack in, thus avoiding the action of the slack and the brake application coming together and producing disagreeable shocks. Where the one application method is being used a split reduction should be made, at first not over six or seven pounds, followed by further reduction if needed. The first reduction should be early enough to avoid making a total application of more than 10 lb. when the stop is completed.

MOUNTAIN GRADE BRAKING

Retaining valves should be used on descending mountain grades whenever the brakes cannot be recharged to within 10 lb. of standard pressure. The application should be sufficient to insure a release, so that the train is retarded by the retaining valves and not by sticking brakes. Graduated release must not be used when retaining valves are cut in, and when retaining valves are not cut in, not more than one release graduation may be used between complete recharges. Limiting the maximum speed to 30 m.p.h. on grades of 3 to 3½ per cent, and 45 m.p.h. on grades of 2 per cent to 2½ per cent, provides for avoiding much of the trouble and annoyance from burned brake shoes and an average margin of safety compared to level grade work.

DOUBLE HEADERS AND PUSHERS

When a train is to have a helper locomotive coupled on, the regular enginemen will apply the train brakes with a 20-lb. brake pipe reduction before the helper couples on, leave them applied and close the double heading cock. The helper engineman after coupling, will release the brakes and make the brake pipe test. When a helper locomotive is to be cut off, its engineman will apply the brakes with a 20-lb. reduction and leave them applied. The regular engineman will then release them and make the brake pipe test. The automatic brake valve on other than the head locomotive must not be cut in at any time or for any reason except for a plainly needed emergency application of which the head engineman is unaware or unable to make.

With a pusher locomotive on the train, the head engineman will, when the train is to be started, allow the pusher engineman to endeavor to start it. When he is using full power the head engineman will carefully assist. When the train is being stopped, the pusher engineman will continue to use steam lightly until the stop to hold in the slack.

BACKING TRAIN MOVEMENTS

When ready to make a backing train movement in which the back-up hose will be depended on for more or less control, the engineman will lap the automatic brake valve on receiving the signal to back. The man at the rear end will make a sufficient discharge from the back-up hose cock to insure a substantial application of the brakes. On noting by the air gage and by the brakes applying that this reduction has been made, the engineman will make the usual release and proceed to back up. In such movements the automatic brake valve should be carried in running position, so that the brakes will release and recharge.

BRAKES STICKING

One cause of brakes sticking or failing to release is attempting to release a lighter application than at least 10 lb. Another cause is some brakes re-applying near the head end after releasing and a failure to make the "kick-off." Another cause is a defective feed valve which allows brake pipe pressure to vary from time to time, or a good feed valve that cannot regulate the pressure uniformly because of too little excess pressure, as a result of too low governor adjustment or a governor defect, or less excess pressure than indicated, due to an error in the gage.

[The report also took up the best methods of handling overcharged brakes of various types and the proper manipulation of the brake valve in the case of brake applications from an unknown cause.—Editor.]

The report is signed by T. F. Lyons, (N. Y. C.), chairman; Eugene Hartenstein (C. & A.); Fredric Kerby (B. & O.); L. S. Ayers, and W. R. Garber (K. & M.).

DISCUSSION

Mention was made of the use of gas engine oil for lubricating the air cylinders of locomotive air compressors, and L. P. Streeter (I. C.) stated that while good results had been secured with automatic lubricators on regularly assigned engines, some difficulty had been experienced in securing successful operation where locomotives were pooled. F. B. Farmer (Westinghouse Air Brake Company) expressed the opinion that a maximum speed of 45 miles an hour on descending grades was too high. In reply, G. H. Wood (A. T. & S. F.) stated that trains could be brought to a stop on descending grades from a speed of 45 miles an hour in the same distance that they could be stopped on level track from 65 to 70 miles an hour and for that reason there was no more danger involved. Where cast iron wheels were used the high rate of speed might result in extensive heating of the wheels and in that case it would be necessary to limit the speed.

ADJUSTING TONNAGE FOR AVERAGE SPEED OF TWELVE MILES AN HOUR

A railroad is most efficient when it produces the maximum ton miles per hour at the least expense consistent therewith. Engine efficiency should not be measured only by the percentage of possible tonnage handled per train, but preferably by the percentage of the maximum ton miles which can satisfactorily be handled per engine per month. Prof. W. J. Cunningham has well said:

"The time element has not generally been given the recognition it deserves. Ton miles per train hour as a unit is analogous to the horsepower unit, but instead of foot pounds per minute we use train ton miles per hour. . . . .

"A large part of the expenses vary with the hours, hence it is important that the ton miles per hour shall increase. The capacity of the road in periods of peak-loads of traffic will vary with the ton mile production per train hour.

"The ultimate unit of freight car efficiency is: 'Net ton miles per car day.' . . . We are all familiar with the reasons which make it difficult to get a larger daily mileage, but sometimes it may appear that we have become too complacent in accepting these reasons as a complete explanation. In times of car shortage, an increase of one car mile per day throughout the country would be equivalent to adding about 100,000 cars to those available for service."

Apparently this condition can be but slightly improved by increasing the speed of freight trains, because of the small percentage of the time that a car is in movement. But in this we may be deceived to a considerable extent, for in hundreds of instances which have come under the observation of every experienced railroad man, a small increase in the running time of a train has resulted in the loss of a car day for each car in the train at destination, and frequently an aggregate loss of many car days, as well as per diem charges (which may again interest us soon) at intermediate stations, terminals and junctions. An increase in the time on road also means less time at terminals for repairs, or fewer trips per locomotive. Continued exhaustive strain on locomotive parts is expensive, as such usage invariably results in failure or excessive repair work and time out of service, which, in addition to the direct expense, necessitates an increase in locomotives owned or under lease.

Generally the fuel consumed per ton mile is reduced as the engine load is increased within a reasonable limit, but the wages per train crew per trip are increased in most instances, and frequently it has been found expedient to reduce train tonnage much below the possible maximum in order to clean up blockaded divisions and thus to best serve the public as well as the stockholders. Solely on a ton mile per hour basis a gradual gain in locomotive efficiency can be shown as speed increases to thirty or thirty-five miles per hour; but when the speed of freight trains averages more than fifteen miles per hour, many factors other than ton miles per hour affect the net economy.

The probability of costly delays and accidents increases very rapidly as the length of train approaches the present maximum. The modern locomotive usually can keep a train moving which it cannot start without running out the slack with such force as to overstrain even the best draft gears and couplers.

The probability of failure of trains to make expected movement, with consequent expensive road and yard congestion, increases rapidly as train tonnage closely approaches the possible maximum, even though there is no breakage.

The modern locomotive attains its maximum fuel and thermal efficiency at speeds of not less than twelve miles per hour while working at approximately 25 to 30 per cent cut-off. As the cut-off is increased, the thermal efficiency decreases rapidly. At lower speeds, high degree superheated steam is not obtained, and the possible economy from this source is not realized. Superheater locomotives are capable of higher sustained speeds than saturated steam engines capable of dragging the same load, and full advantage should be taken of this superiority. On low grade divisions where it is necessary to half stroke or in many instances to nearly full stroke the engine most of the way between terminals, these features are worthy of careful consideration.

Fully as important as any of these considerations is the psychological effect on the train and engine crews. Delays or depressingly slow movement exhaust patience and interest, and without interest and initiative on the part of engine and train crews the best performance cannot be obtained.

Aside from the psychological effect on employees, the time element in calculation of wages of train crews, at one time negligible, has become of great and increasing importance during the past few years. Speaking generally, shortening the distance between terminals, with the cost of consequent new terminals and abandonment or lessening in productiveness of many present terminal facilities, would increase charges to capital account and operating expenses excessively.

On a railroad handling many high-speed and important passenger, express and mail trains on the same tracks used by freight trains, the maximum possible tonnage per train will result disastrously; while on roads having four tracks, for example, a closer approximation to maximum possible tonnage may be satisfactorily maintained. Often on single-track roads where sidings are five or six miles apart, it is with difficulty that trains can make one hundred miles within the sixteen hours unless the average speed exceeds twelve miles per hour, excluding delays.

The committee is of the opinion that the volume and character of traffic, the physical characteristics of the roadway, and the locomotive equipment vary so greatly on the several roads and in many instances on the various divisions or sections of the same system, that the problem of determining the most suitable average speed and tonnage for freight trains generally must be solved for each division or district. Numerous carefully conducted road tests and expert analysis of performance and cost records should be made to determine the most economical operation.

We believe that with very rare exceptions an average speed of more than twelve miles per hour for tonnage freight trains can be attained and maintained without reduction in the properly determined maximum allowable tonnage, and that this tonnage will exceed the present rating in some instances, if the transportation and mechanical departments co-operate effectively in determining the proper rating, and if the officers of these departments, as well as those in the maintenance of way department, put into regular use every possible means for the elimination of delays.

[A table was included in the report showing the average freight train speeds maintained by 23 roads over a period of 10 months. With three exceptions these were all less than 12 m. p. h., the arithmetical average being 10.8 m. p. h.—Editor.]

The report was signed by H. C. Woodbridge, chairman, E. F. Boyle, J. S. Meidroth and F. R. McShane.

Discussion

Several members spoke on the necessity for co-operation between the traveling engineer, trainmaster and despatcher in order to reduce delays and increase the average speed of trains between terminals. The prevailing opinion was that there is little danger of overloading locomotives if the main journal bearings are kept in good condition.

THE ADVANTAGES OF STOKERS ON MODERN LOCOMOTIVES

Heretofore, in considering the application of mechanical stokers to locomotives we have thought in terms of the present only. The time is now at hand when we must consider future needs. Man power and wage costs are the dominating factors, and for economical operation we must use machinery to do work that at one time could profitably be performed by hand. The economical rating of a locomotive is no longer the greatest tonnage it can haul over a division regardless of time, but the greatest tonnage it can haul over a given distance in a given time.

Ever-increasing wages makes it necessary to get more work out of the machines, and we can no longer limit the capacity of the modern locomotive to the capacity of the fireman to shovel coal.

The advantage to be gained by the application of stokers is the realization of maximum boiler capacity, not only through sustained periods, but at any time when needed. The necessity for using mechanical devices arises, not only from a humanitarian standpoint, but more particularly to develop 100 per cent efficiency in each individual, and as this factor enters into the effectiveness of the locomotive more than any other part of railroad operation, it would seem to be the strongest recommendation for the installation of mechanical stokers on all power that is kept in road service.

Years ago the capacity of the firemen at times governed the amount of work performed and not the capacity of the locomotive. There were two reasons for this: First, it is impossible to educate any two men up to a point where they will fire a locomotive exactly the same under all conditions and look ahead to be prepared for any emergency; second, the physical capacity of men to perform the work. The stoker makes it possible to have every engine 100 per cent effective. In some instances it is possible to get full capacity out of the locomotive, while in other instances, even with experienced men, it is not. Therefore it is only fair to assume that the amount of work performed by any given number of locomotives in any given territory will be based on the average poorest firemen on that division rather than on the average best firemen. With the engines equipped with mechanical stokers, receiving proper attention at terminals and by the men on the road, each will give practically the same service.

There is no question but that a scientific job of firing largely affects steam chest temperatures when using superheated engines. By some tests conducted on a superheated engine it was demonstrated that it was possible to increase the steam chest temperatures from 20 to 50 deg. by expert firing, as compared with the work of the regular fireman on the job. Uniform temperatures in the fire-box, together with perfect combustion, will give the highest steam temperatures possible to obtain, and as it takes a given amount of air to produce perfect combustion from a given amount of coal, and as the admission of air to the fire-box can only be regulated by the depth of the fire on the grate, it can readily be seen that in firing an engine by hand where the fire-door has to be opened to admit of the fuel charges, that the admission of air to the fuel bed through the grate must be intermittent, either too much when the door is closed or not enough when the door is open.

The stoker makes it possible to carry the water at a lower uniform level than with a hand-fired engine, for the reason that the steam pressure can be maintained at any time even though the engine is being worked to its maximum capacity through any sustained period.

In all the comparative tests that have been made between the stoker and hand-fired engines no one seems to have come to the same definite conclusion regarding fuel consumption. We have found that in using the same grade of coal with the stoker and hand-fired engines, the boiler capacity of the engine not only is increased to a great extent as far as handling tonnage is concerned, but that it materially reduced the running time between terminals; therefore, with the present stoker in its perfected form, it should not only show much greater efficiency than a hand-fired engine, but also effect a very material reduction in fuel consumption.

Considerable stress is placed on the stack losses of stoker-fired engines due to the extremely fine quality of coal necessary to use on them. With the present perfected stoker and the brick arch extending well back to the door sheet, the stack losses can be reduced to a point nearly as low as is done by using run of mine coal hand fired. In some large Mikado type engines, where originally they used six bricks in the arch, the arch was extended up to within about seventeen inches of the crown-sheet. This not only has made a saving in stack losses, but almost entirely eliminated the smoke. With an arch of this kind and a large combustion chamber it would be possible with careful manipulation to burn 98 per cent of all fuel in the fire-box.

The firemen are demanding another increase, and in addition are requesting that all engines above a certain limit be equipped with mechanical stokers, and all under that limit be equipped with mechanical coal passers and grate shakers. Considering the cost of the mechanical coal passer and grate shaker, it would be much better to take the money expended in this way and equip all engines kept in road service with a stoker.

While committees reporting on this subject in the past have never been able to secure reliable information, records for the past five years show our maintenance cost to have been a little under $10 per thousand miles. As to engine failure due to stoker trouble, the records of the El Paso & South Western show an average of 61,556 miles per stoker failure. The application of stokers on this line has entirely eliminated the stereotyped engineers' report of "engine not steaming." As a rule the size of nozzles has not been increased, but it has been possible to adopt a standard front end and make all engines give a uniform service as far as steaming is concerned. It was never possible to get any class of engines to steam alike when hand fired. One fireman would want a bridge in the nozzle, while another wanted it out; one would want the draft-sheet 15 in. from the bottom of the arch, while another wanted it 21 in.; one would want the petticoat adjusted one inch above the nozzle, while another man would want it six inches. With the stoker, however, practically no work on front ends is necessary by the roundhouse force except to make regular inspections.

Owing to the constantly increased coal burning capacity of the locomotive, the application of a mechanical means of supplying the fuel is the only thing that will make the work sufficiently attractive to get and keep the right kind of men on our engines.

The report was signed by E. Gordon, chairman, J. A. Cooper, A. N. Willsie, J. O. Clendenin and J. R. Bissett.

HANDLING LOCOMOTIVES TO SECURE EFFICIENCY AND FUEL ECONOMY

The essential requisites to locomotive efficiency are proper design, proper operation and proper maintenance of power, the matter of fuel economy always being closely related to any of the three. The matter of proper design should start with having the boiler and grate area designed of ample proportion to furnish enough steam to develop the maximum cylinder horsepower of the cylinders at all times. Every modern locomotive should be equipped with superheater, brick arch and power fire-door; all of which are fuel-saving and capacity-increasing devices. The combustion chamber also makes for fuel economy and is now in successful use on most large locomotives. The mechanical stoker should be applied to all large engines, and although the conditions under which the engine is to operate would govern, generally speaking, engines with over 50,000 lb. tractive power ought to be stoker fired.

Air compressors and headlight turbines of modern and most economical design should be used on new power, and on some old power it will be found in the interest of economy to replace existing auxiliaries with the more economical outfits. There are some as yet undeveloped sources of fuel economy for locomotives, one of which, the feed water heater, while still in the experimental stage, will undoubtedly soon be perfected and put in more or less general use.

In designing the engine, front end, grates and ash-pan should be given plenty of attention. It is necessary to keep the air out of the front end, and yet admit it in plenty to the ash-pan, which means ample ash-pan air openings and all joints tight around the front end. The exhaust nozzle should be made as large in diameter as possible, so as to reduce back pressure and yet furnish the draft required to produce proper action on the fire. The grates should have ample air opening and the grate rigging should be such as to permit shaking freely by the fireman, which cannot be done if too many sections of grate are carried on one shaker.

ESSENTIALS FOR PROPER OPERATION

It is recognized that where locomotives are pooled they are not so well maintained, as the engine crew does not take the same interest in an engine that they may not see again for a month; and they do not make the lighter repairs, nor the thorough inspection and report of defects en route which they do in a case of the regularly assigned engine. Although it may be more economical in general to use pooled engines, particularly when business is heavy, there are instances where regularly assigned engines could be used, and it is preferable to do so when consistent.

Locomotive performance is affected to a considerable extent by the terminal facilities. Terminal facilities may often include various fuel or labor-saving appliances, but these are not always installed in co-ordination with other appliances at the same terminal. Proper terminal layout should be such as to get the quickest movement into and out of the engine-house of engines arriving at and departing from terminals. Considerable fuel is lost, the expense of handling the engine increased, and there are many delays due to improper design of terminals.

Wherever it is possible to change an existing water supply for one of better quality, it should be done, providing the cost of the change is not prohibitive, and then, having obtained the best available water, every water should be given the necessary treatment to prevent scale formation and corrosion within the boiler. Fuel lost from having scaled heating surfaces is a large expense; boilers operate at reduced efficiency when sealed up; engines fail and give up trains on account of flues leaking, and the cost of boiler maintenance is much higher on account of frequent flue, stay-bolt and firebox renewals. Engine failures due to leaking can be reduced to practically nothing; staybolt trouble can be reduced to a minimum, and considerable fuel will be saved with the proper treatment of all waters.

MAINTENANCE OF MACHINERY AND BOILER

Proper maintenance depends first on proper inspection and then on getting the defects corrected which are brought out by this inspection. The pooled locomotive can be run successfully and efficiently if there is adequate terminal inspection and repair. Not infrequently the officer in charge of the terminal is under the impression that the only inspection necessary is searching for loose nuts, missing parts of machinery, cracks, hot bearings, etc., and consequently uses rather low-grade men for this purpose. The best man on the job is none too good for inspection, as a locomotive ought to be tested for steam blows, pounds and such defects as cannot be observed by the eye alone.

If the inspection and repair of locomotives were carried out in accordance with federal inspection laws good results would be secured. All repairs found by the inspector ought to be made, and when possible a check should be made before the engine leaves to see that all work has been done.

A few items of maintenance, or shop practice, that might be mentioned are care in laying out shoes and wedges, and proper maintenance of binders, tramming of engine trucks, drivers and tender trucks, and the fastening of valve bushings so that they cannot move, making it possible to use standard rings for all engines of a class. It will frequently be found that the steam distribution is not correct for engines of the same class, due to slight differences in the position of the valve bushing and size of valve rings used.

Perhaps one of the most important items of maintenance is the proper care of superheaters and superheater flues. The superheater is the greatest fuel-saving device, and as the saving in fuel depends on the amount of superheat, it follows that any obstruction which prevents free passage of the hot gases around the superheating units will result in a reduction in superheat and a corresponding reduction in the efficiency. It does not take many trips for superheater flues to become stopped up and unless constant attention in the way of blowing them out in roundhouses is given superheaters will be found only saving perhaps 50 per cent of what they should when properly maintained.

FUEL DEPARTMENT ORGANIZATION

Although fuel economy depends on proper design, proper operation and proper maintenance of power, it is necessary in order to get real results to have a separate fuel organization. This should consist of a general staff officer, in charge of fuel conservation, who should devote his entire attention to the conservation of fuel on locomotives, in shops, at terminals, water stations and for all miscellaneous purposes. He should also have jurisdiction over the quality, preparation and uniformity of coal furnished.

To carry out his plans, the general fuel officer should have divisional fuel supervisors, who should be assigned a certain territory for all the various details of fuel economy, but whose principal duty should be the education of firemen in the economical firing of engines. The fuel organization should have enough clerical assistants to keep up-to-date records of fuel performances by individual engine, by engineer and by fireman, so that performances on any division can be known and examined at any time. These records give means of locating the cases where an engine or an engine crew is operating wastefully, and they also show what progress is made in saving fuel.

Monthly divisional fuel meetings should be held with the superintendent, master mechanic, divisional officials and such employees as can consistently attend. General fuel officials should attend these division fuel meetings as often as possible, but the superintendent should be the chairman of the divisional fuel committee and conduct the meetings, as this brings about a more thorough and more uniform understanding of the importance of various matters effecting fuel economy by operating officials who otherwise might overlook some of the details and leave it up to the mechanical department.

Any progressive movement must be backed by educational efforts and great stress is laid on the necessity of constant education of enginemen particularly, as they, of all employees, are most responsible for the coal pile, and also of all others who in any way may be concerned in the use or waste of fuel.

The report is signed by J. B. Hurley (Wabash), chairman; Robert Collett (U. S. R. A.); F. P. Roesch (U. S. R. A.); B. J. Feeny (U. S. R. A.); and G. E. Anderson (Gt. Nor.).

DISCUSSION

W. G. Wallace (American Steel Foundries) emphasized the importance of having a record of the coal consumption immediately available at the end of each trip. If this information is given to the train dispatcher at the end of the run, it makes it possible to check up the coal consumption, taking into account all the conditions surrounding the trip. This helps greatly in fixing the responsibility for excessive fuel consumption, whether it is due to the operating conditions, the mechanical condition of the power or the quality of the coal. E. Hartenstein (C. & A.) mentioned the losses due to slow orders and unnecessary stops. He also touched on the qualifications of locomotive inspectors and stated that men who had received their training in road work were often better qualified than men from the shop. V. C. Randolph (U. S. R. A.) called attention to the important part which the locomotive engineer must play in securing economy in the use of fuel, and advocated that these men should be taught how to operate the engines at the greatest efficiency. Among the common wasteful practices he mentioned especially working the locomotive harder than is necessary. H. C. Woodbridge (U. S. R. A.) stated that irregular action of reverse gears was often responsible for excessive fuel consumption and expressed the opinion that it is necessary to make improvements in these devices. A. G. Kinyon (Fuller Engineering Company) advocated a fuel department organization reporting to the chief executive officer. He brought out that instruction must be supplemented by adequate supervision to get the best results. B. J. Feeny (U. S. R. A.) stated that too much attention is given to accounting for oil and far too little attention to fuel records. He also emphasized the fact that the responsibility for saving fuel extends to all departments.

CARING FOR LOCOMOTIVES AT TERMINALS TO SECURE EFFICIENCY AND INCREASED MILEAGE

Assuming that locomotives come from the shops in condition to readily develop the state of efficiency for which they are rated, the efficiency that can thereafter be maintained and the milage obtained, will depend largely upon the thoroughness of the work done upon the locomotive during general overhauling periods. The limited facilities of the average terminal plant should not be required to make good the shortcomings of the general repair shops.

Increased mileage is but another term for maintenance of a high efficiency, as it presupposes less delay along the line due to locomotive troubles, quicker turning at terminals for service and a greater number of trips between shoppings. The efficiency of the practices in use at terminals, the extent of the facilities available for doing work and the excellence of the work done will in a general sense determine the measure of efficiency that can be expected to be maintained at such places. It follows that a constant striving for the betterment of practices, of facilities and of workmanship, are the essential needs at terminals to maintain locomotives in an efficient state and to increase the mileage obtainable. The traveling engineer should be of valuable assistance to those in charge of terminals in bringing these betterments about.

The question as to what are the best methods of caring for locomotives at terminals is synonymous with, what constitutes good roundhouse practice?

Studied from any angle, these two questions constantly intermingle and seemingly resolve themselves into the identical set of fundamental requirements which, in turn, constitute equally the basic principles of good roundhouse practice and of locomotive maintenance.

These requirements are: Caretaking inspection of the locomotive by competent locomotive inspectors as soon as possible after arrival at terminal; the obtaining of an intelligent report from the incoming engineer as to the conditions noted during his trip; the proper cleaning of the fire, ash-pan and front end, and attention to the fire and water while lying at the terminal; a careful inspection by competent workmen of the troubles and defects as reported by the engineer and locomotive inspectors and the making of the necessary repairs and changes in an efficient manner; the furnishing of the proper engine tools and the necessary supplies for the outgoing trip, which will include filling of lubricators and rod cups; frequent riding of the locomotives by the traveling engineer.

With the exception of the last mentioned point, these requirements are incidental to every trip in either direction where inspection and repair facilities are provided for at each terminal. The maintaining of efficiency demands that these requirements must be provided for and carried out at least at the end of each day's work, and is required by the Interstate Commerce Commission rules.

In addition to the points already mentioned, provision should be made for periodical inspections not usually covered in work reports, which will include boiler washing, boiler inspections and inspections of the operating parts enumerated later on; for the carrying in stock of needed supplies of all kinds for making the repairs and for renewals, and for shop equipment and tools necessary for reasonable running repair maintenance.

ENGINEERS' REPORTS

As there are certain troubles and defects such as steam blows, pounds, and conditions affecting the steaming properties, which are only discernible when the locomotive is working, an intelligent report from the engineer as to the conditions noted while running on the road, is of the greatest importance.

There is scarcely a way in which the traveling engineer can be of more use to the mechanical department and be of greater aid in assisting to keep locomotives in an efficient condition than in seeing that engineers' work reports are made out in such a manner as to clearly indicate the nature of the defect, and in cases where a definite cause cannot be given describe just what takes place.

LOCOMOTIVE INSPECTION

The Locomotive Inspection Bureau of the Interstate Commerce Commission has issued rules governing the inspection of locomotives, and including limitations of wear permissible for certain parts. These rules are based upon the practical experience of both the federal inspectors and representatives of the most important railroads of the country, and failure to live up to them constitutes a violation of the law.

Carried out in the spirit intended, they stand for good maintenance. Where observed, however, only within the letter of the law, a high state of efficiency is not necessarily indicated, as many of the rules do not cover the best conditions obtainable, but rather the poorest allowable, and the limitations below which it is not permissible to go. The inspection should be thorough and painstaking, inasmuch as defects that result in delays, breakages and failures, are quite frequently discernible only under the very closest scrutiny.

In addition to those parts covered by the rules, every part subject to wear that would interfere in any way with the efficient working of the locomotive and all parts subject to severe strains, breakages, or loosening effects, including nuts, keys and cotter pins, as well as the condition of all safety appliances, should receive attention. It is a good plan to have an outgoing inspection, covering conditions of air brakes, injectors, electric headlight, and power reverse gear, and for the examination of such parts of the locomotive as were reported for shop attention.

Where for any reason the fire is dumped at the terminal, suitable provision should be made for the inspection and testing of steam and air-operated devices, such as the air brakes, injectors, electric headlight, power reverse gear and similar devices, while still under sufficient steam pressure to operate such parts. This guards against defective conditions in such parts, gives opportunity for repair if any defects are found, and in the case of air brakes, provides for the testing and the adjusting of the piston travel within the proper limits.

All locomotives should be cleaned in order to facilitate the work of inspectors and shop men.

SHOP FACILITIES AND TOOLS

Where the facilities of a general or so-called back shop are not readily accessible, adequate means for doing light repair work of a reasonable nature should be provided in the way of a small machine and blacksmith shop. This should contain at least a lathe, a small shaper, a drill press, a press for pushing bushing in and out, a blacksmith forge and a grindstone. Such a plant is almost invaluable, providing for both quicker and better work as well as assisting in cutting down the cost of maintenance. A supply of tools such as drills, taps, reamers, dies, files, wrenches, pipe fitters' and boilermakers' tools and others not usually provided by the workmen themselves should be at hand.

The weight of various parts which have to be handled demands the use of portable cranes, jacks and block and fall, and these should be provided for quick and safe work. An electric or other type of welding machine has also become a necessity in terminals of any size.

SUPERVISION, QUALIFICATION AND METHODS

Competent supervision over mechanical activities at terminals is a most important factor in efficient locomotive maintenance. Men for these positions should be chosen with particular regard for their experience, good judgment, foresight and resourcefulness, as well as for their ability to handle men. Frequently located at points distant from any large terminal through which immediate assistance could be procured, often with poor facilities for doing work and none too competent help, their success or failure depends largely upon their own capabilities.

Resourcefulness is necessary in devising ways and means to meet the varying conditions incidental to running repair work and the emergencies that are constantly arising. The interest taken in the work by the supervision will be a dominating feature in the results achieved. Not only should the workmen be watched to prevent loose methods and bad practices creeping in, but the completed work should be frequently examined as a guard against poor work and carelessness.

TURNING POWER

Features other than the maintaining of an efficient locomotive enter into the matter of increased mileage and as they have to do with the care of the locomotive while at terminals, they must be given due consideration in connection with terminal work.

Increased mileage necessarily implies a greater number of trips to be made between shoppings and conditions at terminals which interfere with the promptness with which locomotives may be reached for the purpose of making needed repairs and prepared for a quick return to service, tend to prevent increased mileage.

It is usual to consider the cleaning of fires, the obtaining of coal and water and the turning of the locomotive as adjuncts to the maintenance and care of power. The provisions made for doing this work and the ease with which the locomotive can reach the points where the work is to be done, is most important in the quick turning of locomotives as a means of bringing about increased mileage. Inadequate provision in this respect slows up terminal movements, hinders prompt repairs, tends to hurried repairs and to work being left undone. It frequently leads to badly congested conditions and serious delays, and fosters carelessness in the various stages of preparing the locomotives for return to service on account of the necessity of crowding them through the terminal in order to turn them with any degree of promptitude, and in general results in poor conditions and delays.

Poor facilities in this respect are especially troublesome at terminal points where severe winter weather is experienced and during such periods they may be the cause of power conditions becoming very serious.

The trackage about terminal plants insofar as it provides for prompt and free movement of the locomotive in conjunction with cleaning fires, obtaining coal and water, getting to and from the turntable and in reaching and departing from the shop, is important in giving more time for the making of repairs and lessening the time required for preparing the locomotive for dispatching. In a like manner the adequacy of the provisions made for cleaning the fires, for inspection purposes and for coaling, have an important bearing on the time necessary in getting the locomotive ready for service.

RESPONSIBILITY OF THE TRAVELING ENGINEER

The duties of the traveling engineer place upon him a considerable share of the responsibility for the maintenance of the locomotive over which he has nominal control. Being in constant touch with all the conditions that enter into their handling both at the terminals and on the road, he cannot well evade such responsibility.

In various ways, as casual inspection of methods used and work being done when he is around terminals, riding the locomotive, investigation of delays and failures and through his contact with the locomotive crews, it is within his power to know just what conditions are. He has the means of knowing whether his engineers are making intelligent reports or not by occasionally looking over their work reports. He has the means of knowing by personal observation and by information gained from delay and failure reports whether inspectors are competent and painstaking in their work or not. He should know whether or not fire, ash-pan and front-end cleaning is being done properly, and the locomotive cared for in a proper manner while laying over. He should know by the results obtained as well as by the complaints of the locomotive crew, by his personal experience in riding and by results of investigation of delays and failures whether the work being reported is being properly done or neglected. He can easily ascertain what is done with reference to boiler inspection during boiler washing periods and to other parts during periodical inspection.

In the extent to which he avails himself of this information, and the use to which he applies it will lie the measure of his share of the responsibility for the conditions which exist. It is scarcely sufficient that he is able to say in explanation of poor conditions that the work required to better conditions was reported. He must be able to show that he made use of all the means within his power to bring about a betterment of conditions. It comes well within the scope of his authority to consult and advise with those in charge of terminals as to conditions that are detrimental to maintenance and efficiency.

He will almost invariably find that the information and advice that he can offer will be most gladly received. As a rule the terminal authorities are more given to complaining of the lack of assistance given them by the traveling engineer than in regard to his insistance on better conditions.

The traveling engineer should take particular interest in the prevention of practices which tend to decrease locomotive efficiency, such as moving engines without opening the cylinder cocks, with its ill effects on cylinder and piston rod packings and the slipping of locomotives in starting them, with its general racking strains.

The report is signed by T. F. Howley, chairman, Joseph Keller, B. J. Feeny, C. W. Corning and J. W. Burrows.

DISCUSSION

W. H. Gallagher (M. K. & T.) advocated a method of adjusted tonnage rating as a means of securing greater efficiency from locomotives. E. R. Boa (N. Y. C.) brought out the necessity for cooperation between the traveling engineer and the roundhouse foreman. F. L. Pierce (C. & A.) described a method of inspection of outgoing engines by traveling engineers which had brought good results. E. F. Boyle (So. Pac.) spoke of the damage to locomotives resulting from improper operation by hostlers, who often moved the engines when cylinders were filled with water. B. J. Feeny (U. S. R. A.) stated that while good facilities were necessary to secure the best results, a fair degree of efficiency could be secured by giving attention to simple matters which required no elaborate equipment, such as blowing tubes and cleaning grates, as these matters have a great influence on the operating results secured with the engines. W. L. Robinson (B. & O.) mentioned the abuse of locomotives by incompetent hostlers, and stated that traveling engineers should have authority over these men and should instruct them in the proper method of handling engines. E. S. Boyle (So. Pac.) stated that, as a rule, if all the work reported by the enginemen is done, the motive power will be kept in fairly good condition. It is, however, necessary for the traveling engineer to see that the men do not fail to report necessary work. He advocated occasional joint inspection by the traveling engineers, general foremen and master mechanics to check up the engineers' reports. A resolution was passed stating that in the opinion of the association there should be responsible engine inspectors and night roundhouse foremen at all engine terminals.

OTHER BUSINESS

At the session held on Friday, the report of the committee on amalgamation with the American Railroad Association was received and discussed. The committee stated that in view of the fact that the duties of the traveling engineer were not strictly mechanical work nor transportation work, but a combination of the two, it believed that the best results would not follow from amalgamation as a division of either the operating section or the mechanical section, but by the creation of a separate section to take over the activities of the Traveling Engineers' Association. This course had been suggested to the officers of the American Railroad Association, but no answer had been received, and in view of this situation the committee was continued.

The by-laws of the association were amended to leave the selection of the place of meeting entirely in the hands of the executive committee.

The following officers were elected: President G. A. Kell, Grand Trunk; first vice-president, W. E. Preston, Southern; second vice-president, L. R. Pyle, Railroad Administration; third vice-president, E. Hartenstein, Chicago & Alton; fourth vice-president, J. H. DeSalis, New York Central; fifth vice-president, E. F. Boyle, Southern Pacific; secretary, W. O. Thompson, New York Central; treasurer, David Meadows, Michigan Central; members of executive committee, F. P. Roesch, Railroad Administration; B. J. Feeny, Railroad Administration; J. Keller, Lehigh Valley.

FRONT ENDS, GRATES AND ASH PANS*

During the past few years much attention has been given to results obtained from the performance of heavy Mikado and Santa Fe type locomotives. The committee felt that an analysis of some of the apparatus pertaining to the designs of front ends, grates and ash pans was pertinent, and accordingly sent a letter to the mechanical engineers of some of the larger railroads of the country, reading in part as follows:

"In connection with work by the Standing Committee on Front Ends, Grates and Ash Pans of the International Railway Fuel Association, we wish to compile data in regard to improvements in designs of front ends, grates and ash pans which some of the more important railroads have found to produce a saving in fuel. We would like to have this data in connection with the larger type locomotives, preferably the Santa Fe or the Mikado types.

"If your railroad has found a change in design within the last two or three years which is proving to be a more economical design than you originally had on front end arrangements, on grates or on ash pans, also if the designs you now use are giving very good economy, will you please send drawing showing the old and new designs and also advise as to the size of the locomotive, the class of service, the grade of fuel burned and any further information which you see fit to give regarding both old and new designs."

The response to these letters, together with information submitted by individual committeemen, has suggested a comparison of present practice with the practice of some fifteen years ago, particularly in reference to front end design when the Master Mechanics' Association in 1906 endorsed the Purdue University tests on front ends.

The fundamental principle of the Master Mechanics' standard front end is that the height, H, of the portion of the stack extending above the smoke box and the distance, h, that the exhaust nozzle is below the horizontal center line of the smoke box be, for best results, as great as practicable. This being done, dimensions of certain importance are ascertained in accordance with the following formulae in which D is the diameter of the smoke box, P the distance the stack extends below the top of the smoke box, d the diameter at the choke of the stack, b the diameter of the base of the stack, and h the distance from the base of the stack to the choke or smallest dimension of the stack.

$$d = .21D + .16h$$
$$b = 2d \text{ or } .5D$$
$$P = .32D$$
$$p = .22D$$

It is to be remembered that the diameter of the smoke box on which tests were made in establishing the design factors for the standard front end was 74 inches, and that the maximum back pressure of the exhaust blast that produced the draft on this oil-burning locomotive was only a little more than 4 pounds. These are conditions which do not prevail in general practice today. The diameter of the smoke box on the majority of larger engines is from 80 to 91 in. and the back pressure is far in excess of a maximum of 4½ pounds.

The function of the stack is a very important one in its relations to the drafting of the locomotive and its fuel economy. The diameter at the choke of the stack, as determined by the standard formula, is made a function of the diameter of the smoke box, as well as the distance of the exhaust nozzle below the center line of the smoke box. The question arises whether or not this is a proper basis of design with present-day practice with large locomotives, either using saturated or superheated steam, hand fired or stoker fired. Is this the proper equation to give maximum fuel economy? Does it

*Abstract of a committee report presented before the International Railway Fuel Association at the convention held in Chicago, May 19-22, 1919.

give a stack that is large enough to take care of the exhaust steam and the exhaust gases and to deliver them properly and with such a degree of freedom that good fuel economy results?

By comparing the formulae with the practice on present prominent railroads, we find that the maximum calculated diameter of the stack at the choke is 23 in. and that the actual diameter is 21 in. In this case the minimum area of the actual stack is 17 per cent below that required by the formula; no data have been established by experiment on this coal-burning Santa Fe type superheater locomotive to show that a 23-in. or larger stack might not be used.

This railroad in question is notably a leader in the large size of its stacks. Another railroad in an adjacent territory is using a 17-in. stack on this same type of locomotive.

An analysis of all the design dimensions referred to by the formulæ is of great interest as a matter of comparison, and one might possibly draw the conclusion that the dimensions were made to suit other conditions and not made to follow the formulae in that they vary as much as 100 per cent in several instances.

What, then, is the state of the standard Master Mechanics' front end? It may possibly be expressed in the words of a prominent mechanical engineer when he said recently: "So far as present large power is concerned, there is no such thing as a standard Master Mechanic front end. On present-day power, using superheater steam, the arrangement will not permit such a front end."

The Master Mechanics' front end did not provide a front end netting which is common to most locomotives of today, so located as to extend from the table plate at an angle of about 40 degrees to the forward part of the smoke box. This location of the netting for interception of the exhaust gases makes accessibility of the front end rather difficult, and many designers have expended their efforts in developing a different arrangement of the netting or spark arrester.

The Chicago and North Western has had for several years a box arrangement known as the Slater front end which is claimed to give very satisfactory results. The Burlington has an arrangement differing widely from that of other railroads so far as form is concerned, having a basket form over the exhaust pot. The Rock Island has a cylindrical spark arrester. (See *Railway Mechanical Engineer*, January, 1919, page 41.)

"This road has several hundred locomotives fitted with this device, with the most gratifying results."

With these variations of designs of front ends the question arises with this committee as to what should be endorsed as the best form of arrangement of a standard front end and what should be the basis of design of the stack under present day conditions. At this time the committee is unable to make recommendations.

Grates.—In studying the grates in use on large locomotives, we find that they are for the most part of the finger type, and are divided into four sections. During the past few years power shakers have been introduced on a considerable number of the larger locomotives. In such case the arrangement is such that the grates can be shaken either by power or by hand and, of course, in a very much shorter time than by the former method.

There is a tendency on the part of several railroads to change from the finger type grates to the table type. Tests recently made on one road show a decided saving in fuel due to the change from the finger to the table grates.

Ash Pans.—The general design of ash pans must necessarily be adapted to the particular class of locomotives, some locomotives permitting a different arrangement than others. In general it would appear that the ash pan is designed to fill a space that has been left over after other parts of the locomotive have been utilized to the best advantage. So far as the type of hopper is concerned, it seems that the duplex hopper type is in most general use, although there are a considerable number of multiple hopper type ash pans in service.

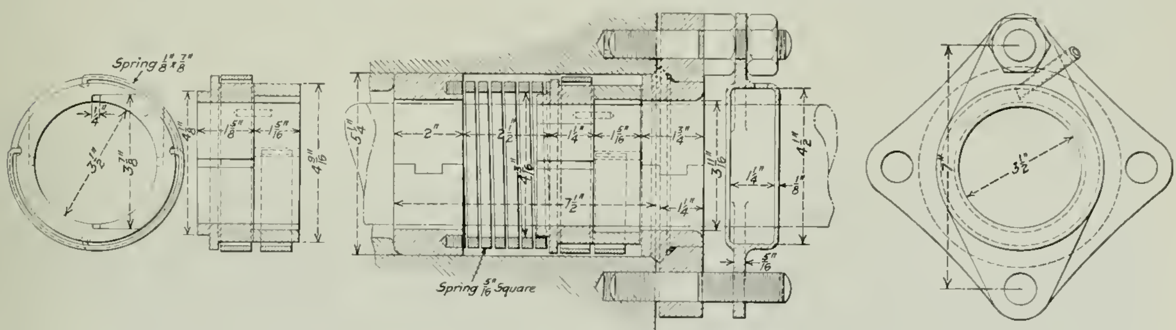
In general the ash pan doors open so as to dump the ashes towards the back end, although on a few railroads the two doors open, the one towards the front and the other towards the back of the locomotive.

In many instances the mechanical engineers are not coordinate in their actions; the designs that are satisfactory on one railroad are sometimes discontinued on another. This is particularly true with reference to the sliding versus the hinged door.

The report was signed by H. B. MacFarland (A., T. & S. F.), chairman; W. J. Bohan (N. P.), E. B. DeVilbiss (Penn. Lines), J. P. Neff (Am. Arch Co.), and Frank Zeleny (C., B. & Q.).

CAST IRON PISTON ROD PACKING

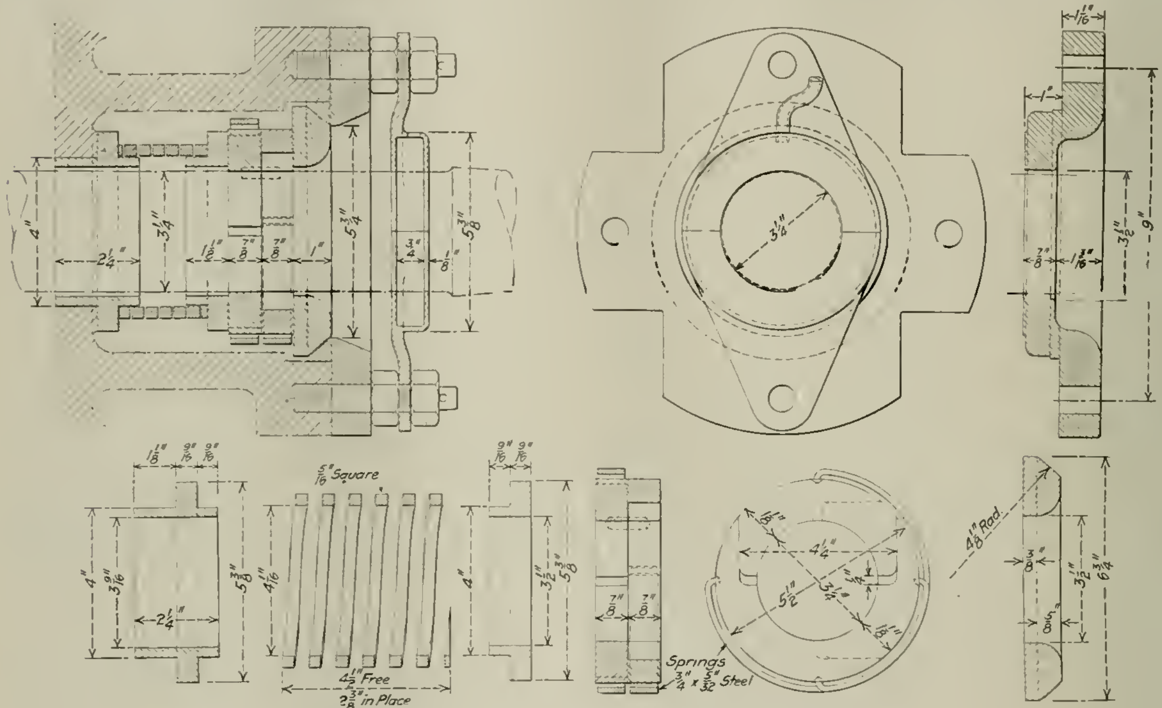
Two of the prominent railways of Great Britain, the London & North Western and the North Staffordshire, having experienced difficulty with their white metal piston rod packing on superheater locomotives have successfully developed a cast iron packing which has given particularly good service for some little time. The packing used on both these railroads is made in their local shops. The London & North Western uses a mixture of 40 per cent selected scrap, 30 per cent Kettering silicious material and 30 per cent old ingot molds (Hematite). The North Staffordshire railway makes its packing from an ordinary commercial quality of cast iron with approximately 33 per cent Barrow Hematite added.



Cast Iron Piston Rod Packing Used on the London & North Western

On both these roads the cast iron packing is used with modern locomotives, both in freight and passenger service. The North Staffordshire railway uses the cast iron packing on saturated steam locomotives as well as on the superheated steam locomotives, the design shown in one of the illustrations being used as a standard for all locomotives on that line. Reports from that railway state that a large saving in maintenance has resulted in the use of this packing, its experience having resulted that the white metal packing is many times more troublesome and expensive than the cast iron packing. For example five engines using the ordinary metal packing under saturated steam required 136 changes during 12 months, while five engines using the cast iron packing under superheated steam required no intermediate changes during the same period. Four of these locomotives had the packing taken out once for general overhauling, and one of the locomotives had the packing removed twice for overhauling during the same period. It is further stated that very little scouring of the piston rods is found with the cast iron packing, and the experience shows that the rods wear longer than they do with the white metal packing.

The design of the cast iron packing used on the London & North Western is also shown, but it should be stated that this design is somewhat restricted on account of the stuffing boxes used on the locomotives on this road. Very satisfactory results have been obtained, however, although more definite information cannot be given because a sufficient quantity of this packing has not been used long.



Cast Iron Piston Rod Packing Used On the North Staffordshire

Fireproof Terminal Oil House

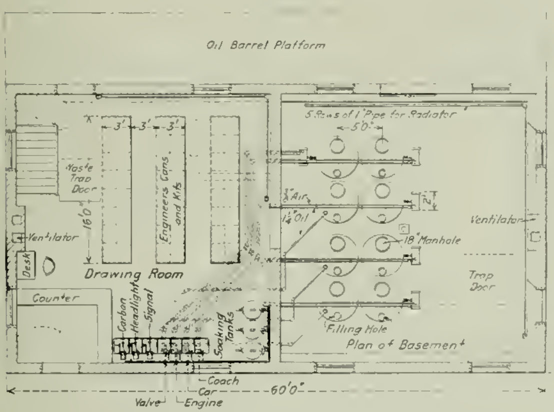
Floor Plans of Tank Arrangement and Details of Apparatus for Convenient Handling of Oil

BY ALBERT P. SHARP

The housing and handling of oils is a subject that has been given considerable study and a layout of an ideal arrangement for a railroad terminal fireproof oil house is shown in the illustrations. This house is equipped with eight tanks of 24 barrels capacity each, but can be enlarged upon or reduced without changing the method of handling the oils.

In this plan a special study has been made of safety and convenience with the greatest economy in handling oils and other materials that are usually kept at a station of this kind, such as waste, engineers' cans and kits.

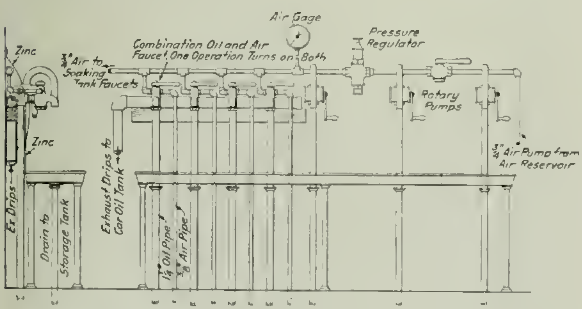
The oil is received from cars, the floors of which are on



Terminal Oil House Plan No. 1

a level with the receiving and shipping platform and is transferred from barrels to the tanks in the basement by gravity through filling pipes, provision being made for the elimination of foreign matter by having the oil pass through a suitable screen or sieve before reaching the tank. The name of the oil contained in the tank is cast on the lid of the cover of the filling box.

All lubricating oils are drawn from tanks by air pressure,



Arrangement of Combination Cocks and Other Fittings—Plan No. 1

but for illuminating oils rotary or other hand-operated pumps should be provided to avoid the serious injury to oil and the resultant accidents that might occur through the failure of a lamp caused by the moisture in the air.

Small auxiliary air tanks or receivers are provided with stop cock and check valve, the latter placed to open away from and thus insure no air reaching the main tanks.

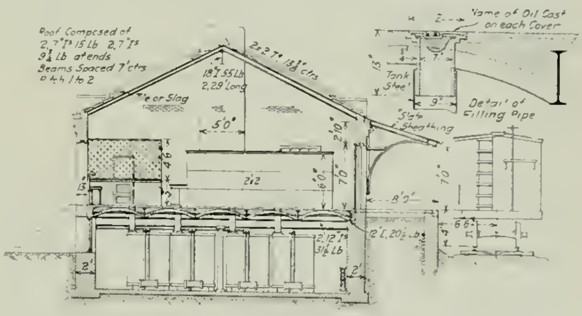
Special attention is called to the arrangement of piping, faucets and delivery counter and to the combination cock or faucet, used in drawing oils, by means of which air pressure is admitted to the auxiliary tanks only during the process of drawing and by the same movement used for drawing the oil, thus eliminating a continuous air pressure on the oil and its resultant moisture.

The convenient arrangement of faucets and delivery counter reduces the time necessary for the delivery of oil to a minimum.

The air enters a receiver placed in the basement, and provided with a connection to a sewer and a stop cock for the purpose of blowing off occasionally and removing any moisture or foreign matter that might have accumulated. It then passes from the receiver through a stop cock, thence through a pressure regulator to faucets at the delivery counter. The regulator is set to avoid splashing of the oils when drawing.

Provision is also made for soaking tanks for the preparation of journal packing, the oil being supplied to these tanks by air pressure also.

While the number of locomotives and cars to be taken care of did not enter very largely into the design of the oil house shown in plan No. 1, it was worked up for the express purpose of showing an ideal arrangement which could



Cross Section of Oil House and Filling Pipe—Plan No. 1

easily be modified to suit the requirements of an oil house under almost any conditions.

When it is possible to receive oils in tank cars, greater economy in handling will be effected by an arrangement of pipes to discharge the oil direct from the tank car to the storage tank in the basement.

A number of houses, one of which is shown in plan No. 2, using the same system and apparatus as outlined in plan No. 1, have been built and are in successful operation. This house is of a considerably larger capacity and shows the tanks lying horizontally and supported on concrete saddles, the oil being received from oil tank cars by gravity, as well as from barrels through filling boxes, if necessary.

The capacity of this house is 750 barrels of oil and provision is made to take care of waste and engineers' kits in a similar way to that shown in plan No. 1, but not repeated here. This house takes care of an assignment of 200 locomotives and a car repair yard of 240 standing room capacity.

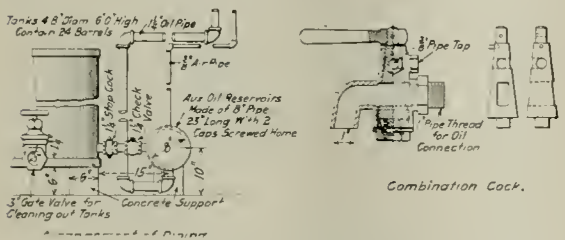
The amount of oil and the various kinds handled is as follows:

Item.	Gallons. For auto trucks	Consumption per month
No. 4 Autoline 150 Degrees	16,000	13,000 gallons
Car	4,200	3,000 gallons
No. 1 CTL	4,200	1,500 gallons
Signal	4,200	1,000 gallons
Air compressor	bbl. lots	100 gallons
Coach-Engine	4,200	2,100 gallons
Turbine	4,200	750 gallons
Transil	bbl. lots	25 gallons
Fuel	4,200	4,000 gallons
G. R. E.	bbl. lots	147 pounds

It will be noted that several kinds of oils are received in small barrel lots and are stored in the barrel, no provision being made in the way of tanks for such small quantities.

There are several details that it might be well to call to the attention of those interested.

While not shown in plan No. 1, it is understood that all

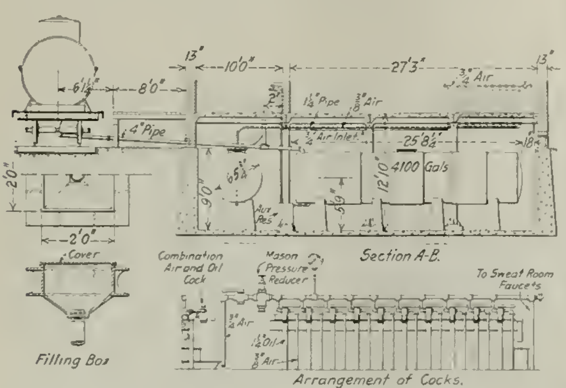


Combination Cock and Arrangement of Piping—Plan No. 1

tanks should have a vent, preferably in the manhole cover, of a 1-in. hole. Some recommend carrying the vent to the outside of the building through a 1-in. or 1¼-in. pipe. The writer thinks this an unnecessary expense, as all oil houses should be provided with ventilators in the roof or through the chimney, as shown in plan No. 1, except in cases of kerosene and gasoline, the latter at all times being stored outside of the building, preferably in a buried tank.

THE COMBINATION COCK

At each application of this combination air and oil cock there is an exhaust of more or less oil, depending on the speed used in operating the cock. This amounts to about

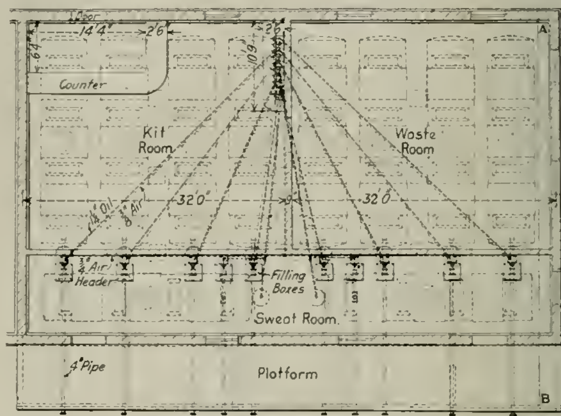


Cross Section of Oil House, Plan No. 2. Arrangement of Cocks and Filling Box

a tablespoonful of oil, the reclaiming of which is provided for by a 1½-in. drip pipe located in the rear of the battery of cocks or faucets and long enough to receive the oil from the ⅜-in. exhaust outlet on each cock. This is outlined in the arrangement of cocks, plan No. 2, which shows how the excess oil reaches the drip can.

FILLING BOXES

The filling boxes are located in the floor of the sweat room in front of and in line with the center of each large receiving tank and are used for the purpose of taking care of oil shipments in barrels, either in receiving or dispatching, the filling of barrels being done by a combination cock located immediately over each filling box. The excess, through spill-



Terminal Oil House Plan No. 2

ing over and from the combination cock, or what might otherwise be wasted oil, is taken care of by the funnel shaped filling box which allows this excess to return to the tank from which it came.

These filling boxes are set to project 1½-in. above the floor level for the purpose of excluding sweepings and other foreign matter which might otherwise find its way into the storage tanks, also to better allow the barrel to rest upon them while filling or emptying, thus preventing the oil from running over the floor and being wasted.

The Port at Stockholm, Sweden

RAILROAD ADMINISTRATION NEWS

Director General Hines took his first vacation since he became connected with the Railroad Administration, during the month of September. He was away from Washington for the two weeks ending September 20.

MECHANICAL COMMITTEE MEETING

At a meeting of the Committee on Mechanical Standards last week a special committee consisting of A. W. Gibbs, H. L. Ingersoll and John Purcell was appointed to consider the elimination of angle cocks from the air brake train line. A report and recommendation will be made to the committee at its next meeting in November. The committee also made some minor changes in the proposed standard designs for caboose cars, which, as amended, will be submitted to W. T. Tyler, director of the Division of Operation, for final approval.

COST OF FREIGHT TRAIN AND LOCOMOTIVE SERVICE

The total cost of freight train service, including locomotive service, continues to show a steady decrease each month as compared with preceding months, although increases as compared with last year, according to the monthly report of the Operating Statistics Section. For the month of June it was 101.8 cents per 1,000 gross ton miles, as compared with 103.9 in May, 112.7 in April, 119.5 in March, and 126.5 in February. No comparison of this figure with last year is given. The cost of freight locomotive service per locomotive mile in June was 107.1 cents, as compared with 97.4 cents in June, 1918, an increase of 10 per cent, and as compared with 110.3 cents in May of this year. The cost of freight train service per train mile was 154.7 cents, as compared with 142.8 cents in June, 1918, an increase of 8.3 per cent, and as compared with 156.8 cents in May. All items of cost continue to show increases as compared with last year. The combined averages for all regions and the comparative figures for last year and for preceding months of this year are as follows:

				June 1919	June 1918
Cost of locomotive service per locomotive mile				107.1	97.4
Locomotive repairs				36.1	31.1
Enginehouse expenses				8.8	6.8
Train enginemen				19.6	18.5
Locomotive fuel				39.1	38.1
Other locomotive supplies				3.5	2.9
Cost of train service per train mile				154.7	142.8
gross ton-miles	101.8	103.9	112.7	119.5	126.5
Enginehouse expenses / Locomotive repairs				51.1	43.7
Locomotive fuel				44.6	43.9
Other locomotive supplies				4.0	3.4
Train enginemen				22.3	22.3
Trainmen				25.6	25.3
Train supplies and expenses				7.1	5.2

	June, 1919	May, 1919	April, 1919	March, 1919	Feb'y, 1919
Cost of train service per 1,000 gross ton-miles	33.7	35.4	38.6	40.8	43.1
Locomotive fuel	29.3	30.6	34.3	37.5	40.3
Other locomotive supplies	2.6	2.6	2.9	3.1	3.4
Enginemen and trainmen	31.5	31.1	32.4	33.5	34.8
Train supplies and expenses	4.7	4.2	4.4	4.6	4.8

HOURS OF SHOP EMPLOYEES INCREASED TO NINE

The effect of the recent strikes of shop employees is plainly seen in the reports of bad order freight cars as of August 9, when the percentage of bad orders had increased to 9.3, although the strikes were not terminated until about a week later. On August 9 there were 144,000 cars requiring heavy repairs and 83,000 requiring light repairs. Since then the shop employees have been put on a nine hour a day basis. On August 2 the bad order cars were 8.5 per cent, as compared with 7.1 per cent on the corresponding date in 1918. About 135,000 required heavy repairs and 73,000 light repairs. A year ago the classification was not recorded. On July 26, the date of the last report preceding the strike, the percentage was 8.5 as compared with 7.2 the year before, and 139,183 required heavy repairs and 68,922 light repairs, a total of 208,105. On that date 106 roads or 77.9 per cent had more than 4 per cent of their cars in bad order and 30 roads, or 22.1 per cent, had less than 4 per cent. Forty per cent of the bad orders were box cars and 25 per cent were gondolas.

The number of bad order cars increased during the spring months while traffic was light and while the Railroad Administration was exerting great pressure to effect economies. In February the hours of the mechanical forces were reduced from the war basis to eight hours a day and in March the forces were reduced. At that time there were 400,000 to 500,000 surplus freight cars. In the latter part of June, when traffic began to pick up and a large number of cars were automatically put in the bad order class by being assigned for grain service, orders were issued to increase the car repair forces, but the strike came before much headway had been made.

SHOP CRAFTS AUTHORIZE LEADERS TO CALL STRIKE

The railroad shop employees affiliated with the American Federation of Labor have voted 325,000 to 25,000 to authorize their officers to call a strike to enforce their original demands for a general increase in wages from 68 to 85 cents an hour rather than to accept the offer recently made to them by the President and Director General Hines of increases of from 4 to 7 cents an hour by way of readjustment. The vote places full authority in the hands of the officers, however, and they apparently decided to take what they can get while waiting for a reduction in the cost of living or an opportunity to renew their demands. Although they had once rejected the offer the officers entered into conferences with Dirctor General Hines and his assistants in the Railroad Administration on September 5, prepared to accept the offer and to negotiate for the national agreement covering rules and working conditions which Mr. Hines had promised them before the negotiaitons were broken off on August 1 by the unauthorized strikes. Mr. Hines attended the conferences on Friday and Saturday and they were continued this week by his assistants after Mr. Hines had left for a vacation of about two weeks.

Director General Hines on September 4 addressed an ultimatum, similar to that issued in the case of the striking trainmen in California, regarding the local and unauthorized shop strikes on the New York Central at Depew, N. Y., on the Baltimore & Ohio at Cumberland, Md., and on the Chicago, Burlington & Quincy at Havelock, Neb., saying that unless the men returned to work not later than their regular reporting time on Saturday, September 6, they would be considered as having permanently left the service, their places would be filled and if they returned to the service later it would be only as new employees. This notice was conveyed in telegrams sent to the regional directors, stating that the chief executives of the shopmen's organizations had definitely instructed their men to return to work, directing that the federal managers post the telegrams conspicuously on bulletin boards and consider them as their instructions to proceed accordingly.

ORDERS OF REGIONAL DIRECTORS

Chicago Joint Agreement Between Brotherhoods.—Circular 88, of the Northwestern regional director, quotes rules of the Chicago Joint Agreement between the Brotherhood of Locomotive Engineers and the Brotherhood of Locomotive Firemen and Enginemen, which are to be incorporated into existing schedules on railroads where such schedules exist and where they are not already included.

Repairs to New Freight Car Equipment.—The Southwestern regional director, in Order 232, states that when new freight car equipment built for the Railroad Administration is placed in shop or on track shop for repairs all bolts should be gone over and nuts tightened to insure taking up all shrinkage that has taken place since the cars were built.

Automobile Cars—Safety Chains on End Doors.—Order 233 canceling Order 227 of the Southwestern regional director states that the Safety Section recommends that chains or some other suitable device be applied on automobile cars with end doors to prevent these doors opening further outward than the line of the side of the car, and suggests that all cars, regardless of ownership, be so equipped as rapidly as possible.

Accident Prevention Drives.—The Northwestern regional director, file 97-1-20, announces the National Railroad Accident Prevention Drive, from October 18 to 31, inclusive, and suggests that federal managers call a meeting of general officers to discuss plans for making this drive a success, the meeting preferably to be held in conjunction with the meeting of the General Safety Committee if the meeting of that committee is scheduled to be held in advance of October 1.

Fire Prevention—Smoking.—Supplement 11 to Circular 32 of the Northwestern regional director states that during 1918 there were reported to the Fire Loss and Property Protection section, 252 fires directly attributable to carelessness in smoking or the use of matches, with a total loss of $159,629, and calls attention to the necessity for strict enforcement of the no smoking rule in wood working shops, paint shops, etc.

DIRT IN COAL*

BY L. J. JOFFRAY
General Fuel Inspector, Illinois Central

The ash content in coal varies widely in different localities and frequently there is considerable variation in the same locality under different conditions of mining and preparation. The normal amount of ash may be considered as that found in the face sample of the seam proper; the excess ash is that which is added to the coal from the roof or bottom in the process of mining and which is not eliminated before the coal leaves the mine.

Lump coal made over a 1¼-in. screen usually shows the normal per cent of ash, while the 1¼-in. screenings in most cases show one and one-half times the percentage of ash contained in the lump.

The ash content in screenings can be reduced nearly to that of the screened lump by the use of a jig gravity washer, with an ample water supply and a convenient place to deposit the refuse. However, the washing of screenings has been considered too expensive while the price of all coal was low, but since prices have gone 60 per cent and more higher, and will probably remain so, it may be well, and at the same time profitable, to eliminate the excess ash by washing in the vicinity of the mines, thereby saving the use of cars for and the long haul on inert material to points where coal is finally consumed, the cost of which would be about six mills per ton-mile.

The following table showing ash and B. t. u. content of coal from a bituminous mine in the central west district illustrates how the ash content of screenings can be reduced by washing:

	Ash, per cent	B. t. u.
Dry or unwashed screenings	22.61	8,895
Washed screenings	14.05	10,085
Lump	12.39	10,499

The excess ash in mine run and prepared sizes, made over an inch and a quarter screen, can easily be removed by hand by the miner at the working face when loading into mine cars, or by having men or boys working on picking tables or belts while the coal is passing to the railroad car.

The performance of this work can be looked after by a regularly assigned fuel inspector. We are using a system of close inspection with suggestions to the mine superintendents on the ground while the coal is being loaded. As a result of this effort, the impurities removable by hand picking and based on actual carload tests have been reduced from an average of 2.733 per cent in the year 1911 to an average of 1.535 per cent in the year 1917, or a net reduction of 1.198 per cent which applied to a consumption of 4,000,000 tons of coal used annually represents 47,920 tons less ash, requiring the use of 958 fifty-ton cars to move same. The transportation cost of moving this excess ash an average distance of 266 miles, based on an "out of pocket" cost of five miles per net ton-mile, equals $63,733.60 per annum. This, however, is but the lesser saving.

Taking the established estimate of increase in efficiency of 1½ per cent for each reduction of one per cent in ash, the saving from this source, i. e., increased evaporative efficiency, with coal at a delivered price of $3.68 per ton equals $264,518.40, or a total saving of $328,252.00 per annum. What the measure of the economies following from reduced engine failures and reduction in enginehouse expense amount to are difficult of computation.

ELEMENTS OF ASH

The effective combustion of coal depends largely on the nature and per cent of impurities it contains, especially so if the ash has a tendency to clinker, which is dependent on the percentage of silica, iron and lime in its composition. Tables I and II give analyses of coal and ash, respectively, used in ten burning tests from ten different mines in Illinois and Indiana.

TABLE I—ANALYSES OF COALS

Test Number	Moisture per cent	Volatile matter per cent	Fixed carbon per cent	Ash per cent	Sulphur per cent	B. t. u.	Clinker?
1	3.37	31.31	55.19	9.63	.64	12,325	No
2	6.02	30.00	53.50	10.30	1.30	12,136	No
3	4.61	31.35	54.05	10.00	1.19	12,368	No
4	2.92	33.10	51.25	12.73	2.96	12,389	Yes
5	4.99	39.22	43.99	11.80	4.43	11,768	Slightly
6	3.41	37.12	45.62	13.85	4.02	11,842	Yes
7	5.13	37.70	44.31	12.80	4.52	11,693	Yes
8	2.86	36.04	43.14	17.96	4.58	11,124	Yes
9	8.49	34.87	48.16	8.48	1.47	12,251	No

Table I gives the usual proximate analyses of the coals. Table II gives analyses of the ash. By referring to the column showing the clinkering and non-clinkering coals and then making a review of the ash table, we observe that the coals with non-clinkering ash are low in both sulphur and lime. In burning they did not clinker in a dazzling white fire of an approximate temperature of 2,900 degrees F., while the ash in the clinkering coals fused at a fire-box temperature of approximately 2,200 degrees F., which indicates clearly that when the sulphur and lime content exist in high proportion to the silica, iron and aluminium oxides, it is the direct cause of the ash fusing at the lower temperature.

*Abstract of a paper presented before the convention of the International Fuel Association at Chicago, May 19-22, 1919.

The bottom line of Table II shows the fusing point of the sulphur and the different oxides. From this it will be seen that by taking each element separately the fusing point is at a higher temperature than is usually obtained in the furnace of a boiler. However, by combining these elements in proper proportion with the sulphur, fusion at a much lower temperature will take place.

The conditions of these ten experiments as to draught, etc., was identical in each case. However, I have since observed that either one of the coals containing the clinkering ash will give better results both as to combustion and reduction of slag in the ash by increasing the draught, which increases the flow of air through the fire bed and has a tendency to keep the temperature of the fire below the fusing point of the ash. Hence it is always good policy to assign the clinkering coals to a lower class of service, as switch engine, local freight, and other light runs. However, when considering the possibility of burning the low grade clinkering coals to profitable advantage, such should not be construed so as to minimize the responsibility of those who are assigned the duty of eliminating all impurities possible when the coal is being prepared at the mines.

SANTA FE TYPE LOCOMOTIVES FOR LIGHT TRACK

A group of three Santa Fe type locomotives has recently been completed by the Baldwin Locomotive Works for the Alabama & Vicksburg. These locomotives are to be used for heavy freight service and are designed to operate on rails weighing 75 lb. per yard and over. They are of special interest as they illustrate the suitability of the Santa Fe type for heavy freight service on lines where the track conditions will not permit the use of motive power having high wheel loads.

As far as practicable, the detail parts of the Santa Fe type locomotives are designed to interchange with those of the Pacific and the Mikado type locomotives previously built for the same road.

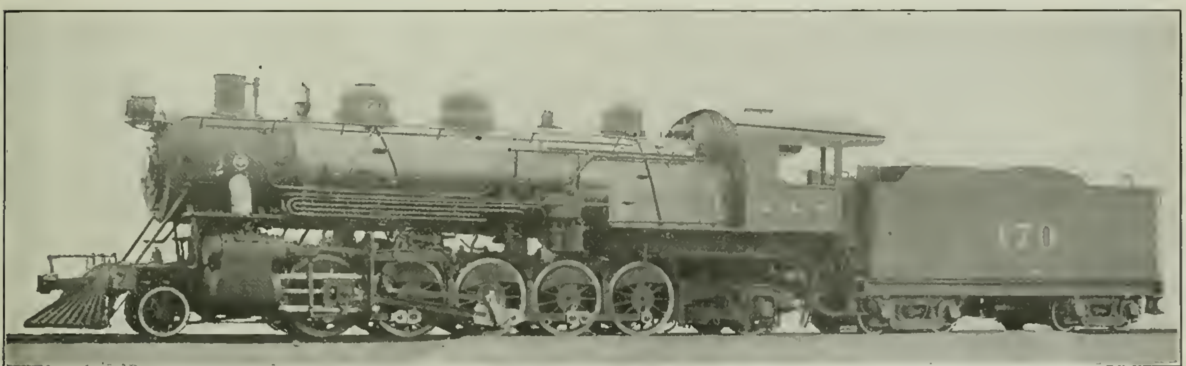
The following table of dimensions will give the comparison between these locomotives and the Mikado type.

	Santa Fe type	Mikado type
Cylinder dimensions	26 in. by 28 in.	22 in. by 28 in.
Drivers, diameter	57 in.	57 in.
Steam pressure	185 lb.	200 lb.
Grate area	58.7 sq. ft.	46 sq. ft.
Water heating surface	3,278 sq. ft.	2,573 sq. ft.
Superheating surface	754 sq. ft.	561 sq. ft.
Weight on drivers	218,390 lb.	168,400 lb.
Weight, total engine	274,715 lb.	217,500 lb.
Tractive effort	52,300 lb.	40,400 lb.

The boiler is a straight top design with a fire tube superheater. A Gaines combustion chamber is applied in connection with a Security firebrick arch, which is supported on four three-inch tubes. The front end of the firebox crown is suspended on three rows of Baldwin expansion stays. The main frames are of annealed vanadium cast steel. The bolster of the front truck is suspended on heart shaped links. The rear truck is of the Delta type and is used in combination with the Commonwealth rear frame cradle.

The Walschaert valve motion is applied and is controlled by a type *B* Ragonnet power reverse gear. The piston heads are of steel and the packing rings are made of gun iron. The latter material is also used for the steam chest bushings and the valve packing rings.

The main driving axles and the rear truck axle are of chrome vanadium steel quenched and tempered in accordance with A. S. T. M. specifications. All wearing brasses, including the crosshead gibs and driving wheel hub liners, are of phosphor bronze. The pedestal wedges and gibs are of brass. The firebox is equipped with a power operated firedoor.



Alabama & Vicksburg 2-10-2 Type for Heavy Freight Service

General Data

Gage	4 ft. 8½ in.
Service	Heavy Freight
Fuel	Soft coal
Tractive effort	52,300 lb.
Weight in working order	274,715 lb.
Weight on drivers	218,390 lb.
Weight on leading truck	26,325 lb.
Weight on trailing truck	30,000 lb.
Weight of engine and tender in working order	440,700 lb.
Wheel base, driving	20 ft. 4 in.
Wheel base, total	37 ft. 2 in.
Wheel base, engine and tender	71 ft. 3¼ in.

Ratios

Weight on drivers ÷ tractive effort	4.2
Total weight ÷ tractive effort	5.2
Tractive effort × diam. drivers ÷ equivalent heating surface*	691.2
Equivalent heating surface* ÷ grate area	73.4
Firebox heating surface ÷ equivalent heating surface,* per cent	6.0
Weight on drivers ÷ equivalent heating surface*	50.7
Total weight ÷ equivalent heating surface*	63.8
Volume both cylinders	18.5 cu. ft.
Equivalent heating surface* ÷ vol. cylinders	232.4
Grate area ÷ vol. cylinders	3.2

Cylinders

Kind	Simple
Diameter and stroke	26 in. by 28 in.

Valves

Kind	Piston
Diameter	14 in.

Wheels

Driving, diameter over tires	57 in.
Driving, thickness of tires	3½ in.
Driving journals, main, diameter and length	11 in. by 12 in.
Driving journals, others, diameter and length	10 in. by 12 in.
Engine truck wheels, diameter	33 in.
Engine truck, journals	6 in. by 10 in.
Trailing truck wheels, diameter	40 in.
Trailing truck, journals	7½ in. by 12 in.

Boiler

Style	Straight
Working pressure	185 lb. per sq. in.
Outside diameter of first ring	75¼ in.
Firebox, length and width	148 1/16 in. by 78⅛ in.
Firebox plates, thickness	Sides and back 5/16, crown ⅜, tube ½ in.
Firebox, water space	Front 5 in., sides and back, 4 in.
Tubes, number and outside diameter	32—2 in.
Flues, number and outside diameter	215—5⅜ in.
Tubes and flues, length	19 ft. 3 in.

Heating surface, tubes and flues	3021 sq. ft.
Heating surface, firebox, including arch tubes	257 sq. ft.
Heating surface, total	3,278 sq. ft.
Superheater heating surface	754 sq. ft.
Equivalent heating surface*	4,309 sq. ft.
Grate area	58.7 sq. ft.
Tender	
Tank	Water bottom
Wheels, diameter	33 in.
Journals, diameter and length	6 in. by 11 in.
Water capacity	10,000 gal.
Coal capacity	16 tons

*Equivalent heating surface = total evaporative heating surface + 1.5 times the superheating surface.

CERTAIN ESSENTIALS*

By EUGENE McAULIFFE
Manager, Fuel Conservation Section, United States Railroad Administration

I wish to today to say a few words on certain compelling features which, if attended to, will accomplish more in one year towards effecting fuel and operating economies than has been accomplished in the past five years. Briefly, the outstanding essentials of the railway fuel problem are:

Clean Coal.—Buy clean coal, get clean coal. There is not a coal contract in existence that does not suppose the delivery of the cleanest coal that the particular mine from which the purchase is made is capable of producing. Do not ask from the coal producer the impossible, but insist on the possible Tests have proved that with coal containing 12.5 per cent of ash taken as 100 per cent the relative efficiency falls as the ash increases until coal with 40 per cent of ash marks a total lack of efficiency. At the mine face, or on the mine tipple, is the place to clean coal. The excess and removable non-combustible matter can be separated cheaper there than in the locomotive firebox. Let the producer do the cleaning, such is a proper part of the cost of production. I have found on a majority of roads an insufficient and frequently untrained inspection force. The roads which most need an inspection force are most lacking in this respect. Ninety-nine per cent of the coal operators, all that are worth considering, will appreciate the help that an intelligent inspection force can give them. Good inspection supposes many things, including contract, quality, weights, clean equipment and proper class of equipment.

Distorted Valve Motion.—The next cheapest thing we can do is to organize the work of establishing and maintaining a proper distribution of the steam made from the coal purchased. I commend to your attention the paper written by J. W. Hardy on fuel losses due to defective valve motion, then read the circular just issued and immediately proceed to carry out the simple recommendations therein contained.

Air Leaks in Locomotive Front Ends.—On August 1, 1918, the Fuel Conservation Section issued Circular No. 8 calling the attention of motive power men to the fuel losses that result from air leaks in locomotive front ends, particularly those that surround the steam pipes where they leave the front end. The recommendations contained in this circular were followed in some instances; in others, ignored. A locomotive suffering from front end leaks invariably fails unless her guardians have compromised with her cost of keep and earning power by choking the nozzle.

Distorted Draft Apparatus.—A limited survey of the interior of locomotive front ends can be easily made by looking down into the stack when the engine is cool, using a common flash light. This casual inspection, if made, will astonish many of you. Here, again, we lack organization and method. Distorted draft apparatus invariably indicates shiftlessness.

Stopped Up Flues, Grates and Ash Pans.—Another essential has been covered briefly by the recent Fuel Conservation Section circular dealing with stopped up flues and choked superheater unit tubes, choked air openings in grates, and restricted air inlets in ash pans. An insufficient air opening in the ash pan represents a defect in design; the rest represents defects in execution. These conditions again result in the application of the well-known remedy, choking the exhaust nozzle, with the result that the engine struggles part or all the way over the division at the expense of the fuel bill, delaying the reduced tonnage handled, with corresponding delays to opposing trains which are side-tracked at meeting points to wait for the crippled engine.

The Superheater.—Another essential I wish to speak of relates to the proper maintenance and handling of what is the most substantial fuel saver ever put on the American locomotive, i. e., the superheater. The purpose of the superheater is to conserve fuel and water, and to increase the general efficiency of the locomotive. In some instances this result is obtained to the extent of 100 per cent, the measure of efficiency shading off in other cases until the apparatus is frequently not able to absorb the load of improper locomotive maintenance put on its shoulders. Certain engineers carry water levels so high as to transform the superheater into an evaporator, getting the train over the road at the expense of much fuel and a few additional tanks of water. We have found superheater units not only improperly installed, but poorly maintained, and often they are not tested with sufficient frequency to locate the steam leaks that occur in the front end when the engine is working. The Fuel Conservation Section recently issued a circular on superheater losses; they deserve your best attention.

Back Pressure Losses.—A condenser cannot be used on a locomotive, and the limitations that surround the locomotive necessitate a restricted exhaust in order that a sufficient rate of combustion can be maintained with a relatively small boiler, generating many hundreds of horsepower. Under the conditions that commonly obtain, of all the fuel that is used in the locomotive, only about six per cent is available for use in moving freight or passengers. Excess back pressure losses, therefore, apply against the six per cent saved for tractive purposes. Under the circumstances, why cripple the locomotive by choking the exhaust to offset lack of proper adjustment of draft apparatus, the closing of air leaks in front ends, the cleaning of tubes, superheater flues, etc.?

The Old Type of Locomotive.—Many of us began with the eight-wheel type of locomotive with low steam pressure and small firebox and grate area. These little engines had no fuel-saving devices, but they played their part in the greatest peaceful drama the world ever saw, the building of the Western Empire. Too many light locomotives have been scrapped in the past; instead they should have been modernized and kept in service suited to their capacity. In many instances locomotives too heavy for the job are employed to the detriment of train-mile costs and the permanent way. The fuel-saving attachments developed in recent years, with the exception of the compound air pump, only earn when the locomotive is moving, and it is very probable that improvements of the above character, if applied to the existing light locomotives now lacking them, would pay an equal or greater return than is being received from their application to the more modern locomotives. We frequently overlook the fact that the heavier types of locomotives, of which these devices are considered an essential part, make a lower average mileage than the lighter and, consequently, a more mobile type.

In conclusion, I wish to suggest the absolute importance of bringing every locomotive now in service, or that will be required for the service, up to the maximum standard of efficiency. I have been told that the work of applying superheaters and brick arches under order, and in some cases in stock has been held up on certain roads because of insufficient funds to apply them. This is unfortunate, and I trust the condition will be quickly remedied.

*Abstract of a paper presented at the convention of the International Railway Fuel Association at Chicago, May 19-22, 1919.

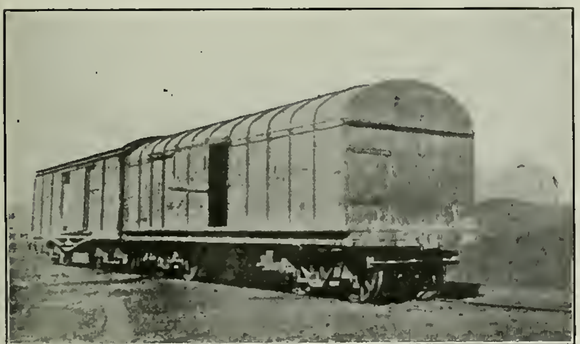
CAR DEPARTMENT

GENERAL CHARACTERISTICS OF CHINESE ROLLING STOCK*

One of the great needs of the Chinese government railways at present is a very considerable increase in freight cars and locomotives. The rolling stock per mile of line of 2,774 miles of Chinese railways, compares with several other countries as follows:

	Chinese Railways	Japan (1916)	Germany (1913)	U. S. (1916)
Number locomotives per mile	.18	.47	.77	.26
Number passenger cars per mile	.38	1.19	2.29	.45
Number of freight cars per mile	3.23	7.42	17.60	9.85

The initial equipment on all the lines (particularly those first constructed) is representative of the practices of the nations furnishing the loan funds. As a result, the Chinese railways today have, as a whole, a more miscellaneous assortment of equipment than any other equal mileage of railways in the world. A considerable part of the rolling stock (particularly the locomotives and goods wagons first acquired) is light and of small carrying capacity. This was very unfortunate, for the reason that the railway business of China is not naturally a classified-goods business but rather the transportation of commodities, and this tendency, as the railways are extended and the traffic grows, will probably become more pronounced. Therefore, the advantage of freight cars of large capacity and heavy motive power, along the lines of American practice, is readily apparent. The character of the early rolling stock forms the explanation for the light design of the bridges, which will have to be corrected at much expense before the type of equipment demanded by this class of traffic can be used. The average tractive effort of all locomotives on the Chinese government railways is now approximately 21,000 lb., the average carrying capacity of all passenger cars is 67.5 persons per car, and the average carrying capacity of all freight cars is 50,350 lb. In connection with the locomotives, however, it should be mentioned that on the Peking-Suiyuan line, which is equipped with 60 American locomotives out of a total of 66, the average tractive effort of all locomotives is about 30,000 lb., which has the effect of reducing the average of all locomotives on the other lines to about 18,700 lb.

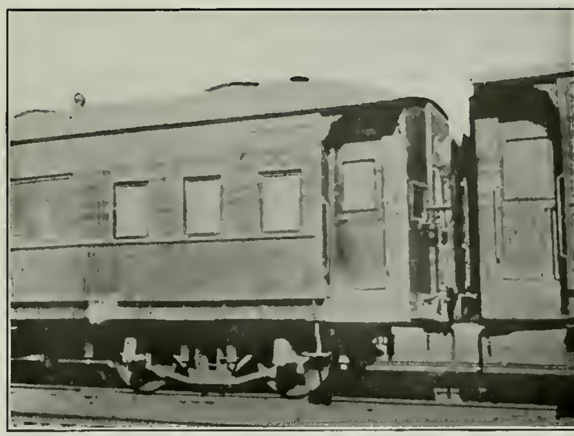


Box Car of Steel Construction Used on the Chinese Government Railways

It is also surprising to find the small amount of freight equipment that is equipped with air brakes. In one instance this lack of power brakes is limiting the coal traffic that one of the roads can handle during the winter when it should be handling the maximum tonnage. The Peking-Suiyuan line, on account of the heavy grades over the West Hills, is well equipped with air brakes on all its equipment, and the lack of brakes on the other lines is an additional restriction on the free interchange of traffic between this line and the other lines not so equipped. The Janney-Penn couple is used very generally on all the lines, and probably its use is more nearly universal than that of any other one device on the Chinese government railways.

TRAIN BRAKES

When used, air brakes are usually of the Westinghouse design of the nation furnishing the equipment. It is not usual for other nations to put as much braking on the locomotive and tenders as is the American practice. The passenger equipment, as a rule, is well equipped with air brakes, but no air train signals are in use on any of the lines. The freight equipment is only partly equipped with air brakes. Most of the lines depend on hand brakes. As a rule, every fifth or sixth car is equipped with a small shelter; the train is arranged for two of these to come together and the braking is done by hand.



Dining Car on the Peking-Mukden Railway, Showing Vestibule Without Steps

PASSENGER EQUIPMENT

Sleepers and first-class passenger cars are usually of the compartment-corridor type. The Peking-Mukden, Tientsin-Pukow, Peking-Hankow, and Shanghai-Nanking

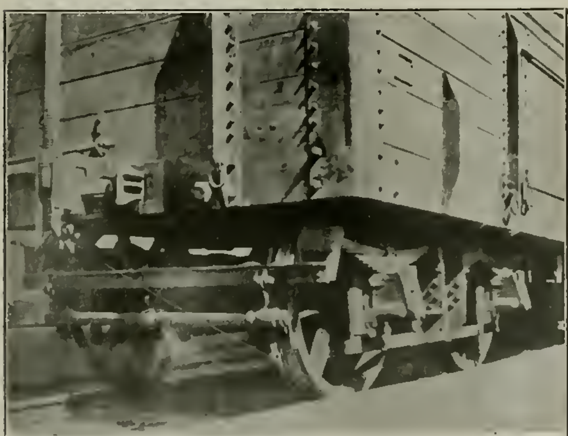
*From Special Agents Series, Report No. 80, Bureau of Foreign and Domestic Commerce, Department of Commerce, by Frank Rhea.

own and operate their own sleeping cars, and on all these lines the same equipment performs the service of first-class passenger car and sleeping car. These are the only lines running sleeping cars, and they, as well as the Peking-Suiyuan, own and operate their own dining cars.

The second-class equipment is usually provided with serviceable wooden seats and the third-class sometimes with cheaper seats, but frequently with benches; in some instances, particularly when the coolie class is carried, no seats of any kind are provided. One of the illustrations shows the vestibules and one end of a diner on the Peking-Mukden Railway. It will be noticed that there are no steps to the vestibule platforms. This requires all station platforms to be built with only a low step from the vestibule. In no instance noted by the writer was any passenger equipment heated from the locomotive, the only hose connection being the one for air brakes.

FREIGHT CARS

The initial equipment on the first Chinese railways (except that purchased from America) was of small capacity, and much of it can best be termed goods wagons, but the tendency has steadily been toward equipment of greater capacity until today practically all new freight cars are 67,200 lb., or 30 long tons capacity. All the Chinese railways use the British practice of a loading gauge. The size of equipment is somewhat restricted, and it would appear very desirable to increase this in the case of new railway construction, to permit of the utilization of larger equipment as the traffic develops, particularly if this development should be along commodity lines.



Type of Freight Car Truck Used on the Peking-Hankow Railway; Note the Vertical Plane Coupler on the End of the Car

A freight-car truck in general use on the Peking-Hankow line is shown in one of the illustrations and another shows a typical box car used on most of the Chinese railways. It was stated that this type of construction is quite satisfactory on all the lines north of the Yangtze River, but that the deterioration of the sheet iron on the southern lines, such as the Shanghai-Nanking, is quite serious. With the scarcity of lumber in China, however, this design would seem to have much merit.

CAR WHEELS

The British have used their typical steel-tired wheel, usually with cast-steel centers and of 42 in. diameter, on passenger and freight cars of all classes and capacities. The Germans have done the same with a wheel 100 cm. (39.37) in. in diameter. On the American equipment, particularly freight cars, most of the wheels have been of the regular chilled cast-iron type and, according to the information obtainable, have given satisfactory results. One of the suggestions that the writer heard mentioned a number of times was the desirability of the Chinese government railways adopting such a standard size of car wheel as can be satisfactorily produced with a chilled cast-iron wheel and then making their own supply of wheels. This seems practicable, taking into account the supply of iron ore and fuel, together with the fact that many of the Chinese shop laborers make good foundry molders.

SERVICE CARS

On account of the large amount of cheap labor in all parts of China, very little attention has been given to labor-saving service cars, and the present equipment is almost entirely confined to that which involves the use of hand labor for all classes of work. One of the most generally seen pieces of special equipment is the small derrick car, sometimes taking the form of a small locomotive crane. Steam shovels and steam wrecking cars are practically never seen.

VACUUM BRAKES

In an article by A. Fuhr published in the Annalen für Gewerbe und Bauwesen, and abstracted in the Technical Supplement of the Review of the Foreign Press, a discussion of the Clayton-Hardy vacuum brake vs. the automatic or pressure brake brings out some interesting features. It may be said that the railways in Europe are giving a great deal of consideration to the adoption of some good type of continuous brakes to their freight trains, in order that they may be handled more expeditiously.

A. Fuhr, in commenting on the vacuum brakes, states that one of the inherent difficulties of this brake is that of the low working pressure which does not generally amount to more than 14 in. of mercury, while pressure brakes operates with pressure six to ten times greater. The low pressure of the vacuum brake requires heavy and bulky machinery where the system is used. For instance, one pressure brake with a 12-in. diameter cylinder and an air receiver of 2 cu. ft. capacity, was found to produce the same effect as two vacuum brakes each with a 21-in. cylinder and an air receiver of 19 cu. ft. capacity. Modern steel cars weighing 30 to 35 tons when empty require three to four such vacuum brakes. For instance the mechanism on a car with four axles fitted with Westinghouse pressure brake weighs 116 lb. including the transmission rod and return spring, while on a car with two vacuum brakes, with 21 in. diameter cylinders, levers, plummer blocks, supports, and other working parts it weighs half a ton, or 1,120 lb. The greater weight, therefore, means more expense.

Another disadvantage of the vacuum system is that leakage in the pipe system causes a constant inflow of air charged with dust, soot, oil, moisture, etc. This occurs regularly when the locomotive is changed, and the valves and fittings therefore become choked and work badly, while the pressure brake remains clean much longer, as any grit or moisture which may be drawn in through the air-compressor is deposited in the main-air receiver and does not reach the brake valves. The number of hose pipes required with the vacuum brake is greater than that required for the pressure brake, as each passenger car fitted with reversing vacuum brakes requires five separate pipes, which must all be reinforced against collapse, while the pressure brake only needs one.

The low pressure is disadvantageous, as it is all but impossible to keep the large bore pipes and fittings tight. They are considered satisfactory according to Austrian regulations when the fall of pressure does not exceed 2½ in. of mercury per minute. The standard vacuum of 14 in. of mercury is thus reduced to 7 in. in 2½ minutes; that is to say, the vacuum brake is very sensitive to the slightest extra leakage, while the pressure brake is still quite effective if the air pressure from some exceptional reason should sink to half the standard pressure.

Expansion of air in the vacuum brake also produces a low temperature, and there is consequently a tendency to freeze up and likelihood of disturbance to traffic, especially in northern latitudes. During the severe winter 1916-1917 this tendency became almost a calamity in Sweden, as there were almost daily delays of 8 to 10 hours in the Lulea-Stockholm train service, exclusively due to the vacuum brake. It was found necessary on the iron ore line Lulea, Riksgrandsen-Narvic to remove the vacuum brakes and refit with pressure brakes.

A. Fuhr further states that the alleged greater simplicity of the vacuum brake has not been borne out in practice, owing to the cocks at the couplings, which are necessary for vacuum brakes, being troublesome, repairs difficult, readjustments frequent, and that the distance in which a train can be stopped is approximately the same as with a pressure brake.

According to tests carried out on the Prussian lines, the steam consumption of the vacuum brake is very considerable, and at least twice as high as that for similar trains fitted with pressure brakes.

Illumination of the Railway Car*

Improved Methods of Regulating Electric Lighting Equipment; New Developments Keep Down Costs

BY E. WANAMAKER
Electrical Engineer, Chicago, Rock Island & Pacific

A RESUME of the history of railway train lighting compiled from the records available shows that great strides have been made in the art since the days of the first experiments. To one Thomas Dixon, driver of the coach "Experiment" on the Stockton and Darlington Railway, in England, in 1825, is given credit for having first used artificial light in a railway car. He was a man of generous motives, and having in mind the comfort and convenience of his passengers on dark winter nights he placed a penny candle on a table, also provided by him, in the center of the car. From this humble beginning railway train lighting has grown and kept pace with the development of illumination in other fields and with the growth of other transportation facilities. Today, electric systems for lighting cars cost hundreds of dollars per car and a large number of employees are necessary to provide and maintain this service.

A review of the progress made in developing car lighting shows it is divided into periods of approximately 25 years for each illuminant used. The period of candle light lasted from 1825 to 1850, when oil lights were introduced. Oil lighting in turn gave away to gas in 1875, and gas continued to be the most generally used illuminant until about 1900, when the application of electricity to car lighting began to receive wide attention by railroads, and in this country at least is now the system generally preferred for new equipment.

Straight Storage

The earliest electric system of which we have a record was a straight storage system used on the London, Brighton and South Coast railway in 1881. Primary batteries were also tried in France in 1885 on cars operating between Paris and Brussels. At about this same time straight storage lighting was tried by the Pennsylvania Railroad and the Boston & Albany in the United States, and on the first-mentioned road this was for many years the electric system most used. Such a system requires an expensive charging plant at each terminal. Its main disadvantage is the limited time which a car can be kept in service without being held for charging and the liability of light failure due to batteries becoming discharged when trains are delayed or held from regular charging terminals. Another disadvantage arises from the fact that cars equipped with this system cannot be operated on branch lines or at isolated points where charging facilities are not available.

The "Head-End" System

"Head-end" equipment was first tried in 1887, when it was installed by the Pullman Palace Car Company in one of its composite cars operating between Jersey City, N. J., and St. Augustine, Fla., in the Atlantic Coast Line Special. In the same year, the Pennsylvania Limited was similarly equipped, and in 1888 the Chicago, Milwaukee & St. Paul also had a train equipped in this manner.

The head-end system was first tried out with a generator in the baggage car and no batteries, but due to frequent light failures caused by the trains being parted and the locomotives being cut off at division points, it was found necessary to place batteries on the first and last cars of each train so that if a train was parted to cut out or cut in cars, each section would have light. In some cases batteries were applied to each car. This greatly increased the time that lights could be depended upon in case of the generator unit being out of service and also made it possible for each car to have light when cut out.

Various means are used to control the lamp voltage and battery charging rates. Each road seems to have developed a system to meet conditions as they exist on its particular lines, which has resulted in several different schemes of wiring, battery charging and operation, all of which give results more or less satisfactory.

An axle-driven head-end system has been designed to furnish power for lighting the train and charging the batteries from a single unit, the batteries being distributed throughout the train, as for instance, one set in the baggage car, one in the observation or dining car, and sometimes one in the middle of the train. The number of batteries used and their location are governed by local conditions.

While this system is not liable to light failures, due to lack of steam, it has the same disadvantages as the steam driven, head-end systems, namely, that cars not equipped with batteries are dark when cut out of a train, that they are not interchangeable when operating on foreign lines, and are liable to light failure due to small battery capacity when trains are delayed or tied up. It would, therefore, seem that this system is unsatisfactory for universal operation.

For suburban and branch line service, the straight head-end system without any auxiliary battery has been found

*Abstract of a paper presented at the opening meeting of the Western Railway Club, Chicago, on September 15.

very economical and successful. The present practice for this class of service is to mount the turbo-generator on the locomotive in a manner similar to that used for mounting headlight turbines, the generator being of sufficient capacity to furnish current for the headlight and cab lamps and the maximum number of cars usually assigned to this class of service.

A three-wire system of wiring and standard train line connectors are used for making connections between cars and locomotive. No doubt, in the near future this system will be used more extensively on branch lines due to the low first cost, low maintenance cost, and the ease with which the installation can be made to existing power and rolling stock. All cars are similarly wired, and the number of cars in a train is only limited to the capacity of the turbo-generator and train line wires. Low first cost results from the simplicity of the car wiring system, which includes only a train line circuit and one lamp circuit connected to it with a fused knife switch in a steel switch box.

Credit for the earliest attempt at lighting a train with axle-driven equipment is given to the London Brighton and South Coast Railway, on which a crude system was tried out in 1883. Since that date development has gone on unceasingly, and individual axle-driven systems are now most generally used for train illumination in this country.

After years of test only one form of transmission for driving the generator is in general use. Various forms of belts and direct drive have been used, but due to the variable relation between the axle pulley and the armature pulley, and the climatic conditions, the rubber belt up to the present has been found to meet the requirements most economically.

Some of the first generators were suspended from the car body, others were mounted on the truck. Much time has been spent in improving generator suspensions, which has resulted in the elimination of many wearing parts, thus simplifying and reducing the maintenance costs.

The body hung suspension is favorable to the maintenance of the generator and possibly to the car truck. With it the belt is considerably longer than with the truck type suspension. Therefore, the belt life must be increased in the same proportion as the length is increased in order to keep the belt cost per car mile the same. Much is claimed for both types of suspensions, each having its possibilities, the conditions under which they operate and the condition in which they are maintained being important factors.

An important point in connection with axle lighting is the proper application of axle pulleys. If they are not properly applied the belt life will be short and the maintenance cost high. In a great many cases axle pulleys are applied to eccentric axles which should have been turned to insure a perfect pulley seat. In some cases pulleys are applied with improper pulley bushings. Eccentric pulleys and small belt clearances over the brake beam comprise two of the main causes of short belt life. Far-sighted mechanical men on some roads have made provisions for successful and economical operation of the belt drive by using turned axles or by turning a pulley seat on hammered axles to insure concentric pulleys. Also in some cases special brake rigging is being used to give ample belt clearance.

MAINTENANCE

To secure good service from the entire equipment at a low operating cost a standardized systematic method of maintenance must be used. With the present design of equipments the belt cost constitutes the second largest single item of expense. Records should be kept from which individual belt mileage can be computed. From these records any car using an excessive number of belts will be noted and steps taken to correct any defects found.

At the periodical shopping of cars the electrical equipment should be thoroughly overhauled and placed in a first-class condition, all worn parts being removed and defects corrected. If this is done thoroughly heavy repairs will seldom be found necessary between the shopping periods.

A systematic inspection of the generator and suspension should be made each trip to see that all parts are in good condition. Once each year the generator should be dismantled and all parts thoroughly cleaned, fields and armature painted with insulating varnish and new grease applied to ball bearings.

TRAIN-LINE FACILITIES AND FIXTURES

On the majority of railroads, facilities are provided for making connections from car to car so as to provide light in a defective one. It is the almost unanimous opinion of car-lighting engineers that with the present equipment, facilities for train-line connections are essential if light failures are to be avoided, connectors being especially desirable for the protection of mail cars.

The tendency in fixtures is toward simplicity of design to harmonize with the interior construction of the car. Center-deck lighting seems to be generally preferred with a sufficient number of units, properly shaded, to give uniform distribution. Enamel finishes the same color as the car walls or ceiling at the point where the fixtures are located are most used, but there is reason for believing that in time the roads will again prefer metal finishes, as these, when properly applied to fixtures of pleasing design, help to improve the interior appearance of the car. In recent years statuary bronze has been the metal finish most used.

A matter of great importance is that of careful selection and design upon which depends effectiveness of the installation, both as regards light distribution and appearance. These various questions involve a study of intrinsic brilliancy, intensity, distribution and color.

BATTERIES

There are two distinct types of storage battery in use in car lighting service at the present time, the lead acid battery and the nickel-iron alkaline battery. Of the lead batteries there are two general types of plates, the Plante and the Faure. For a given output, the Plante is more costly, more bulky, and heavier than the equivalent pasted plate type. Thus far this type is more durable and better able to withstand the operating conditions incidental to car-lighting service. It is the type most used in car-lighting service, but some car-lighting engineers claim that the advantage it has had over the Faure type is decreasing with the increased cost of labor and improved methods for battery protection. The nickel-iron alkaline battery is of comparatively recent development and is radically different from the lead acid battery. It is light in weight and mechanically rugged.

The cost of maintaining batteries constitutes the largest single item of expense in the maintenance of car-lighting equipment, and the entire development of regulators or apparatus for battery protection while the car is enroute has been made with a view of prolonging the life and reducing the cost of maintenance. However, good standard practice for handling batteries is also essential if this cost is to be kept within reasonable limits.

With the present design and construction, the cleaning period is comparatively short. By a change in design the same capacity could be maintained and yet the space for sediment could possibly be doubled, thus greatly prolonging the cleaning period, insofar as it is based on this particular feature. Some manufacturers are now endeavoring to produce a battery which will not have to be removed from the car for cleaning during the life of the positive element, or at least to prolong the period of time between the cleaning far in excess of present practice.

The control of the generator output while the car is enroute has offered one of the most difficult problems to be overcome, since the life of battery and lamps depends to a large extent upon regulation.

Without the proper protection, the battery life may be only a third of what it should be. In a similar manner also the cost of maintaining the generator depends upon the regulation.

Regulators

The duties of the regulator for car-lighting service are: (1) To connect the battery to the generator at the minimum speed and voltage for which the machine is designed to operate and to disconnect the battery when the speed and voltage fall slightly below the first mentioned value; (2) to provide a variable voltage to charge the battery at the proper rate, which is determined by the state of charge, and at the same time carry the lamp load, in the event it is turned on, up to the capacity of the generator; (3) when the battery has attained a full state of charge, the regulating means must prevent further charge thereafter, leaving the generator capable of supplying current to lamps or other translating devices; (4) to provide constant voltage on lamps while the car is in motion or at rest.

There are two types of regulators in general use, designed with the view to meet these requirements: First, ampere hour meter control; second, potential control. The first mentioned method charges the battery by starting at a high rate, which is gradually modified to a predetermined lower rate, and when a predetermined number of ampere hours have been put into the battery as indicated by the meter, the potential is reduced by the regulator sufficiently to prevent further charge. With this method it is necessary, for proper battery protection, to maintain the ampere hour meter in step with the state of charge of the battery.

It is apparent that the proper battery protection depends not only on the proper functioning of the meter itself, but also upon the battery remaining in normal condition in order that the battery and meter may remain in step with each other. Owing to battery characteristics and operating conditions, the meter does not always indicate the true state of charge.

In the second method of charging heretofore referred to as "potential control," inherent characteristics of the battery are taken advantage of to govern the charging rate, and when the battery has attained a full state of charge, to prevent further charge thereafter. With most potential control equipments, a current limit feature is embodied with the potential regulator to hold the maximum current to a value consistent with the generator capacity.

Many forms of potential control equipment have been placed on the market, most of which operate at potentials such that in the course of charging, the battery is caused to gas. In 1913 and 1914, efforts were made by the Rock Island to operate equipment at a maximum voltage of 2.3 volts per cell. At the beginning the experiment was found to be a failure, as in many instances cars on most runs arrived at terminals with the batteries in a decidedly discharged state. There were, however, cars in fast main-line service on which the batteries remained in a full state of charge and at the same time were not being overcharged, the batteries requiring flushing on an average of about every six months. This was encouraging and led to investigations which developed that the failures were not due to the fact that the low voltage would not keep the batteries charged, but resulted from the fact that this voltage of 2.3 volts per cell was not attained except at very high train speeds. In one test covering a period of five hours, the equipment maintained full voltage and load for less than 10 per cent of the running time. On the face of the evidence it looked as though a larger generator designed to give full voltage and load at a lower train speed would be required, but fortunately after further investigation it was found that with certain refinements in the regulating device, a lower cut-in speed could be secured.

A test made with an improved regulator with the same generator that was used on the previous test and over the same run, showed the following comparison:

Full load—Old regulator—35 miles an hour.
Full load—Improved regulator—24 miles an hour.
Full load time in 5 hours—Old regulator—10 per cent.
Full load time in 5 hours—Improved regulator—41 per cent.

In this case the capacity of the unit was increased 300 per cent.

The net results realized from the use of the improved regulator are increased capacity of the unit due to obtaining generator output at low train speed, and increased battery life, which is brought about by the following:

(A) The work imposed upon the battery of furnishing energy for the lights is greatly reduced by the increased working time of generator, and also by the fact that the current for the lights is supplied by the generator, and not by the battery, at all times after the generator cuts in.

(B) The battery is charged at the proper rate to prevent gassing and overheating with the attendant ill effects.

(C) The battery is protected from overcharge and the forming away of the reserve lead in the battery elements.

Even though only a part of the Rock Island equipments have been improved, the cost of operation and maintenance per car per month has not increased, in spite of the increased cost of labor and material, and a very large part of the savings is attributed to the better protection provided for the battery.

Draft Gear Design and Maintenance

General Foremen in Convention Discuss Spring and Friction Draft Gears and Their Function

IN addition to many other important questions, the subject of design and maintenance of draft gear was considered at the fifteenth convention of the International Railway General Foremen's Association, held in Chicago on September 2-5. Several excellent papers on the subject were read, abstracts of which are given below.

DRAFT GEARS

BY J. W. WOMBLE

An ideal draft gear should have not only a suitable friction capacity and travel, but it should also be positive in its nature, simple in design, of few parts, readily applied and removed from the car, and applicable to the standard pocket space. It should be so constructed that a buffing shock greater than sufficient to close the gear will not be apt to injure it in any way, that is, after the gear becomes solid the blow should be transmitted to the draft sills without injuring the draft gear itself, or without it being necessary for the horn of the coupler to go home against the striking plate in order to relieve the shock.

The design of the gear should be such that the frictional load is not dependent upon the speed at which the gear is closed nor should it be dependent on the internal parts of the gear being carefully machined or requiring considerable care in fitting them together. It should be so made that it could be applied and removed from the car and the repair parts substituted, if necessary, by ordinary labor. It ought also to have sufficient area of friction faces to bring the pressure per square inch to a figure that will insure it having a satisfactory life in service.

The term friction draft gear is somewhat of a misnomer, as it is both draft and buffing gear, the latter being undoubtedly its most important function. If the draft and buffing features could be divided and considered separately, no doubt better results could be obtained. Unfortunately, this is not feasible, and the draft gear must necessarily take both of these requirements into consideration.

On this account it is advisable that a draft gear have a low capacity at the start of its movement in order to get the best results in pulling service. This only utilizes a small part of the capacity of the gear, and the capacity at that part of the travel should make it possible to easily start the train. After about the first inch of travel, the capacity should rise quite rapidly, but uniformly, to its ultimate limit in order to absorb a large part of the buffing blow without causing too much shock to the draft sills.

COMMITTEE REPORT

The committee recommends that: The committee's data in the future be obtained from both laboratory and actual service tests. That a large proportion of gears installed be stencilled with date applied and notice to employes to report conditions and all facts whenever they are removed, this information to be used in connection with actual service tests. That draft gears be inspected and maintained at intervals depending on the kind of service. That poor gears be gradually eliminated and good gears be confined to as few as possible. That the General Foremen's Association express its willingness to aid the supply men in developing the best possible protection to the car against shock. That so far as possible the length, width and height of gears be brought to a standard so as to eliminate the different sizes of coupler yokes now required without sacrificing the gear efficiency.

The report is signed by W. W. Scott (D. L. & W.) and C. F. Bauman (C. & N. W.).

MAINTAINING DRAFT GEARS

BY L. A. NORTH,
Superintendent of Shop, Illinois Central, Burnside, Ill.

In taking up the subject of draft gears, it is with the object of bringing to the attention of the general foreman, particularly the general foreman of the locomotive department, the necessity of spending more time in the car department to obtain such knowledge of car department matters as will be of benefit to them when they are advanced to the next step in the ranks, that of master mechanic.

They should thoroughly familiarize themselves with all matters pertaining to the repairs to cars, particularly the draft rigging. From observation, the logical place to examine the draft gear and the results derived from the application of the different designs of draft gears, is the repair track and the scrap pile. The damage caused from shock and rebound, due to defective draft gear, runs into millions of dollars every year. No matter what make of gear is applied to a car, unless the gear is maintained in working order, it will not properly function nor perform the duties that the designer or builder claim for it. There are a number of different friction draft gears on the market today which under test will demonstrate to the observer that the gear will perform just what the manufacturer claims for it, viz.: absorb the shock and decrease the rebound, but, as stated before, unless sufficient attention is paid to the maintenance and upkeep of this gear, the money expended is money thrown away.

A visit to the repair track will show end sills and draft arms broken and bent, center sills buckled up and car underrigging in a generally dilapidated condition. In looking for the cause as the usual thing we find the draft gear worn out, inoperative and parts missing, so that the casual observer's first opinion would be that the draft gear did not perform the duties that it was designed for.

Some railroads have made it a practice to drop the draft gear when the car is placed on the repair track and make a thorough examination of the different parts of the gears to determine what parts need renewing or repairing, with the result that the gear has a chance to function properly and perform the work that it was originally designed for.

With the introduction of the heavy capacity cars, it has become more necessary than ever to pay particular attention to the draft rigging. Hump service is much harder than ordinary switching service on draft gear and has made it necessary to fit cars engaged in this service with substantial draft rigging and draft gear that will properly take care of and absorb the shock and rebound which comes from this service. A visit to any of the hump yards will further verify this statement and will illustrate the necessity of properly providing a substantial draft gear and maintaining it in good repair at all times.

DRAFT GEARS

BY C. F. BAUMAN
Chicago & North Western, Winona, Minn.

The draft gear is a cushioning device applied to cars, and so situated that the rear end of the coupler rests against it in such a way that when the couplers meet one another in the case of cars colliding, the draft gear has a limited movement or travel under resistance, according to its capacity, so as to soften or cushion the shock on the cars and their lading. It is also secured to the coupler by a yoke so as to use the cushioning effect to prevent the pulling shocks from doing damage. I think a better name for the draft gear would be the car protector.

My study of broken or damaged cars leads me to believe that if a draft gear of sufficient capacity to care for the buffing shocks is used it will be ample to care for the pulling forces, as I cannot call to mind a case of damage due to pulling unless the parts were first damaged and weakened by the buffing shocks, excepting very rare cases of coupler yokes breaking under pulling strains where the yokes were made of the old light section of 1 in. by 4 in. bars, and even of lighter section. The new standard yoke section of 1¼ in. by 5 in. has put a stop to this failure and there are very few of the old light sections of yokes in use now. I would strongly recommend replacing these weak yokes with the newer standard as early as possible. The cost would be slight, compared with the saving effected.

Buffing Shocks

If a study is made of the car failures as they pass over the repair shop tracks and the piles of scrap material collected from the repairs to the cars, the necessity for improved draft gear is very plain. Couplers and their parts are found broken, bent and upset, due to the shocks they receive. If a draft gear could be found to assist the car in absorbing these shocks, couplers would wear out instead of being discarded for the defects mentioned above. This would result in a great saving to the railroads.

The following damage to freight cars are common sights to all of us who have to supervise repairs to cars: Ends of cars pushed out by the lading, broken draft sills, broken draft arms, broken center plates, broken center pins, broken and bent steel center sills, broken body and truck bolsters, broken oil boxes where the car has not been derailed. The sides, roofs and superstructures of box, stock and other cars of the house type construction are also often found in a racked and loose condition, all of which is caused by the parts mentioned being forced to do the work of the draft gear. If the shocks were kept out of the cars all these items would have to wear out, which would take a long time. Applying a draft gear that will make it possible to move the cars from point to point without this destructive effect, or that will at least make a material reduction in it, would be an economical measure.

Types of Draft Gear

There are a large number of different types of draft gears in service, a few of which are enumerated below: One of the old designs uses a single spring 8 in. by 7⅞ in., with a front and rear follower, connected to the coupler with a yoke. The spring has a capacity of 30,000 lb. with a travel of 1¾ in. The cushioning value of this assembly is very low. It has no absorbing capacity, as all springs simply store up the energy until the pressure is taken from them, when it is returned with the same force that was required to close them. There are very few cars in service that are equipped with this single spring type. There are also spring draft gears made of two springs, some in tandem and others in twin assembly. They are made up generally of two different sizes of springs. The smaller type consists of two 6½ in. by 8 in. springs, having a combined capacity of 38,000 lb. and a travel of 1¾ in. The capacity and travel are both insufficient to protect the cars and the use of this gear should be discontinued. Other designs are the tandem and twin spring gears made up of two 8 in. by 7⅞ in. springs having a combined capacity of 60,000 lb. and a travel of 1¾ in. The recoil of these heavier springs is such that it is nearing the danger line in its reaction in long trains so that to use more spring capacity would in my opinion be a mistake.

A large number of different types of friction draft gears are in use, some of which are doing good work. There are a few essential features of the friction gears which I will comment on. Since a large committee of prominent mechanical railroad men appointed to design the 100,000 cars purchased by the administration decided to use friction draft gear, also in view of the fact that practically all new car specifications include friction gear, and considering the many thousands of old cars that have been reinforced with steel underframes or metal draft arms equipped with friction draft gear, the spring gear may be eliminated and the discussion confined to the friction type.

Draft Gear Specifications

While the committee performed excellent work in preparing the specifications and designs for the 100,000 freight cars for the Railroad Administration, and this paper should not be considered as criticising in the least sense, in my opinion there are some features of the draft gear question that could have been arranged so as to give the draft gear manufacturers a better chance to build to meet the conditions. For instance, five different makes are named as being satisfactory, but they are required to be interchangeable without changes in the car, so that in case of failure any one of the five kinds could be used to replace the defective one.

This would be ideal if it is granted that this application is perfection in draft gear design, but it is doubtful whether the draft gear manufacturers are willing to admit this. In fact, the manufacturer of one of the five gears used on these cars has several thousand cars equipped with a gear not confined to the spacing and travel specified for the government cars that will furnish double the protection to cars that it is possible to get with a gear travel of 2¾ in. They have given highly satisfactory service for several years and have passed the experimental stage.

One good point in the interchangeability of the gears is that in the course of time it should be possible to learn the relative service value of these five types, and get nearer to a standard by discarding the short lived ones; however, the demands on the draft gear change from year to year so that new developments in draft gear design may be looked for as the demands increase.

Increase in Car Loaded Weights

It is only a short time since the 80,000 lb. capacity car, which would weigh about 125,000 lb. on rails when loaded, was the heavy type. This was followed by the 100,000 lb. capacity car weighing 150,000 lb. on rails when loaded. Next came the 70-ton or 140,000 lb. capacity car which loaded weighed 200,000 lb. The 90-ton or 180,000 lb. capacity car came next, with a total loaded weight of 250,000 lb. The next heavy capacity car to make its appearance is the 120-ton or 240,000 lb. capacity car with a loaded weight of over 300,000 lb. When it is understood that these increases in rail loads per car all came into use during the last 15 or 18 years, and the wide difference in the amount of energy developed by these different weights moving at two or three miles per hour, the need for improved draft gear will be clear to all. Hence, I believe it would be a wise move to give the draft gear manufacturers more to say as to the space required in which to apply the device instead of confining them to 12⅞ in. between the draft sills and 24⅝ in. between the faces of the draft lugs.

Capacity Defined

The Railroad Administration specifications for draft gears call for a minimum capacity of 150,000 lb. with a maximum travel of 2¾ in. Stating capacity in pounds is misleading, as it only gives the final closing pressure, and it is possible to have the first 2½ in. travel of the device with a capacity limited to 20,000, or 25,000 lb., and the last ¼ in. movement might require a pressure of more than 150,000 lb. to close the device. This would make a very poor draft gear for destroying shocks, as the first 2½ in. travel would offer very little resistance to the forces and the last ¼ in. would not have time in which to act.

To make the capacity question clear, the Mechanical Committee of the United States Railway Administration gave the following definition of a 150,000 lb. capacity draft gear. It is the sense of this committee that a 150,000 lb. draft gear should be defined as one that will sustain a drop of 16 in. (including the travel of the gear) of a 9,000 lb. weight without shearing the rivets of one or both lugs, which are to be secured to suitable supporting members by nine ½ in. rivets of .15 carbon or under, driven in 9/16 in. drilled holes. This definition clears the question as it expresses the capacity in foot pounds, which is the correct unit to use, as in order for the gear to stand this drop without shearing the rivets it must offer a high resistance throughout its entire travel. This test requires the gear to have a capacity of 12,000 ft. lb.

This specification could easily be raised to 18,000 ft. lb. developed with the 9,000 lb. drop hammer. A gear that will develop 18,000 ft. lb. capacity, resting on a solid foundation, will show an increase of 66 2/3 per cent when secured to a rolling foundation such as a car, and would, therefore, be equal to 30,000 ft. lb. when applied to the car.

GEAR TRAVEL

The question of coupler or draft gear travel is of great importance, as the capacity of the gears can be increased or decreased as the travel is increased or decreased. The Railroad Administration's Car Committee in regulating the gear movement, specified that the maximum travel should be 2¾ in. It would be better if this regulation was changed to make 2¾ in. the minimum instead of the maximum. This dimension has so much to do with draft gear capacity that a committee of one car man, one air brake man and one operating man appointed to investigate and report back to this association the maximum amount of travel that could be allowed would be a step in the right direction. I am sure that this dimension can be increased.

INSPECTION AND ADJUSTMENT

The draft gears should be applied to the cars in such a way that their different parts can be readily seen and inspected by the men who are assigned to this work. Some are applied so that it is almost impossible to inspect them. Manufacturers should give more attention to this feature. If possible, the gears should be equipped with some practical and quick means of adjustment to take up the wear.

DRAFT GEAR INVESTIGATION

Some of the draft gear manufacturers have especially equipped laboratories for demonstrating purposes and some of them have made exhaustive tests not only of the draft gears but of couplers protected from the shock by the use of different gears, also sills of different weights per foot and of sills having the center line of draft different distances off from the center line of the draft channels, the results of which prove conclusively the cause of many failures in car design. The manufacturers are to be commended for carrying on this research work. If a car user is having trouble with any part of a car that is due to the shocks it receives in handling, these companies will duplicate that section of the car and destroy it in the laboratory, furnishing readings of the work so that the best remedy can be applied.

MAINTENANCE OF DRAFT GEAR

It is only recently that I have been impressed with the importance of keeping the draft gear repaired so that it will be in condition to perform its whole duty at all times. It must be remembered that a car having a good high capacity draft gear colliding with a car having a low or weak gear helps out the car with the weak gear as the amount of protection that each car gets is the sum or combined value of the two. Every car turned away from the repair track with a good draft gear helps every other car it comes in contact with.

The forces applied to cars when they collide, up to the closing point of the gear can only equal the pressure required to push it closed or solid, but if double the energy required to close the gear is applied, this multiplies the pressure on the car by ten. For example, if two cars equipped with 60,000 lb. capacity draft gears should collide with a force that would just close the gears the pressure on the car would be 60,000 lb., but if the colliding forces are doubled the pressure on the car would raise to 600,000 lb., which in most cases would damage one or both of the cars so as to send them to the shops.

With these facts before us, I am convinced that no car should be allowed to leave the shop tracks until the draft gear is put in condition to do all the work that it is constructed to perform. By keeping the draft gear repaired, damaged cars will be reduced, thus effecting a saving and resulting in more efficient equipment. A concerted move along this line, I am convinced, will surprise all of us. The improvement cannot all be made at one shop, as this would create a congestion of defective cars, but let everybody start and all roads will be on a better footing very quickly.

I would recommend discarding the low capacity gears and substituting the better types as fast as possible. The cost of changing would soon be returned by increased car efficiency. I am of the opinion that where cars are repaired in large numbers a special crew of men in charge of a competent leader should be assigned to draft gear maintenance. The men in charge should become familiar with the different makes of draft gear so as to intelligently maintain them.

When draft gears are new or have been repaired the date of application or repairs should be stenciled on the draft sill where it could be plainly seen by the inspectors. At the expiration of three years (this may be changed to a longer period as soon as experience proves it to be good practice), the car or cars should be shopped for another draft gear overhauling. In case of a car being found on a foreign line with the date showing that the three-year period had expired, the road having the car should be obliged to shop it and overhaul the draft gear, billing the owner for the cost of the work. Improper repairs by foreign lines should be penalized by the cancellation of their bill. These few rules worked out more in detail and put into effect will reduce the bad order cars much quicker and in a more permanent way than increasing the number of car repair men and continuing to overlook the draft gear until the car damage forces it out of service for extensive repairs. Keeping the draft gear in shape would cost only a few cents and would save large expenditures for broken parts on account of the draft gear being neglected.

DISCUSSION

There was some difference of opinion as to the advisability of inspecting draft gears at regular intervals. J. H. Hott (A. T. & S. F.) objected to the periodical overhauling upon the grounds that it would have a tendency to cause lax inspection. L. A. North (I. C.) contended that a thorough inspection is necessary to insure that the gears are in serviceable condition. The advantage of draft gears of high capacity was generally recognized by the members. M. H. Westbrook (Grand Trunk) brought out the decrease in the ultimate strength of the draft members which results from locating the center line of the buffing and pulling stresses off the center line of the sills. The usual construction of setting the center line of the gear 2 in. from the center line of the draft members decreases the strength 40 per cent.

Car Inspectors and Foremen Meet

Discussion of the Working of the Rules of Interchange and Changes Proposed by Arbitration Committee

THE nineteenth convention of the Chief Interchange Car Inspectors' and Car Foremen's Association met at the Planters Hotel, St. Louis, Mo., with W. J. Stoll, chief interchange inspector at Toledo, Ohio, presiding. The first session was opened with prayer by Captain Arthur Andrews of the Salvation Army, and the association was welcomed to the city by L. McDaniel, prosecuting attorney, whose address was responded to by T. J. O'Donnell.

PRESIDENT'S ADDRESS

In his address as president of the association, Mr. Stoll spoke in part as follows: The discussion of the M. C. B. rules and other matters pertaining to the construction and maintenance of cars is an important question and one which requires sound judgment and executive ability. The changes in the M. C. B. rules of interchange which take effect October 1, while not numerous, are quite important. The rules now in effect have not as yet been discussed by this association and I hope the members will take advantage of this opportunity to discuss them. I would also call attention to the fact that the loading rules have been rearranged and a discussion of them would be interesting and beneficial, as many cars are being improperly loaded. This association might well recommend that shippers should be furnished with copies of the loading rules. Because of the conditions which have been brought about by the war, such as pooling certain portions of the equipment, routing cars away from home where material was not available to make proper repairs, insufficient help, etc., it is necessary for this association to put forth its best effort to remedy conditions.

The report of the secretary-treasurer was read; it showed the total membership to be 508 and a satisfactory balance in the treasury.

DISCUSSION OF RULES OF INTERCHANGE

At the session on the afternoon of September 23 the discussion of the Rules of Interchange was begun. An abstract of the discussion which followed the reading of the rules is given below:

Rule No. 2—Empty cars offered in interchange must be accepted if in safe and serviceable condition, the receiving road to be the judge.

T. J. O'Donnell (Buffalo): I should like to ask what constitutes a serviceable empty car?

E. Pendleton (C. & A.): My interpretation is that a serviceable car is one that is suitable for any commodity.

Mr. O'Donnell: Should no cars be offered in interchange with defects though they require only light repairs?

F. C. Schultz (Chicago): I believe that in order to expedite traffic minor defects should be ignored.

Mr. O'Donnell: How would you handle coal cars with hopper doors not in serviceable condition?

Mr. Schultz: The repairs should be made by the receiving line.

G. Lynch (Cleveland): A car that must be sent to the repair track is not a serviceable car and the receiving line can refuse it or accept it, as it chooses.

T. J. O'Donnell: I consider that under present conditions it is necessary for the joint inspector to specify where the cars are to be repaired and distribute the bad orders among the various roads.

J. J. Gainey (Southern): I agree with Mr. O'Donnell in his interpretation of Circular No. 37.

F. Trapnell (Kansas City): We have received instructions from the Railroad Administration to regard as serviceable any car that requires less than 20 man hours to put it in condition for any commodity, and we have been working under this interpretation.

F. C. Schultz: It is necessary that we do whatever the local conditions demand to move the traffic.

T. J. O'Donnell: There should be some general ruling which could be applied regardless of the shop facilities at the interchange point.

J. J. Gainey: I believe that all cars having defects that can be repaired on the light repair track should be accepted in interchange.

G. Lynch: The rules make a very definite distinction between the handling of loaded and empty cars. Loaded cars must be accepted by the receiving line, and run, repaired or transferred. On the other hand the empty cars can be rejected if not in safe and serviceable condition. This rule has made it easy for roads that originate a great deal of traffic to get cars off their lines while roads that offer a great many empty cars to connections have suffered from the accumulation of bad order cars which they were unable to dispose of without repairing them.

In an effort to secure an agreement as to the meaning of the rules it was moved that a car which must be placed on the repair track was not a serviceable car within the meaning of the rule. This motion was lost. A second motion stating that a car requiring not over 20 man-hours' work should be considered serviceable was also lost. A motion was made that the exceptions in Rule 2, paragraph *f*, should govern the acceptance of empty as well as loaded cars, but this motion also was rejected. The discussion showed that there was a wide diversity of practice in different sections of the country which was due in part to lack of uniformity in the orders issued by the Regional Directors. A committee was appointed to consider the matter further and present a report to the convention.

CHANGES RECOMMENDED BY THE ARBITRATION COMMITTEE

After the prolonged discussion on Rule 2, the association proceeded to consider the changes in the rules as recommended in the report of the Arbitration Committee presented at the 1919 convention.

Rule 32—(Delivering line responsible) Damage to any car (including cars on ferries or floats) if caused by (a) Derailment, (b) Cornering, (c) Sideswiping, (d) Collision or impact other than that occurring in regular switching, (e) Handling of cars with broken or missing couplers, or couplers out of place, (f) Colliding with or shoving over bumping post or other fixed obstruction, (g) Shifting of loads from other cars, (h) Overloading, (i) Explosion, (j) Collapsing buildings or other structures on right of way, (k) Unconcealed fire damage, (l) Flood, (m) Storm where car is derailed or destroyed, (n) Failure to close hopper or drop doors before moving car.

F. C. Schultz: The rules now in force have made it possible for roads to break up cars in switching and yet hold the owners responsible for the damage if the trucks were not derailed. I think the new rule will be an improvement as it will change this situation.

H. W. L. Porth (Swift & Co.): The intent of the changes is to clarify the meaning of the indefinite term "wreck." The judgment of the inspector will still enter, however, in determining what constitutes regular switching.

G. Lynch: The terms "collision," "impact" and "regular switching" are still indefinite and even the new rule will be hard to interpret. In case of missing material the car owner will no doubt contend that the parts have been stolen while the handling line will assert that they have been lost in fair service.

J. P. Carney (Michigan Central): I believe the changes are intended to put the responsibility for damage to weak equipment on the car owner.

F. H. Hanson (N. Y. C. West): I move that it is the sense of this meeting that if cars are damaged or broken in two the owner is to be held responsible for the damage if the trucks are not derailed and the car is not cornered or sideswiped. (The motion was put to a vote and carried.)

Rule 33—Owners will be responsible for the expense of repairs to safety appliances where not involved with other delivering line damage, except damage to running boards on tank cars when sideswiped or cornered.

A. Herbster (N. Y. C. West): In the past a running board on tank cars had been considered a part of the safety appliances and the owners had been held responsible for damage if no other part of the car was involved. The Arbitration Committee, however, ruled that the running boards on tank cars cannot be damaged in fair usage and this rule has been amended to conform with that interpretation.

H. W. L. Porth: Safety appliances are often damaged when no other injury is done to the car and for that reason it hardly seems proper to hold the owner responsible.

Rule 66—(Owners responsible) Periodical repacking of journal boxes, regardless of the responsibility of delivering company for change of wheels, journal boxes or journal bearings. No charge shall be made for repacking unless all boxes are repacked. No charge shall be made if the repacking is done within nine months from date stenciled on the car. If car bears no stenciling showing date of previous repacking, all journals may be repacked if necessary and charged for.

(*a*) All journal boxes shall be repacked with properly prepared packing (new or renovated) at least once every 12 months, at which time all packing will be removed from the boxes and the boxes cleaned; dust guards to be renewed when wheels are changed.

(*b*) The date and place (railroad and station) where the work is done must be stenciled on the car body near the body bolster at diagonal corners in one inch figures and letters, using the same station initial that is used for air brake stencil.

(*c*) This work to be done as far as possible when cars are on repair track undergoing heavy repairs. Cars which have not had boxes repacked within nine months will have all boxes repacked and the record stenciled as above.

(*d*) This does not contemplate any change in the intermediate packing of boxes when it is necessary to do so. No change should be made in the stenciling unless all boxes are repacked.

J. J. Gainey (Southern): At the present time repacking of journal boxes is often done by removing the waste from the box, shaking out the dirt and short fibers and then replacing it. Such practices should be discontinued as they do not comply with the requirements of the rules.

The opinion was expressed by several members that periodical repacking of journal boxes would improve the operating conditions and effect a large saving. It was suggested that improper repacking could be eliminated by requiring the work to be done only at stations which are equipped with apparatus for reclaiming oil and waste.

Rule 88—In order that repairs of owners' defects may be expedited as fully as possible foreign or private line cars may be repaired by the handling line by using material from their own stock instead of ordering material from the car owner as prescribed by Rule 122 in which event the repairing line must issue its defect card for the labor only of correcting such improper repairs and defect card should be so marked.

In case of delivering line defects, defect card shall be issued for both labor and material for correcting the improper repairs.

F. C. Schultz: I believe it is advisable for the railroads to return private line cars to the owners for repairs as the average railroad repair track is not equipped to make proper repairs to these special types of cars.

F. Trapnell: There has been some criticism of the private car owners because of the fact that these companies often removed parts applied by the railroads after the car was returned to the owner. This inspection is necessary to insure that insulation in refrigerator cars, or other essential parts, have been properly applied.

H. W. L. Porth: It has been our experience that in most cases cars are returned when in need of repairs and the private car lines in general encourage this practice as they prefer to do the work themselves.

[At the time of going to press the convention was still in session, making the publication of a complete account of the proceedings impossible in this issue. The account of the remaining sessions will appear in a later issue.—Editor.]

Bad Order Coal Car Situation

Producers Complain of Car Shortage; Conditions Not Serious, Says Railroad Administration

The relation of the bad order car to the production and transportation of coal, and the impending possibility of a coal shortage, was discussed recently before the Senate committee investigating the coal situation. The situation, so far as it is affected by the repair of cars, as outlined by Frank McManamy, assistant director of the Division of Operation of the Railroad Administration, appears to be well in hand and is not serious. He says in his statements to the Senate committee during the first week in September that cars can be furnished in sufficient numbers to meet the requirements of the coal producers or other shippers if the demand becomes urgent.

That this optimistic view is not shared by the coal producers is indicated by the statements of John Callahan, traffic manager of the National Coal Association, in his testimony before the Senate committee late in the month of August.

Transportation is Insufficient

The Railroad Administration is not furnishing enough transportation to insure production and shipment of sufficient bituminous coal to meet the requirements of the nation this year, stated Mr. Callahan.

"Car shortages caused the coal mines to fail to produce 5,900,000 tons of coal during the weeks ending August 2 and August 9," Mr. Callahan said. "This is sufficient coal to supply the requirements of the state of New Jersey for ten months. The difficulty today is a transportation deficiency and not a car shortage alone. Coal is one of the few commodities which cannot wait on transportation. It is physically impossible in many instances to bring coal to the surface and store it. Moreover, the proper place to store coal is at the point of consumption, where it will be available when required for use. Railroad cars must be ready when the coal is brought out of the ground.

"Many mines are idle today on account of no cars. Two hundred and eighty-five mines were idle because of car shortage in one West Virginia district during the week ended July 26. This was before the shop men's strike. Ninety-seven mines in this district failed to go to work in one day while many others only worked part time that day.

"The total bituminous coal lost through lack of railroad cars at the mines from the week ending June 7 to the week ending August 9, inclusive, was 12,251,762 tons, distributed by weeks as follows—June 7, 338,996; June 14, 655,190; June 21, 936,662; June 28, 644,149; July 5, 385,485; July 12, 428,359; July 19, 1,146,075; July 26, 1,764,264; August 2, 2,311,402; August 9, 3,591,180. This means 245,000 cars, or 7,000 train loads. This is more than six months' supply for all of the New England states; and this loss occurred in 10 weeks only.

"Since July 12, this shortage has been increasing by leaps and bounds. These figures are based on the United States Geological Survey reports, which indicate that whereas for the week ended July 19, where Director General Hines chose to close his recent report to the Senate, the loss on account of car shortage was 7.4 per cent of full time output, the loss on August 9 was 22.5 per cent; this in the face of statements by the Railroad Administration to the effect that conditions are not now normal. In other words, the loss because of no cars at mines has trebled in three weeks, and is now on a parity with the ordinary shortage during severe winter months when the railroads are handicapped by congestions and engine failures.

"The director general points out that 37,000 new cars have been built, of which 17,000 have been put in service. If all of these 37,000 cars had been in service during the week of August 9 there would still be a shortage of 34,000 cars during that one week alone; but these cars are not yet in service and they are going into service very slowly. The director general states they are being stencilled and lettered and placed in service. He does not say how rapidly. In one instance recently where 2,000 of these cars were being lettered, the work was being done at the rate of 10 cars per day; on this basis, more than seven months would be necessary to place this one batch of 2,000 cars in service."

Mr. Callahan said that the movement of traffic is not adequate to the demands of coal to-day, and presented a table indicating that the average miles per car per day of all cars during 1915 was 24.4 miles. "The mileage per car per day for all cars in 1916," he continued, "was 26.9 miles. It declined in 1917 to 26.4 miles per day, and in 1918 it was 24.9 miles per day, but during the first six months of 1919, the average miles per car per day for all cars declined to 21.5 miles. This means a much lower mileage on coal than the average figures shown. If all traffic is moving slower, it is natural to suppose that coal moves much more slowly."

Mr. Callahan also introduced charts showing bad order coal cars by weeks from April 5 to July 19, and indicating that whereas there were 66,192 coal cars in bad order on April 5, on July 5 there were 105,295 of such cars requiring repairs, a rise in the percentage from 6.5 to 10.4 per cent of the total coal cars in the country. He also stated that "while the Railroad Administration statements recently set forth that there were 208,531 bad order cars at the time Mr. Hines's report was written (August 14) and while the director general stated that 'a large number of cars awaiting repairs are held for only light repairs which can be speedily applied' the facts are there were 135,895 cars requiring heavy repairs, and 72,636 cars requiring light repairs at the middle of July. This figure includes all cars and it is assumed that there are relatively as many coal cars requiring heavy repairs as other cars requiring heavy repairs." At the time to which reference is made 47 per cent of these 208,531 cars, or 98,139 cars were coal cars in bad order; and that on August 2, there were still 96,758 of these coal cars to be repaired.

"There are proportionately more coal cars in bad order to-day than closed cars," said Mr. Callahan. "Of a total of 1,183,490 closed cars, 95,928 or 8.1 per cent were in bad order on July 12, as compared with 98,139 bad order coal cars, out of a total of such cars of 974,547 or 10.1 per cent coal cars in bad order. Repairs to coal cars are being neglected through preference to other cars. Moreover a figure of 10 per cent of coal car ownership in shop is abnormal. There should not be to exceed 5 per cent of the total number of coal cars in shop under ordinary good railroad management.

"COUNTRY FULL OF BAD ORDER CARS"

"The country is full of bad order cars. They impede the movement of freight through railroad yards in certain districts and are backing up the current of traffic. Moreover 8 to 10 per cent of the 62,000 locomotives owned by the railroads under federal control are now in the shop for classified repairs. These 5,500 or more engines, according to indications, will be needed quite early this winter. They could be used now in avoiding blocking coal mines with loaded cars. If these engines are not repaired at once, they may, when required for use, be in just the same condition so many cars are in today."

Mr. Callahan also quoted some correspondence with the Railroad Administration in which Mr. Hines said:

"There appears to be quite a disposition on the part of coal operators to exaggerate the argument about car shortage. I hope this disposition will not be persisted in because necessarily if the situation should be habitually exaggerated we would have to take issue with the claims thus made. It would be unfortunate for the Railroad Administration and the coal operators to get into a controversy on this subject because the controversy would tend to encourage people who are postponing the purchase of coal to feel that the coal operators are not justified in urging the purchase of coal. Naturally we prefer to see the purchase of coal expedited so it can be handled before the fall and hence we prefer not to say anything which will tend to encourage purchasers to hold off. Yet we could not remain quiescent under repeated assertions exaggerating the car shortage situation and incorrectly stating the policy of the Railroad Administration as to utilizing and repairing its equipment.

"What I would like very much to do is to get the practical co-operation of the coal operators in notifying us of any serious car shortages that exist in specific regions. Of course these matters are reported through our regular channels and are supervised accordingly, but a systematic and accurate check of the matter from the standpoint of the coal operators would be an additional safeguard of which we would gladly avail ourselves. Specific information along these lines conveyed to us will help us to handle satisfactorily a situation of common interest."

MC MANAMY DESCRIBES BAD ORDER CAR SITUATION

Mr. McManamy discussed the bad order car situation, saying the number of such cars is high at present but that the action which was taken by the Railroad Administration two months ago and which is still being diligently followed will, in his opinion, be sufficient to meet the demand for coal cars unless it reaches abnormal proportions, in which event the difficulty will be due not so much to car shortage as to the terminal facilities.

In July, 1918, Mr. McManamy said, 14.9 per cent of the locomotives were out of service for repairs and 798 were stored in serviceable condition. In January, 1919, there were 16.9 per cent out of service for repairs and 1,582 stored; in April, 18.4 per cent were out of service and 4,604 stored; in July, 17.9 per cent were out of service and 3,668 stored. Therefore, he said, the general condition of the locomotives today is better than at any time during federal operation or during the three years before and there is no ground for apprehension. There will be sufficient motive power to handle all the business offered to the maximum capacity of the terminals.

With respect to freight cars, Mr McManamy said, the situation is somewhat different. On July 1, 1918, there were 167,403 bad order cars, or 7.1 per cent. The force of shopmen was then at its maximum and was working 70 hours a week. In December the number of bad order cars had been reduced to 130,506, or 5.4 per cent. After the armistice the hours were reduced from 10 a day for 7 days a week to 9 hours and 6 days a week and on December 9 to 8 hours a day. This was fully justified, he said, by the prospective decrease in business and was necessary both because of the severe strain under which the employees had been working and because of the importance of reducing maintenance costs by reducing the amounts paid for punitive overtime. The decrease in business was sufficient to make it possible to maintain the low percentage of bad order cars up to March, at which time it was 5.2 per cent, which for the country at large, Mr. McManamy said, is an almost ideal condition. The necessity for further economy on account of expenditures for maintenance of equipment as compared with the test period made it seem advisable to make further reductions in car department forces and this was done by furloughing men at many points and by further reducing the car department hours. As a result the number of bad order cars began to increase in April and until it reached 8.7 per cent in July, a total of 215,953.

With the increase in business the shop forces were increased, first by increasing the work on the box cars to meet the early grain movement, and before the grain movement became heavy sufficient cars were provided to handle it as promptly as elevator capacity and terminal facilities would permit. Meanwhile, Mr. McManamy said, the low coal shipments could not be charged to the Railroad Administration because they were due to no market. Anticipating an increase in production the Railroad Administration on June 19 issued instructions to increase car repair forces and this was followed on June 27 by instructions that wherever the demand for coal cars made it necessary cars requiring light repairs should be given preferential attention. This was followed on August 16 by instructions to increase the hours of the car department forces to nine a day on all roads where the number of bad order cars was sufficient to keep the men profitably employed or where work could be furnished from connecting lines without excessive empty mileage, also to give special attention to grain cars, coal cars and refrigerator cars in sections where they would be most needed.

This action was begun, Mr. McManamy said, at a time when the loss of coal capacity was 41.4 per cent, of which 26.2 was on account of no market and but 3 per cent on account of car shortage. The effect had already become apparent in a reduction of 8,414 in the number of bad order cars and of 5,741 in the number of bad order coal cars. The number of employees was increased about 8,000 and their hours to nine a day, making an increase of 12½ to 15 per cent in the number of hours worked.

"The increase in bad order cars," Mr. McManamy continued, "is not at all due to a slowing up of the repair program. It is to a substantial extent due to the fact that since the close of the war the railroads are endeavoring to get their cars in better condition and are therefore sending cars to the repair tracks which at any time in the past four years would have been continued in service without repairs. They are also holding cars for heavy repairs which at any time in the past four years would have been put in service with comparatively light repairs and which, if the demand for cars becomes sufficiently urgent, can again be returned to service with comparatively light repairs.

"The strike also interfered seriously with the car repair program, but I think we can reduce the number of bad order cars very substantially in the next two months unless we have some unforeseen labor troubles—and I do not look for them."

Mr. McManamy also testified that 68,598 of the 100,000 cars ordered by the Railroad Administration have been built, of which 51,428 are in service and 17,170 in storage waiting to be stenciled, which is being done at the rate of 700 a day. The balance of about 31,400 cars is being turned out at the rate of 220 per day and includes 10,658 double sheath box cars, 12,075 single sheath box cars, 3,562 50-ton gondolas, 949 hoppers, 1,826 low side gondolas and 2,332 70-ton hoppers.

That there is reason to believe that the car shortage has reached considerable proportions is shown by the action of the Railroad Administration in the matter of hours of labor in car repair work. Although the number of cars repaired in May and June, 1919, was fully up to the normal number of cars repaired, the Railroad Administration gave instructions on June 20, 1919, that all car forces be increased to the full standard measure of 48 hours per week and that additional shifts be worked where the additional employees could be obtained and where they could be economically used. The showing naturally to be expected from the putting into effect of these instructions was hampered in July by the intervention of practically a double holiday, and, of course, was temporarily prevented in August by the strikes of a large number of shop employees. Conditions having now been restored to normal, it is expected that these instructions will promptly show a most favorable result. Further than this, the Railroad Administration instructed on August 16, 1919, that all car forces be put on a basis of 54 hours per week.

STATUS OF U. S. R. A. OPEN-TOP CARS

Director General Hines has a statement in connection with the car supply situation, giving the status as of August 26, 1919, of the open-top cars contracted for by the Railroad Administration. Of the total of 50,000 open-top cars mentioned, 45,000 are coal cars.

Open-Top Cars

	55-ton Hopper	Com. Gond.	70-ton Hopper	70-ton low side	Total
Number ordered	22,000	20,000	3,000	5,000	50,000
Completed and in service August 26	12,935	8,051	762	2,397	24,145
Completed and in storage August 26 (the numbering and placing of these cars in service is now in progress)	8,186	8,498	.. ..	794	17,478
To be built	879	3,451	2,238	1,809	8,377

The cars shown as being in storage, the statement says, are being numbered by the car works and placed in service at the rate of 250 to 275 per day. The railroad shops have been called upon to assist in numbering such cars and this will increase the daily number of such cars placed in service hereafter.

The cars shown as yet to be built are being built and placed in service at the rate of 75 per day, so that from 325 to 350 cars of this class are being put into service daily.

The composite gondolas are being delayed because two of the large plants have been on strike for the last month and consequently are turning out very few.

Two plants are building 70-ton low-side cars. One is now on strike.

Interesting Application of Heat.—The General Electric Review describes a method of heat shrinking for fitting parts of electrical machines on to their shafts which overcomes various difficulties experienced with press fittings. Water or steam heating is used for flywheels and couplings, while for armatures and field systems conveniently situated heating resistances answer the requirements. In the case of a large armature, the shaft was 35 in. in diameter. Cold pressing would have required a maximum pressure of 600 tons. By heating the armature to about 80 deg. C., however, the shaft could be pulled into the armature with a five-ton chain hoist.

MODERN METHODS OF PAINTING CARS

At the forty-eighth convention of the Master Car and Locomotive Painters' Association held at the Hotel La Salle, Chicago, September 9-11, the subject of painting was covered by a number of excellent papers and considerable discussion on the part of the delegates. We give below two of the papers presented at this convention, entitled "Preservation of Roofs on Passenger Cars" and "The Advantage of Using Pure Paints and More Time in Painting Steel Equipment." A report of other papers and the proceedings of the convention will be found in another section of this issue.

PRESERVATION OF PASSENGER CAR ROOFS

BY J. J. McNAMARA
Painter Foreman, Baltimore & Ohio, Western Lines

The steel roofs and decks of passenger equipment cars seem to present a vexing question, and correctly so when we consider the loss in metal from corrosion. It would seem that they will continue to be a source of worry until it is generally realized that the steel roof must be protected with paint coatings in a manner as good as the body of the car.

This operation, to my mind, should begin at the factory where the steel sheets should be sand-blasted lightly, heated and primed, while yet hot or before contraction has entirely set in. I am satisfied we can get better results in this way, than by priming the sheets when cold, on account of the absence of moisture on the surface and the primer setting up much more quickly, thereby shutting out moisture and gases, which are apt to cause corrosion.

I do not think it advisable to condemn the steel roof on passenger cars without giving it a fair trial, and this, to my mind, it has not gotten. It should be treated in the aforesaid manner and properly applied, with either strap or lap riveted seams, imbedded in red lead putty. At least three good coats of elastic paint should be applied at the time of application and the bow should be sanded. Thereafter once every twelve months it should be cleaned and touched up, applying according to condition, one or two good coats of elastic paint and sanding the bow. If this is done we will not hear so much about corrosion on passenger car steel roofs. If it becomes absolutely necessary to have this work done at terminal points it should be done by or under the supervision of a practical painter, and not left to the care of inexperienced terminal employees.

We cannot expect to get good results if we continue to paint steel roofs in the same slip-shod manner as in the past. I would suggest taking up with our superior officers and our purchasing department and showing them the necessity for purchasing good material for this class of work and having it applied in a first class manner. If this is done we are going a long way towards protecting passenger car steel roofs from corrosion.

Untreated canvas of proper weight, preferably No. 6, makes a very good and serviceable roof for a wood car, if applied on a surface free from sharp edges. To this three heavy coats of lead and oil paint should be applied. The treated No. 8 canvas, however, cannot be depended upon for roof covering, and I cannot recommend it.

(Mr. McNamara submitted specimen plates to show the results secured by the method of painting which he advocated.)

DISCUSSION

H. H. Morgan (C. of Ga.), in a paper on this subject, stated that the practice on the Central of Georgia is to employ a handy man at each of the larger terminal points whose duty it is to carefully inspect the roofs and wherever one shows signs of wear to paint it immediately. This method keeps the roofs protected with live paint at all times and has proven very successful. Out of sixty-seven steel cars in operation only one has come into the shop with the roof in bad condition, and that car was used in joint through service, running between terminals of other roads. Arrangements have been made to meet this condition by occasionally substituting other cars in the through trains for a sufficient length of time to make it possible to thoroughly inspect the regular equipment and do whatever work is necessary to put it in good condition.

There was considerable difference of opinion as to the advisability of sanding the bow at the end of the roof. B. E. Miller (D. L. & W.) stated that sand was detrimental to the paint. H. M. Butts (N. Y. C.) also considered sanding this surface bad practice, as it causes the paint to peel off in large patches. H. M. Butts and E. L. Younger (Mo. Pac.) advocated the use of sand on the ends of the car. J. W. Gibbons (A. T. & S. F.) expressed the opinion that the results depend largely on the atmospheric conditions, and if enough coats are used under the sand moisture will not work through and start corrosion. J. Sherrin (Penn. Lines) considered repainting every six months practical and economical.

THE ADVANTAGE OF USING PURE PAINTS AND MORE TIME IN PAINTING

BY W. BAILEY
Boston & Maine, Concord, N. H.

Paint should be applied to freight cars with a brush and with as much care as on any other surface. Any well known pigment mixed with linseed oil is the only commercial article worthy of the name of pure paint. Unsatisfactory painting can easily be traced to the use of poor paint and unskilled painting, such as spraying process.

Most of the commercial point used today is a poor article compared with good linseed oil paint. Paint mixed with japan and a thinner when applied dries by evaporation and is consequently non-elastic and almost worthless for durability. On the other hand, a paint, the vehicle of which is linseed oil, dries by the absorption of oxygen and is much thicker when dry due to the amount of oxygen taken up in drying. It is elastic a long time and will resist atmospheric exposures longer than any other vehicle and consequently wear longer than any paint mixed with driers and thinners. Japan, or thinners, should not be used in any paint for outside surfaces and exposure. Nothing but boiled linseed oil should be used for a drier. I am a firm believer in the necessity of the sand-blast process for removing rust and scale, as the smoother the surface the longer the paint will wear.

One thing I am in doubt about, and that is, what is the best primer for steel, lampblack, graphite, white or red lead. I do not believe a paint containing a large percentage of oxide of iron should be used as a primer.

PAINTING SHOULD NOT BE RUSHED

A new car should have at least three coats of paint and ten days' time for painting, if one wants an economical job of painting. When cars are turned out with two coats of commercial paint in a few months 10 to 50 per cent of the surface is a mass of rust and scale. The car is seldom returned to the shops except for repairs, and then the same process is repeated. This is expensive. On the other hand, if a good, economical job is desired the car should be given a coat of lead primer and finished with two coats of paint.

If freight equipment could be shopped as regularly as passenger cars, and I think it just as essential, it would be a great saving to the railroads. As it is they are seldom sent to the shop until something needs repairs, and then the rush comes when in the hands of the painter. Passenger cars are shopped every year, principally for appearance sake, and if freight equipment could be shopped as regularly for protection it would be a great saving.

I think it is a right a painter owes to his own reputation as well as a duty he owes to his company to say all the good things he can of good paint and condemn poor paints. To get good paint you must mix it yourself. Twenty years ago mineral was used without grinding and gave better results than the present commercial prepared paints. Mineral, lampblack and graphite can all be used without grinding. Too much cannot be said in favor of linseed oil as a vehicle for paint. It is one of the few vegetable, fatty oils that dries by absorption of oxygen.

To conclude, it should be said that whenever railroads will take time enough to paint steel equipment with the right materials, and in a way that it should be done, then the work will stand, and in the long run economy will be the sure result. The steel coal cars one sees on every hand today are horrible examples of the poor judgment and haste that has been practiced in the painting of this equipment where it has been turned out of the car manufactories. There is no cure for it now but to sand-blast it off and paint it as it should be with right materials and practices. A stitch in time would have saved nine when the cars were built, but the nine stitches should be taken now to save the equipment before it rusts out completely, for there is nothing that deteriorates faster than steel unprotected with a suitable coating.

DISCUSSION

In discussing the materials used for pigments one member told of tests of paint made by mixing the mud from storage batteries with raw linseed oil. After two years' exposure it showed up well.

Portable Oxy-acetylene Welding Apparatus.—In order to facilitate women's work in the repair shops of the Orleans Railway at Paris, a practical portable oxy-acetylene welding apparatus has been introduced. It consists of the usual cylinder of oxygen, filled under a pressure of 10 kilos, and the acetylene reservoir, these being mounted on a two-wheel wagon which can be easily moved from place to place even by a young girl. Flexible tubes several yards long connect the gases with the blowpipe, which is provided with the customary safety arrangement. It has been found that with this apparatus a woman worker is able to do a multitude of small soldering jobs with great rapidity and a minimum of fatigue.—*Scientific American.*

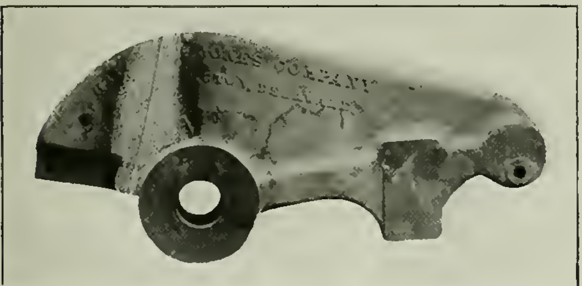
SHOP PRACTICE

LARGE OXY-ACETYLENE WELD IN PENNSYLVANIA SHOPS

BY J. F. CHANDLER
Supervisor, in Charge of Maintenance of Way, Reclamation and Welding, Pennsylvania Railroad

It is not often that the oxy-acetylene welder is called upon to exercise his skill and ingenuity to the extent of welding together two pieces of metal presenting a broken surface of 330 square inches, and there are those who loudly proclaim that a piece of work of such magnitude is beyond the realm of possibility. Hence, a description of the work accomplished so successfully at the Trenton, N. J., shops of the Pennsylvania Railroad, is of more than passing interest.



The Shear Blade After Welding; Line of Fracture Shown on Surface of Weld

Through the lack of care of a yard employee, engaged in cutting up old metal, a piece of 1¼-in. by 4-in. steel was fed into a shearing machine in such a way that a bolt in the metal broke off the shear blade at the heel of the knife. This was caused by the twisting strain presented when the bolt was caught between the shear blades. The broken face was 33 in. in height, 13 in. in thickness at the bottom and 7 in. at the top. An examination of the broken parts showed the metal to be of the highest quality of cast iron, there being no flaws or sand holes, showing that the break was due entirely to misuse. The shear has capacity for cutting 3½-in. round bars, 3¼-in. flat bars, or 10-in. by 1½-in. flat bars, and is as large as cutting machines of this type are usually made.

Immediate repair became a very urgent problem, as it was impossible to order and secure a new machine under several weeks, if not months, and delay in replacement meant much delay in the making of billets and forgings for engine work, inasmuch as this shear is used almost daily in cutting metal for the large furnace from which billets are secured.

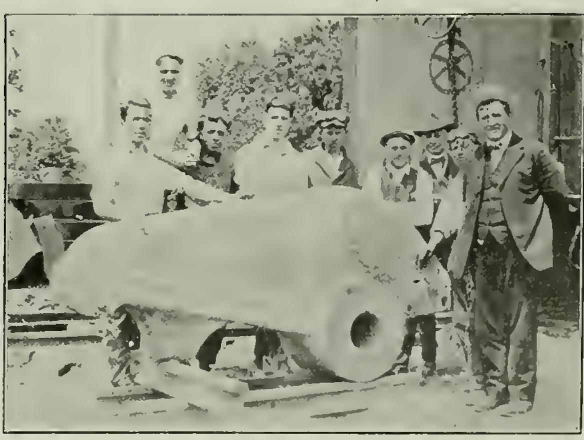
A great deal of work has been done with oxy-acetylene equipment at Trenton, but nothing to compare in size with the case here presented. The question of welding together broken pieces of so large a surface was submitted to an expert who expressed the opinion that the two parts could be welded perfectly.

"Conscientious objectors" and scoffers were all there with their arguments against trying it, not realizing that even if a failure resulted, we would be no worse off than with a broken shear, except for the expense entailed in the attempt. The matter of repairing was finally decided, and permission was given to do the work.

The broken parts were taken to the machine shop and the metal was planed away at an angle of 45 deg. from both sides of each piece, on one side to 65 per cent of the thickness and to 35 per cent on the other, so that when the two parts were brought together, lying on their sides, an edge only about ¼ in. thick remained. This was left as an aid in setting the parts for preheating and welding, and for the purpose of preserving the exact length of the shear blade. This work required two days, after which time the parts were ready for preheating.

The broken parts were laid flat, set accurately and firmly secured. A fire brick furnace was built around them and a charcoal fire started. After eight hours of preheating, the temperature was at the proper point to commence welding.

The deeper cutting, the 65 per cent side, was welded first. Oxweld cast iron alloy rods of ¼-in. and ⅜-in. diameter were fused in from the bottom up and outward from the middle of the cutting. Ferro flux was used in this work, being constantly added to insure fusion of the metal.



The Repaired Blade and the Men Who Did the Work

After it had been filled and slightly re-enforced to prevent fracture in handling the casting was turned over and the other side welded up in the same manner. It will be noted from the illustrations that the cavity to be filled was of an astonishing size.

Six welders were assigned to the work, and were worked in relays of two each, using four Oxweld outfits with No. 15 welding heads. The extra number of men was necessary because of the intense heat generated, not only by the torches but by such a large mass of iron on a large charcoal fire. In fact, the heat was so great that those using the torches protected their faces with asbestos masks, and it was frequently necessary to dip their gloved hands into water to cool them. Compressed air also was used to blow the hot air away from the men at work.

The men engaged in the work were enthusiastic as to its success, and knowing they were engaged in a most extraordinary undertaking, were exceedingly careful to see that nothing untoward should happen to endanger the success of their efforts, nor that any lack of attention should militate against the desired end.

There were used in the repair of this shear:

Oxweld cast iron alloy rod	445 lb.
Oxweld ferro flux	12 lb.
Acetylene	6,116 cu. ft.
Oxygen	7,640 cu. ft.
Labor at 68 cents, in both pre-heating and welding	203 hours
Charcoal	100 bushels
Coke	20 bushels

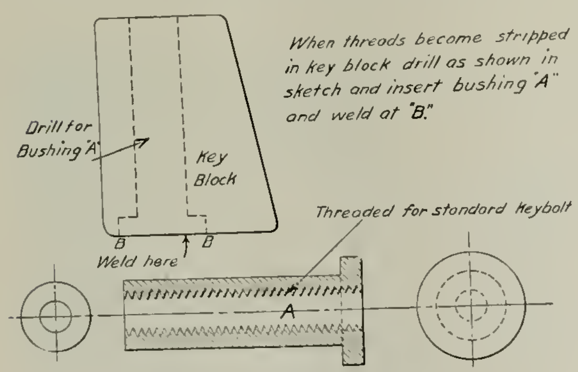
The total cost of making the repair was about $400. The cost of a new shear blade is variously estimated at from $1,500 to $1,700, so that the saving by welding approximated $1,200, to say nothing of the loss by being deprived of the use of this machine.

The shear has been fully tested and is doing business as usual. It appears to be as good as new.

IMPROVED KEY BLOCK FOR MAIN RODS

BY J. H. HAHN

An improved key block for the front ends of main rods is shown in the sketch. Considerable trouble is often experienced with the ordinary design of key block, due to the stripping of the threads, which usually necessitates a new key block. With this improved type of key block, however, when the thread strips, it is only necessary to remove the bushing *A* and replace it with a new one. When the threads in a key block of the ordinary type become stripped, it can easily be converted to the improved design by drilling it out



The Improved Key Block and Bushing

and welding in the bushing *A*, as illustrated. These bushings can be made cheaply on a turret lathe and carried in stock ready for use, and are easily and quickly inserted, thus facilitating the despatch of an engine from the roundhouse and also effecting a considerable saving in the cost of both material and labor.

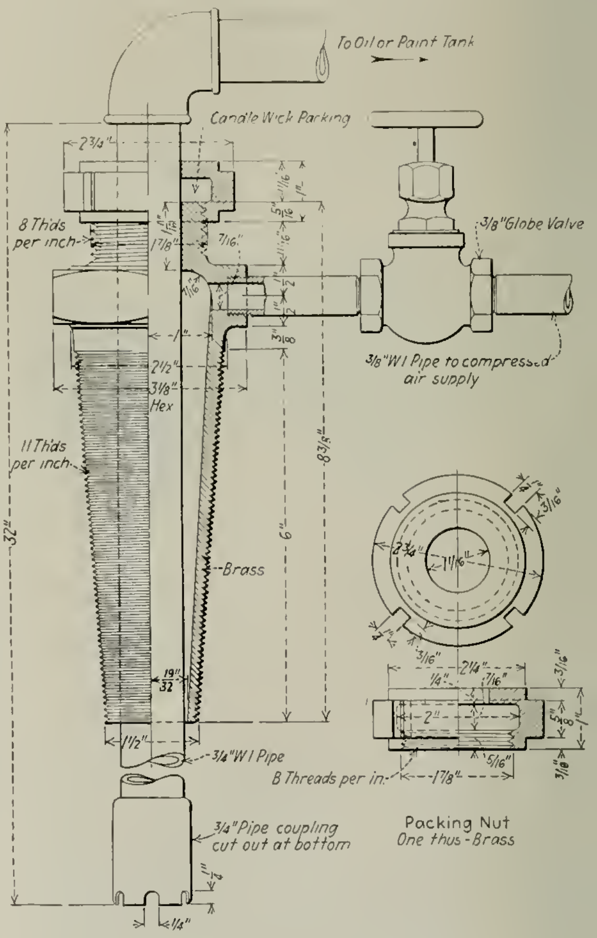
Railway Rolling Stock in France.—During 1913 France produced 700 locomotives, 2,000 passenger cars and 18,000 freight cars. Before the war it was necessary to import rolling stock, but today it is expected that after the equipment plants in the North are reconstructed, France will be able to export both cars and locomotives after the present requirements of 1,000 locomotives, 2,600 passenger cars and 24,000 freight cars are provided. In 1913, France imported railway rolling stock to the value of 23,000,000 francs and exported 7,000,000 francs.—*Le Génie Civil.*

REMOVING LIQUIDS FROM BARRELS OR OTHER CONTAINERS

BY NORMAN McLEOD

A means of removing oil or other liquids from barrels or any closed container is shown in the drawing. This device consists of a ¾-in. pipe inserted through a tapered metal plug, which is threaded to screw into the bung-hole of the container.

The plug is a hollow shell for the greater portion of its length and a hole is drilled and tapped through the side to receive a ⅜-in. air connection which is fitted with a globe valve to control the air pressure. A number of apertures are cut in the lower end of the outlet pipe so that the pipe

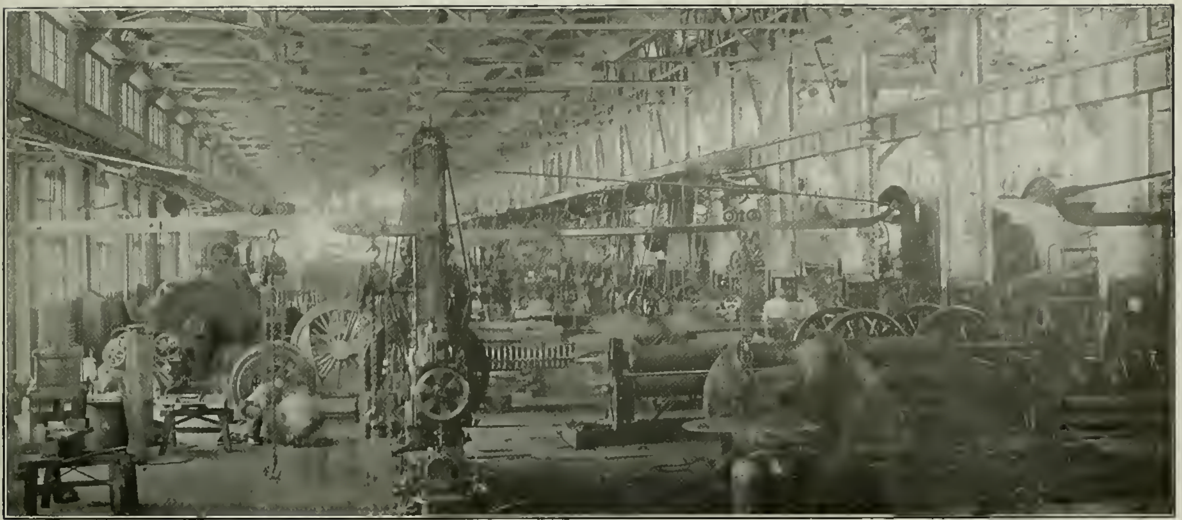


Assembled Plug, Valve and Piping

may rest on the bottom of the container without stopping the flow of liquid.

To remove a liquid from a container the device is inserted and air pressure applied through the air connection, thus forcing the liquid through the outlet pipe. This pipe may be curved at the top so that the liquid may readily flow into any portable vessel or may be connected directly to the tank or any other receptacle into which it is desired to transfer the liquid.

This method has proved very successful in railroad oil houses.



D. L. & W. Locomotive Shops at Scranton, Pa.

General Foremen's Convention

Papers on Accident Prevention in Shops and Enginehouses, and the Welding of Locomotive Cylinders

THE fifteenth convention of the International Railway General Foremen's Association was held at the Hotel Sherman, Chicago, on Sept. 2-5 with a large attendance representing all sections of the country. During the four days' sessions papers dealing with some of the important technical problems in connection with the repairing of locomotives and cars were presented and in addition labor conditions were discussed informally. The convention was opened with an invocation by Bishop Nicholson. The report of the secretary-treasurer was then read which showed the total membership to be 221, and the balance in the treasury $752.

ADDRESS OF R. H. AISHTON

R. H. Aishton, regional director of the Northwestern Region, spoke on the present railroad situation. Mr. Aishton emphasized the importance of securing increased production in all industries and quoted a letter from Walker D. Hines in which the director-general stated that in his opinion less progress had been made in securing increased efficiency in maintenance of equipment than in any other department. The higher railroad officers, Mr. Aishton said, come in contact with the actual operation of the roads only through statistics and because of that fact it is important that the foreman should be competent and progressive in determining the policies in his own department. He endorsed the proposal to put an end to wage controversies and restore more nearly normal conditions, characterizing this policy as necessary from a patriotic standpoint to keep America from falling behind in the contest for world trade.

ADDRESS OF PRESIDENT L. A. NORTH

Following Mr. Aishton's speech L. A. North, superintendent of shops of the Illinois Central, and president of the association, delivered an address. Mr. North spoke in part as follows: The General Foremen's Association was formed primarily for educational purposes only. Our intent and purpose is to furnish a channel for the full, free flow of ideas pertaining to the best mechanical practices and from this stream of experience to add to our store of knowledge. The greater the demand upon the transportation system of the United States, the greater is the responsibility of those charged with its maintenance. This association must be made one of the potent forces in the progress of transportation. During the war period many appeals were made to us to further the common cause of our country. In my opinion, the present crisis of the nation is just as acute. Let us, therefore, rise to the issue and meet it in a loyal and determined spirit and go home from this convention with a high resolve to do our utmost toward strengthening our nation's facilities.

At the conclusion of President North's address W. W. Scott made a short response in which he dwelt on the difficulties which supervising officers experience under present conditions. He stated that in his opinion the efficiency of shops and roundhouses had decreased 50 per cent in the past five years.

ACCIDENT PREVENTION IN SHOPS AND ENGINEHOUSES

The Wednesday session of the convention was devoted to a discussion of methods of preventing injuries. R. C. Richards, claim agent of the Chicago & North Western, made an address in which he reviewed the results of the safety work conducted during the past nine years on the Chicago & North Western. Several papers outlining methods adopted in safety work were read, some of which are abstracted below:

SAFETY FIRST

BY B. F. HARRIS
General Foreman, Southern Pacific, Oakland, Cal.

To generate and maintain a living interest in the movement to protect life and preserve the body from injury, we must face a difficulty that may be relieved by one or more of the following measures: (1) Imposing penalties for gross negligence. (2) Awarding premiums for creditable records. (3) Publishing the names of persons injured. (4) Publishing an honor roll of those who have been uninjured during the month.

Negligence may be generally divided into two classes: Neglect of the injured and neglect contributed by one or more who created the condition causing the accident, or who had guilty knowledge that such condition existed. As any penalty, however mild, may cause resentment and produce an interest that might detract from, rather than contribute to, the effectiveness of Safety First, the most convincing evidence should be required before inflicting a penalty on any party. It should then be tempered with due moderation, should it be imposed on the injured person. Mathematically stated: The punishment suffered from the accident should be subtracted from the penalty that would be due to an uninjured, or second party, who had caused it. This is a period of broken precedents, it follows that a proposal to award premiums to encourage creditable caution, productive of records free from accounts of accidents, will not be met with surprise, but may be thought possible.

Many simple rewards may be given, among them the following:

(1) Cancellation of discredit for former accidents.

(2) Creation of new credits.

(3) Issuance of an annual pass for the best record in each department on every division, (a full year's record included).

(4) A vacation on pay.

The suggestions of four classes of awards should be sufficient to start this phase of Safety First growing.

When a person's name is published as the principal in an accident, there is a condition of mind produced among large bodies of men to discourage all forms of negligence and foolhardiness. Every person of good health and average understanding has enough self pride to avoid public exposure of their identity with accidents. The interest excited by exposure is not pleasant but results are usually forthcoming.

Appreciation is one of the natural cravings of every human mind. The most effective application of the principle is to publicly acknoweldge the caution of employees, at each division point, shop, or yard, by posting an honor roll, each month, of all persons who have passed through the preceding month without being a party to an injury. Although it should not be expected that there will be a marked rivalry to keep one's own name on an honor roll we may well know that the acknowledgment of continued caution on the part of workmen will prevent resentment from those who are sensitive when their efforts are not recognized. A trial of these four measures as outlined will soon demonstrate their value as a means of reducing injuries to a minimum and the advantages to be gained are worth all that it is likely to cost.

SAFETY FIRST IN SHOP AND ENGINEHOUSE SERVICE

BY W. T. GALE
General Foreman, Chicago & North Western, Chicago, Ill.

New lines of thought and action, with Safety First as the slogan, should be ever welcome to all, more especially to those who may have suffered directly or indirectly from the carelessness or thoughtlessness of others. Safety First, when carried to its proper issue, bespeaks life and happiness in its best phases. On the other hand, the cold indifference and selfishness of some, make for suffering for others. The criminally careless, and those who neglect to have a proper care for the safety of others, merit just scorn and severe censure from those to whom they are responsible. Selfishness and carelessness make for discomfort and misery to others.

L. A. North (I. C.)
President

W. T. Gale (C. & N. W.)
First Vice-President

J. B. Wright (H. V.)
Second Vice-President

The results of the safety movement on the Chicago & North Western have been highly gratifying. The shop committees hold semi-monthly meetings, after making inspection of the various departments. At these meetings reports are made of the unsafe condition of tools, machinery, etc., and recommendations covering the same.

These local committees have accomplished most excellent results in shops and roundhouse service; all machines with gears or other working parts exposed and considered a menace to the safety of the operator have received attention and the danger, if any, averted. Line shaft couplings have sheet iron covers, the dangerous setscrew has been abolished, men have been protected from falling belts, all of which make for safety. Glass windows have been placed in all communicating doors between the various shops, in order that employees who are carrying dangerous implements in their hand, or on their shoulders can see and thus avoid injuries. Emery grinders have sheet iron guards around the wheels, and an adjustable frame with glass in it is attached to wheel guard which allows operators to grind tools without getting the flying particles of emery in their eyes, a round smooth iron cup is placed over the end of the emery wheel mandrel nut, preventing employees' working jackets from being caught upon the end of the revolving shaft. Danger sign posts are placed in proper positions in shops when repairs are being made overhead, employees' working tools, such as hammers, chisels, driving mandrels, etc., are examined by the foreman and the safety committee for cracks or breaks, and sharp splintered edges, and when found are replaced by new or repaired ones. Broken and rotted floors are kept in repair, automatic bells and gongs are placed on all transfer tables and moving cranes, air warning whistles for overhead cranes are a feature, the man who oils overhead machinery is supplied with a strong metal warning whistle, in order that the operators of machines below will not start up machinery.

Floor motors in shops have 1 in. pipe guard rails placed around them, open fuses have been replaced by N. E. C. cartridge fuses, all open switches have been enclosed in steel cabinets with spring hinged doors, the replacing of all fuses is done by an electrician only, motors and generator frames have been permanently grounded to avoid accidents by shorts, open wiring has been replaced by conduit and lead cables, all line shaft motors have been equipped with safety stop control buttons, all drop light cords over machines are being removed, and replaced by individual cords, vapor proof lamps have been installed in oil houses and acetylene store houses. Electricians remove main line fuses when going above to do repair work on cranes, especially from automatic floor operated cranes. Crane men are not allowed to keep anything on the crane floor with the exception of grease and waste, safety ropes are attached to cranes for descending in emergency. All employees are required to use and are furnished glass goggles for dangerous work. A large wooden platform fitting over the top of the boiler for grinding in stand pipes is a safe contrivance for men doing this work.

Hoisting chains and wire cable are regularly examined for flaws, lights have been put in dark places and roofs ventilated when necessary. Strong iron cans are used to hold scrap paper and waste during the day, the same being taken out of the shop at night. There are local fire alarm boxes in every shop, water hose pipes and hydrants in and out of the shops, an efficient fire fighting company, a doctor upon the shop grounds with able assistants to care for emergency cases. In engine house service, firing-up wood is not put into the cab until it is time to fire up the engine on account of men working in the cab and danger from nails in wood. Men have been instructed in the use of the blow-down pipe to see that it is laid flat upon the floor, and that connections are properly made so that there will be no danger of the pipe blowing off under pressure, etc., all of which shows that safety first is not a question of dollars and cents, but a question of saving human life, the most valuable thing in the world.

G. H. Logan (C. & N. W.)
Third Vice-President

H. E. Warner (N. Y. C.)
Fourth Vice-President

W. F. Hall
Secretary-Treasurer

ELIMINATING EYE INJURIES

BY L. A. NORTH

Superintendent of Shops, Illinois Central, Burnside, Ill.

One of our greatest obstacles in the Safety First movement has been in getting the employees to wear the goggles which the company have furnished to properly protect their eyes. Comment was received at the start on account of fear of eye infection. This was overcome by constructing a sterilizer so that when the goggles were returned to the toolroom, being given out to the employee on a check, they were thrown in a bath of wood alcohol, and allowed to remain for a stated length of time, after which they are removed and thoroughly dried. This in a great measure overcame any objections from this source. Then, again, complaint was made that the goggles were too heavy and clouded up during the extreme warm weather. This has been overcome by securing a lighter goggle, and a better ventilated one, so that at the present time we do not experience a great deal of trouble in requesting the employee to wear the goggle and carry out the instructions that have been issued in regard to eye protection. As the eye injuries were numerous throughout the entire plant, this was one matter that required a strenuous campaign to decrease personal injury.

Papers dealing with the safety movement were also presented by C. Coleman (C. & N. W.), J. B. Wright (H. V.), J. W. Womble, W. L. Shaffer and J. Powell.

WELDING OF LOCOMOTIVE CYLINDERS

BY L. A. NORTH

The welding of locomotive cylinders and other parts has been made possible and very successful by the introduction of oxy-acetylene and electric welding. It has been possible to weld locomotive cylinders which formerly would have been scrapped or repaired with either a brass patch or a dovetailed insert of some other metal, the weld in the majority of cases making a substantial and satisfactory job provided the expansion and contraction had been properly taken care of.

Experience has taught us that in order to properly weld a locomotive cylinder, or a casting of any make or design, it is necessary to thoroughly pre-heat to insure a uniform temperature in order to properly take care of the contraction and expansion and to avoid cracking after the weld has been made and the metal has been allowed to cool off. The success of any weld of this kind depends largely on the care used in the pre-heating and the judgment of the operator making the weld. We cannot be too particular in the selection of the operator for this class of work.

Some difficult welds have come to my observation, one in particular, where the entire upper portion of the cylinder at the port-area had been totally destroyed. This was repaired by having a grey iron patch cast in the foundry, fastened to the cylinder by means of clamps and welded in place. The cylinder was pre-heated to a uniform temperature to take care of the expansion and contraction. After the weld had been made and the cylinder had cooled down, a reinforcement was added to this weld by drilling through between the stud holes and securing the additional support by tap bolts which were tapped and screwed into the main barrel.

It is possible to weld broken bridges in slide valve cylinders successfully. Recently this was done and effected a saving of two cylinders in place of the one, which was cracked, as the cylinder which was repaired was an obsolete pattern and had we not been able to make this weld, the application of an entire pair of cylinders to this engine would have been necessary. As this engine was one that in a few years will be placed in the scrap pile, I am satisfied that the weld will outwear the present cylinders.

Not having experience with electric welding on cast iron, I am not prepared to enter into a discussion of this method to any great extent, but I have examined a number of castings which have been repaired with the electric welding process and careful examination failed to disclose any flaw or fault in the weld.

AUTOGENOUS WELDING OF CYLINDERS AND OTHER PARTS

BY J. T. LEACH
General Foreman, Pennsylvania Lines, Wellsville, O.

The welding of cylinders and other castings by the carbo-hydrogen, oxy-acetylene or electric process has made great progress in the last few years. Hardly any discovery or invention has meant so much to the railroads and casting manufacturers as the various methods of welding broken or defective castings.

There was a time when it was necessary to inspect all cylinders on locomotives before they were taken into the shop for classified repairs, in order to know that no new cylinders were required, as the stock of cylinders carried by the stores department was limited, and if a broken cylinder could not be patched and the storekeeper had no casting, the locomotive had to be held awaiting repairs until such time as the material could be procured. This was an expensive arrangement at the best, especially in the last few years when power was so badly needed. With the different methods of welding cast iron, a cylinder may be cracked or broken quite badly, yet it can be repaired successfully. The question arises as to the cost compared with a new cylinder, except in case of a new design where patterns have not been provided by the railroad or a foreign type of locomotive for which it would require several months to get a cylinder.

In making electric welds, in case the cylinder is only cracked, it is first necessary to pull the cylinder back in place, as nearly as possible, by the use of a rod and clamp. If this will not do the rod should be heated and the cylinder pulled up in that manner. The entire surface should be cut cut V-shaped at an angle of from 45 to 55 degrees and then drilled and tapped on both sides of the crack for ⅝ in. to ¾ in. studs. These studs should be staggered, that is, one row to be drilled down on the bend and the other staggered in the flat portion of the cylinder. The studs should be screwed in the cylinder ⅝ in. or ¾ in. and then cut off about ¼ in. from the casting. All dirt should be cleaned from the portion to be welded before starting the welding. This welding should be done at a slow rate of speed in order to keep the cast iron cylinder from becoming heated. In welding the cylinder the ordinary grade of Swiss welding rods of ⅜ in. or 5/32 in. diameter should be used. It is not necessary to remove the bushing or do any pre-heating to get a satisfactory weld, although if this is done a much better weld would be the result.

The cost of an acetylene weld is from $50 to $175 for an ordinary weld. This is an average figure, for the jobs vary so much in size and time that it is hard to arrive at a true average, however, the saving in any case amounts to several hundred dollars.

The method of welding by the oxy-acetylene process is as follows: The cracked portion should be cut out V-shaped at an angle of about 60 degrees. If the broken or cracked portion is bulged out, a rod and clamp should be used to pull it up as nearly to the original position as possible. The dirt should be cleaned from the area to be welded. Then a furnace of brick should be built around the cylinder and by means of a charcoal fire or blow torch the cylinder should be heated to a cherry red. In some places an acetylene torch is used for pre-heating the cylinder, but that is expensive.

After the cylinder has been pre-heated to the required heat welding should be begun, always maintaining the charcoal fire so the cylinder will have a uniform heat. In welding special silicon cast iron sticks are used and if this is not available a good grade of air pump rings will answer. The welding of the cylinder should be continuous, and if it is a large break, one operator should relieve the other. This keeps the casting at a uniform heat. If the casting is allowed to cool, the weld will crack. The charcoal or blow torch fire should be kept up for several hours after the weld has been completed and then allowed to die out.

Acetylene welds cost considerably more than welds made by the electric process, but this is often due in part to the lack of experience of the operator and also to the method followed. The experience I have had with carbo-hydrogen has been limited to cutting mostly, but it is possible to get the same result from it in welding cast iron.

Other papers on the subject of autogenous welding were also prepared by W. Gale (C. & N. W.), B. F. Harris (Sou. Pac.), J. H. Frizell (A. T. & S. F.), J. W. Womble and J. Powell.

DISCUSSION

C. D. Walker (Great Northern) advocated banding and bushing cracked cylinders on the ground that the cost of doing the work by that method was lower than when autogenous welding processes were used. Several other members concurred in this opinion, although the majority preferred to weld longitudinal cracks even though the defect could be corrected by the use of clamps or bands. J. M. Horne (M. & St. L.) stated that good results had been secured by using brass wire for cylinder welding, but this method was not generally favored due to the high cost of the wire. M. H. Westbrook (Gd. Trunk) described methods used for burning out bushings by the use of a carbon electrode. He also stated that by using sulphur on the weld the added metal was made soft so that it could be machined readily. Mr. Westbrook gave average figures for the cost of welding as follows: Oxy-acetylene process, $3.00 per hour; electric welding process, .90 per hour.

OTHER BUSINESS

Several papers on the design and maintenance of draft gear were read and discussed, an account of which will be found in Car Department of this issue.

During the convention the question of admitting supervising officers of the car department to the association was considered and the by-laws were amended to make general foremen of the car department eligible for membership. On Thursday V. R. Hawthorne, secretary of the Mechanical Section of the American Railroad Association, outlined the organization under which it was proposed to have the General Foremen's Association affiliate with the American Railroad Association as a division of the Mechanical Section. A committee was appointed to consider and report upon this matter. The following officers were elected: President, W. T. Gale, machine foreman, Chicago & North Western; first vice-president, A. B. Wright, general foreman, Hocking Valley; second vice-president, G. H. Logan, general foreman, Chicago & North Western; third vice-president, H. E. Warner, superintendent shop, New York Central; fourth vice-president, T. J. Mullin, general foreman shop, Lake Erie & Western; secretary-treasurer, William Hall, directing foreman, Chicago & North Western; chairman, executive committee, C. A. Barnes, general foreman, Belt Railway of Chicago.

Convention of Master Painters

Association Amalgamates With A. R. A.; Papers on Standardization and Linseed Oil Substitutes

IMPORTANT changes in the organization of the association and action designed to bring about more satisfactory methods of purchasing paint and varnish were the outstanding features of the forty-eighth convention of the Master Car and Locomotive Painters' Association which was held at the Hotel La Salle, Chicago, September 9-11. For some time past the officers had had under consideration the proposal to amalgamate with the American Railroad Association as a division of the Mechanical Section. This matter was brought before the convention and after considerable discussion the members present by unanimous vote decided to merge with the parent organization, thus becoming a division of Section III, Mechanical.

The first convention session was opened with prayer, following which an address of welcome was delivered by a representative of the Chicago Association of Commerce. J. S. Gearhart, president of the association, then delivered an address in which he reviewed the organization's activities during the past three years and outlined the proposed amalgamation with the American Railroad Association. The convention then proceeded to take up the discussion of the technical papers prepared by the members, which are abstracted below.

WHAT STANDARDIZATION OF PAINTING RAILWAY EQUIPMENT IS NECESSARY?

Two papers were presented on this subject, one by W. O. Quest, master painter of the Pittsburgh & Lake Erie, McKee's Rocks, Pa., and the other by W. A. Buchanan, foreman painter, Delaware, Lackawanna & Western, East Buffalo, N. Y.

PAPER BY W. O. QUEST

At the present hour, the most necessary and essential paint shop standardization would be some practical method of satisfying labor on the matter of wages in the painting of equipment. Will it be possible to standardize the labor operations of the railway car paint shops now under government control? As something of an optimist, strong in the faith that the American workman will soon realize that to bring order out of a threatened social upheaval, he must turn back to the old-time ideas of soberness and thrift, I do believe that it can be, will be, and must be done. But how such desired standardization is to be brought about, is open for the suggestive powers of just such an assembly as this. I believe that it can be happily brought about, if an amicable live and let live arrangement is made in the spirit of fair dealing between the railway organizations as employers and the employees.

PIECE WORK SYSTEM ADVOCATED

The labor of painting cars and locomotives, etc., could be standardized by the adoption of a universal piece price system, the wage paying system that we firmly believe in as the most equitable to employ any kind of labor, the most equitable for all interests, notwithstanding the fact that modern labor federations in recent years have been instrumental in entirely abolishing this method of employing labor in the American railway shop systems. In my opinion, a fair scheduled piece price system is the only method whereby labor can give a fair equivalent for wages paid. Such a proposed piece price schedule, to be standardized, should be job named and not numbered. The unit or fixed prices should be open to shop inspection at all times and never officially juggled in the event of the more skilled labor earning more pay when called upon to help out in a shop rushed for output. If a piece price labor standardization can be put into action, the prices should be so scheduled that the earnings of a first class skilled worker in a railway car paint shop would equal the earning rate of the outside general trade skilled worker. The original schedule of prices should be carefully figured out and classified, each job continuously named regardless of name repetition in the several classifications. The original job prices as scheduled should never be price changed, as we have found it to be no easy matter for the men to follow up such change and it was sure to create dissatisfaction.

When found necessary to advance or lower the wage scale, an up and down percentage method should be used.

STANDARDIZATION OF MATERIALS

Next to the labor problem, the most important issue would be that of specifying the standardization of paint supplies, as there cannot be any fixed material standardization without manufacturing, purchasing, chemical and application specifications. The paint and varnish maker will be called upon to furnish certain standards of car shop specialty material on fixed paint making formulas, that must be lived up to. Something represented as just as good or better at a lower price, unless first tested by some prescribed authority, cannot be consistently introduced without upsetting the primary law that demands standardized materials. Possibly in many instances this material is theoretically or authoritatively formulated from raw paint stock listed on the open market, which is often unsuitable or perhaps ruinously mixed by people who are trying to meet competition in the paint business, but do not know the special requirements of the railway paint shop.

There are no suggestions that will safely promote a material standardization in the railway paint shop, if the purchasing departments continue to buy paint stock on price regardless of known quality or the paint-making reputation of the selling concerns. Companies have in the past and still will in the future break into the railway paint field, without knowing that such paint is a specialty and is especially applied.

If any such suggested railway paint standardization ever becomes a law, the activities of the railway chemical laboratories will be quite strenuous and especially active when they come to the matter of settling the many disputes sure to arise.

METHOD OF APPLICATION IMPORTANT

It is in the application of the paint stock that the master car painter must receive his full recognition. He will have to be put on the standardizing committees with full power to act, as he and he only knows what is necessary to make a good job. If what is termed necessary standardization of certain or all classes of job paint work is adopted, he will as usual be held responsible for the labor and material costs.

I will here offer a list of work items that in my opinion could be readily standardized, if it is found necessary to try the standardization scheme out. If adaptable, locomotive painting should be standardized. The quality of the protective paint and varnish should be the best weather, smoke, acid or grease resisting paint stock that can be found on the market at any price. Every inch of the painted metal surface should be sandblast cleaned. All castings to be painted, should be chipped off smooth and freed of live rust, etc., with the sandblast, as it is a waste of time and money to paint over crusted unremoved grease, mill flash, or live rust of any kind. If the work is standardized, the paint specifications should call for hard, tough, elastic paint stock, as it is a great mistake to apply soft oil paint where it is to come in direct contact with solvent cutting greases and acids, which when deposited on the locomotive's painted surface, can only be removed by heavy erosive cleaning.

The painting of passenger, mail, baggage, and similar cars could be classified as to labor and material. Owing to the sameness of the work the jobs could be readily standardized. When material classifications are being standardized, the many examples of the best paint and varnishing finishing systems which have been successfully used for many years in the railway paint shop should not be forgotten in the standardization arrangements, and the interests of worthy manufacturers should be protected owing to the fact that their specialty products have helped to make car painting history.

UNIFORM STENCILING OF FREIGHT CARS

Based on the past work of this association's efforts to establish standards in freight car painting, especially to standardize the stencil markings, which undoubtedly has been and still is one of the most pronounced wasters of time, labor and material that the railway officials are confronted with, we heartily endorse the idea of standardizing every detail that covers the painting and stencil marking of the railway freight car. In the standardization scheme, the stencil lettering and numbering should be made in the same style and sizes and sent out from a designated manufacturing base in pounce pattern form. If made by skilled stencil makers from established drawings, the stenciled railway freight car would present a neat lettered appearance.

The paint repair costs of the future would be light, owing to the undisputed fact that such a railway freight car stenciling standardization scheme would save thousands of dollars in stencil-making costs for every railway company that will endorse and adopt such standardization.

PAPER BY W. A. BUCHANAN

When locomotives are undergoing heavy repairs, a very careful check should be made of the condition of the paint on cab and tender. If it is found to be blistered or badly fractured and the shopping period will permit, the old surface of the paint should be removed by sandblasting if the steel construction, or any other suitable method. The sandblast is preferable for it not only removes the paint but gives a clean bright surface to again build up a good paint foundation which is very essential on locomotive tanks, where the surrounding elements are so destructive. This is also true of the cab and domes, also the steam chest and drivers.

A well equipped lye vat is almost indispensable for the cleaning of the small parts before painting. Wash tanks, for sash and doors should be installed, equipped with hot and cold water. A good system of stationary scaffolding is found to be a great convenience and time saver, as labor is a factor that cannot be lightly dealt with under the present order of things

METHOD OF PAINTING FOR METAL SURFACES ON LOCOMOTIVES

After the foundation work has been properly prepared a system of surfacing as follows will be found very elastic and durable. The priming coat for steel surfaces should consist of a good elastic primer. After applying it should be allowed to dry at least 48 hours, after which, a second coat consisting of one half primer and one half surfacer, can be applied and allowed to dry for 24 hours. Next all uneven surfaces should be puttied with hard drying lead putty, then the whole surface knifed with No. 3 surfacer or surfacing compound. When sufficiently dry one coat of roughstuff should be applied. If desired, it can be colored and serve as a guide coat, which will save time. This surface can be rubbed the following day.

After being sandpapered the first coat of color should be applied. It has been found a good practice to continue the elastic coatings. If black enamel is to be used the first coat can be reduced one-third with pure turpentine. This method can also be followed in the second coat of enamel. After the lettering and striping is applied two coats of good elastic varnish should be applied. The first coat can be a good quality of rubbing varnish. It should be allowed 12 hours to dry, then a second coat of good elastic finishing varnish should be applied.

Cut-in jobs are treated practically the same excepting sandblasting, and under coatings. With fair usage, surfaces thus built up should last at least five years before again requiring removal of the paint. The engine frames should be thoroughly scraped and cleaned and then painted with one coat of a good quality of frame black. Trucks and tank frames should be treated practically the same, excepting that the outside of the frames should be varnished. The interior of tank frames should be painted with two coats of a good oil black, when new or when decks are removed when undergoing general repairs. Jackets and all upper work usually can be protected with one coat of a good quality of black enamel.

The interior of the cab, including all pipe work, after being thoroughly cleaned and touched up, should receive one coat of enamel of any shade desired. Cab roofs, if of steel construction, should be thoroughly painted with some good quality of steel car paint. The coal spaces and decks of tenders must be carefully cared for as the elements they carry are very destructive to steel plates if not well protected with paint.

PAINTING AND STENCILING FREIGHT CARS

The painting of freight cars has become more essential at present than at any other time since the building of this class of equipment. This is due to the fact that steel is fast replacing wood in their construction. Greater care must be exercised in their upkeep for the life of steel is rather brief if not carefully watched and kept painted.

When cars are new or rebuilt it is very essential, especially on steel cars, to thoroughly clean and paint all laps. Red lead has been found to be the best material for this purpose.

J. Gearhart (Pa.)
President

J. W. Gibbons (A. T. & S. F.)
First Vice-President

A. P. Dane (B. & M.)
Secretary-Treasurer

Freight car bodies of wood construction should be coated with a good metallic paint underneath all corner irons, or plates before they are applied. This also applies to running boards before they are applied.

After cars are ready for painting the priming coat should be applied as soon as possible. A mixture of one part pigment (if metallic semi-paste, ground in oil) to three parts vehicle has proved very satisfactory for this purpose. Additional coats can be followed up each day under favorable climatic conditions.

The stenciling is next in order and should consist of a good plain readable letter or numeral, either of Roman or Egyptian style. Insofar as possible, a uniform practice of grouping the information should prevail on all roads. Master painters will readily see the advantage to be derived in the saving of time and expense, if such an arrangement existed. No class of car men would appreciate it more than the car inspector and yard men who are obliged to get their information very often from the sides of cars and very many times under the most adverse conditions. We would, therefore, recommend that a standard distribution of stenciling for box cars be as follows:

The initials or name of the road together with the number of the car should be placed to the left of the door. The lower markings should include the capacity of the car, the cubical measurements, the date built, the class, date and where last painted, and also the weight of the car and the safety appliance markings. Any special information such as when boxes were last packed should also be placed in this group. All the information a car inspector requires to handle this phase of his duties with despatch are thus placed in one group. To the right of the door can be placed the information showing the class of commodities the car was designed to carry. The lower markings on this side of the door should show the length, height, and width of the car.

On the end of the car should be shown the initials of the road and the number of the car, placed to the right of the brake wheel. The lower marking should consist of the following information: the kind of triple valves the car is equipped with, the kind and size of coupler shank, the kind of draft rigging and brake beams (No. 1 or No. 2). The doors of the car should be stenciled on the inside only, and should show the initial of the road and the number of the car.

Air brake equipment should at all times be kept painted and stenciled showing when last cleaned and where done. When selecting cars for repainting this information should be taken and booked, for if found to be in date, it must be replaced on the cylinder of equipment. The omission of properly maintaining this information is a reportable defect. The stenciling of trucks showing the name of the road and the number of the car the truck belongs to is essential. When cleaning up wrecks or derailment of cars, unless this information can be gathered the sorting out of the right trucks is almost impossible, for in many cases the car body has been completely destroyed.

PREPARING STEEL CARS FOR PAINTING

The painting of steel car equipment should be very carefully watched. The first coatings on new steel cars are very often done with too little regard as to the preparation of the plates before the paint is applied. All dust or flash scale should be removed if possible for unless this is done paint will not adhere to the steel very long and work that should wear at least three years is in bad condition after one year.

If possible, sandblasting is the best method of preparing steel plates for initial coatings. However, should this means of cleaning be unattainable, then we must resort to the book scrapers after which dusting with a steel wire brush is resorted to. This serves the purpose very well for removing rust formations, but will not remove the flash scale. Coatings for steel hopper and steel gondola cars should consist of a good carbon pigment ground in oil and mixed to meet prevailing condition. Under no conditions should one coat of paint be expected to protect this class of equipment.

No system of painting could be considered complete without suitable quarters for handling the work with the least possible delay to shopping periods. We would, therefore, recommend that suitable tracks be assigned, either inside or outside of shops, equipped with a good dry air line of 80 or 90 lb. pressure, for the purpose of air dusting cars and spraying the under portions of bodies and trucks. Ample space between tracks is also very desirable.

The stencilling of this class of equipment should be maintained practically the same as on box cars; i. e., kept to the left of the car, or centrally located. The weighing and stencilling of equipment is a very important feature and should be constantly watched, for in selecting cars for repainting, the old light weight is a part of the record. The painter should place this in a book with the other items, necessary for record, concerning the car. This enables him to properly check any material difference in the new as compared with the old weight.

DISCUSSION

H. M. Butts (N. Y. C.) proposed that the association issue a pamphlet of approved practices for painting railway equipment. There was some difference of opinion regarding the relative merit of carbon and lead paint. J. W. Gibbons (A. T. & S. F.) stated that for steel underframes he considered red lead and carbon black better than two coats of carbon black. W. A. Buchanan told of steel freight cars painted with carbon paint in good condition after 17 years.

SELECTION AND PURCHASE OF PAINT

BY S. E. BREESE
Foreman Painter, New York Central, Collinswood, O.

Previous to the advent of the United States Railroad Administration the master painter of the railroad was the sole authority as regards paint and varnish both as to materials used and methods of application, and was responsible to his immediate superior for the results obtained. By virtue of this authority and through his experience and ability he secured certain desired results acceptable to the road which employed him. He accepted full responsibility as to results obtained and viewed with pride the results of his work. This pride was justified by the condition and appearance of the equipment coming under his jurisdiction. By an interchange of ideas, the foreman painter was constantly striving for progressive methods, economy, labor saving systems and durability in his work. He chose his tools, his men and his materials and through the proper co-ordination of all three secured results. The questions which I believe are of paramount importance are, whether the above conditions still exist and whether we are still responsible for results and have authority as to what tools to use, methods to employ, or materials to apply.

At the present time the purchasing department chooses and gives us our tools and material and asks for results. Are we allowing our responsibility to be shifted, our authority to be questioned and our methods attacked and submitting to it all without a protest? We were employed for a specific purpose, namely, to maintain equipment in good shape, secure economy as to methods, costs and time factors and yet are unable to choose our methods or materials. If this has come about what is the cause and what is the remedy?

MASTER PAINTERS SHOULD CHOOSE MATERIAL

A successful organization is one in which the authority vested in each department is absolute and co-ordinated and results are obtained only by a complete assumption of responsibility by the head of each department. In this way a chain of organization is forged, which is strong, well co-ordinated and successful only when each department has this full authority. Are we allowing our department to become the weak link of the railroad shop organization by a question of divided authority or a shifting of responsibility? It is essential that we become cognizant of the real danger of shifting our responsibility, accepting divided authority and lowering our standard methods and materials.

I believe the greatest trouble has been with material rather than with methods of application. This is primarily in the hands of the purchasing department and there has been some little friction over the materials bought for use. Due to the very nature of each department's position, there must necessarily be some friction, as the office of the purchasing department is the securing of materials designed to accomplish certain specified purposes at as cheap a price as possible with due regard for the quality and durability of the articles purchased. The purchasing department must, because of its lack of knowledge concerning the materials used, be absolutely dependent as to the question of durability and quality on information secured from the mechanical department, which in turn secures this information by co-operation with the master painter. This information is obtained by a consideration of a number of essential points including practical equipment tests and weather tests, chemical tests, information secured through the sales representatives of paint and varnish concerns, regarding the tests made by them of the material in question, and the knowledge and experience of the master painter due to his specialization on these problems.

CHEMICAL TESTING OF PAINT

The chemical testing of varnish or paint materials has been up to date of little value as a reliable source of information, especially as regards durability. In fact, up to date, except in the case of raw materials, a chemical test is of no use to the painting department. The experienced painter by a few practical tests, such as elasticity, working and drying, can usually determine and foretell through his experience the possible durability of the article in question. General Atterbury has stated "In my experience the only materials which we were unable to purchase by specification were paint, varnish and rubber. In the purchase of the above materials, I was absolutely dependent for information on the man in closest touch with the materials, who by his specialization and experience usually could be called upon to adopt the material best suited for the purpose." This still holds true.

The purchasing department backed in many cases by the arguments advanced by sales representatives have succeeded in selling the mechanical department materials against the judgment of the master painter, who accepts these materials rather than get into a controversy. This has brought about changes in materials and standards all tending towards less efficiency and lessened durability, which means higher cost of maintenance in the end. This false economy is now being felt by the equipment upon which it was used. Goods of every description and standards are pouring into the shop; changes are being made from month to month on nearly all materials. Our only duty seems to be to apply them.

INFERIOR MATERIAL NOW BEING USED

As the price of raw materials advances, the price of paint and varnish declines, a queer economic anomaly which is only explained by a reduction in quality. The purchasing department notwithstanding the above, continues to buy at still lower prices, without consideration of durability or the standards of the road. This is a direct infringement on the authority of the man who, by his experience and specialization, has been placed in the position of the final judge of paint efficiency and durability. It is part of our job to make decisions regarding durability and efficiency. We have all seen certain materials installed as a standard for painting, whose false economy, is now becoming apparent, and which was apparent to us in the beginning. What is the remedy of this situation? A sales representative told me that any justifiable complaint made to the person in direct charge was always seriously considered by the purchasing department in placing orders, but as the complaints are not made, the purchasing department establishes a precedent for the purchase of still cheaper material. Have we been afraid to complain, have we refused to use materials for the purpose intended? The refusal of these materials would also establish a precedent for the discontinuance of the purchase of such materials. Let us not close our eyes to apparent faults without attempting by honest argument and frank discussion to remedy the situation. Let us carry this to a successful conclusion and put our association back of the fight for efficiency, economy, and durability of all forms of painting equipment, and retain full and undivided authority as to methods employed and standards adopted.

DISCUSSION

The members as a whole agreed that much poor material was submitted and accepted where paint was bought on specifications only. Several stated that material received under present specifications was not satisfactory. Although experience indicated that the paint would not give good service, it met the tests prescribed and for that reason there was no alternative but to accept it. J. W. Gibbons (A. T. & S. F.) emphasized the fact that the efficiency of painting should be judged not by the number of cars painted for a given expenditure, nor the speed with which the work was completed, but rather by the length of the intervals between painting.

BEST QUALITY AND SIZE OF SAND FOR SAND BLASTING

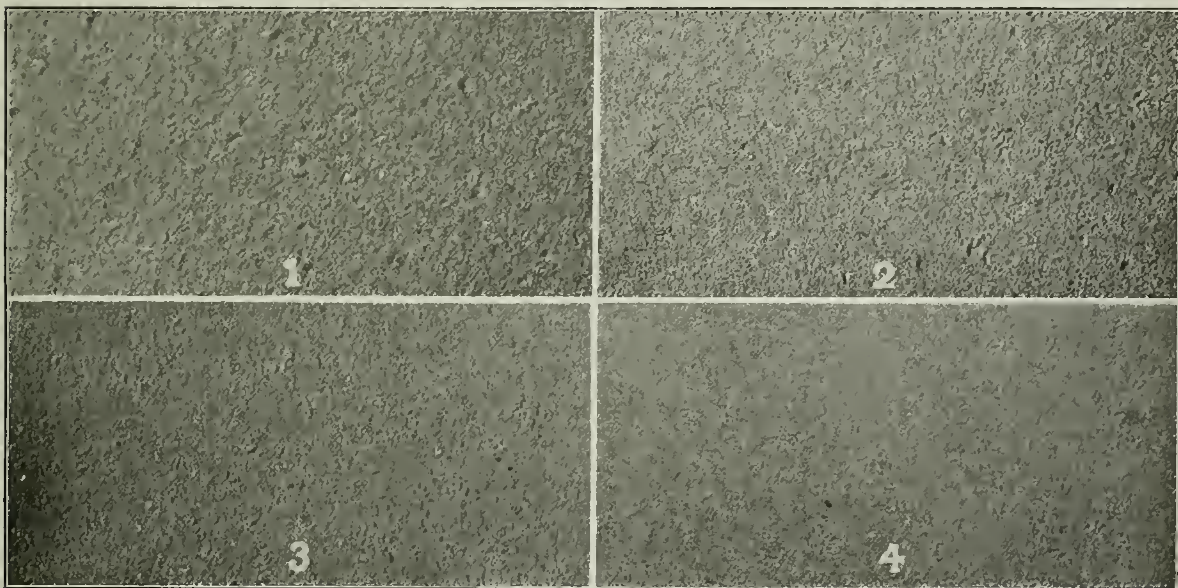
BY J. W. GIBBONS

Foreman Locomotive Painter, Atchison, Topeka & Santa Fe, Topeka, Kan.

Experience having taught us that the sandblast is the most economical and thorough method of removing the flash scale corrosion and old paint from a metal surface, economy of operation has been the only thing considered, durability or cost of finishing the surface has been lost sight of, with the result that a surface which was practically impossible to preserve with paint, has frequently been obtained. This naturally raised a doubt in the minds of some as to the desirability of using a sandblast in preparing a metal surface for paint. Even in conventions of this association, the durability of paint applied over a sandblasted surface compared to a non-sandblasted surface has been questioned. This state of affairs has held particularly true with regard to steel roofs.

The above facts, no doubt, prompted the committee in their selection of the above question for discussion. In my opinion, the essentials necessary to secure good results from sandblasting metal preparatory to paint, are the quality and size of the sand pebbles and the velocity and volume of the projectiles thrown against the surface. As to quality, any sand that is hard and firm will answer. The less dust or dirt it contains the better from every point of view. As to the size of the sand pebbles, I submit four photographs to show the results secured with various sizes.

A photograph of a steel plate sandblasted with sand run through a 4 by 4 mesh sieve is shown in Fig. 1. Note the torn condition of the metal; the pin points are numerous. When paint is applied over a surface like this and subjected to the attrition of wind, rain, sleet and cinders, incident to service conditions, the sharp projections puncture the paint film, allowing moisture to seep under the paint, carrying with it all the destructive agencies of the sulphurous products from coal burning locomotives or furnaces. Corrosion sets in, deteriorates and frequently destroys the metal before we realize that anything is wrong.



No. 1 Blasted with Sand Sifted Through 4 by 4 Mesh, No. 2 Through 6 by 6 Mesh, No. 3 Through 10 by 10 Mesh, No. 4 Through 16 by 16 Mesh Screen

Fig. 2 is a photograph of a plate sandblasted with sand run through a 6 by 6 mesh sieve and is practically as poor a surface to paint over as that shown in Fig. 1. A photograph of a plate sandblasted with sand run through a 10 by 10 mesh sieve is shown in Fig. 3, while Fig. 4 shows a plate sandblasted with sand run through a 16 by 16 mesh sieve. Figs. 3 and 4 present an ideal surface or paint with just sufficient roughness to give tooth to the paint and hold it firm and solid.

These plates were all cut from the same piece of sheet stee and sandblasted with the same quality of sand. The velocity and volume of projectiles was also the same on all plates, the only difference was in the size of the sand pebble and, in my opinion, proves that the size of pebble enters largely in the results obtained by sandblasting.

The second part of my claim, that the velocity and volume of the projectiles are also essential, may not be as susceptible of proof by photographs, but if you take a sheet of steel and throw a heavy volume of sand upon it with a high velocity, you will find that it will not only tear the metal, but will warp the sheet.

When we consider that sand run through a 16 by 16 mesh sieve will clean practically as much surface in a day as sand run through a 6 by 6 mesh and that the only extra cost is in the time required to sift the sand and in the per cent of sand available, and that this extra cost is more than made up in the time required to paint and surface up the metal, there can be no excuse for using a coarse grade of sand. As to velocity and volume of projectiles, in my judgment, the air pressure should not be less than 70 or more than 90 lb. per sq. in., and the size of nozzle should not be over 3/8 in. or less than 1/4 in. in diameter. To secure durability of paint surface and the proper protection of metal, the character of surface obtained by sandblast is as essential as the quality of paint applied.

DISCUSSION

G. M. Oates (Pressed Steel Car Company), presented a paper on this subject. his company formerly used No. 8 crushed quartz from Warsaw, Wis. The material was satisfactory, but on account of the high freight charges, its use was discontinued and No. 3½ silica from Youngstown, O., had been substituted with good results. Silica sand, however, will only remove rust and scale while the quartz will cut old paint as well.

SUBSTITUTE FOR LINSEED OIL

BY. A. H. F. PHILLIPS
Master Painter, New York, Ontario & Western, Middletown, N. Y.

There have been great demands for linseed oil, and some specialists predict that the call for seed to fill these large contracts will become so urgent that higher prices will eventually be realized. If such is the case, it will mean almost a prohibitive price for use in a railway paint shop. We can at least safely say that the demand is very great and is persistent.

There has been a general shortage in flax seed, which still continues. The Canadian and American supply continues light, and Argentine conditions are not changed particularly. Prices and freight are high, and cargo space at a premium. American buyers have been credited with considerable stocks in warehouses, but receipts and available supplies are somewhat limited.

Under the present conditions of the market, the demand for linseed oil is in excess of the supply, and there is no question that there is a genuine shortage of oil. Perhaps, at some future time when the market becomes more normal the supply may possibly equal the demand and prices may not be so high as to almost prohibit the use of linseed oil as a paint making oil.

PROPERTIES OF VEGETABLE PAINT OILS

For some time past the railway paint shops have been receiving many paint oils as substitutes for linseed oil. I believe there is none, as yet, equal to linseed oil as paint making oil. A paint oil as a substitute for linseed oil for use in the railway paint shop can be made, and is being made and sold by many companies, on a linseed oil base, and of the same gravity. This drys with a good gloss, as it contains enough of volatile oils as conveyors to assist materially in the application of the paint when evaporated in drying, leaves a thoroughly elastic and highly protective oil film in combination with the pigment. This paint oil can be used in thinning out paints of any character, oxide, carbon, lead or zinc, where oil is desired as a thinner, without danger of any chemical action. Such oil would probably be called a combination oil. I am not prepared to assert what oils make up such a paint oil.

Vegetable oils are used by many in making up their paint oils, namely, cotton seed oil, soya bean oil, hempseed oil, corn oil, peanut oil, cocoanut oil, etc. These vegetable oils being largely food oils and used extensively in paint making oils as substitutes for linseed have found an increasing market. Mineral oils are also used in the paint oils to some extent, but I do not think it advisable to be too free in the use of paraffin oils. Owing to the great demands for linseed oil and the scarcity of the supply, also prices soaring up almost to a prohibitive figure for general use in the paint shop, substitute oils have found a place in making paint oils for use in the railway paint shop.

OILS OTHER THAN LINSEED USED IN PAINT

There are quite a number of these, drying, semi-drying and non-drying and not a few have their special uses in paint. The most important of the drying variety is China wood oil or tung oil. Poppy seed oil is prominent for grinding the finer grades of zinc white and artists' colors, and must be classed among the drying paint oils for the reason that when pressed from ripe seed it dries very nearly as rapidly as raw linseed oil. The reason for the use of poppyseed in colors or paints is due to the non-darkening of this oil and its free spreading. Bombay nut oil was at one time largely offered at a price somewhat lower than poppyseed oil. It was very clear, almost water white, and its drying property fully equal to that of bleached linseed oil. However, this oil has not been heard from in the market for some time.

Sunflower seed oil is also classed among the drying oils, but it has not found its way into general commerce and therefore nothing more is known about it than has been ascertained in an experimental way. Hempseed oil also belongs to the class of vegetable drying oils, but this seed being raised principally in Russia and a few other localities in Europe, is used mostly there as a paint oil; and if any is brought to this country is comes as an admixture with linseed oil.

Another vegetable drying oil that has been largely imported for some time into this country and Europe, under the name of candle nut oil by soapmakers and is known to science as Kukui oil, is now being tested by progressive varnish and paint manufacturers. It bids fair to be a strong competitor of linseed oil when its characteristics become better known to the trade and it is prepared in a more scientific manner than it is now. Other drying vegetable oils, as nigerseed oil, tobacco seed oil, Scotch firseed oil, etc., that are not readily obtainable in commerce, are not at all interesting to the paint maker and color grinder.

FISH OIL HAS LIMITED USE

Another oil, which is of animal origin, is the fish oil known as Menhaden oil. This is barred out, however, from use in many paint materials, especially in interior paints, because of its offensive odor, and is made use of only in special outside paints as in roof paints and stack paints, and by some manufacturers in other specialties.

Among the substitutes for linseed oil that interest paint manufacturers most should be classed soya bean oil, corn oil and cottonseed oil. Soya bean oil requires fully ten days to dry to a film and then the film will not be as firm as raw linseed oil which requires six days to dry to a film. Since linseed oil is extraordinarly high priced there is quite a demand for bean oil, and it is quite a task for paint makers to discover methods to make their products dry in the ordinary way. The usual practice was to use equal portions of soya bean oil and boiled linseed oil, or when this would not work out well in some paints the bean oil portion was increased and also the driers.

Corn or maize oil has been in use in paints for many years, but is made use of only when linseed oil is high in price. This oil has very little, if any, drying properties, and will harden to a brittle, rather mealy film in from twenty to thirty days. Cottonseed oil has no drying properties, but is a good lubricant, and previous to its rise in price when it came to be used as a cooking and table oil, it was used to adulterate linseed oil. Rosin oils are not only used in printing-ink making, but were largely employed in making paint for rough surfaces, though since their price has advanced to twice, even three times their former cost, they have been replaced by mineral paint oils to a great extent in paint. Rosin oils are practically non-drying, and while they harden in time will soften again under the influence of sun heat and make the paint film part, or alligator. Pine oil and tar oil are products from the distillation of wood spirit and of rosin, and are used in the manufacture of marine paints, especially paints for ships bottoms. These oils are semi-drying and water resisting to a degree.

MINERAL OIL WILL NOT RESISIT MOISTURE

Mineral paint or paint and putty oil, so called among the trade, is refined petroleum or neutral oil, so named because debloomed. These oils cannot be used without being mixed in certain percentages with boiled linseed oil, as they lack binder and are apt to wash off the surface in case of driving rains. Even when used in large portions in a liquid paint for rough surfaces such paints have been known to wash off when they were supposed to have dried hard a month or two before. Petroleum products of this class will sweat, thus causing softening of the film and consequent damage to it by water.

Cheap paints for use on rough lumber or other rough surfaces can be made by grinding the base in linseed oil (usually boiled), thinning with a mixture of about 35 gallons of gloss oil (rosin and benzine mixture), 10 gallons of raw linseed oil and 5 gallons of liquid drier. Or if it must be still cheaper a thinner can be made of 30 gallons of gloss oil, 15 gallons of debloomed neutral paraffin oil and 5 gallons of lead and manganese drier. In any case, however, the pigment to be used as the base for the paint should be ground in linseed oil

So far linseed oil has not found an equal in paint making, although the subject has been one of deep study, and while other fixed oils have been discovered that for certain purposes have been expected to take its place, it has yet to be demonstrated that such is really the case in long practice. China wood or tung oil, while superior to linseed oil in certain directions, especially in its resisting power to water, has not shown itself adapted to replace linseed oil in making oil paints as we know and desire them.

When linseed oil is placed on a strip of glass that has been painted jet black and shows a bloom, or iridescence, it is adulterated with mineral oil or rosin oil. Admixture of linseed oil and corn oil or linseed oil and cottonseed oil can be detected by placing some of the oil between the palms of the hands, rubbing briskly and noting the odor thus emitted. The presence of soya bean oil, however, cannot well be ascertained by simple tests, and a chemical analysis is necessary, though even that is sometimes misleading.

THE FIELD FOR SUBSTITUTE OILS

BY P. J. HOFFMAN
Master Painter, Hocking Valley, Columbus, O.

The shortage of linseed oil makes it imperative that we find an acceptable substitute oil. In some instances, it is absolutely necessary that we use linseed oil, but on the other hand, whenever we can use a substitute with the desired results we are saving that much linseed oil to overcome the present shortage. Tung oil is used very extensively in the place of linseed oil in the manufacture of certain grades of varnish, and a mixture of tung oil and linseed oil has a greater resistance to moisture than the pure raw oil, consequently in cases where the paint is subject to the rains, snows, sleets, etc., such as platforms, trucks, or castings, it is an improvement over linseed oil. Then again, certain oils will stand the heat better than linseed oil, and therefore are better fitted for the heated parts of locomotives, etc. There is on the market a substitute oil for the grinding of pigments that has given universal satisfaction. I have for a number of years used a substitute oil in all our freight car equipment that has fully stood the test, especially in point of service rendered.

Different bodies and surfaces require different substitute oils according to the nature of the object painted and the kind of usage the paint has to withstand. How far we can go with a special paint for a special purpose is in my opinion the solution to the question. If we can by diligent research conserve the linseed oil by the use of a substitute oil, we have overcome some of the shortage of the linseed oil. The difficulty in using substitute oils is that irresponsible companies will make and market an oil substitute that has no virtue and we will try one and then another without getting results until at last we will become so disgusted that we will revert back to the old reliable linseed oil.

Unless we can have a certain paint for a certain purpose, I am skeptical as to the advisability of using substitute oils. Then the question arises is it practical from a money standpoint. We will have great quantities of different kinds of paints that are used only on certain jobs and the stock will be so augmented that the stock room will have to be enlarged and in all probability it will necessitate the adding of more help to take care of the stock. Then again the loss of interest on the money that is tied up in the excess stock paint will have to be considered, loss from evaporation and deterioration from paint exposed at long periods make it even more expensive. These with the many more added expenses that are sure to be incurred with larger stocks will, to my mind, overcome all that can possibly be saved by attempting to use substitute oil.

DISCUSSION

A paper on this subject was also presented by F. B. Davenport (Penn. Lines). J. W. Gibbons (A. T. & S. F.) stated that mineral oil should not be used with putty as it evaporates and leaves a powder that soon flakes off affording no protection for the glass. Good putty effects a saving of glass and labor many times greater than the increased cost of the material. Mr. Gibbons stated that linseed oil is not necessary in paint that is not exposed to the weather.

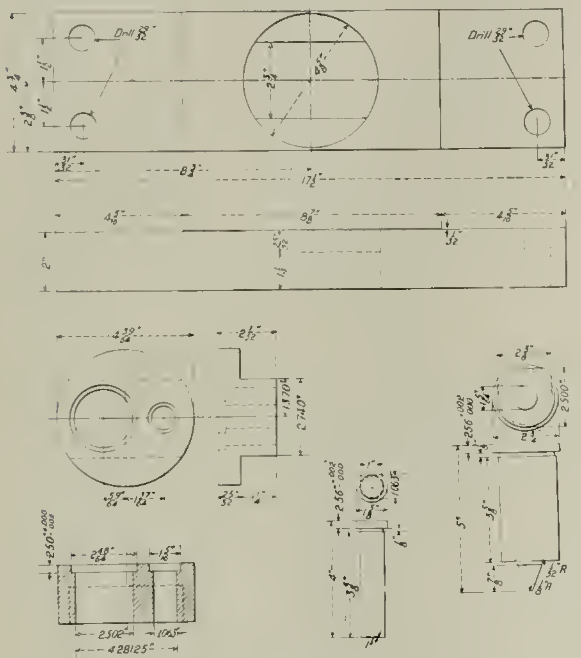
OTHER BUSINESS

F. B. Davenport (Penn. Lines) told of the results secured with a special heat resisting paint developed for use on car roofs. C. E. Copp (B. & M.) presented a paper on the record of the Master Painters' Association. Papers on Painting of Steel Equipment and Roofs of Passenger Cars will be found in the Car Department of this issue.

The secretary-treasurer reported a total membership of 328 and a satisfactory balance in the treasury. The following officers were elected: Chairman, J. W. Gibbons (A. T. & S. F.); first vice-chairman, E. L. Younger (Mo. Pac.); second vice-chairman, J. G. Keil (N. Y. C.); secretary-treasurer, A. P. Dane (B. & M.). Boston was chosen as the place of the next meeting, which will mark the fiftieth anniversary of the founding of the Master Car and Locomotive Painters' Association.

WASHER PUNCHING DIES

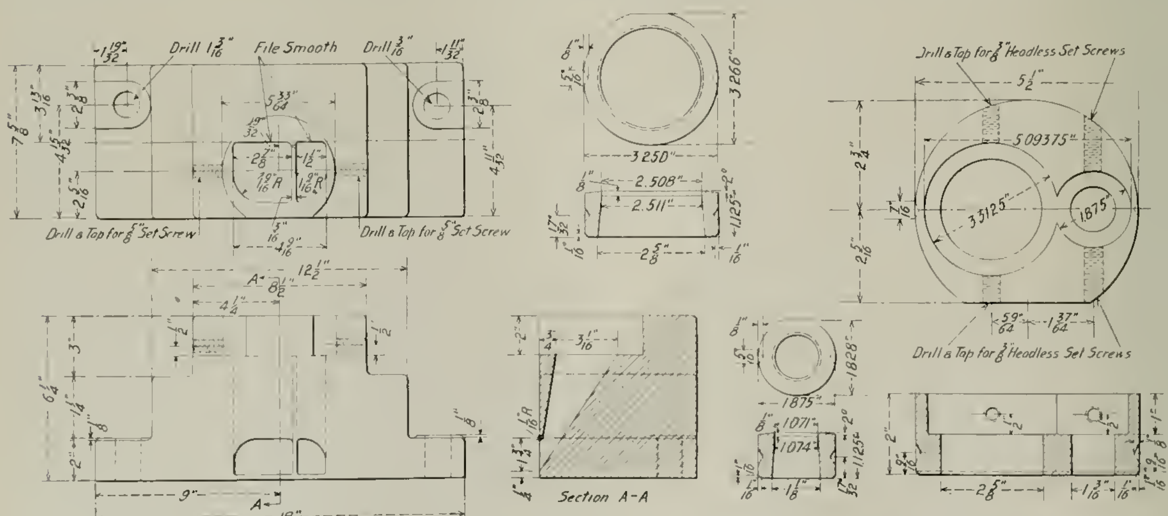
The dies shown in the drawings have been developed for punching washers from scrap material, at the reclamation plant of the Canadian Pacific at Angus shops, at Montreal, Que. The device is arranged in a single unit, consisting of two sets of punches and dies, one of small size to cut



The Punches, Punch Holder and Block for Attaching the Punches to the Machine Crosshead

the bolt hole and the other large enough to cut the washer out of the plate.

The punches are held in a steel holder, which is set in a steel block bolted to the crosshead of the machine. The dies are held in a steel holder set into a cast iron block which is bolted to the table of the machine. The cast iron base block has two chutes cored through it so that the washers and punchings may be kept separate. The large or outside punch has a guide which enters the hole cut by the small or bolt hole punch, thus making the outside of the washer concentric with the bolt hole.



Details of the Dies, Die Holder and Die Block

In operation the plate is first placed under the small punch; thus it is advanced until the guide on the large punch will enter the hole just cut by the small punch. After the first small hole is cut, every stroke of the machine produces a completed washer. A stripper is placed 5/8 in. above the dies which extends half way around both punches from the back, so that as the punches move up the plate is stripped off from them.

The advantage claimed for this device is continuous production. It is simple, and there are no moving parts to the stripper to break or get out of working order. Punches and dies similar to those shown, which are 1-in. washers, have also been designed for 1/2-in., 9/16-in., 5/8-in., 3/4-in. and 7/8-in. washers.

AUTOGENOUS WELDING OF FIREBOXES

In an article entitled Jacobs-Shupert Firebox Repairs, written by H. Louis Hahn of the Santa Fe System and appearing in the August issue of the *Railway Mechanical Engineer*, the following statement was made: "These patches meet the requirements and approval of the Interstate Commerce Commission, Division of Locomotive Inspection."

Exception is taken to this statement by A. G. Pack, chief inspector, Bureau of Locomotive Inspection, Interstate Commerce Commission, in a statement reading as follows: "This bureau has consistently taken the position that autogenous welding should not be permitted on any portion of a locomotive boiler wholly in tension while under working conditions, nor in any part of the boiler where the strain is not carried by other construction, or where the safety of the structure is dependent upon the strength of the weld."

A New Heat Insulating Material.—According to the Valve World, a new heat insulating material, composed of a mixture of a special clay and cork, has been discovered by a Norwegian engineer. The clay and cork mixture is burnt, and the result is the formation of a very light substance that is said to be eminently suitable for all heat insulating purposes.

Railway Tool Foremen's Convention

Standardization of Small Tools and Devices for Facilitating Work Are Principal Topics Discussed

THE American Railway Tool Foremen's Association held its ninth convention at the Hotel Sherman, Chicago, August 27-29. Following the opening prayer, the convention was welcomed by G. C. Niemeyer, representing the states attorney. The president then introduced W. E. Dunham, assistant to the general superintendent motive power and car department, Chicago & North Western, who spoke of the relation of the tool foremen's work to the efficiency of the shop.

ADDRESS OF W. E. DUNHAM

Mr. Dunham said in part: The tool foremen and the tool foremen's organization are the heart and life of a railroad shop. What the tool room is and what the tool room foreman accomplishes affects every department. If the tool room is not furnishing efficient tools, the morale and spirit of the entire shop is gone. The tool foreman ought to give attention to every tool in the plant, and those from which the proper output is not being secured should be overhauled so that the utmost production can be obtained. We must see that the equipment the railroads have in their shops is in efficient condition. In this matter the Tool Foremen's Association has a very vital part to play in the reconstruction period through which the railroads are going.

PRESIDENT'S ADDRESS

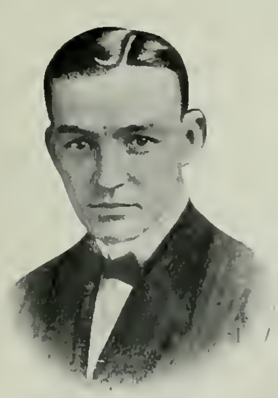
The president, C. A. Shaffer, general supervisor, shop machinery and tools, Illinois Central, reviewed the activities of the association since the last convention in 1916. He urged the members to put forth a special effort to enlarge the organization and to continue the work which would bring about higher efficiency in railroad tool service.

STANDARD DEVICES FOR LOCOMOTIVE

BY B. J. McKERNAN
Supervisor of Tools, A. T. & S. F., Topeka, Kan.

There has been a great demand for practical devices for use in making repairs to locomotives and cars, and through the efforts and cooperation of the American Railway Tool Foremen's Association many good devices and ideas have been disclosed. There are shown below a few devices which have been found to be very practical for the various classes of work here described.

Several practical devices used in making repairs to air brake equipment are shown in Fig. 1. By the use of these tools we have been able to reclaim many parts that otherwise would be considered scrap, and from a financial stand-



C. A. Shaffer (I. C.)
President

J. C. Bevelle (E. P. & S. W.)
First Vice-President

R. D. Fletcher (Belt Ry. of Chic.)
Secretary-Treasurer

point we have made a very creditable showing. These tools are made up in the Topeka shop tool room and standard sets are furnished to all points on the line.

Boiler check reseating tools and reamers which have proven very satisfactory for the repairing of boiler checks in the back shop and especially in the roundhouse in making running repairs are shown in Figs. 3 to 5. These devices are inexpensive and very simple to make and handy to operate, and they are instrumental in eliminating many engine failures and leaky boiler checks. In order to eliminate the possibility of our mechanics using improper tools on the leaky boiler checks, we found it advantageous to stencil each reseating tool with the pattern number of the casting for which it is intended.

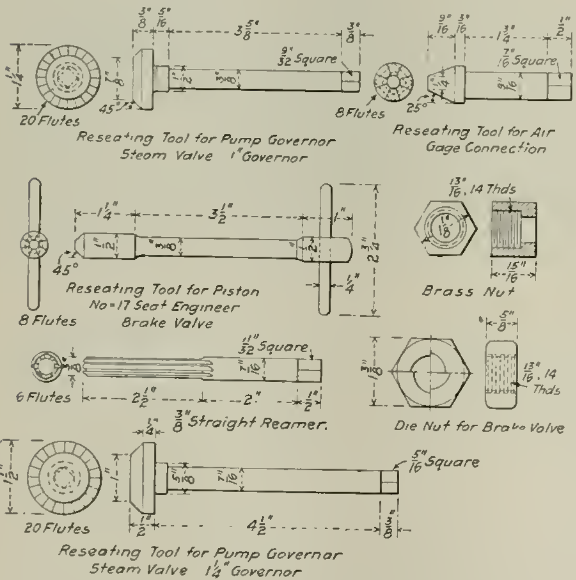


Fig. 1—Tools for Repairing Air Brake Parts

Reseating tools for blow-off cocks are shown in Figs. 5 and 6. By the use of these tools the possibility of leaks can be eliminated and the tool is so constructed that any one can operate it without difficulty. This tool is also stenciled for the particular boiler blow-off cock on which it is to be used.

Fig. 2 shows reseating tools for the outside and inside throttle valves for non-lifting injector, and Fig. 8 shows reseating tools for Chicago lifting injector throttle ram seats.

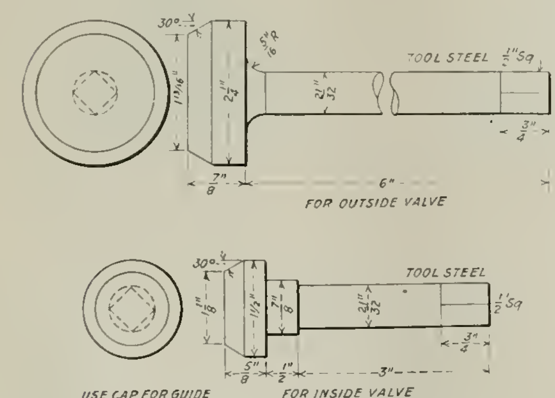

Fig. 2—Non-Lifting Injector Throttle Valve Reseating Tool

A lubricator throttle valve reseating tool is shown in Fig. 9. This tool has proven to be very handy and efficient, and all roundhouses are furnished with tools of this kind.

A reseating tool for superheater damper cylinders is shown in Fig. 10. We find that by the use of this tool we can eliminate the possibility of leaks to the cylinder, and it is indispensable.

STANDARDIZATION OF TOOLS.

In this day and age the individual idea should be subordinated to such an extent that we should adopt practices that would give us better efficiency, reduce the cost of output, and on the other hand simplify the tool situation whenever possible. It has been plainly shown that the adoption of standard practices by the American Railway Master

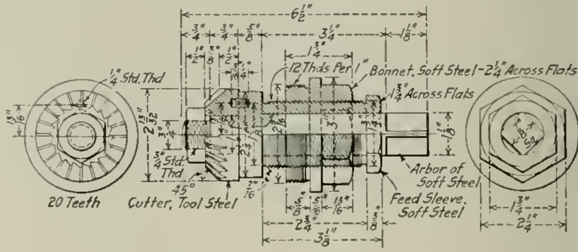

Fig. 3.—Reseating Tool for Ohio Boiler Checks

Mechanics' Association was a good move. When a standard practice was adopted by that body it was carried.

In the past eight years the members of the American Railway Tool Foremen's Association have attended meetings and returned to their respective homes and made reports to their local officials on these subjects, but unfortunately they did not get the co-operation that they should have received. As each of the tool foremen who attend these conventions receive instructions from their superiors to attend, they should be invested with such confidence that when they make a report to their superiors that a certain tool has met with approval of the association and been adopted as

Patt No	A	B		D	E	F	G	H	I	J	K	L	M	N	O	P	Q	R	S	T	Teeth U	Keyway V
LS 924	2"	2 5/16"		1 1/2"	1 3/4"	2 13/16"	1 1/8"	3"	3"	1 1/4"	2 1/4"	3 15/16"	3 1/8"	7/8"	2 3/8"	11/16"	3 9/16"	2 3/4"	5/8"	9 3/4"	30	3/16" x 3/16"
LS 2083	2 3/4"	3 1/8"		2"	2 3/8"	3 9/16"	1 1/2"	3 3/4"	3 3/4"	1 3/4"	2 3/4"	4 1/2"	4 1/8"	1 1/4"	3"	7/8"	4"	4 1/4"	7/8"	12 3/8"	40	1/4" x 1/4"

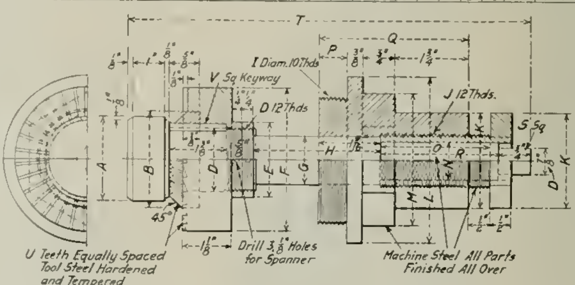

Fig. 4.—Boiler Check Reseating Tool

standard, the higher officers should put forth an effort to put this into practice. If we could standardize the tool equipment on all American railroads and use the same methods and practices there is no question that it would eliminate a great deal of the making of unnecessary tools. While I appreciate the fact that the tool room foremen and the superintendents of motor power have a certain amount of self-pride in the making of all tools for their respective railroads, nevertheless, the progressive man of today must be able to give and take whenever necessary in order that he may develop a method that will insure better production.

In the automobile industry, where all parts must be interchangeable, the first practice is to get the tools made to the standard before starting production and these tools are maintained to an extremely high standard of accuracy. If this is found to be good practice from a manufacturing standpoint, why is it not a good practice in the railroad shop? There is only one solution, and that is co-operation, and the insistence on the adoption of practical methods and standards.

On the Atchison, Topeka & Santa Fe, in order that we may get the proper results, it has been found very essential that the tools be standardized and, whenever possible, drawings are made of the tools and then submitted to the tool-room foreman.

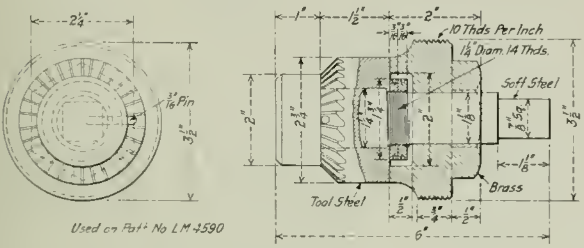

Fig. 5.—Boiler Check Reseating Tool

It is further found advisable that only tools which cannot be secured from the manufacturer for a reasonable price should be made in our tool room. It is not good practice for a railroad shop tool room to manufacture tools that can be secured from the manufacturers for the same price or less than it would cost to make them locally. In some shops such tools are made, but I consider it false economy due to the fact that there is a certain amount of loss incurred by the tool room, and when standard tools are secured from the factory all the possibility of loss is overcome, due to

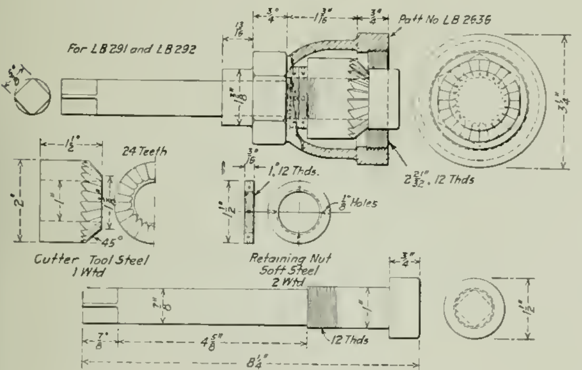

Fig. 6.—Reseating Tool for Blowoff Cock

the fact that all tools are furnished in first-class condition and free from flaws and defects.

There is a vast difference of opinion between railroads in regard to a standard locomotive frame reamer. The greatest difference seems to be in the length overall and in the taper. If a standard length and taper of locomotive frame reamers could be universally agreed on, it would be possible to eliminate the excess cost due to ordering the reamers as a special type from the manufacturer, as well as eliminating the carrying of many different lengths of reamers locally in the tool rooms.

For illustration, on the Sante Fe Lines a standard reamer has been adopted with a left-hand spiral flute and of a standard length that will take care of the maximum and minimum requirements. Heretofore, there were a great number of different lengths which have been eliminated by standardization. By the adoption of the left hand spiral fluted reamer, the breakage has been reduced to about 20 per cent. While using the straight fluted reamer trouble was encountered due to the chipping out of portions of the flute and also chattering, while now this has all been eliminated, for the left hand spiral retards the reamer to such an extent that it does not gouge or seize, especially while reaming steel frames on locomotives. All our reamers are tapered 1/16 in. in 12 in., and I feel confident that with the proper co-operation of the mechanical heads on the various railroads throughout the United States, this point could be agreed upon.

DISCUSSION

Several questions were raised regarding standard forms of reamers. There was some difference of opinion regard-

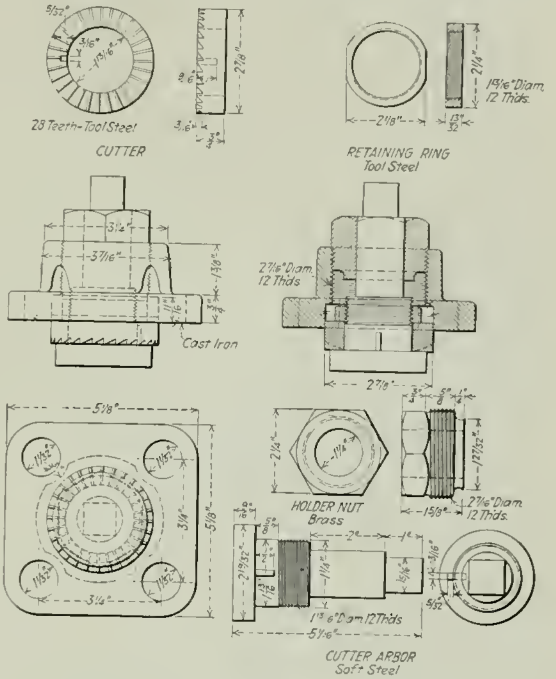

Fig. 7.—Reseating Tool for Blowoff Cock

ing the relative advantages of flute in the form of spirals having short and long pitches. The majority favored long spirals on reamers used with air drills, but the statement was made that the shorter spirals cut more rapidly, but required heavier thrust to feed them.

HEAT TREATMENT OF STEEL BY ELECTRIC FURNACES

BY HENRY OTTO
Tool Foreman, A. T. & S. F., Topeka, Kan.

There are in use at the Topeka tool room two high temperature electric furnaces and an oil tempering bath. The furnace used for extremely high temperatures has a carbon resister and carbon top plate. The service life of these plates is about 125 hr., while the graphite bottom plate and electrode have a life of about 300 working hours. This furnace is expensive to maintain as the high heat used cracks the walls inside of the carbon plate. This must be repaired, and it takes some time for the cement to dry so that the plates can be put back in place. This furnace has a range from 1000 to 2500 deg. F., but is seldom used above 2300 deg. F. In this furnace tools made of high speed steel are brought to the final heat.

A furnace of the hairpin heat unit type designed for lower temperatures is used for carbon steel tools. The maximum temperature secured in this furnace is 1800 deg. F. The heat units are easy to renew and the cost of maintenance is very low. It has been in constant use since March, 1917, and has had one renewal of the hairpin units since that time and one inner lining. It is the most used furnace in the tempering room. All carbon steel tools are heated for

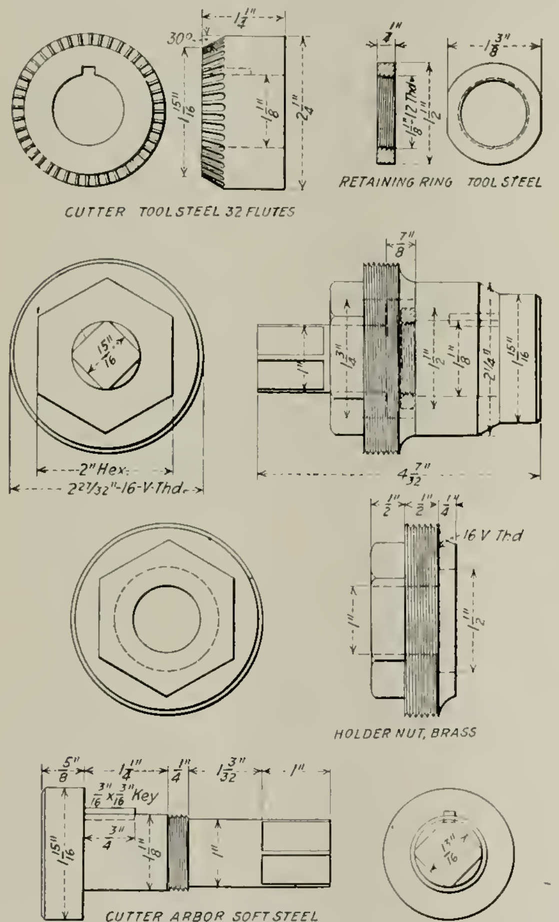

Fig. 8.—Reseating Tool for Throttle Ram Seat for Chicago Lifting Injector

hardening in this furnace and high speed tools are also preheated before going in the high temperature furnace.

The electric oil bath is a very necessary equipment in any up-to-date tempering room, as it draws the temper on carbon steel accurately. The oil is heated to the required temperature, the tool is left in the bath until it is heated through and then cooled in the atmosphere, after which it is ground.

When the blacksmith depended upon the color to judge the temperature at which to quench and draw tools, the work was often not done right. With electric furnaces and tempering bath and the pyrometer, the proper degree of heat can be secured and tools can all be uniformly tempered.

OTHER PAPERS

At the Thursday morning session W. H. Eisenman, of the American Steel Treaters' Society, spoke on the heat treatment of steel. He described the strange method followd by the alchemists in tempering steel, and traced later developments down to the introduction of alloy steel. He emphasized particularly the necessity for better heat treating equipment and the use of scientific methods in railroad shops. During the discussion which followed, much stress was laid on the importance of proper methods of forging and treating steel both for tools and for parts of locomotives or cars to be machined. E. J. McKernan (A. T. & S. F.)

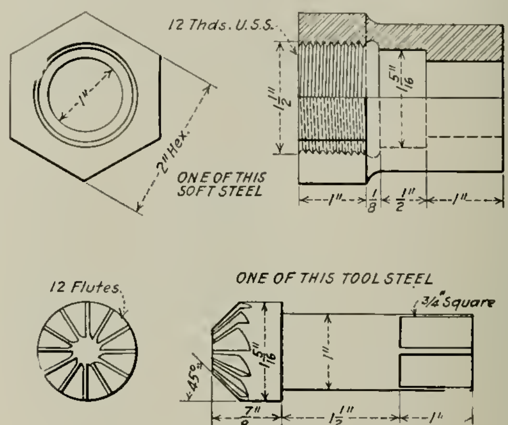

Fig. 9.—Reseating Tool for Lubricator Throttle Valve

stated that the use of pyrometers and scleroscopes had eliminated much of the trouble formerly experienced in hardening tools. F. Peterson (C. & S.) submitted a discussion of motors for tapping staybolt holes.

A discussion of the making of carbon steel forgings for tools was submitted by J. P .Fuhrmann (Great Northern). Descriptions of gages, tools and devices were also received from J. B. Hasty (A. T. & S. F.), A. Connell (K. C. S.), J. B. McFarland (N. Y. C. & St. L.) and J. Berling (S. P.).

GENERAL BUSINESS

The association discussed the advisability of amalgamation with the American Railroad Association, and a com-

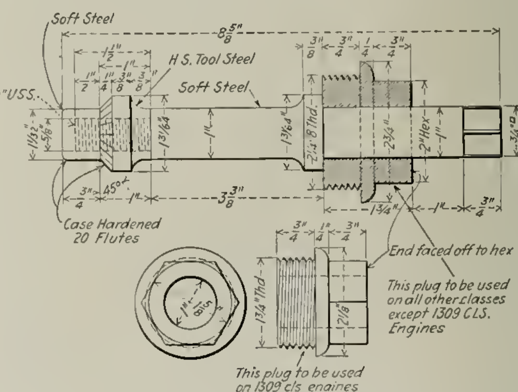

Fig. 10.—Reamer for Reseating Joints in Superheater Damper Cylinders

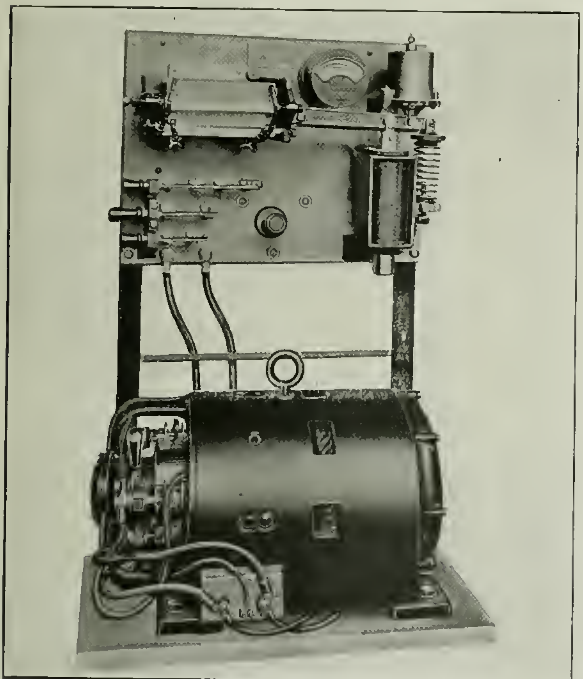
mittee was appointed to consider and report on that question. The secretary reported a substantial increase in the membership. The following officers were elected: President, J. C. Beville (E. P. & S. W.); first vice-president, J. B. Hasty (A. T. & S. F.); second vice-president, G. W. Smith (C. & O.); third vice-president, C. Helm (C. M. & St. P.); secretary-treasurer, R. D. Fletcher (Crucible Steel Company); chairman of executive committee, B. Hendrickson (C. & N. W.).

NEW DEVICES

THE PLASTIC-ARC WELDING OUTFIT

A new Plastic-Arc welding unit has just been brought out by the Wilson Welder & Metals Company, New York. This set is composed of a dynamotor and current control panel. The generator is flat-compound wound, and maintains the normal voltage of 35 on either no load or full load.

The control panel contains many new features. It has been designed to provide a constant-current controlling panel, small in size, of light weight, simple in operation and high in efficiency. The panel is of slate 20 in. by 27 in. and on it are mounted a small carbon pile, a compression spring and a solenoid working in opposition to the spring. The solenoid is in series with the arc so that any variation in current will cause the solenoid to vary the pressure on the carbon pile, thereby keeping the current constant at the value it is adjusted for. This gives a constant heat in the weld, and practically any metal can be welded without preheating or annealing.



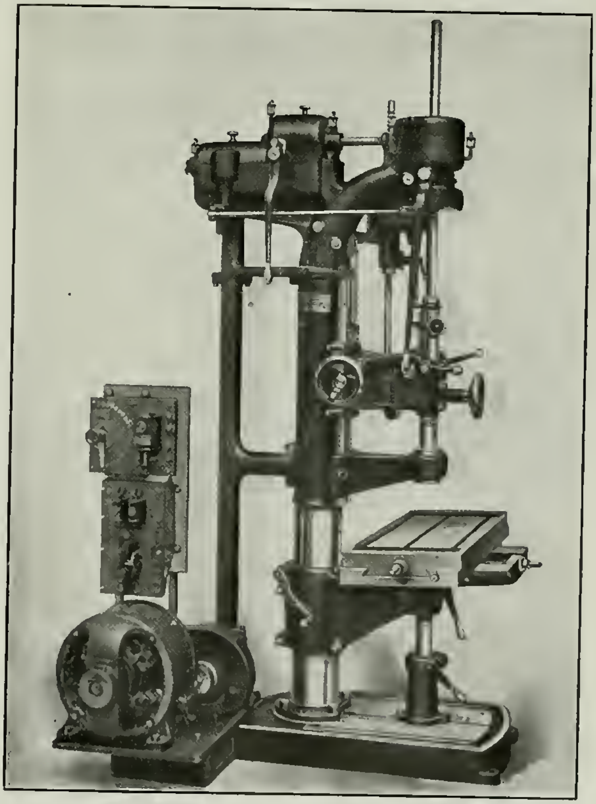
The Plastic-Arc Unit

Three switches on the panel provide an easy means of current adjustment between 25 and 175 amperes. The arrangement of the welding circuit is such that 25 amperes always flows through the solenoid when the main switch is closed whether the welding current is at the minimum of 35 amperes or the maximum of 175 amperes. The balance of the welding current is taken care of in by-pass resistances shunted around the solenoid.

This outfit can be furnished as a dynamotor unit, with standard motor characteristics, as follows: 110 volts 220 volts, DC or 220 440 volts, 60 cycle, two or three-phase, AC, also as a gasoline-driven unit, or it can be furnished without a motor, to be belt-driven. The normal generator speed is 1,800 r. p. m. The net weight of this new outfit in standard characteristics is 800 lb. with DC motor, 807 lb. with AC motor, 1,200 lb. with a gasoline engine, and 550 lb. as a belted outfit without motor. These new dynamotor sets can be mounted on a truck if desired, thus making a portable outfit.

THE FOSDICK HEAVY DUTY UPRIGHT DRILL

The Fosdick Machine Tool Company, Cincinnati, Ohio, have added to their line a new design of upright drilling and tapping machine. In general appearance the machine is similar to the average modern upright drill, but the characteristics are entirely different. The gearing arrangements, frictions, feeds, quick return, etc., are similar in detail to

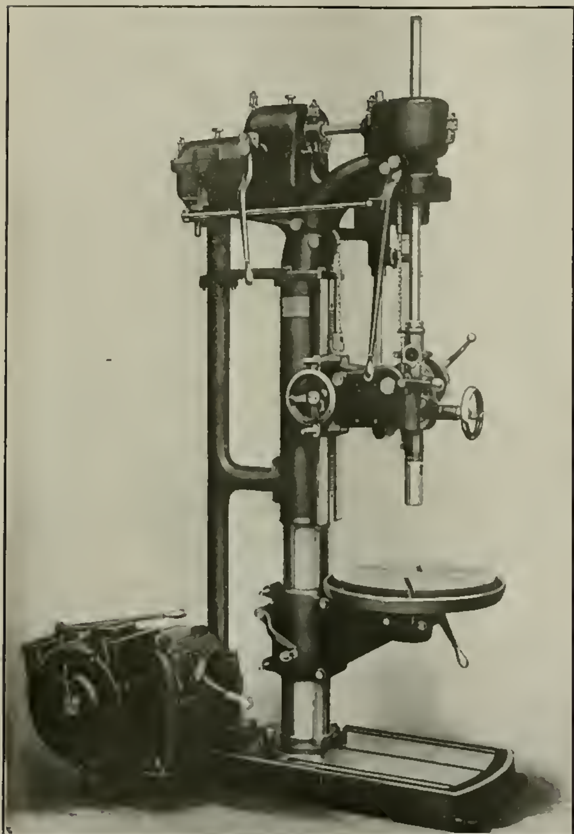


Variable Speed Motor Driven Machine with Compound Table the corresponding parts which are being used on Fosdick heavy duty radial drills.

The illustrations show the regular constant speed belt driven machine with round table, and the variable speed motor driven machine with compound table with micrometer dial adjustments and the vertical milling support. These have a capacity of 25 in. diameter of work and the weight is about 2,350 lb., and they are driven by a 7½-hp. constant speed motor.

The base of this machine is surrounded by a channel draining to a large reservoir for drilling compound, and is so designed that bolts may be entered from either end of the T-slots.

The table arm has an unusually long bearing on the column and is internally ribbed similar to a bridge or roof truss



Constant Speed Belt Driven Machine with Round Table

which greatly increases the rigidity. The table is raised and lowered from either side of the machine, may be swung around the column to clear the base for large work and cannot accidentally drop when unclamped. The unique arrangement of the table T-slots allows them to terminate very close to the center, allows heavy ribs to run directly toward the hub, permits work of any shape to be securely clamped and prevents bolts from flying out should they become loosened while drilling.

The spindle head is raised and lowered by a handwheel, and not being burdened with the heavy feed arrangement, is perfectly counterbalanced. The spindle is provided with a depth gage and automatic trip which may be set to graduations in any position in the entire length of travel. A safety trip at the limit of traverse prevents accidents. The spindle quick return acts instantly, requires but one hand to operate for sensitive drilling, for tapping, for rapid lowering or return of the spindle, with or without disengaging the power feed or the hand wheel feed.

Five feeds are obtainable ranging from .004 in. to .028 in. per revolution of spindle. The power feeds are all obtained by a single lever, within easy reach of the operator while seated, although it has been placed high enough not to interfere with the operating levers on the head. The hand feed may be fed ahead of the power feed without disengaging the latter. This is particularly advantageous in starting large drills.

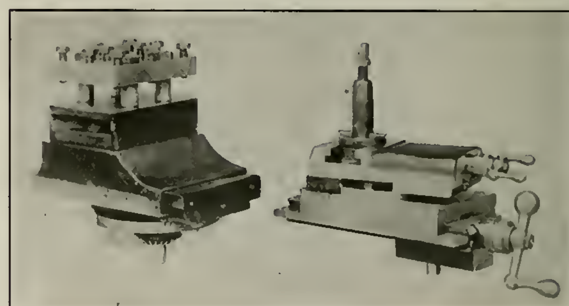
The friction reverse tapping mechanism is embodied in the construction of all machines, and being placed between the initial drive and the back gears, the power transmitted to the spindle is six times as great as in the spindle friction type. The bronze bearings are driven in bored holes, no babbitt metal being used in the machine. Ball bearings take the principal thrusts, including the spindle, both crown gears, the vertical driving shaft and friction bevel pinion, the feed worm and feed bevel gear. A metal chart showing speeds and feeds for high speed work is attached to each machine.

The machine is driven by a constant speed belt through the gear box, which furnishes correct cutting speeds for drills ranging from 3/16 in. carbon to 2½ in. high speed, with slower speeds for heavy tapping and for boring up to 5 in. diameter. Twelve spindle speeds are obtainable ranging from 49 to 550 r.p.m. Constant or variable speed motors may be supplied even after a belt driven machine is installed, as all styles of drive are interchangeable without requiring a special base. Pump and piping for drilling compound include a flexible tube to the point of the drill.

THE MULTI-CUT SERVICE LATHE

The R. K. LeBlond Machine Tool Company, Cincinnati, Ohio, have developed a semi-automatic lathe which has many distinctive features. As its name signifies, a number of tools are in operation at the same time. The machine is easily and quickly set up. There are no cams either fixed or adjustable to consider. One or more facing and turning operations can be performed simultaneously, one operator running several machines.

The work may be centered, held on arbors, expansion or



Multiple Tool Blocks

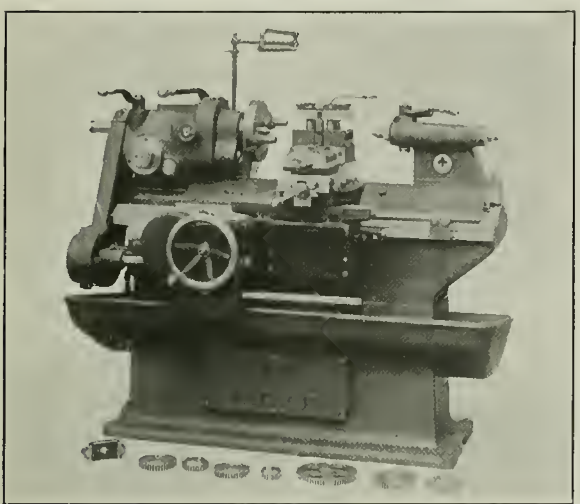
closer chucks, either pneumatic or hand-operated. The Multi-Cut is specially adapted to work that has been previously bored, reamed and rough turned on the turret or automatic lathe and remains to be finished, turned and faced.

PLAIN AND UNIVERSAL FACING ATTACHMENT

The plain facing attachment faces diameters up to the full swing of the lathe at right angles to the turning center. The feed of the facing slide is obtained entirely by the relative movements of flat and dovetail slides accurately gibbed and adjustable to compensate for wear. The facing rest is fed towards the center of the lathe on a broad square lock slide to which it is accurately gibbed. The cross facing slide is movable along the bed and may be rigidly clamped to the shears in any desired position.

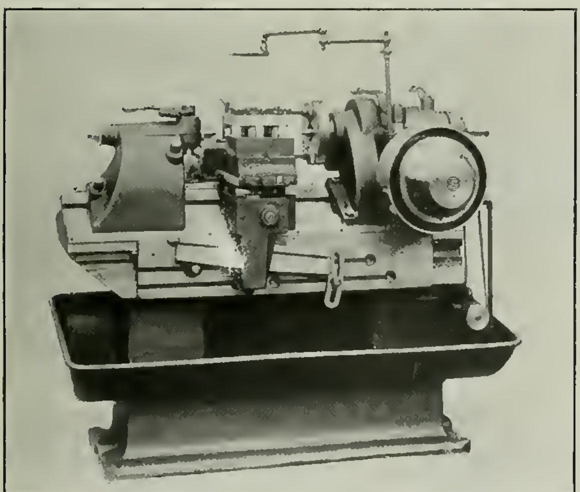
The facing bar slide carries the swivel guide bar which is fed along the bed at varying rates of speed.

A sliding shoe on the facing attachment slide engages the swivel guide bar which may be sent at any angle within the



Multi-Cut Lathe No. 9

range, imparting a vertical motion to the shoe which is transmitted through a rack and pinion to the cross slide. By changing the angularity of the swivel guide bar the feed of the cross slide may be varied to complete its work at the same time as the turning slide or may be accelerated to finish ahead of the turning slide to permit of overlapping on form-



Rear View of Lathe Showing Right Angle Drive

ing and turning tools or it may be retarded to finish after the turning slide.

The feed to both turning and facing slide are tripped by the same clutch and will duplicate within close limits of accuracy.

The standard tool block furnished is arranged for multiple tools which can be held parallel or at any angle by reason of the spacing of the binder screws. The tool block is adjustable to the center of the lathe and firmly clamped in position by two heavy bolts.

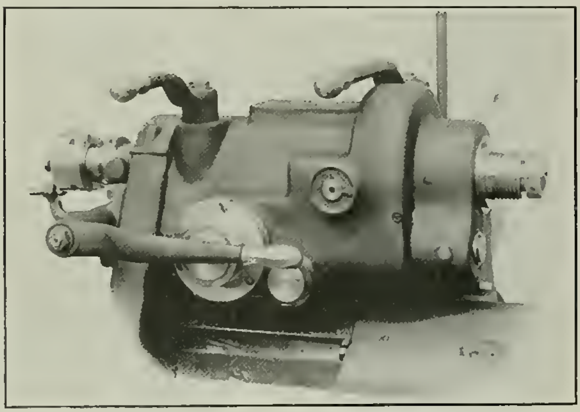
The universal facing attachment, as its name indicates, is adapted to angular facing operations on bevel gears, etc. When used in connection with a taper turning attachment the back and face angles can be turned simultaneously.

The swivel block is accurately graduated to facilitate angular settings and clamped firmly in the selected position by two heavy T slot bolts. The feed is through a pair of miter gears to the feed rack. Aside from this swivel feature the universal attachment and tool blocks are identical with the plain attachment.

Variations in feed for turning and facing slides are obtained by loose change gears applied to the feed bracket and worm box. The feeds read in "thousandths per revolution of spindle," and a simple, direct reading shows the change gear combinations and the resulting feeds.

The feeds of the front slide are fixed by the change gears used while the feeds of the facing slide may be further varied with relation to the feed of the turning slide by the angularity given the swivel guide bar.

The feed worm and wheel are on fixed centers and encased in an oil tight gear box rigidly bolted to the bed. The feeds are tripped to a line by a sensitive acting positive



Style B Headstock with Draw-in Attachment

jaw clutch heat treated and hardened engaging a similar clutch mounted on the worm wheel.

The feed drive is then through changeable gears and a pinion and bull wheel to the rack on the carriage. The drive to the facing slide is through similar change gears through the bed to the feed rack on the facing attachment slide on which the swivel guide bar is mounted.

The feed rack for both carriage and facing attachment is placed in the center of the slides imparting a feed without the usual binding action occasioned by applying the power off the center of the guiding shears.

The handwheel at the front of the worm box provides means of quickly returning the turning and facing slides to the starting position after the completion of each cut.

The worm wheel and clutch are running continuously in oil and the thrust of the worm is taken against ball thrust bearings.

The taper turning attachment consists of a rigid bracket bolted to the front of the bed, which carries an adjustable taper guide bar and a sliding shoe engaging the guide bar. The sliding shoe is attached to a cross slide imparting to it an "in" or "out" movement with relation to the angular setting of the guide bar. The guide bar may be set from straight to 4½ in. taper per ft., either side of center and clamped in the selected position by two heavy T slot bolts. The taper guide bar and sliding shoe may be replaced by a form plate and roller for the automatic duplication of irregular shapes.

The style B headstock is 6-speed selective geared, right angle driven. Three instantaneous changes are obtained with one lever, a shifter knob compounding these changes through a back gear for 6 speeds. The headstock is oil tight, the gears and friction clutches running in a continual bath of oil. The spindle bearings and driving clutch are also continuously flooded with oil from this same supply. The main friction clutch is mounted in the driving pulley, where it is operating at a constant high rate of speed and subject to little strain. It is of the multiple disc type running in oil, with a brake operating from the clutch handle. The driving pulley shaft is at 9 deg. to the spindle to permit of a more compact grouping of the machines. The spindle is fitted with taper bronze boxes, babbitt lined with means of adjustment for wear. The thrust is taken against ball thrust bearings.

A plain block rest, mounted on the cross slide, equipped with a single screw tool post and an adjustable positive cross stop, or a compound rest is supplied as conditions may require. The swivel is large in diameter and graduated in degrees for angular turning or taper boring. Adjustable taper gibs are provided to compensate for wear on the slides.

A quick lever acting tailstock is provided to permit of the quick removal and replacing of work with a single movement of the operating handle.

The center of the tailstock is brought into contact with the work at any desired pressure, by a conveniently placed lever, further movement of the same lever rigidly locking the tailstock barrel and clamping the spindle.

The bed is of a special anvil section, with broad slides for the carriage and bearings for the head and tailstock, and is strongly ribbed internally and mounted on a cabinet base, in which the pan and chamber for cutting compound is cast. The pan becomes an integral part of the bed, and greatly stiffens the entire machine. A strainer separates the chips from the cutting compound, which flows back to the base of the machine. A geared rotary pump and piping for circulating the compound is supplied as regular equipment.

A cover plate is provided for cleaning out the base.

The carriage is a broad slide extending practically the full length of the bed and scraped to a bearing its entire length. The cross slide for mounting the compound or plain rest is massive and cast integral with the carriage. The head and tailstock are located and carried by the rear shear permitting the carriage to travel past them and keep the slides continuously covered.

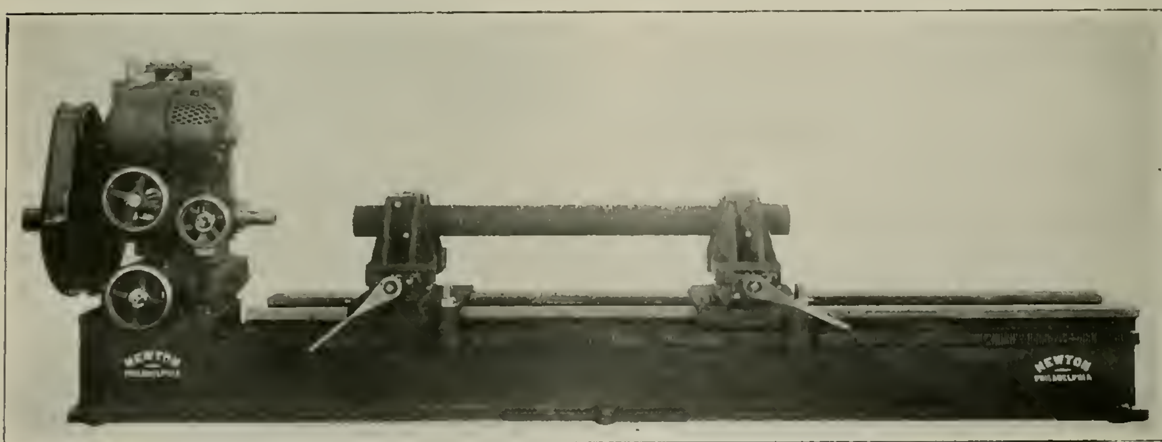
The Multi-Cut lathe is built in two sizes, No. 6, 6-in. swing, 10-in. capacity between centers, and No. 9, 9-in. swing, 16-in. capacity between centers. Several types of headstocks are supplied for each machine.

Some of the headstocks may be motor driven. The motor is attached to a motor plate hinged from the cabinet base of the machine and provided with an adjustable jack for maintaining the desired belt tension.

A constant speed motor A.C. or D.C. running preferably 1,200 r.p.m. is recommended.

NEWTON CENTERING MACHINE

The centering machine shown in the illustration is a recent development of the Newton Machine Tool Works, Philadelphia, Pa. It is designed for centering rough and irregular castings. The spindle is of forged steel 3 in. in diameter, running in bronze bushed bearings and having an 8-in. horizontal hand feed. The maximum distance from the center of the spindle to the top of the base is 17½ in. and the minimum distance 13½ in., giving a vertical adjustment of 4 in. The spindle also has a cross adjustment of 4 in., equally divided each side of the center line of the work. Two universal centering vises of the interlocking type and adjustable on the bed are supplied with the machine. The jaws are adjustable by means of a screw giving a capacity for stock from 2 in. to 12 in. in diameter and of any desired length. The alinement of all of the movable parts is maintained by adjustable tapered shoes. The drive is by direct connected motor through bronze driving gear. The base of this machine is 22 in. wide and 16 ft. long.



The Newton Centering Machine with Round Stock in the Vises

Machine Tools in France.—Before the war the majority of machines imported into France came from Germany. In 1913, France imported 28,000 machine tools at a value of 52,000,000 francs, 50 per cent of which came from Germany. During the same year 11,000 machine tools, valued at 16,000,000 francs, were exported from France. Machine tools to the value of 65,000,000 francs were produced in France in 1913. It is planned that the French aeroplane factories will be converted into plants for the manufacture of machine tools.—*Le Génie Civil.*

THE RAILWAY MECHANICAL ENGINEER is a member of the Associated Business Papers (A. B. P.) and the Audit Bureau of Circulations (A. B. C.).

The Seaboard Air Line has decided to use oil fuel in the locomotives on its lines south of Hamlet, N. C., and has contracted for a supply of oil from Mexico.

A plan for preventing strikes, similar to that embodied in the Canadian law, is provided in a bill, H. R. 9062, introduced in Congress by Representative Wood of Indiana. It provides for the appointment by the President of commissions to investigate labor controversies and would prohibit a strike or lockout pending the conclusion of any investigation by a commission.

The Central Railway Club's annual outing at Grand Island, N. Y., on August 28, was voted one of the most enjoyable in the history of the organization by the 160 members who attended. A brief business session was held, during which announcement was made that the campaign for a membership of 1,000 has been progressing so well that only about 100 more are required to bring the membership list up to the desired number.

Dr. John D. Robertson, health commissioner of the city of Chicago and head of the Smoke Prevention Bureau, recently declared, in connection with a smoke prevention drive he is now conducting, that smoke from locomotives in the city of Chicago must be eliminated. A recent newspaper statement quotes him as saying: "I don't care how the railroads end the smoke nuisance. They can use smokeless coal, change their boilers or do anything they desire, but the smoking engines must stop. No excuses will go." Railway executives, master mechanics, and locomotive firemen and engineers were called into conference in Doctor Robertson's office and plans were formulated for reducing the smoke nuisance insofar as the railroads entering Chicago are concerned.

A delegation representing the railroad shopmen recently called upon Governor J. P. Goodrich of Indiana and urged the establishment of a state mediation committee to investigate strikes and threatened strikes before calling out state troops "unnecessarily." It was pointed out that great expense could have been saved the state had troops not been sent to Hammond, Ind., to end the recent disorders resulting from the strike of employees at the plant of the Standard Steel Car Company. This contention, however, was not concurred in by the governor, who acted without hesitation when local authorities at Hammond admitted their inability to preserve order. Governor Goodrich has taken the matter under advisement and will hold further conferences with the shopmen's representatives.

Arbitration Rules

The Arbitration Committee of the Mechanical Section of the American Railroad Association, calling attention to requests for interpretations and for arbitrations that are not prepared in accordance with the rules, promulgates the following general rules:

1. Requests for interpretation of the Rules of Interchange must be signed personally by the chief mechanical officer of the railroad or company. Questions received from car foremen, bill clerks, inspectors and others in a minor capacity, will not be considered. Many of the questions raised by these minor officers could and would be settled by the chief mechanical officer without being referred to the arbitration committee.
2. In presenting requests for interpretation, all facts in the case should be clearly stated, and, wherever possible, repair cards and other records involved should accompany the letter.
3. Where the question for interpretation is the result of a controversy with another company, the name of the other company should be given in order that the committee may, if necessary, request additional information from both parties to the dispute. Several requests for interpretation of the rules have been presented recently that were in reality disputes that should have been prepared as arbitration cases.
4. All cases presented for arbitration should be prepared in accordance with provisions of Interchange Rule 123. Both parties to the dispute should join in presenting the case. The entire file, including original repair cards, joint evidence certificates, etc., should accompany the prepared statements.

Safety Appliances and Loading Rules

The Interstate Commerce Commission has extended the effective date of its latest order requiring the railroads to make their freight cars conform to its standards of safety appliance equipment, from September 1, 1919, to March 1, 1920. This was done at the request of the Railroad Administration and the American Railroad Association.

The Mechanical Section of the American Railroad Association has therefore changed the effective date of sections G and K of Rule 3 of the 1918 Code of the Rules of Interchange from September 1, 1919, to March 1, 1920. A correction has also been made in Supplement No. 1 to the loading rules. In Figs. 42 and 46, accompanying this supplement, half-inch bolts are shown passing vertically through the ends of the clamping pieces to prevent splitting. These bolts should be applied horizontally instead of vertically, as shown in the drawings.

American Society for Testing Materials

Society headquarters have been established by this association at the Engineers' Club building, 1316 Spruce street, Philadelphia, Pa. Offices were heretofore at the University of Pennsylvania.

The membership of the society has passed the 2,500 mark, now numbering 2,538. While the growth of the society has been steady, it has never been as rapid as during the present year, during the first eight months of which 313 new members were enrolled.

In accordance with the policy inaugurated in 1917 the tentative standards of the society will be published in Part I of the proceedings, and will also be published in a separate volume for the convenience of those who may wish to use them in that form. The 1919 edition will contain the 62 specifications, tests, methods and definitions which have been accepted by the society as tentative, of which 23 are new this year and nine have been revised. This volume will comprise about 350 pages, and is expected to be available for distribution in November, about a month earlier than the proceedings.

Conditions Affecting Trade with Siberia

Numerous inquiries have been received in Washington regarding the conditions and regulations surrounding trade with Siberia. In order to clear up certain misapprehensions regarding trade with this region the following notes have been compiled by the Foreign Trade Advisers' Office of the Department of State.

The so-called Allied Purchasing Committee, of which Capt. George E. Spengler is chairman, is a subcommittee of the Interallied Technical Board of the Committee for Supervision of the Chinese Eastern and Transsiberian Railways. This committee will make purchases of supplies and materials for the Siberian railways by direction of John F. Stevens, president of the Technical Board of the Interallied Committee. All orders for material to be purchased in the United States for use in connection with the railways will be placed by the committee through the Director General of Military Railways, War Department. This committee has nothing to do with purchases of other than railway material and supplies. The Director General of Military Railways is in close touch with all American manufacturers and is in a position to expedite orders for badly needed supplies.

Equipment Conditions on Russian Railways

In January, 1916, there were still 72,743, and in January, 1917, 70,118 freight cars, running daily; in January, 1918, this number had decreased to 16,644, and in January, 1919, it had sunk to 13,193 cars. The working capacity of the engines has fallen off in a similar degree. In 1918 they were capable of travelling only about 35 miles per day. The workshops were obliged to hand over important parts of their machinery to the munition workshops. This absence of necessary machinery and instruments is especially felt in the locomotive shops. The number of railway engines out of repair amounted in March, 1916, to 17.3 per cent; March, 1917, 23 per cent; March, 1918, 35.3 per cent; March, 1919, 52.4 per cent. The number of freight cars out repair amounted in March, 1916, to 3.4 per cent; March, 1917, to 5.4 per cent; March, 1918, to 9.1 per cent; March, 1919, to 18.8 per cent.

The railway bridges and railway lines are also in a state of decay and have in some cases been badly damaged as a result of civil war. Little is heard in the press of the numerous accidents that take place in consequence of trains running off the lines. The work of repair is often hindered by the passive resistance of railway workers antagonistic to the Soviet regime. For lack of raw material, the number of engines built in 1918 was considerably reduced. In 1917, 520 locomotives were able to be built in Russian foundries, but only 191 in 1918, 152 of which were intended for goods traffic, and only 39 for passenger trains. Since the taking of the Urals by Kolchak's army, the production of pig-iron for rails has entirely ceased as far as the requirements of Soviet Russia are concerned and few new lines can be built.

Lack of Railroad Facilities Hampers All Eastern Europe

"Transportation is the chief difficulty alike in relief work and reconstruction throughout eastern Europe. Adequate railways in the Balkan States would unlock great natural resources and open up endless possibilities. The next decade in this part of the world must be an era of railroad building if the people are to live and prosper."

This paragraph, quoted from the monthly report of the American Red Cross mission at Bucharest, says a correspondent to the Philadelphia Public Ledger, points out the most serious problem which faces the new governments of the countries of eastern Europe. There are at present fewer than 100 trains in the whole of Rumania and no more than 400 locomotives, counting every available engine—good, bad and indifferent.

The most luxurious train in Rumania today includes one first-class coach and three coaches of a nondescript third-class type. Thousands of men are at work repairing the lines, but their work is hampered by lack of material. Bridges by the score were destroyed during the war by both Rumanians and Germans. These have been repaired in part only. Trains in Rumania creep along at one-third the old-time speed, with peasants and other travelers riding wherever they can find foot room, either on the steps of the coaches, on the couplers or on the roof.

As a rule, about 50 persons are accommodated on the roof of each coach. This is fine enough in fair weather, until the train pulls into a tunnel, when the roof-riders and those on the steps are half asphyxiated by the thick black coal smoke that pours from the locomotive. The locomotives used fuel oil before the war, Rumania being an oil-producing country; but the Germans took away all the oil burners from the engine fire-boxes and the locomotives have to get along now as best they can with whatever fuel is available.

It is reported in Berne that more than 50 German and American locomotives will shortly be sent from France through Switzerland to Rumania and Poland to supply the urgent need for engines in those countries. Rumanian en-

RAILROAD CLUB MEETINGS

Club	Next Meeting	Title of Paper	Author	Secretary	Address
Canadian	Oct. 14			W. A. Booth	131 Charron Street, Montreal, Que.
Central	Nov. 13	Annual dinner		H. D. Vought	95 Liberty Street, New York.
Cincinnati	Nov. 11	Annual banquet and entertainment		H. Boutet	201 Carew Building, Cincinnati, Ohio.
New England	Oct. 14	Shop Efficiency	Frank McManamy	W. E. Cade, Jr.	683 Atlantic Ave., Boston, Mass.
New York	Oct. 17	Utilization of Freight Cars	W. C. Kendall	H. D. Vought	95 Liberty Street, New York.
Pittsburgh	Oct. 23	Annual meeting and election of officers		J. D. Conway	515 Grandview Avenue, Pittsburgh, Pa.
St. Louis	Oct. 10	Can the Railway Problem Be Solved?	S. O. Dunn	B. W. Frauenthal	Union Station, St. Louis, Mo.
Western	Oct. 20	Design, Inspection and Maintenance of Freight Car Equipment	L. K. Sillcox	J. M Byrne	547 West Jackson Blvd., Chicago.

gine drivers have already arrived in France (says a (London) Times correspondent) to take charge of some of these locomotives.

Shortage of German Rolling Stock

The Technical Supplement to the Review of the Foreign Press (London) publishes an extract from the Kolnische Zeitung of June 15, giving an account of the causes for the shortage of German rolling stock.

"In the Ruhr district there are renewed complaints as to the 'shortage of wagons.' This expression is generally used to express a state of things for which it is not really appropriate. There seems rather to be a shortage of locomotives to bring the wagons to the places where they are required than a shortage of wagons themselves. The terms of the armistice, requiring the surrender of so many locomotives, are responsible for this.

"The Prussian Railway Administration meanwhile has given orders for 2,463 new locomotives, and the engine works are doing their best to deliver them. On the whole they have executed the orders satisfactorily. The reason why the stock of locomotives is not increasing is explained by the bad condition of the old engines, the result being that every week as many come to be repaired as have been sent out from the repair shops. There is an incontestable shortage of passenger carriages. The Railway Administration has consequently ordered 2,896 coaches and 45,000 freight cars. The total orders given amount to 2,000,000,000 marks. But even by these orders the stock of locomotives and wagons is brought to its proper level, the whole difficulty is by no means solved. There is not a trained personnel available to enable such a stock of wagons to be utilized as fully as necessary. This problem is rendered more acute by the eight-hour day difficulty, while the abolition of piece-work delays the repairs to the rolling stock. Then there are the constant interruptions to work by elections, meetings and councils. The unsatisfactory state of things in the railway world is another of the 'achievements' of the revolution."

MEETINGS AND CONVENTIONS

The following list gives names of secretaries, dates of next or regular meeting, and places of meeting of mechanical associations:

Air-Brake Association.—F. M. Nellis, Room 3014, 165 Broadway, New York City.

American Railroad Association, Section III—Mechanical.—V. R. Hawthorne, 431 South Dearborn St., Chicago.

American Railroad Master Tinners', Coppersmiths' and Pipefitters' Association.—O. E. Schlink, 485 W. Fifth St., Peru, Ind.

American Railway Tool Foremen's Association.—R. D. Fletcher, Belt Railway, Chicago.

American Society for Testing Materials.—C. L. Warwick, University of Pennsylvania, Philadelphia, Pa.

American Society of Mechanical Engineers.—Calvin W. Rice, 29 W. Thirty-ninth St., New York.

Association of Railway Electrical Engineers.—Joseph A. Andreucetti, C. & N. W., Room 411, C. & N. W. Station, Chicago.

Car Foremen's Association of Chicago.—Aaron Kline, 841 Lawler Ave., Chicago. Meetings second Monday in month, except June, July and August, Hotel Morrison, Chicago.

Car Foremen's Association of St. Louis.—Thomas B. Koeneke, secretary, Federal Reserve Bank Bldg., St. Louis, Mo. Meetings first Tuesday in month at the American Hotel Annex, St. Louis.

Chief Interchange Car Inspectors' and Car Foremen's Association.—H. J. Smith, D. L. & W., Scranton, Pa.

International Railroad Master Blacksmiths' Association.—A. L. Woodworth, C. H. & D., Lima, Ohio.

International Railway Fuel Association.—J. G. Crawford, 542 W. Jackson Blvd., Chicago.

International Railway General Foremen's Association.—William Hall, 1061 W. Wabasha Ave., Winona, Minn.

Master Boilermakers' Association.—Harry D. Vought, 95 Liberty St., New York.

Master Car and Locomotive Painters' Association of U. S. and Canada.—A. P. Dane, B. & M., Reading, Mass.

Niagara Frontier Car Men's Association.—George A. J. Hochgrebe, 623 Brisbane Bldg., Buffalo, N. Y. Meetings, third Wednesday in month, Statler Hotel, Buffalo, N. Y.

Railway Storekeepers' Association. J. P. Murphy, Box C, Collinwood, Ohio.

Traveling Engineers' Association. W. O. Thompson, N. Y. C. R. R., Cleveland, Ohio.

PERSONAL MENTION

GENERAL

W. P. Christie has been appointed superintendent of safety of the Toledo, St. Louis & Western, with headquarters at Frankfort, Ind., succeeding F. E. Myers, resigned.

William D. Hannah, chief fuel inspector of the Grand Trunk, with headquarters at Montreal, Que., has retired after 40 years of continuous service with that road.

A. H. Kendall has been appointed master mechanic of the Quebec district of the Canadian Pacific, with office at Montreal, Canada, succeeding C. A. Wheeler, transferred

R. W. Lipscomb, assistant superintendent on the Galveston, Harrisburg & San Antonio, at El Paso, Texas, has been appointed chief assistant mechanical superintendent on the Southern Pacific Louisiana Lines and Texas Lines, with headquarters at Houston, Texas, succeeding J. P. Nolan, retired on pension.

J. J. Maginn, formerly master mechanic of the Cincinnati Northern at Van Wert, Ohio, has been appointed superintendent of motive power of the Lake Erie & Western, with headquarters at Lima, Ohio, succeeding George J. Duffey, deceased.

CAR DEPARTMENT

C. J. Nelson has been appointed general foreman of the car department on the Chicago & North Western, in charge of the Galena and Wisconsin divisions and Chicago Terminals, succeding L. R. Wink.

L. R. Wink, general foreman of the car department on the Chicago & North Western, has been appointed assistant superintendent of the car department, with offices at Chicago.

SHOP AND ENGINEHOUSE

L. B. Shearer has been appointed tank shop foreman of the Erie Railroad at Huntington, Ind., succeeding J. E. Shavey, transferred.

PURCHASING AND STOREKEEPING

F. A. Hamilton has been appointed purchasing agent of the Colorado Springs & Cripple Creek District Railway, with headquarters at Colorado Springs, Colo.

T. C. Hopkins has been appointed local storekeeper of the Baltimore & Ohio at Cleveland, Ohio, succeeding L. F. Ryan, resigned.

J. A. Laughlin, storekeeper of the New York Central, Lines West of Buffalo, at Elkhart, Ind., has been appointed an assistant general storekeeper at Collinwood, Ohio.

W. A. Miller has been appoinated division storekeeper on the Southern Railroad, with office at Spencer, N. C., succeeding C. J. Norman, deceased.

Henry Stephens has been appointed an assistant general storekeeper on the New York Central, Lines West of Buffalo, with headquarters at Collinwood, Ohio.

OBITUARY

Edward Salley, supervisor of locomotive operation on the New York division of the Erie Railroad, died on August 13 at his home in Jersey City, N. J., at the age of 74. Mr. Salley had been in the employ of the Erie for more than 50 years, for the past 15 years as supervisor of locomotive operation.

SUPPLY TRADE NOTES

Richard Pintsch, inventor of the Pintsch gas lighting system, is reported to have died recently at Berlin, Germany, at the age of 80.

The American Locomotive Company is planning to carry out improvements to double the capacity of its steel plant at Chester, Pa. The work will cost about $1,000,000.

The Hutchins Car Roofing Company, Chicago, has opened an office in the Railway Exchange building, St. Louis, Mo., in charge of Charles F. Pace as district sales manager.

S. B. Andrews has resigned as mechanical engineer of the Seaboard Air Line at Portsmouth, Va., and has been elected vice-president and general manager of the Union Iron Works, Inc., Berkley-Norfolk, Va.

George A. Cooper, of the sales and advertising department of the United States Graphite Company, Saginaw, Mich., has been appointed advertising and export manager of the Detroit Lubricator Company, Detroit, Mich.

Paul Mitchell has resumed his duties as traveling representative of the Chicago sales office of the Independent Pneumatic Tool Company, Chicago. Mr. Mitchell was a sergeant in the American Expeditionary Forces in France.

H. W. Johns-Manville Company, New York, has commenced excavating for a large plant at Waukegan, Ill. No contracts have been let for the building itself as the type of construction and the specifications have not been fully decided upon.

E. M. Cutting, Pacific coast manager for the Edison Storage Battery Company, with office at San Francisco, Cal., has been appointed manager of the railroad department with office at Orange, N. J. Mr. Cutting entered railway work in 1888 in the signal department of the Southern Pacific. In 1898 he was appointed supervisor of signals for the Western division and in 1902, in addition to his duties in the signal department, he was given charge of all electric train lighting. In 1908 he became engineer of train lighting, heating and ventilation, resigning in 1912 to become Pacific coast manager for the Edison Storage Battery Company, which position he held until his recent promotion. Mr. Cutting was instrumental in initiating the movement which culminated in the formation of the Association of Railway Electrical Engineers, of which he was elected president in 1909.

E. M. Cutting

D. B. Fulton, assistant to the chief engineer of the American Brake Shoe & Foundry Company, New York, has entered the sales department of the Railway Steel Spring Company, Chicago, where he will be associated with N. C. Naylor, sales agent in the Chicago office.

The Carborundum Company, Niagara Falls, N. Y., has opened a branch office and warehouse in the Burkhardt building at Second and Larned streets, Detroit, Mich. This branch is under the management of Anthony Dobson, who will have charge of the Detroit sales district.

The Pollak Steel Company, Cincinnati, Ohio, has appointed the Lake Shore Engine Works, Marquette, Mich., as its agent for the upper peninsula of Michigan, and the E. R. Hensel Steel & Copper Company, Security building, St. Louis, Mo., agents for the St. Louis district.

George W. Bender, district manager in charge of the New York office of Mudge & Co., Chicago, has been promoted to manager of sales and service with headquarters in Chicago. Mr. Bender was born at Pittsburgh, Pa., on August 20, 1884. At the age of 17, he entered the engineering department of the Pressed Steel Car Company of that city. In 1906, he accepted a position with the American Locomotive Company, where he had charge of the extra work order department. In 1910 he became associated with Mudge & Co. as chief draftsman, and subsequently was given charge of the mechanical department. Later he was made assistant to the vice-president, a position he held until his appointment in April, 1918, as eastern manager in the New England and Atlantic Coast states, in which capacity he served until his recent promotion.

George W. Bender

Paul Sutcliffe, advertising manager of the Edison Storage Battery Company, Orange, N. J., has been appointed manager of the industrial truck and tractor department of the same company. Mr. Sutcliffe has been with the Edison Storage Battery Company for the past five years.

The Bucyrus Company, South Milwaukee, Wis., announces that it has opened a Cleveland office at 808 American Trust building in charge of E. G. Lewis, formerly with the New York office of the Bucyrus Company and more recently president of the New Jersey Slag Products Company, of Dover, N. J.

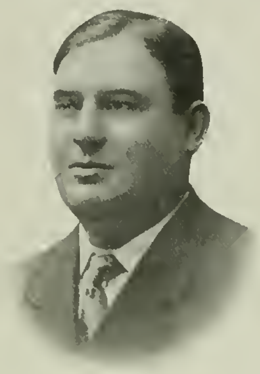
The Chicago Pneumatic Tool Company, Chicago, has removed its Cincinnati (Ohio) office from the Mercantile Library building to the Walsh building, Pearl and Vine streets, where a service station with a complete stock of pneumatic tools, electric tools, air compressors, oil engines, rock drills and repair parts will be maintained.

E. G. Buckwell, secretary and manager of sales of the Cleveland Twist Drill Company, Cleveland, Ohio, has recently returned from a three-months' visit to England and the Continent, where he has made a thorough trade investigation in conjunction with the Cleveland Twist Drill Company of Great Britain, Ltd., London, the European branch of the Cleveland Twist Drill Company.

John D. Rogers has received his discharge as captain of engineers in the office of the director general of military railways in Washington, D. C., and is now in the foreign sales department of the Baldwin Locomotive Works at Philadelphia. Prior to entering the army, Mr. Rogers was shop superintendent on the Virginian Railroad, having previously served on the Chesapeake & Ohio, the Pere Marquette, and the Union Pacific railroads.

Charles Riddell has resumed his duties as manager of the Chicago office of the Baldwin Locomotive Works and the Standard Steel Works Company. Mr. Riddell, who was formerly manager of the Chicago office, has been serving as assistant secretary and treasurer in the financial department at the Philadelphia, Pa., office for the past year and a half. Arthur S. Goble, manager of the Chicago office of the Baldwin Locomotive Works, has been transferred to the St. Louis, Mo., office.

John Kelly, who for a number of years was New York district manager of the Edison Storage Battery Company, has been appointed general sales manager of the company, with headquarters at Orange, N. J. This promotion for Mr. Kelly follows closely upon his promotion, on July 1 of this year, to the position of assistant general sales manager. Mr. Kelly brings to his new position the experience of a long and varied career in the storage battery, electric vehicle and accessory business. For nine and one-half years he was district manager of the New York office of the Edison Storage Battery Company. Before that he had been a salesman for the Westinghouse Storage Battery Company for two years, for the Swinehart Tire & Rubber Company for three years, for the Firestone Tire & Rubber Company for two years, and for the New York Edison Company for nearly four years.



John Kelly

Major H. C. Bayless, formerly mechanical engineer on the Minneapolis, St. Paul & Sault Ste. Marie and the Great Northern, but more recently chief inspector of ordnance for the War Department at the Standard Steel Car Company's plant at Hammond, Ind., has been appointed combustion engineer and manager of the Superior Pulverizer Company, Chicago, in which capacity he will have entire charge of engineering and sales and general supervision of coal installations.

The Fastfeed Drill & Tool Corporation, recently incorporated under the laws of the state of New York with an authorized capital of $500,000, has purchased the factory, together with the business and good will, of the McCarthy Drill & Tool Corporation, Toledo, Ohio. John D. McGrath, formerly treasurer of the McCarthy Drill & Tool Corporation, is managing director of the new organization, which will continue to operate the plant in Toledo. Additions to the present equipment are planned for the near future.

F. H. Crawford, sales manager of F. H. Niles & Co., Inc., Woolworth building, New York, has been appointed secretary, and J. E. Haetten, assistant sales manager has been appointed sales manager. G. P. Goodman, who for several years has represented the Hisey-Wolf Machine Company, Cincinnati, Ohio, in the east, becomes associated with the F. H. Niles & Co., Inc., having charge of its portable tool department. This company handles in the east the Hisey-Wolf line of electric machine tools, and the Canton pneumatic hammers and drills made by the Pittsburgh Pneumatic Company, Canton, Ohio.

The Baldwin Locomotive Works and the Standard Steel Works Company have opened a branch office in the Merchants National Bank building, St. Paul, Minn. Henry Blanchard, sales representative in the Chicago office of the concerns, has been appointed manager of the new branch offices. Mr. Blanchard entered the service of the Baldwin Locomotive Works and the Standard Steel Works Company in the latter part of 1915, in the Philadelphia office. In April, 1919, he resigned as assistant to the vice-president in the Philadelphia office and was transferred to the Chicago office as sales representative. Prior to entering the service of these companies he served as sales engineer of the American Steel Foundries, with office in Chicago.

The Electrolytic Oxy-Hydrogen Laboratories, Inc., announce the formation of a sales and manufacturing company under the name of the Electrolabs Company. The Electrolytic Oxy-Hydrogen Laboratories, Inc., will continue in charge of the laboratories and maintain a technical supervision over the work of the new company. The general offices and works of both companies have been moved from Dayton, Ohio, into larger quarters at 2635 Penn avenue, Pittsburgh, Pa. The general sales offices are being continued at 15 William street, New York City, and branch sales offices have been opened in the Morris building, Philadelphia, and in the Merchants Exchange building, San Francisco. I. H. Levin continues in charge of technical and research work, and D. J. Tonkonogy in general charge of sales.

John F. Schurch, operating vice-president of the T. H. Symington Company Lincoln Park Works, Rochester, N. Y., has been elected vice-president in charge of all western sales, with headquarters in Chicago. Mr. Schurch graduated from the University of Minnesota in 1893. He entered the service of the Minneapolis, St. Paul & Sault Ste. Marie the same year, serving consecutively in the office of the auditor, and of the general superintendent and in the transportation departments, resigning in 1905 after obtaining the position of chief clerk to the vice-president. From 1905 until 1914 he was associated with the Railway Materials Company of Chicago. In February, 1914, he was elected vice-president of the Damascus Brake Beam Company with office in Cleveland, Ohio, and in June, 1914, he was elected president of that company, which position he resigned the same year and was elected vice-president in executive charge, under President C. H. Symington, of the Symington interests in the production of 75 mm. guns, shells and forgings. The Symington interests included the Symington Anderson Company, the Symington Machine Corporation, the Symington Forge Corporation, with office in Rochester, N. Y., and the Symington Chicago Corporation, with office in Chicago. In August, 1918, in addition to these offices, he was made operating vice-president of the T. H. Symington Lincoln Park Works. Mr. Schurch is also vice-president of the Railway Supply Manufacturers' Asociation.

J. F. Schurch

CATALOGUES

Data on Shafts.—Three charts giving the relations for any shaft between power, shaft diameter, torsional stress and speed have been prepared by one of the engineers of the Wellman-Seaver-Morgan Company, Cleveland, Ohio, which has published them in bulletin No. 22 for the use of engineers and draftsmen.

Color Chart for Heating Steel.—The Onondaga Steel Company, Syracuse, N. Y., has prepared a graphic color chart containing directions for cutting "ON" high speed steel for tool lengths, for forging and hardening forged tools, milling cutters and finished tools, and for tempering and annealing, with the temperatures for the different operations shown in color.

Steam Motor.—A description of its steam motor is given in bulletin No. 5, issued by the Steam Motors Company, Springfield, Mass. The bulletin contains 23 pages of descriptive material and many illustrations showing the parts and construction of the motor and the method of its application. The motor is a steam turbine designed for use in direct connected centrifugal pump and blower units.

Machine Tool Equipment.—A number of two-page bulletins have been issued by the Bilton Machine Tool Company, Bridgeport, Conn. These bulletins are bound in a cover with punched holes to which others may be added from time to time and each briefly describes and illustrates a machine made by this company. These include gear milling and hobbing machines, automatic milling machines, automatic cam feed drill presses, drilling and riveting machines, etc.

Fans, Blowers and Exhausters.—The various types of blowers, exhausters and fans manufactured by the Buffalo Forge Company, Buffalo, N. Y., are described in catalogue No. 400, with illustrations and tables of specifications. Diagrams and illustrations of countershafts designed for use with these blowers and exhausters are shown, together with dimensions and price lists. This booklet, consisting of 35 pages, contains information of special value to fan users.

Leather Belting.—A 20-page pamphlet issued by the Leather Belting Exchange, Philadelphia, Pa., contains information obtained during the course of an investigation on power transmission by belting conducted by the Mellon Institute of Industrial Research of the University of Pittsburgh for the Leather Belting Exchange. The booklet is entitled "A Study of Various Types of Belting," and was written by Professor Ernest D. Wilson of the Mellon Institute. It describes the equipment used in the tests and the results obtained, and is illustrated with several photographs.

Boiler Feed Control.—An eight-page bulletin, embodying specifications for the Copes system of boiler feed regulation, has been published by the Northern Equipment Company, Erie, Pa. A cover is provided with punched holes for adding future bulletins or specifications that will be published by the company. The bulletin discusses the principle and operation of the regulator and its mechanical construction, heat storage, reduction of furnace temperature fluctuations on sudden load changes, service performance, and the Copes steam pump governor. It contains a number of charts and photographs.

Steam Jet Air Pumps.—Preliminary bulletin No. 113, illustrating and describing the Wheeler steam jet air pump is now being distributed by the Wheeler Condenser & Engineering Company, Carteret, N. J. This steam jet air pump has two or more steam jets working in series with a condenser between the jets, which permits more efficient operation. The pump is applicable to jet condensers, as well as to surface condensers. The bulletin explains the operating principles, gives reasons for high efficiency, describes the inter-condenser and shows an operating test curve. It includes a cross sectional drawing and shows how to connect double machines or triple machines to surface condensers.

Pneumatic Tools.—In a temporary catalogue, containing 48 pages, issued pending the publication of a larger book, the Keller Pneumatic Tool Company, Grand Haven, Mich., shows briefly its line of pneumatic tools, including valve and valveless types of rotary and piston drills, which are new additions to the line. All models of Keller-Made Master-Built chipping hammers, riveting hammers, holders-on, dolly bars, jam riveters and sand rammers are illustrated and described, with detailed specifications and information as to the uses for which each is designed. This company has also published a four-page folder containing a list of their special tool making and production equipment, with a few illustrations of representative operations and productions.

Electric Furnaces.—Booklet 5-B, published by the Electric Furnace Company, Alliance, Ohio, is an attractive 24-page catalogue describing the Baily types of electric furnaces for melting non-ferrous metals. These types embrace pusher type continuous furnaces for heating and annealing steel, copper, brass and aluminum, automatic control type continuous furnaces for heat treating steel castings and forgings, and car type furnaces for annealing steel, copper, brass and aluminum, and have electrical capacities of from 150 kw. to 1,500 kw., and furnace capacities of 1,000 lb. to 10 tons per hour. These furnaces are all of the resistance type and have several distinct features. The booklet contains illustrations of a number of actual installations and records of tests made with the equipment in several industrial plants.

Automatic Cut-Off Valves.—The Lagonda Manufacturing Company, Springfield, Ohio, in catalogue S-2 describes the Lagonda automatic cut-off valves for power plants, which are designed to close automatically in case of an abnormal flow of steam in either direction through the valve. The booklet contains an account of tests made by the Department of Commerce of the United States to determine their reliability of operation and adaptability for different conditions. External dashpot valves for use when the flow of steam from boilers to the header is practically constant, and internal dashpot valves for installation where load conditions are unsteady are fully described, with illustrations showing sectional views of the various classes of valves. Lagonda non-return valves which close in case of tube rupture or an accident to the boiler are also covered in the catalogue, which contains 32 pages.

Fuel Oil.—This is the title of a 46-page booklet published by the Tidewater Oil Company, New York, which gives a brief survey of experiences of various users of fuel oil and gas oil, and is intended to be of service not only to non-technical executives and plant managers, but also to plant engineers. It contains many charts, diagrams and illustrations and is divided into 15 chapters. The following chapter headings will give some idea of its contents: Advantages of Fuel Oil over Coal; the Nature and Refining of Crude Oil; Greater Economy of Heavy over Light Fuel Oils; Results Obtained Where Fuel has been Changed from Coal to Oil; Installation, Burner and Furnace Requirements. Under the heading Estimating the Saving, Fuel Oil Vs. Coal, a formula is given for computing roughly the amount which a particular plant can afford to pay for oil as computed from the present price of coal firing.

Railway Mechanical Engineer

Volume 93 November, 1919 Issued December 12, 1919 No. 11

CONTENTS

CAN YOU WRITE A GOOD STORY?

Does the romance in the day's work appeal to you?

Do you take a keen interest in the study of human nature?

From your personal experience have you a clear vision of some of the unsolved problems in the motive power or car departments? Better yet, have you some ideas of your own as to what might be done to improve supervision, put production on a better basis, or take the kinks out of the organization?

If you can answer "Yes" to these four questions, or even to the first three of them, would you like to give expression to your conception of the unsolved problems of the department, or to your ideas for their solution, in the form of a story with the shop, roundhouse, repair yard or office as the scene, and the characters those with whose qualities you have become so well acquainted by daily contact in the conduct of your part in the game of railroading?

For the three best stories received at our office in the Woolworth Building, New York, on or before April 1, 1920, we offer a first, second and third prize of $75, $50 and $25 respectively. All stories accepted for publication will be paid for on acceptance at our regular space rates and any received in time will be published in the issues intervening before the contest closes. After the competition closes those to whom the prizes are awarded will receive the prize in addition to the amount paid for the story at space rates. Although there are no conditions other than those already mentioned, it is suggested that a good story of this kind can probably be told within the limits of 1,200 to 2,500 words.

In judging the relative merits of the stories submitted and selecting the prize winners we shall, of course, give some attention to the use of English and the literary finish. But do not be unduly concerned by this fact, for we shall give far more weight to the theme of the story, the quality of the plot, the ability to reproduce the atmosphere of the surroundings, the truth of the character portrayal and the naturalness with which the plot is developed.

Try it and see how it goes.

Why Your Copy Is Late

Because of labor difficulties the publication of the October and November issues of the *Railway Mechanical Engineer* has been greatly delayed. The October issue was held up when it was practically ready for mailing and work was not resumed for two months. The difficulties have now been settled and all the issues will be brought out as quickly as possible. It is expected that the usual schedule will be resumed within a few weeks. In the meantime we must ask the indulgence of our readers if they do not receive their copies promptly.

Economy and the Test Department

The high cost of labor and of the materials needed in railroad work makes it imperative that nothing be left undone that will tend toward economy of operation. A most important adjunct to the modern railroad organization is the test department, and if it is given the wholehearted co-operation of both the managing and the operating officials it can do most effective work. Too often the cost of making a test is allowed to stand in the way of securing data that would mean a lasting improvement in the operation of the locomotive or some other part of the equipment. This is a short-sighted policy —one that is penny wise and pound foolish. Frequently a saving effected in material or an increase in the efficiency of some particular part of the railroad equipment is due entirely to the work of the test department, and these improvements, if given proper attention by those charged with the daily operations, will produce lasting results. It is a noticeable fact that those railroads having the most active test departments are usually the most efficient. Give the test department an adequate force of engineers and the proper co-operation, and beneficial results will surely follow.

Injustice to Helpers and Apprentices

That portion of the shopmen's new agreement with the Railroad Administration which affects the car shop stipulates that in certain cases helpers or apprentices who have served two or more years may be promoted to mechanic with a mechanic's rate of pay. This is very good and an incentive to good work on the part of a helper or apprentice. Another clause of the agreement, however, provides that if a mechanic having had four or more years' experience applies for work, the helper or apprentice so promoted must be demoted and the mechanic put at work. This is an injustice to the demoted helper and apprentice and is certain to become a source of dissatisfaction. This rule applied, as it evidently is intended to be, may cause the demotion or even discharge of good workers, who may perhaps have homes in the vicinity of the shop in question, to make a place for itinerant mechanics who shift about from shop to shop, and in actual service rendered are not equal in value to a good helper or apprentice. This rule should be given further consideration and changes made so that there may be some discretion on the part of the shop officials as to the demotion of any helper or apprentice under such circumstances.

Development of Shop Foremen

A vital factor in an efficient shop organization is the staff of foremen, and their selection must be given more careful consideration than has been the case in the past. Under the conditions which prevailed in the industrial world until recent years the foreman did not occupy a position of great responsibility, except as he was directly concerned in the work turned out by his department. The foreman was usually selected for his own ability to perform the manual tasks of his craft and so judged as being qualified to direct others. Where the organization was a small one and the superintendent or owner in close touch with the men this practice served very well. But with the expansion of industries this intimate contact has been lost and the shop foremen have become a very vital cog in the organization wheel. The ideal foreman of the present is one who not only is proficient in his craft, but who has the tact necessary to smooth out diplomatically the friction resulting from the real or fancied grievances of the workers. In short, the modern foreman must not only direct the work of his subordinates, but must also act as an intermediary between employer and employee, and this last is a quality that must be brought to the fore if the lion and lamb—employer and employee—are ever to lie down together peacefully.

This condition applies just as much to the railroads as to industries in general and with the return of the roads to private operation the need for foremen of high calibre will become more pressing. While the selection of foremen is given careful consideration on many railroads, most roads make practically no attempt to train men for such positions. Would not a training school conducted along the lines of the officers' training camps, which gave such splendid results in the rapid development of the American army, be a long step toward the solution of the foreman problem? It would be quite possible for a number of the larger railroads to conduct such schools within their own organizations, but for the greater number of railroads this would be impracticable and the benefits to be derived, by the larger as well as the smaller roads, would be much greater in a general training school. To this school might be sent not only men who gave promise of developing into competent foremen, but also those men already occupying the position of foreman. Many of the latter would benefit, by the close contact with others in similar positions, to an extent that is not possible in conventions of the foremen's organizations now in existence. Further, the incentive given to young men in the shops to qualify for a term in such a school and a place on a foremen reserve list would result in more efficient work by the individual and consequently a more efficient shop as a whole.

The plan would involve a general training school supported by the railroads pro rata; men detailed to the school on the basis of shop performance and a foreman's reserve list. The results would be felt in increased efficiency and would insure a source of qualified men for positions of authority.

Paint the Steel Cars

The poor condition of great numbers of steel cars, particularly gondola and hopper cars, is very apparent, as may be seen in any railroad yard, and not the least of the defects is the lack of paint. Recent observations of such cars in various parts of the country showed a large number to be scaled so badly that it was possible to pick off great patches of the paint with the hand. The steel plate underneath paint scaling in this manner is so rusted that it is a question of only a short time before such cars will be useless without extensive repairs to the car body. This condition at the present time is partly due to the necessity of keeping this class of car—used largely for coal—in service, but there is a limit beyond which this is not justifiable. There has been considerable difference of opinion among railroad master painters as to the best method of painting such cars, but it is obvious that the progress of decay—rust—must be stopped and the steel protected from further injury by the elements. If no better method can be found, the surface should be thoroughly cleaned by a sand blast, using a fine screened sand gravel, and then given a priming coat and a finish coat of a good linseed oil paint. Various substitutes for linseed oil have been tried and found wanting. There has also been much criticism of the paint specification called for by the Railroad Administration and this phase of the question should be given attention, as it would be very poor practice to apply paint that is not suitable for the purpose and will not give satisfactory service. Paint the steel cars and do it before it is too late.

Bearing Pressures on Tender Truck Journals

The lubrication of locomotive tenders is recognized as a matter that requires constant attention at terminals. In spite of the fact that the journal boxes are inspected every trip and repacked if necessary, many roads find it advisable to run hose from the tank to each wheel as a precaution against delays due to hot boxes. Such conditions apparently indicate that the loads on tender journals are becoming excessive. Designers will no doubt protest that the weights carried are generally within the limits prescribed by the Master Car Builders' Rules for the association's standard sizes of journals. It is true that the limit weights have seldom been exceeded, but standards established for freight cars are not necessarily applicable to locomotive tenders. An analysis shows that some of the conditions met in tender service are favorable for good lubrication while others are unfavorable and in the end actual service results alone deserve to be considered. The weight of a tender when loaded can seldom be distributed equally between the front and rear trucks; furthermore, the surging of the water causes periods during which one side carries an undue share of the load. On the other hand, tenders are never fully loaded over the entire division.

Since the total weights of tenders for large locomotives often reach the limit of weight for four 6 in. by 11 in. journals, the next logical step to reduce the unit bearing pressure is the adoption of the six-wheel truck. It is interesting to note that one road which has used six-wheel tender trucks for several years has made this type standard for new power. While the adoption of six-wheel trucks is dictated by the necessity of overcoming the difficulties of lubrication, the change to the longer wheel base will probably show good results in a reduction of wear on wheel flanges and better riding qualities as well.

What About the Valve Setter?

There are probably few jobs within the whole range of locomotive repair work which, if they have the right kind of pride in good workmanship, the men performing them do not feel they are among the most highly essential to the best service of the locomotive. If the opinion of these men were to determine what jobs should carry with them a differential above the minimum established rate because of some special skill or care required for their proper performance, the result would be a much longer list than the comparatively few differentials fixed in the wage agreement between the Railroad Administration and the shop crafts, which went into effect October 20 last. As far as one set of rules can be made to meet the many sets of conditions as to shop practice and equipment which must be dealt with in the United States, the list of differentials established in this agreement may be considered fairly comprehensive. There is one notable exception, however, the high degree of skill for the proper performance of which is generally recognized. That is valve setting. The valve setter's work is reflected in the cost of operation of the locomotive for the entire period between shoppings. It is true that with the prevalence of outside valve gears on modern locomotives, the value of the skill of the old time valve setter may easily lost sight of. Even with these gears, however, a high degree of skill is required not only properly to maintain the correct steam distribution, but to get the work done without wasting a lot of time. Furthermore, the fact must not be lost sight of that there are still a large number of old locomotives with inside valve gears in service and as long as these engines run they burn coal, which is no less valuable because it may be consumed in branch line rather than in main line service. The valve setter's job is still one requiring a degree of skill and intelligence above the average and the only way to secure such a degree of skill and intelligence is to pay adequately for it.

Reinstating the Rules of Interchange

During the period of federal control the Rules of Interchange have been modified by circulars and by local agreements and some of the most important provisions have been suspended. When the railroads are turned back to their owners on January 1, it will be necessary to put the rules into effect once more in their entirety. Present conditions indicate that this will prove a serious task. Although some of the modifications of the rules have been recalled and defect carding has been reestablished, the regulations governing interchange are not being observed as they were prior to federal control. The men who were familiar with the workings of the rules prior to 1918 will not find it difficult to carry them out when they are once more put into force. Few changes have been made in the rules themselves during the period of federal control. For the most part the old rules have been retained and necessary modifications have been taken care of by supplementary circulars. Among the important changes appearing in the 1919 code of rules is the revision of Rule 32 to clarify fair and unfair usage and the addition of Rule 66 providing for the periodical repacking of journal boxes. Rule 88 has also been modified to facilitate repairing foreign cars and Rule 120 has been reinstated as issued in Circular 25.

With the small number of modifications of the rules and with experienced inspectors to form the basis of the new organization, it should not be difficult to put the rules in force once more if a concerted drive is made now to educate the new men. Railroad mechanical officers should consider that the period of federal control will soon be ended and should take immediate steps to insure that all car inspectors become conversant with the new rules in order that there may be no difficulty in putting them into effect on January 1. In order to assist our readers, the editors will welcome discussions of disputed points and will try to answer in the car department section any questions which are sent in regarding the application of the rules.

NEW BOOKS

Official Proceedings of the Eleventh Annual Convention of the Master Boiler Makers' Association.—192 pages, illustrated, 6 in. by 9 in. Bound in cloth. Published by the secretary, Harry D. Vought, 95 Liberty street, New York.

A complete report of the convention of the association, held at the Hotel Sherman, Chicago, Ill., May 26 to 29, 1919. Of especial interest are the committee reports and the discussion on "Threading Radial Stays and Tapping Holes for Same" and "The Best Method of Bracing Locomotive Tenders." The book is very well compiled and nicely bound and reflects credit on the association.

Storing. By H. B. Twyford. 200 pages, illustrated, 6 in. by 9 in., bound in cloth. Published by D. Van Nostrand Company, 25 Park Place, New York.

The necessity for storing stocks of materials of various kinds arises from the practical impossibility of obtaining a constant and uniform flow of materials from the raw state to the finished product at the point of consumption, and with the growing complexity of the modern industrial operations storage problems have also grown in complexity as well as in importance. In its broadest sense, the problem of modern storage not only involves questions of efficient methods of protecting and handling material, but many questions of a commercial nature must also be considered. In this volume the author has attempted to consider the whole range of questions involved in the storage problem, both economic and technical. The former are dealt with in a general way only, defining the fundamentals, and pointing out some of the more common mistakes of an economic nature. The technical problems are dealt with at greater length. Two chapters are devoted to the question of location, equipment and appliances for the storeroom, while the greater part of the work deals with storehouse operations, including discussions of clerical work, the storehouse organization and methods of accounting for and disposing of material received and delivered from the storeroom. Although, beyond the rather general discussion of the economic phases of storing, it has been the intention of the author to confine the discussion to the problems of the storekeeper rather than to include the related problems of purchasing, a brief discussion of the value of stores inventories is included. The book contains a large number of illustrations showing storehouse equipment and methods of handling material, as well as various forms required in properly listing and accounting for stores stock.

COMMUNICATIONS

INADEQUATE MAIN DRIVING BOXES

To the Editor: Allston, Mass.

In reply to Mr. Prescott's communication, appearing in your issue of September 1919, as to an error in quoting the taper of wedges, I would say that the locomotives under my observation have that taper and my statement in relation to the coefficient of friction holding them in position against the piston thrust along the zero line is practically acknowledged by his figures. That is to say, if the resulting moment of slip is 1 in. per ft., ¾ in. per ft. will be 25 per cent inside of the resulting moment.

As regards the spring thrust equipped wedges my observation of locomotives so equipped is, that where they do not hold the box as regards wedge adjustment, they do not cure the other troubles which cause the main driving box to pound.

The tendency of a wedge to unload may be demonstrated in practice in this manner: If, when on the road, a wedge should stick solid, the man running the locomotive will often get down and slack off the check nut supporting the wedge, leave the other two nuts below the wedge support locked together, and then drive the engine without any attempt to pull the wedge down, with the result that on arriving at the terminal point all that is necessary is to set the wedge up.

As an example of an opposite condition, we may assume a wedge forced up with a rigid wedge bolt, causing a tension strain from the wedge sticking, thus causing the bolt to part and the wedge to crawl up and stick. In this case the resistance offered to the wedge by the rigid wedge bolt below causes still further overload with a final result that oftentimes it is necessary to take down the pedestal brace and spring the jaws of the frame open to release the wedge.

These examples are intended to show that my line of thought is not in the direction of an equipment to do away with adjustment, but to argue for a more general application of an equipment to compensate for inequalities which, at times, it may be impossible for the persons concerned to conceive. If practice teaches us the wedge will unload, make provision for it when natural causes make it necessary.

My argument against the spring thrust is this: The physical law is that action and reaction are opposite and equal. In this case the wedges must unload against resistance, which means work set up against the force exerted to unload, and this brings us back to the horizontal along the zero line of the piston.

As to the boring out of the crown of the brass I have this to say: Twenty-eight years ago, as an apprentice, I observed the practice of filing out the crown of the brasses, after being perfectly fitted to the shaft, as the last operation before applying them to the shaft. At this time the oil groove was in the top of the crown and I have seen these boxes, after the locomotives were running, fitting the journal so tight that you could fill the oil hole with engine oil and not have the oil leak down around the sides of the journal.

Since that time, as locomotives increased in size to meet the needs of the transportation department, the oil groove has been moved down near to the zero line of the piston in the crown brasses, and the brasses are now scraped out in line with the piston thrust before they are run, in order to make them slightly larger than the journal and bear hard in the crown, which is directly opposite to the former practice.

In new locomotives coming direct from the builders the crown brasses are splined out one inch back into the crown in direct line with the piston thrust, which would indicate that the trouble was caused by the brasses gripping the journal across the zero line of the piston thrust.

This was the condition on locomotives equipped before the advent of the grease lubricated driving box and the trouble experienced when running at high speed was, perhaps, the cause of bringing about the grease equipped driving box.

At the same time that this trouble was experienced in running high speed locomotives equipped with oil I have seen both heavy Consolidation and switching locomotives shopped, with high mileage, on which the boxes would have to be scraped out in line with the piston thrust in order to get them back on the journal. These locomotives were shopped to turn the tires before the laws governing these things were in vogue and sometimes had ⅜-in. tread wear.

My purpose in speaking of these facts is to try to show that the generating of heat in high speed service is a factor which causes wear in line with the piston thrust.

I will state also that my observation of the way in which the wear takes place in heavy locomotives running at high speed, with high piston thrust, leads me to the conclusion that if a bearing was so designed as to completely surround the journal in direct line with the piston thrust that they will still continue to wear and pound if no provision is made in the design to compensate for the distance to the outside of the bearing beyond the neutral axis of the journal.

Friction is measured by the weight, the load being greatest at the point most distant from the neutral axis and no rigid parallel condition in line with the journal across the frames will meet the requirements of bringing sufficient surface into play to compensate for the tendency of the bearing to wear at the outside and next to the wheel hub.

I am in agreement with Mr. Prescott in regard to the importance of growing piston thrust and also as to the importance of getting into it at this time when the tendency in building is in the direction of simple engines and superheat, with greater mean effective pressure at high piston speed and increasing tractive effort. If we do not talk now and get the changes made, the locomotives will do the talking later on. John C. Murdock.

THERMIT vs. AUTOGENOUS WELDING

New Haven, Conn.

To the Editor:

In his letter in the July issue of the *Railway Mechanical Engineer* E. A. Murray quite pertinently sets forth the advantage of the Thermit process for a job such as he described. But apparently the damage was confined to distortion of members requiring straightening. The photograph and description do not disclose that there was any breaking up of the frame, as was the case with the frame welded at New Haven.* An inspection of the photograph shown on page 99 of the February, 1919, issue discloses the fact that both ends of the frame were practically destroyed. At each end, as far back as the transom member, the casting was broken up into many pieces, some so small as to be impossible to replace and for which it was necessary to substitute flanged steel plates, which were partly riveted and partly welded into place.

Three out of five of the sections making up the under portion of the underframe were distorted so that they had to be cut and straightened, and this portion of the operation of reclaiming presumably was practically the same as that in the case of the frame which Mr. Murray handled.

I have been familiar for a great many years with the merits of the Thermit process and know the fine work which can be done with it under some conditions. But the frame which we welded was so badly broken up that it would have been a physical impossibility to have repaired it with the Thermit process. I am taking the liberty of again bringing the matter up in order that the difference in the nature of the two jobs may be clearly drawn. W. L. Bean.

*See the February, 1919, issue of the *Railway Mechanical Engineer*, page 97.

Mikado Type Locomotive for Canadian Pacific Freight Service

New Canadian Pacific Locomotives

Mikado Type for Freight Service; Heavy Frame Construction and Interchangeable Side Rods

BY W. A. NEWMAN
Engineer of Locomotive Construction

The locomotive building program now being carried out by the Canadian Pacific Railway includes four new types of locomotives; a Mikado type locomotive having a tractive effort of 56,000 lb., two classes of Pacific type locomotives with 43,700 and 42,600 lb. tractive effort respectively, and a Santa Fe type locomotive with a tractive effort of 66,000 lb. All of these locomotives have been designed by the mechanical engineering department of the Canadian Pacific and are being contsructed at the Augus shops in Montreal.

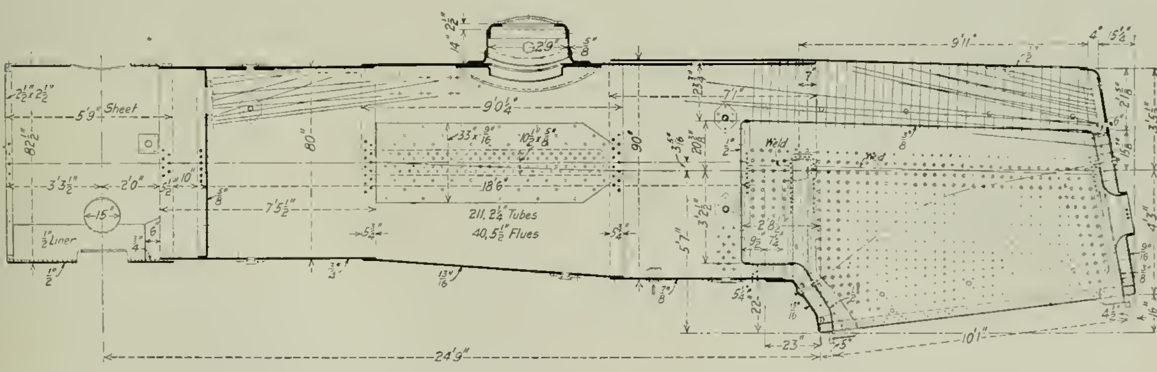
The initial order of 10 Mikado type locomotives has already been completed and one of them is described in this article. The other new types of locomotives are now building and will be described in later issues of this publication.

The design of the Mikado locomotives is largely based on the experience obtained from the earlier Mikado type which was designed and constructed by the Canadian Pacific in 1912. There are no radical departures from what is commonly accepted as standard practice. Close attention has, however, been paid to the design of every detail and no effort spared to produce a common-sense locomotive which will give reliable and efficient service.

The locomotives have a total weight of 320,500 lb., with 235,000 lb. on the driving wheels, which gives a factor of adhesion of 4.18. The cylinders are 25 in. by 32 in., driving wheels 63 in. outside diameter, which with a normal boiler pressure of 200 lb. per sq. in., gives a maximum calculated tractive effort of 56,000 lb.

THE BOILER

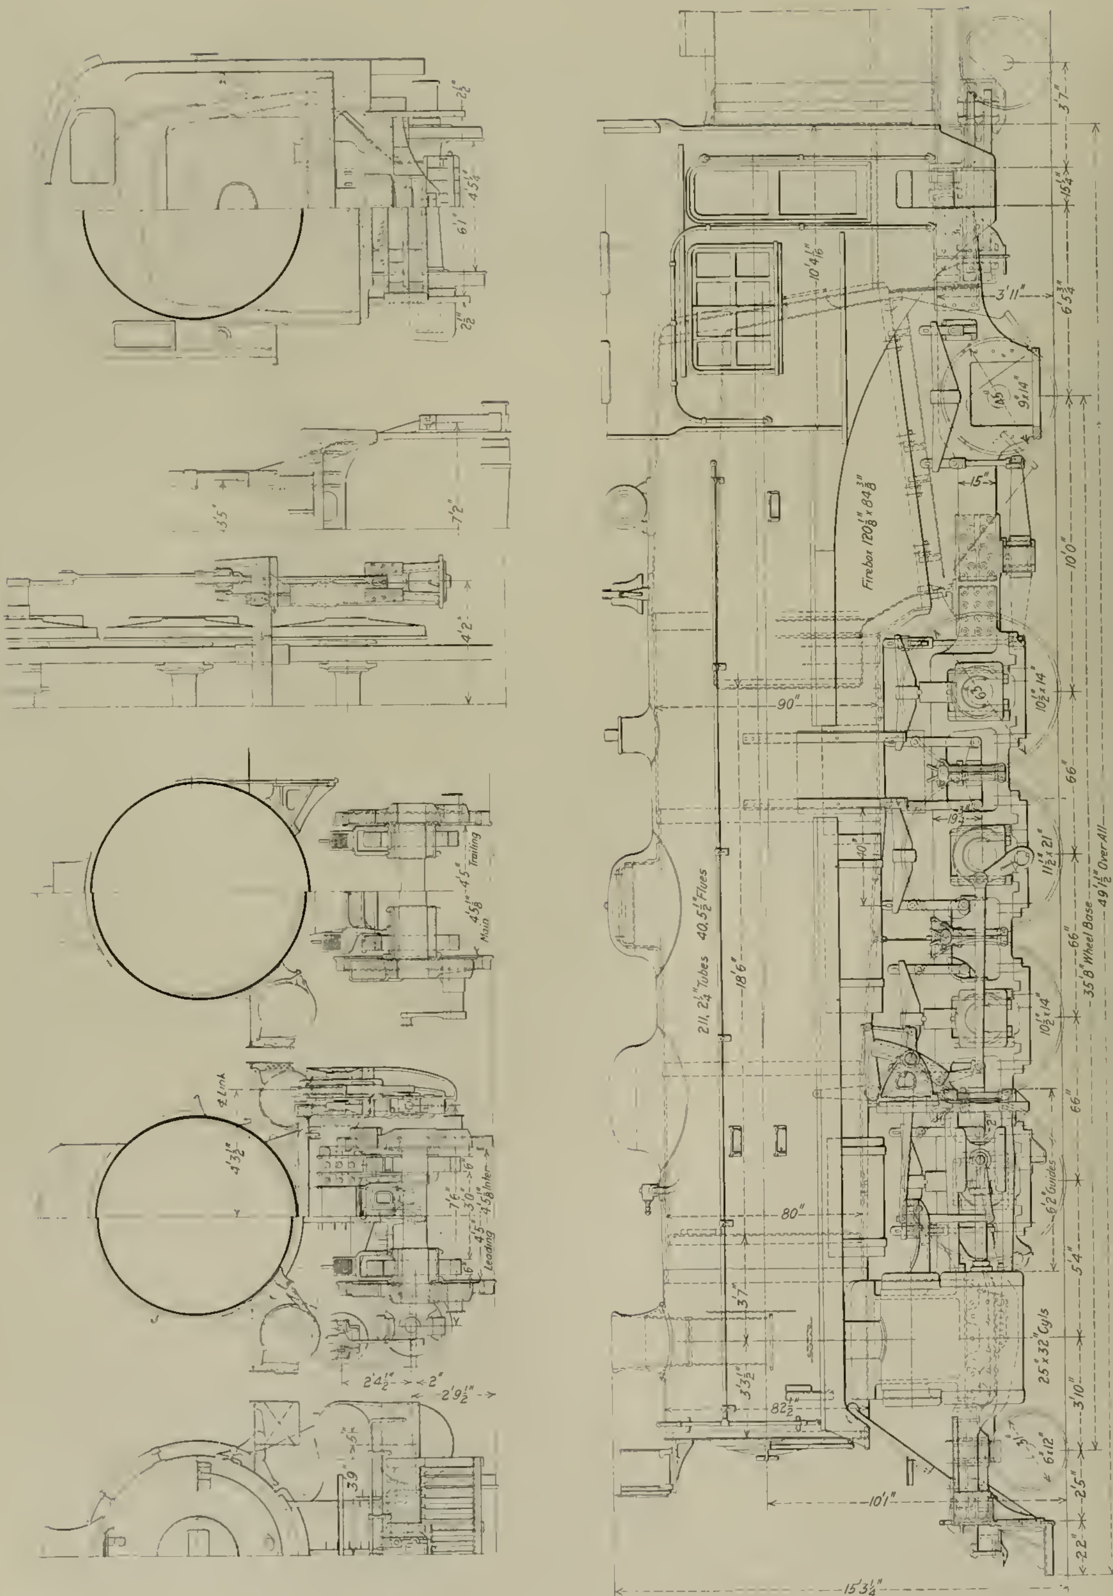
The boilers are of the extension wagon bottom type, and are the first of this kind to be used on Canadian Pacific locomotives. This type of construction was adopted for several reasons: the steam dome can be located on the second course, which simplifies the seam construction on the third course; the standpipe is further away from the crown sheet where the greatest ebullition occurs; it shortens the dry pipe and consequently the length of the steam passage, and provides a greater steam storage space, which should be of material advantage in increasing superheater efficiency.



Extension Wagon Bottom Boiler for Canadian Pacific Mikado Type Locomotive

The boiler design is the result of a very careful study of boiler proportions and construction, every care being taken to insure ample steam generating capacity, combined with easy steaming qualities. The smallest details of construction were given close attention with ease of maintenance in view.

The capacity of the boiler in relation to the cylinder requirements is 102.5 per cent, based on Cole's ratios. The



Elevation and Cross Sections of Mikado 2-8-2 Locomotive and Arrangement of Ragonnet Reverse Gear length of tubes is 18 ft. 6 in., which is a close approximation of the most efficient ratio of tube length to diameter. A 28-in. barrel combustion chamber is used, this being the first combustion chamber of this type on the Canadian Pacific Railway. The mudring ends are of cast steel welded to wrought iron side pieces. The ends have drop corners to allow through riveting for the corner fastening of the inside firebox sheet.

THE FRAMES

The frames are a little heavier than is usually found in general locomotive practice. This is chiefly on account of the difficulty experienced with frame breakages, particularly in sections of Canada in which extremely low winter temperatures are experienced. The frames are of the single front rail type and it has been the experience of the Canadian Pacific that the majority of breakages with such frames come directly behind the cylinders. This apparently has been largely due to insufficient fastening to the cylinders and on account of the twisting strains set up due to the narrow bolting face of the cylinders in comparison with the total depth of the frame through the pedestals. In an attempt to correct this, a 15-in. depth of frame section at the back of the cylinders has been used and an extension lug carried forward from the top rail of the frame, which engages with and bolts to a vertical lug on the back wall of the cylinder casting. This gives a total vertical bolting face at the back of the cylinders of 29½ in., which it is expected will effectively counteract any twisting strain to which this section of the frame will be subjected. This construction is shown in detail in the illustrations.

Special Wedge Casting to Reinforce the Frame and Cylinder Casting

In addition to being bolted to the usual side vertical bolting face underneath the cylinders, each frame is further secured by being bolted through a casting which extends between the locomotive frames and bears against extension lugs at the center of the cylinder castings. These lugs have a tapered face, and the whole casting is first driven in place, secured by vertical bolts, and then bolted horizontally through the frame and cylinders.

The frames are of a uniform width of 6 in. throughout. The depth of section at the top of the pedestal is 6¾ in., the minimum depth of the top rail between pedestals 5¾ in., and the minimum depth at the bottom rail 4½ in.

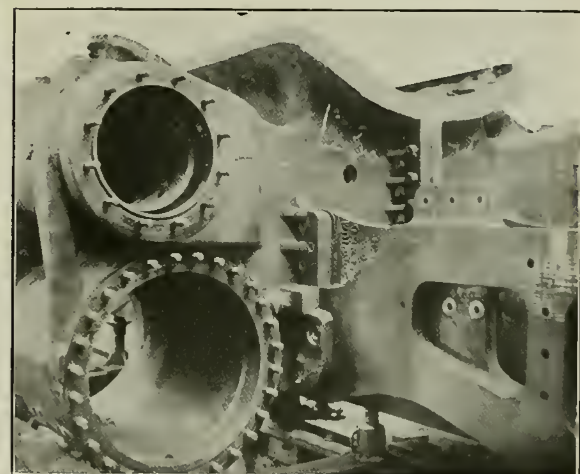
TRAILING TRUCK

The locomotives are equipped with the Vaughan trailing truck, the extension frame being outside the trailing wheels and spaced 6 ft. 3½ in. center to center. No radius bar is used with these trucks, the guiding motion being obtained from inclined vertical faces on the journal boxes which bear against faces having the same incline, on the pedestals attached to the extension frame. This type of truck has been used on Canadian Pacific locomotives for the past 13 years and has given satisfactory service.

ASH PAN AND GRATES

The chief advantages of this construction of rear frame are simplicity and that an ash pan of ample capacity can be obtained with very few relatively flat horizontal surfaces, as will be seen by a study of the ash pan drawing. An ash pan of ample capacity and with quick slopes is absolutely imperative for locomotives operating in cold climates, and a great deal of attention was given to the design of this ash pan. As far as possible, all corner angles are located outside the pan and straight joints in the plate formed by flanging the plate to the outside, the joint being made with sheet asbestos. This construction removes a great many bolt heads from the inside of the pan. The ash pan doors are of the swinging type and are supported from pivot points located back of the door center of gravity, so that the doors are self-closing by their own weight. This is particularly advantageous from a standpoint of fire risk. The ash pan is supported by a combination cast steel bracket, which also forms a support for the grate side carriers.

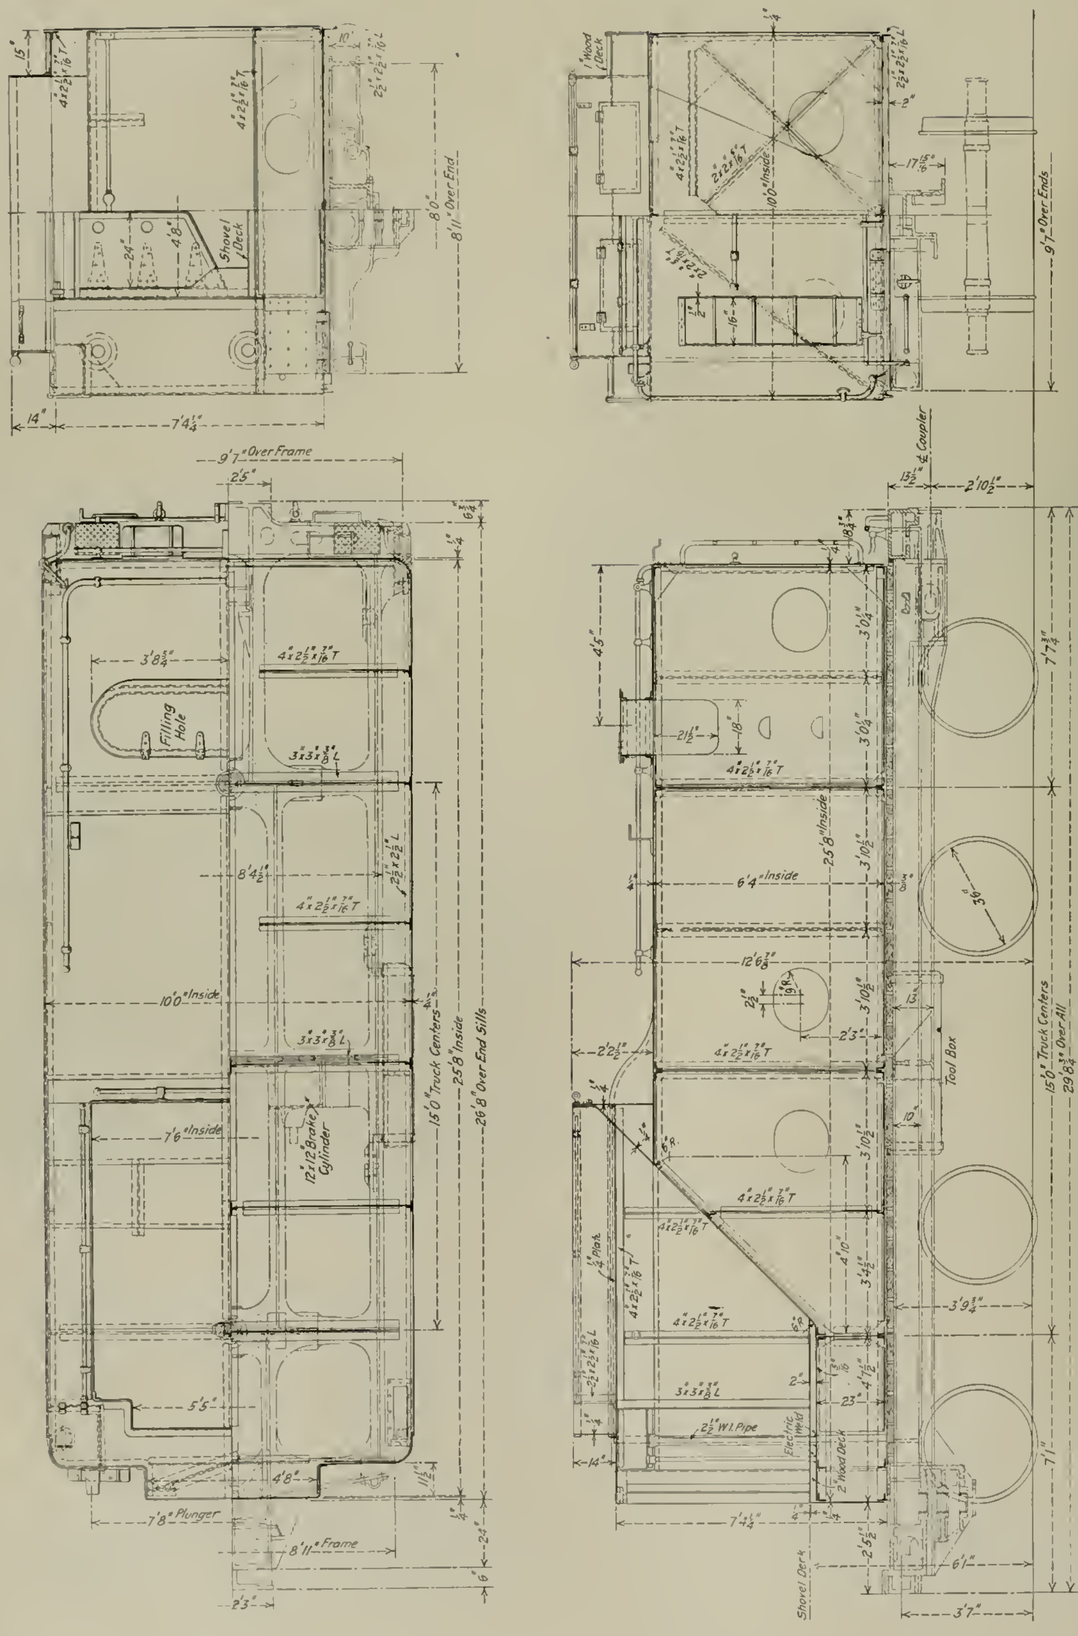
The grates are of the butt finger type, 10 in. wide, are in four sections, and are all moving grates. Dead grates at the front and back have been eliminated. The center carrier is of very light cast steel construction and is reinforced along the bottom or tension member by a structural tee iron, shrunk in place and riveted. Careful attention was given to the design of the grate side carriers to eliminate warping. The design finally adopted has the side carriers in two sections. This permits a stiffer construction and also facilitates any repairs to firebox corners, as only one section of the grates need be removed.



Extension Lug on the Frame Bolted to Vertical Lug on the Cylinder Casting

RODS AND MOTION WORK

The main and side rods are of ordinary carbon steel and present no unusual features, except that the front and back side rods have been made interchangeable; that is, the back right and front left side rods are identical. The piston heads are of cast iron and are considerably lighter than heads two inches smaller in diameter which have been used as standard on other Canadian Pacific locomotives. This is



Two-Piece Water Bottom, 8000 Imperial Gal. Capacity Tender with 45 Deg. Coal Sheet and Special Swash Plate Bracing the result of a very close analysis, both mathematically and by actual tests, of the stresses in piston heads. The crosshead is a modification of that previously used as standard by the Canadian Pacific. The body of the crosshead is cast in one piece and takes removable cast iron wearing pads, which are in three sections, top and bottom, and are retained in place by side plates which are bolted to the crosshead body.

The union link connection to the crosshead is slightly unusual. It is apparently carried by the wrist pin, but actually works on a bearing which is part of the inside washer. This washer fits on a tapered shoulder on the crosshead body, so that the wrist pin is relieved of any thrust from the union link.

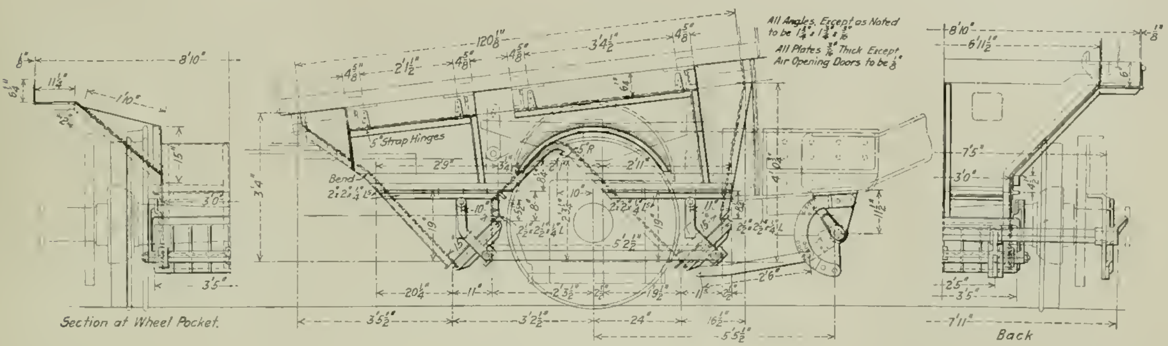
Although all motion parts are of ordinary carbon steel, particular attention has been given in their design, to the reduction of weight, with the result that the reciprocating parts are only 96 lb. heavier than those used on the lighter Mikado type engine, which is an increase in weight of 5.87 per cent, as against an increase in piston load of 31 per cent.

SAND BOX AND CAB FITTINGS

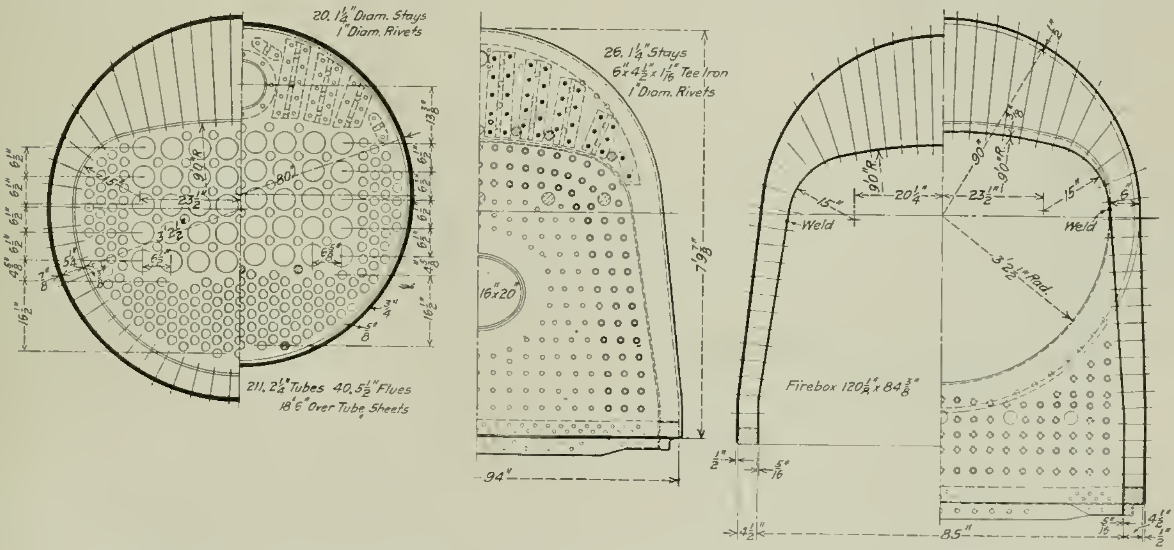
An oval sand box is used which has a capacity of 20 cu. ft. This is of built-up construction, the bottom being flanged in two parts and joined at the center by a riveted butt joint. The top is flanged in one piece. This gives an extremely light construction for the large carrying capacity, the total weight of the sand box empty being 975 lb.

Every effort was made to obtain the most efficient layout on the back head of the boiler so that all valves, the throttle lever, lubricator, air brake equipment, etc., would all be properly located, and at the same time permit both the engineman and fireman to have an unobstructed view of the water glass and steam gage.

The width of the firebox prevented locating the brakeman's seat in the usual position ahead of the fireman's seat and between the firebox and the cab side. The cab is of the Canadian Pacific standard vestibule type, and it was finally decided to locate the brakeman's seat directly behind the fireman's. The vestibule cab includes two lockers, one on either side of the cab, back of the doors. To make room for the brakeman's seat, the locker on the left hand side was omitted and the height of the locker on the right side increased to six feet. A fold-up brakeman's seat was then located on the left side in such a way that with the seat dropped in place and the door closed, a drop panel in the door forms a window to enable the brakeman to look out. This window is provided with a small arm rest of the usual construction, which folds inward when the door panel



Arrangement of Ashpan for Canadian Pacific Mikado Locomotive



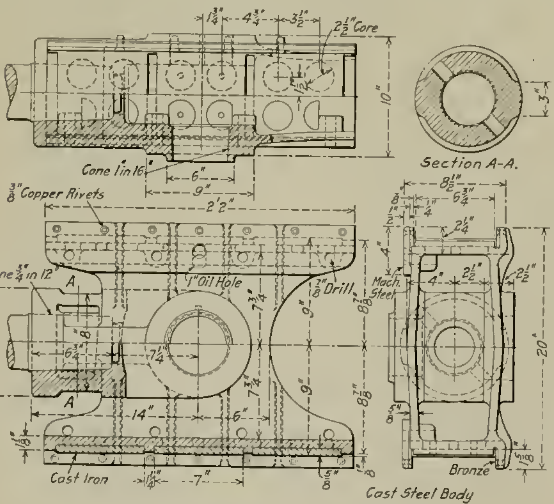
Half Views of Front Firebox Sheet, Front Tube Sheet and Back Head and Section Through Firebox at Throat is raised. The locker on the right side of the cab is divided into two parts, the 4-ft. upper locker being lined with wood and furnished with coat hangers to take the crew's clothes. The bottom locker is used for supplies, and the signal equipment is carried in a wire rack located under the roof of the cab.

THE TENDER

The tender is of the water bottom construction with a total capacity of 8,000 Imperial gallons, which is equivalent to 9,600 American gallons, and has a coal capacity of 12 tons. The slope of the back coal sheet is 45 deg., which is sufficient to insure that all the coal is fed to the front of the coal space, and dispenses with the use of a coal pusher. This is Canadian Pacific standard construction, all locomotive tenders being fitted in this way. The tank bottom is in two pieces, having one longitudinal butt joint with inside and outside welts. The swash plate bracing has been very carefully worked out in order to eliminate all unnecessary strains on the riveting and to insure freedom from trouble from leaky tenders. The tank is supported by a Commonwealth one-piece cast steel underframe. The tender trucks are of the equalizer type with combination semi-elliptic and coil springs.

SPECIAL EQUIPMENT AND AIR BRAKE

These locomotives are equipped with Security brick arches, Cole extension main driving boxes, Franklin automatic driving box wedges, Franklin radial buffers, Franklin unit safety bar (of standard C. P. R. laminated design), Franklin vertical type steam grate shakers, Franklin No. 8 automatic firedoors, Economy engine truck, Nathan type "T" top checks, World safety valves, Detroit lubricators, Hancock non-lifting type "H. N. L." inspirators on the left



Crosshead With Cast Iron Wearing Pads

side, and Hancock type "A" lifting inspirators on the right side, Ragonnet reverse gear, Never-Clog air-sanders and Pyle-National turbo generators with incandescent headlights.

The air brake is the Westinghouse schedule "ET" with cross-compound air compressors. Ample cooling surface is provided in the air brake piping, 2-in. pipes being used between the compressor and the first reservoir. A parasite reservoir is also part of the air system with which this locomotive is equipped, and the pressure is controlled by a Westinghouse Parasite governor.

The locomotives are hand-fired and have proved exceptionally easy steamers, and quite live up to the expectations of economy in coal and water.

The principal data and dimensions are as follows:

General Data

Gage	4 ft. 8½ in
Service	Freight
Fuel	Bit coal
Tractive effort	56,147 lb.
Weight in working order	320,500 lb.

Brazilian Coal.—According to the British Chamber of Commerce in Brazil, it is reported that experiments have recently been made by the Central Railway with briquettes composed of national coal from the Caçapava mines and American fuel. The experiments, which were carried out under strict technical requirements, gave excellent results and fully satisfied the experts who were present. It is believed, says the Chamber of Commerce, that the tests made with the Caçapava coal, from mines in the state of Sao Paulo, situated close to the Central Railway, with which it will shortly be linked up by a branch line of 12 km., may eventually lead to a decrease of over 50 per cent in the imports of American coal making an appreciable economy.

Shop Employees' Wage Agreement

Negotiated with Railroad Administration; Includes the Wage Adjustments and Working Conditions

Director General Hines entered into the following agreement, effective October 20, with the shop employees on roads under federal operation, represented by the Railway Employees' Department of the American Federation of Labor and it affiliated organizations of the Mechanical Section and Divisions Nos. 1, 2 and 3, thereof, including the International Association of Machinists, International Brotherhood of Boilermakers, Iron Ship Builders and Helpers of America, International Brotherhood of Blacksmiths and Helpers, Amalgamated Sheet Metal Workers' International Alliance, International Brotherhood of Electrical Workers, and the Brotherhood Railway Carmen of America.

It is understood that this agrement shall apply to those who perform the work specified in this agreement in the maintenance of equipment, maintenance of way, signal maintenance (except electricians engaged in signal maintenance, telegraph maintenance and all other departments of all railroads in federal operation, shop employees of American Railway Express, and Pullman Car Line employees having the same working conditions as specified in Supplement No. 4 to General Order No. 27. It is understood that this agreement does not annul agreements already in effect with other organizations unless and until a majority of the employees concerned express a desire for a change.

GENERAL RULES

Hours of Service.—Rule 1. Eight hours shall constitute a day's work. All employees coming under the provisions of this schedule, except as provided for in Rule 15, shall be paid on the hourly basis.

Rule 2. When one shift is employed, the starting time shall be not earlier than 7 o'clock, and not later than 8 o'clock. The time and length of the lunch period shall be subject to mutual agreement.

Rule 3. Where two shifts are employed, the starting time of the first shift shall be governed by Rule 2, and the second shift shall start immediately following the first shift, or at 8 p. m. The spread of the second shift shall consist of eight consecutive hours, including an allowance of 20 minutes for lunch within the limits of the fifth hour.

Rule 4. Where three shifts are employed, the starting time of the first shift shall be governed by Rule 2, and the starting time for each following shift shall be regulated accordingly. The spread of each shift shall consist of eight consecutive hours, including an allowance of 20 minutes for lunch within the limits of the fifth hour.

Rule 5. The time established for commencing and quitting work for all men on each shift shall be the same at the respective points, but where three shifts are worked by running repair forces, and two shifts by back shop forces, the quitting time of the first shift and the commencing and quitting time of the second shift of the back shop forces will be governed by the provisions of Rule 3.

Exception.—It is agreed that three eight hour shifts may be established under the provisions of Rule 4, for the employees necessary to the continuous operation of power houses, millwright gangs, heat treating plants, train yard running repair and inspection forces (not repair tracks) without extending the provisions of Rule 4 to the balance of the shop forces.

Rule 6. All overtime, except as the provisions of Rules 7, 9, 10 and 15 apply, outside of bulletin hours, up to and including the sixteenth hour of service in any one 24-hour period, computed from the starting time of the employee's regular shift, shall be paid for at the rate of time and one-half and thereafter at the rate of double time, up to the starting time of the employee's regular shift. This to include work performed on Sundays, New Year's Day, Washington's Birthday, Decoration Day, Fourth of July, Labor Day, Thanksgiving Day, Christmas and such state holidays as are now recognized as punitive overtime days at the various points on the respective railroads within the different states.

Rule 7. For continuous service after regular working hours, employees will be paid one hour for forty minutes' service or less, and shall not be required to work more than one hour without being permitted to go to meals. Employees called or required to return to work will be allowed five hours for three hours and twenty minutes' service or less. They shall be required to do only such work as held or called for.

Rule 8. Employees regularly assigned to work on Sundays or holidays, or those called to take the place of such employees, will be allowed to complete the balance of the day unless released at their own request. Those who are called will be advised as soon as possible after vacancies become known.

Rule 9. Employees required to work during lunch period shall receive pay for one hour straight time and be allowed necessary time to procure lunch without loss of time. This does not apply where employees are allowed the twenty minutes for lunch without deduction therefor.

Rule 10. Employees, except as the provisions of Rules 12 and 15 apply, sent out on the road for emergency service, shall receive continuous time from the time called until their return as follows:

Overtime Emergency Service Road Work.—Overtime rates for all overtime hours and straight time for the recognized straight time hours at home station, whether working, waiting or traveling, except that after the first 24 hours, if relieved from duty and permitted to go to bed for five or more hours, they will not be allowed time for such hours, provided that in no case shall an employee be paid for less than eight hours on week days, and eight hours at one and one-half time for Sundays and recognized holidays, for each calendar day. Where meals and lodging are not provided by the railroad, actual expenses will be allowed. Employees will receive all allowances for expenses not later than the time when they are paid for the service rendered. Employees will be called as nearly as possible, one hour before leaving time, and on their return will deliver tools at point designated

Rule 11. When it becomes necessary for employees to work overtime, they shall not be laid off during regular working hours to equalize the time. At points where sufficient number of employees are employed, employees shall not work two consecutive Sundays (holidays to be considered as Sundays). Record will be kept of overtime worked and men called with the purpose in view of distributing the overtime equally.

Rule 12. When necessary to fill temporary vacancies at outlying points, employees, excluding those specified in Rules 14 and 15, will be sent out and will be paid for this service as follows: Continuous time for time called up to time of reporting at point to which sent, overtime rates for all overtime hours, and straight time for the recognized straight time hours at home station, whether waiting or traveling (the same provisions to apply for return trip). While at such point they will be paid straight time and overtime in accordance with practice at home point with a guarantee of not less than eight hours' pay, at the established rate, for each calendar day, including Sundays and holidays at overtime rates. Where meals and lodging are not provided by the railroad, actual expenses will be allowed. Rules in existing agreements or shop rules covering the road service described in Rules 10 and 12, which are more favorable to the employees, are to be preserved.

Rule 13. Employees changed from one shift to another will be paid overtime rates for the first shift of each change. Employees working two shifts or more on a new shift shall be considered transferred.

Rule 14. Employees regularly assigned to road work whose tour of duty is regular, and who leave and return to home station daily (a boarding car to be considered a home station) shall be paid continuous time from the time of leaving the home station to the time they return, whether working, waiting or traveling, exclusive of the meal period, at straight time for the regular hours, and overtime rates for all overtime hours, as per overtime rules. The starting time to be not earlier than 6 a. m., nor later than 8 a. m. Where two or more shifts are worked, the starting time of each following shift will be regulated accordingly.

Rule 15. Employees regularly assigned to perform road work and paid on a monthly basis, shall be paid not less than the minimum hourly rate established for the corresponding class or employees coming under the provisions of this schedule, on the basis of 365 eight-hour days per calendar year, with pay at the rate of time and one-half time for Sundays and holidays designated herein; otherwise, overtime will not be paid. Where meals and lodging are not furnished by the railroad, or when the service requirements make the purchase of meals and lodging necessary, while away from home point, employees will be paid actual expenses. This service is distinct and separate from that performed by any other class of employees coming under the provisions of this schedule and is not to be confused therewith; the employees assigned to it shall not be assigned to or used to perform the construction, repair and emergency work assigned to the other employees under the provisions of the general and special rules of this schedule.

NOTE

The following is an example to be followed in arriving at the monthly rate:

365 days multiplied by 8 equals	2,920 hours
59 Sundays and holidays at one-half time will be 59 x 4, equaling	236 hours
Total hours to be paid for	3,156 hours

The monthly salary is arrived at by dividing the total earnings of 3,156 hours by 12; no overtime is allowed for time worked in excess of eight hours per day; on the other hand, no time is to be deducted unless the employee lays off of his own accord.

Filling Vacancies.—Rule 16. When an employee is required to fill the place of another employee receiving a higher rate of pay, he shall receive the higher rate, but if required to fill, temporarily the place of another employee receiving a lower rate, his rate will not be changed.

Rule 17. Employees serving on night shifts, desiring day work, shall have preference when vacancies occur, according to their seniority.

Rule 18. When new jobs are created or vacancies occur in the respective crafts, the oldest employees in point of service shall, if sufficient ability is shown by trial, be given preference in filling such new jobs or any vacancies that may be desirable to them. All vacancies or new jobs created will be bulletined. Bulletins must be posted five days before vacancies are filled permanently. Employees desiring to avail themselves of this rule will make application to the official in charge and a copy of the application will be given to the local chairman.

Rule 19. Mechanics in service will be considered for promotion to positions as foremen. When vacancies occur in positions of gang foremen men from the respective crafts will have preference in promotion.

Rule 20. Employees transferred from one point to another, with a view of accepting a permanent transfer, will, after 30 days, lose their seniority at the point they left and their seniority at the point to which transferred will begin on date of transfer, seniority to govern. Employees will not be compelled to accept a permanent transfer to another point.

Rule 21. When the requirements of the service will permit, employees, on request, will be granted leave of absence for a limited time, with privilege of renewal. An employee absent on leave who engages in other employment, will lose his seniority unless special provisions shall have been made therefor by the proper official and committee representing his craft. The arbitrary refusal of a reasonable amount of leave of employees when they can be spared, or failure to handle promptly cases involving sickness or business matters of serious importance to the employee, is an improper practice and may be handled as unjust treatment under this agreement.

Absence from Work.—Rule 22. In case an employee is unavoidably kept from work he will not be discriminated against. An employee detained from work on account of sickness or for any other good cause shall notify his foreman as early as possible.

Faithful Service.—Rule 23. Employees who have given long and faithful service in the employ of the company and who have become unable to handle heavy work to advantage, will be given preference of such light work in their line as they are able to handle.

Attending Court.—Rule 24. When attending court as witnesses for the railroad, employees will receive pay for all time lost at home station, with a minimum of eight hours' time each week day and eight hours at rate and one-half for Sundays and holidays, either at home station, away from home, or traveling. Time and one-half will be paid for traveling during overtime hours where emplyoees are unable to secure sleeping car accommodation. Actual expenses will be allowed when away from home station, and necssary expenses will be allowed when at home. When necessary, the company will furnish transportation and will be entitled to certificate for witness fees in all cases.

Paying Off.—Rule 25. Employees will be paid off during their regular working hours, semi-monthly, except where existing state laws provide a more desirable paying off condition. Should the regular pay day fall on a holiday or days when the shops are closed down, men will be paid on the preceding day. Where there is a shortage equal to one day's pay or more in the pay of an employee, a voucher will be issued to cover the shortage. Employees leaving the service of the company will be furnished with a time voucher covering all time due within 24 hours where D. C. checks are issued and within 48 hours at other points, or earlier when possible.

Rule 26. During inclement weather provision will be made where buildings are available to pay employees under shelter.

Reduction of Forces.—Rule 27. When it becomes necessary to reduce expenses, the force at any point or in any department or sub-division thereof shall be reduced, seniority as per Rule 31 to govern; the men affected to take the rate of the job to which they are assigned. Five days' notice will be given men affected before reduction is made, and lists will be furnished local committee. In the restoration of forces, senior laid off men will be given preference of re-employment, if available, within a reasonable time, and shall be returned to their former position; local committee will be furnished list of men to be restored to service; in reducing force the ratio of apprentices will be maintained.

Rule 28. Employees laid off on account of reduction in force, who desire to seek employment elsewhere, will, upon application, be furnished with a pass to any point desired on the same railroad.

Rule 29. When reducing forces, if men are needed at any other point they will be given preference to transfer to nearest point, with privilege of returning to home station when force is increased, such transfer to be made without expense to the company. Seniority to govern all cases.

Rule 30. Employees required to work when shops are closed down, due to breakdown in machinery, floods, fires, and the like, will receive straight time for regular hours, and overtime for overtime hours.

Seniority.—Rule 31. Seniority of employees in each craft covered by this agreement shall be confined to the point employed in each of the following departments: Maintenance of Way (Bridge and Building where separate from Maintenance of Way Department); Maintenance of Equipment; Maintenance of Telegraph; Maintenance of Signals; four subdivisions of the Carmen as follows: Patternmakers, Upholsters, Painters, and other Carmen. The seniority lists will be open to inspection and copy furnished the committee.

Assignment of Work.—Rule 32. None but mechanics or apprentices regularly employed as such shall do mechanics' work as per special rules of each craft, except foreman at points where no mechanics are employed.

Rule 33. In compliance with the special rules included in this agreement, none but mechanics and their apprentices in their respective crafts shall operate oxy-acetylene, thermit, or electric welders; where oxy-acetylene or other welding processes are used, each craft shall perform the work which was generally recognized as work belonging to that craft prior to the introduction of such processes, except the use of the cutting torch when engaged in wrecking service.

Filling Foremanship Temporarily.—Rule 34. Should an employee be assigned temporarily to fill the place of a foreman, he will be paid his own rate, straight time for straight time hours and overtime for overtime hours, if greater than the foreman's rate. If it is not, he will get the foreman's rate. Such positions shall be filled only by mechanics of the respective craft in their departments.

Grievances.—Rule 35. Should any employee subject to this agreement believe he has been unjustly dealt with, or any of the provisions of this agreement have been violated, the case shall be taken to the foreman, general foreman, master mechanic, or shop superintendent, each in their respective order, by the duly authorized local committee or their representative. If stenographic report of investigation is taken, the committee shall be furnished a copy. If the result still be unsatisfactory, the duly authorized general committee, or their representatives, shall have the right of appeal, preferably in writing, to the higher officials designated to handle such matters in their respective order, and conference will be granted within ten days of application. All conferences between local officials and local committees to be held during regular working hours without loss of time to committeemen.

Rule 36. Should the highest designated railroad official or his duly authorized representative and the duly authorized representative of the employees fail to agree, the case shall then be jointly submitted in writing to the chief executive officer of the railroad and the chief executive officer of the Railway Employees' Department of the American Federation of Labor for adjudication or final disposition. The methods of procedure will be those prescribed by the Railroad Administration. To the extent that these rules may remain in force after the expiration of federal operation, the methods of procedure will thereafter be such as may be agreed to by the representatives of the railroads and the representatives of the organizations herein specified. Prior to the assertion of grievances as herein provided, and while questions of grievances are pending, there will neither be a shut down by the employer nor a suspension of work by the employees.

Rule 37. An employee who has been in the service of the railroad 30 days shall not be dismissed for incompetency, neither shall an employee be discharged for any cause without first being given an investigation.

Rule 38. If it is found that an employee has been unjustly discharged or dealt with, such employee shall be reinstated with full pay for all time lost.

Committees.—Rule 39. The company will not discriminate against any committeemen, who from time to time, represent other employees, and will grant them leave of absence and free transportation when delegated to represent other employees.

Apprentices.—Rule 40. All appretices must be able to speak, read, and write the English language and understand at least the first four rules of arithmetic. Applicants for regular apprenticeship shall be between 16 and 21 years of age, and if accepted, shall serve four years of 290 days each calendar year. If retained in the service at the expiration of their apprenticeship they shall be paid not less than the minimum rate established for journeymen mechanics of their respective crafts. In selecting helper apprentices, seniority will govern and all selections will be made in conjunction with the respective craft shop committees. (Note: See special rules of each craft for additional apprentice rules.)

Rule 41. All apprentices must be indentured and shall be furnished with a duplicate of indenture by the company, who will also furnish every opportunity possible for the apprentice to secure a complete knowledge of the trade.

No apprentice will be started at points where there are not adequate facilities for learning the trade.

Rule 40 shall govern in the employment of apprentices.

FORM OF INDENTURE

This will certify that............................... ...was employed as a ....apprentice by the.............................Railroad, at...........................on.......... ....19..., to serve four years, a minimum of two hundred and ninety days each.

....
(Title of officer in charge.)

SERVICE PERFORMED DURING APPRENTICESHIP

....
....
....

This will certify that on................, 19.... .... completed the course of apprenticeship specified above and is entitled, if employed by the..........................Railroad to the rates of pay and conditions of service of...

....
(Title of officer in charge.)

Note: *The above form is to be used both for regular and helper apprentices. (Helper apprentices to serve 3 years.)*

Rule 42. The ratio of apprentices in their respective crafts, shall not be more than one to every five mechanics. Two apprentices will not be worked together as partners. The distribution of apprentices among shops where general repairs are made on the division shall be as nearly as possible in proportion to the mechanics in the respective trades employed therein. In computing the number of apprentices that may be employed in a trade on a division, the total number of mechanics of that trade employed on the division will be considered. If, within six months, an apprentice shows no aptitude to learn the trade, he will not be retained as an apprentice. An apprentice shall not be dismissed or leave the service of his own accord, except for just and sufficient cause, before completing his apprenticeship. Apprentices shall not be assigned to work on night shifts. An apprentice shall not be allowed to work overtime during the first three years of his apprenticeship. If an apprentice is retained in the service upon completing the apprenticeship, his seniority rights as a mechanic will date from the time of completion of apprenticeship. Preference will be given to sons of employees in the selection of apprentices to the extent of at least 80 per cent of the number employed.

Rates of Pay.—Rule 43. The rate for all mechanics who were receiving 68 cents per hour or more under Supplement 4 to General Order 27, except those provided for in Rule 45, will be increased 4 cents per hour, effective May 1, 1919. Steel car workers and other mechanics in the car department who were receiving the rate of 63 cents per hour, under Supplement 4 to General Order 27, will be increased 4 cents per hour, effective May 1, 1919. Other mechanics in the car department who were receiving 58 cents per hour, under Supplement 4 to General Order 27, will be increased 9 cents per hour, making a rate of 67 cents per hour, effective May 1, 1919.

Rule 44. Apprentices, helpers, and other classes of workmen covered by Supplement 4 to General Order 27, except those provided for in Rule 45, will be increased 4 cents per hour above the present rate, effective May 1, 1919. This increase to apply also to men paid on the step-rates provided for in Section 2 and 2a of Article 2, Supplement 4 to General Order 27, except those provided for in Rule 45, effective May 1, 1919.

Rule 45. Linemen and others covered by Rule 141 shall receive 68 cents per hour, effective May 1, 1919. Groundmen covered by Rule 142 shall receive 62 cents per hour, effective May 1, 1919. Coal pier elevator operators and coal pier electric hoist operators as covered by Rule 143 shall receive 55 cents per hour, effective May 1, 1919.

Applicants for Employment.—Rule 46. Applicants for employment will be required to make statement only as to their ability, and address of relatives, except when their duties require them to distinguish signals or do flagging when they shall be required to pass the usual eyesight and hearing tests.

Conditions of Shops, Etc.—Rule 47. Good drinking water and ice will be furnished. Sanitary drinking fountains will be provided where necessary. Pits and floors, lockers, toilets and wash rooms will be kept in good repair and in a clean, dry and sanitary condition. Shops, locker rooms and wash rooms will be lighted and heated in the best manner possible consistent with the source of heat and light available at the point in question.

Personal Injuries.—Rule 48. Employees injured while at work will not be required to make accident reports before they are given medical attention, but will make them as soon as practicable thereafter. Proper medical attention will be given at the earliest possible moment, and employees shall be permitted to return to work without signing a release pending final settlement of the case. At the option of the employee, personal injury settlements may be handled under the provisions of Rules 35 and 36. Where death or permanent disability results from injury, the lawful heirs of the deceased may have the case handled as herein provided.

Rule 49. A place will be provided inside all shops and roundhouses where proper notices of interest to employees may be posted.

Shop Trains.—Rule 50. Existing conditions in regard to shop trains will be maintained unless changed by mutual agreement. The company will endeavor to keep shop trains on schedule time, properly heated and lighted, and in a safe, clean and sanitary condition. This not to apply to temporary service provided in case of emergency.

Free Transportation.—Rule 51. Employees covered by this agreement, and those dependent upon them for support, will be given the same consideration in granting free transportation as is granted other employees in service. General committees representing employees covered by this agreement to be granted same consideration as is granted general committees representing employees in other branches of the service.

Rule 52. Employees will not be required to work on engines or cars outside of shops during inclement weather, if shop room and pits are available. This does not apply to work in engine cabs or emergency work on engines or cars set out for or attached to trains. Should it become necessary to establish a regular night shift in shops, such men will not be used on running repair work unless work is brought to shop. When it is necessary to make repairs to engines, boilers, tanks and tank cars, such parts shall be cleaned before mechanics are required to work on same. This will also apply to cars undergoing general repairs. Employees will not be assigned to jobs where they will be exposed to sand blast and paint blowers while in operation. All acetylene or electric welding or cutting will be protected by a suitable screen when its use is required.

Rule 53. Emery wheels and grindstones will be installed at convenient places in the shop and will be kept true and in order.

Help to be Furnished.—Rule 54. Craftsmen and apprentices will be furnished sufficient competent help, when needed to handle the work, if available. When experienced helpers are available, they will be employed in preference to inexperienced men. Laborers when used as helpers will be paid the helpers' rate.

Rule 55. When dismantling or scrapping engines, boilers, tanks, cars (except wood cars) or other machinery, this work will be done by mechanics of their respective crafts. Sufficient help will be furnisbed. When wood cars are dismantled for scrapping, parts to be removed before car is burned or destroyed will be removed by carmen.

Rule 56. No employee will be required to work under a locomotive or car without being protected by proper signals. Where the nature of the work to be done requires it, locomotives or passenger cars will be placed over a pit, if available.

Rule 57. In shops and roundhouses not now equipped with connections for taking the steam from engines arrangements will be made to equip them so that steam from locomotives will not be blown off inside the house.

Rule 58. All engines will be placed under smoke jacks in roundhouses where practicable, when being fired up.

Rule 59. At shops and roundhouses equipped with electricity, electric light globes and extensions will be kept in tool rooms available for use.

Rule 60. When employees are required to check in and out on their own time, they will be paid one hour extra at the close of each week, regardless of the number of hours worked during the week.

MACHINISTS' SPECIAL RULES

Qualifications.—Rule 61. Any man who has served an apprenticeship or has had four years' experience at the machinists' trade and who, by his skill and experience, is qualified and capable of laying out and fitting together the metal parts of any machine or locomotive, witb or without drawings, and competent to do either sizing, shaping, turning, boring, planing, grinding, finishing, or adjusting the metal parts of any machine or locomotive whatsoever shall constitute a machinist.

Classification of Work.—Rule 62. Machinists' work shall consist of laying out, fitting, adjusting, shaping, boring, slotting, milling, and grinding of materials used in building, assembling, maintaining, dismantling, and installing locomotives and engines (operated by steam or other power), pumps, cranes, hoists, elevators, pneumatic and hydraulic tools and machinery, scale building, shafting, and other shop machinery; ratchet and other skilled drilling and roaming; tool and die making, tool grinding and machine grinding, axle truing, axle, wheel and tire turning and boring; engine inspecting; air equipment, lubricator and injector work; removing, replacing, grinding, bolting, and breaking of all joints on superheaters; oxy-acetylene, thermit and electric welding on work generally recognized as machinists' work; the operation of all machines used in such work, including drill presses and bolt threaders using a facing, boring or turning head or milling apparatus, and all other work generally recognized as machinists' work.

Machinist Apprentices.—Rule 63. Include regular and helper apprentices in connection with the work defined by Rule 62.

Machinist Helpers.—Rule 64. Employees assigned to help machinists and apprentices, operators of drill presses and bolt threaders not equipped with a facing, boring or turning head or milling apparatus, bolt pointing and centering machines, wheel presses, bolt threaders, nut tappers and facers; crane men helpers, tool room attendants, machinery oilers, box packers, grease cup fillers and oilers, and applying all couplings between engine and tenders; locomotive tender and draft rigging work except when performed by carmen.

Assignment to Running Repairs.—Rule 65. Machinist assigned to running repairs, shall not be required to work on dead work, at points where dead work forces are maintained.

Dead Work.—Rule 66. Dead work means all work on an engine which can not be handled wtihin 24 hours by the regularly assigned running repair forces maintained at point where the question arises.

Dead Work and Running Repair Forces.—Rule 67. Dead work forces will not be assigned to perform running repair work, except when tbe regularly assigned running repair forces are unable to get engines out in time to prevent delay to train movement.

Work at Wrecks.—Rule 68. In case of wrecks where engines are disabled, machinist and helper (more if necessary) shall accompany the wrecker. They will work under the direction of the wreck foreman.

Apprentices Classification of Work.—Rule 69. Apprentices shall be instructed in all branches of the machinists' trade. They will serve three years on machines and special jobs. Apprentices will not be required to work more than four months on any one machine or special job. During the last year of their apprenticeship they will work on the floor. Apprentices shall not work on oxy-acytylene, thermit, electric or other welding processes until they are in their last year.

Helper Apprentices.—Rule 70. Helpers who have had not less than two consecutive years' experience as machinist helper at tbe point where employed, at the time application for apprenticeship is made may become a helper apprentice. When assigned as a belper apprentice they must not be over 25 years of age.

Rule 71. Helper apprentices shall serve three years, a minimum of 290 days each calendar year, and sball be governed by the same laws and rules as governed regular apprentices.

Rule 72. The number of helper apprentices must not at any time exceed 50 per cent of the combined number of regular and belper apprentices assigned.

Rule 73. Helper apprentices shall receive the minimum helper rate for the first six months, with an increase of 2 cents per hour for every six months thereafter until they have served three years.

Helpers.—Rule 74. Helpers, when used in any way in connection with machinists' work shall in all cases work under the orders of tbe macbinist, both under the direction of the foremen.

Rule 75. When vacancies occur under classification of macbinist helper (temporary or permanent) machinist helpers in the service will be given preference in promotion to position paying either same or higher rate at station employed, seniority to govern.

Rule 76. Laborers, or similar class of workmen, shall not be permitted to do helpers' work as outlined in Rule 64 if regular macbinist helpers are available.

Differentials for Machinists.—Rule 77. Machinists required to inspect locomotives and swear to reports required by the Federal Locomotive Inspection Law shall receive 5 cents per hour above the minimum rate paid machinists at the point employed. Autogenous welders shall receive 5 cents per hour above the minimum rate paid machinists at the point employed.

BOILERMAKERS' SPECIAL RULES

Qualifications.—Rule 78. Any man wbo has served an apprenticeship, or has had four years' experience at the trade, who can witb the aid of tools, with or without drawings, and is competent to either lay out, build or repair boilers, tanks and details tbereof, and complete same in a mechanical manner shall constitute a boilermaker.

Classification of Work.—Rule 79. Boilermakers' work shall consist of laying out, cutting apart, building or repairing boilers, tanks and drums; inspecting, patching, riveting, chipping, calking, flanging and flue work; building, repairing, removing and applying steel cabs and runnin boards; laying out and fitting up any sheet iron or steel work made of 16 gauge or heavier; (present practice between boilermakers and sheet metal workers on railroads to continue relative to guage of iron), including fronts and doors; grate and grate rigging, ash pans, front end netting and diapbragm work; engine tender steel underframe and steel tender truck frames, except where other mechanics perform tbis work, removing and applying all staybolts, radials, flexible caps, sleeves, crown bolts, stay rods and braces in boilers, tanks and drums, applying and removing arcb pipes; operating punches and shears for shaping and forming, pneumatic stay bolt breakers, air rams and hammers; bull, jam and yoke riveters; boilermakers' work in connection with the building and repairing of steam shovels, derricks, booms, housing, circles and coal buggies; eye beam, channel iron, angle iron and tee iron work; all drilling, cutting and tapping, and operating rolls in connection with boilermakers' work; oxy-acetylene, tbermit and electric welding, on work generally recognized as boilermakers' work, and all other work generally recognized as boilermakers' work. It is understood that present practice in tbe performance of work between boilermakers and carmen will continue.

Boilermaker Apprentices.—Rule 80. Include regular and helper apprentices in connection with the work as defined by Rule 79.

Boilermaker Helpers.—Rule 81. Employees assigned to belp boilermakers and their apprentices, operators of drill presses and bolt cutters in the boiler shop, boilerwashers, punch and shear operators (cutting only bar stock and scrap).

Running Repair Work.—Rule 82. Running repair work for boilermakers shall consist of such boilermakers' work as is necessary to fit locomotive to make a successful trip. It shall include staybolt inspection, ordinary repairs to ash pan and front end nettings, calking and repairing leaks in fireboxes and exterior of boiler tanks. The application of staybolts, patcbes and flues, will be done by dead work forces, but at points where no dead work forces are employed, the roundhouse men will be expected to do such work as will be necessary to fit engine to return to main terminal.

Special Services.—Rule 83. Flange turners, layer outs, and fitter ups shall be assigned in shops where flue sheets and half side sheets or fireboxes are flanged, removed and applied. One man may perform all these operations where the service does not require more than one man. Boiler inspectors—staybolt inspectors will be assigned at all points where monthly staybolts and boiler inspection of 15 or more engines is required. When such employees have no inspection work to perform, they may be assigned to other boilermakers' work.

Protection for Employees.—Rule 84. Boilermakers, apprentices and helpers will not be required to work on boilers or tanks while electric or other welding processes are in use or when tires are being heated, unless proper protection is provided.

Rule 85. Not more than one oxy-acetylene welding or cutting operator or electric operator will be required to work in firebox or shell of boiler at the same time, unless proper protection is provided.

Rule 86. Oxy-acetylene welding or cutting operator or electric operator will be furnished with helper when necessary or when, in the opinion of the operator, it is essential for personal safety.

Rule 87. Should it become necessary to send oxy-acetylene welder or cutter or electric operator out of the shop in cold weather, he will be given ample time to dry off before being sent out.

Rule 88. When it is necessary to renew, remove or replace flue, door, side or crown sheets, by means of oxy-acetylene or other cutting and welding processes, such portion of the ash pan wings and grates as interfere with the operator, will be removed. Dome caps will be removed and front ends opened up if required, for proper ventilation.

Rule 89. Boilers will have steam blown off and be sufficiently cooled before boilermakers or apprentices are required to work in them; blowers will be furnished when possible to do so. Fireboxes, front ends and ash pans will be properly cleaned out before boilermakers or apprentices are required to work in them. Front ends and fireboxes of engines held in for other than running repairs will be washed out before boilermakers or apprentices are required to work in them. Fire brick interfering with the work to be performed will be removed.

Rule 90. Two boilermakers, or one boilermaker and a competent apprentice with at least two years' experience will be used to operate a long stroke hammer: that is, an air hammer capable of driving staybolts or rivets 5/8 in. diameter or larger, or of expanding flues or tubes. Double gun work will not be permitted. When rolling or expanding superheater flues, two boilermakers, or one boilermaker and a competent apprentice with at least two years' experience, will be used.

Rule 91. No tapping or reaming will be done in fireboxes when same is near enough to endanger the men working on inside of firebox. A space of 10 rows of staybolts will be considered sufficient, it being understood that the helper will protect the men with a sleeve over a tap when tapping is being done.

Furnishing Help.—Rule 92. Boilermakers engaged on running repair work will be furnished a helper when necessary, or when it is essential for personal safety.

Rule 93. Boilermakers sent out on the road to do boilermakers' work will be accompanied by helper, when such work requires a helper at home points.

Removal of Fines.—Rule 64. When flues (other than burst flues) are to be removed, the front end will be opened and such parts of the draft appliances as interfere with the boilermaker will be removed. Center arch pipes in engine, other than those equipped with combustion chambers, which interfere with boilermakers in the performance of their work, will be removed.

Helpers on Flange Fires.—Rule 95. Sufficient competent help will be furnished on flange fires.

Rule 96. Helpers on flange fires will not be asked to go outside of shop to handle fuel during cold weather.

Rule 97. Helpers while engaged on flange fires will not be requested to do other work than that in connection with flanging, and, as far as practicable, regularly assigned men will be used on flange fires.

Helpers.—Rule 98. There will be two helpers used in helping a boilermaker or apprentice in breaking down ten or more staybolts with a hand ram.

Rule 99. Classified boilermaker helpers will attend tool room in boiler shop.

Rule 100. Holding on all staybolts and rivets, striking chisel bars, side sets and backing out punches, scaling boilers, and heating rivets (except when performed by apprentices) will be considered boilermaker helpers' work.

Rule 101. When rivets larger than five-eighths inch are to be cut off or backed out, sufficient help will be furnished.

Rule 102. Boilermakers or apprentices, when using compound motors, will be furnished sufficient competent help.

Rule 103. Two helpers will be furnished, when holding on rivets, with wedge bars.

Rule 104. Helpers will do all other work generally recognized as boilermaker helpers' work.

Helper Apprentices.—Rule 105. Fifty per cent of the apprentices may consist of boilermaker helpers who have had not less than two consecutive years' experience as boilermaker helper at the point where employed at the time application for apprenticeship is made. They shall be between the ages of 21 and 40 years and shall serve three years, a minimum of 290 days each calendar year. Helper apprentices shall be governed by the same laws and rules as regular apprentices. Apprentices shall not work on oxy-acetylene, thermit, electric, or other welding processs until they are in their last year. They shall receive the minimum helpers' rate for the first six months, with an increase of two cents per hour for every six months thereafter until they have served their apprenticeship.

Schedule of Work, Regular Apprentices.—Rule 106. The following schedule for regular apprentices showing the division of time on the various classes of work is designed as a guide and will be followed as closely as the conditions will permit.

6 months—heating rivets and helping boilermakers.
6 months—Tank repairing and sheet iron work
6 months—Rolling flues; ash pan work.
6 months—Staybolts and setting flues.
15 months—General boiler work.
3 months—Electric or oxy-acetylene welding.
6 months—Laying out and flanging.

Rule 107. The following schedule for helper apprentices showing the division of time on the various classes of work is designed as a guide and will be followed as closely as the conditions will permit:

6 months—Tank repairing and sheet iron work.
6 months—Rolling flues; ash pan work.
6 months—Staybolts and setting flues.
9 months—General boiler work.
3 months—Electric or oxy-acetylene welding.
6 months—Laying out and flanging.

Differentials for Boilermakers.—Rule 108. Boilermakers assigned as boiler inspectors, also flangers, layers-out, and autogenous welders shall receive 5 cents per hour above the minimum rate paid boilermakers at the point employed.

Rule 109. Helpers on flange fires shall receive 5 cents per hour above the helpers' rate at point employed.

BLACKSMITHS' SPECIAL RULES

Qualifications.—Rule 110. Any man who has served an apprenticeship, or who has had four years' varied experience at the blacksmiths' trade shall be considered a blacksmith. He must be able to take a piece of work pertaining to his class, and with or without the aid of drawings, bring it to a successful completion within a reasonable length of time.

Classification of Work.—Rule 111. Blacksmiths' work shall consist of welding, forging, heating, shaping, and bending of metal; tool dressing and tempering, spring making, tempering and repairing, potashing, case and bichloride hardening; flue welding under blacksmith foreman; operating furnaces, bulldozers, forging machines, drop-forging machines, bolt machines and Bradley hammers; hammersmiths, drop hammermen, trimmers, rolling mill operators; operating punches and shears doing shaping and forming in connection with blacksmiths' work; oxy-acetylene, thermit and electric welding on work generally recognized as blacksmiths' work, and all other work generally recognized as blacksmiths' work.

Blacksmith Apprentices. Rule 112. Include regular and helper apprentices in connection with the work as defined by Rule 111.

Blacksmith Helpers.—Rule 113. Employees assigned to helping blacksmiths and apprentices; heaters, hammer operators, machine helpers, drill press and boltcutter operators, punch and shear operators (cutting only bar stock and scrap) in connection with blacksmiths' work.

Helper Apprentices.—Rule 114. Fifty per cent of the apprentices may consist of helpers who have had not less than two consecutive years' experience in shop on the division where advanced. Seniority shall prevail in the selection of helper apprentices; those selected to be not over 30 years of age. Apprentices selected from helpers shall serve three years, a minimum of 290 days each calendar year. When started as an apprentice they shall receive the minimum helpers' rate of pay for the first six months, at the end of that time they shall receive 2 cents per hour increase and 2 cents per hour increase each succeeding six months while serving their apprenticeship. Helper apprentices shall be governed by the same laws and rules as regular apprentices. If after the first three months, they show no aptitude to learn the tradt, they shall be set back to helping and retain their former seniority as a helper. After completing their apprenticeship, they shall receive prevailing rate paid blacksmiths, if retained in the service.

Rule 115. Apprentices shall be given an opportunity to learn all branches of the trade, and will not be kept on any one class of work longer than four months. Apprentices shall not work on oxy-acetylene, electric or other welding processes until they are in their last year.

Rates to be Maintained.—Rule 116. A rate established on a certain class of work shall remain the same and the men placed on such work shall receive such rate.

Helpers Building Fires.—Rule 117. Blacksmith helpers required to prepare furnaces or build fires on their own time will be allowed 30 minutes straight time for each fire built or furnace prepared.

Running Repair Work.—Rule 118. Regularly assigned blacksmiths and helpers engaged on running repair work located at engine houses will work the same hours as other crafts in engine houses.

Furnace operators and Heaters.—Rule 119. Furnace operators (heaters) will be assigned to operate furnaces making or working material 6 in. or over and heating it for foremen. Heaters will be assigned to operate furnaces used in connection with forging machines 4 in. and over, or to heat any material 4 in. and over to be forged. Heaters will also be assigned to heavy fires. When operators are required on other furnaces, helpers will be used.

Rule 120. Coal and oil suitable for smithing purposes will be furnished at all times.

Rule 121. Competent steam hammer drivers will be furnished.

Rule 122. Blacksmiths sent out on the road to do blacksmiths' work will be accompanied by helper.

Rule 123. Helpers will do all other work generally recognized as blacksmith helpers' work.

Differentials for Blacksmiths.—Rule 124. Blacksmiths working or making material 6 in. or over shall be classified as hammersmiths and shall receive 10 cents per hour above the minimum rate paid blacksmiths at the point employed. Blacksmiths working material 4 in. or over, shall be classified as heavy fire blacksmiths and shall receive 5 cents per hour above the minimum rate paid blacksmiths at the point employed. Heaters on heavy fires shall receive 10 cents per hour above the minimum rate paid helpers at point employed. Hammer operators, and helpers working with hammersmiths or heavy fire blacksmiths shall receive 5 cents per hour above the minimum rate paid helpers at the point employed. Furnace operators (heaters) operating furnaces for hammersmiths shall receive the minimum rate paid blacksmiths at the point employed. Autogenous welders shall receive 5 cents per hour above the minimum rate paid blacksmiths at the point employed.

SHEET METAL WORKERS' SPECIAL RULES

Qualifications.—Rule 125. Any man who has served an apprenticeship or has had four or more years' experience at the various branches of the trade, who is qualified and capable of doing sheet metal work or pipe work as applied to buildings, machinery, locomotives, cars, etc., whether it be tin, sheet iron, or sheet copper, and capable of bending, fitting and brazing pipe, shall constitute a sheet metal worker.

Classification of Work.—Rule 126. Sheet metal workers shall include tinners, coppersmiths and pipe fitters employed in shop yards and buildings and on passenger coaches and engines of all kinds, skilled in the building, erecting, assembling, installing, dismantling, and maintaining parts made of sheet copper, brass, tin, zinc, white metal, lead, black, planished, pickled and galvanized iron of 10 gage and lighter (present practice between sheet metal workers and boilermakers on railroad to continue relative to gage of iron), including brazing, soldering, tinning, loading and babbitting; the bending, fitting, cutting, threading, brazing; connecting and disconnecting of air, water, gas, oil and steam pipes; the operation of babbitt fires and pipe-threading machines; oxy-acetylene, thermit and electric welding on work recognized as sheet metal workers' work, and all other work generally recognized as sheet metal workers' work.

Sheet Metal Worker Apprentices.—Rule 127. Include regular and helper apprentices in connection with the work as defined by Rule 126.

Sheet Metal Worker Helpers.—Rule 128. Employees regularly assigned as helpers to assist sheet metal workers and apprentices in their various classifications of work.

Rule 129 Sheet metal workers shall not be required to remove or apply blow-off or surface pipes or ash-pan blowers on boilers under steam

Rule 130. Sheet metal workers will be sent out on line of road and to outlying points, when their services are required, but not for small, unimportant running repair jobs.

Assignment or Running Repair Force to Dead Work.—Rule 131. The assignment of running repairs sheet metal workers to dead work shall not be the recognized practice; but at points where no dead work sheet metal workers are employed, they may be so assigned if the service requires it.

Assignment of Dead Work Force to Running Repairs.—Rule 132. Dead work forces will not be assigned to perform running repair work, except when the regularly assigned running repair forces are unable to get engines out in time to prevent delay to train movement.

Rule 133. Sheet metal workers will not be assigned to work not applicable to them, except in emergency cases.

Helper Apprentices.—Rule 134. Fifty per cent of the apprentices may be selected from helpers of this craft who have had not less than two consecutive years' experience as a sheet metal worker helper at the point where employed, and shall not be more than 30 years of age; such apprentice shall serve three calendar years, a minimum of 290 days each calendar year, seniority to govern

Rule 135. Helper apprentices will start at the third classification of regular apprentices' schedule when entering their apprenticeship, and continue through as regular apprentices. Helper apprentices will receive the minimum helpers' rate for the first six months, with an increase of 2 cents per hour for every six months thereafter until they have served three years.

Rule 136. Laborers, or similar class of workmen, shall not be permitted to do helpers' work as outlined in Rule 128 if regular sheet metal workers' helpers are available.

Rule 137. Regular apprentices' schedule and division of time:

6 months—Helping.
6 months—Light pipe work.
12 months—Tinning, babbitting and brazing, laying out and forming.
12 months—Engine and car work.
12 months—General work, including one month's experience with the oxy-acetylene torch.

Differentials for Sheet Metal Workers.—Rule 138. Autogenous welders shall receive 5 cents per hour above the minimum rate paid sheet metal workers at point employed.

ELECTRICAL WORKERS' SPECIAL RULES

Qualifications.—Rule 139. Any man who has served an apprenticeship or who has had four years' practical experience in electrical work and is competent to execute same to a successful conclusion will be rated as an electrical worker. An electrician will not necessarily be an armature winder.

Classification of Electricians.—Rule 140. Electricians' work shall consists of repairing, rebuilding, installing, inspecting and maintaining the electric wiring of generators, switchboards, motors and control, rheostats and control, static and rotary transformers, motor generators, electric headlights and headlight generators, electric welding machines, storage batteries, and axle lighting equipment; winding armatures, fields, magnet coils, rotors, transformers, and starting compensators. Inside wiring in shops and on steam and electric locomotives, passenger train and motor cars; include cable splicers, wiremen, armature winders, electric crane operators for cranes of 40 ton capacity or over, and all other work properly recognized as electricians' work.

Classification of Linemen, Etc.—Rule 141. Linemen's work shall consist of building, repairing and maintaining pole lines and supports for service wires and cables, catenary and monorail conductors and feed wires, overhead and underground and all outside wiring in yards. Men employed as motor attendants, generator attendants and substation attendants who start, stop and oil and keep their equipment clean and change and adjust brushes for the proper running of their equipment, switchboard operators, coal in connection with loading and unloading vessels. Electric crane operators for cranes of less than 40-ton capacity.

Rule 142. Groundmen's work shall consist of assisting linemen in their duties when said work is performed on the ground.

Rule 143. Coal pier elevator operators and coal pier electric hoist operators in connection with loading and unloading vessels.

Apprentices Electrical Workers.—Rule 144. Include regular and helper apprentices in connection with electrical workers.

Electrical Worker Helpers.—Rule 145. Employees regularly assigned as helpers to assist electrical workers and apprentices, including electric lamp trimmers who do no mechanical work.

Rule 146. Fifty per cent of the apprentices may consist of electrical workers' helpers who have had two years continuous service at the point where employed. When assigned as helper apprentices, they must not be over 25 years of age, and shall serve three years, a minimum of 290 days each calendar year.

Rule 147. The following schedule for regular apprentices, showing the division of time on the various classes of work, is designed as a guide and will be followed as closely as possible:

12 months—Inside wiring and electrical repairing.
6 months—Outside line work.
6 months—Locomotive headlight work.
6 months—Car lighting department.
6 months—Armature winding.
12 months—General electrical work.

Rule 148. Helper apprentices will receive the minimum helpers' rate for the first six months, with an increase of two cents per hour for every six months thereafter until their apprenticeship is completed. If within six months they show no ability to acquire the trade, they will be set back to helping and retain their former seniority as a helper. After completing their apprenticeship they shall receive the minimum rate paid for the work to which they are assigned, if retained in the service.

Rule 149. The following schedule for helper apprentice showing the division of time on the various classes of work, is designed as a guide and will be followed as closely as possible:

6 months—Inside wiring and electrical repairing.
6 months—Outside line work.
6 months—Locomotive headlight work.
6 months—Car lighting department.
6 months—Armature winding.
6 months—General electrical work.

Rule 150. Laborers or similar class of workmen shall not be permitted to do helpers' work as outlined in Rule 145 if regular electrical worker helpers are available

Rule 151. Men engaged in the handling of storage batteries and mixing acid must be provided with acid-proof rubber gloves, hip boots and aprons.

Rule 152. Autogenous welders shall receive 5 cents per hour above the minimum rate paid electrical workers at point employed.

CARMEN'S SPECIAL RULES

Qualifications.—Rule 153. Any man who has served an apprenticeship or who has had four years' practical experience at car work, and who with the aid of tools, with or without drawings, can lay out, build or perform the work of his craft or occupation in a mechanical manner, shall constitute a carman.

Classification of Work.—Rule 154. Carmen's work shall consist of building, maintaining, dismantling, painting, upholstering and inspecting all passenger and freight cars, both wood and steel, planing mill, cabinet and bench carpenter work, pattern and flask making, and all other carpenter work in shop and yards; carmen's work in building and repairing motor cars, lever cars, hand cars and station trucks; building, repairing and removing and applying locomotive cabs, pilots, pilot beams, running boards, foot and headlight boards, tender frames and trucks; pipe and inspection work in connection with air brake equipment on freight cars; applying patented metal roofing; repairing steam heat hose for locomotives and cars; operating punches and shears doing shaping and forming, hand forges and heating torches in connection with carmen's work; painting, varnishing, surfacing, lettering, decorating, cutting of stencils, and removing paint; all other work generally recognized as painters' work, under the supervision of the locomotive and car departments; joint car inspectors, car inspectors, safety appliance and train car repairers, wrecking derrick engineers, and wheel record keepers; oxy-acetylene, thermit and electric welding on work generally recognized as carmen's work, and all other work generally recognized as carmen's work. It is understood that present practice in the performance of work between the carmen and boilermakers will continue.

Carmen Apprentices.—Rule 155. Include regular and helper apprentices in connection with the work as defined by Rule 154.

Carmen Helpers.—Rule 156. Employees regularly assigned to help carmen and apprentices, employees engaged in washing and scrubbing the inside and outside of passenger coaches, preparatory to painting, car oilers and packers, stock keepers (Car Department). Material carriers, rivet heaters (except when performed by apprentices), operators of bolt threaders, nut tappers, drill presses and punch and shear operators (cutting only bar stock and scrap), holding on rivets, striking chisel bars, side sets and backing out punches, using backing hammer and sledges in assisting carmen in straightening metal parts of cars, cleaning journals, assist carmen in erecting scaffolds and all other work generally recognized as carmen helper's work.

Wrecking Crews.—Rule 157. Wrecking crews, including engineers and firemen shall be composed of regularly assigned carmen, and will be paid for such service as per General Rules from time called until return to their home station. Meals and lodging will be provided by the company while crews are on duty in wrecking service.

Rule 158. When wrecking crews are called for wrecks or derailments outside of yard limits, the regularly assigned crew will accompany outfit. For wrecks or derailments within yard limits, sufficient carmen will be called to perform the work.

Inspectors.—Rule 159. Men assigned to inspecting must be able to speak and write the English language, and have a fair knowledge of the M. C. B. rules and safety appliance laws.

Rule 160. Inspectors and other carmen in train yards will not be required to take record, for conducting transportation purposes, of seals, commodities, or destination or cars.

Safety Appliance Men.—Rule 161. Men assigned to follow inspectors in yards to make safety appliance and light running repairs, shall not be required to work on cars taken from trains to repair tracks.

Protection for Repairmen.—Rule 162. Switches of repair tracks will be kept locked with special locks and men working on such tracks shall be notified before any switching is done. A competent person will be regularly assigned to perform this duty and held responsible for seeing it is performed properly.

Rule 163. Trains or cars while being inspected or worked on by train yard men will be protected by blue flag by day and blue light by night, which will not be removed except by men who place same.

One Man Points.—Rule 164. A "one main point" is an outlying point where there is employed one carman, day, and one, night, or where there is only one carman employed. Carmen stationed at one man points shall be paid by the hour and under the rules governing running repair forces, except that the eight hours constituting a day's work may be worked within a spread of ten consecutive hours.

Rule 165. Air hammers, jacks and all other power driven machinery and tools, operated by carmen or their apprentices will be furnished by the company and maintained in safe working condition.

Rule 166. Crayons, soapstone, marking pencils, tool handles, saw-files, motor bits, brace bits, cold chisels, bars, steel wrenches, steel sledges, hammers (not claw-hammers), reamers, drills, taps, dies, lettering and striping pencils and brushes will be furnished by the company.

Rule 167. The application of blacking to fireboxes and smoke boxes of locomotives, in roundhouses, will not be considered painters' work.

Rule 168. When necessary to repair or inspect cars on the road or away from the shops, carmen will be sent out to perform such work. Two carmen will be sent to perform such work as putting in couplers, draft rods, draft timbers, arch bars, center pins, putting cars on center, truss rods and wheels, and work of similar character.

Rule 169. Shops, repair yards and train yards where carmen are employed shall be kept clean of all rubbish.

Apprentices.—Rule 170. Regular apprenticeships will be established in all branches of the trade. Apprentices shall be governed by the general rules covering apprentices.

Rule 171. Apprentices shall not work on oxy-acetylene, thermit, electric or other welding processes until they are in their last year.

Helper Apprentices.—Rule 172. Fifty per cent of the apprentices may be selected from carmen's helpers who have had not less than two consecutive years' experience at the point employed, at the time application for apprenticeship is made. Helper apprentices shall not be over thirty years of age and will serve three years, a minimum of 290 days each calendar year. Helper apprentices shall be governed by the same laws and rules as regular apprentices. Helper apprentices shall receive the minimum helpers' rate for the first six months, with an increase of two cents per hour each succeeding six months until they have served three years. At the completion of their apprenticeship eriod, if retained in the service, they shall receive the mechanic's rate of pay.

Painter Apprentices, Regular.—Rule 173. Regular apprentices—Division of time for painter apprentices.

The following schedule for regular aprentices, painter, showing the division of time on the various classes of work, is designed as a guide and will be followed as closely as the conditions will permit:

6 months—Freight car painting.
6 months—Color room, mixing paint.
6 months—General locomotive painting.
12 months—Brush work, passenger equipment.
18 months—Lettering, striping, varnishing, and such laying-out and designing as the shop affords.

Schedule of Work, Painter Helper Apprentices.—Rule 174. Helper apprentices, division of time for painter apprentices. The following schedule for heler apprentices, painter, showing the division of time on the various classes of work, is designed as a guide and will be followed as closely as the conditions will permit:

4 months—Freight car painting,
4 months—Color room, mixing paint,
4 months—General locomotive painting,
10 months—Brush work, passenger equipment,
14 months—Lettering, striping, varnishing, and such laying-out and designing as the shop affords.

Regular Apprentices Carmen Schedule of Work.—Rule 175. The following schedule for regular apprentices, showing the division of time on the various classes of work, is designed as a guide and will be followed as closely as the conditions will permit. Where sufficient passenger car department work is not available without exceeding the regular ratio of apprentices, in the passenger car department, apprentices will complete their apprenticeship in the freight car department.

18 months—General freight work, wood and steel.
6 months—Air brake work.
6 months—Mill machine work.
18 months—General coach work, wood and steel.

Helper Apprentice Carmen Schedule of Work.—Rule 176. The following schedule for helper apprentices, showing the division of time on the various classes of work, is designed as a guide and will be followed as closely as the conditions will permit. Where sufficient passenger car department work is not available without exceeding the regular ratio of apprentices, in the passenger car department, apprentices will complete their apprenticeship in the freight car department.

12 months—General freight work, wood and steel.
6 months—Air brake work.
6 months—Mill machine work.
12 months—General coach work, wood and steel.

Rule 177. In the event of not being able to employ carmen with four years' experience and the regular and helper apprentice schedule not providing men enough to do the work, the force may be increased in the following manner: Regular apprentices who have served two years and helper apprentices who have served two years, may be promoted to mechanics at point employed and will be paid the minimum rate for carmen, seniority to govern. Helpers who have had four or more years' experience at point empolyed, may be promoted to mechanics, they to receive the minimum rate for carmen and be given an opportunity to learn the trade, seniority to govern. The duly authorized committee in each shop covered by this agreement will be consulted and mutual understanding arrived at in promoting helpers. The ratio of helpers to be promoted, to the number of mechanics in any one shop shall not exceed twenty per cent. The general chairman on each railroad affected shall be furnished a complete record of the men promoted. When a reduction is made in force of mechanics, promoted helpers in accordance with their seniority shall be set back first; then advanced apprentices. No mechanics to be laid off until all such promoted helpers and apprentices have been set back. Promoted apprentices and promoted helpers who have not served four years as mechanics, will be set back at any time that mechanics with four or more years' experience make application for employment.

Differentials for Carmen.—Rule 178. Autogenous welders shall receive 5 cents per hour above the minimum rate paid carmen at point employed.

Differentials for Coach Cleaners.—Rule 179. For coach cleaners establish basic minimum rate of 41 cents per hour and to this rate and all rates above 41 cents per hour add 4 cents making a minimum of 45 cents. Coach cleaners to be included in the national agreement and will receive overtime as provided therein.

MISCELLANEOUS

Scope of General and Special Rules.—Rule 180. Except as provided for under the special rules of each craft, the general rules shall govern in all cases.

Effect on Existing Agreements.—Rule 181. In consideration of the standardization of hours of service and rules governing working conditions hereby established on all railroads in Federal operation, the general and special rules of this agreement shall supersede and be substituted for the general and special rules of existing agreements in conflict herewith; rules of existing agreements dealing with conditions of employment not specifically provided for herein shall remain in effect and be recognized as addenda to this agreement by the several railroads who negotiated such rules. Rulings that have been made by the Director General of Railroads and Railroad Board of Adjustment No. 2, where not in conflict with the rules of this agreement, shall remain in effect.

Duration of Agreement.—Rule 182. These general and special rules and regulations shall remain in full force and effect during federal operation unless superseded or amended as herein provided. They shall be printed by the railroads and each employe affected thereby shall be provided with a copy on request.

Revision of Agreement, Etc.—Rule 183. Should either the Railroad Administration or the organizations desire to revise these rules, a written statement containing the proposed changes shall be given and conference held within thirty days to arrange details necessary to negotiate to a conclusion.

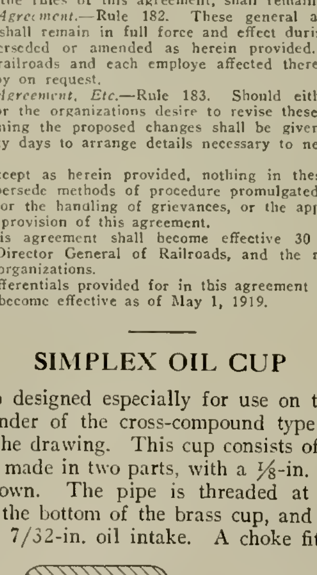
Rule 184. Except as herein provided, nothing in these rules shall be construed to supersede methods of procedure promulgated by the Railroad Administration for the handling of grievances, or the application or interpretation of the provision of this agreement.

Rule 185. This agreement shall become effective 30 days after date signed by the Director General of Railroads, and the representatives of the employees' organizations.

Rule 186. Differentials provided for in this agreement for highly skilled employees shall become effective as of May 1, 1919.

SIMPLEX OIL CUP

An oil cup designed especially for use on the high pressure air cylinder of the cross-compound type of air pump is shown in the drawing. This cup consists of a cylindrical brass casting made in two parts, with a 1/8-in. brass pipe inserted as shown. The pipe is threaded at one end and screwed into the bottom of the brass cup, and the other end is reduced to 7/32-in. oil intake. A choke fitting 5/64 in.



Cross Section of Simplex Oil Cup

in diameter is fitted into the outlet, thus preventing the cylinder from being flooded with oil. These cups require no regulating as they operate only while the air pumps are running, and as the feed is regular and the amount of oil only sufficient to meet the requirement of the pump, they are very economical.

In the cup illustrated old choke plugs from bull's-eye lubricators were used. As will be seen from the drawing, the oil syphons over the bend in the feed pipe, by this means feeding the oil in regular quantities when the pumps are in operation.

THE COST OF BRITISH LOCOMOTIVES

BY ROBERT E. THAYER

European Editor of the *Railway Mechanical Engineer*

Our London contemporary, the Railway Gazette, in a recent editorial criticizes the Egyptian State Railway Administration for spending several thousand pounds for locomotives in America, indicating that the purchases were made without due consideration of prices even though the British concerns quoted prices from 76 per cent to 81 per cent higher than that quoted by the successful American locomotive builder. Its implication was, although they took great pains to forestall any criticism in this respect, that even though the quotations of the British manufacturers were much higher than those of the American manufacturer "the quality of British workmanship and the class of material put into the engines, compared with those produced in other countries, result in an economy in repairs and maintenance and an increased life which more than repay the higher first cost."

The figures quoted as the bids of the British manufacturers were from £15,000 ($63,000)* to £17,000 ($71,400)* with a possible delivery in 1921, as against the American locomotive builder's figures of £8,500 ($35,000)* to £9,400 ($39,500)* with delivery in four months. In other words the Railway Gazette would imply that the workmanship of the British locomotive builders is sufficiently better to warrant the Egyptian State railways paying from $27,000 (76 per cent) to $32,000 (81 per cent) more a piece for their locomotives! We are well aware that the expense of maintenance and repairs should be as carefully considered as the first cost of an article, but at the same time we also believe that the interest on the investment is as important a factor as the cost of maintenance. Figuring money at five per cent, which is an exceedingly conservative rate at the present time, had the Egyptian State Railways purchased their locomotives from the British manufacturers at the quoted figures they would have had additional yearly capital charges varying from $1,400 to $1,600 to apply to each one of these engines.

Before the war, the manufacturers in Great Britain were in a particularly advantageous position as regards the cost of labor. They could economically put more labor in their manufactured articles and produce a product of greater refinement at a much lower cost than was possible in the United States. At the same time the low cost of labor made unnecessary the development and use of the so-called labor saving machinery. During and since the war, however, the cost of labor has increased in Great Britain to such an extent that the cost of the final product when made according to pre-war practice, is greatly increased. America, on the other hand, having had to carefully watch its labor cost has constantly improved its manufacturing methods by the installation of improved machinery, and on the other hand, found it impractical and uneconomical, in the final analysis, to go to the refinement of the British manufacturers.

The real lesson to be learned from the fact that the colonies of Great Britain can buy so much cheaper from America is that greater development has been made in America in the use of improved machinery. It has been repeatedly stated by careful students in manufacturing costs that with the greatly increased cost of labor, both Great Britain and many of the European countries will find it increasingly necessary to improve their manufacturing methods and to use more modern labor saving machinery than they have in the past.

RAILROAD ADMINISTRATION NEWS

The Railroad Administration, according to a statement authorized by Director General Hines on November 15, has proposed to the four brotherhoods representing the train and engine employees that in order to give an additional measure of compensation to the employees in the slow freight service, time and one-half will be paid for time required to make their runs in excess of what would be required if an average speed of 12½ miles per hour were maintained, provided, however, that all arbitraries and special allowances now paid in various forms of freight train service are entirely eliminated. The proposal was taken under consideration by the officials of the brotherhoods that have been conferring with Mr. Hines and Railroad Administration officials, with a view to consideration and further discussion. The statement says it is estimated that the net cost of this proposal will be approximately $3,000,000 a month, or $36,000,000 a year.

VOCATIONAL EDUCATION FOR MECHANICS AND APPRENTICES IN RAILROAD SHOPS

For the guidance of railroads contemplating the establishment of schools and classes for training of mechanics and apprentices under provisions of the federal vocational education act and the Division of Operation circular of August 1, 1919, the following additional information on the matter is submitted in a circular issued by Frank McManamy, assistant director of the division:

The federal vocational education act provides that schools organized under its provisions shall be conducted by the particular state in which the school or class may be located, and under the general direction of the state board for vocational education.

It is expressly stated in the act that the controlling purpose of the work to be aided under its provisions is to fit for useful employment those who are preparing for a trade or industrial pursuit or who have entered upon the work of a trade or industrial pursuit.

The purpose for which federal money has been appropriated and may be expended by the state and under what conditions the state may allot such funds is determined in general by the provisions of the law, all details of which will be furnished upon application to the state board for vocational education.

The general conditions for the conduct of the schools set up in the act are as follows:

1. The school or class must be under public supervision or control.
2. The controlling purpose must be to prepare for useful employment.
3. The instruction given in the schools must be of less than college grade.
4. All pupils must be over 14 years of age.
5. To meet the requirements of the vocational education act, the instruction must be given for not less than 144 hours per year. The United States Railroad Administration authorization for 208 hours of instruction per year meets this condition.
6. Every dollar of federal funds must be matched by a dollar of state or local money, or both. The expenditures are to be made by the state board or by the local community, and reimbursement made from federal funds by the state board for vocational education.
7. Reimbursements may be made from federal funds only for money expended for salaries of teachers. This does not include any reimbursement for buildings, equipment, or supplies.
8. The railroad must supply the plant and equipment adequate for the type of instruction to be given. This has

already been authorized by the Railroad Administration in circular issued August 1, 1919.

9. The course of study may include trade drawing, trade science, trade mathematics, and actual shop work. In all cases the instruction given shall be of the trade-extension type, supplementing in character the regular employment of the pupil.

10. The methods of instruction must be such as will insure the functioning of that instruction in the trade which the apprentice is learning. This means that the instruction should be given as far as possible by the individual method rather than through lectures. Demonstrations, illustrations, and examples should be drawn from the shop in which the pupil is employed. A careful coordination must be maintained between the instructor responsible for the related instruction in the classroom and the training which the apprentice is receiving in the shop.

11. All instructors for whose work reimbursement is to be made through the state board for vocational education must be thoroughly qualified and meet the qualifications set up by the state plan in the state in which the work is to be given. The instructor of related subjects should be a man possessing at least two years' technical education of college grade, or equivalent technical education, and having a satisfactory practical experience and contact in one or more of the trades represented in the railroad shop—a contact giving an appreciation and working knowledge of the principal trade processes. It is recognized that whenever a man can be found possessing, in addition to the technical training, a journeyman's experience in a trade, he is more likely to be successful as an instructor.

The Federal Board for Vocational Education, in co-operation with the United States Railroad Administration, will prepare suggested courses of study for at least three trades, namely, machine shop, boiler making, and sheet-metal work, and these suggested courses of study will be placed at the disposal of the various state boards, and through these boards can be obtained by the railroads upon application.

There are certain conditions which should be considered in making arrangements for railroad shop apprentices' schools under this plan:

1. There should be an advisory committee. Such committee may properly include representatives of the workers in the trades, the shop management, and public school.

2. This advisory committee should be responsible for insuring cooperation between the workers, shop management and public-school authorities.

3. The instructors employed for this work should be satisfactory to the advisory committee, as well as meeting the qualifications set up in the state plans.

4. The courses of study should be satisfactory to this advisory committee.

5. The classrooms to be used should be suitably fitted up for the instruction which is to be given, and they should be so located that the apprentices may readily have access from the shop to the classroom and the classroom to the shop without the necessity of making an entire change of clothing or entailing an unnecessary loss of time.

It is understood that railroads may conduct their own schools independent of these arrangements with the Federal Board for Vocational Education, but in such cases the entire expense will be borne by the railroad, and no reimbursement can be made from federal funds under provisions of the federal vocational education act.

ORDERS OF REGIONAL DIRECTORS

Condition of Locomotive Cabs.—The Northwestern regional director, file 66-1-122, states that the condition of many locomotive cabs is such that in cold weather severe hardships to the men as well as loss of efficiency will result. Openings in cabs around boilerheads, injector pipes, reverse levers and other places must be properly closed; clear vision windows must open and close properly; cab heaters must be applied and be put in proper condition for service, and suitable cab curtains must be provided as soon as needed.

Curtailment of Passenger Service.—The Railroad Administration has made drastic reductions in passenger service in all sections of the country in order to meet the threatened shortage of fuel due to decreased production of coal, which has fallen to less than 50 per cent of normal following the strike of bituminous miners. In the west one-third of the trains were discontinued, in New England 10 per cent were taken off and in the Eastern region practically the same reductions made during the war were again put into effect. The orders in some cases were even more drastic than the wartime restrictions. The Twentieth Century Limited, which had run all during the war was ordered discontinued after December 9.

The order limiting the number of trains in the Northwestern, Central Western and South western regions was issued by P. S. Eustis, chairman of the Western Passenger Committee. It called for the elimination of passenger trains which could be spared with the least inconvenience to the traveling public and the discontinuance of all parlor, club and lounge cars and the elimination of all special trains.

The order reducing the number of trains on the eastern roads was issued on December 5 by A. T. Hardin, regional director of the Eastern region and read in part as follows: "For the purpose of conserving fuel and to protect and provide sufficient transportation, an order has been given for a reduction in train service, effective 12:01 a.m., December 10, on all railroads in the Eastern region. This is necessary not only to conserve fuel, but also to afford the freest facility for expeditious movement of fuel where there may be acute shortages.

"The reduction in service will be general on all roads and will be made so far as practicable on the several lines having common termini, to support each other and afford the maximum service with the minimum number of trains and the least inconvenience to the traveling public. No special trains are to be run for pleasure travel; no second sections of regular trains will be operated except in cases of coach travel to and from cities of dense population, and then only when absolutely indispensable."

STEEL FIREBOXES IN EUROPEAN LOCOMOTIVES

BY W. G. LANDON

Steel fireboxes have not been popular in Europe and in the absence of any other explanation, the treatment the firebox gets in service—in other words, the methods of firing and boiler feeding—may account for this.

Abroad the old fashioned flat ash pan is universal and it is fitted with one or two dampers, which effectually exclude all air when they are closed. The lever controlling the damper is matched, thus permitting a graduated opening. The grates are usually of the fixed pattern. On the Continent shaking grates are used to a small extent but they are so arranged that they do not rock far enough to shake down the fire. Short brick arches are always installed, but arch tubes are not used. The smokebox contains no deflector plate or other arrangement for equalizing draft. Sometimes a netting is arranged around the petticost pipe.

In England boiler feeding is done uniformly on long runs, the injector being left on continuously as in America. Firing intervals are, however, much longer, three to five minutes or more. The practice is to put 10 to 15 shovelsful to a fire and as the grate areas are only 20 to 25 sq. ft., the cooling effect on the firebox must be considerable. All locomotives are supplied with lump coal, which makes this kind of firing possible. Usually the damper is partly closed and a considerable amount of air admitted through the firedoor. The firedoor opens inward on the locomotives of many English railways. In cases where it does not a deflector plate is used, thus driving the incoming air down on the fire. As the fire gets dirty, the damper is opened up and the firedoor closed if necessary. At the running shed or roundhouse, the fire is dumped by knocking out a few grate bars, and the smokebox door is opened and the cinders cleared out. In firing up, natural draft is used and, of course, if the boiler is cool d temperature difference in great is set up between the upper and lower portions of the firebox. Washing out is generally done with cold water, although a few hot water systems have been installed.

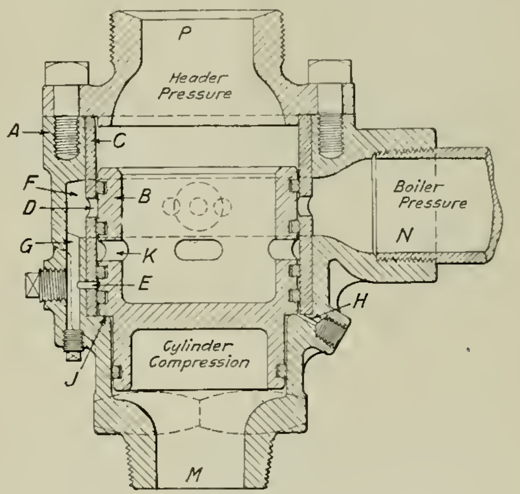
In France the methods are the same, except that injectors are usually over size, so that it is impossible to cut down the feed fine enough for continuous feeding. There is an exception to this—the Paris, Lyons & Mediterranean Railway. Both injectors of these locomotives are on the fireman's side and one is of the proper size for continuous pumping. The idea of the over-size injector originated many years ago, when French engines were supplied with lump coal. Just before firing, the injector was shut off and a large fire put in. Thus the cooling effect of the feedwater would be arrested while the cold air was entering through the firedoor. After the door was closed, the injector was again put on for four or five minutes until firing was again necessary. Now, however, the engines are supplied with coals having a large proportion of slack, so the firing intervals have to be shorter. Consequently the injector is left on for the same length of time, while the firing intervals are reduced to one or two minutes. The slack is wetted down copiously, forming a mush, and siz or seven shovels of this cause a considerable drop in firebox temperature, which together with the excessive amount of feedwater entering the boiler, must cool the lower flues and firebox more than is desirable. The theory of drenching the coal is that although heat is used in evaporating the water, the fusible part of the coal will run and bind the small particles before they are light enough to be lifted from the fire bed, and that the steam escaping from the wet slack forms air passages which assist in combustion. While this theory may have some basis the smokebox of an engine which has been worked on a long run is often nearly half filled with cinders and consequently a large number of the lower flues are plugged up. The firedoor is not left open while running, the draft being controlled by the variable exhaust.

At the roundhouse the fire is cleaned with a variety of implements carried on each engine, the good fire being pulled to the back and covered over, and the clinkers pushed forward. Before the crew leaves the engine, both injectors are frequently put on, thus filling the boiler at a very rapid rate when the fire is practically dead. When the fire is made up the clinkers are pushed out through a dump grate at the front of the firebox.

These practices may be followed occasionally without apparent injury to the boiler, but when they are persisted in the effect must be evident and it would seem that if steel firebox are to be introduced in Europe, some active propaganda on boiler treatment must be conducted.

RIPKEN AUTOMATIC DRIFTING VALVE FOR LOCOMOTIVES

Since superheated steam has come into general use the trouble experienced with deposits on locomotive pistons and cylinders has increased greatly. The use of the drifting throttle has proved effective in eliminating this trouble, but it is difficult to insure that the engineer uses the proper amount of steam and for that reason an automatic drifting valve has important advantages over the drifting throttle. Several types of drifting valves are in use at present, the majority being arranged to come into action when a vacuum is formed in the cylinder. Since the vacuum which operates the valve will also draw in the front end gases which cause



Section Showing the Construction of the Ripken Automatic Drifting Valve

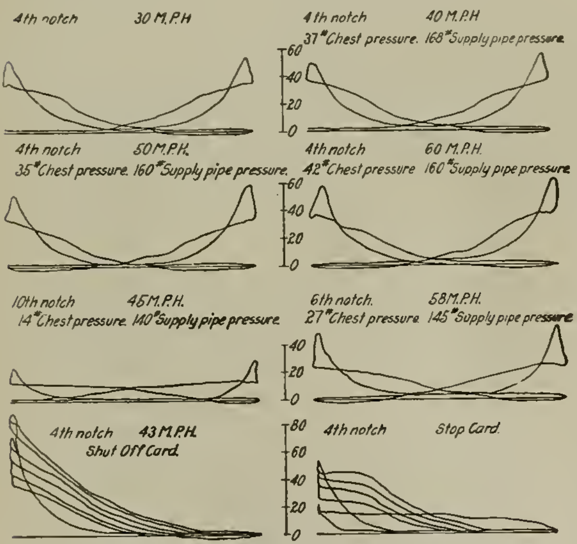
deposits on the cylinder walls, any drifting valve operated on this principle cannot entirely remove the trouble.

In order to do away with the formation of a vacuum in the cylinder a valve has been devised which is operated by the compression in the cylinder. This device is known as the Ripken automatic drifting valve and is in use on the Minneapolis, St. Paul & Sault Ste. Marie. The valve comes into operation before the cylinders are emptied of steam pressure after the throttle has been closed and is kept in operation and furnishes the needed amount of steam until the pistons cease to move. It is automatically closed just as the engine stops by the building up of pressure in the steam chest.

Only one valve per engine is used as the steam is passed directly to the branch pipe or the saturated end of the superheater header. This arrangement is advantageous as it reduces the amount of steam required and also protects the superheater elements against overheating. It is unnecessary to use either air relief valves or by-pass valves in conjunction with the Ripken drifting valve.

The illustration below shows a section of the valve which serves to illustrate its operation. The operating portion consists of a cage *A*, and a differential piston valve *B*. The cage has an opening *M*, at the bottom which is connected by the most direct means possible with one end of the cylinder so that the cylinder pressure is transmitted to the lower side of the piston. The side opening *N* is connected through a two-inch pipe to a live steam line from the turret. The opening *P* at the top of the valve communicates with the branch pipe or superheater header.

Within cage *A* is a bushing *C*, in which are ports *D* and *E*. The port *D* is surrounded by a duct *F*, which is always filled with live steam. From duct *F* live steam passes through the passage *G* to port *E*. At the lower end of the bushing *C* is a small regulating and relief port *H*,



Typical Indicator Cards from an Engine Equipped with the Ripken Drifting Valve

connected by piping to the exhaust chamber of the locomotive.

When the main throttle is closed the pressure on top of the differential piston *B* falls and the compression in the cylinders acting on the bottom of the valve being in excess of the steam chest pressure raises the valve *B* off the shoulder *J*, upon which it normally rests, placing the port *K* in communication with port *D*. This permits steam to flow through the valve into the steam chest maintaining the required pressure to prevent a vacuum while drifting. The raising of the valve also uncovers port *E* and the steam entering the annular cavity under the valve is restricted by the port *H* and furnishes the counter pressure necessary to hold ports *D* and *K* in communication until the engine is almost at a standstill. As the speed decreases the pressure in the steam chest will rise, and overcoming the pressure on the bottom of the differential valve, will force the valve to its seat, where the friction of the rings will hold it closed. Any slight leakage past the lower rings is taken care of by the port *H* and it is, therefore, practically impossible for the valve to open while the engine is at rest.

Tests on a superheater locomotive with 25 in. by 26 in. cylinders supplied with steam from a two-inch pipe showed that the valve when adjusted to close at about 40 lb. per sq. in. would maintain between 25 and 30 lb. pressure in the steam chest at 25 per cent cutoff at a speed of 60 miles an hour, preventing the formation of a harmful vacuum even at such high speed. After a shut-off with the reverse lever in running position, the valve would open when the steam chest pressure dropped to about 30 lb. The valve would close again when the steam chest pressure arose to 40 lb. which occurred just before the stop, allowing time for the superheater to empty itself before the engine came to rest. The Ripken drifting valve has been in use nearly two years with excellent results. It has required little attention and has prolonged the life of both the cylinder and the piston rod packing on the engines to which it has been applied.

A CONVENIENT RECORD FOR AIR BRAKE MATERIAL

BY J. A. JESSON

The Westinghouse Air Brake Company's part catalogues are issued in numerical order, and each shop is usually furnished with a complete set in a loose leaf binder. Each sheet illustrates one unit with its accessories, and gives a list of the parts and the numbers of the items. In order to render this catalogue more serviceable it has been our practice

for some time to insert an extra sheet for each separate device. This covers in an abbreviated form the items which are ordered, and has columns for the name, the old and new piece number, and a separate column for each month of the year, as shown in the sample sheet illustrated above. This provides a daily, monthly and yearly record, all in one book, and has proved useful in checking this material.

CAR DEPARTMENT

THE TANK CAR MAINTENANCE PROBLEM

BY PAUL BATEMAN
Manager People's Tank Line Co., Coffeyville, Kan.

SINCE tank cars constitute a large item of initial expense to almost every producer and marketer of petroleum products, it is of some importance that they be maintained at a point of greatest efficiency with minimum up-keep expense. As an engineer and designer for several years, in the employ of two of the largest car builders in the country, it was a matter of circumstance that one of the outstanding ideas of car builders was forcibly brought to my notice. That is, in substance, design *something different*. The best engineering practice is sometimes made subservient to the principle of designing something on which a claim for a patent may be made.

This practice has resulted in innumerable types of cars,

Fig. 1. Typical Arrangement of Underframe and Draft Gear

each type with its own variations, and has greatly complicated the problem of maintenance of equipment. Repair shops have been called into existence by the impossibility of car owners carrying a sufficient variety of parts to repair their cars properly. Although there are some few concerns which employ experienced repair men, the owners of cars must in general trust to inefficient labor to perform work that requires specialized knowledge and experience. Behind the experience, also, there must be knowledge, not only knowledge of how to make repairs, but of why the part requires repairs and of how to prevent a recurrence of the same trouble. To make this clear we will refer to Fig. 1. showing the end of the underframe of a car. There are innumerable variations in the end structure, but the principle must remain the same in all.

REPAIR OF FRICTION DRAFT GEAR

The yoke, Fig. 1., is riveted to the butt end of the coupler and contains certain friction parts, which, in buffing, are compressed by the coupler against stops, or lugs, riveted to the longitudinal beams, or sills. In pulling, the yoke is brought into play and performs the same duty in a reverse direction, by compressing the friction parts against the front stops or lugs.

When originally installed the friction draft gear is provided with sufficient travel to enable the full capacity of the gear to be utilized. Any shock in excess of the capacity of the gear is absorbed by the horn of the coupler striking against the buffer on the end of the sills, after the gear is compressed to its full capacity.

The gear, as installed, is not at the center of the sills, due to details of construction based on truck clearances, and the necessity of keeping the center of gravity of the loaded car as low as possible and there is approximately a 200,000-lb. shock on a 13 in. to 15 in. girder with an eccentricity of about 4 in. to 6 in. Any shock above the absorption capacity of the gear is absorbed by a direct blow against the fully compressed gear which now acts as a rigid block. When wear on the friction elements develops, the end clearance between coupler and buffer block is eliminated and the impact load in excess of the gear capacity is received by the buffer. The gear, as originally installed, gives protection to the car, but when the friction parts wear, more and more of the impact load is directly transmitted to the buffer. As the latter has relatively little resiliency, it is only a question of a short time before it is broken, thus bringing the full load on the gear and thence directly to the sills. The obvious result is that the sills spread and buckle, or else the rivets on the rear draft lugs are sheared, sometimes both. The usual procedure has always been to say, "Oh, let it ride, the sills are all right, we'll fix it sometime." When it is finally released for repairs the first and only thing done to the car is to put on a new buffer and let the worn-out gear alone.

If the gear has worn so that the first 1½ in. of travel has become non-effective, there will be left only 1¾ in of useful travel of the original 3¼ in. giving a retarding value of only about one-fourth of the capacity of the gear. (Fig. 2.) With the full load of a moving train, having a possible buffing shock up to 1,000,000 ft-lb., it is not hard to imagine the effect on the new buffer casting. This is not an isolated case but is the usual procedure all over the

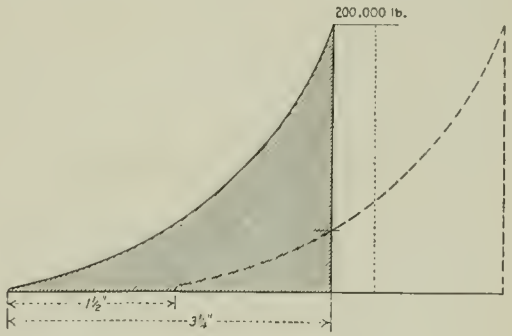

Fig. 2. Diagram Showing Reduction of Draft Gear Capacity with Decrease in Travel

country, not alone with the refiners, but also with the railroad companies and even some of the private repair shops.

In dealing with these buffing forces, kinetic energy must be considered, which does not permit of the same assumption for fiber stresses as in the case of static loads. Under static loads a column can be figured at its full value, with each of the fibers bearing an equal portion of the load. Under these conditions, however, there are two variable forces, one along the center line of the coupler and the other along the center line of buffer impact, the latter after the frictional resistance of the gear has been absorbed. In addition there are the forces compounded by secondary forces which cause torsional stresses. These latter are caused by inequalities of tracks, different heights of couplers, impacts on curved track, couplers being off center, etc. Although termed secondary forces, they are really as much a part of the primary forces as are any others. In tank car designs, it is not necessary to consider the deflection due to loading on account of the loads usually being concentrated at the bolsters and thence transmitted directly to the truck, so the sills bear only the compound load which is due to the conditions previously mentioned.

The above case, as illustrated, is indicative of the usual methods employed in making repairs. No thought is given to the cause. The best way to make repairs, of course, is to prevent the necessity. However, in conditions as they are, the best procedure is to remove the slack travel of the coupler by renewal of necessary parts and by placing shims between the gear and the lugs. After that, see that the correct position is maintained.

TRUCK REPAIRS

Reference to Fig. 3 shows the usual design of arch bar truck construction and the lines of force with their attendant results. We will suppose a loaded car to be in a rapidly-moving train, when an emergency application of the brakes is made. The braking power is from 70 per cent to 90 per cent of the light weight of the car which, in a 38,000-lb. car of 8,000 gal. capacity, loaded with gasoline, is 30 per cent to 40 per cent of the total weight of the car. The result is that the trucks receive a direct load at the center plate due to the inertia of the entire loaded body of the car at whatever speed it is traveling.

It has seemed inconsistent that one part of the car—the sills, through the coupler—should be used to start the car, and another and much lighter part—the brakes operating on the trucks—should be used to stop it. The writer sees no way, at the present time, to improve the basic principle of this.

The resultant tendency in brake application is to transmit a load to *one* side of the center plate and generate torsional stresses tending to rotate the bolster. This load very naturally comes on only one side of the truck springs, which are intended always to act as a unit. The result is that the springs compress unequally and throw the bolster against the columns with unequal bearing. This causes failure in the columns by tearing the column bolt through the wearing surface of the column. A condition of this kind is usually caused by neglect in allowing nuts of column bolts to become loose, thus permitting the arch bars to spread and allowing excess clearance. Quite frequently the cars, as originally built, have entirely too much clearance.

The material wear of the column guides on the bolster should be taken up by placing shims on one column or else on the column guide on the bolster. This is almost never done as it requires that the truck be practically dismantled. Another cause of trouble is the rapid rounding of curves at which time the loaded car seeks a tangent and the trucks must follow the rails. That causes the bolsters to exert more pressure on one set of springs than on the other, thus allowing the springs to slip and quite frequently lose out. Improper side bearing spacing and clearance are very usual causes of truck failure and are also often responsible for derailments.

The principal instructions would seem to be to keep the truck tight and see that the wooden shims, above or below springs, are renewed at sufficient intervals to insure that they are solid. These shims are made of seasoned oak but they decay very rapidly and allow the springs to settle into them, thus increasing clearances to an unsafe margin. Side bearing clearances must be kept at the proper point, 1/8 in. to 1/4 in. between top and bottom.

REPAIR OF TANKS

Of the tanks proper little need be said except that all *indications* of leaks should be immediately looked into as stains on the outside usually mean that the caulking edge of the sheets and rivets on the inside has deteriorated. The tank should not only be caulked on the outside but more especially on the inside. It might be stated that caulking on the inside is almost never practiced except in the shop where its necessity is understood. The fact that inside caulking is obligatory, under Bureau of Explosives' Rules, seems to be overlooked. Leaks are quite commonly caused by deflection

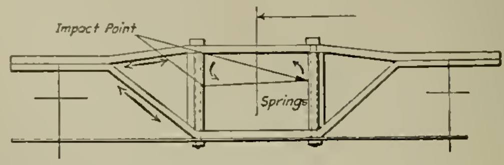

Fig. 3. Forces Acting on Arch Bar Truck

of the sheets of the unsupported end portion of the tank which causes distortion of the sheets at riveted joints.

The safety valves ordered to be used have always been a source of wonder to the writer, particularly as to why it seemed necessary to provide 40 sq. in. of safety valve outlet surface while the largest locomotive using superheated steam and a pressure of up to 250 lb. per sq. in. has only about 10 per cent of this area. The Master Car Builders Association has designed a device using a spring balance to determine the proper point at which to set the valve. Inequalities of bearing surface on the valve seats seem to be overlooked, consequently there is practically no guarantee that the valves will hold any pressure whatever. All valves should be removed and ground in with emery in oil, then set to the proper point under a test by compressed air. The valve question is not only a maintenance problem but one in design, which it is to be hoped will have the attention of qualified engineers.

The advisability of keeping cars well protected by paint is too well known to require more than passing comment. That comment is mostly directed toward the policy of merely making the cars a good advertising sign board instead of seeing that the painting is properly done. Cars, particularly the tanks, should be thoroughly cleaned preparatory to painting as the improperly cleaned car will not held the best paint made. The company with which I am connected has found it advisable to put the problems of painting up to the paint manufacturers, using their knowledge and experience in connection with our own.

One of the greatest causes of tank cars being neglected is the attitude of certain railroads, particularly at competitive points. When an inspector refuses a "bad order car," a competing road's inspector will take it and so drum up business for his road. If it is impossible to run the car in its condition as accepted, temporary repairs are made. In fact, anything is done that will get it out of the yard at the point of origin. The owner is very grateful to the railroads accepting the car and consequently the accommodating railroad gets the future business.

This policy can have only one result, and that is evident when it is stated that the policy is pursued in endless chain fashion, the original road accepting cars that even the first offending road refused to handle.

Delegates to the Convention of Car Inspectors and Foremen.

Car Inspectors and Foremen Meet

Continuation of the Discussion of the Changes in the Rules of Interchange; Other Business

A REPORT of the preceedings of the opening session of the nineteenth annual convention of the Chief Interchange Car Inspectors' and Car Foremen's Association was published in the October issue of the *Railway Mechanical Engineer*, page 593. This included a discussion on Rule No. 2, at the close of which a committee was appointed to consider the wide diversity of practice in interpreting this rule in different sections of the country and report later to the convention. The following report was later submitted and adopted unanimously: "The committee does not feel it consistent with the basic interest and purpose of this rule and the decisions given thereon by the administration that we should recommend any changes in the application of the rule other than the proper supervision by those in authority at the several terminals and interchange points, consistent with local conditions, more especially on point of inspection and repair track facilities."

Following the discussion on Rule No. 2 the association proceeded to the consideration of the changes in the rules as recommended in the report of the Arbitration Committee presented at the 1919 convention of Section III, Mechanical. An abstract of a portion of the discussion of the rules under this head was published in the October issue. Only a part of the rules was covered, however, and a more complete abstract of the discussion of all of the rules is given below.

RULE 32.

(Delivering company responsible.) Dome cover or safety valves missing from tank cars. Material missing from cars due to handling on unloading machines. Removing or cutting out parts of car to facilitate loading or unloading. Known theft of parts of car occurring on handling line. Damage to any car (including cars on ferries or floats) if caused by: (a) derailment, (b) cornering, (c) sideswiping, (d) collision or impact other than that occurring in regular switching, (e) handling of cars with broken or missing couplers, or couplers out of place, (f) colliding with or shoving over bumping posts or other fixed obstruction, (g) shifting of loads from other cars, (h) overloading, (i) explosion, (j) collapsing buildings or other structures on right-of-way, (k) unconcealed fire damage (l) flood, (m) storm where car is derailed or destroyed, (n) failure to close hopper or drop doors before moving car.

T. S. Cheadle: I would like to know if any trouble is experienced with the shifting of loads?

F. C. Schultz: It is our practice to charge the delivering line for any damage on account of improper loading or shifting of the lading.

T. J. O'Donnell: Have any of you considered what the Arbitration Committee means by "impact." Wouldn't that run into the combination of defects?

F. G. Schultz: If a car is damaged in a collision with a number of cars in a train, it is not an owner's responsibility.

J. C. Keene: (Wabash) Unless the car is derailed, cornered or sideswiped, the owner is responsible.

F. C. Schultz: I think this was changed to take care of a case where a private line car was broken entirely in two and there was no evidence of derailment.

T. J. O'Donnell: If investigation showed the damage occurred in connection with an accident, it would be straightened out.

N. Marple: (M. C.) I am a member of an O. S. & D. committee and am watching all cars that come in on the repair track to ascertain the condition of the lading. Cars have to be opened to make repairs to draft gears, and 90 per cent of them have the loads scattered all over the car and the draft gear damaged. Therefore, we want to be careful in what we say is ordinary switching.

T. S. Cheadle: Regular switching service on one road isn't regular switching service on another. I would be glad if we could get an idea of just what that term means as commonly used.

H. W. L. Porth (Swift & Co.): I think the intention was to clarify the terms wreck and fair and unfair switching. It is a matter of judgment as to the damage done to the car. Under the old term, the case brought up was a private line car that had been demolished in unfair switching, but the trucks of the car had not left the rails, hence there was no derailment. The intent of the rules is fairness and judgment of course must enter into the interpretation of these rules.

G. Lynch: The term "wreck" has been eliminated and "collision, impact and regular switching" substituted. If impact is to be considered we will have a great deal of damage done by impact because we must couple automatic couplers by impact.

T. J. O'Donnell: Isn't it fair to presume that this rule is a help to us? We had nothing to guide us before.

G. Lynch: We had owner's responsibility for all missing parts of a car in fair service, and we had Rule 32 which covered unfair usage.

J. P. Carney (M. C.): That rule is to get rid of the old, weak equipment and make the owners responsible.

F. H. Hanson (N. Y. C.): You are not going to be able to tell whether the car was moving 5 or 20 miles an hour. I think we should go on record as saying the owner was responsible unless the car was derailed, sideswiped or cornered.

President Stoll: In the absence of any proof that the car was in a wreck, how can it be proved when the car is delivered to the other road in interchange? If the railroad is honest, it is an easy matter.

C. M. Hitch: This rule is plain enough, I believe, if we are all fair. A man who is guilty of damaging another man's car knows whether he is responsible or not; let him comply with the rules and card the car; he knows whether it was fair switching or not. If a cut of cars runs down without a rider and smashes a car, I would call that unfair switching.

A. Armstrong: I know less about Rule 32 now than I knew when I left home and an explanation will be expected of me when I return. I would like to ask an interpretation of this rule.

W. S. Elliott (St. Louis): Mr. Carney brought the situation out very clearly. There are times when a weak car is broken in two. There is another case where a car is in good condition and 10 or 12 loads of coal are dropped down against it. That is not regular switching.

G. Lynch: If anyone can tell me what a collision is and what a wreck is, or can tell me what impact is, I would be very glad to get a definite understanding of these terms.

W. S. Elliott: It seems strange that the chief interchange inspectors should disagree on this rule. It is not a new condition with us. On the steel cars we have had practically the same rule. I have had to call Mr. Halbert over time and again to verify my judgment on whatever the case might be. Where there is a chief joint inspector, there should be no trouble. You ought to be able to know what reasonable switching is. I take a fair and liberal interpretation of it and do not anticipate any trouble at all.

M. W. Halbert (St. Louis): The only contention I see is on collision or impact. The chief interchange inspectors at large interchange points inspect all cars that are damaged sufficiently to require carding. The only thing we can do is to use good broad judgment and treat both companies fairly in making a decision. When a car is broken in two you can invariably detect evidence to show whether the damage was done in ordinary switching or rough usage. As chief interchange inspector, I make a decision, and it is up to the road that gets the car to protest afterwards. If it is decided I am wrong there is no harm done. I always try to give the receiving line and the delivering line the best of my judgment. If we make a mistake, let the Arbitration Committee correct us.

E. H. Wood (M. C.): Rule 32 is as clear as water. It shows us how to get rid of a lot of old equipment that should not be in service at all. If a car wont stand up in regular switching, it should be taken out of service.

F. H. Hanson: I move that it is the sense of this association if cars are broken in two, but the trucks do not leave the rails, the owner will be held responsible if there is no evidence of derailment, cornering or sideswiping.

The motion was seconded and carried.

G. Lynch: In regard to missing cross braces, before it was owner's responsibility. Now there is a line drawn there. Damage caused by unloading machines is delivering lines responsibility. That should be made clear.

T. J. O'Donnell: Don't you make the owner responsible for a missing hopper door; aren't we safer with this rule?

G. Lynch: The owner will contend that it was removed.

T. J. O'Donnell: Sometimes when opening hoppers the doors are broken or torn off. Those are cases where the Arbitration Committee is trying to protect the owner. It is better to be liberal than technical.

F. C. Schultz: Who can decide whether the material has been actually stolen or thrown away?

G. Lynch: At Cleveland there are six coal loading machines where cars are unloaded into boats. The inspection does not determine whether the inside cross braces are missing or not. They may be missing. The car is returned to the delivering line and these inside braces are found missing and there is a possibility that they were missing when the car was offered in interchange. Is the unloading road to be made responsible for the missing parts? How are we to decide on the interchange track or when cars are found on the repair track damaged, when there is no other damage to the car?

A. Berg (N. Y. C.): Shippers use clam-shells and other devices for unloading or dumping cars. It was felt that if the road that delivered the car was made responsible they would take steps to prevent industries unloading cars from damaging the equipment. The rule will accomplish just what was intended.

T. J. O'Donnell: I think Mr. Berg has struck the keynote.

J. S. Naery (C. I. & L.): A missing inside brace is a small item but bolsters are also borken on unloaders.

C. M. Hitch: I have seen a great many cars handled on dumping machines but I never saw a truck bolster or body bolster damaged. If that condition prevails there is a weakness in the construction of the bolster.

H. A. Lightner (I. C.): As to missing parts when the car is unloaded, you would to be able to determine whether the part was missing when the car was loaded or was damaged in unloading.

RULE 33

Owners will be responsible for the expense of repairs to safety appliances where not involved with other delivering line damage, except damage to running boards on tank cars when sideswiped or cornered.

F. W. Trapnell: Under the present rules in some parts of the country, defect cards are being secured for running boards on tank cars that have been cornered and sideswiped that have no other delivering line damage. I cannot see how they can be furnished under the rule.

T. J. O'Donnell: The old rule does not give any authority to handle it on that basis.

F. C. Schultz: If the ladder on the end of a car is bent, it is owner's responsibility, but when the car body is damaged as well it is delivering line responsibility. The construction on a tank is such that the running board is invariably broken.

F. W. Trapnell: Rule 33 now exempts running boards from owner's responsibility because they are safety appiances. I believe that is a reasonable exemption. If it was not owner's defect before this recommendation came in, why the necessity of making this recommendation?

H. W. L. Porth: We have had cases of cars coming into our yard with grab irons entirely broken and no evidence of any defect or damage to the car that could be carded, although the safety appliances were damaged beyond repair.

A. Herbster: The Arbitration Committee does not feel that a running board on a tank car can be damaged in fair usage and, therefore, makes it a delivering company responsibility.

T. S. Cheadle: A tank car with a running board damaged is a delivering line responsibility under the new rule, but a car other than a tank car with the running board or safety appliances damaged is owner's responsibility.

RULE 66.

(Owners responsible.) Periodical repacking of journal boxes, regardless of the responsibility of delivering company for change of wheels, journal boxes or journal bearings. No charge shall be made for repacking unless all boxes are repacked. No charge shall be made if the repacking is done within nine months from date stenciled on car. If car bears no stenciling, showing date of previous repacking, all journal boxes may be repacked, if necessary, and charged for.

(a) All journal boxes shall be repacked with properly prepared packing (new or renovated) at least once every twelve months, at which time all packing will be removed from the boxes and the boxes cleaned; dust guards to be renewed when wheels are changed.

(b) The date and place (railroad and station) where the work is done must be stenciled on the car body near the body bolster at diagonal corners in 1-in. figures and letters, using the same station initial that is used for air-brake stencil.

(c) This work to be done as far as possible when cars are on repair track undergoing heavy repairs. When on repair track for heavy repairs, cars which have not had boxes repacked within nine months will have all boxes repacked and the record stenciled on the car as above.

(d) This does not contemplate any change in the intermediate packing of boxes when it is necessary to do so. No change should be made in the stenciling unless all boxes are repacked.

J. J. Gainey: What is meant by repacking boxes? Is it intended to remove all the packing and take it to a vat and renovate it, or just have a man who goes around with a pan, put it in the pan and shake it out and put it back in the box again? Fifty per cent are doing it that way with unsatisfactory results.

J. C. Keene: If that is being done it ought to be corrected. The packing should be taken to a renovating plant and thoroughly renovated and returned. Either new or reclaimed packing can be used as desired.

T. S. Cheadle: It is not proper to render a bill under Rule 9 unless renovated or new packing is used.

J. C. Burke (U. P.): The rule states plainly that new or renovated packing must be used.

C. M. Hitch: This is one of the best rules that has been passed. I certainly would not render a bill if the boxes were not repacked in accordance with instructions, but I will use reclaimed packing the same as new. It should be understood that in cases where all boxes on a car are not repacked, no bill is to be presented.

N. Marple: The cost of performing the work is greater than charge allowed under the rules.

RULE 88.

In order that repairs of owners' defects may be expedited as fully as possible, foreign or private line cars may be repaired by the handling line by using material from their own stock instead of ordering material from car owner, as prescribed by Rule 122, in which event the repairing line must issue its defect card for the labor only of correcting such improper repairs, and defect cards should be so marked.

In case of delivering line defects, defect card shall be issued for both labor and material for correcting the improper repairs.

N. Marple: Are there any private car owners here who can state whether it is the practice, when cars that have been repaired come home, to tear the work down to see that the repairs are done properly.

A. Herbster: I have been in one shop that made it a practice to tear out everything that railroad repair men put on the car; it was not a large corporation.

N. Marple: We all want to play fair as near as we know how, but even when we make repairs as near like the original construction as we can, we get joint evidence cards showing wrong repairs were made.

F. C. Schultz: I believe it is advisable for the railroads to return private line cars to the owners for repairs as the average railroad repair shop is not equipped to make proper repairs to these specially constructed cars.

F. W. Trapnell: The private car owners must know that the car is in shape to carry the contents to its destination with proper icing. We have discouraged making any repairs to wrecked refrigerator cars and are sending the cars to the owner's plant.

J. J. Gainey: A railroad company can repair a refrigerator car properly. We had a refrigerator car in a while ago, and I gave instructions to have the car absolutely perfect when it went home. Every day I looked to see what work was being done on it. The car went to an interchange point and joint evidence was issued for 3¼ in. roofing instead of 5¼ in.; joint evidence also covered lemon color instead of a deep orange. The joint evidence card came back from our staff officer and I wrote to the owners. They stated that all they were going to ask for was a card to change the color. In ten days no one could have told one color from the other.

N. Marple: You have to make the car safe to go home and you are losing all the money that you expend on temporary repairs.

H. W. L. Porth: There is a difference between an ordinary refrigerator car and one that has to carry beef. It has been my experience that in most cases cars are returned when in need of repairs, and the private lines in general encourage this practice as they prefer to do the work themselves.

J. J. Gainey
First Vice President

W. J. Stoll
President

J. C. Keene
Secretary-Treasurer

RULE 95.

In reference to a recommendation that this rule be changed to include missing brake beams and other brake details, as formerly covered, the Arbitration Committee recommends the rule remain as at present for the reason that in case of bill for defective or missing brake beams, the average credits allowed under Rule 101 are high enough to offset the value of occasional missing beams, and the billing is thereby greatly simplified. Furthermore, the condition of the missing beam cannot be ascertained and is no doubt frequently defective.

T. S. Cheadle: Would it be proper to issue a defect card if the brake beam was on the line delivering the car?

President Stoll: Look at the changes made by the M.

C. B. in 1918 and you will find that a missing brake beam is owner's responsibility.

J. C. Keene: The price allowed for the beam was made to take care of the condition.

A. Herbster: I do not believe there are enough missing brake beams in interchange to argue about. Repairs are almost invariably made by the company on whose roads the car becomes defective.

RULE 108.

No labor to be charged for the inspection of cars, testing or adjusting brakes, adjusting angle cocks, tightening unions or spreading cotters; still steps, ladder treads or handholds, tightening or straightening on car.

No material or labor to be charged for the following items of repairs: 1. Air-hose gaskets, applied, except with hose complete, applied. 2. Brake pins or key bolts, applied. 3. Brake ratchet wheel keys, applied. 4. Brake-shaft rings, applied. 5. Brake-shoe keys, applied. 6. Carrier iron, Bettendorf type, when turned over, no charge for adjustment. 7. Coupler release clevises, clevis links or chains, clevis pins or bolts, applied. 8. Lag screws, applied except when used to complete other items of repairs not herein listed. 9. Nuts or lag screws, tightened. 10. Nuts, ¾in. or less, applied, except when used in renewal of bolts. 11. Nut locks, or lock nuts, applied. 12. Release-valve rods, repaired or applied. 13. Straightening brake shafts and uncoupling levers when not removed from car. 14. Spring cotters and split keys, applied. 15. Staples, applied. 16. Wood screws, applied, except when used in renewal of running board. 17. Washers, applied, except when used in renewal of bolts.

No charge to be made for the material or labor of lubrication, except as provided in Rule 66.

N. Marple: Do you not think that minor items of repairs on which no bill is to be rendered under the rule will be neglected especially in train yards?

President Stoll: The general opinion was that the items of repairs referred to were necessary from a safety standpoint and would be taken care of.

CIRCULAR 25, RULE 8.

In compliance with the recommendation of the Interstate Commerce Commission in Case No. 4906, "In the Matter of Private Cars," a second paragraph is added to Rule 8, effective April 1, 1919, as follows.

When repairs of any kind are made to cars of private ownership where such cars are equipped with suitable receptacle, a copy of the billing repair card shall be inserted in such receptacle. The loss of such card from the receptacle referred to, will not invalidate bill for the repairs. This receptacle to be applied by owner at any convenient location on car, provided the location selected will not require inspectors or repairmen to go underneath or between the cars.

C. M. Hitch: In many places the M. C. B. repair data is furnished by the inspectors and their books are sent to the foreman's office. The inspector should be enabled to place a repair card in the receptacle at the time. The best way to handle that would be to have an extra copy of the repair card made and mailed to the owner of the car.

M. W. Halbert: There are only a few private cars being equipped with repair card receptacles.

A Member: Why should the private line car be given more consideration than a railroad car, or why should we be required to put the repair card in that receptacle?

A. Herbster: That was recommended due to the fact that private cars come home more regularly than railroad cars and the owner can check the card with the actual repairs made to the cars, but I do not believe that it has met with the result that the car owner anticipated.

INSPECTION OF LOADS IN OPEN TOP CARS

A question was raised as to the advisability of inspectors making records of depressions in loads shipped in open top cars in order to eliminate leakage enroute and to protect the railroads in case claims for shortage are filed by the shipper. The discussion brought out that at most terminals the inspectors who examine the roofs of the cars are required to note any apparent shortage. A report is made to the agent and the cars are weighed to determine the loss of contents and to establish the amount occurring on each line in case the shipment is hauled over more than one road. In general, if the road does not transfer the load it must participate in any expense due to loss of lading.

UNIFORM INTERCHANGE INSPECTION RECORDS

President Stoll: I received a communication from one of the large interchange points asking me to bring up at this meeting the possibility of making the records of inspection uniform at all large interchange points.

T. J. O'Donnell: Under our present method of inspection in the receiving line yard, there are certain roads that take only the numbers of the defective cars. There are other roads that take the numbers of all cars. I think it is decided if bad order cars are shown that those that are not shown are O.K. We are throwing money away to take the initials and numbers of the good order cars, and I feel that it would serve the purpose for interchange throughout the country, if only the bad order cars were noted.

J. C. Keene: The question was not as to what cars would be recorded, but to adopt some sort of a standard record. At one point a book is used, at another a sheet and at another a card form. It is my thought that we should adopt a standard form of interchange record similar to the interchange sheet which the transportation department has adopted and which accompanies delivery of cars to the other lines. Our road reaches several division points and at no two points do they have the same kind of record or form sheet.

I would recommend the appointment of a committee to look into the matter and report at our next convention. It will take considerable time to go over this subject and I believe that that committee should confer with the car service men or car accountants. We find that in a period of six or seven days there will be as many as 75 errors made in interchange and that the car inspector is usually correct. A great many movements of cars in interchange are lost because of the fact that the roads fail to get the proper record. We feel that the interchange sheets should be checked against the car inspector's record.

F. W. Trapnell: There isn't any more important record for a railroad than the car inspector's record when properly made and if, as a body, we could devise some suitable blank that could be used at all interchange points, we could accomplish a great deal. We use the car inspector's record to verify the agent's record and when we find a discrepancy, we take the car inspector's record in preference to the agent's because the agents sometimes get the seal number in place of the car number.

Secretary Smith: It seems to me that a uniform record is a desirable thing to have, but I do not like the idea of putting all the work on the car inspector. In many places he takes the number of all cars that are interchanged, but in a great many more places he does not take the record of any cars except those to which he takes exceptions, as defective. If we are to recommend a blank which compels the car inspector to write the number of every car that passes through interchange, it is going to put some work on him. He is too busy and besides he is too highly paid to just take car numbers.

F. W. Trapnell: I believe the railroad companies ask that all cars in interchange be recorded by the car inspector. We have no trouble and we interchange several hundred cars a day.

A. Herbster: The elimination of the record of car numbers and initials on all cars was primarily started in order to get the inspector to make more repairs and do less clerical work.

F. H. Hanson: A great many roads have issued instruction to inspectors not to take the numbers and initials of good order cars. The agent has a complete record of all cars interchanged and we are carrying out the instructions of the administration in reporting bad order cars only.

B. M. Waldo (Dallas): We are taking a record of cars that are defective only, but we really would rather take a record of every car. It is embarrassing when the claim agent comes for a record. As long as they depend on us for a record we ought to have something on file from which we can answer the questions. The car inspectors have a great deal of work to do, and I appreciate all that has been said, but I am in favor of keeping a record of all cars interchanged. It is a small matter to take down the number and initial.

J. C. Keene: I had a little experience on the question of abrogating the taking of the initial and number of all cars in interchange. Where that practice is followed there is no record whatever to protect your department. To illustrate: in going through the yards, I found two or three cars in bad order, showing defects that should have been detected on interchange inspection. The inspector had nothing in his book on these cars and he answered me: "I cannot tell you whether I inspected these cars or not. Perhaps the switch engine got hold of them and took them away. Perhops they were placed on another track when delivered." Unless the inspector has the number and initial he cannot go in any court and make an affidavit that he inspected the car and found it O.K.

President Stoll: Nine years ago the car men of the different railroads at Toledo decided to have the inspectors take a record of all cars. Just before the government took over the railroads they decided to eliminate it. Then the terminal manager took over the bureau and said he wanted a record of all cars taken and the order was put into effect again to take all car numbers. The sheet has been beneficial, not so much to the car department as to the other departments, especially the claim department. Men come from Columbus and Cincinnati to look up records of cars that have been interchanged to fix responsibility, and in every case where the company did not have a record they fixed their claims accordingly. For the good of the service, I believe it is advisable to have a record of all cars.

A. Kipp: That question was taken up on our road five years ago. Our law department prior to that time expected the car inspector to take the number of every car so that he might be able to go into a court and swear as to whether he inspected that particular car, but after two or three years, they decided that it would be better for the car inspector to have a closer inspection and make more repairs and do less clerical work.

E. Head (Wabash): The thought has occurred to me that we will get back to the time when the roads will be in the hands of their owners and a fine will be imposed for penalty defects. We have had suits entered against roads for penalty defects and the record was one of the most important things in the case. Where we did not have a record of the car number and initial the court ruled we had no record and that omission cost us $100.

A. Herbster: If an accident happens it is the actual condition of the car and not the previous inspection record of the inspector that governs.

T. S. Cheadle: Various methods are used for obtaining records. I do not require any record to be kept except of the bad order cars.

On motion the Association authorized the appointment of a committee of five to approve or present to the association at its next regular session for approval a blank form of car inspector's record of cars inspected at interchange points. A committee was appointed, consisting of F. W. Trapnell, T. J. O'Donnell, A. Kipp, A. Armstrong and F. C. Schultz.

ADDRESS BY A. E. BOUGHNER

At the session on Thursday morning, an address was delivered by A. E. Boughner, superintendent of the Missouri, Kansas & Texas, and chairman of the Interchange Committee of St. Louis, Mo. Mr. Boughner said in part: The terminal facilities of St. Louis for the interchange of traffic are really not very good and it has required a united effort on the part of all concerned to keep the business moving. The different avenues choke up very quickly and for that reason rules have been worked out here to always keep cars going forward. They seldom go backward. Some of the government requirements demand that cars with certain defects move backward. Outside of that we do not figure on anything moving back in St. Louis. I believe at the present time an immense amount of good has been brought about and a lot of money has been saved, as well as a lot of controversy avoided by working for the benefit of the whole in connection with the matter of interchange of cars. That is facilitated by government control which has permitted the consolidation of interchange inspection.

OTHER BUSINESS

On motion of T. J. O'Donnell (Buffalo), a telegram was sent to Director General Hines conveying to him the full support of the association.

J. R. Mitchell (W. H. Miner) suggested that since the association is made up of car foremen as well as interchange inspectors, the organization should take up car subjects in addition to the discussion of the rules of interchange. W. G. Wallace called attention to the fact that the International Railway General Foreman's Association at the 1919 convention changed the constitution and by-laws to make car foremen eligible for membership. This action was taken because the members felt the need of educating the general foremen in car department matters as this knowledge would be essential if they were promoted to the position of master mechanic where they would have charge of both departments. He urged the association to broaden its activities in order to stimulate interest and secure recognition from the higher mechanical officers.

Arrangements were made with the Simmons-Boardman Publishing Company to publish the convention report in the *Railway Mechanical Engineer* and the membership dues were increased to include subscription for the perodical.

On Wednesday a special train was provided for the members in order that they might make an inspection trip around the St. Louis Terminal District.

At the closing session L. T. Canfield of the Union Draft Gear Company delivered an address in which he emphasized the importance of the work done by the association and called attention to the opportunity the members had for noting the defects which developed in cars after they had been placed in service and for recommending improvements in the design.

Invitations were received from several cities asking that these places be considered when deciding on the location for the next meeting. Among the places suggested were Niagara Falls, Ont.; Buffalo, N. Y.; Saratoga Springs, N. Y.; Asbury Park, N. J.; Cleveland, Ohio; Detroit, Mich.; Harrisburg, Pa.; New York City and San Francisco, Cal.

ELECTION OF OFFICERS

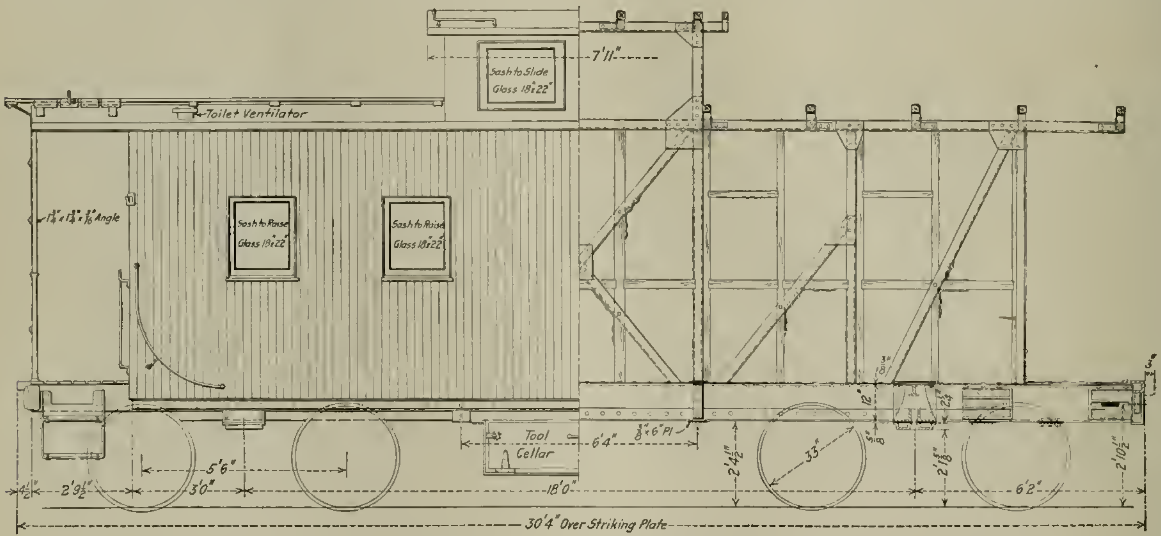
The following officers were elected for the year 1919-1920: President, J. J. Gainey, general foreman, car department, Southern; first vice-president, E. Pendleton, car foreman, Chicago & Alton; second vice-president, A. Armstrong, chief interchange inspector, Atlanta, Ga.; secretary-treasurer, J. C. Keene, chief car inspector, Wabash. Members of executive committee, W. J. Stoll, Toledo, chairman; H. J. Smith (D. L. & W.); W. P. Elliott (T. R. R. A. of St. L.); J. E. Gordon (N. Y. C.); C. M. Hitch (B. & O.); E. H. Mattingley (B. & O.); E. H. Hall (C. G. W.) and Charles Adams (N. Y. C.)

Cars and Locomotives in Russia.—The Ironmonger states that at the declaration of war Russia possessed in the neighborhood of 30,000 locomotives and 570,000 cars and that at the time of the revolution there were 6,200 locomotives and 120,000 cars in good condition, with 3,600 locomotives and 145,000 cars needing repairs. This has been considerably reduced and this year a new commission of the Russian government does not record more than 4,000 locomotives and 95,000 cars.

U. S. R. A. Standard Caboose Car

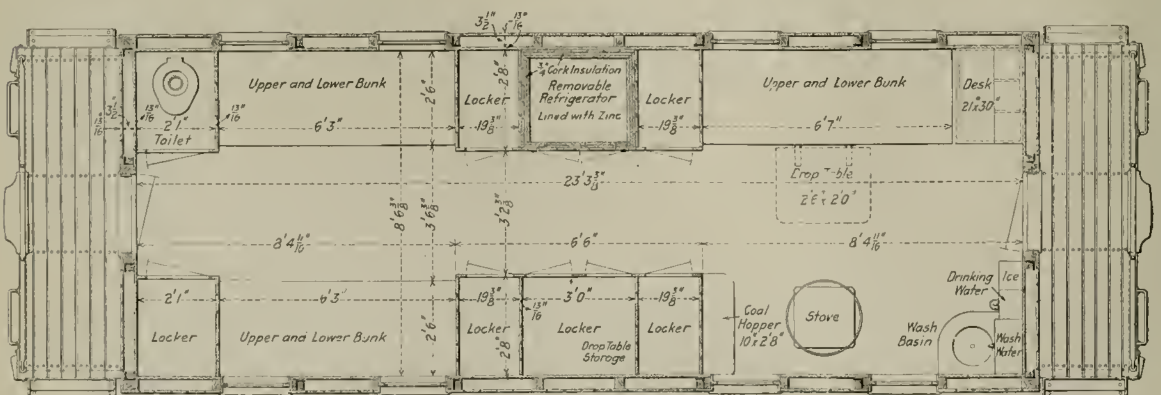
Design Recommended by the Railroad Administration; Strong Underframe for Heavy Pusher Service

The requirements of the laws of the various states in this country regarding railway caboose cars make it very desirable that a standard design be adopted for the construction of this class of car. To meet this need the United States Railroad Administration has issued an approved standard design for such cars. It is not proposed to require that cars must be built to these drawings, but to



Side Elevation of U. S. R. A. Standard Caboose Car

provide a design that, if conformed to by the railroads in building new caboose equipment, will insure the gradual elimination of cabooses of weak construction or faulty design. The proposed design is a 24-ft. caboose of the composite type, having a steel underframe and superstructure, with wood outside sheathing and interior finish.



Floor Plan of Proposed U. S. R. A. Standard Caboose Car

This design supersedes the original designs which provided for an all-steel caboose and a composite type. The first plan called for a caboose 25 ft. long but was only a preliminary draft and was never approved for the use of the railroads. This article shows the 24 ft. caboose recommended by the Railroad Administration for the future construction of cars of this class.

The Superstructure

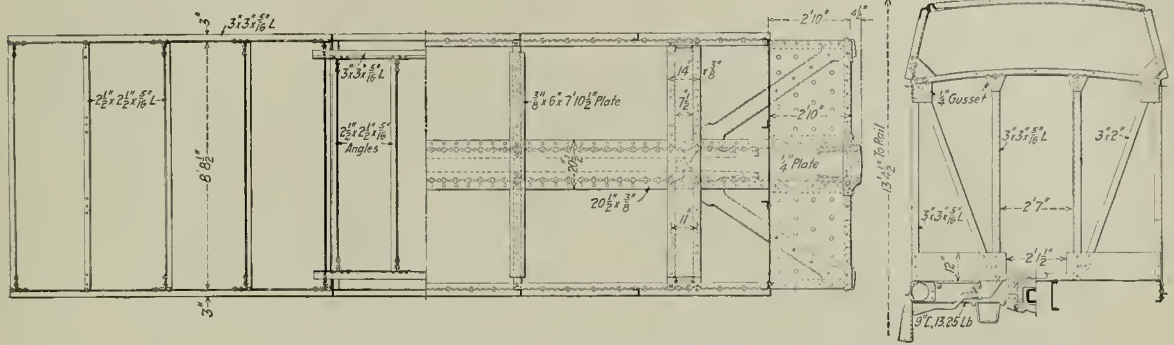
The body framing is built up of 3-in. by 3-in. by 5/16-in. angles, the side and end posts being adequately braced by angles of the same size and with gussets of ¼-in. steel plate securely riveted at the side sills and top plates and at intermediate points on the side posts.

The carlines are of the composite type with 2½-in. by 2½-in. by 5/16-in. angles, formed to a 24-ft. radius and secured by rivets to the side top plates. The cupola frame is constructed of 3-in. by 3-in. by 5/16-in. angles with the same type of carline that is used on the main body framing. The roof may be a canvas or plastic covering over roof boards secured to the carlines. Wooden filler posts and plates are secured to the angle iron frame and to these the 13/16-in. inside and outside sheathing is secured.

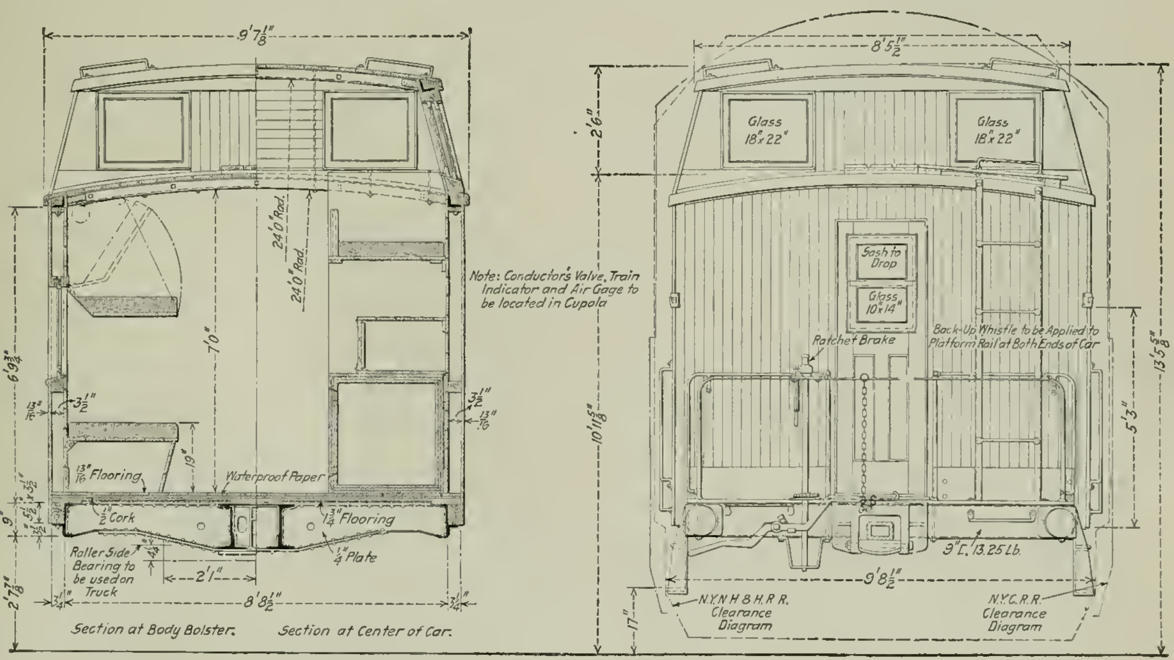
THE INTERIOR

The floor space is 23 ft. 3⅜ in. by 8 ft. 6⅜ in. inside of the sheathing, with a clear space of 3 ft. 2⅜ in. at the closest point in the aisle between the interior fittings. Two upper and two lower bunks, 6 ft. 3 in. by 2 ft. 6 in., and one upper and one lower bunk, 6 ft. 7 in. by 2 ft. 6 in. are conveniently located. The upper bunks fold upward against the carlines, giving ample headroom above the fixed lower bunks, which can be used as seats when not in use for sleeping purposes. The conductor's valve, train indicator and air gage are located in the cupola and seats are provided in each side of the cupola for observation purposes. The headroom in the main body of the car is 7 ft. and in the cupola 9 ft. 2 in. A desk is provided for clerical purposes, being so located that one end of a lower bunk serves as a seat. The tank for wash water, the wash basin and a drinking water tank are conveniently arranged in one corner of the caboose. A refrigerator, numerous lockers and drop tables, a toilet, a coal stove for heating the car, make up the complete equipment.

There are four windows, which may be raised, having 18-in. by 22-in. glass, in each side of the car, a window having a glass area of 10 in. by 28 in., with an upper drop sash, in the door at each end, and four windows with sliding sash having glass 18 in. by 22 in. in the cupola. The floor consists of 1¾-in. rough flooring, a half-inch layer of cork covered with a waterproof paper, and a 13/16-in. top flooring. A platform of ample width, formed of ¼-in. steel plate with wooden cleats laid crosswise of the car, is provided at each end. The roof canopies over the platform, thus giving some protection from the weather. Hand holds, ladders and steps are placed in the most convenient locations. A ratchet hand brake is applied and provision made for the application of a back-up signal whistle at both ends of the car. The uncoupling apparatus is connected by a



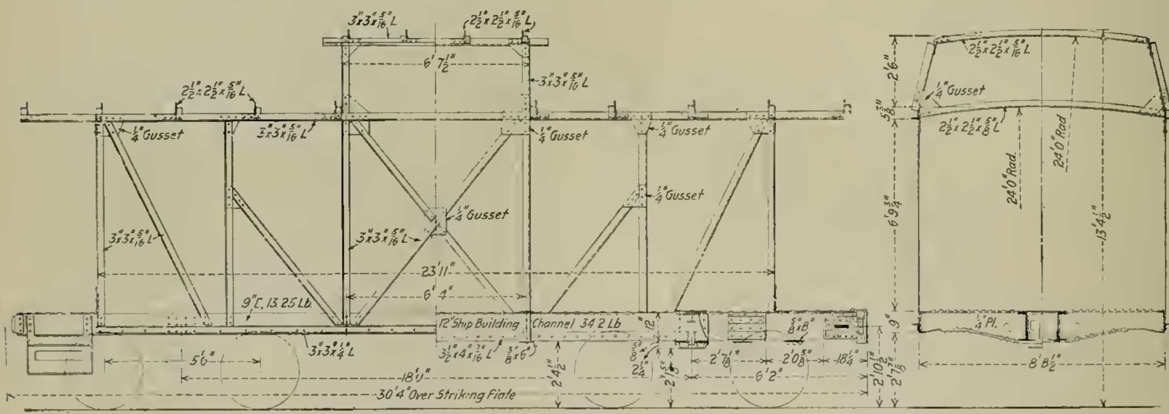
Plan of Underframe and Plan and End View of Body Framing of U. S. R. A. Standard Caboose Car



Cross Sections and End Elevation of U. S. R. A. Standard Caboose Car chain to the platform rail so that the car may be uncoupled without leaving the platform.

THE UNDERFRAME

In order to withstand the severe service in which many cabooses are used, where there are heavy grades and pusher service is required, the underframe is of unusually strong construction. The center sill is built up of 12-in., 34 2-lb. shipbuilding channel with a 3½-in. by 4-in. by 7/16-in. angle riveted to the bottom inside edge of the channel for the entire length of the sill. The top cover plate is of ⅜-in. steel plate 20½ in. wide. The side sills and end sills are made of 9-in., 13.25-lb. channel section, the side sills being reinforced on the outside with a 3-in. by 3-in. by ¼-in angle, which also serves as a support for the side nailing strips. The body bolster diaphragms are formed of ¼-in. pressed steel plate with a 3-in. flange. The top bolster cover plate is of ⅜-in. and the bottom cover plate of ⅝-in. steel plate, both 14 in. wide. The two intermediate cross-bearers are of ¼-in. pressed steel plate with a ⅜-in. steel top and bottom cover plate 6 in. wide. Diagonal braces at each end give additional rigidity to the underframe, and it should meet the requirements of the most severe service. The draft sills are designed to permit the application of any of the standard draft gears. A tool cellar of ample size is secured to the underframe.



Side Elevation and Cross Section of Steel Frame for U. S. R. A. Standard Caboose Car

THE TRUCK

The car trucks recommended by the Railroad Administration are of the four-wheel type with cast steel bolsters and side frames, and have a 5-ft. 6-in. wheel base. The wheels are to be 33 in. in diameter, mounted on axles having a 4¼-in. by 8-in. M. C. B. journal.

General Data

Length over striking plate	30 ft. 4 in.
Length over end framing	24 ft. 0 in.
Width over body framing	9 ft. 2½ in.
Width over side sills	8 ft. 8½ in.
Height from rail to top of main roof	11 ft. 1 in.
Height from rail to top of cupola roof	13 ft. 4½ in.
Diameter of truck wheels	33 in.
Wheel base	5 ft. 6 in.
Distance center to center of trucks	18 ft. 0 in.

This design is made to conform to the laws of all of the states except those of Missouri, which differ radically from those of the other states. It is intended to prevent the agitation of railway employees for state laws which, if adopted, might make it impossible in such states to use cabooses that are lawful in other states, and would result in the poorest cabooses collecting in those states having no stringent laws on the subject.

No attempt has been made by the Railroad Administration to specify all of the details of construction, but only to provide a general design for common use by the various railroads.

SUGGESTIONS FOR IMPROVING DRAFT GEAR MAINTENANCE*

BY L. T. CANFIELD

At the present time very few people are giving the question of draft gear maintenance serious thought, and the cost of car maintenance, damaged lading and loss of service due to bad order cars, leads me to make a few suggestions.

First. The car inspectors should be carefully instructed on the question of draft gear inspection and its importance to economical operation. I realize that for a while it will be necessary to continue to let some gears run for a while longer, but each repair track should take all it can handle.

Second. Each repair track where a large number of cars are repaired should have as a part of its organization a crew of men in charge of a competent foreman, to repair draft gear, specializing on this just as the air brakes are handled. The foreman should be familiar with all makes of draft gear. In a short time this would result in a reduction in the number of bad order cars as well as in the maintenance cost.

Third. There should be rules making it compulsory to take the draft gear down and make needed repairs at the expiration of three years. Should a car be on a foreign line with draft gears that have had more than three years' service without repairs, the road having the car should make the repairs. The time between repairs may be lengthened if found too short. This would not be a big task. Reduced to the number of cars per day it is only 2,777 cars for the entire country. I would not be surprised if there are not more than 2,777 repair tracks. If so, it would be only one car per day per repair track. There is no rule in effect now, the gears are allowed to run as long as they are not broken or pulled out, or some more expensive part of the car or lading is injured because of the neglect to the draft gear.

The practice of using old draft gear springs in repairs to cars should be watched very closely. If they have taken any permanent set they should be discarded and new ones used. This is not an extravagant suggestion, as the saving of $3.30, the approximate cost of a new spring, may take a couple of inches work (as represented by the drop hammer) out of the draft gear and result in breaking a coupler which would cost $25 to $30, or turn over a piano inside the car, at even greater cost.

*From a paper presented at the General Car Foremen's Association of St. Louis.

Maintenance of Freight Equipment*

Economy of Retiring Old Cars; Better Repair Facilities and Greater Interchangeability Desirable

By L. K. SILLCOX

THE economic situation with respect to the performance of that great vehicle of commerce, the freight car, is one of basic importance. Any success in railroad operation corresponds largely to the net number of car miles attained per car per day, which figure ought to be as nearly 40 or above as possible. Why many roads are only showing 30 or even less miles is probably due to many causes beyond the exact knowledge of the writer, but in any event, so far as the problem is affected from the standpoint of design, maintenance and inspection of freight car equipment, a number of conditions deserve calm analysis.

WEAK DRAFT MEMBERS MOST SERIOUS DEFECT

One noteworthy fact, the explanation of which I have tried to investigate, should be first mentioned. Of all the complaints which are general in the operation of freight train equipment at the present time, the behavior of the weakly constructed design of car is found to be the most perplexing, principally due to draft attachment failures in combination with dangerously inadequate running gear members, such as truck, side frames, axles and bolsters. Although this difficulty is in greater measure due to wooden underframe cars, yet it is also noticeable in the case of improperly designed steel cars. Right at the present time, there is a tremendous demand for suitable cars, which is not being satisfied and yet, it would appear to any thoughtful man that too many cars are standing idle which ought to be making their just proportion of revenue mileage. It does not seem to be altogether a case as to shortage of cars, but rather a matter of having more cars made really fit.

It has been said that a very large percentage of cars should be destroyed, especially those of wooden construction. A careful check, extending over a period of seven months in normal heavy trunk line service, has demonstrated that we can expect about 20 per cent or 30 per cent of the house cars used at this time to be of the type which we generally term as weakly constructed not being as yet reinforced with metal draft attachments or ends. The problem to be determined in a decision concerning the retirement or reconstruction of any such car is generally influenced by the distinctive demand for the equipment on the owner's line and a knowledge of whether the expense of betterment or improvement to the existing equipment is offset by the capitalized value of the saving which can be realized in the maintenance account, as well as keeping in mind the better characteristic operation which is practically guarranteed from such a program. Extended observation has often brought out the fact that the capitalized saving in the repair account through the adoption of an intensive retirement program and the acquisition of new high capacity units in equal number or tonnage which are bound to present very much greater service capacity and earning power, if there is a paying demand for tonnage space, has proven most practical. It will never be found possible satisfactorily to determine upon any general policy without a most careful unit study for each class of car, besides being fortified with a liberal knowledge of the exact operating possibilities of the property owning the equipment.

REPAIRS ON FOREIGN LINES MUST BE CONSIDERED

Another serious limitation to our field of selection in the matter of deciding between reinforcement or retirement, and subsequent replacement in satisfactory designs, is the fact that the majority of defects occurring in connection with car equipment when off home lines, except in case of derailment or fire, have only in late years been made owner's responsibility. This is where a vast amount of money is apt to be applied beyond the control of the car owner and will undoubtedly bring about, of its own accord, more systematic analysis in the future as to deficiencies in each class of car in order to guard against the possibility of duplicating repairs to failed members which do not meet present day requirements; so that the sum total of expense for any class of rolling stock does not become excessive, due to a large part of the work being repeated so continuously and carried out beyond the immediate observation of the car owner, resulting in extravagance, though not necessarily for the total equipment owned. Of course, under these circumstances excessive maintenance charges will not often be so easily reflected in system statements covering total ownership, as in grouped classes, which it is desired to observe.

ATTENTION BEFORE LOADING PREVENTS DELAYS

It is especially urgent that the best interests of the shippers and dealers, as well as of the railroads which serve them, be maintained by the inauguration of substantial repair practices which will insure a minimum delay of cars on shop tracks and lines of roads chargeable to their general condition and style of construction. Thorough inspection and repairs of cars before loading and careful attention to brakes, lubrication, running gear and lading after classification at originating terminals are a fundamental necessity. Cars set off on the line of road due to bad order condition of couplers, draft rigging, wheels, brakes, heated bearings, shifted lading and other similar causes are usually the outcome from lack of proper attention at the originating terminal, which results in accidents, destroyed lading and cars, reduced train rating, delays to traffic, blocking of passing tracks, engine and train crew overtime and extraordinary expense for sending men and materials out on the line to eventually make repairs.

WEAK CARS SHOULD BE KEPT ON OWNER'S LINES

As already referred to, it is a fact that at the present time nearly all systems are offering in interchange some loaded and empty cars that are of such design or condition as to make them entirely unfit for the service to be performed on the average trunk line railroad. This class of equipment, which cannot be depended upon to pass properly in main line movements, should be restricted to owner's lines, where it can haul the maximum amount of commercial and company lading with the least liability for delays, transfer or repairs. When a freight car of undesirable class and capacity has outlived its usefulness from the standpoint of commercial utility, age, decay, corrosion, obsolescence or accident, so that the expenditure necessary to put it in serviceable condition is not justified, it should be dismantled forthwith. The intensive movement of tonnage, creating an acute demand for power and a severe congestion in terminals, has at many points made it impractical, due to the time consumed and necessary switching required, to place weakly constructed cars in the rear of long trains. That is why this subject looms so prominently before us today. Tremendous damage is done to these weak cars and especially when not protected against the hammer blows of

*From a paper presented before the Western Railway Club.

modern operation. Not only this, but delays and accidents result from this condition.

REPAIR FACILITIES ARE INADEQUATE

Freight car repair yards have been located at inconvenient out of the way places; repair tracks have been set too closely together for convenience: the facilities for repairing have not been the best, and the consequence has been that cars which should have been returned to service promptly and with repairs properly made have been held out of service longer than necessary and were not properly repaired. Never before has there been such pressing necessity for intelligent work, for proper tool equipment and for shelter for the men employed as at the present time. It is a reflection on good judgment when cars are held out of service for which there is a paying demand at the time, and it would appear that with the attention now concentrated on the railroads, best efforts are not only desirable, but absolutely necessary for a relief of the conditions.

The scope of the operations in commercial value; the great numbers of men coming under the control of the mechanical department; the drift of the times concerning methods for carrying out the work and the very intensive service necessary to transportation matters, as well as the growing importance of economies, all tend to make us focus our attention on these questions. There is no denying the fact that all these matters involve, more than any one thing, the element of men, and if we are going to best the best from our men, we must provide responsible supervision with necessary support and initiative so as to maintain action and make good from day-to-day. The moral responsibility of everyone is as great and as constant whether one is here or there, or doing one thing or another, and this responsibility is in exact proportion to the intelligence of the individual coupled with whatever measure of freedom for action is allowed. It implies leadership and teaching, not in some things to be sure, but in all of the relations that bring individuals together in industry and business, so that our choice, especially among our highest supervisors, should be along most practical and fundamental lines. This is only referred to as a timely suggestion, since it has so far reaching an effect that words fail to emphasize its importance.

GREATER INTERCHANGEABILITY DESIRABLE

The first division of the subject assigned to me has regard for the design of rolling stock. I do not think it is reasonable to believe that the roads will adopt and maintain one standard type of car indefinitely to a single inflexible pattern. There are sure to be improvements and modifications, which different groups of railroad men think it desirable to make and such motive would be difficult to subdue. It would seem proper for the draft lugs, truck frames, truck bolsters, center plates, striking castings, coupler carriers, brake beams, truck springs, drawbar yokes, uncoupling mechanism, brake hangers, drawgear carriers and center plate height of truck to be standardized and made interchangeable to a greater degree than at present, both in new and repair work. It does seem indefensible, that the slight variations made in these parts should necessitate their being obtained from the car owners. In designing a car, what must be considered is the service in which its paying demand rests, not the service in which it may possibly run. It is only fair to assume that every railroad management aims to place into service cars built in a substantial manner. Standards in detail construction have been adopted by the Master Car Builders' Association which have assisted greatly in reducing the amount of stock necessary to be carried. The difficulty seems to be that these standards have not been enforced under mandatory rules and their full practical value has never been properly felt on this account. I believe the time has arrived to introduce additional standards affecting the maintenance of box cars which can also be applied to all types used in interstate service.

The application of steel center sills, as well as draft arms, to old cars will not only prolong their life, but cause them to have a more continuous earning capacity, due to not becoming marked out to shop tracks every few hundred miles for the application of draft timbers and end sills, as well as avoiding damage to adjacent equipment and delays to trains, and in terminals, to say nothing of the tremendous losses due to damaged lading and loss of patronage, where delays and slow delivery become epidemic.

POORLY DESIGNED CARS ARE A SOURCE OF TROUBLE

Mechanical and transportation officers have seen and appreciate the results of poor designing and inferior construction, both as regards wooden and steel cars. One of the surprising features with regard to many steel cars in service which cause the greatest trouble and embarrassment, is that they are not of particularly light construction, but the metal has been disposed with very little regard to the engineering feature of service requirements actually encountered. There is no doubt whatsoever but that many of these cars could be built with at least equal or even lass weight than originally set aside and a perfectly satisfactory structure obtained. This is what is so confusing to the minds of executive officers, when they have purchased and placed into service, not a cheap or even a light car and it fails, then on top of it all, it is necessary later to recommend reconstruction and additional expense in order to stop permanently, a severe leak in the maintenance account. New fads in the design and building of car equipment should not be permitted, or any innovations, until thoroughly tried out and known to be reasonable and capable of standing up in normal heavy service for at least a period of five years, besides being passed upon by uninterested, competent authorities.

It is not alone the larger locomotives being used today which have called for a more thorough investigation of the subject of car design and construction, but also the severe shocks which cars are receiving in classification yards. The superstructure of box cars should receive just as much attention as the underframe and trucks, otherwise, leakage and subsequent loss of metal roof sheets through racking and frames not being kept in alinement is bound to result, and when this happens, it places restrictions on the ultimate utility of the car for service where leakage is harmful.

WOODEN FRAMED CARS NEED STEEL CENTERSILLS

In discussing any problem dealing with the continuance in service of the all-wood car, as compared to an intensive program of replacement in the all-steel and steel underframe classes, the strongest argument in favor of the general adoption of the latter, and one which is barely, if ever, touched upon, is the fact that wooden framed cars are always damaged when in collision with steel underframe cars, while the latter escape uninjured. If, because of their decided economy, the more recent designs of metal construction are continued in use, then it is essential that other cars associated with them should be made strong enough to withstand the severe shocks incident to the movement of heavy tonnage trains now so generally experienced. There is no doubt that the light wooden cars may be strong enough to carry the load for which they were designed, but they need a stiff backbone in the underframe to protect them from being crushed in the middle of a long train or between two heavy cars under impact. The same argument of uniformity holds true of couplers, draft gear and brake equipment. It is for this reason that we must at this time give more positive backing to the need of metal reinforcement programs for cars of light design, rather than hesitating on a questionable economy in operating expense, due to carrying larger loads and less dead weight. It simply must carrying larger loads and less dead weight. It is a question of modernizing cars or retiring them from service.

WOODEN VERSUS STEEL CARS

With respect to the life of the wooden car, compared with steel, it is well to state that none of the modern steel cars have been in use long enough in general operation to determine their ultimate length of useful service. It has been found, however, what may be expected of all metal coal and other special classes of cars on prescribed lines, having a given commodity and territory; this, of course, is of valuable comparative local use only. There is great difference of opinion about the loss of weight in steel due to corrosion and this may well be expected due to varying climatic conditions experienced, and until some definite conclusions can be drawn, based on a wide range of observation under every service condition, any data used must be employed with caution. Records indicate foundation for the opinion that wooden cars have been in continuous use from 20 to 30 years, but it is probable that such cars have been rebuilt from the sills up once or even more times in that period, so that we ought not to be disposed to question the assumption of the average life of such cars being 20 years. With respect to the high cost of repairs to wooden, as compared to steel equipment referred to, and which is almost always carried on gradually, we must not forget that for steel cars, up until the time rebuilding is necessary, usually only light repairs are carried out, due to the various roads not being equipped to do the heavy work at this time. Therefore, any comparative costs should be viewed with these thoughts in mind and wrong conclusions avoided.

INCREASE IN COST OF FREIGHT CAR REPAIRS

Such a large proportion of failures in units of freight car equipment, as is now being experienced, appears to indicate that there is something radically defective in the elementary handling of the transportation problem or else the maintenance features have been neglected and not kept in stop with the advance movement of the service to be rendered. The cost of freight car repairs has been continually increasing and in somewhat greater proportion than the advance in labor and material accounts would explain. The tendency for such increases can only be offset by providing all means that aim to reduce the number employed and get the greatest possible output from each man. This not only makes itself felt upon the payrolls, but reduces the time cars are held out of service, which is another source of revenue. In dealing with concrete cases showing the increase in freight car repair costs, a table is shown below for eight of the largest Western railroads.

Road	Year	No. of freight equipment cars	Average miles per freight car per year	Cost of freight car repairs per car per year	Cost of freight car repairs per mile—cents
A	1916	66,409	11,593	$69.13	0.599
	1917	70,396	11,853	68.12	0.558
	1918	70,400	12,064	146.52	1.221
B	1916	57,401	8,931	53.98	0.60
	1917	58,256	8,396	66.64	0.80
	1918	55,819	8,987	147.13	1.64
C	1916	47,985	10,974	58.76	0.54
	1917	47,845	11,171	74.98	0.67
	1918	50,079	10,376	133.60	1.29
D	1916	46,925	11,098	85.59	0.80
	1917	46,281	11,191	126.92	1.13
	1918	45,993	10,459	201.23	1.92
E	1916	68,339	13,059	74.66	0.57
	1917	67,828	14,553	88.46	0.61
	1918	69,622	11,145	149.88	1.35
F	1916	67,370	13,053	98.16	0.75
	1917	67,168	11,214	122.93	1.09
	1918	61,457	11,905	266.57	2.24
G	1916	63,143	11,646	120.20	1.03
	1917	64,919	12,377	113.12	0.91
	1918	66,741	12,810	177.18	1.38
H	1916	81,034	9,468	71.48	0.76
	1917	83,147	9,499	84.84	0.89
	1918	72,141	9,377	146.36	1.58

The serious increases in total expense from year to year are attributed more to the character of equipment owned than any other feature and the logical proposal is, therefore, that more rapid retirement of obsolete equipment should be carried out. When such cars are dismantled and permanently removed from service, one of the features which can be expected to effect a saving and prevent such increases as indicated above is the relative reduction in the amount of material used for repairs to old cars. It can be fairly well stated that the total car repair expense is about equally divided between labor and material, under normal conditions where extensive reclamation operations are resorted to locally, thus holding down the amount of new material obtained to a minimum. Most wooden cars are at least 15 years old and many have seen 25 or more years service. Comparatively few of the weakly designed cars complained of have been reinforced with metal draft rigging. Failure of draft attachments and associated parts contribute to the serious increase in cost of repairs.

LIMIT FOR REPAIRS DOES NOT FORCE RETIREMENT OF CARS

It seems to be a general practice to place small limits of expense on these older cars with the idea in mind that these limits would force such cars to be automatically taken out of service as they become deteriorated beyond a point where repairs would be economical. It can be shown tbat this equipment is on the repair track a large portion of the time, and in each instance just sufficient work is done to run the car a little further owing to the policy of concentrating on light repair work first where a demand for equipment exists. Such a plan of retirement does not work satisfactorily and in the end the roads have far exceeded any proposed sum of money which they planned on placing against these old cars to keep them in service. I do not think anyone who has followed the plan in question has ever found the result in practice any different than stated.

LOW STRESSES PROLONG LIFE OF PARTS

During winter months, and at times of heavy tonnage movement, wrecks and delays caused through breaking down of trucks are very serious matters and the question is always asked as to why such things happen. Fatigue failure in metal truck frames, axles, bolsters and other portions of equipment is characterized by suddenness, and oftentimes occurs immediately after careful inspection has been made. The fractures sometimes disclose a crystalline appearance over part of the surface and it is this feature which has many times given rise to the term crystallized. This supposition, however, has been found generally false, since close examination of metals under stress show no change of the general scheme of internal structure, but under severely heavy stress there appears a gradual breakdown of the crystals forming the member. Metal used for the running gear of cars is more or less ductile, and when these parts are deformed cold, the first yielding occurs in the particular grains which either take the most stress or have the lowest elastic limit. The failure in such metals subjected to repeated stress takes place with substantially no general deformation, but there is, however, considerable localized distress among the structural particles, which increases directly with the number of applications of stress. Car trucks have imposed upon them repeated stress in service and failure seems to develop in proportion to the continuous mileage made. In analyzing specific cases of breakages, they seem to appear almost exclusively through the unification of yielding particles, with the result that cracks develop with final added stress, promoting the extension of this crack into the adjacent area on both sides. Steel must be considered as filled with a multitude of minute flaws, originating at the time the metal becomes solidified. In static testing, steel under stress of about one-half its ultimate strength passes into a semi-plastic condition, in which there is a gradual flow of the material. Under such condition, the small flaws have almost no effect upon the flow or upon the static strength. When steel is loaded to moderate stresses, the yield is almost entirely elastic in general, but a small portion of its inelastic energy being taken up by the steel itself. In this way it can be reasoned that sufficient material is necessary to any truck side frame or bolster in order to keep down the working load of the material and give long life to the part. Of course, where springs are improperly designed to carry the load, truck members receive hammer blows in service for which they were never designed and this seems to be particularly true in the case of the M. C. B. grouping of springs for 50 ton cars as often they stand practically solid under the static weight of the car and lading. This is a subject which should be placed before the proper committee of the M. C. B. Association.

As a plan of interesting local foremen in the discharge of their duties, it is well for them to have a working knowledge of the money they are spending and a form has been adopted which is filled out daily by the foremen and is wired to the general offices twice a month. Very interesting results have been obtained from this practice and establishes the plan of foremen going over time slips personally to know that labor charges are being properly distributed. With this data, and knowing the amount of work turned out, a good practical analysis is obtained concerning relative efficiency month by month which guards against excess overtime payments and similar wastes.

FREIGHT TRAIN INSPECTION

Before closing this paper, I will only refer briefly to the question of freight train inspection. On the road with which I am connected practices have been adopted which have done a very great deal to couple and unify our efforts, especially in through business, besides positively maintaining the responsibility of each individual engaged and avoiding as much as possible any duplication of inspection.

The desire to save time and cost of inspection by resorting to the so-called safety inspection of some roads has about reached its limit. The class of men that railroads are obliged to draw from, in some districts at least, do not make the most expert inspectors. The saving in reducing the number of men and time to make the usual superficial safety inspection oftentimes proves a serious less, for the result of a derailment or wreck on account of a loose or defective wheel or some other important part of the running gear or brakes which have been overlooked on account of time or judgment, is worthy of serious consideration. No one will deny that all cars are rankly abused, but very little is heard of crews being suspended or even censured on account of damage to rolling stock, no matter what the extent. The ultimate loss cannot be measured by figuring the cost of renewing certain broken parts when cars are abused for premature failure of other parts will follow.

Consideration of overtime and the sixteen hour law, as well as expeditious train movement, demands the minimum lapse of time between that for which the crew is called and that when the train departs. Hence, a train prepared for departure should require no more brake work after the engine is coupled than, at the most, stopping a few leaks in hose couplings and making the formal test. But often today there are greater delays due to making other repairs, or the train proceeds with less efficient brakes than required.

To avoid this, the repairs required must be determined with arriving trains. The incoming engineer should add to the reduction required for stopping enough to fully apply the brakes, and the brakeman should await his advice that this has been done before cutting off the engine. Car inspectors should be present to make an immediate examination and to bad order all defective brakes. Such repairs as ordinary brake pipe leaks, defective hose and wrong piston travel, should next be made, but cars requiring heavy brake repairs be marked for the repair tracks.

In this matter, judgment must be exercised as perishable or other very important loads as well as empties needed at once for such lading, must not be delayed. Neither should other less important cars be held in numbers far greater than the local force can repair in a day if such force is as great as the regular amount of work, including such repairs, would keep busy. The car foreman and the yard master should consult to adjust the foregoing, but when the former removes bad order marks without repairs having been made, he should fill out and apply an air brake defect card to insure repairs at the earliest possible date.

DISCUSSION

G. S. Goodwin (C. R. I. & P. Ry.) stated that at the present time the railroads were justified in making more extensive alterations when reinforceing old cars. He cited the fact that steel frame box cars which formerly could be purchased for $900 now cost $3,000.

T. H. Goodnow (C. & N. W.) expressed the opinion that the retirement of wooden cars is one of the most important problems confronting the mechanical department at the present time. There are still in service a great many wooden cars of 80,000 lb. capacity built between 1902 and 1907 which have as high cubical capacity as cars being built, at the present time. These cars will give good service if reinforced and the work should be done without delay. Mr. Goodnow called attention to the many circumstances which must be considered in analyzing statistics regarding freight cars. He doubted whether any reliable figures showing the relative life and cost of wooden and steel cars were available because the early all steel cars were confined almost exclusively to gondola and hopper types which cost less to maintain than house cars. He called attention to the large percentage of foreign cars which all the railroads had on their lines during 1918 and stated that for this reason the expenditures for freight car repairs did not furnish a true indication of the relative cost of maintenance of the equipment of the various companies. He said the past two years had proved that cars cannot be taken care of as well away from home as when the equipment occasionally reaches the owning road and favored greater standardization of truck and draft gear parts to facilitate maintenance. He indorsed the system of organization in force on the C. M. & St. P. and stated that an individual car department was necessary in order to get the best results from the local organization.

J. W. Luke (A. T. & S. F.) expressed the opinion that some roads are not keeping cars in such fit condition at the present time and the standard of equipment maintenance would not be improved unless the burden of repair work could be distributed among all the roads. From the year 1917 to 1919 the Santa Fe's expenditure for repairs to foreign cars rose from $1,690,000 to $7,700,000, an increase of 355 per cent. Mr. Luke advocated the reinforcement of wooden cars with steel channel center sills and stated that the cost of maintenance of cars so improved compared favorably with modern equipment.

C. Wymer (C. & E. I.) mentioned that sometimes the equipment is designed with no thought of future repairs and the replacement of minor parts necessitates expensive dismantling. Such construction inevitably increases the cost of repairs. In the course of the discussion Mr. Sillcox elaborated on some of the points brought out in the paper. To emphasize the necessity for retiring cars of wooden construction, he quoted statistics showing that 76 per cent of the cars damaged in service were cars with wooden underframes. The failures were distributed as follows: draft gear 63 per cent, knocked off center 14 per cent, end frame failure 14 per cent, cornered 9 per cent.

SHOP PRACTICE

SHOP PRACTICE AT TRANSCONA

BY S. LEWIS
General Foreman Blacksmith, Canadian National Railways

The bulldozer has contributed greatly toward the present high efficiency of the railway blacksmith shop, and can be used for a variety of work other than that for which it was originally designed.

When a die or tool is considered, the first thing to be decided is whether or not it can be made to pay, and if so, how much. The answer to this question often involves very many others, but can generally, if not always, be resolved into computations based on the number of pieces to be made, and the probable cost of labor per piece when made with and without a die, and also the cost of the die, including maintenance.

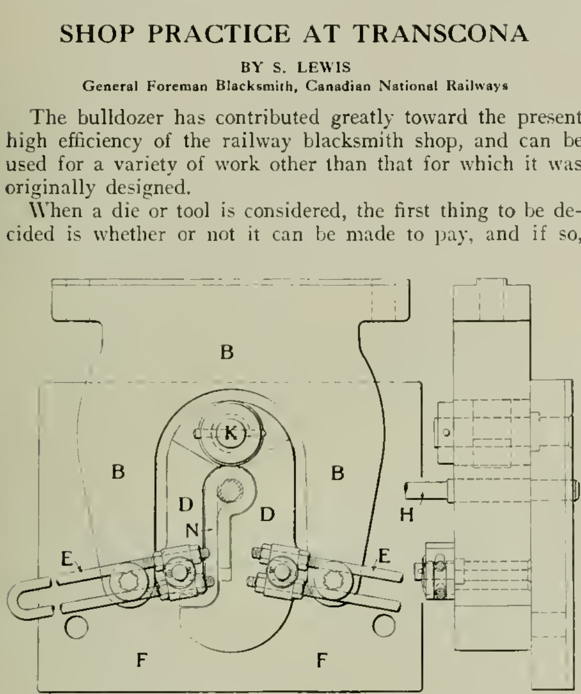


Fig. 1—Arrangement of Dies for Forming Hinge Butts

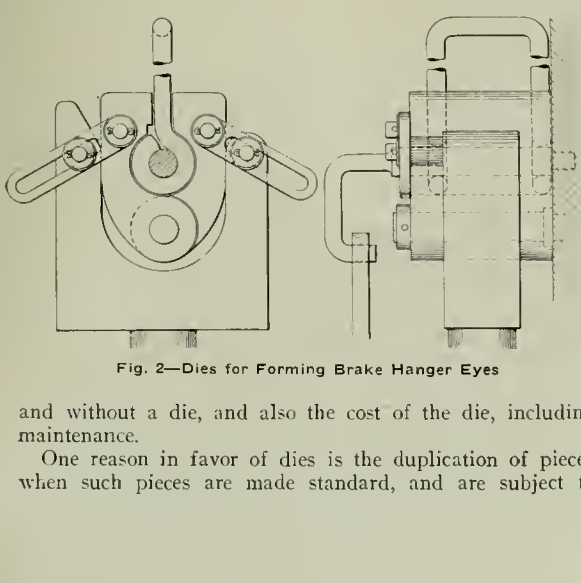

Fig. 2—Dies for Forming Brake Hanger Eyes

One reason in favor of dies is the duplication of pieces when such pieces are made standard, and are subject to great wear and tear. Another reason is accuracy, which can only be attained by the use of such dies. There are certain classes of work which could not be finished at all within the limits of uniformity and accuracy demanded if dies of some sort were not used.

Typical examples of dies which have been used successfully on this class of machine in the Transcona shops of the Canadian National Railways are shown in the illustrations.

Fig. 1 is a compound arrangement intended to form apron hinge butts for Hart cars, with which dies thousands of hinges were successfully formed in one operation. The moveable head *B* takes the form of a *U* shape; attached to the head are two adjustable links *EE*, which cause the two inner arms *DD* to swing open. These two arms are closed by the forward movement of the *U*-shaped head. The swing arms *DD* hinge around the pin *K*, which is fastened to the plate *F* and is bolted to the table of the machine.

The arms, when forming the hinge butt *N*, swing around the adjustable pin *H*, which can be pulled out, and with a few taps of the hand hammer the hinge falls off. All these parts are made from mild steel and very little machine work is necessary.

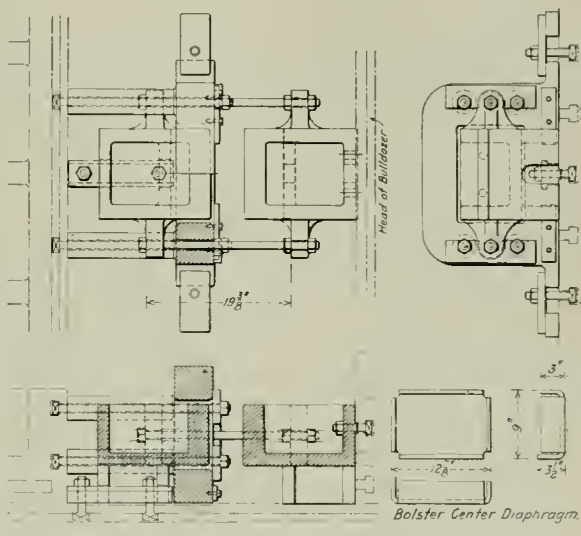

Fig. 3—Dies for Forming Bolster Diaphragms

The economy of this arrangement is obvious and all that is required to form a variety of hinges are the swing arms, several sizes of which can easily be adapted to the one arrangement.

In designing dies of this nature a great deal depends on the character of the work to be done. To insure an easy movement of members with a minimum strain and a maximum formation of parts to be produced, the dies should be made as light as is consistent. Care should always be taken when planning tools of this character so that the work may easily and accurately be located in order to prevent mistakes. This will add considerably to the efficiency of the operator.

Fig. 2 is an arrangement similar to Fig. 1. This arrangement is assembled on an air bulldozer and has served a great purpose in the pioneering days of the transcontinental road. Brake hangers are made on this machine in two heats and two operations. This die bends both eyes of the leases the pieces from the dies after forming them as shown in the illustration.

Fig. 4 is an example of a simple drill jig used at the Transcona shop to drill holes in coupler pins. A cover of the simplest design contains the guide bushings, which are changeable to suit whatever drillings are required and can handle a variety of such work with great rapidity. The bushing holder can be raised or covered to suit different diameters of work. Both V blocks in which the work rests are adjustable, by means of the screws, for different lengths

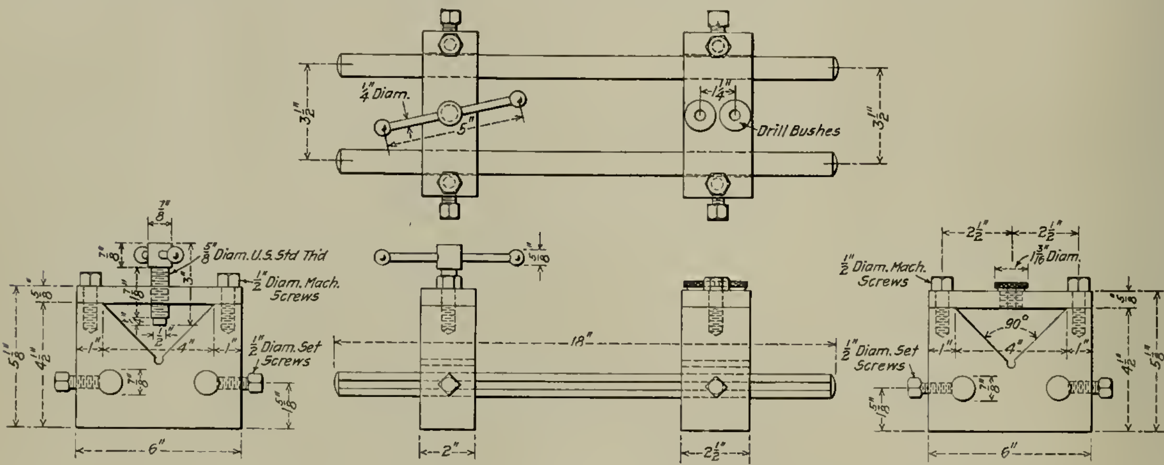

Fig. 4—Drilling Jig for Drilling Holes in Coupler Pins

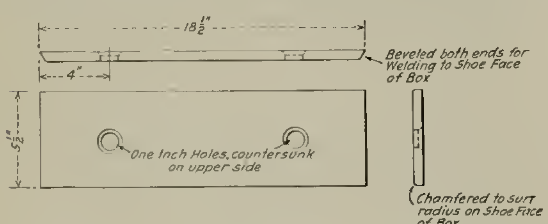
hanger simultaneously at one operation at a cost of 1½ cents.

A die to form a bolster center diaphragm is shown in Fig. 3, assembled on a 150-ton hydraulic bulldozer. The diaphragm plates are 4-in. by ½-in. by 1 ft. 5⅜-in. and are partly heated. The backward stroke of the machine re- of pins and lend themselves well to a variety of work of all descriptions. It also provides a clamping device, which is very essential to keep the work in position while being drilled. It is simple, efficient, and a characteristic example of an adjustable type of jig.

LINERS FOR DRIVING BOXES AND PEDESTAL CAPS

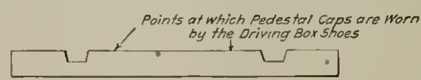
BY A. W. CONWAY

When the shoe faces of driving boxes have become worn below the standard limits by wear and repeated facings, it has been the usual practice to have dovetailed slots cut lengthwise in the shoe face and then pour them with bronze. An improved method of renewing the shoe face is to electrically weld on steel plate liners of suitable thickness to replace the amount the box is worn, making a more durable liner than the bronze. By making the liner of suitable thick-



Driving Box Liner

ness it need only by skinned off when planing it, thus reducing machine work to a minimum. When the bronze liners were used it was necessary to pour an excessive amount, as it was difficult to gage just the proper amount to pour, so there was usually an inch, more or less, to plane off. This new method saves the work of dovetailing to hold the bronze, the time necessary to melt and pour the bronze, and we have a bronze shoe wearing against a steel pedestal jaw on one side and against the steel box liner on the other side, which is far better than bronze against bronze. The holes are placed about four inches from the ends, as the



Pedestal Cap Re-Lined by Welding

only time when the liner is likely to tear away is during the planing.

It has also been common practice when pedestal caps are worn by the movement of the shoes, to true up the worn surface on a shaper, and then drill and tap the pedestal cap to secure on it a liner of a thickness that will make it flush with the unworn surface of the cap. This worn surface can be built up by the acetylene process and then hammered, making a very neat job, which is far superior to the older method of renewing the bearing surface.

CHECK LEAKS IN WELDING APPARATUS.—Never permit the slightest leak to go unchecked in a welding or cutting apparatus. An oxygen leak is expensive, and an acetylene leak is not only expensive but dangerous. Slight leaks in the hose or connections can be detected by shutting off the regulator valves and closing the cylinder valves, and noting how long the pressure holds up in the pressure gages. If the pressure falls, hunt for the leak.—*Autogenous Welding.*

Steel Treaters' Society Convenes

Modern Shop Practice and Equipment for Heat Treatment of Cutting Tools and Forgings Discussed

The American Steel Treaters' Society held its first convention at the Seventh Regiment Armory, Chicago, September 23-27. This organization which was formed in September, 1918, for the study and development of the art of heat treating steel, now has a large membership with chapters in nine cities. Many railroad men have become identified with the society and it is planned to give special attention to problems in which the railroads are interested. The convention was opened with addresses of welcome by H. H. Merrick, president of the Chicago Chamber of Commerce, and by the acting president of the society, T. E. Barker of the Miehle Printing Press & Manufacturing Company. At the later sessions a large number of subjects were discussed. Some of the papers are not available, but abstracts of two having direct application in railroad shop practice are given below and others will be published in future issues.

TYPES OF PYROMETERS AND THEIR USES

BY RICHARD P. BROWN
President, The Brown Instrument Company, Philadelphia, Pa.

Greater progress has been made during the past ten years in the use of pyrometers than was made in the 200 preceding years during which pyrometers were known and used to some small extent. The old methods of measuring temperature by the expansion or fusing points of clay, by the expansion or contraction of metals, and by numerous other means, have largely been eliminated today and there are practically only two methods of measuring high temperatures. The thermo-electric pyrometer embraces either a thermo-couple inserted directly in the heat, or in the form of a radiation pyrometer with the thermo-couple heated by the furnace rays; second, the optical pyrometer, in which a color comparison of an incandescent body and the steel under treatment is made. The optical pyrometer is used only portably, as this instrument is not suitable for permanent installation or for automatically recording temperature. It is used quite extensively where it is necessary to focus on a particular piece of steel in a furnace to secure its temperature, or where excessively high temperatures are measured, around 3,000 deg. F. or 1,600 deg. C., where a thermo-electric pyrometer is not suitable.

THERMO-ELECTRIC PYROMETERS

A thermo-electric pyrometer consists of a thermo-couple, a measuring instrument, and the leads connecting the thermo-couple and the meter. The thermo-couple is formed of two dissimilar metals, usually drawn into wire and with one pair of ends twisted together. When this junction is heated, it generates a small current of electricity which can be measured on a milli-voltmeter.

A thermo-couple produces current, dependent on the temperature of the twisted junction extending into the furnace, known as the hot end, and the opposite end outside the furnace, known as the cold end or cold junction. It is at these ends that the leads running to the meter are joined to the thermo-couple. In accurately measuring temperature with a thermo-couple it is, therefore, essential that the cold junction be maintained at a known fixed and uniform temperature, which may be 75 deg. F. or any other temperature. If the cold junction of a thermo-couple is at 75 deg. F. and the hot junction in the furnace is at 1,400 deg. F., the actual millivoltage generated is proportioned to the difference in temperature between the hot end and the cold end of the thermo-couple, equivalent to 1,325 deg. F. If we heat this cold junction to 100 deg. F. we will then only have a millivoltage produced by the thermo-couple equivalent to the difference in temperature of 1,300 deg. F. instead of 1,325 deg. F., as previously cited.

The effect of heating the cold junction of a base metal thermo-couple is such that with a rise in temperature of the cold junction of 25 deg. F. the instrument will read approximately 25 deg. low. With a platinum thermo-couple this error is approximately one-half. In other words, with a platinum couple, the error would amount to only approximately 12 deg. F. for a rise in temperature of the cold junction of 25 deg. F. above normal.

In the use of any thermo-electric pyrometer it is essential that this point be realized, because far too many thermo-electric pyrometers are still in use today with the old junction of the thermo-couple located high above a furnace and subject to constant changes in temperature and to probably a normal temperature of not less than 200 deg. F.

Assuming that the pointer on the instrument is set at 75 deg. F., such an instrument is actually reading 125 deg. too low. Of course, if the user of the instrument only realizes this fact he will set the pointer of his instrument for the proper cold junction temperature 200 deg. F. instead of that usually adopted in supplying the pyrometer, 75 deg. F.

All modern pyrometers are equipped with zero adjusters which permit of setting the pointer to any desired cold junction temperature and this point can be readily taken care of. Unfortunately in the case where a thermo-couple is located just above the furnace, when the furnace is first started up, the temperature of the thermo-couple inside might attain 1,400 deg. F. and the cold junction outside will have only reached 100 deg. F.; after the furnace has been run six hours, the heat radiation from the crown of the furnace may be such that the cold junction temperature will reach 200 deg. F. In consequence, the pyrometer is reading 100 deg. lower than it did formerly for exactly the same temperature in the furnace. In consequence, the operator in order to make the pyrometer read the desired temperature, 1,400 deg. F., is actually carrying 1,500 deg. F. in the furnace.

COLD JUNCTION COMPENSATION

There are a number of ways in which this source of error due to changes in temperature of the cold junction of the thermo-couple are overcome. First, compensating leads, as they are called, consisting of material the same as that forming the thermo-couple, which will remove the cold junction to some distant point where the temperature will be constant. These compensating leads can be selected of material the same as the thermo-couples or of the other alloys which will offset the effect of change in temperature at the cold end of the thermo-couple.

There are several ways in which we can further reduce this possible error. First, we can run the compensating leads into a pipe driven into the ground for some 10 ft. and at the bottom of the pipe we make our junction with the copper leads running to the instrument. The cold junction is now in the ground where the changes from winter to summer under usual conditions vary 5 deg. F. Where precautions are taken this is an excellent method of maintaining a constant cold junction temperature.

Another common method is to place the cold end of the compensating leads in a compensating box, which consists of a thermostat and lamps or heating units. By means of the thermostat it is possible to maintain any desired temperature usually up to 150 deg. F. within a limit of + or — 2 deg. F. The ordinary compensating box is designed to take care of as many as 20 thermo-couples, which are led into the one compensating box and this affords an easy method of maintaining a constant temperature.

The compensating leads from the thermo-couples can also be run to the instrument, which may be located in the room subject to variation in temperature from probably 70 to 100 deg. F. from winter to summer. In this case it is possible to have an error of as much as 30 deg. F.

Thermo-electric pyrometers are now supplied with automatic compensating means at the instrument so that, provided the compensating leads are run to the instrument, automatic compensation takes place to overcome changes in temperature at the instrument itself. This compensation can be readily incorporated in the thermo-electric pyrometers through a shunt of large temperature coefficient, which will be materially affected with atmospheric changes in temperature.

BASE METAL THERMO-COUPLES

I have referred previously to the use of thermo-couples formed of base metal and of platinum wire. Base metal thermo-couples are almost universally used for measuring temperatures to 2,000 deg. F. or 1,100 deg. C. These base metal thermo-couples for temperatures up to 1,200 deg. F. or 650 deg. C. are usually formed with one wire of constantan, a nickel copper alloy, and the other a pure iron. This form of thermo-couple is advantageous for use in a reducing atmosphere within the above temperature limits. For temperatures above 1,200 deg. F. up to 2,000 deg. F., equivalent to 650 deg. C. or to 1,100 deg. C., a thermo-couple formed of one wire of 90 per cent nickel and 10 per cent chrome and the other wire of 98 per cent nickel with balance manganese, silicon and aluminum, would give the most satisfactory service.

Base metal thermo-couples as supplied today are furnished in all diameters from .01 in. up to ¼ in. in diameter; sensitive thermo-couples of wire .01 in. in diameter can be used experimentally to advantage in testing the temperature of the surfaces of metal, particularly at moderate temperatures, whereas thermo-couples formed of wire ⅛ in. or ¼ in. in diameter are better suited for constant service in large heat-treating furnaces.

PLATINUM THERMO-COUPLES

Where we have to measure temperatures from 2,000 deg. F. or 1,100 deg. C. up to a maximum of 3,000 deg. F. or 1,000 deg. C., it is best to use a platinum rhodium thermo-couple, one wire being of pure platinum and the other platinum 90 per cent and rhodium 10 per cent. The wires forming this thermo-couple are usually .02 in. in diameter. A platinum rhodium thermo-couple gives very satisfactory life even under severe service at temperatures up to 2,500 and 2,600 deg. F., provided the wires are suitably protected from the gases with a tube of porcelain or silica, which is impervious to gases. These tubes are in turn protected with a tube of graphite, carborundum, fire brick or other suitable material which serves to protect the fragile porcelain or silica tube from mechanical injury and introduces a slight lag to prevent breakage through contraction and expansion due to sudden changes in temperature.

While it is of the utmost importance to properly protect a platinum rhodium thermo-couple to exclude gases which very actively attack the platinum, it is equally desirable to properly protect a base metal thermo-couple if maximum life is to be secured. The usual method of protecting a thermo-couple for temperatures up to 1,400 deg. F. (750 deg. C.) or below, is to use a common wrought iron pipe with the lower end plugged or welded. The life of common wrought iron pipe can be increased to some extent by calorizing, a process of impregnating the pipe with an aluminum oxide.

A material increase in the life of base metal thermo-couples for temperatures above 1,400 deg. F. or 750 deg. C. is secured by the use of protecting tubes of nickel chromium or of a special alloy. The nickel chromium tubes withstand to a satisfactory extent normal use in heat treating furnaces where the temperature does not exceed 1,600 deg. F., but for the most common conditions, and where maximum life is secured this special alloy tube is giving the best results.

To insulate the wires forming a thermo-couple from each other and from the protecting tube, it is common practice to use beads of porcelain or lavite, which are the most satisfactory for this service. Formerly asbestos tubing or string was used to insulate each wire and this was painted with a solution of sodium silicate and carborundum, but this form of insulation rapidly disintegrates at temperatures above 1,000 deg. F. The porcelain or lavite insulation is most certainly to be recommended.

STANDARDIZED VOLTAGE FROM THERMO-COUPLES

A platinum rhodium thermo-couple, on account of the care taken in the refining of the precious metals and the proper alloying, can be reproduced continuously with the same millivoltage. As new ingots are cast every few years from which this wire is drawn, it has been possible to carefully duplicate these ingots so that the millivoltage is reproduced within some 5 deg. F. of the millivoltage produced by a previous lot.

With base metal thermo-couples it has been extremely difficult to select wires which will accurately reproduce the standard millivoltage of a certain base metal thermo-couple. It seems that the limit in this respect is approximately 15 deg. plus or minus or a total possible error of 30 deg. F. We have, however, made some progress through special care in selecting wire producing the desired millivoltage, and it is possible today to supply wire for thermo-couples with an accuracy within 10 deg. F. plus or minus.

Where extreme accuracy is required it is possible to shunt the thermo-couples to a definite or standard millivoltage by reducing the voltage produced by the thermo-couple by some two millivolts. With this method it is possible to standardize any thermo-couple with extreme precision and an accuracy within plus or minus 4 deg. F. can be easily obtained.

A shunted thermo-couple can be used to advantage where the immersion of the thermo-couple in the furnace does not exceed 18 in. For unusual immersions where the thermo-couple must project, for example, several feet inside the furnace, the unshunted thermo-couple is preferable. Where the shunted thermo-couple is used it has the advantage that it is possible to re-standardize this thermo-couple at any time provided it falls off in voltage. With the unshunted thermo-couples should this occur, it must be either junked or shortened if this is possible.

The shunted thermo-couple has the disadvantage that the shunt may be broken accidentally or through mechanical injury. Both the shunted and unshunted thermo-couples have their advantages and disadvantages and each has its uses.

There are two common methods of measuring the voltage produced by the thermo-couple, the milli-voltmeter method and the potentiometer method.

THE MILLI-VOLTMETER METHOD OF MEASURING TEMPERATURE

The milli-voltmeter method has been in use for a great many years. The original milli-voltmeters were constructed with a movable element swinging in the airgap of a permanent magnet and hung by a fine suspension wire. As a platinum thermo-couple produces some 20 thousandths of a volt for 3,000 deg. F. and a base metal thermo-couple some 40 thousandths for 3,000 deg. F., the usual temperature scale, the internal resistance of an instrument is dependent on the type of thermo-couple used and the voltage is consequently available.

These suspension type instruments which were largely made in France, England and Germany some 20 or more years ago, had an internal resistance of 300 to 600 ohms with a platinum thermo-couple with full scale of 20 millivolts. On account of the delicate construction of these instruments and the continual breakage of the suspension wires, certain manufacturers in this country produced a low resistance form of milli-voltmeter pyrometer consisting of the standard form of switchboard or portable milli-voltmeter used with a shunt as an ammeter. This instrument usually had from 3 to 5 ohms internal resistance. While it was true that such an instrument was exceedingly robust and could be handled without likelihood of injury, it was equally true that the accuracy of such an instrument was exceedingly poor on account of the low internal resistance of the instrument. Frequently the total resistance of the thermo-couple and the leads connected to such an instrument might vary from a total of 1 ohm to 2 ohms, affecting the actual readings of the instruments as much as 20 per cent.

If an instrument of this kind was calibrated for a 3-ft. thermo-couple of the usual ⅛-in. wire and it had later to be used with a 4-ft. thermo-couple, unless the instrument was re-calibrated it read 20 deg. F. too low. If the instrument was calibrated from 25-ft. double conductor No. 12 gage copper leads and it had later to be located at a greater distance where 75 ft. of the above leads were required, the instrument read some 18 deg. F. too low. Under such conditions it was absolutely impossible to secure any precision in measuring temperature.

In the past five or six years, high resistance milli-voltmeter pyrometers have been developed with an internal resistance with a platinum couple of as high as 600 ohms or with a base metal thermo-couple as high as 1,200 ohms, which have a standard double pivoted construction used in the ordinary low resistance instrument.

Where an instrument of 600 ohms resistance is used, a change in line resistance from 5 ft. to 500 ft., which is naturally very excessive, will affect the readings of the pyrometer only 4 deg. F. where the scale is graduated to 2,000 deg. F. Any likely change in the length of the thermo-couple has absolutely no effect on the readings of such a pyrometer.

In the last couple of years, instruments have been brought out in which the effect of line resistance can be entirely eliminated by balancing the voltage of the thermo-couples against that of another source of electromotive force such as a dry cell. Usually an adjustable resistance is installed for a total of 15 ohms and any variation in line resistance can be compensated for in this type of instrument up to a total of 15 ohms. After this adjustment has been made, the instrument is direct reading and independent of line resistance.

Messrs. Harrison and Foote of the Bureau of Standards, Washington, have recently hit upon a method of accomplishing this result by using the voltage of the thermo-couple itself. This new instrument requires no dry cell or standard cell as a source of electromotive force. The instrument is similar to the ordinary milli-voltmeter in appearance, with the addition of the small key and resistance knob. The operator has only to read the temperature in the usual way. He presses the key and if the reading is any different from that which was previously observed, he turns the resistance knob until there is no change, whether the key

Exhibit at Convention of American Steel Treaters Society is depressed or not. The instrument has then been adjusted for line resistance, which may be any amount whatsoever up to 15 ohms, equivalent to many miles of copper leads. What little temperature coefficient exists in the ordinary high resistance milli-voltmeter is balanced out in this instrument. Accuracy in calibration of an instrument of this kind can be guaranteed within 1/10 of a milli-volt equivalent on the base metal scale of 4 deg. F.

THE POTENTIOMETER METHOD OF MEASURING TEMPERATURE

The potentiometer method of measuring the voltage produced by a thermo-couple has been quite extensively adopted in the past six or eight years where extreme precision is required. The potentiometer method differs from the milli-voltmeter method in that the milli-voltmeter uses the current produced by the thermo-couple to deflect the instrument. The potentiometer opposes the current of the thermo-couple to that of a dry cell and the dry cell current, equivalent to that of the thermo-couple, is measured in the usual way.

A galvanometer is used to indicate the point at which no current is flowing, and when the pointer on the galvanometer indicates zero, the voltage of the dry cell is equivalent to that of the thermo-couple. The line resistance from the dry cell to the galvanometer is exceedingly small and constant. When the thermo-couple voltage has been opposed to the voltage of the dry cell and balanced, the actual measurement is that of the dry cell circuit. Hence this measurement is entirely independent of the resistance of the circuit including the thermo-couple, lead wires and galvanometer resistance.

The potentiometer can be used with any length of leads desired, and the indications are entirely independent of line resistance or changes in resistance due to atmospheric changes in temperature along the leads. The potentiometer has a disadvantage as compared with the milli-voltmeter method of temperature measurement in that some outside source of current, a dry cell and standard cell, for example, are necessary as a source of current and the dry cell must be replaced from time to time. The standard cell likewise is liable to injury if subjected to temperatures below 40 deg. or above 104 deg. F. and the standard cells must be checked occasionally.

RECORDING PYROMETERS

Potentiometer pyrometers are available in recording form, in which the mechanism automatically balances the voltage of the cell against that of the thermo-couples, and in this instrument the records are automatic and no hand balancing is required.

In either the milli-voltmeter or in the potentiometer type, recording pyrometers are available to plot a continuous record of the temperatures on a chart daily, weekly or monthly, as desired. The recording pyrometers are supplied either to make a single record on a chart, or with two or more galvanometers side by side making individual records on one recording sheet. Multiple recording pyrometers are also available incorporating a switching mechanism, which alternately connects the various thermo-couples to the galvanometer or milli-voltmeter in a recording instrument, and many records can be secured on one chart. This is a distant advantage in certain cases.

Where a recording instrument operates on the milli-voltmeter method, the frictionless type of recorder is required, and the pointer is depressed only momentarily at intervals on the recording chart. In the potentiometer type of recorder, sufficient power is available from the motor operating the instrument to imprint a record directly on the recording chart.

SIGNALING PYROMETERS

Automatic signaling pyrometers have been used for some years in the larger heat-treating plants where it is desirable that the operator should not decide, but should be signaled by lights, as to whether the temperature is within the correct limits. For some years it has been common practice to install a central indicating pyrometer with switchboard, and by means of three colored lights at each furnace, usually red, white and green, to signal from the central station whether the temperature is too low, correct, or too high. Usually 25 deg. F. is considered a limit within which the temperature should be maintained.

The white light burns when the temperature is correct. If the temperature drops below, the green light glows, or if it rises above the desired temperature the red light burns. A step farther is the automatic signaling of the temperature by an automatic signalling pyrometer which can be incorporated in the standard form of milli-voltmeter pyrometer giving instantaneous readings.

AUTOMATIC TEMPERATURE CONTROL PYROMETERS

The day when the furnace temperatures will be accurately controlled automatically is coming very rapidly and notable progress has been made in this respect during the last few years. The application of automatic control pyrometers to electric furnaces is a comparatively easy problem, as automatic switches can easily be operated by a solenoid which can in turn be operated by the same contact device in the pyrometer as used in the signaling instrument. We have applied automatic temperature control to electric furnaces most successfully and some 100 electric furnaces to my knowledge are being controlled automatically at present. This control may be secured by the opening and closing of the main circuit or line, or by cutting in and out a small portion of the available current.

Automatic control of gas fired furnaces is a little more difficult, as a gas valve to be tight and not leak under continual operation, must be well packed and considerable power is required to operate the valve. We have, however, by the use of powerful solenoids or by motor operated valves, been able to overcome this, and we have a number of gas-fired furnaces of large dimensions which are automatically controlled.

There is no question that within the next year or two the automatic control of furnace temperatures will be very generally adopted wherever a constant temperature is to be maintained and it is desirable to eliminate the human element and hand control.

THE PART PYROMETERS PLAY IN STEEL TREATMENT

Many are not aware of the part pyrometers play in steel treatment from the smelting of the iron until the finished product. Let us take a part made from high grade alloy steel. First in the blast furnace where the iron is smelted; the hot blast temperatures and the temperature of the escaping gases from the furnace are accurately controlled by thermo-electric pyrometers. Next, the open hearth furnace where the steel is refined. Temperatures are very largely controlled in these furnaces by installing a platinum thermo-couple in the slag pocket or the gases from the checker brick. A very satisfactory record can be secured on a recording pyrometer of the working of the open hearth furnaces in this indirect manner. Optical pyrometers are also used to focus on the molten steel in the furnace or on the steel in pouring. This form of pyrometer has not come into general use.

The forging of steel carried on in forging furnaces at a temperature of around 2,300 deg. F. is accurately controlled with the aid of thermo-electric pyrometers, using platinum thermo-couples with special tubes.

The annealing, hardening, re-heating and the quenching temperatures are realized by everyone to be of the utmost importance and should be accurately controlled with pyrometers. Where oil or water is used for quenching, recording thermometers or resistance thermometers are applied to advantage.

While we are continually striving to improve pyrometers and to design these instruments to better meet each requirement, our efforts are a failure provided we cannot educate the users of pyrometers in how to use and care for them.

The best of pyrometer installations often give unsatisfactory results simply because it was assumed that when pyrometers were installed that the steel in some miraculous manner would come out perfectly heat-treated without any attention whatsoever. The pyrometers were apparently supposed to be infallible, and while a watch has to be wound and adjusted occasionally the pyrometer should require no such attention. There are no pyrometers produced today which do not require some attention.

If you install pyrometers, take the time to make a little study of how the instruments operate, how they can best be installed, and how they are to be cared for after they are in use in your plant. If you have quite a number of furnaces and a considerable pyrometer installation, place a man in charge of the instruments who has been first instructed in the information anyone should have to handle such a job. Do not take an office boy to look after your pyrometer equipment as I have seen so often done. A first class pyrometer equipment will pay for itself time after time during the year, and will be of infinite benefit to the user provided, first, it is properly designed to meet the conditions; second, it is properly installed; third, it is properly understood and cared for.

PRACTICAL INFORMATION CONCERNING HIGH SPEED STEEL

BY ROY C. McKENNA
President, Vanadium-Alloys Steel Company, Latrobe, Pa.

The manufacturer of high speed steel, knows and appreciates the troubles and difficulties that may sometimes arise in the heat treating of his product. The manufacturer's aim is to make a uniform high speed steel which will best meet the requirements of the average machine shop on general work, and at the same time allow the widest variation in heat treatment to give desired results.

High speed steel is one of the most complex alloys known. A representative high speed steel contains approximately 24 per cent of alloying metals, namely: tungsten, chromium, vanadium, silicon, manganese, and in addition there is often found cobalt, molybdenum, uranium, nickel, tin, copper and arsenic.

COMPOSITION OF HIGH SPEED STEEL

The selection of a standard analysis by the manufacturer is the result of a series of compromises between various properties imparted to the steel by the addition of different elements. There is a wide range of chemical analyses of various brands of high speed steel. Although there are being manufactured as high speed steel, brands that do not come within the standard of what is commercially known as high speed steel, there are certain well defined limits to the contents of certain elements.

The steel, to be within the range of generally accepted analysis should contain over 16 per cent and under 20 per cent tungsten. If of lower tungsten content it should carry proportionately more chromium and vanadium. Further discussion in this paper is confined to high speed steels containing approximately 18 per cent tungsten.

The combined action of tungsten and chromium in steel gives to it the remarkable property of maintaining its cutting edge at relatively high temperature. This property is commonly spoken of as "red-hardness." The percentage of tungsten and chromium present should bear a definite relationship to each other. Chromium imparts to steel a hardening property similar to that given by carbon, although to a less degree. The hardness imparted to steel by chromium is accompanied by brittleness. The chromium content should be between 3½ and 5 per cent.

Vanadium was first introduced in high speed steel as a "scavenger," thereby producing a more homogeneous product, of greater density and physical strength. It soon became evident that vanadium used in larger quantities than necessary as a scavenger, imparted to high speed steel a much greater cutting efficiency. Recently, no less an authority than Professor J. O. Arnold, of the University of Sheffield, England, stated that "high speed steels containing vanadium have a mean efficiency of 108.9, as against a mean efficiency of 61.9 obtained from high speed steel without vanadium content." A wide range of vanadium content in high speed steel from ½ to 1½ per cent, is permissible.

An ideal analysis for high speed steel containing 18 per cent tungsten is a chromium content of approximately 3.85 per cent; vanadium .85 per cent to 1.10 per cent and carbon between .62 and .77 per cent.

INGREDIENTS WHICH ARE DETRIMENTAL

Sulphur and phosphorus are two elements known to be detrimental to all steels. Sulphur causes "red-shortness" and phosphorus causes "cold-shortness." The detrimental effect of these two elements counteract each other to some extent but the content should be not over .02 sulphur and .025 phosphorus. The serious detrimental effect of small quantities of sulphur and phosphorus is due to their not being uniformly distributed, owing to their tendency to segregate. The contents of manganese and silicon are relatively unimportant in the percentage usually found in high speed steel.

The detrimental effects of tin, copper and arsenic are not generally realized by the trade. Small quantities of these impurities are exceedingly harmful. These elements are very seldom determined in customers' chemical laboratories and are somewhat difficult for public chemists to analyze for.

In justice to the manufacturer of high speed steel, attention should be called to the variation in chemical analyses between the best of laboratories. Generally speaking, a steel works laboratory will obtain results much nearer true and accurate than is possible by a customer's laboratory, or public chemist. This can reasonably be expected for the steel works' chemist is a specialist, analyzing the same material for the same elements day in and day out.

METHOD OF MANUFACTURE IS IMPORTANT

The chemical composition of steel for any purpose is a basic consideration and must be such as will meet the requirements, but the quality of the steel does not depend wholly upon the chemical composition. Assuming the chemical composition to be within the permissible limits, the quality depends upon local conditions surrounding its manufacture. If the quality of steel were entirely dependent upon the chemical composition and not influenced by its working and handling in accordance with tool steel practice, the tool steel industry would be unable to exist.

The successful manufacture of high speed steel can only be obtained by those companies who become specialists. The art and skill necessary in the successful working of such steel can be attained only by a man of natural ability in his chosen trade, and trained under the supervision of experts. To become an expert operator in high speed steel in any department of its manufacture, it is necessary that the operator works almost exclusively in the production of such steel.

As to the heat treatment of high speed steel, it is customary for the manufacturer to recommend to the user a procedure that will give to his steel a high degree of cutting efficiency. The recommendations of the manufacturer should be conservative, embracing fairly wide limits, as the tendency of the user is to adhere very closely to the manufacturer's recommendation. Unless one of the manufacturer's expert service men has made a detailed study of the customer's problem, the manufacturer is not justified in laying down set rules, for if the customer does a little experimenting he can probably modify the practice so as to produce results that are particularly well adapted to his line of work.

GENERAL PRACTICE IN HARDENING

It is not the writers' intention to make any definite recommendations as to the heat treating of high speed steel by the users. It is recognized that such steel can be heat treated to give satisfactory results by different methods. It is, however, believed that the American practice of hardening and tempering high speed steel is becoming more uniform. The trend of American practice for hardening high speed steel is towards the following: First: Slowly and carefully preheat the tool to a temperature of approximately 1,500 deg. F., taking care to prevent the formation of excessive scale. Second: Transfer to a furnace, the temperature of which is approximately 2,250 deg. to 2,400 deg. F., and allow to remain in the furnace until the tool is heated uniformly to the above temperature. Third: Cool rapidly in oil, dry air blast, or lead bath. Fourth: Draw back to a temperature to meet the physical requirements of the tool, and allow to cool in air.

It was not very long ago that the desirability of drawing hardened high speed steel to a temperature of 1,100 deg. F. was first pointed out, and it is indeed encouraging to learn that comparatively few treaters of high speed steel have failed to make use of this fact. Many steel treaters at first contended that the steel would be soft after drawing to this temperature and it is only recently, since numerous actual tests have demonstrated its value, that the old prejudice has been eliminated.

With an understanding of some of the difficulties inherent in the manufacture of high speed steel, I will try to give you the justification of some of the trade practices and customs which have been generally accepted.

DISCUSSION OF TRADE PRACTICES

High speed steel should be delivered only in the annealed condition because annealing relieves the internal strains inevitable in the manufacture and puts it in vastly improved physical condition. The manufacturer's inspection after annealing also discloses defects not visible in the unannealed state.

The only true test for a brand of high speed steel is the service that it gives by continued performance month in and month out under actual shop conditions.

The value of the file test depends upon the quality of the file and the intelligence and experience of the person using it. The file test is not reliable, but in the hands of an experienced operator, gives some valuable information. The manufacturer of small tools from high speed steel sometimes carries the file test to extremes. Almost every steel treater knows of numerous instances where a lathe tool which could be touched with a file has shown wonderful results as to cutting efficiency.

The practice of buying high speed steel by brand names is justifiable. The guarantee behind high speed steel is the standing and reputation of the manufacturer, who should maintain in his employ metallurgists and experienced service men who will be ready at any time to heat-treat and demonstrate to the buyer's satisfaction that the product furnished will meet any reasonable requirements. The customer's specifying the chemical, physical or metallurgical properties relieves the manufacturer of his responsibility as to quality. Quality is not dependent upon the chemical composition and poor high speed steel can be made within any limits of chemical content that could be commercially met by a manufacturer of best quality high speed steel. In purchasing high speed steel by brand name the buyer places responsibility for performance clearly with the manufacturer. The specifying of phyiscal, chemical or metallurgical limits by the buyer would lead to endless controversy and would positively retard, in fact, completely arrest the progress of the industry.

The manufacturers of high speed steel should co-operate to the extent of submitting upon request rejection limits as to chemical content of those elements which vitally affect the steel treater's work. It is not desirable that the manufacturer's rejection limits be published broadcast. The buyer has the right to demand that high speed steel purchased by him should be within the generally accepted analysis of high speed steel. Chemical composition is a basic consideration, but the quality is dependent upon many other factors, the most important of which is the human element. No steel treater can question the fact that the results obtained from heat-treating depend upon the operator. The operator will use all modern appliances, such as pyrometer, automatic temperature control, quenching machines, etc., but the results obtained depend upon his individual experience and skill. The manufacture of tool steel is and will continue to be a handicraft industry.

Modern tool steel practice has changed from that of the past, not by the use of labor-saving machinery, but by the use of scientific devices which aid and guide the skilled craftsman in producing a steel of higher quality and greater uniformity. It is upon the intelligence, experience and skill of the individual that the quality of tool steel depends.

ELECTION OF OFFICERS

The following national officers of the society were elected: president, T. E. Barker, Miehle Printing Press & Manufacturing Company, Chicago; first vice-president, E. J. Janitzky, Illinois Steel Company, South Chicago; second-vice-president, D. K. Bullens, Cann & Saul, Royersford, Pa.; secretary, Arthur G. Henry, Illinois Tool Works, Chicago; treasurer, A. F. Boissoneau, William Ganschow Company, Chicago; directors, H. G. Weidenthal, James H. Herron Co., Cleveland, Ohio; A. F. MacFarland, Vanadium-Alloys Steel Company, Latrobe, Pa.; J. Fletcher Harper, Allis-Chalmers Company, Milwaukee, Wis., and J. O. Pollak, Pollak Steel Company, Cincinnati, Ohio.

On September 25 a banquet was held at the Morrison Hotel which 620 members and guests attended. Addresses were delivered by J. W. O'Leary of A. J. O'Leary & Son, Chicago; Doctor H. Marion Howe, consulting metallurgist and scientific attaché to the American Peace Commission; and Professor J. W. Richards, professor of metallurgy at Lehigh University.

Air Power for Driving Locomotives.—A recent issue of the New York Times contains a special dispatch from Rome describing an invention for driving locomotives by air power, which has been submitted to the Italian State Railways by a young Italian engineer. The secret of the invention lies in a new system of compressed air by which big central tanks may store enormous power to be distributed to "fuel" stations along the railway lines by strong pipes. Steam is superseded, coal, water power and electricity are no longer needed. The inventor claims his system is cheaper and its adapatability to railway systems quicker than any other existing. Steam locomotives can be used almost without changes, only the coal tender must be converted into an air tank. In the new scheme the main expenditure is for the building of big plants for compressing air and the laying of pipes, all of which is said to be vastly cheaper than electrical installation. It is not stated where the compressor power is to come from.

Setting Locomotive Valves

Instructions for Setting Walschaert, Young and Stephenson Gears; Simple Individual Operations

By L. D. FREEMAN

THE railroads are spending considerable money and effort on fuel economy, but at the same time do not pay enough attention to correct valve setting and steam distribution, and frequently by the wasteful use of steam more than offset the economies of efficient steam generation.

There are two reasons why locomotives of the same class in the same state of repairs do not pull the same tonnage at the same speed over the same division. The first reason is different valve events, and the second, enginemen do not have the reverse lever in the proper notch to produce maximum drawbar pull under given conditions. This latter cause was thoroughly investigated by B. B. Milner, engineer motive power, New York Central Lines, and published in the *Daily Railway Age* of June 25, 1919.

To secure more uniform and efficient results, simple instructions have been worked out for valve setting and have had considerable success in use on the Seaboard Air Line.

The object of these instructions for valve setting was to investigate the different valve events possible with the existing parts on each different class of locomotive; to adopt the setting best suited to that class of locomotive; by means of fixed gages to enable any mechanic of ordinary skill not only to set the valves with the least amount of work, but to duplicate the setting on any number of locomotives at any future time; and to so divide the work into simple individual operations that any mechanic could perform the different operations even if he did not possess the skill to do so without definite instructions.

The expert valve setter of 10 or 15 years ago has almost entirely disappeared, due principally to the flat rate for all mechanics of the same craft removing the incentive of extra compensation for diligent study of the art.

Correct valve setting depends on the ability of the valve setter to identify the various defects in the assembling of a valve gear on each locomotive and to make such corrections as are necessary to produce the desired valve events.

Numerous details that had to be worked out do not appear in the instructions, but are described in detail under the heading of each kind of gear.

GENERAL CONDITIONS

Maximum valve travel—In full gear for slide valves and outside admission piston valves, limit the maximum travel

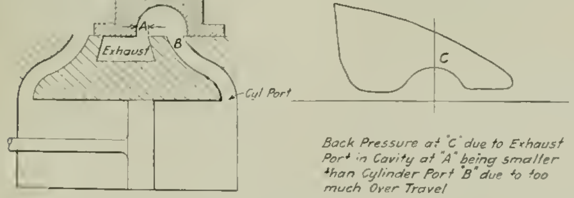


Fig. 1—Indicator Card Showing Restriction of Exhaust Caused by Over Travel

to twice the lap, plus twice the steam port opening, plus ¼ in.

Many slide valve engines over travel so far that the steam pressure under the lower face unbalances the valve, causing it to lift off the seat and blow through the exhaust. While this occurs only with the reverse lever in full gear, either way, it is a condition that is very difficult to detect.

A more common disturbance caused by the over travel is that the valve moves so far off center that the exhaust cavity partly closes and restricts the exhaust at about half stroke, builds up back pressure and makes an indicator card with a "hump" in the exhaust line as shown in Fig. 1. It was usually claimed that this was due to the exhaust "blowing over" the bridge in the exhaust stand, but that this could not be the cause is evident, since this defect has not been found in all engines using the same design of exhaust stand.

Steam Lap—This should be as large as possible, since the larger the steam lap, the larger the exhaust port opening will be for any given valve travel. For example: with 5/16 in. steam port opening at shortest cut-off, with one inch lap, the exhaust port opening is 1 5/16 in., while if the lap can be 1¼ in. the resultant steam port will be 1 9/16 in., or nearly 20 per cent increase and consequently a "smarter" engine is obtained.

Exhaust Lap—The exhaust lap simply holds the steam later than necessary to get useful work from it, and makes it more difficult to get rid of the exhaust, building up back pressure that offsets any gain in useful work and therefore is not to be recommended.

Exhaust Clearance—At high speeds it is necessary to have the exhaust open earlier to get rid of the steam and stay open later to prevent excessive compression. With slide valves on fast freight engines 1/32 in. will take care of the exhaust. Should any excessive compression occur the slide valve is unbalanced and blows through into the exhaust. With piston valves it is necessary to give about 3/32 in. to protect against excessive compression.

For passenger locomotives, an exhaust clearance of 1/16 in. should be allowed for slide valves and ⅛ in. to 3/16 in. for piston valves, depending on the speed at which the locomotive is to operate.

Maximum Cut-off—Lay out Zeuner valve diagram for each class of locomotive and arrange lap, lead and valve travel so that the maximum cut-off is 85 per cent of the stroke, taking advantage of any chance to increase steam lap with a given travel.

Minimum Cut-off—To prevent excessive strains to the machinery, limit the minimum cut-off to 20 per cent of stroke, handling the throttle to reduce drawbar pull below this limit.

WALSCHAERT GEAR

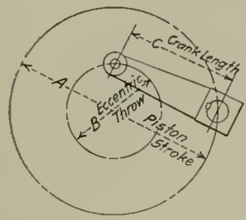
Lead should be limited so that the crosshead is within one inch or less of the end of stroke before the combination lever opens the valve for lead. Limit the lead to ¼ in.

Locomotives having Walschaert valve gear are designed for constant lead at all position of the reverse lever and should be so set unless ordered to be set with variable lead on passenger locomotives. In any valve gear obtaining motion from the crosshead and a crank arm on the main pin, the combination of these two movements gives the desired valve events. Lap and lead travel comes from the crosshead and is in complete control of the valve when the main pin is on either front on back dead center. In this position the crank arm is on the top or bottom quarter and has no control over the valve. The crank arm passing through a given circle *B*, Fig. 2, has full control over the valve at full travel in any position of the reverse lever.

Before attempting to set valves it is first necessary to prove that all parts are in accordance with the drawings for that class of engine.

First Operation—Set the crank correctly as shown in Fig. 2.

Second Operation—Prove the length of the reach rod. Set the reverse lever in vertical position and plumb the reverse shaft. Measure the true length of the reach rod at *D*, as in Fig. 3.



Engine Number New	Engine Number Old	Class	A	B	C
645-649 Constant	46-50 Lead	L-2	28"	15 5/8"	16
645-649 Variable	46-50 Lead	L-2	28"	15 5/8"	16 5/8"
778-787	778-787	L-4	28"	15 5/8"	16"
763-777	763-777	L-4	28"	17 1/2"	17"

Fig. 2

Third Operation—Prove the length of the radius bar hangers. Place the reverse lever on center with the proper

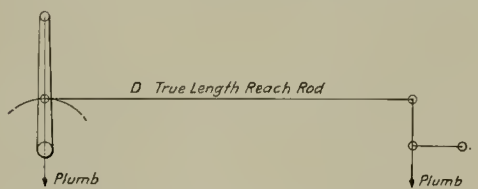


Fig. 3

length of roach rod. After proving that the lifter arms are parallel, swing the link back and forth and adjust hangers *E* until a still valve is obtained, as in Fig. 4.

It is not necessary to place valve rollers under each engine. All adjustments can be made by trailing with another

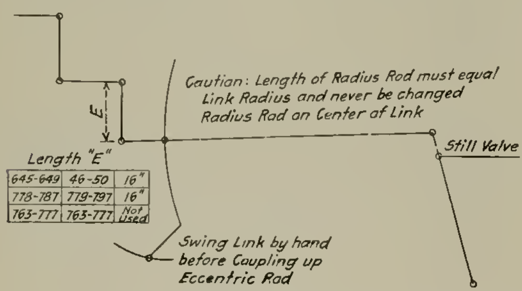

Fig. 4

engine. The most common error in valve setting is to attempt to make all changes with one trailing. It is absolutely necessary that the engine be trailed twice, once to adjust the lead and once to adjust the cut-off.

Fourth Operation—Adjust the lead, change the valve rod, place the reverse lever on center and trail the engine; adjust the valve rod to equalize the lead on both sides of the port marks. No further change can be made on the valve rod. The valve rod must be changed before trailing for the cut-off.

Fifth Operation—Adjust the cut-off, change the eccentric rod, trail the engine with the lever at half stroke and equalize the cut-off on the eccentric rod. To find the amount of change, multiply the change desired by the distance from the link center to the center of the eccentric rod pin and divide by the distance from the link center to the center of the link block. See Fig. 5.

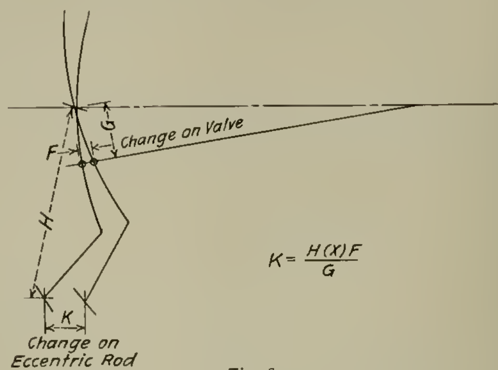

Fig. 5

The method of compiling valve data for engines having Walschaert valve gear is shown in the following table:

Engine class	Max. valve travel, in.	Steam lap, in.	Lead, constant, in.	Exhaust clearance, in.
L-2	6	1 1/8	1/4	3/32
P-1	6 1/2	1 1/16	3/16	3/16
L-5	5 1/2	1	3/16	....
L-4	6 1/4	1 1/8	1/4	3/64
L-4	6	1 1/8	1/4	3/32
P-1	6 1/2	1 1/16	3/16	1/8
H-1	6	1	3/16	....

STEPHENSON GEAR

Back set the saddle pin as in Fig. 6. This is not an exact science, that is, there is no absolute definite point that can be calculated. O. W. Young, formerly valve gear designer for the American Locomotive Company, made extensive experiments on a full size model and the conclusion reached was that back set calculated in accordance with his formula published in the *Railway Age Gazette*, Mechanical Edition, page 647, December, 1913, was close enough for all practical purposes, but could be varied as much as 1/4 in. without detrimental results. This has been proved by investigation of engines in actual service.

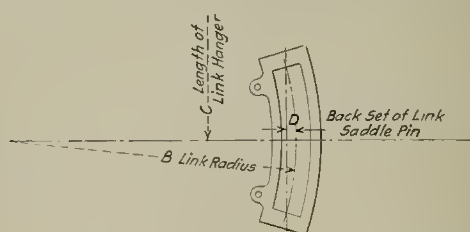

Fig. 6

Data Used With Figure 6

Engine class	A, in.	Reverse shaft, in. Top arm B	Reverse shaft, in. Link arm C	Rocker arms, in. Valve end	Rocker arms, in. Link end
G-1	9 1/2	23	18	11	9 3/4
G-2	6 1/2	23	17 1/2	11 1/2	10
H	2 1/2	22	15	13 1/2	11 1/4
L-4	1 1/2	18	18	11 1/4	10 1/4
L-5	2 1/4	20	17	11 1/4	10 1/4
L-2	2 1/8	27	18	18 1/2	16 1/4
L-2	2 1/2	27	18	17 1/8	16 3/8
L-3	2 1/2	25	17	13	10
L-4	2 1/2	27	18	18 1/2	16 1/4
L-4	2 1/2	27	18	18 1/2	16 1/4
L-5	2 1/2	27	18	12 1/2	11 1/2

The proportions of the link determine the amount the lead increases from full to mid gear and in many cases of the older Stephenson link engines, this increase of lead amounts to from 7/16 in. to 9/16 in., which means that with the reverse lever on center, the smallest possible port opening is 7/16 in. to 9/16 in., or whatever the increase amounts to, if set line and line in full gear. The shortest possible cut-off under these conditions is frequently 33 per cent of the stroke, which is entirely too much and is wasteful in the use of steam. It makes a sluggish engine as well, due to too great a volume of steam to get rid of through the limited exhaust port opening at short cut-off travel.

Data Used With Figure 6

Engine, Class	Link radius B, in.	Link hanger C, in.	Saddle pin backset D, in.	Link print	Valve travel, in B. P.	Valve travel, in Limit to
G-2	60	16¼	½	2161-D	5¾	5¼
H	44¾ 40	19¾	1⅝	3009-D	6	6
I-4	45	17¼	1	1034-D	5 7/16	5⅜
I-4	45	17¼	1	1034-D	5 7/16	5⅜
I-5	45¾	....	11/16	2981-C	5 7/16	5⅜
L-2	56	18½	13/16	3009-D	6¼	6¼
L-2	56	18½	21/32	2589-C	6	6
L-3	46	18⅞	1⅜	2589-C	6½	6½
L-4	56	18½	13/16	3009-D	6¼	6¼
L-4	56	18½	13/16	3009-D	6¼	6¼
L-5	42	20½	1½	2589-C	6	6
L-5	42	20½	1½	2589-C	6	6

The manner of calculating the increase in lead and the calculation of the amount of blind to make the back up to maintain at least line and line in full forward gear is shown in the diagrams.

Investigation has developed that it is possible by means of a set of trams to take exact measurements of the length of the eccentric blades and fit up eccentric straps and blades on the floor before assembling, thereby requiring a minimum of skill and work on the part of the valve setter.

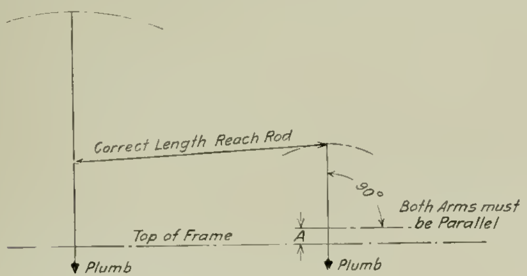

Fig. 7

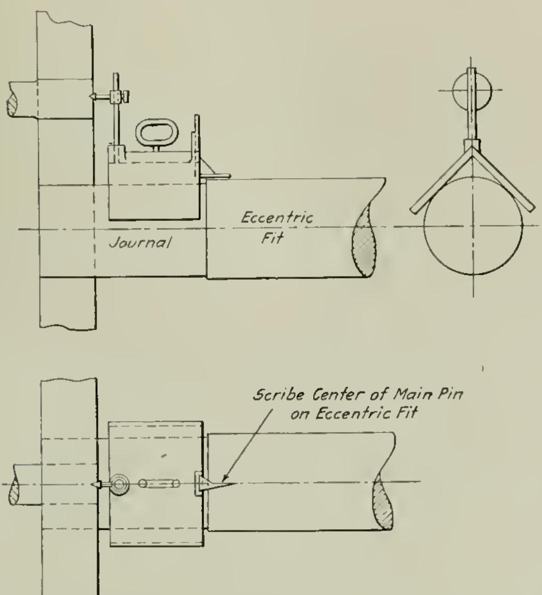

Fig. 8

Setting valves is simply making adjustments for various inaccuracies in the assembling of the locomotive. If all parts had the same relation to each other as called for in the drawings the valves would be set correctly when assembled. Therefore, the more parts that conform to the drawings before starting to set valves, the less adjustment will be necessary to produce the desired results.

First Operation—Prove the length of the valve over the edges of the steam and exhaust ports in the valve chamber by means of a standard gage.

Second Operation—Take port marks in the usual manner.

Third Operation—Prove the length of the reach rod, reverse shaft and rocker arms as in Fig. 7.

Fifth Operation—Locate the eccentrics on the axle before wheeling the engine. First, transfer the center of the main crank pin to the eccentric fit on the axle with a box gage, Fig. 8. Locate eccentric keyways with the standard gage for each class of engine. For engines having slide valves with indirect rocker, see Fig. 9. The gages are to be made in accordance with the following table:

Engine, Class	Gage No.	Lap, in.	Lead, in. F	Lead, in. B	Ecc. fit Z, in.	Distance from pin, in. F. M	Distance from pin, in. B. M.	Ecc. throw, in.
G-1	2	⅞	line and line	⅛ blind	9	5-9/32	5-15/32	2½
G-2	3	1	line and line	..	8	4⅞	4⅞	2½
I-4	4	⅞	line and line	⅛ blind	7¾	4½	4-21/32	2½
I-4 .	4	⅞	line and line	⅛ blind	7¾	4½	4-21/32	2½
I-5	5	⅞	line and line	⅛ blind	8¼	4-25/32	5	2½

Note—Engines not covered by above table to be set line and line.

Fourth Operation—Prove the link and hangers as in Fig. 6.

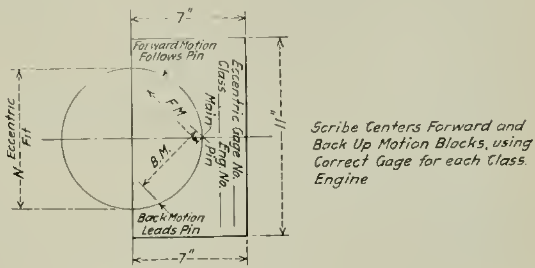

Fig. 9

For engines having piston valves (inside admission) and direct rockers, use gages similar to those described for slide

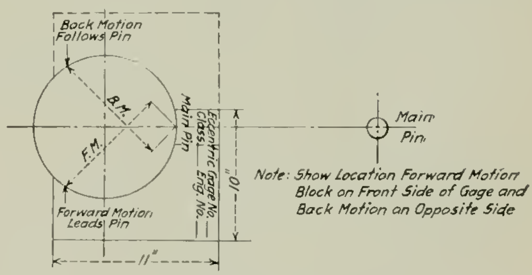

Fig. 10

valves, but made to the dimensions shown in the following table:

Engine, Class	Gage No.	Lap, in.	Lead, in F	Lead, in B	Ecc. fit Z, in.	Distance from pin, in, F. M.	Distance from pin, in, B. M	Ecc. throw, in.
L-2	1-A	1⅛	..	¼ blind	9 5/16	5 3/16	5 9/16	2¼
L-2	1	1⅛	..	¼ blind	9 5/16	5¼	5⅝	2¼
L-4	1	1⅛	..	¼ blind	9 5/16	5¼	5⅝	2¼

For engines having piston valves (inside admission) and indirect rockers, see Fig. 10, the gage to be made in accordance with the following table:

Engine, Class	Gage No.	Lap, in.	Lead, in. F	Lead, in. B	Ecc. fit Z, in.	Distance from pin. in. F. M.	Distance from pin. in. B. M	Ecc. throw, in.
H	6	1⅛	1/16	1/16	9⅞	8¼	8¼	5
L-3	7	1	⅛	⅛	8 13/16	7-7/32	7-7/32	5
L-5	8	1	⅛	⅛	9 5/16	7-23/32	7-23/32	5½
L-5	8	1	⅛	⅛	9 5/16	7-23/32	7-24/32	5½

Sixth Operation—Prove the keyways in the blocks. After locating all keyways correctly on the axle, check the keyways

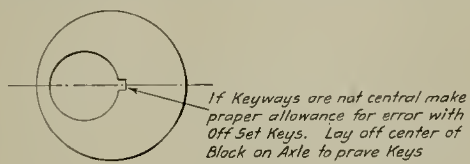

Fig. 11

in the old eccentrics to prove that they are centrally located. See Fig. 11.

Seventh Operation—Approximate length of valve rod. Plumb the rocker arm or transmission hanger and alter the valve rod until the tram is central between port marks as in Fig. 12.

After performing the above operations correctly it is possible to take direct from the engine by a set of five trams,

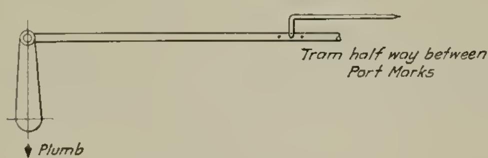

Fig. 12

the correct length of each eccentric blade. After using the proper tram to set the link correctly the following rules must be observed:

(1) Place the engine on the forward dead center for each side separately. This applies to all engines except classes H, L-3 and L-5, having inside admission piston valves, with indirect rocker, which engines are placed on the back dead center.

(2) Place the reverse lever on the center.

(3) Move the valve stem in the direction to open the valve off the central position (found by operation seven)

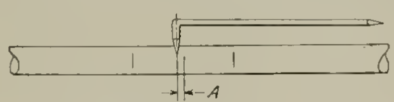

Fig. 13

an amount equal to the increase lead from corner to mid-gear, as shown in operation eight.

Eighth Operation—Move the valve stem toward the lead opening. The amount of lead increases from corner to mid-gear. See Fig. 13.

Engine, Class	A, in.	Direction of A
G-1	5/16	Toward lead
G-2	11/32	Toward lead
H	¼	Toward lead
I-4	5/16	Toward lead
I-5	⅜	Toward lead
L-2	5/16	Toward lead
L-3	3/16	Toward lead
L-4	5/16	Toward lead
L-5	3/16	Toward lead

Ninth Operation—Set the link and clamp it in position to tram the length of the blade. The lever must be on center. See Fig. 14.

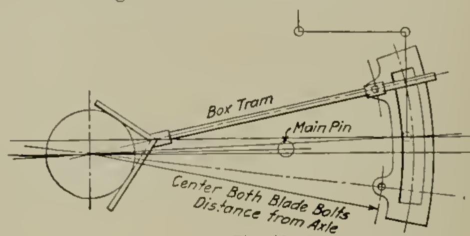

Fig. 14

Tenth Operation—Take the length of each blade separately with the engine on forward dead center for the side on which lengths are being taken. This applies to all engines

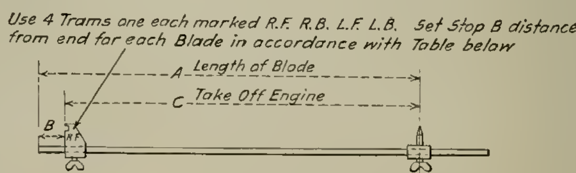

Fig. 15

except class H, L-3 and L-5, which are to be on the back dead center, as in Fig. 15.

Engine, Class	Distance B, in. Forward	Distance B, in. Back
G-1	25/32	21/32
G-2	⅞	⅞
H	1⅛	1⅛
I-4	25/32	11/16
I-5	25/32	11/16
L-2	1	¾
L-3	1	1
L-4	1	¾
L-5	1⅛	1⅛

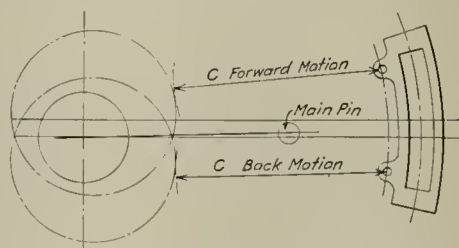

Fig. 16

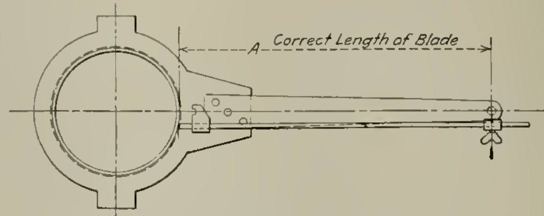

Fig. 17

Eleventh Operation—Take length distance *C* as in Fig. 16.

Twelfth Operation—Assemble the blades and straps to correct length *A* on the floor before applying to the engine. See Fig. 17.

GAGE FOR CHECKING CYLINDER PORTS AND SLIDE VALVES, SEE FIG. 18

H.....	22½	2-21/32	27-13/16	24¾	1⅝	28	1⅛	3/32

The amount of increase in lead from full gear to mid-gear is determined by the radius of the link and the distance between blade pins. On all locomotives having open eccentric rods the lead increases when hooked up. On all locomotives having crossed eccentric rods the lead decreases when hooked up and the engine becomes very blind in mid-gear, in some cases as much as 9/16 in. blind. This gear is very undesirable. To overcome this give 5/16 in. lead

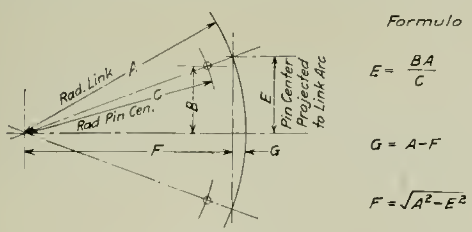

Fig. 20

in the corner and the engine will not go blind until worked at less than half stroke. See Fig. 20.

Open Rods—Lead increases from full gear to mid-gear. This combination is used on all engines having (1) inside admission piston valves and direct rocker or (2) outside admission valves and indirect rocker. See Fig. 21.

Crossed Rods—Lead decreases from full gear to mid-gear. This combination is used on all locomotives having

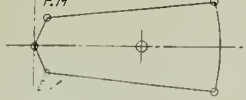

Fig. 21

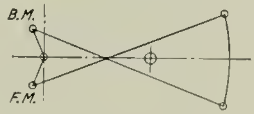

Fig. 22

inside admission piston valves and direct rocker. See Fig. 22.

By using indirect rocker with this combination of rods the lead can be changed from decrease to increase.

Valve Diagrams—After determining the amount the lead increases from full gear to mid-gear, it usually develops that if both forward and back motion blocks are set line and line the lead increases to such an amount that the port opening is so great even with the reverse lever on center that the shortest cut-off possible has been found to be nearly 30 per cent of the stroke. To overcome this defect set the back motion blind enough to reduce the lead to 5/16 in. in mid-gear, as determined by the Zeuner valve diagram.

Example: Valve travel 6¼ in., lead increase 7/16 in.

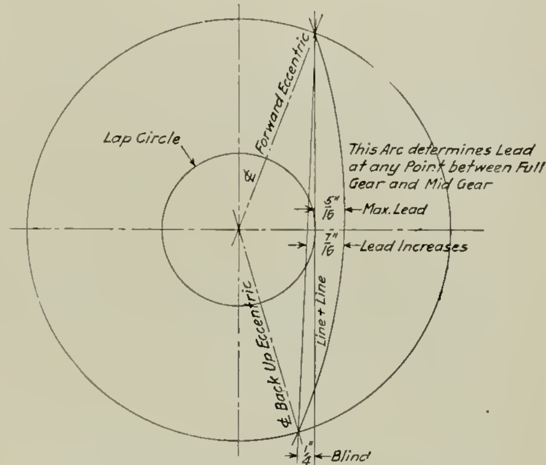

Fig. 23

from line and line, lap 1⅛ in. To find the amount to blind, back up to produce 5/16 in. lead on center with forward motion line and line. See Fig. 23.

For some unknown reason the lead does not increase as it should by using the indirect rocker with crossed rods and it has been found necessary to set one class of Consolidation type with 5/16 in. lead in the corner to have 3/16 in. lead on the center, but this type of construction is very old and only a few such engines are still in existence.

SOUTHERN VALVE GEAR

All locomotives having Southern valve gear are designed for constant lead, and should be so set. It is not possible to set this gear for variable lead and it should never be attempted. By adopting the process of elimination, proving one part at a time, the best results are obtained.

All of the motion to the valve is imparted from the eccentric crank. Since the lap and lead depends on the

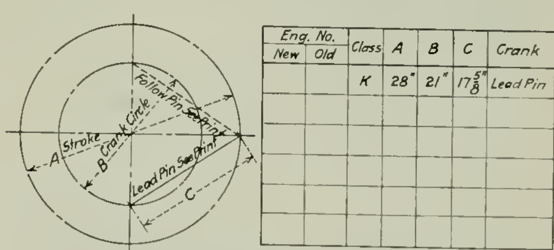

Fig. 24

length of the eccentric rod, the correct length must be maintained. In this gear the center of the main axle is the fixed point and the link must be brought to the proper relation to the main wheel center. The best results can be obtained by following the instructions given below.

First Operation—Set eccentric crank in accordance with the drawings of the gear. See Fig. 24.

Second Operation—Prove the reach rods and links. See Fig. 25.

Third Operation—Square the lead and adjust the valve rod. With the engine on dead centers take lead marks on the valve rod and equalize the lead by altering the valve rod. Have the lever on center when taking the lead marks.

If the above work has been properly performed the reverse lever can be placed in any position with the engine on either dead center and prove constant lead. Squaring the

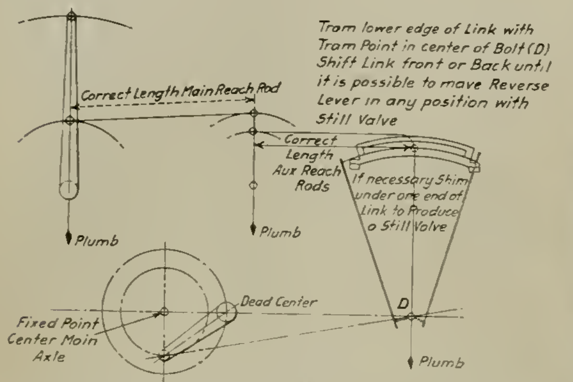

Fig. 25

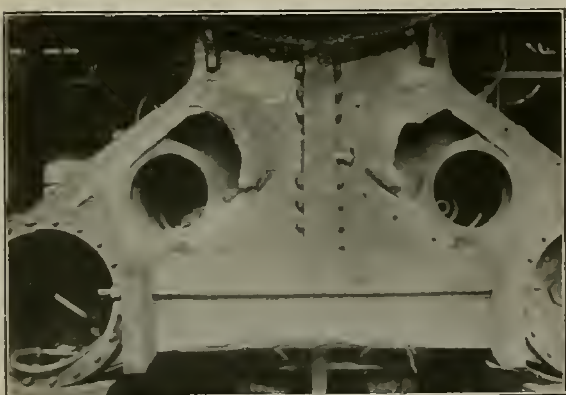
lead is done on the valve rod and automatically takes care of any reasonable error in the vertical location of the link.

A convenient rule is as follows: To square the lead, adjust the valve rod only. To equalize the cut-off adjust the link until a still valve is obtained when the engine is on either dead center and a square cut-off is the result. If over-all cut-off on one side is greater than the other, shorten the auxiliary reach rod ¼ in. for each inch of cut-off it is desired to reduce.

PATCHING PISTON VALVE CYLINDER

An interesting job of welding, performed in the repairing of a pair of piston valve cylinders, was recently done at the Stony Island shop of the New York, Chicago & St. Louis.

The broken parts of the cylinders were first drilled and chipped off flush with the main body of the casting, forming a smooth surface. Two flanged patches, as shown in



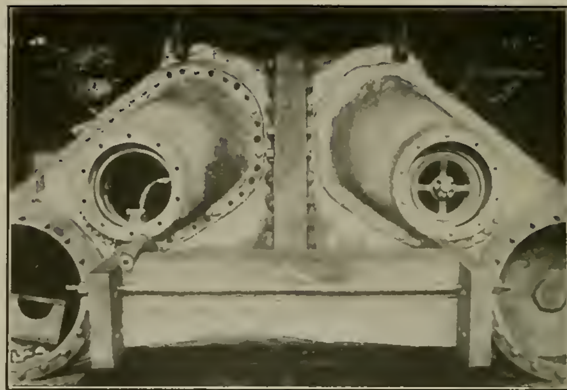
The Broken Cylinder as Received in the Shop

the sketch, were formed of ½-in. boiler plate and a ½-in. by 5-in. by 5-in. angle. The boiler plate extended to the center line of the piston valve cylinder, as shown, and the back half of the circle was formed of the ½-in. angle, the two parts of the patch being welded together with acetylene. The holes for the valve chamber were then cut out with an acetylene torch.

A ring was shaped from ¾-in. steel plate and faced and welded to the main patch, forming the valve chamber head joint and the body for the cylinder head studs.

Four holes were punched in the patch, the patch put on the cylinder, and the flange heated and set up with a flatter. After the patch was properly shaped the holes were drilled in the flanges, on 2½-in. centers, the patch again applied and reset. The patch was then taken off and put on a boring mill and the joint faced and the hole bored to admit the valve.

The patch was then reapplied to the cylinder with a



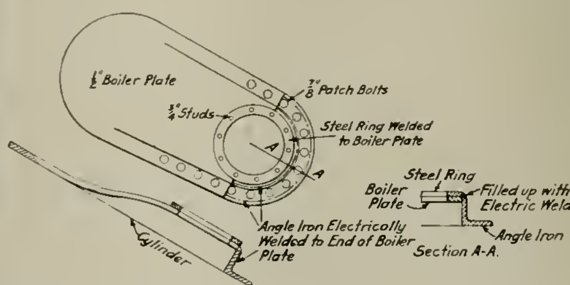
The Cylinder Casting with Patches Applied

1/16-in. copper gasket and patch bolts put in and set as the work progressed. The patch bolts being applied, the edges of the patch and the heads of the bolts were caulked and the job was complete.

The cost of the material and labor for the repairs to this cylinder were as given below:

LABOR		
Erecting shop	$251.04	
Boiler shop	129.32	
Tin shop (gasket)	.68	
Total for labor		$381.04
MATERIAL		
300 lb. ½-in. by 36 in. by 96-in. steel	$10.19	
76 ⅞-in. patch bolts	8.29	
20 ¾-in. by 3-in. studs	1.20	
11 lb. 1/16-in. copper	.24	
3 ft. 5-in. by 5-in. by ½-in. angle iron	1.70	
Total for material		21.62
Total for application of the two patches		$402.66

This method of repairing proved effective and permitted



Construction of Patch for Piston Valve Cylinder

the reclamation of these cylinder castings without the necessity of removing them from the locomotive, thus considerably reducing the length of time the locomotive was out of service.

The Casehardening of Steel

Methods Employed; Their Effects, Proper Packing and Control of Temperature Are Important Factors

BY J. F. SPRINGER

THE casehardening of steel is quite an old process, but it is, nevertheless, one of great usefulness, both from a technical and an economic standpoint. It can not be said, however, that it is a thoroughly understood process; nor that the practitioners are everywhere succeeding uniformly in getting the best possible results. In the United States the problem does not seem to have had from our best technical men the attention it deserves nor even the attention given to certain other subjects of no greater industrial importance.

Casehardening is a process of impregnating the exterior layer of low-carbon steel with a high percentage of carbon, thereby making it possible to harden this external layer and leave the interior soft. It is an exceedingly valuable result when adequately achieved.

It is frequently of very great importance to get a thorough understanding of what is *not* wanted, as this greatly assists in getting the results actually desired. The regulation procedure in casehardening is briefly as follows: The articles to be treated are packed in boxes or cases in a packing material competent to supply carbon, such as bone dust, charred leather or the like. The box is sealed and the whole then heated to a fairly high temperature and maintained at this temperature for a considerable period. The heat causes the packing to give off carbon and the metal to absorb it. The impregnation which takes place involves first the external shell or case of the various articles. There is no great difficulty in getting this general result, nor in carrying it to the point that the impregnated shell is moderately thick and possesses a high local percentage of carbon. It is, however, difficult to avoid one or more of the following results, undesirable in the best work:

(1) The zone or shell of high carbon percentage may be very sharply defined from the soft interior. Upon giving the hardening treatment, a shell of very hard steel inclosing a core of soft metal is the result. There is a sudden change from the very hard to the soft. The effects of concentrated shocks on the exterior are accordingly localized upon the soft interior. This means that the interior is unable to present the resistance of which it is really capable, because of the lack of distribution of the shock. The exterior shell being thin and brittle is, accordingly, liable to break.

(2) The highly carbonized shell may vary in thickness. This is undesirable because it means regions of unequal resistance to externally applied wearing pressures. If a shell of 1/32 in. thickness is sought as the thing really desired, then spots only 1/64 in. thick will not be desirable.

(3) The external shell when heated and quenched may prove insufficiently hard. This is a serious matter. Hardness is wanted frequently, not to say generally, for the purpose of resisting the abrasive action of wear and tear. As this resistance is fairly proportional to the degree of hardness, a falling off in hardness is not wanted.

(4) The depth of the hardening effect may be insufficient. This means that the shell of high impregnation is not thick enough. The external hardness desired may be fully attained; but the life of the article in actual service may be greatly shortened because the resistance to wear is gone long before the depth of wear really permissible in the part is reached.

(5) The hardness developed may be found to vary in different regions. This will often be a highly objectionable result. In a machine, it is not desirable that a part should wear unevenly as uneven wear generally means distortion.

(6) Finally, the interior may have lost in physical qualities. Such loss is due to the overheating necessarily a part of the casehardening procedure. This is a very serious matter, probably appreciated by a comparative few. It is, nevertheless, a fact that steel heated above a medium cherry red (1,274 deg. F.) is subject to enlargement of its crystals. This enlargement increases as the temperature is carried further. It is pretty well established that enlarged grains mean reduced physical strength—particularly tensile strength—and that this reduction varies with the overheating beyond medium cherry red. The casehardening temperatures are all above this level, so that the interior of any casehardened article is probably more or less damaged in quality when it comes from the furnace.

In general, what is desired is casehardened articles not subject to any one of these defects. I call attention to one or two of these by way of emphasis. The same degree of hardness over the whole region is manifestly dependent upon the evenness of carburization. Anything in the technique on the materials that will tend to produce regional differences of impregnation are the things to discover and provide against. This should not be confused with variation in depth of penetration. Again, the gradual shading off in the degree of carburization is highly important. It is probably the only thing that will serve to distribute the effects of concentration of shocks from the outside. Finally, the need to restore, as far as possible, the damaged steel of the interior is perhaps the least appreciated.

THE BOXES

The boxes or cases used to hold the work and the packing material during carburization and to retain the carbon and thus force impregnation can not be made from any and all materials, if economy in the cost of such boxes is to be kept in view. Two materials are generally approved—cast steel and sheet steel. Usually, the cast steel box will outlive the one of sheet steel, the conditions being the same. A rough estimate would give the cast box a life from 25 to 30 per cent longer. "Life" is not to be understood as measured by the total elapsed time, but by the number of operations. Under very good conditions the cast steel box may be used anywhere from 15 to 20 times, but the life of the box depends on a number of things—the temperature of carburization, the period of high heat, the strength of the oxidizing atmosphere in the furnace, the mechanical treatment, etc. A furnace having a reducing atmosphere—such as these burning heavy oil—will serve to prolong the life of the boxes. The first cost of the cast steel box will probably be greater, and this will be more or less of an offset to the longer life. The weight of this box will also be greater, which is a disadvantage.

If cast steel is employed, the box should be cast of soft steel. The lid may be of the same material or it may be of sheet metal. For a cast steel box 12 in. by 14 in. by 24 in. in size, wall thickness of 4/5 in. or 1 in. will be proper. If sheet steel is selected, the carbon percentage should be low. The wall thickness for a box of the foregoing dimensions may properly be 2/5-in. or 3/5-in. The seams may be gas or electrically welded.

The size of the box is important. In general, for miscellaneous work the size already given may be considered suitable. Dimensions much exceeding those given should be considered well before they are adopted. The cubic contents should be limited to two cubic feet, or in exceptional cases to three cubic feet, as large boxes generally mean that the heat penetration will be slow. The following objections to such boxes have been expressed: (1) Considerable deformation of the pieces constituting the work, this deformation arising from the inequality of temperature at different points in the box; (2) considerable irregularity in the impregnation, due to the same cause, and (3) the excessive time period necessary to get results. When very large pieces are to be treated the fixed heating compartment may be used. Quite small boxes are desirable, if the work permits. Thus, a box 12 in. by 10 in. by 10. in. is a good one for small, miscellaneous work. Homogeneous impregnation is promoted by the cylindrical box, but this type does not lend itself so readily to handling. This point needs to be considered, as much of the handling is done while the workman is exposed to the heat.

The inside dimensions of a box should be such that the work may be placed in it in such a position that there is no less distance than 1¼ in. or 1½ in. between the work and box at any point.

The cover may, for the box made of either approved material, be of cast iron, cast steel or sheet steel. In all cases, however, the joint is to be such that a good closure may be effected. The cover may fit over the sides of the box.

CHARGING THE BOXES

The bottom of the box is coated with a paste made from clay and water. This should be done some considerable time before the work is to be put in, as it is necessary to wait for the paste to dry thoroughly before taking the next step. The packing material is then put in until a layer, when compressed, is 1½ in. thick. The condition of the packing material is of importance. It should be very dry and well pulverized. If the work consists of rather small pieces, a layer, one article thick, may be arranged. The intervals between articles is nowhere to be less than 1 or 1¼ in. A similar rule applies to the intervals between the walls of the box and the sides of the work, whether the work be large or small. The large single article or the layer of small articles is now packed tightly with the packing material, until the latter is at the highest level of the work. Then a layer of packing not less than 1½ in. thick is packed in tight.

The object in allowing generous intervals between metal surfaces is to guard against actual contact and to provide an adequate amount of material to supply the required carbon. If the final layer of packing will not, when 1½ in. thick, completely fill the box, enough is to be put in to do so. The cover is now put on and the joint sealed everywhere with a paste or mortar made by mixing fire-clay and water.

The whole is now ready for the furnace, except for the possible presence inside of moisture and for the wetness of the seal. However, the box may be put into the heating compartment and left near the door or in some other comparatively cool spot until one is satisfied that all water, especially inside, has escaped.

THE PACKING MATERIAL

The character and condition of the packing material are exceedingly important, not to say vital. There has probably been a good deal of nonsense promulgated in extolling the virtues of complicated preparations. Nevertheless, a good deal of success no doubt has attended the use of some mixtures of this character. But why use complicated mixtures when comparatively simple ones will give equal results? Of course, we should all elect to be "from Missouri" and stand willing to be convinced by actual test.

The packing must contain carbon in some form, otherwise there will result no impregnation with carbon. Various varieties of wood charcoal, such as oak and beech charcoals, are suitable for packing. Charcoal made from leather, or horn, soot, barium carbonate, coke, etc., have all been used as sources of carbon.

But the packing should have certain physical properties as well as possess a carbon content. There should, for example, be more or less porosity to permit the gases to get through. Then there should exist a capability to maintain its volume despite the heat and the escape of gases from its substance. Otherwise, the work might settle unevenly and so suffer deformation. Again, it should be a fair conductor of heat. If not, then there may be great differences of temperature in the interior of the box, the center being much cooler than points near the surfaces of the box. It is also considered advantageous if the packing consolidates well and is at no time of a dusty character. Both these qualities may at times be imparted to packing which lack them but are otherwise suitable. Thick oil may be mixed with the material. The specifications as to heat conductivity and porosity are more or less incompatible, so that a compromise may often be necessary.

Uniformity of action is something to be prized. Simple mixtures are probably the best from this point of view, especially if they tend to retain the gases which they produce until a red heat has been attained—that is, a temperature of some 1,200 deg. F. Vegetable or animal charcoal alone meets this requirement very well. However, wood and bone charcoals do not act to the best advantage through the earlier part of the carburizing range. They may be stimulated to activity by the addition of an alkaline carbonate. Barium carbonate and sodium carbonate—both low-priced chemicals—are advantageous additions to wood charcoal. As between beech and oak charcoals on one hand, and charcoals from other woods, the former are probably better than the latter; but the mode of making the charcoal is of greater importance than the precise kind of wood.

The use of barium carbonate with wood charcoal tends to produce a coloring effect upon the work. That is, the work is apt to come out covered with a thin layer or deposit of graphite. This tendency, if objected to, may be corrected by the addition of 10 per cent of saw dust to the mixture, W. H. Dyson being authority for this statement. It is thought that the deposit is due to the contact with the work of carbon monoxide (CO) which has been liberated at temperatures below 1,475 deg. F. In actual practice, however, the undesirable temperatures ought to be passed in a short time. The deposit ought then to be rather a thin one, if it is present at all. If trouble is experienced, the saw dust remedy may, of course, be readily applied.

Granulated bone is the usual material employed in the United States. It gives satisfactory results in many cases, but it seems to possess an objectionable characteristic when used for a prolonged period at a high temperature. As the extended period and the elevated temperature may be needed to get certain results, it will be of advantage to consider this matter further. If bone is ignited and burnt, the ash, amounting perhaps to anything from 50 to 80 per cent of the weight of the original charcoal, will be found to consist principally of calcium phosphate. In a carburizing box, under the influence of the heated metal and charcoal, a reduction of calcium phosphate may take place. This would mean the liberation of phosphorus, which may then combine with the iron of the soft steel, and phosphide of iron would be the result. This substance is brittle and melts at a low point. Forming on the surface of a casehardened object, it will at times produce a roughening of that surface, or a blister may be formed. In an actual case, splinters were secured and tested. Phosphorus to the amount of 2½ per cent was found to be present. There was also reason to think that the carburizing temperature had reached 1,800 deg. F., or some higher level.

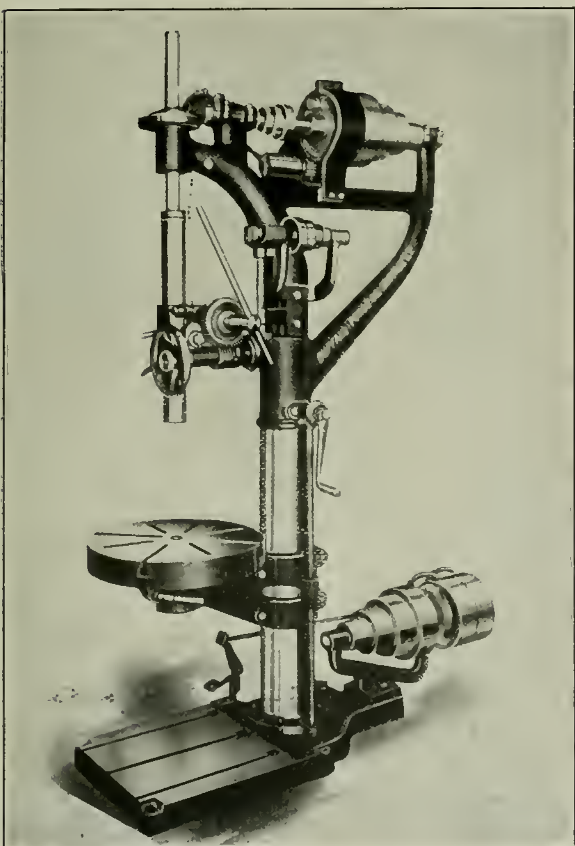
(To be continued.)

NEW DEVICES

A BACK GEARED UPRIGHT POWER DRILL

The Buffalo Forge Company, Buffalo, N. Y., is making a 25-in. back geared upright power drill as shown in the illustration. This machine has a 21-in. diameter table and a spindle travel of 14½ in. It has eight speeds, four power feeds and a hand lever feed. The handle is adjustable from 6 to 18 in. and is held in place by a tension spring. The worm feed wheel runs in oil and is latch-hinged to take up wear.

The mechanism can be thrown from plain to back geared drive without using a wrench. This is done by disengaging a knurled knob in the top gear and throwing in the back gears by means of the hand lever, and it is held in place by a locking screw.



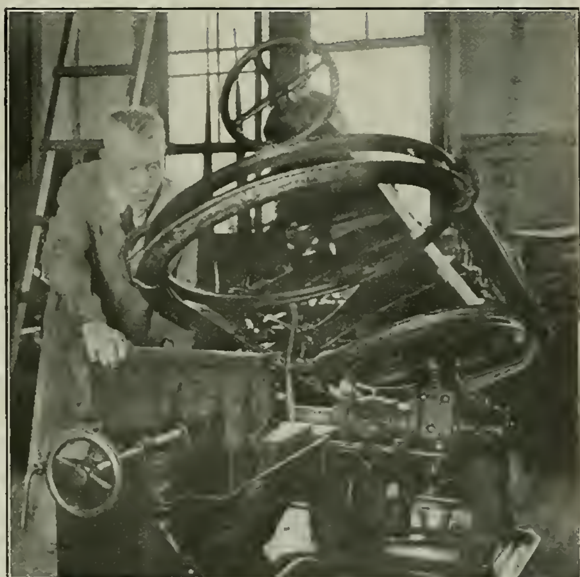
The Buffalo Upright Power Drill

Adjustable split bearings are provided for all shafts and ball thrust bearings are used where necessary. This machine is designed for accurate work and an automatic trip throws out the power feed instantly when the piece has been drilled to the required depth.

GRAVITY FEED BAND SAW

The idea of a continuous stroke hack saw has been embodied in the band saw machine, developed by the Napier Saw Works, Inc., Springfield, Mass.

The saw blade feeds into the work by gravity, due to the balanced weight of the tilting head. A spring at the back of the machine is in such a position and of such tension that the feeding weight is constant from start to finish of any cut which can be made on the machine. The gravity feed feature of this machine is a rather distinct departure from any other type of feed used for this work. When in operation the gravity feed does not force the saw band into the metal beyond the band's capacity to withstand the strain. When tough and hard metal is being cut, the feed is just heavy enough so that the teeth of the band take hold and this feed is constant as long as the uniformity of the steel remains constant. Should a softer metal be cut, the feed is heavier and better time is made.



Napier Band Saw Cutting Heavy Rail Section

The base of the machine is of cabinet type with lubricating tank enclosed. All bearings are large and those in clutch pulley and in the driving and idle wheels, which carry the tension of the saw, are extra heavy and rigid to withstand the strain.

The cutting band is lower than the returning band, as shown in the illustration, thus making it possible to cut off any length required. The cutting band is supported by truss arms, each carrying a pair of specially designed guides.

By means of the rolling guides the band saw is directed so that its vertical travel between the truss arms is in perfect alignment, thus assuring a straight cut. These guides once set are in perfect adjustment for any saw that may be placed in the machine.

A rotary pump of simple design provides ample cutting compound for the saw. The teeth of the band saw are downward in the cut, which insures that the cutting compound flows at once to the point of the saw tooth where it is needed. The capacity of the machine is greatly increased by this ample flow of cutting compound.

An important advantage of this type of machine is the saving in metal due to taking a narrow cut. For most kinds of work the band saw blade thickness is less than .049 in. while a circular saw would be 3/16 in. thick or more. In other words, when cutting up expensive material, an appreciable saving results from the use of a band saw with a thin blade.

The following is a table of specifications and of speeds recommended:

Floor space	4 ft. by 6 ft.
Height, floor to table	26¾ in.
Length, band saw	12 ft. 3 in.
Size of band saw	1 in. by .035
Net weight	1,700 lb.

Speeds

Soft steel, 120 lin. ft. per min. of band saw; 80 rev. of driving pulley.
Tool steel, 100 lin. ft per min. of band saw; 70 rev. of driving pulley.
Soft metals, 150 lin. ft. per min. of band saw; 100 rev. of driving pulley

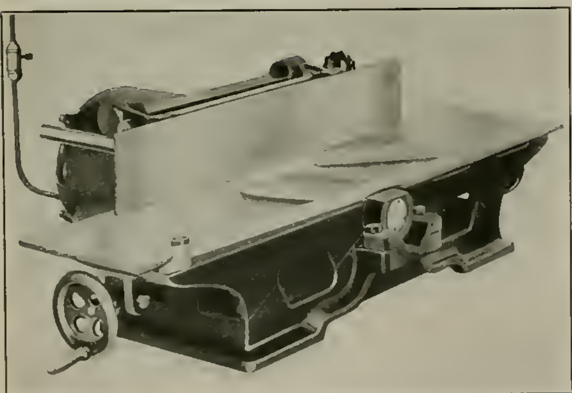
Power required	1 bp.
Geared	4 to 1
Driving pulley	12 in. by 3 in.

THE WALLACE BENCH JOINTER

A portable six-inch, motor-driven bench type of jointer has been developed and is being marketed by J. D. Wallace & Co., Chicago.

This machine was designed to place in the shop at points convenient to the workmen, thus eliminating the loss of time due to walking to and from the stationary machines. It can easily be carried by one man and thus practically becomes part of an individual tool kit.

An especially interesting feature is a new fence that has been developed in connection with this machine. This fence is mounted on the motor and slides backward or forward on rods, rendering it more quickly and accurately adjustable than any ordinary machine. The fence is designed so that only a fraction of an inch is lost on the table when the fence is set for beveling.



Side View of the Jointer Showing Adjustable Front and Rear Tables and Safety Guards

The cutter head can easily be taken out and other heads inserted in a few seconds. The tables are arranged to slide backward to permit the use of these special heads, or forward so as to work with the narrowest possible throat opening, a feature that will prove especially desirable when the machine is doing small or very close work.

Ball bearings are used on all motor and cutter head bearings, thus eliminating friction and prolonging the life of the machine.

An ingenious and apparently very efficient arrangement of the flap and shutter guard has been effected by mounting the shutter guard on the cutter head bearing rather than in grooves.

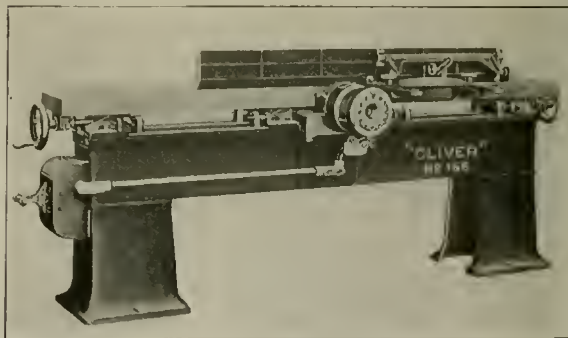
Each machine is equipped with a motor, lamp cord and plug for connection to the ordinary lighting circuit.

OLIVER HAND PLANER AND JOINTER

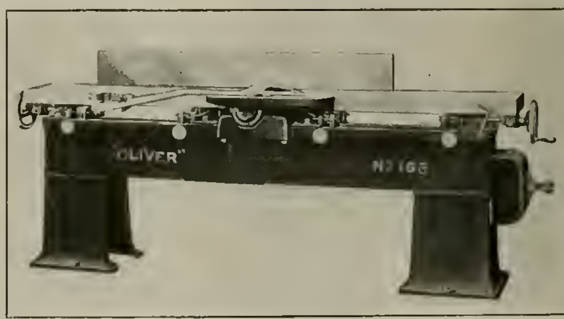
The Oliver Machinery Company, Grand Rapids, Mich., have placed on the market a new motor-driven hand planer and jointer.

As shown in the illustrations, this machine is provided with a self-contained direct mounted motor drive. A 3,600-r.p.m., three-phase, 60-cycle, 220-volt A. C. motor and a three-knife cylinder are used.

On the outer end of the cylinders, where the pulley usually is mounted. the cylinder is shaped to receive the rotor of the motor. On the outside of this rotor and concentric with it is the stator of the motor, held by means of the adapter and the outer end cover. The direct mounted motor drive runs in extra large ball bearings which insures long life to the bearing and smooth operation of the motor.



Rear View of the Hand Planer and Jointer Showing how the Motor is Mounted



Front View of the Hand Planer and Jointer

This hand planer and jointer is adapted to a wide range of work and the drive is suitable where three-phase, 60-cycle, . 220-volt electric current is available.

A CONVERTIBLE STOCK CAR

A DEVICE DESIGNED to convert the ordinary live stock car into a box car for general merchandise purposes has been placed on the market by the U. S. Convertible Car Company of Fort Worth, Texas.

This equipment consists of moveable floors of 2-in. pine and steel folding side walls, which are hinged to the moveable floor and to the inside of the car near the roof. As shown in the illustrations the moveable sides and floor are operated by means of ratchet cranks attached to a worm and sector device located under the car and connected to the moveable floor at each corner by a ⅜-in. steel cable moving over sheaves located inside of the car.

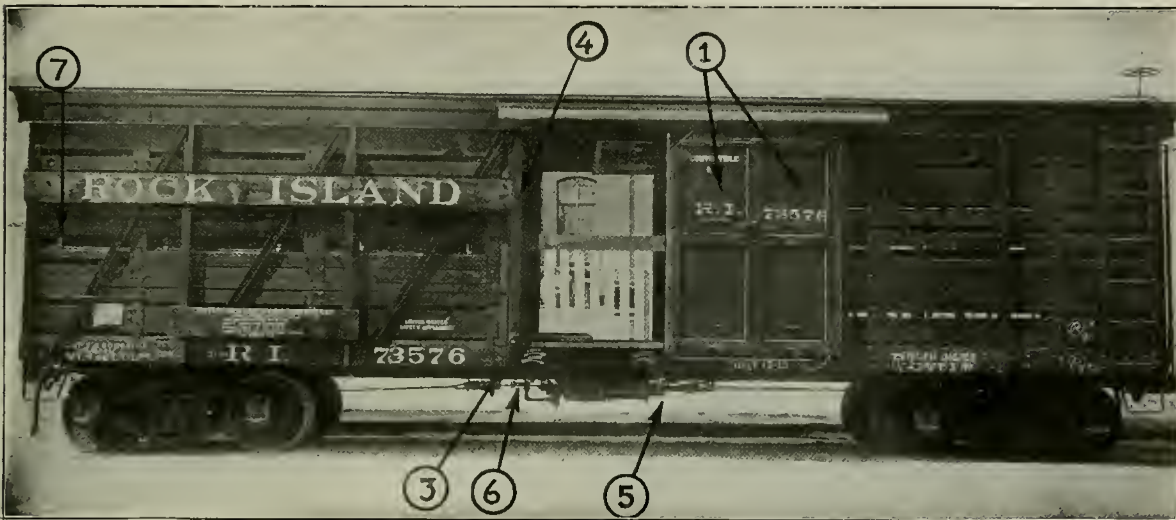


Fig. 1—A Rock Island Stock Car Equipped With the Convertible Device.

An old stock car to which this device has been applied is shown in Fig. 1. The water-tight live stock door 1, with the protector or water seal 4, is part of the necessary equipment, although not an integral part of the convertible device. The worm and sector 3, the ratchet cranks 5 and 6, and the side lock bolts are located as shown. This car operated successfully for a period of more than a year.

Fig. 2—One End of Car Arranged for Merchandise. (1) Safety Lock; (2) Movable Floor; (3) Showing Absence of Any Nails or projections to Injure Live Stock; (4) Instructions for Operating Device; (5) Door water Seal; (6) Provision for Fastening Grain Doors.

In Fig. 2 the car is shown with one end having the convertible device raised to the top of the car as when live stock is carried, and the other end with the device in place as when the car is used for general merchandise or grain.

The manner in which the device operates is clearly shown in Fig. 3, which shows the folding side walls 6 and 7 as they automatically unfold, as the moveable floor 8 is lowered into position on top of the permanent live stock floor 10. In the foreground of Fig. 3 the merchandise, or moveable, floor 8 is lowered down on top of the live stock floor 10 by operating the ratchet crank. The cable 4 running over the sheave 5 lowers the floor and the side walls unfold, the slot hinge 1 and 2, secured by the U-bolt 3, permitting the movement without any binding. The side walls are then secured against the slatted sides 11 of the car by the side lock bolts which are secured in place by the lock bolt button 13.

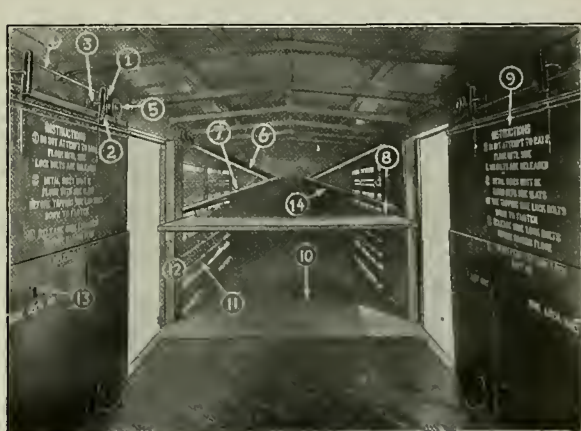

Fig. 3—One End of Car Ready for Merchandise and Convertible Device Lowering Into Position in the Other End.

The general appearance of the interior of the car when arranged for merchandise is shown in Fig. 4. This shows the clean merchandise floor 2 in place on top of the live stock floor and the ventilated door 3 closed for merchandise loading. An end door 1 is provided so that live stock can be given necessary attention. The ends of the steel folding side walls are crimped so that the door jamb 4 is exposed to permit the application of a grain door. With the addition of a grain door this arrangement can also be used for the transportation of grain.

There are a number of advantages to be gained by the use of this device. The transportation of live stock necessitates a type of car for which it has been impossible to find freight, of a kind that can be handled in them, in sufficient quantities to load in the cars on their return trip to the stock raising sections of the country. This results in an immense

Fig. 4—Interior of Car as Arranged for General Merchandise.

loss due to non-revenue or empty car-miles. As there are long periods when there is no live stock business these cars must frequently lie idle, and it is estimated that the average time in service of such cars is only from 25 to 40 per cent.

This convertible appliance makes it possible to keep stock cars in practically continuous service, and the operation of the device is so simple that a station agent or any other person can convert from one type of car to another without any assistance from the mechanical department.

FORGED-CUTTER TOOL HOLDER

A new line of tool holders known as the Vulcan Forged-Cutter tool holders has been placed on the market by J. H. Williams & Co., Brooklyn, N. Y. As the name implies, these holders are drop forged of special steel and with their inserted cutters are adapted to the heaviest service in any regular machining operation on the lathe, planer or shaper.

Williams Forged-Cutter Tool Holder

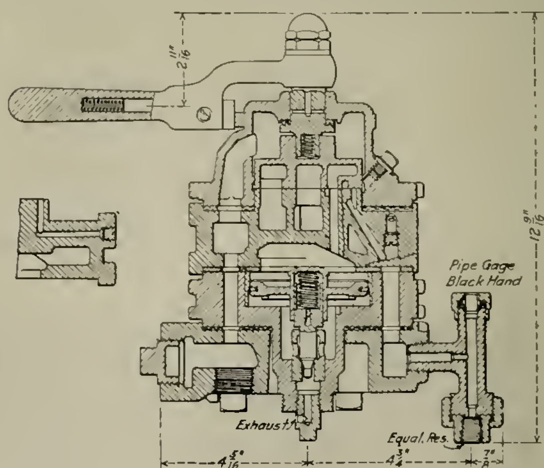
The main advantages of this type of tool are its low cost due to the small amount of high speed steel used, and the fact that by maintaining an ample stock of cutters for all regular needs, the machine operator can give his entire attention to the turning out of work and is insured against interruption due to dull or broken tools.

Referring to the illustration, the construction of the Vulcan tool holder is shown in phantom. The angular seat on the rear of the shoulder in the small figure permits the locking pin to force the heel or step of the shoulder directly against the holder proper. This method of locking provides the necessary bearing to support the cutter pressure and prevents all rocking movement of the cutter itself.

The holders are all drop-forged from a special steel, so treated as to develop its maximum toughness and stiffness. The cutters, extra heavy in design, are drop-forged from high speed steel and are finished and hardened ready for use. They are furnished in a variety of sizes and shapes, such as side, diamond point, roughing, hog nose, flat nose or threading.

COLLAPSIBLE EQUALIZING PISTON FOR H-6 AUTOMATIC BRAKE VALVE

A collapsible equalizing piston incorporated in the H-6 automatic brake valve is an innovation recently introduced by the Westinghouse Air Brake Company, Wilmerding, Pa. The device has proved of material benefit in overcoming a prevalent undesirable condition in passenger service of overcharging the equalizing reservoir. This condition is brought about on account of the increased length of trains, brake pipe volume, main reservoir pressures and high differentials of pressures, which require a close fitting piston. The collapsible feature insures equality of brake pipe and equalizing reservoir pressure without which brake manipulation is in-



Cross Section of H-6 Brake Valve with Collapsible Equalizing Piston

terfered with more or less when making the second application of a two application stop. The collapsible equalizing piston accomplishes its purpose more completely than does the solid equalizing piston as with this feature it is possible at any time during the release of the brake to move the brake valve handle to application position and secure an immediate response of the brakes.

In construction the collapsible type of equalizing piston, as shown in the illustration, consists of the piston and its stem held in normal relative position by a spring in the hollow sleeve in which the equalizing discharge valve proper slides. Whenever the equalizing reservoir pressure is raised slightly higher than brake pipe pressure, as usually occurs when releasing a train of any length owing to the small volume of the equalizing reservoir, as compared with the brake pipe and auxiliary and supplementary reservoirs, the excess pressure on the top of the equalizing piston compresses the spring and forces the equalizing piston down to a position in which the by-pass grooves in its bushing are uncovered, thereby permitting the pressure in the equalizing reservoir and brake pipe to equalize.

The collapsible equalizing piston is furnished as a part of the H-6 brake valve when so ordered, or can be supplied as a separate or repair part for brake valves already equipped with a solid piston. The only modification required in the brake valve, when substituting the collapsible piston for the solid piston, consists in cutting four by-pass grooves .044 in. deep by .088 in. wide by ½ in. long in the bottom of the equalizing piston bushing and equally spaced around the bushing.

DETACHABLE AIR DRILL

In the new air drill recently placed on the market by the Duntley-Dayton Company, Chicago, there is a unique departure from standard air drill construction. The motor

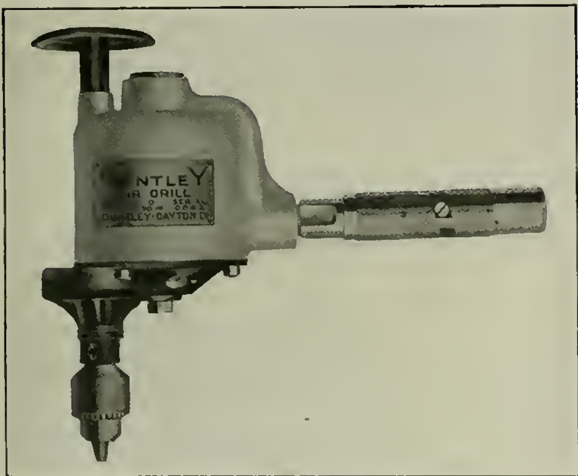


Fig. 1—Duntley Air Drill

or power unit is quickly detachable, thus making it possible by the removal of three screws and a nut, to replace or repair the motor should this become necessary. Two of the screws

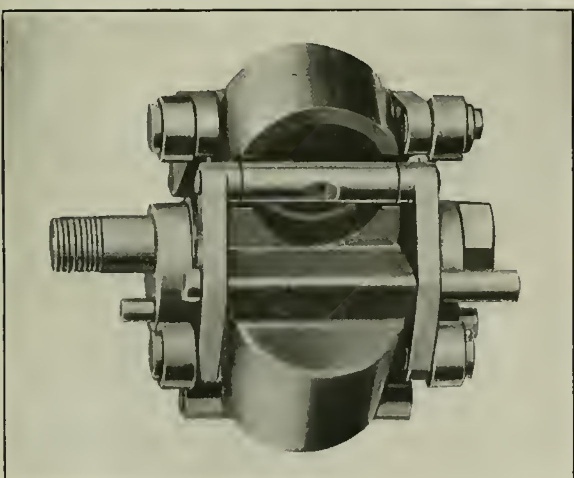

Fig. 2—Self Contained Air Motor

and the nut are shown in Fig. 1 which is a general view of the drill.

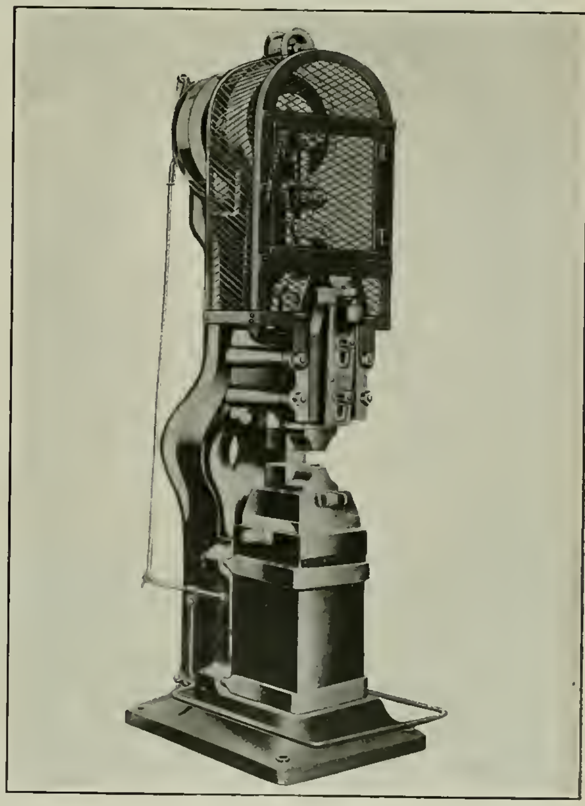
Up to the present time two sizes of breast drill have been manufactured with capacities up to ¼ in. and ⅜ in. These drills are especially adapted for drilling tell-tale holes in staybolts, and work of that character. As the motor is self-contained and well balanced, there is practically no vibration, a desirable feature in the performance of accurate work. The drill weighs only 4-½ lb.

The self-contained motor shown in Fig. 2 consists of three cylinders and pistons mounted in a frame, the entire engine rotating about a fixed crankshaft or spindle. The cylinders oscillate from a fixed base and cams on the spindle operate the valves. All working parts run in a bath of oil.

It is claimed that the Duntley air drill due to economical air consumption and lack of vibration can be used to good advantage on work hitherto performed almost exclusively by electric drills.

FAIRBANKS POWER HAMMER GUARD

To provide full protection to operators of this machine, the United Hammer Company, Boston, Mass., has designed a guard for its Fairbanks power hammer, which completely covers the working parts of the machine. The guard is made



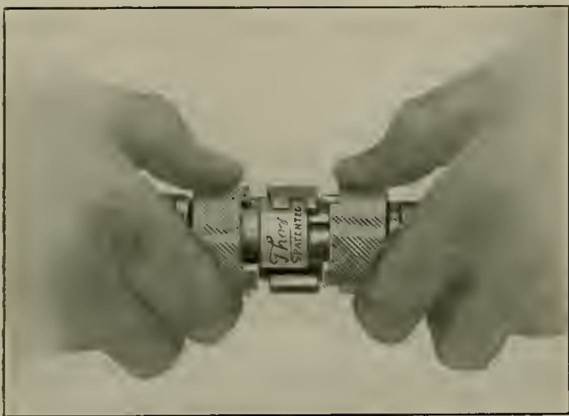
Safety Guard for Power Hammer

of woven wire stretched across a metallic frame work which fits the upper part of the machine.

By means of a door shown in the illustration, the parts are easily accessible as before, for the purpose of oiling and adjusting. The safety guard interferes in no way with the operator and is easily attached to Fairbanks hammers already in operation. It may also be applied to the new 400-lb. and 500-lb. hammers recently developed for locomotive and other heavy classes of work.

A QUICK OPERATING HOSE COUPLING

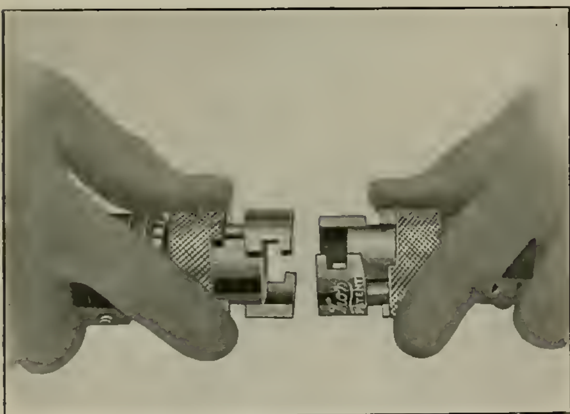
A new hose coupling with several important advantages has been placed on the market by the Independent Pneumatic Tool Company, Chicago, and is known as the New Thor Perfect Hose coupling. Its particular advantage lies in the fact that it may be disconnected instantly by a straight pull on the knurled sliding sleeves. These sleeves are plainly shown in the illustration and when they are pulled



New Thor Perfect Hose Coupling with Sleeves Pulled Back Ready to Disconnect

back the coupling ends may be disconnected without unscrewing or even twisting, as is necessary with many hose couplings. The jaws separate as soon as the locking shoulder moves back.

The beveled jaws and locking shoulders are heavy with large bearing surfaces and cannot easily bend, break, or work loose. The operating spring is large and durable, but can be easily replaced if necessary by removing the washer. An L-shaped gasket is held in place by the air pressure when the coupling is connected. It cannot be blown out when the coupling is disconnected, because of the beveled



Hose Coupling Disconnected

face on the gasket and protecting shoulder in the coupling. Gaskets are interchangeable in ⅜-in., ½-in. and ¾-in. sizes and those in the 1-in. and 1¼-in. sizes are interchangeable. The New Thor Perfect hose couplings are interchangeable between the various sizes and combinations up to ¾-in. inclusive. Each hose end is identical with the other, making a universal coupling which requires no reducers.

THE SILVER RADIAL DRILL

A radial drilling machine of well balanced design and embodying several new features, has been placed on the market recently by the Silver Manufacturing Company, Salem, Ohio. The base of this machine is strongly ribbed both lengthwise and crosswise, and the T-slots are accurately planed, ample allowance of metal being left to prevent springing. The column is of semi-steel, ground to size, the inner column or post being reinforced by heavy ribs running nearly the entire length. The outer column telescopes the post and rests on a ball thrust bearing, making the swinging of the arm extremely easy and also taking the thrust load. The arm, which is of pipe section design, has a wide bearing on the column and is heavily ribbed to resist torsional and bending strains. It is raised and lowered by power and is provided with an automatic "knock out" at both limits of travel.

The arm is firmly clamped to the column by two conveniently located levers, the bolts of which serve a three-fold purpose. As shown in Fig. 1, these bolts act as limit screws to prevent sagging and also as binders. In addition to this, when the levers are placed in the clamping position they

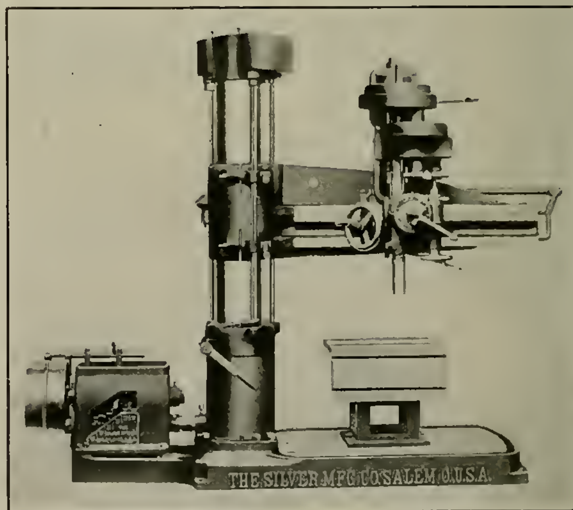


Fig 1—Silver Radical Drilling Machine

tighten the split hub through which the elevating controller shaft runs, which prevents the elevating screw from being set in motion while the arm is clamped to the column. This avoids any danger of wrecking the machine.

Another feature is the safety nut shown in Fig. 2. The purpose of this nut is to prevent the arm from dropping when the threads become worn in the elevating nut. The safety nut runs idle with ⅛-in. clearance between it and the arm, and when the threads wear out in the elevating nut, the load is transferred to the safety nut, which brings it flush with the arm, thus warning the operator in ample time to make replacement and avoid serious accident. The safety nut also provides for continuous use of the machine while the elevating nut is being replaced.

The head is arranged for rapid travel along the arm and contains a two-speed back gearing that may be shifted while running. The spindle is accurately ground to size and double splined. The rack is cut directly on the sleeve, insuring a wide bearing for the hardened rack pinion. Eight feed changes are provided, any one of which may be obtained while drilling by two conveniently located T-handles, which are plainly indexed. Other advantages are a depth gage, automatic feed trip and tapping attachment. Six speed changes are available, which, with back gears on the head, provide 12 speeds in all. All gears in the speed box run in an oil bath.

The silver radial drill is manufactured in three sizes—2½-ft., 3-ft. and 3½-ft.—and it drills to the center of 5-ft.

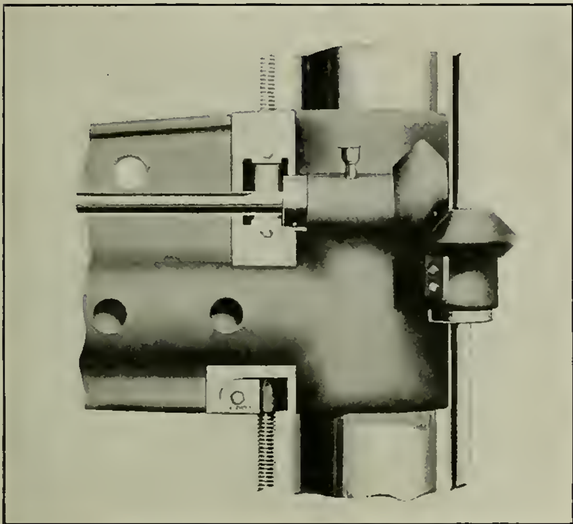

Fig. 2—Safety Nut Applied to Radial Arm

6-in., 6-ft. 6-in. and 7-ft. 6-in., respectively. The maximum height under the spindle and above the base is 50-in. The table height is 19-in. Motive power may be furnished by a 3-h.p. constant speed motor or a 3 to 1 variable speed motor as desired.

HYDROGEN GAS FOR CUTTING AND WELDING

While acetylene in combination with oxygen is widely used for welding and cutting, there are certain disadvantages in the process due to the explosive character of the acetylene. In order to eliminate the disadvantages incident to the use of acetylene, the Carbo-Hydrogen Company of America, Pittsburgh, Pa., has developed a gas known as carbo-hydrogen with the view to furnishing an efficient and safe medium for use in cutting and certain classes of welding.

Carbo-hydrogen is a product of the destructive distillation of suitable hydro-carbons and has a general analysis of 85 per cent hydrogen, the balance being light hydro-carbons. It is a fixed gas, permanent under all weather conditions, and does not solidify or leave any residue in the tank. Being a combustible gas and not an explosive, it is easy to use and safer than acetylene. No air or free oxygen is mixed with the gas in the process of manufacture.

Gases having a high B.t.u. value are necessarily slow in combustion and require a longer time to deliver a given amount of heat and a larger expenditure of oxygen than gases having a higher rate of combustion. For this reason, a smaller portion of oxygen is needed for a given amount of work where carbo-hydrogen is used. The gas maintains a very high rate of combustion and ignition and consequently generates an intense heat.

In cutting ferrous metals gases having a high carbon content change the character of the metal at the cut, hardening it so that machining or caulking is exceedingly difficult. It is claimed that metal cut by the carbo-hydrogen process on the other hand retains soft surfaces that can readily be worked, while the absence of slag increases the speed of cutting and produces a smoother surface.

The use of carbo-hydrogen for heavy welding on steel parts is not advocated by the manufacturers, although the process is said to be superior to the oxy-acetylene flame for welding softer metals, such as cast iron, copper, brass and aluminum. Carbo-hydrogen is also used on light gage iron and steel welding and for lead burning.

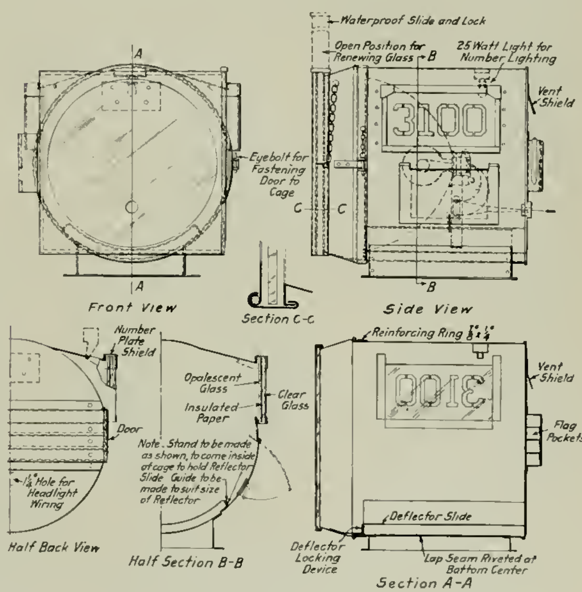
Among the advantages of carbo-hydrogen may be mentioned the absence of dangerous and poisonous gases in the products of combustion which often prove injurious to operators. Being composed largely of pure hydrogen, carbo-hydrogen burns almost entirely to water, while the combustion of acetylene and oxygen produces at least 50 per cent carbon monoxide. Carbo-hydrogen is supplied in drawn steel cylinders compressed to 1800 lb. per sq. in. The working pressure varies from 5 to 10 lb. per sq. in., making it possible to withdraw practically all the gas from the tank.

LUCAS HEADLIGHT AND MARKER LAMPS

A headlight casing having a number of improvements over the older types of casings, and a combination flag holder and electric classification or marker lamp, have been developed by A. N. Lucas, shop superintendent of the locomotive department of the Chicago, Milwaukee & St. Paul shops at Milwaukee.

HEADLIGHT CASING

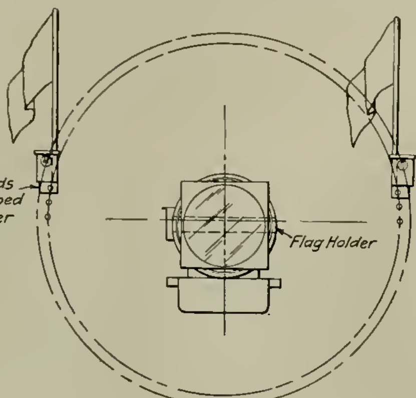
The headlight casing is designed to use an 18-in. square glass instead of the usual 18-in. round glass, thus eliminat-



Construction of the Headlight Casing

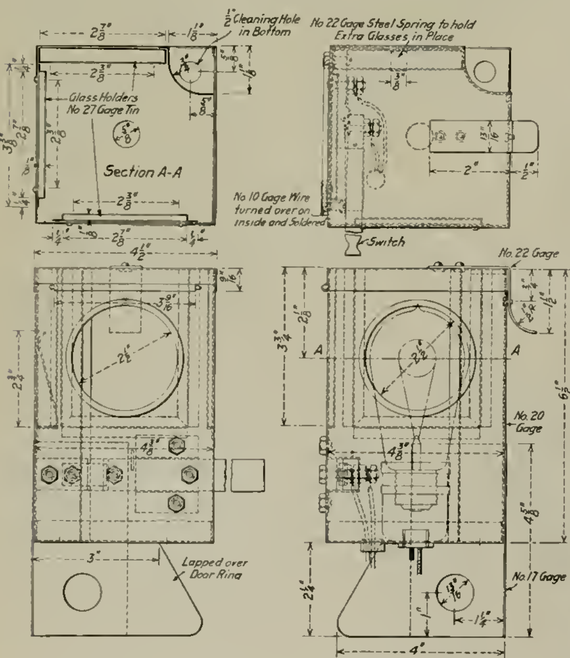
ing much of the breakage experienced in cutting and applying the round glass. The glass can be applied to this headlight without the use of putty or bolts or any cutting to fit, as standard 18-in. square glass is used, or the glass may be applied in two or more pieces.

The body of the casing is made so that the base plate passes through a slot at the bottom of the cage, stiffening it at the proper point. The slide for the reflector and the base plate are in one piece. This avoids double thickness and prevents the rusting of the headlight casing at this point, thereby increasing its life considerably. The extension for the glass showing the engine number is provided with a cover having a hinge, so that the numbers can readily be changed without the use of thumb screws, which might become rusted and inoperative. The front door is pro-



The Headlight Marker Lamp and Signal Flags Applied to the Front End

vided with a strong hinge and lock so that it may be fastened securely. On the left side below the engine number, a hinged door gives access to the interior of the case so that adjustment of the reflector or repairs may be made readily. Four pockets on the back of the headlight casing



Combination Marker Lamp and Signal Flag Holder

provide a storage place for the signal flags, which are shown in the illustration of the classification lamp.

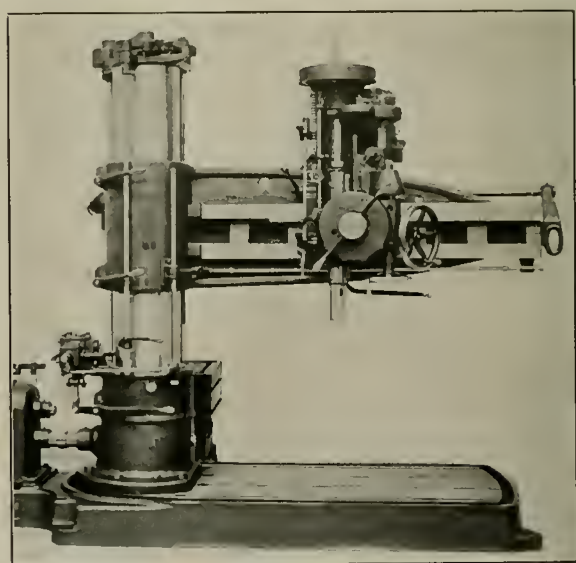
CLASSIFICATION LAMP

A combination flag holder and classification or marker lamp, which has been giving good results on the Chicago, Milwaukee & St. Paul, is shown in the illustration. This lamp is made of heavy galvanized sheet iron and all the joints are spot welded or riveted with eight-ounce rivets. Its construction is clearly shown in the drawing. The socket for the electric light bulb is at the bottom of the lamp and the switch is located at the lamp, making it necessary to go to the lamp in order to turn on the light, thus insuring that the engineman will know if the light is in operation. The lamp contains the usual lens and is provided with a receptacle to hold four extra lenses. After the lamp has been securely bolted to the front end, the part of the lamp flange extending over the front ring is turned down and prevents the lamp from turning in either direction.

A socket for a signal flag is located in one corner of the lamp, making a separate flag holder unnecessary. The flags used in the sockets of these lamps are somewhat smaller than the flags generally used, being 12 in. by 18 in. and the staff 22 in. long. The flags formerly in use were 18 in. by 24 in. and the staff 36 in. long. Due to the size of the flags and the long staff, breakages and losses of flags were frequent because of strong winds, but this smaller flag and shorter staff have eliminated practically all loss from this cause. These flags are of proper size to be inserted in the flag pockets shown in the illustration of the headlight casing; thus locating them in a convenient place and at the same time preventing the soiling or loss of flags which usually takes place when flags are thrown in the locomotive cab because no storage space is provided for them.

COLUMN CLAMPING DEVICE

The column of the Fosdick radial drill illustrated is clamped by a special combination pneumatic and hand clamping device, of which the most noticeable feature is the location of the air cylinder, bringing the pressure directly to the point of clamping. The device will operate equally well on high or low pressures. The clamping is accomplished by an air cushion at each end of the cylinder, formed



Fosdick Radial Drill with Clamping Device

by additional ports in the valve to insure a compression at the proper termination of each stroke. The valve is operated by mechanical connection to a horizontal shifter bar running along the radial arm. The advantage of this device is that it has no connection with and does not interfere with the movement of the spindle head. In case of failure of the air the pet cocks at either end of the cylinder are opened and the usual method of clamping by hand is used.

Subscriptions, including the eight daily editions of the Railway Age, published in June, in connection with the annual convention of the American Railroad Association. Section III—Mechanical, payable in advance and postage free: United States, Canada and Mexico, $2.00 a year; Foreign Countries, $3.00 a year; Single Copy, 20 cents.

WE G ARANTEE, that of this issue 12,000 copies were printed; that of these 12,000 copies 11,191 were mailed to regular paid subscribers, 20 were provided for counter and news company sales, 223 were mailed to advertisers, 29 were mailed to employees and correspondents, and 537 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 107,710, an average of 9,792 copies a month.

THE RAILWAY MECHANICAL ENGINEER is a member of the Associated Business Papers (A. B. P.) and the Audit Bureau of Circulations (A. B. C.).

The Italian State Railways are said to have ordered a large number of oil-driven locomotives in Italy and the United States, in order to effect an immediate economy in coal.

The Belgian Minister of Railways, states Modern Transport, has bought from the British government 8,750 freight cars formerly used by the British army, which are still in France.

The British Ministry of Transport, according to a press report, is making arrangements for turning a number of munitions factory buildings into shops for the repairing of locomotives and cars now being returned from France, where they were used during the war.

Railway companies subject to the jurisdiction of the Board of Railway Commissioners for Canada have been granted an extension of time until September 30, 1920, within which to equip freight cars with safety appliances, as required by a recent order of the board.

The contract awarded by the German government to the Krupp Works for the construction of rolling stock, is reported by the United States commercial attache at The Hague, as calling for 2,000 freight cars of 15 tons capacity and 100 locomotives each year. It is said that the contract stipulates that the price must correspond to costs of material and labor and that the factory shall make a profit of only two per cent.

Exports of locomotives in August totaled 69, of a value of $1,539,540. This was considerably more than in July, but not as great as the exports of some of the preceding months. Over half the August total from the standpoint of value were destined for Japanese China. The exports of car wheels and axles in August totaled $1,302,546, nearly one-half of which total was destined for Japan. There were also large shipments to British India and to France.

Frank H. Clark, consulting engineer of New York City, has left the country temporarily, going to Peking to act as technical adviser to the Ministry of Communications of the Republic of China. Mr. Clark recently resigned as general superintendent of motive power of the Baltimore & Ohio and opened offices in New York City to undertake engineering investigations, report upon railway conditions and operations and co-operate in the preparation of plans and specifications for railway equipment and materials as well as to advise export firms, foreign railways and other concerns purchasing materials or equipment from United States manufacturers. He was at one time associated with David L. Barnes, consulting engineer of Chicago for four years, and later entered the service of the Chicago, Burlington & Quincy, where he held

successively the position of chief draftsman, mechanical engineer, superintendent of motive power and general superintendent of motive power. Resigning from that company in 1910, he joined the staff of the Baltimore & Ohio as general superintendent of motive power, a position he held for eight years. Mr. Clark is a member and has served as president of the American Railway Master Mechanics' Association and the Master Car Builders' Association.

Alfred LaMar, assistant director of sales of the war department, who went to Europe early in April to survey European markets, has returned to Washington and resumed his duties in the office of the director of sales. Mr. LaMar has the immediate supervision of sales of surplus war materials made for export, and directs the activities of the machine tool section of the office of the director of sales. While in Europe Mr. LaMar arranged the details of the visit recently made to the United States by a commission from the Construction Metallique which came to this country under the auspices of the Belgian government to inspect government-owned machine tools, with a view to purchasing. Mr. LaMar organized the machine tool section of the office of the director of sales shortly after the establishment of that office by the secretary of war.

MEETINGS AND CONVENTIONS

Master Boiler Makers' Association.—The executive committee of the Master Boiler Makers' Association has announced that the next annual meeting of that association will be held at the Curtis Hotel, Minneapolis, Minn., May 25-28.

Chicago Car Foremen's Association.—At the annual meeting of the Car Foremen's Association of Chicago, held at the Hotel Morrison on October 13, the following officers were elected: President, M. F. Covert, Standard Car Construction Company; first vice-president, James Reed, assistant master car builder, New York Central; second vice-president, E. H. Mattingly, general car foreman, Baltimore & Ohio; treasurer, F. C. Schultz, Chicago Car Interchange Bureau; secretary, Aaron Kline.

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations:

Air-Brake Association.—F. M. Nellis, Room 3014, 165 Broadway, New York City.

American Railroad Association, Section III.—Mechanical.—V. R. Hawthorne, 431 South Dearborn St., Chicago.

American Railroad Master Tinners', Coppersmiths' and Pipefitters' Association.—O. E. Schlink, 485 W. Fifth St., Peru, Ind.

American Railway Tool Foremen's Association.—R. D. Fletcher, Belt Railway, Chicago.

American Society for Testing Materials.—C. L. Warwick, University of Pennsylvania, Philadelphia, Pa.

American Society of Mechanical Engineers.—Calvin W. Rice, 29 W. Thirty-ninth St., New York.

Association of Railway Electrical Engineers.—Joseph A. Andreucetti. C. & N. W., Room 411, C. & N. W. Station, Chicago.

Car Foremen's Association of Chicago.—Aaron Kline, 841 Lawlor Ave., Chicago. Meetings second Monday in month, except June, July and August, Hotel Morrison, Chicago.

Car Foremen's Association of St. Louis.—Thomas B. Koeneke secretary, Federal Reserve Bank Building, St. Louis, Mo. Meetings first Tuesday in month at the American Hotel Annex, St. Louis.

Chief Interchange Car Inspectors' and Car Foremen's Association.—H. J. Smith, D. L. & W., Scranton, Pa.

International Railroad Master Blacksmiths' Association.—A. L. Woodworth, C. H. & D., Lima, Ohio.

International Railway Fuel Association.—J. G. Crawford, 542 W. Jackson Blvd., Chicago.

International Railway General Foremen's Association.—William Hall, 1061 W. Wabasha Ave., Winona, Minn.

Master Boilermakers' Association.—Harry D. Vought, 95 Liberty St., New York.

Master Car and Locomotive Painters' Association of U. S. and Canada. A. P Dane, B. & M., Reading, Mass.

Niagara Frontier Car Men's Association.—George A. J. Hochgrebe, 623 Brisbane Bldg., Buffalo, N. Y. Meetings, third Wednesday in month, Statler Hotel, Buffalo, N. Y.

Railway Storekeepers' Association.—J. P. Murphy, Box C. Collinwood, Ohio.

Traveling Engineers' Association.—W. O. Thompson, N. Y. C. R. R., Cleveland, Ohio.

PERSONAL MENTION

GENERAL

A. B. Corbett, shop superintendent of the Missouri, Kansas & Texas, at Parsons, Kan., has been appointed assistant mechanical superintendent of the Missouri, Kansas & Texas of Texas, with office at Denison, Tex., succeeding R. W. Burnett.

W. Malthaner, general master mechanic of the Northwest district of the Baltimore & Ohio, Western Lines, with headquarters at Cleveland, Ohio, has been appointed acting superintendent of maintenance of equipment, with headquarters at Cincinnati, Ohio, succeeding the late Matthew J. McCarthy. Mr. Malthaner was born at Salem, N. Y., on August 4, 1874. He entered railroad service as a machinist apprentice on the Delaware & Hudson at Green Island, N. Y., in 1889, and at the end of four years was made a gang foreman in the same shop, serving in this capacity on various classes of work until 1896. He then left railway work, taking employment with the General Electric Company as a machinist, but returned after two years to the Green Island shops of the Delaware & Hudson as foreman of the air brake department. In 1900 he became terminal foreman of the same road at Schenectady, N. Y., and after two years in this capacity was appointed general foreman at Plattsburg, N. Y. In 1914 he was made division master mechanic of the Saratoga & Champlain divisions of the Delaware & Hudson, occupying this position until 1912, when he was transferred to the Susquehanna division. Early in 1915 he accepted the position of shop superintendent of the Baltimore & Ohio at Newark, Ohio. and in 1917 was appointed general master mechanic of the Northwest district. This is the position he held when he was recently appointed acting superintendent maintenance of equipment.

W. Malthaner

F. W. Boardman has been appointed fuel supervisor of the Texas & Pacific, the Trans-Mississippi Terminal Railroad, the Weatherford, Mineral Wells & Northwestern, the Gulf, Texas & Western, the Denison & Pacific Suburban Railroad, and the Fort Worth Belt Railroad, with headquarters at Dallas, Texas, succeeding W. L. McMurray, assigned to other duties.

MASTER MECHANICS AND ROAD FOREMEN OF ENGINES

J. O. Goodwin, road foreman of engines of the Michigan Central, with office at West Bay City, Mich., has been appointed division master mechanic to succeed J. S. Jennings, at Bay City.

W. G. Johnston, master mechanic of the Newark division of the Baltimore & Ohio, Western Lines, at Newark, Ohio, has been appointed general master mechanic of the

Northwest district, with headquarters at Cleveland, Ohio, succeeding W. Malthaner.

A. M. Meston has been appointed district road foreman of engines and oil burning inspector of the Southern Pacific, with headquarters at Los Angeles, Cal., succeeding F. W. Corcoran, assigned to other duties.

H. L. Moore, road foreman of engines of the Southern Pacific at Tucson, Ariz., has been appointed road foreman of engines of the Coast division, Southern Pacific, with headquarters at San Francisco, Cal., succeeding C. H. Holdredge.

Franklin E. Cooper, shop superintendent of the Baltimore & Ohio Western Lines at Newark, Ohio, has been appointed master mechanic with headquarters at Newark, to succeed W. D. Johnson. Mr. Cooper was born on October 22, 1882, at Connellsville, Pa., and was educated in the public schools at McKees Rocks, Pa., and at Pittsburgh High School. His railroad service dates from February 1, 1903, when he took employment with the Pittsburgh & Lake Erie at McKees Rocks as a machinist apprentice, later being employed there as machinist. Afterwards for a time he was material inspector for the New York Central, but subsequently returned to the Pittsburgh & Lake Erie as apprentice instructor at McKees Rocks, and was later assistant machine shop foreman and then machine shop foreman. On April 16, 1916, he accepted a position with the Baltimore & Ohio as general foreman of the Newark shops, being appointed superintendent of shops on February 1, 1917. On August 1, 1919, the positions of master mechanic and superintendent of shops were combined, and Mr. Cooper was appointed to the position with the title of master mechanic, having jurisdiction over the locomotive and car departments of the Newark division.

F. E. Cooper

SHOP AND ENGINEHOUSE

J. C. Brekenfeld has been appointed shop supervisor of the St. Louis-San Francisco, with headquarters at Springfield, Mo., succeeding A. J. Devlin.

John J. Davis, general foreman of the machine shops of the Pennsylvania at Philadelphia, Pa., has been transferred to Altoona, succeeding Henry S. Schum, assigned to other duties because of illness.

PURCHASING AND STOREKEEPING

W. W. Blowney has been appointed assistant purchasing agent, in charge of purchases and stores, of the Toledo, St. Louis & Western and the Detroit & Toledo Shore Line, with headquarters at Toledo, Ohio.

G. V. Booth, storekeeper of the Detroit, Toledo & Ironton, has been appointed general storekeeper at Jackson, Ohio.

C. B. Porter has been appointed acting purchasing agent of the Texas & Pacific and allied lines, with office at Dallas, Tex., R. I. Irwin, purchasing agent, having been granted leave of absence.

OBITUARY

Eugene Chamberlain, who recently retired as manager of the equipment clearing house of the New York Central lines, died suddenly September 30 at his home in Mt. Vernon, N. Y. Mr. Chamberlain was in his 70th year. He began railroad service in Ohio with the Wabash. Some time after entering the employ of the New York Central he was appointed master car builder of the Western division with headquarters in Buffalo. In 1893 he left railroad service to engage in business, but in 1899 became superintendent of equipment of the Brooklyn Rapid Transit and five years later was called back by the New York Central to the position he held at the time of his retirement. He was a founder and senior past president of the Central Railway Club of Buffalo, past president of the New York Railroad Club and was active in the Master Car Builders' Association and the American Railway Master Mechanics' Association, now known as Section III—Mechanical, American Railroad Association.

E. Chamberlain

Morgan K. Barnum, corporate mechanical engineer of the Baltimore & Ohio, died October 26 at Baltimore, Md. Beginning in 1917, Mr. Barnum acted as assistant to the vice-president of the Baltimore & Ohio, giving special attention to the conservation of materials. He graduated from Syracuse University in 1884 with the degree of A.B., and later received the degree of A.M. After graduation he began work in the shops of the New York, Lake Erie & Western, at Susquehanna, Pa. He soon became machinist and mechanical inspector and two years later general foreman at Salamanca, N. Y. In 1889 he was appointed general foreman of the Louisville & Nashville at New Decatur, Ala., and in September of the following year became superintendent of shops of the Atchison, Topeka & Santa Fe at Cheyenne, Wyo. During the years between 1890 and 1904 he served with the Union Pacific, Southern and the Chicago, Rock Island & Pacific. In 1904 he was appointed mechanical expert of the Chicago, Burlington & Quincy. In April, 1910, he became general superintendent of motive power of the Illinois Central and the Yazoo & Mississippi Valley. He became general mechanical inspector of the Baltimore & Ohio in July, 1913, and in September, 1914, superintendent of motive power, the position he held when he was appointed corporate mechanical engineer.

M. K. Barnum

SUPPLY TRADE NOTES

The Southern Wheel Company, St. Louis, Mo., is considering plans for additions to its plant to cost approximately $400,000.

The American Brake Company, St. Louis, Mo., is planning on erecting a four-story machine shop, at an estimated cost of $225,000.

James S. Hearons has become affiliated with the Gustin-Bacon Manufacturing Company, Kansas City, Mo., as railroad representative.

The Bowen Motors Railway Corporation, Terre Haute, Ind., has completed plans for a plant to produce gasoline-propelled passenger cars.

The Chesapeake Iron Works, Baltimore, Md., have opened an office in the Woolworth building, New York, which is in charge of H. L. Mode.

The Chicago Pneumatic Tool Company, Chicago, on October 1, removed its Birmingham office from 801 Brown Marx building to 1925 Fifth avenue, north.

The name of the Schroeder Headlight & Generator Company, Evansville, Ind., was changed to Sunbeam Electric Manufacturing Company on September 27, 1919.

Horace S. Wilkinson, of Syracuse, N. Y., has been elected chairman of the Crucible Steel Company of America, Pittsburgh, Pa., to succeed Herbert Du Puy, resigned.

T. W. Holt, assistant general manager of the Curtain Supply Company, Chicago, has been elected a director and secretary, in place of William S. Estell, resigned.

Louis J. Schneider has been appointed general sales manager of the Clark Tructractor Company, Chicago. Mr. Schneider is a graduate of Stevens Institute of Technology, Hoboken, N. J., and is a member of the Society of Automotive Engineers, as well as the American Society of Mechanical Engineers. He served in the engineering department of the Hyatt Roller Bearing Company during 1911 and in the sales department from 1912 to 1916; during the early part of 1917 he was sales manager of the Jackson Rim Company, Jackson, Mich., and later in the same year he became sales manager of the Harrison Radiator Company, Lockport, N. Y., which position he resigned to take charge of the sales department of the Clark Tructractor Company.

L. J. Schneider

L. A. Muttart, railroad salesman for the Western Electric Company, Inc., Chicago, with headquarters in that city, has been promoted to manager of the Chicago railroad sales department of that company.

C. N. Replogle has resigned as general manager of the Ralston Steel Car Company, Columbus, Ohio, to become general manager of the new plant of the Timken Roller Bearing Company, Canton, Ohio.

R. H. Brown, Jr., of the St. Louis, Mo., office of the Ingersoll-Rand Company, New York, has been appointed manager of the new offiice of the company in the Sam Houston Life Building, Dallas, Tex.

The Vapor Car Heating Company of Canada, Ltd., with headquarters at Montreal, Que., has taken over the business of the Canadian branch at Montreal of the Vapor Car Heating Company, Inc., of Chicago.

The Vanadium Corporation of America, New York, has bought the property and rights of the American Vanadium Company, and has elected officers as follows: J. Leonard Replogle, president, Merrill G. Baker, vice-president; Lawrence E. Diffenderfer, treasurer, and Edward F. Nickerson, secretary. J. Leonard Replogle was born in Bedford county, Pa., on May 6, 1876, and was educated in the public schools of Johnstown. He entered the employ of the Cambria Steel Company as office boy at the age of 13, and served successively as clerk, shipper, assistant superintendent of the axle department, superintendent of the forge, axle and bolt departments, assistant to the assistant general manager, superintendent of the order department, assistant general manager, assistant to president, and in September, 1912, was elected vice-president and general manager of sales. In February, 1915, he resigned from the Cambria Steel Company to become vice-president and general manager of sales of the American Vanadium Company, and subsequently became president and general manager of sales of the same company. He is also president of the Wharton & Northern Railroad, and chairman of the board of directors of the Wharton Steel Company. Mr. Replogle, during the war, also served as director of steel supplies for the War Industries Board and had conferred upon him recently by the French government the decoration of Chevalier of the Legion of Honor in recognition of the service he rendered for the Allied cause.

J. Leonard Replogle

A. Clark Moore, vice-president of the Safety Car Heating & Lighting Company, Chicago, has resigned to become associated with the Globe Seamless Steel Tube Company, Chicago, with temporary headquarters in that city.

O. A. Phenix, associated with the sales department of the United States Graphite Company, Saginaw, Mich., with office at Birmingham, Ala., has been promoted to advertising manager with office at Chicago, succeeding George A. Cooper.

The Lyon Metallic Manufacturing Company, Aurora, Ill., has opened a New England district sales branch at 161 Devonshire street, Boston, Mass., in charge of J. B. Throckmorton, formerly New York City representative of the company.

The American Car & Foundry Company has purchased two pieces of property adjacent to its plant in Chicago at a consideration of approximately $90,000. One of the properties is 361 ft. by 240 ft. and the other 100 ft. by

240 ft. The company contemplates the building of an addition to the present plant which, together with the rebuilding of the old plant, will cost approximately $2,000,000.

The Rock Island Brake Shoe & Foundry Company, Rock Island, Ill., has been incorporated with $200,000 capital stock to manufacture brake shoes and other railway supplies. The incorporators are Simon Lewis, Hyman Lewis and M. I. Morris.

E. L. Chollman, formerly with the Southern Locomotive Valve Gear Company, has been made vice-president and sales manager of the Paxton-Mitchell Company, Omaha, Neb. Mr. Chollman was born on August 5, 1877, at Omaha, Neb. He entered railway service in 1892 as a machinist apprentice on the Union Pacific at its Omaha shops. From 1897 to 1901 he was machinist on various railroads and from 1901 to 1902 was roundhouse foreman on the Union Pacific, with office at Evanston, Wyo. In 1902, he was appointed assistant general foreman at Cheyenne, Wyo. From 1903 to 1904 he was master mechanic for the La Follette Coal & Iron Railway Company, La Follette, Tenn. In the latter year he was appointed general foreman on the Southern, with office at Alexandria, Va. In 1905 he was appointed general foreman at Danville, Va., and in 1906 was transferred to Greensboro, N. C., which position he held until 1909 when he was appointed superintendent of car shops at Knoxville, Tenn. In July, 1914, he was elected vice-president of the Southern Locomotive Valve Gear Company, Knoxville, Tenn., a position which he held until his recent election as vice-president and also manager of the Paxton-Mitchell Company.

E. L. Chollman

C. E. Hutchison, formerly district representative at St. Louis, Mo., of the La Belle Iron Works, Steubenville, Ohio, has resigned to become associated with the Youngstown Sheet & Tube Company, Youngstown, Ohio, with headquarters at Cleveland, Ohio.

The Armstrong Brothers Tool Company, Chicago, is erecting an addition to the drop forge department, a new building for the hardening and heat treating department and a new reinforced concrete building for the general office, finished stock and shipping department.

G. E. Anderson, formerly assistant to the vice-president of the American Locomotive Company, has been appointed assistant eastern sales manager of the Duff Manufacturing Company, Pittsburgh, Pa., with headquarters at the eastern sales offices, 50 Church street, New York.

The Pollak Steel Company, Cincinnati, Ohio, has appointed the C. A. S. Engineering Company, 790 Woodward avenue, Detroit, Mich., as its representative in the Detroit district, which embraces Michigan and northern Ohio, including the cities of Toledo, Elyria and Cleveland.

Charles H. Small and George F. Shade have established an office in the Monadnock building, San Francisco, Cal., as agents for the Sargent Company, Chicago, auxiliary locomotive device manufacturers. They will also act as agents for other manufacturers of railway specialties.

George R. Woods has resigned from the Allied Machinery Company of America, New York, to become manager of the New York office of R. S. Stokvis & Zonen, Ltd., Rotterdam, Holland. Mr. Woods has been in Europe studying industrial and economical conditions and returns to New York to take up his new duties.

H. V. McKedy, assistant to the vice-president in charge of sales of the American Locomotive Company, New York, has severed his connection with that company. He has been appointed eastern representative of the Glidden Company, Cleveland, Ohio, with headquarters at 636 West Thirty-fourth street, New York.

J. H. Mitchell, who has for some time been manager of sales of the western district for the Pressed Steel Car Company and the Western Steel Car & Foundry Company, with headquarters in Chicago, left recently for Havana, Cuba, to assume the position of executive vice-president of the American Steel Company of Cuba.

Louis W. Ulmer, has been appointed eastern railway sales representative of the Detroit White Lead Works, with office in Philadelphia, Pa. Mr. Ulmer has recently been released from his duties in the United States Marine Corps and was connected with the Detroit White Lead Works before he entered the military service.

C. W. Cross, special railroad representative of the Chicago Pneumatic Tool Company, with office at Chicago, has been appointed manager of western railroad sales with the same headquarters, succeeding L. C. Sprague, who has resigned to become general mechanical inspector of the Galena-Signal Oil Company, with office at Minneapolis, Minn.

Major C. G. Carothers who served in the U. S. Army as captain and major from September, 1917, to September, 1919, has been appointed Chicago railroad representative of the B. F. Goodrich Rubber Company, with headquarters at Akron, Ohio, succeeding F. O. Slutz, promoted. Major Carothers was born on August 31, 1881, at Mattoon, Ill., and was educated in the grade and high schools of his native town. He served an apprenticeship as machinist at Mattoon on the Cleveland, Cincinnati, Chicago & St. Louis, and then worked for a number of western railroads. He subsequently attended Purdue University, Lafayette, Ind., and was graduated as a railway mechanical engineer in 1912. From August of that year to August, 1914, he was mechanical engineer with the Falls Hollow Staybolt Company, Cuyahoga Falls, Ohio. He then served to September, 1917, as senior mechanical engineer with the Interstate Commerce Commission, Division of Valuation, Southern District, with headquarters at Chattanooga, Tenn. In July, 1917, he received a commission as captain in the Engineers Reserve Corps and was called to active service the following September to attend the Second Engineer Officers' Training Camp, American University, Washington, D. C. He subsequently was attached to the 301st Engineers of the 76th Division at Camp Devens, Ayer, Mass., and in January, 1918, was sent to France to report to the general superintendent of motive power, Colonel H. H. Maxfield of the Railway Trans-

Maj. C. G. Carothers

portation Corps. He subsequently served in the railroad yard at Is-sur-Tille as master mechanic and built a shop there, also one at Villa-le-Sex, the advance section ammunition depot. He later served as superintendent of motive power of the 13th Grand Division, with headquarters at Is-sur-Tille.

Fred J. Holden, who has represented B. M. Jones & Co., Inc., New York, for a number of years, has been appointed manager of the railway department. Austin Savage, formerly of Samuel Osborn & Co., Ltd., Sheffield, England, is now located in New York and has been elected secretary and treasurer of B. M. Jones & Co., Inc.

Lawrence A. Rowe, mechanical inspector on the Atchison, Topeka & Santa Fe, with headquarters at Chicago, has been appointed general manager of the Universal Packing & Service Company, with office at Chicago. This company has been organized to manufacture and sell spring journal box packing and in addition will maintain a service department.

The Detroit Star Grinding Wheel Company has been formed by merging the business of the Detroit Grinding Wheel Company and the Star Corundum Wheel Company, both of Detroit, Mich. The officers of the new company are John R. Kempf, president; J. T. Wing, vice-president; F. H. Whelden, secretary and treasurer. Edward N. Dodge, formerly with the Norton Company, Worcester, Mass., has been appointed general sales manager. The company's plant and offices will be at 241-61 Cavalry avenue, Detroit, Mich.

H. W. Ross has been elected vice-president of Templeton, Kenly & Co., Ltd., Chicago, manufacturers of Simplex jacks. In 1916 Mr. Ross was designated as engineer in charge of installing a bureau of standards for the Quartermaster Corps, U. S. A., for the purpose of testing and selecting various motor machine shop tools and accessory equipment for the United States government. In 1917 he was called to Washington to purchase machinery, tools and auto accessories for use of the Motor Transport Corps in France, on August 1, 1917, receiving his commission as captain, later being promoted to major. He went overseas, where he was connected with the Motor Transport Corps in an engineering and purchasing capacity and was later sent to Spain and Portugal in connection with the general purchasing board. After the close of hostilities Major Ross was selected as officer in charge of sales of Motor Transport Corps equipment in connection with the United States Liquidation Commission, and he had charge of the appraisal and selling of the vast quantities of motor cars, trucks, motor cycles and machinery that the government had accumulated in France. Major Ross returned to the United States on September 15, and at his request was mustered out of the service soon thereafter. His new work covers the general sales management of Simplex jacks, and he will give particular attention to the Simplex pole pulling and pole straightening and special emergency jacks used by steam and electric railways and other public utility companies.

H. W. Ross

CATALOGUES

Forging.—A series of pamphlets entitled National Forging Machine Talks is being distributed by the National Machinery Company, Tiffin, Ohio. No. 36 describes a method of forming the eyes on brake hangers.

Curtain Fixtures.—Bulletin F-1, published by the Curtain Supply Company, New York, describes and illustrates the action of the ring curtain fixtures developed by this company and contains sketches showing standard types of open and enclosed grooves to aid in selecting the proper style of ring fixture.

Electric Arc Welding.—The Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., has issued Circular No. 7149, covering the process of electric arc welding and the necessary apparatus required. A comparison is made of the different processes of welding and the advantages of electric arc welding are pointed out.

Care of Electric Hoists.—Facts for Operators of Electric Hoists is the title of a four-page pamphlet published by the Electric Hoist Manufacturers' Association, New York, for the guidance of electric hoist operators. It deals with such matters as connections, lubrication, and the care of the motor, controllers and ropes.

Asbestos.—The Magnesia Association of America, Philadelphia, Pa., is now publishing a monthly booklet which is devoted to the interests of the asbestos and magnesia industries. The magazine is known as "Asbestos" and contains information regarding market conditions and prices, and articles on subjects of special interest to users and manufacturers of asbestos and allied products.

Steel Treating. — Detailed instructions for treating Colonial tool steel and tools have been compiled as the result of experience, by the Colonial Steel Company, Pittsburgh, Pa., and published in a booklet entitled The Colonial Tool Steel Treating Book. In addition to the directions for hardening and treating, the book contains a complete list of tools with the grades of Colonial steel best adapted for their use, with a separate list of railroad tools.

Feedwater Heater.—Bulletin 5 of the Locomotive Feed Water Heater Company, New York, is a complete treatise on the application and operation of the Type *E* locomotive feedwater heater developed by this company. A colored chart shows how the heater performs its functions and is arranged to show in a graphical manner just where all of the heat that comes from the burning coal on the grates of the locomotive is distributed and its amount at various points throughout the route between the fuel bed and the top of the stack. A sectional drawing shows the arrangement of the equipment on a locomotive, with all pipe connections.

Welding Locomotive Fireboxes.—The Air Reduction Sales Company, New York, has prepared and published a 40-page booklet, No. 4, describing the Airco process of oxy-acetylene welding as applied to locomotive firebox welding instead of riveting. The booklet is designed to help the operator by showing him the proper methods to follow when welding a firebox. It describes the operations necessary for full and semi-welded side sheets, cracks in side sheets, full welded door and flue sheets, patches on fireboxes and flue sheets, patches on mudring, welding of door collars and door holes, building up worn edges of fireboxes, etc. The different operations are very clearly illustrated by full page drawings.

Railway Mechanical Engineer

Volume 93 — December, 1919; Issued December 30, 1919 — No. 12

CONTENTS

THE STORY WRITING CONTEST

In the November issue of this publication a story writing contest was announced which any one in the railroad field is eligible to enter.

The type of story desired must depict the romance of railroad life or deal with the problems that arise in the shops or yards, on the road, or in the office. The writer need not offer a solution of the problem he may describe—though that would be desirable—but should set forth as clearly as possible the thought he wishes to bring out; others may find the solution.

Literary finish is desirable, but the merits of a story will be judged more by the presentation of the subject and the clearness with which the action is described or the characters portrayed.

These stories may be told in as many words as are necessary to tell the tale properly, but if it is feasible they should range from 1,200 to 2,500 words.

The contest closes on April 1, 1920. In addition to paying at our regular space rates for any stories deemed suitable for publication, the writer of the story adjudged to be the best will receive a first prize of $75, the second $50 and the third $25.

Deflection of Staybolts

In an article appearing elsewhere in this issue, George L. Fowler describes a series of tests conducted to determine the action of the firebox sheets and the resulting deflection of the staybolts in locomotive boilers. The tests demonstrate the superiority of the flexible staybolt over the rigid bolt. The effect of changes of temperature on the firebox sheets, not only proved the absolute necessity of a flexible construction, but also suggests a line of study as to the effect—on the firebox sheets—of the opening of the firedoor for the purpose of firing. A careful study of the data covering these tests will show the desirability of further investigation of this subject and it is to be hoped that the work will be continued.

Failures of Welded Firebox Seams

The annual report of the chief of the Bureau of Locomotive Inspection calls attention to several serious failures which occurred in fireboxes having seams welded by autogenous processes. The examples cited bring out very clearly that while low water was directly responsible for the failures, the welded seams apparently gave way at a lower temperature than riveted seams, causing more extensive rupture with consequent greater damage, which no doubt contributed to the increased number of deaths due to boiler explosions. It will be conceded that the safety of men operating the locomotive is of prime importance and no method of construction should be used which increases the hazard due to low water. For this reason the recommendation for limitation in the use of autogenous welding in boilers must be carefully considered. Before discarding the practice, however, it would be well to give a thorough test to methods of examination of welds to determine the quality of the metal added, which have been developed during the past year to a point where they will serve as a fairly reliable indication of the strength of the seam.

If this method does not prove satisfactory it is possible that minor changes could be made in the construction of the firebox to lessen the explosive force of the escaping steam. It has been the practice on some roads to install several rows of crown stays with small heads at the front of the crown sheet. In case the sheet became overheated these stays would offer little resistance and the sheet would bag before the water level fell any great distance. This has been found to be a satisfactory method of reducing the violence of boiler explosions and a similar type of construction used in connection with welded seams might overcome the objections mentioned in Mr. Pack's report.

The Shop Employees' Wage Agreement

The agreement covering wages and working conditions, which went into effect in October includes some remarkable provisions. No one can deny the justice of having definite rules to govern the practices in shops and these are on the whole not open for serious criticism. In the classification of the employees, however, the policy of placing the skilled and unskilled workers on the same basis has prevailed, with evident injustice to the more highly skilled men. Apparently an effort has been made to broaden the scope of the work assigned to each craft as much as possible. As a result, a tool maker and the operator of a tool grinder are placed in the same class. The valve setter and the man who removes superheater units from the front end receive the same rate of pay. It is hardly clear why the work of removing parts from cars to be dismantled should demand such special skill that carmen are required to handle it. On the whole the agreement seems to provide plenty of positions on the railroads for inferior mechanics, but little to attract the better class. The rule specifying that applicants for employment will be required to make statement only as to their ability and the addresses of relatives apparently furnishes abundant opportunity for undesirables of all kinds to enter railroad service.

The rigid application of the seniority rule, with the provision for posting bulletins concerning vacancies, removes from the foreman the right to select the men best fitted for the work. The only assurance provided is that the workman must be able to meet the minimum requirements of the position. Such abrogation of one of the very important functions of the foreman can hardly fail to have a bad effect upon the supervision. Some of the provisions of the agreement result in increasing the actual hourly rate of pay to a considerable extent. All employees required to check in and out on their own time are paid for an extra hour each week. Where three shifts are employed, 20 minutes are allowed for lunch without a corresponding deduction from the wages. In case a machinist worked an eight-hour shift for seven days a week, these two rules would increase the hourly rate of pay from 72 cents to 76.4 cents, or over six per cent. With the large number of employees working in roundhouses this increase in the pay-roll is quite appreciable.

Should the Front Waste Plug Be Retained

For some time a number of railroads have had in use a method of packing journal boxes without the use of the plug which is ordinarily placed at the end of the journal. Those who have been active in securing the adoption of this method of packing journal boxes claim that by its use a saving of 15 per cent in oil and waste is effected and better lubrication is obtained. The practice has not been in sufficiently general use to determine conclusively whether these claims are borne out in practice.

It would no doubt be feasible to operate cars with very small pads of waste under the journal if the cars were given attention at short and regular intervals. The question arises whether the elimination of the front waste plug necessitates more frequent inspection and setting up of the packing. Those who still adhere to the use of the front waste plug claim that it serves as an extra reservoir of oil, assists in keeping the dirt out and prevents the waste from working forward when the car is in motion. Considerable trouble has been experienced on cars packed without the front plug, due to the packing working forward, causing the inner end of the journal to become dry and heat. Some attempt has been made to standardize the method of packing without the front plug. If the operating results are as satisfactory as those secured by the former method this would no doubt be desirable. Delays due to hot boxes are so serious and costly that this method should be subjected to long and thorough trial before it is adopted as a standard practice.

Watch the Brake Shoes

The braking of modern railroad trains is so important a subject and the cost of the brake shoes such a large item in railroad expenditures that the use of brake shoes must be given very careful attention to keep the costs within reasonable limits. As the most efficient brake rigging ever made can function only through the brake shoe, which comes in contact with the wheel, it is obvious that the composition and use of the brake shoe is a vital matter. With the high speeds and heavy equipment in use at the present time the brake shoe not only must possess high frictional qualities, but must be of such texture and be reinforced in such a manner that it will also be durable and safe. By long experiment these desirable qualities have been attained in a very high degree.

The cost of the type of brake shoe required for the average service is considerably in excess of that of an ordinary plain casting and it is incumbent on those men who apply them to get the greatest possible wear from each brake shoe before it is sent to the scrap pile. An inspection of the brake shoe scrap in almost any railroad yard will reveal great numbers of brake shoes that have been removed and scrapped because of taper wear, with only a small part of the casting worn off in service. This is a condition that can in most cases be remedied by giving closer attention to the wear of the shoes, removing the shoe from the brakehead when the tapered wear becomes apparent, and applying it to another wheel with the position of the shoe reversed. This is particularly true of driving brake shoes, and as the average weight of the type of driver shoe most commonly used is over 50 lb., it is possible to effect a great saving in locomotive brake shoe cost by reversing the shoes before the tapered wear has progressed too far to permit of doing this. Another means of brake shoe conservation is to remove partly worn shoes from the most severe service, where a brake shoe failure might prove disastrous and utilize such shoes on lighter equipment.

These and other means of brake shoe economy are very well known to most railroad men, but unfortunately the brake shoe is too often regarded as a secondary matter and is not given the attention that its importance merits. That it pays to give close attention to brake shoe wear was proved on at least one railroad, where in the course of a year the brake shoe costs were reduced many thousands of dollars without any appreciable increase in the labor cost of application. This result was achieved, despite the fact that there was a very considerable increase in both the number and size of the rolling stock.

The foremen at roundhouses and terminals should be on the alert and by close attention to the application and removal of brake shoes should keep the consumption at the lowest possible figure.

Car Department Apprentices

The provisions for apprentices in the car department are not sufficiently attractive as compared with the rules for apprenticeship in the other crafts to make car work attractive to young men, and it is doubtful whether the railroads will find it possible to recruit the necessary number of car department apprentices under these rules.

The rate of pay in the car department is lower, yet the length of apprenticeship is the same as in the other trades. Even if a young man for some reason preferred to enter the car department it would be to his advantage to enter as a helper apprentice, where he would receive 49 cents an hour instead of the 29-cent rate paid the regular apprentices. The helper apprentice, to be sure, is required to spend five years before he is rated as a mechanic, but the compensation is so much greater that it would more than offset the disadvantage of the longer apprenticeship. Those who framed the agreement apparently realized that there would be difficulty in securing apprentices in the car department and a special provision has been made for promoting helpers if necessary. The need of apprentices in the car department is becoming more generally recognized and if the present schedule operates as is anticipated it is to be hoped that service in the car department will be made more attractive for those who desire to enter apprenticeship courses.

Draft Gear for High Capacity Cars

The performance of freight cars of unusually high capacity has proved so satisfactory from an operating standpoint on the roads where they have been tried that this type is finding much favor and it is probable that cars with capacities of approximately 100 tons will be built in considerable numbers when the railroads again enter the market for equipment. With any such radical increase in the size of the unit there are important points in design to be worked out and the question naturally arises whether some of the standards developed for smaller cars will serve satisfactorily on cars of such high capacity. In some cases it is possible to increase the number of parts used, thereby keeping down the stresses to which each unit is subjected. Where the maximum journal capacity of eight pairs of wheels is not sufficient to carry the load six-wheel trucks have been used and other difficulties can be met in a similar manner.

One of the important appliances used on freight cars which is limited in size because of standard dimensions is the draft gear. With heavier cars greater draft gear capacity will be needed and it is doubtful whether the necessary capacity to absorb shocks can be obtained within the present narrow space restrictions. No satisfactory tandem arrangement of friction draft gear has been devised, and if it could be developed it is doubtful whether its use would be advisable, due to the difficulty of inspection. Under certain circumstances one gear might be placed above the other, but this would raise the floor level and therefore could be applied only to certain types of cars.

It would seem that the first change that should be made in adapting draft gears for higher capacity cars would be to increase the travel to approximately four inches. This extra travel should not be objectionable because the large size of the cars reduces the number of units in the train. This would offer an opportunity for increasing the capacity of the gear approximately 75 per cent. Even with the increased travel the large amount of work to be absorbed might cause unduly rapid wear of the gear. If this proves to be the case it would be advisable to increase the space between the center sills and possibly also the distance between the front and rear coupler stops.

An incidental advantage to be gained by wider spacing between the center sills would be greater angular movement of the couplers. The present spacing allows very little side play for the coupler shank and in rounding curves the coupler often bears very heavily against the sides of the striking casting. In fact, the stresses set up are sometimes sufficient to bend the coupler shank. In designing long cars provision should be made for greater angular movement of the coupler. This can only be provided by an increase in the distance between the center sills.

Machine Shop Limits Output

That the output of practically every locomotive repair shop is limited by its machine shop capacity no one familiar with the conditions will be likely to deny. Should there be a doubt on this point it can be set at rest by even a casual inspection of the average railway machine shop. In most shops the floor is so congested with motion work and running gear parts in various stages of repair that it is difficult to pass from one machine to another. The link job, in particular, is usually behind, with link hangers, trunnion blades, radius bars and combination levers everywhere in evidence and all waiting for machine work. Perhaps the rod job has been "caught up" but the unexpected receipt of four or five sets of rods from the roundhouse, (marked "rush") places this work hopelessly in arrears again. The wheel and driving box job is another bugbear and many a locomotive has been delayed in the shop one or more days due to late wheeling.

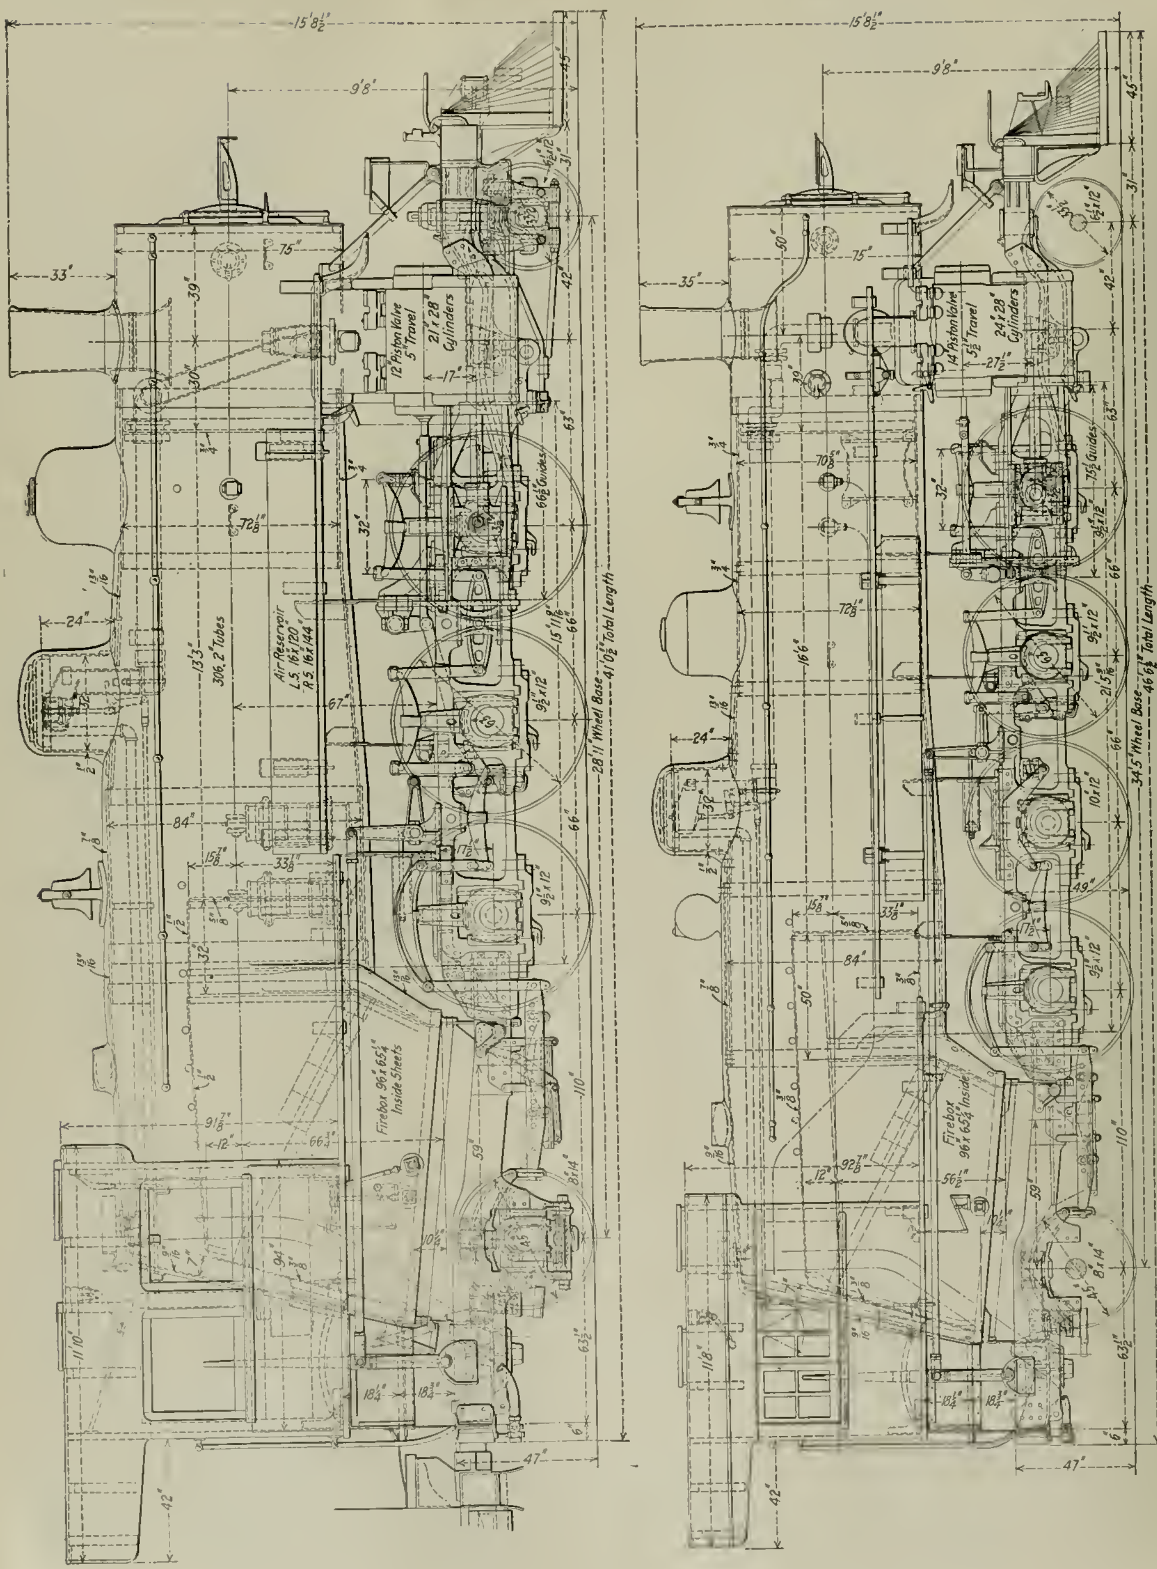
With an increase of 57 per cent in freight traffic alone in the past four and one-half years, it is evident that the new business cannot be handled unless locomotives are kept on the road. They cannot be held in repair shops while repairs are made with the present inadequate machine shop equipment and facilities, consequently the number held in roundhouses for heavy work is rapidly increasing. It is hoped that Congress in turning the roads back to their owners will make arrangements that will permit the roads to finance improvements and bring all their equipment up to the standard necessary to take care of the increased business.

Not only is it essential to provide increased machine tool equipment; machine foremen can help out the situation by keeping posted on improved methods and using what machines they have to the best advantage. Are they doing this? It is generally conceded that driving box shoes and wedges should be machined on a horizontal miller, but many shops are still planing them. Slightly worn guides should be trued up by grinding, but here again the planer is used, which requires more time for a poorer job. Such modern machines as are already installed should be used to their utmost capacity and in addition new machinery must be purchased in the near future or the country's industries will be seriously handicapped by the lack of motive power.

NEW BOOKS

Applied Science for Wood-Workers. By W. H. Dooley, 446 pages, 5¼ in. by 7½ in., illustrated, bound in cloth. Published by the Ronald Press, New York.

The purpose of this book is to provide an elementary course in applied science for the woodworking trades to bridge over the gap between the abstract knowledge of the principles of science acquired by the average high school student and the practical application of these principles in industrial life. The book is a compilation of considerable generally known data, supplemented by knowledge gained through practical experience. Of particular interest to woodworkers are the chapters on trees, lumber, defects of wood. In addition the book treats in a clear and concise manner of woodworking tools and their uses, modern foundry methods, heating, ventilating, paints and varnishes, electricity and other subjects, which although not directly related to the woodwarking trades, are of value to anyone engaged in mechanical pursuits. A series of questions and problems at the end of each chapter serves to bring out the salient points of each subject and to test the student's power of concrete application of the principles set forth in the text.



Elevation of the Mikado Type and the Prairie Type from Which It Was Built

Changing Prairie Type to Mikado

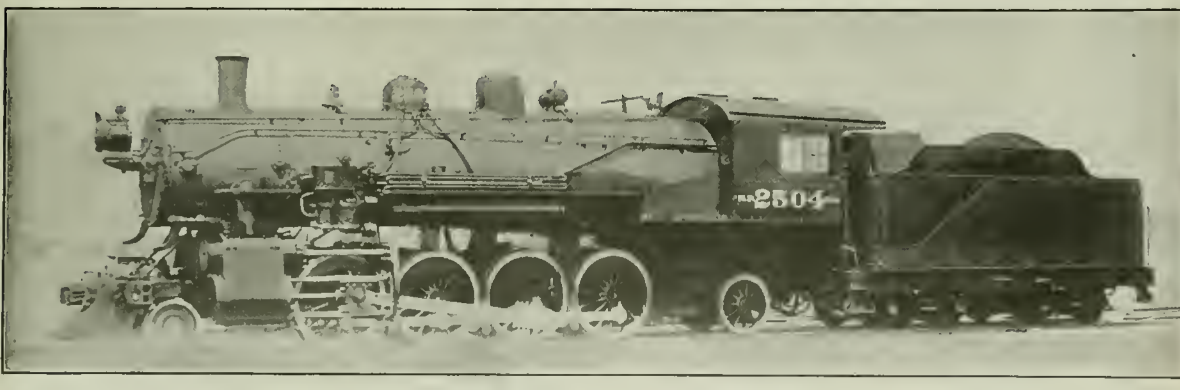
Redesigned Boiler Gives Higher Efficiency and Ample Steaming Capacity for Larger Cylinders

Among the equipment owned by the Northern Pacific there is a considerable number of locomotives of the Prairie type which were built about the year 1906. As these engines used saturated steam and had a rated tractive effort of 33,300 lb., they were not economical units for through freight service as regards either fuel or train loads. With a view to improving the performance of the engines and prolonging their period of usefulness, the operating department considered the advisability of converting them to the Mikado type. Plans were accordingly made in 1914, and six locomotives were changed at the Brainerd, Minn., shop in 1918 and 1919.

Northern Pacific Prairie Type Locomotive, Class T

The Prairie type locomotives had a total weight of 204,500 lb. and a tractive effort of 33,300 lb., while the Mikados weighed 249,000 lb. with 40,300 lb. tractive effort. In working out the alterations to be made, the original parts of the machinery and running gear were retained as far as possible. The addition of a fourth pair of driving wheels made new main frames necessary. The increased tractive effort desired called for larger cylinders and, to take care of the greater stresses, cast steel frames of larger section were designed. The engines as originally built had a short rigid wheel base, and the distance from the transverse center of the cylinder to the front axle was unusually short for locomotives of the Prairie type. It was, therefore, possible to keep the same dimension from the cylinder to the front driving wheel and also to retain the uniform spacing of 66 in. between the centers of the drivers. Since the weight per driving axle remained practically unchanged, no greater stresses were introduced in the equalizing system and the same springs, equalizers and hangers were used on the Mikado engine with the additional parts required to take care of the extra wheel. On both engines the equalizing system is divided between the second and third pair of drivers.

The cylinders on the Prairie type, or class T engine, were 21 in. by 28 in., but on the Mikado, or class W-4, they were enlarged to 24 in. by 28 in. with outside steam pipes. In order to provide for the greater piston thrust, the main axle was made 10 in. in diameter, but on the other wheels the original 9½ in. axle was retained. The piston rod was made 3½ in. longer and the main rod was shortened the same amount. As the position of the center line of the valve chamber was changed, a new rocker was made for the valve gear. The valve travel was also increased from 5 in. to 5½ in.



Mikado Type, Class W-4, Rebuilt from Class T

In changing the boiler the original barrel was retained, and a new front course and an enlarged smoke box were added. The increase in the length of the frame, as before mentioned, was 66 in. The space required for the superheater header made it necessary to set the front tube sheet

9 in. farther back from the center line of the stack. The remaining 57 in. was utilized by adding 39 in. to the length of the tubes, making them 16 ft. 6 in. long, and by increasing the length of the combustion chamber from 32 in. to 50 in. The brick arch was retained in its original position and no other change was made in the firebox. A superheater with 28 elements was added which, with the other changes, increased the equivalent heating surface from 2,359 sq. ft. to 3,186 sq. ft.

A comparison of the ratios of the class T and class W-4 is of particular interest in view of the restrictions placed on the design of the Mikado due to the necessity of conforming to many of the main dimensions of the Prairie type. The tractive effort was increased not in the same ratio as the weight on drivers but in the same ratio as the total weight, or about 21 per cent. The extension of the boiler barrel in a saturated engine would have increased the heating surface about 20 per cent, but with the addition of the superheater the equivalent heating surface was raised 35 per cent. The benefit of this change is shown by the decrease of the total weight per square foot of heating surface from 86.7 to 78.2 and the increase in the square feet of heating surface per cubic foot of cylinder volume from 210.6 to 217.9 square feet.

Excellent operating results have been secured with the new class W-4 engine. They have been placed in service on the division between Glendive and Billings, Montana, where the heaviest ruling grade westbound is 26 ft. per mile. In this direction the rating of the Prairie type is 1,600 tons, while the rating for the Mikado is 2,600 tons, an increase of 62 per cent. On the eastbound movement the length of the trains is controlled by the passing siding, and the ratings for the two types are as follows: From Billings to Forsyth, class T, 2,900 tons; class W-4, 3,400 tons; from Forsyth to Glendive, class T, 2,800 tons; class W-4, 3,300 tons.

The improvements in the smoke box were designed to overcome the trouble of throwing sparks. With the class T engines this has been very annoying in the past, particularly when used in the district where semi-bituminous coal is burned.

The converted engines ride much easier than the Prairie type and, because of the better load distribution, are much easier on the track.

An additional advantage secured by the conversion to the Mikado type is uniformity of train loads on several divisions. The heavier Mikados in use on the Northern Pacific have tractive efforts of 46,000 lb. and 57,100 lb. and, in conjunction with the class T and class W-4, provide motive power units adapted for hauling approximately equal tonnage on lines where the grades vary widely, thus facilitating through movement without breaking up trains at division points.

For the purpose of comparison the principal dimensions, weights and ratios for the two types of locomotives are as follows:

	Class T 6-3-2	Class W-4 2-8-2
General Data		
Gage	4 ft. 8½ in.	4 ft. 8½ in.
Service	Freight	Freight

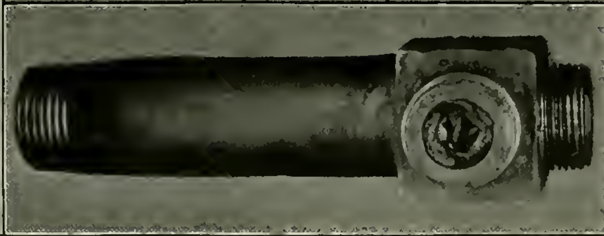
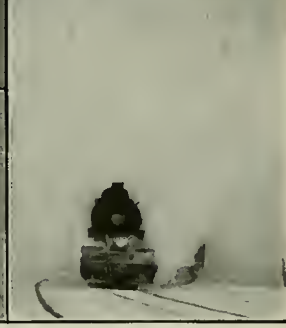
I. C. C. Locomotive Inspection Report

Disastrous Results of Low Water in Welded Fire-Boxes Blamed for Increase in Fatal Accidents





The eighth annual report of the chief inspector of the Bureau of Locomotive Inspection, which covers the year ending June 30, 1919, has recently been published. Tables I to IV show the number of locomotives inspected and the defects found. As the amendment to the boiler inspection law, extending its scope to include the entire locomotive and tender and all appurtenances, did not become effective until September 4, 1915, the record of the

Water Glass Cock Opening Almost Closed by Scale

fiscal year ended June 30, 1916, includes accidents and casualties for only nine months and 26 days.

Table I—Comparative Statement Showing Locomotives Inspected and Number Found Defective

	1919	1918	1917	1916
Number of locomotives inspected	59,772	41,611	47,542	52,650
Number found defective	34,557	22,196	25,909	24,685
Percentage found defective	58	53	54.5	47
Number ordered out of service	4,433	2,125	3,294	1,943
Total defects found	135,300	78,277	84,883	71,527

Table II—Number of Accidents, Number Killed and Number Injured

Result of Explosion Caused by Low Water. Welded Seam Between Crown and Side Sheets Gave Way

a decrease of 11.8 per cent in the number of accidents, an increase of 23.9 per cent in the number killed, with a decrease of 14.4 per cent in the number injured, as compared with the year ended June 30, 1918.

A summary of all accidents and casualties, caused by the failure of the locomotive boiler and its appurtenances only, for the fiscal year ended June 30, 1912, which was the first year of the existence of the law, compared with a summary of all accidents and personal injuries which occurred during the fiscal year ended June 30, 1919, shows the substantial decrease in the number of accidents, due to such failures, of 60.2 per cent; a decrease in the number of persons killed of 50.5 per cent, and decrease in the number injured of 58.9 per cent.

FAILURES OF AUTOGENOUS WELDS IN FIREBOXES.

It will be noted from Tables II and IV that the number of fatalities due to locomotive failures has not been reduced in proportion to the number of accidents. This fact is commented on as follows:

The increase in the number of persons killed during the last year, over the year previous, is, to a considerable extent, due to some very violent explosions which occurred because of fire box crown sheet failures, which serve to illustrate the prime importance of proper fire box construction, inspection and repair, together with the location, inspection and maintenance of such appliances as water glasses, gage cocks, injectors, steam gages and safety valves, upon which to a very great extent, rest the safety of locomotive boiler operation.

While some of these explosions were primarily caused by low water, it is believed that their violence and consequent results were greatly increased by failure of crown sheet seams which had been welded by the autogenous process. The failure of such seams, which have come into extensive use during the past few years, in most cases evidently caused the initial rupture and, in some cases, occurred with slight overheating.

Investigation of these accidents indicated that the failure of the welds occurred with a higher level of water in the boiler, and consequently a lower temperature in the sheet, than in other cases where the crown sheets failed and did not tear.

It will be recognized that the force of a boiler explosion depends upon the extent and suddenness of the initial rupture, together with the volume and temperature of the water in the boiler at the time of explosion. This feature is clearly brought out in the illustrations showing fireboxes which have failed in actual service.

It is true that not all autogenously welded fire box seams fail at the time of boiler explosion, but inasmuch as our records show that 80 per cent of all such welds involved have failed under such conditions, it is believed that, until

Dropped Crown Sheet Due to Low Water, Showing Failure of Welded Seam

some way has been discovered through which the quality and tenacity of a weld so made may be established in advance of its failure, fire box crown sheet seams so constructed should be avoided, where overheating and failure are liable to occur, and that autogenous welding should not be used where the strength of the structure is dependent upon the weld, nor where the strain, to which the structure is subjected, is not carried by other construction; nor in any part of a locomotive boiler wholly in tension while under working conditions.

It has been our purpose to co-operate with the United States Railroad Administration and the officials of the various carriers to the fullest extent consistent with our duties and the purpose of the law, and avoid as far as possible being compelled to order locomotives removed from service for unsafe conditions at a time when traffic might be seriously delayed. The fact that not a single formal appeal from the decision of any inspector, as provided for in section 6 of the law, has been filed during the fiscal year clearly demonstrates the wisdom and good judgment that has been exercised by them.

During the year, 198 applications were filed for an extension of time for the removal of flues, as provided for in rule 10. Investigation showed that, in 28 of these cases, the condition of the locomotives was such that no extension could properly be granted. Twenty-two were in such condition that the full extension requested could not be granted, but an extension for a shorter period within the limits of safety was allowed. Eleven extensions were granted after defects disclosed by our investigation had been repaired. Twenty-eight applications were withdrawn for various reasons, and the remaining 109 applications were granted for the full period as requested.

As provided in rule 54, there were filed 3,324 specification cards and 5,949 alteration reports. These were carefully checked in order to determine whether or not the boilers represented were so constructed as to be in safe and proper condition for service, and that the stresses given therein had been correctly calculated. The provisions of rule 2, by which all boilers are required to have a factor of safety to meet the requirement, has made necessary the strengthening of various parts of numerous boilers.

LOCOMOTIVE HEADLIGHTS

Substantial progress has been made in equipping locomotives with lights which will meet the requirements of the commission's orders of December 26, 1916, and December 17, 1917. The effective date of the commission's orders was fixed as of July 1, 1918.

Notwithstanding the strenuous oppositon offered by certain carriers to the promulgation of these requirements, these lights are meeting with the general approval of the employees who are employed where locomotives are so equipped; and the general expression is that "they are a great safety device." A number of the railroad officials, under whose jurisdiction these lights are being operated, have expressed their opinion that "they are economical and add materially to the safety of operation."

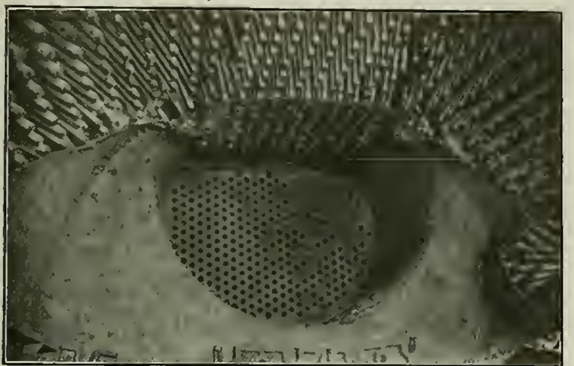
Under the order of the commission of April 7, 1919, certain modifications in the rules, which were granted in their order of September 20, 1917, because of conditions brought on by war, were abrogated, and others substituted. Experience had demonstrated that certain modifications, granted in the commission's order of September 20, 1917, could be made permanent, without adversely affecting the safety of operation; therefore, such modifications were retained in the permanent rules.

BOILER EXPLOSIONS

It is interesting to note that during the fiscal year ended June 30, 1912, there were 97 boiler explosions from all causes, resulting in the death of 81 persons and the serious injury of 209 others, while during the last year there were 67 explosions, resulting in the death of 39 persons and the serious injury of 112 others. These reductions amount to 30.9 per cent in the number of explosions, 51.8 per cent in the number killed, and 46.4 per cent in the number injured.

Attention is also directed to the fact that, since the inception of this bureau, 516 boiler explosions have occurred, resulting in the death of 277 persons and the serious injury of 889 others.

Five of these explosions, resulting in the death of 29 persons and serious injury of 50 others, were due to failure of shell sheets, caused by overpressure or defective sheets, which could have been detected and their failure avoided by proper inspection and repairs; 289, causing the death of 156 persons and the serious injury of 486 others, were due to failure of crown sheets, caused by low water, and where no contributory defects were found; 195, resulting in the death of 83 persons and the serious injury of 317 others, were due



Failure in Wootten Type Firebox Due to Low Water. Riveted Seam at Tube Sheet Intact, Welded Seam Failed

to failure of crown sheets caused by low water and where contributory defects, constituting violation of the law or rules, such as defective water glasses, gage cocks, injectors, broken stays or crown bolts, etc., were found; 22, causing the death of 4 persons and the serious injury of 31 others, were caused by failure of firebox sheets, due to defective or broken staybolts or crown stays; 5, causing the death of 5 persons and the serious injury of 5 others, were due to foaming of the water in the boiler, allowing the firebox sheets to become overheated.

Investigation showed that in 19 of the explosions which occurred during the last year, due to low water, defective water glasses and connections contributed to the cause of such failures, which fact clearly demonstrates again the importance of properly locating and maintaining such parts before placing boilers in service.

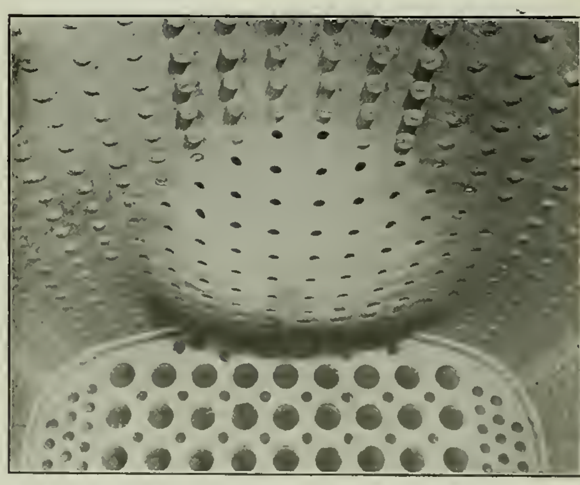
PRINCIPAL CAUSES OF ACCIDENTS

Our records show that during the past eight years, failure of squirt hose and their connections caused 976 accidents, resulting in the death of one person and the serious injury of 984 others; failure of 362 flues caused the death of three persons and the serious injury of 425 others; failure of 511 water glasses or their connections caused the death of one person and the serious injury of 515 others; failure of 148 grate-shaking appliances resulted in the death of one person and the serious injury of 147 others.

It is a physical impossibility for 50 inspectors to inspect at regular intervals and be familiar with the condition of any large percentage of 69,000 locomotives. The law places the responsibility for the general design, construction, and maintenance of all locomotives and tenders upon the carriers owning or operating them. It appears, however, that many officials and employees of the carriers, who are responsible for the inspection and repair of locomotives, have tried to evade this responsibility, and have, apparently, endeavored to transfer it to the federal inspectors, by allowing locomotives to remain in service with serious violations of the law and rules known to them, until our inspectors found them and caused the locomotives to be removed from service for needed repairs. The data shown in this report should impress the necessity of proper performance of duties upon those who are required to inspect and report defects on locomotives, as well as upon those who are responsible for the proper repair of such defects.

CHANGES RECOMMENDED

The following recommendations are made for the betterment of the service: First. That the act of February 17, 1911, be amended so as to provide for at least 50 additional inspectors. Second. That all locomotives not equipped with mechanical stokers or those using oil for fuel shall have a mechanically operated fire door, so constructed that it may be operated by pressure of the foot on a pedal, or other suitable device, located on the floor of the cab or tender at a proper distance from the fire door so that it may be conveniently operated by the person firing the locomotive. Third. That a power-reversing gear be applied to all locomotives and the air-operated power-reversing gear have a steam connection with the operating valves conveniently located in the cab, so arranged that, in case of air failure, steam may be quickly used to operate the reversing gear. Fourth. That a power grate shaker be applied to all coal-burning locomotives. Fifth. That all locomotives shall be provided with a bell, so arranged and maintained that it may be operated from the engineer's cab by hand and by power. Sixth. That cabs of all locomotives not equipped with front doors or windows of such size as to permit of easy exit shall have a suitable stirrup or other step and a horizontal handhold on each side, approximately the full length of the cab, which will enable the enginemen to go from the cab to the running board in front of it—handholds and steps or stirrups to be securely attached with bolts or rivets; the distance between



Typical Bagged Crown Sheet in a Firebox with Riveted Seams

the step and handhold to be not less than 60 in. nor more than 72 in.

In conclusion the report recommends that these appliances should be applied to all new locomotives before they are placed in service, that locomotives now in service without such appliances should be so equipped the first time they pass through the shop for classified repairs, as specified by the United States Railroad Administration, and all locomotives in service should be so equipped within a reasonable time.

CONVERTING CROSS COMPOUND LOCOMOTIVES TO SIMPLE

During the years 1905 and 1906 the Minneapolis, St. Paul & Sault Ste. Marie purchased a considerable number of cross-compound locomtives of the Consolidation type. These engines were among the heaviest of their class at the time they were built, the total weight in working order being 101 tons. At the present time they are still used in through freight service and in order to eliminate the unsatisfactory features of the compound, one of the class was recently converted into a simple locomotive using superheated steam. Tests conducted to determine the relative fuel consumption of the compound and the simple superheated engine showed that the change in the design resulted in a substantial saving of fuel.

For the purpose of the test two engines were chosen which were in practically the same mechanical condition. Engine 448 was a cross-compound, while engine 468 was superheated with simple cylinders. One engine crew was assigned to the test and was used on all the runs. In order to obtain a close check on the fuel used, approximately the correct amount of coal for the run was weighed and put into the coal space of the tender. An additional supply was weighed out into 100-lb. sacks and was carried on the back of the tender. The fuel used in firing up and before the test started was taken from the sacks and accounted for separately. After the main supply had been burned, sacked coal was used or in case the pit was not emptied, the remainder was removed and weighed. A record of the water used was made by means of a gage each time the tank was filled.

The division on which the test trains were run extends from Moose Lake to Boylston Junction, Minn., a distance of 38 miles. The regular tonnage for the cross-compound locomotives is 90 cars or 1,440 tons and the majority of the trips were made with this tonnage. On two trips with the superheated simple engine, the train was increased to 100 cars of 1,600 tons. Although the increase in the rated tractive effort of the simple over the cross-compound is only six per cent. these runs showed that engine 468 would handle 100 cars better than engine 448 would handle 90 cars. On hauls out of the ore mines, the regular rating for the compounds is 50 cars, but on test trips engine 468 hauled 55, 59 and 60 cars without any difficulty. Another trial run was made from Superior, Minn., to Glenwood, a distance of 200 miles. On this division the tonnage rating for the cross-compound engine is 2,200 tons, but in order to make the trip in less than 16 hours the train must be reduced to from 1,800 to 2,000. With engine 468 a train of 2,157 tons was hauled from Superior to Glenwood in 10 hrs. 7 min. actual running time, making an average speed of nearly 20 miles an hour.

The fuel performance with the two engines on the trips between Boylston Junction and Moose Lake are summarized in the accompanying table.

Engine No.	Test No.	No. of cars	Tonnage	Coal per 1,000 ton miles	Decrease for Engine 468 per cent	Coal per sq. ft. of grate per hour	Actual Evap. per lb. coal	Running time
468	1 and 2	90	1,440	124	13.9	78.0	6.93	1 h 32m
448	5 and 6	90	1,440	144	...	56.5	7.78	2 h 37m
468	3 and 4	100	1,600	128	...	80.0	6.96	1 h 52m

It will be noted that the actual evaporation per pound of coal with the superheated locomotive was 10.9 per cent less than with the saturated locomotive, due no doubt to the reduction in tube heating surface resulting from the application of the superheater. In spite of this, the superheated engine used 13.9 per cent less coal per 1,000 ton miles than the compound saturated engine.

The principal dimensions, weights, and ratios for the original and the converted locomotives are given below:

General Data

	Engine 448 (Cross-compound)	Engine 468 (Simple superheated)
Gage	4 ft. 8½ in.	4 ft. 8½ in.
Service	Freight	Freight
Fuel	Bit. coal	Bit. coal

*Equivalent heating surface = total evaporative heating surface + 1.5 times the superheating surface.

A New Means of Cooling Pistons.—A recent British invention has been made whereby the piston of an internal-combustion engine may be cooled by means of a draft of air circulating through a space in the piston. The draft is provided by means of fan blades on the engine flywheel. On either side of the hollow piston are ports which register with corresponding ports in the cylinder walls at the end of the stroke. A draft of air is thus forced through the hollow space in the piston while all the ports are in line.—*Compressed Air Magazine.*

The High Cost of Tool Breakage.—A complete record of total breakage kept by a far western American steel company shows convincingly the expense of putting good tools in the hands of careless or incompetent workmen and indicates that it is particularly heavy when numbers of new men are being put to work. Even in normal times the company found that the damage in tools is a big problem and it actually happened on one or two occasions that careless men destroyed in a moment tools far in excess of the value of their labor for weeks and months. Before labor turnover became a problem last fall, two tool room clerks with eight assistants easily dispensed the equipment required by 500 men, whereas toward the end of the year 39 were required and 11 men were engaged solely on grinding the tools.—*Scientific American.*

The Deflection of Staybolts

Movement of Sheets of Locomotive Fireboxes; Relative Action of Rigid and Flexible Bolts

BY GEORGE L. FOWLER

For many years the breakage of staybolts in locomotive boilers has been a source of danger and this danger was emphasized very soon after the locomotive took its rapid leap ahead in size when it was found that it was no longer necessary to limit firebox dimensions to the space available between the driving axles and the frames.

The increase in the length of fireboxes caused a corresponding increase in staybolt breakages. It was assumed that this breakage was caused by the bending of the staybolts due to a variation in the expansion of the two sheets which they connected, by which they were strained beyond their elastic

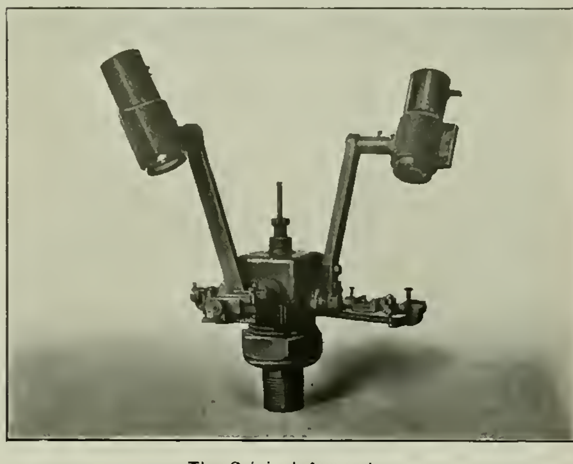
Screen for Recording the Movement of the Beams of Light Reflected by the Mirrors

limits, thus producing a progressive fracture. It was also assumed when the boiler was working under normal conditions that staybolts were straight in their normal position and were subjected only to that stress which would be imposed upon them by the steam pressure acting upon the plates. It was further assumed that the deflection of the bolts occurred during the process of raising steam, and that, because the breakage occurred at the ends of the firebox, there was a neutral vertical zone at the longitudinal center of the firebox along which there was no staybolt deflection. But, while assumptions and theories were as plentiful as autumn leaves, there was no data on the subject and no one knew. The most that had been done, in the way of investigation, was to determine that, under certain conditions, there was an upward and downward movement of the crown-sheet and the tubes.

The object of the investigation described in this article was to determine, by actual measurement, the amount of relative movement between the inner and outer sheets of a locomotive firebox and also when that motion occurred as well as its general character. There was no precedent upon which to proceed nor any thing more than the vaguest of guesses as to the amount of motion to be looked for—except that probably it would be very slight.

The apparatus used was of a very simple character and involved only one moving part. Its work consisted of resolving the motion of the inner sheet relatively to the outer one, into its vertical and horizontal components and projecting them on a screen. These were afterwards recombined to plot this relative movement in the form of a diagram. The mechanism of the apparatus consisted of two small metallic mirrors that were first adjusted to a perfect parallel. A beam of light from a narrow slit was reflected back to a screen. One mirror was fastened rigidly to the outer sheet and traveled with it and remained parallel to it at all times. The main body of the apparatus including all lenses and adjustments was also attached to this same sheet. The second mirror was suspended on the main body of the apparatus but was so connected to the inner sheet that, if any motion took place between the two sheets, the mirror would be rotated. This would cause a separation of the two beams of light on the screen and the amount of separation was a measure of the relative movement of the sheets. The calculation of the motion was simply dependent upon the distance at which the screen was set from the mirrors.

The first setting was such that separation of 1/16 in. indicated a relative movement of 1/20,000 in. between the two plates. This was found to give finer measurements than were needed and the whole of the work, hereinafter detailed, was done with the screen so set that each 1/16 in. separation



The Original Apparatus

of the beams of light indicated a relative movement of 1/6400 in. between the plates.

The first boilers subjected to investigation were of the radial stayed type as illustrated in the accompanying engravings. There were two of them that were identical in construction except that one was fitted with a complete installation of the ordinary rigid staybolts and the other with a complete installation of the Tate flexible staybolts.

The firebox dimensions were:

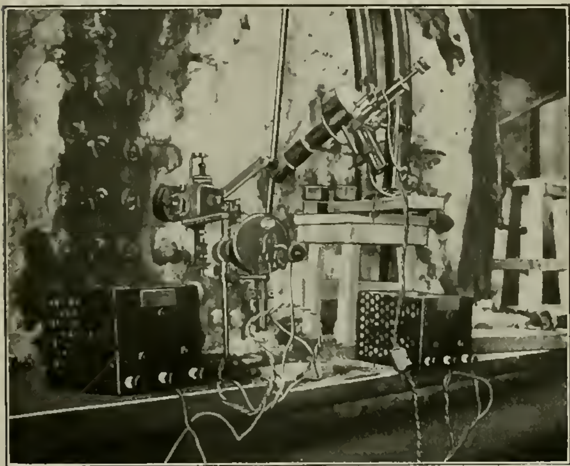
Length at bottom	8 ft. 3 in.
Length at top	8 ft. 8½ in.
Width at bottom	5 ft. 2 in.
Width at top	4 ft. 8 in.

The general arrangement of the apparatus is shown in the illustrations. Each firebox was fitted with four water tubes for carrying a brick arch which was located as shown.

New fireboxes had been placed in each of the boilers immediately prior to the tests so that all of the sheets affected were fresh and clean.

SCOPE OF INVESTIGATION

The scope of the investigation was as follows: Determination of the difference in the movement of the inner and outer side sheets of the firebox at eight points; the difference in movement of the crownsheet relatively to the roofsheet; of the back firebox sheet relatively to the back head; of the throat sheet relatively to the front tubesheet and of the front tubesheet relatively to the shell. Determination of the temperature of the fire and water sides of the inner firebox sheet at the side at five points; the water temperatures in the throat at the foundation ring and in front of the arch tube openings, while steam was being raised in the boiler and while it was at work.



The Original Apparatus Applied to a Radially Stayed Boiler

Two methods of conducting the tests were employed. In one the fire was kindled and the fireman instructed to raise steam in the manner usual in regular roundhouse work. When the safety valve opened, the fire was maintained so as to keep the valve blowing for from 10 to 20 minutes, when the fire was dumped and the boiler allowed to cool. The time required to raise the steam pressure to the blowing off point varied from 50 to 90 minutes.

The second method was the same as the first insofar as the raising of steam pressure is concerned; but, when this was done, the distribution valves having been removed from the locomotive, the throttle was opened and, with the injector running to capacity, the fire was maintained so as to hold the steam pressure at the blowing-off point—195 lb.—for about 30 minutes and then the fire was dumped and the boiler cooled.

In raising steam the shop blower, carrying a pressure of about 60 lb. per sq. in., was attached to the locomotive and used until the boiler pressure reached that amount, after which the regular locomotive blowers were used.

In cooling the boiler steam was blown out so as to cause a fall of pressure of about 1 lb. per min., taking about three hours to reduce the pressure to zero.

In making the tests the apparatus was successively located at the staybolts marked 1, 2, 3, 4, 5, 6, 7 and 8.

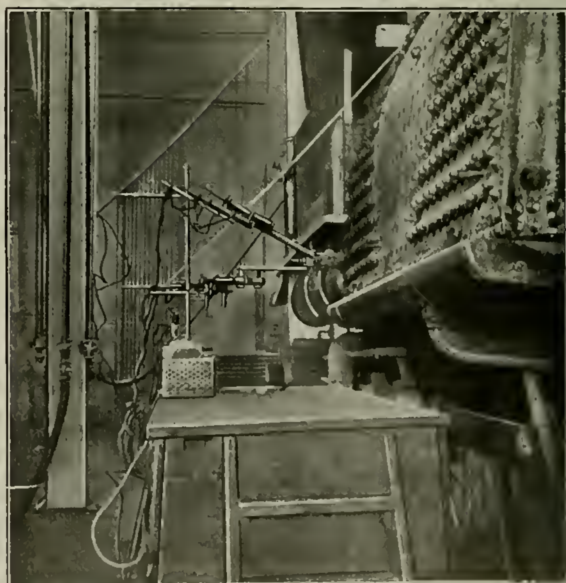
Lack of space will make it impossible to enter into the details of all of the work done, and only enough of it will be described to give an idea of what was learned and the basis for the tentative conclusions that have been reached. I say "tentative" because the investigation has not yet been completed and full information is not available as to how all kinds of fireboxes act in service. The reasons for this will appear as the description proceeds.

In the tests at staybolt No. 1, which was at the front upper corner of the firebox, the first method of testing was used, and the results obtained are shown in the diagram. In this, as in all diagrams to follow, the scale of movement is in thousandths of an inch, on either side, vertically or horizontally, of the starting point at O which denotes the normal position of the two sheets when the boiler was cold at the commencement of the test.

In the first test at staybolt No. 1, it will be noticed that the initial movement of the inner sheet relatively to the outer one was downward and to the rear, and it will be seen later that this initial downward movement was characteristic of nearly all of the tests. Both the downward and rearward movements were, however, quickly reversed and the inner sheet moved up and to the front.

There are features brought out in this diagram that are characteristic of all of the others and to which attention may be called here. One is that the sheets do not expand and return to their normal position when a steam pressure is raised; a second that the sheets are in constant motion relatively to each other at all times, and that the relative motion is much greater with a boiler fitted with flexible stays than it is with one having rigid stays.

In the case of staybolt No. 1, this difference in movement

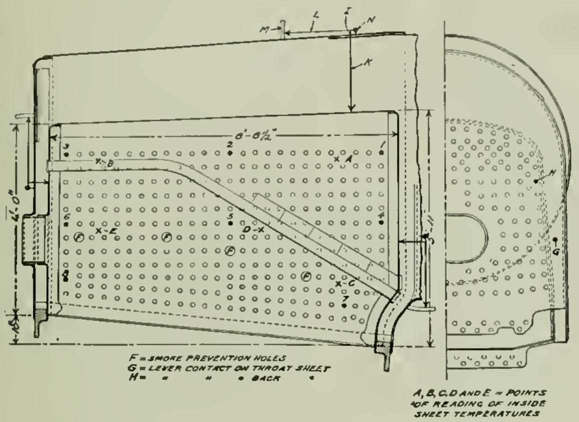


The Redesigned Apparatus Applied to a Boiler Having a Wootten Firebox

is very marked and the total maximum deflection of the flexibly stayed boiler is more than twice that of the rigidly stayed. If the variation of vertical movement alone is taken into consideration, that of the flexibly stayed boiler is more than five times as great as that of the rigidly stayed. It will be seen, too, that there is a general progressive movement until the blowing-off pressure is reached, then, while that is being maintained, there was a movement of the sheets to and fro, with a general return movement towards the original normal position after the fire was dumped and until the boiler had been cooled to the disappearance of all pressure.

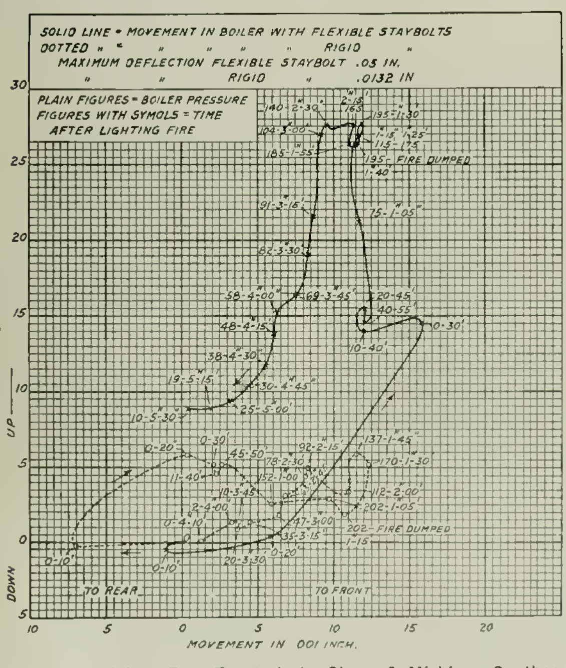
In this first diagram, the rigidly stayed sheet returned to within about .001 in. of its original position, while the flexibly stayed sheet was out about .009 in. at the conclusion of the test.

Owing to the fact that, in rigidly stayed boilers, the breakage at the upper front and back corners of the side sheet was much greater than it was midway between the two, it has been assumed that there was a neutral point on this midway



Arrangement of Firebox in Lake Shore & Michigan Southern Locomotive for Temperature and Expansion Tests

line, on which the staybolt deflection was little or nothing. That this surmise was approximately correct is shown by the diagram of the tests made at staybolt No. 2 which was at the center of the upper row. Here, in both the flexibly and rigidly stayed boiler, we find that the horizontal motion was



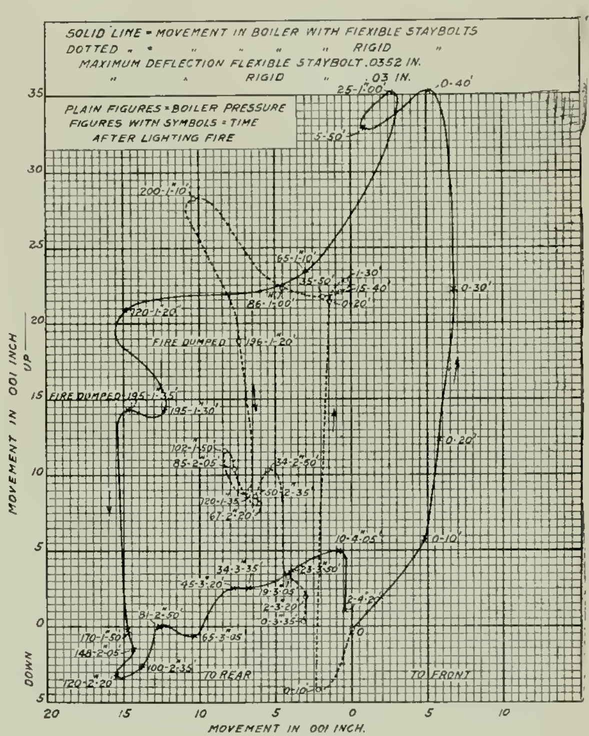
Staybolt No. 1 Top Row Front—Lake Shore & Michigan Southern Locomotive

much less than the vertical, indicating an approach to a neutral zone, but, as at staybolt No. 1, we find the horizontal movement of the sheet to be something more than twice as much on the flexible as on the rigidly stayed boiler.

It is impossible to state positively that there is no neutral line with the rigid boiler, but the statement can be made regarding the flexibly stayed boiler. Of course, if the front end of the inner sheet goes to the front and the back end to the rear there is, possibly, an instantaneous neutral line, but it must be in constant motion and, therefore, does not fulfil the preconceived ideas as to the neutral line.

From a study of the curves of movement of the staybolts examined on the rigidly stayed boiler, the evidence is that the same holds true for that boiler, namely, that the point of no movement—that is, where the two sheets occupy their original or normal positions—is in constant motion. This means that all staybolts are being constantly bent back and forth, which is corroborated by the determination of sheet temperatures which formed a part of this investigation.

In the case of staybolt No. 3, which was at the back end



Staybolt No. 2 Top Row Center—Lake Shore & Michigan Southern Locomotive

of the top row and close to the back head, there was a sudden and rapid movement of the inner sheet to the rear on both rigidly and flexibly stayed boilers, and the maximum of the horizontal movement was reached in a very short time after the kindling of the fire; the rigidly stayed boiler reaching it in 10 and the flexibly stayed in 20 minutes.

Without going into details of the other tests, it may be stated that while the amount of movement varied, the character of the motion did not vary essentially and the same relationship between the rigidly and the flexibly stayed boilers was maintained.

When tests were made at the next to the bottom row of staybolts, however, a matter developed that proved to be of very great importance. Attention has already been called to the fact that in the test at staybolt No. 1, the first apparent motion of the sheet was downward, but as this only amounted to .00075 in. it was regarded as a negligible quantity. At the bolt below it, (No. 4,) there was a drop of .00225 in. which was still not enough to excite suspicion, but at No. 7 this drop increased to .009 in., apparently indicating a downward movement of the inner sheet at a point only a few inches above where it was riveted to the mud ring. Evidently this is an impossibility, and the only explanation to be made was that the sheet had buckled and, by throwing the apparatus out of line, caused it to indicate a downward movement.

These first tests therefore must be regarded as showing but two things: the constant movement of the staybolts while in service and the relative movement of the sheets of a rigidly and flexibly stayed boiler.

With no precedent to serve as guide, the apparatus had been designed on the assumption that the two sheets would remain parallel to each other at all times. When this evident buckling was discovered the apparatus was redesigned so as to indicate not only the movement of the sheets but any buckling that might take place.

This redesigned apparatus was used on some boilers having a Wootten firebox with general dimensions as follows:

Length	10 ft. 1 in.
Width at foundation ring	8 ft. 11¾ in.
Height at front	5 ft. 8 in.
Height at back	5 ft. 1½ in.
Depth of combustion chamber	5¼ in.
Number of 2 in. tubes	411
Length of tubes	14 ft. 6 in.
Inside diameter of shell (front)	6 ft. 1 in.
Height of roof over crown (front)	1 ft. 6¾ in.
Height of roof over crown (rear)	1 ft. 9½ in.

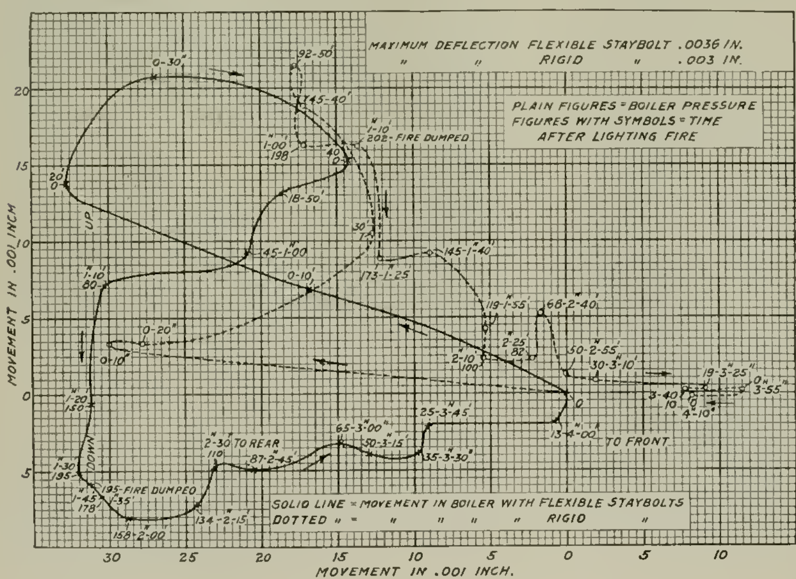
There were three rows of expansion stays at the front to hold the crown sheet and eight on each side of the center line as shown in the drawing. The staybolts were spaced on four in. centers and the rigid bolts were ⅞ in. in diameter.

The two boilers were not as distinctly flexibly and rigidly stayed as were those used in the first tests. The boiler which has been designated as the rigidly stayed had a number of Tate flexible staybolts as indicated in the drawing. In the throat sheet all of the bolts in the seven upper rows and all of the bolts in the outer row, were flexible. In the side sheets there were 15 Tate flexible bolts in the front row, and 12 other scattering Tate bolts that had been put in for repairs, in the locations shown in the drawing.

The other boiler, which is designated as the flexibly stayed boiler, had a complete installation of flexible bolts in the throat sheet, with the exception of 20 bolts near the foundation ring that were rigid as shown in the drawing. Of a total of 510 staybolts in the side sheet, 248 were flexible bolts. These were located in equal numbers and with the same arrangement at the front and back end of the firebox. There were six in the top horizontal row next to the crown sheet, with a gradual increase from the top to the bottom as shown in the drawing and the photograph. This left a wide section of firebox at the center that was stayed by rigid bolts and which, evidently, exerted an important influence on the results as will be pointed out later.

The staybolts at which these tests were made were located at the numbered points 1 to 9 on the two drawings, and the tests were made as before, by raising steam, holding the throttle open for 30 minutes and then blowing down at the rate of 1 lb. per min., readings of the sheet movements having been made during the whole period at 10-minute intervals.

Whether it is because the apparatus used on the radially stayed boilers only indicated the apparent motion of the sheets while that used on the Wootten boilers indicated the actual movement, that the diagrams of these movements are much more complicated for the latter boilers cannot be stated positively. That the buckling that evidently did occur in the sheet of the radially stayed boilers had its effect on the actual movement of the sheets is a reasonable supposition, but certainly there is a great difference in the character of the two.



Staybolt No. 3 Top Row Back—Lake Shore & Michigan Southern Locomotive

COMPARISON OF TWO TYPES OF BOILERS

Let us compare those for staybolts No. 1, in the two types of boilers: In the radial stayed boilers there is a steady even motion of the sheet with little or no doubling back and looping over itself. There was a constant movement, but it was, in the main, a progressive movement ending with an apparent deflection of about .008 in. from the starting point of the flexibly stayed boiler.

The rigidly stayed boiler was a little more complicated in its motion, but still not at all confusing, and ended with a deflection of a little more than .001 in. from the starting point.

The diagram for the corresponding staybolt of the Wootten boiler is a mass of knots and loops and back doubling. This is especially true of the period prior to the development of the first steam pressure. This appeared at the point marked O-2H-10′ in the diagram when steam began escaping from the whistle valve. Then there was a rapid upward movement for 20 minutes until a pressure of 75 lb. was reached followed by an equally rapid forward and downward movement during a quick building up of the pressure to 200 lb. Then came a quick recovery horizontally during the period that the throttle was open with only a very slight change in vertical position between the beginning and the end.

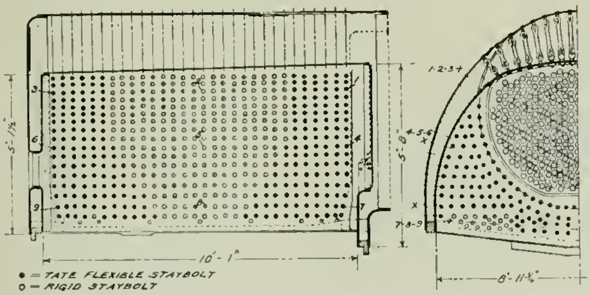
This movement is easily explicable if the tube action as indicated by other tests is taken into consideration. It was found that during the early period of raising steam the tubes were heated more rapidly than the shell with the result that the back tube sheet and with it, probably, the front end of the firebox was pushed to the rear. This explains the slight rearward movement of the staybolt at the starting of the test. Then, as the water became heated there was a tending toward equalization of the temperatures of the tubes and the shell. This resulted in a relative forward movement of the tube sheet permitting the firebox to expand normally. Then, when the throttle was opened, there was a rapid increase of firebox temperature resulting in a corresponding increase in the temperature of the gases in the tubes themselves, which again pushed the tubesheet to the rear carrying the front end of the firebox with it. Then followed the looping and doubling of the movement during the cooling down, ending with the staybolt a little more than .002 in. from its original position.

In the rigidly stayed boiler the entanglement of the line of the movement is equally marked and is of the same general character, but, as in the other cases, the extent of the movement is much less.

This condition holds throughout the whole range of the work, varying in extent with the location of the staybolt and the method of staying. In general the movement was greater at the ends and upper portions of the firebox than at the center and lower portions.

There is another matter in connection with the rigidly stayed boilers that does not fully appear in the diagrams: The evident reason for the lesser deflection of the rigidly stayed boiler is that it is rigid. The staybolts tend to hold the sheets in one position and resist all tendency to move, and this manifests itself in the jerky character of such motion as takes place. That is to say, there are sudden variations in the distance from the original position which indicate that the stays resist the effect of the expansion of the sheet to move them, possibly buckling the sheet, and then when the pressure becomes more than they can carry, they suddenly yield.

The one point where a close comparison and check between the radially stayed and Wootten type is possible is in the movement of the staybolts when the boiler is in service. In both cases it was found that the sheets were in constant motion relatively to each other from the instant the fire was built until the boiler was cold. Also the extent



Delaware & Hudson Locomotive No. 813 with Flexibly Stayed Wooten Firebox

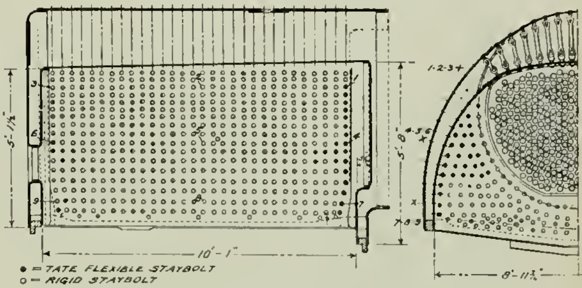
of the movement was much greater in the flexibly stayed boiler than in the rigidly stayed.

The character of the movement was, however, apparently quite different in the two types of boilers. There was more bending to and fro in the Wootten as well as a much greater movement. This is especially manifest in staybolt No. 1, where the maximum deflection of the flexible bolt in the Wootten type was about nine times that of the radially stayed, and this amount entirely in a vertical direction.

There may have been several reasons for this. The Wootten firebox was 1 ft. 4½ in. longer and 1 ft. 1½ in. deeper and the staybolt was 8 in. long as against 5¾ in. for the radially stayed boiler. Each of these items would tend to increase the deflection, while the comparatively small amount of horizontal deflection is explicable from the fact that there was a complete installation of flexible bolts in the radially stayed boiler, while, in the Wootten type there was a line of 18 rigid bolts in the central section that tended to stiffen the boiler and prevent a relative movement of the sheets. These are suggested as reasons, not as demonstrated proofs.

The main fact, however, stands out very prominently that the character and amount of the staybolt deflection is quite different in the two boilers. As yet, there is not sufficient data accumulated to be able to state definitely as to just why this is so, and what should be done to the general design of one or both of the boilers to put the least possible strain on each.

In the matter of the buckling of the sheets caused by the



Delaware & Hudson Locomotive No. 794 with Rigidly Stayed Wooten Firebox

combined action of sheet expansion and resultant staybolt deflection, it was found that the buckling was greater with the flexible than with the rigid bolts; but, it must be borne in mind that the deflection was also greater, and a study of the details shows that the ratio of the buckling of the flexibly stayed to the rigidly stayed was less than the corresponding ratio of deflection. In other words, given a fixed amount of staybolt deflection the buckle put in the sheet would be less with a flexible than with a rigid staybolt.

While at work on the rigidly stayed boiler having the Wootten firebox an attachment was made in the space just ahead of the No. 5 staybolt. As might have been expected, the actual movement of the sheet was about the same as at the No. 5 staybolt but there was less buckling. This developed the probability that, in this long and wide firebox at least, the whole sheet, while under steam pressure, assumes a series of shallow corrugations that hold it out of alinement with its original shape, and which are sweeping over it in waves, as it were, according as the sheet expands or contracts. The depth of the corrugations is slight and the angle made by the sides of the same with the original line of the sheet is never as much as one degree. The greatest angle obtained on the Wootten type was 48 minutes 52 seconds with a general average for all points tested on the flexibly stayed boiler of 7 minutes 29 seconds.

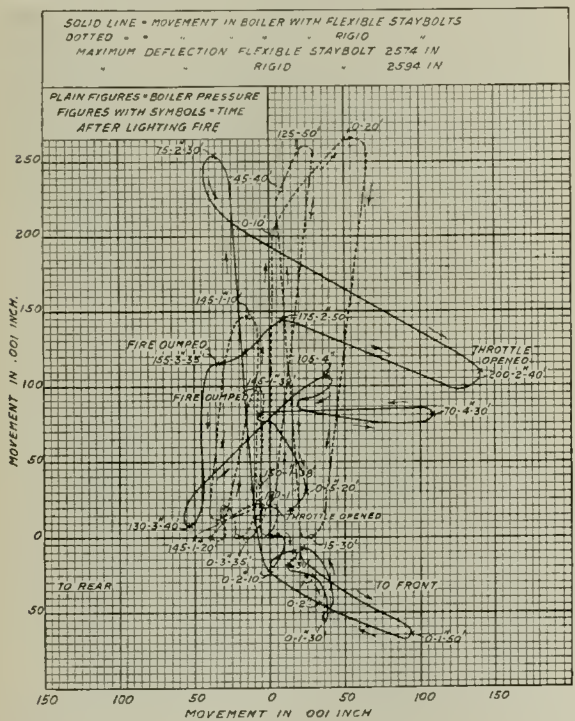
It is also possible that the buckling of the sheet might be appreciably decreased by a change in the original adjustment of the flexible staybolts, and also that there might be an increase in the deflection of the bolts. The suggested methods of accomplishing this is to give a little more play in the head of the bolt and the allowing of a little slack under the heads in the first place. This would permit of an easier adjustment to the movement of the sheet during the period of raising steam, when there is no load on the bolt, and the allowance of a little freedom of angular motion when the sheet and bolt are under strain.

Other matters were taken up in connection with this investigation for which there is no space to deal at this time. There were the effects of cold air in the firebox on sheet temperature and the lack of circulation in the water leg.

CONCLUSIONS

The fundamental facts fully brought out were that the staybolt deflection is much greater in a flexibly stayed boiler than in a rigidly stayed boiler, that certainly during the whole period of operation and probably until the boiler temperature had reached that of the atmosphere the staybolt is in constant motion as evidenced by the fact that, out of the hundreds of measurements taken, there were no two consecutive measurements alike; that the two types of boiler construction (Wootten and radially stayed) have quite different effects on staybolt deflection; and that firebox temperatures and the action of the tubes have a marked influence on staybolt deflection at the front end of the firebox.

These tests also showed in a marked degree the extreme



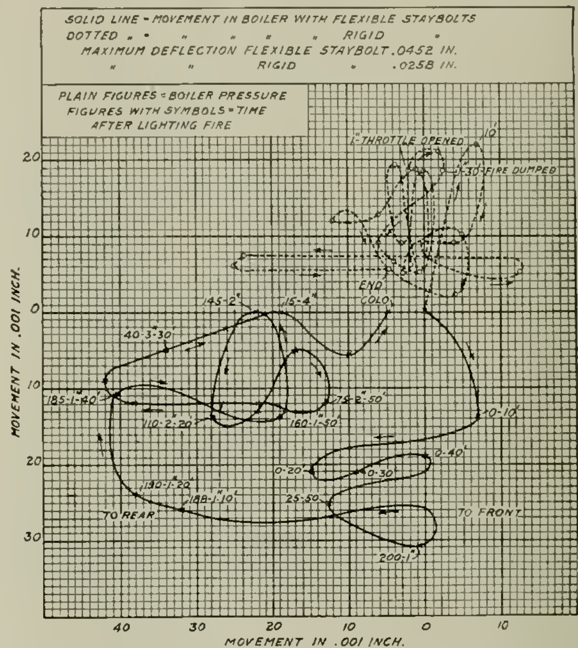
Staybolt No. 1 Top Row Front—Delaware & Hudson Locomotive

sensitiveness of the plates to changes of temperature. For example, a cold boiler may be filled with water of any temperature from cold to boiling and there will be no relative motion between the sheets. But let the fire be laid and a piece of lighted waste thrown in to ignite it, and it has, thus far, been impossible to get a reading before the sheets would show a movement, though this has been done within ten seconds from the time of the ignition of the waste.

This investigation is merely indicative and not conclusive. The absence of any data upon which to estimate the probable movement and buckling of the sheets made a redesigning of the apparatus necessary, and the use of boilers with a mixed assortment of staybolts in the second case, gave results that would probably be greatly modified were boilers with complete installations to be used. But there is this indication, that the boiler will expand and the staybolts deflect if they have a chance, and that this chance is much greater with a flexible bolt than it is with a rigid one.

As has already been intimated, the difference in the conditions of operation of the apparatus makes a clean-cut comparison between the Wootten type and the wide firebox radially stayed boiler impossible. But the impression left by the test is that the Wootten firebox is much more rigid than the wide firebox when rigidly stayed with the radial stays, and that if it were given a complete installation of flexible bolts the difference between the two would be very much greater than that indicated in these tests.

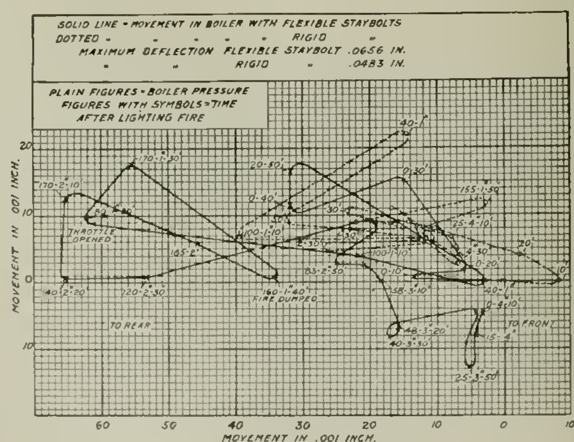
In every case the extreme sensitiveness of the sheets to



Staybolt No. 2 Top Row Center—Delaware & Hudson Locomotive

any changes of firebox temperature was noted. This fully explains the constant bending motion to which the bolts are subjected while the boiler is at work.

It naturally follows from this that a boiler which is so



Staybolt No. 3 Top Row Back—Delaware & Hudson Locomotive

built as to permit the sheets to expand under the influence of temperature changes, will put less stress upon the staybolts and sheets than one where such freedom of motion does not exist. There is no reason to think that there was any great difference in the temperatures of the sheets of the two boilers, and yet, as I have already indicated, there was a marked difference in the movements of the staybolts and the sheets. If a given change of temperature produces a definite change of dimension in the sheet, anything that prevents this change must itself be subjected to stress and must put a similar stress upon the sheets. Hence, so far as these investigations have been carried, they indicate the value of using the flexible in preference to the rigid bolt as a means of reducing stresses in the firebox.

There is one point that cannot be expressed in cold figures and that is the impression that this work makes on observers. After watching the delicate and sensitive movement of the sheets and staybolts and the difference in the action of the flexible and the rigid bolts, everyone was greatly impressed with the superiority of the flexible bolt as a means of reducing the probable stresses that the several parts of the boiler are called upon to sustain. The progress of this work has driven home in a convincing manner the advantages of flexibility in boiler construction.

Progress and Standardization

Development of Brake Beam and Air Brake Illustrates Need for Free Play of Inventive Genius

During the hearings before the House Committee on Interstate and Foreign Commerce, a number of manufacturers of railway equipment presented voluntary statements as to certain phases of the question of the disposition of the railroads at the expiration of federal operation. During their appearance before the committee these men were practically all asked for their opinions relative to standardization of railway equipment. In response to these questions the following letter was addressed to Representative Esch, chairman of the committee, by Alba B. Johnson, president of the Railway Business Association. The letter, which presents a concrete illustration of the part competition and initiative have played in the rapid development and improvement of railway facilities, is as follows:

Manufacturers of railway equipment upon concluding voluntary statements before your committee were asked by you their opinion regarding standardization. They replied that they favored interchangeability of car or locomotive parts through standardization of dimensions, but regarded it as essential to progress that there be variety of design and ocmpetition among inventors and developers of appliances.

It is due to you and to ourselves that a fuller explanation of our view and of the reasons underlying it should be made. By conference and correspondence we have obtained the knowledge and judgment of members of our association and others. In the subjoined statement we endeavor to demonstrate that competition is essential to progress in service and in economy, that voluntary standardization by the railways acting collectively has long afforded and can continue to afford all desirable interchangeability, and that diversity of design is the indispensable condition for exertions by inventors and by developers of appliances. As bearing upon diversity of design, a description is given of a typical competitive appliance, the brake beam rigging. Authorities quoted in the statement are connected with the several concerns which make such rigging, and speak in response to our request.

As a factor in progress what is at stake is competition. If Congress adopts the principle set forth in Section 9 of the Cummins Bill (S. 2906), which deals with consolidations, the 20 to 35 ultimate systems will be so formed that "competition shall be preserved as fully as possible." The government determines rates, in which competition has therefore largely ceased. What remains is competition in service and economy.

Such competition in the past has been maintained between railways and between makers of devices. The makers' occupational motive for maintaining competition in both directions is self-preservation; but the public has a vital interest in the preservation of these manufacturing enterprises and in the continuance of competing railway systems, since upon such enterprises and such railway competition depends quality and cheapness of transportation performance.

From economical operation, the public benefits through larger railway income, stronger railway credit, more vigorous improvements of and additions to facilities and through a tendency to keep down rates.

Standardization means the elimination of competition.

Insofar as standardization is desirable for the sake of practical stability and convenience of repairs, the railroads themselves, with the co-operation of the manufacturers, have in the natural course of business adopted and employed it. A standard specification in vogue on American railways is not the edict of a potentate or board of potentates. It comes up from below. It must make its way into general approval before it can have the force of a regulation which the minority will observe. So far as the manufacturer goes, the matter of applicability, of usability, which is the same thing as interchangeability is out of his hands without action of government.

For several decades the Master Car Builders' Association and the Railway Master Mechanics' Association (locomotive), scientific institutes of railway officers, have annually added to the appliances whose dimensions and requirements for performance are "specified." These the American Railway Association, as it existed prior to government control, recommended to all the roads. Generally, they were put into effect as soon as announced.

The need of standardization of locomotives is almost wholly imaginary. A locomotive rarely leaves the road owning it or even the division for which it was built; hence in time of peace and almost entirely in time of war all locomotive repairs are made at home.

As to cars, interchangeability has been made universal in the United States. Accompanying this statement we present to your committee copies of two dictionaries issued annually by the Simmons-Boardman Company, publishers of the *Railway Mechanical Engineer*, one dealing with locomotive appliances, the other with car appliances. The latter part of each book contains the standards referred to, with pictures and drawings. From these books your committee can derive a conception of the extent to which the railroads when occasion required have standardized voluntarily.

To grasp the significance of the burden which a developing mechanical practice sustains in transportation progress, it is necessary to bear in the mind the fundamental of railroad economy.

In freight, the problem is the number of tons that can be hauled by one locomotive with one crew—in a word, the train-load. Possibly the largest single factor in the notable prosperity of such a road as the Union Pacific has been the success of the management in attaining heavy train-loading. It was in pursuit of this economy that the late Mr. Harriman gave his days to experiment and devoted hundreds of millions to capital improvements. For augmentation of train-load, railroads in all parts of the country which had been permitted to accumulate the investment basis have poured out expenditures. They have built larger and stronger cars. They have constructed more powerful engines to haul the larger cars and more of these cars to the train. They have provided heavier roadway, rails, and bridges to sustain the enormously more ponderous train and cargo.

These expenditures, by reducing the cost of drawing freight per ton per mile, not only paid for themeselves, but so far offset the rising cost in wages and material as to postpone for years before 1910 the necessity for asking that freight rates be raised. The trainload as a foundation basis of railroading explains the despair of managers when employees proposed extra men in crews and a limit on length of trains.

Passenger trains have been made heavier also. More persons are carried to the car. Steel has taken the place of wood for safety. Speed has been increased for convenience.

To all this development there has been at every stage and in every phase a mechanical limit. For instance, the movement of the train must be controlled. The engineer must be able to slow down or stop in any emergency. That is to say, railways can progress in economy of operation no faster than the development of the brake. The air brake of the 60's replacing for more exacting uses the hand brake, achieved a stupendous advance; but stopping the toy trains of that era was to the stopping of the 100-car train of 125-ton loaded cars of today what the air brake of 1870 was to the air brake of 1919. Progress in the trainload and in the brake has gone hand in hand.

Even in the years when because of patent protection there was only one maker of air brakes, competition was an ever-present influence.

First there was the competition between railways. The most progressive-minded of the managers were perpetually engaged in rivalry for cheaper operation. If practice had been standardized for all lines no departure could have been undertaken on any of them until the whole national system, perhaps a central omnipotent board, could be persuaded. Cars of a certain capacity would have been obligatory until all new cars for all lines contracted for after a specified date might be built larger. Territorial and topographical contrasts in conditions confronting the several lines might imperfectly and tardily be met. The working of this tendency in practice can be observed in the government standard cars allocated to some roads which had long since adopted larger capacity as best suited to their special problems.

Second there was the potential competition of makers who might bring out competing brakes sufficiently original to convince the patent office. A rival actually established itself, though it now in part covers its patent situation by a license arrangement. What kept one concern so long alone in the field was that it diligently developed improvements—in short, it acted as it would have had to act if competition had been actual instead of merely potential. A vivid form of potential competition was that of makers ready to enter the field the moment patent rights expired. To maintain its commercial position the single maker long before each such expiration abandoned the air brake of yesterday and substituted a new device, protected in turn by new patents. The public was benefited because the essential advantage which induced progressive railways to try and use the newer appliance was the net saving in cost of operation through enlargement of the trainload.

A significant feature of the standard vehicles built by the United States Railroad Administration was the effort, in some cases successful, to use an appliance upon which patent rights had run out and thus to exclude from the bidding more recent inventions still protected. From the point of view of the public this is penny wise and pound foolish. It attains a little immediate cheapness. In doing so it exterminates by starvation the breed of inventors whose work is to promote not alone little economies but great ones.

An illustration more typical than the air brake is its adjunct, the brake beam. In what follows it has been thought convenient to employ for concrete illustration one appliance rather than several. For this purpose the device selected is the brake beam. This appliance is attached both to locomotives and to cars. Rigid standardization of its dimensions and of its strength is necessary and is enforced. From six to a dozen types are in use, while unsolved problems with regard to it are today the object of study and experiment. A somewhat full description of this rigging will facilitate an understanding of subsequent references.

The air brake can develop no faster than the beam. For between the air cylinder, whose piston is operated by pressure initiated in the locomotive cab, and the metal shoe which in action is forced against the wheel, there is a mechanism which directly applies the power to the shoe. A failure of that mechanism puts the brake out of commission.

The cylinder piston operates a rod located under the vehicle midway laterally, and by a system of levers moves the two, three or four trussed brake beam structures toward the pairs of wheels which they are to brake.

The performance which is expected of the beam rigging is this: that it receive the cylinder power; that it move so that simultaneously the shoe, which is fastened to it, will be pressed against the wheel; and that it stand the strain.

It is in standing the strain—that is, in the dependability and durability—that progress has been made and is still promised in the brake beam. If a manufacturer claims superiority for his type it is to those qualities that he refers.

The Master Car Builders' standards tell him how many inches the beam must measure from tip to tip and throughout its external outline in order to fit the various cars. They prescribe the height at which the beam must hang above the rail. They require specified dimensions and locations for certain parts of trussed structures. Consequently when a car off the rails of the owning road is found with a damaged brake beam and the road on whose rails it is sojourning is addicted to a beam of another type, the defective beam can be replaced by one carried in stock by the road which does the repairing.

The argument in favor of standardization is that while interchangeability of beams as a whole is maintained with variety of detail, each several part of the beam structure cannot be replaced by a part from another type of beam, but the whole beam must be substituted. Another view prevails. This is that serviceable and safe brake beam repairs are only made when the parts of the beam structure have been put together under the same tests and conditions as surround the manufacture, inspection and acceptance of new beams; whereas such conditions are not and cannot be present on yard repair tracks. The discarded beam is not wasted. It is subsequently carried to a place where under rigid conditions qualified mechanics restore it; and it takes its course of standard inspection like a new beam before it can again be placed on a vehicle.

In their requirements the Master Car Builders' Association includes loads that beams shall successfully carry; but the means by which the maker shall impart the specified power of resistance to the beam and its parts is within his own province. That is the field in which progress lies.

The original brake beam was wooden. As trainloads began to enlarge it was seen that a wooden beam strong enough for the new conditions would be a monstrosity in size. Mr. C. F. Huntoon writes that "the best design of truss metal beam 15 years ago weighing approximately 63 lb., carried a load of 6,500 lb. at 1/16-in. deflection, this deflection being the maximum allowed by the M. C. B. Association, while today a beam of 77 lb. weight, or 20 per cent increase, will carry a load of 15,000 lb. at 1/16-in. deflection, an increase of over 125 per cent in strength and efficiency." Mr. Huntoon attributes such progress "to specialists who have directed their efforts to some one device or detail—each vying with the other to produce an article of superior merit;" and he says, "without this competition and the protection afforded by letters patent, there would be no fast schedule trains and boats, no telephones on the desk or automobiles for convenience or pleasure; in fact, the industrial progress of this country has been stimulated by and is largely due to these very factors."

The advance proceeded through various forms in metal. At first light metal beams met the situation, beginning with a trussed structure of pipe. Further increase in train weights led from year to year to development of more adequate trussed brake beam structures by various manufacturers, differing in the various parts, most notably in the "beam" or "compression" part proper—for example, the "U," the solid bar, the "channel," the angle, the "T" and so on. Each of these types taken in cross section has a distinctive value within itself and within its relation to other parts of the brake beam structure. Each of them represents the means by which inventive genius competes for superiority in meeting conditions as they evolve. Tests of these types and features are continually going on in the railway shops.

There have been strong and eminent advocates of a standard beam. The railway men as a whole have preferred to leave the opportunity open for continued improvement. Since the proposal for a standard beam was made seriously in 1910, substantial improvement has been made.

Mr. A. H. Peycke writes: "The brake beam manufacturers have conferred with the Brake Shoe and Brake Beam Committee" (of the Master Car Builders' Association) "this last year with a view to straightening out a good many points in relation to interchange dimensions, clearance conditions, etc.," and cites a report delivered before the M. C. B. convention in Atlantic City in 1919 by Mr. B. B. Milner, of the New York Central, suggesting changes which are necessary; also giving a complete synopsis of the brake beam situation since about 1905. Mr. Peycke's opinion is that "The standardization of brake beams would be decidedly disadvantageous to the railroads and people of the country, and any attempt to adopt a standard beam would suppress initiative, invention, genius and progress."

Mr. Albert Waycott observes: "Seven or eight different types of brake beams, all interchangeable on equipment in service and all meeting the M. C. B. tests, will surely illustrate how both improvement and competition might easily have been greatly reduced had any one 'type' been insisted upon."

The manifest need today, according to Mr. C. Haines Williams, "is a more strict enforcement of existing M. C. B. rules and more rigid application of test and manufacturing requirements. . . . No single design of beam has advantages sufficient to compensate for the penalty of having brake beams stand still for years. . . . The initiative and unhampered genius that produced the brake beam and brake transmission rigging that has always satisfactorily controlled our high speed trains cannot with safety be destroyed. . . . The success of past practice guarantees proper care of future problems if not interfered with by standardization, which would unquestionably develop indifference on the part of the interested brake beam manufacturers of today. All the present M. C. B. rules, specifications, requirements and safeguards have come, without exception, from the recommendations and practices of brake beam manufacturers."

Whatever may be the future of voluntary standardization, it is our conviction that the best interest of the public lies in leaving the railways free without any government participation in the process.

An important consideration cognate to this view in every line of railway requirements is that of centralized buying. Standardization would, we fear, do more than put a stop to the maintenance of vigorous departments of the manufacturing establishments for the testing and development of new devices and features. Not only would all the companies be reduced, so to speak, to automata filling orders to specifications, but there would be the further tendency to concentration of purchasing in some central bureau. Its responsible heads would probably not get and keep personal knowledge of the reliability and resources of individual makers. Bidding would tend to be controlled more and more by the element of price, and less and less by the element of quality and durability. The bureau would tend to leave in the hands of subordinates the designation of those makers permitted to bid. Inevitably this would degenerate into a stereotyped process bereft of commercial enterprise and intelligence on both sides of the counter.

What demands the future will make, who can prophesy? Mr. Charles J. Graham remarks: "Had the thought of standardization of parts been put into effect some years ago, we would still be using wooden brake beams. . . . The same is true today. There remains ample field for further improvements if they are not stifled by the fixing of standard details for parts."

We are told that locomotives and cars have reached nearly if not quite their maximum capacity; that they already crowd the overhead clearance of bridges and tunnels; that to widen the traffic gage would involve expenditures of appalling magnitude not only in acquirements of wider rights of way but in shifting and relaying existing tracks while traffic was carried on; that to lengthen the vehicles would involve us in costly track problems and complications involving station platforms and the like.

Such pessimism is a counsel of sloth. For freight transportation at least higher actual speeds may be a possibility contained in the now rapid elimination of grade crossings. To what extent will this and other tendencies toward fuller use of cars affect the stresses placed upon every part of the rolling stock? Is it certain that electric propulsion will bring no new conditions in this respect, or that fuel or other source of motive energy in the future is even yet identified? Who can affirm that the controlling factor in future transportation development is yet dreamed of in our physics and chemistry or other branch of scientific pioneering?

The manufacturer has always anticipated each new demand. When it came he was ready for it. He can exist and perform that function only if experimentation is free on the several railway systems and if achievements for the welfare of mankind promise reward to the inventor of appliances and profit to the developer.

Japanese Laborers' Wages.—The average wage for an unskilled Japanese male laborer today is 48 cents and for a female laborer 32 cents a day. A skilled laborer earns from $1.10 to $1.68 a day. These rates are about 70 per cent above pre-war rates. Besides the daily rates, however, yearly bonuses are given of a month's wages, and often considerable more. The working hours may be given generally as 70 hours per week, and the amount of work produced per hour by a Japanese workman is about one-half that produced by an average British workman where large jobs and heavy machinery are concerned.—*The Engineer.* (London.)

RAILROAD ADMINISTRATION NEWS

The number of passengers carried one mile in August was 4,375,694,522, according to the monthly report of the Operating Statistics Section. This was an increae of 8.8 per cent over August, 1918. For the eight months ending with August 31 the number of passengers carried one mile was 28,793,142,453, an increase of 6.3 per cent.

RAILROAD FACILITIES BELOW DEMAND OF TRAFFIC

The railroads of the country are now doing a heavier business for the present season of the year than was ever done in the history of the railroads in normal years, and practically as heavy business as was done at this season in 1918, which exceeded all previous records, according to a statement authorized by the director general on October 12. They have more cars in actual service, after excluding cars held out of service for repairs, than in 1917 or 1918. While the bad-order car situation was greatly embarrassed by the extensive strikes among shopmen in August, the percentage of bad-order cars is now rapidly improving. There was an increase of 52,456 cars in serviceable condition between August 16 and October 4, of which 12,110 were added in the one week ending October 4.

MILES PER CAR PER DAY INCREASING

As indicative of increased efficiency in the use of freight cars, the average mileage per freight car per day in October, 1919, was 27.3, as compared with 26.7 in September, 1919, according to a statement authorized by the director general. The comparison with October of the two preceding years is as follows:

October, 1919	27.3
October, 1918	26.0
October, 1917	25.9

The comparative progress thus made in October is even better than that made in September, as is shown by the following comparison with September of the two preceding years:

September, 1919	26.7
September, 1918	26.5
September, 1917	26.4

NUMBER OF BAD ORDER CARS BEING REDUCED

Steady and gratifying progress continues to be made in connection with the bad-order car situation, according to a statement recently authorized by the director general of railroads.

Excluding cars held out of service as not worth repairing, bad-order cars had fallen on November 15 to 130,833, or 5.2 per cent. The figures since October 4 have been listed as follows:

	No.	Per Cent
October 4	172,210	6.9
October 11	169,343	6.7
October 18	163,986	6.5
October 25	156,372	6.3
November 1	146,702	5.8
November 8	136,238	5.4
November 15	130,833	5.2

Including cars held out of service as not worth repairing, the number of bad-order cars has decreased to 150,133, or 5.9 per cent on November 15. The figures since October 4 follow:

	No.	Per Cent
October 4	191,656	7.6
October 11	188,308	7.4
October 18	183,070	7.2
October 25	175,348	7.0
November 1	166,514	6.5
November 8	155,564	6.1
November 15	150,133	5.9

TRAINMEN SEEK INTERPRETATION OF OVERTIME PROPOSAL

A committee representing the four brotherhoods of train service employees was to confer with Director General Hines on Tuesday, December 2, to ask a more specific interpretation of his recent proposal to allow time and one-half for overtime in freight service, contingent upon the elimination of all arbitraries and special allowances. The committee, which has full power to accept or reject the overtime proposal, was appointed at a conference of the general chairmen of the four brotherhoods at Cleveland, called to consider Mr. Hines' proposal, after the conference had voted to accept his offer of a held-away-from-home terminal rule providing for payment of wages for time held at other than the home terminal after 16 hours. This was as a substitute for rules proposed by the trainmen and firemen providing for pay after 10 hours. About 180 general chairmen of the firemen's brotherhood held a conference to consider what should be done in connection with their demand for a general wage increase, which has not been acted upon by the Railroad Administration.

ORDERS OF THE REGIONAL DIRECTORS

American Red Cross.—The Northwestern regional director, file 33-1-17, urges that every officer and employee be given an opportunity to take a Red Cross membership for the coming year in view of the great humanitarian work the American Red Cross has performed.

Employment of Men in Train and Engine Service.—The Northwestern regional director, file 42-1-87, requires that men entering the service to fill the position of brakemen, flagmen, baggagemen, switchmen and firemen must be able to read and write; will be required to pass uniform examination and will comply with the regulations governing the use of standard watches.

Incomplete Brakes on Gondola Cars.—Supplement 2 to Circular 201 of the Southwestern regional director states that 500 U. S. Standard hopper cars, allocated to the Pere Marquette, built by the Ralston Steel Car Company and numbered 13,000 to 13,499, were placed in service without sheave wheels on brake and hand brake pull rod. The circular instructs that where these cars are found with sheave wheels omitted on the end of the hand brake rod changes should be made at once, regardless of ownership.

Improved Car Handling.—Circular 86 of the Northwestern regional director calls attention to the necessity for the improving of car handling, especially in view of the present acute situation in connection with car supply. In addition to this, particular attention should be paid to the prompt delivery of cars to connections, early arrivals at freight houses and team track deliveries, prompt unloading of equipment and movement of "company" material utilizing the full capacity for loading, which will result in saving of much equipment for revenue loading.

Substitute for Pneumatic Tires.—From Christiania, Norway, Consul General Marion Letcher reports that Lieut. Col. Fridtjof Andersen, a retired Norwegian army officer, has just perfected an invention which he claims will serve a sa substitute for pneumatic tires now used on motor vehicles. The invention involves the use of steel springs tangentially applied to the wheels, with an outer rim of solid rubber, steel, wood or other material. The inventor claims that spring wheels, manufactured according to his designs, may be used on street cars and railway trains, as well as on lighter vehicles. No arrangements have as yet been made for the manufacture of spring wheels.—*Manufacturers News.*

CAR DEPARTMENT

INSULATING TRAIN STEAM PIPES

BY W. N. ALLMAN

THE subject of fuel conservation has been one of considerable discussion during the past few years and at the present time is a matter of paramount importance. The conservation of fuel should therefore not be treated lightly and every phase of the subject should be carefully studied and investigated. There has been much literature published by the various departments of the government, treating the subject in a most complete manner and it is now acknowledged by all to be a vital factor and therefore must not be neglected even to the smallest detail.

In the operation of passenger train equipment there is considerable exposure of the train steam heat line. The radiating surface on an 80-ft. line for a 10-car train would be 500 sq. ft., and there would be a large loss in heat units if this surface was not adequately protected by some efficient form of insulation.

There are a number of types of insulation on the market to-day which may be generally grouped under the laminated type, the moulded type and the cellular type. Primarily, the load is placed on the locomotive and by reducing the amount of steam required to a minimum the saving in dollars and cents is realized.

The problem is to carry the heat to destination—interior of the cars—with the least amount of loss, and this can only be done by properly insulating the train steam pipes. It should also be understood that the efficiency of all insulations varies according to the size of the pipe to which it is applied; according to the temperature of steam in the pipes and the temperature of the surrounding air; another factor is the thickness of the insulation.

The efficiency of pipe covering is the per cent saving which would be obtained by insulating that pipe with a certain material over what would be lost if the pipe were left bare or uninsulated.

This per cent is obtained by subtracting the heat loss of the insulated pipe from that of the bare pipe and dividing the difference by the heat loss from the bare pipe. Expressed as a formula this would then be:

$$E = \frac{A - B}{A}$$

where

E = Efficiency

A = Heat loss through bare pipe.

B = Heat loss through insulated pipe.

The heat losses may therefore be compared directly as follows:

Bare pipes .... 100 per cent
Efficiency .... percent saving
100 per cent—per cent efficiency = loss through insulation expressed as a percentage of bare pipes.

For example, an insulation having an efficiency of 86 per cent allows a loss of only 14 per cent of the loss from bare pipes.

TYPES OF COVERINGS

Not all pipe coverings can be termed good insulation, some being efficient at low pressures, but very inefficient at higher pressures. Some coverings are fairly efficient when first applied but soon deteriorate and do not maintain their efficiency, while others maintain their initial efficiency indefinitely. The underlying principle of efficient insulation is confined to dead air cells, and perhaps one of the best forms of pipe covering is that of the laminated type, which consists of a number of layers of felt composed of asbestos fibre and particles of finely ground spongy material, this combination forming an extremely cellular felt. These layers of felt, being built up in laminated form, confine a large volume of minute dead air cells between the layers, and the general construction makes it a highly efficient covering and one that is most durable as well as maintaining its efficiency indefinitely.

The next best form, perhaps, is the moulded type of insulation, known as magnesia, and which is a light highly efficient insulation. In this type of covering there is also a large number of miscroscopically small dead air cells. These dead air cells cause the air to become stagnant, and thus a very poor conductor, thereby increasing the efficiency. This form of covering, however, is not as adaptable to service on train pipes as is the laminated form, because of the constant vibration which is more or less detrimental to this form of covering. The cellular type would then be considered the next best class of covering for train service and it may be of interest to note the saving that may be realized from the following analysis, which is based on pipe covering one inch thick in each instance, this being the thickness now generally recognized to be the most efficient for train service.

SAVING DUE TO INSULATION

In making this comparison three types of pipe insulation are used, having a known efficiency, and for the sake of convenience they will be designated as *A*, *B* and *C* coverings—all one inch thick.

A = Laminated form.

B = Cellular type, corrugations running around the pipe, not parallel with pipe.

C = Larger form with indentations in layers.

The efficiency of these coverings for a two-inch pipe and for the temperature difference dealt with hereafter, are as follows:

A = 85.84 per cent.

B = 82.00 per cent.

C = 78.60 per cent.

For our investigation we will consider a 10-car train, each car having 80 ft. of two-inch pipe, which is equivalent to 500 sq. ft. of radiating surface. Train line pressure 50 lb., outside temperature 20 deg. F. above zero. The results are calculated as follows:

Temperature of steam in train line at 50 lb. pressure	334.3 deg.
Outside temperature	20.0 deg.
Temperature difference	314.3 deg.

Loss in B.t.u.'s per hour, per sq. ft. bare pipe...	1,070.0
Total radiating surface, sq. ft................	500
Total loss in B.t.u.'s per hour................	535,000
Hours of service per day....................	16
Total loss in B.t.u.'s per day.................	8,560,000

Assuming coal to have a thermal content of 10,000 B.t.u.'s, this would be equivalent to 856 lb. of coal per day loss, or at four dollars per ton $\frac{4.00}{2,000} = .002 \times 856 = \$1,712$ loss per day from bare pipes.

The saving per day effected by using the three types of covering which have been described would be as follows:

Type of covering	Efficiency	Saving per day
A	85.84 per cent	$1.47
B	82.00 per cent	1.40
C	78.60 per cent	1.35

The initial cost of the covering would soon pay for itself and the saving of wasted heat units and ultimate dollars and cents would soon amount to a considerable item. The temperature of steam in train line of 354.3 deg. F. as covered in the above analysis, is obtained from the following formula:

Temperature of steam (saturated) at boiler pressure of 200 lb. per sq. in............	388 deg. F.
Total heat in saturated steam at 200 lb. per sq. in.	1,199.2 B.t.u.
Total heat in saturated steam at 50 lb. per sq. in.	1,178.5 B.t.u.
	20.7 B.t.u.

Since change through reducing valve has been a constant heat change, that is, no work done and no heat gained or lost, the heat in steam at 50 lb. per sq. in. above normal saturation content must be in the form of superheat. Therefore:

$$H_t = S\ (T_s - T_n)$$

Where:

H_t = Total heat above saturation heat content
S = Specific heat of superheated steam
T_s = Highest temperature of superheat
T_n = Normal temperature of steam at pressure given.

Therefore:

$$H_t = 20.7 \qquad S = .57$$

$$20.7 = .57\ (T_s - T_n)$$

$$\text{or } (T_s - T_n) = \frac{20.7}{.57} = 36.3$$

$$T_n = 298.0$$

$$\text{or } T_s = 298.0 + 36.3 = 334.3$$

The above conditions and analysis may be considered normal, and results would vary with temperature conditions. For example, in certain sections of the country during the winter the temperature would be much lower than that considered above, also, as the velocity of train increases the loss is greater and as the foregoing is based entirely on still air conditions, the saving would be even greater and more so by using the best insulation or that having the highest efficiency.

The following table will be convenient for determining the heat loss in B.t.u.'s from bare pipes:

TOTAL HEAT LOSS IN B. T. U.'S PER HOUR PER LINEAL FOOT OF BASE PIPE OF DIFFERENT SIZES AND AT VARIOUS TEMPERATURE DIFFERENCES AS GIVEN BELOW

Pipe Size	Area of Pipe Surface per lin. ft.	50 Deg.	100 Deg.	150 Deg.	200 Deg.	250 Deg.	300 Deg.	350 Deg.	400 Deg.	450 Deg.	500
½-inch	.220	21.5	47.3	79.2	117.3	162.3	215.2	279.1	355.1	451.4	569.8
¾-inch	.274	26.8	59.0	98.6	146.8	202.1	268.5	347.6	442.2	562.2	709.7
1 -inch	.344	33.6	74.0	123.8	183.4	253.7	337.4	436.5	555.2	705.4	891
1¼-inch	.435	42.5	93.6	156.6	231.9	320.8	425.4	551.9	702.1	892.6	1126.7
1½-inch	.498	48.7	107.2	179.3	265.4	367.3	487	631.8	803.8	1021.9	1289.8
2 -inch	.622	60.9	133.9	331.5	331.5	458.7	608.3	789.2	1003.9	1276.3	1611
2½-inch	7.51	73.4	161.6	270.4	400.3	553.9	734.5	952.8	1212.1	1541.1	1945.1

NOTE: For other temperatures than those shown in the table, the heat losses can be determined by interpolation.

Locotractors in South Africa.—A contemporary states that owing to the high cost of operating the usual forms of motor truck in South Africa, a modification of the truck tractor is being used. Roads are very poor and during the rainy season are often impassable. The light railway is advocated as the solution and suitable motive power is believed to have been definitely discovered in a gasoline locotractor, a special form of machine intended to take the place of the locomotive on pioneer light railways. The locotraction system uses load-carrying cars running wholly upon rails. The guiding portion of the locotractor also runs on the rails, but the driving wheels, shod with solid rubber tires, run on prepared strips of road metal on each side of the railway track and have greater traction. For a given horsepower and weight the hauling power is stated to be four times as great as with ordinary locomotives having driving wheels running on tracks.

Wood Fuel on Swiss Railways.—*The Times Trade Supplement* states that the results obtained from the use of wood fuel in Switzerland are of considerable interest. The technical difficulties were not so great as was anticipated. On lighting the fires with one cubic meter of wood a steam pressure of from five to six atmospheres was obtained in 1½ hours, for which otherwise 300 kilos of coal would have been required. The cost was approximately $13 (pre-war rate), as against approximately $15 (pre-war rate) with coal. The same maximum driving rates were obtained as with coal. The difficulty of storing fuel for long journeys was met by running a special truck behind the engine.

Refrigerator Cars For The C. P. R.

Steel Underframe Construction, 41 ft. Long, Fitted with Tank Bunkers, Meat Racks and Ventilators

The Canadian Pacific has recently built at its Angus shops, Montreal, an order of steel underframe refrigerator cars, which embody a number of interesting features, both in the underframe and body construction as well as in the refrigerating equipment. The cars are designed for satisfactory service when handling any of the several different commodities which require transportation in insulated cars because of the need of protection from heat or frost, and also for other miscellaneous freight which may properly be loaded in refrigerator cars when they are not required for the transportation of perishables.

As packing house products are regularly handled in Canada by railroad owned refrigerators, these cars are equipped with galvanized iron tank bunkers which permit the use of salt as required to obtain the proper degree of temperature. To prevent the exchange of air through the hatch openings at any time, and especially when the hatches are opened for re-icing, the tanks fit well around the ceiling. Regulation meat racks are included as part of the roof and ceiling construction.

For berry and fruit traffic it is necessary to provide a means of ventilation. This has been taken care of by providing openings in the fronts of the ice tanks near the top, so that when the hatch covers and plugs are opened, air will circulate freely into and through the car. The ventilator openings are fitted with malleable iron frames and close-fitting plate slides, which are secured in a closed position at all times except when the cars are operating under ventilation.

The use of ice or ice and salt when operating under ventilation, is optional, thus providing a wide range of regulation which may be varied to suit the seasons, conditions of the load, and the distance to be moved. Fruit fresh from the field is a very difficult commodity to transport, as the field heat and heat generated by the ripening process produces a condition that is difficult to handle. However, the brine tank ventilator car when equipped with suitable floor racks arranged so that free circulation will take place around the ice and out under the racks, is particularly suited to this traffic. as the use of salt on the initial icing lowers the temperature of the car rapidly, absorbing the field heat and checking the process of ripening. For fruit shipments it is well to apply temporary slats along the sides of the car to provide space for circulation at the sides as well as underneath. All other perishables may easily be transported safely in these cars, provided reasonable care is used in leading so that the air within the car may circulate freely.

Steel Underframe Refrigerator Car with Brine Tanks and Ventilators, for the Canadian Pacific

Whenever the lading requires protection from frost, charcoal heaters are placed in the corner ice tanks, two or more per car, as required.

THE REFRIGERATING EQUIPMENT

Permanent floor racks made of 1¾-in. by 3¾-in. fir are installed in sections, five sections on each side of the car. They are secured with hinges, similar to those used on side doors, to the lining base plank, and when propped up against the car sides, the racks are entirely clear of the floor, thus permitting the floor to be thoroughly and easily cleaned and swept out through the side door openings. The racks are made of relatively heavy material to insure durability, especially when the car is loaded with general freight.

The ice bunkers consist of four rectangular galvanized iron tanks at each end of the car; the tank bottoms are ⅛-in. pressed steel, galvanized after pressing, and the sides are 16-gage galvanized iron. Substantial lugs are riveted near the top. These lugs bear against the underside of the hatch frame and prevent the tanks from jumping when the cars are being switched. The tank supports consist of angle irons which are arranged so that the front supporting angle may be removed without disturbing any tank. After the removal of this angle one or more tanks may be removed and reapplied without disturbing the others.

The drip pan under the tank is sloped from the rear end towards the front of the tank, so as to be as nearly self-clearing as possible. The front edge of the drip pan is made of ⅛-in. pressed steel plate, galvanized. This arrangement avoids, to a considerable degree, the obstruction of free circulation of air down around the tanks and out under the floor racks.

Only the center tanks at the ladder corners are equipped with a drain valve. The remaining three tanks at each end of the car are coupled to this tank by hose connections located two feet above the tank bottom. The drain valve is connected to a pipe extending directly through the car floor.

Insulated bulkheads are provided in front of the ice bunkers. These bulkheads are hinged at one side of the car so that they may easily be swung open for inspection, cleaning or repairing the tanks. These bulkheads have an extension at the bottom with horizontal slats to prevent small crates or boxes from sliding under the bulkhead.

The ice hatches are of U. S. R. A. design, modified only as absolutely necessary to suit conditions.

INSULATION

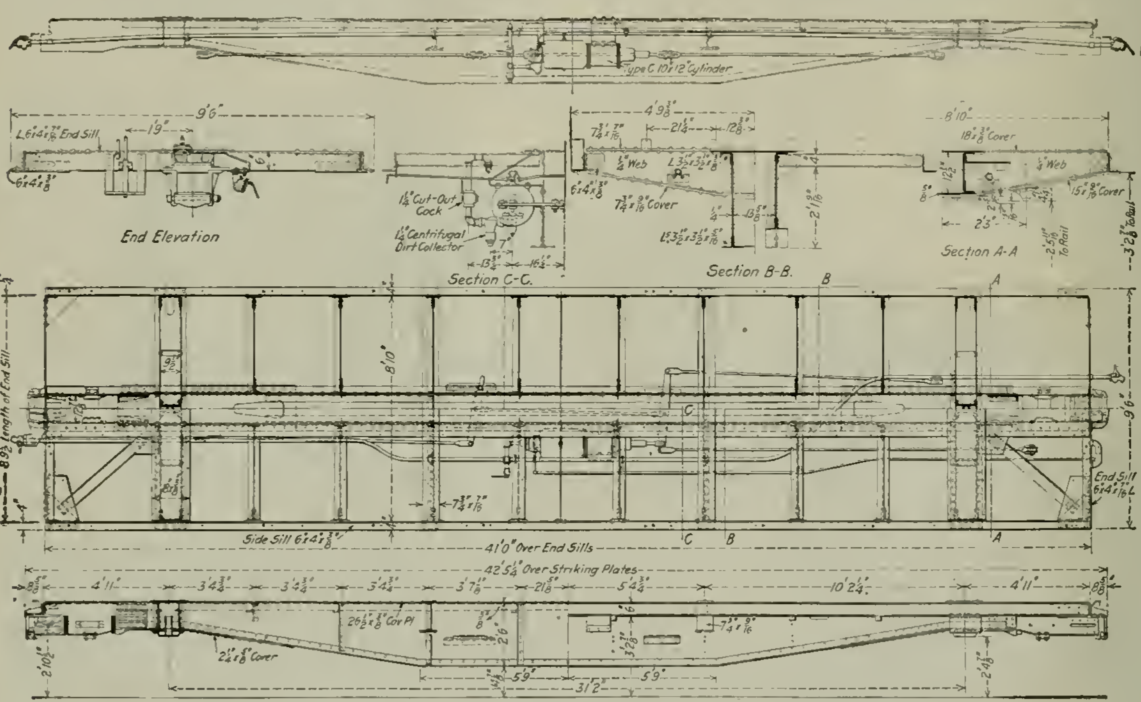
The floor insulation consists of one layer of 90-lb. waterproof insulation paper applied in one piece from side to side and end to end of the car, thereby covering the entire underframe and sub-floor. On top of this are placed the floor stringers. The center stringers rest on and are bolted to the edge of the center sill cover plate, while the intermediate stringers rest on and are bolted to the bolsters, cross-bearers and floor beams. Between the stringers four layers of ½-in. insulation are applied in strips, continuous from end to end of the car. Each layer consists of hair or fibre felt stitched between two courses of 90-lb. waterproof insulation paper. The four layers are applied in two courses of double layers, with nailing strips and ⅜-in. tongued and grooved boards between.

The floor consists of two courses of tongued and grooved boards, the under course ⅝ in. thick, over which is spread a heavy coating of hot, waterproof asphalt, and over this one layer of two-ply asphaltum roofing paper. The top course boards are 1⅛ in thick.

The side and end walls are insulated with three layers of ½-in. insulating material, each layer stitched between two layers of 90-lb. waterproof insulation paper. Side and end walls insulation extends continuously from floor to ceiling and from the door opening to the end of the car, across the end and to the door post opposite the starting point. One layer of the insulation is applied on the outside of the superstructure frame, overlapping and fastened to the sills and plates. Two courses are applied on the inside of the framing, against the ⅜-in. tongued and grooved sheathing. The outside sheathing consists of standard 13/16-in. tongued and grooved car sheathing and the inside lining is 13/16-in. tongued and grooved basswood or spruce. The total thickness through the side walls is 6½ in.

The roof insulation consists of six layers of ½-in. insulating material, each layer stitched between two courses of 90-lb. waterproof insulation paper. The insulation is applied in one piece between the carlines from side plate to side plate. It is applied in three double layers, each double layer supported on ⅜-in. tongued and grooved boards.

On the top side of the ceiling boards one layer of 90-lb. waterproof insulation paper is applied in one piece from side to side and end to end of the car.



Steel Underframe for the Canadian Pacific 41-ft. Refrigerator Cars

SUPERSTRUCTURE FRAME

The principal framing members of the car body are fir, excepting end sills, end posts and end braces, which are of oak or maple. All of the posts and braces are set in cast iron pockets with the exception of the end post and braces, which are set in special cast steel pockets, each having a high flange on the outside to prevent the lower ends of the posts and braces from springing over the top of the casting. Each casting is bolted directly through the steel end sill flange with two ⅝-in. bolts. This is to prevent the pocket from tipping out and also to avoid trouble caused by dowels splitting the wood end sill.

Diagonal brace rods are employed at each side frame panel to reduce racking to a minimum.

The spacing of the carlines coincides with the spacing of the meat rack cross supports, and the supporting bolts pass through the car-lines, thus avoiding longitudinal blocking, which is undesirable, particularly on account of interference with insulation. At alternate carlines ¾-in. cross tie rods are applied.

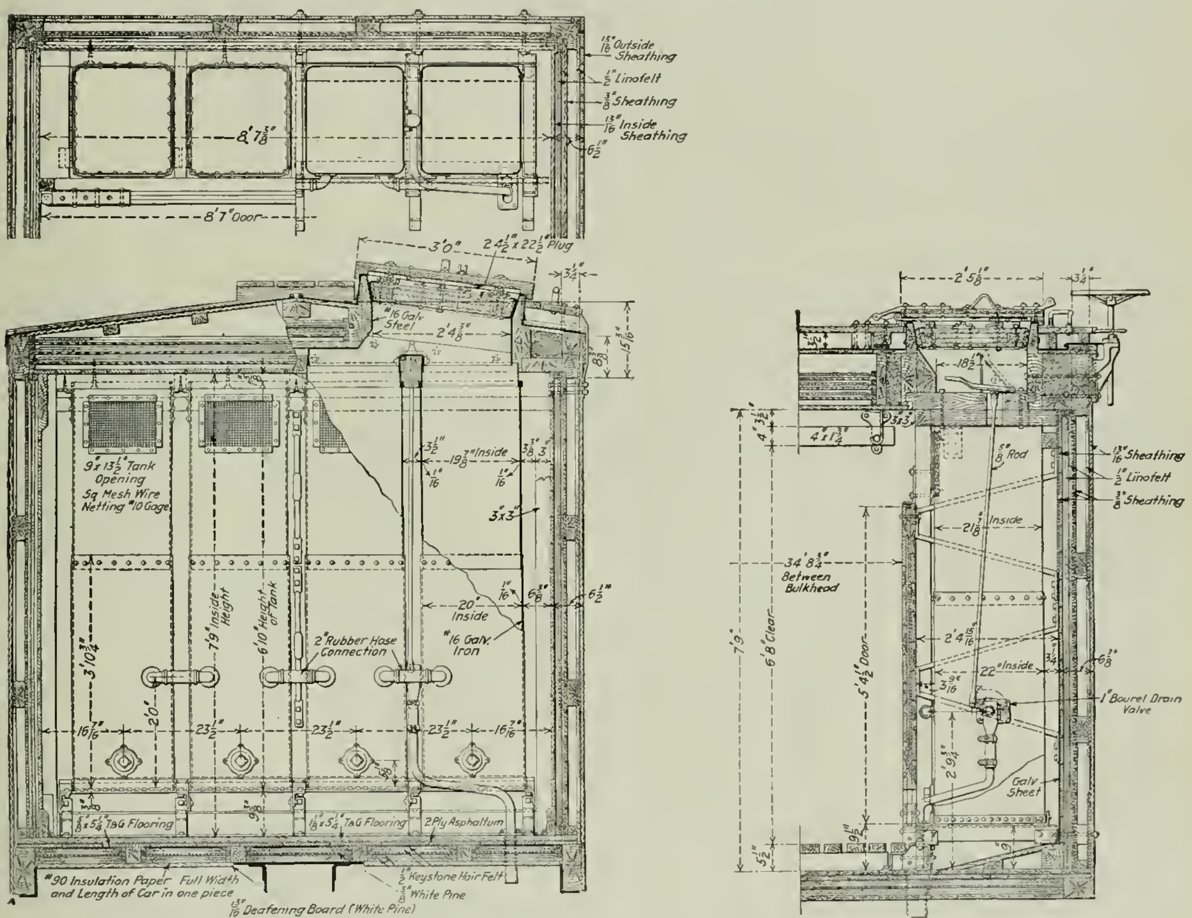
The framing and insulation of this car are so arranged that the roof frame may be assembled on the shop floor and then placed on edge, while the ceiling boards are applied. This enables the builders to work at all times to the best advantage, which results in good work rapidly done.

The roof is galvanized iron, type XLA, flexible, applied over a single course of boards and one layer of two-ply asphaltum roof paper. As already noted, the spacing of the carlines is governed by the spacing of the meat rack supports and on account of the roof insulation the roof mullions and running board saddles are spaced to coincide with the carline centers; this provides a solid construction for nailing the mullions.

The roof sheet pivot saddles are secured by carriage bolts applied through a special washer nailed on the underside of the ridge pole; this washer when applied is L-shaped and is secured by two nails. After the carriage bolt has been applied the projecting end of the washer is bent back under the bolt head to prevent the bolt from dropping down. The hole in the washer is square, to suit the shank in the bolt head.

The side doors are equipped with W. H. Miner fasteners. The threshold plates are of pressed steel with a shallow shoulder at the inside edge for the stripping on the lower inside edge of the door to close against. The open door fastener consists of a link and bolt arrangement that cannot become unfastened accidentally.

Side door thresholds and all metal work on the interior of the cars are heavily galvanized by the most reliable known process.



Arrangement of the Brine Tanks and Body Construction Details of the C. P. R. Refrigerator Cars

THE UNDERFRAME

The underframe is of the center carrying type. The center sills are 30 in. deep at the center portion, composed of web plates ¼-in. thick, a ⅜-in. by 26½-in. top cover plate continuous one piece from end to end of the car, top flange angles of 3½-in. by 3½-in. by ⅜-in. section, and 3½-in. by 3½-in. by 5/16-in. bottom flange angles. The center sill bottom cover is of ⅝-in. by 21¼-in. plate.

The bolsters are of the box girder type, composed of ¼-in. pressed steel diaphragms, with a ⅜-in. top cover plate, 18 in. wide, and a 9/16-in. bottom cover plate, 15 in. wide. The crossbearers are of single web girder construction, consisting of ¼-in. pressed steel diaphragms, with a 7/16-in. by 7¾-in. top cover and a 9/16-in. by 7¾-in. bottom cover. The floor beams are 4-in., 8.2-lb. Z-bars, and the side sills are 6-in. by 4-in. by ⅜-in. angles. The end sill angles are of 6-in. by 4-in. by 7/16-in. section.

The draft arms are of ⅜-in. pressed steel. The rear draft lugs are secured to the draft arm and center sill splice, and are also riveted to the center sill bottom cover. The front draft lugs are designed to receive a cast steel coupler striking plate and cast steel carry iron; the latter is secured by a 1⅜-in. bolt passing through the lower front corners of the draft lugs. The cast steel striking plate has an extension arm for the angle cock bracket, so arranged that the bracket may be located correctly for 9¼-in. or 12-in. coupler heads.

The cars are equipped with friction draft gear, cast steel yokes and 5-in. by 1⅛-in. coupler yoke keys.

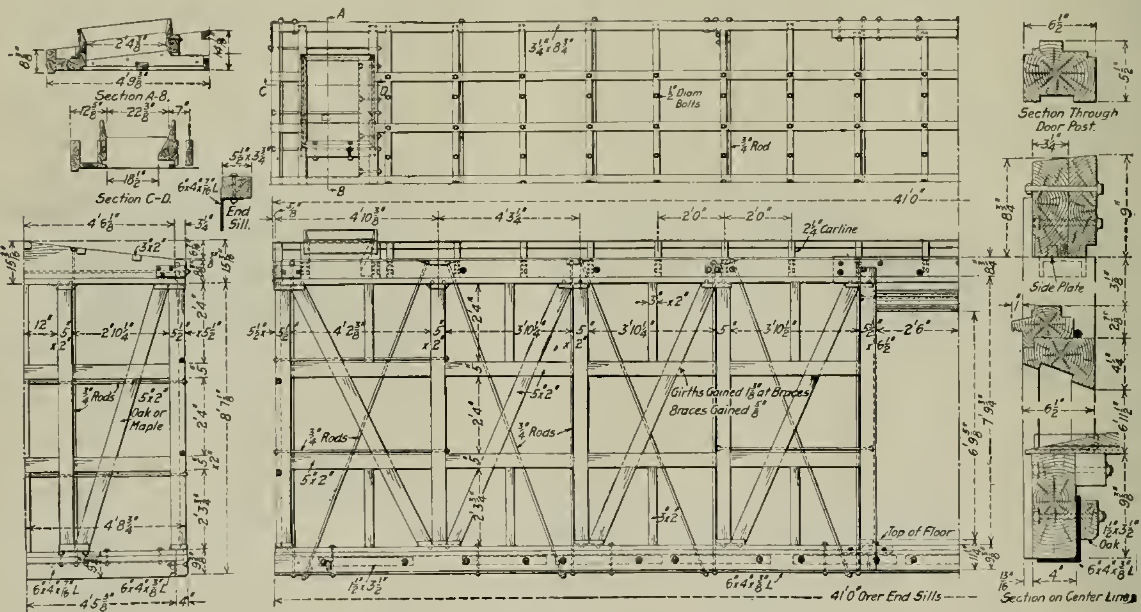
TRUCKS

The cars are equipped with C. P. R. standard 40-ton arch bar type trucks, having Simplex bolsters designed to support the center pin in the truck bolster. The truck columns are of the Harrigan pinless brake hanger bracket type. Side bearings are of the roller type located 27-in. from the car center.

Adjustment of brake piston travel is provided for on the floating lever fulcrum, making it unnecessary to change the adjustment on the trucks after they have been correctly adjusted when the car is built, except that variations in the dimensions of brake beams and rods applied in renewals may require the truck levers to be readjusted.

The brake mast is 1¼-in. square and is fitted with a snow and ice proof ratchet and dog.

The tare weights of these cars average between 59,000 and 60,000 lb., resulting in a limit load capacity, including ice, of 72,000 to 73,000 lb.



Superstructure Frame of the Canadian Pacific Refrigerator Cars

SOME CAUSES OF HOT BOXES*

BY S. W. CRAWFORD
President, More Jones Brass Company, St. Louis, Mo.

The M. C. B. type of journal bearing used in railroad cars has been standard for a great many years, although there have been many efforts to develop other types to substitute it. The first bearings were made of solid bronze, and the first linings used in bearings were made by sweating in a sheet of lead, which was done to overcome the variation in size of journals due to wear. The solid bronze bearing, when applied, would not fit the journal and consequently, it would frequently cause trouble until it was worn down to a journal fit. The thin sheet lead lining was a decided improvement on the solid bronze, as it would give under the load and fit the journal, but as it was very thin, it only provided a starter for the bearing, following which the lining was increased in thickness, by making the lining of babbitt metal, until we finally developed the filled type of bearing, which was a bronze shell, filled with babbitt.

As the lining thickness was increased the babbitt was made comparatively harder, so it would withstand the load. This provided a cheaper bearing, but they have been universally discarded for the reason they were not capable of withstanding the same load or strain as the solid bearing and as a result, caused a great many hot boxes.

A classification of bearings was provided by the M. C. B. Association for filled journal bearing linings ⅜ in. or over in thickness; solid bearings having lining less than ⅜ in. thickness.

A reaction took place. As the use of hard babbitt had been developed, and the thickness of the lining gradually reduced without reducing the hardness of lining, many hot boxes were the result. Bearings would not fit themselves to the journals with the bearing area so small. If the load is too great for the surface area of bearing, the filament of lubrication will break, and a hot bearing will be the result.

I had a case on a road, where they had been using filled

*From a paper read before the St. Louis Car Foremen's Association.

journals bearings for years, and decided, due to the fact that they had very carefully figured over the cost on solid bearings, as compared to filled bearings, to adopt the use of solid bearings, with ¼ in. thickness of lining. The road had specifications, and the lining metal they had been using was what we call an 18 per cent lining, a good one in a filled bearing. But as the thickness of lining had been reduced, the lining metal proved to be too hard and resulted in a great many hot boxes. I was called on to investigate these conditions, and found in some cases as many as a dozen bearings to have been applied to one pair of wheels, all of which were removed before they had fitted themselves to the journal. A conference was called of the car men, and as the universal opinion was that the lining was too hard, we suggested a change, reducing to 10 per cent. As this was quite a big reduction in the degree of hardness, it raised the question as to whether we would shorten the life of the bearing from a wearing standpoint. Quite the opposite proved to be the case, as the bearings lasted longer, and as a result, we today exercise as a standard, the 10 per cent lining, unless the specification of the railroad is otherwise.

I believe our hot box troubles are less than at any time I have ever known, but there is no doubt room for further improvement. We can build up better efficiency in bearings as we do in everything else, by close co-operation. We are doing in the brass business now what we did not think of years ago, and that is to get out on the road with the men using these bearings, studying their side of the situation, and studying conditions under which they are operating.

If we are going to get best results, we must establish the best practice, not at one point, but at all points. Men must be made familiar with the material they are using—not only the bearings, to see that they properly fit the wedge and journal, but they must know that the waste, etc., which they are using is of a quality to furnish the lubrication for that bearing. I have found cases, which showed, upon examination, that the oil from the waste in the oil box would only feed out of the packing one-half to one inch in depth. The remainder of the packing in the box had a great quantity of oil, sufficient to lubricate for a long time, but it could not get to the journal. That was due to the fact that the waste was not of a quality to feed the lubrication. You can have a lamp full of oil, but produce a poor light, because the wick is not of a quality that will feed the proper amount of oil to produce the light. The same applies in the oil box with the waste, which is the wick.

Generally, wherever you find cracked linings in journal bearings, you will find very careful inspection. The cracked lining is caused where the bearing is not getting enough lubrication. The temperature reaches a point where it fuses the solder which holds the lining in the bearing at about 400 deg. F. The fusing temperature of the lining is about 500 deg. As there is 100 deg. difference between the fusing point of the solder, which holds the lining in the bearing, when the temperature reaches the fusing point of the solder, it will loosen the lining. Then, if the bearing is given attention, and you re-establish the proper lubrication, the bearing will cool down, and when it is cooled down, that portion unsoldered remains loose. The result is, the vibration of the loose lining running over frogs and crossings, causes it to crack. That is why I say, wherever you find cracked linings, the road is giving close inspection to the cars. If it did not, instead of having cracked linings, the babbitt would have been melted out.

A great many hot boxes are brought about through some carelessness in applying bearings, such as allowing waste or dirt to get between the journal and the bearing. If it does, it will almost always produce a hot box, because it will stop the flow of lubricant, and cause the bearings to pinch. The waste between the bearing and journal will burn and carbonize, in which case it will make a very hard spot, and cut the journal. We have a great many times received complaints regarding hard spots in the lining. The hard spots are usually caused by the filament of lubrication being broken, and allowing the lining metal to come in contact with the axle, which will burnish it, and make a bright spot in the bearing. That spot is no harder under the polished surface than the other metal, because we cannot produce a lining metal harder in one part of a bearing than in the other. If a spot is burnished in a journal bearing, it takes on a very bright, smooth surface, like glass, and the oil will not lubricate under the polished surface. If the spot is removed by scraping, the bearing can safely be reapplied.

I have found a lot of cases where journal bearing wedges did not have the proper clearance on the bevels of the brass, and in some cases the wedges extended down so that they formed a bearing on the lower edge or lugs of the brass. This would cause the brass to pinch on the journal, resulting in hot boxes. Under no circumstances should wedges be a tight fit on journal bearings.

If we get together and work for a standard practice, we can get results that would probably mean eliminating the necessity of sending men along with a pair of wheels when applying new bearings, which is the practice on some railroads, and not on others. I can see no good reason why it should be necessary to send men along with a pair of wheels, to see that bearings will run, if the care is exercised to see that the bearings fit properly in wedges, box and journal, and the proper packing and lubrication is applied.

METHOD OF DETERMINING THE MOISTURE CONTENT OF WOOD

The moisture content of lumber gives a good indication of the amount of shrinkage which may be expected to take place during seasoning. For that reason many railroads specify the maximum percentage of moisture permissible in lumber for freight cars, particularly in single sheathed cars. The following directions for determining the moisture content of wood, issued by the Forest Products Laboratory of the United States Forest Service, are therefore of interest.

FIVE STEPS IN MAKING A MOISTURE DETERMINATION

(1) Select a representative sample of the material. (2) Immediately after sawing, remove all loose splinters and weigh the sample. (3) Put the sample in an oven maintained at a temperature of 212 deg. F. (100 deg. C.) and dry until constant weight is attained. (4) Reweigh the sample to obtain the oven-dry weight. (5) Divide the loss in weight by the oven-dry weight and multiply the result by 100 to get the percentage of moisture in the original sample. Thus,

$$\text{Percentage moisture} = \frac{(W-D)}{D} 100$$

where

W = Original weight as found under 2 above
D = Oven-dry weight as found under 4 above.

Selection of the Sample.—If possible, the sample should be taken from near the center of the piece. Wood gives off or takes on moisture more rapidly from the end grain than from the side grain and as a result there may be considerable difference between the moisture content of the ends and center of a stick. For this reason a sample from within about a foot of the end of a long board may not be representative. Short pieces of wood dry out much more rapidly than longer ones. In order to reduce the time required for drying, therefore, the length of the sample in the direction of the grain should usually be about one inch. With material one square inch or less in cross-sectional area, however, a sample over one inch long is generally desirable and the length in this case may be chosen so as to give the sample a volume of two or more cubic inches. The other dimensions may be equal to the cross section of the board from which the sample is taken.

Weighing.—It is important that the weight be taken immediately after the sample is cut, for the material is subject to moisture changes on exposure to the air. The degree and rapidity of change are dependent on the moisture content of the piece and the air conditions to which it is exposed. In order to insure good results the weights should be correct to within at least one-half of one per cent.

Drying.—When placed in the oven for drying, the samples should be open piled to allow free access of air to each piece. The oven should have some ventilation, thus allowing the evaporated moisture to escape. A thermometer should be provided by which the temperature can be ascertained at any time. The temperature should at no time exceed the boiling point of water (212 deg. F.) or distillation of the wood may take place, and erroneous results be secured. From 24 to 96 hrs. of oven drying may be required for the sample to reach a constant weight, depending on the size and kind of wood and the amount of moisture it contains.

Reweighing.—As in the case of the first weight taken, it is essential that the sample be weighed soon after being removed from the oven.

A typical example of the computation necessary for determining the percentage of moisture is given below: A 2-in. by 2-in. by 1-in. sample of air-dry Sitka spruce weighed 30.8 grams. The sample after oven-drying weighed 27.5 grams. Find the moisture content of the sample.

$$\text{Percentage moisture} = \frac{(30.8 - 27.5)}{27.5} 100 = \frac{330}{27.5} = 12.$$

HANDLING EQUIPMENT WITH DEFECTIVE SAFETY APPLIANCES

BY M. J. LACOURT
District General Car Foreman, Chicago, Milwaukee & St. Paul

Railroad officers often place wrong interpretations on the handling of equipment having penalty safety appliance defects. Reportable safety appliance defects should not be confused with penalty defects. A car having a reportable defect may be moved in trains; a car having a penalty defect cannot be moved except for the purpose of repairs when repairs cannot be made where the car is found defective, and the movement must be to the nearest point where repairs can be made. The car must not be otherwise used between stations or yards.

Any movement of a car having a penalty defect was held to be a violation of the law as originally passed. However, it was practically impossible to enforce this act and Congress in adopting the amendment of 1910 undoubtedly had this in mind. The following is a verbatim extract of the section of the Safety Appliance Act bearing on this subject:

Section 4.—That any common carrier subject to this Act using, hauling or permitting to be used or hauled on its line any car subject to the requirements of this Act not equipped as provided in this Act shall be liable to a penalty of one hundred dollars for each and every such violation, to be recovered as provided in Section six of the Act of March second, eighteen hundred and ninety-three; as amended April first, eighteen hundred ninety-six; Provided: That where any car shall have been properly equipped, as provided in this Act and the other Acts mentioned herein, and such equipment shall have become defective or insecure while such car was being used by such carrier upon its line of railroad, such car may be hauled from the place where such equipment was first discovered to be defective or insecure to the nearest available point where such car can be repaired, without liability for the penalties imposed by Section four of this Act or Section six of the Act of March second, eighteen hundred and ninety-three, as amended by the Act of April first, eighteen hundred and ninety-six, if such movement is necessary to make such repairs and such hauling of such car shall be at the sole risk of the carrier, and nothing in this section shall be construed to relieve such carrier from liability in any remedial action for the death or injury of any railroad employee, caused to such employee by reason of or in connection with the movement or hauling of such car with equipment which is defective or insecure, or which is not maintained in accordance with the requirements of this Act and the other Acts herein referred to; and nothing in this proviso shall be construed to permit the hauling of defective cars by means of chains instead of drawbars, in revenue trains or in association with other cars that are commercially used, unless such defective cars contain live stock or "perishable freight."

In applying the act care and good judgment must be used in interpreting it as to the nature or extent of the damage which a car must carry in order to permit of moving it to a shop. The place where the car is located should be considered as well as the nature of the defect. By moving the necessary facilities and material to the car any defect could be repaired. If necessary, a car could be built at any outlying point, but that is not the intent of the law. The law should be interpreted to mean that a car found defective at a point where the road does not maintain the necessary facilities and men, undoubtedly could be moved for the purpose of repairs to the nearest available point where that class of repairs is ordinarily made. In choosing between two points where the class of work intended might be handled, one point may be a little nearer, but the other point more readily available, due to the fact that the car could be moved to this point by one train movement, whereas the nearest point may require the switching of the car at some terminal point. In such cases the most available point would be the proper point to which to haul the car for repairs.

The law requires that a car which becomes defective while being used by the railroad should be repaired where the car is first discovered, thus avoiding injury to switchmen and others who are required to move the car in case it is to be moved for the purpose of repairs. The law is for the protection of all employees. The lives of carmen should not be endangered by requiring them to take unnecessary chances in a yard where switching is going on constantly to make repairs which might require considerable work between or underneath cars. In endeavoring to make repairs to a car on a yard track there is danger of tying up the terminals or seriously interfering with the operation of trains, all of which should be taken into consideration.

The Safety Appliance Act applies to equipment used on side tracks and yard tracks, as well as on main lines. A car having a penalty defect must under no circumstances be offered in interchange, nor must a car in this condition be received in interchange, as under the amendments above mentioned only the railroad on which the car becomes defective has a right to move a car for repairs on its own line.

The hauling of cars by means of chains in revenue trains or in connection with cars commercially used, except cars containing live stock or perishable freight is prohibited, unless such cars, when hauled, are not in revenue trains or in association with cars commercially used. It would be permissible to send a locomotive to haul in chained up cars to the nearest available point where the cars can be repaired. It would be a violation of the law to haul such cars even in a non-revenue train out of or through a point where the requisite repairs can be made; further the hauling of the car must be for the purpose of repairs and not for the purpose of disposing of the contents.

It might be well to sum up the Safety Appliance defects involving various parts of the car.

	Combinations of defects		Combinations of defects
Air brakes	34	Ladders	9
Hand brakes	101	Height of couplers	3
Hand holds	7	Sill steps	8
Uncoupling attachments	28	Safety railing	3
Coupler and parts	20	Hand railing	4
Running boards	16		

It may be noted by the above list of safety appliances that each becomes defective in numerous ways, many cases constituting reportable defects only, but all of sufficient importance to require close attention to avoid injury to employees and the traveling public.

Car Wheels and Their Defects*

A History of the Chilled Iron Wheel With a Discussion of Methods for Securing Maximum Service

BY W. F. TIDSWELL
Michigan Central, Detroit, Mich.

The first wheels designed to run on rails were made of wood, with the flange built up about an inch. These were introduced in 1649 and were used in all classes of service. They continued in general use until about 1753, at which time the cast iron wheel came into use. It took about fifteen years to convince people that the iron wheel had come to stay and in 1767 the cast iron wheel came into general use. The wheel hub was split and clamped on the axle with bolts through the hub and was also keyed to the axle.

In the years from 1767 to 1843 many different forms of wheels were brought out, the principal one of which was the double plate wheel. The general tread outline was the same as that in use at the present time. The tread was narrower, being 3¾ in. wide, the flange about 1¼ in. high and the standard wheel was 24 in. in diameter. The inside and outside plates extended from tread to tread, in a convex form.

Vertical Flange

Slid Flat Spots Causing Comby Tread

with a hollow space between the plates. The hub between the plates was separated about ½ in. The wheel was either shrunk on the axle or pressed on.

In 1849 a patent was granted to I. Van Kurran for a new design of wheel, and it became popular for a while. This was quite a departure from the wheel of 1843. It was a double plate wheel, but the plates met about half-way between the tread and hub, with a cored space between the tread and the center of the plate, and another cored space between the hub and the center, making two separate cores between the hub and tread. The tread was about 4 in. wide, 28 in. in diameter, and had a chilled tread. Chilled iron tires were used on locomotive drivers until 1865.

On October 8, 1850, N. Washburn was granted a patent for a double plate wheel, the two plates merging into one, and reinforced on the back by brackets or ribs. This style of wheel has been in general use since that time.

Previous to 1843, wheels were made of soft iron, the method of chilling the tread not being in use. The discovery of this, like many other important improvements was said to be accidental. About 1804, or 1805, a foundry man in England accidentally spilled some molten iron on a cold iron plate, and on examination, found it to be very much harder than iron poured into a sand mould, and from this simple beginning, the chilled iron car wheel was evolved.

The Washburn wheel weighed about 500 lb. The tread widths had been a subject which each railroad settled to suit its own particular ideas, there being no interchange of cars on different roads. Each car was run to the exchange point and the freight transferred to other roads. Another thing which prevented exchange of cars was the track widths. Each railroad established its own track gauge without any consideration for the other.

After the Master Car Builders Association was organized in 1866, many of the differences between different railroads were ironed out, and some agreement arrived upon, looking toward a standard system not only of car wheels, but many other car parts.

At that time cast iron wheels were in use under both freight and passenger cars. The design of the wheel and the method of manufacture had been left to the wheel makers, and it was not until 1893 a standard wheel was adopted.

In the early 70's, steel wheels came into use under passenger equipment, and in 1872 Mr. Adams, of the Boston & Albany, stated in the M. C. B. Convention, that the B. & A. was equipped with steel wheels under their entire passenger equipment. In 1868, a resolution was offered in the M. C. B. Convention, to make the standard track gage 4 ft. 8½ in., and the wheel tread 5 in. wide.

The standard axle also adopted at this time had journals 3¾ in. by 5½ in. It was not long after this, that a car of greater capacity was designed, with an axle with journal 3½ in. by 6 in. This was known as an E. L. L. (extra long and large). It is a wide step from this size to the 6 in. by 11 in. journal of the present.

WHEEL FAILURES

Briefly, the wheel failures or defects which justify renewal are as follows: Sharp flange or worn flange, shelled out, burnt chill, either from sliding or from brake application, worn tread, worn through the chill, chipped flange, chipped rim, etc. The most common cause for removal is worn flanges, next worn tread, tread worn hollow, then brake burn, brake slid, shelled out, worn through tread and cracked flanges. If there are no inherent defects which would cause their early removal, and if they are not subjected to abuses, such as wheels sliding, truck out of true, air brake not properly repaired, etc., etc., will last out their alloted time and mileage barring accidents.

WORN OR SHARP FLANGES

The first defect of car wheels to be considered is worn flanges. There are several reasons for worn flanges. One

*From a paper presented before the Car Foremen's Association of Chicago.

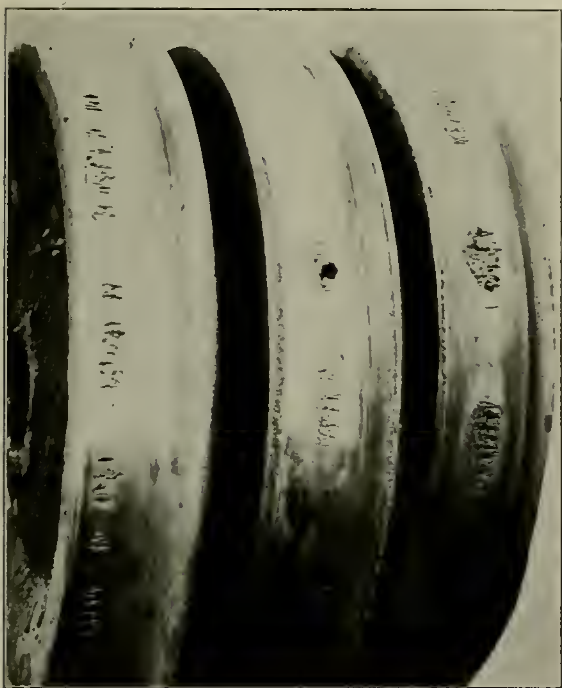
is the mismating of wheels when first mounted. When cast wheels are first made at the foundry, one of the first things done after the wheel is cleaned is to measure the circumference and mark the wheel accordingly. This is called "tapping" and the sizes marked on the plate of the wheel are called tape sizes. Wheels whose tape sizes do not correspond should not be mounted on the same axle.

Another reason for flange wear is that the truck may be out of square. When this is a fact, the wheels do not track properly. One wheel is ahead of its mate, consequently the flange hugs the rail, making an undue amount of wear on the flange of one wheel.

Another cause for sharp flanges that car repairers can do much to rectify is improper clearance of side bearings. If the car rests heavily on the side bearings, the truck is not able to adjust itself readily to the tracks. Too much space between the car body and side bearings will cause the car to sway. This swaying is very bad on the trucks, axles, wheels and rails.

WORN TREAD

Worn tread is first cousin to sharp flange. Worn treads may occur from the same causes as sharp flanges. If a pair of wheels, one of which has a sharp flange, is examined, it



Chilled Iron Wheels with Treads Destroyed by Brake Burns

is very liable that the companion wheel will be found with a worn tread, because the wheel having been run in one position grinds out the tread either on account of one wheel being larger than the other or the truck out of square.

There is one other cause which will produce these defects, and that is the wheels not being mounted equidistant from the ends of the axle. This not only causes the wheels to crowd against the rail, but it also brings an extra amount of wear on the journal collars.

BRAKE BURN OR BURNT CHILL

A wheel that is brake burnt is easily distinguished by cracks across the tread of the wheel. Sometimes these cracks are only hairlines, and in other cases there is a separation of the metal, a sixteenth of an inch or more in width, and covering the entire periphery of the wheel. This is caused by the brake application continuing for a long period, heating the tread of the wheel, and causing the iron to separate on account of the expansion of the metal.

Brake burns occur in some classes of equipment more frequently than in others, for instance, fast refrigerator line cars. These cars are designed for 60,000 lb. capacity, and are equipped with 4¼ in. by 8 in. axles and 625 lb. wheels. This class of car is not in the same kind of service as a 30 ton merchandise car, but on fast freight service. The speed at which these trains move is much faster than the ordinary freight train, consequently when it is necessary to stop the train there is a longer application of the brake. This naturally generates heat on the tread of the wheel, and as a result brake burns and broken plates occur more frequently in this service.

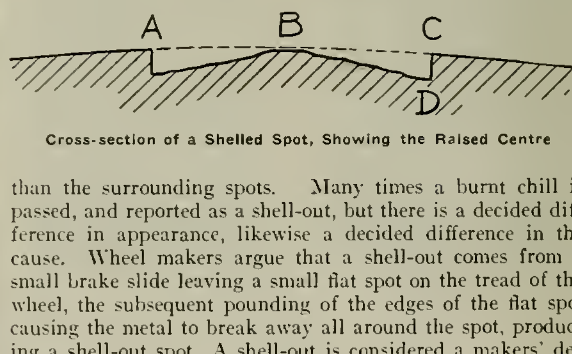
The design of the wheel does not provide sufficient metal to take up the heat. This causes the tread to expand, and as the tread expands the hairlines or separation of the metal occurs on the tread, or a crack in the plate of the wheel, resulting in either brake burns, cracked plates, cracked flanges or brake slides.

CHIPPED RIM

This occurs from the wheel tread being worn hollow, the high part of the rim striking on the switch frogs or switch points, breaking off the rim of the wheels. The heating of the treads is also responsible for cracks occurring in flanges, particularly so if the brake shoe crowds against the flange of the wheel. The flange not being large enough to carry away the heat, the expansion causes the flange to crack at the throat or fillet of the flange.

SHELLED OUT

A shelled-out wheel is one where the metal of the tread has shelled away from the center, leaving the center higher



Cross-section of a Shelled Spot, Showing the Raised Centre

than the surrounding spots. Many times a burnt chill is passed, and reported as a shell-out, but there is a decided difference in appearance, likewise a decided difference in the cause. Wheel makers argue that a shell-out comes from a small brake slide leaving a small flat spot on the tread of the wheel, the subsequent pounding of the edges of the flat spot causing the metal to break away all around the spot, producing a shell-out spot. A shell-out is considered a makers' defect, and subject to replacement by them.

I have been told by some wheel makers that brake slides have been found on engine truck wheels. I have never seen this, but I have seen a typical shell-out on wheels in this service.

Greater care should be taken in reporting the defects for which wheels are removed. If the inspector calls a brake burn a shell-out, and the next man who sees the defect reports it something else, there is bound to be confusion. It is this report that guides the man in the office in making up his records and charges.

CRACKED PLATES

Another frequent cause for wheel removals is cracked plates. Cracked plates are caused by the expansion of the tread through heat generated by the brake shoe. The heating of the tread produces a strain on the wheel, at the juncture of the front and back plates.

BRAKE SLIDE

A brake slid wheel can do more damage to equipment and rails than any other wheel defect. The continual pounding of the flat spots on the rails will loosen every bolt in the truck, and broken rails are very often traced back to brake slid wheels. Spots where the wheel has worn through the chill have a close resemblance to brake slides, but are easily distinguished. The brake slide will have a flat spot with more or less sharp edges, whereas, a spot worn through the chill will have the edges worn over or rounded, leaving no well defined flat spot. A wheel worn through the chill is clearly a maker's defect, and one that cannot be told by inspection of the wheel when new. The wheel when made may have a much thinner chill on one side of the wheel than on the other, and there is no way of telling this except by breaking the wheel.

Shelled Out Spots on Wheel Tread

A very common cause for brake slides, and the causes are numerous, is defective brake rigging, due largely to lack of inspection to the air brakes. Another is the angle at which the brake shoe is hung from the truck. If the angle of the brake hanger in relation to the wheel is too great, the shoe on one pair of wheels in the truck will lock against the tread of the wheel producing tremendous leverage, while the other pair in the same truck will have but little leverage depending on the direction the wheel is revolving. This can be remedied in nearly all cases by bringing the point of suspension of the hanger closer to the wheel.

The number of accidents, the safety of the traveling public, and the successful transportation of freight depends largely on the careful inspection of each wheel under every car, so that defective wheels may be discovered and removed before there is a possibility of accident. The inspector should take no chances on a defective wheel, nor at the same time cause the removal of a wheel which is in the safe limits of good practice.

DISCUSSION

F. K. Vial (Association of Manufacturers of Chilled Car Wheels, emphasized the importance of the correct mating of car wheels when mounted on axles, and illustrated his remarks by figures showing that one wheel would slide a considerable distance even though tape figures are within 1/8 in. of each other. He also spoke of the difficulty of deciding the cause of shell-outs.

In answer to a question Mr. Tidswell stated that in many cases the breaking of flanges in the throat or fillet of the flange is caused by the brake shoe crowding against the flange of the wheel, which, when the brake is applied heats the flange of the wheel, which is not big enough to carry off the heat. He recommended that the brake beam and brake shoes be hung as nearly central with the axle as possible, which, if the beams are properly made, will bring the brake shoe square against the tread of the wheel.

It was brought out that a large part of the damage done to wheels was caused through neglect or improper inspection of the air brake equipment. Particularly Lawrence Wilcox (Westinghouse Air Brake Company) stated that four points which cover some of the more important features of air brake maintenance in which car foremen are directly interested and which are important factors in wheel damage are improper levers, proper maintenance of triple valves, a sufficient piston travel to eliminate excessive brake cylinder pressure for a given brake pipe reduction, and failure to make certain that the small exhaust port in the retaining valve is open when cars are on repair tracks, the percentage of these cases running as high as 35 per cent.

E. H. Mattingly (B. & O.) stated that the relationship of the triple valve with the brake burned wheel or the heated wheel is a very serious one and that it is the duty of the owners of cars to see that the triple valve is put in the best condition possible. Mr. Mattingly also laid stress on the importance of having minimum and maximum standards of adjustment of side bearing clearance.

Representatives of private car lines stated that the 625-lb. wheel was too light for refrigerator service, which includes high speed work with heavy breaking wear, but as the M. C. B. standards specified this weight for the type of car used, the private owners had no protection on the exchange of wheels should they adopt a heavier standard. It was generally agreed that a heavier wheel, weighing about 740 lb., would give increased efficiency in high speed freight cars of this type.

E. S. Way (General American Tank Car Company) stated that many wheels are removed for brake burns and chipped rims which are not at all dangerous and have a great deal of mileage left in them. He advocated closer personal instruction of shop and yard inspectors as to what constitutes a dangerous wheel.

A committee was appointed to look into the cause of wheel defects and report their finding, together with a recommendation for heavier wheels on refrigerator cars, to the American Railroad Association.

The Aeroplane Engine in Industry.—That the airplane engine is not above ordinary humdrum work is shown by the fact that one has recently been installed in a London factory as a stand-by power unit. It burns gas instead of petrol and the cooling water is circulated through a common cast-iron radiator. It is an eight-cylinder engine, surplus from the war, and at the aerial rate of living would develop 200 hp., but has been rated at 75 hp. on earth to give it a reasonable length of life.—*Compressed Air Magazine.*

Inspecting Cars in Interchange

Methods to be Followed to Comply Fully with the M. C. B. Rules and to Locate All Important Defects

The following suggestions are for the purpose of educating and impressing upon the minds of all inspectors and follow-up men the practices to be observed in their everyday duties and to bring about uniformity of inspection.

The first duty of the inspectors is to be in the yard when the train pulls in, to see if they can detect, as the train passes, by sound or sight, any defect, especially of the truck and wheels, which would not be detected when car is not in motion, and checking such equipment with a mark so that it will immediately come to their attention when they reach the car in their regular duties. Contrary to this, many inspectors remain in their buildings until the road engine cuts off, which indicates that the inspector does not have the proper spirit nor take the lively interest in the work that he should.

Before going over the train, as he reaches the end of the string of cars the inspector should be absolutely certain that the blue flag or blue light is on each end of the string.

The method of inspecting a car should be as follows: On reaching the end of the car, the two ground inspectors must view all parts on the end of the car, including the couplers, carrier irons and outward parts up to the roof. They should then look beneath the car at the outer pair of wheels to inspect the brake beam, connections, bolster, draft rigging, sills, etc. They should next advance to the inner wheel, making a similar inspection of all parts under the car and before advancing to the center of the car for door inspection, etc., should cover the complete side of the car including side ladders, raising all box covers to see that the packing, brasses and wedges are in good condition and, above all, be extremely careful in inspecting the truck sides, arch bars, etc. The inspectors should then pass on to the center of the car, stooping to examine all truss rods, cross tie beams, vital parts of the air brakes and brake connections and repeat the same performance on the other end of the car.

OVERHEAD INSPECTION

The overhead inspection is usually covered as a whole, by a special man going over the top of the string in advance of the ground men in some yards, but the most thorough inspection, with the best results, is secured by having the overhead inspection made in the presence of the ground men, so that the hand brake can be set up and tried by the overhead inspector, and the two ground men can observe that everything is in good condition. It is strongly recommended that this practice be carried out to give a more perfect overhead inspection, not neglecting the lateral and longitudinal running boards and all parts of the brake staff, including the brake step-board, ratchet and other parts, and the usual careful attention of the roof handholds.

On open-top loaded cars special attention must be given to the condition of the load; where it is loaded with bulk commodities, such as coal, etc., it must be observed and depressions recorded that would indicate loss. On cars loaded with boxes, cases or other parts, the overhead inspection should include the condition of bracing and blocking and general method of securing the load and damage and breaking that may be observed on the parts.

On open-top, empty cars, special attention must be given to the inside cross braces, the condition of the floor, and where any refuse is left in the car it should be had ordered for cleaning.

On empty box or other closed cars, before classifying for loading, an interior inspection must be made for leaks through the roof, floor and siding, stains or odors of oil, fertilizer and other objectionable matter; refuse of material that will leave such stains or odors injurious to grain or flour. Cars with such defects and otherwise physically fit should be classed for rough freight or merchandise loading.

INSPECTING THE BODY OF THE CAR

The center sills or channels, extending from end to end in the center of the car, to which the draft gear is attached, should be in perfect condition to withstand the pulling and buffing stresses. The draft timbers are attached to the center sills by bolts to support the coupler and attachments, and it is necessary that these timbers be tightly drawn up to the center sills to prevent movement back and forward thereby elongating the draft bolt holes in the center sills and consequently weakening the sills.

In wooden cars the end-sill extends across the end of the longitudinal sills, retaining the longitudinal sills in position. The end sill also holds the body truss rods and distributes buffing shocks of all the sills.

The body bolster, commonly called body transom, connects and retains in position the longitudinal sills over which the weight of the load is distributed. Fractures in this member usually develop in the center, near or at the center plate, rendering the bolster liable to collapse, causing contact of the side sills with the truck sides or frames and severe binding at the side bearings, and also causing the possibility of derailment.

The cross tie timbers, and body truss rods support the car at the center and should be kept in good condition, insofar as retaining the truss rod castings in place is concerned. The rods should at all times be tight to prevent sagging of the car in the center when loaded.

The coupler should at all times be maintained in first class condition and should, therefore, receive careful inspection and attention with respect to the proper contour of the coupler head and knuckle, also to see that the lock and parts, knuckle pin, uncoupling lever and parts are in good condition and always operative. A test should be made by inspectors of the uncoupling device to determine its condition, also of the knuckle pins, defect in which are usually easily discernible.

The coupler yoke rivets, by which the coupler is secured to the yoke, must receive careful attention, as these are very essential parts. When found defective they should be condemned for immediate repairs, depending upon the number remaining effective and the coupler yoke having a gib. Failure of these parts causes considerable damage to sills and draft gear.

The carrier iron is attached to the front end of the draft timbers supporting the coupler and allowing lateral motion, also preventing the spreading of draft timbers. The bolts holding it in place are very essential in order to maintain proper coupler height.

DEFECTS OF TRUCKS

Trucksides and arch bars are the foundation of the car and are designed of sufficient strength to support the weight of the car, plus the weight of lading the car is supposed to carry. A fracture or crack reduces the margin of safety to such an extent that the part is liable to break off with added strain or motion. The fracture usually occurs at the lower web of the arch, as the greatest weight is distributed to that point by its construction. This should not confine the examination to this point, however, as the arch bar or truck side is frequently broken at the top or other points.

The bolster is the key to the truck, distributing the motion in curving, binding the two sides, and absorbing the greatest shocks of irregular track. A broken bolster may cause the truck to collapse or the body to fall down on the truck sides. The fracture usually occurs at the center or near the spring seat.

The spring plank is a secondary binder of the two sides and a fracture may cause the collapse of the truck. Fracture occurs mostly at the spring seat, in modern type of truck.

Broken journal boxes should not be allowed to run as they cause loss of lubrication, misplacement of the journal bearing and consequent cut journals.

The truck column and journal box bolts and nuts are used to tie the various parts into one piece. The loss or looseness of the nuts of such parts may cause the bars to spread, by taking away the strength of the arch, tie scraps to fall down on the track, or the journal box to slide out of the arch, causing derailment. Special attention must be paid to these parts on all repair tracks and in all yards.

DEFECTS OF WHEELS AND AXLES

Flat sliding (Rule 68): A wheel slid 2½ in. or over in length, or one with adjoining spots 2 in. in length, produces a continuous pound with each revolution of the wheel. This pound is destructive to the rail as well as to the wheel itself and may cause either or both to break. This defect can best be detected when the car is in motion and should be looked for on incoming trains.

Broken flange, chipped flange (Rule 78): A wheel having a broken or chipped flange may mount the rail in motion and cause derailment. Measurements may be made with the wheel gage; the lengths from the journal collar notch to the second notch measures 1½ in.

Broken rim (Rule 70): A broken rim if inside the 3¾ in. limit reduces the surface of tread so much that the wheel may leave the rail. Measurements are made by placing the gage horizontally on the tread. When the break occurs inside the semi-circular slot, it is condemnable.

Shelled out wheels and brake burn (Rule 71): Shelled out wheels are distinguishable by comby spots on the tread. When such a single spot is 2½ in. or over in diameter, it will pound similar to a slid flat wheel with the same danger to the wheel and the rail. Brake burn is the first symptom of shelled out wheels. Hard and prolonged applications of the brakes having destroyed the chill, or hardened outer surface renders it subject to breakage.

Seamed wheel (Rule 72): A seam ½ in. long in the tread ½ in. from throat of the flange or 3 in. long, within 3¾ in. from the flange may cause either the flange or rim to break off and derail the car, by mounting or leaving the rail.

Worn through chill (Rule 73): Many inspectors call this "worn flat wheel." It shows up by a spot 2½ in. long or over, worn smoothly flat. This is caused by the hardened surface in the tread, known as the "chill" wearing through into the inner, softer metal of the wheel. This condition destroys the bearing surface of the wheel and renders it subject to breakage.

Worn flange (Rule 74): Wheels under cars of less than 80,000 lb. capacity 15/16 in. or less in thickness and wheels under cars of more than 80,000 lb. capacity 1 in. or less in thickness, ⅜ in. from the tread are condemnable. A vertical flange may not take this gage, but when the wheel is less than 80,000 lb. capacity, with a vertical flange extending 1 in. or more from the tread or on wheels of 80,000 lb. capacity or over extend ⅞ in. or more from the tread, the flange and tread contour are worn out to such an extent that the wheel may mount switch points or cause the flange to break off. Great care must be shown in the use of the gage in order to condemn wheels only when actually defective.

Tread worn hollow (Rule 76): A hollow tread may be brought about by an irregularity in the truck, or the improper mounting of wheels, or in other cases by long wear. The tread becomes concave, making the rim liable to break off.

Burst plate, hub or brackets (Rule 77-78): Wheels cracked outward by axle pressure and wheel plates and brackets cracked by expansion from severe brake heating are very dangerous, more especially so because of the difficulty in detection. Both the outside and inside plates must be most carefully examined.

Loose wheel (Rule 81): A wheel loose on the axle is usually caused by imperfect mounting. It is a most difficult defect at all times to define with certainty, but good and general indications are grease on the axle, hub or seat inside the wheel. Care must be exercised not to confuse grease with the paint used for mounting the wheel on the axle. This defect is most easily seen from the opposite side of the car.

Bent axle. An axle bent to any extent will shorten. The distance between the wheels, at one point of its revolution, and the tread of the wheel will not bear fully on the rail at this point, which may cause a derailment. This is a very dangerous defect and can best be detected while the car is in motion, when it is indicated by a jumping movement. If a car shows evidence of having been derailed the inspector should gage the wheels to test for bent axles.

Cut journals, hot journals and associated defects may lead to crystalization of the journal and breaking off, twisting off by burning and severe heating. This is one of the defects that causes greater delay to freight than any other item. Defective journals can most readily be detected immediately after the train comes to a stop by indications of heat and burning of packing. When this is not possible, or the journal has been cooled off and repacked, the face of the journal will show a blackened surface or the wheel plate will be smeared with oil. Such journals must be tested with the inspectors' hook, and if they show ridges, they should be cut out for truing up at the shops.

Brake beams, levers, hangers, connections, lever pins and cotters, brake shoes and keys, in order to perform the function for which they are put on the car, must be in place and properly secured. No part of the truck or brake rigging should be below 2½ in. from the rail. Worn cut pins, brake hangers, brake beam eyes, etc., should be renewed or shopped for repairs. Cotters should be spread to prevent dropping out. Owing to the fact that these parts are all connected with each other, the loss of one item may mean a further loss and many times may cause derailment; or the inability of the brakeman to stop the car may result in its entire destruction and loss of life.

SAFETY APPLIANCE INSPECTION

It is very important that close and careful inspection be made of all safety appliances to see that they are perfect in all details, as such parts are in constant use and must of necessity be free from defects both in parts themselves and parts that are used in application, having in mind at all times the requirements of the government insofar as proper size of material and location is concerned, regarding handholds, sill steps, ladder treads, etc. The inspection should be thorough in order to detect defects, particularly in the offset of handholds, ladder treads and sillsteps, to see that the brake pawl and parts are secure and engage the ratchet wheel.

Interchange and industrial inspection is a distinct and absolute necessity and so realized by all branches of the service, and the object of these suggestions is to concentrate our very best effort on keeping the inspection forces alive to their duties and thereby improve the service and overcome any negligence tending to lower the standard and warrant criticism.

STANDARD FREIGHT CARS PRACTICALLY COMPLETED

The orders for standard freight cars, placed by the United States Railroad Administration, have been completed, except for a very small number and have been allocated to the various railroads under Federal control.

The orders for the building of these cars were distributed, by the Railroad Administration, to the car building companies throughout the United States and were constructed with a speed and in a manner to reflect credit on the builders.

After the signing of the armistice many of the railroads were reluctant to accept allottments of these standard cars because of a falling off in railroad business and a considerable number of cars were held in storage for some months. However, business conditions improved considerably in the latter half of the year 1919, and practically all of these cars have now been distributed.

Of the total of 100,000 freight cars ordered by the Railroad Administration on May 1, 1918, but 16,636 remained to be built on November 8, and these were being constructed and put into service at the rate of over two hundred a day. By November 1 all the cars which had been completed and placed in storage on account of some of the railroad corporations refusing to accept the cars allocated to them had been stenciled and put into service, so that, from August 1 to November 8, 53,305 new freight cars had been added to the rolling stock of the railroads. Only 168 of those completed remained to be lettered, numbered and placed in service on November 6.

Tables of equipment purchased by Railroad Administration for the railway companies, showing contract cost, character, and allocation to the various railroads and attitude of railroads touching its acceptance.

SHOP PRACTICE

JIGS AND SPECIAL DEVICES IN LOCOMOTIVE REPAIR SHOPS

By J. C. BEVELLE
Tool Foreman, El Paso & Southwestern, El Paso, Tex.

In Figure 1 there are shown two flue sheet cutters, one for small boiler flue holes and the other for large superheater flue holes. The advantages in the small cutter is that the maintenance cost is very small on account of the cutter blade being made of flat bar stock and not requiring much machining. The blade is made of high speed steel similar to a counterbore and the cutter holder is made of a low carbon steel, hardened and tempered. The cutting edge of the blade is ground with a lip which makes it free cutting and curls the clips. This tool drills the hole in 40 sec. and stands up well under all conditions.

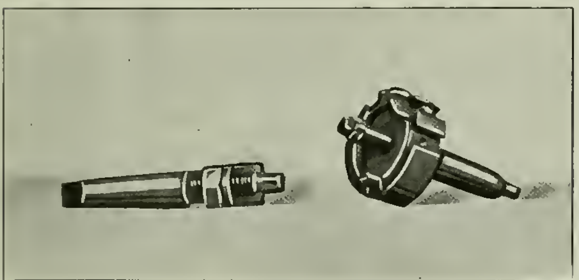

Fig. 1

The superheater flue sheet cutter is made so that it will cut all sizes required for superheater flues with one set of blades. With the milled places in the cutter body as shown in Fig. 1, it is only necessary to remove the blades and place them in the desired set of slots, which have the diameters stencilled on them. This cutter is made to cut two sizes but has space for one more set of slots. The cutter so designed eliminates the many different kinds of blades and different sizes to be carried on hand as the one set of blades will cut any size wanted by transferring to the proper slots. The blades are made of high speed steel and the cutter body is made of machine steel.

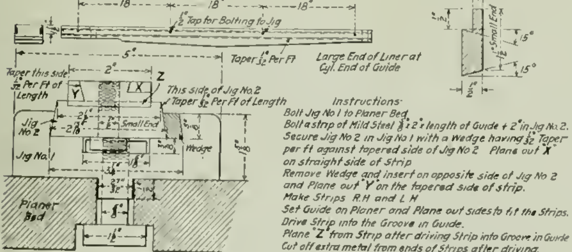

Fig. 2

The construction of jigs used in reclaiming locomotive guide bars, is illustrated in Fig. 2, which is self explanatory. These bars are reclaimed by planing a dove-tailed slot on each edge of the bar and applying an iron strip planed to suit the slot, then planing it off to size, bringing the guide bar back to standard size. This has proved to be a great success and all guide bars are being so reclaimed. After the bar has been planed out, if the strips are worn out, new strips can be applied and the life of the bar is prolonged indefinitely.

Fig. 3 illustrates the method of milling throttle lever quadrants on a universal milling machine. The quadrants are placed on a jig as shown, and held in place by the dividing head, the length of the jig giving the proper radius for the quadrant. The cutter is made with the proper pitch and the same radius as the quadrant and has 20 teeth. The

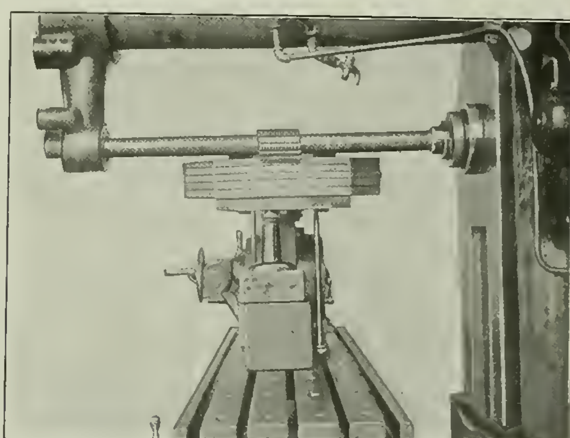

Fig. 3

quadrants are placed on the jig, six at one time, clamped down and the cutter put to work. The cutter finishes the quadrant teeth on the face as well as at the bottom of the tooth, making it unnecessary to turn the outside radius as it was when a single cutter was used. There being six quadrants on the jig at one time and twenty teeth in the milling cutter, 120 teeth are finished per traverse of the table of the machine. Six quadrants can be milled in one and one-half hours, or 15 min. per quadrant. The cutter is made of carbon steel and the dimensions are 3½ in. by 3½ in. with 1¼-in. arbor hole.

Fig. 4 shows a method of milling throttle quadrant latches with a cutter similar to that shown in Fig. 3. The latches are held in a vise, two rows, six latches in a row, making 12 latches completed in one setting of the machine and with two traverses of the table. The time for this operation milling the teeth in 12 latches is 40 min. or about 3 min. per latch. The cutter is 3 in. in diameter, 1½ in. wide, with a 1¼-in. arbor hole and is of carbon steel. The face of the cutter is formed, on the segment of a circle having the same center as that of the cutter for quadrants, giving the latch the proper radius on the face, allowing the teeth to fit each other and making a much better job than when the latch was milled straight.

A set of forging machine dies used for manufacturing superheater element tubes is shown in Fig. 5. This is done on a 2-in. Ajax forging machine. The tubes are of steel tubing and the end is upset with these dies in two

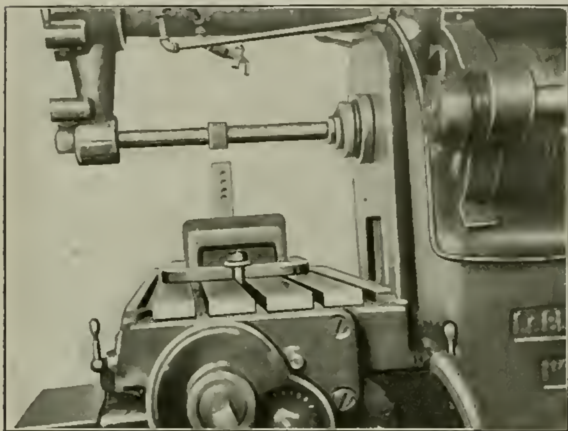

Fig. 4

operations and two heats. The first operation does about half the upsetting and the second operation completes the upsetting and forms the end to its proper shape. The tubes are then taken to a turret lathe and the ball joint is finished. They are then taken to the pipe shop where they are bent, threaded elbows applied, and bands applied. This shop manufactures all superheater unit tubes for renewals, and they have proved to be just as good or better than those

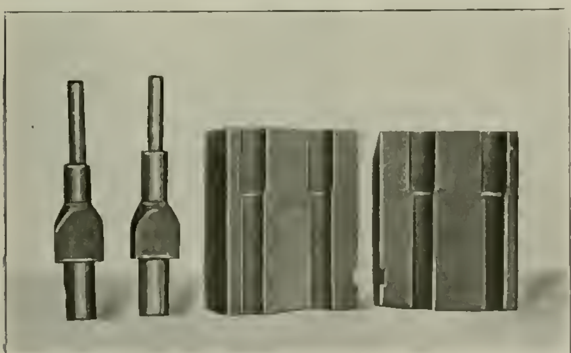

Fig. 5

bought and very much cheaper. These dies are made of machine steel and the heading tools are made of tool steel. The dies have been in service for four years and have made a large number of tubes.

A special prepared lubrication for air drills has recently been adopted on the E. P. & S. W. This consists of No. 2 compression cup grease and valve oil. The proportions are two-thirds cup grease and one-third valve oil thoroughly mixed together which gives a splendid mixture for air motors. The grease and oil are mixed with a butterfly paddle driven with an air motor. Air hammers are lubricated in a bath of coal oil and lard oil. The proportions are one-third lard oil and two-thirds coal oil. This is done at night when all air hammers are turned in to the tool room. They are allowed to remain in the oil all night, and if there is any dirt collected in the hammer or strainer it is dissolved by the oil which eliminates many repairs of the hammer.

Fig. 6 shows a method of machining the key-way in wrist

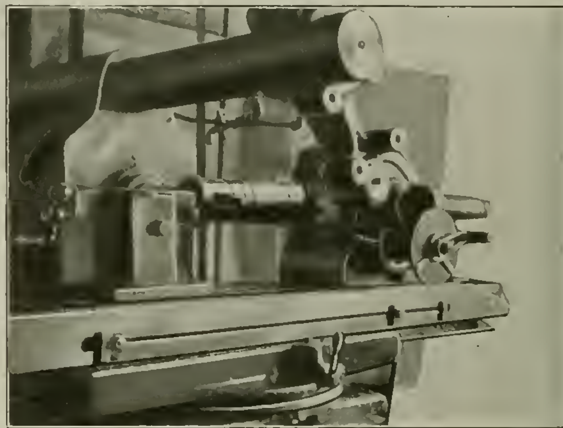

Fig. 6

pins on a universal milling machine, which is the same method used on piston rod key-ways. The key is milled with a radius cutter. The knuckle pin or wrist pin is first drilled with one hold and then milled, finishing the job. It is not necessary to touch the key-way by hand. Knuckle pins and wrist pins are milled in 10 min. each. The adop-

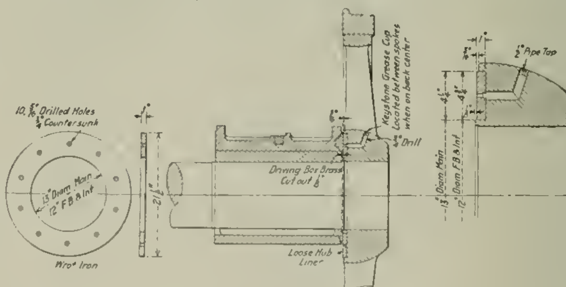

Fig. 7

tion of the key is so far better than the old method that we never apply a threaded pin.

It is the practice on this road to apply hardened steel bushings and pins on all link motion work. This has been our practice for many years and is very successful. The bushings are not ground on the inside after they have been hardened but are lapped out, making the hole as good as possible for the fitting of the pin. The pins are ground on a Brown & Sharpe grinding machine to fit the bushing. We don't know what it is to find a galled pin and our running repairs on this work are very light. It is rightly believed that after the bushings have been applied to the various rods, etc., that they should be placed on an internal grinding machine and the hole ground out to a standard size.

The pin can then be ground to have a more perfect bearing, giving the job a much higher effectiveness. Internal grinding in locomotive repair shops is somewhat new outside of the tool work but has a large field in the shop, and the sooner we admit this to ourselves the sooner we will overcome some of our troubles.

Fig. 7 shows the application of a floating hub liner. This liner is applied to a number of our Pacific and Mikado type engines. With this floating liner it is not necessary to shop the engine for lateral before it has made the required mileage which is 80,000 miles. On a recent date one of our Pacific type engines which has made 80,000 miles was put in the back shop for a classified repair, and on examining the hub liners and checking the lateral it was found that the lateral was 1/8 in. less than the limit, which is 3/4 in. A Mikado engine which made 65,000 miles was given the same inspection and found to be 3/16 in. less than the limit for lateral. The liners were scarcely worn at all and it was not necessary to renew them. This is becoming a standard liner on our system.

We must not forget that while manufacturing new devices and tools that in each case we should keep in mind the need of safety. The prevention of injuries should be considered even more than the efficiency of the tool or device. Do you ever inspect the tools that are in daily use in your shop to see that they are in a safe condition? The tool foreman should make this his business as he is more capable of determining the safety of tools. Our shop safety committee demands a report from the tool foreman on tools in all departments and this has brought about wonderful results in a decrease of injuries. The blacksmith shop, boiler shop, and even the different tool rooms are good places to find defective tools. Handle tools, chisel bars and chisels are very dangerous and are as a rule given very little attention. Safeguards on machines should be watched, grinding wheels should be daily inspected, the tool rests should be up in place at all times, the mounting of wheels should be watched very closely. There are numerous things in the shops and engine houses that are unsafe at their best and we must see that they are kept at their best and in a safe condition.

Efficiency in Railroad Shops*

The Importance with Increased Labor Costs of Improved Shop Facilities and New Machine Tools

BY FRANK McMANAMY

Assistant Director, Division of Operation

SHOP efficiency is a subject that is usually very closely associated in the minds of most of us with intensive production and stop-watch studies of the different operations in connection with shop output, and from that viewpoint it is a subject which can never be exhausted. There is no doubt but that a great deal has been and can be accomplished in that way in the matter of increasing production, although it is usually done at the expense of a more or less serious dispute with the workmen. I have sometimes found that while making time studies of shop operations with split-second stop-watches, we were overlooking conditions and methods where the time that might be saved could be measured with the hour-glass, and that we are, in many of our shops, using machines and methods that are as far behind the most modern and up-to-date practices as the hour-glass is behind the split-second stop-watch.

The transportation machine has, perhaps, been left by the war in more nearly a normal condition than any other industry for the reason that while it was worked to capacity during the war—in fact, most of the time was overworked—yet, owing to the limited facilities, it was not possible to greatly enlarge the plant and there are no greatly increased forces because both were impossible to obtain during the war. The increased transportation furnished represented almost wholly increased effort on the part of those producing transportation and increased output of existing railroad facilities.

The change which appears to be most important and far-reaching so far as the railroad shops are concerned, is the change in working conditions and the increase in the rates of pay of railroad shop labor both skilled and unskilled, and to my mind, this is a change which is permanent; therefore, it must be reckoned with in all calculations relating to the purchase or maintenance of shop equipment. These changes have made it essential to see that our men are provided with modern tools and improved facilities, because in no other way can operating costs be reduced and kept at a reasonable figure.

*Abstract of a paper read before the New England Railway Club.

The use of out-of-date tools and machinery in railroad shops—although never satisfactory—may have been in the interests of economy at the rates paid for labor before the war, but under the rates now paid the use of inefficient machinery is not only unsatisfactory but decidedly expensive.

It is a well-known fact that many railroad shops, together with their equipment, were at the time the railroads were taken over by the government, and are today almost hopelessly out of date, and that the methods which this lack of facilities makes necessary are such that no manufacturing industry operated on a competitive basis could practice and exist. In fact, it has been stated that $10,000,000 spent for shops and shop machinery prior to 1917 would have made it unnecessary for the government to have assumed control of the railroads. Whether or not this statement is true, it is a fact that one of the principal reasons for taking over the railroads was the condition of locomotives and cars in certain sections of the country which, together with insufficient terminal facilities and the effort of many shippers to use the cars as storehouses, caused such a congestion that nothing short of centralized control with complete authority could have met the situation.

A survey of the situation immediately following federal control showed many railroads hopelessly behind in the matter of repairs to equipment, due to their limited shop capacity, although it was proved that the total shop capacity of the country, if properly distributed, was sufficient to maintain the equipment. The inadequacy of existing shops and the character and quantity of shop machinery was one of the things that received immediate consideration from the Railroad Administration, and while it was impossible in the time at hand and under war conditions to start and complete large, new projects, the matter of providing additional equipment and facilities at existing shops received earnest consideration and vigorous handling.

Investigations of shops and shop facilities during this period confirmed a belief that many of us had that the importance of having shop facilities on any railroad keep pace with other improvements is usually neglected and frequently entirely overlooked. To promote efficient operation, grades are cut down, curvature reduced, terminal facilities are added, bridges and roadbed improved and strengthened to meet the requirements of new and heavier equipment, but the last thing that is given consideration—if, in fact, it receives any consideration at all until it is forced by the condition of power and terminal delays—is the question of providing shop and roundhouse facilities for the new and heavier equipment.

The general rule in the matter of making improvements is that if the saving to be brought about by the improved facility will pay the carrying charge on the investment, the improvement is a justifiable one, and under this rule, we have all seen locomotives and other equipment scrapped because of obslescence—that is because the work performed by the more modern equipment was sufficient to pay the carrying charge on the investment, and therefore, the additional investment was justifiable. Locomotives from 15 to 20 years old are either modernized by rebuilding or scrapped to make room for modern power, yet a trip through the shops on practically any railroad will show that we are trying to maintain this modern power with shop tools and machinery, much of which is more than 50 years old and which should have been replaced by modern equipment years ago.

I am familiar with the statements which will probably be made that the reason for failure to provide proper equipment in the shops is because of the difficulty of financing, but this does not cover the case because a check of the service performed by locomotives and the time lost at terminals will show that in many cases it would have been profitable to have spent the money that was spent for the last order of locomotives in providing shop facilities to maintain locomotives already on the line, and that if this had been done, the additional locomotives would not have been needed.

EFFICIENCY

Efficiency, as applied to railroad shops, is, therefore, the ratio of the shop output to the time, labor, material and capital expended. In order that a railroad shop may be efficient, it is necessary to have: first, suitable shop buildings with proper equipment and lay-out; second, an effective shop organization; third, necessary schedules so that the various departments of the railroad in any way related to the shop organization may be able to coordinate their efforts.

The efficient railroad shop must have as its fundamentals proper equipment suitably disposed and properly housed. It is difficult to understand, in view of the saving to be effected thereby, why we have so long failed to erect suitable buildings for shop purposes, and this not only applies to the car department where suitable buildings do not exist, but also to the locomotive department where the loss of output in decreased efficiency due to placing machines in badly lighted, poorly arranged buildings where unusual effort is required to deliver material to and from machines which are not accessible even to an ordinary warehouse truck, is really a very serious question. So far as possible, the travel of material through the shop should be arranged to eliminate back-hauls. The material should move in as nearly a straight line as possible from the foundry or smith shop to the locomotive or car. I have seen shops where driving box brasses were machined at one end of the shop and pressed into the box at the other end of the shop several hundred feet distant; then returned for boring.

When any new shop machinery is requisitioned at the present time, the purchase is objected to on the grounds of its high cost, and this argument has been very effectively used. We must now, however, consider this in the light of the comparative cost for machinery and labor, and when we consider the rate paid to shop labor at the present time, we will realize that in the life of the average machine, its cost will be paid many times by the saving in the time of the workmen, to say nothing of the increase in efficiency and shop output and the additional service obtained from locomotives and cars, which are often sorely needed.

A very costly part of shop operation is the handling of material in the shop. For that reason, crane transportation, where it can be installed, is desirable, and in any event, wide aisles for the trucking of materials should be provided.

Shop machinery should be located with a view to the use to be made of it, with machines or appliances for each particular kind of work in one group. For example, all the work belonging to the valve motion should be handled in one place. Similarly, driving box work and brake rigging work should be located in one particular portion of the shop.

Someone has said, "Information is the essence of efficient operation." Nowhere is this more true than in the proper conduct of a railroad shop, and generally speaking, in few places is information as to probable requirements so sparingly furnished. Locomotives sent to the shop for repairs which are said to require the removal of a set of flues are found to require fireboxes, and locomotives sent to the shop for fireboxes are found to need only a set of flues. It is of great importance that proper record of the condition of locomotives and cars be kept and the shops furnished as much in advance as possible with information as to the repairs which will be required on equipment destined for the shop within the next two or three months in order that the shops can provide the necessary material when the locomotive or car is placed in the shop, thereby avoiding the too common practice of having them occupy valuable space while waiting on material.

ORGANIZATION

Organization is defined as, "A systematic union of individuals in a body whose officers, agents and members work together for a common end." This is especially applicable to railroad shops where the ends sought are efficient production and minimum costs. While to some it may seem unfair that brilliant, individual performances should be submerged in an average, at the same time, whether in baseball or business, team work is essentially the thing that counts.

Without an organization embodying as well as implying co-operation, little, if anything, will be gained, and this is entirely up to the supervision. Each investigation made of points where shop output is unsatisfactory confirms the belief which I have long had that effective and constant supervision is necessary in order to obtain a satisfactory output. Quality as well as quantity in production comes from the top downward. The average workman will give you, in the matter of output, exactly what you are willing to take. If the supervision is satisfied with a minimum performance and low-grade work, that is exactly what they will get.

If we are to have efficient operation in any shop, we must have supervision that is constantly on the job, and will show that the officials and foremen are as much interested in both the quantity and quality of output as they expect the workmen to be, and that they are willing to aid in promoting efficiency by seeing that the workmen have: first, a suitable place to work; second, necessary tools that are as well maintained as they can be; and third, material and supplies promptly delivered so that the workmen will not be required to lose time waiting for their helpers to obtain material from a storehouse inconveniently located, or have to hunt it themselves from the scrap pile, or rob other locomotives or cars in order to obtain it.

An important factor in obtaining shop output is properly scheduling the work through the shop so that the work of the various departments may be properly co-ordinated and in harmony. Scheduling will have a decided influence to keep everything moving and avoid delays due to one department waiting on another, and these schedules should not be interrupted from day to day by switching in jobs of running repairs which could perhaps be better performed in the roundhouse.

Locomotive schedules must be made very carefully. It is almost as much of a task to make out a proper schedule for locomotives through the shop as it is to make out a time card for a division. Schedules that work satisfactorily in one shop will no more apply to another than a time card for one division can be made to apply to another A schedule once made must be carefully followed, or one gang or machine will be crowded with more work to be done at one time than it is possible to accomplish without increased facilities.

Locomotive schedules bear the same relation to getting work through the shop that time cards do to getting trains over the line. Every possible effort should be made to live up to the schedule, but when something goes wrong, the dispatcher in the case of trains, or the general foreman in the case of the shop, must take a hand, make new meeting points, or devise new methods, hold some work back and advance other; in fact, take whatever action is necessary until the business is straightened out again.

It is no more possible to keep every engine in a big shop moving on schedule time than it is to keep every train between New York and Boston on time. If it is found that locomotives are continually behind schedule, it may be due to two causes: first, the schedule may be too fast; or second, something may be wrong in the shop that needs straightening out.

A schedule of any kind is of very little use unless some real and earnest effort is made to live up to it in the regular operation of the shop.

EQUIPMENT

The equipment of railroad shops is an important factor with respect both to efficiency and output. It is not efficient to continue in service machine tools which have long since outlived their usefulness. A few conditions noted on a trip over a railroad which operates about 1,500 locomotives will, perhaps, explain more clearly than any other method of discussing the situation, the conditions I have in mind which must be given attention if we are to reduce shop costs.

The principal shop is an old structure that has been added to from time to time, and has no modern facilities or crane service. Locomotive driving wheels are removed on drop pits in the shop. On account of the length of the shop, when removing wheels from 2-10-2 type locomotives, they are moved over a pit and spotted with the shop locomotive, and two pairs of driving wheels are removed. The locomotive is then taken out of the shop to the roundhouse turntable about 150 yards distant and turned around, returned to the shop, and the other three pairs of driving wheels are removed. To handle these wheels requires all the men that can get around them. In re-wheeling the locomotive the same process is followed; that is, three pairs of wheels are applied to the locomotive, it is then taken to the roundhouse turntable, turned around and returned to the shop so that the other two pairs of drivers may be applied.

At another shop on the same railroad, in checking the movement of parts of locomotives from the stripping pit, it was found that the driving boxes, rods, cross-heads, driver brake rigging, springs, hangers, etc., are trucked through the entire length of the shop to the lye vat, a distance of 700 feet, and then distributed to the respective places for repairs, and finally returned to the point they started from. This movement of material which is trucked through a congested shop could be eliminated by placing the lye vat at the stripping pit and in re-grouping some machines in the shop.

The driving boxes move 1,900 feet from the stripping pit until returned finished. This could be reduced to 400 feet by re-grouping the machines.

At various other points on the same railroad, we found repairs being made with the following obsolete machinery and equipment:

Wheel lathe which was installed in 1878 on which it requires seven hours to bore a driving wheel tire which could be done with a modern, heavy duty boring mill in 30 minutes.

Tender truck wheels being turned on a 36-in. engine lathe in which but one tire can be turned at a time; therefore, the operation is very expensive. It requires five hours to turn tires which on a modern, heavy duty wheel lathe could be turned in 30 minutes.

Crown brass turning machine, built in 1861, which is entirely unsuitable for doing this work.

Wheel lathe, date of installation not obtainable, but is very old and requires seven hours to turn one pair of driving wheel tires and six hours to turn one pair of engine or tender truck wheels.

Wheel lathe, old type, which requires six hours to turn one pair of 50-in. driving wheels, and four and one-half hours to turn tires on one pair of engine or tender truck wheels.

Wheel lathe, which was placed in the shop in 1879 and was second-hand at that time. On this machine, it requires from three and one-half to four hours to bore one driving wheel tire.

At another point locomotives are used to haul a transfer table, and this practice has been in existence for about six years.

Planers of different sizes, built in 1864 and in 1867. These machines have but one cross rail head and no side head, and are entirely unsuitable for present day requirements.

On a mountain railroad with over 100 locomotives, a large percentage of which are Mallets, there is no wheel lathe. Tires are removed from the wheel centers and turned on a boring mill, and when necessary to turn the journals, the wheels are pressed off the axles and the journals turned in an engine lathe.

This list could be added to either on this same railroad or by going to any one of a number of others where this is fairly representative of their shop conditions, and when we consider that these and other similar machines must be used to maintain some of the heaviest, modern locomotives now in service, we will realize what some of the mechanical departments are up against in their efforts to maintain equipment.

Modern appliances are an absolute necessity, and it seems a shame that some of the up-to-date shops should be filled with hopelessly back-number machinery. In such cases, aside from improved facilities for handling, no decrease in the cost of machine work and no adequate output can be expected, and a road with such equipment will require a greater investment in motive power and cars to handle the business. The principal question is not how many locomotives a road has, but how many good, serviceable locomotives, and this depends entirely upon the facilities which the road may have for repairing them and keeping them in service.

Next to the machine installation, it seems to me that the problem presented in shop operation which is most deserving of study is the question of transportation of parts;

traveling cranes, mono-rail runways and jib cranes are wonderful factors in efficient shop operation, as they expedite the delivery of material.

MANUFACTURE OF PARTS

It is usual for railroad shops to purchase some material and manufacture other. In some shops, the manufacturing of material is a large portion of the work done. In others, the material purchased much outweighs the material manufactured. Of course, shops, generally speaking, are repair plants and not manufacturing establishments; therefore, if we are to manufacture material or parts, I believe that a sharp line should be drawn as between material or parts to be purchased and material or parts to be manufactured, and having decided what is to be manufactured, those in charge of the shop should prepare to do it in an economical and efficient manner.

The railroads have not as a general rule organized their mechanical departments on a manufacturing basis, but have depended upon outside sources for the majority of their manufactured products and such shop facilities as they have maintained have been largely for repair and maintenance work. Because of the diversified products of the ordinary railroad repair shop of today, the question of production has not been given the consideration it has in other fields. On some railroads, a start has been made towards the introduction of manufacturing methods by the establishment of centralized shop facilities which act as manufacturing plants for such commodities as can be distributed to outlying points where facilities for economical manufacture are not maintained. Such work, however, has usually been carried on as a side line at the largest repair shops on the individual roads. On this basis, it has been found economical to install special machinery and methods at a centralized point and manufacture pieces in quantities for storehouse stock to be distributed on requisition to the smaller shops or terminals over the system.

It is hardly to be expected that in railroad work, it will be possible to introduce the methods used in automobile manufacture or kindred lines, but it should be quite possible profitably to produce parts used in sufficiently large quantities at a centralized shop or manufacturing plant. Inasmuch as the finished parts for locomotives and cars are not designed to be absolutely interchangeable either in design or manufacturing tolerances, it is necessary for the most part to provide sufficient latitude to permit of the final fitting of each piece at the point where application is to be made.

During the past few years, great improvement has been made and is being made in the design of machine tools and special machinery for railroad shop work. The installation of automatic and semi-automatic machinery adapted for railroad shop uses has been extended. The introduction of modern high capacity and special machinery into railroad shops has not always been an economical procedure, however, because of the fact that the output of the shop where installed has not been particularly adapted to the machinery, or because in the average shop such machinery can only be used a part of the time for the purpose to which it is particularly adapted. If parts are to be manufactured on a substantial scale, it could probably best be accomplished through the establishment of centralized manufacturing shops equipped with up-to-date machine tools and shop equipment, with particular attention to automatic and semi-automatic machines for the production of locomotive and car parts in quantities.

One of the most important factors in the successful operation of a centralized shop for manufacturing purposes is the relation between the mechanical and storehouse departments. In order to derive the maximum or even satisfactory results from such an organization, it is essential that the shop be organized for quantity production on requisitions originating with the stores department; otherwise, we would be apt to have duplication of unnecessary parts and an accumulation of expensive manufactured parts which represent obsolete designs and have no value other than scrap.

With increasing cost for material and labor, it will be necessary to reorganize railroad shop facilities with a view to keeping equipment maintenance costs within reason; therefore, modern methods of shop production should be applied to railroad work in a much greater degree than is prevalent today. Locomotives and cars should be looked at from the viewpoint of a large investment, the productivity of which increases in exact ratio to the percentage which is available for service. It is usually estimated that the locomotives on a railroad represent approximately eight per cent of the total cost of the property, but it is this eight per cent which makes the other 92 per cent profitable, so that even assuming that by suitable shop facilities and efficient shop operation we are able to reduce our percentage of unserviceable locomotives from 12 per cent to 10 per cent, we have done more than the percentage figures indicate, since the amount of transportation which can be furnished by any railroad is represented by the number of serviceable locomotives which it has.

STEEL CAR REPAIRS

While it is true that there has been failure in many instances on the part of railroads to provide locomotive shop facilities, the situation is even worse so far as steel freight cars are concerned, and with the exception of a very few railroads practically nothing has been done along the line of facilities for the repair of steel freight cars. Where these facilities are provided, they are, as a rule, of the most meagre character; frequently home-made furnaces, which result in extravagant consumption of fuel, totally inadequate equipment of clamps, formers, etc., worn out pneumatic tools, an insufficient supply of compressed air and, in a great many cases, actual shortage of repair material is found to exist.

Hundreds of thousands of rivets are being cut by hand which could be cut by proper pneumatic appliances in a fraction of the time. With proper buildings, proper equipment and a sincere and determined effort on the part of those responsible, the steel car plant can and should be as well organized and as efficient as any portion of our repair facilities. It can be made so only by presenting to the proper officers, a list of needs, clearly showing the saving which will result from their installation, and if they are installed, by making efficient use of them. The only locomotive and the only car that earns revenue is the serviceable one.

Do not understand this as a criticism of the men in charge of the mechanical departments on the various railroads, except as it may be considered a criticism of their failure more aggressively to urge that adequate facilities more promptly and economically to repair equipment be provided. Neither is it intended to make us dissatisfied with what we have, because all must realize that we must do the best we can with existing facilities, however poor they may be.

It is rather intended to be an outline of existing conditions and is given for the purpose of directing attention to the importance of formulating and following a definite and progressive policy of railroad shop improvement, because under the changed conditions which confront the railroads at the present time, with respect to labor costs, if we are to keep shop costs within reason, efficient and adequate facilities for doing the work in the way of improved shops and shop equipment, particularly machine tools, must be provided.

The Casehardening of Steel

Generation of Gases Necessary to Caseharden; Composition of Packing Materials Important

BY J. F. SPRINGER

II.[1]

Sulphur is an objectionable substance which may occur in packings containing charred leather. Coke would also be a source of sulphur. It seems, however, that whatever sulphides form during carburization are limited to positions on the surface and would often be cut away in a subsequent grinding operation. However, where grinding or some other machine operation is not contemplated it will be well to bear in mind this possibility of a damaged surface on casehardened objects.

We have, in the foregoing, reasons to watch our use of granulated bone and charred leather or leather meal.

One of the best packings is the following mixture:

Wood charcoal (powdered)	3 parts
Barium carbonate	2 parts

The action of this preparation is understood to be as follows: The wood charcoal itself acts upon the metal, and in addition, the charcoal acts on the barium carbonate, producing the gas carbon monoxide (CO). The present mixture is very suitable where it is desired to produce a thin layer of impregnated steel that shall be highly homogeneous. When the packing loses strength it may readily be regenerated by simply leaving it exposed to the air in a thin layer after having recovered it from the boxes. The reason that this regeneration is possible is that the atmosphere always contains carbon dioxide (CO_2) in small percentages. When the barium carbonate ($BaCO_3$) is decomposed during carburization, barium oxide (BaO) is formed. Upon exposure to the air this barium oxide absorbs carbon dioxide and is accordingly transformed into barium carbonate again. *

$BaO+CO_2=BaCO_3$.

Barium carbonate is readily obtainable, in normal times, at prices in the neighborhood of five or six cents per pound. This should be sufficiently pure for carburizing purposes. Again, the natural form of barium carbonate, known as witherite and obtainable in crystalline, granular or columnar masses, may be substituted for the powder form of the artificially prepared substance. However, if the natural witherite be used, it is first to be ground and then mixed with the charcoal. If the artificial product is employed, the white powder may be mixed directly with the granulated charcoal and the mixture then ground to a powdered form. Barium carbonate, whether artificial or natural, is a poison, consequently, care should be taken in handling it.

It will be pertinent to reproduce here some experimental results, originally obtained it seems by the investigator Guillet. He varied the proportions of wood charcoal and barium carbonate, using 4:1, 3:2 and 2:3 mixtures. The steel was a very soft article, containing only about 0.03 per cent of carbon. The period of carburization was eight hours and the temperature 1832 deg. F. Two layers each 0.01 in. thick were analyzed and the local percentages of carbon ascertained. The following table gives the results.

Carburizing Effects of Mixtures of Wood, Charcoal and Barium Carbonate

Proportions		Carbon percentages	
Wood charcoal	Barium carbonate	External layer	Inner layer
4	1	1.14	0.75
3	2	1.32	1.19
2	3	0.94	0.77

I do not know whether Guillet previously heated the wood charcoal or not. There is reason to suppose, however, from experiments made by Nolly and Veyret that this preheating of the charcoal results in the more active production of carbon monoxide during the carburizing process, especially when the temperatures are high.

It may be as well to pause here and get a good glimpse of the carburizing action as now understood in the world of scientific research.

It is understood that a casehardening material acts though the gases emanating from it. Carbon alone will caseharden iron—but in a manner and to an extent that are of interest only to laboratory workers. Solid material operating without any assistance from gases has, from the point of view of actual practice, no effect. As we are, at present, interested only in practical matters, we note that the rule for us is: *Apart from the generation of gases, there will be no casehardening results.*

Further, in commercial work, it is understood that the gases do not act as mere carriers of carbon; or, if so, then only to a small extent. It is rather understood that the carburizing gas—which contains within itself the carbon—decomposes partially when it comes into contact with the highly heated metal. The carbon set free is absorbed by the metal, and the gas penetrates into the interior and there continues to decompose. This sets free additional carbon which is absorbed by the adjacent metal.

In actual practice, then, a substance must be supplied which when heated is capable of generating one or more carbonaceous gases and these gases must decompose as they penetrate into the interior of the metal.

Take the case of the packing material consisting of a mixture of pulverized wood charcoal and of pulverized barium carbonate. We are to understand that the solid wood charcoal exercises little or no direct influence on the metal. The heat has the effect of decomposing the barium carbonate ($BaCO_3$) into barium oxide (BaO) and carbon dioxide (CO_2). Here the carbon has only half as many atoms as the oxygen. Carbon in the form of wood charcoal enters into chemical combination with the carbon dioxide. The result is a gas in which there are as many atoms of carbon as of oxygen. This is carbon monoxide (CO). It is the real carburizing agent. As it comes into contact with the highly heated steel it seems partially to decompose and partially to go further in. As it gets in further, more of it decomposes, and so on. When carbon monoxide decomposes, free oxygen and free carbon are the result. Just what becomes of the oxygen, I do not know. The carbon enters into combination with the iron and forms iron carbide. There can hardly be any doubt but that this is substantially what takes place. This iron carbide is the cementite of the newly produced steel.

It will now perhaps not be difficult to understand that

[1] The first part of this article appeared in the November issue of this publication.

*During carburization, free carbon is present in the form of the wood charcoal. When the barium carbonate decomposes, the C and O_2 or else CO_2 given off is converted by this charcoal carbon into carbon monoxide. This gas is a powerful carburizing agent and is understood to be active upon the metal when the charcoal-barium-carbonate method is employed.

it is a matter of importance to know the gases which are given off by proposed packing materials and the relative amounts of carbon monoxide and similar gases.

Take wood charcoal for example. Between shop temperature and, say, 572 deg. F., the following gases will be evolved—carbon dioxide (CO_2), oxygen (O), carbon monoxide (CO), hydrogen (H), methane (CH_4) and nitrogen (N). These temperatures are entirely too low for carburization. Besides, the only gases produced in considerable percentages are CO_2, O and N. When the temperature of the wood charcoal has, however, been brought up, say, to 1,562 deg., F., the case will be somewhat different. Hydrogen becomes the principal product, but there is now increased relative amounts of CO and CH_4. Carrying the temperature on up to say to 1,922 deg., F., H. and CO become the principal gases evolved, the hydrogen predominating. That is to say, the CO now evolved amounts to about 20 per cent of the total being given off, while hydrogen amounts to some 73 or 74 per cent.

In short, the true agent of carburization (CO) is evolved, when the temperatures get up to casehardening levels, in very moderate relative amounts. Hydrogen is the plentiful gas. Even if we count CO and CH_4 both, for the temperature 1,562 deg., the combined percentage is only 21.3. At 1,922 deg., CH_4 is scarcely coming off at all. It should perhaps not be difficult to understand, after this disclosure, that wood charcoal alone is not much of a casehardening agent. It doesn't produce the thing wanted in sufficiently great relative amounts.

Suppose, now, we consider a table exhibiting at the temperatures 1,562 and 1,922 (fair limits for the casehardening range) the relative amounts of CO, H and CH_4 evolved by various combinations of wood charcoal and barium carbonate. Combinations 4 and 5 are understood to be identical with 2 and 3, respectively, except that in 4 and 5, the wood charcoal has been previously heated to about the boiling point of water (212 deg., F.).

Relative Volumes of Cases Given Off by Mixtures of Wood Charcoal and Barium Carbonate

Temperature	Gas	No. 1 Wood charcoal 90% $BaCO_3$ 10% Per cent	No. 2 Wood charcoal 70% $BaCO_3$ 30% Per cent	No. 3 Wood charcoal 50% $BaCO_3$ 50% Per cent	No. 4 Wood charcoal 70% $BaCO_3$ 30% Per cent	No. 5 Wood charcoal 50% $BaCO_3$ 50% Per cent
1562° F...	CO	28.1	25.3	30.8	42.2	28.4
	H	52.8	57.7	53.4	20.0	37.0
	CH_4 ...	8.7	8.7	7.0	2.0	1.2
1922° F...	CO	37.3	56 1	63.8	71.7	75.2
	H	60.0	32.0	28.0	15.0	12.0
	CH_4 ...	0.9	0.9	0.8	0.7	0.8

These results are understood to have been obtained by Nolly and Veyret. The percentage of CO given off at 1,562 deg. F., by the 50-50 mixture, the charcoal having been heated, seems anomalous. The loss due to the preliminary heating would be insufficient to account for the figures 28.4. Aside from this, the table shows pretty satisfactorily that the higher the percentage of barium carbonate, up to 50, the greater the relative amount of CO given off. The table also shows the considerable increases in relative amounts due to higher temperatures. Further, the preliminary heating of the charcoal appears to be beneficial. It is to be borne in mind that the percentages do not tell us the relative amounts of gases as between one temperature and the other, nor do they tell us the comparative amounts from different mixtures at the same temperature. They do tell us the relative amounts of various gases given off by one mixture at one temperature.

It will be well then to have before us in tabular form the relative total volumes of gases given off. Presumably these figures are comparable, for these total volumes, whether we attend to the rise of temperature for a single mixture, or whether, for a single temperature, we pass from one mixture to another. This data is also understood to be due to the same investigators.

Relative Volumes of Gases Set Free from Mixtures of Wood Charcoal and Barium Carbonate

Mean temperature	No. 1 Wood charcoal 90% $BaCO_3$ 10%	No. 2 Wood charcoal 70% $BaCO_3$ 30%	No. 3 Wood charcoal 50% $BaCO_3$ 50%	No. 4 Wood charcoal 70% $BaCO_3$ 30%	No. 5 Wood charcoal 50% $BaCO_3$ 50%
1472° F.	125	78	80	25	40
1652° F.	198	129	69	36	34
1832° F.	180	63	78	70	115

The following is a very simple mixture which appears to have given very satisfactory results. It seems to be superior to simple wood charcoal, but is scarcely the fine casehardening packing that the 3:2 mixture of powdered wood charcoal and barium carbonate is.

Wood charcoal .... 9 parts
Common salt .... 1 part

As to the apparent superiority over simple wood charcoal, one authority says: "for this it is not easy to give a scientific reason."

Other mixtures are:

I

Pulverized wood charcoal (oak).... 5 parts
Pulverized leather charcoal......... 2 parts
Lamp black ....3 parts

II

Pulverized wood charcoal (beech)... 3 parts
Pulverized horn charcoal........... 2 parts
Pulverized animal charcoal......... 2 parts

The authority Grenet is understood to recommend the following three recipes, all parts by weight:

I

Pulverized wood charcoal......... 10 parts
Common salt .... 1 part
Sawdust .... 15 parts

II

Coal (having 30% volatiles), pulverized .... 5 parts
Charred leather, pulverized........ 5 parts
Common salt .... 1 part
Sawdust .... 15 parts

III

Charred leather, pulverized........ 5 parts
Yellow prussiate of potash........ 1 part
Sawdust .... 5 parts

The rapidity of carburizing action is understood to increase from the first to the third of these mixtures. The sawdust is supposed to be advantageous because it makes the packing porous and consequently easily penetrable by the gases.

It will be well, I think, to quote some remarks by an authority on casehardening: "As I have already said, there are in use in machine shops numerous mixtures of the most varied and complex composition. The results of accurate and precise experiments do not justify, however, the use of such complex mixtures, which do not furnish results superior to those which are obtained with the less complicated cements; and, further, because of their complexity, do not furnish results which are constant or uniform and can be exactly predicted. The best and surest results are always obtained by using the simplest cements."

THE DAMAGED INTERIOR

The casehardening process is carried out within the range, say, of 1,472-2,012 deg., F. As the temperature level at which grain enlargement begins is 1,274 deg., it will be seen that the process necessarily involves over-heating and the consequent damage. There are, in general practice, two remedies for grain-enlargement—mechanical working, and re-heating. Naturally, the mechanical cure will practically never be available in cases where the exterior is casehardened. This leaves us with the heat-treatment procedure. One great advantage that the heat-treatment method has over the mechanical consists in its penetrative power. This, in ordinary practice, is often sufficient to make it preferable. Here, where no choice is permitted, the same advantage naturally obtains. Heat goes everywhere—into the interior, into big and small parts, etc., carrying its beneficial effects with it. On the other hand, the restoration of overheated steel by heat treatment is not equally successful with all the varieties of carbon steel. It is doubtless at its maximum of success when the carbon content is around 0.90 per cent. The steels generally used in work that is to be casehardened have carbon contents that are much below this figure. Probably the great majority have carbon percentages below 0.40 per cent. These are not the varieties of carbon steel that one would choose in order to display the effects of restoration by heat treatment. The reason is this. The annealing point for such steels runs up to temperatures considerably above 1,274 deg. These temperatures are to be attained, and yet every degree above 1,274 means further grain enlargement. Still, one has to deal with facts and not with wishes. While the restoration is not ideal, it is the thing to apply, because there is nothing else.

After the operation of carburizing has been completed, the work must be cooled below 1,274 deg. (medium cherry red), before applying the heat treatment. This is an essential point. There is a question, however, as to whether it should be cooled slowly or suddenly, and to this I will return later. Just now, let us master the essential point that the cooling must go below 1,274 deg. It matters not how far below 1,274 the cooling proceeds—the important thing is that it drops below. A black heat is good, especially as a black outside probably means—except for heavy work—an inside cool enough. Naturally, it is necessary that the interior as well as the outside cools off enough. Work made to cool down to shop temperature will certainly be all right, although this may seem a useless waste of heat, since the work is to be reheated.

But there is really no waste, or but little, for the reason that it is approved practice not to cool the work off slowly from the carburization point but rapidly. That is, the work is quenched. There is a partial exception to this. If the work has been carburized at a very high temperature (1,922-2,012 deg. F.), then it will be well to permit a slow cooling, say to 1,740-1,800 deg. and then carry out the quenching. The objection to the slow-cooling from the carburizing temperature centers on the possibility of the liquation of the ferrite and perhaps of the cementite as well, if the cooling is slow.

If there is any tendency to cracking, oil may be substituted for water as a quenching medium. Indeed, hot oil—with a temperature as high as 200 or 250 deg. F. — may be used and a still better correction realized.

There is still another quenching operation. This is the one which produces the hardening effect on the external shell. It is properly carried out at a temperature slightly in excess of 1,274 deg. — that is, at a full cherry red. Hardening can be done at higher temperatures, but why run the risks? The best practice everywhere in respect to the hardening of tool steel—and that is the kind of steel in the shell—prescribes hardening at a low temperature. However, Giolitti seems to sanction a hardening temperature for casehardening as high as about 1,470 deg. Whatever temperature is decided on. note particularly that it is not necessary that the interior be at this temperature. It is only the external shell that will be sensibly affected as to hardness by the operation now in hand, because that is the only part containing a high percentage of carbon. But, it is important that the surface heat desired shall exist everywhere. This is sufficiently obvious, once it is stated.

As to the choice of the exact temperature, it may be necessary to do a little experimenting. This is a very good rule to keep in mind when reading any statements as to the proper temperatures for all kinds of heat treatment operations. There are so many factors at work and these factors are so often variable that rigid statements that a metal will do thus and thus precisely at such and such temperatures are hardly permissible. The results may have been realized once with a certain piece of metal. The next piece that is tried may refuse to act as expected at precisely the temperature named; but may do so at a point a little higher or a little lower. The quenching having been carried out, one may then or later apply the heat treatment. This consists in heating to the annealing point proper for the carbon content, making sure that this heat has penetrated everywhere that restoration is desired, and then quenching the work. There will be more or less reduction of the grain size. The amount of this reduction will, it is understood, depend upon the maximum temperature of the re-heat. The more moderate it is, other things being equal, the greater the reduction to be expected.

The temperature of restoration for steels having carbon contents between 0.00 and 0.50 per cent may be taken to vary between 1,675 deg., F., and 1,425 deg. This is a temperature range of 250 deg. to be divided along 50 points of carbon variation. One readily gets the rule: *For every carbon point above zero, subtract 5 degrees of temperature from 1675 deg.* Thus if the carbon content is 0.08, subtract from 1,675 the product of eight and five, getting 1,635 as the temperature for the maximum of the reheat. If the steel be one having 0.20 per cent of carbon, subtract 20 x 5 giving 1,575 as the right temperature at which to stop the re-heating. Manifestly, if the case permits, we should choose a stock having as high a carbon content as would be available for the reason that it requires a lower re-heating temperature upon the re-heat, and this lower temperature is an advantage in the success of restoration. This is a matter that is probably very generally overlooked, since the eagerness to get a steel easily machined drives the choice to low carbon contents. The natural hardness of steel, not that produced by quenching, varies with the carbon content—the more carbon, the harder the steel. The choice of steel, however, should depend more upon the effectiveness of the restoration of quality than upon the ease of machining. In general, then, one should select as high a carbon content as is permissible, all things taken into consideration.

Having settled on the proper temperature for the restoration of the heart of the carburized steel in hand, the work is heated very slowly to the proper point. It is sometimes found that the restoration has to be carried out by heating to still higher points than those given and then quenching. This seems to be especially the case with steel of a very low carbon content. Thus, A. Portevin states that it is often advisable to quench from as high a temperature as 1,832 deg. F., "since the transformation into gamma-iron, which destroys the grain, is subject to retardations, like all polymorphic transformations."

The Temperature of Casehardening

The choice and control of the temperature at which the casehardening procedure is carried out constitutes one of the vital items of a proper technique.

Comparatively recent investigations show that the temperature of carburization affects both the rate of carbon penetration and the depth of such penetration. Martin-Siemens steel of low carbon content was employed in the form of square bars 1.6 in. by 1.6 in. in section and eight inches long. The particular packing material consisted of pulverized wood charcoal that had been treated with five per cent of potassium ferrocyanide and then mixed with an equal weight of barium carbonate in a dry condition. This may be regarded as substantially a half-and-half mixture of charcoal and carbonate. The following table and the accompanying curves exhibit the results:

EFFECTS OF TEMPERATURE ON DEPTH AND RATE OF PENETRATION

Number of hours in casehardening period	Penetrations in inches corresponding to temperatures				
	About 1292° F.	About 1382°-1436° F.	About 1562°-1652° F.	About 1742°-1832° F.	Above 1832° F.
12	0.030	0.044	0.078	0.098	0.106
24	.046	.064	.114	.148	.160
36	.060	.090	.146	.204	.232
48	.076	.112	.180	.236	.292
60	.088	.126	.212	.280	.338
72	.102	.144	.236	.312	....
84	.112	.158	.270	.348	....
96	.120	.180	.298	....	....
108	.132	.198	.324	....	....
120	.138	.218	.350	....	....

Referring to the curves, it will be seen at once that they do not cross one another. Each is altogether above the ones belonging to lower temperatures.

This means that when the temperature of casehardening is raised, the effect is to get a greater depth of penetration whatever the length of the period. This is a good general rule to remember. Again, splendid results, comparatively,

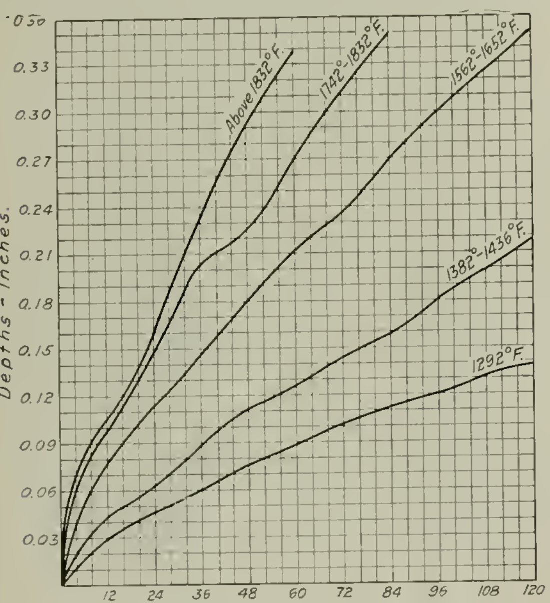

Chart Showing Relation of Time and Temperature to Depth of Impregnation

may be gotten with the temperature 1,562-1,652 deg. For general work, then, this is a good casehardening temperature. Raising the temperature quickens results, but except in special cases, hardly enough to warrant the practice. Good results are obtainable at temperatures below 1,562°-1,652°, so that, if there is need to use them, one may still expect results in a reasonable time.

Note especially that the curves are substantially straight lines. This means that the depth of penetration, at any given temperature of casehardening, is practically proportional to the length of the period. The simplicity of this rule gives it great practical value. If penetration to double the depth is wanted, then double the time will be required; if three times the depth, then three times the period, and so on.

DISTRIBUTION OF CARBON

It is of service to know the distribution of the carbon in the casehardened shell. Naturally, the local percentage of carbon falls off as the depth increases. Experiments have been tried for the purpose of getting at these facts. Probably, each packing material and each temperature of casehardening will affect this matter. Also, the period, the pressure inside the box, etc., will influence the distribution of carbon. It will, nevertheless, be useful to have some representative results before us: The packing material consisted of a mixture of wood and animal charcoal in the proportions of 7:3; the steel was a very low carbon variety (0.05 per cent); the carbon content of successive layers was determined after casehardening for 36 hours at 1,562-1,616 deg. F. The first layer was 0.2 in. thick; the following ones, 0.04 in. each. The carbon percentages for 12 layers, having a total thickness of 0.460 in. were as follows:

1.02, 1.00, 0.94, 0.66, 0.43, 0.22, 0.16, 0.14, 0.12, 0.10, 0.08, 0.07.

It will be noticed that the percentage of carbon in the steel fell off rapidly. This is, in fact, generally characteristic of casehardening. The high carbon steel is all located in a thin shell at the surface. However, by prolonging the period, tool steel (say, steel having more than 0.80 per cent carbon) may be produced to a pretty good depth. In the present case, the 0.80 per cent mark was reached at a depth of about 0.12 in.

It will be of interest to compare this with the results obtained on the same steel at the same temperature when the period was lengthened out to 10 times the original length—that is, to 15 days of 24 hours each. The carbon percentages follow, but the layers are, except for the first 0.02 in. of double thickness to what they were before. If one wishes to compare these results with the former, the missing percentages may be inserted. They may, in each case, be taken as the average of the pair between which the percentage is to have its place. They are as follows:

1.01, 0.95, 0.90, 0.85, 0.79, 0.73, 0.67, 0.62, 0.57, 0.52, 0.47, 0.43, 0.37, 0.33, 0.28, 0.25, 0.22, 0.18, 0.17, 0.15, 0.14.

The total depth of penetration here involved is 1.62 inches. If a curve be formed, it will be found to approach somewhat to a straight line. A curve for the former results (corresponding to 36 hours) would differ very considerably from such a line. This suggests the principle that the concentration of carbon falls off with a greater approach to regularity, the longer the period of casehardening. In the case of the 360-hour period, the increase of the depth by 0.08 meant, in the earlier part, a drop of five or six points in the carbon percentage.

In view of what is now known about casehardening, it seems permissible to state that, if the temperature is maintained at one level throughout the casehardening period, then he may with confidence expect that there will be no abrupt variations in the concentrations of carbon as the process penetrates from the outside towards the center. The rate of change may not remain the same, but it will not alter suddenly. This is a very important thing, since it enables us to avoid producing a shell or layer very distinctly different from the next above or the next below. Generally, abrupt changes in the carbon content of the steel are not desirable. All that we have to do is to maintain the conditions, especially the temperature, throughout the casehardening period.

CONTROL OF TEMPERATURE

Control of temperature—holding it at a given level—is much more easily specified than accomplished. A proper furnace is necessary and it must be capable not merely of producing the required temperature but it must provide a heating space where the fluctuations of temperature, as to various locations, are very slight. Good casehardening can hardly be done if the variations in temperature in different parts of the furnace—except, perhaps, for a space near the door, or some other special spot—are considerable.

Giolitti sets a maximum permissible variation at 30 deg. C. This is 54 deg. F. I will venture to say that there are any number of furnaces where this requirement is not met and where nevertheless casehardening, after a fashion, is being done. This evenness of temperature in the heat chamber is doubtless difficult to get where solid fuel is used, but a properly constructed furnace operated by oil or gas should accomplish the desired result.

A second prime requirement of the furnace is the capability of being run for long periods of time—up to 100 or more hours, depending upon the work—at the same temperature. This is another requirement that the furnace fired with solid fuel will probably find it difficult to satisfy. Oil and gas, however, when used in properly designed and constructed furnaces lend themselves to accurate regulation and should satisfy the requirement for an extended run.

A REPRESENTATIVE PROCEDURE

It will be useful to summarize for a representative case a good deal of what has been set forth. Let us assume that we have to caseharden a lot of small articles of low carbon steel.

1. Prepare the packing, making sure of its purity, fineness and dryness.
2. Prepare the box by casting the bottom with a fire-clay paste.
3. Heat the box or otherwise provide for drying this paste.
4. Tamp in place a bottom layer of packing 1½ in. thick.
5. Place one layer of the work on top of this layer, making sure that minimum space between articles and between the articles and sides of the box is 1½ in. or 1¼ in.
6. Put packing in and around articles and overlay them until the minimum depth of packing above tops of articles is 1½ in. or 1¼ in. Tamp the packing in place.
7. Repeat five and six for each layer of work put in.
8. Add a top layer of tamped packing to a depth of at least 1¼ in. or 1½ in.
9. Put top on, luting it with mortar of fire clay and water.
10. Set box, thus loaded, in furnace, but near door, until the interior moisture is all gone and the fire clay seal is dry.
11. Push the box into the furnace and bring temperature of boxes and contents to about 1,600 deg. F. There will be a variation between the center of the box and the exterior; 1,650 outside may be needed to get 1,600 inside near the center.
12. Maintain heat at an even level for the necessary time.
13. Remove box from furnace, open and suitably quench.
14. Re-heat slowly to restoration point.
15. Quench again.
16. Re-heat to proper hardening point.
17. Quench.

LOCOMOTIVE FAILURES

BY J. F. DONELLON
Master Mechanic, Delaware & Hudson

Locomotive failures, that awful nightmare to every conscientious roundhouse foreman, general foreman and master mechanic, can be given a knockout blow by applying the proper remedy in the roundhouse. If they cannot be eliminated entirely, they can be decreased to such an extent that the superintendent of motive power will wonder what happened.

This is what should happen: Cover the most important jobs in the roundhouse with specialists. The more specialists, the more efficient the organization will be. No matter how poor a mechanic a man may be, if he is interested in his work, he is bound to become more proficient if given regular work on a locomotive or machine. With the eight-hour day in effect and mechanics being paid while they eat, it is not asking too much to insist on 100 per cent efficiency.

It would be well for any master mechanic or shop superintendent to pattern his shop organization after a winning ball team—the master mechanic should be a good live manager, the general foreman or enginehouse foreman the captain, the gang foreman or leaders to be the coaches, training the players thoroughly, encouraging them when they are slipping and cheering them when they make a home run, or in other words when they do a good quick job.

Post the locomotive failure sheet, which in reality is a score board, every day. They will then quickly learn the items that cause failures and they will feel their pride hurt when fellow employees refer to some locomotive they worked on as failing between terminals and delaying other trains.

A careful analysis of the monthly failure sheet on any railroad will shown that 90 per cent of the failures are caused by improper inspection in the shops. Too much stress cannot be laid on the practice of educating locomotive inspectors, calling their attention to items that cause failures and giving them breakage diagrams of all the parts that fail, regardless of whether the locomotive on which the failure occurred was out of their respective station or some other station.

It is my belief that every rod, frame, link hanger, or in fact, any of the particular parts that fail frequently, have what I consider a breaking zone; that is, some part of the rod stands considerable more stress than the other sections and is more liable to fail.

A list of the parts that failed and caused locomotive failures on a prominent railroad is given below:

Air pump	4
Axle (driver) broken	2
Brake beam down (driver)	1
Brass broken (tank)	[illegible]
Bolts, eccentric hook gone	1
Brace, tank binder broken	1
Bolt, front side rod broken	1
Bolt, lost out back end of valve rod	3
Link saddle bolts broken	1
Rocker arm bolt lost	1
Cylinder head broken	2
Cylinder packing	2
Firebox door	1
Drawbars broken	1
Flues, superheater, leaking	2
Flues, bursted	4
Dump grates disconnected	1
Guide yokes broken	1
Leaky tank hose	1
Spring hanger broken	2
Driver hub cracked	1
Transmitter bar broken	2
Tender brake beam hanger broken	1
Link block hanger broken	1
Injectors not working	2
Hot tender truck journals	2
Hot trailer truck journals	1
Hot driver axle journals	7
Hot engine truck journals	3
Lining, front end main rod keys	1
Main rod key lost	1
Nuts off guide	2
Hot main pins	5
Broken air pipe	5
Packing rings, valve	1
Piston head broken	1
Plug out of release valve	1
Main rod working loose	1
Intermediate rod broken	2
Bolt blown out, reservoir	1
Reverse gear in back motion	1
Reverse lever casting broken	1
Low steam	2
Low steam due to leaky flues	1
Main rod strap broken	1
Relief valve spring broken	1
Strap on drawbar down	1
Tires loose	4
Throttle connection broken	1
Valve stem broken	1
Wrist pin nut lost off	1

This list extends over a period from January 1 to August 1, 1919. On this particular division there were 38,000 engines dispatched during this time, including yard engines and all classes of power, so there were approximately 430 engines dispatched per engine failure.

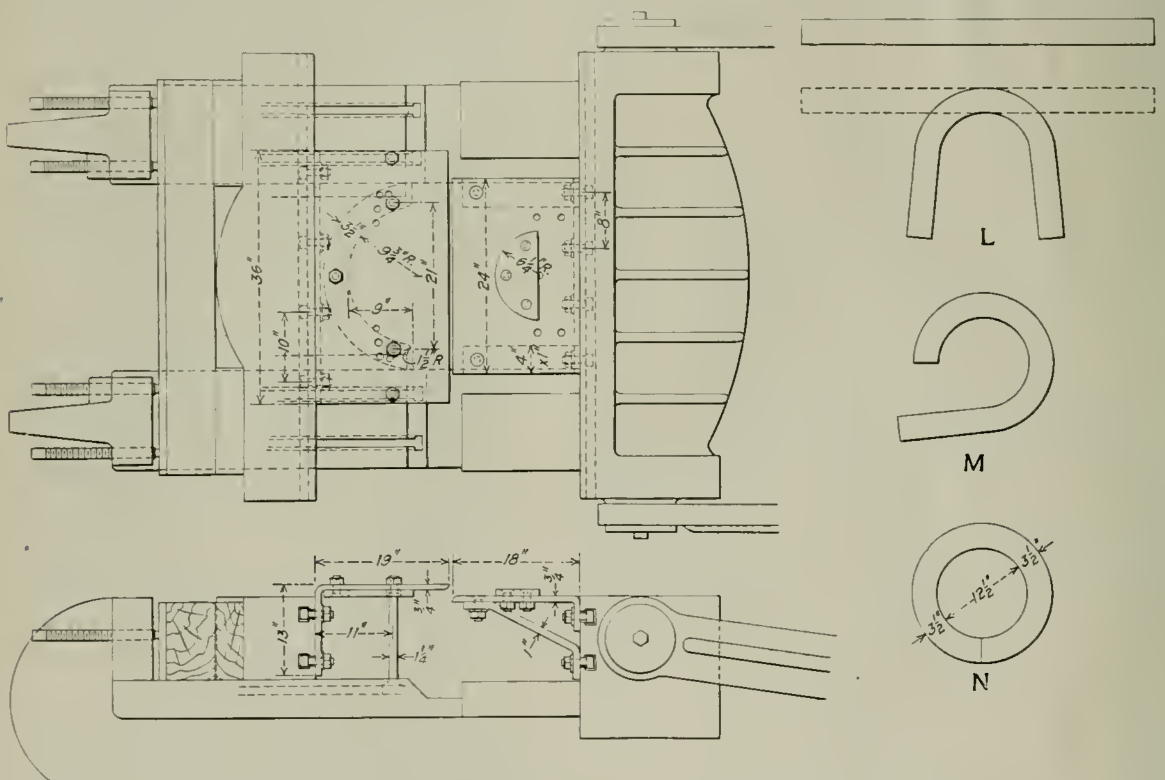
A careful study of the causes of failures, both by the mechanics and the inspectors, will add greatly to the capacity and efficiency of the roundhouse organization.

FORMING HUB LINERS ON THE BULLDOZER

BY F. G. LISTER
Mechanical Engineer, El Paso & Southwestern, El Paso, Tex.

On the El Paso & Southwestern there has been in use for some time a device for forming wrought iron hub liners for locomotive driving wheels on the bulldozer. This has proved very satisfactory as it forms a good hub liner at a very nominal cost. The device as applied to the machine is shown in the drawing. The dies *A* and *B* are made to correspond to the inside and outside diameters respectively of the hub liners, *A* being bolted to the top of one plate and *B* being bolted to the bottom of the other.

To form the liner, a piece of wrought iron 1 in. by 3½ in. and of the proper length to make a full circle is brought to a cherry red heat and laid across the bottom plate and against the periphery of die *A*. The first stroke of the bulldozer forms a piece similar to the shape shown at *L*. The iron is then moved until the center of the die is about one-fourth the distance from the end, and the second stroke of the bulldozer forms it to the shape shown at *M*. A similar operation on the opposite end at the third stroke forms the iron almost circular as shown at *N*. It is turned several times on the plate until a perfect circle is obtained and the ends join well together. The dies *A* and *B* are bolted to the plates ⅞-in. countersunk head bolts, so that they may be removed and other dies having different radii, depending on the diameter of the hub liner required, may be applied in their place.



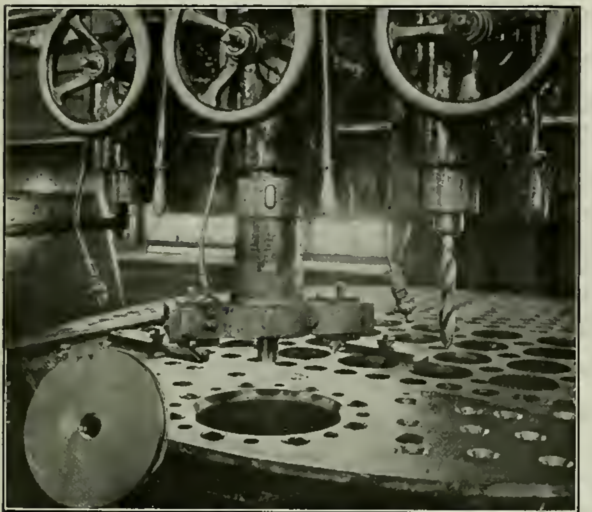
Details of the Bulldozer Dies and Sequence of the Operations for Forming Hub Liners

CORN USED AS FUEL IN ARGENTINA.—Because of the impossibility of securing coal from England, from which country Argentina formerly imported its supply, according to an article in the Railway Gazette (London), the demand for hard wood, obtained from forests in the northern part of the country, grew so rapidly that the railways found it difficult to haul to the south sufficient wood to supply themselves and other consumers. Experiments were then made with corn (maize), of which there was an abundance in the republic, and it was found that maize would burn freely and had practically the same calorific value as hard wood. It gave good results in the stationary boilers of power houses where thousands of tons were burned each month. Some was also used in locomotives. It was burned sometimes in the form of grain, but more often on the cob. Firebars had to be placed about ½ in. apart, otherwise the grain fell through into the ash pit or ash pan. This closing up of the bars was particularly necessary when maize was used on locomotives. In such cases it was burned mostly on shunting engines. The relative calorific values of maize and coal are found to be in practice as 2.5 to 1; similar values for hard wood and coal vary between 2.1 of wood to 1 of coal, and 2.5 of wood to 1 of coal. If the maize is ground down until the particles are about the size of those of a medium sand, and it is then blown by a fan into a heated combustion chamber, it immediately bursts into flame and is much more economically consumed. The maize sold for about $15 a ton and a large quantity is still being burned in the Argentine, but fuel oil in reasonable quantities is now arriving from the Mexican and other oil fields.

CUTTING DRY PIPE HOLES IN TUBE SHEETS

BY J. J. SHEEHAN
Tool Foreman, Norfolk & Western, Roanoke, Va.

The photograph herewith shows our method of drilling and facing front flue sheet for steam pipe joint. This tool



Tool for Cutting Dry Pipe Holes in Tube Sheets

fits the drill press spindle on the outside and is held in place by a key fitted to the drift slot in the spindle. The cutter heads are adjustable, having a range of boring size from 5 in. to 15 in. The size of steel used for tools is ⅝ in. by 1 in.

HOT DRIVING BOXES ON A. E. F. LOCOMOTIVES

BY C. E. LESTER
Shop Superintendent, Nevers (Nievre), France, Shops of the American Expeditionary Forces

In our repair work at the Nevers (Nievre), France, shops of the American Expeditionary Forces, among other things we experienced considerable trouble due to driving boxes running hot on one type of Consolidation locomotives immediately after leaving the shops after being overhauled. It was noticed that some 12 or 15 locomotives of this type had been sent to our shop within a few weeks' time to have the crown bearings renewed, and upon comparing the date of shopping and the date that the locomotives were built, it was found that they had been in active service only from one to three months.

When two or three of these locomotives had run hot after receiving new crown bearings, it was decided to watch the next one closely to determine the cause for this condition.

On the next locomotive received for repairs the driving boxes were removed, the crown bearings were shimmed, and in so doing several of them became out of parallel at the shoe and wedge face, making it necessary that these faces be planed. All the boxes were then bored to fit the journal, allowing enough to scrape them to a perfect bearing. The proper amount of clearance was given to the bottom ends of the crown bearings so that the oil would not have any difficulty in staying on the journal and that the box would not have a tendency to ride the journal.

In boring the boxes they were set on the boring mill on parallel strips with the hub face of the box up, to which they were lined with a surface gage so that the bore of the bearing would be at exactly right angles to the hub face. The boxes were then drilled and the bearings chipped, in order to have the oil from the oil cavity on top of the box distributed as evenly as possible over the entire surface of the crown.

The boxes were then sent to the erecting shop, applied to the journals, and checked by the erecting shop inspector, who found them anywhere from 1/16 in. to 5/16 in. out of center on the inside faces of the boxes. This condition existed on the boxes that had been planed, as well as on those that had not been planed, and on removing them from the journals and laying off a center on both the hub face as well as on the inside face of the box, it was found that the hub face was exactly in the center when compared with the shoe and wedge faces, but that the center on the inside face of the box was out of line the amounts stated above.

At this time we received in the machine shop another set of boxes of the same type, and before any work was done on them, centers were applied to both faces, as had been done to the other set, for the purpose of determining what their condition was when they were removed from the engine. It was found that these boxes also were out of center on the inside face of the box.

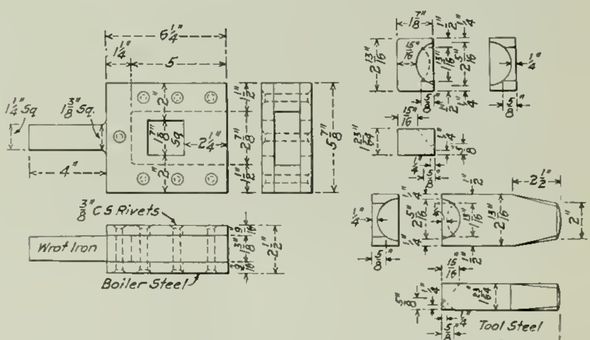
Previous to this time, when we had any of the boxes of this type in the shop to have the shoe and wedge faces planed, we clamped them down to the planer table on parallel strips applied under the shoe and wedge face, depending on which one was to be planed, which of course caused the box to be planed in the same manner as when it was placed on the planer, with the exception of having the faces running parallel lengthwise.

From the investigation made the opinion was formed that the hub face bore of the crown bearing and the shoe wedge faces were not square with each other when they were first built at the manufacturing works. This, we think, caused a twisting movement of the box, which had the same tendency to make the crown beating run hot as would a bearing with the crown bored tapering.

As we had no means of obtaining a casting of the proper dimensions to make a planer face plate on which the boxes could be clamped against the hub face, a large square was made, to which the boxes were set before planing the shoe and wedge face.

SHAPING THE ENDS OF TRACK CHISELS

In dressing track chisels the usual practice is to taper the cutting end under the hammer and term the edge to the



Details of the Track Chisel Sharpener

proper contour on a grinding wheel. This operation requires considerable time and unless care is taken the steel may be heated to such an extent that it cannot be tempered. In the Shoreham shops of the Minneapolis, St. Paul & Sault Ste.

Marie, an interesting device is in use which shapes the end of the chisel after it has been drawn down and makes grinding unnecessary. This combined shaper and sharpener is shown in the illustration herewith. It consists of a guide which fits on an anvil and holds two dies. The chisel after being drawn down under the hammer is inserted between the cutting edges of the dies and a single blow cuts off the end and shapes the edge. By this method considerable labor is saved and the danger of burning the steel on the grinding wheel is avoided.

A COVERED HOSE REEL

The covered hose reel shown in the illustration affords a simple and effective means of protecting fire hose from the elements and at the same time permitting easy access to the hose when it is necessary to use it.

The cover is made of sheet metal formed to cover the reel and the upper portion of the fire hose and is firmly secured to the reel standard, which can be permanently placed near a water hydrant.

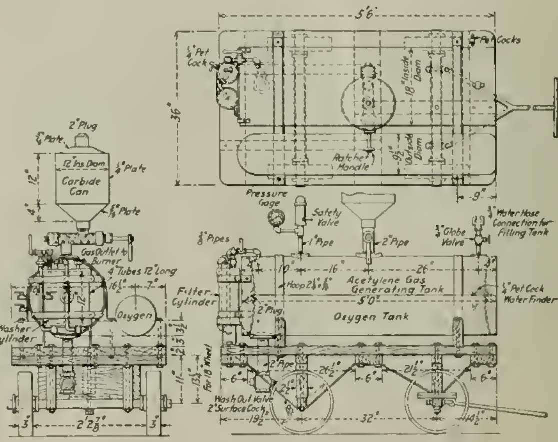
This cover can be easily and cheaply made in the shop

The Covered Reel Installed Near a Hydrant

and applied to hose reels about the yards. Its cost is not great and the protection afforded to the hose and to the reel itself will result in a much longer life of both. This effects an economy that will more than offset the cost of the cover and at the same time insures that snow or ice may not interfere with the use of the hose. This type of hose reel cover has been in use in the yards of an eastern railroad for some time past.

ACETYLENE GENERATOR, SACRAMENTO SHOPS, SOUTHERN PACIFIC

An old Pintsch gas tank or any other suitable tank that will hold a pressure of 50 lb. per sq. in. can be used for the generator. In generating gas the pressure should not exceed 12 lb. per sq. in. On the top of the generator is a reservoir to hold the carbide which is fed into the lower tank as wanted by a screw fitting in the inside of a two-inch pipe. The generating tank and washer should be kept about half full of water; the water level in the cylinders can be gaged by the use of pet cocks. The water level in the generator tanks should never be allowed to fall below the lower pet



Arrangement of Acetylene Generating Equipment

cock. The filter cylinder is to be filled with hair.

The gas from the generator tank enters the bottom of the washer cylinder, comes out of the top and enters the bottom of the filter cylinder from which it is drawn off through the hose and connections to the torch. Care should be taken to keep the carbide dry until used for making gas. At the end of the day, the generator tank should be washed out and fresh water put in both the tank and the washer cylinder. Every four months, or oftener if necessary, all plugs should be removed and the tank, pipes and cylinders should be given a thorough cleaning. No iron or metallic tools should be used in cleaning the tank. The contents should not be emptied into a sewer but should be deposited on the ground in some suitable location.

Diesel and Semi-Diesel Engines.—A Diesel engine is a prime mover actuated by the gases resulting from the combustion of a liquid or pulverized fuel injected in a fine state of sub-division into the engine cylinder at or about the conclusion of a compression stroke. The heat generated by the compression to a high temperature of air within the cylinder is the sole means of igniting the charge. The combustion of the charge proceeds at, or approximately at, constant pressure. A semi-Diesel engine is a prime mover actuated by the gases resulting from the combustion of a hydro-carbon oil. A charge of oil is injected in the form of a spray into a combustion space open to the cylinder of the engine at or about the time of maximum compression in the cylinder. The heat derived from an uncooled portion of the combustion chamber, together with the heat generated by the compression of air to a moderate temperature, ignites the charge. The combustion of the charge takes place at, or approximately at, constant volume.—*Compressed Air Magazine.*

NEW DEVICES

HIGH POWER TURRET LATHE

To meet the demand for a turret lathe of greater power and strength to finish gear blanks, forgings and tough alloy steel parts, the Warner & Swasey Company, Cleveland, Ohio, has developed the new No. 6 turret lathe, shown in Fig. 1. It is expected that on account of its increased power this machine will be able to do work formerly done by heavier and more expensive machines.

The increase in power and productive ability of the No. 6 turret lathe is secured by means of the double friction back gears, shown in Fig. 2. With the construction indicated, nine spindle speeds are available, three for each step of the driving cone. The extra power permits taking heavy forming and facing cuts on both bar and chucking jobs, which are beyond the capacity of the single back geared type of lathe.

The general view of the turret lathe shows it equipped with a heavy duty carriage provided with power cross and hand longitudinal feed. Six power cross feeds and reverse are obtainable in the apron. The three finer feeds are suitable for forming and the three coarser feeds for facing operations. The front toolpost, with an adjustable wedge, is arranged to be swiveled at any angle, and a cutting off tool holder is regularly furnished for the rear. Either of these tool holders may be removed and forming tool holders substituted. The automatic chuck and bar feed are provided, operated by a long lever in front of the head, and a stepped wedge automatically adjusts the collet for slightly varying diameters. A master collet and bushing pads are regularly furnished with the machine for holding $2\frac{1}{4}$-in. round stock, but bushings for hexagon stock can be held in this collet also. Square stock requires a square stock master collet and bushing pads. Extra capacity collets can be furnished for holding short-length work larger in diameter than the capacity through the spindle.

The hexagon turret is arranged for holding tools with or without shanks. The six tool holes, counterbored for centering plate tools, are fitted with draw bolts and are bored $1\frac{3}{4}$ in. in diameter, unless ordered otherwise. Bolt holes are provided for securing plate tools to the faces.

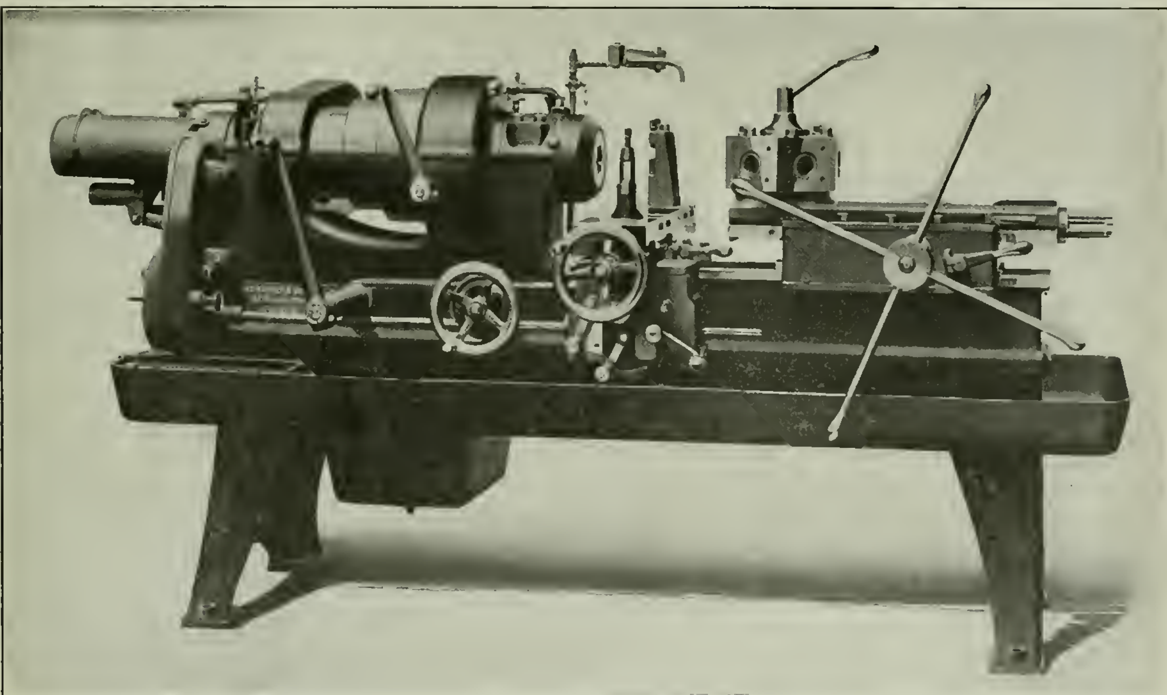


Fig. 1—No. 6 Warner & Swasey High Production Turret Lathe.

The turret is revolved automatically by the backward movement of the slide. The locking bolt is at the front end of the slide and works into steel taper bushings inserted in the bottom of the turret close to its outside edge directly under the cutting tool.

Independent adjustable stops operate automatically from each position of the turret and disengage the power feeds.

They are readily adjustable for the proper length of each cut.

The turret saddle has a supplementary taper base to adjust the tool holes in the turret to the exact height of the spindle center. Taper gibs, fitted the whole length of the saddle on each side, provide means for adjusting the slide sideways.

Power feed for the turret slide is furnished only when especially ordered, and any one of four feed changes is easily obtainable. The automatic trip operates in connection with independent adjustable stops for each hole in the turret.

An oil pump, which operates when the machine is run in either direction, delivers a steady and abundant flow of cutting lubricant to the cutting tools.

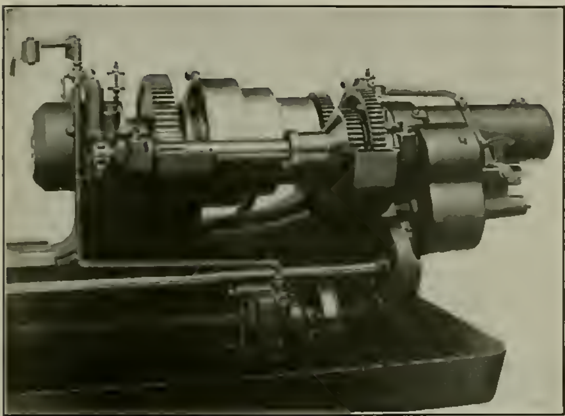

Fig. 2—Rear Head Showing Double Friction Back Gears.

The Warner & Swasey No. 6 turret lathe has a maximum swing of 20⅝ in. and a bar capacity of 2¼ in. On soft machinery steel the threading capacity with a self-opening die head is 1¾ in. The total cross travel of the carriage slide is 10 in. and the total longitudinal travel 14 in. A three-horsepower motor is required to drive this machine.

PRODUCTION FACE GRINDER

After being thoroughly tested over a considerable period of time a new self-contained face grinder, shown in Fig. 1, has been placed on the market by the Cleveland Machine Tool Company, Cleveland, Ohio. The particular advantages claimed for this machine are high production, freedom from breakdown and ease of operation. The L-shaped column is a one-piece box section designed for rigidity and strength. A door in front permits of easy access to the working parts of the machine for oiling, inspection and adjustment. The table is 42 in. long by 9¾ in. wide. One V-shaped and one flat way give ample bearing surface, and because of the fact that the table is larger than the ways the latter are always covered and kept free from dust and grit. The table is provided with a crank handle adjustment, as shown in Fig. 2, by which the arc of oscillation can be readily adjusted to the work to be ground. The throw, or arc of oscillation, can be adjusted up to six inches, which permits of handling work up to 12 in. in diameter. The table is oscillated by a crank disk, driven by a worm and worm gear, insuring a firm and steady motion. Six changes of feed are secured by means of a three-step cone pulley on the machine and a two-speed countershaft.

The grinding wheel head is fitted to a saddle, secured to the main part of the column by a dovetail slide, and gibbed to provide adjustment for wear. The adjusting screw for the saddle is provided with a micrometer dial. The grinding wheel head is pivoted and can be turned to any desired angle, thus permitting the use of wheels of various shapes. The head is graduated in degrees for a space of 30 deg.

The grinding wheel spindle is made extra large, of a special steel, hardened and ground, the bearings being of phosphor bronze. Large grinding wheel flanges are provided, and a wheel guard large enough to accommodate 8-in. grinding wheels is made a part of the machine.

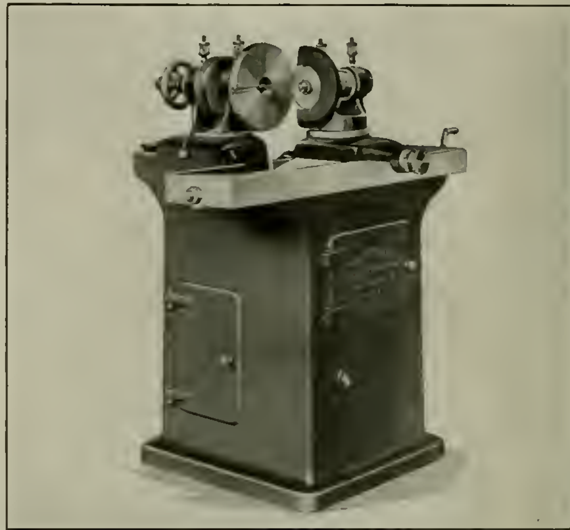

Fig. 1—Cleveland Production Face Grinder.

The work head is secured to the wing of the column by means of a dovetail slide and rests on its own saddle, which has longitudinal adjustment of 6 in. The saddle is attached to the column by a hand clamping screw, thus providing easy adjustment, and a gib makes this slide adjustable for wear. The machine will accommodate work 6 in. in thickness without overhang of the saddle. By making proper allowance for saddle overhang it is possible to handle work up to

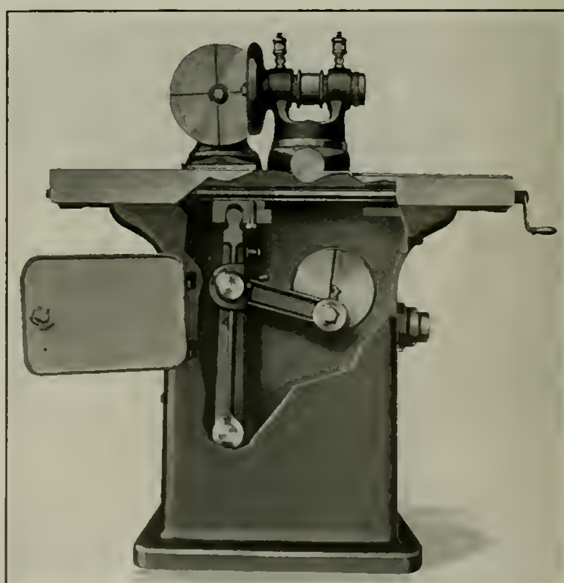

Fig. 2—The Arc of Oscillation Is Easily Adjustable.

10 or more inches in thickness. The work is pivoted on the saddle and can be swung to any angle.

The work spindle is extra large, made of special steel, hardened and ground, and has a No. 11 Brown & Sharpe taper hole. The spindle bearings are of phosphor bronze, and are adjustable for wear. The nose of the spindle is threaded to receive a 10-in. face plate, which has two 7/16-in. T-slots at right angles, permitting rapid clamping of the work. Careful consideration has been given to lubrication and protection from dust. The four spindle bearings are provided with large sight-feed oil cups, and all cylindrical and flat bearings have oil holes fitted up with dustproof oil caps. The machine is designed especially for grinding metal slitting saws, hubs of milling cutters, faces of bushings, arbor collars, etc.

HEAVY QUICK CHANGE LATHE

A powerful cone type lathe has been placed on the market recently by the Cincinnati Lathe & Tool Company, Cincinnati, Ohio. The lathe is made in four sizes, varying from 22 in. to 28 in. in capacity, and is designed especially with the idea of utilizing the best grade of high-speed steel tools

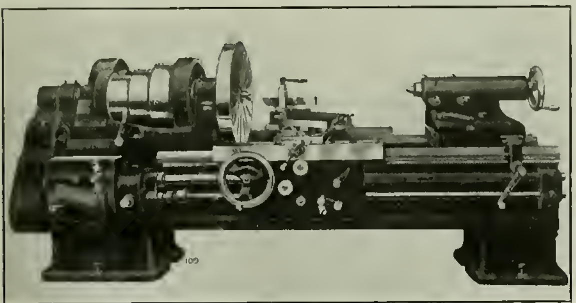

Fig. 1—Cincinnati Heavy Duty Lathe.

to their utmost capacity. The attempt has been made to design a lathe powerful in every detail and without intricate mechanism which may be easily broken or worn out.

The lathe bed, as shown in Fig. 1, is exceptionally heavy

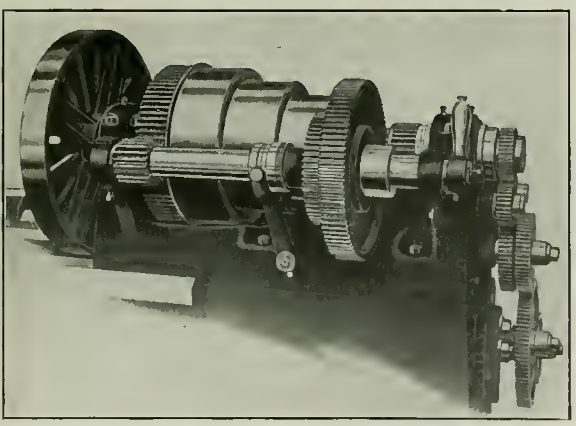

Fig. 2—Rear View of Sliding Double Back Gears.

and, being braced with box section girths, is well able to withstand all twisting strains. The carriage is especially designed to withstand all strains due to heavy cuts, and exceptionally long bearing on the ways is provided. This insures greater accuracy in the cuts taken and also reduces the wear. The apron, of box type construction, is provided with a chasing dial and automatic stop.

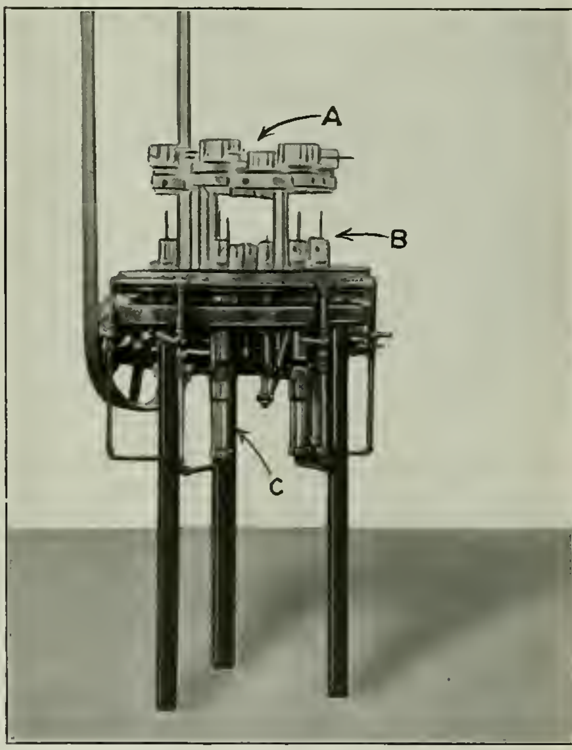
Ample power to drive this lathe is secured by means of the three-cone pulley, which is driven by a 5½-in. belt. The power is transmitted through the sliding double back gear shown in Fig. 2. An idea of the proportions of the headstock may be obtained from the bearings. The front bearing is 4½ in. by 7¾ in., the back bearing 3⅜ in. by 5⅜ in. The quick change gear box of standard Cincinnati construction gives a wide range of speeds and feeds.

The tailstock is equipped with a crank operated pinion, which meshes with the rack and insures easy movement of the tailstock. The two spindle locking devices for clamping the spindle hold it in rigid alinement and obviate the possibility of springing under heavy cuts.

If desired, this lathe can be furnished with turrets on the carriage or the bed, oil pan and pump, taper, relieving or draw-in attachments and turret tool posts. Either cone type or geared head for belt or motor drive may be specified.

STAYBOLT DRILLING MACHINE

Considerable difficulty has been experienced in drilling stay-bolt telltale holes, even before the bolts were applied to the boiler, due to drill breakage, and a five-spindle drilling machine has been especially designed with a view to obviating this difficulty. As shown in the illustration, the



Five-spindle Staybolt Drilling Machine.

machine is belt-driven, the driving shaft being geared to five drill spindles *B*, mounted in an equal number of small air cylinders *C*. Five chucks for holding the stay-bolts are supported on a framework, as shown at *A*. The chucks, which are self-centering and take all sizes of staybolts, are provided with a jig for supporting the drills.

By connecting the cylinders through the connecting pipes and three-way valves to the shop air line, the drills are forced up into the bolts when the three-way operating valve is opened. By drilling upward the chips may fall out easily, which eliminates a large proportion of the drill breakage. When the three-way valve is placed in release position the spindles drop, thus insuring a quick release. The capacity of the machine illustrated is 75 bolts per hour, with telltale holes 1½ in. deep, or 25 bolts per hour with telltale holes 8 in. deep. This machine is the invention of J. B. Hasty, San Bernardino, Cal., to whom a patent covering the principal features has been issued.

COMBINATION PUNCHING AND SHEARING MACHINE

During the past few years the general tendency in machine tool design has been to combine as many operations as possible in one machine and sometimes to combine the machines themselves. The result of this policy has been to reduce the cost of the machines, cut down the floor space occupied and render the operation of the machine more economical by the elimination of lost motion.

This principle of consolidating machines has been embodied by Joseph T. Ryerson & Son, Chicago, Ill., in a new quintuple combination punching and shearing machine. This machine has also been designed with the idea of obtaining maximum power, efficiency and simplicity of operation. Five metal working machines are combined in one unit, as illustrated in Fig. 1. The operations of shearing of plates, round and square bars, coping and notching, section cutting and punching may be performed without changing any of the tools or attachments; therefore no time is lost due to the interchange of attachments for the various operations. Samples of the work that can be performed are shown in Fig. 2.

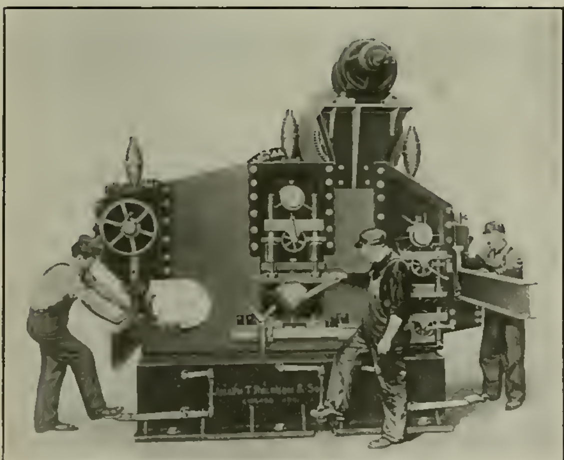


Fig. 1—Ryerson Quintuple Punching and Shearing Machine.

The operating side of the machine is entirely free from all overhanging machine parts, the entire mechanism, such as gears, clutches, fly-wheels, etc., being on the opposite side, as illustrated in Fig. 3. This constitutes a most important safety feature. Ample space is provided in order that the operators will not interfere with one another in handling different kinds of work at the same time. The section cutter especially is given generous space, so that the operator may cut material right or left handed, as desired.

All the foot-lever connections for operating the three clutches are arranged so that they do not interfere with long plates when passing through the full length of the machine frame in the splitting operation. This avoids the necessity for disconnecting clutch rods, as is sometimes necessary. The machines are furnished with heavy ribbed bases on both side to balance them properly and to insure a rigid foundation. The right-hand foot casting is cut away to provide necessary clearance for plates when cut in any length and width.

All machines are equipped with three-jaw automatic clutches for operating the sliding heads independent of each other. The automatic clutch on the front end is provided with a loose disk to permit adjustment of the stroke at any desired position. The clutch for the splitting shear, bar cutter and coping and notching machine can be operated by either hand or foot. The clutches for the punch and section cutter are operated by foot only. All gears except the motor gear are made of cast steel, having teeth from the solid metal. The gears run in extra long bronze bushings and are covered by gear guards, ample provision being made for lubrication. Heavily constructed outboard bearing brackets, illustrated in Fig. 3, take up all the strain when the three tools are operated at the same time.

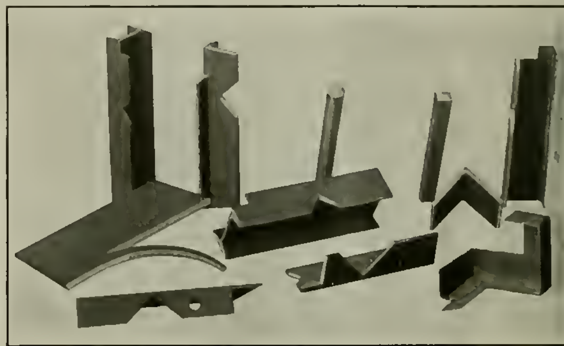

Fig. 2—Samples of Work.

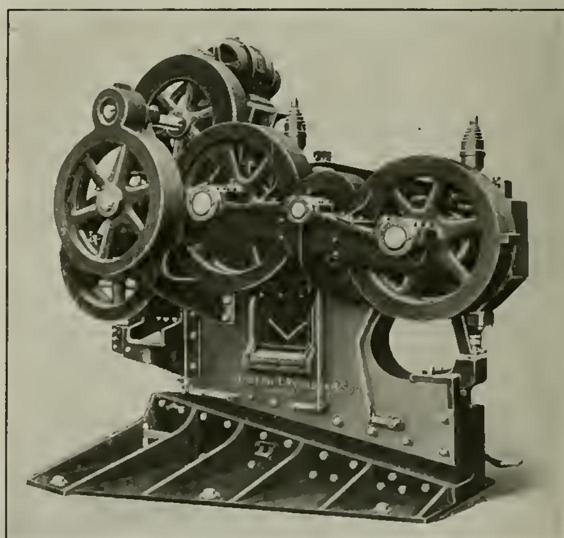

Fig. 3—Back View Showing Arrangement of Overhanging Machine Parts.

The main frame of the machine consists of a skeleton offset shear body, which is reinforced by heavy steel plates, making the machine extremely rigid and able to withstand severe stresses. The skeleton frame and plates are properly interlocked by means of machine steel pins. The universal plate shear permits of splitting plates up to the maximum capacity in any length and width. An adjustable hold-down for the material is provided.

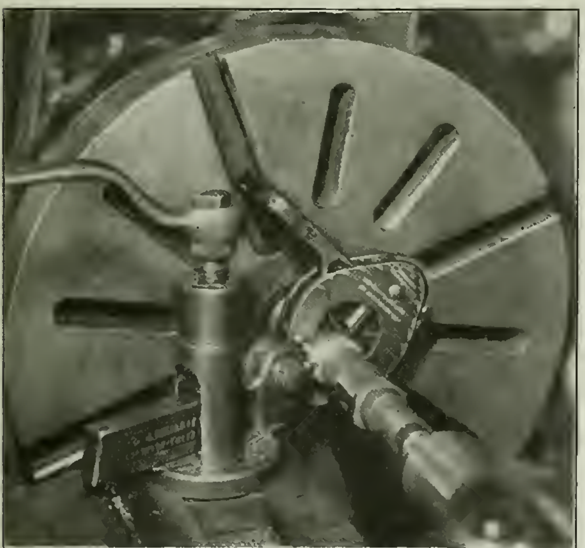
All clutches are equipped with standard architectural jaws, which permit the punching of standard I-beams, channels and sections, both in the flange and the web. Here again adjustable hold-downs are provided, and a cam shaft and hand-wheel arrangement permits the centering of the punch to the full length of the stroke. A shear for cutting round and square bars is provided in the sliding head of the plate shear. Depending upon the capacity of the machine, blades with three or four notches can be provided.

The original design of this quintuple punching and shearing machine provides for direct motor drive, but if desired a belt drive with tight and loose pulley belt shifter can be furnished.

CAM TYPE LATHE DOG

There is more or less danger connected with the use of the common type of lathe dog with its projecting set screw. To obviate this difficulty the Efficiency Device Corporation, Long Island City, N. Y., has devised the lathe dog shown in the illustration, which depends for its action upon the cam principle. It is also claimed that a considerable saving in time is realized, due to the fact that no time is wasted in hunting for wrenches to tighten or loosen the set screw used in the lathe dog of the ordinary type.

A swing of the smooth-jawed cam will open the dog to any size within its capacity and, after the work is inserted, springs actuate the cam and close it automatically. The lathe dogs do not depend upon the springs, however, for their driving power, because the harder the pull the tighter the grip. Due to the absence of teeth on the cam, the work is not scored or marked.



Cam Type Lathe Dog in Operation.

This lathe dog is made of a steel drop forging, heavily case-hardened. There are five dogs in a set, with a capacity ranging from ½ in. to 3 in. in diameter, each size having an automatic adjustment of ½ in.

A RADICAL DEPARTURE IN FREIGHT CAR DOOR FIXTURES

One of the trying problems which railway employees have to face is that of opening freight car doors without damage to the doors. A new device which is intended to remove this difficulty is the Jerry Loc-Lever. The Loc-Lever works on the leverage principle and when applied takes the place of locks, hasps and starters. The iron bar which forms the lever proper is suspended from the side plate of the car by a bolt and reaches a point a few inches below the lower edge of the car door. Another bar is fastened to the car door and extends across it horizontally about one-third the way from the top. To this are attached four fulcrum pinions formed of bolts inserted through steel tubes, large enough in diameter to revolve around the bolt and thus form a roller bearing. The handle of the main lever is so constructed that the seal or the lock of the car can be inserted through convenient orifices. In operation, when the door is closed the Loc-Lever bar lies against the last pinion and holds the door securely in place. When the door is to be opened the seal is broken, thus releasing the lever, which is then raised away from the car a distance sufficient to pass it over the last pinion, against which it then lies in a diagonal position. A pull is exerted on the handle and from the resulting leverage the door is forced open a short distance. The operation is repeated on the three other pinions in turn, with the result the door is fully opened without damage.

A Combined Door Lock and Opener

The device takes its name from the nickname of its inventor, H. F. Jerolaman, of the traffic department of the Atchison, Topeka & Santa Fe, who is familiarly known as "Jerry." In his work Mr. Jerolaman noted the difficulties encountered in connection with the opening of car doors and this device is his idea for overcoming the trouble. Besides effecting a considerable saving in the damage ordinarily done the car door, it is anticipated that the device will also save time at stops and transfer points.

INTERCHANGEABLE UNIT SCREW MACHINES

A new line of hand-screw machines, embracing five sizes, to handle work from 7/16 in. to 2-9/16 in., has been designed recently by the Foster Machine Company of Elkhart, Ind. The unit principle of design has been carried out and, as applied to this line of machines, each machine is assembled from a number of separate units built and kept in stock as independent units. For instance, three different styles of cut-off units are available, the lever feed cut-off, hand screw feed cut-off and power feed cut-off. These are interchangeable, one with the other, and can be furnsihed as required. The power feed of the turret is a separate unit, and a machine can therefore be built either with power feed for the turret slide or with hand feed. The automatic chuck and bar feed are independent units and can be furnished or omitted as required.

The No. O and No. 1 screw machines, which are of 7/16-in. and 15/16-in. bar capacity, respectively, are designed for high spindle speeds and the sensitiveness of operation essential in machines of small bar capacity.

The No. 3 screw machine, the bar capacity of which is 1 5/16 in., is built in both the plain head and friction head types. The No. 5 and the No. 7 screw machines, with a bar capacity of 1-13/16 in. and 2-9/16 in., respectively, are built in the friction head type only. The large diameter cone pulley and the powerful friction provide ample power for heavy requirements. The turret slide has an effective travel of 7 in. for the No. 3, 9 in. for the No. 5 and 11 in. for the No. 7 screw machine.

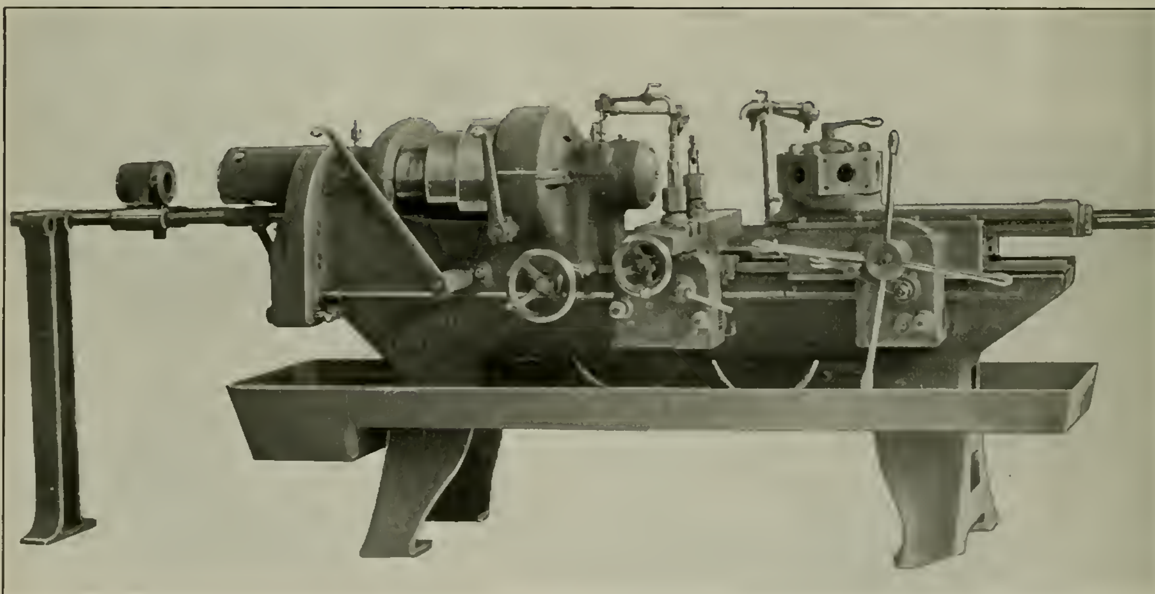


Fig. 1—No. 7 Foster Hand Screw Machine.

The gear friction head, as shown in Fig. 2, has a powerful friction clutch, mounted on the spindle between the cone pulley and the friction gear, which serves to engage the spindle into driving connection direct with the cone pulley on one side or with the back gears through the large diameter spindle gear on the other side. The frictions are of the cone type and are operated by the hand lever through the

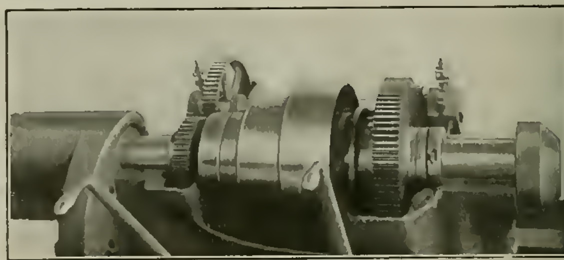

Fig. 2—Arrangement of Friction Head.

medium of a long, movable sleeve and four fingers mounted on the spindle. They are powerful but sensitive in operation.

The automatic chuck is of a standard spring collet type, and the operating machanism differs materially from previous designs. The fork lever principle has been utilized instead of the sliding fork principle, which eliminates the cocking action and reduces friction. The automatic chuck fingers are equipped with rollers to eliminate friction at this point. It is claimed that with this type of chucks 40 per cent of the force usually applied at the handle of the operating lever will hold the stock.

The bar feed operating mechanism also is new, in that the continuous motion of the automatic chuck lever as it opens the collet feeds the bar forward. This is accomplished through a system of links and levers in such a manner that the automatic chuck and the bar feed are operated intermittently.

On the heavier screw machines a hexagon turret is used with an indexing mechanism, which is very sensitive in operation. The vertical lock bolt is mounted underneath the front side of the turret, directly beneath the working tool. The end of the lock bolt lever, which intermittently engages the tumbler for withdrawing the lock bolt preliminary to the indexing of the turret, is equipped with a roller for the sake of sensitiveness and reduction of wear.

A system of revolving independent stops are gibbed to the turret and index with it. The power feed apron for the turret slide is shown in Fig. 3. The three sliding gears, together with a cluster of two sliding gears in the gear box at the end of the machine, provide six different speed changes. The

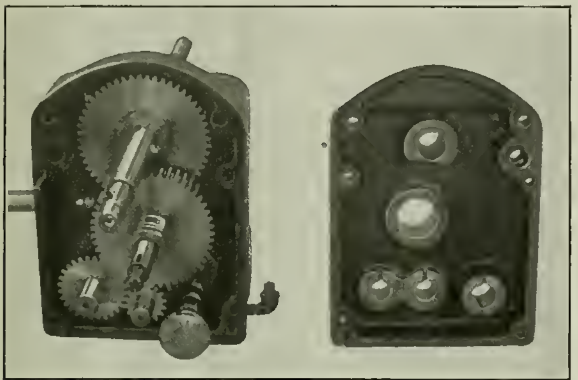

Fig. 3—Power Feed Apron for Turret Slide.

power feed is engaged and disengaged by a friction working in conjunction with the gear engaging the large driving gear of the pinion shaft. The apron is oil-tight, and the lower gears in the gear train, including the worm gear, run in a bath of oil.

The arrangement of gears in the cross feed apron is similar to that in the turret slide, except for the introduction of sliding gears to obtain a reverse of the feed movement. The feed friction, which works in conjunction with the two large intermediate gears, is operated by a ratchet acting as a powerful cam, manipulated by a hand lever. The three-step sliding

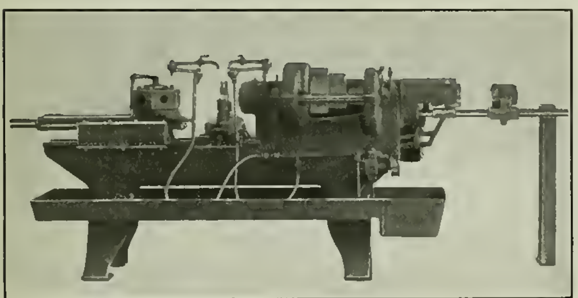

Fig. 4—Rear View Showing Double System of Piping.

gear nests in the apron in conjunction with the two changes obtainable in the gear box at the head of the machine, as described, provide six changes of speed to the cross slide.

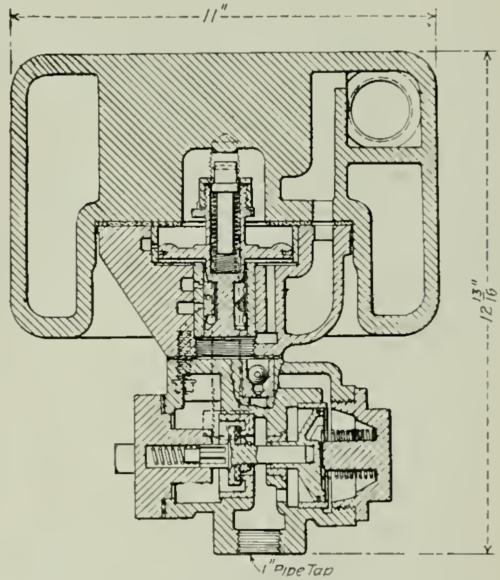
The location of the hand longitudinal feed screw between the ways of the bed is an important feature of this machine. The force moving the cut-off carriage on the bed is applied in the middle of the guards instead of on the front side, where a slight cocking action may result in inaccuracy of adjustment and undue wear of the machine at this point. Large diameter graduated dials, equipped with observation stops, are provided for both the hand longitudinal feed and also for the cross feed.

A double system of piping is provided, as shown in Fig. 4, together with a suitable rotary pump, to furnish the proper amount of coolant to the worm and cutting tools. One system works in conjunction with the turret slide and the other with the cut-off. On the smaller machines, where a smaller amount of coolant is required, only a single system of piping is used.

NO. 4 BRAKE PIPE VENT VALVE

The Westinghouse Air Brake Company, Wilmerding, Pa., has recently developed a brake pipe vent valve to provide a more positive means than has heretofore been available for initiating and propagating quick action throughout a train. Changes in service conditions involving the handling of trains of greater weight and length, with increased brake pipe volume, have made it increasingly difficult to insure the proper quick action throughout the train. This is especially true when double heading, or when the first car or cars in a train are cut out, or when the cars are so coupled together (in cases where the triple valves are installed on the ends) that they are too far apart for quick action to be carried from one to another and throughout the train.

The No. 4 brake pipe vent valve has been designed to

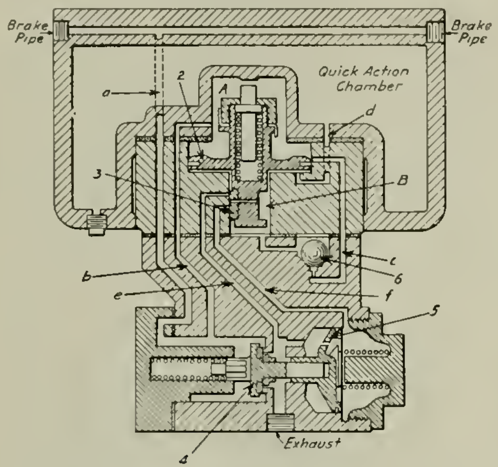


Cross Section of Vent Valve

meet these conditions and, to insure the necessary stability of operation, has been made a separate device to operate independently of the triple valve, distributing valve or other venting devices. Thus the reliability of the vent valve is uniformly insured, at the same time undesired quick action due to erratic action of the service parts of other brake devices or to the overcharging of the brake pipe on the engine and tender is eliminated.

The No. 4 brake pipe vent valve comprises an emergency piston, *2* (Figs. 1 and 2), with its slide valve, *3*, a vent valve *4*, and quick action piston, *5*, and an actuating volume called the quick action chamber. When the system is being charged, brake pipe air flows through passage *a* to the left of vent valve *4*, and thence through passage *b* to chamber *A* above the emergency piston *2*, forcing the piston to its lowest position. This opens charging port *c* in the piston bushing, permitting brake pipe air to flow past ball check valve *6* to the slide valve chamber *B* and thence through passage *d* to the quick action chamber, charging the latter to brake pipe pressure.

When a service reduction is made in brake pipe pressure, the emergency piston moves upward until stopped by its graduating stem. The charging port is now closed by the piston and the slide valve chamber is connected through the slide valve to the exhaust passage *e*. This permits quick action chamber pressure to reduce in pressure at the same rate as the brake pipe pressure, thus preventing operation of the vent valve during service applications. (When the brakes are released, the quick action chamber is again



Diagrammatic View of the Brake Pipe Vent Valve

charged as above described with the increasing brake pipe pressure.)

When an emergency rate of brake pipe reduction is made, the sudden drop in pressure causes the emergency piston *2* to move upward to its limit of travel, that is, against the cap gasket, opening port *f*. Quick action chamber air in chamber *B* then flows through port *f* to the outer face of quick action piston *5*, and since there is no pressure on the other face of this piston at this time it is moved to the left, opening the vent valve *4*. This makes a direct opening from the brake pipe to the atmosphere through large ports and consequently accomplishes the rapid venting of brake pipe air so necessary for propagating quick action on adjacent vehicles.

A small vent port through the quick action piston allows quick action chamber air to bleed down until the spring operating against vent valve *4* can force both the valves and piston to their normal position, thus closing the outlet to the atmosphere and permitting the brake pipe (and quick action chamber) to be recharged when desired, as above described.

KEROSENE BURNING FURNACE

A high-sustained temperature, generated in a short period of time, with strict economy of operation, are features of the furnace illustrated, which is manufactured by the Champion Kerosene-Burner Company, Kenton, Ohio. This heating unit is self-contained and may be used in heating rivets, hardening tools and similar operations.

In operation a quick, intense flame is obtained, as the kerosene is reduced to a gas the moment before being ignited. The effect is the same as that secured by the vaporizing jet in the carburetor of an internal combustion engine. It is claimed that all of the fuel units of the kerosene are utilized and no waste remains to form smoke or unpleasant odors. The flame gives a range of heat of from 2,500 to 3,000 deg. F.

The self-contained feature of the furnace gives it a distinct advantage. The fuel storage tank, carried on the lower platform of the stand, is of sufficient capacity to operate the furnace, with the feed valve wide open, for a 10-hour day. For this reason no electric or pipe connections need be installed in the shop or field. The furnace can be lifted by a crane and moved from place to place without extinguishing the flames. This insures a considerable saving in time both of the operator in changing connections and in cooling and reheating the furnace again.

Compressed air, at a pressure of from 80 to 90 lb., draws the fuel from the storage tank to the burner. This air is forced into the tank by means of an ordinary automobile pump, a pressure gage on the top of the tank showing the air pressure at all times. In spite of the fact that fuel is constantly being drawn out of the tank, with a consequent lowering of the fluid level and enlargement of the air space, the original air pressure still remains adequate to properly feed the burner, and only in exceptional cases does the air supply have to be given extra attention after it has once been taken care of in the morning.

The furnace is economical in the use of fuel. It is claimed that the kerosene consumption, with the furnace operating

Champion Kerosene Burner Furnace.

at its utmost capacity, does not exceed three-quarters of a gallon an hour. In a 10-hour shift the consumption is seven and one-half gallons. At a wholesale price of 14 cents a gallon, the daily cost of fuel would amount to $1.05. The non-oxidizing character of the flame permits leaving the work in the furnace for a long period without danger of burning it or diminishing its size.

If necessary a whole keg of rivets can be dumped into the hearth of this furnace and preheated. Rivets rfo immediate use can be placed directly under the flame of the burner, while the others, already in a semi-heated condition, can be raked in as needed. The Champion Kerosene-Burner furnaces are made in various sizes and provided with one or more burners, depending upon the type of work for which they are intended.

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

Subscriptions, including the eight daily editions of the Railway Age, published in June, in connection with the annual convention of the American Railroad Association. Section III—Mechanical, payable in advance and postage free: United States, Canada and Mexico, $2.00 a year; Foreign Countries, $3.00 a year; Single Copy, 20 cents.

WE GUARANTEE, that of this issue 12,200 copies were printed; that of these 12,200 copies, 11,124 were mailed to regular paid subscribers, 20 were provided for counter and news company sales, 229 were mailed to advertisers, 29 were mailed to employees and correspondents, and 798 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 119,910, an average of 9,992 copies a month.

THE RAILWAY MECHANICAL ENGINEER is a member of the Associated Business Papers (A. B. P.) and the Audit Bureau of Circulations (A. B. C.).

George Bradshaw, supervisor of safety of the Grand Trunk Western lines and the Pere Marquette, says that the Grand Trunk Western had the fewest casualties per 100 employees during the period of the recent "No accident drive" of any railroad in the United States having the same or a greater number of employees.

Press despatches from Paris, dated November 27, say that on the day preceding the first locomotive on a French railroad to use oil as fuel was sent out on an experimental trip and hauled a heavy train with complete success. It is announced that railroads in France have planned to alter their engines to use oil fuel instead of coal and that 200 locomotives may be thus changed.

Several important Bohemian banks have formed a ten million crown company for the renting of freight cars under the name of Tschechoslovakische Wagonleih-A. G. Negotiations will be taken up with foreign car manufacturers. The cars will be purchased outright and rented only to such industrial undertakings as are stockholders and in proportion to the amount of stock they hold.

Commercial Attache J. E. Philippi, Rio de Janeiro, reports that a commission has been appointed to make a special study looking to the adoption of uniform types of equipment and material for the government railways of Brazil. The members of the commission are to be engineers from the Federal Department of Railway Inspection and the federal railways. The first study will be devoted to the selection of uniform types of locomotives, passenger cars and freight cars for the railroads of one meter gage.

Arrangements for the use of oil as locomotive fuel on the lines of the Missouri, Kansas & Texas in Texas and on some of its Oklahoma lines have been practically concluded and engines are being changed. On the Wichita Falls & Northwestern the work will be completed by January 1. Next, the engines in service in the Smithville district of the Missouri, Kansas & Texas of Texas will be changed, and by the end of the summer of 1920 it is expected that all of the engines on the Texas lines will be equipped to use oil instead of coal. Because of the large expenditure required to equip the locomotives it was necessary to make a long-time contract for fuel in order to protect the additional investment.

The materials clearing house organization of the Pennsylvania Railroad has been transferred from Altoona, Pa., to Philadelphia, in order that the work may be concentrated as far as possible under the supervision of G. W. Snyder, 2d, recently appointed general storekeeper. A number of the clerks were transferred to the Philadelphia office, while a few were retained at Altoona under the jurisdiction of W. F. Vogt, district storekeeper. The remainder have been furloughed until positions can be found for them in other departments.

In order to standardize both equipment and operating practices, the Board of Railway Commissioners for Canada recently ordered that all passenger cars and cabooses hereafter constructed shall be equipped with marker sockets fixed at such elevation as will permit lamps and flags to be placed therein from the platform or floor of the car without the use of steps. Furthermore, according to the order, all passenger cars and cabooses now in use and not equipped with marker sockets in this position must be so equipped on or before May 1, 1920. The action was taken because of the placing of marker sockets at the corners of the roofs in addition to the lower position on some of the passenger cars of the Grand Trunk.

Fuel conservation measures on the Chicago Great Western resulted in such substantial savings during the early months of 1919 that W. L. Park, federal manager, has addressed a letter of commendation to all enginemen as well as others who contributed less directly in securing such a satisfactory record. A comparison of the fuel performance for January, February and March, 1919, with the same months of the previous year, showed a decrease in coal per 1,000 gross ton-miles in freight service equal to 10.7 lb., or 4.1 per cent., equivalent to a monetary saving of $13,956. In passenger service, based on pounds of coal per passenger train car-mile, there was a decrease of 3.1 lb. or 12.9 per cent, amounting in money to $23,650, or a total saving in freight and passenger service of $37,606 for the three months.

J. H. Thomas, the general secretary of the National Union of Railwaymen, who has been conducting negotiations with the British Government relating to railwaymen's wages, in a speech before railwaymen at Bristol on November 16, outlined the government's offer to the railwaymen regarding their participation in government control of the railways. In brief, the plan is that three union representatives will join the Railway Executive Committee with powers equal to those of the general managers on this committe; a joint board is to be formed composed of five general managers and five representatives of the unions to deal with conditions of service; a committee of 12 is to be formed composed of four representatives from the unions, four from the railway companies and four from the public, with an independent chairman, which will consider questions on which the joint board fails to agree, and, further, local committees will be formed made up of an equal number of representatives from the management and the men to deal with local grievances.

Railroad Reserve Force Proposed

A bill introduced by Senator Thomas of Colorado just before the Senate adjourned on November 19 provides for the creation of a railroad army reserve force of 200,000 men to be trained at land grant agricultural colleges for service on the railroads in times of emergency. Men between 18 and 30 years of age will be eligible for enlistment, but not for re-enlistment. The term of enlistment would be for 10 years, with a provision for 12 months' training for work as train operatives, hostlers or telegraph operators, and during the training period the men would receive regular army pay. If in time of emergency they were put to work on railroads they would receive the usual railroad pay, but would be barred from having any connection with a labor union.

Electrification in Foreign Countries

Electrification of railway lines is constantly receiving more attention and reports indicate that it is being given serious consideration in Sweden, France, Belgium, England, Italy, Switzerland, Australia, Brazil, Chile and Jamaica. In most of these countries electrification is particularly desirable on account of the increased cost of coal and because of the fact that there are in certain sections large water supplies which can very easily be used for the operation of hydro-electric plants.

A committee of French railway engineers has given the electrification situation in America a careful study. A special committee appointed to draw up a program for the electrification of the principal railroads has been able to gather together much valuable data concerning the use of hydro-electricity. Its program proposes the electrification of 5,220 miles of lines of three of the principal railroads, the Paris-Orleans, the Paris, Lyons & Mediterranean and the Midi. In determining upon lines to be electrified, the Midi and the Paris-Orleans considered the relation of the cost of electric power as compared with the cost of power with steam locomotives, and the comparison showed that mountain lines with sufficient traffic should be among the first to be electrified. They also considered the location of the source of hydro-electric energy in relation to the lines, and the importance of this power to other industries. On the Paris, Lyons & Mediterranean, however, the possibility has been considered of using electricity on lines of low grade where there is a heavy traffic, even before putting it on mountain lines where the traffic of these lines is very small. The probable cost, based on prices before the war, is estimated to be $335,000,000. With the traffic of 1913, electrification would save 1,500,000 metric tons of coal, and in the near future the economy should not be less than 3,000,000 metric tons.

Electrification of Belgian railways has been decreed by the Minister of Railways, following a favorable report on such a project made by a committee appointed to investigate such a course. The first line to be electrified will be that from Brussels to Luxemburg, and later the Brussels-Ostend Railway. It is planned to begin the reconstruction work early in 1920.

In Jamaica the government is reported as arranging to have a survey made of the water power of the large rivers to see if electrification of the railways is feasible. The heavy cost of coal and the necessity of a considerable railroad extension owing to an expected agricultural development explain the proposed change. The local agent of the Westinghouse Company, of New York, is collecting data on which the Westinghouse Company might tender plans for laying down the electric railroads.

In Brazil plans have been made for the electrification of the suburban lines of the road and the trunk line from Barra to Pirahy, as well as general plans for the suburban service and the closing of the roadbed from the main station to Deodoro, writes Commercial Attache J. E. Philippi, Rio de Janeiro. The approximate cost of the rolling stock, substations, aerial lines, etc., is estimated at $4,307,377. This does not include the cost of car sheds at the main station and at Deodoro.

MEETINGS AND CONVENTIONS

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations:

Air-Brake Association.—F. M. Nellis, Room 3014, 165 Broadway, New York City.
American Railroad Association, Section III.—Mechanical.—V. R. Hawthorne, 431 South Dearborn St., Chicago.
American Railroad Master Tinners', Coppersmiths' and Pipefitters' Association.—O. E. Schlink, 485 W. Fifth St., Peru, Ind.
American Railway Tool Foremen's Association.—R. D. Fletcher, Belt Railway, Chicago.
American Society for Testing Materials.—C. L. Warwick, University of Pennsylvania, Philadelphia, Pa.
American Society of Mechanical Engineers.—Calvin W. Rice, 29 W. Thirty-ninth St., New York.
Association of Railway Electrical Engineers.—Joseph A. Andreucetti, C. & N. W., Room 411, C. & N. W. Station, Chicago.
Car Foremen's Association of Chicago.—Aaron Kline, 841 Lawlor Ave., Chicago. Meetings second Monday in month, except June, July and August, Hotel Morrison, Chicago.
Car Foremen's Association of St. Louis.—Thomas B. Koeneke, secretary, Federal Reserve Bank Building, St. Louis, Mo. Meetings first Tuesday in month at the American Hotel Annex, St. Louis.
Chief Interchange Car Inspectors' and Car Foremen's Association.—H. J. Smith, D. L. & W., Scranton, Pa.
International Railroad Master Blacksmiths' Association.—A. L. Woodworth, C. H. & D., Lima, Ohio.
International Railway Fuel Association.—J. G. Crawford, 542 W. Jackson Blvd., Chicago.
International Railway General Foremen's Association.—William Hall, 1061 W. Wabasha Ave., Winona, Minn.
Master Boilermakers' Association.—Harry D. Vought, 95 Liberty St., New York. Convention May 25-28, Curtis Hotel, Minneapolis, Minn.
Master Car and Locomotive Painters' Association of U. S. and Canada. A. P. Dane, B. & M., Reading, Mass.
Niagara Frontier Car Men's Association.—George A. J. Hochgrebe, 623 Brisbane Bldg., Buffalo, N. Y. Meetings, third Wednesday in month, Statler Hotel, Buffalo, N. Y.
Railway Storekeepers' Association.—J. P. Murphy, Box C, Collinwood, Ohio.
Traveling Engineers' Association.—W. O. Thompson, N. Y. C. R. R., Cleveland, Ohio.

RAILROAD CLUB MEETINGS

Club	Next Meeting	Title of Paper	Author	Secretary	Address
Canadian	Dec. 9, 1919	The House That Jack Built (Moving Picture); first aid demonstration by E. E. Stevens		W. A. Booth	131 Charron Street, Montreal, Que.
Central	Jan. 9, 1920			H. D. Vought	95 Liberty Street, New York.
Cincinnati				H. Boutet	101 Carew Building, Cincinnati, O.
New England	Dec. 9, 1919	Operation of Railroad Terminals, New York Terminal District	I. J. Mantell	W. E. Cade, Jr.	683 Atlantic Ave., Boston, Mass.
New York	Dec. 19, 1919	The Industrial Conflict	William L. Chenery	H. D. Vought	95 Liberty Street, New York.
Pittsburgh	Dec. 26, 1919			J. D. Conway	515 Grandview Avenue, Pittsburgh, Pa.
St. Louis	Dec. 19, 1919	The Cummins Bill	Ex-Senator N. P. Wilfrey	B. W. Frauenthal	Union Station, St. Louis, Mo.
Western	Dec. 15, 1919	Increasing Necessity for Steam Railway Electrification	N. W. Storer	J. M. Byrne	916 West 78th Street, Chicago.

PERSONAL MENTION

GENERAL

J. V. B. DUER, assistant engineer of the Pennsylvania at Altoona, has been made electrical engineer of the new electrical engineering department operated in conjunction with the mechanical engineering department at Altoona.

HENRY GARDNER, supervisor material conservation of the Baltimore & Ohio, with headquarters at Baltimore, Md., has been appointed corporate mechanical engineer, succeeding Morgan K. Barnum, whose death was noted in the November issue. Mr. Gardner was born in Salem, Mass., in 1872 and graduated from the Massachusetts Institute of Technology in 1896. Immediately after graduation he began railroad work as a special apprentice in the Boston & Maine shops at Boston, Mass., at which work he remained until 1900, when he was appointed shop draftsman and inspector at Concord, N. H. During 1904 and part of 1905 he was assistant master mechanic at Concord; between 1905 and 1911 he was respectively erecting shop foreman for the American Locomotive Company at Allegheny, Pa., locomotive designer for the H. K. Porter Company, Pittsburgh, Pa., assistant superintendent of apprentices of the New York Central at New York City; and from 1911 to 1914 was superintendent of apprentices and shop systems. In 1914 he went to the Baltimore & Ohio as assistant superintendent of shops at Baltimore, and the following year was appointed special engineer in the office of the vice-president, also at Baltimore, an office he held until 1917, when he was chosen for the position of supervisor of material conservation, which he filled until the time of his recent appointment, of which mention is made above.

H. Gardner

A. B. CORBETT, whose appointment as assistant mechanical superintendent of the Missouri, Kansas & Texas, with headquarters at Denison, Tex., was announced in the November issue, was born in 1874 at Hannibal, Mo., and received his education in the public schools of Denison, Tex. His entire railroad service has been with the Missouri, Kansas & Texas, he having entered the employ of this road in June, 1888, as a machinist apprentice. After completing his apprenticeship he worked as a machinist until February 1, 1908, when he was appointed night roundhouse foreman at Denison, later being made day roundhouse foreman. On December 1, 1915, he was transferred to Smithville, Tex., as general foreman. On March 1, 1916, he was appointed shop superintendent at Denison and on April 1, 1917, was transferred to Parsons, Kans., in the same capacity, remaining there until September 15, 1919, when he received his appointment as assistant mechanical superintendent.

G. H. HASELTON, general locomotive inspector of the New York Central Lines East, with office in New York, has been retired after 53 years of service in the motive power department, having been general locomotive inspector for the past 12 years.

C. H. HOLDREDGE, road foreman of engines of the Southern Pacific, with headquarters at San Francisco, Cal., has been appointed assistant general air brake inspector succeeding A. M. Meston, promoted.

HARRY A. HOKE, acting assistant mechanical engineer of the Pennsylvania at Altoona, Pa., has been appointed assistant mechanical engineer, succeeding W. F. Kiesel, Jr. Mr. Hoke was born on October 13, 1873, at Union City, Ind. He was graduated from Purdue University in 1896, and on March 1, 1898, entered the employ of the Lake Shore & Michigan Southern as a draftsman at Cleveland. Since December, 1898, however, he has been with the Pennsylvania Railroad at Altoona, being promoted to the position of assistant chief draftsman on September 1, 1902, and to assistant engineer of the mechanical engineering department on June 1, 1906. On February 1, 1919, he was appointed acting assistant mechanical engineer, and on October 20, 1919, was made assistant mechanical engineer.

J. S. JENNINGS, division master mechanic on the Michigan Central at Bay City, Mich., has been promoted to assistant superintendent of motive power, with headquarters at Detroit, Mich., a newly created position.

W. F. KIESEL, JR., who was appointed acting mechanical engineer of the Pennsylvania at Altoona, Pa., on the retirement of A. S. Vogt, has been appointed mechanical enginner. A photograph and sketch of Mr. Kiesel's career were published in the March, 1919, issue, page 165.

B. J. PEASLEY, master mechanic of the Vicksburg, Shreveport & Pacific, has been appointed superintendent of motive power of that road and of the Alabama & Vicksburg and the Louisiana & Mississippi Transfer, at Monroe, La. Mr. Peasley was born on December 21, 1867, at Decorra, Ill., and entered railway service at the age of 16 as a laborer and machinist apprentice with the Chicago, Burlington & Quincy, at West Burlington, Iowa. After serving his apprenticeship he entered a business college at Burlington, Iowa, and on completion of the course again entered railway service as a machinist with the Atchison, Topeka & Santa Fe, at Ft. Madison, Iowa. From 1894 to 1901 he was employed respectively by the Ft. Madison Gas & Gasoline Engine Company, by the Chicago, Ft. Madison & Des Moines, as fireman and engineman, and by the Illinois Central at East St. Louis, Ill., as a machinist and later division and wrecking foreman at Carbondale, Ill. In 1901 he entered the service of the Denver & Rio Grande as roundhouse foreman at Helper, Utah, where he remained a short time, returning to the Illinois Central at East St. Louis, Ill., acting successively as roundhouse foreman, shop foreman and general foreman until September, 1906. At that time he was appointed general foreman of the Missouri Pacific at Bixby, Ill., later being promoted to master mechanic at Ferriday, La., where he remained for six months, being then transferred to De Soto, Mo., as master mechanic of the Missouri division. From February, 1914, to the early part

B. J. Peasley

of 1918 he was superintendent of shops at Argenta, Ark., when he was appointed mechanical superintendent of the St. Louis-Southwestern of Texas, with office at Tyler, Tex. During the early part of the present year he accepted the position of master mechanic of the Vicksburg, Shreveport & Pacific, which he held until his recent promotion.

F. A. McArthur has been appointed mechanical valuation engineer in charge of the valuation of rolling stock of the St. Louis-San Francisco.

Major C. E. Lester has been discharged from military service and appointed assistant supervisor of equipment with the Railroad Administration at Meadville, Pa.

D. M. Pearsall, shop superintendent of the Atlantic Coast Line at Waycross, Ga., has been appointed superintendent of motive power, second and third divisions, with the same headquarters.

S. A. Schickedanz, chief draftsman of the Chicago & Eastern Illinois at Chicago, has been promoted to mechanical engineer at Danville, Ill., succeeding W. H. Hauser, who has resigned to become connected with the A. B. C. Transit Refrigeration Company, Chicago.

R. Tawse, master mechanic of the Detroit, Toledo & Ironton, at Jackson, Ohio, has been promoted to superintendent of motive power and equipment, with the same headquarters.

E. W. Smith, superintendent motive power of the Pennsylvania Railroad, Central division, at Williamsport, Pa., has been transferred to Altoona, Pa., as acting superintendent motive power, relieving R. K. Reading, granted leave of absence because of illness.

S. M. Viele has been appointed assistant electrical engineer of the new electrical engineering department of the Pennsylvania at Altoona.

MASTER MECHANICS AND ROAD FOREMEN OF ENGINES

William H. Menner, road foreman of engines of the Erie, with headquarters at Jersey City, N. J., has been appointed supervisor of locomotive operation, succeeding E. Salley, deceased.

G. T. Bourne, traveling engineer and trainmaster of the Salt Lake division of the Denver & Rio Grande, with headquarters at Soldier Summit, Utah, has been transferred to the Green River division, with the same headquarters.

Lon Byers, terminal engine inspector on the Atchison, Topeka & Santa Fe Coast Lines at Needles, Cal., has been promoted to road foreman of engines of the first district of the Arizona division, with the same headquarters, succeeding L. H. Ledger.

A. L. Crew, road foreman on the Atchison, Topeka & Santa Fe Coast Lines, with headquarters at Los Angeles, Cal., has been promoted to general road foreman of engines, with the same headquarters, a newly created position.

Andrew J. Devlin, supervisor of shops of the St. Louis-San Francisco, has been appointed master mechanic of the Western division, with headquarters at Enid, Okla. Mr. Devlin was born on June 20, 1868, at Philadelphia, Pa., and was educated in the public schools and Quaker private school. His railroad service dates from August 1, 1904, when he entered the employ of the Atchison, Topeka & Santa Fe as assistant machine foreman. On June 8, 1906, he became shop demonstrator, and on March 1, 1910, supervisor of efficiency work. Since March, 1914, he has been with the St. Louis-San Francisco, first as traveling roundhouse foreman, later as inspector of shop efficiency and then as supervisor of shops, which latter position he held at the time he was appointed master mechanic of the Western division.

Guy F. Egbers has resigned from service with the Russian Railway Service Corps and returned to the Northern Pacific as master mechanic, Pasco division, at Pasco, Wash.

L. H. Ledger, road foreman of engines of the first district, Arizona division, of the Atchison, Topeka & Santa Fe Coast Lines, at Needles, Cal., has been transferred to the second district, with the same headquarters, succeeding C. C. Reynolds.

G. M. Lillis, locomotive engineman of the Denver & Rio Grande, has been appointed traveling engineer and trainmaster of the Salt Lake division, with headquarters at Soldier Summit, Utah, succeeding G. T. Bourne.

William D. Johnston, whose appointment as general master mechanic of the Northwest territory of the Baltimore & Ohio Western Lines, with office at Cleveland, Ohio, was announced in the November issue, was born in Ohio on November 12, 1869. After graduating from the Nickerson (Kansas) high school he took employment as a machinist apprentice with the Atchison, Topeka & Santa Fe. Later he was roundhouse foreman of the Cotton Belt at Pine Bluff, Ark., then general foreman of the Trinity & Brazos Valley at Teague, Texas. Afterwards for different periods of time he was with the Oregon Short Line as general roundhouse foreman at Pocatello, Idaho, general foreman of the Chicago, Rock Island & Pacific, and master mechanic of the International and Great Northern at Palestine, Texas. On May 15, 1914, he entered the service of the Baltimore & Ohio as master mechanic of the Toledo division, was transferred to the Newark division on December 1, 1917, and was appointed general master mechanic of the Northwest territory on August 1, 1919.

W. D. Johnston

J. C. Love, road foreman of engines of the first and second districts of the Los Angeles division of the Atchison, Topeka & Santa Fe Coast Lines, with headquarters at San Bernardino, Cal., has been transferred to the third and fourth districts, with headquarters at Los Angeles, Cal.

F. P. Miller, master mechanic on the Chicago, Milwaukee & St. Paul, with headquarters at Marion, Iowa, has been transferred to Portage, Wis., succeeding M. F. Smith.

C. C. Reynolds, road foreman on the Atchison, Topeka & Santa Fe Coast Lines, at Needles, Cal., has been transferred to the first and second districts of the Los Angeles division, with headquarters at San Bernardino, Cal., succeeding J. C. Love.

M. F. Smith, master mechanic on the Chicago, Milwaukee & St. Paul, with headquarters at Portage, Wis., has been transferred to Minneapolis, Minn.

C. E. Trotter has been appointed master mechanic of the Lake Erie & Western, the Fort Wayne, Cincinnati & Louisville and the Northern Ohio, at Lima, Ohio.

Christian A. Worth, acting master mechanic on the Pasco division of the Northern Pacific, has resumed his former position as road foreman of engines of the Pasco division.

CAR DEPARTMENT

H. G. Griffin, manager of the National Bridge Company, Montreal, Quebec, has resigned to become general superintendent of the car department of Morris & Co., Chicago.

Samuel Lenzner, master car builder of the Michigan Central with headquarters at Detroit, Mich., has been appointed supervisor of passenger equipment, a newly created position. Mr. Lenzner was born June 30, 1861, at Lancaster, N. Y., and has been with the Michigan Central since July 12, 1886, when he began railway work as a coach carpenter. In September, 1889, he was made foreman of the cabinet department, and in March, 1909, was advanced to general foreman of the car department, which position he held until early in 1913, when he was appointed master car builder.

C. J. Wymer, sales representative of the Grip Nut Company of Chicago, has been appointed superintendent of the car department of the Chicago & Eastern Illinois, with headquarters at Danville, Ill. Mr. Wymer entered railroad service in 1891 with the Atchison, Topeka & Santa Fe. He later became connected with the car inspecting department of the Chicago & Eastern Illinois, resigning as general car inspector in 1912. He was then appointed general car foreman on the Belt Railroad of Chicago. In May, 1916, he was appointed sales representative at the Chicago office of the Grip Nut Company, in which capacity he served until his recent appointment. Mr. Wymer's appointment places him in entire charge of the car department of the Chicago & Eastern Illinois and is the first appointment of this nature made by that road.

SHOP AND ENGINEHOUSE

T. J. Mullin, general foreman, shops of the Lake Erie & Western at Lima, Ohio, has been appointed shop superintendent of that road, as well as of the Fort Wayne, Cincinnati & Louisville and the Northern Ohio, with the same headquarters.

PURCHASING AND STOREKEEPING

Clifford C. Harrold, storekeeper on the West Virginia general division of the Chesapeake & Ohio, with offices at Huntington, W. Va., has resigned that position to become assistant manager for the Tri-State Credit and Adjustment Bureau, Huntington, W. Va.

F. E. Outerbridge has been appointed storekeeper of the Detroit & Toledo Shore Line, with headquarters at Lang, Ohio.

J. M. Strong has been appointed division storekeeper of the Schuylkill division, Pennsylvania Eastern Lines, with headquarters in Reading, Pa.

J. V. Bland, storekeeper of the Virginian at Sewalls Point, Va., has been appointed storekeeper at Roanoke, succeeding J. M. Mitchell.

F. H. Fechtig, purchasing agent of the Atlantic Coast Line at Wilmington, N. C., has been appointed purchasing agent of the Georgia and the Charleston & Western Carolina.

J. M. Mitchell, storekeeper of the Virginian at Roanoke, Va., has been transferred to Victoria, Va., succeeding K. A. Fernstrom, assigned to other duties.

W. N. Pollard, division storekeeper of the Southern & Columbia, S. C., has been transferred to South Richmond, Va., succeeding W. F. Lamb, deceased.

J. H. Smith has been appointed division storekeeper of the Southern at Columbia, S. C., succeeding W. N. Pollard.

SUPPLY TRADE NOTES

H. S. Waterman, sales manager for the Hutchins Car Roofing Company, Detroit, Mich., died in that city on December 1, after an illness of 10 days.

The Ralston Steel Car Company, Columbus, Ohio, has opened an office at 20 E. Jackson boulevard, Chicago, in charge of Ford S. Clark, formerly of the Philadelphia office of the company.

F. C. Wallace, of Pittsburgh, Pa., has withdrawn his resignation as president of the Canadian Locomotive Company, Kingston, Ont., and will continue in office. He has been granted a six months' leave of absence.

F. W. Sinram, general manager of the Van Dorn & Dutton Company, gear specialists, of Cleveland, Ohio, has been elected president of the company. Mr. Sinram is also president of the American Gear Manufacturers' Association.

The Sherwin-Williams Company, Cleveland, Ohio, is contemplating the erection of a factory at Kansas City, Mo., to cost $500,000. The first unit will be equipped for the manufacture of paint and will be followed by the construction of a varnish factory.

John Kopf, formerly associated with the Bureau of Air Craft Production, with headquarters at Dayton, Ohio, has been appointed manager of the engineering department of the Duff Manufacturing Company, Pittsburgh, Pa., with office in that city.

John B. Jordan, assistant manager of the railroad sales department of the Crane Company, with headquarters at Chicago, has been appointed manager of the department with the same headquarters, succeeding F. D. Finn, who has been granted an indefinite leave of absence.

John L. Bender has resigned as sales manager of the Anderson Forge & Machine Company, Detroit, Mich., to become connected with the engineering department of the C. A. S. Engineering Company, at Detroit, sales agent of the Pollak Steel Company, Cincinnati, Ohio.

Frank J. Walsh, mechanical expert with the Galena-Signal Oil Company, New York, has resigned to become secretary of the Douglas Wray Paper Company, Chicago. Previous to his service with the Galena-Signal Oil Company, Mr. Walsh was a division master mechanic on the Chesapeake & Ohio.

W. D. Horton, district sales manager of the Patton Paint Company, has resigned to accept a position in the western railway department of the Murphy Varnish Company, with headquarters at Chicago. Mr. Horton was circulation manager of the *Railway Mechanical Engineer* prior to his connection with the Patton Paint Company.

The International Railway Supply Company, New York, announces that it has incorporated the International Railway Supply Company of Cuba, with Otis R. Hale, former locomotive superintendent of the United Railways of Havana, as manager. The office of the company in Havana is at Edificio Abreu, Room 501, corner Mercaderes y O'Reilly.

A. C. Allshul, in charge of the Milwaukee, Wis., district office of Joseph T. Ryerson & Son, Chicago, has been appointed branch manager of the new warehouse plant at Buffalo, N. Y., this company having recently bought the warehouse plant, stock and good will of the Ferguson Steel & Iron Company, Buffalo. The property covered by the purchase includes a main building of about 100,000 sq. ft., a large crane-served yard, office building, garage and storehouse. Plans are being made to carry out extensive improvements to the property this coming winter. The Ryerson Company now has plants for warehouse service at Chicago, New York, Detroit, St. Louis and Buffalo.

G. O. Helmstaedter, Chicago district manager of the Hyatt Roller Bearing Company, has been promoted to sales manager of the industrial bearings division with office at New York, succeeding Carl E. Eby, who has been appointed to the board of directors of Hyatt, Ltd., London, a new company formed to market Hyatt bearings in Europe.

The A. Gilbert & Sons Brass Foundry Company, St. Louis, Mo., has recently completed a two-story with basement addition, 25 ft. by 180 ft., to its plant. The basement is to be used for the heating plant, wash rooms and lockers; the first floor for metal storage and melting rooms, and the second floor for the office and wood and metal pattern department.

Joseph T. Ryerson & Son Company, Chicago, has purchased a block of property adjoining its plant in that city, with an area of 380,290 sq. ft. A brick foundry building valued at $100,000, located on the property and at present occupied by the Crane Company, Chicago, will be used by the purchaser as the first unit of an addition to its facilities.

Work is now under way on the Niles, Ohio, plant of the Youngstown Steel Car Company, Hazelton, Ohio. The new plant will be used for repairing cars for railroad companies and private owners. Industrial cars of smaller dimensions than standard rolling stock will be built early in 1920. It is said the complete new plant will be in operation in January, 1920.

K. C. Gardner, assistant manager of sales of the Pressed Steel Car Company and the Western Steel Car & Foundry Company, has been appointed manager of sales for the central district with offices in the Farmers Bank Building, Pittsburgh, Pa. Mr. Gardner entered the employ of the Pressed Steel Car Company in 1901, and was connected with the operating department at McKees Rocks, Pa., until 1911. He was transferred to the New York office, remaining there for a period of eight years, and on January 1, 1919, returned to Pittsburgh as assistant manager of sales, central district, which position he held until his recent promotion to the position of manager of sales of the same district.

K. C. Gardner

C. F. Neudorfer, general plant superintendent for the Standard Tank Car Company, Masury, Ohio, has been promoted to general manager. N. L. Mabey, chief engineer, becomes assistant general manager. J. W. Todd, becomes assistant purchasing agent in the office of the superintendent of transportation, and J. T. O'Connor, superintendent of transportation, has been appointed purchasing agent.

The Keller Pneumatic Tool Company, Chicago, has opened branch offices in Birmingham, Ala., Jefferson County Bank building, under the management of H. I. Kahn; at Salt Lake City, Utah, in the Newhouse building, under the management of the C. H. Jones Company; and in San Francisco, Cal., Los Angeles, Cal., and Portland, Ore., all under the management of the Eccles & Smith Company, San Francisco.

Extensions are contemplated by the Lima Locomotive Works, Lima, Ohio, which will increase the plant's capacity approximately 50 per cent and involve an expenditure of $1,250,000. Additions to the present plant include a new erecting shop with a capacity of 70 locomotives a month, and a superheater shop extension for the boiler and tank works. New machinery costing approximately $300,000 will be purchased.

Huntley H. Gilbert, assistant manager of sales of the Pressed Steel Car Company and the Western Steel Car & Foundry Company, has been appointed manager of sales for the western district, at 425 Peoples Gas building, Chicago, Ill. Mr. Gilbert was graduated from Cornell University in June, 1907, with the degree of mechanical engineer. He then was in the employ of the Illinois Steel Company, the Scully Steel & Iron Company and the George E. Molleson Company, and in June, 1912, entered the employ of the Pressed Steel Car Company, as sales agent in the Chicago office. In 1915 he was sent to England and France as special representative to investigate the manufacture of shell forgings. In July, 1917, he was commissioned captain in the Ordnance Officers Reserve Corps and reported for duty July 25, 1917, as assistant to the chief of the Field Artillery Section, Carriage division, Ordnance Department, serving in Washington until February, 1918, when he was transferred to the Rock Island Arsenal as executive assistant to the commanding officer, later administrative officer, and on July 25, 1918, he was promoted to major. He attended the October, 1918, staff class at the War College, and was then appointed division ordnance officer, 97th Division, Camp Cody, N. M., serving there until the division was demobilized, at which time he was honorably discharged from military service. In January, 1919, he re-entered the service of the Pressed Steel Car Company and Western Steel Car & Foundry Company as assistant manager of sales, western district, and was recently promoted to manager of sales of the same.

H. H. Gilbert

H. H. Harris has been appointed manager of the heat treating equipment department of the Quigley Furnace Specialties Company, New York. Mr. Harris was formerly general sales manager for the Swedish Crucible Steel Company and has devoted several years to the practical application of materials for heat treating purposes, especially to steel mixtures and special alloys for carbonizing and annealing boxes, cyanide pots, etc.

A. G. Gibbons has become associated with the Wetmore Reamer Company, Milwaukee, Wis., as production engineer. He was formerly superintendent of tools and supplies for Winslow Brothers Company, Chicago. He also served with the Cadillac Company and the Brown & Sharpe Manufacturing Company for many years. The Wetmore plant has been rearranged and additional equipment installed under the direction of Mr. Gibbons.

The International Steel Tube Company has been incorporated under the laws of Delaware with a capital of $2,500,000, and is planning the immediate construction of the first unit of a seamless tube plant at Cleveland, Ohio. William P. Day, president of the International Steel Tie Company, is president, and Thomas Parrock, former superintendent of the Republic Steel Company, Youngstown, Ohio, is vice-president of the new concern.

Norton Company

Among the changes in personnel of the Norton Company, Worcester, Mass., following the reorganization of that company, were the appointments of Herbert Duckworth as sales manager of the grinding wheel division and of Howard W. Dunbar as sales manager of the grinding machine division. Mr. Duckworth is a native of Worcester county and attended the public schools in Worcester until 1895, when he accepted a position with the Norton Company, then known as the Norton Emery Wheel Company. In 1897 he was appointed head of the order department of that organization, in which capacity he served for about nine years. Subsequently he became a Norton representative in the outside field, covering successively New York state, Pennsylvania and New England. He was promoted to assistant sales manager in February, 1915. This position was held until the reorganization of the company, when Mr. Duckworth was appointed to the position which he now holds of sales manager of the grinding wheel division.

H. Duckworth

The appointment of Howard W. Dunbar as sales manager of the grinding machine division of the Norton Company brings to this position a man with comprehensive experience along general manufacturing and engineering lines. Mr. Dunbar's education in the general high school was supplemented by business and technical courses, and on leaving school he entered the employ of the Stanley Instrument Company, Great Barrington, Mass., as an apprentice on general work in the test division and drafting department. He later served an apprenticeship in tool-making for the same concern. After his experience with the Stanley Instrument Company Mr. Dunbar was employed by the New York Adding Typewriter Company as draftsman and tool designer. Later he was employed by the Ellis Adding Typewriter Company, J. M. Quimby Company, Newark, N. J., and for eight years by the Western Electric Company, New York, in the capacity of draftsman, designing engineer, assistant master mechanic and chief efficiency engineer. In March, 1915, Mr. Dunbar came to the Norton Grinding Company as assistant chief engineer, being engaged in development and engineering work under the direction of Charles H. Norton, designer of the Norton cylindrical grinding machines. Upon the merger of the Norton Grinding Company with the Norton Company Mr. Dunbar was appointed to his present position.

H. W. Dunbar

The T. H. Symington Company

At a meeting of the board of directors of this company, held in New York on October 22, C. J. Symington was elected president in charge of sales and operation, succeeding T. H. Symington, elected chairman of the board, both with headquarters at New York. Donald Symington, vice-president in charge of operation at Rochester, has resigned from the company.

Thomas H. Symington, chairman of the board, was born on May 14, 1869, at Baltimore, Md., and educated at Lehigh University. In 1885 he served as an apprentice at the Mt. Clare shops of the Baltimore & Ohio and subsequently was consecutively journeyman-machinist, inspector of engines and inspector of materials on the same road. From August to November, 1893, he was draftsman at the Richmond Locomotive Works and then for two years was general outside inspector of the same works. From November, 1895, to June, 1898, he was assistant superintendent of the Richmond Locomotive & Machine Works and then to April, 1901, was superintendent of motive power on the Atlantic Coast Line. He then organized and became president of the T. H. Symington Company, with a plant at Corning, N. Y. In 1908 he reorganized the company and built one of the largest malleable iron plants in the country at Rochester. In 1916 he organized the Symington Machine Corporation, Rochester, for handling large shell contracts for Great Britain and Russia. Two years later he extended the operations of the machine company to handle government orders for shells and he organized and operated additional plants, including The Symington Anderson Company, to manufacture 75 mm. French model 1897 field pieces; also organized the Symington Forge Corporation to manufacture 75 mm. shell forgings and the Symington Chicago Corporation to manufacture 155 mm. shell forgings and machine shells. He was appointed assistant chief of ordnance in September, 1918, and since November of the same year, when he resigned his commission from the army, served as president of the T. H. Symington Company, malleable iron foundrymen and manufacturers of railroad equipment, with headquarters at New York.

Charles J. Symington, president, was born on February 2, 1883, at Baltimore, Md., and was educated at Amherst College. He entered the service of the T. H. Symington Company in 1908 as assistant manager, eastern sales, with headquarters at Baltimore, Md. In 1910 he went to Chicago as general sales agent and in 1912 was appointed vice-president in charge of sales, with headquarters in New York. He became president of the Symington Machine Corporation in 1918, with offices in Rochester and Washington; vice-president of the Symington Anderson Company, and vice-president of the Symington Chicago Corporation.

M. J. Keane, manager of the steam goods branch of the Canadian Fairbanks-Morse Company, with headquarters at Toronto, Ont., has resigned and organized the Valve Engineering Company, with office at 160 King street West, Toronto. The new concern will act as agents for the Pennsylvania Flexible Metal Hose Company, the Penberthy Injector Company, Spands & Witwyte, manufacturers of pressure packing for steam and gas engines.

CATALOGUES

BALANCING APPARATUS.—A small pamphlet has been issued by the Vibration Specialty Company, Philadelphia, Pa., describing briefly the service which this company is prepared to render and its balancing apparatus to eliminate vibration in heavy machinery. Several illustrations show rotors and crank shafts which were put in balance on equipment of this company.

VALVE FACING TOOLS, ETC.—An illustrated catalogue and price list of valve facing tools, ball check valves, solid and hollow balls, pneumatic tube welding machines, ball finishing tools for repairing superheater ball joints, pnuematic locomotive turntable motors, etc., products of the Draper Manufacturing Company, Port Huron, Mich., has been issued by this company and is known as Catalogue No. 7.

METALLIC PACKING.—A four-page folder, issued by Harry Vissering & Company, Inc., Chicago, describes and illustrates the construction of Crescent metallic packing for valve stems and piston rods of locomotives. This packing is made of four flexible pieces, all the points overlapping, and is adapted for use with either saturated or superheated steam.

AEROIL THAWING OUTFITS AND TORCHES.—Bulletin No. 10 has recently been issued by the Aeroil Burner Company, Inc., 400 Main street, Union Hill, N. J. This illustrates the Aeroil thawing outfit and shows their application in thawing out hoppers of coal cars. The outfits are designed especially for use in the removal of ice and snow from frozen coal, sand and ore cars, hoppers, pockets, tracks and switches, etc.

DRILL SIZES FOR THREADED HOLES.—The Western Tool & Manufacturing Company, Springfield, Ohio, has issued a card which will be found useful for determining the proper size drill to be used for holes that are to be tapped. It gives the drill sizes for machine and hand taps from 1/4 in. to 2 in. for the various numbers of threads per inch commonly used and also the sizes for pipe taps and machine screws.

PULVERIZED COAL FOR LOCOMOTIVES.—The Fuller Engineering Company, Allentown, Pa., describes its equipment for burning pulverized fuel on locomotives in Bulletin No. 21. Figures are given covering the cost of drying and pulverizing coal and of installing a pulverizing plant. The advantages of this method of firing locomotives are described and sectional drawings show the equipment applied to locomotives.

HIGH SPEED ALLOY STEEL.—An attractive cloth bound book of 92 pages, 4 in. by 6 in., entitled Catalogue and Hints on Steel, is being distributed by the Halcomb Steel Company, Syracuse, N. Y. This catalogue contains a brief description of the company's various grades of crucible and electric tool and alloy steel and their uses, with instructions for treating. It also contains a large number of tables of useful information on areas, weights, etc.

MALLEABLE IRON.—The American Malleable Castings Association, Cleveland, Ohio, has prepared a short treatise on malleable iron, explaining its structure, uses and treatment, and indicating a few of the principles on which the process of making malleable iron castings is based, as well as some of the results that have been attained. The booklet is illustrated with a number of photographs showing results of various kinds of tests to determine the strength of the material.

TANK FRAME LOCOMOTIVES.—In Record No. 94 the Baldwin Locomotive Works describes tank frame locomotives for narrow gage railways. These locomotives have been designed for operation on rough tracks and sharp curves and are particularly suitable for industrial, contractors and other classes of special service. Illustrations of a number of locomotives of this type built by the Baldwin Locomotive Works are contained in the booklet, with tables showing their general dimensions.

WELDING AND CUTTING EQUIPMENT.—The Carbo-Hydrogen Company of America, Pittsburgh, Pa., has issued nine bulletins bound in a folder, describing cutting and welding torches and tips, regulators, and a portable cutting outfit mounted on a truck. All of the parts for carbo apparatus are catalogued in one of the bulletins and another contains directions for operating carbo cutting torches, bringing out some points that should be carefully observed when operating any cutting torch.

HIGH TEMPERATURE CEMENT.—Hytempite, a material for bonding firebrick and kindred uses, which is manufactured by the Quigley Furnace Specialties Company, New York, is described in a pamphlet entitled Hytempite in the Foundry. This material can be used as a binder wherever fire clay, silica brick or tile are used, requiring no heat to effect a bond between materials jointed. A number of applications of Hytempite in foundry work are described, with directions for applying the material.

STANDARD LOCOMOTIVES.—The Locomotive Superheater Company, New York, has compiled and published in Bulletin No. 7, general arrangement drawings and details of construction, together with a photograph and general data for each of the 12 types of standard locomotives designed by the United States Railroad Administration. Wheel loading and clearance diagrams for each are also given, making it a convenient reference book for information pertaining to the standard locomotives.

CHAIN DRIVES.—"A Chain of Evidence" is the title of a 20-page illustrated booklet published by the Morse Chain Company, Ithaca, N. Y., describing the construction of Morse silent chains, a distinguishing feature of which is the "rocker joint," consisting of a rolling or rocking bearing in each joint, which permits a rolling friction in place of the sliding friction common to other types of joints. Among a number of illustrations of large power drives is one showing the largest chain drive in the world—of 5,000 h.p. for hydroelectric purposes.

CUTTERS, ETC.—The Cleveland Milling Machine Company, Cleveland, Ohio, has revised its list of cutters in Catalogue B. This catalogue contains 140 pages, giving standard sizes and prices, and illustrating the line of tools, such as cutters, end mills, collets, hobs, etc., made by this company. Many valuable tables are contained in the catalogue, including tables of cutting speeds, corresponding diametral and circular pitches, decimal and millimeter equivalents, drill size decimal equivalents, screw threads and spur gear tooth spacing and thickness.

SUPERHEATERS.—Two circulars dealing with the maintenance and operation of superheaters are being distributed by the Locomotive Superheater Company, New York. Bulletin No. 6 is entitled "The Most from Superheating" and contains a reprint of the committee report of the Traveling Engineers' Association on superheating locomotive performance. Bulletin No. 8 contains instructions for properly maintaining and operating superheaters. It deals with such matters as lubrication and drifting, flue cleaning, handling units during repairs, etc. Another bulletin, No. 5, describes the company's model "496" pyrometer equipment for locomotive service.
